   - **VERIFY_CA** : Connection succeeds if Vertica verifies that the LDAP server's certificate is from a trusted CA. Using this TLSMODE forces all connections without a certificate to use plaintext.
   - **VERIFY_FULL** : Connection succeeds if Vertica verifies that the LDAP server's certificate is from a trusted CA and the cn (Common Name) or subjectAltName attribute matches the hostname or IP address of the LDAP server.
     The cn is used for the username, so subjectAltName must match the hostname or IP address of the LDAP server.

> **Note**
> The value of TLSMODE only applies to authentication records where the starttls LDAP authentication parameter is set to hard or not set at all.

> If starttls is set to soft , Vertica establishes a TLS connection without verifying the LDAP server's certificate and falls back to a plaintext connection if the LDAP server does not support TLS. For details, see the next section.

For example:

```
=> ALTER TLS CONFIGURATION LDAPAuth TLSMODE 'verify_ca';
ALTER TLS CONFIGURATION
```

Creating an LDAP authentication record

After a client successfully establishes a connection with Vertica, they must authenticate as a user before they can interact with the database. If the user has the ldap authentication method, Vertica connects to the LDAP server and attempts a bind to authenticate the user.

To view existing authentication records, query CLIENT_AUTH .

For details on the parameters referenced in this procedure, see LDAP authentication parameters .

1. CREATE an authentication record with an LDAP method.
   Syntax for creating an LDAP authentication record:

   ```
   => CREATE AUTHENTICATION auth_record_name method 'ldap' HOST 'user_connection_source';
   ```

   For example, to create an LDAP authentication record that applies to users that connect from any host:

   ```
   => CREATE AUTHENTICATION ldap_auth METHOD 'ldap' HOST '0.0.0.0/0';
   ```

2. ALTER the authentication record to to set the host and port (optional) of the LDAP server and the domain name (*basedn*) and bind distinguished name (binddn).
   - To use a plaintext connection between Vertica and the LDAP server (disable TLS):
     - Begin the host URL with ldap:// .
     - Set the TLSMODE of LDAPAuth to DISABLE and verify that starttls is not set.
   - To use StartTLS and reject plaintext connections:
     - Begin the host URL with ldap:// .
     - Set the TLSMODE of LDAPAuth to ENABLE or higher. Vertica only verifies the LDAP server's certificate if TLSMODE is set to TRY_VERIFY or higher.
     - Verify that starttls is set to hard or not set.
   - To use StartTLS, but still accept a plaintext connection if the LDAP server cannot be upgrade the connection to TLS:
     - Begin the host URL with ldap:// .
     - Set starttls to soft and the TLSMODE of LDAPAuth to ENABLE or higher. Vertica does not verify the server's certificate before establishing the connection and ignores the certificate verification policy of the LDAPAuth TLSMODE.
   - To use LDAPS:
     - Begin the host URL with ldaps://
     - TLSMODE of LDAPAuth to ENABLE or higher.

   This example authentication record searches for users in the active directory orgunit.example.com on an LDAP server with an IP address of 192.0.2.0 on port 5389 and requires a TLS connection to the LDAP server:

   ```
   => ALTER AUTHENTICATION ldap_auth SET
      host='ldap://192.0.2.0:5389',
      basedn='ou=orgunit,dc=example,dc=com',
      binddn_prefix='cn=',
      binddn_suffix=',ou=orgunit,dc=example,dc=com',
      starttls='hard';
   ```

   The binddn_prefix and binddn_suffix combine to create the full DN. That is, for some Vertica user asmith, ' cn=asmith,ou=orgunit,dc=example,dc=com ' is the full DN when Vertica attempts the bind.
   To modify the ldap_auth authentication record to request StartTLS, but still accept plaintext connections, set the starttls parameter to soft :

   ```
   => ALTER AUTHENTICATION ldap_auth SET starttls='soft';
   ```

3. Enable the authentication record:

   ```
   => ALTER AUTHENTICATION ldap_auth ENABLE;
   ```

4. GRANT the authentication record to a user or role.
   For example:

   ```
   => GRANT AUTHENTICATION ldap_auth TO asmith;
   ```

In this case, when the user asmith attempts to log in, Vertica constructs the distinguished name 'cn=asmith,ou=orgunit,dc=example,dc=com' from the search base specified in the ldap_auth, connects to the LDAP server, and attempts to bind it to the Vertica user. If the bind succeeds, Vertica allows asmith to log in.

Configuring multiple LDAP servers

If you need to configure multiple LDAP servers that have different URLs, create a separate authentication record for each server. Use the PRIORITY keyword to indicate which search the LDAP server performs first.

The following statements create two authentication methods, vldap1 and vldap2 . They specify that the LDAP server first search the entire directory (basedn=dc=example,dc=com) for a DN with an OU attribute Sales . If the first search returns no results, or otherwise fails, the LDAP server next searches for a DN with the OU attribute Marketing :

```
=> CREATE AUTHENTICATION vldap1 method "ldap" HOST 10.0.0.0/8;
=> ALTER AUTHENTICATION vldap1 SET
    host='ldap://ldap.example.com/search',
    basedn='dc=example,dc=com',
    search_attribute='Sales'
    PRIORITY 1;
=> GRANT AUTHENTICATION vldap1 to public;
=> CREATE AUTHENTICATION vldap2 method "ldap" HOST 10.0.0.0/8;
=> ALTER AUTHENTICATION vldap2 SET
    host='ldap://ldap.example.com/search',
    basedn='dc=example,dc=com',
    search_attribute='Marketing'
    PRIORITY 0;
=> GRANT AUTHENTICATION vldap2 to public;
```

LDAP bind methods

There are two LDAP methods that you use to authenticate your Vertica database against an LDAP server.

- Bind—Use LDAP bind when Vertica connects to the LDAP server and binds using the CN and password. (These values are the username and password of the user logging into the database). Use the bind method when your LDAP account's CN field matches that of the username defined in your database. For more information see Workflow for configuring LDAP bind .
- Search and Bind —Use LDAP search and bind when your LDAP account's CN field is a user's full name or does not match the username defined in your database. For search and bind, the username is usually in another field such as UID or sAMAccountName in a standard Active Directory environment. Search and bind requires your organization's Active Directory information. This information allows Vertica to log into the LDAP server and search for the specified field. For more information see Workflow for configuring LDAP search and bind .
  If you are using search and bind, having a service account simplifies your server side configuration. In addition, you do not need to store your Active Directory password.

LDAP anonymous binding

Anonymous binding is an LDAP server function. Anonymous binding allows a client to connect and search the directory (bind and search) without logging in because binddn and bindpasswd are not needed.

You also do not need to log in when you configure LDAP authentication using Management Console.

In this section

- Workflow for configuring LDAP bind
- Workflow for configuring LDAP search and bind

Workflow for configuring LDAP bind

To configure your Vertica database to authenticate clients using LDAP bind, follow these steps:

1. Obtain a service account. For information see the LDAP product documentation .You cannot use the service account in the connection parameters for LDAP bind.
2. Compare the user's LDAP account name to their Vertica username. For example, if John Smith's Active Directory (AD) sAMAccountName = jsmith, his Vertica username must also be jsmith.
   However, the LDAP account does not have to match the database user name, as shown in the following example:

```
=> CREATE USER r1 IDENTIFIED BY 'password';
=> CREATE AUTHENTICATION ldap1  METHOD 'ldap' HOST '172.16.65.177';
=> ALTER AUTHENTICATION ldap1 SET HOST=
   'ldap://172.16.65.10',basedn='dc=dc,dc=com',binddn_suffix=',ou=unit2,dc=dc,dc=com',binddn_prefix='cn=use';
=> GRANT AUTHENTICATION ldap1 TO r1;
\! ${TARGET}/bin/vsql -p $PGPORT -U r1 -w $LDAP_USER_PASSWD -h ${HOSTNAME} -c
   "select user_name, client_authentication_name from sessions;"
 user_name | client_authentication_name
-----------+----------------------------
 r1        | ldap
(1 row)
```

3. Run ldapsearch from a Vertica node against your LDAP or AD server. Verify the connection to the server and identify the values of relevant fields. Running ldapsearch helps you build the client authentication string needed to configure LDAP authentication.
   In the following example, ldapsearch returns the CN, DN, and sAMAccountName fields (if they exist) for any user whose CN contains the username jsmith. This search succeeds only for LDAP servers that allow anonymous binding:

```
$ ldapsearch -x -h 10.10.10.10 -b "ou=Vertica Users,dc=CompanyCorp,dc=com"
'(cn=jsmith*)' cn dn uid sAMAccountName
```

   ldapsearch returns the following results. The relevant information for LDAP bind is in **bold** :

```
# extended LDIF
#
# LDAPv3
# base <ou=Vertica Users,dc=CompanyCorp,dc=com> with scope subtree
# filter: (cn=jsmith*)
# requesting: cn dn uid sAMAccountName
#
# jsmith, Users, CompanyCorp.com
dn:cn=jsmith,ou=Vertica Users,dc=CompanyCorp,dc=com
cn: jsmith
uid: jsmith
# search result
search: 2
result: 0 Success
# numResponses: 2
# numEntries: 1
```

4. Create a new authentication record based on the information from ldapsearch . In the ldapsearch entry, the CN is username jsmith, so you do not need to set it. Vertica automatically sets the CN to the username of the user who is trying to connect. Vertica uses that CN to bind against the LDAP server.

```
=> CREATE AUTHENTICATION v_ldap_bind METHOD 'ldap' HOST '0.0.0.0/0';
=> GRANT AUTHENTICATION v_ldap_bind TO public;
=> ALTER AUTHENTICATION v_ldap_bind SET
host='ldap://10.10.10.10/',
basedn='DC=CompanyCorp,DC=com',
binddn_prefix='cn=',
binddn_suffix=',OU=Vertica Users,DC=CompanyCorp,DC=com';
```

For more information see LDAP Bind Parameters .

Workflow for configuring LDAP search and bind

To configure your Vertica database to authenticate clients using LDAP search and bind, follow these steps:

1. Obtain a service account. For information see the LDAP product documentation .
2. From a Vertica node, run ldapsearch against your LDAP or AD server. Verify the connection to the server, and identify the values of relevant fields. Running ldapsearch helps you build the client authentication string needed to configure LDAP authentication.
   In the following example, ldapsearch returns the CN, DN, and sAMAccountName fields (if they exist) for any user whose CN contains the username, John. This search succeeds only for LDAP servers that allow anonymous binding:

```
$ ldapsearch -x -h 10.10.10.10 -b 'OU=Vertica Users,DC=CompanyCorp,DC=com' -s sub -D
'CompanyCorp\jsmith' -W '(cn=John*)' cn dn uid sAMAccountName
```

3. Review the results that ldapsearch returns.The relevant information for search and bind is in bold:

```
# extended LDIF
#
# LDAPv3
# base <OU=Vertica Users,DC=CompanyCorp,DC=com> with scope subtree
# filter: (cn=John*)
# requesting: cn dn sAMAccountName
#
# John Smith, Vertica Users, CompanyCorp.com
dn: CN=jsmith,OU=Vertica Users,DC=CompanyCorp,DC=com
cn: Jsmith
sAMAccountName: jsmith
# search result
search: 2
result: 0 Success
# numResponses: 2
# numEntries: 1
```

4. Create the client authentication record. The cn attribute contains the username you want—jsmith. Set your search attribute to the CN field so that the search finds the appropriate account.

```
=> CREATE AUTHENTICATION v_ldap_bind_search METHOD 'ldap' HOST '10.10.10.10';
=> GRANT AUTHENTICATION v_ldap_bind_search TO public;
=> ALTER AUTHENTICATION v_ldap_bind_search SET
host='ldap://10.10.10.10',
basedn='OU=Vertica,DC=CompanyCorp,DC=com',
binddn='CN=jsmith,OU=Vertica Users,DC=CompanyCorp,DC=com',
bind_password='password',
search_attribute='CN';
```

For more information see LDAP Bind and Search Parameters

OAuth 2.0 authentication

Rather than with a username and password, users can authenticate to Vertica by first verifying their identity with an identity provider, receiving an OAuth token, and then passing the token to Vertica.

OAuth in Vertica is tested with Keycloak and Okta, but other providers should work if they support the RFC 7662 Token Introspection standard.

In this section

- Configuring OAuth authentication

Configuring OAuth authentication

For a list of ODBC OAuth connection properties, see Data source name (DSN) connection properties .

The following procedure:

1. Configures Keycloak 18.0.
2. Creates an OAuth authentication record.
3. Retrieves an access token with a POST request.
4. Uses sample applications to authenticate to Vertica, passing the access token as an argument and, optionally, parameters for token refresh.

Configuring Keycloak

The following procedure configures a Keycloak 18.0.0 server on 203.0.113.1.

Using TLS (optional)

If you want to use TLS, you must obtain a certificate and key for Keycloak signed by a trusted CA. This example uses a self-signed CA for convenience.

1. Generate the CA certificate:

```
=> CREATE KEY SSCA_key TYPE 'RSA' LENGTH 2048;
CREATE KEY

=> CREATE CA CERTIFICATE SSCA_cert
SUBJECT '/C=US/ST=Massachusetts/L=Cambridge/O=Micro Focus/OU=Vertica/C N=Vertica Root CA'
VALID FOR 3650
EXTENSIONS 'nsComment' = 'Self-signed root CA cert'
KEY SSCA_key;
CREATE CERTIFICATE
```

2. Generate a server key and certificate, signed by your CA, setting the **subjectAltName** of the certificate to the DNS and/or IP address of your Keycloak server:

```
=> CREATE KEY keycloak_key TYPE 'RSA' LENGTH 2048;
CREATE KEY

=> CREATE CERTIFICATE keycloak_cert
SUBJECT '/C=US/ST=Massachussets/L=Cambridge/O=Micro Focus/OU=Vertica/CN=Vertica Server'
SIGNED BY SSCA_cert
EXTENSIONS 'nsComment' = 'Keycloak CA', 'extendedKeyUsage' = 'serverAuth', 'subjectAltName' = 'DNS.1:dnsserver,IP:203.0.113.1'
KEY keycloak_key;
CREATE CERTIFICATE
```

3. Create the file *keycloak_directory* /conf/keyfile.pem with the content from the key column for the generated key:

```
=> SELECT key FROM cryptographic_keys WHERE name = 'keycloak_key';
```

4. Create the file *keycloak_directory* /conf/certfile.pem with the content from the certificate_text column for the generated certificate:

```
=> SELECT certificate_text FROM certificates WHERE name = 'keycloak_cert';
```

5. Append to your system's CA bundle the content from the certificate_text column for the generated CA certificate. The default CA bundle path and format varies between distributions; for details, see SystemCABundlePath :

```
=> SELECT certificate_text FROM certificates WHERE name = 'SSCA_cert';
```

6. Set the SystemCABundlePath configuration parameter:

```
=> ALTER DATABASE DEFAULT SET SystemCABundlePath = 'path/to/ca_bundle';
```

Starting Keycloak

1. Enter the following commands for a minimal configuration to create the Keycloak admin and to start Keycloak in start-dev mode:

```
$ KEYCLOAK_ADMIN=kcadmin
$ export KEYCLOAK_ADMIN
$ KEYCLOAK_ADMIN_PASSWORD=password
$ export KEYCLOAK_ADMIN_PASSWORD
$ cd keycloak_directory/bin/
$ ./kc.sh start-dev --hostname 203.0.113.1 --https-certificate-file ../conf/certfile.pem --https-certificate-key-file=../conf/keyfile.pem
```

2. Open the Keycloak console with your browser (these examples use the default ports):
   - For HTTP: http://203.0.113.1:8080
   - For HTTPS: http://203.0.113.1:8443
3. Sign in as the admin.
4. (Optional) To make testing OAuth more convenient, navigate to **Realm Settings** > **Tokens** and increase **Access Token Lifespan** to a greater value (the default is 5 minutes).

Creating the Vertica client

1. Navigate to **Clients** and click on **Create** . The **Add Client** page appears.
2. In **Client ID** , enter vertica .
3. Click **Save** . The client configuration page appears.
4. In the **Settings** tab, use the **Access Type** dropdown to select **confidential** .
5. In the **Credentials** tab, make a note of the **Secret** . This is the client secret used to refresh the token when it expires.

Creating a Keycloak user

Keycloak users map to Vertica users with the same name. This example creates a the Keycloak user oauth_user .

1. In the **Users** tab, click **Add user** . The **Add user** page appears.
2. In **Username** , enter oauth_user .

3. In the **Credentials** tab, enter a password.

Configuring Vertica

Creating the authentication record

Create an authentication record for OAuth.

The following authentication record v_oauth authenticates users from any IP address with an OAuth token (rather than a username and password) and uses the following parameters. The identity provider is Keycloak 18.0.0:

- client_id : The confidential client, vertica , registered in Keycloak.
- client_secret : The client secret, generated by Keycloak.
- discovery_url : Also known as the OpenID Provider Configuration Document , this is the endpoint that contains information about the identity provider's configuration and endpoints.

```
=> CREATE AUTHENTICATION v_oauth METHOD 'oauth' HOST '0.0.0.0/0'
=> ALTER AUTHENTICATION v_oauth SET client_id = 'vertica';
=> ALTER AUTHENTICATION v_oauth SET client_secret = 'client_secret';
=> ALTER AUTHENTICATION v_oauth SET discovery_url = 'https://203.0.113.1:8443/realms/myrealm/.well-known/openid-configuration';
=> ALTER AUTHENTICATION v_oauth SET introspect_url = 'https://203.0.113.1:8443/realms/myrealm/protocol/openid-connect/token/introspect';
```

Creating a Vertica user

Vertica users map to Keycloak users with the same username.

1. To map to the Keycloak user oauth_user , create a Vertica user with the same name. You do not need to specify a password because authentication is performed by the identity provider:
   ```
   => CREATE USER oauth_user;
   ```
2. Grant the OAuth authentication record to the user (or their role):
   ```
   => GRANT AUTHENTICATION v_oauth TO oauth_user;
   => GRANT ALL ON SCHEMA PUBLIC TO oauth_user;
   ```

Retrieving an access token

The simple way to get an OAuth access token is to send a POST request to the token endpoint, providing the credentials of the Keycloak user. For example, oauth_user :

```
$ curl --location --request POST 'http://203.0.113.1:8080/realms/master/protocol/openid-connect/token' \
--header 'Content-Type: application/x-www-form-urlencoded' \
--data-urlencode 'username=oauth_user' \
--data-urlencode 'password=oauth_user_password' \
--data-urlencode 'client_id=vertica' \
--data-urlencode 'client_secret=client_secret' \
--data-urlencode 'grant_type=password'
```

Keycloak responds with a JSON if you authenticated correctly. You can then use the returned access token, refresh token, and scope with the corresponding connection properties.

```
{
  "access_token":"access_token",
  "expires_in":60,
  "refresh_expires_in":1800,
  "refresh_token":"refresh_token",
  "token_type":"Bearer",
  "not-before-policy":0,
  "session_state":"6745892a-aa74-452f-b6b9-c45637193859",
  "scope":"profile email"
}
```

Running the sample applications

The OAuth sample applications, at a minimum, take an access token as an argument to authenticate to the database until the token expires. If you want the sample application to refresh the token after it expires, you must specify the following:

- Refresh token
- Client ID

- Client secret
- Token URL

ODBC

1. Follow the instructions in the README .
2. Run the sample application, passing the OAuth parameters as arguments:
   - To authenticate until the token expires:

     ```
     $ ./a.out --access-token OAuthAccessToken
     ```

   - To authenticate and silently refresh the access token when it expires:

     ```
     $ ./a.out --access-token OAuthAccessToken
       --refresh-token OAuthRefreshToken
       --client-id OAuthClientID
       --client-secret OAuthClientSecret
       --token-url OAuthTokenURL
     ```

JDBC

1. Follow the instructions in the README .
2. Run the sample application, passing the OAuth parameters as arguments:
   - To authenticate until the token expires:

     ```
     $ mvn compile exec:java -Dexec.mainClass=OAuthSampleApp -Dexec.args="vertica_host database_name --access-token oauthaccesstoken"
     ```

   - To authenticate and silently refresh the access token when it expires:

     ```
     $ mvn compile exec:java -Dexec.mainClass=OAuthSampleApp -Dexec.args="vertica_host database_name --access-token oauthaccesstoken
       --refresh_token oauthrefreshtoken
       --client-id oauthclientid
       --client-secret oauthclientsecret
       --token-url oauthtokenurl"
     ```

Troubleshooting

To get debugging information for TLS, use the -Djavax.net.debug=ssl flag.

Importing CA certificates into the Java truststore

If you configure your identity provider with TLS (that is, if you use HTTPS endpoints for your token or refresh URLs) and its certificate isn't issued by a well-known CA, you must import the issuer's CA certificate with keytool .

For example, to add the certificate keycloak/cert.crt to the Java truststore:

```
$ keytool -trustcacerts -keystore /usr/lib/jvm/java-1.7.0-openjdk-1.7.0.261-2.6.22.2.el7_8.x86_64/jre/lib/security/cacerts -storepass changeit -importcert -alias keycloak -file /keycloak/cert.crt
```

TLS authentication

This section contains information about the tls authentication method, which is one of several authentication methods used to manage client connections.

Before creating a tls authentication method, you must configure your server to use TLS (TLS is disabled by default). The supported modes are:

- **Server Mode** : In server mode, the client must confirm the server's identity before connecting. The client verifies that the server's certificate and public key are valid and were issued by a certificate authority (CA) listed in the client's list of trusted CAs. This helps prevent man-in-the-middle attacks.
- **Mutual Mode** : In mutual mode, the client and server must verify each other's identity before connecting. Client authentication is optional because Vertica can authenticate the client at the application protocol level with the client's username and password.

You can use the tls authentication method with either Server Mode or Mutual Mode. However, to use client self-authentication , your server must use Mutual Mode.

Before you create a tls authentication method, perform the pre-requisite tasks necessary for your environment (for example, certificate creation). Refer to TLS protocol and all subsections applicable to your environment.

To create a tls authentication method, see Creating authentication records .

In this section

- Implementing client self-authentication

Implementing client self-authentication

To use a client self-authentication method, your server must be in SSL Mutual Mode.

To create an authentication method for client self-authentication, use the CREATE AUTHENTICATION statement. Specify the *auth_type* 'tls' and with HOST TLS.

Important
You use the 'tls' *auth_type* only when you want to create an authentication method for client self-authentication. You must use the 'tls' *auth_type* with the HOST TLS syntax.

Create an authentication method with client self-authentication method

This section provides sample chronological steps for setting up a client for self-authentication, creating an authentication method, and associating the method with a user through a grant statement.

1. Follow all applicable procedures for implementing SSL and distributing certificates and keys. Refer to TLS protocol as it applies to your environment.

   When you create a client key, make sure to include a Common Name (CN) that is the database user name you want to use with the target database.
   ```
   $ Common Name <server hostname> []:<database username>
   ```
2. Create the authentication method with CREATE AUTHENTICATION . Authentication methods are automatically enabled when you create them.
   ```
   => CREATE AUTHENTICATION myssltest METHOD 'tls' HOST TLS '10.0.0.0/23;
   ```
3. Associate the method with the user through a grant statement.
   ```
   => GRANT AUTHENTICATION myssltest TO mydatabaseusername;
   ```

Your client can now log on and be recognized.

Specify TLS for client connections

You can require clients to use TLS when connecting to Vertica. To do so, create a client authentication method for them that uses the HOST TLS syntax with CREATE AUTHENTICATION .

Specific clients might connect through a network connection known to be insecure. In such cases, you can choose to limit specific users to connecting through TLS. You can also require all clients to use TLS.

Create authentication method RejectNoSSL that rejects users from any IP address that are trying to authenticate without TLS:

```
=> CREATE AUTHENTICATION RejectNoSSL METHOD 'reject' HOST NO TLS '0.0.0.0/0';  --IPv4
=> CREATE AUTHENTICATION RejectNoSSL METHOD 'reject' HOST NO TLS '::/0';       --IPv6
```

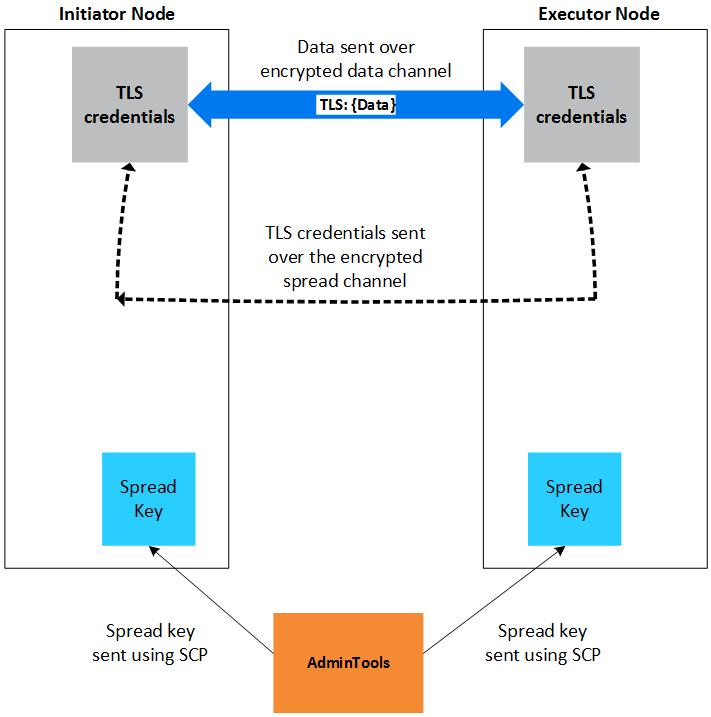
See Creating authentication records for more information about creating client authentication methods.

Internode TLS

Internode TLS secures communication between nodes within a cluster. It is important to secure communications between nodes if you do not trust the network between the nodes.

Before setting up internode TLS, check the current status of your configuration with SECURITY_CONFIG_CHECK .

```
=> SELECT SECURITY_CONFIG_CHECK('NETWORK');
```



Communication between the server nodes uses two channels: the control channel and data channel. To enable internode encryption, set the EncryptSpreadComm parameter (disabled by default) to encrypt Spread communication on the control channel and configure the data_channel TLS CONFIGURATION to encrypt the data channel:

1. Encrypt Spread communication on the control channel with EncryptSpreadComm . See Control channel spread TLS for details.
2. Encrypt the data channel with the data_channel TLS CONFIGURATION. See Data channel TLS for details.

If you enable internode encryption, some of your queries may run slower than expected. The performance you experience depends on the data sent and the network's quality.

Admintools generates or retrieves the spread key to encrypt all traffic on the control channel and ships the spread key to all nodes. Vertica uses TLS to encrypt all traffic on the data channel. TLS credentials are shared between nodes over the encrypted control channel.

The following graphic illustrates the internode encryption process.

See also

- Control channel spread TLS
- Data channel TLS
- TLS overview

In this section

- Control channel spread TLS
- Data channel TLS

Control channel spread TLS

The control channel allows nodes to exchange plan information with one another, and to distribute calls among nodes. Enabling spread security secures this communication. See Internode TLS for more information.

Internode TLS uses the following channels. Both must be enabled, and in the following order, before setting other parameters:

1. Control Channel to exchange plan information and distribute calls. It is implemented using Spread . For more information, visit spread.org .
2. Data Channel to exchange table data. It is implemented using TCP.

Enabling EncryptSpreadComm

EncryptSpreadComm can be set with one of two values:

- *vertica* . Vertica generates the spread encryption key for the cluster when the database starts up.
- aws-kms| *<key_name>* . Vertica fetches the user-specified key from the AWS Key Management Service when the database starts up, rather than generating one itself.

In general, you should set the EncryptSpreadComm parameter to enable spread encryption before setting any other security parameters.

1. Set the EncryptSpreadComm parameter with ALTER DATABASE .
   ```
   => ALTER DATABASE DEFAULT SET PARAMETER EncryptSpreadComm = 'vertica';
   ```
2. Restart the database.
3. Verify your settings with SECURITY_CONFIG_CHECK .
   ```
   => SELECT SECURITY_CONFIG_CHECK('NETWORK');
   ```

Privileges

Superuser

Restrictions

After setting this parameter, you must restart your database.

Example

This enables the EncryptSpreadComm parameter and tells Vertica to generate a spread encryption key the next time the database starts up.

```
=> ALTER DATABASE DEFAULT SET PARAMETER EncryptSpreadComm = 'vertica';
```

For more information on this and other security parameters, see Security parameters .

See also

- Internode TLS
- Data channel TLS
- TLS overview

Data channel TLS

Nodes use the data channel to exchange table data during operations such as queries.

Internode communication uses the following channels. Their associated components and parameters must be enabled, and in the following order, before enabling other components:

1. Control Channel to exchange plan information and distribute calls. It is implemented using Spread . For more information, visit spread.org .
2. Data Channel to exchange table data. It is implemented using TCP.

Configuring the data_channel TLS CONFIGURATION

1. Enable TLS on the control channel .
2. Generate or import the following:
   - **A CA (Certificate Authority) certificate.**
     For example, to create a self-signed CA certificate, generate a key and sign CA certificate with the key:
     ```
     => CREATE KEY SSCA_key TYPE 'RSA' LENGTH 2048;
     ```
     ```
     => CREATE CA CERTIFICATE SSCA_cert
     SUBJECT '/C=US/ST=Massachusetts/L=Cambridge/O=Micro Focus/OU=Vertica/CN=Vertica Root CA'
     VALID FOR 3650
     EXTENSIONS 'nsComment' = 'Self-signed root CA cert'
     KEY SSCA_key;
     ```
   - **The internode TLS certificate's private key.**
     For example, to generate the key with CREATE KEY :
     ```
     => CREATE KEY internode_key TYPE 'RSA' LENGTH 2048;
     ```
   - **The internode TLS certificate.** This must have a full chain that ends in a CA, and must be either a x509v1 certificate or use the extendedKeyUsage extensions serverAuth and clientAuth .
     For example, to generate internode_cert and sign it with SSCA_cert :
     ```
     => CREATE CERTIFICATE internode_cert
     SUBJECT '/C=US/ST=Massachusetts/L=Cambridge/O=Micro Focus/OU=Vertica/CN=data channel'
     SIGNED BY SSCA_cert
     EXTENSIONS 'nsComment' = 'Vertica internode cert', 'extendedKeyUsage' = 'serverAuth, clientAuth'
     KEY internode_key;
     ```
3. Set the certificate in the data_channel TLS CONFIGURATION. The TLSMODE is automatically set to VERIFY_CA, and should not be changed.
   ```
   => ALTER TLS CONFIGURATION data_channel CERTIFICATE internode_cert;
   ```
4. Verify that data channel encryption is enabled with SECURITY_CONFIG_CHECK('NETWORK') :

```
=> SELECT SECURITY_CONFIG_CHECK('NETWORK');
  SECURITY_CONFIG_CHECK
---------------------------
 Spread security details:
* EncryptSpreadComm = [vertica]
Spread encryption is enabled
It is now safe to set/change other security knobs

Data Channel security details:
 TLS Configuration 'data_channel' TLSMODE is VERIFY_CA
TLS on the data channel is enabled
```

Privileges

Superuser

Restrictions

- In general, you should set EncryptSpreadComm before configuring data_channel.
- Changes to the data_channel take effect immediately and interrupt all ongoing queries in order to update the connections between your nodes.

TLS protocol

TLS (Transport Layer Security) is a cryptographic protocol used to secure communications between servers, their nodes, and clients.

When enabled, a Vertica database and the clients that connect to it use TLS 1.2.

Although TLS, SSL, and TLS/SSL are often used interchangeably, the Vertica documentation always uses TLS to reference the protocol. Some Vertica parameters and components use SSL, and in these cases the documentation uses SSL to reference them, but these too can be categorized under the TLS umbrella.

Enabling TLS is a multi-step process. First, check the status of your security configuration with SECURITY_CONFIG_CHECK . Then, you can configure TLS authentication records to reject non-TLS connections.

In this section

- TLS overview

TLS overview

To secure communications and verify data integrity, you can configure Vertica and database clients to use TLS. The TLS protocol uses a key and certificate exchange system along with a trusted third party called a Certificate Authority (CA). Both the owner of a certificate and the other party that relies on the certificate must trust the CA to confirm the certificate holder's identity.

Vertica also supports the following authentication methods using the Transport Layer Security (TLS) v1.2 protocol. Both methods encrypt and verify the integrity of the data in transit:

- **Server Mode** - In server mode, the client must confirm the server's identity before connecting. The client verifies that the server's certificate and public key are valid and were issued by a certificate authority (CA) listed in the client's list of trusted CAs. This helps prevent man-in-the-middle attacks.
- **Mutual Mode** - In mutual mode, the client and server must verify each other's identity before connecting.

In addition to the requirements detailed in this section, you must create TLS authentication records to reject non-TLS client connections.

TLS handshake process

The following is a high-level/simplified overview of one possible "handshake" process for the client to verify the identity of the server in **Server Mode** . Additional actions taken in **Mutual Mode** for the server to identify the client are marked as such.

Public and Private Key Pairs - Key pairs are generated by clients and servers. The owner of a public key must be verified by a certificate authority. The key pairs are used to encrypt messages. For example, suppose Alice wants to send confidential data to Bob. Because she wants only Bob to read it, she encrypts the data with Bob's public key. Even if someone else gains access to the encrypted data, it remains protected. Because only Bob has access to his corresponding private key, he is the only person who can decrypt Alice's encrypted data back into its original form.

Certificates - Certificates contain a public key and identify the owner of the key. They are issued by the certificate authority (CA).

Certificate Authority (CA) - A certificate authority is a trusted party that verifies the identity of public key owners.

Client and Server Random - Client Random and Server Random are random strings that used to created a shared secret which encrypts communication if the handshake succeeds.

1. Before connecting, the server and client generate their own public and private key pairs. The CA then distributes identifying certificates to the server and client for their respective public keys.
2. The client sends its Client Random to the server and requests the server's certificate.
3. The server sends its certificate and its Server Random, encrypted with its private key, to the client. In **Mutual Mode** , the server also requests the client's certificate.
4. In **Mutual Mode** , the client sends its certificate.
5. The client uses the certificate to verify that the server owns its public key, then decrypts the Server Random with the server's public key to verify that the server owns its private key.
6. In **Mutual Mode** , the server uses the certificate to verify that the client owns its public key.
7. The server and client use the Client and Server Randoms to generate a new secret, called a session key, which encrypts future communication.

Generating TLS certificates and keys

This page includes examples and sample procedures for generating certificates and keys with CREATE KEY and CREATE CERTIFICATE . To view your keys and certificates, query the CRYPTOGRAPHIC_KEYS and CERTIFICATES system tables.

For more detailed information on creating signed certificates, OpenSSL recommends the OpenSSL Cookbook .

For more information on x509 extensions, see the OpenSSL documentation .

Importing keys and certificates

Keys

You only need to import private keys if you intend to use its associated certificate to sign something, like a message in client-server TLS, or another certificate. That is, you only only need to import keys if its associated certificate is one of the following:

- Client/server certificate
- CA certificate used to sign other certificates while in Vertica

If you only need your CA certificate to validate other certificates, you do not need to import its private key.

To import a private key:

```
=> CREATE KEY imported_key TYPE 'RSA' AS '-----BEGIN PRIVATE KEY-----...-----END PRIVATE KEY-----';
```

Certificates

To import a CA certificate that only validates other certificates (no private key):

```
=> CREATE CA CERTIFICATE imported_validating_ca AS '-----BEGIN CERTIFICATE-----...-----END CERTIFICATE-----';
```

To import a CA that can both validate and sign other certificates (private key required):

```
=> CREATE CA CERTIFICATE imported_signing_ca AS '-----BEGIN CERTIFICATE-----...-----END CERTIFICATE-----'
KEY ca_key;
```

To import a certificate for server mode TLS:

```
=> CREATE CERTIFICATE server_mode_cert AS '-----BEGIN CERTIFICATE-----...-----END CERTIFICATE-----' KEY imported_key;
```

To import a certificate for mutual mode TLS or client authentication, you must specify its CA:

```
=> CREATE CERTIFICATE imported_cert AS '-----BEGIN CERTIFICATE-----...-----END CERTIFICATE-----'
SIGNED BY imported_ca KEY imported_key;
```

Generating private keys and certificates

Keys

To generate an 2048-bit RSA private key:

```
=> CREATE KEY new_key TYPE 'RSA' LENGTH 2048;
```

Self-signed CA certificates

> **Note**
> The subjects of CA certificates must be different from the subjects of the certificates they sign.

CAs are trusted entities that use their CA certificates to sign and validate other certificates. The example that follows generates a self-signed root CA:

Important
While self-signed CA certificates are convenient, you should always use a proper certificate authority in a production environment.

1. Generate or import a private key:
   ```
   => CREATE KEY SSCA_key TYPE 'RSA' LENGTH 2048;
   ```
2. Generate and sign the certificate with the private key using the following format:
   ```
   => CREATE CA CERTIFICATE certificate_name
   SUBJECT '/C=country_code/ST=state_or_province/L=locality/O=organization/OU=org_unit/CN=Vertica Root CA'
   VALID FOR days_valid
   EXTENSIONS 'authorityKeyIdentifier' = 'keyid:always,issuer', 'nsComment' = 'Vertica generated root CA cert'
   KEY ca_key;
   ```

   For example:
   ```
   => CREATE CA CERTIFICATE SSCA_cert
   SUBJECT '/C=US/ST=Massachusetts/L=Cambridge/O=Micro Focus/OU=Vertica/CN=Vertica Root CA'
   VALID FOR 3650
   EXTENSIONS 'nsComment' = 'Self-signed root CA cert'
   KEY SSCA_key;
   ```

Intermediate CA certificates

In addition to server certificates, CAs can also sign the certificates of other CAs. This process produces an intermediate CA and a chain of trust between the top-level CA and the intermediate CA. These intermediate CAs can then sign other certificates.

> **Note**
> Intermediate CA certificates generated with CREATE CERTIFICATE cannot sign other CA certificates.

1. Generate or import the CA that signs the intermediate CA. The example that follows generates and uses a self-signed root CA:
   ```
   => CREATE KEY SSCA_key TYPE 'RSA' LENGTH 2048;
   ```

   ```
   => CREATE CA CERTIFICATE SSCA_cert
   SUBJECT '/C=US/ST=Massachusetts/L=Cambridge/O=Micro Focus/OU=Vertica/CN=Vertica Root CA'
   VALID FOR 3650
   EXTENSIONS 'nsComment' = 'Self-signed root CA cert'
   KEY SSCA_key;
   ```
2. Generate or import a private key:
   ```
   => CREATE KEY intermediate_key TYPE 'RSA' LENGTH 2048;
   ```
3. Generate the intermediate CA certificate, specifying its private key and signing CA using the following format:

```
=> CREATE CERTIFICATE intermediate_certificate_name
SUBJECT '/C=country_code/ST=state_or_province/L=locality/O=organization/OU=org_unit/CN=Vertica intermediate CA'
SIGNED BY ca_name
KEY intermediate_key;
```

For example:

```
=> CREATE CA CERTIFICATE intermediate_CA
SUBJECT '/C=US/ST=Massachusetts/L=Cambridge/O=OpenText/OU=Vertica/CN=Vertica Intermediate CA'
SIGNED BY SSCA_cert
KEY intermediate_key;
```

Client/server certificates

CREATE CERTIFICATE generates x509v3 certificates, which allow you to specify extensions to restrict how the certificate can be used. The value for the extendedKeyUsage extension will differ based on your use case:

- Server certificate:
  ```
  'extendedKeyUsage' = 'serverAuth'
  ```
- Client certificate:
  ```
  'extendedKeyUsage' = 'clientAuth'
  ```
- Server certificate for internode encryption :
  ```
  'extendedKeyUsage' = 'serverAuth, clientAuth'
  ```

Because these certificates are used for client/server TLS, you must import or generate their private keys.

The following example certificates are all signed by this self-signed CA certificate:

```
=> CREATE KEY SSCA_key TYPE 'RSA' LENGTH 2048;
```

```
=> CREATE CA CERTIFICATE SSCA_cert
SUBJECT '/C=US/ST=Massachusetts/L=Cambridge/O=Micro Focus/OU=Vertica/CN=Vertica Root CA'
VALID FOR 3650
EXTENSIONS 'nsComment' = 'Self-signed root CA cert'
KEY SSCA_key;
```

To generate a server certificate:

```
=> CREATE KEY server_key TYPE 'RSA' LENGTH 2048;
```

```
=> CREATE CERTIFICATE server_cert
SUBJECT '/C=US/ST=Massachusetts/L=Cambridge/O=OpenText/OU=Vertica/CN=Vertica server/emailAddress=example@example.com'
SIGNED BY SSCA_cert
EXTENSIONS 'nsComment' = 'Vertica server cert', 'extendedKeyUsage' = 'serverAuth'
KEY server_key;
```

To generate a client certificate:

```
=> CREATE KEY client_key TYPE 'RSA' LENGTH 2048;
```

```
=> CREATE CERTIFICATE client_cert
SUBJECT '/C=US/ST=Massachusetts/L=Cambridge/O=OpenText/OU=Vertica/CN=Vertica client/emailAddress=clientexample@example.com'
SIGNED BY SSCA_cert
EXTENSIONS 'nsComment' = 'Vertica client cert', 'extendedKeyUsage' = 'clientAuth'
KEY client_key;
```

To generate an internode TLS certificate:

```
=> CREATE KEY internode_key TYPE 'RSA' LENGTH 2048;
```

```
=> CREATE CERTIFICATE internode_cert
SUBJECT '/C=US/ST=Massachusetts/L=Cambridge/O=Micro Focus/OU=Vertica/CN=data channel'
SIGNED BY SSCA_cert
EXTENSIONS 'nsComment' = 'Vertica internode cert', 'extendedKeyUsage' = 'serverAuth, clientAuth'
KEY internode_key;
```

Configuring client-server TLS

Vertica offers two connection modes for client-server TLS:

- In **Server Mode** , the client must verify the host's certificate. Hosts must have a server private key and certificate.
- In **Mutual Mode** , the client and host must each verify the other's certificate. Hosts must have a server private key, server certificate, and CA certificate(s).

Keep in mind that this page covers the connection step between Vertica and clients, not the following authentication step for Vertica users to the database. To configure authentication for TLS connections, see TLS authentication .

Setting certificates with TLS CONFIGURATION

1. Generate or import the following according to your use case:
   - **Server Mode** : server certificate private key, server certificate
   - **Mutual Mode** : server certificate private key, server certificate, CA certificate(s)
2. Run the following commands according to your desired configuration. New connections will use TLS.
   - To use **Server Mode** , set the server certificate for the server's TLS CONFIGURATION.
     ```
     => ALTER TLS CONFIGURATION server CERTIFICATE server_cert;
     ```
   - To use **Mutual Mode** , set a server and CA certificate. This CA certificate is used to verify client certificates.
     ```
     => ALTER TLS CONFIGURATION server CERTIFICATE server_cert ADD CA CERTIFICATES ca_cert;
     ```
     To use multiple CA certificates, separate them with commas:
     ```
     => ALTER TLS CONFIGURATION server CERTIFICATE server_cert
       ADD CA CERTIFICATES intermediate_ca_cert, ca_cert;
     ```
3. Enable TLS (disabled by default). Choose one of the following TLSMODEs, listed in ascending security. For **Server Mode** , choose ENABLE . For **Mutual Mode** , choose TRY_VERIFY or higher.
   - DISABLE : Disables TLS. All other options for this parameter enable TLS.
   - ENABLE : Enables TLS. Vertica does not verify client certificates.
   - TRY_VERIFY : Establishes a TLS connection if one of the following is true:
     - The client presents a valid certificate.
     - The client doesn't present a certificate

     If the client presents an invalid certificate, the connection is rejected.
   - VERIFY_CA : Connection succeeds if Vertica verifies that the client certificate is from a trusted CA. If the client does not present a client certificate, the connection is rejected.

   For example, for **Server Mode** :
   ```
   => ALTER TLS CONFIGURATION server TLSMODE 'ENABLE';
   ```
   For example, for **Mutual Mode** :
   ```
   => ALTER TLS CONFIGURATION server TLSMODE 'TRY_VERIFY';
   ```

Managing CA bundles

Certificate authority (CA) bundles allow you to group CA certificates together and use them to validate connections to your database.

You can view existing CA bundles by querying the CA_BUNDLES system table.

Creating a CA bundle

To create a CA bundle, use CREATE CA BUNDLE and specify one or more CA certificates. If you don't specify a CA certificate, the CA bundle will be empty.

This example creates a CA bundle called ca_bundle that contains CA certificates root_ca and root_ca2:

```
=> CREATE CA BUNDLE ca_bundle CERTIFICATES root_ca, root_ca2;
CREATE CA BUNDLE

=> SELECT * FROM ca_bundles WHERE name='ca_bundle';
       oid       |   name    |       owner       |                certificates
-----------------+-----------+-------------------+-------------------------------------
 45035996274026954 | ca_bundle | 45035996273704962 | [45035996274026764, 45035996274026766]
(1 row)
```

Modifying existing CA bundles

CA_BUNDLES only stores OIDs. Since operations on CA bundles require certificate and owner names, you can use the following query to map bundles to certificate and owner names:

```
=> SELECT user_name AS owner_name,
      owner     AS owner_oid,
      b.name    AS bundle_name,
      c.name    AS cert_name
FROM   (SELECT name,
               STRING_TO_ARRAY(certificates) :: array[INT] AS certs
        FROM   ca_bundles) b
      LEFT JOIN certificates c
             ON CONTAINS(b.certs, c.oid)
      LEFT JOIN users
             ON user_id = owner
ORDER  BY 1;

 owner_name |     owner_oid     | bundle_name  | cert_name
------------+-------------------+--------------+-----------
 dbadmin    | 45035996273704962 | ca_bundle    | root_ca
 dbadmin    | 45035996273704962 | ca_bundle    | ca_cert
(2 rows)
```

Adding and removing CA certificates

If you have ownership of a CA bundle, you can add and remove certificates with ALTER CA BUNDLE .

This example modifies ca_bundle by adding ca_cert and removing root_ca2:

```
=> ALTER CA BUNDLE ca_bundle ADD CERTIFICATES ca_cert;
ALTER CA BUNDLE

=> SELECT * FROM ca_bundles WHERE name='ca_bundle';
       oid       |   name    |       owner       |                      certificates
-----------------+-----------+-------------------+-------------------------------------------------------
 45035996274027356 | ca_bundle | 45035996273704962 | [45035996274027342, 45035996274027348, 45035996274027396]
(1 row)

=> ALTER CA BUNDLE ca_bundle REMOVE CERTIFICATES root_ca2;
ALTER CA BUNDLE

=> SELECT * FROM CA_BUNDLES;
       oid       |   name    |       owner       |                certificates
-----------------+-----------+-------------------+-------------------------------------
 45035996274027356 | ca_bundle | 45035996273704962 | [45035996274027342, 45035996274027396]
(1 row)
```

Managing CA bundle ownership

Superusers and CA bundle owners can see whether a bundle exists by querying the CA_BUNDLES system table, but only owners of a given bundle can see the certificates inside.

In the following example, the dbadmin user owns ca_bundle. After giving ownership of the bundle to 'Alice', the dbadmin can no longer see the certificates inside the bundle:

```
=> => SELECT * FROM ca_bundles WHERE name='ca_bundle';
       oid       |   name    |       owner       |                certificates
-----------------+-----------+-------------------+--------------------------------------
 45035996274027356 | ca_bundle | 45035996273704962 | [45035996274027342, 45035996274027396]
(1 row)

=> ALTER CA BUNDLE ca_bundle OWNER TO Alice;
ALTER CA BUNDLE

=> SELECT * FROM ca_bundles WHERE name='ca_bundle';
       oid       |   name    |       owner       | certificates
-----------------+-----------+-------------------+--------------
 45035996274027356 | ca_bundle | 45035996274027586 | []
(1 row)
```

Dropping CA bundles

You must have ownership of a CA bundle to drop it:

```
=> DROP CA BUNDLE ca_bundle;
DROP CA BUNDLE
```

Generating certificates and keys for MC

A *certificate signing request (CSR)* is a block of encrypted text generated on the server on which the certificate is used. You send the CSR to a certificate authority (CA) to apply for a digital identity certificate. The CA uses the CSR to create your SSL certificate from information in your certificate; for example, organization name, common (domain) name, city, and country.

Management Console (MC) uses a combination of OAuth (Open Authorization), Secure Socket Layer (SSL), and locally-encrypted passwords to secure HTTPS requests between a user's browser and MC, and between MC and the agents . Authentication occurs through MC and between agents within the cluster. Agents also authenticate and authorize jobs.

The MC configuration process sets up SSL automatically, but you must have the openssl package installed on your Linux environment first.

When you connect to MC through a client browser, Vertica assigns each HTTPS request a self-signed certificate, which includes a timestamp. To increase security and protect against password replay attacks, the timestamp is valid for several seconds only, after which it expires.

To avoid being blocked out of MC, synchronize time on the hosts in your Vertica cluster, and on the MC host if it resides on a dedicated server. To recover from loss or lack of synchronization, resync system time and the Network Time Protocol.

Create a certificate and submit it for signing

For production, you must use certificates signed by a certificate authority. You can create and submit a certificate and when the certificate returns from the CA, import the certificate into MC .

Use the openssl command to generate a new CSR, entering the passphrase "password" when prompted:

```
$ sudo openssl req -new -key /opt/vconsole/config/keystore.key -out server.csr
Enter pass phrase for /opt/vconsole/config/keystore.key:
```

When you press **Enter** , you are prompted to enter information to be incorporated into your certificate request. Some fields contain a default value, which you should change for security reasons. Other fields you can leave blank, such as password and optional company name. To leave the field blank, type '.' .

Important

The keystore.key value for the -key option creates private key for the keystore. If you generate a new key and import it using the Management Console interface, the MC process does restart properly. You must restore the original keystore.jks file and restart Management Console .

This information is contained in the CSR and shows both the default and replacement values:

```
Country Name (2 letter code) [GB]:USState or Province Name (full name) [Berkshire]:Massachusetts
Locality Name (eg, city) [Newbury]: Cambridge
Organization Name (eg, company) [My Company Ltd]:Vertica
Organizational Unit Name (eg, section) []:Information Management
Common Name (eg, your name or your server's hostname) []:console.vertica.com
Email Address []:mcadmin@vertica.com
```

The **Common Name** field is the fully qualified domain name of your server. Your entry must exactly match what you type in your web browser, or you receive a name mismatch error.

Self-sign a certificate for testing

To test your new SSL implementation, you can self-sign a CSR using either a temporary certificate or your own internal CA, if one is available.

> **Note**
> A self-signed certificate generates a browser-based error notifying you that the signing certificate authority is unknown and not trusted. For testing purposes, accept the risks and continue.

The following command generates a temporary certificate, which expires after 365 days:

```
$ sudo openssl x509 -req -days 365 -in server.csr -signkey /opt/vconsole/config/keystore.key -out server.crt
Enter passphrase for /opt/vconsole/config/keystore.key:
Enter same passphrase again:
```

The previous example prompts you for a passphrase. This is required for Apache to start. To implement a passphrase you must put the SSLPassPhraseDialog directive in the appropriate Apache configuration file. For more information see your Apache documentation.

This example shows the command's output to the terminal window:

```
Signature oksubject=/C=US/ST=Massachusetts/L=Cambridge/O=Vertica/OU=IT/
CN=console.vertica.com/emailAddress=mcadmin@vertica.com
Getting Private key
```

You can now import the self-signed key , server.crt , into Management Console.

See also

- Configuring TLS for JDBC clients
- Configuring TLS for ODBC Clients
- Key and Certificate Management Tool

Importing a new certificate to MC

Use this procedure to import a new certificate into Management Console.

> **Note**
> To generate a new certificate for Management Console, you must use the keystore.key file, which is located in /opt/vconsole/config on the server on which you installed MC. Any other generated key/certificate pair causes MC to restart incorrectly. You will then have to restore the original keystore.jks file and restart Management Console . See Generating Certifications and Keys for Management Console .

1. Connect to Management Console, and log in as an administrator.
2. On the Home page, click MC **Settings** .
3. In the button panel on the left, click **SSL certificates** .
4. To the right of "Upload a new SSL certificate," click **Browse** to import the new key.
5. Click **Apply** .
6. Restart Management Console .

Replacing the agent certificate

The Agent uses a preinstalled Certificate Authority (CA) certificate. You can replace it copying the your preferred certificate and its private key to the host.

To view your current agent certificate:

```
$ openssl s_client -prexit -connect database_IP:database_port
```

Generating a certificate

If you don't already have one, you can generate a self-signed certificate. For more information, see Generating TLS certificates and keys

1. Generate the private key and certificate.

```
$ openssl req -new -newkey rsa:4096 -x509 -sha256 -days 365 -nodes -out agent.cert -keyout agent.key

You are about to be asked to enter information that will be incorporated
into your certificate request.
What you are about to enter is what is called a Distinguished Name or a DN.
There are quite a few fields but you can leave some blank
For some fields there will be a default value,
If you enter '.', the field will be left blank.
-----
Country Name (2 letter code) [AU]:US
State or Province Name (full name) [Some-State]:MA
Locality Name (eg, city) []:Cambridge
Organization Name (eg, company) [Internet Widgits Pty Ltd]:My Company
Organizational Unit Name (eg, section) []:IT
Common Name (e.g. server FQDN or YOUR name) []:*.mycompany.com
Email Address []:myaddress@mycompany.com
```

2. Make a copy of the certificate in PEM format.

```
$ openssl x509 -in agent.cert -out agent.pem -outform PEM
```

3. Review the certificate.

```
$ openssl x509 -in agent.pem -text
```

Replacing the agent certificate on a host

The following procedure replaces the Agent's current private key and certificate on a single host. To replace this certificate and key across an entire cluster, repeat this procedure for all the hosts.

1. Stop the Agent service on the host.

```
$ /etc/init.d/vertica_agent stop
```

2. Backup and rename the existing agent certificate and key.

```
$ cd /opt/vertica/config/share
$ mv agent.cert agent.cert.bck
$ mv agent.key agent.key.bck
$ mv agent.p em agent.pem.bck
```

3. Transfer the new certificate and key to the host's /opt/vertica/config/share directory.

```
$ scp agent.* root@123.12.12.123:/opt/vertica/config/share
```

4. Change the owner of the certificate and key to uidbadmin and the group to verticadba .

```
$ chown installed_Vertica_user:installed_Vertica_group agent.*
```

5. Make the certificate and key files read-only.

```
$ chmod -R 400 agent.*
```

6. Start the Agent service.

```
$ /etc/init.d/vertica_agent start
starting agent
Opening PID file "/opt/vertica/log/agent.pid".
Overwriting /opt/vertica/log/agent_uidbadmin.log
Overwriting /opt/vertica/log/agent_uidbadmin.err
start OK for user: uidbadmin
```

7. Verify that you can view information about your database with your API key.

```
$ curl -X GET https://10.20.80.145:5444/databases -H "VerticaApiKey:wCgXny3Wm+8OhEvGkAclv7v9+VIlxgXblpr4rf" -k
```

8. Verify that the Agent is using the new certificate.

```
$ openssl s_client -prexit -connect 10.20.80.145:5444
```

Importing and exporting data with TLS

Vertica uses TLS to secure connections and communications between clients and servers. When you import or export data between Vertica clusters, one of the clusters functions as a client, which means you can use TLS to protect that connection, too.

The ImportExportTLSMode parameter controls the strictness of TLS when importing or exporting data.

By default, ImportExportTLSMode is set to PREFER. With this setting, Vertica attempts to use TLS and falls back to plaintext; you can change this to always require encryption and, further, to validate the certificate on each connection. For more information about TLS during import and export operations, see Configuring connection security between clusters .

LDAP link service

LDAP Link enables synchronization between the LDAP and Vertica servers. This eliminates the need for you to manage two sets of users and groups or roles, one on the LDAP server and another on the Vertica server. With LDAP synchronization, the Vertica server becomes a replication database for the LDAP server.

Automatic synchronization

With LDAP Link the Vertica server closely integrates with an existing directory service such as MS Active Directory or OpenLDAP. The Vertica server automatically synchronizes:

- LDAP users to Vertica users
- LDAP groups to Vertica roles

You manage all user and group properties in the LDAP server. If you are the Vertica database administrator, you need only to set up permissions for Vertica Analytic Database access on the users and groups.

Configure LDAP Link with LDAP Link connection parameters that reside in the catalog. See General and Connection Parameters for more information.

Configure LDAP link with dry runs

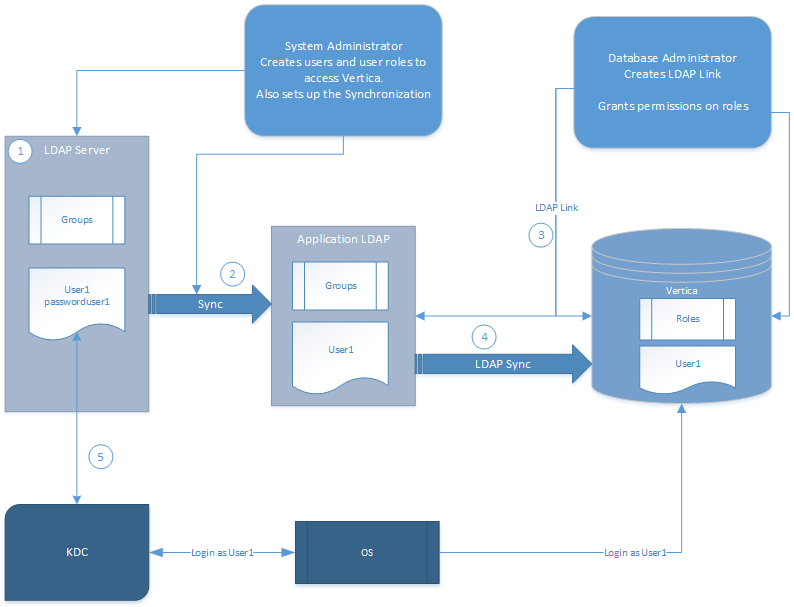
The LDAP Link dry run meta-functions allow you to configure the service in discrete stages before making any changes to your database. These stages are:

1. LDAP Link Bind : Establishing a connection between the LDAP server and the Vertica database
2. LDAP Link Search : Searching the LDAP server for users and groups
3. LDAP Link Sync : Mapping LDAP users and groups to their equivalents in Vertica

Query the system table LDAP_LINK_DRYRUN_EVENTS to view the results of each dry run.

For more information on dry runs and configuring LDAP Link, see Configuring LDAP link with dry runs .

Enable LDAP link



Enable LDAP Link as shown:

```
=> ALTER DATABASE dbname SET PARAMETER LDAPLinkURL='ldap://example.dc.com',
   LDAPLinkSearchBase='dc=DC,dc=com', LDAPLinkBindDN='CN=jsmith,OU=QA,DC=dc,DC=com,
   LDAPLinkBindPswd='password',LDAPLinkFilterUser='(objectClass=inetOrgPerson)', LDAPLinkFilterGroup='(objectClass=group)', LDAPLinkOn=1;
=> SELECT ldap_link_sync_start();
```

See LDAP link parameters .

LDAP link workflow

After you enable LDAP Link, synchronization occurs according to this workflow:

1. The System Administrator creates users and user groups on the LDAP server.
2. The System Administrator sets up LDAP Link service parameters as required and enables the service.
3. Using the LDAP Link service, Vertica Analytic Database replicates the users and user groups from the Application LDAP to the Vertica database, creating Vertica users and roles.
4. The LDAP server uses Kerberos (KDC) to authenticate the user logging in to Vertica.
   - The LDAP user can log in to Vertica if assigned the appropriate authentication type.
   - After logging in, you can grant users privileges using GRANT statements or as part of a Group.

> **Note**
> After synchronization, the Vertica user does not have an associated authentication method. To allow the user to log in, you must assign an authentication method to the user. See Implementing client authentication .

In this section

- Configuring LDAP link with dry runs
- Using LDAP link
- LDAP link parameters
- TLS for LDAP link
- Troubleshooting LDAP link issues

Configuring LDAP link with dry runs

Vertica supports several meta-functions that let you tweak LDAP Link settings before syncing with Vertica. Each meta-function takes LDAP Link parameters as arguments and tests a separate part of LDAP Link:

- LDAP_LINK_DRYRUN_CONNECT connects to the LDAP server.
- LDAP_LINK_DRYRUN_SEARCH searches for LDAP users and groups.
- LDAP_LINK_DRYRUN_SYNC maps and synchronizes LDAP users and groups to their equivalents in Vertica, creating and orphaning them accordingly.

These meta-functions should be used and tested in succession, and their arguments are cumulative. That is, the parameters you use to configure LDAP_LINK_DRYRUN_CONNECT are used for LDAP_LINK_DRYRUN_SEARCH, and the arguments for those functions are used for LDAP_LINK_DRYRUN_SYNC.

The dryrun and LDAP_LINK_SYNC_START functions must be run from the clerk node. To determine the clerk node, query NODE_RESOURCES :

```
=> SELECT node_name, dbclerk FROM node_resources WHERE dbclerk='t';
    node_name     | dbclerk
------------------+---------
v_vmart_node0001 | t
(1 row)
```

Be sure to query the LDAP_LINK_DRYRUN_EVENTS system table to verify the results of each dry run before moving to the next meta-function.

Configuring TLS for dry runs

Like the standard LDAP Link functions, LDAP Link dry-run functions pull from the 'LDAPLink' TLS CONFIGURATION for managing TLS connections. Query the TLS_CONFIGURATIONS system table to view existing TLS CONFIGURATIONs.

```
=> SELECT * FROM tls_configurations WHERE name='LDAPLink';
   name   |  owner  | certificate | ca_certificate | cipher_suites |  mode
----------+---------+-------------+----------------+---------------+---------
 LDAPLink | dbadmin | client_cert | ldap_ca        |               | DISABLE
(1 row)
```

For instructions on configuring TLS for LDAP Link and its dry run functions, see TLS for LDAP link .

Configuring LDAP link bind

Before configuring LDAP users and importing them to Vertica, you must first connect or "bind," with the LDAP server. Connections are managed with several parameters. For more information on each parameter, related functions, options, and default values, see LDAP link parameters .

LDAP_LINK_DRYRUN_CONNECT requires a Distinguished Name (DN), a password to authenticate with the LDAP server, and the URL to the LDAP server.

To encrypt the connection, configure the LDAPLink TLS CONFIGURATION .

By providing an empty string for the LDAPLinkBindPswd argument, you can also perform an anonymous bind if your LDAP server allows unauthenticated binds.

```
=> SELECT LDAP_LINK_DRYRUN_CONNECT('LDAPLinkURL','LDAPLinkBindDN','LDAPLinkBindPswd');
```

Dry run bind example

This tests the connection to an LDAP server at ldap://example.dc.com with the DN CN=amir,OU=QA,DC=dc,DC=com .

```
=> SELECT LDAP_LINK_DRYRUN_CONNECT('ldap://example.dc.com','CN=amir,OU=QA,DC=dc,DC=com','password');

                ldap_link_dryrun_connect
-------------------------------------------------------------------------------
Dry Run Connect Completed. Query v_monitor.ldap_link_dryrun_events for results.
```

To check the results of the bind, query the system table LDAP_LINK_DRYRUN_EVENTS.

```
=> SELECT event_timestamp, event_type, entry_name, role_name, link_scope, search_base from LDAP_LINK_DRYRUN_EVENTS;
       event_timestamp       |       event_type       |       entry_name       | link_scope | search_base
-----------------------------+------------------------+------------------------+------------+-------------
2019-12-09 15:41:43.589398-05 | BIND_STARTED           | ---------- | ---------- | ----------
2019-12-09 15:41:43.590504-05 | BIND_FINISHED          | ---------- | ---------- | ----------
```

Configuring LDAP link search

After a successful connection between Vertica and the LDAP server, you should configure and test your user and group search space for correctness and efficiency.

To search for users and groups on the LDAP server to import to your database, pass both the connection and search parameters to the LDAP_LINK_DRYRUN_SEARCH meta-function. The LDAP server responds with a list of users and groups that would be imported into Vertica with the given parameters.

By providing an empty string for the LDAPLinkBindPswd argument, you can also perform an anonymous search if your LDAP server's Access Control List (ACL) is configured to allow unauthenticated searches. The settings for allowing anonymous binds are different from the ACL settings for allowing anonymous searches.

```
=> SELECT LDAP_LINK_DRYRUN_SEARCH('LDAPLinkURL','LDAPLinkBindDN','LDAPLinkBindPswd','LDAPLinkSearchBase',
'LDAPLinkScope','LDAPLinkFilterUser','LDAPLinkFilterGroup','LDAPLinkUserName','LDAPLinkGroupName',
'LDAPLinkGroupMembers',[LDAPLinkSearchTimeout],['LDAPLinkJoinAttr']);
```

Dry run search example

This searches for users and groups in the LDAP server. In this case, the LDAPLinkSearchBase parameter specifies the dc.com domain and a sub scope, which replicates the entire subtree under the DN.

To further filter results, the function checks for users and groups with the person and group objectClass attributes. It then searches the group attribute cn , identifying members of that group with the member attribute, and then identifying those individual users with the attribute uid .

```
=> SELECT LDAP_LINK_DRYRUN_SEARCH('ldap://example.dc.com','CN=amir,OU=QA,DC=dc,DC=com','$vertica$','dc=DC,dc=com','sub',
'(objectClass=person)','(objectClass=group)','uid','cn','member',10,'dn');

            ldap_link_dryrun_search
-------------------------------------------------------------------------------
Dry Run Search Completed. Query v_monitor.ldap_link_dryrun_events for results.
```

To check the results of the search, query the system table LDAP_LINK_DRYRUN_EVENTS.

```
=> SELECT event_timestamp, event_type, entry_name, ldapurihash, link_scope, search_base from LDAP_LINK_DRYRUN_EVENTS;
       event_timestamp          |    event_type    |       entry_name       | ldapurihash | link_scope | search_base
--------------------------------+------------------+------------------------+-------------+------------+-------------
2020-01-03 21:03:26.411753+05:30 | BIND_STARTED     | ---------------------- |           0 | sub        | dc=DC,dc=com
2020-01-03 21:03:26.422188+05:30 | BIND_FINISHED    | ---------------------- |           0 | sub        | dc=DC,dc=com
2020-01-03 21:03:26.422223+05:30 | SYNC_STARTED     | ---------------------- |           0 | sub        | dc=DC,dc=com
2020-01-03 21:03:26.422229+05:30 | SEARCH_STARTED   | **********             |           0 | sub        | dc=DC,dc=com
2020-01-03 21:03:32.043107+05:30 | LDAP_GROUP_FOUND | Account Operators      |           0 | sub        | dc=DC,dc=com
2020-01-03 21:03:32.04312+05:30  | LDAP_GROUP_FOUND | Administrators         |           0 | sub        | dc=DC,dc=com
2020-01-03 21:03:32.043182+05:30 | LDAP_USER_FOUND  | user1                  |           0 | sub        | dc=DC,dc=com
2020-01-03 21:03:32.043186+05:30 | LDAP_USER_FOUND  | user2                  |           0 | sub        | dc=DC,dc=com
2020-01-03 21:03:32.04319+05:30  | SEARCH_FINISHED  | **********             |           0 | sub        | dc=DC,dc=com
```

Configuring LDAP link sync

After configuring the search space, you'll have a list of users and groups. LDAP sync maps LDAP users and groups to their equivalents in Vertica. The LDAPLinkUserName maps to the Vertica usernames and the LDAPLinkGroupName maps to Vertica roles.

```
=> SELECT LDAP_LINK_DRYRUN_SYNC('LDAPLinkURL','LDAPLinkBindDN','LDAPLinkBindPswd','LDAPLinkSearchBase',
'LDAPLinkScope','LDAPLinkFilterUser','LDAPLinkFilterGroup','LDAPLinkUserName','LDAPLinkGroupName',
'LDAPLinkGroupMembers',[LDAPLinkSearchTimeout],['LDAPLinkJoinAttr']);
```

Dry run sync example

To perform a dry run to map the users and groups returned from LDAP_LINK_DRYRUN_SEARCH, pass the same parameters as arguments to LDAP_LINK_DRYRUN_SYNC.

```
=> SELECT LDAP_LINK_DRYRUN_SYNC('ldap://example.dc.com','CN=amir,OU=QA,DC=dc,DC=com','$vertica$','dc=DC,dc=com','sub',
'(objectClass=person)','(objectClass=group)','uid','cn','member',10,'dn');

                    LDAP_LINK_DRYRUN_SYNC
-----------------------------------------------------------------------------------------
Dry Run Connect and Sync Completed. Query v_monitor.ldap_link_dryrun_events for results.
```

To check the results of the sync, query the system table LDAP_LINK_DRYRUN_EVENTS.

```
=> SELECT event_timestamp, event_type, entry_name, ldapurihash, link_scope, search_base from LDAP_LINK_DRYRUN_EVENTS;
       event_timestamp          |     event_type     |       entry_name       | ldapurihash | link_scope | search_base
--------------------------------+--------------------+------------------------+-------------+------------+-------------
2020-01-03 21:08:30.883783+05:30 | BIND_STARTED       | ---------------------- |           0 | sub        | dc=DC,dc=com

```

Using LDAP link

When you use LDAP Link, the following are directly affected and help you manage and monitor the LDAP Link - Vertica Analytic Database synchronization:

- User and Group management
- LDAP Link User Flag
- Blocked Commands
- Client Authentication types

To cancel an in-progress synchronization, use LDAP_LINK_SYNC_CANCEL .

User and group management

Users and groups created on the LDAP server have a specific relationship with those users and roles replicated to the Vertica server:

- The user-group relationship on the LDAP server is maintained when those users and groups (roles) are synchronized with Vertica Analytic Database.
- If a user or group name exists on the Vertica database and a user or group with the same names is synchronized from the LDAP Server using LDAP Link, the users or groups become conflicted. Vertica cannot support multiple users with the same name. To resolve this, see User Conflicts .
- If the LDAP server contains a circular relationship, Vertica accepts and creates roles for the first non-circular part of the relationship returned by the LDAP server and ignores the rest.

  For example, suppose the LDAP server contains groups A and B , where A contains B , and B contains A , creating a circular relationship.

  If the LDAP server first returns that A contains B , Vertica creates roles A and B , and grants role A to role B . Vertica then ignores the fact that group B also contains A .

LDAP Link uses the entries in the dn: section of the LDAP configuration file as the unique user identifier when synchronizing a user to the Vertica Analytic Database:

```
dn: cn=user1,ou=dev,dc=example,dc=com
cn: user1
ou: dev
id: user1
```

The uid parameter in the LDAP configuration file indicates the LDAP user name.

```
uid: user1
```

Upon synchronization, the dn: entry gets mapped to the uid: to identify the Vertica Analytic Database user.

If you change a setting in the dn: and do not change the uid: , LDAP Link interprets the user as a new user when re-synchronizing with the Vertica Analytic Database. In this case, the existing Vertica Analytic Database user with that uid: gets deleted from Vertica and a new Vertica Analytic Database user is created.

If you change the uid: and not the dn: on LDAP, the uid on the Vertica Analytic Database gets updated to the new uid. Since you did not change the dn: LDAP Link does not interpret the user as a new user.

LDAP link user flag

As a dbadmin user, you can access the vs_users table to monitor user behavior on the Vertica Analytic Database. The users table contains an ldap_dn field that identifies whether or not the Vertica Analytic Database user is also an LDAP Link user. This example shows the ldap_dn field set to dn indicating the Vertica Analytic Database user is also an LDAP Link user:

```
=> SELECT * FROM vs_users;
-[ RECORD 1 ]---------+----------------------------------------------------
user_id               | 45035996273704962
user_name             | dbadmin
is_super_user         | t
profile_name          | default
is_locked             | f
lock_time             |
resource_pool         | general
memory_cap_kb         | unlimited
temp_space_cap_kb     | unlimited
run_time_cap          | unlimited
max_connections       | unlimited
connection_limit_mode | database
idle_session_timeout  | unlimited
all_roles             | dbduser*, dbadmin*, pseudosuperuser*
default_roles         | dbduser*, dbadmin*, pseudosuperuser*
search_path           |
ldap_dn               | dn
ldap_uri_hash         | 0
is_orphaned_from_ldap | f
```

Blocked commands

Be aware that the following SQL statements are blocked for Vertica users with ldapdn set to dn in the vs_users table:

- DROP USER and DROP ROLE
- ALTER ROLE
- ALTER USER name IDENTIFIED BY 'password' [REPLACE 'old_password']
- ALTER USER name PASSWORD EXPIRE
- ALTER USER name PROFILE
- ALTER USER name SECURITY_ALGORITHM...
- ALTER USER name DEFAULT ROLE role-name
- GRANT (Role)

Client authentication types

LDAP user and groups cannot log in to Vertica if client authentication is not assigned to the user or group. You can use the following valid authentication types for LDAP users and groups:

- GSS
- Ident
- LDAP
- Reject
- Trust

LDAP link parameters

Use LDAP Link parameters to determine:

- LDAP Link operations, such as enabling or disabling LDAP Link and how often to perform replication
- Authentication parameters, including SSL authentication parameters
- Users and groups that inherit unowned objects
- How to resolve conflicts

To configure TLS for LDAP Link, see TLS for LDAP link .

Set LDAP link parameters

This example shows how you can set:

- LDAPLinkURL , the URL of the LDAP server.
- LDAPLinkSearchBase , the base DN from which to start replication.

You also see how to set the LDAP Link Bind authentication parameters (LDAPLinkBindDN and LDAPLinkBindPswd) and enables LDAP Link (LDAPLinkOn).

```
=> ALTER DATABASE myDB1 SET PARAMETER LDAPLinkURL='ldap://10.60.55.128',
LDAPLinkSearchBase='dc=corp,dc=com',LDAPLinkBindDN='dc=corp,dc=com',LDAPLinkBindPswd='password';

=> ALTER DATABASE myDB1 SET PARAMETER LDAPLinkOn = '1';
```

General and connection parameters

Parameter	Description
LDAPLinkOn	Enables or disables LDAP Link. **Valid Values:** **0** —LDAP Link disabled **1** —LDAP Link enabled **Default:** 0
LDAPLinkURL	The LDAP server URL. To use a plaintext connection between Vertica and the LDAP server, begin the LDAPLinkURL with ldap:// and set the TLSMODE of LDAPLink to DISABLE . To use StartTLS, begin the LDAPLinkURL with ldap:// and set the TLSMODE of LDAPLink to ENABLE or higher. To use LDAPS, begin the LDAPLinkURL with ldaps:// and set the TLSMODE of LDAPLink to ENABLE or higher. **Example:** => SET PARAMETER LDAPLinkURL='ldap://example.dc.com';
LDAPLinkInterval	The time interval, in seconds, by which the LDAP Server and Vertica server synchronize. **Default:** 86400 (one day).
LDAPLinkFirstInterval	The first interval, in seconds, for LDAP/Vertica synchronization after the clerk node joins the cluster. **Default:** 120
LDAPLinkRetryInterval	The time, in seconds, the system waits to retry a failed synchronization. **Default:** 10
LDAPLinkRetryNumber	The number of retry attempts if synchronization failed. **Default:** 10.
LDAPLinkSearchBase	The base dn from where to start replication. **Example:** => SET PARAMETER LDAPLinkSearchBase='ou=vertica,dc=mycompany,dc=com'; Vertica recommends using a separate OU for database users.
LDAPLinkSearchTimeout	The timeout length, in seconds, for the LDAP search operation during an LDAP Link Service run. **Default:** 10

LDAPLinkScope	Indicates what dn level to replicate. **Valid Values:** • **sub** —Replicate entire subtree under baseDN • **one** —Replicate to one level under baseDN • **base** —Replicate only the baseDN level If you decrease the scope (for example, sub to one), some users may not be recognized during the next synchronization. **Default:** sub
LDAPLinkFilterUser	Determines how to filter users to be replicated. **Default:** "(objectClass=inetOrgPerson)"
LDAPLinkFilterGroup	Determines how to filter groups to be replicated. **Default:** "(objectClass=groupofnames)"
LDAPLinkGroupName	[Optional] The LDAP field to use when creating a role name in Vertica. **Default:** cn
LDAPLinkGroupMembers	The LDAP group that identifies the members of an LDAP group. This attribute returns a Fully Qualified Domain Name (FQDN). **Default:** member
LDAPLinkUserName	The LDAP field to use when creating a user name in Vertica. **Default:** uid
LDAPLinkJoinAttr	Specifies the attribute on which you want to join to assign users to their roles. **Default:** dn **Example:** POSIX groups associate users and groups with the uid attribute instead of dn . => SET PARAMETER LDAPLinkJoinAttr='uid';

Authentication parameters

Parameter	**Description**
LDAPLinkBindDN	The LDAP Bind DN used for authentication. **Example:** => SET PARAMETER LDAPLinkBindDN='CN=amir,OU=QA,DC=dc,DC=com';
LDAPLinkBindPswd	The valid password for the LDAP Bind DN to access the server. Only accessible by the dbadmin user. **Example:** => SET PARAMETER LDAPLinkBindPswd='password';

Miscellaneous parameters

Parameter	Description
LDAPLinkConflictPolicy	Determines how to resolve a user conflict. **Valid Values:** IGNORE—Ignores the incoming LDAP user and maintains the existing Vertica user. MERGE—Converts the existing user to an LDAP user. **Default:** MERGE
LDAPLinkStopIfZeroUsers	Enables or disables the shutdown of LDAPLink synchronization if no users are found in LDAP. **Valid values:** 0 - Disables the LDAPLink synchronization shutdown if no users are found. This may lead to inadvertent dropping of Vertica users. 1 - Enables the LDAPLink synchronization shutdown if no users are found. This prevents inadvertent dropping of Vertica users.
LDAPLinkDryRun	[Optional] Tests the connection to the LDAP server and logs the response without doing a synchronization. Also tests if parameters are correctly set. Note that this parameter is not the preferred dry run method. Instead, the LDAP_Link_Dryrun family of meta-functions provides more granular control over configurations and is the preferred way to perform LDAP Link dry runs . **Valid Values:** 0 - Disables LDAPLinkDryRun 1 - Enables LDAPLinkDryRun **Default:** 0
LDAPLinkConfigFile	[Optional] If this parameter is set with the path to a .LDIF file, the LDAP Link service will use the file as the source tree instead of connecting to the LDAP server.

See Managing configuration parameters: VSQL for information on setting LDAP Link parameters.

> **Note**
> When you change any Connection or Authentication parameter, LDAP Link reconnects and re-initializes the synchronization.

TLS for LDAP link

Vertica establishes a connection to an LDAP server in two contexts, and each context has a corresponding TLS CONFIGURATION that controls if each connection should use TLS:

1. **LDAPLink** : using the LDAPLink service or its dry run functions to synchronize users and groups between Vertica and the LDAP server.
2. **LDAPAuth** : when a user with an ldap authentication method attempts to log into Vertica, Vertica attempts to bind the user to a matching user in the LDAP server. If the bind succeeds, Vertica allows the user to log in.

Query TLS_CONFIGURATIONS to view existing TLS CONFIGURATIONs:

```
=> SELECT * FROM tls_configurations WHERE name IN ('LDAPLink', 'LDAPAuth');
   name   |  owner  | certificate | ca_certificate | cipher_suites |  mode
----------+---------+-------------+----------------+---------------+----------
 LDAPLink | dbadmin | client_cert | ldap_ca        |               | VERIFY_CA
 LDAPAuth | dbadmin | client_cert | ldap_ca        |               | DISABLE
(2 rows)
```

This page covers the LDAPLink context. For details on the LDAPAuth context, see TLS for LDAP authentication .

Configuring LDAP link TLS

Vertica uses the LDAP Link service to retrieve users and groups from the LDAP server and to create corresponding users and roles in the database. To configure TLS for LDAP Link and its dry run functions , use the following procedure.

For details on key and certificate generation, see Generating TLS certificates and keys .

1. If you want Vertica to verify the LDAP server's certificate before establishing the connection, generate or import a CA certificate and add it to the LDAPLink TLS CONFIGURATION.
   For example, to import the existing CA certificate LDAP_CA.crt :

   ```
   => \set ldap_ca '\''`cat ldap_ca.crt`'\''
   => CREATE CA CERTIFICATE ldap_ca AS :ldap_ca;
   CREATE CERTIFICATE
   ```

   Then, to add the ldap_ca CA certificate to LDAPLink:

   ```
   ALTER TLS CONFIGURATION LDAPLink ADD CA CERTIFICATES ldap_ca;
   ```

2. If your LDAP server verifies client certificates, you must generate or import a client certificate and its key and add it to the LDAPLink TLS CONFIGURATION. Vertica presents this certificate to the LDAP server for verification by its CA.
   For example, to import the existing certificate client.crt (signed by the imported CA) and key client.key :

   ```
   => \set client_key '\''`cat client.key`'\''
   => CREATE KEY client_key TYPE 'RSA' AS :client_key;
   CREATE KEY

   => \set client_cert '\''`cat client.crt`'\''
   => CREATE CERTIFICATE client_cert AS :client_cert SIGNED BY ldap_ca KEY client_key;
   CREATE CERTIFICATE
   ```

   Then, to add client_cert to LDAPLink:

   ```
   => ALTER TLS CONFIGURATION LDAPLink CERTIFICATE client_cert;
   ```

3. Enable TLS or LDAPS (the exact protocol used depends on the value of host in the AUTHENTICATION object) by setting the TLSMODE to one of the following. TRY_VERIFY or higher requires a CA certificate:
   - **ENABLE** : Enables TLS. Vertica does not check the LDAP server's certificate.
   - **TRY_VERIFY** : Establishes a TLS connection if one of the following is true:
     - The LDAP server presents a valid certificate.
     - The LDAP server doesn't present a certificate.

     If the LDAP server presents an invalid certificate, a plaintext connection is used.
   - **VERIFY_CA** : Connection succeeds if Vertica verifies that the LDAP server's certificate is from a trusted CA. Using this TLSMODE forces all connections without a certificate to use plaintext.
   - **VERIFY_FULL** : Connection succeeds if Vertica verifies that the LDAP server's certificate is from a trusted CA and the cn (Common Name) or subjectAltName attribute matches the hostname or IP address of the LDAP server.
     The cn is used for the username, so subjectAltName must match the hostname or IP address of the LDAP server.

   For example:

   ```
   => ALTER TLS CONFIGURATION LDAPLink TLSMODE 'verify_ca';
   ALTER TLS CONFIGURATION
   ```

4. Set the LDAP Link Parameters according to your use case.

Troubleshooting LDAP link issues

Various issues can arise with LDAP Link service, including:

- Disconnected (Orphaned) users and roles
- Lost objects

- User conflicts

Disconnected (orphaned) users and roles

Vertica users and roles synchronized through LDAP Link can become disconnected, or orphaned, if an issue arises with the LDAP Link service. For example, users and roles become orphaned when you change the connection to the LDAP server as the following scenario describes:

1. Create an LDAP connection as follows:
```
=> ALTER DATABASE MyDB1 SET PARAMETER LDAPLinkURL='ldap://ebuser',
LDAPLinkSearchBase='dc=example,dc=com', LDAPLinkBindDN='mega',
LDAPLinkBindPswd='$megapassword$';
=> ALTER DATABASE MyDB1 SET PARAMETER LDAPLinkOn = '1';
```
2. Run an LDAP Link session to synchronize LDAP and Vertica users.
3. Change one or more connection parameters from Step 1. You can change the connection only if you change one of the LDAPLinkURL or LDAPLinkSearchBase parameters. Users will not be orphaned if the new and old LDAPLinkURL and LDAPLinkSearchBase contain the same set of users.
4. Run another LDAP Link session. The system attempts to re-synchronize LDAP and Vertica users. Because the connection has changed, the existing Vertica users cannot be synchronized with the LDAP users from the new connection. These Vertica users become orphaned.

As the dbadmin, you can identify orphaned users by checking the is_orphaned_from_ldap column in the USERS system table:

```
=> SELECT is_orphaned_from_ldap FROM users;
```

A field value of t indicates that the user is an orphaned user. Orphaned Vertica users cannot connect to the LDAP server and cannot login to Vertica using LDAP authentication (however, other authentication methods assigned to the user still work). In this case, you can delete the orphaned Vertica user and run the LDAP Link service to resynchronize users.

Re-parented objects

When you delete users or groups from the LDAP server, the LDAP Link service removes the same users and roles from Vertica, but does not delete objects owned by the deleted users and roles. To give these unowned objects a new owner, use the GlobalHeirUsername parameter, which specifies a user as the new parent for all objects originally owned by deleted users.

For example, to give ownership of unowned objects to user1, creating the user if it does not already exist:

```
=> ALTER DATABASE example_db SET PARAMETER GlobalHeirUsername=user1;
```

By default, this parameter is set to <auto> which re-parents objects to the dbadmin user.

If GlobalHeirUsername is empty, objects are not re-parented to another user.

For details, see Security Parameters .

User conflicts

Vertica users and roles synchronized using LDAP Link can become conflicted. Such conflicts can occur, for example, when you create a new user or group on the LDAP server and another user or role with the same name exists on the Vertica.

As the dbadmin, use one of the following parameters to resolve user conflicts:

- LDAPLinkConflictPolicy
- LDAPLinkStopIfZeroUsers

LDAPLinkConflictPolicy

LDAPLinkConflictPolicy controls how Vertica behaves when it encounters a conflict. Changes to this parameter take effect during the next synchronization.

- LDAPLinkConflictPolicy=IGNORE ignores the incoming LDAP users and retains the existing Vertica user
- LDAPLinkConflictPolicy=MERGE (default) merges the incoming LDAP user with the Vertica user and converts the database user to an LDAP user, retaining the database user's objects.

For example, to set the parameter:

```
=> ALTER DATABASE example_db SET PARAMETER LDAPLinkConflictPolcy='MERGE';
```

LDAPLinkStopIfZeroUsers

LDAPLinkStopIfZeroUsers controls how Vertica behaves when the LDAP server has zero users during synchronization.

- LDAPLinkStopIfZeroUsers=0 does not stop the synchronization if no users are found in the LDAP server and all Vertica users with are dropped.

- LDAPLinkStopIfZeroUsers=1 stops the synchronization if no users are found in the LDAP server and returns an error. No Vertica users are dropped.

LDAP_LINK_DRYRUN and LDAP_LINK_SYNC_START do not populate tables

The dryrun and LDAP_LINK_SYNC_START functions must be run from the clerk node. To determine the clerk node, query NODE_RESOURCES :

```
=> SELECT node_name, dbclerk FROM node_resources WHERE dbclerk='t';
   node_name     | dbclerk
-----------------+---------
 v_vmart_node0001 | t
(1 row)
```

Monitoring LDAP link

Use the ldap_link_events table to monitor LDAP Link synchronization:

```
=> SELECT transaction_id, event_type, entry_name, entry_oid FROM ldap_link_events;
  transaction_id |    event_type      | entry_name | entry_oid
-----------------+--------------------+------------+-----------
45035996273705317 | SYNC_STARTED       |            |         0
45066962732553589 | SYNC_FINISHED      |            |         0
45066988112255317 | PROCESSING_STARTED |            |         0
23411234566789765 | USER_CREATED       | tuser      | 234548899
(4 rows)
```

Connector framework service

The Connector Framework Service (CFS) allows secure indexing of documents from IDOL to the Vertica Analytic Database. Access control lists determine which users have permissions to access documents. Documents transferred from IDOL are stored in a flex table (Flex tables).

Important

Vertica 9.1.1 does not support the IdolLib function library. If you have the IdolLib function library installed and are upgrading to Vertica 9.1.1, you see an error and you cannot access the IdolLib function library.

To determine if the IdolLib library is installed, run the following script:

```
$ /opt/vertica/packages/idol/ddl/isinstalled.sql
```

To uninstall the IdolLib library, run the following script:

```
$ /opt/vertica/packages/idol/ddl/uninstall.sql
```

CFS components

Use the following CFS components to implement the service on the Vertica:

- IDOL document metadata
- CFS Configuration file

For detailed information, see Implementing CFS .

IDOL document metadata

Vertica Analytic Database stores IDOL document metadata in a flex table. Set the name of the flex table with the TableName parameter in the CFS configuration file (see Implementing CFS). The metadata includes the following:

- AUTONOMYMETADATA (Mandatory): An alphanumeric designation for the ACL designated for the document.
- DREFIELD: Assigns permission levels to users and groups for accessing IDOL documents.
- DRETITLE: The document title.

CFS configuration file

You must index IDOL metadata in Vertica Analytic Database to be available for queries. See Implementing CFS .

In this section

- Implementing CFS

Implementing CFS

After Vertica ingests documents from IDOL into flex tables, you can implement CFS to secure those documents. Implementing the security requires that the Vertica database administrator modify the CFS configuration file.

Modify the CFS configuration file

The database administrator must modify the following in the CFS configuration file to have CFS automatically index the metadata:

1. In the [Indexing] section, set the IndexerSections parameter to vertica:

```
[Indexing]
IndexerSections=vertica
IndexBathSize=1
IndexTimeInterval=30
```

2. Create a new section with the same name you entered in the IndexerSections parameter and enter the following parameters and keywords:

```
[vertica]
IndexerType=Library
ConnectionString=Driver=Vertica;Server=123.456.478.900;Databaswe=myDb;UID=dbadmin;PWD=password
TableName=myFlexTable
LibraryDirectory= ./shared_library_indexers
LibraryName=VerticaIndexer
```

The VerticaIndexer (LibraryName above) is part of CFS. To use this tool, you must install and configure the Vertica ODBC drivers on the same machine as CFS. CFS sends JSON-formatted data to the Flex table using ODBC.

For more information, see Installing ODBC drivers on Linux .

Query the IDOL data

To query the IDOL data in a flex table, run a simple SELECT query. In this example, idol_table is the name of the flex table:

```
=> SELECT * FROM idol_table;
```

Federal information processing standard

When running on a FIPS-compliant operating system that Vertica supports , Vertica uses a certified OpenSSL FIPS 140-2 cryptographic module. This meets the security standards set by the National Institute of Standards and Technology (NIST) for Federal Agencies in the United States or other countries.

The standard specifies the security requirements that a cryptographic module needs in a system protecting sensitive information. For details on the standard see the Computer Security Resource Center .

> **Note**
> Vertica itself is not FIPS compliant but it is compatible with running on a FIPS-enabled system using FIPS resources.

For a list of FIPS prerequisites, see FIPS 140-2 supported platforms .

In this section

- OpenSSL behavior
- FIPS-Enabled databases: limitations
- Implementing FIPS 140-2
- FIPS 140-2 compliance statement

OpenSSL behavior

Dynamic OpenSSL linking is a requirement for a FIPS implementation on the client and server. The Vertica server uses the OpenSSL that resides on the host system (as indicated in FIPS 140-2 supported platforms). OpenSSL dynamically links with LDAP and Kerberos.

For more information see Locate OpenSSL Libraries .

Libraries on CentOS systems

On a FIPS-compliant CentOS system, Vertica runs only with the OpenSSL libraries listed in FIPS 140-2 supported platforms . Other versions of these libraries do not run on a FIPS system. This incompatibility occurs because the FIPS security policy checksums the library to which an application is linked and verifies that the library the application executes with the same checksum.

Library versioning on Non-FIPS systems

Be aware that on some non-FIPS systems, versioning anomalies can occur when you install a new version of OpenSSL. Sometimes, the default OpenSSL build procedure produces libraries with versions named 1.0.0. For Vertica to recognize that a library has a higher version number, you must provide the library name with a higher version number. For example, when installing OpenSSL version 1.0.1t, name the libraries libcrypto.so.1.0.1t or libssl.1.0.1t (symbolic links with these names are sufficient).

FIPS-Enabled databases: limitations

FIPS-enabled databases have the following limitations:

- You cannot create a FIPS-enabled database on a non-FIPS machine.
- You cannot create a non-FIPS database on a FIPS-enabled machine.
- The Management Console and its daemon, Agent , are not available on FIPS-enabled databases.
- Copying data generated with the MD5 hashing algorithm from a non-FIPS machine to a FIPS-enabled machine results in data corruption.
- Due to limitations in the FIPS cryptographic module, Vertica does not recommend enabling internode encryption in FIPS environments. If you use FIPS and internode encryption, you may experience occasional query failure due to socket closure in workloads that send a high volume of data across the network.

Implementing FIPS 140-2

Implementing FIPS 140-2 on your Vertica Analytic Database requires configuration on the server and client. While Vertica server uses FIPS-approved algorithms, Vertica clients may be running on non-FIPS-approved systems. Therefore, you must implement FIPS 140-2 compliance from end to end.

For more information on implementing FIPS, see:

- FIPS compliance for the Vertica server
- Implement FIPS on the client

In this section

- FIPS compliance for the Vertica server
- Implement FIPS on the client

FIPS compliance for the Vertica server

To make Vertica FIPS-compliant, you must:

- Set the RequireFIPS parameter to 1.
- Hash your passwords with SHA-512. See Hash authentication for details.
- Generate a signed TLS certificate to establish a secure connection to the client.

RequireFIPS parameter

Vertica sets the RequireFIPS configuration parameter on the server on startup to reflect the state of FIPS on the system: 1 if FIPS is enabled and 0 if FIPS is disabled.

The value of RequireFIPS matches the value of crypto.fips_enabled file.

Vertica sets the RequireFIPS parameter based on the contents of crypto.fips_enabled :

- If the file /proc/sys/crypto/fips_enabled exists and contains a 1 (FIPS-enabled), Vertica sets RequireFIPS to 1.
- If the file /proc/sys/crypto/fips_enabled does not exist, or exists and contains a 0 (non-FIPS), Vertica automatically sets RequireFIPS to 0.
- If the FIPS state of a node, as determined from the existence of /proc/sys/crypto/fips_enabled , differs from the state received from the cluster initiator, the node fails. This behavior prevents the creation of clusters of mixed FIPS and non-FIPS systems.

Important
If you attempt to restore a FIPS-enabled node to a non-FIPS cluster, the restore will fail.

Secure client-server connection

It's important to secure client-server connections with TLS. For instructions on setting up client-server TLS, see Configuring client-server TLS .

FIPS-Compliant AWS endpoints

To configure AWS to use a FIPS-compliant S3 Endpoint , set the following S3 parameters :

```
AWSEndpoint = s3-fips.dualstack.us-east-1.amazonaws.com
S3EnableVirtualAddressing = 1
```

Implement FIPS on the client

Vertica provides a FIPS-compliant client driver, which you can install on a FIPS-enabled system. The 64-bit client includes vsql and ODBC drivers.

For information about installing the FIPS client, and installation, refer to the following

- Installing the FIPS client driver for ODBC and vsql
- Installing the FIPS client driver for JDBC

FIPS 140-2 compliance statement

Contents

1. Summary

2. Overview

a. About Vertica

b. About FIPS 140-2

3. Vertica and FIPS 140-2

1. summary

Vertica complies with Federal Information Processing Standard 140-2 (FIPS 140-2), which defines the technical requirements to be used by Federal Agencies when these organizations specify cryptographic-based security systems for protection of sensitive or valuable data. The compliance of Vertica with FIPS 140-2 is ensured by: 1) Integrating validated and NIST-certified third party cryptographic module(s), and using the module(s) as the only provider(s) of cryptographic services; 2) Using FIPS-approved cryptographic functions; 3) Using FIPS-approved and NIST-validated technologies applicable for Vertica design, implementation and operation.

2. overview

a. About Vertica

- Vertica is a high performance relational database management system used for advanced analytics applications. Its performance and scale is achieved through a columnar storage and execution architecture that offers a massively parallel processing solution. Aggressive encoding and compression allows Vertica analytics to perform by reducing CPU, memory and disk I/O Processing times.
- For more details about Vertica and its usage, see Architecture .

b. About FIPS 140-2

FIPS (Federal Information Processing Standard) 140-2, *Security requirements for cryptographic modules* , is the Federal standard for proper cryptography for computer systems purchased by the government.

The Federal Information Processing Standards Publication (FIPS) 140-2, “Security Requirements for Cryptographic Modules,” was issued by the National Institute of Standards and Technology (NIST) in May, 2001.

The benefits of using FIPS 140-2 validated crypto module is that the crypto algorithms are deemed appropriate and that they perform the encrypt/decrypt/hash functions correctly. The standard specifies the security requirements for cryptographic modules utilized within a security system that protects sensitive or valuable data. The requirements can be found in the following documents:

- SECURITY REQUIREMENTS FOR CRYPTOGRAPHIC MODULES
- Annex A: Approved Security Functions for FIPS PUB 140-2, Security Requirements for Cryptographic Modules

3. Vertica and FIPS 140-2

FIPS 140-2 validated third party module

Vertica conforms with FIPS 140-2 Level 1 compliance by dynamically linking to the FIPS 140-2 approved OpenSSL cryptographic module provided by the Operating System, which in our initial release is Red Hat Enterprise Linux 6.6 OpenSSL Module.

Vertica can be configured to operate in FIPS-compliant mode ensuring its functions and procedures like SSL/TLS connections, which require cryptography (secure hash, encryption, digital signatures, etc.) makes use of the crypto services provided by RedHat Enterprise Linux 6.6 OpenSSL Module v3.0 which is validated for FIPS 140-2. If you are not running on a FIPS-compliant operating system that Vertica supports , you will not be able

to run Vertica on FIPS mode. The assurance that Vertica is using the right FIPS 140-2 encryption modules is managed at the operating system level by RedHat's implementation.

Vertica checks the OS level flag setting /proc/sys/crypto/fips_enabled to kick off Vertica's FIPS mode installation. Further details about how to install and configure Vertica and its components to conform to FIPS 140-2 standard appear in the installation and security guides:

- Installing Vertica with the installation script
- Federal information processing standard

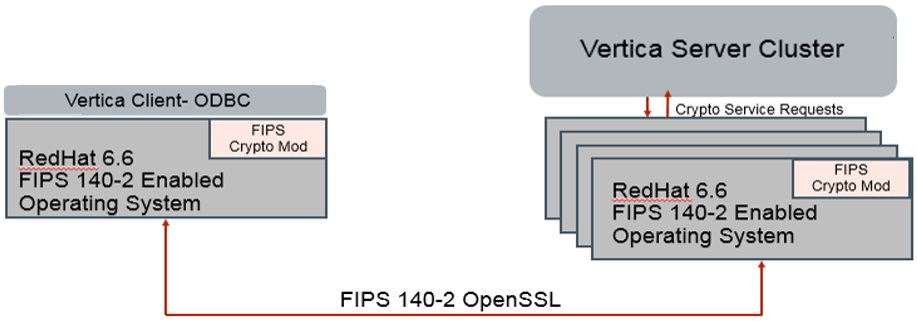
Modes of Operation

Vertica Server operates in one of two modes determined by the OS configuration.

- FIPS-compliant mode – supports FIPS 140-2 compliant cryptographic functions. In this mode, all cryptographic functions, default algorithms and key lengths are bound to those allowed by FIPS 140-2.
- Standard mode – non-FIPS 140-2 compliant mode which utilizes all existing Vertica cryptography functions.

TLS/SSL3.x

All the Vertica client/server communications can be secured with FIPS-compliant Transport Layer Security TLS1.2/SSL3.1 or higher. It is relying on FIPS 140-2 approved hash algorithms and ciphers.



- TLS handshake, key negotiation and authentication provides data integrity and uses secure hash and FIPS 140-2 approved cryptography and digital signature.
- TLS encryption of data in transit provides confidentiality and making use of FIPS 140-2 approved cryptography.

Secure Hash

Per FIPS 140-2 standards, Vertica, in the FIPS 140-2 compliant mode, can be configured to use only the SHA-512 algorithm.

FIPS 140-2 Architecture

Vertica is a relational database system that is comprised of a client component and a server component. On the Client Side, we offer a suite of drivers for host clients to access the Vertica Server Side component. Both client and server Vertica components conform to FIPS 140-2 Level 1 compliance by dynamically linking to the FIPS 140-2 approved OpenSSL cryptographic module provided by RedHat Enterprise Linux 6.6 OpenSSL Module.

Supported Platforms

See FIPS 140-2 supported platforms for information about FIPS-compliant operating systems and client drivers that Vertica supports.

Design Assurance

Vertica uses the security provider Red Hat Enterprise Linux 6.6 OpenSSL Module v3.0 . This is the only supported security provider for FIPS 140-2.

Once you have configured Vertica to be compliant with FIPS 140-2, you cannot revert back to the standard configuration unless you disable FIPS 140-2 at the operating system level. Please reference the following documentation section for considerations:

- FIPS compliance for the Vertica server
- Implement FIPS on the client

Database auditing

Database auditing often involves observing a database to be aware of the actions the database users are taking. Auditing can help with security, for example, to ensure that a user does not change information to which they should not have access. Audit categories make it easier to track changes within the database. You can see system tables that will bring together logged queries, tables, and changes to configuration parameters.

For example, the authentication audit category tracks queries, system tables, and configuration parameters related to security and authentication, such as:

- DROP AUTHENTICATION statement
- GRANT/REVOKE authentication statements
- LDAP Link related configuration parameters

You can also use the authentication audit category for weekly security reports to better understand attempts to gain access to data or to view unauthorized changes.

There are three system tables that can be used to track changes for queries, parameters, and tables as follows:

- LOG_PARAMS
- LOG_QUERIES
- LOG_TABLES

There is also a system table for tracking changes to privileges for users:

- AUDIT_MANAGING_USERS_PRIVILEGES

System table restriction and access

Two functions let you restrict and open access to system tables for a given session:

- RESTRICT_SYSTEM_TABLES_ACCESS restricts access to non-superuser-only tables that are not accessible during lockdown.
- RELEASE_SYSTEM_TABLES_ACCESS allows access to non-superuser-only tables that are not accessible during lockdown.

Connecting to Vertica

This book explains several methods of connecting to Vertica, including:

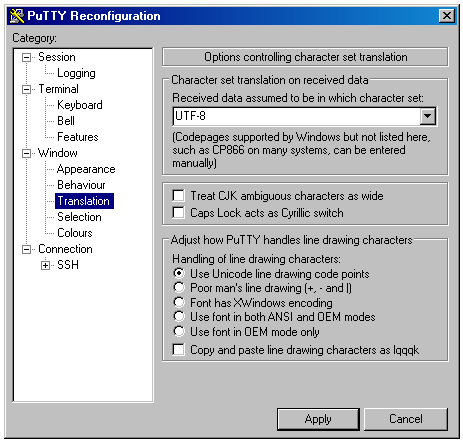
- Directly connecting to Vertica using the vsql client application.
- Installing and configuring the Vertica client libraries to allow client applications to access Vertica.
- Developing your own client applications using the Vertica client libraries.

In this section

- Using vsql
- Client libraries
- Management API
- SQLTools Vertica driver
- Connect with an SSH tunnel

Using vsql

vsql is a character-based, interactive, front-end utility that lets you type SQL statements and see the results. It also provides a number of meta-commands and various shell-like features that facilitate writing scripts and automating a variety of tasks.



If you are using the vsql client installed on the server, then you can connect from the:

- Administration Tools
- Linux command line

You can also install the vsql client for other supported platforms.

General notes

- SQL statements can be spread over several lines for clarity.
- vsql can handle input and output in UTF-8 encoding. The terminal emulator running vsql must be set up to display the UTF-8 characters correctly. The following example shows the settings in PuTTy:

See also Best Practices for Working with Locales .

- Cancel SQL statements by typing Ctrl+C.
- Traverse command history by typing Ctrl+R.
- When you disconnect a user session, any transactions in progress are automatically rolled back.
- To view wide result sets, use the Linux less utility to truncate long lines.

  1. Before connecting to the database, specify that you want to use less for query output:

     ```
     $ export PAGER=less
     ```

  2. Connect to the database.
  3. Query a wide table:

     ```
     => select * from wide_table;
     ```

  4. At the less prompt, type:

     ```
     -S
     ```

  If a shell running vsql fails (crashes or freezes), the vsql processes continue to run even if you stop the database. In that case, log in as root on the machine on which the shell was running and manually terminate the vsql process. For example: $ ps -ef | grep vertica ... fred 2401 1 0 06:02 pts/1 00:00:00 /opt/vertica/bin/vsql -p 5433 -h test01_site01 quick_start_single ... $ kill -9 2401

In this section

- Installing the vsql client
- Connecting from the administration tools
- Connecting from the command line
- Meta-commands
- Variables
- Prompting
- Command line editing
- vsql environment variables
- Locales
- Entering data with vsql
- Files
- Exporting data using vsql
- Copying data using vsql
- Output formatting examples

Installing the vsql client

The vsql client is installed as part of the Vertica server rpm. It is also available as a download for other Unix-based systems.

Linux and macOS

> **Note**
> For Linux: The vsql client is automatically installed as part of the Vertica server .rpm .

To install vsql manually on another system:

1. Download vsql.
2. Extract or install vsql:

- If you downloaded the .tar , create the /opt/vertica/ directory if it does not already exist, copy the .tar to it, navigate to it, and extract the .tar :

```
$ mkdir -p /opt/vertica/
$ cp driver_name.tar.gz /opt/vertica/
$ tar vzxf driver_name.tar.gz
```

- If you downloaded the .rpm , install it with:

```
$ rpm -Uvh driver_name.rpm
```

3. Optionally add the vsql directory to your PATH. For example:

```
$ export PATH=$PATH:\opt\vertica\bin
```

4. Make the vsql client executable. For example, to allow all users to run vsql:

```
$ chmod ugo+x /path/to/vsql
```

5. Set your shell locale to a locale supported by vsql (which ones?). For example, in your .profile , add:

```
export LANG=end_US.UTF-8
```

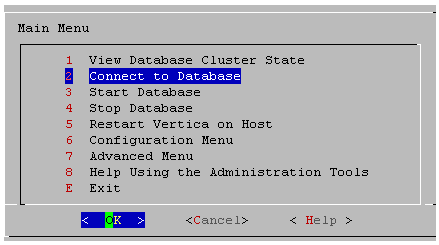
Windows installation

vsql on Windows is installed as part of the Windows Client Driver package. For installation details, see The Vertica client drivers and tools for windows .

See Using vsql for windows users for details on using vsql in a Windows console.

Connecting from the administration tools

You can use the Administration tools to connect to a database using vsql on any node in the cluster.



1. Log in as the database administrator user; for example, dbadmin.

> **Note**
> Vertica does not allow users with root privileges to connect to a database for security reasons.

2. Run the Administration Tools.

```
$ /opt/vertica/bin/admintools
```

3. On the Main Menu, select **Connect to Database** .

4. If prompted, enter the database password:

```
Password:
```

When you create a new user with the CREATE USER command, you can configure the password or leave it empty. You cannot bypass the password if the user was created with a password configured. You can change a user's password using the ALTER USER command.

5. The Administration Tools connect to the database and transfer control to vsql .

```
Welcome to vsql, the Vertica Analytic Database interactive terminal.
Type:  \h or \? for help with vsql commands
     \g or terminate with semicolon to execute query
     \q to quit

=>
```

> **Note**
> See Meta-commands for the various commands you can run while connected to the database through the Administration Tools.

Connecting from the command line

You can connect to a database using vsql from the command line on multiple client platforms.

If the connection cannot be made for any reason—for example, you have insufficient privileges, or the server is not running on the targeted host—vsql returns an error and terminates.

Syntax

```
/opt/vertica/bin/vsql [-h host] [ option...] [ dbname [ username ] ]
```

Parameters

host

Optional if you connect to a local server. You can provide an IPv4 or IPv6 IP address or a host name.

For Vertica servers that have both IPv4 and IPv6 addressed and you have provided a host name instead of an IP address, you can prefer to use an IPv4 address with the -4 option and to use the IPv6 adddress with the -6 option if the DNS is configured to provide both IPv4 and IPv6 addresses. If you are using IPv6 and provide an IP address, you must append the address with an % *interface name* .

option

One or more vsql command-line options .

If the database is password protected, you must specify the -w or --password command line option.

*** dbname ***

The name of the target database, by default your Linux user name.

*** username ***

A database username, by default your Linux user name.

Exit codes

vsql returns 0 to the shell when it terminates normally. Otherwise, it returns one of the following:

- 1: A fatal error occurred—for example, out of memory or file not found.
- 2: The connection to the server went bad and the session was not interactive
- 3: An error occurred in a script and the variable ON_ERROR_STOP was set.
- Unrecognized words in the command line might be interpreted as database or user names.

Examples

The following example shows how to capture error messages by redirecting vsql output to the output file retail_queries.out :

```
$ vsql --echo-all < retail_queries.sql > retail_queries.out 2>&1
```

In this section

- Command-line options
- Connecting from a non-cluster host

Command-line options

This section contains the command-line options for vsql.

General options

--command command

-c command

Runs one command and exits. This command is useful in shell scripts.

Variables set with -v are not processed when referenced in a -c command. To use variables, create a .sql file that references the variable and pass it to vsql with the -f option.

--dbname dbname

-d dbname

Specifies the name of the database to which you want to connect. Using this command is equivalent to specifying **dbname** as the first non-option argument on the command line.

--file filename

-f filename

Uses the *filename* as the source of commands instead of reading commands interactively. After the file is processed, vsql terminates.

--help

Displays help about vsql command line arguments and exits.

--timing

-i

Enables the \timing meta-command.

--list

-l

Returns all available databases, then exits. Other non-connection options are ignored. This command is similar to the internal command \list .

--set ***assignment***

--variable ***assignment***

-v ***assignment***

Performs a variable assignment, like the vsql command \set .

--version -V

Prints the vsql version and exits.

--no-vsqlr

-X

Disables all command line editing and history functionality.

Connection options

-4

When resolving hostnames in dual stack environments, prefer IPv4 addresses.

-6

When resolving hostnames in dual stack environments, prefer IPv6 addresses.

-B ***server:port*** **[,...]**

Sets connection backup server/port. Use comma-separated multiple hosts (default: not set). If using an IPv6 address, enclose the address in brackets ([,]) and place the port outside of the brackets. For example \B [2620:0:a13:8a4:9d9f:e0e3:1181:7f51]:5433

--enable-connection

-load-balance -C

Enables connection load balancing (default: not enabled).

> **Note**
> You can only use load balancing with one address family in dual stack environments. For example, if you've configured load balancing for IPv6 addresses, then when an IPv4 client connects and requests load balancing the server does not allow it.

--host ***hostname***

-h ***hostname***

Specifies the host name of the machine on which the server is running.

-k ***krb-service***

Provides the service name portion of the Kerberos principal (default: vertica). Using -k is equivalent to using the drivers' KerberosServiceName connection string.

-K ***krb-host***

Provides the instance or host name portion of the Kerberos principal. -K is equivalent to the drivers' KerberosHostName connection string.

--sslmode

-m

Specifies the policy for making SSL connections to the server. Options are require, prefer, allow, and disable. You can also set the VSQL_SSLMODE variable to achieve the same effect. If the variable is set, the command-line option overrides it.

--port ***port***

-p ***port***

Specifies the TCP port or the local socket file extension on which the server is listening for connections. Defaults to port 5433.

--username ***username***

-U ***username***

Connects to the database as the user *username* instead of the default.

-w *password*

Specifies the password for a database user.

> **Note**
> Using this command-line option displays the database password in plain text. Use it with care, particularly if you are connecting as the database administrator, to avoid exposing sensitive information.

--password

-W

Forces vsql to prompt for a password before connecting to a database.The password is not displayed on the screen. This option remains set for the entire session, even if you change the database connection with the meta-command \connect .

Output formatting

--no-align

-A

Switches to unaligned output mode. (The default output mode is aligned.)

-b

Beep on command completion.

--field-separator *separator*

-F *separator*

Specifies the field separator for unaligned output (default: "|") (-P fieldsep=). (See -A --no-align .) Using this command is equivalent to \pset fieldsep or \f .

--html

-H

Turns on HTML tabular output. Using this command is equivalent to using the \pset format html or the \H command.

--pset *assignment*

-P * assignment *

Lets you specify printing options in the style of \pset on the command line. You must separate the name and value with an equals (=) sign instead of a space. Thus, to set the output format to LaTeX, you could write -P format=latex .

-Q

Turns on trailing record separator. Use \pset trailingrecordsep to toggle the trailing record separator on or off.

--record-separator *separator*

-R *separator*

Uses *separator* as the record separator. Using this command is equivalent to using the \pset recordsep command.

--tuples-only

-t

Disables printing of column names, result row count footers, and so on. This is equivalent to the vsql meta-command \t .

--table-attr *options*

-T * options *

Allows you to specify options to be placed within the HTML table tag. See \pset for details.

--expanded

-x

Enables extended table formatting mode. This is equivalent to the vsql meta-command \x .

Input and output options

--echo-all

-a

Prints all input lines to standard output as they are read. This approach is more useful for script processing than interactive mode. It is the same as setting the variable ECHO to all .

--echo-queries

-e

Copies all SQL commands sent to the server to standard output. Using this command is equivalent to setting the variable ECHO to queries.

-E

Displays queries generated by internal commands.

-n

Disables command line editing.

--output *filename*
-o *filename*

Writes all query output to *filename* . Using this command is equivalent to using the vsql meta-command \o .

--quiet
-q

Specifies that vsql do its work quietly (without informational output, such as welcome messages). This command is useful with the -c option. Within vsql you can also set the QUIET variable to achieve the same effect.

--single-step
-s

Runs in single-step mode for debugging scripts. Forces vsql to prompt before each statement is sent to the database and allows you to cancel execution.

--single-line -S

Runs in single-line mode where a newline terminates a SQL command, as if you are using a semicolon.

> **Note**
> This mode is provided only by customer request. Vertica recommends that you not use single-line mode in cases where you mix SQL and meta-commands on a line. In single-line mode, the order of execution might be unclear to the inexperienced user.

In this section

- -V --version
- -v --variable --set
- -X --no-vsqlrc
- -x --expanded

-A --no-align

-A or --no-align switches to unaligned output mode. The default output mode is aligned.

-a --echo-all

-a or --echo-all prints all input lines to standard output as they are read. This is more useful for script processing than interactive mode. It is equivalent to setting the variable ECHO to all .

-U --username

-U user-name or --username user-name connects to the database as the user user-name instead of the default.

-c --command

-c *command* or --command *command* runs one command and exits. This is useful in shell scripts.

Use either:

- A command string that can be completely parsed by the server that does not contain features specific to vsql
- A single meta-command

You cannot mix SQL and vsql meta-commands. You can, however, pipe the string into vsql as shown:

```
echo "\\timing\\\\select * from t" | ../Linux64/bin/vsql
        Timing is on.
        i | c | v
        ---+---+---
        (0 rows)
```

> **Note**
> If you use double quotes (") with echo , you must double the backslashes ().

-d --dbname

-d *db-name* or --dbname *db-name* specifies the name of the database to connect to. This is equivalent to specifying *db-name* as the first non-option argument on the command line.

-E

-E displays queries generated by internal commands.

-e --echo-queries

-e --echo-queries copies all SQL commands sent to the server to standard output as well. This is equivalent to setting the variable ECHO to queries .

-F --field-separator

-F *separator* or --field-separator *separator* specifies the field separator for unaligned output (default: "|") (-P fieldsep=). (See -A --no-align .) This is equivalent to \pset fieldsep or \f .

To set the field separator value to a control character, use your shell's control character escape notation. In Bash, you specify a control character in an argument using a dollar sign ($) followed by a string contained in single quotes. This string can contain C-string escapes (such as \t for tab), or a backslash () followed by an octal value for the character you want to use.

The following example demonstrates setting the separator character to tab (\t), vertical tab (\v) and the octal value of vertical tab (\013).

```
$ vsql -At -c "SELECT * FROM testtable;"
A|1|2|3
B|4|5|6

$ vsql -F $'\t' -At -c "SELECT * FROM testtable;"
A	1	2	3
B	4	5	6

$ vsql -F $'\v' -At -c "SELECT * FROM testtable;"
A
 1
  2
   3
B
 4
  5
   6
$ vsql -F $'\013' -At -c "SELECT * FROM testtable;"
A
 1
  2
   3
B
 4
  5
   6
```

-f --file

-f *filename* or --file *filename* uses *filename* as the source of commands instead of reading commands interactively. After the file is processed, vsql terminates.

If *filename* is a hyphen (-), standard input is read.

Using this option is different from writing vsql < *filename* . Using -f enables some additional features such as error messages with line numbers. Conversely, the variant using the shell's input redirection should always yield exactly the same output that you would have gotten had you entered everything manually.

? --help

-? --help displays help about vsql command line arguments and exits.

-H --html

-H --html turns on HTML tabular output. This is equivalent to \pset format html or the \H command.

-h --host

-h *hostname* or --host *hostname* specifies the host name of the machine on which the server is running. Use this flag to connect to Vertica remotely.

The following requirements and restrictions apply:

- If you use client authentication with a Kerberos connection method of either gss or krb5 , you must specify -h *hostname* .
- Use the -h option if you want to connect to Vertica from a local connection, but want to use the an authentication record with the access method HOST (rather than LOCAL).

-i -- timing

Enables the \timing meta-command. You can only use this command with the -c --command and -f --file commands:

```
$VSQL -h host1 -U user1 -d VMart -p 15 -w ****** -i -f transactions.sql
```

You can only use -i with the -c (command) and -f (filename) commands. For more information see Command-line options .

From the command line enter the -i option before running a session to turn timing on. For example:

```
$VSQL -h host1 -U user1 -d VMart -p 15 -w ****** -i -f transactions.sql
```

```
$VSQL-h host1 -U user1 -d VMart -p 15 -w ****** -i -c "SELECT user_name,
ssl_state, authentication_method, client_authentication_name, client_type FROM sessions
WHERE session_id=(SELECT session_id FROM current_session);"
```

-l --list

-l or --list returns all available databases, then exits. Other non-connection options are ignored. This command is similar to the internal command \list .

-m --sslmode

-m or --sslmode specifies the policy for making SSL connections to the server. Options are verify_full , verify_ca require , prefer , allow , and disable . You can also set the VSQL_SSLMODE variable to achieve the same effect. If the variable is set, the command-line option overrides it.

For information on these modes see Configuring TLS for ODBC Clients .

-n

-n disables command line editing.

-o --output

-o *filename* or --output *filename* writes all query output into file *filename* . This is equivalent to the vsql meta-command \o .

-P --pset

-P *assignment* or --pset *assignment* lets you specify printing options in the style of \pset on the command line. Note that you have to separate name and value with an equal sign instead of a space. Thus to set the output format to LaTeX, you could write -P format=latex .

-p --port

-p *port* or --port *port* specifies the TCP port or the local socket file extension on which the server is listening for connections. Defaults to port 5433.

-q --quiet

-q or --quiet specifies that vsql do its work quietly. By default, it prints welcome messages and various informational output. If this option is used, none of this appears. This is useful with the -c option. Within vsql you can also set the QUIET variable to achieve the same effect.

-R --record-separator

-R *separator* or --record-separator *separator* specifies *separator* as the record separator. This is equivalent to the \pset recordsep command.

-S --single-line

-S --single-line runs in single-line mode where a newline terminates a SQL command, like the semicolon does.

> **Note**
> This mode is provided for those who insist on it, but you are not necessarily encouraged to use it, particularly if you mix SQL and meta-commands on a line. The order of execution might not always be clear to the inexperienced user.

-s --single-step

-s --single-step runs in single-step mode for debugging scripts. Forces vsql to prompt before each statement is sent to the database and allows you to cancel execution.

-T --table-attr

-T *table-options* or --table-attr *table-options* lets you specify options to be placed within the HTML table tag. See \pset for details.

-t --tuples-only

-t or --tuples-only disables printing of column names, result row count footers, and so on. This is equivalent to the vsql meta-command \t .

-V --version

-V or --version prints the vsql version and exits.

-v --variable --set

-v *assignment* , --variable *assignment* , and --set *assignment* perform a variable assignment, like the vsql meta-command \set .

> **Note**
> You must separate name and value, if any, by an equals sign (=) on the command line.

To unset a variable, omit the equal sign. To set a variable without a value, use the equals sign but omit the value. Make these assignments at a very early stage of start-up, so that variables reserved for internal purposes can get overwritten later.

-X --no-vsqlrc

-X --no-vsqlrc prevents the start-up file from being read: the system-wide vsqlrc file or the user's ~/.vsqlrc file.

-x --expanded

-x or --expanded enables extended table formatting mode. This is equivalent to the vsql meta-command \x .

Connecting from a non-cluster host

You can use the Vertica vsql executable image on a non-cluster Linux host to connect to a Vertica database.

- On Red Hat, CentOS, and SUSE systems, you can install the client driver RPM, which includes the vsql executable. See Installing the client RPM on red hat and SUSE for details.
- If the non-cluster host is running the same version of Linux as the cluster, copy the image file to the remote system. For example:
  ```
  $ scp host01:/opt/vertica/bin/vsql .$ ./vsql
  ```
- If the non-cluster host is running a different distribution or version of Linux than your cluster hosts, you must install the Vertica server RPM in order to get vsql:
  1. Download the appropriate RPM package by browsing to Vertica website. On the **Support** tab, select **Customer Downloads** .
  2. If the system you used to download the RPM is not the non-cluster host, transfer the file to the non-cluster host.
  3. Log into the non-cluster host as root and install the RPM package using the command:
     ```
     # rpm -Uvh filename
     ```
     Where *filename* is the package you downloaded. Note that you do not have to run the install_vertica script on the non-cluster host to use vsql.

Notes

- Use the same Command-line options that you would on a cluster host.
- You cannot run vsql on a Cygwin bash shell (Windows). Use ssh to connect to a cluster host, then run vsql.

Meta-commands

Anything you enter in vsql that begins with an unquoted backslash is a vsql meta-command that is processed by vsql itself. These commands help make vsql more useful for administration or scripting. Meta-commands are more commonly called slash or backslash commands.

The format of a vsql command is the backslash, followed immediately by a command verb, then any arguments. The arguments are separated from the command verb and each other by any number of whitespace characters.

To include whitespace into an argument you can quote it with a single quote. To include a single quote into such an argument, precede it by a backslash. Anything contained in single quotes is furthermore subject to C-like substitutions for \n (new line), \t (tab), \ *digits* , \0 *digits* , and \0x *digits* (the character with the given decimal, octal, or hexadecimal code).

If an unquoted argument begins with a colon (:), it is taken as a vsql variable and the value of the variable is used as the argument instead.

Arguments that are enclosed in backquotes (```) are taken as a command line that is passed to the shell. The output of the command (with any trailing newline removed) is taken as the argument value. The above escape sequences also apply in backquotes.

Some commands take a SQL identifier (such as a table name) as argument. These arguments follow the syntax rules of SQL: Unquoted letters are forced to lowercase, while double quotes (") protect letters from case conversion and allow incorporation of whitespace into the identifier. Within double quotes, paired double quotes reduce to a single double quote in the resulting name. For example, FOO"BAR"BAZ is interpreted as fooBARbaz , and "A weird"" name" becomes A weird" name .

Parsing for arguments stops when another unquoted backslash occurs. This is taken as the beginning of a new meta-command. The special sequence \\ (two backslashes) marks the end of arguments and continues parsing SQL commands, if any. That way SQL and vsql commands can be freely mixed on a line. But in any case, the arguments of a meta-command cannot continue beyond the end of the line.

Meta-commands quick reference

Syntax	**Summary**	**Command-line Options**
\! [*cmd*]	Executes a command in a Linux shell (passing arguments as entered) or starts an interactive shell.	
\?	Displays help information about all meta-commands, the same as \h .	?
\a	Toggles output format alignment. For details, see \pset format aligned .	-A -no-align
\b	Toggles beep on command completion.	
\c[connect] [*db* [*user-name*]]	Establishes a connection to database *db* , under the specified user *user-name* . For details, see \connect .	
\C [' *title-str* ']	Sets a title *title-str* that precedes query result output. For details, see \pset title * title-str *.	
\cd [*dir*]	Changes the current working directory to *dir* , changes to your home directory if you omit specifying a directory.	
\d commands	See \d meta-commands	
\e[dit] [*file*]	Edits the query buffer (or specified file) with an external editor. For details, see \edit .	
\echo [*str*]	Writes *str* to standard output. **Tip** Use \qecho to redirect query output to the query output stream, as set by \o .	
\f [*str*]	Sets the field separator for unaligned query output. The default is the vertical bar (|).	-F --field-separator

\g [*file-name* | *shell-command*]	Sends the query in the input buffer (see \p) to the server. You can send query results to *file-name* , or pipe results to *shell-comand* ; otherwise, \g sends query results to standard output.	
\H	Renders output in HTML markup as a table. For details, see \pset format aligned .	-H --html
\h[elp]	Displays help information about the meta-commands, the same as \? .	--help
\i *file*	Reads and executes input from filename.	-f --file
\l \list	Lists available databases and owners.	-l --list
\locale [*locale*]	Displays the current locale setting or sets a new locale for the session. For details, see \locale .	
\o [*file-name* | *shell-command*]	Controls where vsql directs query output. You can send query results to *file-name* , or pipe results to *shell-comand* ; otherwise, \o sends query results to standard output.	-o --output
\p	Prints the current query buffer to standard output.	
\password [*user-name*]	Starts the password change process. Superusers can specify a user name to change that user's password; otherwise, users can only change their own passwords.	
\pset *output-option*	Sets options that control how Vertica formats query result output. For details, see \pset .	-P --pset
\q	Quits the vsql program	
\qecho [*str*]	Writes *str* to the query output stream, as specified by by \o .	
\r	Clears (resets) the query buffer	
\s [*file*]	Valid only if vsql is configured to use the GNU Readline library, prints or saves the command line history to *file* , or to standard output if no file name is supplied.	
\set [*var* [*value*]...]	Sets internal variable *var* to *value* . If you specify multiple values, var is set to their concantenated values. If no values are specified, *var* is set to no value.	--set -v --variable
\t	Toggles between tuples only and full display. For details, see \pset format tuples_only .	-t --tuples-only
\T *html-attribute* [...]	Specifies attributes to be placed inside the HTML table tag—for example, cellpadding or bgcolor , the same as \pset tableattr *html-attribute* [...] . For sample usage, see Output formatting examples .	-T --table-attr
\timing	If set to on, returns how long (in milliseconds) each SQL statement runs. For details, see \timing .	-i -- timing
\unset *var*	Deletes internal variable *var* that was set by the meta-command \set .	
\w *file-name*	Outputs the current query buffer to file *file-name* .	
\x	Toggles between regular and expanded format. For details, see \pset format expanded .	-x --expanded

\z	Returns a summary of privileges on all objects in system table V_CATALOG.GRANTS : grantee, grantor, privileges, schema, and object name (equivalent to \dp).
	
	\z supports the same options as \dp for filtering output by schema and object name patterns, . For example:
	
	`> \z *.*myseq*`
	`  Access privileges for database "dbadmin"`
	`Grantee | Grantor | Privileges | Schema | Name`
	`---------+---------+------------+--------+--------`
	`dbadmin | dbadmin | SELECT* | public | mySeq`
	`dbadmin | dbadmin | SELECT* | public | mySeq2`
	`(2 rows)`	

\connect

Establishes a connection to database *db* , under the specified user *user-name* . The previous connection is closed. If you omit specifying a database name, Vertica connects to the current database. If you omit specifying a user name argument, Vertica assumes the current user.

Syntax

```
\c[onnect] [db [user-name]]
```

Error handling

Errors that prevent execution include specifying an unknown user and denial of access to the specified database. Vertica handles errors differently, depending on whether this command is executed interactively in vsql, or in a script:

- VSQL handling: The current connection is maintained.
- Script: Processing immediately stops with an error. This is prevents scripts from acting on the wrong database.

\d meta-commands

Vertica supports a number of \d commands, which return information on different categories of database objects. For a full list, see \d Reference below.

Syntax

Unless otherwise noted, \d commands generally conform to the following syntax:

```
\dCommand [ [schema.]pattern ]
```

Arguments

You can supply most \d commands with a string pattern argument, which filters the results that the command returns. The pattern can optionally be qualified by a schema name.

schema

Valid for most \d commands, specifies to return only database objects in *schema* . For example, the following \dp command obtains privileges information for all V_MONITOR tables that contain the string resource :

```
=> \dp V_MONITOR.*resource*
                Access privileges for database "dbadmin"
 Grantee | Grantor | Privileges |  Schema   |           Name
---------+---------+------------+-----------+---------------------------
 public  | dbadmin | SELECT     | v_monitor | resource_rejections
 public  | dbadmin | SELECT     | v_monitor | disk_resource_rejections
 public  | dbadmin | SELECT     | v_monitor | resource_usage
 public  | dbadmin | SELECT     | v_monitor | resource_acquisitions
 public  | dbadmin | SELECT     | v_monitor | resource_rejection_details
 public  | dbadmin | SELECT     | v_monitor | resource_pool_move
 public  | dbadmin | SELECT     | v_monitor | host_resources
 public  | dbadmin | SELECT     | v_monitor | node_resources
 public  | dbadmin | SELECT     | v_monitor | resource_queues
 public  | dbadmin | SELECT     | v_monitor | resource_pool_status
(10 rows)
```

pattern

Returns only the database objects that match the specified string. Pattern strings can include one or more of two wildcards:

Wildcard character	Represents...
* (asterisk)	Zero or more characters
? (question mark)	Any single character

For example, the following \dt command returns tables that start with the string store :

```
=> \dt store*
                List of tables
 Schema |       Name        | Kind  |  Owner  | Comment
--------+-------------------+-------+---------+---------
 public | store_orders      | table | dbadmin |
 public | store_orders_2018 | table | dbadmin |
 public | store_overseas    | table | dbadmin |
 store  | store_dimension   | table | dbadmin |
 store  | store_orders_fact | table | dbadmin |
 store  | store_sales_fact  | table | dbadmin |
(6 rows)
```

\d reference

\d

Unqualified by a pattern argument, returns all tables with their schema names, owners, and comments. If qualified by a pattern argument, \d returns all matching tables and all columns in each table, with details about each column, such as data type, size, and default value.

\df

Returns all function names, the function return data type, and the function argument data type. Also returns the procedure names and arguments for all procedures that are available to the user.

\dj

Returns all projections showing the schema, projection name, owner, and node. The returned rows include superprojections, live aggregate projections, Top-K projections, and projections with expressions.

\dn

Returns the schema names and schema owner.

\dp

Returns a summary of privileges on all objects in system table V_CATALOG.GRANTS : grantee, grantor, privileges, schema, and object name (equivalent to \z).

\dS

Unqualified by a pattern argument, returns all V_CATALOG and V_MONITOR system tables. To obtain system tables for just one schema, qualify the command with the schema name, as follows:

```
\dS { V_CATALOG | V_MONITOR }.*
```

\ds

Returns sequences and their parameters.

\dT

Returns all data types that Vertica supports.

> **Note**
> \dT returns no results if qualified with a pattern argument.

\dt

Unqualified by a pattern argument, returns the same information as an unqualified \d command. If qualified by a pattern argument, \dt returns matching tables with the same level of detail as an unqualified \dt command.

\dtv

Returns tables and views.

\du

Returns database users and whether they are superusers.

\dv

Unqualified by a pattern argument, returns all views with their schema names, owners, and comments. If qualified by a pattern argument, \dv returns all matching views and the columns in each view, with each column's data type and size.

\edit

Edits the query buffer (or specified file) with an external editor. When the editor exits, its content is copied back to the query buffer. If no argument is given, the current query buffer is copied to a temporary file which is then edited in the same fashion.

The new query buffer is then re-parsed according to the normal rules of vsql, where the whole buffer up to the first semicolon is treated as a single line. (Thus you cannot make scripts this way. Use \i for that.) If there is no semicolon, vsql waits for one to be entered (it does not execute the query buffer).

> **Tip**
> vsql searches the environment variables VSQL_EDITOR, EDITOR, and VISUAL (in that order) for an editor to use. If all of them are unset, vi is used on Linux systems, notepad.exe on Windows systems.

Syntax

```
\e[dit] [ file ]
```

\i

R eads and executes input from the specified file.

> **Note**
> To see the lines on the screen as they are read, set the variable ECHO to all.

Syntax

```
\i filename
```

Examples

The Vertica vsql client on Linux supports backquote (backtick) expansion. For example:

1. Set an environment variable to a path that contains scripts you want to run:
   ```
   $ export MYSCRIPTS=/home/dbadmin/testscripts
   ```
2. Issue the vsql command.
   ```
   $ vsql
   ```
3. Use backquote expansion to include the path for running an existing script—for example, sample.sql .
   ```
   => \i `echo $MYSCRIPTS/sample.sql`
   ```

\locale

Displays or sets the locale setting for the current session.

> **Note**
> This command does not alter the default locale for all database sessions. To change the default for all sessions, set configuration parameter DefaultSessionLocale .

Syntax

```
\locale [locale-identifier]
```

Arguments

locale-identifier

Specifies the ICU locale identifier to use, by default set to:

```
en_US@collation=binary
```

If set to an empty string, Vertica sets locale to en_US_POSIX .

If you omit this argument, \locale returns the current locale setting.

For details on identifier options, see About locale . For a complete list of locale identifiers, see the ICU Project .

Examples

View the current locale setting:

```
=> \locale
en_US@collation=binary
```

Change the default locale for this session:

```
=> \locale en_GBINFO:
INFO 2567:  Canonical locale: 'en_GBINFO:'
Standard collation: 'LEN'
English (GBINFO:)
```

Notes

The server locale settings impact only the collation behavior for server-side query processing. The client application is responsible for ensuring that the correct locale is set in order to display the characters correctly. Below are the best practices recommended by Vertica to ensure predictable results:

- The locale setting in the terminal emulator for vsql (POSIX) should be set to be equivalent to session locale setting on server side (ICU) so data is collated correctly on the server and displayed correctly on the client.
- The vsql locale should be set using the POSIX LANG environment variable in terminal emulator. Refer to the documentation of your terminal emulator for how to set locale.
- Server session locale should be set using the set as described in Specify the default locale for the database .
- All input data for vsql should be in UTF-8 and all output data is encoded in UTF-8.
- Non UTF-8 encodings and associated locale values are not supported.

\pset

Sets options that control how Vertica formats query result output.

Syntax

```
\pset output-option
```

Output options

> **Note**
> Unless otherwise specified, output options are valid for all formats.

format *format-option*

Sets output format, where *format-option* is one of the following:

- u[naligned] writes all column data of each row on a single line, where each field is separated only by the current separator character. Use this output for use as input to other programs—for example, comma-delimited fields for CSV input.
- a[ligned] (default): Renders column-aligned output.
- h[tml] : Renders output in HTML markup as a table.
- l[atex] : Renders output in LaTex markup.

border *int*

Valid only if output format is set to html , specifies the table border, where *int* specifies the border type.

expanded

Toggles between regular and expanded format. When expanded format is enabled, all output has two columns with the column name on the left and the data on the right. This mode is especially useful for wide tables.

fieldsep ' *arg* '

Valid only if output format is set to unaligned , specifies the field separator, by default | (vertical bar).

For example, to specify tab as the field separator:

```
\pset fieldsep '\t'
```

footer

Toggles display of the default footer:

(*int* rows)

null ' *string* '

Specifies to represent column null values as *string* . By default, Vertica renders null values as an empty field, which might be mistaken as an empty string.

For example:

```
\pset null '(null)'
```

pager [*always*]

Toggles use of a pager for query and vsql help output. If the environment variable PAGER is set, the output is piped to the specified program. Otherwise a platform-dependent default (such as more) is used.

When the pager is off, the pager is not used. When the pager is on, the pager is used only when appropriate; that is, the output is to a terminal and does not fit on the screen. (vsql does not do a perfect job of estimating when to use the pager.)
If qualified with the argument always, the pager is always used.

recordsep ' *char* '

Valid only if output format is set to unaligned , specifies the character used to delimit table records (tuples), by default a newline character.

tableattr *html-attribute* [...]

Specifies attributes to be placed inside the HTML table tag—for example, cellpadding or bgcolor .

title [' *title-str* ']

Sets a title that precedes query result output, to *title-str* . HTML output renders this as follows:

```
<caption>title-str</caption>
```

To remove the title, reissue the command omit the *title-str* argument.

trailingrecordsep

Toggles on or off the trailing record separator to use in unaligned output mode.

t[uples_only]

Toggles between tuples only and full display. Full display might show extra information such as column headers, titles, and various footers. In tuples only mode, only actual table data is shown.

Shortcuts

The following \pset commands have short-cuts:

\pset expanded

```
\x
```

\pset fieldsep ' *arg* '

\f

\pset format aligned

```
\a
```

\pset format html

```
\H
```

\pset tableattr *html-attribute* [...]

```
\T html-attribute[...]
```

\pset title *title-str*

```
\C ['title-str']
```

\pset tuples_only

```
\t
```

Examples

See Output formatting examples .

\set

S ets an internal variable to one or more values. If multiple values are specified, they are concantenated. An unqualified \set command lists all internal variables.

To unset a variable, use vsql meta-command \unset .

Syntax

```
\set [var [value]...]
```

Arguments

var

The name of an internal variable to set. Valid variable names are case sensitive and can contain characters, digits, and underscores. vsql treats several variables as special, which are described in Variables .

value

A value to set in variable *var* . If no value is specified, the variable is set to no value.

If set to an empty string, the variable is set to no value. If you omit this argument, \set returns all internal variables.

If no arguments are supplied, \set returns all internal variables. For example:

```
=> \set
VERSION = 'vsql'
AUTOCOMMIT = 'off'
VERBOSITY = 'default'
PROMPT1 = '%/%R%# '
PROMPT2 = '%/%R%# '
PROMPT3 = '>> '
ROWS_AT_A_TIME = '1000'
DBNAME = 'dbadmin'
USER = 'dbadmin'
PORT = '5433'
LOCALE = 'en_US@collation=binary'
HISTSIZE = '500'
```

\timing

If set to on, returns how long (in milliseconds) each SQL statement runs. Results include:

- Length of time required to fetch the first block of rows
- Total time until the last block is formatted.

Unqualified, \timing toggles timing on and off. You can explicitly turn timing on and off by qualifying the command with options ON and OFF , respectively.

> **Note**
> You can also enable \timing from the command line using the vsql -i command.

Syntax

```
\timing [ON | OFF]
```

Examples

The following unqualified \timing commands toggle timing on and off:

```
=> \timing
Timing is on
=> \timing
Timing is off
```

The following example shows a SQL command with timing on:

```
=> \timing
Timing is on.
=> SELECT user_name, ssl_state, authentication_method, client_authentication_name,
    client_type FROM sessions WHERE session_id=(SELECT session_id FROM current_session);
 user_name | ssl_state | authentication_method | client_authentication_name | client_type
-----------+-----------+-----------------------+----------------------------+-------------
 dbadmin   | None      | ImpTrust              | default: Implicit Trust    | vsql
(1 row)

Time: First fetch (1 row): 73.684 ms. All rows formatted: 73.770 ms
```

Variables

vsql provides variable substitution features similar to common Linux command shells. Variables are name/value pairs, where the value can be a string of any length. To set variables, use the vsql meta-command \set . For example, the following statement sets the variable fact to the value dim :

```
=> \set fact dim
```

If you call \set on a variable and supply no value, the variable is set to an empty string.

> **Note**
> The arguments of \set are subject to the same substitution rules as with other commands. For example, \set dim :fact is a valid way to copy a variable.

Getting variables

To retrieve the content of a given variable, precede the name with a colon and use it as the argument of any slash command. For example:

```
=> \echo :fact
dim
```

An unqualified \set command returns all current variables and their values:

```
dbadmin=> \set
VERSION = 'vsql'
AUTOCOMMIT = 'off'
VERBOSITY = 'default'
PROMPT1 = '%/%R%# '
PROMPT2 = '%/%R%# '
PROMPT3 = '>> '
ROWS_AT_A_TIME = '1000'
DBNAME = 'dbadmin'
USER = 'dbadmin'
PORT = '5433'
LOCALE = 'en_US@collation=binary'
HISTSIZE = '500'
```

Deleting variables

To unset (or delete) a variable, use the vsql meta-command \unset .

Variable naming conventions

vsql internal variable names can contain letters, numbers, and underscores in any order and any number. Some variables are treated specially by vsql. They indicate certain option settings that can be changed at run time by altering the value of the variable or represent some state of the application. Although you can use these variables for any other purpose, this is not recommended. By convention, all specially treated variables

consist of all upper-case letters (and possibly numbers and underscores). To ensure maximum compatibility in the future, avoid using such variable names for your own purposes.

SQL interpolation

You can substitute ("interpolate") vsql variables into regular SQL statements. You do so by prepending the variable name with a colon (:). For example, the following statements query the table my_table :

```
=> \set fact 'my_table'
=> SELECT * FROM :fact;
```

The value of the variable is copied literally, so it can even contain unbalanced quotes or backslash commands. Make sure that it makes sense where you put it. Variable interpolation is not performed into quoted SQL entities. One exception applies: the contents of backquoted strings (``) are passed to a system shell, and replaced with the shell's output. See Using Backquotes to Read System Variables below.

Using backquotes to read system variables

In vsql, the contents of backquotes are passed to the system shell to be interpreted (the same behavior as many UNIX shells). This is particularly useful in setting internal vsql variables, since you may want to access UNIX system variables (such as HOME or TMPDIR) rather than hard-code values.

For example, to set an internal variable to the full path for a file in your UNIX user directory, you can use backquotes to get the content of the system HOME variable, which is the full path to your user directory:

```
=> \set inputfile `echo $HOME`/myinput.txt=> \echo :inputfile
/home/dbadmin/myinput.txt
```

The contents of the backquotes are replaced with the results of running the contents in a system shell interpreter. In this case, the echo $HOME command returns the contents of the HOME system variable.

AUTOCOMMIT

When AUTOCOMMIT is set 'on', each SQL command is automatically committed upon successful completion; for example:

```
\set AUTOCOMMIT on
```

To postpone COMMIT in this mode, set the value as off.

```
\set AUTOCOMMIT off
```

If AUTOCOMMIT is empty or defined as off, SQL commands are not committed unless you explicitly issue COMMIT.

Notes

- AUTOCOMMIT is off by default.
- AUTOCOMMIT must be in uppercase, but the values, on or off, are case insensitive.

- In autocommit-off mode, you must explicitly abandon any failed transaction by entering ABORT or ROLLBACK.
- If you exit the session without committing, your work is rolled back.
- Validation on vsql variables is done when they are run, not when they are set.
- The COPY statement, by default, commits on completion, so it does not matter which AUTOCOMMIT mode you use, unless you issue COPY NO COMMIT. Please note that DDL statements are autocommitted.
- To tell if AUTOCOMMIT is on or off, issue the set command:

```
$ \set...
AUTOCOMMIT = 'off'
...
```

- AUTOCOMMIT is off if a SELECT * FROM LOCKS shows locks from the statement you just ran.

```
$ \set AUTOCOMMIT off
$ \set
...
AUTOCOMMIT = 'off'
...
SELECT COUNT(*) FROM customer_dimension;
 count
-------
 50000
(1 row)
SELECT node_names, object_name, lock_mode, lock_scope
FROM LOCKS;
 node_names |      object_name         | lock_mode | lock_scope
------------+--------------------------+-----------+-------------
 site01     | Table:customer_dimension | S         | TRANSACTION
(1 row)
```

DBNAME

The name of the database to which you are currently connected. DBNAME is set every time you connect to a database (including program startup), but it can be unset.

ECHO

If set to all , all lines entered from the keyboard or from a script are written to the standard output before they are parsed or run.

To select this behavior on program start-up, use the switch -a . If set to queries , vsql merely prints all queries as they are sent to the server. The switch for this is -e .

ECHO_HIDDEN

When this variable is set and a backslash command queries the database, the query is first shown. This way you can study the Vertica internals and provide similar functionality in your own programs. (To select this behavior on program start-up, use the switch -E .)

If you set the variable to the value noexec , the queries are just shown but are not actually sent to the server and run.

ENCODING

The current client character set encoding.

HISTCONTROL

If this variable is set to ignorespace , lines that begin with a space are not entered into the history list. If set to a value of ignoredups , lines matching the previous history line are not entered. A value of ignoreboth combines the two options. If unset, or if set to any other value than those previously mentioned, all lines read in interactive mode are saved on the history list.

Source: Bash.

HISTSIZE

Sets the amount of space to store the command history. This value roughly approximates the number of commands vsql will store in its command history buffer. This value only impacts the number of lines stored by the current vsql session. It does not affect the history stored in the .vsql_history file.

The default value is 500.

> **Note**
> vsql multiplies the HISTSIZE value by 50 bytes (an approximation of the average length of a SQL statement) to arrive at the amount of memory to set aside for the command history. Depending on the actual length of your SQL statements, vsql may be able to store more or less commands than the value you set in HISTSIZE.

Source: Bash.

HOST

The database server host you are currently connected to. This is set every time you connect to a database (including program startup), but can be unset.

IGNOREEOF

If unset, sending an EOF character (usually Control+D) to an interactive session of vsql terminates the application. If set to a numeric value, that many EOF characters are ignored before the application terminates. If the variable is set but has no numeric value, the default is 10.

Source: Bash.

ON_ERROR_STOP

By default, if a script command results in an error, for example, because of a malformed command or invalid data format, processing continues. If you set ON_ERROR_STOP to ON in a script and an error occurs during processing, the script terminates immediately.

For example:

```
=> \set ON_ERROR_STOP ON
```

> **Note**
> If you invoke the script on Linux with vsql -f , vsql returns with error code 3 to indicate that an error occurred in the script.

PORT

The database server port to which you are currently connected. This is set every time you connect to a database (including program start-up), but can be unset.

PROMPT1 PROMPT2 PROMPT3

These specify what the prompts vsql issues look like. See Prompting for details.

QUIET

This variable is equivalent to the command line option -q . It is probably not too useful in interactive mode.

ROWS_AT_A_TIME

ROWS_AT_A_TIME is set by default to 1000, and retrieves results as blocks of rows of that size. The column formatting for the first block is used for all blocks, so in later blocks some entries could overflow.

When formatting results, Vertica buffers ROWS_AT_A_TIME rows in memory to calculate the maximum column widths. It is possible that rows after this initial fetch are not properly aligned if any of the field values are longer than those see in the first ROWS_AT_A_TIME rows. ROWS_AT_A_TIME can be unset with vsql meta-command \unset to guarantee perfect alignment. However, this requires re-buffering the entire result set in memory and might cause vsql to fail if the result set is too big.

SINGLELINE

This variable is equivalent to the command line option -S .

SINGLESTEP

This variable is equivalent to the command line option -s .

USER

The database user you are currently connected as. This is set every time you connect to a database (including program startup), but can be unset.

VERBOSITY

This variable can be set to the values default , verbose , or terse to control the verbosity of error reports.

VSQL_HOME

By default, the vsql program reads configuration files from the user's home directory. In cases where this is not desirable, the configuration file location can be overridden by setting the VSQL_HOME environment variable in a way that does not require modifying a shared resource.

In the following example, vsql reads configuration information out of /tmp/jsmith rather than out of ~.

```
# Make an alternate configuration file in /tmp/jsmith
mkdir -p /tmp/jsmith
echo "\\echo Using VSQLRC in tmp/jsmith" > /tmp/jsmith/.vsqlrc
# Note that nothing is echoed when invoked normally
vsql
# Note that the .vsqlrc is read and the following is
# displayed before the vsql prompt
#
# Using VSQLRC in tmp/jsmith
VSQL_HOME=/tmp/jsmith vsql
```

VSQL_SSLMODE

VSQL_SSLMODE specifies how (or whether) clients (like admintools) use SSL when connecting to servers. The default value is prefer , meaning to use SSL if the server offers it. Legal values are require , prefer , allow , and disable . This variable is equivalent to the command-line -m option (or --sslmode).

Prompting

The prompts vsql issues can be customized to your preference. The three variables PROMPT1 , PROMPT2 , and PROMPT3 contain strings and special escape sequences that describe the appearance of the prompt. Prompt 1 is the normal prompt that is issued when vsql requests a new command. Prompt 2 is issued when more input is expected during command input because the command was not terminated with a semicolon or a quote was not closed. Prompt 3 is issued when you run a SQL COPY command and you are expected to type in the row values on the terminal.

The value of the selected prompt variable is printed literally, except where a percent sign (%) is encountered. Depending on the next character, certain other text is substituted instead. Defined substitutions are:

%M

The full host name (with domain name) of the database server, or [local] if the connection is over a socket, or [local:/dir/name], if the socket is not at the compiled in default location.

%m

The host name of the database server, truncated at the first dot, or [local].

%>

The port number at which the database server is listening.

%n

The database session user name.

%/

The name of the current database.

%~

Like %/, but the output is ~ (tilde) if the database is your default database.

%#

If the session user is a database superuser, then a #, otherwise a >. (The expansion of this value might change during a database session as the result of the command SET SESSION AUTHORIZATION.)

%R

In prompt 1 normally =, but ^ if in single-line mode, and ! if the session is disconnected from the database (which can happen if \connect fails). In prompt 2 the sequence is replaced by -, *, a single quote, a double quote, or a dollar sign, depending on whether vsql expects more input because the command wasn't terminated yet, because you are inside a /* ... */ comment, or because you are inside a quoted or dollar-escaped string. In prompt 3 the sequence doesn't produce anything.

%x

Transaction status: an empty string when not in a transaction block, or * when in a transaction block, or ! when in a failed transaction block, or ? when the transaction state is indeterminate (for example, because there is no connection).

%digits

The character with the indicated numeric code is substituted. If digits starts with 0x the rest of the characters are interpreted as hexadecimal; otherwise if the first digit is 0 the digits are interpreted as octal; otherwise the digits are read as a decimal number.

%:name:

The value of the vsql variable name. See the section Variables for details.

%`command`

The output of command, similar to ordinary "back- tick" substitution.

%[... %]

Prompts may contain terminal control characters which, for example, change the color, background, or style of the prompt text, or change the title of the terminal window. In order for the line editing features of Readline to work properly, these non-printing control characters must be designated as invisible by surrounding them with %[and %]. Multiple pairs of these may occur within the prompt. The following example results in a boldfaced (1;) yellow-on-black (33;40) prompt on VT100-compatible, color-capable terminals:

```
testdb=> \set PROMPT1 '%[%033[1;33;40m%]%n@%/%R%#%[%033[0m%] '
```

To insert a percent sign into your prompt, write %%. The default prompts are '%/%R%# ' for prompts 1 and 2, and '>> ' for prompt 3.

Note: See the specification for terminal control sequences (applicable to gnome-terminal and xterm).

Command line editing

vsql supports the tecla library for convenient line editing and retrieval.

The command history is automatically saved when vsql exits and is reloaded when vsql starts up. Tab-completion is also supported, although the completion logic makes no claim to be a SQL parser. If for some reason you do not like the tab completion, you can turn it off by putting this in a file named .teclarc in your home directory:

```
bind ^I
```

Read the tecla documentation for further details.

Notes

The vsql implementation of the tecla library deviates from the tecla documentation as follows:

- Recalling Previously Typed Lines
  Under pure tecla, all new lines are appended to a list of historical input lines maintained within the GetLine resource object. In vsql, only different, non-empty lines are appended to the list of historical input lines.
- History Files
  tecla has no standard name for the history file. In vsql, the file name is called ~/.vsql_hist.
- International Character Sets (Meta keys and locales)
  In vsql, 8-bit meta characters are no longer supported. Make sure that meta characters send an escape by setting their EightBitInput X resource to False. You can do this in one of the following ways:
  - Edit the ~/.Xdefaults file by adding the following line:
    ```
    XTerm*EightBitInput: False
    ```
  - Start an xterm with an -xrm ' *EightBitInput: False ' command-line argument.
- Key Bindings:
- The following key bindings are specific to vsql:

- *Insert* switches between insert mode (the default) and overwrite mode.
- *Delete* deletes the character to the right of the cursor.
- *Home* moves the cursor to the front of the line.
- *End* moves the cursor to the end of the line.
- ^R Performs a history backwards search.

vsql environment variables

Set one or more of the following environment variables to be used by the defined properties automatically, each time you start vsql:

PAGER

If the query results do not fit on the screen, they are piped through this command. Typical values are more or less . The default is platform-dependent. Use the \pset command to enable/disable the pager.

VSQL_DATABASE

The database to which you are connecting. For example, VMart .

TMPDIR

Directory for storing temporary files. The default is platform-dependent. On Unix-like systems the default is /tmp .

VSQL_EDITOR
EDITOR
VISUAL

Editor used by the \e command. The variables are examined in the order listed; the first that is set is used.

VSQL_HOME

By default, the vsql program reads configuration files from the user's home directory. In cases where this is not desirable, the configuration file location can be overridden by setting the VSQL_HOME environment variable in a way that does not require modifying a shared resource.

VSQL_HOST

Host name or IP address of the Vertica node.

VSQL_PASSWORD

The database password. Using this environment variable increases site security by precluding the need to enter the database password on the command line.

VSQL_PORT

Port to use for the connection.

VSQL_SSLMODE

Specifies whether and how clients such as admintools use SSL when connecting to servers.

VSQL_USER

User name to use for the connection.

Locales

The default terminal emulator under Linux is gnome-terminal, although xterm can also be used.

Vertica recommends that you use gnome-terminal with vsql in UTF-8 mode, which is its default.

To change settings on Linux

1. From the tabs at the top of the vsql screen, select Terminal.
2. Click **Set Character Encoding** .
3. Select **Unicode (UTF-8)** .

> **Note**
> This works well for standard keyboards. xterm has a similar UTF-8 option.

To change settings on Windows using PuTTy

1. Right click the vsql screen title bar and select **Change Settings** .
2. Click **Window** and click **Translation** .
3. Select **UTF-8** in the drop-down menu on the right.

Notes

- vsql has no way of knowing how you have set your terminal emulator options.
- The tecla library is prepared to do POSIX-type translations from a local encoding to UTF-8 on interactive input, using the POSIX LANG, etc., environment variables. This could be useful to international users who have a non-UTF-8 keyboard. See the tecla documentation for details. Vertica recommends the following (or whatever other .UTF-8 locale setting you find appropriate):

```
export LANG=en_US.UTF-8
```

- The vsql \locale command invokes and tracks the server SET LOCALE TO command, described. vsql itself currently does nothing with this locale setting, but rather treats its input (from files or from tecla), all its output, and all its interactions with the server as UTF-8. vsql ignores the POSIX locale variables, except for any "automatic" uses in printf , and so on.

Entering data with vsql

You often need to insert literal data when using vsql. For example:

- Adding a row of data to a table using an INSERT statement.
- Adding multiple rows of data through a COPY FROM STDIN statement.

The following table lists the data types that Vertica supports, and the format you use to enter that data in queries when using vsql.

Data Type	**Inserting to vsql using**	**Example Use in INSERT INTO *table* ...**	**For More Information See...**
Binary types, such as BINARY and VARBINARY	Helper functions such as HEX_TO_BINARY, octal strings, specified data format in COPY statements, casting string values to binary.	VALUES(HEX_TO_BINARY('0x3D'), '\\141\\337\\');	• Binary data types (BINARY and VARBINARY) • Binary (native) data
BOOLEAN	Literal values TRUE and FALSE or strings such as 'y' , 't' , 'true' , or 'false' .	VALUES(TRUE, 'f');	Boolean data type
Character data types such as CHAR or LONG VARCHAR	Strings enclosed in single quotes.	VALUES('my string');	Character data types (CHAR and VARCHAR)
Date and time data types, such as TIMESTAMPTZ	Formatted text string	VALUES('16:43:00', '2016-09-15 04:55:00 PDT');	• Date/time data types • Date/time expressions
Numeric Data Types	Literal numeric values, including scientific notation, hexadecimal, and BINARY scaling.	VALUES(3.1415, 42, 6.0221409e23);	Numeric data types
UUID	Formatted text string	VALUES('12345678-1234-1234-1234-123456789012');	UUID data type

Files

Before starting up, vsql attempts to read and execute commands from the system-wide vsqlrc file and the user's ~/.vsqlrc file. The command-line history is stored in the file ~/.vsql_history.

> **Tip**
> If you want to save your old history file, open another terminal window and save a copy to a different file name.

Exporting data using vsql

You can use vsql for simple data-export tasks by changing its output format options so the output is suitable for importing into other systems (tab-delimited or comma-separated files, for example). These options can be set either from within an interactive vsql session, or through command-line arguments to the vsql command (making the export process suitable for automation through scripting). After you have set vsql's options so it outputs the data in a format your target system can read, you run a query and capture the result in a text file.

The following table lists the meta-commands and command-line options that are useful for changing the format of vsql's output.

Description	Meta-command	Command-line Option
Disable padding used to align output.	\a	-A or --no-align
Show only tuples, disabling column headings and row counts.	\t	-t or --tuples-only
Set the field separator character.	\pset fieldsep	-F or --field-separator
Send output to a file.	\o	-o or --output
Specify a SQL statement to execute.	N/A	-c or --command

The following example demonstrates disabling padding and column headers in the output, and setting a field separator to dump a table to a tab-separated text file within an interactive session.

```
=> SELECT * FROM my_table;
 a |   b   | c
---+-------+---
 a | one   | 1
 b | two   | 2
 c | three | 3
 d | four  | 4
 e | five  | 5
(5 rows)
=> \a
Output format is unaligned.
=> \t
Showing only tuples.
=> \pset fieldsep '\t'
Field separator is "    ".
=> \o dumpfile.txt
=> select * from my_table;
=> \o
=> \! cat dumpfile.txt
a       one     1
b       two     2
c       three   3
d       four    4
e       five    5
```

Note

You could encounter issues with empty strings being converted to NULLs or the reverse using this technique. You can prevent any confusion by explicitly setting null values to output a unique string such as NULLNULLNULL (for example, \pset null 'NULLNULLNULL'). Then, on the import end, convert the unique string back to a null value. For example, if you are copying the file back into a Vertica database, you would give the argument NULL 'NULLNULLNULL' to the COPY statement.

When logged into one of the database nodes, you can create the same output file directly from the command line by passing the right parameters to vsql:

```
$ vsql -U username -F $'\t' -At -o dumpfile.txt -c "SELECT * FROM my_table;"
Password:
$ cat dumpfile.txt
a	one	1
b	two	2
c	three	3
d	four	4
e	five	5
```

If you want to convert null values to a unique string as mentioned earlier, you can add the argument -P null='NULLNULLNULL' (or whatever unique string you choose).

By adding the -w vsql command-line option to the example command line, you could use the command within a batch script to automate the data export. However, the script would contain the database password as plain text. If you take this approach, you should prevent unauthorized access to the batch script, and also have the script use a database user account that has limited access.

To set the field separator value to a control character, use your shell's control character escape notation. In Bash, you specify a control character in an argument using a dollar sign ($) followed by a string contained in single quotes. This string can contain C-string escapes (such as \t for tab), or a backslash () followed by an octal value for the character you want to use.

The following example demonstrates setting the separator character to tab (\t), vertical tab (\v) and the octal value of vertical tab (\013).

```
$ vsql -At -c "SELECT * FROM testtable;"
A|1|2|3
B|4|5|6

$ vsql -F $'\t' -At -c "SELECT * FROM testtable;"
A	1	2	3
B	4	5	6

$ vsql -F $'\v' -At -c "SELECT * FROM testtable;"
A
 1
  2
   3
B
 4
  5
   6
$ vsql -F $'\013' -At -c "SELECT * FROM testtable;"
A
 1
  2
   3
B
 4
  5
   6
```

Copying data using vsql

You can use vsql to copy data between two Vertica databases. This technique is similar to the technique explained in Exporting data using vsql , except instead of having vsql save data to a file for export, you pipe one vsql's output to the input of another vsql command that runs a COPY statement from STDIN. This technique can also work for other databases or applications that accept data from an input stream.

> **Note**
> The following technique only works for individual tables. To copy an entire database to another cluster, see Copying the database to another cluster .

The easiest way to copy using vsql is to log in to a node of the target database, then issue a vsql command that connects to the source Vertica database to dump the data you want. For example, the following command copies the store.store_sales_fact table from the vmart database on node testdb01 to the vmart database on the node you are logged into:

```
vsql -U username -w passwd -h testdb01 -d vmart -At -c "SELECT * from store.store_sales_fact"  \
| vsql -U username -w passwd -d vmart -c "COPY store.store_sales_fact FROM STDIN DELIMITER '|';"
```

Note
The above example copies the data only, not the table design. The target table for the data copy must already exist in the target database. You can export the design of the table using EXPORT_OBJECTS or EXPORT_CATALOG .

If you are using the Bash shell, you can escape special delimiter characters. For example, DELIMITER E'\t' specifies tab. Shells other than Bash may have other string-literal syntax.

Monitoring progress (optional)

You may want some way of monitoring progress when copying large amounts of data between Vertica databases. One way of monitoring the progress of the copy operation is to use a utility such as Pipe Viewer that pipes its input directly to its output while displaying the amount and speed of data it passes along. Pipe Viewer can even display a progress bar if you give it the total number of bytes or lines you expect to be processed. You can get the number of lines to be processed by running a separate vsql command that executes a SELECT COUNT query.

Note
Pipe Viewer isn't a standard Linux command, so you will need to download and install it yourself. See the Pipe Viewer page for download packages and instructions. Vertica does not support Pipe Viewer. Install and use it at your own risk.

The following command demonstrates how you can use Pipe Viewer to monitor the progress of the copy shown in the prior example. The command is complicated by the need to get the number of rows that will be copied, which is done using a separate vsql command within a Bash backquote string, which executes the string's contents and inserts the output of the command into the command line. This vsql command just counts the number of rows in the store.store_sales_fact table.

```
vsql -U username -w passwd -h testdb01 -d vmart -At -c "SELECT * from store.store_sales_fact"  \
| pv -lpetr -s `vsql -U username -w passwd -h testdb01 -d vmart -At -c "SELECT COUNT (*) FROM store.store_sales_fact;"` \
| vsql -U username -w passwd -d vmart -c "COPY store.store_sales_fact FROM STDIN DELIMITER '|';"
```

While running, the above command displays a progress bar that looks like this:

```
0:00:39 [12.6M/s] [==============================>                    ] 50% ETA 00:00:40
```

Output formatting examples

By default, Vertica formats query output as follows:

```
=> SELECT DISTINCT category_description FROM product_dimension ORDER BY category_description;
     category_description
----------------------------------
 Food
 Medical
 Misc
 Non-food
(4 rows)
```

You can control the format of query output in various ways with the \pset command—for example, change the border:

```
=> \pset border 2
Border style is 2.
=> SELECT DISTINCT category_description FROM product_dimension ORDER BY category_description;
+----------------------------------+
|       category_description       |
+----------------------------------+
| Food                             |
| Medical                          |
| Misc                             |
| Non-food                         |
+----------------------------------+
(4 rows)
=> \pset border 0
Border style is 0.
=> SELECT DISTINCT category_description FROM product_dimension ORDER BY category_description;
     category_description
--------------------------------
Food
Medical
Misc
Non-food
(4 rows)
```

The following sequence of pset commands change query output in several ways:

- Set border style to 1.
- Remove column alignment.
- Change the field separator to a comma.
- Remove column headings

```
=> \pset border 1
Border style is 1.
=> \pset format unaligned
Output format is unaligned.
=> \pset fieldsep ','
Field separator is ",".
=> \pset tuples_only
Showing only tuples.
=> SELECT product_key, product_description, category_description FROM product_dimension LIMIT 10;
1,Brand #2 bagels,Food
1,Brand #1 butter,Food
2,Brand #6 chicken noodle soup,Food
3,Brand #11 vanilla ice cream,Food
4,Brand #14 chocolate chip cookies,Food
4,Brand #12 rash ointment,Medical
6,Brand #18 bananas,Food
7,Brand #25 basketball,Misc
8,Brand #27 french bread,Food
9,Brand #32 clams,Food
```

The following example uses meta-commands to toggle output format—in this case, \a (alignment), \t (tuples only), and -x (extended display):

```
=> \a \t \x
Output format is aligned.
Tuples only is off.
Expanded display is off.
=> SELECT product_key, product_description, category_description FROM product_dimension LIMIT 10;
 product_key |       product_description        |       category_description
-------------+----------------------------------+----------------------------------
           1 | Brand #2 bagels                  | Food
           1 | Brand #1 butter                  | Food
           2 | Brand #6 chicken noodle soup     | Food
           3 | Brand #11 vanilla ice cream      | Food
           4 | Brand #14 chocolate chip cookies | Food
           4 | Brand #12 rash ointment          | Medical
           6 | Brand #18 bananas                | Food
           7 | Brand #25 basketball             | Misc
           8 | Brand #27 french bread           | Food
           9 | Brand #32 clams                  | Food
(10 rows)
```

The following example sets output format to HTML, so Vertica renders query results in HTML markup as a table:

```
=> \pset format html
Output format is html.
=> \pset tableattr 'border="2" cellpadding="3"'
Table attribute is "border="2" cellpadding="3"".
=> SELECT product_key, product_description, category_description FROM product_dimension LIMIT 2;
<table border="1" border="2" cellpadding="3">
 <tr>
  <th align="center">product_key</th>
  <th align="center">product_description</th>
  <th align="center">category_description</th>
 </tr>
 <tr valign="top">
  <td align="right">1</td>
  <td align="left">Brand #2 bagels</td>
  <td align="left">Food                          </td>
 </tr>
 <tr valign="top">
  <td align="right">1</td>
  <td align="left">Brand #1 butter</td>
  <td align="left">Food                          </td>
 </tr>
</table>
<p>(2 rows)<br />
</p>
```

Client libraries

The Vertica client driver libraries provide interfaces for connecting your client applications (or third-party applications such as Cognos and MicroStrategy) to your Vertica database. The drivers simplify exchanging data for loading, report generation, and other common database tasks.

There are three separate client drivers:

- Open Database Connectivity (ODBC)—the most commonly-used interface for third-party applications and clients written in C, Python, PHP, Perl, and most other languages.
- Java Database Connectivity (JDBC)—used by clients written in the Java programming language.
- ActiveX Data Objects for .NET (ADO.NET)—used by clients developed using Microsoft's .NET Framework and written in C#, Visual Basic .NET, and other .NET languages.

Client driver standards

The Vertica client drivers are compatible with the following driver standards:

- The ODBC driver complies with version 3.5.1 of the ODBC standard.
- Vertica's JDBC driver is a type 4 driver that complies with the JDBC 3.0 standard. It is compiled using JDK version 1.5, and is compatible with client applications compiled using JDK versions 1.5 and 1.6.
- ADO.NET drivers conform to .NET framework 3.0 specifications.

The drivers do not support some of the optional features in the standards. See ODBC feature support and JDBC feature support and Using ADO.NET for details.

In this section

- Client driver and server version compatibility
- Client drivers
- Creating an ODBC data source name (DSN)
- Programming ODBC client applications
- Programming JDBC client applications
- Programming ADO.NET applications
- Programming Python client applications
- Programming Perl client applications
- Programming PHP client applications
- Managing query execution between the client and Vertica

Client driver and server version compatibility

Backward compatibility between Vertica server and client drivers works in both directions; Vertica server is compatible with all previous versions of client drivers, and all new client drivers are compatible with most versions of Vertica server. This compatibility lets you upgrade your Vertica server without having to immediately upgrade your client software, and use new client software with older versions of Vertica. Occasionally, however, individual features of a new server version might be unavailable through older drivers.

Client	Compatible Server Versions
ODBC	7.1.x and above
JDBC	7.2.x and above
ADO.NET	7.2.x and above
FIPS-enabled ODBC	FIPS-enabled 8.0.x and above (FIPS cannot be enabled in Vertica 9.3.x and 10.0.x.).
FIPS-enabled JDBC	FIPS-enabled 8.1.x and above (FIPS cannot be enabled in Vertica 9.3.x and 10.0.x.)

Client drivers

You must install the Vertica client drivers to access Vertica from your client application. The drivers create and maintain connections to the database and provide APIs that your applications use to access your data. The client drivers support connections using JDBC, ODBC, and ADO.NET .

Client driver standards

The client drivers support the following standards:

- ODBC drivers conform to ODBC 3.5.1 specifications.
- JDBC drivers conform to JDK 5 specifications.
- ADO.NET drivers conform to .NET framework 3.0 specifications.

Installing the client drivers

How you install client drivers depends on the client's operating system:

- For Linux and UNIX clients, you must first install a Linux driver manager . After you have installed the driver manager, there are two different ways to install the client drivers:
  - On Red Hat Enterprise Linux 5, 64-bit and SUSE Linux Enterprise Server 10/11 64-bit, you can use the Vertica client RPM package to install the ODBC and JDBC drivers as well as the vsql client.
  - On other Linux platforms and UNIX-like platforms you can download the ODBC and JDBC drivers and install them individually.

> **Note**

> The ODBC and JDBC client drivers are installed by the server .rpm files. If you have installed Vertica on your Linux system for development or testing purposes, you do not need to download and install the client drivers on it—you just need to configure the drivers. To use ODBC, you need to create a DSN (see Creating an ODBC DSN for Linux). To use JDBC, you need to add the JDBC client driver to the Java CLASSPATH (see Modifying the Java CLASSPATH). (The JDBC client driver is not available on FIPS-compliant systems.)
>
> For details, see Supported platforms .

- On Mac OS X clients, download the ODBC client driver .pkg file. The driver is compatible with both 32-bit and 64-bit applications.
- On Windows clients, download the 32-bit or 64-bit client installer. The installer provides the ODBC client driver, the ADO.NET client driver, the OLE DB client driver, the vsql client, the Microsoft Connectivity Pack, and the Visual Studio plug-in.
- There is a cross-platform JDBC client driver .jar file available for installation on all platforms.

The remainder of this section explains the requirements for the Vertica client drivers, and the procedure for downloading, installing, and configuring them.

In this section

- Driver prerequisites
- Upgrading the client drivers
- Setting a client connection label
- Additional parameter settings
- Using legacy drivers
- Modifying the Java CLASSPATH
- Installing the client drivers on Linux and UNIX-Like platforms
- Installing the FIPS client drivers
- Installing the client drivers and tools on Windows
- Components of the client drivers and tools on Windows
- Installing the client drivers on Mac OS X

Driver prerequisites

The following topics describe the system requirements for the client drivers. You need to ensure that your client system meets these requirements before installing and using the client drivers.

In this section

- ODBC prerequisites
- ADO.NET prerequisites
- Python prerequisites
- Perl prerequisites
- PHP prerequisites

ODBC prerequisites

There are several requirements your client systems must meet before you can install the Vertica ODBC drivers.

Operating system

The Vertica ODBC driver requires a supported platform. The list of currently-supported platforms can be found at Client drivers support .

ODBC driver manager

ODBC driver requires that the client system have a supported driver manager. See Installing driver managers on Linux and other UNIX-like platforms for details.

UTF-8, UTF-16 and UTF-32 support

The Vertica ODBC driver is a universal driver that supports UTF-8, UTF-16, and UTF-32 encoding. The default setting depends on the client platform. (see Required ODBC driver configuration settings for Linux and UNIX for more information).

When using the driver with the DataDirect Connect driver manager, DataDirect Connect adapts to the ODBC driver's text encoding settings. You should configure the ODBC driver to use the encoding method that your application requires. This allows strings to be passed between the driver and the application without intermediate conversion.

- Client drivers

- Programming ODBC client applications
- Creating an ODBC data source name (DSN)

ADO.NET prerequisites

The Vertica driver for ADO.NET requires the following software and hardware components:

Operating system

The Vertica ADO.NET driver requires a supported Windows operating system. The list of supported platforms can be found in the Supported Platforms document at https://docs.vertica.com/latest .

Memory

Vertica suggests a minimum of 512MB of RAM.

.NET framework

The requirements for the .NET framework for ADO.NET in Vertica can be found in the Supported Platforms document at https://docs.vertica.com/latest .

See also

- Programming ADO.NET applications

Python prerequisites

Python is a free, agile, object-oriented, cross-platform programming language designed to emphasize rapid development and code readability. Python has been released under several different open source licenses.

Vertica's ODBC driver is tested with multiple versions of Python. See Perl and Python requirements for details.

Python driver

Vertica requires the open source Vertica Python Client or the pyodbc driver module. See your system's Python documentation for installation and configuration information.

Supported operating systems

The Vertica ODBC driver requires one of the operating systems listed in ODBC prerequisites .

For usage and examples, see Programming Python client applications .

Perl prerequisites

Perl is a free, stable, open source, cross-platform programming language licensed under its Artistic License, or the GNU General Public License (GPL).

Your Perl scripts access Vertica through its ODBC driver, using the Perl Database Interface (DBI) module with the ODBC Database Driver (DBD::ODBC). The Vertica ODBC driver is known to be compatible with these versions of Perl:

- 5.8
- 5.10

Later Perl versions may also work.

Perl drivers

The following Perl driver modules have been tested with the Vertica ODBC driver:

- The DBI driver module, version 1.609
- The DBD::ODBC driver module, version 1.22

Other versions may also work.

Supported client systems

The Vertica ODBC driver requires one of the operating systems and driver managers listed in ODBC prerequisites .

PHP prerequisites

PHP is a widely-used general-purpose scripting language that is especially suited for Web development and can be embedded into HTML. PHP is licensed under the PHP License, an open-source BSD-style license certified by the Open Source Initiative.

PHP modules

The following PHP modules are required:

- php
- php-odbc
- php-pdo
- UnixODBC (if you are using the Unix ODBC driver)
- libiodbc (if you are using the iODBC driver)

Supported client systems

The Vertica ODBC driver requires one of the operating systems and driver managers listed in ODBC prerequisites .

Upgrading the client drivers

The Vertica client drivers are usually updated for each new release of the Vertica server. The client driver installation packages include the version number of the corresponding Vertica server release. Usually, the drivers are forward-compatible with the next release, so your client applications are still be able to connect using the older drivers after you upgrade to the next version of Vertica Analytics Platform server. See Client driver and server version compatibility for details on which client driver versions work with each version of Vertica server.

> **Note**
> Vertica ODBC, JDBC and ADO.NET client drivers are backwards compatible to all supported Vertica server versions.

You should upgrade your clients as soon as possible after upgrading your server, to take advantage of new features and to maintain maximum compatibility with the server.

To upgrade your drivers, follow the same procedure you used to install them in the first place. The new installation will overwrite the old. See the specific instructions for installing the drivers on your client platform for any special instructions regarding upgrades.

> **Note**
> Installing new ODBC drivers does not alter existing DSN settings. You may need to change the driver settings in either the DSN or in the odbcinst.ini file, if your client system uses one. See Creating an ODBC Data Source Name for details.

Setting a client connection label

You can set a client connection label when you connect to a Vertica database. You can also set or return the client connection label using the SET_CLIENT_LABEL and GET_CLIENT_LABEL functions.

Set the client connection label:

```
=> SELECT SET_CLIENT_LABEL('py_data_load_application');
             SET_CLIENT_LABEL
-----------------------------------------------
 client_label set to py_data_load_application
(1 row)
```

Return the current client connection label:

```
=> SELECT GET_CLIENT_LABEL();
    GET_CLIENT_LABEL
---------------------------
 py_data_load_application
(1 row)
```

JDBC

The JDBC Client has a method to set and return the client connection label: getClientInfo() and setClientInfo(). You can use these methods with the SQL Functions GET_CLIENT_LABEL and SET_CLIENT_LABEL .

When you use these two methods, make sure you pass the string value APPLICATIONNAME to both the setter and getter methods.

Use setClientInfo() to create a client label, and use getClientInfo() to return the client label:

```
import java.sql.*;
import java.util.Properties;

public class ClientLabelJDBC {

   public static void main(String[] args) {
      Properties myProp = new Properties();
      myProp.put("user", "dbadmin");
      myProp.put("password", "");
      myProp.put("loginTimeout", "35");
      Connection conn;
      try {
         conn = DriverManager.getConnection(
               "jdbc:vertica://docc05.verticacorp.com:5433/doccdb", myProp);
         System.out.println("Connected!");
         conn.setClientInfo("APPLICATIONNAME", "JDBC Client - Data Load");
         System.out.println("New Conn label: " + conn.getClientInfo("APPLICATIONNAME"));
         conn.close();
      } catch (SQLTransientConnectionException connException) {
         // There was a potentially temporary network error
         // Could automatically retry a number of times here, but
         // instead just report error and exit.
         System.out.print("Network connection issue: ");
         System.out.print(connException.getMessage());
         System.out.println(" Try again later!");
         return;
      } catch (SQLInvalidAuthorizationSpecException authException) {
         // Either the username or password was wrong
         System.out.print("Could not log into database: ");
         System.out.print(authException.getMessage());
         System.out.println(" Check the login credentials and try again.");
         return;
      } catch (SQLException e) {
         // Catch-all for other exceptions
         e.printStackTrace();
      }
   }
}
```

When you run this method, it prints the following result to the standard output:

```
Connected!
New Conn Label: JDBC Client - Data Load
```

Additional parameter settings

The following parameters can be set for the Vertica client drivers.

Logging settings

These parameters control how messages between the client and server are logged. None of these settings are required. If they are not set, then the client library does not log any messages. They apply to both ADO.NET and ODBC.

- **LogLevel** —The severity of messages that are logged between the client and the server. The valid values are:
  - 0—No logging
  - 1—Fatal errors
  - 2—Errors
  - 3—Warnings
  - 4—Info
  - 5—Debug
  - 6—Trace (all messages)

  The value you specify for this setting sets the minimum severity for a message to be logged. For example, setting LogLevel to 3 means that the client driver logs all warnings, errors, and fatal errors.

> **Note**
> On a Windows client, you have the option of directing ODBC or OLE DB log entries to Event Tracing for Windows (ETW). Once set, ODBC log entries appear in the Windows Event Viewer. See Diverting ODBC log entries to ETW . for ODBC, or Diverting OLE DB log entries to ETW for OLE DB.

- **LogPath** —The absolute path of a directory to store log files . For example: /var/log/verticaodbc
- **LogNamespace** —Limits logging to messages generated by certain objects in the client driver.

> **Note**
> These settings are also available for the Vertica JDBC driver through connection properties. See Connection Properties for details.

ODBC-specific settings

The following settings are used only by the Vertica ODBC client driver.

- **DriverManagerEncoding** —The UTF encoding standard that the driver manager uses. This setting needs to match the encoding the driver manager expects. The available values for this setting are:
  - UTF-8
  - UTF-16 (usually used by unixODBC)
  - UTF-32 (usually used by iODBC)

  See the documentation for your driver manager to find the correct value for this setting.

  > **Note**
  > While both UTF-16 and UTF-8 are valid settings for DataDirect, Vertica recommends that you set the DataDirect driver manager encoding to UTF-16.

  If you do not set this parameter, the ODBC driver defaults to the value shown in the following table. If your driver manager uses a different encoding, you must set this value for the ODBC driver to be able to work.

Client Platform	Default Encoding
Linux 32-bit	UTF-32
Linux 64-bit	UTF-32
Linux Itanium 64-bit	UTF-32
OS X	UTF-32
Windows 32-bit	UTF-16
Windows 64-bit	UTF-16

- **ErrorMessagesPath** —The absolute path to the parent directory that contains the Vertica client driver's localized error message files. These files are usually stored in the same directory as the Vertica ODBC driver files.

> **Note**
> This setting is required. If you do not set it, then any error the ODBC driver encounters will result in an error message about a missing ODBCMessages.xml file.

- **ODBCInstLib** —The absolute path to the file containing the ODBC installer library (ODBCInst). This setting is required if the directory containing this library is not set in the LD_LIBRARY_PATH or LIB_PATH environment variables. The library files for the major driver manager are:
- UnixODBC: libodbcinst.so
- iODBC: libiodbcinst.so (libiodbcinst.2.dylib on OS X)
- DataDirect: libodbcinst.so

ADO.NET-specific settings

This setting applies only to the ADO.NET client driver:

C#PreloadLogging —Tells the Vertica ADO.NET driver to begin logging as soon as possible, before the driver has fully loaded itself. Normally, logging only starts after the driver has fully loaded. Valid values for this setting are:

- 0—Do not start logging before the driver has loaded.
- 1—Start logging as soon as possible.

Using legacy drivers

The Vertica server supports connections from previous versions of the client drivers. For detailed information the compatibility between versions of the Vertica server and Vertica client, see Client driver and server version compatibility .

Modifying the Java CLASSPATH

The CLASSPATH environment variable contains the list of directories where the Java run time looks for library class files. For your Java client code to access Vertica, you need to add the directory where the Vertica JDBC .jar file is located.

> **Note**
> In your CLASSPATH, use the symbolic link vertica-jdbc-x.x.x.jar (where x.x.x is a version number) that points to the JDBC library .jar file, rather than the .jar file itself. Using the symbolic link ensures that any updates to the JDBC library .jar file (which will use a different filename) will not invalidate your CLASSPATH setting, since the symbolic link's filename will remain the same. You just need to update the symbolic link to point at the new .jar file.

Linux and OS X

If you are using the Bash shell, use the export command to define the CLASSPATH variable:

```
# export CLASSPATH=/opt/vertica/java/lib/vertica-jdbc-x.x.x.jar
```

If environment variable CLASSPATH is already defined, use the following command to prevent it from being overwritten:

```
# export CLASSPATH=$CLASSPATH:/opt/vertica/java/lib/vertica-jdbc-x.x.x.jar
```

If you are using a shell other than Bash, consult its documentation to learn how to set environment variables.

You need to either set the CLASSPATH environment variable for every login session, or insert the command to set the variable into one of your startup scripts (such as ~/.profile or /etc/profile).

Windows

Provide the class paths to the .jar , .zip , or .class files.

```
C:> SET CLASSPATH=classpath1;classpath2...
```

For example:

```
C:> SET CLASSPATH=C:\java\MyClasses\vertica-jdbc-x.x.x.jar
```

As with the Linux/UNIX settings, this setting only lasts for the current session. To set the CLASSPATH permanently, set an environment variable:

1. On the Windows Control Panel, click **System** .
2. Click **Advanced** or **Advanced Systems Settings** .
3. Click **Environment Variables** .
4. Under User variables, click **New** .
5. In the Variable name box, type CLASSPATH .
6. In the Variable value box, type the path to the Vertica JDBC .jar file on your system (for example, C:\Program Files (x86)\Vertica\JDBC\vertica-jdbc-x.x.x.jar)

Specifying the library directory in the Java command

There is an alternative way to tell the Java run time where to find the Vertica JDBC driver other than changing the CLASSPATH environment variable: explicitly add the directory containing the .jar file to the java command line using either the -cp or -classpath argument. For example, on Linux, start your client application using:

```
# java -classpath /opt/vertica/java/lib/vertica-jdbc-x.x.x.jar myapplication.class
```

Your Java IDE may also let you add directories to your CLASSPATH, or let you import the Vertica JDBC driver into your project. See your IDE documentation for details.

Installing the client drivers on Linux and UNIX-Like platforms

This topic explains how to install the client drivers on Linux and UNIX-like platforms.

In this section

- Installing driver managers on Linux and other UNIX-like platforms
- Installing the client RPM on red hat and SUSE
- Installing JDBC driver on Linux
- Installing ODBC drivers on Linux

Installing driver managers on Linux and other UNIX-like platforms

If your client platform does not already have an ODBC driver manager, you need to install one before you can use the Vertica ODBC client driver. The driver manager provides an interface between your client operating system and the ODBC drivers. See Client drivers support for a list of driver managers that are supported on each of the client platforms.

Driver managers can be downloaded from your operating system specific repository and from the links below.

Vertica does not provide instructions for installing and configuring these third-party binaries. For download and configuration information, see the respective driver manager websites for installation and configuration information:

- UnixODBC: http://www.unixodbc.org/
- iODBC: http://www.iodbc.org

Installing the client RPM on red hat and SUSE

For Red Hat Enterprise Linux and SUSE Linux Enterprise Server, you can download and install a client driver RPM that installs both the ODBC and JDBC driver libraries and the vsql client.

Important
Vertica provides the FIPS-compliant client driver only as an rpm for 64-bit clients. You can install this rpm only on FIPS-enabled machines. The FIPS client includes vsql and ODBC drivers. If you are installing the FIPS-specific client, refer to the section, Installing the FIPS client driver for ODBC and vsql .

To install the client driver RPM package:

1. Open a Web browser and go to Vertica driver downloads page .
2. Find the drivers for your version of Vertica.
3. Download the client package file that matches your client platform's architecture.

   > **Note**
   > The 64-bit client driver RPM installs both the 64-bit and 32-bit ODBC driver libraries on non-FIPS compliant systems.

4. If you did not directly download the driver package on the client system, transfer the file to the client.
5. Install the driver package you downloaded. On Windows and Mac, double-click the package file to start the install process. On Linux, if your distribution uses RPm package, install the RPM with the command:

   ```
   # rpm -Uvh package_name.rpm
   ```

   If your Linux distribution does not use RPM packages, expand the .tar.gz file in a convenient location on your system.

> **Note**
> You receive one or more conflict error messages if there are existing Vertica client driver files on your system. This can happen if you are trying to install the client driver package on a system that has the server package installed, since the server package also includes the client drivers. In this case, you don't need to install the client drivers, and can instead use the drivers installed by the server package. If the conflict arises from an old driver installation or from a server installation for an older version, you can use the rpm command's --force switch to force it to overwrite the existing files with the files in the client driver package.

Once you have installed the client package, you need to create a DSN (see Creating an ODBC DSN for Linux) and set some additional configuration parameters (see Required ODBC driver configuration settings for Linux and UNIX) to use ODBC. To use JDBC, you need to modify your class path (see Modifying the Java CLASSPATH) before you can use JDBC.

You may also want to add the vsql client to your PATH environment variable so that you do not need to enter its full path to run it. You add it to your path by adding the following to the .profile file in your home directory or the global /etc/profile file:

```
export PATH=$PATH:/opt/vertica/bin
```

Installing JDBC driver on Linux

Note
The ODBC and JDBC client drivers are installed by the server .rpm files. If you have installed Vertica on your Linux system for development or testing purposes, you do not need to download and install the client drivers on it—you just need to configure the drivers. To use ODBC, you need to create a DSN (see Creating an ODBC DSN for Linux). To use JDBC, you need to add the JDBC client driver to the Java CLASSPATH (see Modifying the Java CLASSPATH). (The JDBC client driver is not available on FIPS-compliant systems.)

For details, see Supported platforms .

The JDBC driver is available for download from the Vertica driver downloads page . There is a single .jar file that works on all platforms and architectures. To download and install the file:

1. Open a Web browser and go to the Vertica driver downloads page .
2. In section that corresponds to your version of Vertica, click the link for the JDBC driver.
3. You need to copy the .jar file you downloaded to a directory in your Java CLASSPATH on every client system with which you want to access Vertica. You can either:
   - Copy the .jar file to its own directory (such as /opt/vertica/java/lib) and then add that directory to your CLASSPATH (recommended). See Modifying the Java CLASSPATH for details.
   - Copy the .jar file to directory that is already in your CLASSPATH (for example, a directory where you have placed other .jar files on which your application depends).

Note
In the directory where you copied the .jar file, you should create a symbolic link named vertica_jdbc.jar to the .jar file. You can reference this symbolic link anywhere you need to use the name of the JDBC library without having to worry any future upgrade invalidating the file name. This symbolic link is automatically created on server installs. On clients, you need to create and manually maintain this symbolic link yourself if you installed the driver manually. The Installing the client RPM on red hat and SUSE create this link when they install the JDBC library.

Installing ODBC drivers on Linux

Read Driver prerequisites before you proceed.

For Red Hat Enterprise Linux and SUSE Linux Enterprise Server, you can download and install a client RPM that installs both the ODBC and JDBC driver and the vsql client. See Installing the client RPM on red hat and SUSE .

Note
The ODBC and JDBC client drivers are installed by the server .rpm files. If you have installed Vertica on your Linux system for development or testing purposes, you do not need to download and install the client drivers on it—you just need to configure the drivers. To use ODBC, you need to create a DSN (see Creating an ODBC DSN for Linux). To use JDBC, you need to add the JDBC client driver to the Java CLASSPATH (see Modifying the Java CLASSPATH). (The JDBC client driver is not available on FIPS-compliant systems.)

For details, see Supported platforms .

The ODBC driver installation packages are broken down by client platform on the Vertica driver downloads page . The package's filename is named based on its operating system and architecture (for example, vertica_ 11.1.x .xx_odbc_x86_64_linux.tar.gz)

Important
Vertica provides the FIPS-compliant client driver only as an rpm for 64-bit clients. You can install this rpm only on FIPS-enabled machines. The FIPS client includes vsql and ODBC drivers. If you are installing the FIPS-specific client, refer to the section, Installing the FIPS client driver for ODBC and vsql .

Installation procedure

1. Open a web browser and browse to the Vertica driver downloads page .
2. Locate and download the driver package that matches your Vertica version and platform.
3. If you did not directly download to the client system, transfer the downloaded file to it.
4. Log in to the client system as root.
5. If the directory /opt/vertica/ does not exist, create it:
   ```
   # mkdir -p /opt/vertica/
   ```
6. Copy the downloaded file to the /opt/vertica/ directory. For example:
   ```
   # cp vertica_11.1.x.xx_odbc_x86_64_linux.tar.gz /opt/vertica/
   ```
7. Change to the /opt/vertica/ directory:
   ```
   # cd /opt/vertica/
   ```
8. Uncompress the file you downloaded. For example:
   $ tar vzxf vertica_ 11.1.x .xx_odbc_x86_64_linux.tar.gz
   Two folders are created: one for the include file, and one for the library files. The path of the library file depends on the processor architecture: lib for 32-bit libraries, and lib64 for 64-bit libraries. So, a 64-bit driver client download creates the directories:
   - /opt/vertica/include , which contains the header file
   - /opt/vertica/lib64 , which contains the library file

Post driver installation configuration

You must configure the ODBC driver before you can use it. There are two required configuration files:

- The odbc.ini configuration file defines the Data Source Names (DSNs) that tell the ODBC how to access your Vertica databases. See Creating an ODBC Data Source Name for instructions to create this file.
- The vertica.ini configuration file defines some Vertica-specific settings required by the drivers. See Required ODBC driver configuration settings for Linux and UNIX for instructions to create this file.

> **Note**
> If you are upgrading your ODBC driver, you must either update your DSNs to point to the newly-installed driver or create new DSNs. If your odbc.ini file references drivers defined in an odbcinst.ini file, you just need to update the odbcinst.ini file. See Creating an ODBC data source name (DSN) for details.

In this section

- Required ODBC driver configuration settings for Linux and UNIX
- Setting ODBC driver settings on Linux and UNIX-Like platforms

Required ODBC driver configuration settings for Linux and UNIX

In addition to DSN settings, Vertica provides additional ODBC client driver configuration parameters. These settings control the following:

- The text encoding used by the driver manager (for example, UTF-8 or UTF-16).
- The location of the directory containing the Vertica ODBC driver's error message files.
- Whether and how the ODBC driver logs messages.

On Linux and UNIX platforms, you must provide these additional settings manually so that the ODBC driver can function properly. To do so, edit the vertica.ini file to supply the necessary additional configuration settings. You specify where the ODBC driver can find the vertica.ini file using an environment variable named VERTICAINI. See Setting ODBC driver settings on Linux and UNIX-Like platforms .

Setting ODBC driver settings on Linux and UNIX-Like platforms

Driver settings specific to Vertica are stored in a text file named vertica.ini (although you may choose a different file name). On Linux and UNIX platforms, you must edit the vertica.ini file to supply additional configuration settings before the ODBC driver can function properly. You tell the Vertica ODBC driver where to find the vertica.ini file using an environment variable named VERTICAINI.

Required settings

On Linux and UNIX platforms, you must configure two settings in order for the ODBC driver to work correctly:

- ErrorMessagesPath
- ODBCInstLib (unless the driver manager's installation library is in a directory listed in the LD_LIBRARY_PATH or LIB_PATH environment variables).

If your driver manager does not use UTF-8 encoding, you need to set DriverManagerEncoding to the proper encoding.

Create a vertica.ini file

There is no standard location for the vertica.ini file—you can store the file anywhere that it is convenient for you on your client system. One possible location is in the /etc directory if you have multiple users on your client system that need to access it. You can also have a vertica.ini file in each user's home directory so users can alter their own settings. Wherever you store it, be sure users have read access to the file.

The format of the vertica.ini file is similar to the odbc.ini file, with a section followed by parameter definitions. Unlike the odbc.ini file, vertica.ini contains a single section named Driver:

```
[Driver]
```

Following the section definition, you add setting definitions, one per line. A setting definition consists of the setting name, followed by an equal sign (=), followed by the value. The value does not need quotes. For example, to set the ODBCInstLib setting, you add a line like this:

```
ODBCInstLib=/usr/lib64/libodbcinst.so
```

See Additional parameter settings for a list of the additional settings.

Set the VERTICAINI environment variable

You must set an environment variable named VERTICAINI to the absolute path of the vertica.ini file. The Vertica ODBC driver uses this variable to find the settings.

Where you set this variable depends on whether users on your client system need to have separate vertica.ini files. If you want to have a single, system-wide vertica.ini file, you can add a command to set VERTICAINI in /etc/profile or some other system-wide environment file. For example:

```
export VERTICAINI=/etc/vertica.ini
```

If users need individual vertica.ini files, set VERTICAINI in their ~/.profile or similar configuration file. For example:

```
export VERTICAINI=~/.vertica.ini
```

Example vertica.ini file

The following example vertica.ini file configures the ODBC driver to:

- use the 64-bit UNIXODBC driver manager.
- get its error messages from the standard Vertica 64-bit ODBC driver installation directory.
- log all warnings and more severe messages to log files stored in the temporary directory.

```
[Driver]
DriverManagerEncoding=UTF-16
ODBCInstLib=/usr/lib64/libodbcinst.so
ErrorMessagesPath=/opt/vertica
LogLevel=4
LogPath=/tmp
```

Installing the FIPS client drivers

This topic details how to install the FIPS client drivers for JDBC and ODBC.

In this section

- Installing the FIPS client driver for ODBC and vsql
- Installing the FIPS client driver for JDBC

Installing the FIPS client driver for ODBC and vsql

Vertica offers a FIPS client for FIPS-compatible systems. A FIPS-compatible system is FIPS-enabled and includes the OpenSSL libraries.

The FIPS client supports ODBC and vsql and is offered in 64-bit only.

Prerequisites

Verify that your host system is running a FIPS-compliant operating system that Vertica supports .

The FIPS client installer checks your host system for the value of the sysctl parameter, crypto.fips_enabled. You must set this parameter to 1 (enabled). If your host is not enabled, the client does not install.

For other prerequisites, related specifically to ODBC, see ODBC prerequisites .

Installing the FIPS client

To install the FIPS client driver package:

1. Download the FIPS client package from the Vertica driver downloads page .
2. Log in to the client system as root.
3. Install the RPM package that you downloaded:

```
# rpm -Uvh package_name.rpm
```

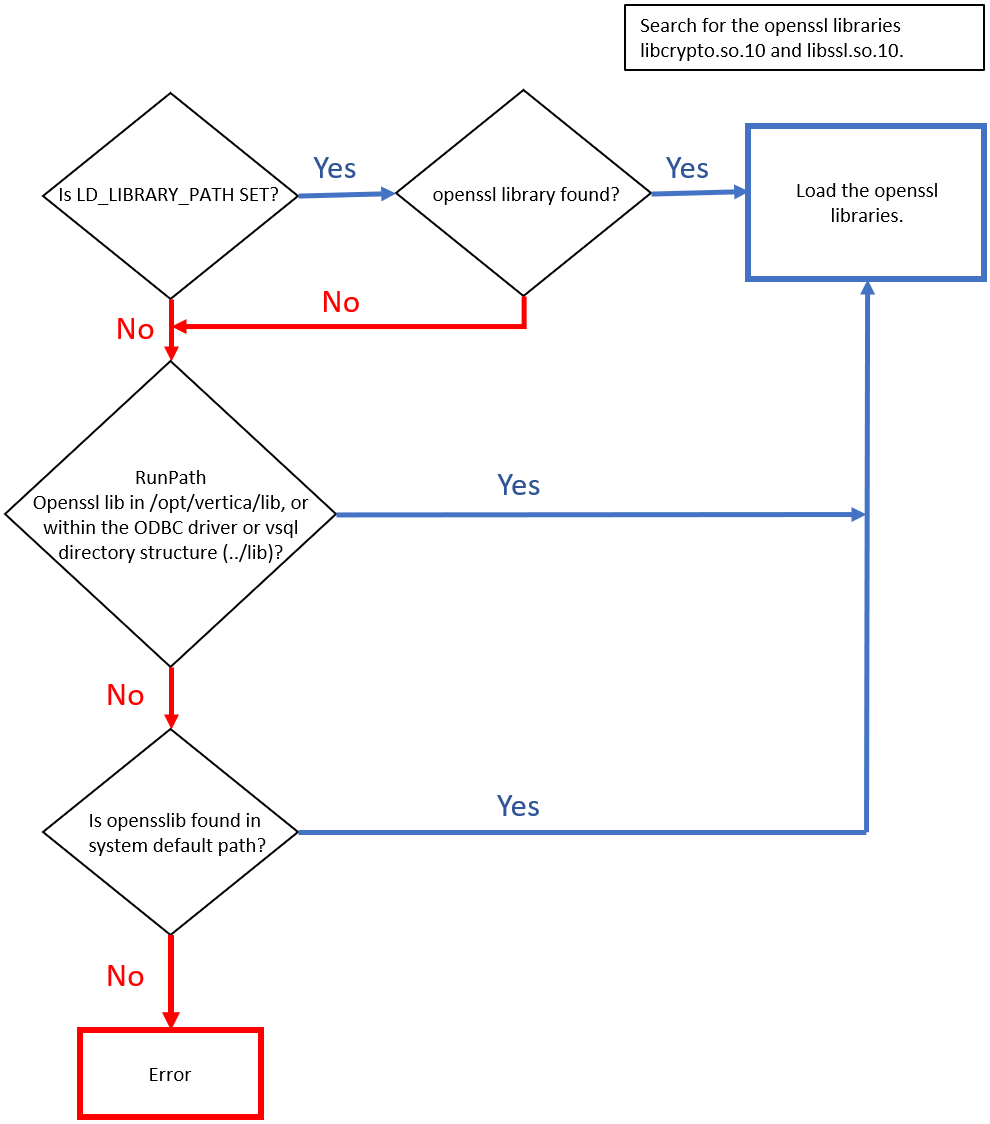
For ODBC, once you have installed the client package, you need to create a DSN and set some additional configuration parameters. For more information, see:

- Creating an ODBC DSN for Linux
- Required ODBC driver configuration settings for Linux and UNIX

You may also want to add the vsql client to your PATH environment variable so that you do not need to enter its full path to run it. To do so, add the following to the .profile file in your home directory or the global /etc/profile file:

```
export PATH=$PATH:/opt/vertica/bin
```

Client searches for OpenSSL libraries



When you launch the client application to connect to the server, the client searches for and loads the OpenSSL libraries libcrypto.so.10 and libssl.so.10 for supported OpenSSL versions :

- The client first checks to see if LD_LIBRARY_PATH is set.
- If the LD_LIBARY_PATH location does not include the libraries, it checks RunPath , either /opt/vertica/lib or within the ODBC or vsql directory structure (../lib).

Important

The LD_LIBRARY_PATH , if set, directs the search path for the OpenSSL libraries. Be aware that the client loads the libraries from any set or preset LD_LIBRARY_PATH location.

The following figure depicts the search for the OpenSSL libraries:

Installing the FIPS client driver for JDBC

Vertica offers a JDBC client driver that is compliant with the Federal Information Processing Standard (FIPS). Use this JDBC client driver to access systems that are FIPS-compatible. For more information on FIPS in Vertica, see Federal information processing standard .

Implementing FIPS on a JDBC client requires a third-party JRE extension called BouncyCastle , a collection of APIs used for cryptography. Use BouncyCastle APIs with JDK 1.7 and 1.8, and a FIPS-compliant operating system that Vertica supports .

Important
When using the JDBC FIPS-compliant client, expect some time lag for the client to connect efficiently and securely. If necessary, increase your system's entropy to ensure a fast and secure connection.

You need to add the FIPS BouncyCastle jar as the JVM JSSE provider, as follows:

1. Download the BouncyCastle FIPS jar file bc-fips-1.0.0.jar from the BouncyCastle download page .
2. Add bc-fips-1.0.0.jar as a JRE library extension:
   ```
   <path to jre>/lib/ext/bc-fips-1.0.0.jar
   ```
3. Add BouncyCastle as an SSL security provider in <path to jre>/lib/security/java.security :
   ```
   security.provider.1=org.bouncycastle.jcajce.provider.BouncyCastle FipsProvider
   security.provider.2=com.sun.net.ssl.internal.ssl.Provider BCFIPS
   security.provider.3=sun.security.provider.Sun
   ```
4. Use the following JVM java -D system property command arguments to set the KeyStore and TrustStore files to BCFIPS:
   ```
   export JAVA_OPTS="$JAVA_OPTS -Djavax.net.ssl.keyStoreProvider=BCFIPS export JAVA_OPTS="$JAVA_OPTS -
   Djavax.net.ssl.trustStoreProvider=BCFIPS
   ```

For information on setting the SSL Keystore and Truststore, see Configuring TLS for JDBC clients .

5. Set the default type for the KeyStore implementation to BCFKS in <path to jre>/lib/security/java.security :

```
keystore type=BCFKS
ssl.keystore.type=BCFKS
```

> **Note**
> If you are using FIPS with BouncyCastle, you must create all client keys and certificates with the BCFKS store type, including the Vertica–>Kafka key/certs.

6. On the command line, run the following command from <path to jre>/lib/ext to create the keystore and truststore. Make sure you use the BCFKS type:

```
$ <java bin path> keytool -keystore vertica.kafka.keystore.bcfks
-storetype BCFKS
-providername BCFIPS
-providerclass org.bouncycastle.jcajce.provider.BouncyCastleFipsProvider
-provider org.bouncycastle.jcajce.provider.BouncyCastleFipsProvider
-providerpath bc-fips-1.0.0.jar -alias CARoot -import -file (server.crt.der file path)
```

7. Enter the keystore password when prompted. The following message appears:

```
"Certificate was added to the keystore"
```

8. Run the Java program with SSL DB:
   1. Copy the vertica.kafka.keystore.bcfks keyStore from <path to jre>/lib/ext/ to the java program folder.
   2. Convert the Vertica server certificate to a form that java understands:

```
<java bin path> keytool -keystore verticastore -keypasswd -storepass password -importkeystore -noprompt -alias verticasql -import -file server.crt.der
```

   3. Download the latest vertica JDBC driver from the Vertica download page .
9. After creation of verticastore, keyStore, and download jar, execute the following command to run Java with debugging to test the implementation:

```
$ java -Djavax.net.debug=ssl -Djavax.net.ssl.keyStore='vertica.kafka.keystore.bcfks' -Djavax.net.ssl.keyStorePassword='password' -
Djavax.net.ssl.trustStore='<path to verticastore>/verticastore' -Djavax.net.ssl.trustStorePassword='password' -cp .:vertica-jdbc-11.1.0-0.jar FIPSTest
```

Installing the client drivers and tools on Windows

This section details how to install the client drivers and tools on Windows.

For connectivity through a JDBC connection, see Installing the JDBC client driver for windows . For all other client drivers and tools, see The Vertica client drivers and tools for windows .

In this section

- Installing the JDBC client driver for windows
- The Vertica client drivers and tools for windows

Installing the JDBC client driver for windows

To install the Vertica JDBC driver on your Windows client system, download the cross-platform JDBC driver .jar file to your system from the Vertica driver downloads page .

Choose how Java locates the JDBC driver library

For your Java client application to use the Vertica JDBC driver, the Java interpreter must be able to find the driver's library file. Choose one of these methods to tell the Java interpreter where to look for the library:

- Copy the JDBC .jar file you downloaded to the system-wide Java Extensions folder (for example, C:\Program Files\Java\jre *x.x.x_x* \lib\ext).
- Add the directory containing the JDBC .jar file to the CLASSPATH environment variable (see Modifying the Java CLASSPATH).
- Specify the directory containing the JDBC .jar using the -cp argument in the Java command line you use to start your Java application.

The Vertica client drivers and tools for windows

Download the Vertica Client Drivers and Tools for Windows installer from the Vertica driver downloads page . You can run the installer on a 32-bit or 64-bit system.

Components

The Vertica Client Drivers and Tools for Windows installs the following components on your system:

- The ODBC client driver for windows
- The OLE DB client driver for windows
- The vsql client for windows
- The ADO.NET driver for windows
- The Microsoft connectivity pack for windows
- The visual studio plug-in for windows

Read System prerequisites before you proceed.

In this section

- System prerequisites
- Download the client drivers and tools for windows
- Install or upgrade client drivers and tools for windows
- Post-installation steps for ODBC driver and vsql client
- Uninstalling, modifying, or repairing the client drivers and tools

System prerequisites

The Vertica Client Drivers and Tools for Windows has basic system prerequisite requirements. The pack also requires that specific Microsoft components be installed for full integration.

For a list of all prerequisites, see Client drivers support in the Supported Platforms document.

Fully update your system

Before you install the Vertica driver package, verify that your system is fully up to date with all Windows updates and patches. See the documentation for your version of Windows for instructions on how to run Windows update. The Vertica client libraries and vsql executable install updated Windows libraries that depend on Windows service packs. Be sure to resolve any issues that block the installation of Windows updates.

If your system is not fully up-to-date, you may receive error messages about missing libraries such as api-ms-win-crt-runtime-l1-1-0.dll when starting vsql.

In this section

- .NET framework
- Microsoft visual studio
- Microsoft SQL server

.NET framework

The .NET framework is not bundled into the Vertica Client Drivers and Tools for Windows. However, during installation, a web installer launches if Microsoft .NET 3.5 SP1 is not detected on your system. You then have the opportunity to download the framework. Also, if your operating system version includes .NET 3.5 SP1, but it is not turned on, the installer turns on the feature.

If you have Visual Studio 2010 or 2012 installed, your system already includes Microsoft .NET Framework 4.0 or 4.5, respectively. You also need Microsoft .NET 3.5 SP1 to use the Vertica Client Drivers and Tools for Windows integration features.

Use the following links to download the appropriate version of .NET framework directly from Microsoft:

- For .NET Framework 3.5 SP1:
  http://www.microsoft.com/en-us/download/details.aspx?id=22
- For .NET Framework 4.0:
  http://www.microsoft.com/en-us/download/details.aspx?id=17851
- For .NET Framework 4.5:
  http://www.microsoft.com/en-us/download/details.aspx?id=17851

Microsoft visual studio

The Vertica Client Drivers and Tools for Windows installer provides a Visual Studio plug-in which allows you to use Vertica as a Visual Studio Data Source for Visual Studio 2008, 2010, 2012, 2013, or 2015. The connection properties for the plug-in are the same as ADO.NET connection properties .

Important

Important: You must have Visual Studio and the matching SDK installed to use the Visual Studio plug-in.

After installing the plug-in, you can use it to access your Vertica database from within Visual Studio. If you do not have the SDK installed, download the SDK specific to your version of Visual Studio.

> **Note**
> For Visual Studio 2015, you do not need to download the SDK separately as it is included as an installation option with the Visual Studio installation. For more information, refer to the Microsoft documentation .

- For the Microsoft Visual Studio 2008 SDK: http://www.microsoft.com/en-us/download/details.aspx?id=508
- For the Microsoft Visual Studio 2008 SP1 SDK: http://www.microsoft.com/en-us/download/details.aspx?id=21827
- For the Microsoft Visual Studio 2010 SDK: http://www.microsoft.com/en-us/download/details.aspx?id=2680
- For the Microsoft Visual Studio 2010 SP1 SDK: http://www.microsoft.com/en-us/download/details.aspx?id=21835
- For the Microsoft Visual Studio 2012 SDK: http://www.microsoft.com/en-us/download/details.aspx?id=30668
- For the Microsoft Visual Studio 2013 SDK: http://www.microsoft.com/en-us/download/details.aspx?id=40758

If the Microsoft Visual Studio SDK is missing when you begin the installation, a dialog box opens to tell you so. You can choose to ignore this dialog box.

Configuring BIDS or SSDT-BI integration

The Vertica Client Drivers and Tools for Windows installer provides BIDS (Visual Studio 2008) or SSDT-BI (Visual Studio 2010, 2012, 2013, or 2015) integration. To use BIDS or SSDT-BI, follow this process:

1. Install the BIDS or SSDT-BI development tool add-on for Visual Studio.
2. Verify that SQL Server is installed on the same or a different machine.
3. Verify that the SQL Server Shared Features for BIDS or SSDT-BI have been activated.

You can then develop packages using BIDS or SSDT-BI, creating your projects using SQL Server's SSIS, SSAS, SSRS features. To use these features, you must connect to Vertica through the Vertica ADO.NET driver (for SSIS and SSRS) or the OLE DB driver (for SSAS).

For more information, see Microsoft components .

Microsoft SQL server

Use SQL Server 2012, 2014 or 2016. The Vertica Client Drivers and Tools for Windows installer enables support for the following:

- **SQL Server 2012, 2014, and 2016:**
  - SQL Server Integration Services (SSIS)
  - SQL Server Reporting Services (SSRS)
  - SQL Server Analysis Services (SSAS)
- **SQL Server using Visual Studio 2010, 2012, 2013, and 2015** —SQL Server Data Tool - Business Intelligence (SSDT-BI)

> **Note**
> For SQL Server 2012, you can use either SQL Server 2012 or SQL Server 2012 SP1.

To use the enhanced Vertica .NET support, you must first install SQL Server. Then, you can install the Client Drivers and Tools for Windows. The following components must be installed on the SQL server:

For...	Install...
SSAS	The Analysis Services Instance Feature.
SSRS	The Reporting Services Instance Feature.
SSIS (Data Type Mappings)	The SQL Server Integration Services Shared Feature.

BIDS (for Visual Studio 2008)	Business Intelligence Development Studio Shared Feature only *after* installing Microsoft Visual Studio 2008.
SSDT-BI (Visual Studio 2010, 2012, 2013, or 2015)	SQL Server Data Tool - Business Intelligence Shared Feature only *after* installing Microsoft Visual Studio 2010, 2012, 2013, or 2015.

Download the client drivers and tools for windows

The Vertica driver downloads page has the client drivers for all currently-supported versions of Vertica. The installation package works on both 32-bit and 64-bit versions of Windows.

Install or upgrade client drivers and tools for windows

You can install or upgrade the Windows client drivers and tools with the Windows installer or from the command line.

Important
Upgrading does not require you to uninstall Client Drivers and Tools for Windows. The installation program upgrades existing drivers and tools in place.

Windows installer

As Windows Administrator, double-click the Windows installer to start the installation. Follow the installer prompts as it guides you through each step of the process.

By default, the installer installs the client drivers and tools in C:\Program Files\Vertica Systems. You can change this location during installation.

> **Note**
> The installer wizard lets you specify which components to install. The installer adds a program for each installed component in the Windows Control Panel. Programs include Vertica Client Installer, which you can use to modify, repair, or uninstall the Vertica client.

Important
Client Drivers and Tools for Windows includes the Vertica Microsoft Connectivity Pack. To use the Connectivity Pack to access Microsoft Business Intelligence tools, reboot your system after installation to ensure integration.

Command-line

1. As Windows Administrator, open a command-line session.
2. Navigate to the folder that contains the installer.
3. Run this command:

```
VerticaSetup.exe -q -install InstallFolder="C:\Program Files\Vertica Systems"
```

The client drivers and tools are silently installed in C:\Program Files\Vertica Systems.

Post-installation steps for ODBC driver and vsql client

After you install the Vertica Client Drivers and Tools for Windows, there are additional steps you must take for the ODBC driver and vsql client to function correctly.

- **ODBC Driver** — After installing the ODBC driver, you must create a DSN to be able to connect to your Vertica database. For the procedure, see Creating an ODBC DSN for windows clients .
- **vsql Client** — The vsql client does not have a shortcut. Before you can start using vsql, you must add the vsql executable to the Windows PATH environment variable. The method for altering the PATH environment variable depends on the version of the Microsoft Windows operating system you are running. To start vsql and show the help list, open a command window, and type vsql -? at the command prompt. See Using vsql for windows users for important details about using vsql in a Windows console.

Uninstalling, modifying, or repairing the client drivers and tools

To uninstall, modify, or repair the client drivers and tools, run the Client Drivers and Tools for Windows installer.

The installer provides three options:

Action	Description
Modify	Remove installed client drivers and tools or install missing client drivers and tools.
Repair	Reinstall already-installed client drivers and tools.
Uninstall	Uninstall all of the client drivers and tools.

Silently uninstall the client drivers and tools

1. As a Windows Administrator, open a command-line session, and change directory to the folder that contains the installer.
2. Run the command:

```
VerticaSetup.exe -q -uninstall
```

The client drivers and tools are silently uninstalled.

Components of the client drivers and tools on Windows

The following sections describe the components in the Client Drivers and Tools for Windows in more detail:

- The ODBC client driver for windows
- The vsql client for windows
- The Microsoft connectivity pack for windows
- The OLE DB client driver for windows
- The ADO.NET driver for windows
- The visual studio plug-in for windows

In this section

- The ODBC client driver for windows
- The vsql client for windows
- The Microsoft connectivity pack for windows
- The OLE DB client driver for windows
- The ADO.NET driver for windows
- The visual studio plug-in for windows

The ODBC client driver for windows

The Vertica ODBC driver for Windows is installed as part of the Client Drivers and Tools for Windows. See the Client Drivers downloads page .

After installing the ODBC driver

After installing the ODBC driver, you must create a DSN to be able to connect to your Vertica database. For the procedure, see Creating an ODBC DSN for windows clients .

In this section

- ODBC driver settings on Windows
- Diverting ODBC log entries to ETW

ODBC driver settings on Windows

ODBC driver settings are automatically configured using the Vertica Client Drivers and Tools installer on Windows. The values for the settings are stored in the Windows registry under the path HKEY_LOCAL_MACHINE\SOFTWARE\Vertica\ODBC\Driver. It is not necessary to configure additional ODBC driver settings on Windows platforms beyond what is automatically configured by the installer. You can, however, set the ODBC driver settings using the Windows ODBC Data Source Configuration window.

See Additional parameter settings for a list of additional settings for the ODBC client driver. See Diverting ODBC log entries to ETW for information on how to send ODBC log entries to Event Tracing for Windows (ETW).

Diverting ODBC log entries to ETW

On Windows clients, you can direct Vertica to send ODBC log entries to Event Tracing for Windows (ETW). Once set, ODBC log entries appear in the Windows Event Viewer. To use ETW:

- Register the driver as a Windows Event Log provider, and enable the logs.
- Activate ETW by adding a string value to your Windows Registry.

- Understand how Vertica compresses log levels for the Windows Event Viewer.
- Know where to find the logs within Event Viewer.
- Understand the meaning of the Event IDs in your log entries.

Register the ODBC driver as a windows event log provider, and enable the logs

To use ETW logging, you must register the ODBC driver as a Windows Event Log provider. You can choose to register either the 32-bit or 64-bit driver. Once you have registered the driver, you must enable the logs.

Important
If you do not both register the driver and enable the logs, output is directed to stdout.

1. Open a command prompt window as Administrator, or launch the command prompt with the Run as Administrator option.
   Important
   You must have administrator privileges to successfully complete the next step.

2. Run the command wevtutil im to register either the 32-bit or 64-bit version of the driver.
   1. For the 64-bit ODBC driver, run:
      ```
      wevtutil im "c:\Program Files\Vertica Systems\ODBC64\lib\VerticaODBC64.man"
      /resourceFilePath:"c:\Program Files\Vertica Systems\ODBC64\lib\vertica_9.1_odbc_3.5.dll"
      /messageFilePath:"c:\Program Files\Vertica Systems\ODBC64\lib\vertica_9.1_odbc_3.5.dll"
      ```
   2. For the 32-bit ODBC driver, run:
      ```
      wevtutil im "c:\Program Files (x86)\Vertica Systems\ODBC32\lib\VerticaODBC32.man"
      /resourceFilePath:"c:\Program Files (x86)\Vertica Systems\ODBC32\lib\vertica_9.1_odbc_3.5.dll"
      /messageFilePath:"c:\Program Files (x86)\Vertica Systems\ODBC32\lib\vertica_9.1_odbc_3.5.dll"
      ```
3. Run the command wevtutil sl to enable the logs.
   1. For 64-bit ODBC driver logs, run:
      ```
      wevtutil sl VerticaODBC64/e:true
      ```
   2. For the 32-bit ODBC driver logs, run:
      ```
      wevtutil sl VerticaODBC32/e:true
      ```

> **Note**
> Should you want to later disable the logs, you can use the same wevtutil sl command, substituting /e:false in place of /e:true when you issue the statement. Alternatively, you can enable or disable logs within the Windows Event Viewer itself.

Add the string value LogType

By default, Vertica does not send ODBC log entries to ETW. To activate ETW, add the string LogType to your Windows registry, and set its value to ETW .

1. Start the registry editor by typing regedit.exe in the Windows Run command box.
2. Navigate to the correct location in the registry.
   ```
   HKEY_LOCAL_MACHINE\SOFTWARE\Vertica\ODBC\Driver
   ```
3. Right-click in the right pane of the **Registry Editor** window. Select **New** and then select **String Value** .
4. Change the name of the string value from New Value #1 to LogType .
5. Double-click the new LogType entry. When prompted for a new value, enter ETW .
6. Exit the registry editor.

ETW is off by default. When ETW is activated, you can subsequently turn it off by clearing the value ETW from the LogType string.

Event viewer log levels

The LogLevel parameter setting is described in the section, Additional parameter settings . The parameter allows you to specify a LogLevel of 0 through 6. Be aware that Vertica compresses the log levels for the Windows Event Viewer. The six levels are compressed to four in Event Viewer.

Vertica LogLevel Setting	Vertica LogLevel Description	Entries are sent to Event Viewer as log level...	Event Viewer Displays...
0	(No logging)	0	(No logging)

1	Fatal Errors	1	Critical
2	Errors	2	Error
3	Warnings	3	Warning
4	Info	4	Information
5	Debug	4	
6	Trace (all messages)	4	

Examples:

- A LogLevel setting of 5 sends fatal errors, errors, warnings, info and debug log level entries to Event Viewer as Level 4 (Information).
- A LogLevel setting of 6 sends fatal errors, errors, warnings, debug and trace log level entries to Event Viewer as Level 4.

Where to find logs in event viewer

1. Launch the **Windows Event Viewer** .
2. From **Event Viewer (Local)** , expand **Applications and Services Logs** .
3. Expand the folder that contains the log you want to review (for example, VerticaODBC64).
4. Select the Vertica ODBC log under the folder. Entries appear in the right pane.

Event log entry: event ID

Once you have chosen an ODBC log in Event Viewer, note the value in the **Event ID** field.

Each Event Log entry includes one of four Event IDs. An Event ID of 0 is informational (debug, info, and trace events), 1 is an error, 2 is a fatal event, and 3 is a warning.

The vsql client for windows

The Vertica vsql client for Windows is installed as part of the Client Drivers and Tools for Windows.

There is no shortcut for the vsql client. Before you can start using vsql, you must add the vsql executable to the Windows PATH environment variable. The method for altering the PATH environment variable depends on the version of the Microsoft Windows operating system you are running. After you have made the change to your PATH environment variable, start a command window and type vsql -? at the command prompt to start vsql and show the help list.

For information about editing the Window PATH environment variable, see How do I set or change the PATH system variable?

For important details about using vsql in a Windows console, see Using vsql for windows users .

In this section

- Using vsql for windows users

Using vsql for windows users

Font

The default raster font does not work well with the ANSI code page. Set the console font to "Lucida Console."

Console encoding

vsql is built as a "console application." The Windows console windows use a different encoding than the rest of the system, so take care when you use 8-bit characters within vsql. If vsql detects a problematic console code page, it warns you at startup.

To change the console code page, set the code page by entering cmd.exe /c chcp 1252 .

> **Note**
> 1252 is a code page that is appropriate for European languages. Replace it with your preferred locale code page.

Running under cygwin

Verify that your cygwin.bat file does not include the "tty" flag. If the "tty" flag is included in your cywgin.bat file, then banners and prompts are not displayed in vsql.

To verify, enter:

```
set CYGWIN=binmode tty ntsec
```

To remove the "tty" flag, enter:

```
set CYGWIN=binmode ntsec
```

Additionally, when running under Cygwin, vsql uses Cygwin shell conventions as opposed to Windows console conventions.

Tab completion

Tab completion is a function of the shell, not vsql. Because of this, tab completion does not work the same way in Windows vsql as it does on Linux versions of vsql.

On Windows, instead of using tab-completion, press F7 to pop-up a history window of commands. You can also press F8 after typing a few letters of a command to cycle through commands in the history buffer which begin with the same letters.

The Microsoft connectivity pack for windows

The Vertica Microsoft Connectivity Pack for Windows provides a configuration file for you to access Microsoft Business Intelligence tools. The Connectivity Pack is installed as part of the Client Drivers and Tools for Windows.

To learn about which Microsoft components are configured with the Microsoft Connectivity Pack, see Microsoft components .

In this section

- Microsoft components
- Compatibility issues and limitations

Microsoft components

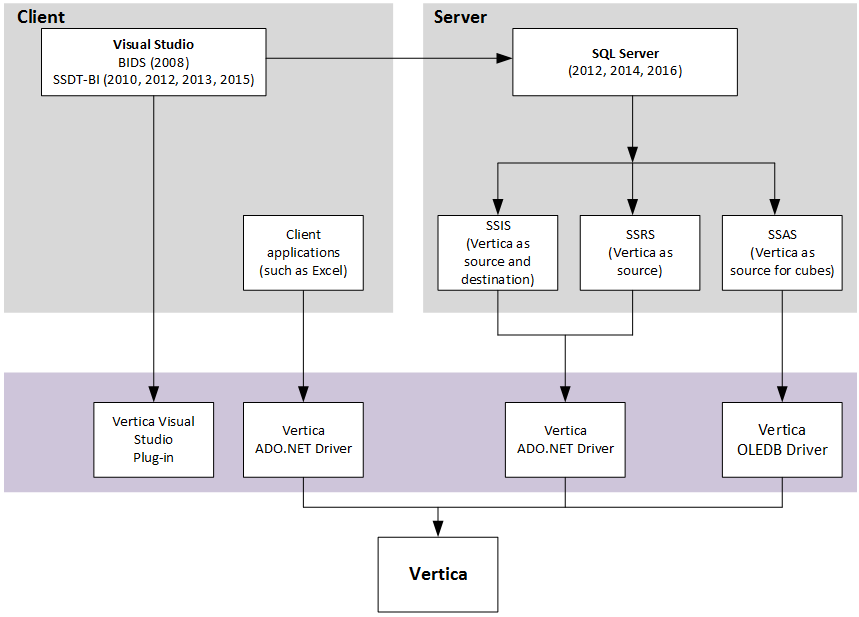
This section describes the Microsoft Business Intelligence components you can use with Microsoft Visual Studio and Microsoft SQL Server. After configuration, you can use these Microsoft components to develop business solutions using your Vertica server.

Important

Client Drivers and Tools for Windows includes the Vertica Microsoft Connectivity Pack. To use the Connectivity Pack to access Microsoft Business Intelligence tools, reboot your system after installation to ensure integration.

In this section

- Microsoft component configuration
- BIDS and SSDT-BI
- SQL server analysis services (SSAS) support
- SQL server integration services (SSIS) support
- SQL server reporting services (SSRS) support



Microsoft component configuration

The Vertica ADO.NET driver, the Visual Studio plug-in, and the OLE DB driver allow you to integrate your Vertica server with an environment that includes Microsoft components previously installed on your system. Additional tools are also available for integration with Microsoft SQL Server.

The available drivers provide integration with the following Microsoft components:

- Business Intelligence Development Studio (BIDS) for Visual Studio 2008 for use with SQL Server 2012. BIDS is a client-based application used to develop business intelligence solutions based on the Microsoft Visual Studio development environment. It includes additional project types specific to SQL Server Business Intelligence. As a developer, you can use BIDS to develop business solutions.
- SQL Server Data Tool - Business Intelligence (SSDT-BI) for Visual Studio 2008/2010/2012/2013/2015 for use with SQL Server 2012, 2014, and 2016. SSDT-BI replaces BIDS for Visual Studio 2008, 2010, 2012, 2013, and 2015. It serves the same purpose as BIDS, providing a development environment for developing business intelligence solutions.
- SQL Server Analysis Services (SSAS) for SQL Server 2012, 2014, and 2016. Use SSAS for OLAP and data mining, while using Vertica as the source for cube creation.
- SQL Server Integration Services (SSIS) for SQL Server 2012, 2014, and 2016. SSIS provides SQL Server Type Mappings to map data types between Vertica and SQL Server. Use SSIS for data migration, data integration and workflow, and ETL.

The following figure displays the relationship between Microsoft components and Vertica dependencies.

BIDS and SSDT-BI

Business Intelligence Development Studio (BIDS) is available in Microsoft Visual Studio 2008 with additional project types that are specific to SQL Server business intelligence. BIDS is the primary environment that you use to develop business solutions that include Analysis Services, Integration Services, and Reporting Services projects.

SQL Server Data Tool - Business Intelligence (SSDT-BI) replaces BIDS for Visual Studio 2010, 2012, 2013, and 2015. It serves the same purpose as BIDS, providing a development environment for developing business solutions.

Both BIDS and SSDT-BI are client-based applications that include additional project types specific to SQL Server Business Intelligence.

You can use the Visual Studio Shell Integration plug-in to browse a database from within the Visual Studio Server Explorer. This capability allows you to work outside of BIDS or SSDT-BI development to perform tasks, such as listing tables or inserting data. When you use Visual Studio in BIDS or SSDT-BI mode, you can develop business solutions using the data in your Vertica database. For example, you can create cubes or open tables.

Microsoft does not support the following configurations:

- You cannot use Microsoft Visual Studio 2008 with BIDS development to create a SQL Server 2012 Business Intelligence solution.
- You cannot use Microsoft Visual Studio 2010/2012/2013/2015 with SSDT-BI development to create a SQL Server 2008 Business Intelligence solution.

SQL server analysis services (SSAS) support

BIDS or SSDT-BI includes the Analysis Services project for developing online analytical processing (OLAP) for business intelligence applications. This project type includes templates for:

- Cubes
- Dimensions
- Data sources
- Data source views

It also provides the tools for working with these objects.

> **Note**
> **Note** : OpenText recommends that you use the Vertica OLE DB driver when connecting to the Vertica server from SSAS due to improved performance.

You can find the OLE DB connection properties in OLE DB connection properties .

SQL server integration services (SSIS) support

BIDS or SSDT-BI includes the Integration Services project for developing ETL solutions. This project type includes templates for:

- Packages
- Data sources
- Data source views

It also provides the tools for working with these objects.

You can find support for using Vertica as a data source and target from both SSIS and the import/export wizard. You must install mapping files specific to Vertica on the Integration Server and BIDS or SSDT-BI workstation to enable this capability. The Vertica Client Drivers and Tools for Windows installs these mapping files as the "SQL Server Type Mappings" component(s) in both 32-bit and 64-bit versions.

> **Note**
> **Note** : Always use the Vertica ADO.NET driver when connecting to the Vertica server from SSIS.

SQL server reporting services (SSRS) support

BIDS or SSDT-BI includes Report projects for developing reporting solutions.

You can use Vertica as a data source for Reporting Services. The installer implements various configuration file modifications to enable this capability on both the BIDS or SSDT-BI workstation and the Reporting Services server.

Compatibility issues and limitations

This section lists compatibility issues and limitations for integrating the Microsoft Connectivity Pack with Microsoft Visual Studio and Microsoft SQL Server.

In this section

- BIDS and SSDT-BI limitations
- SSAS limitations
- SSIS data type limitations
- SSRS limitations

BIDS and SSDT-BI limitations

BIDS and SSDT-BI are 32-bit development environments for Analysis Services, Integration Services, and Reporting Services projects. They are not designed to run on the Itanium 64-bit architecture and thus are not installed on Itanium servers.

SSAS limitations

- The SSAS Tabular Model is not supported.
- If, after installing the Vertica OLE DB driver, an SSAS cube build fails, restart the SSAS service.

SSIS data type limitations

The following sections cover data type limitations when using SQL Server Integration Services (SSIS).

Time data transfer

When transferring time data, SSIS uses the TimeSpan data type that supports precision greater than six digits. The Vertica ADO.NET driver translates TimeSpan as an Interval data type that supports up to six digits. The Interval type is not converted to the TimeSpan type during transfer. As a result, if the time value has a precision of more than six digits, the data is truncated, not rounded.

For information on ADO.NET data types, refer to ADO.NET data types .

DATE and DATETIME precision

To function without errors, DATE and DATETIME have a range from 0001-01-01 00:00:00.0000000 to 9999-12-31 23:59:59.999999.

In SSIS, the DATETIME type (DT_TIMESTAMP) supports only a scale up to three decimal places for seconds. Any decimal places after that are automatically discarded. You can perform derived column transformations only on DATETIME values between January 1, 1753 through December 31, 9999.

Numeric precision

The maximum and minimum decimal allowed is:

- Max: +79,228,162,514,264,337,593,543,950,335
- Min: -79,228,162,514,264,337,593,543,950,335

For example, if the scale is 16, the range of values is:

+/- 7,922,816,251,426.4337593543950335

The valid scale range is any number that is smaller than 29 and greater than 38. Using a scale between 29 and 38 does not generate an error.

See: http://msdn.microsoft.com/en-us/library/system.decimal.maxvalue.aspx

Unsupported floating point values

SQL Server does not support NaN, Infinity, or –Infinity values. These values are supported when you use SSIS to transfer between Vertica instances, but they are not supported with a SQL Server Destination.

String Conversion

The CHAR and VARCHAR data types used in SSIS are DT_WSTR, with a maximum length of 4000 characters.

In SSIS, Vertica strings are converted to Unicode strings in SSIS to handle multi-lingual data. You can convert these strings to ASCII using a Data Conversion Task.

Scale

Whenever you use a scale greater than 38, SSIS replaces it with a value of 4.

Interval conversion

SSIS does not support interval types. It converts them to TIME and strips off the day component. Any package that has interval types greater than a day returns incorrect results.

Data mapping issues with SQL server import and export wizard

When you create an Integrated Services package (SSIS) using the SQL Server Import and Export Wizard, certain data types do not automatically map correctly. A mapping issue can occur when you use the wizard with:

- SQL Server Native OLE DB Provider for SQL Server 2008 or 2012
- SQL Server Native Client 10.0/11.0 Provider for SQL Server 2010/2012

To avoid this issue, manually change the type mappings with BIDS or SSDT-BI.

Data transfer failures

When using an Integrated Services package (SSIS) with the SQL Server OLE DB Provider for SQL Server 2008 or 2012, certain data type transfers can fail when transferring from Vertica to SQL Server. To avoid this issue, use either BIDS or SSDT-BI when transferring data.

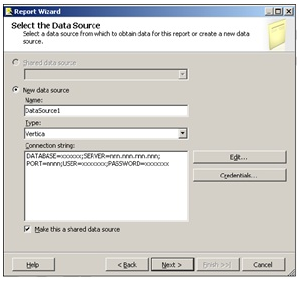
Batch insert of VARBINARY/LONG VARBINARY data types

Sometimes, one row of a batch insert of VARBINARY or LONG VARBINARY data types exceeds the data type limit:

- VARBINARY: 65 KB
- LONG VARBINARY: 32 MB

In such cases, all rows are rejected, rather than just the one row whose length exceeds the type limit. The batch insert fails with the message "row(s) are rejected".

To avoid this issue, use a predicate to filter out rows from the source that do not fit into the receiving database.



Boolean queries in SQL server query designer

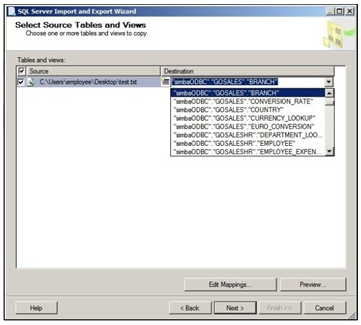
When issuing a Boolean query in SQL Server Query Designer, you must enclose Boolean column values in quotes. Otherwise, you receive a SQL execution error (for example, `someboolean = 'true'`).

SSRS limitations

Data Connection Wizard Workaround

The SSRS Report Wizard provides a data connection wizard. After you select the wizard and enter all the connection information, the **OK** button is disabled. You cannot save your work and continue. The workaround is to not use the wizard and to use the following panel instead:

Report Wizard - Query Designer



Vertica uses the Report Wizard's Generic Query Designer. Other data sources use a Graphical Query Designer that supports building queries visually. The Graphical Query Designer is a part of a package called Visual Data Tools (VDT). The Graphical Query Designer works only with Generic OLE DB providers and the built-in providers. You cannot use it with the Vertica Data Provider.

Report Builder

Report Builder is a web-based report design tool. It does not support creating reports using custom data extensions, so you cannot use it with Vertica. When you create a report using Report Builder, existing Vertica data sources appear in the list of available data sources. However, choosing a Vertica data source causes an error.

Schema Name Not Automatically Provided when Mapping Vertica **Destination**

Currently, when you map a Vertica destination, the schema name is not automatically provided. You must enter it manually or pick it from the drop-down menu as follows:

The OLE DB client driver for windows

The Vertica OLE DB driver for Windows is installed as part of the Client Drivers and Tools for Windows. See the Client Drivers downloads page .

The values for the OLE DB driver's settings are stored in the Windows registry under the path HKEY_LOCAL_MACHINE\SOFTWARE\Vertica\OLEDB\Driver.

For information on how the OLE DB driver integrates with Microsoft components previously installed on your system, see Microsoft component configuration .

In this section

- OLE DB connection properties
- Diverting OLE DB log entries to ETW

OLE DB connection properties

Use the Connection Manager to set the OLE DB connection string properties, which define your connection. You access the Connection Manager from within Visual Studio.

These connection parameters appear on the Connection page.

Parameters	**Action**
Provider	Select the native OLE DB provider for the connection.
OLE DB Provider	Indicates Vertica OLE DB Provider.

Server or file name	Enter the server or file name.
Location	Not supported.
Use Windows NT Integrated Security	Not supported.
Use a specific user name and password	Enter a user name and password. **Connect with No Password** : Select the **Blank password** check box. **Save and Encrypt Password:** Select **Allow saving password** .
Initial Catalog	The name of the database running on the server.

The **All** page from the **Connection Manager** dialog box includes all possible connection string properties for the provider.

The table that follows lists the connection parameters for the **All** page.

For OLE DB properties information specific to Microsoft, see the Microsoft documentation OLE DB Properties .

Parameters	**Action**
Extended Properties	Not supported.
Locale Identifier	Indicates the Locale ID. **Default:** 0
Mode	Specifies access permissions. **Default:** 0
Connect Timeout	Not supported. **Default:** 0
General Timeout	Not supported.
File Name	Not supported.
OLE DB Services	Specifies which OLE DB services to enable or disable.
Password	Specifies the password for the user ID. For no password, insert an empty string.
Persist Security Info	A security measure. When False, security sensitive-information, such as the password, is not returned as part of the connection if the connection is open or has ever been in an open state. **Default:** true
User ID	The database username.

Data Source	The host name or IP address of any active node in a Vertica cluster. You can provide an IPv4 address, IPv6 address, or host name. In mixed IPv4/IPv6 networks, the DNS server configuration determines which IP version address is sent first. Use the PreferredAddressFamily option to force the connection to use either IPv4 or IPv6.
Initial Catalog	The name of the database running on the server.
Provider	The name of the OLE DB Provider to use when connecting to the Data Source. **Default:** VerticaOLEDB.1
BackupServerNode	A designated host name or IP address to use if the ServerName host is unavailable. Enter as a string. Connection attempts continue until successful or until the list of server nodes is exhausted. **Valid values:** Comma-separated list of servers optionally followed by a colon and port number. For example: server1:5033,server2:5034
ConnectionLoadBalance	A Boolean value that determines whether the connection can be redirected to a host in the database other than the ServerNode. This parameter affects the connection only if load balancing is set to a value other than NONE. When the node differs from the node that the client is connected to, the client disconnects and reconnects to the targeted node. See About Native Connection Load Balancing in the Administration Guide. **Default:** false
ConnSettings	SQL commands that the driver should execute immediately after connecting to the server. Use to configure the connection, such as setting a schema search path. **Reserved symbol:** ';' To set multiple parameters in this field use '%3B' for ','. Spaces: Use '+'.
ConvertSquareBracketIdentifiers	Controls whether square-bracket query identifiers are converted to a double quote identifier for compatibility when making queries to a Vertica database. **Default:** false
DirectBatchInsert	Deprecated, always set to true.
KerberosHostName	Provides the instance or host name portion of the Vertica Kerberos principal; for example: vertica/host@EXAMPLE.COM
KerberosServiceName	Provides the service name portion of the Vertica Kerberos principal; for example: vertica/host@EXAMPLE.COM
Label	Sets a label for the connection on the server. This value appears in the session_id column of system table SESSIONS .
LogLevel	Specifies the amount of information included in the log. Leave this field blank or set to 0 unless otherwise instructed by Vertica Customer Support.
LogPath	The path for the log file.

Port	The port number on which Vertica listens for OLE DB connections. **Default:** port 5433
PreferredAddressFamily	The IP version to use if the client and server have both IPv4 and IPv6 addresses and you have provided a host name, one of the following: • ipv4 : Connect to the server using IPv4. • ipv6 : Connect to the server using IPv6. • none : Use the IP address provided by the DNS server.
SSLCertFile	The absolute path of the client's public certificate file. This file can reside anywhere on the system.
SSLKeyFile	The absolute path to the client's private key file. This file can reside anywhere on the system.
SSLMode	Controls whether the connection to the database uses SSL encryption, one of the following: • require : Requires the server to use SSL. If the server cannot provide an encrypted channel, the connection fails. • prefer : Prefers that the server use SSL. If the server does not offer an encrypted channel, the client requests one. The first attempt is made with SSL. If that attempt fails, the second attempt is over a clear channel. • allow : Makes a connection to the server whether or not the server uses SSL. The first attempt is made over a clear channel. If that attempt fails, a second attempt is over SSL. • disable : Never connects to the server using SSL. Typically, you use this setting for troubleshooting. **Default:** prefer

Diverting OLE DB log entries to ETW

On Windows clients, you can direct Vertica to send OLE DB log entries to Event Tracing for Windows (ETW). Once set, OLE DB log entries appear in the Windows Event Viewer. To use ETW:

- Register the driver as a Windows Event Log provider, and enable the logs.
- Activate ETW by adding a string value to your Windows Registry.
- Understand how Vertica compresses log levels for the Windows Event Viewer.
- Know where to find the logs within Event Viewer.
- Understand the meaning of the Event IDs in your log entries.

Register the OLE DB driver as a windows event log provider, and enable the logs

To use ETW logging, you must register the OLE DB driver as a Windows Event Log provider. You can choose to register either the 32-bit or 64-bit driver. Once you have registered the driver, you must enable the logs.

Important
If you do not both register the driver and enable the logs, output is directed to stdout.

1. Open a command prompt window as Administrator, or launch the command prompt with the Run as Administrator option.
   Important
   You must have administrator privileges to successfully complete the next step.

2. Run the command wevtutil im to register either the 32-bit or 64-bit version of the driver.
   1. For the 64-bit OLE DB driver, run:

      ```
      wevtutil im "c:\Program Files\Vertica Systems\OLEDB64\lib\VerticaOLEDB64.man"
      /resourceFilePath:"c:\Program Files\Vertica Systems\OLEDB64\lib\vertica_8.1_oledb.dll"
      /messageFilePath:"c:\Program Files\Vertica Systems\OLEDB64\lib\vertica_8.1_oledb.dll"
      ```

   2. For the 32-bit OLE DB driver, run:

```
wevtutil im "c:\Program Files (x86)\Vertica Systems\OLEDB32\lib\VerticaOLEDB32.man"
/resourceFilePath:"c:\Program Files (x86)\Vertica Systems\OLEDB32\lib\vertica_8.1_oledb.dll"
/messageFilePath:"c:\Program Files (x86)\Vertica Systems\OLEDB32\lib\vertica_8.1_oledb.dll"
```

3. Run the command wevtutil sl to enable the logs.
   1. For 64-bit OLE DB driver logs, run:
      ```
      wevtutil sl VerticaOLEDB64/e:true
      ```
   2. For the 32-bit ODBC driver logs, run:
      ```
      wevtutil sl VerticaOLEDB32/e:true
      ```

> **Note**
> Should you want to later disable the logs, you can use the same wevtutil sl command, substituting /e:false in place of /e:true when you issue the statement. Alternatively, you can enable or disable logs within the Windows Event Viewer itself.

Add the string value LogType

By default, Vertica does not send OLE DB log entries to ETW. To activate ETW, add the string LogType to your Windows registry, and set its value to ETW .

1. Start the registry editor by typing regedit.exe in the Windows Run command box.
2. Navigate to the correct location in the registry.
   ```
   HKEY_LOCAL_MACHINE\SOFTWARE\Vertica\OLEDB\Driver
   ```
3. Right-click in the right pane of the **Registry Editor** window. Select **New** and then select **String Value** .
4. Change the name of the string value from New Value #1 to LogType .
5. Double-click the new LogType entry. When prompted for a new value, enter ETW .
6. Exit the registry editor.

ETW is off by default. When ETW is activated, you can subsequently turn it off by clearing the value ETW from the LogType string.

Event viewer log levels

The LogLevel parameter setting is described in the section, Additional parameter settings . The parameter allows you to specify a LogLevel of 0 through 6. Be aware that Vertica compresses the log levels for the Windows Event Viewer. The six levels are compressed to four in Event Viewer.

Vertica LogLevel Setting	Vertica LogLevel Description	Entries are sent to Event Viewer as log level...	Event Viewer Displays...
0	(No logging)	0	(No logging)
1	Fatal Errors	1	Critical
2	Errors	2	Error
3	Warnings	3	Warning
4	Info	4	Information
5	Debug	4	
6	Trace (all messages)	4	

Examples:

- A LogLevel setting of 5 sends fatal errors, errors, warnings, info and debug log level entries to Event Viewer as Level 4 (Information).
- A LogLevel setting of 6 sends fatal errors, errors, warnings, debug and trace log level entries to Event Viewer as Level 4.

Where to find logs in event viewer

1. Launch the **Windows Event Viewer** .
2. From **Event Viewer (Local)** , expand **Applications and Services Logs** .
3. Expand the folder that contains the log you want to review (for example, VerticaOLEDB64).
4. Select the Vertica OLE DB log under the folder. Entries appear in the right pane.

Event log entry: event ID

Once you have chosen an OLE DB log in Event Viewer, note the value in the **Event ID** field.

Each Event Log entry includes one of four Event IDs. An Event ID of 0 is informational (debug, info, and trace events), 1 is an error, 2 is a fatal event, and 3 is a warning.

The ADO.NET driver for windows

The Vertica ADO.NET driver for Windows is installed as part of the Client Drivers and Tools for Windows.

The ADO.NET driver is installed in the ADO.NET folder of the installation folder. The driver is also installed into the Windows Global Assembly Cache (GAC).

For information on how the ADO.NET driver integrates with Microsoft components previously installed on your system, see Microsoft components .

The visual studio plug-in for windows

The Visual Studio plug-in for Windows is installed as part of the Client Drivers and Tools for Windows.

For information on how the Visual Studio plug-in integrates with Microsoft components previously installed on your system, see Microsoft components .

In this section

- Visual studio limitations

Visual studio limitations

Visual Studio 2012 May Require Update 3

You may need to install update 3 to Visual Studio 2012 if:

- You launch Server Explorer to view and work with your Vertica server, but the Vertica data source is not visible.
- You create a SSAS cube, connect to Vertica, and find either an empty list of tables or tables not functioning correctly.

This issue does not occur for other versions of Visual Studio supported by Vertica.

Results Viewer Limited to 655 Columns

The Visual Studio results viewer cannot execute a query that includes more than 655 columns. If a table includes more than 655 columns, select specific columns (up to 655 total) rather than selecting all columns.

Manually Refresh Settings for Visual Studio

If, after installing the Visual Studio plug-in, you do not see Vertica listed as a data provider, manually refresh.

To do so, run devenv.exe/setup , which you can find in the Visual Studio installation folder.

SQL Pane Issues

- **ALTER TABLE** or **CREATE TABLE**
  You use Visual Studio 2008, 2010, 2012, 2013, or 2015 and issue the ALTER TABLE or CREATE TABLE statement in the SQL pane. However, a message displays telling you that the statement is not supported. To resolve the error, click **Continue** , and the query executes.
- **Queries with Semicolons**
  You use Visual Studio 2008, 2010, 2012, 2013, or 2015 and execute a SQL query in the SQL pane. If you include a semicolon (;) with your query, the query executes, but the result returned cannot be edited. To avoid this issue, enter the same query in the SQL pane without the semicolon.
- **Quoting Boolean Values**
  You use Visual Studio 2008, 2010, 2012, 2013, or 2015 to connect to the Vertica database and execute a SQL query in the SQL pane. When attempting to insert a value into a Boolean column without putting quotes around the value, subsequent execution of the SQL statement returns an error. To work around this issue, include quotes.

Uninstalling Client Drivers and Tools for Windows **Error**

There is a scenario where an uninstall of the Client Drivers and Tools for Windows package fails with a message that the .NET framework is required. What follows is the scenario that causes this issue.

1. You Install the Client Drivers and Tools for Windows.
2. You then install Visual Studio 2010 or 2012, which includes installation of the .NET framework 4.0 or 4.5.

3. You uninstall the .NET framework using the Windows Control Panel.
4. You then attempt to uninstall the Client Drivers and Tools for Windows. The uninstall fails with the message that .NET framework is required.

Perform the following to correct this issue:

1. Reinstall the .NET framework 4.0 or 4.5 manually, using the Windows Control Panel.
2. Uninstall the Client Drivers and Tools for Windows.

Installing the client drivers on Mac OS X

This section details how to install the client drivers on Mac OS X.

In this section

- Installing the JDBC driver on Mac OS X
- Installing the ODBC driver on Mac OS X

Installing the JDBC driver on Mac OS X

To install the Vertica JDBC driver on your Mac OS X client system, download the JDBC driver .jar file from the Vertica driver downloads page .

Ensuring Java can find the JDBC driver

In order for your Java client application to use the Vertica JDBC driver, the Java interpreter needs to be able to find its library file. Choose one of these methods to tell the Java interpreter where to look for the library:

- Copy the JDBC .jar file you downloaded to either the system-wide Java Extensions folder (/Library/Java/Extensions) or your user Java Extensions folder (/Users/ *username* /Library/Java/Extensions).
- Add the directory containing the JDBC .jar file to the CLASSPATH environment variable (see Modifying the Java CLASSPATH).
- Specify the directory containing the JDBC .jar using the -cp argument in the Java command line you use to start your Java command line.

Installing the ODBC driver on Mac OS X

You can download the Vertica ODBC driver for Mac OS X as a .pkg file from the Vertica driver downloads page . You can run the installer as a regular Mac OS X installer or silently .

The installer is designed to be used with the standard iODBC Driver Manager included in Mac OS X. While Mac OS X ships with the iODBC Driver Manager already installed, you may choose to download the most recent version of the driver at the iODBC.org website.

By default, the installer installs the driver in the following location: /Library/Vertica/ODBC/lib/libverticaodbc.dylib . The installer also automatically registers a driver named "Vertica" with the iODBC Driver Manager.

To use the unixODBC Driver Manager instead of Apple's iODBC Driver Manager, see the unixODBC.org website.

Before you download the driver

If you installed a previous version of the Vertica ODBC driver for Mac OS X, your system might already have a registered driver named "Vertica." In this case, you must remove or rename the older version of the driver before installing the Vertica ODBC driver .pkg file.

To have multiple versions of the driver installed on your system at the same time, you must rename the currently installed version of the driver to something other than "Vertica."

In this section

- Download the driver
- Install the Mac OS X ODBC driver
- Silently install the Mac OS X ODBC driver
- Uninstall the Mac OS X ODBC driver
- Upgrade or downgrade the Mac OS X ODBC driver
- ODBC driver settings on Mac OS X

Download the driver

Download the Macintosh OS X driver package from the Vertica driver downloads page .

Install the Mac OS X ODBC driver

As a Mac OS X Administrator, double-click the installer to start the installation. Follow the prompts as the wizard guides you through each step of the process.

> **Note**
> After installing the ODBC driver, you must create a DSN to be able to connect to your Vertica database. For the procedure, see Creating an ODBC DSN for Macintosh OS X clients .

Silently install the Mac OS X ODBC driver

1. Log into the client Mac in one of two ways:
   - As an administrator account, if you are installing the driver for system-wide use
   - As the user who needs to use the Vertica ODBC driver
2. Open a terminal window. In the Finder, click **Applications** > **Utilities** > **Terminal** .
3. Install the .pkg file containing the ODBC driver using the command:

   ```
   sudo installer -pkg ~/Downloads/vertica-odbc11.1.xpkg -target /
   ```

   In the preceding .pkg command, change the path to that of the downloaded file, *if* :
   - You downloaded the driver .pkg file to a directory other than your Downloads directory.
   - You downloaded the driver using another user account.

> **Note**
> After installing the ODBC driver, you must create a DSN to be able to connect to your Vertica database. For the procedure, see Creating an ODBC DSN for Macintosh OS X clients .

Uninstall the Mac OS X ODBC driver

Uninstalling the Mac OS X ODBC Client-Driver does not remove any existing DSNs associated with the driver.

To uninstall:

1. Open a terminal window.
2. Enter the command:

   ```
   sudo /Library/Vertica/ODBC/bin/Uninstall
   ```

Upgrade or downgrade the Mac OS X ODBC driver

All installations of the Vertica ODBC driver for Mac OS X are uniquely identified by a package ID and version number. The package ID does not change between versions, but the version number does. If you attempt multiple installations of the same version of the driver, a name collision error occurs. Therefore, multiple installations of the same version of the driver cannot coexist on a single operating system.

- **Upgrading** —Newly installed versions of the Vertica ODBC driver for Mac OS X automatically upgrade the relevant driver system settings. Any DSNs associated with a previous version of the driver are not affected, except that they begin using the newer version of the driver.
- **Downgrading** —Run the uninstall script to remove the current version of the Vertica ODBC driver for Mac OS X. Complete this step before installing an older driver version.

ODBC driver settings on Mac OS X

ODBC driver settings are automatically configured using the Vertica ODBC driver installer on Mac OS X. It is not necessary to configure additional ODBC driver settings on Mac OS X platforms beyond what is automatically configured by the installer. You can, however, set the ODBC driver settings by editing the VERTICAINI environment variable in each user's ~/.MacOSX/environment.plist file. See the Environment Variables entry in the Apple Developer's Library for more information.

See Additional parameter settings for a list of the additional settings.

Creating an ODBC data source name (DSN)

A Data Source Name (DSN) is the logical name that is used by Open Database Connectivity (ODBC) to refer to the driver and other information that is required to access data from a data source. Whether you are developing your own ODBC client code or you are using a third-party tool that needs to access Vertica using ODBC, you need to configure and test a DSN. The method you use depends upon the client operating system you are using.

Refer to the following sections for information specific to your client operating system.

In this section

- Creating an ODBC DSN for Linux
- Creating an ODBC DSN for windows clients
- Creating an ODBC DSN for Macintosh OS X clients
- Data source name (DSN) connection properties
- Setting DSN connection properties

Creating an ODBC DSN for Linux

You define DSN on Linux and other UNIX-like platforms in a text file. Your client's driver manager reads this file to determine how to connect to your Vertica database. The driver manager usually looks for the DSN definitions in two places:

- /etc/odbc.ini
- ~/.odbc.ini (a file named .odbc.ini in the user's home directory)

Users must be able to read the odbc.ini file in order to use it to connect to the database. If you use a global odbc.ini file, consider creating a UNIX group with read access to the file. Then, add the users who need to use the DSN to this group.

The structure of these files is the same—only their location differs. If both files are present, the ~/.odbc.ini file usually overrides the system-wide /etc/odbc.ini file.

> **Note**
> See your ODBC driver manager's documentation for details on where these files should be located and any other requirements.

odbc.ini file structure

The odbc.ini is a text file that contains two types of lines:

- Section definitions, which are text strings enclosed in square brackets.
- Parameter definitions, which contain a parameter name, an equals sign (=), and then the parameter's value.

> **Caution**
> The unixODBC driver manager supports parameter values of up to 1000 characters in odbc.ini . If your parameter value is greater than 1000 characters (for example, OAuthAccessToken), you must pass it through a connection string rather than specifying it in odbc.ini .

The first section of the file is always named [ODBC Data Sources], and contains a list of all the DSNs that the odbc.ini file defines. The parameters in this section are the names of the DSNs, which appear as section definitions later in the file. The value is a text description of the DSN and has no function. For example, an odbc.ini file that defines a single DSN named Vertica DSN could have this ODBC Data Sources section:

```
[ODBC Data Sources]
VerticaDSN = "vmartdb"
```

Appearing after the ODBC data sources section are sections that define each DSN. The name of a DSN section must match one of the names defined in the ODBC Data Sources section.

Configuring the odbc.ini file:

To create or edit the DSN definition file:

1. Using the text editor of your choice, open odbc.ini or ~/.odbc.ini .
2. Create an ODBC Data Sources section and define a parameter:
   - Whose name is the name of the DSN you want to create
   - Whose value is a description of the DSN

   For example, to create a DSN named VMart, you would enter:

   ```
   [ODBC Data Sources]
   VMart = "VMart database on Vertica"
   ```
3. Create a section whose name matches the DSN name you defined in step 2. In this section, you add parameters that define the DSN's settings. The most commonly-defined parameters are:

- **Description** – Additional information about the data source.
- **Driver** – The location and designation of the Vertica ODBC driver, or the name of a driver defined in the odbcinst.ini file (see below). For future compatibility, use the name of the symbolic link in the library directory, rather than the library file:
  - (/opt/vertica/lib , on 32-bit clients
  - /opt/vertica/lib64 , on 64-bit clients

  For example, the symbolic link for the 64-bit ODBC driver library is:

  ```
  /opt/vertica/lib64/libverticaodbc.so
  ```

  The symbolic link always points to the most up-to-date version of the Vertica client ODBC library. Use this link so that you do not need to update all of your DSNs when you update your client drivers.
- **Database** – The name of the database running on the server. This example uses vmartdb for the vmartdb.
- **ServerName** — The name of the server where Vertica is installed. Use localhost if Vertica is installed on the same machine.
  You can provide an IPv4 address, IPv6 address, or host name.
  In mixed IPv4/IPv6 networks, the DNS server configuration determines which IP version address is sent first. Use the PreferredAddressFamily option to force the connection to use either IPv4 or IPv6.
- **UID** — Either the database superuser (same name as database administrator account) or a user that the superuser has created and granted privileges. This example uses the user name dbadmin.
- **PWD** —The password for the specified user name. This example leaves the password field blank.
- **Port** — The port number on which Vertica listens for ODBC connections. For example, 5433.
- **ConnSettings** — Can contain SQL commands separated by a semicolon. These commands can be run immediately after connecting to the server.
- **SSLKeyFile** — The file path and name of the client's private key. This file can reside anywhere on the system.
- **SSLCertFile** —The file path and name of the client's public certificate. This file can reside anywhere on the system.
- **Locale** — The default locale used for the session. By default, the locale for the database is: en_US@collation=binary (English as in the United States of America). Specify the locale as an ICU Locale. See the ICU User Guide (http://userguide.icu-project.org/locale) for a complete list of parameters that can be used to specify a locale.
- **PreferredAddressFamily** :
  The IP version to use if the client and server have both IPv4 and IPv6 addresses and you have provided a host name, one of the following:
  - ipv4 : Connect to the server using IPv4.
  - ipv6 : Connect to the server using IPv6.
  - none : Use the IP address provided by the DNS server.

For example:

```
[VMart]
Description = Vmart Database
Driver = /opt/vertica/lib64/libverticaodbc.so
Database = vmartdb
Servername = host01
UID = dbadmin
PWD =
Port = 5433
ConnSettings =
AutoCommit = 0
SSLKeyFile = /home/dbadmin/client.key
SSLCertFile = /home/dbadmin/client.crt
Locale = en_US@collation=binary
```

See Data source name (DSN) connection properties for a complete list of parameters including Vertica-specific ones.

Using an odbcinst.ini file

Instead of giving the path of the ODBC driver library in your DSN definitions, you can use the name of a driver defined in the odbcinst.ini file. This method is useful method if you have many DSNs and often need to update them to point to new driver libraries. It also allows you to set some additional ODBC parameters, such as the threading model.

Just as in the odbc.ini file, odbcinst.ini has sections. Each section defines an ODBC driver that can be referenced in the odbc.ini files.

In a section, you can define the following parameters:

- **Description** — Additional information about the data source.
- **Driver** — The location and designation of the Vertica ODBC driver, such as /opt/vertica/lib64 /libverticaodbc.so

For example:

```
[Vertica]
Description = Vertica ODBC Driver
Driver = /opt/vertica/lib64/libverticaodbc.so
```

Then, in your odbc.ini file, use the name of the section you created in the odbcinst.ini file that describes the driver you want to use. For example:

```
[VMart]
Description = Vertica Vmart database
Driver = Vertica
```

If you are using the unixODBC driver manager, you should also add an ODBC section to override its standard threading settings. By default, unixODBC serializes all SQL calls through ODBC, which prevents multiple parallel loads. To change this default behavior, add the following to your odbcinst.ini file:

```
[ODBC]
Threading = 1
```

Configuring additional ODBC settings

On Linux and UNIX systems, you need to configure some additional driver settings before you can use your DSN. See Required ODBC driver configuration settings for Linux and UNIX for details.

In this section

- Testing an ODBC DSN using isql

Testing an ODBC DSN using isql

The unixODBC driver manager includes a utility named isql, which is a simple ODBC command-line client. It lets you to connect to a DSN to send commands and receive results, similarly to vsql.

To use isql to test a DSN connection:

1. Run the following command:
   ```
   $ isql –v DSNname
   ```
   Where *DSNname* is the name of the DSN you created.
   A connection message and a SQL prompt display. If they do not, you could have a configuration problem or you could be using the wrong user name or password.
2. Try a simple SQL statement. For example:
   ```
   SQL> SELECT table_name FROM tables;
   ```
   The isql tool returns the results of your SQL statement.

> **Note**
> If you have not set the ErrorMessagesPath in the additional driver configuration settings, any errors during testing will trigger a missing error message file ("The error message NoSQLGetPrivateProfileString could not be found in the en-US locale"). See Required ODBC driver configuration settings for Linux and UNIX for more information.

Creating an ODBC DSN for windows clients

To create a DSN for Microsoft Windows clients, you must perform the following tasks:

In this section

- Setting up an ODBC DSN
- Encrypting passwords on ODBC DSN
- Testing an ODBC DSN using Excel

Setting up an ODBC DSN

A *Data Source Name (DSN)* is the ODBC logical name for the drive and other information the database needs to access data. The name is used by Internet Information Services (IIS) for a connection to an ODBC data source.

This section describes how to use the Vertica ODBC Driver to set up an ODBC DSN. This topic assumes that the driver is already installed, as described in Installing Client Drivers on Windows .

To set up a DSN

1. Open the ODBC Administrator. For example, you could navigate to **Start > Control Panel > Administrative Tools > Data Sources (ODBC)** .

   > **Note**
   > The method you use to open the ODBC Administrator depends on your version of Windows. Differences between Windows versions and **Start Menu** customizations could require you to take a different action to open the ODBC Administrator.

2. Decide if you want all users on your client system to be able to access to the DSN for the Vertica database.
   - If you want all users to have access, then click the **System DSN** tab.
   - Otherwise, click the **User DSN** tab to create a DSN that is only usable by your Windows user account.
3. Click **Add** to create a new DSN to connect to the Vertica database.
4. Scroll through the list of drivers in the Create a New Data Source dialog box to locate the Vertica driver. Select the driver, and then click **Finish** .

   > **Note**
   > If you have installed more than one version of the Vertica client drivers on your Windows client system, you may see multiple versions of the driver in this list. Choose the version that you know is compatible with your client application and Vertica Analytic Database server. If you are unsure, use the latest version of the driver.

   The Vertica ODBC DSN configuration dialog box appears.
5. Click the **More >>>** button to view a description of the field you are editing and the connection string defined by the DSN.
6. Enter the information for your DSN. The following fields are required:
   - **DSN Name** — The name for the DSN. Clients use this name to identify the DSN to which they want to connect. The DSN name must satisfy the following requirements:
     - Its maximum length is 32 characters.
     - It is composed of ASCII characters except for the following: □ { } , ; ? * = ! @ \
     - It contains no spaces.
   - **Server** — The host name or IP address of the Vertica server to which you want to connect. Use localhost, if Vertica is installed on the same machine.
     You can provide an IPv4 address, IPv6 address, or host name.
     In mixed IPv4/IPv6 networks, the DNS server configuration determines which IP version address is sent first. Use the PreferredAddressFamily option to force the connection to use either IPv4 or IPv6.
     The PreferredAddressFamily option is available on the Client Settings tab.
   - **Backup Servers** — A comma-separated list of host names or IP addresses used to connect to if the server specified by the Server field is down. Optional.
   - **Database** —The name of the Vertica database.
   - **User Name** — The name of the user account to use when connecting to the database. If the application does not supply its own user name when connecting to the DSN, this account name is used to log into the database.

   The rest of the fields are optional. See DSN Parameters for detailed information about the DSN parameters you can define.
7. If you want to test your connection:
   1. Enter at least a valid **DSN name** , **Server name** , **Database** , and either **User name** or select **Windows authentication** .
   2. If you have not selected **Windows authentication** , you can enter a password in the **Password** box. Alternately, you can select **Password for missing password** to have the driver prompt you for a password when connecting.

      > **Caution**
      > Passwords entered into the **Password** box are saved, in plaintext, to the Windows registry.

   3. Click **Test Connection** .
8. When you have finished editing and testing the DSN, click **OK** . The Vertica ODBC DSN configuration window closes, and your new DSN is listed in the ODBC Data Source Administrator window.
9. Click **OK** to close the ODBC Data Source Administrator.

After creating the DSN, you can test it using Microsoft Excel 2007 .

Setting up a 32-Bit DSN on 64-Bit versions of Microsoft windows

On 64-bit versions of Windows, the default ODBC Data Source Administrator creates and edits DSNs that are associated with the 64-bit Vertica ODBC library.

Attempting to use these 64-bit DSNs with a 32-bit client application results in an architecture mismatch error. Instead, you must create a specific 32-bit DSN for 32-bit clients by running the 32-bit ODBC Administrator usually located at:

```
c:\Windows\SysWOW64\odbcad32.exe
```

This administrator window edits a set of DSNs that are associated with the 32-bit ODBC library. You can then use your 32-bit client applications with the DSNs you create with this version of the ODBC administrator.

Encrypting passwords on ODBC DSN

When you install an ODBC driver and create a Data Source Name (DSN) the DSN settings are stored in the registry, including the password. Encrypting passwords on ODBC DSN applies only to Windows systems.

Encrypting passwords on an ODBC data source name (DSN) provides security against unauthorized database access. The password is not encrypted by default and is stored in plain-text.

> **Note**
> ODBC DSN passwords that were created in Vertica ≤8.0.x are not encrypted when you upgrade to a higher version, regardless of encryption settings.

Enable password encryption

Use the EncryptPassword parameter to enable or disable password encryption for an ODBC DSN:

- EncryptPassword = true enables password encryption
- EncryptPassword = false (default) disables password encryption

Set EncryptPassword in the Windows registry - HKEY_LOCAL_MACHINE > Software > Vertica > ODBC > Driver EncryptPassword=<true/false> .

> **Note**
> For 32 bit driver running on 64 bit windows verify password encryption here:
>
> HKEY_LOCAL_MACHINE > Software > Wow6432Node > Vertica > ODBC >
>
> Driver > EncryptPassword=<true/false>

Encrypted passwords get updated in the following registry locations:

For a user DSN:

HKEY_CURRENT_USER-> Software -> ODBC -> ODBC.INI -> DSNNAME -> PWD

For a system DSN:

HKEY_LOCAL_MACHINE-> Software -> ODBC -> ODBC.INI -> DSNNAME -> PWD

Verify password encryption

Use Windows Registry editor to determine if password encryption is enabled based on the value of EncryptPassword. Depending on the type of DSN you installed, check the following:

For a user DSN: HKEY_CURRENT_USER > Software > ODBC > ODBC.INI > dsn name > isPasswordEncrypted=<1/0>

For a system DSN: HKEY_LOCAL_MACHINE > Software > ODBC > ODBC.INI > dsn name > isPasswordEncrypted=<1/0>

For each DSN, the value of the isPasswordEncrypted parameter indicates the status of the password encryption, where 1 indicates an encrypted password and 0 indicates an unencrypted password.

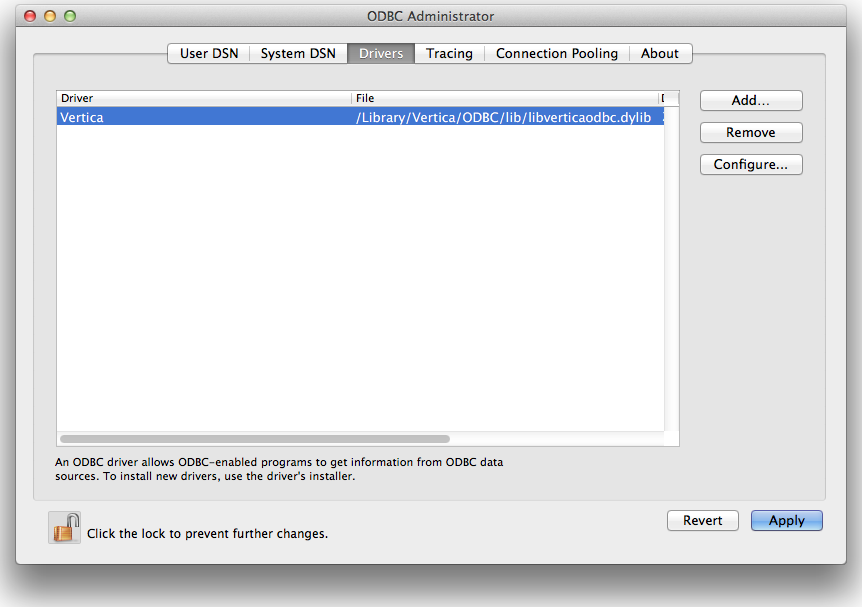
Testing an ODBC DSN using Excel

You can use Microsoft Excel to verify that an application can connect to an ODBC data source or other ODBC application.

1. Open Microsoft Excel, and select **Data > Get External Data > From Other Sources > From Microsoft Query** .
2. When the Choose Data Source dialog box opens:
   1. Select **New Data Source** , and click **OK** .
   2. Enter the name of the data source.
   3. Select the Vertica driver.
   4. Click **Connect** .
3. When the Vertica Connection Dialog box opens, enter the connection information for the DSN, and click **OK** .
4. Click **OK** on the Create New Data Source dialog box to return to the Choose Data Source dialog box.
5. Select **VMart_Schema** , and verify that the Use the Query Wizard check box is deselected. Click **OK** .
6. When the Add Tables dialog box opens, click **Close** .
7. When the Microsoft Query window opens, click the **SQL** button.
8. In the SQL window, write any simple query to test your connection. For example:

```
SELECT DISTINCT calendar_year FROM date_dimension;
```

> * If you see the caution, "SQL Query can't be represented graphically. Continue anyway?" click **OK**. * The data values 2003, 2004, 2005, 2006, 2007 indicate that you successfully connected to and ran a query through ODBC.



10. Select **File > Return Data to Microsoft Office Excel** .
11. In the Import Data dialog box, click **OK** .
    The data is now available for use in an Excel worksheet.

Creating an ODBC DSN for Macintosh OS X clients

You can use the Vertica ODBC Driver to set up an ODBC DSN. This procedure assumes that the driver is already installed, as described in Installing the ODBC Driver on Macintosh OS X .

Setting up a DSN

1. Using your web browser, download and install the Apple ODBC Administrator Tool .
2. Locate and open the ODBC Administrator Tool after installation:
   1. Navigate to **Finder** > **Applications** > **Utilities** .
   2. Open the ODBC Administrator Tool.
3. Click the **Drivers** tab, and verify that the Vertica driver is installed.

4. Specify if you want all users on your client system to be able to access the DSN for the Vertica database:
   - If you want all users to have access, then click the **System DSN** tab.
   - Otherwise, click the **User DSN** tab to create a DSN that is only usable by your Macintosh user account.
5. Click **Add...** to create a new DSN to connect to the Vertica database.
6. Scroll through the list of drivers in the Choose A Driver dialog box to locate the Vertica driver. Select the driver, and then click **OK** . A dialog box opens that requests DSN parameter information.

7. In the dialog box, enter the **Data Source Name (DSN)** and an optional **Description** . To do so, click **Add** to insert keywords (parameters) and values that define the settings needed to connect to your database, including database name, server host, database user name (such as dbadamin), database password, and port. Then, click **OK** .
8. In the ODBC Administrator dialog box, click **Apply** .
   See Data source name (DSN) connection properties for a complete list of parameters including those specific to Vertica.

After configuring the ODBC Administrator Tool, you may need to configure additional driver settings before you can use your DSN, depending on your environment. See Additional ODBC Driver Configuration Settings for details.

> **Note**
> If you want to test your connection, use the iodbctest utility. For the procedure, see Testing a DSN Using iodbctest .

In this section

- Testing an ODBC DSN using iodbctest

Testing an ODBC DSN using iodbctest

The standard iODBC Driver Manager on OS X includes a utility named iodbctest that lets you test a DSN to verify that it is correctly configured. You pass this command a connection string in the same format that you would use to open an ODBC database connection. After configuring your DSN connection, you can run a query to verify that the connection works.

For example:

```
# iodbctest "DSN=VerticaDSN;UID=dbadmin;PWD=password"
iODBC Demonstration program
This program shows an interactive SQL processor
Driver Manager: 03.52.0607.1008
Driver: 07.01.0200 (verticaodbcw.so)
SQL> SELECT table_name FROM tables;
table_name
-----------------------------------------------------------------------------------------------------------------------------
customer_dimension
product_dimension
promotion_dimension
date_dimension
vendor_dimension
employee_dimension
shipping_dimension
warehouse_dimension
inventory_fact
store_dimension
store_sales_fact
store_orders_fact
online_page_dimension
call_center_dimension
online_sales_fact
numbers
result set 1 returned 16 rows.
```

Data source name (DSN) connection properties

The following tables list the connection properties you can set in the DSNs for use with Vertica's ODBC driver.

Required connection properties

These connection properties are the minimum required to create a functioning DSN.

> **Note**
> If you use a host name (Servername) whose DNS entry resolves to multiple IP addresses, the client attempts to connect to the first IP address returned by the DNS. If a connection cannot be made to the first address, the client attempts to connect to the second, then the third, continuing

until it either connects successfully or runs out of addresses.

Property	Description
Driver	The file path and name of the driver used.
Database	The name of the database running on the server.
Servername	The host name or IP address of any active node in a Vertica cluster. You can provide an IPv4 address, IPv6 address, or host name. In mixed IPv4/IPv6 networks, the DNS server configuration determines which IP version address is sent first. Use the PreferredAddressFamily option to force the connection to use either IPv4 or IPv6. You can also use the aliases "server" and "host" for this property.
UID	The database username.

Optional properties

Property	Description
Port	The port number on which Vertica listens for ODBC connections. **Default:** 5433
PWD	The password for the specified user name. You may insert an empty string to leave this property blank. **Default:** None, login only succeeds if the user does not have a password set.
PreferredAddressFamily	The IP version to use if the client and server have both IPv4 and IPv6 addresses and you have provided a host name, one of the following: • ipv4 : Connect to the server using IPv4. • ipv6 : Connect to the server using IPv6. • none : Use the IP address provided by the DNS server. **Default:** none

Advanced settings

Property	Description
AutoCommit	A Boolean value that controls whether the driver automatically commits transactions after executing a DML statement. **Default:** true
BackupServerNode	A string containing the host name or IP address that client libraries can try to connect to if the host specified in ServerName is unreachable. Connection attempts continue until successful or until the list of server nodes is exhausted. **Valid values:** Comma-separated list of servers optionally followed by a colon and port number.

ConnectionLoadBalance	A Boolean value that indicates whether the connection can be redirected to a host in the database other than the ServerNode. This affects the connection only if the load balancing. is set to something other than "none". When the node differs from the node the client is connected to, the client disconnects and reconnects to the targeted node. See About Native Connection Load Balancing in the Administration Guide. **Default:** false
ConnSettings	A string containing SQL commands that the driver should execute immediately after connecting to the server. You can use this property to configure the connection, such as setting a schema search path. **Reserved symbol:** In the connection string semicolon (;) is a reserved symbol. To set multiple properties as part of ConnSettings properties, use %3B as the comma delimiter, and + (plus) for spaces.
ConvertSquareBracketIdentifiers	Controls whether square-bracket query identifiers are converted to a double quote identifier for compatibility when making queries to a Vertica database. **Default:** false
DirectBatchInsert	Deprecated, always set to true.
DriverStringConversions	Controls whether the ODBC driver performs type conversions on strings sent between the ODBC driver and the database. Possible values are: • NONE: No conversion in either direction. This results in the highest performance. • INPUT: Strings sent from the client to the server are converted, but strings sent from the server to the client are not. • OUTPUT: Strings sent by the server to the client are converted, but strings sent from the client to the server are not. • BOTH: Strings are converted in both directions. **Default:** OUTPUT
Locale	The locale used for the session. Specify the locale as an ICU Locale. **See **the ICU User Guide for a complete list of properties that can be used to specify a locale. **Default:** en_US@collation=binary
PromptOnNoPassword	[Windows only] Controls whether users are prompted to enter a password, if none is supplied by the connection string or DSN used to connect to Vertica. See Prompting Windows users for passwords . **Default:** false
ReadOnly	A true or false value that controls whether the connection can read data only from Vertica. **Default:** false
ResultBufferSize	Size of memory buffer for the large result sets in streaming mode. A value of 0 means ResultBufferSize is turned off. **Default:** 131072 (128KB)

TransactionIsolation	Sets the transaction isolation for the connection, one of the following: • Read Committed • Serializable • Server Default See Changing Transaction Isolation Levels for an explanation of transaction isolation. **Default:** Server Default

Identification

Property	Description	Standard/Vertica
Description	Description for the DSN entry. **Required?** No Insert an empty string to leave the description empty.	Standard
Label / SessionLabel	Sets a label for the connection on the server. This value appears in the client_label column of the V_MONITOR.SESSIONS system table. Label and SessionLabel are synonyms and can be used interchangeably.	Vertica

OAuth connection parameters

The following connection properties pertain to OAuth in ODBC.

> **Caution**
> The unixODBC driver manager supports parameter values of up to 1000 characters in odbc.ini . If your parameter value is greater than 1000 characters (for example, OAuthAccessToken), you must pass it through a connection string rather than specifying it in odbc.ini .

Property	Description
OAuthAccessToken	Required if OAuthRefreshToken is unspecified, an OAuth token that authorizes a user to the database.
OAuthRefreshToken	Required if OAuthAccessToken is unspecified, allows a user to refresh and obtain a new OAuthAccessToken when their old one expires. This property is part of a set; all of the following properties must be set to enable token refresh: • OAuthRefreshToken • OAuthDiscoveryUrl or OAuthTokenUrl • OAuthClientId • OAuthClientSecret In cases where introspection fails (e.g. when the access token expires), Vertica responds to the request with an error. If introspection fails and OAuthRefreshToken is specified, the driver attempts to refresh and silently retrieve a new access token. Otherwise, the driver passes error to the client application.

OAuthClientId	The client ID of the client application registered in the identity provider. This property is part of a set; all of the following properties must be set to enable token refresh: • OAuthRefreshToken • OAuthDiscoveryUrl or OAuthTokenUrl • OAuthClientId • OAuthClientSecret
OAuthClientSecret	The client secret of the client application registered in the identity provider. This property is part of a set; all of the following properties must be set to enable token refresh: • OAuthRefreshToken • OAuthDiscoveryUrl or OAuthTokenUrl • OAuthClientId • OAuthClientSecret
OAuthTokenUrl	The endpoint to which token refresh requests are sent. This property is part of a set; all of the following properties must be set to enable token refresh: • OAuthRefreshToken • OAuthDiscoveryUrl or OAuthTokenUrl • OAuthClientId • OAuthClientSecret **Examples:** • Keycloak • Okta
OAuthDiscoveryUrl	Also known as the OpenID Provider Configuration Document , this endpoint points to a JSON containing information about the configuration and endpoints of the identity provider. This parameter is only supported for Keycloak. For other identity providers like Okta, set the OAuthTokenUrl instead. If you specify this parameter, you do not have to set the OAuthTokenUrl. The driver automatically resolves the OAuthTokenUrl. If you specify both the OAuthDiscoveryUrl and OAuthTokenUrl, the OAuthDiscoveryUrl takes precedence.
OAuthScope	The requested OAuth scopes, delimited with spaces. These scopes define the extent of access to the resource server (in this case, Vertica) granted to the client by the access token. For details, see the OAuth documentation . For example, to request the scopes offline_access and openid : offline_access openid

Encryption

Property	Description	Standard/Vertica

SSLMode	Controls whether the connection to the database uses SSL encryption. Valid values follow. For descriptions of these values, refer to Configuring TLS for ODBC Clients . • require : Requires that the server use TLS. If the TLS connection attempt fails, the client rejects the connection. • prefer : Prefers that the server use TLS. The client first attempts to connect using TLS. If that attempt fails, the client attempts to connect again in plaintext. • allow : Makes a connection to the server whether the server uses TLS or not. The first connection attempt to the database is attempted over a clear channel. If that fails, a second connection is attempted over TLS. • verify_ca : The client verifies that the server's certificate was issued by a trusted certificate authority (CA). • verify_full : The client verifies that the following conditions are met: • The server's certificate was issued by a trusted CA. • One of the following: ◦ The server's hostname matches the common name specified in the server's certificate. ◦ The server's hostname or IP address appears in the Subject Alternative Name (SAN) field of the server's certificate. • disable : Never connect to the server using TLS. This setting is typically used for troubleshooting. **Default:** prefer	Vertica
SSLCertFile	The absolute path of the client's public certificate file. This file can reside anywhere on the system.	Vertica
SSLKeyFile	The absolute path to the client's private key file. This file can reside anywhere on the system.	Vertica

Third-party compatibility

Property	Description	Default	Standard/Vertica
ColumnsAsChar	Specifies how character column types are reported when the driver is in Unicode mode. When set to false, the ODBC driver reports the data type of character columns as WCHAR. If you set ColumnsAsChar to true, the driver identifies character column as CHAR. You typically use this setting for compatibility with some third-party clients. **Default:** false	false	Vertica
ThreePartNaming	A Boolean value that controls how catalog names are interpreted by the driver. When this value is false, the driver reports that catalog names are not supported. When catalog names are not supported, they cannot be used as a filter in database metadata API calls. In this case, the driver returns NULL as the catalog name in all driver metadata results. When this value is true, catalog names can be used as a filter in database metadata API calls. In this case, the driver returns the database name as the catalog name in metadata results. Some third-party applications assume a certain catalog behavior and do not work properly with the default values. Enable this option if your client software expects to get the catalog name from the database metadata and use it as part of a three-part name reference. **Default:** false for UNIX, true for Windows	false (UNIX) true (Window)	Vertica

EnforceBatchInsertNullConstraints	Prevents NULL values from being loaded into columns with a NOT NULL constraint during batch inserts. When this value is set to true, batch inserts roll back when NULL values are inserted in to columns with NOT NULL constraints. When this value is set to false, batch insert behavior is unchanged. Vertica recommends only using this property with SAP Data Services as it could negatively impact database performance.	false	Vertica

Kerberos connection properties

Use the following properties for client authentication using Kerberos.

Property	Description	Standard/Vertica
KerberosServiceName	Provides the service name portion of the Vertica Kerberos principal; for example: vertica/host@EXAMPLE.COM **Default:** vertica	Vertica
KerberosHostname	Provides the instance or host name portion of the Vertica Kerberos principal; for example: vertica/host@EXAMPLE.COM **Default:** Value specified in the servername connection string property	Vertica

Required ODBC driver configuration settings for Linux and UNIX

Setting DSN connection properties

The properties in the following tables are common for all user and system DSN entries. The examples provided are for Windows clients.

To edit DSN properties:

- On UNIX and Linux client platforms, you can edit the odbc.ini file. The location of this file is specific to the driver manager. See Creating an ODBC DSN for Linux .
- On Windows client platforms, you can edit some DSN properties using the Vertica ODBC client driver interface. See Creating an ODBC DSN for windows clients .
- You can also edit the DSN properties directly by opening the DSN entry in the Windows registry (for example, at HKEY_LOCAL_MACHINE\SOFTWARE\ODBC\ODBC.INI\ *DSNname*). Directly editing the registry can be risky, so you should only use this method for properties that cannot be set through the ODBC driver's user interface, or via your client code.
- You can set properties in the connection string when opening a connection using the SQLDriverConnect() function:

```
sqlRet = SQLDriverConnect(sql_hDBC, 0, (SQLCHAR*)"DSN=DSNName;Locale=en_GB@collation=binary", SQL_NTS, szDNS, 1024,&nSize, SQL_DRIVER_NOPROMPT);
```

> **Note**
> In the connection string ';' is a reserved symbol. If you need to set multiple properties as part of the ConnSettings property use '%3B' in place of ';'. Also use '+' instead of spaces.
>
> For example:
>
> ```
> sqlRet = SQLDriverConnect(sql_hDBC, 0, (SQLCHAR*)"DSN=Vertica
> SQL;ConnSettings=set+search_path+to+a,b,c%3Bset+locale=ch;SSLMode=prefer", SQL_NTS,
> szDNS, 1024,&nSize, SQL_DRIVER_NOPROMPT);
> ```

- Your client code can retrieve DSN property values after a connection has been made to Vertica using the SQLGetConnectAttr() and SQLGetStmtAttr() API calls. Some properties can be set and using SQLSetConnectAttr() and SQLSetStmtAttr() .
  For details of the list of properties specific to Vertica see ODBC Header Files specific to Vertica .

Programming ODBC client applications

Vertica provides an Open Database Connectivity (ODBC) driver that allows applications to connect to the Vertica database. This driver can be used by custom-written client applications that use the ODBC API to interact with Vertica. ODBC is also used by many third-party applications to connect to Vertica, including business intelligence applications and extract, transform, and load (ETL) applications.

This section details the process for configuring the Vertica ODBC driver. It also explains how to use the ODBC API to connect to Vertica in your own client applications.

This section assumes that you have already installed the ODBC libraries on your client system. If you have not, see Client drivers .

In this section

- ODBC architecture
- ODBC feature support
- Vertica and ODBC data type translation
- ODBC header file specific to Vertica
- Connecting to the database
- Load balancing in ODBC
- Configuring TLS for ODBC Clients
- ODBC connection failover
- Prompting windows users for missing connection properties
- Prompting Windows users for passwords
- Setting the locale and encoding for ODBC sessions
- AUTOCOMMIT and ODBC transactions
- Retrieving data through ODBC
- Loading data through ODBC

ODBC architecture

The ODBC architecture has four layers:

- **Client Application**
  Is an application that opens a data source through a Data Source Name (DSN). It then sends requests to the data source, and receives the results of those requests. Requests are made in the form of calls to ODBC functions.
- **Driver Manager**
  Is a library on the client system that acts as an intermediary between a client application and one or more drivers. The driver manager:
  - Resolves the DSN provided by the client application.
  - Loads the driver required to access the specific database defined within the DSN.
  - Processes ODBC function calls from the client or passing them to the driver.
  - Retrieves results from the driver.
  - Unloads drivers when they are no longer needed.

  On Windows and Mac client systems, the driver manager is provided by the operating system. On Linux and UNIX systems, you usually need to install a driver manager. See ODBC prerequisites for a list of driver managers that can be used with Vertica on your client platform.
- **Driver**
  A library on the client system that provides access to a specific database. It translates requests into the format expected by the database, and translates results back into the format required by the client application.
- **Database**
  The database processes requests initiated at the client application and returns results.

ODBC feature support

The ODBC driver for Vertica supports the most of the features defined in the Microsoft ODBC 3.5 specifications. The following features are *not* supported:

- Updatable result sets
- Backwards scrolling cursors
- Cursor attributes
- More than one open statement per connection. Simultaneously executing statements must each belong to a different connection. For example, you cannot execute a new statement while another statement has a result set open. To execute another statement with the same connection/session, wait for the current statement to finish executing and close its result set, then execute the new statement.
- Keysets
- Bookmarks

The Vertica ODBC driver accurately reports its capabilities. If you need to determine whether it complies with a specific feature, you should query the driver's capabilities directly using the SQLGetInfo() function.

Vertica and ODBC data type translation

Most data types are transparently converted between Vertica and ODBC. This section explains several data types require special handling.

Vertica Data Types	C Data Type	ODBC C Typedef	C Type Identifier
BINARY , VARBINARY	char[]	SQL_BINARY	SQL_C_BINARY
LONG VARBINARY	char[]	SQL_LONGVARBINARY	SQL_C_BINARY
BOOLEAN	SQLSMALLINT	SQL_SMALLINT	SQL_C_SSHORT
CHAR , VARCHAR	char[]	SQL_CHAR	SQL_C_CHAR
LONG VARCHAR	char[]	SQL_LONGVARCHAR	SQL_C_CHAR
DATE	SQL_DATE_STRUCT	SQL_TYPE_DATE	SQL_C_TYPE_DATE
TIME	SQL_TIME_STRUCT	SQL_TYPE_TIME	SQL_C_TYPE_TIME
TIMESTAMP	SQL_TIMESTAMP_STRUCT	SQL_TYPE_TIMESTAMP	SQL_C_TYPE_TIMESTAMP
INTERVAL	SQL_INTERVAL_STRUCT	SQL_INTERVAL_DAY_TO_SECOND	SQL_C_INTERVAL_DAY_TO_SECOND
INTERVAL DAY TO SECOND	SQL_INTERVAL_STRUCT	SQL_INTERVAL_DAY_TO_SECOND	SQL_C_INTERVAL_DAY_TO_SECOND
INTERVAL YEAR TO MONTH	SQL_INTERVAL_STRUCT	SQL_INTERVAL_YEAR_TO_MONTH	SQL_C_INTERVAL_YEAR_TO_MONTH
DOUBLE PRECISION FLOAT	SQLREAL	SQL_REAL	SQL_C_FLOAT
INTEGER , BIGINT , SMALLINT	SQLBIGINT	SQL_BIGINT	SQL_C_SBIGINT
NUMERIC , DECIMAL , NUMBER , MONEY	SQL_NUMERIC_STRUCT	SQL_NUMERIC	SQL_C_NUMERIC
GEOMETRY	char[]	SQL_LONGVARBINARY	SQL_C_CHAR
GEOGRAPHY	char[]	SQL_LONGVARBINARY	SQL_C_CHAR
UUID	SQLGUID (see note below)	SQL_GUID	SQL_C_GUID

Notes

- The GEOMETRY and GEOGRAPHY data types are treated as LONG VARCHAR data by the ODBC driver.
- Vertica supports the standard interval data types supported by ODBC. See Interval Data Types in Microsoft's ODBC reference.
- Vertica version 9.0.0 introduced the UUID data type, including JDBC support for UUIDs. The Vertica ADO.NET, ODBC, and OLE DB clients added full support for UUIDs in version 9.0.1. Vertica maintains backwards compatibility with older supported client driver versions that do not support the UUID data type, as follows:

When an older client...	Vertica...
Queries tables with UUID columns	Translates the native UUID values to CHAR values.
Inserts data into a UUID column	Converts the CHAR value sent by the client into a native UUID value.
Queries a UUID column's metadata	Reports its data type as CHAR.

ODBC header file specific to Vertica

The Vertica ODBC driver provides a C header file named verticaodbc.h that defines several useful constants that you can use in your applications. These constants let you access and alter settings specific to Vertica.

This file's location depends on your client operating system:

- /opt/vertica/include on Linux and UNIX systems.
- C:\Program Files (x86)\Vertica\ODBC\include on Windows systems.

The constants defined in this file are listed below.

Parameter	Description
SQL_ATTR_VERTICA_RESULT_BUFFER_SIZE	Sets the size of the buffer used when retrieving results from the server. **Associated functions** : SQLSetConnectAttr() SQLGetConnectAttr()
SQL_ATTR_VERTICA_DIRECT_BATCH_INSERT	Deprecated, always set to 1. **Associated functions:** SQLSetConnectAttr() SQLSetStmtAttr() SQLGetConnectAttr() SQLGetStmtAttr()
SQL_ATTR_VERTICA_LOCALE	Changes the locale from en_US@collation=binary to the ICU locale specified. See Setting the locale and encoding for ODBC sessions for an example of using this parameter. **Associated functions** : SQLSetConnectAttr() SQLGetConnectAttr()

Connecting to the database

The first step in any ODBC application is to connect to the database. When you create the connection to a data source using ODBC, you use the name of the DSN that contains the details of the driver to use, the database host, and other basic information about connecting to the data source.

There are 4 steps your application needs to take to connect to a database:

1. Call SQLAllocHandle() to allocate a handle for the ODBC environment. This handle is used to create connection objects and to set application-wide settings.
2. Use the environment handle to set the version of ODBC that your application wants to use. This ensures that the data source knows which API your application will use to interact with it.
3. Allocate a database connection handle by calling SQLAllocHandle() . This handle represents a connection to a specific data source.
4. Use the SQLConnect() or SQLDriverConnect() functions to open the connection to the database.

> **Note**
> If you specify a locale either in the connection string or in the DSN, the call to the connection function returns SQL_SUCCESS_WITH_INFO on a successful connection, with messages about the state of the locale.

When creating the connection to the database, use SQLConnect() when the only options you need to set at connection time is the username and password. Use SQLDriverConnect() when you want to change connection options, such as the locale.

The following example demonstrates connecting to a database using a DSN named ExampleDB. After it creates the connection successfully, this example simply closes it.

```
// Demonstrate connecting to Vertica using ODBC.
// Standard i/o library
#include <stdio.h>
#include <stdlib.h>
// Only needed for Windows clients
// #include <windows.h>
// SQL include files that define data types and ODBC API
// functions
#include <sql.h>
#include <sqlext.h>
#include <sqltypes.h>
int main()
{
   SQLRETURN ret;  // Stores return value from ODBC API calls
   SQLHENV hdlEnv;  // Handle for the SQL environment object
   // Allocate an a SQL environment object
   ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hdlEnv);
   if(!SQL_SUCCEEDED(ret)) {
      printf("Could not allocate a handle.\n");
      exit(EXIT_FAILURE);
   } else {
      printf("Allocated an environment handle.\n");
   }

   // Set the ODBC version we are going to use to
   // 3.
   ret = SQLSetEnvAttr(hdlEnv, SQL_ATTR_ODBC_VERSION,
         (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_UINTEGER);
   if(!SQL_SUCCEEDED(ret)) {
      printf("Could not set application version to ODBC 3.\n");
      exit(EXIT_FAILURE);
   } else {
      printf("Set application version to ODBC 3.\n");
   }
   // Allocate a database handle.
   SQLHDBC hdlDbc;
    ret = SQLAllocHandle(SQL_HANDLE_DBC, hdlEnv, &hdlDbc);
    if(!SQL_SUCCEEDED(ret)) {
       printf("Could not allocate database handle.\n");
       exit(EXIT_FAILURE);
    } else {
       printf("Allocated Database handle.\n");
    }
   // Connect to the database using
   // SQL Connect
   printf("Connecting to database.\n");
   const char *dsnName = "ExampleDB";
   const char* userID = "ExampleUser";
   const char* passwd = "password123";
   ret = SQLConnect(hdlDbc, (SQLCHAR*)dsnName,
      SQL_NTS,(SQLCHAR*)userID,SQL_NTS,
      (SQLCHAR*)passwd, SQL_NTS);
   if(!SQL_SUCCEEDED(ret)) {
```

```
    printf("Could not connect to database.\n");
    exit(EXIT_FAILURE);
} else {
    printf("Connected to database.\n");
}
// We're connected. You can do real
// work here

// When done, free all of the handles to close them
// in an orderly fashion.
printf("Disconnecting and freeing handles.\n");
ret = SQLDisconnect( hdlDbc );
if(!SQL_SUCCEEDED(ret)) {
    printf("Error disconnecting from database. Transaction still open?\n");
    exit(EXIT_FAILURE);
}

SQLFreeHandle(SQL_HANDLE_DBC, hdlDbc);
SQLFreeHandle(SQL_HANDLE_ENV, hdlEnv);
exit(EXIT_SUCCESS);
```

Running the above code prints the following:

```
Allocated an environment handle.
Set application version to ODBC 3.
Allocated Database handle.
Connecting to database.
Connected to database.
Disconnecting and freeing handles.
```

See Setting the locale and encoding for ODBC sessions for an example of using SQLDriverConnect to connect to the database.

Notes

- If you use the DataDirect ® driver manager, you should always use the SQL_DRIVER_NOPROMPT value for the SQLDriverConnect function's DriverCompletion parameter (the final parameter in the function call) when connecting to Vertica. Vertica's ODBC driver on Linux and UNIX platforms does not contain a UI, and therefore cannot prompt users for a password.
- On Windows client platforms, the ODBC driver can prompt users for connection information. See Prompting windows users for missing connection properties for more information.
- If your database does not comply with your Vertica license agreement, your application receives a warning message in the return value of the SQLConnect() function. Always have your application examine this return value to see if it is SQL_SUCCESS_WITH_INFO. If it is, have your application extract and display the message to the user.

Load balancing in ODBC

Native connection load balancing

Native connection load balancing helps spread the overhead caused by client connections on the hosts in the Vertica database. Both the server and the client must enable native connection load balancing. If enabled by both, then when the client initially connects to a host in the database, the host picks a host to handle the client connection from a list of the currently up hosts in the database, and informs the client which host it has chosen.

If the initially-contacted host does not choose itself to handle the connection, the client disconnects, then opens a second connection to the host selected by the first host. The connection process to this second host proceeds as usual—if SSL is enabled, then SSL negotiations begin, otherwise the client begins the authentication process. See About native connection load balancing for details.

To enable native load balancing on your client, set the ConnectionLoadBalance connection parameter to true either in the DSN entry or in the connection string. The following example demonstrates connecting to the database several times with native connection load balancing enabled, and fetching the name of the node handling the connection from the V_MONITOR. CURRENT_SESSION system table.

```
// Demonstrate enabling native load connection balancing.
// Standard i/o library
#include <stdlib.h>
#include <iostream>
#include <assert.h>
// Only needed for Windows clients
```

```
// Only needed for Windows clients
// #include <windows.h>
// SQL include files that define data types and ODBC API
// functions
#include <sql.h>
#include <sqlext.h>
#include <sqltypes.h>

using namespace std;
int main()
{
   SQLRETURN ret;   // Stores return value from ODBC API calls
   SQLHENV hdlEnv;  // Handle for the SQL environment object
   // Allocate an a SQL environment object
   ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hdlEnv);
   assert(SQL_SUCCEEDED(ret));

   // Set the ODBC version we are going to use to
   // 3.
   ret = SQLSetEnvAttr(hdlEnv, SQL_ATTR_ODBC_VERSION,
         (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_UINTEGER);
   assert(SQL_SUCCEEDED(ret));

   // Allocate a database handle.
   SQLHDBC hdlDbc;
   ret = SQLAllocHandle(SQL_HANDLE_DBC, hdlEnv, &hdlDbc);
   assert(SQL_SUCCEEDED(ret));

   // Connect four times. If load balancing is on, client should
   // connect to different nodes.
   for (int x=1; x <= 4; x++) {

      // Connect to the database using SQLDriverConnect. Set
      // ConnectionLoadBalance to 1 (true) to enable load
      // balancing.
      cout << endl << "Connection attempt #" << x << "... ";
      const char *connStr = "DSN=VMart;ConnectionLoadBalance=1;"
         "UID=ExampleUser;PWD=password123";

      ret = SQLDriverConnect(hdlDbc, NULL, (SQLCHAR*)connStr, SQL_NTS,
            NULL, 0, NULL, SQL_DRIVER_NOPROMPT );
      if(!SQL_SUCCEEDED(ret)) {
         cout << "failed. Exiting." << endl;
         exit(EXIT_FAILURE);
      } else {
         cout << "succeeded" << endl;
      }
      // We're connected. Query the v_monitor.current_session table to
      // find the name of the node we've connected to.

      // Set up a statement handle
      SQLHSTMT hdlStmt;
      SQLAllocHandle(SQL_HANDLE_STMT, hdlDbc, &hdlStmt);
      assert(SQL_SUCCEEDED(ret));

      ret = SQLExecDirect( hdlStmt, (SQLCHAR*)"SELECT node_name FROM "
         "V_MONITOR.CURRENT_SESSION;", SQL_NTS );

      if(SQL_SUCCEEDED(ret)) {
         // Bind varible to column in result set.
         SQLTCHAR node_name[256];
```

```
    SQLGetData(hdlStmt, 1, SQL_C_TCHAR, node_name, sizeof(node_name), NULL);
    ret = SQLBindCol(hdlStmt, 1, SQL_C_TCHAR, (SQLPOINTER)node_name,
        sizeof(node_name), NULL);
    while(SQL_SUCCEEDED(ret = SQLFetchScroll(hdlStmt, SQL_FETCH_NEXT,1))) {
        // Print the bound variables, which now contain the values from the
        // fetched row.
        cout << "Connected to node " << node_name << endl;
    }
  }
  // Free statement handle
  SQLFreeHandle(SQL_HANDLE_STMT,hdlStmt);
  cout << "Disconnecting." << endl;
  ret = SQLDisconnect( hdlDbc );
  assert(SQL_SUCCEEDED(ret));
}
// When done, free all of the handles to close them
// in an orderly fashion.
cout << endl << "Freeing handles..." << endl;
SQLFreeHandle(SQL_HANDLE_DBC, hdlDbc);
SQLFreeHandle(SQL_HANDLE_ENV, hdlEnv);
cout << "Done!" << endl;
exit(EXIT_SUCCESS);
```

Running the above example produces output similar to the following:

```
Connection attempt #1... succeeded
Connected to node v_vmart_node0001
Disconnecting.

Connection attempt #2... succeeded
Connected to node v_vmart_node0002
Disconnecting.

Connection attempt #3... succeeded
Connected to node v_vmart_node0003
Disconnecting.

Connection attempt #4... succeeded
Connected to node v_vmart_node0001
Disconnecting.

Freeing handles...
Done!
```

Hostname-based load balancing

You can also balance workloads by resolving a single hostname to multiple IP addresses. The ODBC client driver load balances by automatically resolving the hostname to one of the specified IP addresses at random.

For example, suppose the hostname verticahost.example.com has the following entries in etc/hosts :

```
192.0.2.0 verticahost.example.com
192.0.2.1 verticahost.example.com
192.0.2.2 verticahost.example.com
```

Specifying the hostname verticahost.example.com randomly resolves to one of the listed IP addresses.

Configuring TLS for ODBC Clients

You can configure TLS for ODBC clients by setting the DSN connection properties for the following. For details on these parameters, see Data source name (DSN) connection properties :

- SSLMode: Determines whether TLS is required and how the client should behave if the TLS connection attempt fails.

- SSLCertFile (SSL CA file in Windows): The absolute path of the client's public certificate file.
- SSLKeyFile (SSL cert file in Windows): The absolute path to the client's private key file.

SSLModes: Verify_ca and verify_full

You can use the SSLMode property values verify_ca and verify_full if you want the client to verify the server's information before establishing the connection. If any of these verifications fail, the connection fails:

- verify_ca : The client verifies that the server's certificate is from a trusted certificate authority (CA).
- verify_full : The client verifies both that the server's certificate is from a trusted CA and that the server's hostname matches the hostname on the certificate.

If verify_ca or verify_full are specified, the client requires the following to establish the connection:

- The root.crt , which is the certificate of a CA trusted by both the server and the client.
- The server must have:
  - server.crt , a certificate signed by the trusted CA.
  - server.key , the server's private key.
- For verify_full , each server node must meet one of the following requirements:
  - Its hostname matches the common name specified in server.crt .
  - Its hostname or IP address appears in the Subject Alternative Name (SAN) field of server.crt .

TLS behavior flowchart

The following diagram shows an example flowchart for a client connecting with TLS.

In this example:

- If SSLMode is set to none or allow , the client connects without authentication.
- If SSLMode is set to verify_ca or verify_full and the client does not have root.crt , the connection fails.
- At the SSL authentication node, if the SSLMode connection is set to verify_full and the server hostname differs from the hostname specified by the client, authentication fails.

ODBC connection failover

If a client application attempts to connect to a host in the Vertica cluster that is down, the connection attempt fails when using the default connection configuration. This failure usually returns an error to the user. The user must either wait until the host recovers and retry the connection or manually edit the connection settings to choose another host.

Due to Vertica Analytic Database's distributed architecture, you usually do not care which database host handles a client application's connection. You can use the client driver's connection failover feature to prevent the user from getting connection errors when the host specified in the connection settings is unreachable. The JDBC driver gives you several ways to let the client driver automatically attempt to connect to a different host if the one specified in the connection parameters is unreachable:

- Configure your DNS server to return multiple IP addresses for a host name. When you use this host name in the connection settings, the client attempts to connect to the first IP address from the DNS lookup. If the host at that IP address is unreachable, the client tries to connect to the second IP, and so on until it either manages to connect to a host or it runs out of IP addresses.
- Supply a list of backup hosts for the client driver to try if the primary host you specify in the connection parameters is unreachable.
- (JDBC only) Use driver-specific connection properties to manage timeouts before attempting to connect to the next node.

For all methods, the process of failover is transparent to the client application (other than specifying the list of backup hosts, if you choose to use the list method of failover). If the primary host is unreachable, the client driver automatically tries to connect to other hosts.

Failover only applies to the initial establishment of the client connection. If the connection breaks, the driver does not automatically try to reconnect to another host in the database.

Choosing a failover method

You usually choose to use one of the two failover methods. However, they do work together. If your DNS server returns multiple IP addresses and you supply a list of backup hosts, the client first tries all of the IPs returned by the DNS server, then the hosts in the backup list.

> **Note**
> If a host name in the backup host list resolves to multiple IP addresses, the client does not try all of them. It just tries the first IP address in the list.

The DNS method of failover centralizes the configuration client failover. As you add new nodes to your Vertica Analytic Database cluster, you can choose to add them to the failover list by editing the DNS server settings. All client systems that use the DNS server to connect to Vertica Analytic Database automatically use connection failover without having to change any settings. However, this method does require administrative access to the DNS server that all clients use to connect to the Vertica Analytic Database cluster. This may not be possible in your organization.

Using the backup server list is easier than editing the DNS server settings. However, it decentralizes the failover feature. You may need to update the application settings on each client system if you make changes to your Vertica Analytic Database cluster.

Using DNS failover

To use DNS failover, you need to change your DNS server's settings to map a single host name to multiple IP addresses of hosts in your Vertica Analytic Database cluster. You then have all client applications use this host name to connect to Vertica Analytic Database.

You can choose to have your DNS server return as many IP addresses for the host name as you want. In smaller clusters, you may choose to have it return the IP addresses of all of the hosts in your cluster. However, for larger clusters, you should consider choosing a subset of the hosts to return. Otherwise there can be a long delay as the client driver tries unsuccessfully to connect to each host in a database that is down.

Using the backup host list

To enable backup list-based connection failover, your client application has to specify at least one IP address or host name of a host in the BackupServerNode parameter. The host name or IP can optionally be followed by a colon and a port number. If not supplied, the driver defaults to the standard Vertica port number (5433). To list multiple hosts, separate them by a comma.

The following example demonstrates setting the BackupServerNode connection parameter to specify additional hosts for the connection attempt. The connection string intentionally has a non-existent node, so that the initial connection fails. The client driver has to resort to trying the backup hosts to establish a connection to Vertica.

```
// Demonstrate using connection failover.
// Standard i/o library
#include <stdlib.h>
#include <iostream>
#include <assert.h>

// Only needed for Windows clients
// #include <windows.hgt;

// SQL include files that define data types and ODBC API
// functions
#include <sql.h>
#include <sqlext.h>
#include <sqltypes.h>

using namespace std;

int main()
{
   SQLRETURN ret;  // Stores return value from ODBC API calls
   SQLHENV hdlEnv;  // Handle for the SQL environment object
   // Allocate an a SQL environment object
   ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hdlEnv);
   assert(SQL_SUCCEEDED(ret));

   // Set the ODBC version we are going to use to
   // 3.
   ret = SQLSetEnvAttr(hdlEnv, SQL_ATTR_ODBC_VERSION,
         (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_UINTEGER);
   assert(SQL_SUCCEEDED(ret));

   // Allocate a database handle.
   SQLHDBC hdlDbc;
   ret = SQLAllocHandle(SQL_HANDLE_DBC, hdlEnv, &hdlDbc);
   assert(SQL_SUCCEEDED(ret));
```

```
/* DSN for this connection specifies a bad node, and good backup nodes:
[VMartBadNode]
Description=VMart Vertica Database
Driver=/opt/vertica/lib64/libverticaodbc.so
Database=VMart
Servername=badnode.example.com
BackupServerNode=v_vmart_node0002.example.com,v_vmart_node0003.example.com
*/

   // Connect to the database using SQLConnect
   cout << "Connecting to database." << endl;
   const char *dsnName = "VMartBadNode"; // Name of the DSN
   const char* userID = "ExampleUser"; // Username
   const char* passwd = "password123"; // password
   ret = SQLConnect(hdlDbc, (SQLCHAR*)dsnName,
      SQL_NTS,(SQLCHAR*)userID,SQL_NTS,
      (SQLCHAR*)passwd, SQL_NTS);
   if(!SQL_SUCCEEDED(ret)) {
      cout << "Could not connect to database." << endl;
      exit(EXIT_FAILURE);
   } else {
      cout << "Connected to database." << endl;
   }
   // We're connected. Query the v_monitor.current_session table to
   // find the name of the node we've connected to.

   // Set up a statement handle
   SQLHSTMT hdlStmt;
   SQLAllocHandle(SQL_HANDLE_STMT, hdlDbc, &hdlStmt);
   assert(SQL_SUCCEEDED(ret));

   ret = SQLExecDirect( hdlStmt, (SQLCHAR*)"SELECT node_name FROM "
      "v_monitor.current_session;", SQL_NTS );

   if(SQL_SUCCEEDED(ret)) {
      // Bind varible to column in result set.
      SQLTCHAR node_name[256];
      ret = SQLBindCol(hdlStmt, 1, SQL_C_TCHAR, (SQLPOINTER)node_name,
         sizeof(node_name), NULL);
      while(SQL_SUCCEEDED(ret = SQLFetchScroll(hdlStmt, SQL_FETCH_NEXT,1))) {
         // Print the bound variables, which now contain the values from the
         // fetched row.
         cout << "Connected to node " << node_name << endl;
      }
   }

   cout << "Disconnecting." << endl;
   ret = SQLDisconnect( hdlDbc );
   assert(SQL_SUCCEEDED(ret));

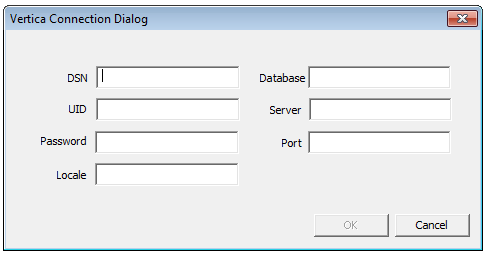
   // When done, free all of the handles to close them
   // in an orderly fashion.
   cout << endl << "Freeing handles..." << endl;
   SQLFreeHandle(SQL_HANDLE_STMT,hdlStmt);
   SQLFreeHandle(SQL_HANDLE_DBC, hdlDbc);
   SQLFreeHandle(SQL_HANDLE_ENV, hdlEnv);
   cout << "Done!" << endl;
   exit(EXIT_SUCCESS);
```

When run, the example's output on the system console is similar to the following:

```
Connecting to database.
Connected to database.
Connected to node v_vmart_node0002
Disconnecting.

Freeing handles...
Done!
```

Notice that the connection was made to the first node in the backup list (node 2).



> **Note**
> When native connection load balancing is enabled, the additional servers specified in the BackupServerNode connection parameter are only used for the initial connection to a Vertica host. If host redirects the client to another host in the database cluster to handle its connection request, the second connection does not use the backup node list. This is rarely an issue, since native connection load balancing is aware of which nodes are currently up in the database. See Load balancing in ODBC for more information.

Prompting windows users for missing connection properties

The Vertica Windows ODBC driver can prompt the user for connection information if required information is missing. The driver displays the Vertica Connection Dialog if the client application calls SQLDriverConnect to connect to Vertica and either of the following is true:

- the DriverCompletion property is set to SQL_DRIVER_PROMPT.
- the DriverCompletion property is set to SQL_DRIVER_COMPLETE or SQL_DRIVER_COMPLETE_REQUIRED and the connection string or DSN being used to connect is missing the server, database, or port information.

If either of the above conditions are true, the driver displays a Vertica Connection Dialog to the user to prompt for connection information.

The dialog has all of the property values supplied in the connection string or DSN filled in.

> **Note**
> Your connection string at least needs to specify Vertica as the driver, otherwise Windows will not know to use the Vertica ODBC driver to try to open the connection.

The required fields on the connection dialog are Database, UID, Server, and Port. Once these are filled in, the form enables the **OK** button.

If the user clicks **Cancel** on the dialog, the SQLDriverConnect function call returns SQL_NO_DATA immediately, without attempting to connect to Vertica. If the user supplies incomplete or incorrect information for the connection, the connection function returns SQL_ERROR after the connection attempt fails.

> **Note**
> If the DriverCompletion property of the SQLDriverConnect function call is SQL_DRIVER_NOPROMPT, the ODBC driver immediately returns a SQL_ERROR indicating that it cannot connect because not enough information has been supplied and the driver is not allowed to prompt the user for the missing information.

Prompting Windows users for passwords

If the connection string or DSN supplied to the SQLDriverConnect function that client applications call to connect to Vertica lacks any of the required connection properties needed to connect, the Vertica's Windows ODBC driver opens a dialog box to prompt the user to enter the missing information (see Prompting windows users for missing connection properties). The user's password is not normally considered a required connection property, since Vertica user accounts may not have a password. If the password property is missing, the ODBC driver still tries to connect to Vertica without supplying a password.

You can use the PromptOnNoPassword DSN parameter to force ODBC driver to treat the password as a required connection property. This parameter is useful if you do not want to store passwords in DSN entries. Passwords saved in DSN entries are insecure, since they are stored as clear text in the Windows registry and therefore visible to other users on the same system.

There are two other factors which also decide whether the ODBC driver displays the Vertica Connection Dialog. These are (in order of priority):

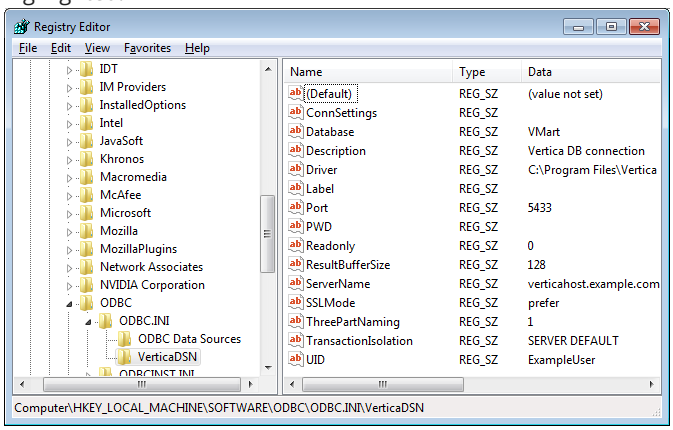
- The SQLDriverConnect function call's DriverCompletion parameter.
- Whether the DSN or connection string contain a password

The following table shows how the PromptOnNoPassword DSN parameter, the DriverCompletion parameter of the SQLDriverConnect function, and whether the DSN or connection string contains a password interact to control whether the Vertica Connection dialog appears.

PromptOnNoPassword Setting	DriverCompletion Value	DSN or Connection String Contains Password?	Vertica Connection Dialog Displays?	Notes
any value	SQL_DRIVER_PROMPT	any case	Yes	This DriverCompletion value forces the dialog to always appear, even if all required connection properties are supplied.
any value	SQL_DRIVER_NOPROMPT	any case	No	This DriverCompletion value always prevents the dialog from appearing.
any value	SQL_DRIVER_COMPLETE	Yes	No	Connection dialog displays if another required connection property is missing.
true	SQL_DRIVER_COMPLETE	No	Yes	
false (default)	SQL_DRIVER_COMPLETE	No	No	Connection dialog displays if another required connection property is missing.

The following example code demonstrates using the PromptOnNoPassword DSN parameter along with a system DSN.

```
wstring connectString = L"DSN=VerticaDSN;PromptOnNoPassword=1;";
retcode = SQLDriverConnect(
            hdbc,
            0,
            (SQLWCHAR*)connectString.c_str(),
            connectString.length(),
            OutConnStr,
            255,
            &OutConnStrLen,
            SQL_DRIVER_COMPLETE );
```



No password entry vs. empty passwords

There is a difference between not having a password property in the connection string or DSN and having an empty password. The PromptOnNoPassword DSN parameter only has an effect if the connection string or DSN does not have a PWD property (which holds the user's password). If it does, even if it is empty, PromptOnNoPassword will not prompt the Windows ODBC driver to display the Vertica Connection Dialog.

This difference can cause confusion if you are using a DSN to provide the properties for your connection. Once you enter a password for a DSN connection in the Windows ODBC Manager and save it, Windows adds a PWD property to the DSN definition in the registry. If you later delete the password, the PWD property remains in the DSN definition—value is just set to an empty string. The PWD property is created even if you just use the Test button on the ODBC Manager dialog to test the DSN and later clear it before saving the DSN.

Once the password has been set, the only way to remove the PWD property from the DSN definition is to delete it using the Windows Registry Editor:

1. On the Windows Start menu, click Run.
2. In the Run dialog, type regedit, then click OK.
3. In the Registry Editor window, click Edit > Find (or press Ctrl+F).
4. In the Find window, enter the name of the DSN whose PWD property you want to delete and click OK.
5. If find operation did not locate a folder under the ODBC.INI folder, click Edit > Find Next (or press F3) until the folder matching your DSN's name is highlighted.

6. Select the PWD entry and press Delete.
7. Click Yes to confirm deleting the value.

The DSN now does not have a PWD property and can trigger the connection dialog to appear when used along with PromptOnNoPassword=true and DriverConnect=SQL_DRIVER_COMPLETE.

Setting the locale and encoding for ODBC sessions

Vertica provides the following methods to set the locale and encoding for an ODBC session:

- Specify the locale for all connections made using the DSN:
  - On Linux and other UNIX-like platforms: Creating an ODBC DSN for Linux
  - On Windows platforms, set the locale in the ODBC DSN configuration editor's Locale field on the Server Settings tab. See Creating an ODBC DSN for windows clients for detailed information.
- Set the Locale connection parameter in the connection string in SQLDriverConnect() function. For example:

```
SQLDriverConnect(conn, NULL, (SQLCHAR*)"DSN=Vertica;Locale=en_GB@collation=binary", SQL_NTS, szConnOut, sizeof(szConnOut), &iAvailable, SQL_DRIVER_NOPROMPT)
```

- Use SQLSetConnectAttr() to set the encoding and locale. In general, you should always set the encoding with this function as opposed to, for example, setting it in the DSN.
  - Pass the SQL_ATTR_VERTICA_LOCALE constant and the ICU string as the attribute value. For example:

```
=> SQLSetConnectAttr(hdlDbc, SQL_ATTR_VERTICA_LOCALE, (SQLCHAR*)newLocale,
     SQL_NTS);
```

  - Pass the SQL_ATTR_AP_WCHAR_TYPE constant and the encoding as the attribute value. For example:

```
=> rc = SQLSetConnectAttr (hdbc, SQL_ATTR_APP_WCHAR_TYPE, (void *)SQL_DD_CP_UTF16, SQL_IS_INTEGER);
```

Notes

- Having the client system use a non-Unicode locale (such as setting LANG=C on Linux platforms) and using a Unicode locale for the connection to Vertica can result in errors such as "(10170) String data right truncation on data from data source." If data received from Vertica isn't in UTF-8 format. The driver allocates string memory based on the system's locale setting, and non-UTF-8 data can trigger an overrun. You can avoid these errors by always using a Unicode locale on the client system.
  If you specify a locale either in the connection string or in the DSN, the call to the connection function returns SQL_SUCCESS_WITH_INFO on a successful connection, with messages about the state of the locale.
- ODBC applications can be in either ANSI or Unicode mode:
  - If Unicode, the encoding used by ODBC is UCS-2.
  - If ANSI, the data must be in single-byte ASCII, which is compatible with UTF-8 on the database server.

  The ODBC driver converts UCS-2 to UTF-8 when passing to the Vertica server and converts data sent by the Vertica server from UTF-8 to UCS-2.
- If the end-user application is not already in UCS-2, the application is responsible for converting the input data to UCS-2, or unexpected results could occur. For example:
  - On non-UCS-2 data passed to ODBC APIs, when it is interpreted as UCS-2, it could result in an invalid UCS-2 symbol being passed to the APIs, resulting in errors.
  - Or the symbol provided in the alternate encoding could be a valid UCS-2 symbol; in this case, incorrect data is inserted into the database.

ODBC applications should set the correct server session locale using SQLSetConnectAttr (if different from database-wide setting) in order to set the proper collation and string functions behavior on server.

The following example code demonstrates setting the locale using both the connection string and with the SQLSetConnectAttr() function.

```
// Standard i/o library
#include <stdio.h>
#include <stdlib.h>
// Only needed for Windows clients
// #include <windows.h>
// SQL include files that define data types and ODBC API
// functions
#include <sql.h>
#include <sqlext.h>
#include <sqltypes.h>
// Vertica-specific definitions. This include file is located as
// /opt/vertica/include on database hosts.
#include <verticaodbc.h>
int main()
{
   SQLRETURN ret;   // Stores return value from ODBC API calls
   SQLHENV hdlEnv;  // Handle for the SQL environment object
   // Allocate an a SQL environment object
   ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hdlEnv);
   if(!SQL_SUCCEEDED(ret)) {
      printf("Could not allocate a handle.\n");
      exit(EXIT_FAILURE);
   } else {
      printf("Allocated an environment handle.\n");
   }
   // Set the ODBC version we are going to use to 3.
   ret = SQLSetEnvAttr(hdlEnv, SQL_ATTR_ODBC_VERSION,
      (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_UINTEGER);
   if(!SQL_SUCCEEDED(ret)) {
      printf("Could not set application version to ODBC 3.\n");
      exit(EXIT_FAILURE);
   } else {
      printf("Set application version to ODBC 3.\n");
   }
   // Allocate a database handle.
   SQLHDBC hdlDbc;
   ret = SQLAllocHandle(SQL_HANDLE_DBC, hdlEnv, &hdlDbc);
   if(!SQL_SUCCEEDED(ret)) {
      printf("Could not allocate database handle.\n");
      exit(EXIT_FAILURE);
   } else {
      printf("Allocated Database handle.\n");
   }
   // Connect to the database using SQLDriverConnect
   printf("Connecting to database.\n");
   // Set the locale to English in Great Britain.
   const char *connStr = "DSN=ExampleDB;locale=en_GB;"
      "UID=dbadmin;PWD=password123";
   ret = SQLDriverConnect(hdlDbc, NULL, (SQLCHAR*)connStr, SQL_NTS,
            NULL, 0, NULL, SQL_DRIVER_NOPROMPT );
   if(!SQL_SUCCEEDED(ret)) {
      printf("Could not connect to database.\n");
      exit(EXIT_FAILURE);
   } else {
      printf("Connected to database.\n");
   }
   // Get the Locale
```

```
char locale[256];
SQLGetConnectAttr(hdlDbc, SQL_ATTR_VERTICA_LOCALE, locale, sizeof(locale),
    0);
printf("Locale is set to: %s\n", locale);
// Set the locale to a new value
const char* newLocale = "en_GB";
SQLSetConnectAttr(hdlDbc, SQL_ATTR_VERTICA_LOCALE, (SQLCHAR*)newLocale,
    SQL_NTS);

// Get the Locale again
SQLGetConnectAttr(hdlDbc, SQL_ATTR_VERTICA_LOCALE, locale, sizeof(locale),
    0);
printf("Locale is now set to: %s\n", locale);

// Set the encoding
SQLSetConnectAttr (hdbc, SQL_ATTR_APP_WCHAR_TYPE, (void *)SQL_DD_CP_UTF16,
    SQL_IS_INTEGER);

// When done, free all of the handles to close them
// in an orderly fashion.
printf("Disconnecting and freeing handles.\n");
ret = SQLDisconnect( hdlDbc );
if(!SQL_SUCCEEDED(ret)) {
    printf("Error disconnecting from database. Transaction still open?\n");
    exit(EXIT_FAILURE);
}
SQLFreeHandle(SQL_HANDLE_DBC, hdlDbc);
SQLFreeHandle(SQL_HANDLE_ENV, hdlEnv);
exit(EXIT_SUCCESS);
```

AUTOCOMMIT and ODBC transactions

The AUTOCOMMIT connection attribute controls whether INSERT, ALTER, COPY and other data-manipulation statements are automatically committed after they complete. By default, AUTOCOMMIT is enabled—all statements are committed after they execute. This is often not the best setting to use, since it is less efficient. Also, you often want to control whether a set of statements are committed as a whole, rather than have each individual statement committed. For example, you may only want to commit a series of inserts if all of the inserts succeed. With AUTOCOMMIT disabled, you can roll back the transaction if one of the statements fail.

If AUTOCOMMIT is on, the results of statements are committed immediately after they are executed. You cannot roll back a statement executed in AUTOCOMMIT mode.

For example, when AUTOCOMMIT is on, the following single INSERT statement is automatically committed:

```
ret = SQLExecDirect(hdlStmt, (SQLCHAR*)"INSERT INTO customers VALUES(500,"
  "'Smith, Sam', '123-456-789');", SQL_NTS);
```

If AUTOCOMMIT is off, you need to manually commit the transaction after executing a statement. For example:

```
ret = SQLExecDirect(hdlStmt, (SQLCHAR*)"INSERT INTO customers VALUES(500,"
  "'Smith, Sam', '123-456-789');", SQL_NTS);
// Other inserts and data manipulations
// Commit the statements(s)
ret = SQLEndTran(SQL_HANDLE_DBC, hdlDbc, SQL_COMMIT);
```

The inserted row is only committed when you call SQLEndTran() . You can roll back the INSERT and other statements at any point before committing the transaction.

> **Note**
> Prepared statements cache the AUTOCOMMIT setting when you create them using SQLPrepare() . Later changing the connection's AUTOCOMMIT setting has no effect on the AUTOCOMMIT settings of previously created prepared statements. See Using prepared statements for details.

The following example demonstrates turning off AUTOCOMMIT, executing an insert, then manually committing the transaction.

```
// Some standard headers
#include <stdio.h>
#include <stdlib.h>
// Only needed for Windows clients
// #include <windows.h>
// Standard ODBC headers
#include <sql.h>
#include <sqltypes.h>
#include <sqlext.h>
int main()
{
  // Set up the ODBC environment
  SQLRETURN ret;
  SQLHENV hdlEnv;
  ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hdlEnv);
  if(!SQL_SUCCEEDED(ret)) {
    printf("Could not allocate a handle.\n");
    exit(EXIT_FAILURE);
  } else {
    printf("Allocated an environment handle.\n");
  }
  // Tell ODBC that the application uses ODBC 3.
  ret = SQLSetEnvAttr(hdlEnv, SQL_ATTR_ODBC_VERSION,
    (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_UINTEGER);
  if(!SQL_SUCCEEDED(ret)) {
    printf("Could not set application version to ODBC3.\n");
    exit(EXIT_FAILURE);
  } else {
    printf("Set application to ODBC 3.\n");
  }
  // Allocate a database handle.
  SQLHDBC hdlDbc;
  ret = SQLAllocHandle(SQL_HANDLE_DBC, hdlEnv, &hdlDbc);
  if(!SQL_SUCCEEDED(ret)) {
    printf("Could not allocate database handle.\n");
    exit(EXIT_FAILURE);
  } else {
    printf("Allocated Database handle.\n");
  }
  // Connect to the database
  printf("Connecting to database.\n");
  const char *dsnName = "ExampleDB";
  const char* userID = "dbadmin";
  const char* passwd = "password123";
  ret = SQLConnect(hdlDbc, (SQLCHAR*)dsnName,
    SQL_NTS,(SQLCHAR*)userID,SQL_NTS,
    (SQLCHAR*)passwd, SQL_NTS);
  if(!SQL_SUCCEEDED(ret)) {
    printf("Could not connect to database.\n");
    exit(EXIT_FAILURE);
  } else {
    printf("Connected to database.\n");
  }
  // Get the AUTOCOMMIT state
  SQLINTEGER  autoCommitState;
  SQLGetConnectAttr(hdlDbc, SQL_ATTR_AUTOCOMMIT, &autoCommitState, 0, NULL);
  printf("Autocommit is set to: %d\n", autoCommitState);
```

```
// Disable AUTOCOMMIT
printf("Disabling autocommit.\n");
ret = SQLSetConnectAttr(hdlDbc, SQL_ATTR_AUTOCOMMIT, SQL_AUTOCOMMIT_OFF,
    SQL_NTS);
if(!SQL_SUCCEEDED(ret)) {
    printf("Could not disable autocommit.\n");
    exit(EXIT_FAILURE);
}

// Get the AUTOCOMMIT state again
SQLGetConnectAttr(hdlDbc, SQL_ATTR_AUTOCOMMIT, &autoCommitState, 0, NULL);
printf("Autocommit is set to: %d\n", autoCommitState);

// Set up a statement handle
SQLHSTMT hdlStmt;
SQLAllocHandle(SQL_HANDLE_STMT, hdlDbc, &hdlStmt);

// Create a table to hold the data
SQLExecDirect(hdlStmt, (SQLCHAR*)"DROP TABLE IF EXISTS customers",
    SQL_NTS);
SQLExecDirect(hdlStmt, (SQLCHAR*)"CREATE TABLE customers "
    "(CustID int, CustName varchar(100), Phone_Number char(15));",
    SQL_NTS);

// Insert a single row.
ret = SQLExecDirect(hdlStmt, (SQLCHAR*)"INSERT INTO customers VALUES(500,"
    "'Smith, Sam', '123-456-789');", SQL_NTS);
if(!SQL_SUCCEEDED(ret)) {
    printf("Could not perform single insert.\n");
} else {
    printf("Performed single insert.\n");
}

// Need to commit the transaction before closing, since autocommit is
// disabled. Otherwise SQLDisconnect returns an error.
printf("Committing transaction.\n");
ret = SQLEndTran(SQL_HANDLE_DBC, hdlDbc, SQL_COMMIT);
if(!SQL_SUCCEEDED(ret)) {
    printf("Error committing transaction.\n");
    exit(EXIT_FAILURE);
}

// Clean up
printf("Free handles.\n");
ret = SQLDisconnect(hdlDbc);
if(!SQL_SUCCEEDED(ret)) {
    printf("Error disconnecting from database. Transaction still open?\n");
    exit(EXIT_FAILURE);
}
SQLFreeHandle(SQL_HANDLE_STMT, hdlStmt);
SQLFreeHandle(SQL_HANDLE_DBC, hdlDbc);
SQLFreeHandle(SQL_HANDLE_ENV, hdlEnv);
exit(EXIT_SUCCESS);
```

Running the above code results in the following output:

```
Allocated an environment handle.
Set application to ODBC 3.
Allocated Database handle.
Connecting to database.
Connected to database.
Autocommit is set to: 1
Disabling autocommit.
Autocommit is set to: 0
Performed single insert.
Committing transaction.
Free handles.
```

> **Note**
> You can also disable AUTOCOMMIT in the ODBC connection string. See Setting DSN connection properties for more information.

Retrieving data through ODBC

To retrieve data through ODBC, you execute a query that returns a result set (SELECT , for example), then retrieve the results using one of two methods:

- Use the SQLFetch() function to retrieve a row of the result set, then access column values in the row by calling SQLGetData() .
- Use the SQLBindColumn() function to bind a variable or array to a column in the result set, then call SQLExtendedFetch() or SQLFetchScroll() to read a row of the result set and insert its values into the variable or array.

In both methods you loop through the result set until you either reach the end (signaled by the SQL_NO_DATA return status) or encounter an error.

> **Note**
> Vertica supports one cursor per connection. Attempting to use more than one cursor per connection will result in an error. For example, you receive an error if you execute a statement while another statement has a result set open.

The following code example demonstrates retrieving data from Vertica by:

1. Connecting to the database.
2. Executing a SELECT statement that returns the IDs and names of all tables.
3. Binds two variables to the two columns in the result set.
4. Loops through the result set, printing the ids and name values.

Loading data through ODBC

A primary task for many client applications is loading data into the Vertica database. There are several different ways to insert data using ODBC, which are covered by the topics in this section.

In this section

- Using a single row insert
- Using prepared statements
- Using batch inserts
- Using the COPY statement
- Streaming data from the client using COPY LOCAL

Using a single row insert

The easiest way to load data into Vertica is to run an INSERT SQL statement using the SQLExecuteDirect function. However this method is limited to inserting a single row of data.

```
ret = SQLExecDirect(hstmt, (SQLTCHAR*)"INSERT into Customers values"
    "(1,'abcda','efgh','1')", SQL_NTS);
```

Using prepared statements

Vertica supports using server-side prepared statements with both ODBC and JDBC. Prepared statements let you define a statement once, and then run it many times with different parameters. The statement you want to execute contains placeholders instead of parameters. When you execute the statement, you supply values for each placeholder.

Placeholders are represented by question marks (?) as in the following example query:

```
SELECT * FROM public.inventory_fact WHERE product_key = ?
```

Server-side prepared statements are useful for:

- Optimizing queries. Vertica only needs to parse the statement once.
- Preventing SQL injection attacks. A SQL injection attack occurs when user input is either incorrectly filtered for string literal escape characters embedded in SQL statements or user input is not strongly typed and thereby unexpectedly run. Since a prepared statement is parsed separately from the input data, there is no chance the data can be accidentally executed by the database.
- Binding direct variables to return columns. By pointing to data structures, the code doesn't have to perform extra transformations.

The following example demonstrates a using a prepared statement for a single insert.

```
// Some standard headers
#include <stdio.h>
#include <stdlib.h>
// Only needed for Windows clients
// #include <windows.h>
// Standard ODBC headers
#include <sql.h>
#include <sqltypes.h>
#include <sqlext.h>
// Some constants for the size of the data to be inserted.
#define CUST_NAME_LEN 50
#define PHONE_NUM_LEN 15
#define NUM_ENTRIES 4
int main()
{
   // Set up the ODBC environment
   SQLRETURN ret;
   SQLHENV hdlEnv;
   ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hdlEnv);
   if(!SQL_SUCCEEDED(ret)) {
      printf("Could not allocate a handle.\n");
      exit(EXIT_FAILURE);
   } else {
      printf("Allocated an environment handle.\n");
   }
   // Tell ODBC that the application uses ODBC 3.
   ret = SQLSetEnvAttr(hdlEnv, SQL_ATTR_ODBC_VERSION,
      (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_UINTEGER);
   if(!SQL_SUCCEEDED(ret)) {
      printf("Could not set application version to ODBC3.\n");
      exit(EXIT_FAILURE);
   } else {
      printf("Set application to ODBC 3.\n");
   }
   // Allocate a database handle.
   SQLHDBC hdlDbc;
   ret = SQLAllocHandle(SQL_HANDLE_DBC, hdlEnv, &hdlDbc);
   // Connect to the database

SQLFreeHandle(SQL_HANDLE_ENV, hdlEnv);
exit(EXIT_SUCCESS);
```

Using batch inserts

You use batch inserts to insert chunks of data into the database. By breaking the data into batches, you can monitor the progress of the load by receiving information about any rejected rows after each batch is loaded. To perform a batch load through ODBC, you typically use a prepared statement with the parameters bound to arrays that contain the data to be loaded. For each batch, you load a new set of data into the arrays then execute the prepared statement.

When you perform a batch load, Vertica uses a COPY statement to load the data. Each additional batch you load uses the same COPY statement. The statement remains open until you end the transaction, close the cursor for the statement, or execute a non-INSERT statement.

Using a single COPY statement for multiple batches improves batch loading efficiency by:

- reducing the overhead of inserting individual batches
- combining individual batches into larger ROS containers

> **Note**
> If the database connection has AUTOCOMMIT enabled, then the transaction is automatically committed after each batch insert statement which closes the COPY statement. Leaving AUTOCOMMIT enabled makes your batch load much less efficient, and can cause added overhead in your database as all of the smaller loads are consolidated.

Even though Vertica uses a single COPY statement to insert multiple batches within a transaction, you can locate which (if any) rows were rejected due to invalid row formats or data type issues after each batch is loaded. See Tracking load status (ODBC) for details.

> **Note**
> While you can find rejected rows during the batch load transaction, other types of errors (such as running out of disk space or a node shutdown that makes the database unsafe) are only reported when the COPY statement ends.

Since the batch loads share a COPY statement, errors in one batch can cause earlier batches in the same transaction to be rolled back.

Batch insert steps

The steps your application needs to take in order to perform an ODBC Batch Insert are:

1. Connect to the database.
2. Disable autocommit for the connection.
3. Create a prepared statement that inserts the data you want to load.
4. Bind the parameters of the prepared statement to arrays that will contain the data you want to load.
5. Populate the arrays with the data for your batches.
6. Execute the prepared statement.
7. Optionally, check the results of the batch load to find rejected rows.
8. Repeat the previous three steps until all of the data you want to load is loaded.
9. Commit the transaction.
10. Optionally, check the results of the entire batch transaction.

The following example code demonstrates a simplified version of the above steps.

```
// Some standard headers
#include <stdio.h>
#include <stdlib.h>
// Only needed for Windows clients
// #include <windows.h>
// Standard ODBC headers
#include <sql.h>
#include <sqltypes.h>
#include <sqlext.h>
int main()
{
  // Number of data rows to insert
  const int NUM_ENTRIES = 4;

  // Set up the ODBC environment
  SQLRETURN ret;
  SQLHENV hdlEnv;
```

```
ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hdlEnv);
if(!SQL_SUCCEEDED(ret)) {
    printf("Could not allocate a handle.\n");
    exit(EXIT_FAILURE);
} else {
    printf("Allocated an environment handle.\n");
}
// Tell ODBC that the application uses ODBC 3.
ret = SQLSetEnvAttr(hdlEnv, SQL_ATTR_ODBC_VERSION,
    (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_UINTEGER);
if(!SQL_SUCCEEDED(ret)) {
    printf("Could not set application version to ODBC3.\n");
    exit(EXIT_FAILURE);
} else {
    printf("Set application to ODBC 3.\n");
}
// Allocate a database handle.
SQLHDBC hdlDbc;
ret = SQLAllocHandle(SQL_HANDLE_DBC, hdlEnv, &hdlDbc);
if(!SQL_SUCCEEDED(ret)) {
    printf("Could not allocate database handle.\n");
    exit(EXIT_FAILURE);
} else {
    printf("Allocated Database handle.\n");
}
// Connect to the database
printf("Connecting to database.\n");
const char *dsnName = "ExampleDB";
const char* userID = "dbadmin";

    }  else {
        printf("successful.\n");
    }
}
// Done with batches, commit the transaction
printf("Committing transaction\n");
ret = SQLEndTran(SQL_HANDLE_DBC, hdlDbc, SQL_COMMIT);
if(!SQL_SUCCEEDED(ret)) {
    printf("Could not commit transaction\n");
}  else {
    printf("Committed transaction\n");
}

// Clean up
printf("Free handles.\n");
ret = SQLDisconnect( hdlDbc );
if(!SQL_SUCCEEDED(ret)) {
    printf("Error disconnecting. Transaction still open?\n");
    exit(EXIT_FAILURE);
}
SQLFreeHandle(SQL_HANDLE_STMT, hdlStmt);
SQLFreeHandle(SQL_HANDLE_DBC, hdlDbc);
SQLFreeHandle(SQL_HANDLE_ENV, hdlEnv);
exit(EXIT_SUCCESS);
```

The result of running the above code is shown below.

```
Allocated an environment handle.
Set application to ODBC 3.
Allocated Database handle.
Connecting to database.
Connected to database.
Creating prepared statement
Created prepared statement.
Bound CustIDs array to prepared statement
Bound CustNames array to prepared statement
Bound phoneNums array to prepared statement
Adding Batch #1...successful.
Adding Batch #2...successful.
Adding Batch #3...successful.
Adding Batch #4...successful.
Adding Batch #5...successful.
Committing transaction
Committed transaction
Free handles.
```

The resulting table looks like this:

```
=> SELECT * FROM customers;
 CustID |  CustName   |  Phone_Number
--------+-------------+----------------
    100 | Allen, Anna | 1-617-555-1234
    101 | Brown, Bill | 1-781-555-1212
    102 | Chu, Cindy  | 1-508-555-4321
    103 | Dodd, Don   | 1-617-555-4444
    100 | Allen, Anna | 1-617-555-1234
    101 | Brown, Bill | 1-781-555-1212
    102 | Chu, Cindy  | 1-508-555-4321
    103 | Dodd, Don   | 1-617-555-4444
    100 | Allen, Anna | 1-617-555-1234
    101 | Brown, Bill | 1-781-555-1212
    102 | Chu, Cindy  | 1-508-555-4321
    103 | Dodd, Don   | 1-617-555-4444
    100 | Allen, Anna | 1-617-555-1234
    101 | Brown, Bill | 1-781-555-1212
    102 | Chu, Cindy  | 1-508-555-4321
    103 | Dodd, Don   | 1-617-555-4444
    100 | Allen, Anna | 1-617-555-1234
    101 | Brown, Bill | 1-781-555-1212
    102 | Chu, Cindy  | 1-508-555-4321
    103 | Dodd, Don   | 1-617-555-4444
(20 rows)
```

> **Note**
> An input parameter bound with the SQL_C_NUMERIC data type uses the default numeric precision (37) and the default scale (0) instead of the precision and scale set by the SQL_NUMERIC_STRUCT input value. This behavior adheres to the ODBC standard. If you do not want to use the default precision and scale, use SQLSetDescField() or SQLSetDescRec() to change them in the statement's attributes.

In this section

- Tracking load status (ODBC)
- Error handling during batch loads

Tracking load status (ODBC)

After loading a batch of data, your client application can get the number of rows that were processed and find out whether each row was accepted or rejected.

Finding the number of accepted rows

To get the number of rows processed by a batch, you add an attribute named SQL_ATTR_PARAMS_PROCESSED_PTR to the statement object that points to a variable to receive the number rows:

```
SQLULEN rowsProcessed;
SQLSetStmtAttr(hdlStmt, SQL_ATTR_PARAMS_PROCESSED_PTR, &rowsProcessed, 0);
```

When your application calls SQLExecute() to insert the batch, the Vertica ODBC driver saves the number of rows that it processed (which is not necessarily the number of rows that were successfully inserted) in the variable you specified in the SQL_ATTR_PARAMS_PROCESSED_PTR statement attribute.

Finding the accepted and rejected rows

Your application can also set a statement attribute named SQL_ATTR_PARAM_STATUS_PTR that points to an array where the ODBC driver can store the result of inserting each row:

```
SQLUSMALLINT   rowResults[ NUM_ENTRIES ];
SQLSetStmtAttr(hdlStmt, SQL_ATTR_PARAM_STATUS_PTR, rowResults, 0);
```

This array must be at least as large as the number of rows being inserted in each batch.

When your application calls SQLExecute to insert a batch, the ODBC driver populates the array with values indicating whether each row was successfully inserted (SQL_PARAM_SUCCESS or SQL_PARAM_SUCCESS_WITH_INFO) or encountered an error (SQL_PARAM_ERROR).

The following example expands on the example shown in Using batch inserts to include reporting the number of rows processed and the status of each row inserted.

```
// Some standard headers
#include <stdio.h>
#include <stdlib.h>
// Only needed for Windows clients
// #include <windows.h>
// Standard ODBC headers
#include <sql.h>
#include <sqltypes.h>
#include <sqlext.h>
// Helper function to print SQL error messages.
template <typename HandleT>
void reportError(int handleTypeEnum, HandleT hdl)
{
    // Get the status records.
    SQLSMALLINT    i, MsgLen;
    SQLRETURN ret2;
    SQLCHAR       SqlState[6], Msg[SQL_MAX_MESSAGE_LENGTH];
    SQLINTEGER    NativeError;
    i = 1;
    printf("\n");
    while ((ret2 = SQLGetDiagRec(handleTypeEnum, hdl, i, SqlState, &NativeError,
      Msg, sizeof(Msg), &MsgLen)) != SQL_NO_DATA) {
          printf("error record %d\n", i);
          printf("sqlstate: %s\n", SqlState);
          printf("detailed msg: %s\n", Msg);
          printf("native error code: %d\n\n", NativeError);
          i++;
    }
}
int main()
{
    // Number of data rows to insert
    const int NUM_ENTRIES = 4;

    SQLRETURN ret;
    SQLHENV hdlEnv;
```

```

Error handling during batch loads

When loading individual batches, you can find information on how many rows were accepted and what rows were rejected (see Tracking load status (ODBC) for details). Other errors, such as disk space errors, do not occur while inserting individual batches. This behavior is caused by having a single COPY statement perform the loading of multiple consecutive batches. Using the single COPY statement makes the batch load process perform much faster. It is only when the COPY statement closes that the batched data is committed and Vertica reports other types of errors.

Your bulk loading application should check for errors when the COPY statement closes. Normally, you force the COPY statement to close by calling the SQLEndTran() function to end the transaction. You can also force the COPY statement to close by closing the cursor using the SQLCloseCursor() function, or by setting the database connection's AutoCommit property to true before inserting the last batch in the load.

> **Note**
> The COPY statement also closes if you execute any non-insert statement. However having to deal with errors from the COPY statement in what might be an otherwise-unrelated query is not intuitive, and can lead to confusion and a harder to maintain application. You should explicitly end the COPY statement at the end of your batch load and handle any errors at that time.

Using the COPY statement

COPY lets you bulk load data from a file stored on a database node into the Vertica database. This method is the most efficient way to load data into Vertica because the file resides on the database server. You must be a superuser to use COPY to access the file system of the database node.

Important
In databases that were created in versions of Vertica ≤ 9.2, COPY supports the DIRECT option, which specifies to load data directly into ROS rather than WOS. Use this option when loading large (>100MB) files into the database; otherwise, the load is liable to fill the WOS. When this occurs, the Tuple Mover must perform a moveout operation on the WOS data. It is more efficient to directly load into ROS and avoid forcing a moveout.

In databases created in Vertica 9.3, Vertica ignores load options and hints and always uses a load method of DIRECT. Databases created in versions ≥ 10.0 no longer support WOS and moveout operations; all data is always loaded directly into ROS.

> **Note**
> The exceptions/rejections files are created on the client machine when the exceptions and rejected data modifiers are specified on the COPY command. Specify a local path and filename for these modifiers when executing a COPY query from the driver.

The following example demonstrates using the COPY command:

```
// Some standard headers
#include <stdio.h>
#include <stdlib.h>
// Only needed for Windows clients
// #include <windows.h>
// Standard ODBC headers
#include <sql.h>
#include <sqltypes.h>
#include <sqlext.h>
// Helper function to determine if an ODBC function call returned
// successfully.
bool notSuccess(SQLRETURN ret) {
    return (ret != SQL_SUCCESS && ret != SQL_SUCCESS_WITH_INFO);
}

int main()
{
    // Set up the ODBC environment
    SQLRETURN ret;
    SQLHENV hdlEnv;
    ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hdlEnv);
    if(notSuccess(ret)) {
        printf("Could not allocate a handle.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Allocated an environment handle.\n");
    }
    // Tell ODBC that the application uses ODBC 3.
    ret = SQLSetEnvAttr(hdlEnv, SQL_ATTR_ODBC_VERSION,
        (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_UINTEGER);
    if(notSuccess(ret)) {
        printf("Could not set application version to ODBC3.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Set application to ODBC 3.\n");
    }
    // Allocate a database handle.
    SQLHDBC hdlDbc;
    ret = SQLAllocHandle(SQL_HANDLE_DBC, hdlEnv, &hdlDbc);
    // Connect to the database
    printf("Connecting to database.\n");
```

```
printf("Connecting to database\n");
const char *dsnName = "ExampleDB";

// Note: User MUST be a database superuser to be able to access files on the
// filesystem of the node.
const char* userID = "dbadmin";
const char* passwd = "password123";
ret = SQLConnect(hdlDbc, (SQLCHAR*)dsnName,
    SQL_NTS,(SQLCHAR*)userID,SQL_NTS,
    (SQLCHAR*)passwd, SQL_NTS);
if(notSuccess(ret)) {
    printf("Could not connect to database.\n");
    exit(EXIT_FAILURE);
} else {
    printf("Connected to database.\n");
}

// Disable AUTOCOMMIT
printf("Disabling autocommit.\n");
ret = SQLSetConnectAttr(hdlDbc, SQL_ATTR_AUTOCOMMIT, SQL_AUTOCOMMIT_OFF, SQL_NTS);
if(notSuccess(ret)) {
    printf("Could not disable autocommit.\n");
    exit(EXIT_FAILURE);
}

// Set up a statement handle
SQLHSTMT hdlStmt;
SQLAllocHandle(SQL_HANDLE_STMT, hdlDbc, &hdlStmt);
// Create table to hold the data
SQLExecDirect(hdlStmt, (SQLCHAR*)"DROP TABLE IF EXISTS customers",
    SQL_NTS);
SQLExecDirect(hdlStmt, (SQLCHAR*)"CREATE TABLE customers"
    "(Last_Name char(50) NOT NULL, First_Name char(50),Email char(50), "
    "Phone_Number char(15));",
    SQL_NTS);

// Run the copy command to load data.
ret=SQLExecDirect(hdlStmt, (SQLCHAR*)"COPY customers "
    "FROM '/data/customers.txt'",
    SQL_NTS);
if(notSuccess(ret)) {
    printf("Data was not successfully loaded.\n");
    exit(EXIT_FAILURE);
} else {
    // Get number of rows added.
    SQLLEN numRows;
    ret=SQLRowCount(hdlStmt, &numRows);
    printf("Successfully inserted %d rows.\n", numRows);

}

// Done with batches, commit the transaction
printf("Committing transaction\n");
ret = SQLEndTran(SQL_HANDLE_DBC, hdlDbc, SQL_COMMIT);
if(notSuccess(ret)) {
    printf("Could not commit transaction\n");
}  else {
    printf("Committed transaction\n");
}

// Clean up
printf("Free handles.\n");
```

```
    SQLFreeHandle(SQL_HANDLE_STMT, hdlStmt);
    SQLFreeHandle(SQL_HANDLE_DBC, hdlDbc);
    SQLFreeHandle(SQL_HANDLE_ENV, hdlEnv);
    exit(EXIT_SUCCESS);
}
```

The example prints the following when run:

```
Allocated an environment handle.
Set application to ODBC 3.
Connecting to database.
Connected to database.
Disabling autocommit.
Successfully inserted 10001 rows.
Committing transaction
Committed transaction
Free handles.
```

Streaming data from the client using COPY LOCAL

COPY LOCAL streams data from a client system file to your Vertica database. This statement works through the ODBC driver, which simplifies the task of transferring data files from the client to the server.

COPY LOCAL works transparently through the ODBC driver. When a client application executes a COPY LOCAL statement, the ODBC driver reads and streams the data file from the client to the server.

> **Note**
> COPY LOCAL must be the first statement in a query,otherwise Vertica returns an error.

This example demonstrates loading data from the client system using the COPY LOCAL statement:

```
// Some standard headers
#include <stdio.h>
#include <stdlib.h>
// Only needed for Windows clients
// #include <windows.h>
// Standard ODBC headers
#include <sql.h>
#include <sqltypes.h>
#include <sqlext.h>
int main()
{
    // Set up the ODBC environment
    SQLRETURN ret;
    SQLHENV hdlEnv;
    ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hdlEnv);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not allocate a handle.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Allocated an environment handle.\n");
    }
    // Tell ODBC that the application uses ODBC 3.
    ret = SQLSetEnvAttr(hdlEnv, SQL_ATTR_ODBC_VERSION,
        (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_UINTEGER);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not set application version to ODBC3.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Set application to ODBC 3.\n");
    }
```

```
}
// Allocate a database handle.
SQLHDBC hdlDbc;
ret = SQLAllocHandle(SQL_HANDLE_DBC, hdlEnv, &hdlDbc);
if(!SQL_SUCCEEDED(ret)) {
    printf("Could not aalocate a database handle.\n");
    exit(EXIT_FAILURE);
} else {
    printf("Set application to ODBC 3.\n");
}
// Connect to the database
printf("Connecting to database.\n");
const char *dsnName = "ExampleDB";
const char* userID = "dbadmin";
const char* passwd = "password123";
ret = SQLConnect(hdlDbc, (SQLCHAR*)dsnName,
    SQL_NTS,(SQLCHAR*)userID,SQL_NTS,
    (SQLCHAR*)passwd, SQL_NTS);
if(!SQL_SUCCEEDED(ret)) {
    printf("Could not connect to database.\n");
    exit(EXIT_FAILURE);
} else {
    printf("Connected to database.\n");
}

// Set up a statement handle
SQLHSTMT hdlStmt;
SQLAllocHandle(SQL_HANDLE_STMT, hdlDbc, &hdlStmt);

// Create table to hold the data
SQLExecDirect(hdlStmt, (SQLCHAR*)"DROP TABLE IF EXISTS customers",
    SQL_NTS);
SQLExecDirect(hdlStmt, (SQLCHAR*)"CREATE TABLE customers"
    "(Last_Name char(50) NOT NULL, First_Name char(50),Email char(50), "
    "Phone_Number char(15));",
    SQL_NTS);

// Run the copy command to load data.
ret=SQLExecDirect(hdlStmt, (SQLCHAR*)"COPY customers "
    "FROM LOCAL '/home/dbadmin/customers.txt'",
    SQL_NTS);
if(!SQL_SUCCEEDED(ret)) {
    printf("Data was not successfully loaded.\n");
    exit(EXIT_FAILURE);
} else {
    // Get number of rows added.
    SQLLEN numRows;
    ret=SQLRowCount(hdlStmt, &numRows);
    printf("Successfully inserted %d rows.\n", numRows);
}

// COPY commits automatically, unless it is told not to, so
// there is no need to commit the transaction.

// Clean up
printf("Free handles.\n");
ret = SQLDisconnect( hdlDbc );
if(!SQL_SUCCEEDED(ret)) {
    printf("Error disconnecting. Transaction still open?\n");
    exit(EXIT_FAILURE);
}
```

```
SQLFreeHandle(SQL_HANDLE_STMT, hdlStmt);
SQLFreeHandle(SQL_HANDLE_DBC, hdlDbc);
SQLFreeHandle(SQL_HANDLE_ENV, hdlEnv);
exit(EXIT_SUCCESS);
```

This example is essentially the same as the example shown in Using the COPY statement , except it uses the COPY statement's LOCAL option to load data from the client system rather than from the file system of the database node.

> **Note**
> On Windows clients, the path you supply for the COPY LOCAL file is limited to 216 characters due to limitations in the Windows API.

Programming JDBC client applications

The Vertica JDBC driver provides you with a standard JDBC API. If you have accessed other databases using JDBC, you should find accessing Vertica familiar. This section explains how to use the JDBC to connect your Java application to Vertica.

You must first install the JDBC client driver on all client systems that will be accessing the Vertica database. For installation instructions, see Installing the Vertica Client Drivers .

For more information about JDBC:

- Loading data through JDBC
- Handling errors
- Routing JDBC queries directly to a single node

JDBC feature support

The Vertica JDBC driver complies with the JDBC 4.0 standards (although it does not implement all of the optional features in them). Your application can use the DatabaseMetaData class to determine if the driver supports a particular feature it wants to use. In addition, the driver implements the Wrapper interface, which lets your client code discover Vertica-specific extensions to the JDBC standard classes, such as VerticaConnection and VerticaStatement classes.

Some important facts to keep in mind when using the Vertica JDBC driver:

- Cursors are forward only and are not scrollable. Result sets cannot be updated.
- A connection supports executing a single statement at any time. If you want to execute multiple statements simultaneously, you must open multiple connections.
- While Vertica has Stored procedures , CallableStatement is not supported. The DatabaseMetaData.getProcedures() and .getProcedureColumns() methods return information about SQL functions (including User Defined Functions) instead of stored procedures.

Multiple SQL statement support

The Vertica JDBC driver can execute strings containing multiple statements. For example:

```
stmt.executeUpdate("CREATE TABLE t(a INT);INSERT INTO t VALUES(10);");
```

Only the Statement interface supports executing strings containing multiple SQL statements. You cannot use multiple statement strings with PreparedStatement . COPY statements that copy a file from a host file system work in a multiple statement string. However, client COPY statements (COPY FROM STDIN) do not work.

Multiple batch conversion to COPY statements

The Vertica JDBC driver converts all batch inserts into Vertica COPY statements. If you turn off your JDBC connection's AutoCommit property, the JDBC driver uses a single COPY statement to load data from sequential batch inserts which can improve load performance by reducing overhead. See Batch inserts using JDBC prepared statements for details.

Multiple JDBC version support

The Vertica JDBC driver implements both JDBC 3.0 and JDBC 4.0 compliant interfaces. The interface that the driver returns to your application depends on the JVM version on which it is running. If your application is running on a 5.0 JVM, the driver supplies your application with JDBC 3.0 classes. If your application is running on a 6.0 or later JVM, the driver supplies it with JDBC 4.0 classes.

Multiple active result sets (MARS)

The Vertica JDBC driver supports Multiple active result sets (MARS) . MARS allows the execution of multiple queries on a single connection. While ResultBufferSize sends the results of a query directly to the client, MARS stores the results first on the server. Once query execution has finished and all of the results have been stored, you can make a retrieval request to the server to have rows returned to the client.

Creating and configuring a connection

Before your Java application can interact with Vertica, it must create a connection. Connecting to Vertica using JDBC is similar to connecting to most other databases.

Importing SQL packages

Before creating a connection, you must import the Java SQL packages. A simple way to do so is to import the entire package using a wildcard:

```
import java.sql.*;
```

You may also want to import the Properties class. You can use an instance of this class to pass connection properties when instantiating a connection, rather than encoding everything within the connection string:

```
import java.util.Properties;
```

If your application needs to run in a Java 5 JVM, it uses the older JDBC 3.0-compliant driver. This driver requires that you to manually load the Vertica JDBC driver using the Class.forName() method:

```
// Only required for old JDBC 3.0 driver
try {
  Class.forName("com.vertica.jdbc.Driver");
} catch (ClassNotFoundException e) {
  // Could not find the driver class. Likely an issue
  // with finding the .jar file.
  System.err.println("Could not find the JDBC driver class.");
  e.printStackTrace();
  return; // Exit. Cannot do anything further.
}
```

Your application may run in a Java 6 or later JVM. If so, then the JVM automatically loads the Vertica JDBC 4.0-compatible driver without requiring the call to Class.forName . However, making this call does not adversely affect the process. Thus, if you want your application to be compatible with both Java 5 and Java 6 (or later) JVMs, it can still call Class.forName .

Opening the connection

With SQL packages imported, you are ready to create your connection by calling the DriverManager.getConnection() method. You supply this method with at least the following information:

- The IP address or host name of a node in the database cluster.
  You can provide an IPv4 address, IPv6 address, or host name.
  In mixed IPv4/IPv6 networks, the DNS server configuration determines which IP version address is sent first. Use the PreferredAddressFamily option to force the connection to use either IPv4 or IPv6.
- Port number for the database
- Name of the database
- Username of a database user account
- Password of the user (if the user has a password)

The first three parameters are always supplied as part of the *connection string,* a URL that tells the JDBC driver where to find the database. The format of the connection string is:

```
"jdbc:vertica://VerticaHost:portNumber/databaseName"
```

The first portion of the connection string selects the Vertica JDBC driver, followed by the location of the database.

You can provide the last two parameters, username and password, to theJDBC driver, in one of three ways:

- As part of the connection string. The parameters are encoded similarly to URL parameters:
  ```
  "jdbc:vertica://VerticaHost:portNumber/databaseName?user=username&password=password"
  ```
- As separate parameters to DriverManager.getConnection() :
  ```
  Connection conn = DriverManager.getConnection(
      "jdbc:vertica://VerticaHost:portNumber/databaseName",
      "username", "password");
  ```
- In a Properties object:
  ```
  Properties myProp = new Properties();
  myProp.put("user", "username");
  myProp.put("password", "password");
  Connection conn = DriverManager.getConnection(
    "jdbc:vertica://VerticaHost:portNumber/databaseName", myProp);
  ```

Of these three methods, the Properties object is the most flexible because it makes passing additional connection properties to the getConnection() method easy. See Connection Properties and Setting and getting connection property values for more information about the additional connection properties.

If there is any problem establishing a connection to the database, the getConnection() method throws a SQLException on one of its subclasses. To prevent an exception, enclose the method within a try-catch block, as shown in the following complete example of establishing a connection.

```
import java.sql.*;
import java.util.Properties;

public class VerySimpleVerticaJDBCExample {
    public static void main(String[] args) {
        /*
         * If your client needs to run under a Java 5 JVM, it will use the older
         * JDBC 3.0-compliant driver, which requires you manually load the
         * driver using Class.forname
         */
        /*
         * try { Class.forName("com.vertica.jdbc.Driver"); } catch
         * (ClassNotFoundException e) { // Could not find the driver class.
         * Likely an issue // with finding the .jar file.
         * System.err.println("Could not find the JDBC driver class.");
         * e.printStackTrace(); return; // Bail out. We cannot do anything
         * further. }
         */
        Properties myProp = new Properties();
        myProp.put("user", "dbadmin");
        myProp.put("password", "vertica");
        myProp.put("loginTimeout", "35");
        myProp.put("KeystorePath", "c:/keystore/keystore.jks");
      myProp.put("KeystorePassword", "keypwd");
      myProp.put("TrustStorePath", "c:/truststore/localstore.jks");
      myProp.put("TrustStorePassword", "trustpwd");
        Connection conn;
        try {
            conn = DriverManager.getConnection(
                    "jdbc:vertica://V_vmart_node0001.example.com:5433/vmart", myProp);
            System.out.println("Connected!");
            conn.close();
        } catch (SQLTransientConnectionException connException) {
            // There was a potentially temporary network error
            // Could automatically retry a number of times here, but
            // instead just report error and exit.
            System.out.print("Network connection issue: ");
            System.out.print(connException.getMessage());
            System.out.println(" Try again later!");
            return;
        } catch (SQLInvalidAuthorizationSpecException authException) {
            // Either the username or password was wrong
            System.out.print("Could not log into database: ");
            System.out.print(authException.getMessage());
            System.out.println(" Check the login credentials and try again.");
            return;
        } catch (SQLException e) {
            // Catch-all for other exceptions
            e.printStackTrace();
        }
    }
```

Creating a connection with a keystore and truststore

You can create secure connections with your JDBC client driver using a keystore and a truststore. For more information on security within Vertica, refer to Security and authentication .

For examples and instructions on how to generate (or import external) certificates in Vertica, see Generating TLS certificates and keys .

To view your keys and certificates in Vertica, see CERTIFICATES and CRYPTOGRAPHIC_KEYS .

1. Generate your own self-signed certificate or use an existing CA (certificate authority) certificate as the root CA. For information on this process, refer to the Schannel documentation .
2. **Optional** : Generate or import an intermediate CA certificate signed by your root CA. While not required, having an intermediate CA can be useful for testing and debugging your connection.
3. Generate and sign (or import) a server certificate for Vertica.
4. Use ALTER TLS CONFIGURATION to configure Vertica to use client/server TLS for new connections. For more information, see Configuring client-server TLS .

   For **Server Mode** (no client-certificate verification):

   ```
   => ALTER TLS CONFIGURATION server TLSMODE 'ENABLE';
   => ALTER TLS CONFIGURATION server CERTIFICATE server_cert;
   ```

   For **Mutual Mode** (client-certificate verification of varying strictness depending on the TLSMODE):

   ```
   => ALTER TLS CONFIGURATION server TLSMODE 'TRY_VERIFY';
   => ALTER TLS CONFIGURATION server CERTIFICATE server_cert ADD CA CERTIFICATES ca_cert;
   ```

5. Optionally, you can disable all non-SSL connections with CREATE AUTHENTICATION .

   ```
   => CREATE AUTHENTICATION no_tls METHOD 'reject' HOST NO TLS '0.0.0.0/0';
   => CREATE AUTHENTICATION no_tls METHOD 'reject' HOST NO TLS '::/128';
   ```

6. Generate and sign a certificate for your client using the same CA that signed your server certificate.
7. Convert your chain of pem certificates to a single pkcs 12 file.
8. Import the client key and chain into a keystore JKS file from your pkcs12 file. For information on using the keytool command interface, refer to the Java documentation .

   ```
   $ keytool -importkeystore -srckeystore -alias my_alias -srcstoretype PKCS12 -srcstorepass my_password -noprompt -deststorepass my_password -destke
   ```

9. Import the CA into a truststore JKS file.

   ```
   $ keytool -import -file certs/intermediate_ca.pem -alias my_alias -trustcacerts -keystore /tmp/truststore.jks -storepass my_truststore_password -noprompt
   ```

Usage considerations

- When you disconnect a user session, any uncommitted transactions are automatically rolled back.
- If your database is not compliant with your Vertica license terms, Vertica issues a SQLWarning when you establish the connection to the database. You can retrieve this warning using the Connection.getWarnings() method. See Managing licenses for more information about complying with your license terms.

- JDBC connection properties
- Setting and getting connection property values
- Configuring TLS for JDBC clients
- Setting and returning a client connection label
- Setting the locale for JDBC sessions
- Changing the transaction isolation level
- Using a pooling data source
- Load balancing in JDBC
- JDBC connection failover

JDBC connection properties

You use connection properties to configure the connection between your JDBC client application and your Vertica database. The properties provide the basic information about the connections, such as the server name and port number to use to connect to your database. They also let you tune the performance of your connection and enable logging.

You can set a connection property in one of the following ways:

- Include the property name and value as part of the connection string you pass to the method DriverManager.getConnection() .
- Set the properties in a Properties object, and then pass it to the method DriverManager.getConnection() .
- Use the method VerticaConnection.setProperty() . With this approach, you can change only those connection properties that remain changeable after the connection has been established.

Also, some standard JDBC connection properties have getters and setters on the Connection interface, such as Connection.setAutoCommit() .

Connection properties

The properties in the following table can only be set before you open the connection to the database. Two of them are required for every connection.

Property	Description
BinaryTransfer	Boolean value that determines which mode Vertica uses when connecting to a JDBC client: • **true** : binary transfer (default) • **false** : text transfer Binary transfer is generally more efficient at reading data from a server to a JDBC client and typically requires less bandwidth than text transfer. However, when transferring a large number of small values, binary transfer may use more bandwidth. The data output by both modes is identical with the following exceptions for certain data types: • FLOAT: Binary transfer has slightly better precision. • TIMESTAMPTZ: Binary transfer can fail to get the session time zone and default to the local time zone, while text transfer reliably uses the session time zone. • NUMERIC: Binary transfer is forcibly disabled for NUMERIC data by the server for Vertica 11.0.2+.
ConnSettings	A string containing SQL statements that the JDBC driver automatically runs after it connects to the database. You can use this property to set the locale or schema search path, or perform other configuration that the connection requires.
DisableCopyLocal	When set to true, disables file-based COPY LOCAL operations, including copying data from local files and using local files to store data and exceptions. You can use this property to prevent users from writing to and copying from files on a Vertica host, including an MC host. **Default:** false
Label	Sets a label for the connection on the server. This value appears in the client_label column of the SESSIONS system table. **Default:** jdbc- *driver-version - random_number*
SSL	When set to true, use SSL to encrypt the connection to the server. Vertica must be configured to handle SSL connections before you can establish an SSL-encrypted connection to it. See TLS protocol . This property has been deprecated in favor of the TLSmode property. **Default:** false
TLSmode	TLSmode identifies the security level that Vertica applies to the JDBC connection. Vertica must be configured to handle TLS connections before you can establish an encrypted connection to it. See TLS protocol for details. Valid values are: • disable : JDBC connects using plain text and implements no security measures. • require : JDBC connects using TLS without verifying the CA certificate. • verify-ca : JDBC connects using TLS and confirms that the server certificate has been signed by the certificate authority. This setting is equivalent to the deprecated ssl=true property. • verify-full : JDBC connects using TLS, confirms that the server certificate has been signed by the certificate authority, and verifies that the host name matches the name provided in the server certificate. If this property and the SSL property are set, this property takes precedence. **Default:** disable
HostnameVerifier	If TLSmode is set to verify-full, this property the fully qualified domain name of the verifier that you want to confirm the host name.
Password	Required (for non-OAuth connections), the password to use to log into the database.
User	Required (for non-OAuth connections), the database user name to use to connect to the database.

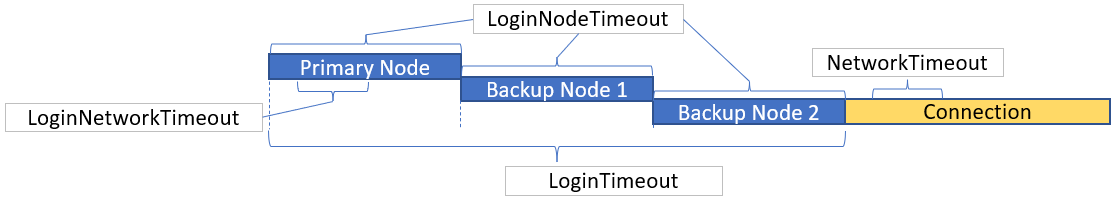
ConnectionLoadBalance	A Boolean value indicating whether the client is willing to have its connection redirected to another host in the Vertica database. This setting has an effect only if the server has also enabled connection load balancing. See About native connection load balancing for more information about native connection load balancing. **Default:** false
BackupServerNode	A string containing the host name or IP address of one or more hosts in the database. If the connection to the host specified in the connection string times out, the client attempts to connect to any host named in this string.The host name or IP address can also include a colon followed by the port number for the database. If no port number is specified, the client uses the standard port number (5433) . Separate multiple host name or IP address entries with commas.
PreferredAddressFamily	The IP version to use if the client and server have both IPv4 and IPv6 addresses and you have provided a host name, one of the following: • ipv4 : Connect to the server using IPv4. • ipv6 : Connect to the server using IPv6. • none : Use the IP address provided by the DNS server. **Default:** none
KeyStorePath	The server path to a .JKS file containing your private keys and their corresponding certificate chains. For information on creating a keystore, refer to documentation for your development environment. For information on creating a keystore, refer to the Java documentation .
KeyStorePassword	The password protecting the keystore file. If individual keys are also encrypted, the keystore file password must match the password for a key within the keystore.
TrustStorePath	The local path to a .JKS truststore file containing certificates from authorities you trust.
TrustStorePassword	The password protecting the truststore file.

OAuth properties

The following connection properties pertain to OAuth in JDBC.

Property	**Description**
oauthaccesstoken	Required if oauthrefreshtoken is unspecified, an OAuth token that authorizes a user to the database.
oauthrefreshtoken	Required if oauthaccesstoken is unspecified, allows a user to refresh and obtain a new oauthaccesstoken when their old one expires. This property is part of a set; all of the following properties must be set to enable token refresh: • oauthrefreshtoken • oauthdiscoveryurl or oauthtokenurl • oauthclientid • oauthclientsecret In cases where introspection fails (e.g. when the access token expires), Vertica responds to the request with an error. If introspection fails and OAuthRefreshToken is specified, the driver attempts to refresh and silently retrieve a new access token. Otherwise, the driver passes error to the client application.

oauthclientid	The client ID of the client application registered in the identity provider. This property is part of a set; all of the following properties must be set to enable token refresh: • oauthrefreshtoken • oauthdiscoveryurl or oauthtokenurl • oauthclientid • oauthclientsecret
oauthclientsecret	The client secret of the client application registered in the identity provider. This property is part of a set; all of the following properties must be set to enable token refresh: • oauthrefreshtoken • oauthdiscoveryurl or oauthtokenurl • oauthclientid • oauthclientsecret
oauthtokenurl	The endpoint to which token refresh requests are sent. This property is part of a set; all of the following properties must be set to enable token refresh: • oauthrefreshtoken • oauthdiscoveryurl or oauthtokenurl • oauthclientid • oauthclientsecret **Examples:** • Keycloak • Okta
oauthdiscoveryurl	Also known as the OpenID Provider Configuration Document , this endpoint points to a JSON containing information about the configuration and endpoints of the identity provider. This parameter is only supported for Keycloak. For other identity providers like Okta, set the oauthtokenurl instead. If you specify this parameter, you do not have to set the oauthtokenurl. The driver automatically resolves the oauthtokenurl. If you specify both the oauthdiscoveryurl and oauthtokenurl, the oauthdiscoveryurl takes precedence.
oauthscope	The requested OAuth scopes, delimited with spaces. These scopes define the extent of access to the resource server (in this case, Vertica) granted to the client by the access token. For details, see the OAuth documentation . For example, to request the scopes offline_access and openid : offline_access openid



Timeout properties

With the following parameters, you can specify various timeouts for each step and the overall connection of JDBC to your Vertica database.

Property	**Description**
LoginTimeout	The number of seconds Vertica waits for the client to log in to the database before throwing a SQLException . **Default:** 0 (no timeout)

LoginNodeTimeout	The number of seconds the JDBC client waits before attempting to connect to the next node if the Vertica process is running, but does not respond. The "next" node is determined by the either the BackupServerNode connection property or DNS resolution. If you only provide a single IP address, the JDBC client returns an error. A timeout value of 0 instructs JDBC to wait indefinitely for an error/a successful connection rather than attempt to connect to another node. **Default:** 0 (no timeout)
LoginNetworkTimeout	The number of seconds the JDBC client has to establish a TCP connection to a Vertica node. A typical use case for this property is to let JDBC connect to another node if the system is down for maintenance and modifying the JDBC application's connection string is infeasible. **Default:** 0 (no timeout)
NetworkTimeout	The number of milliseconds for the server to reply to a request after the client has established a connection with the database. **Default:** 0

The relationship between these properties and the role they play when JDBC attempts to connect to a Vertica database is illustrated in the following diagram:

General properties

The following properties can be set after the connection is established. None of these properties are required.

Property	**Description**
AutoCommit	Controls whether the connection automatically commits transactions. Set this parameter to false to prevent the connection from automatically committing its transactions. You often want to do this when you are bulk loading multiple batches of data and you want the ability to roll back all of the loads if an error occurs. **Set After Connection:** Connection.setAutoCommit() **Default:** true
DirectBatchInsert	Deprecated, always set to true.
MultipleActiveResultSets	Allows more than one active result set on a single connection via MultipleActiveResultSets (MARS). If both MultipleActiveResultSets and ResultBufferSize are turned on, MultipleActiveResultSets takes precedence. The connection does not provide an error, however ResultBufferSize is ignored. **Set After Connection:** VerticaConnection.setProperty() **Default:** false

ReadOnly	When set to true, makes the data connection read-only. Any queries attempting to update the database using a read-only connection cause a SQLException . **Set After Connection:** Connection.setReadOnly() **Default:** false
ResultBufferSize	Sets the size of the buffer the Vertica JDBC driver uses to temporarily store result sets. A value of 0 means ResultBufferSize is turned off. **Note:** This property was named maxLRSMemory in previous versions of the Vertica JDBC driver. **Set After Connection:** VerticaConnection.setProperty() **Default:** 8912 (8KB)
SearchPath	Sets the schema search path for the connection. This value is a string containing a comma-separated list of schema names. See Setting Search Paths for more information on the schema search path. **Set After Connection:** VerticaConnection.setProperty() **Default:** "$user", public, v_catalog, v_monitor, v_internal
ThreePartNaming	A Boolean value that controls how DatabaseMetaData reports the catalog name. When set to true, the database name is returned as the catalog name in the database metadata. When set to false, NULL is returned as the catalog name. Enable this option if your client software is set up to get the catalog name from the database metadata for use in a three-part name reference. **Set After Connection:** VerticaConnection.setProperty() **Default:** true
TransactionIsolation	Sets the isolation level of the transactions that use the connection. See Changing the transaction isolation level for details. **Note:** In previous versions of the Vertica JDBC driver, this property was only available using a getter and setter on the PGConnection object. You can now set it in the same way as other connection properties. **Set After Connection:** Connection.setTransactionIsolation() **Default:** TRANSACTION_READ_COMMITTED

Logging properties

The properties that control client logging must be set before the connection is opened. None of these properties are required, and none can be changed after the Connection object has been instantiated.

Property	**Description**

LogLevel	Sets the type of information logged by the JDBC driver. The value is set to one of the following values: • "DEBUG" • "ERROR" • "TRACE" • "WARNING" • "INFO" • "OFF" **Default:** "OFF"
LogNameSpace	Restricts logging to just messages generated by a specific packages. Valid values are: • com.vertica — All messages generated by the JDBC driver • com.vertica.jdbc — All messages generated by the top-level JDBC API • com.vertica.jdbc.kv — A ll messages generated by the JDBC KV API) • com.vertica.jdbc.core — Connection and statement settings • com.vertica.jdbc.io — Client/server protocol messages • com.vertica.jdbc.util — Miscellaneous utilities • com.vertica.jdbc.dataengine — Query execution and result set iteration • com.vertica.dataengine — Query execution and result set iteration
LogPath	Sets the path where the log file is written. **Default:** The current working directory

Kerberos connection parameters

Use the following parameters to set the service and host name principals for client authentication using Kerberos.

Parameters	**Description**
JAASConfigName	Provides the name of the JAAS configuration that contains the JAAS Krb5LoginModule and its settings **Default:** verticajdbc
KerberosServiceName	Provides the service name portion of the Vertica Kerberos principal, for example: vertica/host@EXAMPLE.COM **Default:** vertica
KerberosHostname	Provides the instance or host name portion of the Vertica Kerberos principal, for example: vertica/host@EXAMPLE.COM **Default:** Value specified in the servername connection string property

Routable connection API connection parameters

Use the following parameters to set properties to enable and configure the connection for Routable Connection lookups.

Parameters	**Description**
EnableRoutableQueries	Enables Routable Connection lookup. See Routing JDBC queries directly to a single node **Default:** false

FailOnMultiNodePlans	If the query plan requires more than one node, then the query fails. Only applicable when EnableRoutableQueries = true. **Default:** true
MetadataCacheLifetime	The time in seconds to keep projection metadata. Only applicable when EnableRoutableQueries = true. **Default:**
MaxPooledConnections	Cluster-wide maximum number of connections to keep in the VerticaRoutableConnection's internal pool. Only applicable when EnableRoutableQueries = true. **Default:** 20
MaxPooledConnections PerNode	Per-node maximum number of connections to keep in the VerticaRoutableConnection's internal pool. Only applicable when EnableRoutableQueries = true. **Default:** 5

> **Note**
> You can also use VerticaConnection.setProperty() method to set properties that have standard JDBC Connection setters, such as AutoCommit.

For information about manipulating these attributes, see Setting and getting connection property values .

Setting and getting connection property values

You can set a connection property in one of the following ways:

- Include the property name and value as part of the connection string you pass to the method DriverManager.getConnection() .
- Set the properties in a Properties object, and then pass it to the method DriverManager.getConnection() .
- Use the method VerticaConnection.setProperty() . With this approach, you can change only those connection properties that remain changeable after the connection has been established.

Also, some standard JDBC connection properties have getters and setters on the Connection interface, such as Connection.setAutoCommit() .

Setting properties when connecting

When creating a connection to Vertica, you can set connection properties by:

- Specifying them in the connection string.
- Modifying the Properties object passed to getConnection() .

Connection string properties

You can specify connection properties in the connection string with the same URL parameter format used for usernames and passwords. For example, the following string enables a TLS connection:

```
"jdbc:vertica://VerticaHost:5433/db?user=UserName&password=Password&TLSmode=require"
```

Setting a host name using the setProperty() method overrides the host name set in a connection string. If this occurs, Vertica might not be able to connect to a host. For example, using the connection string above, the following overrides the VerticaHost name:

```
Properties props = new Properties();
props.setProperty("dataSource", dataSourceURL);
props.setProperty("database", database);
props.setProperty("user", user);
props.setProperty("password", password);
ps.setProperty("jdbcDriver", jdbcDriver);
props.setProperty("hostName", "NonVertica_host");
```

However, if a new connection or override connection is needed, you can enter a valid host name in the hostname properties object.

The NonVertica_host hostname overrides VerticaHost name in the connection string. To avoid this issue, comment out the props.setProperty("hostName", "NonVertica_host"); line:

```
//props.setProperty("hostName", "NonVertica_host");
```

Properties object

To set connection properties with the Properties object passed to the getConnection() call:

1. Import the java.util.Properties class to instantiate a Properties object.
2. Use the put() method to add name-value pairs to the object.

```
Properties myProp = new Properties();
myProp.put("user", "ExampleUser");
myProp.put("password", "password123");
myProp.put("LoginTimeout", "35");
Connection conn;
try {
   conn = DriverManager.getConnection(
      "jdbc:vertica://VerticaHost:/ExampleDB", myProp);
} catch (SQLException e) {
   e.printStackTrace();
}
```

> **Note**
> The data type of all of the values you set in the Properties object are strings, regardless of the property value's data type.

Getting and setting properties after connecting

After you establish a connection with Vertica, you can use the VerticaConnection methods getProperty() and setProperty() to set the values of some connection properties, respectively.

The VerticaConnection.getProperty() method lets you get the value of some connection properties. Use this method to change the value for properties that can be set after you establish a connection with Vertica.

Because these methods are Vertica-specific, you must cast your Connection object to the VerticaConnection interface with one of the following methods:

- Import the Connection object into your client application.
- Use a fully-qualified reference: com.vertica.jdbc.VerticaConnection .

The following example demonstrates getting and setting the value of the ReadOnly property .

```
import java.sql.*;
import java.util.Properties;
import com.vertica.jdbc.*;

public class SetConnectionProperties {
   public static void main(String[] args) {
      // Note: If your application needs to run under Java 5, you need to
      // load the JDBC driver using Class.forName() here.
      Properties myProp = new Properties();
      myProp.put("user", "ExampleUser");
      myProp.put("password", "password123");
      // Set ReadOnly to true initially
      myProp.put("ReadOnly", "true");
      Connection conn;
      try {
         conn = DriverManager.getConnection(
                     "jdbc:vertica://VerticaHost:5433/ExampleDB",
                     myProp);
         // Show state of the ReadOnly property. This was set at the
         // time the connection was created.
         System.out.println("ReadOnly state: "
                     + ((VerticaConnection) conn).getProperty(
                           "ReadOnly"));

         // Change it and show it again
         ((VerticaConnection) conn).setProperty("ReadOnly", false);
         System.out.println("ReadOnly state is now: " +
                     ((VerticaConnection) conn).getProperty(
                           "ReadOnly"));
         conn.close();
      } catch (SQLException e) {
         e.printStackTrace();
      }
   }
```

When run, the example prints the following on the standard output:

```
ReadOnly state: true
ReadOnly state is now: false
```

Configuring TLS for JDBC clients

To configure TLS for JDBC clients:

- Configure Vertica for client-server TLS .
- Set the keystore and truststore properties.
- Set the TLSmode parameter.
- (Optional) Run the SSL debug utility to test your configuration.

Setting keystore/truststore properties

You can set the keystore and truststore properties in the following ways, each with their own pros and cons:

- At the driver level.
- At the JVM level.

Driver-level configuration

If you use tools like DbVizualizer with many connections, configure the keystore and truststore with the JDBC connection properties . This does, however, expose these values in the connection string:

- KeyStorePath
- KeyStorePassword
- TrustStorePath

- TrustStorePassword

For example:

```
Properties props = new Properties();
props.setProperty("KeyStorePath", keystorepath);
props.setProperty("KeyStorePassword", keystorepassword);
props.setProperty("TrustStorePath", truststorepath);
props.setProperty("TrustStorePassword", truststorepassword);
```

JVM-level configuration

Setting keystore and truststore parameters at the JVM level excludes them from the connection string, which may be more accommodating for environments with more stringent security requirements:

- javax.net.ssl.keyStore
- javax.net.ssl.trustStore
- javax.net.ssl.keyStorePassword
- javax.net.ssl.trustStorePassword

For example:

```
System.setProperty("javax.net.ssl.keyStore","clientKeyStore.key");
System.setProperty("javax.net.ssl.trustStore","clientTrustStore.key");
System.setProperty("javax.net.ssl.keyStorePassword","new_keystore_password")
System.setProperty("javax.net.ssl.trustStorePassword","new_truststore_password");
```

Set the TLSmode connection property

You can set the TLSmode connection property to determine how certificates are handled. TLSmode is disabled by default.

TLSmode identifies the security level that Vertica applies to the JDBC connection. Vertica must be configured to handle TLS connections before you can establish an encrypted connection to it. See TLS protocol for details. Valid values are:

- disable : JDBC connects using plain text and implements no security measures.
- require : JDBC connects using TLS without verifying the CA certificate.
- verify-ca : JDBC connects using TLS and confirms that the server certificate has been signed by the certificate authority. This setting is equivalent to the deprecated ssl=true property.
- verify-full : JDBC connects using TLS, confirms that the server certificate has been signed by the certificate authority, and verifies that the host name matches the name provided in the server certificate.

If this property and the SSL property are set, this property takes precedence.

For example, to configure JDBC to connect to the server with TLS without verifying the CA certificate, you can set the TLSmode property to 'require' with the method VerticaConnection.setProperty() :

```
Properties props = new Properties();
props.setProperty("TLSmode", "verify-full");
```

Run the SSL debug utility

After configuring TLS, you can run the following for a debugging utility:

```
$ java -Djavax.net.debug=ssl
```

You can use several debug specifiers (options) with the debug utility. The specifiers help narrow the scope of the debugging information that is returned. For example, you could specify one of the options that prints handshake messages or session activity.

For information on the debug utility and its options, see Debugging Utilities in the Oracle document, JSSE Reference Guide .

For information on interpreting debug information, refer to the Oracle document, Debugging SSL/TLS Connections .

Setting and returning a client connection label

The JDBC Client has a method to set and return the client connection label: getClientInfo() and setClientInfo(). You can use these methods with the SQL Functions GET_CLIENT_LABEL and SET_CLIENT_LABEL .

When you use these two methods, make sure you pass the string value APPLICATIONNAME to both the setter and getter methods.

Use setClientInfo() to create a client label, and use getClientInfo() to return the client label:

```
import java.sql.*;
import java.util.Properties;

public class ClientLabelJDBC {

   public static void main(String[] args) {
      Properties myProp = new Properties();
      myProp.put("user", "dbadmin");
      myProp.put("password", "");
      myProp.put("loginTimeout", "35");
      Connection conn;
      try {
         conn = DriverManager.getConnection(
               "jdbc:vertica://docc05.verticacorp.com:5433/doccdb", myProp);
         System.out.println("Connected!");
         conn.setClientInfo("APPLICATIONNAME", "JDBC Client - Data Load");
         System.out.println("New Conn label: " + conn.getClientInfo("APPLICATIONNAME"));
         conn.close();
      } catch (SQLTransientConnectionException connException) {
         // There was a potentially temporary network error
         // Could automatically retry a number of times here, but
         // instead just report error and exit.
         System.out.print("Network connection issue: ");
         System.out.print(connException.getMessage());
         System.out.println(" Try again later!");
         return;
      } catch (SQLInvalidAuthorizationSpecException authException) {
         // Either the username or password was wrong
         System.out.print("Could not log into database: ");
         System.out.print(authException.getMessage());
         System.out.println(" Check the login credentials and try again.");
         return;
      } catch (SQLException e) {
         // Catch-all for other exceptions
         e.printStackTrace();
      }
   }
}
```

When you run this method, it prints the following result to the standard output:

```
Connected!
New Conn Label: JDBC Client - Data Load
```

Setting the locale for JDBC sessions

You set the locale for a connection while opening it by including a SET LOCALE statement in the ConnSettings property, or by executing a SET LOCALE statement at any time after opening the connection. Changing the locale of a Connection object affects all of the Statement objects you instantiated using it.

You can get the locale by executing a SHOW LOCALE query. The following example demonstrates setting the locale using ConnSettings and executing a statement, as well as getting the locale:

```
import java.sql.*;
import java.util.Properties;

public class GetAndSetLocale {
    public static void main(String[] args) {

    // If running under a Java 5 JVM, you need to load the JDBC driver
    // using Class.forname here

    Properties myProp = new Properties();
        myProp.put("user", "ExampleUser");
        myProp.put("password", "password123");

        // Set Locale to true en_GB on connection. After the connection
        // is established, the JDBC driver runs the statements in the
        // ConnSettings property.
        myProp.put("ConnSettings", "SET LOCALE TO en_GB");
        Connection conn;
        try {
            conn = DriverManager.getConnection(
                        "jdbc:vertica://VerticaHost:5433/ExampleDB",
                        myProp);

            // Execute a query to get the locale. The results should
            // show "en_GB" as the locale, since it was set by the
            // conn settings property.
            Statement stmt = conn.createStatement();
            ResultSet rs = null;
            rs = stmt.executeQuery("SHOW LOCALE");
            System.out.print("Query reports that Locale is set to: ");
            while (rs.next()) {
                System.out.println(rs.getString(2).trim());
            }

            // Now execute a query to set locale.
            stmt.execute("SET LOCALE TO en_US");

            // Run query again to get locale.
            rs = stmt.executeQuery("SHOW LOCALE");
            System.out.print("Query now reports that Locale is set to: ");
            while (rs.next()) {
                System.out.println(rs.getString(2).trim());
            }
            // Clean up
            conn.close();
        } catch (SQLException e) {
            e.printStackTrace();
        }
    }
```

Running the above example displays the following on the system console:

```
Query reports that Locale is set to: en_GB (LEN)
Query now reports that Locale is set to: en_US (LEN)
```

Notes:

- JDBC applications use a UTF-16 character set encoding and are responsible for converting any non-UTF-16 encoded data to UTF-16. Failing to convert the data can result in errors or the data being stored incorrectly.
- The JDBC driver converts UTF-16 data to UTF-8 when passing to the Vertica server and converts data sent by Vertica server from UTF-8 to UTF-16 .

Changing the transaction isolation level

Changing the transaction isolation level lets you choose how transactions prevent interference from other transactions. By default, the JDBC driver matches the transaction isolation level of the Vertica server. The Vertica default transaction isolation level is READ_COMMITTED , which means any changes made by a transaction cannot be read by any other transaction until after they are committed. This prevents a transaction from reading data inserted by another transaction that is later rolled back.

Vertica also supports the SERIALIZABLE transaction isolation level. This level locks tables to prevent queries from having the results of their WHERE clauses changed by other transactions. Locking tables can have a performance impact, since only one transaction is able to access the table at a time.

A transaction retains its isolation level until it completes, even if the session's isolation level changes during the transaction. Vertica internal processes (such as the Tuple Mover and refresh operations) and DDL operations always run at the SERIALIZABLE isolation level to ensure consistency.

You can change the transaction isolation level connection property after the connection has been established using the Connection object's setter (setTransactionIsolation()) and getter (getTransactionIsolation()). The value for transaction isolation property is an integer. The Connection interface defines constants to help you set the value in a more intuitive manner:

Constant	Value
Connection.TRANSACTION_READ_COMMITTED	2
Connection.TRANSACTION_SERIALIZABLE	8

Note
The Connection interface also defines several other transaction isolation constants (READ_UNCOMMITTED and REPEATABLE_READ). Since Vertica does not support these isolation levels, they are converted to READ_COMMITTED and SERIALIZABLE , respectively.

The following example demonstrates setting the transaction isolation level to SERIALIZABLE.

```
import java.sql.*;
import java.util.Properties;

public class SetTransactionIsolation {
  public static void main(String[] args) {
    Properties myProp = new Properties();
    myProp.put("user", "ExampleUser");
    myProp.put("password", "password123");
    Connection conn;
    try {
      conn = DriverManager.getConnection(
                "jdbc:vertica://VerticaHost:5433/ExampleDB",
                myProp);
      // Get default transaction isolation
      System.out.println("Transaction Isolation Level: "
                + conn.getTransactionIsolation());
      // Set transaction isolation to SERIALIZABLE
      conn.setTransactionIsolation(Connection.TRANSACTION_SERIALIZABLE);
      // Get the transaction isolation again
      System.out.println("Transaction Isolation Level: "
                + conn.getTransactionIsolation());
      conn.close();
    } catch (SQLException e) {
      e.printStackTrace();
    }
  }
```

Running the example results in the following being printed out to the console:

```
Transaction Isolation Level: 2Transaction Isolation Level: 8
```

Using a pooling data source

A pooling data source uses a collection of persistent connections in order to reduce the overhead of repeatedly opening network connections between the client and server. Opening a new connection for each request is more costly for both the server and the client than keeping a small pool of connections open constantly, ready to be used by new requests. When a request comes in, one of the pre-existing connections in the pool is assigned to it. Only if there are no free connections in the pool is a new connection created. Once the request is complete, the connection returns to the pool and waits to service another request.

The Vertica JDBC driver supports connection pooling as defined in the JDBC 4.0 standard. If you are using a J2EE-based application server in conjunction with Vertica, it should already have a built-in data pooling feature. All that is required is that the application server work with the PooledConnection interface implemented by Vertica's JDBC driver. An application server's pooling feature is usually well-tuned for the works loads that the server is designed to handle. See your application server's documentation for details on how to work with pooled connections. Normally, using pooled connections should be transparent in your code—you will just open connections and the application server will worry about the details of pooling them.

If you are not using an application server, or your application server does not offer connection pooling that is compatible with Vertica, you can use a third-party pooling library, such as the open-source c3p0 or DBCP libraries, to implement connection pooling.

> **Note**
> The Vertica Analytic Database client driver's native connection load balancing feature works with third-party connection pooling supplied by application servers and third-party pooling libraries. See Load balancing in JDBC for more information.

Load balancing in JDBC

Native connection load balancing

Native connection load balancing helps spread the overhead caused by client connections on the hosts in the Vertica database. Both the server and the client must enable native connection load balancing. If enabled by both, then when the client initially connects to a host in the database, the host picks a host to handle the client connection from a list of the currently up hosts in the database, and informs the client which host it has chosen.

If the initially-contacted host does not choose itself to handle the connection, the client disconnects, then opens a second connection to the host selected by the first host. The connection process to this second host proceeds as usual—if SSL is enabled, then SSL negotiations begin, otherwise the client begins the authentication process. See About native connection load balancing for details.

To enable native load balancing on your client, set the ConnectionLoadBalance connection parameter to true. The following example demonstrates:

- Connecting to the database several times with native connection load balancing enabled.
- Fetching the name of the node handling the connection from the V_MONITOR. CURRENT_SESSION system table.

```
import java.sql.*;
import java.util.Properties;
import java.sql.*;
import java.util.Properties;

public class JDBCLoadingBalanceExample {
    public static void main(String[] args) {
        Properties myProp = new Properties();
        myProp.put("user", "dbadmin");
        myProp.put("password", "example_password123");
        myProp.put("loginTimeout", "35");
        myProp.put("ConnectionLoadBalance", "1");
        Connection conn;

        for (int x = 1; x <= 4; x++) {
            try {
                System.out.print("Connect attempt #" + x + "...");
                conn = DriverManager.getConnection(
                    "jdbc:vertica://node01.example.com:5433/vmart", myProp);
                Statement stmt = conn.createStatement();
                // Set the load balance policy to round robin before testing the database's load balancing.
                stmt.execute("SELECT SET_LOAD_BALANCE_POLICY('ROUNDROBIN');");
                // Query system to table to see what node we are connected to. Assume a single row
                // in response set.
                ResultSet rs = stmt.executeQuery("SELECT node_name FROM v_monitor.current_session;");
                rs.next();
                System.out.println("Connected to node " + rs.getString(1).trim());
                conn.close();
            } catch (SQLTransientConnectionException connException) {
                // There was a potentially temporary network error
                // Could automatically retry a number of times here, but
                // instead just report error and exit.
                System.out.print("Network connection issue: ");
                System.out.print(connException.getMessage());
                System.out.println(" Try again later!");
                return;
            } catch (SQLInvalidAuthorizationSpecException authException) {
                // Either the username or password was wrong
                System.out.print("Could not log into database: ");
                System.out.print(authException.getMessage());
                System.out.println(" Check the login credentials and try again.");
                return;
            } catch (SQLException e) {
                // Catch-all for other exceptions
                e.printStackTrace();
            }
        }
    }
```

Running the previous example produces the following output:

```
Connect attempt #1...Connected to node v_vmart_node0002
Connect attempt #2...Connected to node v_vmart_node0003
Connect attempt #3...Connected to node v_vmart_node0001
Connect attempt #4...Connected to node v_vmart_node0002
```

Hostname-based load balancing

You can load balance workloads by resolving a single hostname to multiple IP addresses. When you specify the hostname for the DriverManager.getConnection() method, the hostname resolves to a random listed IP address from the each connection.

For example, the hostname verticahost.example.com has the following entries in etc/hosts :

```
192.0.2.0 verticahost.example.com
192.0.2.1 verticahost.example.com
192.0.2.2 verticahost.example.com
```

Specifying verticahost.example.com as the connection for DriverManager.getConnection() randomly resolves to one of the listed IP address.

JDBC connection failover

If a client application attempts to connect to a host in the Vertica cluster that is down, the connection attempt fails when using the default connection configuration. This failure usually returns an error to the user. The user must either wait until the host recovers and retry the connection or manually edit the connection settings to choose another host.

Due to Vertica Analytic Database's distributed architecture, you usually do not care which database host handles a client application's connection. You can use the client driver's connection failover feature to prevent the user from getting connection errors when the host specified in the connection settings is unreachable. The JDBC driver gives you several ways to let the client driver automatically attempt to connect to a different host if the one specified in the connection parameters is unreachable:

- Configure your DNS server to return multiple IP addresses for a host name. When you use this host name in the connection settings, the client attempts to connect to the first IP address from the DNS lookup. If the host at that IP address is unreachable, the client tries to connect to the second IP, and so on until it either manages to connect to a host or it runs out of IP addresses.
- Supply a list of backup hosts for the client driver to try if the primary host you specify in the connection parameters is unreachable.
- (JDBC only) Use driver-specific connection properties to manage timeouts before attempting to connect to the next node.

For all methods, the process of failover is transparent to the client application (other than specifying the list of backup hosts, if you choose to use the list method of failover). If the primary host is unreachable, the client driver automatically tries to connect to other hosts.

Failover only applies to the initial establishment of the client connection. If the connection breaks, the driver does not automatically try to reconnect to another host in the database.

Choosing a failover method

You usually choose to use one of the two failover methods. However, they do work together. If your DNS server returns multiple IP addresses and you supply a list of backup hosts, the client first tries all of the IPs returned by the DNS server, then the hosts in the backup list.

> **Note**
> If a host name in the backup host list resolves to multiple IP addresses, the client does not try all of them. It just tries the first IP address in the list.

The DNS method of failover centralizes the configuration client failover. As you add new nodes to your Vertica Analytic Database cluster, you can choose to add them to the failover list by editing the DNS server settings. All client systems that use the DNS server to connect to Vertica Analytic Database automatically use connection failover without having to change any settings. However, this method does require administrative access to the DNS server that all clients use to connect to the Vertica Analytic Database cluster. This may not be possible in your organization.

Using the backup server list is easier than editing the DNS server settings. However, it decentralizes the failover feature. You may need to update the application settings on each client system if you make changes to your Vertica Analytic Database cluster.

Using DNS failover

To use DNS failover, you need to change your DNS server's settings to map a single host name to multiple IP addresses of hosts in your Vertica Analytic Database cluster. You then have all client applications use this host name to connect to Vertica Analytic Database.

You can choose to have your DNS server return as many IP addresses for the host name as you want. In smaller clusters, you may choose to have it return the IP addresses of all of the hosts in your cluster. However, for larger clusters, you should consider choosing a subset of the hosts to return. Otherwise there can be a long delay as the client driver tries unsuccessfully to connect to each host in a database that is down.

Using the backup host list

To enable backup list-based connection failover, your client application has to specify at least one IP address or host name of a host in the BackupServerNode parameter. The host name or IP can optionally be followed by a colon and a port number. If not supplied, the driver defaults to the standard Vertica port number (5433). To list multiple hosts, separate them by a comma.

The following example demonstrates setting the BackupServerNode connection parameter to specify additional hosts for the connection attempt. The connection string intentionally has a non-existent node, so that the initial connection fails. The client driver has to resort to trying the backup hosts to establish a connection to Vertica.

```
import java.sql.*;
import java.util.Properties;

public class ConnectionFailoverExample {
   public static void main(String[] args) {
      // Assume using JDBC 4.0 driver on JVM 6+. No driver loading needed.
      Properties myProp = new Properties();
      myProp.put("user", "dbadmin");
      myProp.put("password", "vertica");
      // Set two backup hosts to be used if connecting to the first host
      // fails. All of these hosts will be tried in order until the connection
      // succeeds or all of the connections fail.
      myProp.put("BackupServerNode", "VerticaHost02,VerticaHost03");
      Connection conn;
      try {
         // The connection string is set to try to connect to a known
         // bnad host (in this case, a host that never existed).
         conn = DriverManager.getConnection(
               "jdbc:vertica://BadVerticaHost:5433/vmart", myProp);
         System.out.println("Connected!");
         // Query system to table to see what node we are connected to.
         // Assume a single row in response set.
         Statement stmt = conn.createStatement();
         ResultSet rs = stmt.executeQuery(
               "SELECT node_name FROM v_monitor.current_session;");
         rs.next();
         System.out.println("Connected to node " + rs.getString(1).trim());
         // Done with connection.
         conn.close();
      } catch (SQLException e) {
         // Catch-all for other exceptions
         e.printStackTrace();
      }
   }
```

When run, the example outputs output similar to the following on the system console:

```
Connected!
Connected to node v_vmart_node0002
```

Notice that the connection was made to the first node in the backup list (node 2).

Specifying connection timeouts

LoginTimeout controls the timeout for JDBC to establish establish a TCP connection with a node and log in to Vertica.

LoginNodeTimeout controls the timeout for JDBC to log in to the Vertica database. After the specified timeout, JDBC attempts to connect to the "next" node, which is determined by either the connection property BackupServerNode or DNS resolution. This is useful if the node is up, but something is wrong with the Vertica process.

LoginNetworkTimeout controls the timeout for JDBC to establish a TCP connection to a Vertica node. If you do not set this connection property, if the node to which the JDBC client attempts to connect is down, the JDBC client will wait "indefinitely," but practically, the system default timeout of 70 seconds is used. A typical use case for LoginNetworkTimeout is to let JDBC connect to another node if the current Vertica node is down for maintenance and modifying the JDBC application's connection string is infeasible.

NetworkTimeout controls the timeout for Vertica to respond to a request from a client after it has established a connection and logged in to the database.

To set these parameters in a connection string:

```
# LoginTimeout is 30 seconds, LoginNodeTimeout is 10 seconds, LoginNetworkTimeout is 2 seconds, NetworkTimeout is 0.5 seconds
Connection conn = DriverManager.getConnection("jdbc:vertica://VerticaHost:5433/verticadb?user=dbadmin&loginTimeout=30&loginNodeTimeout=10"&loginN
```

To set these parameters as a connection property:

```
Properties myProp = new Properties();
myProp.put("user", "dbadmin");
myProp.put("loginTimeout", "30"); // overall connection timeout is 30 seconds to make sure it is not too small for failover
myProp.put("loginNodeTimeout", "10"); // JDBC waits 10 seconds before attempting to connect to the next node if the Vertica process is running but does not respond
myProp.put("loginNetworkTimeout", "2"); // node connection timeout is 2 seconds
myProp.put("networkTimeout", "500"); // after the client has logged in, Vertica has 0.5 seconds to respond to each request
Connection conn = DriverManager.getConnection("jdbc:vertica://VerticaHost:5433/verticadb", myProp);
```

Interaction with load balancing

When native connection load balancing is enabled, the additional servers specified in the BackupServerNode connection parameter are only used for the initial connection to a Vertica host. If host redirects the client to another host in the database cluster to handle its connection request, the second connection does not use the backup node list. This is rarely an issue, since native connection load balancing is aware of which nodes are currently up in the database.

See Load balancing in JDBC for more information.

JDBC data types

The JDBC driver transparently converts most Vertica data types to the appropriate Java data type. In a few cases, a Vertica data type cannot be directly translated to a Java data type; these exceptions are explained in this section.

In this section

- The VerticaTypes class
- Numeric data alias conversion
- Using intervals with JDBC
- UUID values
- Complex types in JDBC
- Date types in JDBC

The VerticaTypes class

JDBC does not support all of the data types that Vertica supports. The Vertica JDBC client driver contains an additional class named VerticaTypes that helps you handle identifying these Vertica-specific data types. It contains constants that you can use in your code to specify Vertica data types. This class defines two different categories of data types:

- Vertica's 13 types of interval values. This class contains constant properties for each of these types. You can use these constants to select a specific interval type when instantiating members of the VerticaDayTimeInterval and VerticaYearMonthInterval classes:

  ```
  // Create a day to second interval.
  VerticaDayTimeInterval dayInt = new VerticaDayTimeInterval(
      VerticaTypes.INTERVAL_DAY_TO_SECOND, 10, 0, 5, 40, 0, 0, false);
  // Create a year to month interval.
  VerticaYearMonthInterval monthInt = new VerticaYearMonthInterval(
      VerticaTypes.INTERVAL_YEAR_TO_MONTH, 10, 6, false);
  ```

- Vertica UUID data type. One way you can use the VerticaTypes.UUID is to query a table's metadata to see if a column is a UUID. See UUID values for an example.

See the JDBC Documentation for more information on this class.

Numeric data alias conversion

The Vertica server supports data type aliases for integer, float and numeric types. The JDBC driver reports these as its basic data types (BIGINT, DOUBLE PRECISION, and NUMERIC), as follows:

Vertica Server Types and Aliases	Vertica JDBC Type

INTEGER INT INT8 BIGINT SMALLINT TINYINT	BIGINT
DOUBLE PRECISION FLOAT5 FLOAT8 REAL	DOUBLE PRECISION
DECIMAL NUMERIC NUMBER MONEY	NUMERIC

If a client application retrieves the values into smaller data types, Vertica JDBC driver does not check for overflows. The following example demonstrates the results of this overflow.

```
import java.sql.*;
import java.util.Properties;

public class JDBCDataTypes {
    public static void main(String[] args) {
        // If running under a Java 5 JVM, use you need to load the JDBC driver
        // using Class.forname here

        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser");
        myProp.put("password", "password123");
        Connection conn;
        try {
            conn = DriverManager.getConnection(
                    "jdbc:vertica://VerticaHost:5433/VMart",
                     myProp);
            Statement statement = conn.createStatement();
            // Create a table that will hold a row of different types of
            // numeric data.
            statement.executeUpdate(
                    "DROP TABLE IF EXISTS test_all_types cascade");
            statement.executeUpdate("CREATE TABLE test_all_types ("
                    + "c0 INTEGER, c1 TINYINT, c2 DECIMAL, "
                    + "c3 MONEY, c4 DOUBLE PRECISION, c5 REAL)");
            // Add a row of values to it.
            statement.executeUpdate("INSERT INTO test_all_types VALUES("
                    + "111111111111, 444, 555555555555.5555, "
                    + "77777777.77,  88888888888888888.88, "
                    + "10101010.10101010101010)");
            // Query the new table to get the row back as a result set.
            ResultSet rs = statement
```

```
                .executeQuery("SELECT * FROM test_all_types");
        // Get the metadata about the row, including its data type.
        ResultSetMetaData md = rs.getMetaData();
        // Loop should only run once...
        while (rs.next()) {
            // Print out the data type used to defined the column, followed
            // by the values retrieved using several different retrieval
            // methods.

            String[] vertTypes = new String[] {"INTEGER", "TINYINT",
                    "DECIMAL", "MONEY", "DOUBLE PRECISION", "REAL"};

            for (int x=1; x<7; x++) {
                System.out.println("\n\nColumn " + x + " (" + vertTypes[x-1]
                        + ")");
                System.out.println("\tgetColumnType()\t\t"
                        + md.getColumnType(x));
                System.out.println("\tgetColumnTypeName()\t"
                        + md.getColumnTypeName(x));
                System.out.println("\tgetShort()\t\t"
                        + rs.getShort(x));
                System.out.println("\tgetLong()\t\t" + rs.getLong(x));
                System.out.println("\tgetInt()\t\t" + rs.getInt(x));
                System.out.println("\tgetByte()\t\t" + rs.getByte(x));
            }
        }
        rs.close();
        statement.executeUpdate("drop table test_all_types cascade");
        statement.close();
    } catch (SQLException e) {
        e.printStackTrace();
    }
}
```

The above example prints the following on the console when run:

```
Column 1 (INTEGER)
    getColumnType()       -5
  getColumnTypeName()   BIGINT
  getShort()       455
  getLong()       111111111111
  getInt()       -558038585
  getByte()       -57
Column 2 (TINYINT)
  getColumnType()       -5
  getColumnTypeName()   BIGINT
  getShort()       444
  getLong()       444
  getInt()       444
  getByte()       -68
Column 3 (DECIMAL)
  getColumnType()       2
  getColumnTypeName()   NUMERIC
  getShort()       -1
  getLong()       55555555555
  getInt()       2147483647
  getByte()       -1
Column 4 (MONEY)
  getColumnType()       2
  getColumnTypeName()   NUMERIC
  getShort()       -13455
  getLong()       77777777
  getInt()       77777777
  getByte()       113
Column 5 (DOUBLE PRECISION)
  getColumnType()       8
  getColumnTypeName()   DOUBLE PRECISION
  getShort()       -1
  getLong()       88888888888888900
  getInt()       2147483647
  getByte()       -1
Column 6 (REAL)
  getColumnType()       8
  getColumnTypeName()   DOUBLE PRECISION
  getShort()       8466
  getLong()       10101010
  getInt()       10101010
  getByte()       18
```

Using intervals with JDBC

The JDBC standard does not contain a data type for intervals (the duration between two points in time). To handle Vertica's INTERVAL data type, you must use JDBC's database-specific object type.

When reading an interval value from a result set, use the ResultSet.getObject() method to retrieve the value, and then cast it to one of the Vertica interval classes: VerticaDayTimeInterval (which represents all ten types of day/time intervals) or VerticaYearMonthInterval (which represents all three types of year/month intervals).

> **Note**
> The units interval style is not supported. Do not use the SET INTERVALSTYLE statement to change the interval style in your client applications.

Using intervals in batch inserts

When inserting batches into tables that contain interval data, you must create instances of the VerticaDayTimeInterval or VerticaYearMonthInterval classes to hold the data you want to insert. You set values either when calling the class's constructor, or afterwards using setters. You then insert your interval values using the PreparedStatement.setObject() method. You can also use the .setString() method, passing it a string in " *DD HH* : *MM* : *SS* " or "

YY - MM " format.

The following example demonstrates inserting data into a table containing a day/time interval and a year/month interval:

```
import java.sql.*;
import java.util.Properties;
// You need to import the Vertica JDBC classes to be able to instantiate
// the interval classes.
import com.vertica.jdbc.*;

public class IntervalDemo {
    public static void main(String[] args) {
        // If running under a Java 5 JVM, use you need to load the JDBC driver
        // using Class.forname here
        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser");
        myProp.put("password", "password123");
        Connection conn;
        try {
            conn = DriverManager.getConnection(
                    "jdbc:vertica://VerticaHost:5433/VMart", myProp);
            // Create table for interval values
            Statement stmt = conn.createStatement();
            stmt.execute("DROP TABLE IF EXISTS interval_demo");
            stmt.executeUpdate("CREATE TABLE interval_demo("
                    + "DayInt INTERVAL DAY TO SECOND, "
                    + "MonthInt INTERVAL YEAR TO MONTH)");
            // Insert data into interval columns using
            // VerticaDayTimeInterval and VerticaYearMonthInterval
            // classes.
            PreparedStatement pstmt = conn.prepareStatement(
                    "INSERT INTO interval_demo VALUES(?,?)");
            // Create instances of the Vertica classes that represent
            // intervals.
            VerticaDayTimeInterval dayInt = new VerticaDayTimeInterval(10, 0,
                    5, 40, 0, 0, false);
            VerticaYearMonthInterval monthInt = new VerticaYearMonthInterval(
                    10, 6, false);
            // These objects can also be manipulated using setters.
            dayInt.setHour(7);
            // Add the interval values to the batch
            ((VerticaPreparedStatement) pstmt).setObject(1, dayInt);
            ((VerticaPreparedStatement) pstmt).setObject(2, monthInt);
            pstmt.addBatch();
            // Set another row from strings.
            // Set day interval in "days HH:MM:SS" format
            pstmt.setString(1, "10 10:10:10");
            // Set year to month value in "MM-YY" format
            pstmt.setString(2, "12-09");
            pstmt.addBatch();
            // Execute the batch to insert the values.
            try {
                pstmt.executeBatch();
            } catch (SQLException e) {
                System.out.println("Error message: " + e.getMessage());
            }
```

Reading interval values

You read an interval value from a result set using the ResultSet.getObject() method, and cast the object to the appropriate Vertica object class: VerticaDayTimeInterval for day/time intervals or VerticaYearMonthInterval for year/month intervals. This is easy to do if you know that the column contains an interval, and you know what type of interval it is. If your application cannot assume the structure of the data in the result set it reads in,

you can test whether a column contains a database-specific object type, and if so, determine whether the object belongs to either the VerticaDayTimeInterval or VerticaYearMonthInterval classes.

```
        // Retrieve the interval values inserted by previous demo.
        // Query the table to get the row back as a result set.
        ResultSet rs = stmt.executeQuery("SELECT * FROM interval_demo");
        // If you do not know the types of data contained in the result set,
        // you can read its metadata to determine the type, and use
        // additional information to determine the interval type.
        ResultSetMetaData md = rs.getMetaData();
        while (rs.next()) {
            for (int x = 1; x <= md.getColumnCount(); x++) {
                // Get data type from metadata
                int colDataType = md.getColumnType(x);
                // You can get the type in a string:
                System.out.println("Column " + x + " is a "
                        + md.getColumnTypeName(x));
                // Normally, you'd have a switch statement here to
                // handle all sorts of column types, but this example is
                // simplified to just handle database-specific types
                if (colDataType == Types.OTHER) {
                    // Column contains a database-specific type. Determine
                    // what type of interval it is. Assuming it is an
                    // interval...
                    Object columnVal = rs.getObject(x);
                    if (columnVal instanceof VerticaDayTimeInterval) {
                        // We know it is a date time interval
                        VerticaDayTimeInterval interval =
                                (VerticaDayTimeInterval) columnVal;
                        // You can use the getters to access the interval's
                        // data
                        System.out.print("Column " + x + "'s value is ");
                        System.out.print(interval.getDay() + " Days ");
                        System.out.print(interval.getHour() + " Hours ");
                        System.out.println(interval.getMinute()
                                + " Minutes");
                    } else if (columnVal instanceof VerticaYearMonthInterval) {
                        VerticaYearMonthInterval interval =
                                (VerticaYearMonthInterval) columnVal;
                        System.out.print("Column " + x + "'s value is ");
                        System.out.print(interval.getYear() + " Years ");
                        System.out.println(interval.getMonth() + " Months");
                    } else {
                        System.out.println("Not an interval.");
                    }
                }
            }
        }
    } catch (SQLException e) {
        e.printStackTrace();
    }
}
```

The example prints the following to the console:

```
Column 1 is a INTERVAL DAY TO SECOND
Column 1's value is 10 Days 7 Hours 5 Minutes
Column 2 is a INTERVAL YEAR TO MONTH
Column 2's value is 10 Years 6 Months
Column 1 is a INTERVAL DAY TO SECOND
Column 1's value is 10 Days 10 Hours 10 Minutes
Column 2 is a INTERVAL YEAR TO MONTH
Column 2's value is 12 Years 9 Months
```

Another option is to use database metadata to find columns that contain intervals.

```
// Determine the interval data types by examining the database
// metadata.
DatabaseMetaData dbmd = conn.getMetaData();
ResultSet dbMeta = dbmd.getColumns(null, null, "interval_demo", null);
int colcount = 0;
while (dbMeta.next()) {

  // Get the metadata type for a column.
  int javaType = dbMeta.getInt("DATA_TYPE");

  System.out.println("Column " + ++colcount + " Type name is " +
              dbMeta.getString("TYPE_NAME"));

  if(javaType == Types.OTHER) {
    // The SQL_DATETIME_SUB column in the metadata tells you
    // Specifically which subtype of interval you have.
    // The VerticaDayTimeInterval.isDayTimeInterval()
    // methods tells you if that value is a day time.
    //
    int intervalType = dbMeta.getInt("SQL_DATETIME_SUB");
    if(VerticaDayTimeInterval.isDayTimeInterval(intervalType)) {
      // Now you know it is one of the 10 day/time interval types.
      // When you select this column you can cast to
      // VerticaDayTimeInterval.
      // You can get more specific by checking intervalType
      // against each of the 10 constants directly, but
      // they all are represented by the same object.
      System.out.println("column " + colcount + " is a " +
                  "VerticaDayTimeInterval intervalType = "
                  + intervalType);
    } else if(VerticaYearMonthInterval.isYearMonthInterval(
                intervalType)) {
      //now you know it is one of the 3 year/month intervals,
      //and you can select the column and cast to
      // VerticaYearMonthInterval
      System.out.println("column " + colcount + " is a " +
                  "VerticaDayTimeInterval intervalType = "
                  + intervalType);
    } else {
      System.out.println("Not an interval type.");
    }
  }
```

UUID values

UUID is a core data type in Vertica. However, it is not a core Java data type. You must use the java.util.UUID class to represent UUID values in your Java code. The JDBC driver does not translate values from Vertica to non-core Java data types. Therefore, you must send UUID values to Vertica using generic object methods such as PreparedStatement.setObject() . You also use generic object methods (such as ResultSet.getObject()) to retrieve UUID values from Vertica. You then cast the retrieved objects as a member of the java.util.UUID class.

The following example code demonstrates inserting UUID values into and retrieving UUID values from Vertica.

```
package jdbc_uuid_example;

import java.sql.*;
import java.util.Properties;

public class VerticaUUIDExample {

    public static void main(String[] args) {

        Properties myProp = new Properties();
        myProp.put("user", "dbadmin");
        myProp.put("password", "");
        Connection conn;

        try {
            conn = DriverManager.getConnection("jdbc:vertica://doch01:5433/VMart",
                                               myProp);
            Statement stmt = conn.createStatement();

            // Create a table with a UUID column and a VARCHAR column.
            stmt.execute("DROP TABLE IF EXISTS UUID_TEST CASCADE;");
            stmt.execute("CREATE TABLE UUID_TEST (id UUID, description VARCHAR(25));");

            // Prepare a statement to insert a UUID and a string into the table.
            PreparedStatement ps = conn.prepareStatement("INSERT INTO UUID_TEST VALUES(?,?)");

            java.util.UUID uuid;  // Holds the UUID value.

            for (Integer x = 0; x < 10; x++) {
                // Generate a random uuid
                uuid = java.util.UUID.randomUUID();
                // Set the UUID value by calling setObject.
                ps.setObject(1, uuid);
                // Set the String value to indicate which UUID this is.
                ps.setString(2, "UUID #" + x);
                ps.execute();
            }

            // Query the uuid
            ResultSet rs = stmt.executeQuery("SELECT * FROM UUID_TEST ORDER BY description ASC");
            while (rs.next()) {
                // Cast the object from the result set as a UUID.
                uuid = (java.util.UUID) rs.getObject(1);
                System.out.println(rs.getString(2) + " : " +  uuid.toString());
            }
        } catch (SQLException e) {
            e.printStackTrace();
        }
    }
```

The previous example prints output similar to the following:

```
UUID #0 : 67b6dcb6-c28c-4965-b9f7-5c830a04664d
UUID #1 : 485d3835-2887-4233-b003-392254fa97e0
UUID #2 : 81421f51-c803-473d-8cfc-2c184582a117
UUID #3 : bec8b86a-b650-47b0-852c-8229155332d9
UUID #4 : 8ae5e3ec-d143-4ef7-8901-24f6d0483abf
UUID #5 : 669696ce-5e86-4e87-b8d0-a937f5fc18d7
UUID #6 : 19609ec9-ec56-4444-9cfe-ad2b8de537dd
UUID #7 : 97182e1d-5c7e-4da1-9922-67e804fde173
UUID #8 : c76c3a2b-a9ef-4d65-b2fb-7c637f872b3c
UUID #9 : 3cbbcd26-c177-4277-b3df-bf4d9389f69d
```

Determining whether a column has a UUID data type

JDBC does not support the UUID data type. This limitation means you cannot use the usual ResultSetMetaData.getColumnType() method to determine column's data type is UUID. Calling this method on a UUID column returns Types.OTHER . This value is also to identify interval columns. You can use two ways to determine if a column contains UUIDs:

- Use ResultSetMetaData.getColumnTypeName() to get the name of the column's data type. For UUID columns, this method returns the value "Uuid" as a String .
- Query the table's metadata to get the SQL data type of the column. If this value is equal to VerticaTypes.UUID , the column's data type is UUID.

The following example demonstrates both of these techniques:

```
// This example assumes you already have a database connection
// and result set from a query on a table that may contain a UUID.

//  Get the metadata of the result set to get the column definitions
ResultSetMetaData meta = rs.getMetaData();
int colcount;
int maxcol = meta.getColumnCount();

System.out.println("Using column metadata:");
for (colcount = 1; colcount < maxcol; colcount++) {
// .getColumnType() always returns "OTHER" for UUID columns.
    if (meta.getColumnType(colcount) == Types.OTHER) {
        // To determine that it is a UUID column, test the name of the column type.
        if (meta.getColumnTypeName(colcount).equalsIgnoreCase("uuid")) {
            // It's a UUID column
            System.out.println("Column "+ colcount + " is UUID");
        }
    }
}

// You can also query the table's metadata to find its column types and compare
// it to the VerticaType.UUID constant to see if it is a UUID column.
System.out.println("Using table metadata:");
DatabaseMetaData dbmd = conn.getMetaData();
// Get the metdata for the previously-created test table.
ResultSet tableMeta = dbmd.getColumns(null, null, "UUID_TEST", null);
colcount = 0;
// Each row in the result set has metadata that describes a single column.
while (tableMeta.next()) {
    colcount++;
    // The SQL_DATA_TYPE column holds the Vertica database data type. You compare
    // this value to the VerticvaTypes.UUID constant to see if it is a UUID.
    if (tableMeta.getInt("SQL_DATA_TYPE") == VerticaTypes.UUID) {
        // Column is a UUID data type...
        System.out.println("Column " + colcount + " is a UUID column.");
    }
}
```

This example prints the following to the console if it is run after running the prior example:

```
Using column metadata:
Column 1 is UUID
Using table metadata:
Column 1 is a UUID column.
```

Complex types in JDBC

The results of a java.sql query are stored in a ResultSet . If the ResultSet contains a column of complex type , you can retrieve it with one of the following:

- For columns of type ARRAY , SET , or MAP , use getArray() , which returns a java.sql.Array .
- For columns of type ROW , use getObject() , which returns a java.sql.Struct .

Type conversion table

The objects java.sql.Array and java.sql.Struct each have their own API for accessing complex type data. In each case, the data is returned as java.lang.Object and will need to be type cast to a Java type. The exact Java type to expect depends on the Vertica type used in the complex type definition, as shown in this type conversion table:

java.sql Type	Vertica Type	Java Type
BIT	BOOL	java.lang.Boolean
BIGINT	INT	java.lang.Long
DOUBLE	FLOAT	java.lang.Double
CHAR	CHAR	java.lang.String
VARCHAR	VARCHAR	java.lang.String
LONGVARCHAR	LONGVARCHAR	java.lang.String
DATE	DATE	java.sql.Date
TIME	TIME	java.sql.Time
TIME	TIMETZ	java.sql.Time
TIMESTAMP	TIMESTAMP	java.sql.Timestamp
TIMESTAMP	TIMESTAMPTZ	com.vertica.dsi.dataengine.utilities.TimestampTz
getIntervalRange(oid, typmod)	INTERVAL	com.vertica.jdbc.VerticaDayTimeInterval
getIntervalRange(oid, typmod)	INTERVALYM	com.vertica.jdbc.VerticaYearMonthInterval
BINARY	BINARY	byte[]
VARBINARY	VARBINARY	byte[]
LONGVARBINARY	LONGVARBINARY	byte[]
NUMERIC	NUMERIC	java.math.BigDecimal
TYPE_SQL_GUID	UUID	java.util.UUID
ARRAY	ARRAY	java.lang.Object[]

ARRAY	SET	java.lang.Object[]
STRUCT	ROW	java.sql.Struct
ARRAY	MAP	java.lang.Object[]

ARRAY, SET, and MAP columns

For example, the following methods run queries that return an ARRAY of some Vertica type, which is then type cast to an array of its corresponding Java type by the JDBC driver when retrieved with getArray() . This particular example starts with ARRAY[INT] and ARRAY[FLOAT], so they are type cast to Long[] and Double[] , respectively, as determined by the type conversion table.

- getArrayResultSetExample() shows how the ARRAY can be processed as a java.sql.ResultSet . This example uses getResultSet() which returns the underlying array as another ResultSet . You can use this underlying ResultSet to:
  - Retrieve the parent ResultSet .
  - Treat it as an Object array or ResultSet .
- getArrayObjectExample() shows how the ARRAY can be processed as a native Java array. This example uses getArray() which returns the underlying array as an Object array rather than a ResultSet . This has the following implications:
  - You cannot use an underlying Object array to retrieve its parent array.
  - All underlying arrays are treated as Object arrays (rather than ResultSet s.

```
package com.vertica.jdbc.test.samples;

import java.sql.Connection;
import java.sql.SQLException;
import java.sql.Statement;
import java.sql.ResultSet;
import java.sql.Array;
import java.sql.Struct;

public class ComplexTypesArraySamples
{
  /**
   * Executes a query and gets a java.sql.Array from the ResultSet. It then uses the Array#getResultSet
   * method to get a ResultSet containing the contents of the array.
   * @param conn A Connection to a Vertica database
   * @throws SQLException
   */
  public static void getArrayResultSetExample (Connection conn) throws SQLException {
    Statement stmt = conn.createStatement();

    final String queryText = "SELECT ARRAY[ARRAY[1,2,3],ARRAY[4,5,6],ARRAY[7,8,9]]::ARRAY[ARRAY[INT]] as array";
    final String targetColumnName = "array";

    System.out.println ("queryText: " + queryText);
    ResultSet rs = stmt.executeQuery(queryText);
    int targetColumnId = rs.findColumn (targetColumnName);

    while (rs.next ()) {
      Array currentSqlArray = rs.getArray (targetColumnId);
      ResultSet level1ResultSet = currentSqlArray.getResultSet();
      if (level1ResultSet != null) {
        while (level1ResultSet.next ()) {
          // The first column of the result set holds the row index
          int i = level1ResultSet.getInt(1) - 1;
          Array level2SqlArray = level1ResultSet.getArray (2);
          Object level2Object = level2SqlArray.getArray ();
          // For this ARRAY[INT], the driver returns a Long[]
          assert (level2Object instanceof Long[]);
          Long [] level2Array = (Long [])level2Object;
```

```
            System.out.println (" level1Object [" + i + "]: " + level2SqlArray.toString () + " (" + level2SqlArray.getClass() + ")");

            for (int j = 0; j < level2Array.length; j++) {
              System.out.println (" Value [" + i + ", " + j + "]: " + level2Array[j] + " (" + level2Array[j].getClass() + ")");
            }
          }
        }
      }
    }

/**
 * Executes a query and gets a java.sql.Array from the ResultSet. It then uses the Array#getArray
 * method to get the contents of the array as a Java Object [].
 * @param conn A Connection to a Vertica database
 * @throws SQLException
 */
public static void getArrayObjectExample (Connection conn) throws SQLException {
    Statement stmt = conn.createStatement();

    final String queryText = "SELECT ARRAY[ARRAY[0.0,0.1,0.2],ARRAY[1.0,1.1,1.2],ARRAY[2.0,2.1,2.2]]::ARRAY[ARRAY[FLOAT]] as array";
    final String targetColumnName = "array";

    System.out.println ("queryText: " + queryText);
    ResultSet rs = stmt.executeQuery(queryText);
    int targetColumnId = rs.findColumn (targetColumnName);

    while (rs.next ()) {
      // Get the java.sql.Array from the result set
      Array currentSqlArray = rs.getArray (targetColumnId);
      // Get the internal Java Object implementing the array
      Object level1ArrayObject = currentSqlArray.getArray ();
      if (level1ArrayObject != null) {
        // All returned instances are Object[]
        assert (level1ArrayObject instanceof Object[]);
        Object [] level1Array = (Object [])level1ArrayObject;
        System.out.println ("Vertica driver returned a: " + level1Array.getClass());

        for (int i = 0; i < level1Array.length; i++) {
          Object level2Object = level1Array[i];
          // For this ARRAY[FLOAT], the driver returns a Double[]
          assert (level2Object instanceof Double[]);
          Double [] level2Array = (Double [])level2Object;
          for (int j = 0; j < level2Array.length; j++) {
            System.out.println (" Value [" + i + ", " + j + "]: " + level2Array[j] + " (" + level2Array[j].getClass() + ")");
          }
        }
      }
    }
}
```

The output of getArrayResultSetExample() shows that the Vertica column type ARRAY[INT] is type cast to Long[] :

```
queryText: SELECT ARRAY[ARRAY[1,2,3],ARRAY[4,5,6],ARRAY[7,8,9]]::ARRAY[ARRAY[INT]] as array
 level1Object [0]: [1,2,3] (class com.vertica.jdbc.jdbc42.S42Array)
 Value [0, 0]: 1 (class java.lang.Long)
 Value [0, 1]: 2 (class java.lang.Long)
 Value [0, 2]: 3 (class java.lang.Long)
 level1Object [1]: [4,5,6] (class com.vertica.jdbc.jdbc42.S42Array)
 Value [1, 0]: 4 (class java.lang.Long)
 Value [1, 1]: 5 (class java.lang.Long)
 Value [1, 2]: 6 (class java.lang.Long)
 level1Object [2]: [7,8,9] (class com.vertica.jdbc.jdbc42.S42Array)
 Value [2, 0]: 7 (class java.lang.Long)
 Value [2, 1]: 8 (class java.lang.Long)
 Value [2, 2]: 9 (class java.lang.Long)
```

The output of getArrayObjectExample() shows that the Vertica column type ARRAY[FLOAT] is type cast to Double[] :

```
queryText: SELECT ARRAY[ARRAY[0.0,0.1,0.2],ARRAY[1.0,1.1,1.2],ARRAY[2.0,2.1,2.2]]::ARRAY[ARRAY[FLOAT]] as array
Vertica driver returned a: class [Ljava.lang.Object;
 Value [0, 0]: 0.0 (class java.lang.Double)
 Value [0, 1]: 0.1 (class java.lang.Double)
 Value [0, 2]: 0.2 (class java.lang.Double)
 Value [1, 0]: 1.0 (class java.lang.Double)
 Value [1, 1]: 1.1 (class java.lang.Double)
 Value [1, 2]: 1.2 (class java.lang.Double)
 Value [2, 0]: 2.0 (class java.lang.Double)
 Value [2, 1]: 2.1 (class java.lang.Double)
 Value [2, 2]: 2.2 (class java.lang.Double)
```

ROW columns

Calling getObject() on a java.sql.ResultSet that contains a column of type ROW retrieves the column as a java.sql.Struct which contains an Object[] (itself retrievable with getAttributes()).

Each element of the Object[] represents an attribute from the struct, and each attribute has a corresponding Java type shown in the type conversion table above.

This example defines a ROW with the following attributes:

```
 Name    | Value        | Vertica Type | Java Type
-----------------------------------------------------------------
 name    | Amy          | VARCHAR      | String
 date    | '07/10/2021' | DATE         | java.sql.Date
 id      | 5            | INT          | java.lang.Long
 current | false        | BOOLEAN      | java.lang.Boolean
```

```
package com.vertica.jdbc.test.samples;

import java.sql.Connection;
import java.sql.SQLException;
import java.sql.Statement;
import java.sql.ResultSet;
import java.sql.Array;
import java.sql.Struct;

public class ComplexTypesSamples
{
    /**
     * Executes a query and gets a java.sql.Struct from the ResultSet. It then uses the Struct#getAttributes
     * method to get the contents of the struct as a Java Object [].
     * @param conn A Connection to a Vertica database
     * @throws SQLException
     */
    public static void getRowExample (Connection conn) throws SQLException {
        Statement stmt = conn.createStatement();

        final String queryText = "SELECT ROW('Amy', '07/10/2021'::Date, 5, false) as rowExample(name, date, id, current)";
        final String targetColumnName = "rowExample";

        System.out.println ("queryText: " + queryText);
        ResultSet rs = stmt.executeQuery(queryText);
        int targetColumnId = rs.findColumn (targetColumnName);

        while (rs.next ()) {
            // Get the java.sql.Array from the result set
            Object currentObject = rs.getObject (targetColumnId);
            assert (currentObject instanceof Struct);
            Struct rowStruct = (Struct)currentObject;

            Object[] attributes = rowStruct.getAttributes();

            // attributes.length should be 4 based on the queryText
            assert (attributes.length == 4);
            assert (attributes[0] instanceof String);
            assert (attributes[1] instanceof java.sql.Date);
            assert (attributes[2] instanceof java.lang.Long);
            assert (attributes[3] instanceof java.lang.Boolean);

            System.out.println ("attributes[0]: " + attributes[0] + " (" + attributes[0].getClass().getName() +")");
            System.out.println ("attributes[1]: " + attributes[1] + " (" + attributes[1].getClass().getName() +")");
            System.out.println ("attributes[2]: " + attributes[2] + " (" + attributes[2].getClass().getName() +")");
            System.out.println ("attributes[3]: " + attributes[3] + " (" + attributes[3].getClass().getName() +")");
        }
    }
```

The output of getRowExample() shows the attribute of each element and its corresponding Java type:

```
queryText: SELECT ROW('Amy', '07/10/2021'::Date, 5, false) as rowExample(name, date, id, current)
attributes[0]: Amy (java.lang.String)
attributes[1]: 2021-07-10 (java.sql.Date)
attributes[2]: 5 (java.lang.Long)
attributes[3]: false (java.lang.Boolean)
```

Date types in JDBC

Converting a date to a string

For the purposes of this page, a large date is defined as a date with a year that exceeds 9999.

If your database doesn't contain any large dates , then you can reliably call toString() to convert the dates to strings.

Otherwise, if your database contains large dates, you should use java.text.SimpleDateFormat and its format() method:

1. Define a String format with java.text.SimpleDateFormat . The number of characters in yyyy in the format defines the minimum number of characters to use in the date.
2. Call SimpleDateFormat.format() to convert the java.sql.Date object to a String.

Examples

For example, the following method returns a string when passed a java.sql.Date object as an argument. Here, the year part of the format, YYYY indicates that this format is compatible with all dates with at least four characters in its year.

```
#import java.sql.Date;

private String convertDate (Date date) {
   SimpleDateFormat dateFormat = new SimpleDateFormat ("yyyy-MM-dd");
   return dateFormat.format (date);
```

Executing queries through JDBC

To run a query through JDBC:

1. Connect with the Vertica database. See Creating and configuring a connection .
2. Run the query.

The method you use to run the query depends on the type of query you want to run:

- a DDL query that does not return a result set.
- a DDL query that returns a result set.
- a DML query

Executing DDL (data definition language) queries

To run DDL queries, such as CREATE TABLE and COPY , use the Statement.execute() method. You get an instance of this class by calling the createStatement method of your connection object.

The following example creates an instance of the Statement class and uses it to execute a CREATE TABLE and a COPY query:

```
Statement stmt = conn.createStatement();
stmt.execute("CREATE TABLE address_book (Last_Name char(50) default '',' +
   "First_Name char(50),Email char(50),Phone_Number char(50))");
stmt.execute("COPY address_book FROM 'address.dat' DELIMITER ',' NULL 'null'");
```

Executing queries that return result sets

Use the Statement class's executeQuery method to execute queries that return a result set, such as SELECT . To get the data from the result set, use methods such as getInt , getString , and getDouble to access column values depending upon the data types of columns in the result set. Use ResultSet.next to advance to the next row of the data set.

```
ResultSet rs = null;
rs = stmt.executeQuery("SELECT First_Name, Last_Name FROM address_book");
int x = 1;
while(rs.next()){
   System.out.println(x + ". " + rs.getString(1).trim() + " "
                  + rs.getString(2).trim());
   x++;
```

> **Note**
> The Vertica JDBC driver does not support scrollable cursors. You can only read forwards through the result set.

Executing DML (data manipulation language) queries using executeUpdate

Use the executeUpdate method for DML SQL queries that change data in the database, such as INSERT , UPDATE and DELETE which do not return a result set.

```
stmt.executeUpdate("INSERT INTO address_book " +
                   "VALUES ('Ben-Shachar', 'Tamar', 'tamarrow@example.com'," +
                   "'555-380-6466')");
stmt.executeUpdate("INSERT INTO address_book (First_Name, Email) " +
                   "VALUES ('Pete','pete@example.com')");
```

> **Note**
> The Vertica JDBC driver's Statement class supports executing multiple statements in the SQL string you pass to the execute method. The PreparedStatement class does not support using multiple statements in a single execution.

Loading data through JDBC

You can use any of the following methods to load data via the JDBC interface:

- Executing a SQL INSERT statement to insert a single row directly.
- Batch loading data using a prepared statement.
- Bulk loading data from files or streams using COPY .

The following sections explain in detail how you load data using JDBC.

In this section

- Using a single row insert
- Batch inserts using JDBC prepared statements
- Bulk loading using the COPY statement
- Streaming data via JDBC

Using a single row insert

The simplest way to insert data into a table is to use the SQL INSERT statement. You can use this statement by instantiating a member of the Statement class, and use its executeUpdate() method to run your SQL statement.

The following code fragment demonstrates how you can create a Statement object and use it to insert data into a table named address_book:

```
Statement stmt = conn.createStatement();
stmt.executeUpdate("INSERT INTO address_book " +
                   "VALUES ('Smith', 'John', 'jsmith@example.com', " +
                   "'555-123-4567')");
```

This method has a few drawbacks: you need convert your data to string and escape any special characters in your data. A better way to insert data is to use prepared statements. See Batch inserts using JDBC prepared statements .

Batch inserts using JDBC prepared statements

You can load batches of data into Vertica using prepared INSERT statements—server-side statements that you set up once, and then call repeatedly. You instantiate a member of the PreparedStatement class with a SQL statement that contains question mark placeholders for data. For example:

```
PreparedStatement pstmt = conn.prepareStatement(
                   "INSERT INTO customers(last, first, id) VALUES(?,?,?)");
```

You then set the parameters using data-type-specific methods on the PreparedStatement object, such as setString() and setInt() . Once your parameters are set, call the addBatch() method to add the row to the batch. When you have a complete batch of data ready, call the executeBatch() method to execute the insert batch.

Behind the scenes, the batch insert is converted into a COPY statement. When the connection's AutoCommit parameter is disabled, Vertica keeps the COPY statement open and uses it to load subsequent batches until the transaction is committed, the cursor is closed, or your application executes anything else (or executes any statement using another Statement or PreparedStatement object). Using a single COPY statement for multiple batch

inserts makes loading data more efficient. If you are loading multiple batches, you should disable the AutoCommit property of the database to take advantage of this increased efficiency.

When performing batch inserts, experiment with various batch and row sizes to determine the settings that provide the best performance.

The following example demonstrates using a prepared statement to batch insert data.

```
import java.sql.*;
import java.util.Properties;

public class BatchInsertExample {
   public static void main(String[] args) {
      Properties myProp = new Properties();
      myProp.put("user", "ExampleUser");
      myProp.put("password", "password123");

    //Set streamingBatchInsert to True to enable streaming mode for batch inserts.
    //myProp.put("streamingBatchInsert", "True");

    Connection conn;
      try {
         conn = DriverManager.getConnection(
                     "jdbc:vertica://VerticaHost:5433/ExampleDB",
                     myProp);
         // establish connection and make a table for the data.
         Statement stmt = conn.createStatement();

         // Set AutoCommit to false to allow Vertica to reuse the same
         // COPY statement
         conn.setAutoCommit(false);

         // Drop table and recreate.
         stmt.execute("DROP TABLE IF EXISTS customers CASCADE");
         stmt.execute("CREATE TABLE customers (CustID int, Last_Name"
                     + " char(50), First_Name char(50),Email char(50), "
                     + "Phone_Number char(12))");
         // Some dummy data to insert.
         String[] firstNames = new String[] { "Anna", "Bill", "Cindy",
                  "Don", "Eric" };
         String[] lastNames = new String[] { "Allen", "Brown", "Chu",
                  "Dodd", "Estavez" };
         String[] emails = new String[] { "aang@example.com",
                  "b.brown@example.com", "cindy@example.com",
                  "d.d@example.com", "e.estavez@example.com" };
         String[] phoneNumbers = new String[] { "123-456-7890",
                  "555-444-3333", "555-867-5309",
                  "555-555-1212", "781-555-0000" };
         // Create the prepared statement
         PreparedStatement pstmt = conn.prepareStatement(
                  "INSERT INTO customers (CustID, Last_Name, " +
                  "First_Name, Email, Phone_Number)" +
                  " VALUES(?,?,?,?,?)");
         // Add rows to a batch in a loop. Each iteration adds a
         // new row.
         for (int i = 0; i < firstNames.length; i++) {
            // Add each parameter to the row.
            pstmt.setInt(1, i + 1);
            pstmt.setString(2, lastNames[i]);
            pstmt.setString(3, firstNames[i]);
            pstmt.setString(4, emails[i]);
```

```
            pstmt.setString(5, phoneNumbers[i]);
            // Add row to the batch.
            pstmt.addBatch();
        }

        try {
            // Batch is ready, execute it to insert the data
            pstmt.executeBatch();
        } catch (SQLException e) {
            System.out.println("Error message: " + e.getMessage());
            return; // Exit if there was an error
        }

        // Commit the transaction to close the COPY command
        conn.commit();

        // Print the resulting table.
        ResultSet rs = null;
        rs = stmt.executeQuery("SELECT CustID, First_Name, "
                    + "Last_Name FROM customers ORDER BY CustID");
        while (rs.next()) {
            System.out.println(rs.getInt(1) + " - "
                        + rs.getString(2).trim() + " "
                        + rs.getString(3).trim());
        }
        // Cleanup
        conn.close();
    } catch (SQLException e) {
        e.printStackTrace();
    }
}
```

The result of running the example code is:

```
1 - Anna Allen
2 - Bill Brown
3 - Cindy Chu
4 - Don Dodd
5 - Eric Estavez
```

Streaming batch inserts

By default, Vertica performs batch inserts by caching each row and inserting the cache when the user calls the executeBatch() method. Vertica also supports streaming batch inserts. A streaming batch insert adds a row to the database each time the user calls addBatch() . Streaming batch inserts improve database performance by allowing parallel processing and reducing memory demands.

> **Note**
> Once you begin a streaming batch insert, you cannot make other JDBC calls that require client-server communication until you have executed the batch or closed or rolled back the connection.

To enable streaming batch inserts, set the streamingBatchInsert property to True. The preceding code sample includes a line enabling streamingBatchInsert mode. Remove the // comment marks to enable this line and activate streaming batch inserts.

The following table explains the various batch insert methods and how their behavior differs between default batch insert mode and streaming batch insert mode.

Method	Default Batch Insert Behavior	Streaming Batch Insert Behavior

addBatch()	Adds a row to the row cache.	Inserts a row into the database.
executeBatch()	Adds the contents of the row cache to the database in a single action.	Sends an end-of-batch message to the server and returns an array of integers indicating the success or failure of each addBatch() attempt.
clearBatch()	Clears the row cache without inserting any rows.	Not supported. Triggers an exception if used when streaming batch inserts are enabled.

Notes

- Using the PreparedStatement.setFloat() method can cause rounding errors. If precision is important, use the .setDouble() method instead.
- The PreparedStatement object caches the connection's AutoCommit property when the statement is prepared. Later changes to the AutoCommit property have no effect on the prepared statement.

In this section

- Error handling during batch loads
- Identifying accepted and rejected rows (JDBC)
- Rolling back batch loads on the server

Error handling during batch loads

When loading individual batches, you can find how many rows were accepted and what rows were rejected (see Identifying Accepted and Rejected Rows for details). If you have disabled the AutoCommit connection setting, other errors (such as disk space errors, for example) do not occur while inserting individual batches. This behavior is caused by having a single SQL COPY statement perform the loading of multiple consecutive batches (which makes the load process more efficient). It is only when the COPY statement closes that the batched data is committed and Vertica reports other types of errors.

Therefore, your bulk loading application should be prepared to check for errors when the COPY statement closes. You can trigger the COPY statement to close by:

- ending the batch load transaction by calling Connection.commit()
- closing the statement using Statement.close()
- setting the connection's AutoCommit property to true before inserting the last batch in the load

> **Note**
> The COPY statement also closes if you execute any non-insert statement or execute any statement using a different Statement or PreparedStatement object. Ending the COPY statement using either of these methods can lead to confusion and a harder-to-maintain application, since you would need to handle batch load errors in a non-batch load statement. You should explicitly end the COPY statement at the end of your batch load and handle any errors at that time.

Identifying accepted and rejected rows (JDBC)

The return value of PreparedStatement.executeBatch is an integer array containing the success or failure status of inserting each row. A value 1 means the row was accepted and a value of -3 means that the row was rejected. In the case where an exception occurred during the batch execution, you can also get the array using BatchUpdateException.getUpdateCounts() .

The following example extends the example shown in Batch inserts using JDBC prepared statements to retrieve this array and display the results the batch load.

```
import java.sql.*;
import java.util.Arrays;
import java.util.Properties;

public class BatchInsertErrorHandlingExample {
  public static void main(String[] args) {
    Properties myProp = new Properties();
    myProp.put("user", "ExampleUser");
    myProp.put("password", "password123");
    Connection conn;
```

```
// establish connection and make a table for the data.
try {
    conn = DriverManager.getConnection(
                  "jdbc:vertica://VerticaHost:5433/ExampleDB",
                  myProp);

    // Disable auto commit
    conn.setAutoCommit(false);

    // Create a statement
    Statement stmt = conn.createStatement();
    // Drop table and recreate.
    stmt.execute("DROP TABLE IF EXISTS customers CASCADE");
    stmt.execute("CREATE TABLE customers (CustID int, Last_Name"
                  + " char(50), First_Name char(50),Email char(50), "
                  + "Phone_Number char(12))");

    // Some dummy data to insert. The one row won't insert because
    // the phone number is too long for the phone column.
    String[] firstNames = new String[] { "Anna", "Bill", "Cindy",
                  "Don", "Eric" };
    String[] lastNames = new String[] { "Allen", "Brown", "Chu",
                  "Dodd", "Estavez" };
    String[] emails = new String[] { "aang@example.com",
                  "b.brown@example.com", "cindy@example.com",
                  "d.d@example.com", "e.estavez@example.com" };
    String[] phoneNumbers = new String[] { "123-456-789",
                  "555-444-3333", "555-867-53093453453",
                  "555-555-1212", "781-555-0000" };

    // Create the prepared statement
    PreparedStatement pstmt = conn.prepareStatement(
                  "INSERT INTO customers (CustID, Last_Name, " +
                  "First_Name, Email, Phone_Number)" +
                  " VALUES(?,?,?,?,?)");

    // Add rows to a batch in a loop. Each iteration adds a
    // new row.
    for (int i = 0; i < firstNames.length; i++) {
        // Add each parameter to the row.
        pstmt.setInt(1, i + 1);
        pstmt.setString(2, lastNames[i]);
        pstmt.setString(3, firstNames[i]);
        pstmt.setString(4, emails[i]);
        pstmt.setString(5, phoneNumbers[i]);
        // Add row to the batch.
        pstmt.addBatch();
    }

    // Integer array to hold the results of inserting
    // the batch. Will contain an entry for each row,
    // indicating success or failure.
    int[] batchResults = null;

    try {
        // Batch is ready, execute it to insert the data
        batchResults = pstmt.executeBatch();
    } catch (BatchUpdateException e) {
        // We expect an exception here, since one of the
        // inserted phone numbers is too wide for its column. All of the
        // rows that did not have errors were inserted.
```

```
            // rest of the rows will be inserted.
            System.out.println("Error message: " + e.getMessage());

            // Batch results isn't set due to exception, but you
            // can get it from the exception object.
            //
            // In your own code, you shouldn't assume the a batch
            // exception occurred, since exceptions can be thrown
            // by the server for a variety of reasons.
            batchResults = e.getUpdateCounts();
        }
        // You should also be prepared to catch SQLExceptions in your own
        // application code, to handle dropped connections and other general
        // problems.

        // Commit the transaction
        conn.commit();

        // Print the array holding the results of the batch insertions.
        System.out.println("Return value from inserting batch: "
                           + Arrays.toString(batchResults));
        // Print the resulting table.
        ResultSet rs = null;
        rs = stmt.executeQuery("SELECT CustID, First_Name, "
                + "Last_Name FROM customers ORDER BY CustID");
        while (rs.next()) {
            System.out.println(rs.getInt(1) + " - "
                    + rs.getString(2).trim() + " "
                    + rs.getString(3).trim());
        }

        // Cleanup
        conn.close();
    } catch (SQLException e) {
        e.printStackTrace();
    }
}
```

Running the above example produces the following output on the console:

```
Error message: [Vertica][VJDBC](100172) One or more rows were rejected by the server.Return value from inserting batch: [1, 1, -3, 1, 1]
1 - Anna Allen
2 - Bill Brown
4 - Don Dodd
5 - Eric Estavez
```

Notice that the third row failed to insert because its phone number is too long for the Phone_Number column. All of the rest of the rows in the batch (including those after the error) were correctly inserted.

> **Note**
> It is more efficient for you to ensure that the data you are inserting is the correct data type and width for the table column you are inserting it into than to handle exceptions after the fact.

Rolling back batch loads on the server

Batch loads always insert all of their data, even if one or more rows is rejected. Only the rows that caused errors in a batch are not loaded. When the database connection's AutoCommit property is true, batches automatically commit their transactions when they complete, so once the batch finishes loading, the data is committed.

In some cases, you may want all of the data in a batch to be successfully inserted—none of the data should be committed if an error occurs. The best way to accomplish this is to turn off the database connection's AutoCommit property to prevent batches from automatically committing themselves. Then, if a batch encounters an error, you can roll back the transaction after catching the BatchUpdateException caused by the insertion error.

The following example demonstrates performing a rollback if any error occurs when loading a batch.

```
import java.sql.*;
import java.util.Arrays;
import java.util.Properties;

public class RollbackBatchOnError {
    public static void main(String[] args) {
        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser");
        myProp.put("password", "password123");
        Connection conn;
        try {
            conn = DriverManager.getConnection(
                        "jdbc:vertica://VerticaHost:5433/ExampleDB",
                        myProp);
            // Disable auto-commit. This will allow you to roll back a
            // a batch load if there is an error.
            conn.setAutoCommit(false);
            // establish connection and make a table for the data.
            Statement stmt = conn.createStatement();
            // Drop table and recreate.
            stmt.execute("DROP TABLE IF EXISTS customers CASCADE");
            stmt.execute("CREATE TABLE customers (CustID int, Last_Name"
                        + " char(50), First_Name char(50),Email char(50), "
                        + "Phone_Number char(12))");

            // Some dummy data to insert. The one row won't insert because
            // the phone number is too long for the phone column.
            String[] firstNames = new String[] { "Anna", "Bill", "Cindy",
                        "Don", "Eric" };
            String[] lastNames = new String[] { "Allen", "Brown", "Chu",
                        "Dodd", "Estavez" };
            String[] emails = new String[] { "aang@example.com",
                        "b.brown@example.com", "cindy@example.com",
                        "d.d@example.com", "e.estavez@example.com" };
            String[] phoneNumbers = new String[] { "123-456-789",
                        "555-444-3333", "555-867-53094535", "555-555-1212",
                        "781-555-0000" };
            // Create the prepared statement
            PreparedStatement pstmt = conn.prepareStatement(
                        "INSERT INTO customers (CustID, Last_Name, " +
                        "First_Name, Email, Phone_Number) "+
                        "VALUES(?,?,?,?,?)");
            // Add rows to a batch in a loop. Each iteration adds a
            // new row.
            for (int i = 0; i < firstNames.length; i++) {
                // Add each parameter to the row.
                pstmt.setInt(1, i + 1);
                pstmt.setString(2, lastNames[i]);
                pstmt.setString(3, firstNames[i]);
                pstmt.setString(4, emails[i]);
                pstmt.setString(5, phoneNumbers[i]);
                // Add row to the batch.
                pstmt.addBatch();
            }
            // Integer array to hold the results of inserting
            // the batch. Will contain an entry for each row.
```

```
        // indicating success or failure.
        int[] batchResults = null;
        try {
            // Batch is ready, execute it to insert the data
            batchResults = pstmt.executeBatch();
            // If we reach here, we inserted the batch without errors.
            // Commit it.
            System.out.println("Batch insert successful. Committing.");
            conn.commit();
        } catch (BatchUpdateException e) {
                System.out.println("Error message: " + e.getMessage());
                // Batch results isn't set due to exception, but you
                // can get it from the exception object.
                batchResults =  e.getUpdateCounts();
                // Roll back the batch transaction.
                System.out.println("Rolling back batch insertion");
                conn.rollback();
        }
        catch  (SQLException e) {
            // General SQL errors, such as connection issues, throw
            // SQLExceptions. Your application should do something more
            // than just print a stack trace,
            e.printStackTrace();
        }
        System.out.println("Return value from inserting batch: "
                    + Arrays.toString(batchResults));
        System.out.println("Customers table contains:");

        // Print the resulting table.
        ResultSet rs = null;
        rs = stmt.executeQuery("SELECT CustID, First_Name, "
                + "Last_Name FROM customers ORDER BY CustID");
        while (rs.next()) {
            System.out.println(rs.getInt(1) + " - "
                        + rs.getString(2).trim() + " "
                        + rs.getString(3).trim());
        }

        // Cleanup
        conn.close();
    } catch (SQLException e) {
        e.printStackTrace();
    }
}
```

Running the above example prints the following on the system console:

```
Error message: [Vertica][VJDBC](100172) One or more rows were rejected by the server.Rolling back batch insertion
Return value from inserting batch: [1, 1, -3, 1, 1]
Customers table contains:
```

The return values indicate whether each rows was successfully inserted. The value 1 means the row inserted without any issues, and a -3 indicates the row failed to insert.

The customers table is empty since the batch insert was rolled back due to the error caused by the third column.

Bulk loading using the COPY statement

One of the fastest ways to load large amounts of data into Vertica at once (bulk loading) is to use the COPY statement . This statement loads data from a file stored on a Vertica host (or in a data stream) into a table in the database. You can pass the COPY statement parameters that define the format of the data in the file, how the data is to be transformed as it is loaded, how to handle errors, and how the data should be loaded. See the COPY documentation for details.

Important
In databases that were created in versions of Vertica ≤ 9.2, COPY supports the DIRECT option, which specifies to load data directly into ROS rather than WOS. Use this option when loading large (>100MB) files into the database; otherwise, the load is liable to fill the WOS. When this occurs, the Tuple Mover must perform a moveout operation on the WOS data. It is more efficient to directly load into ROS and avoid forcing a moveout.

In databases created in Vertica 9.3, Vertica ignores load options and hints and always uses a load method of DIRECT. Databases created in versions ≥ 10.0 no longer support WOS and moveout operations; all data is always loaded directly into ROS.

Only a superuser can use COPY to copy a file stored on a host, so you must connect to the database with a superuser account. If you want to have a non-superuser user bulk-load data, you can use COPY to load from a stream on the host (such as STDIN) rather than a file or stream data from the client (see Streaming data via JDBC). You can also perform a standard batch insert using a prepared statement , which uses the COPY statement in the background to load the data.

> **Note**
> When using COPY parameter ON ANY NODE , confirm that the source file is identical on all nodes. Using different files can produce inconsistent results.

The following example demonstrates using the COPY statement through the JDBC to load a file name customers.txt into a new database table. This file must be stored on the database host to which your application connects—in this example, a host named VerticaHost.

```
import java.sql.*;
import java.util.Properties;
import com.vertica.jdbc.*;

public class COPYFromFile {
   public static void main(String[] args) {
      Properties myProp = new Properties();
      myProp.put("user", "ExampleAdmin"); // Must be superuser
      myProp.put("password", "password123");
      Connection conn;
      try {
         conn = DriverManager.getConnection(
                     "jdbc:vertica://VerticaHost:5433/ExampleDB",myProp);
         // Disable AutoCommit
         conn.setAutoCommit(false);
         Statement stmt = conn.createStatement();
         // Create a table to hold data.
         stmt.execute("DROP TABLE IF EXISTS customers;");
         stmt.execute("CREATE TABLE IF NOT EXISTS customers (Last_Name char(50) "
                     + "NOT NULL, First_Name char(50),Email char(50), "
                     + "Phone_Number char(15))");

          // Use the COPY command to load data. Use ENFORCELENGTH to reject
         // strings too wide for their columns.
         boolean result = stmt.execute("COPY customers FROM "
                     + " '/data/customers.txt' ENFORCELENGTH");

         // Determine if execution returned a count value, or a full result
         // set.
         if (result) {
            System.out.println("Got result set");
         } else {
            // Count will usually return the count of rows inserted.
            System.out.println("Got count");
            int rowCount = stmt.getUpdateCount();
            System.out.println("Number of accepted rows = " + rowCount);
         }

         // Commit the data load
         conn.commit();
      } catch (SQLException e) {
         System.out.print("Error: ");
         System.out.println(e.toString());
      }
   }
```

The example prints the following out to the system console when run (assuming that the customers.txt file contained two million valid rows):

```
Number of accepted rows = 2000000
```

Streaming data via JDBC

There are two options to stream data from a file on the client to your Vertica database:

- Use the VerticaCopyStream class to stream data in an object-oriented manner - details on the class are available in the JDBC Documentation
- Execute a COPY LOCAL SQL statement to stream the data

The topics in this section explain how to use these options.

In this section

- Using VerticaCopyStream
- Using COPY LOCAL with JDBC

Using VerticaCopyStream

The VerticaCopyStream class lets you stream data from the client system to a Vertica database. It lets you use COPY directly without first copying the data to a host in the database cluster. Using COPY to load data from the host requires superuser privileges to access the host's file system. The COPY statement used to load data from a stream does not require superuser privileges, so your client can connect with any user account that has INSERT privileges on the target table.

To copy streams into the database:

1. Disable the database connections AutoCommit connection parameter.
2. Instantiate a VerticaCopyStreamObject , passing it at least the database connection objects and a string containing a COPY statement to load the data. This statement must copy data from the STDIN into your table. You can use any parameters that are appropriate for your data load.

   > **Note**
   > The VerticaCopyStreamObject constructor optionally takes a single InputStream object, or a List of InputStream objects. This option lets you pre-populate the list of streams to be copied into the database.

3. Call VerticaCopyStreamObject.start() to start the COPY statement and begin streaming the data in any streams you have already added to the VerticaCopyStreamObject .
4. Call VerticaCopyStreamObject.addStream() to add additional streams to the list of streams to send to the database. You can then call VerticaCopyStreamObject.execute() to stream them to the server.
5. Optionally, call VerticaCopyStreamObject.getRejects() to get a list of rejected rows from the last .execute() call. The list of rejects is reset by each call to .execute() or .finish() .

   > **Note**
   > If you used either the REJECTED DATA or EXCEPTIONS options in the COPY statement you passed to VerticaCopyStreamObject the object in step 2, .getRejects() returns an empty list. You can only use one method of tracking the rejected rows at a time.

6. When you are finished adding streams, call VerticaCopyStreamObject.finish() to send any remaining streams to the database and close the COPY statement.
7. Call Connection.commit() to commit the loaded data.

Getting rejected rows

The VerticaCopyStreamObject.getRejects() method returns a List containing the row numbers of rows that were rejected after the previous .execute() method call. Each call to .execute() clears the list of rejected rows, so you need to call .getRejects() after each call to .execute() . Since .start() and .finish() also call .execute() to send any pending streams to the server, you should also call .getRejects() after these methods as well.

The following example demonstrates loading the content of five text files stored on the client system into a table.

```
import java.io.File;
import java.io.FileInputStream;
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.Statement;
import java.util.Iterator;
import java.util.List;
import java.util.Properties;
import com.vertica.jdbc.VerticaConnection;
import com.vertica.jdbc.VerticaCopyStream;

public class CopyMultipleStreamsExample {
    public static void main(String[] args) {
        // Note: If running on Java 5, you need to call Class.forName
        // to manually load the JDBC driver.
        // Set up the properties of the connection
```

```
Properties myProp = new Properties();
myProp.put("user", "ExampleUser"); // Must be superuser
myProp.put("password", "password123");
// When performing bulk loads, you should always disable the
// connection's AutoCommit property to ensure the loads happen as
// efficiently as possible by reusing the same COPY command and
// transaction.
myProp.put("AutoCommit", "false");
Connection conn;
try {
    conn = DriverManager.getConnection(
                "jdbc:vertica://VerticaHost:5433/ExampleDB", myProp);
    Statement stmt = conn.createStatement();

    // Create a table to receive the data
    stmt.execute("DROP TABLE IF EXISTS customers");
    stmt.execute("CREATE TABLE customers (Last_Name char(50), "
                 + "First_Name char(50),Email char(50), "
                 + "Phone_Number char(15))");

    // Prepare the query to insert from a stream. This query must use
    // the COPY statement to load data from STDIN. Unlike copying from
    // a file on the host, you do not need superuser privileges to
    // copy a stream. All your user account needs is INSERT privileges
    // on the target table.
    String copyQuery = "COPY customers FROM STDIN "
                 + "DELIMITER '|' ENFORCELENGTH";

    // Create an instance of the stream class. Pass in the
    // connection and the query string.
    VerticaCopyStream stream = new VerticaCopyStream(
                (VerticaConnection) conn, copyQuery);

    // Keep running count of the number of rejects
    int totalRejects = 0;

    // start() starts the stream process, and opens the COPY command.
    stream.start();

    // If you added streams to VerticaCopyStream before calling start(),
    // You should check for rejects here (see below). The start() method
    // calls execute() to send any pre-queued streams to the server
    // once the COPY statement has been created.

    // Simple for loop to load 5 text files named customers-1.txt to
    // customers-5.txt
    for (int loadNum = 1; loadNum <= 5; loadNum++) {
        // Prepare the input file stream. Read from a local file.
        String filename = "C:\\Data\\customers-" + loadNum + ".txt";
        System.out.println("\n\nLoading file: " + filename);
        File inputFile = new File(filename);
        FileInputStream inputStream = new FileInputStream(inputFile);

        // Add stream to the VerticaCopyStream
        stream.addStream(inputStream);

        // call execute() to load the newly added stream. You could
        // add many streams and call execute once to load them all.
        // Which method you choose depends mainly on whether you want
        // the ability to check the number of rejections as the load
        // progresses so you can stop if the number of rejects gets too
```

```
            // high. Also, high numbers of InputStreams could create a
            // resource issue on your client system.
            stream.execute();

            // Show any rejects from this execution of the stream load
            // getRejects() returns a List containing the
            // row numbers of rejected rows.
            List<Long> rejects = stream.getRejects();

            // The size of the list gives you the number of rejected rows.
            int numRejects = rejects.size();
            totalRejects += numRejects;
            System.out.println("Number of rows rejected in load #"
                               + loadNum + ": " + numRejects);

            // List all of the rows that were rejected.
            Iterator<Long> rejit = rejects.iterator();
            long linecount = 0;
            while (rejit.hasNext()) {
                System.out.print("Rejected row #" + ++linecount);
                System.out.println(" is row " + rejit.next());
            }
        }
        // Finish closes the COPY command. It returns the number of
        // rows inserted.
        long results = stream.finish();
        System.out.println("Finish returned " + results);

        // If you added any streams that hadn't been executed(),
        // you should also check for rejects here, since finish()
        // calls execute() to

        // You can also get the number of rows inserted using
        // getRowCount().
        System.out.println("Number of rows accepted: "
                           + stream.getRowCount());
        System.out.println("Total number of rows rejected: " + totalRejects);

        // Commit the loaded data
        conn.commit();

    } catch (Exception e) {
        e.printStackTrace();
    }
}
```

Running the above example on some sample data results in the following output:

```
Loading file: C:\Data\customers-1.txtNumber of rows rejected in load #1: 3
Rejected row #1 is row 3
Rejected row #2 is row 7
Rejected row #3 is row 51
Loading file: C:\Data\customers-2.txt
Number of rows rejected in load #2: 5Rejected row #1 is row 4143
Rejected row #2 is row 6132
Rejected row #3 is row 9998
Rejected row #4 is row 10000
Rejected row #5 is row 10050
Loading file: C:\Data\customers-3.txt

Rejected row #8 is row 29998
Loading file: C:\Data\customers-5.txt
Number of rows rejected in load #5: 1
Rejected row #1 is row 39997
Finish returned 39995
Number of rows accepted: 39995
Total number of rows rejected: 26
```

> **Note**
> The above example shows a simple load process that targets one node in the Vertica cluster. It is more efficient to simultaneously load multiple streams to multiple database nodes. Doing so greatly improves performance because it spreads the processing for the load across the cluster.

Using COPY LOCAL with JDBC

To use COPY LOCAL with JDBC, just execute a COPY LOCAL statement with the path to the source file on the client system. This method is simpler than using the VerticaCopyStream class (details on the class are available in the JDBC Documentation). However, you may prefer using VerticaCopyStream if you have many files to copy to the database or if your data comes from a source other than a file (streamed over a network connection, for example).

You can use COPY LOCAL in a multiple-statement query. However, you should always make it the first statement in the query. You should not use it multiple times in the same query.

The following example code demonstrates using COPY LOCAL to copy a file from the client to the database. It is the same as the code shown in Bulk loading using the COPY statement , except for the use of the LOCAL option in the COPY statement, and the path to the data file is on the client system, rather than on the server.

> **Note**
> The exceptions/rejections files are created on the client machine when the exceptions and rejected data modifiers are specified on the copy local command. Specify a local path and filename for these modifiers when executing a COPY LOCAL query from the driver.

```
import java.sql.*;
import java.util.Properties;

public class COPYLocal {
   public static void main(String[] args) {
      // Note: If using Java 5, you must call Class.forName to load the
      // JDBC driver.
      Properties myProp = new Properties();
      myProp.put("user", "ExampleUser"); // Do not need to superuser
      myProp.put("password", "password123");
      Connection conn;
      try {
         conn = DriverManager.getConnection(
                     "jdbc:vertica://VerticaHost:5433/ExampleDB",myProp);
         // Disable AutoCommit
         conn.setAutoCommit(false);
         Statement stmt = conn.createStatement();
         // Create a table to hold data.
         stmt.execute("DROP TABLE IF EXISTS customers;");
         stmt.execute("CREATE TABLE IF NOT EXISTS customers (Last_Name char(50) "
                     + "NOT NULL, First_Name char(50),Email char(50), "
                     + "Phone_Number char(15))");

         // Use the COPY command to load data. Load directly into ROS, since
         // this load could be over 100MB. Use ENFORCELENGTH to reject
         // strings too wide for their columns.
         boolean result = stmt.execute("COPY customers FROM LOCAL "
                     + " 'C:\\Data\\customers.txt' DIRECT ENFORCELENGTH");

         // Determine if execution returned a count value, or a full result
         // set.
         if (result) {
            System.out.println("Got result set");
         } else {
            // Count will usually return the count of rows inserted.
            System.out.println("Got count");
            int rowCount = stmt.getUpdateCount();
            System.out.println("Number of accepted rows = " + rowCount);
         }

         conn.close();
      } catch (SQLException e) {
         System.out.print("Error: ");
         System.out.println(e.toString());
      }
   }
```

The result of running this code appears below. In this case, the customers.txt file contains 10000 rows, seven of which get rejected because they contain data too wide to fit into their database columns.

```
Got countNumber of accepted rows = 9993
```

Handling errors

When the Vertica JDBC driver encounters an error, it throws a SQLException or one of its subclasses. The specific subclass it throws depends on the type of error that has occurred. Most of the JDBC method calls can result in several different types of errors, in response to which the JDBC driver throws a specific SQLException subclass. Your client application can choose how to react to the error based on the specific exception that the JDBC driver threw.

> **Note**
> The specific SQLException subclasses were introduced in the JDBC 4.0 standard. If your client application runs in a Java 5 JVM, it will use the older JDBC 3.0-compliant driver which lacks these subclasses. In that case, all errors throw a SQLException .

The hierarchy of SQLException subclasses is arranged to help your client application determine what actions it can take in response to an error condition. For example:

- The JDBC driver throws SQLTransientException subclasses when the cause of the error may be a temporary condition, such as a timeout error (SQLTimeoutException) or a connection issue (SQLTransientConnectionIssue). Your client application can choose to retry the operation without making any sort of attempt to remedy the error, since it may not reoccur.
- The JDBC driver throws SQLNonTransientException subclasses when the client needs to take some action before it could retry the operation. For example, executing a statement with a SQL syntax error results in the JDBC driver throwing the a SQLSyntaxErrorException (a subclass of SQLNonTransientException). Often, your client application just has to report these errors back to the user and have him or her resolve them. For example, if the user supplied your application with a SQL statement that triggered a SQLSyntaxErrorException , it could prompt the user to fix the SQL error.

See SQLState mapping to Java exception classes for a list Java exceptions thrown by the JDBC driver.

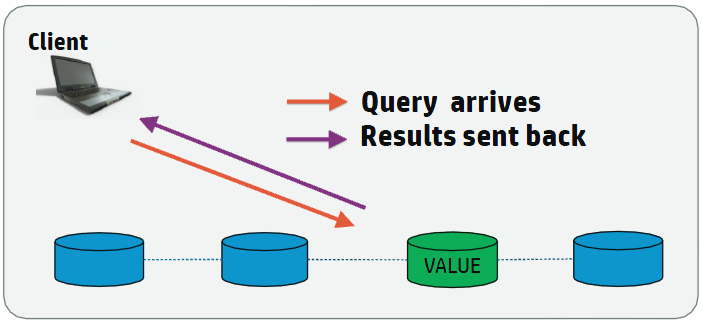
Class VC	Configuration File Error	SQLNonTransientException
Class VD	DB Designer errors	SQLNonTransientException
Class VP	User procedure errors	SQLNonTransientException
Class VX	Internal Error	SQLException

Routing JDBC queries directly to a single node

The JDBC driver has the ability to route queries directly to a single node using a special connection called a Routable Connection. This feature is ideal for high-volume "short" requests that return a small number of results that all exist on a single node. The common scenario for using this feature is to do high-volume lookups on data that is identified with a unique key. Routable queries typically provide lower latency and use less system resources than distributed queries. However, the data being queried must be segmented in such a way that the JDBC client can determine on which node the data resides.



Vertica Typical Analytic Query

Typical analytic queries require dense computation on data across all nodes in the cluster and benefit from having all nodes involved in the planning and execution of the queries.

Vertica Routable Query API Query

For high-volume queries that return a single or a few rows of data, it is more efficient to execute the query on the single node that contains the data.

To effectively route a request to a single node, the client must determine the specific node on which the data resides. For the client to be able to determine the correct node, the table must be segmented by one or more columns. For example, if you segment a table on a Primary Key (PK) column, then the client can determine on which node the data resides based on the Primary Key and directly connect to that node to quickly fulfill the request.

The Routable Query API provides two classes for performing routable queries: VerticaRoutableExecutor and VGet. VerticaRoutableExecutor provides a more expressive SQL-based API while VGet provides a more structured API for programmatic access.

- The **VerticaRoutableExecutor** class allows you to use traditional SQL with a reduced feature set to query data on a single node.
  For joins, the table must be joined on a key column that exists in each table you are joining, and the tables must be segmented on that key. However, this is not true for unsegmented tables, which can always be joined (since all the data in an unsegmented table is available on all nodes).

- The **VGet** class does not use traditional SQL syntax. Instead, it uses a data structure that you build by defining predicates and predicate expressions and outputs and output expressions. This class is ideal for doing Key/Value type lookups on single tables.
  The data structure used for querying the table must provide a predicate for each segmented column defined in the projection for the table. You must provide, at a minimum, a predicate with a constant value for each segmented column. For example, an id with a value of 12234 if the table is segmented only on the id column. You can also specify additional predicates for the other, non-segmented, columns in the table. Predicates act like a SQL *WHERE* clause and multiple predicates/predicate expressions apply together with a SQL AND modifier. Predicates must be defined with a constant value. Predicate expressions can be used to refine the query and can contain any arbitrary SQL expressions (such as less than, greater than, and so on) for any of the non-segmented columns in the table.

Java documentation for all classes and methods in the JDBC Driver is available in the Vertica JDBC Documentation .

> **Note**
> The JDBC Routable Query API is read-only and requires JDK 1.6 or greater.

- Routable query performance and troubleshooting
- Pre-segmenting data using VHash

Creating tables and projections for use with the routable query API

For routable queries, the client must determine the appropriate node to get the data. The client does this by comparing all projections available for the table, and determining the best projection to use to find the single node that contains data. You must create a projection segmented by the key column(s) on at least one table to take full advantage of the routable query API. Other tables that join to this table must either have an unsegmented projection, or a projection segmented as described below.

> **Note**
> Tables must be segmented by hash for routable queries. See Hash segmentation clause . Other segmentation types are not supported.

Creating tables for use with routable queries

To create a table that can be used with the routable query API, segment (by hash) the table on a uniformly distributed column. Typically, you segment on a primary key. For faster lookups, sort the projection on the same columns on which you segmented. For example, to create a table that is well suited to routable queries:

```
CREATE TABLE users (
id INT NOT NULL PRIMARY KEY,
username VARCHAR(32),
email VARCHAR(64),
business_unit VARCHAR(16))
ORDER BY id
SEGMENTED BY HASH(id)
ALL NODES;
```

This table is segmented based on the id column (and ordered by id to make lookups faster). To build a query for this table using the routable query API, you only need to provide a single predicate for the id column which returns a single row when queried.

However, you might add multiple columns to the segmentation clause. For example:

```
CREATE TABLE users2 (
   id INT NOT NULL PRIMARY KEY,
   username VARCHAR(32),
   email VARCHAR(64),
   business_unit VARCHAR(16))
ORDER BY id, business_unit
SEGMENTED BY HASH(id, business_unit)
ALL NODES;
```

In this case, you need to provide two predicates when querying the users2 table, as it is segmented on two columns, id and business_unit . However, if you know both id and business_unit when you perform the queries, then it is beneficial to segment on both columns, as it makes it easier for the client to determine that this projection is the best projection to use to determine the correct node.

Designing tables for single-node JOINs

If you plan to use the VerticaRoutableExecutor class and join tables during routable queries, then you must segment all tables being joined by the same segmentation key. Typically this key is a primary/foreign key on all the tables being joined. For example, the customer_key may be the primary key in a customers dimension table, and the same key is a foreign key in a sales fact table. Projections for a VerticaRoutableExecutor query using these tables must be segmented by hash on the customer key in each table.

If you want to join with small dimension tables, such as date dimensions, then it may be appropriate to make those tables unsegmented so that the date_dimension data exists on all nodes. It is important to note that when joining unsegmented tables, you still must specify a segmented table in the createRoutableExecutor() call.

Verifying existing projections for tables

If tables are already segmented by hash (for example, on an ID column), then you can determine what predicates are needed to query the table by using the Vertica function GET_PROJECTIONS to view that table's projections. For example:

```
=> SELECT GET_PROJECTIONS ('users');
...
Projection Name: [Segmented] [Seg Cols] [# of Buddies] [Buddy Projections] [Safe] [UptoDate] [Stats]
-------------------------------------------------------------------------------------------------------
public.users_b1 [Segmented: Yes] [Seg Cols: "public.users.id"] [K: 1] [public.users_b0] [Safe: Yes] [UptoDate: Yes] [Stats: RowCounts]
public.users_b0 [Segmented: Yes] [Seg Cols: "public.users.id"] [K: 1] [public.users_b1] [Safe: Yes] [UptoDate: Yes] [Stats: RowCounts]
```

For each projection, only the public.users.id column is specified, indicating your query predicate should include this column.

If the table is segmented on multiple columns, for example id and business_unit , then you need to provide both columns as predicates to the routable query.

Creating a connection for routable queries

The JDBC Routable Query API provides the VerticaRoutableConnection (details are available in the JDBC Documentation) interface to connect to a cluster and allow for Routable Queries. This interface provides advanced routing capabilities beyond those of a normal VerticaConnection. The VerticaRoutableConnection provides access to the VerticaRoutableExecutor and VGet classes. See Defining the query for routable queries using the VerticaRoutableExecutor class and Defining the query for routable queries using the VGet class respectively.

You enable access to this class by setting the EnableRoutableQueries JDBC connection property to true.

The VerticaRoutableConnection maintains an internal pool of connections and a cache of table metadata that is shared by all VerticaRoutableExecutor/VGet objects that are produced by the connection's createRoutableExecutor()/prepareGet() method. It is also a fully-fledged JDBC connection on its own and supports all the functionality that a VerticaConnection supports. When this connection is closed, all pooled connections managed by this VerticaRoutableConnection and all child objects are closed too. The connection pool and metadata is only used by child Routable Query operations.

Example:

You can create the connection using a JDBC DataSource:

```
com.vertica.jdbc.DataSource jdbcSettings = new com.vertica.jdbc.DataSource();
jdbcSettings.setDatabase("exampleDB");
jdbcSettings.setHost("v_vmart_node0001.example.com");
jdbcSettings.setUserID("dbadmin");
jdbcSettings.setPassword("password");
jdbcSettings.setEnableRoutableQueries(true);
jdbcSettings.setPort((short) 5433);

VerticaRoutableConnection conn;
conn = (VerticaRoutableConnection)jdbcSettings.getConnection();
```

You can also create the connection using a connection string and the DriverManager.getConnection() method:

```
String connectionString = "jdbc:vertica://v_vmart_node0001.example.com:5433/exampleDB?user=dbadmin&password=&EnableRoutableQueries=true";
VerticaRoutableConnection conn = (VerticaRoutableConnection) DriverManager.getConnection(connectionString);
```

Both methods result in a conn connection object that is identical.

> **Note**
> Avoid opening many VerticaRoutableConnection connections because this connection maintains its own private pool of connections which are not shared with other connections. Instead, your application should use a single connection and issue multiple queries through that connection.

In addition to the setEnableRoutableQueries property that the Routable Query API adds to the Vertica JDBC connection class, the API also adds additional properties. The complete list is below.

- EnableRoutableQueries : Enables Routable Query lookup capability. Default is false.
- FailOnMultiNodePlans : If the plan requires more than one node, and FailOnMultiNodePlans is true, then the query fails. If it is set to false then a warning is generated and the query continues. However, latency is greatly increased as the Routable Query must first determine the data is on multiple nodes, then a normal query is run using traditional (all node) execution and execution. Defaults to true. Note that this failure cannot occur on simple calls using only predicates and constant values.
- MetadataCacheLifetime : The time in seconds to keep projection metadata. The API caches metadata about the projection used for the query (such as projections). The cache is used on subsequent queries to reduce response time. The default is 300 seconds.
- MaxPooledConnections : Cluster-wide maximum number of connections to keep in the VerticaRoutableConnection's internal pool. Default 20.
- MaxPooledConnectionsPerNode : Per-node maximum number of connections to keep in the VerticaRoutableConnection's internal pool. Default 5.

Defining the query for routable queries using the VerticaRoutableExecutor class

Use the VerticaRoutableExecutor class to access table data directly from a single node. VerticaRoutableExecutor directly queries Vertica only on the node that has all the data needed for the query, avoiding the distributed planning and execution costs associated with Vertica query execution. You can use VerticaRoutableExecutor to join tables or use a GROUP BY clause, as these operations are not possible using VGet.

When using the VerticaRoutableExecutor class, the following rules apply:

- If joining tables, all tables being joined must be segmented (by hash) on the same set of columns referenced in the join predicate, unless the table to join is unsegmented.
- Multiple conditions in a join WHERE clause must be AND'd together. Using OR in the WHERE clause causes the query to degenerate to a multi-node plan. You can specify OR, IN list, or range conditions on columns *outside* the join condition if the data exists on the same node.
- You can only execute a single statement per request. Chained SQL statements are not permitted.
- Your query can be used in a driver-generated subquery to help determine whether the query can execute on a single node. Therefore, you cannot include the semi-colon at the end of the statement and you cannot include SQL comments using double-dashes (--), as these cause the driver-generated query to fail.

You create a VerticaRoutableExecutor by calling the createRoutableExecutor method on a connection object:

```
createRoutableExecutor( schema-name, table-name )
```

For example:

```
VerticaRoutableConnection conn;
    Map<String, Object> map = new HashMap<String, Object>();
    map.put("customer_key", 1);
try {
  conn = (VerticaRoutableConnection)
    jdbcSettings.getConnection();
  String table = "customers";
  VerticaRoutableExecutor q = conn.createRoutableExecutor(null, table);
  ...
...
```

If *schema-name* is set to null, then the search path is used to find the table.

VerticaRoutableExecutor methods

VerticaRoutableExecutor has the following methods:

- execute
- close
- getWarnings

For details on this class, see the JDBC Documentation .

Execute

```
execute( query-string, { column, value | map } )
```

Runs the query.

query-string	The query to execute

column, *value*	The column and value when the lookup is done on a single value. For example:
	`String column = "customer_key";`
	`Integer value = 1;`
	`ResultSet rs = q.execute(query, column, value)`

map	A Java map of the column names and corresponding values if the lookup is done on one or more columns. For example: ResultSet rs = q.execute(query, map); . The table must have at least one projection segmented by a set of columns that exactly match the columns in the map. Each column defined in the map can have only one value. For example:
	`Map<String, Object> map = new HashMap<String, Object>();`
	`map.put("customer_key", 1);`
	`map.put("another_key", 42);`
	`ResultSet rs = q.execute(query, map);`

The following requirements apply:

- The query to execute must use regular SQL that complies with the rules of the VerticaRoutableExecutor class. For example, you can add limits and sorts, or use aggregate functions, provided the data exists on a single node.
- The JDBC client uses the *column* / *value* or *map* arguments to determine on which node to execute the query. The content of the query must use the same values that you provide in the column/value or map arguments.
- The following data types cannot be used as column values: * INTERVAL * TIMETZ * TIMESTAMPTZ
  Also, if a table is segmented on any columns with the following data types then the table cannot be queried with the routable query API:

The driver does not verify the syntax of the query before it sends the query to the server. If your expression is incorrect, then the query fails.

Close

```
close()
```

Closes this VerticaRoutableExecutor by releasing resources used by this VerticaRoutableExecutor . It does not close the parent JDBC connection to Vertica.

getWarnings

```
getWarnings()
```

Retrieves the first warning reported by calls on this VerticaRoutableExecutor . Additional warnings are chained and can be accessed with the JDBC method getNextWarning() .

Example

The following example shows how to use VerticaRoutableExecutor to execute a query using both a JOIN clause and an aggregate function with a GROUP BY clause. The example also shows how to create a customer and sales table, and segment the tables so they can be joined using the VerticaRoutableExecutor class. This example uses the date_dimension table in the VMart schema to show how to join data on unsegmented tables.

1. Create the customers table to store customer details, and then create projections that are segmented on the table's customer_key column:

```
=> CREATE TABLE customers (customer_key INT, customer_name VARCHAR(128), customer_email VARCHAR(128));
=> CREATE PROJECTION cust_proj_b0 AS SELECT * FROM customers SEGMENTED BY HASH (customer_key) ALL NODES;
=> CREATE PROJECTION cust_proj_b1 AS SELECT * FROM customers SEGMENTED BY HASH (customer_key) ALL NODES OFFSET 1;
=> CREATE PROJECTION cust_proj_b2 AS SELECT * FROM customers SEGMENTED BY HASH (customer_key) ALL NODES OFFSET 2;
=> SELECT start_refresh();
```

2. Create the sales table, then create projections that are segmented on its customer_key column. Because the customer and sales tables are segmented on the same key, you can join them later with the VerticaRoutableExecutor routable query lookup.

```
=> CREATE TABLE sales (sale_key INT, customer_key INT, date_key INT, sales_amount FLOAT);
=> CREATE PROJECTION sales_proj_b0 AS SELECT * FROM sales SEGMENTED BY HASH (customer_key) ALL NODES;
=> CREATE PROJECTION sales_proj_b1 AS SELECT * FROM sales SEGMENTED BY HASH (customer_key) ALL NODES OFFSET 1;
=> CREATE PROJECTION sales_proj_b2 AS SELECT * FROM sales SEGMENTED BY HASH (customer_key) ALL NODES OFFSET 2;
=> SELECT start_refresh();
```

3. Add some sample data:

```
=> INSERT INTO customers VALUES (1, 'Fred', 'fred@example.com');
=> INSERT INTO customers VALUES (2, 'Sue', 'Sue@example.com');
=> INSERT INTO customers VALUES (3, 'Dave', 'Dave@example.com');
=> INSERT INTO customers VALUES (4, 'Ann', 'Ann@example.com');
=> INSERT INTO customers VALUES (5, 'Jamie', 'Jamie@example.com');
=> COMMIT;

=> INSERT INTO sales VALUES(1, 1, 1, '100.00');
=> INSERT INTO sales VALUES(2, 2, 2, '200.00');
=> INSERT INTO sales VALUES(3, 3, 3, '300.00');
=> INSERT INTO sales VALUES(4, 4, 4, '400.00');
=> INSERT INTO sales VALUES(5, 5, 5, '400.00');
=> INSERT INTO sales VALUES(6, 1, 15, '500.00');
=> INSERT INTO sales VALUES(7, 1, 15, '400.00');
=> INSERT INTO sales VALUES(8, 1, 35, '300.00');
=> INSERT INTO sales VALUES(9, 1, 35, '200.00');
=> COMMIT;
```

4. Create an unsegmented projection of the VMart date_dimension table for use in this example. Call the meta-function START_REFRESH to unsegment the existing data:

```
=> CREATE PROJECTION date_dim AS SELECT * FROM date_dimension UNSEGMENTED ALL NODES;
=> SELECT start_refresh();
```

Using the customer , sales , and date_dimension data, you can now create a routable query lookup that uses joins and a group by to query the customers table and return the total number of purchases per day for a given customer:

```
import java.sql.*;
import java.util.HashMap;
import java.util.Map;
import com.vertica.jdbc.kv.*;

public class verticaKV_doc {
   public static void main(String[] args) {
      com.vertica.jdbc.DataSource jdbcSettings
         = new com.vertica.jdbc.DataSource();
      jdbcSettings.setDatabase("VMart");
      jdbcSettings.setHost("vertica.example.com");
      jdbcSettings.setUserID("dbadmin");
      jdbcSettings.setPassword("password");
      jdbcSettings.setEnableRoutableQueries(true);
      jdbcSettings.setFailOnMultiNodePlans(true);
      jdbcSettings.setPort((short) 5433);
      VerticaRoutableConnection conn;
            Map<String, Object> map = new HashMap<String, Object>();
            map.put("customer_key", 1);
      try {
         conn = (VerticaRoutableConnection)
            jdbcSettings.getConnection();
         String table = "customers";
         VerticaRoutableExecutor q = conn.createRoutableExecutor(null, table);
         String query = "select d.date, SUM(s.sales_amount) as Total ";
            query += " from customers as c";
            query += " join sales as s ";
            query += " on s.customer_key = c.customer_key ";
            query += " join date_dimension as d ";
            query += " on d.date_key = s.date_key ";
            query += " where c.customer_key = " + map.get("customer_key");
            query += " group by (d.date) order by Total DESC";
         ResultSet rs = q.execute(query, map);
         while(rs.next()) {
            System.out.print("Date: " + rs.getString("date") + ":  ");
            System.out.println("Amount: " + rs.getString("Total"));
         }
         conn.close();
      } catch (SQLException e) {
         e.printStackTrace();
      }
   }
```

The example code produces output like this:

```
Date: 2012-01-15:  Amount: 900.0
Date: 2012-02-04:  Amount: 500.0
Date: 2012-01-01:  Amount: 100.0
```

> **Note**
> Your output might be different, because the VMart schema randomly generates dates in the date_dimension table.

Defining the query for routable queries using the VGet class

The VGet class is used to access table data directly from a single node when you do not need to join the data or use a group by clause. Like VerticaRoutableExecutor, VGet directly queries Vertica nodes that have the data needed for the query, avoiding the distributed planning and execution costs associated with a normal Vertica execution. However, VGet does not use SQL. Instead, you define predicates and values to perform key/value

type lookups on a single table. VGet is especially suited to key/value-type lookups on single tables.

You create a VGet by calling the prepareGet method on a connection object:

```
prepareGet( schema-name, { table-name | projection-name } )
```

For example:

```
VerticaRoutableConnection conn;
try {
   conn = (VerticaRoutableConnection)
      jdbcSettings.getConnection();
      System.out.println("Connected.");
      VGet get = conn.prepareGet("public", "users");
         ...
...
```

VGet operations span multiple JDBC connections (and multiple Vertica sessions) and do not honor the parent connection's transaction semantics. If consistency is required across multiple executions, the parent VerticaRoutableConnection's consistent read API can be used to guarantee all operations occur at the same epoch.

VGet is thread safe, but all methods are synchronized, so threads that share a VGet instance are never run in parallel. For better parallelism, each thread should have its own VGet instance. Different VGet instances that operate on the same table share pooled connections and metadata in a manner that enables a high degree of parallelism.

VGet methods

VGet has the following methods:

- addPredicate
- addPredicateExpression
- addOutputColumn
- addOutputExpression
- addSortColumn
- setLimit
- clearPredicates
- clearOutputs
- clearSortColumns
- execute
- close
- getWarnings

By default, VGet fetches all columns of all rows that satisfy the logical AND of predicates passed via the addPredicate method. You can further customize the get operation with the following methods: addOutputColumn , addOutputExpression , addPredicateExpression , addSortColumn , and setLimit .

addPredicate

```
addPredicate(string, object)
```

Adds a predicate column and a constant value to the query. You must include a predicate for each column on which the table is segmented. The predicate acts as the query WHERE clause. Multiple addPredicate method calls are joined by AND modifiers. The VGet retains this value after each call to execute. To remove it, use clearPredicates .

The following data types cannot be used as column values. Also, if a table is segmented on any columns with these data types then the table cannot be queried with the Routable Query API:

- INTERVAL
- TIMETZ
- TIMESTAMPTZ

addPredicateExpression

addPredicateExpression(*string*)

Accepts arbitrary SQL expressions that operate on the table's columns as input to the query. Predicate expressions and predicates are joined by AND modifiers. You can use segmented columns in predicate expressions, but they must also be specified as a regular predicate with addPredicate . The VGet retains this value after each call to execute. To remove it, use clearPredicates .

The driver does not verify the syntax of the expression before it sends it to the server. If your expression is incorrect then the query fails.

addOutputColumn

```
addOutputColumn(string)
```

Adds a column to be included in the output. By default the query runs as SELECT * and you do not need to define any output columns to return the data. If you add output columns then you must add all the columns to be returned. The VGet retains this value after each call to execute. To remove it, use clearOutputs .

addOutputExpression

```
addOutputExpression(string)
```

Accepts arbitrary SQL expressions that operate on the table's columns as output. The VGet retains this value after each call to execute. To remove it, use ClearOutputs.

The following restrictions apply:

- The driver does not verify the syntax of the expression before it sends it to the server. If your expression is incorrect then the query fails.
- addOutputExpression is not supported when querying flex tables . If you use addOutputExpression on a flex table query, then a *SQLFeatureNotSupportedException* is thrown.

addSortColumn

```
addSortColumn(string, SortOrder)
```

Adds a sort order to an output column. The output column can be either the one returned by the default query (SELECT *) or one of the columns defined in addSortColumn or addOutputExpress. You can defined multiple sort columns.

setLimit

```
setLimit(int)
```

Sets a limit on the number of results returned. A limit of 0 is unlimited.

clearPredicates

```
clearPredicates()
```

Removes predicates that were added by addPredicate and addPredicateExpression .

clearOutputs

```
clearOutputs()
```

Removes outputs added by addOutputColumn and addOutputExpression .

clearSortColumns

```
clearSortColumns()
```

Removes sort columns previously added by addSortColumn .

Execute

```
execute()
```

Runs the query. Care must be taken to ensure that the predicate columns exist on the table and projection used by VGet, and that the expressions do not require multiple nodes to execute. If an expression is sufficiently complex as to require more than one node to execute, execute throws a SQLException if the FailOnMultiNodePlans connection property is true.

Close

```
close()
```

Closes this VGet by releasing resources used by this VGet. It does not close the parent JDBC connection to Vertica.

getWarnings

```
getWarnings()
```

Retrieves the first warning reported by calls on this VGet. Additional warnings are chained and can be accessed with the JDBC method getNextWarning.

Example

The following code queries the users table that is defined in Creating tables and projections for use with the routable query API . The table defines an id column that is segmented by hash.

```
import java.sql.*;
import com.vertica.jdbc.kv.*;

public class verticaKV2 {
  public static void main(String[] args) {
    com.vertica.jdbc.DataSource jdbcSettings
      = new com.vertica.jdbc.DataSource();
    jdbcSettings.setDatabase("exampleDB");
    jdbcSettings.setHost("v_vmart_node0001.example.com");
    jdbcSettings.setUserID("dbadmin");
    jdbcSettings.setPassword("password");
    jdbcSettings.setEnableRoutableQueries(true);
    jdbcSettings.setPort((short) 5433);

    VerticaRoutableConnection conn;
    try {
      conn = (VerticaRoutableConnection)
        jdbcSettings.getConnection();
        System.out.println("Connected.");
      VGet get = conn.prepareGet("public", "users");
      get.addPredicate("id", 5);
      ResultSet rs = get.execute();
      rs.next();
      System.out.println("ID: " +
        rs.getString("id"));
      System.out.println("Username: "
        + rs.getString("username"));
      System.out.println("Email: "
        + rs.getString("email"));
      System.out.println("Closing Connection.");
      conn.close();
    } catch (SQLException e) {
      System.out.println("Error! Stacktrace:");
      e.printStackTrace();
    }
  }
```

This code produces the following output:

```
Connected.
ID: 5
Username: userE
Email: usere@example.com
Closing Connection.
```

Routable query performance and troubleshooting

This topic details performance considerations and common issues you might encounter when using the routable query API.

Using resource pools with routable queries

Individual routable queries are serviced quickly since they directly access a single node and return only one or a few rows of data. However, by default, Vertica resource pools use an AUTO setting for the execution parallelism parameter. When set to AUTO, the setting is determined by the number of CPU cores available and generally results in multi-threaded execution of queries in the resource pool. It is not efficient to create parallel threads on

the server because routable query operations return data so quickly and routable query operations only use a single thread to find a row. To prevent the server from opening unneeded processing threads, you should create a specific resource pool for routable query clients. Consider the following settings for the resource pool you use for routable queries:

- Set execution parallelism to 1 to force single-threaded queries. This setting improves routable query performance.
- Use CPU affinity to limit the resource pool to a specific CPU or CPU set. The setting ensures that the routable queries have resources available to them, but it also prevents routable queries from significantly impacting performance on the system for other general queries.
- If you do not set a CPU affinity for the resource pool, consider setting the maximum concurrency value of the resource pool to a setting that ensures good performance for routable queries, but does not negatively impact the performance of general queries.

Performance considerations for routable query connections

Because a VerticaRoutableConnection opens an internal pool of connections, it is important to configure MaxPooledConnections and MaxPooledConnectionsPerNode appropriately for your cluster size and the amount of simultaneous client connections. It is possible to impact normal database connections if you are overloading the cluster with VerticaRoutableConnection s.

The initial connection to the initiator node discovers all other nodes in the cluster. The internal-pool connections are not opened until a VerticaRoutableExecutor or VGet query is sent. All VerticaRoutableExecutors/VGets in a connection object use connections from the internal pool and are limited by the MaxPooledConnections settings. Connections remain open until they are closed so a new connection can be opened elsewhere if the connection limit has been reached.

Troubleshooting routable queries

Routable query issues generally fall into two categories:

- Not providing enough predicates.
- Queries having to span multiple nodes.

Predicate Requirements

You must provide the same number of predicates that correspond to the columns of the table segmented by hash. To determine the segmented columns, call the Vertica function GET_PROJECTIONS . You must provide a predicate for each column displayed in the Seg Cols field.

For VGet, this means you must use addPredicate() to add each of the columns. For VerticaRoutableExecutor, this means you must provide all of the predicates and values in the map sent to execute() .

Multi-node Failures

It is possible to define the correct number of predicates, but still have a failure because multiple nodes contain the data. This failure occurs because the projection's data is not segmented in such a way that the data being queried is contained on a single node. Enable logging for the connection and view the logs to verify the projection being used. If the client is not picking the correct projection, then try to query the projection directly by specifying the projection instead of the table in the create/prepare statement, for example:

- Using VerticaRoutableExecutor:
```
conn.createRoutableExecutor(schema, table/projection);
```
- Using VGet:
```
conn.prepareGet("schema"."table/projection")
```

Additionally, you can use the EXPLAIN command in vsql to help determine if your query can run in single node. EXPLAIN can help you understand why the query is being run as single or multi-node.

Pre-segmenting data using VHash

The VHash class is an implementation of the Vertica hash function for use with JDBC client applications.

Hash segmentation in Vertica allows you to segment a projection based on a built-in hash function. The built-in hash function provides even data distribution across some or all nodes in a cluster, resulting in optimal query execution.

Suppose you have several million rows of values spread across thousands of CSV files. Assume that you already have a table segmented by hash. Before you load the values into your database, you probably want to know to which node a particular value loads. For this reason, using VHash can be particularly helpful, by allowing you to pre-segment your data before loading.

The following example shows the VHash class hashing the first column of a file named "testFile.csv". The name of the first column in this file is *meterId* .

Segment the data using VHash

This example demonstrates how you can read the testFile.csv file from the local file system and run a hash function on the meteterId column. Using the database metadata from a projection, you can then pre-segment the individual rows in the file based on the hash value of meterId.

```
import java.io.BufferedReader;
import java.io.FileNotFoundException;
import java.io.FileOutputStream;
import java.io.FileReader;
import java.io.UnsupportedEncodingException;
import java.util.*;
import java.io.IOException;
import java.sql.*;

import com.vertica.jdbc.kv.VHash;

public class VerticaKVDoc {

   final Map<String, FileOutputStream> files;
   final Map<String, List<Long>> nodeToHashList;
   String segmentationMetadata;
   List<String> lines;

   public static void main(String[] args) throws Exception {
      try {
         Class.forName("com.vertica.jdbc.Driver");
      } catch (ClassNotFoundException e) {
         System.err.println("Could not find the JDBC driver class.");
         e.printStackTrace();
         return;
      }

      Properties myProp = new Properties();
      myProp.put("user", "username");
      myProp.put("password", "password");

      VerticaKVDoc ex = new VerticaKVDoc();

      // Read in the data from a CSV file.
      ex.readLinesFromFile("C:\\testFile.csv");

      try (Connection conn = DriverManager.getConnection(
            "jdbc:vertica://VerticaHost:portNumber/databaseName", myProp)) {

      // Compute the hashes and create FileOutputStreams.
      ex.prepareForHashing(conn);

      }

      // Write to files.
      ex.writeLinesToFiles();
   }

   public VerticaKVDoc() {
      files = new HashMap<String, FileOutputStream>();
      nodeToHashList = new HashMap<String, List<Long>>();
   }

   public void prepareForHashing(Connection conn) throws SQLException,
         FileNotFoundException {

      // Send a query to Vertica to return the projection segments.
      try (ResultSet rs = conn.createStatement().executeQuery(
            "SELECT get_projection_segments('public.projectionName')")) {
```

```
            SELECT get_projection_segments('public.projectionName')")) {
        rs.next();
        segmentationMetadata = rs.getString(1);
    }

    // Initialize the data files.
    try (ResultSet rs = conn.createStatement().executeQuery(
            "SELECT node_name FROM nodes")) {
        while (rs.next()) {
            String node = rs.getString(1);
            files.put(node, new FileOutputStream(node + ".csv"));
        }
    }
  }

  public void writeLinesToFiles() throws UnsupportedEncodingException,
        IOException {
    for (String line : lines) {

        long hashedValue = VHash.hashLong(getMeterIdFromLine(line));

        // Write the row data to that node's data file.
        String node = VHash.getNodeFor(segmentationMetadata, hashedValue);

        FileOutputStream fos = files.get(node);
        fos.write(line.getBytes("UTF-8"));
    }
  }

  private long getMeterIdFromLine(String line) {

    // In our file, "meterId" is the name of the first column in the file.
    return Long.parseLong(line.split(",")[0]);
  }

  public void readLinesFromFile(String filename) throws IOException {
    lines = new ArrayList<String>();
    String line;
    try (BufferedReader reader = new BufferedReader(
            new FileReader(filename))) {
        while ((line = reader.readLine()) != null) {
            lines.add(line);
        }
    }
  }

}
```

Programming ADO.NET applications

The Vertica driver for ADO.NET allows applications written in C# to read data from, update, and load data into Vertica databases. It provides a data adapter (Vertica Data Adapter) that facilitates reading data from a database into a data set, and then writing changed data from the data set back to the database. It also provides a data reader (VerticaDataReader) for reading data. The driver requires the .NET framework version 3.5+.

For more information about ADO.NET, see:

- Overview of ADO.NET
- .NET Framework Developer Guide

> **Note**
> All of the examples provided in this section are in C#.

In this section

- ADO.NET data types
- Setting the locale for ADO.NET sessions
- Connecting to the database
- Querying the database using ADO.NET
- Canceling ADO.NET queries
- Handling messages (ADO.NET)
- Getting table metadata (ADO.Net)

ADO.NET data types

This table details the mapping between Vertica data types and .NET and ADO.NET data types.

.NET Framework Type	ADO.NET DbType	VerticaType	Vertica Data Type	VerticaDataReader getter
Boolean	Boolean	Bit	Boolean	GetBoolean()
byte[]	Binary	Binary VarBinary LongVarBinary	Binary VarBinary LongVarBinary	GetBytes() **Note** The limit for LongVarBinary is 32 Million bytes. If you attempt to insert more than the limit during a batch transfer for any one row, then they entire batch fails. Verify the size of the data before attempting to insert a LongVarBinary during a batch.
Datetime	DateTime	Date Time TimeStamp	Date Time TimeStamp	GetDateTime() **Note** The Time portion of the DateTime object for vertica dates is set to DateTime.MinValue. Previously, VerticaType.DateTime was used for all date/time types. VerticaType.DateTime still exists for backwards compatibility, but now there are more specific VerticaTypes for each type.
DateTimeOffset	DateTimeOffset	TimestampTZ TimeTZ	TimestampTZ TimeTZ	GetDateTimeOffset() **Note** The Date portion of the DateTime is set to DateTime.MinValue
Decimal	Decimal	Numeric	Numeric	GetDecimal()

Double	Double	Double	Double Precision	GetDouble() **Note** Vertica Double type uses a default precision of 53.
Int64	Int64	BigInt	Integer	GetInt64()
TimeSpan	Object	13 Interval Types	13 Interval Types	GetInterval() **Note** There are 13 VerticaType values for the 13 types of intervals. The specific VerticaType used determines the conversion rules that the driver applies. Year/Month intervals represented as 365/30 days
String	String	Varchar LongVarChar	Varchar LongVarChar	GetString()
String	StringFixedLengt	Char	Char	GetString()
Guid	Guid	UUID (see note below)	UUID	GetGuid()
Object	Object	N/A	N/A	GetValue()

UUID backwards compatibility

Vertica version 9.0.0 introduced the UUID data type, including JDBC support for UUIDs. The Vertica ADO.NET, ODBC, and OLE DB clients added full support for UUIDs in version 9.0.1. Vertica maintains backwards compatibility with older supported client driver versions that do not support the UUID data type, as follows:

When an older client...	**Vertica...**
Queries tables with UUID columns	Translates the native UUID values to CHAR values.
Inserts data into a UUID column	Converts the CHAR value sent by the client into a native UUID value.
Queries a UUID column's metadata	Reports its data type as CHAR.

Setting the locale for ADO.NET sessions

- ADO.NET applications use a UTF-16 character set encoding and are responsible for converting any non-UTF-16 encoded data to UTF-16. The same cautions as for ODBC apply if this encoding is violated.
- The ADO.NET driver converts UTF-16 data to UTF-8 when passing to the Vertica server and converts data sent by Vertica server from UTF-8 to UTF-16.
- ADO.NET applications should set the correct server session locale by executing the SET LOCALE TO command in order to get expected collation and string functions behavior on the server.
- If there is no default session locale at the database level, ADO.NET applications need to set the correct server session locale by executing the SET LOCALE TO command in order to get expected collation and string functions behavior on the server. See the SET LOCALE command.

Connecting to the database

In this section

- Using TLS: installing certificates on Windows

- Opening and closing the database connection (ADO.NET)
- ADO.NET connection properties
- Load balancing in ADO.NET
- ADO.NET connection failover
- Configuring log properties (ADO.Net)

Using TLS: installing certificates on Windows

You can optionally secure communication between your ADO.NET application and Vertica using TLS. The Vertica ADO.NET driver uses the default Windows key store when looking for TLS certificates. This is the same key store that Internet Explorer uses.

Before you can use TLS on the client side, you must implement TLS on the server. See TLS protocol , perform those steps, then return to this topic to install the TLS certificate on Windows.

To use TLS for ADO.NET connections to Vertica:

- Import the server and client certificates into the Windows Key Store.
- If required by your certificates, import the public certificate of your Certifying Authority.

Import the server and client certificates into the windows key store:

1. Copy the server.crt file you generated when you enabled TLS on the server to your Windows Machine.
2. Double-click the certificate.
3. Let Windows determine the key type, and click **Install** .

Import the public certificate of your CA:

You must establish a chain of trust for the certificates. You may need to import the public certificate for your Certifying Authority (CA) (especially if it is a self-signed certificate).

1. Using the same certificate as above, double-click the certificate.
2. Select **Place all certificates in the following store** .
3. Click **Browse,** select **Trusted Root Certification Authorities** and click **Next** .
4. Click **Install** .

Enable SSL in your ADO.NET applications

In your connection string, be sure to enable SSL by setting the SSL property in VerticaConnectionStringBuilder to true, for example:

```
//configure connection properties    VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
   builder.Host = "192.168.17.10";
   builder.Database = "VMart";
   builder.User = "dbadmin";
   builder.SSL = true;
   //open the connection
   VerticaConnection _conn = new VerticaConnection(builder.ToString());
   _conn.Open();
```

Opening and closing the database connection (ADO.NET)

Before you can access data in Vertica through ADO.NET, you must create a connection to the database using the VerticaConnection class which is an implementation of System.Data.DbConnection. The VerticaConnection class takes a single argument that contains the connection properties as a string. You can manually create a string of property keywords to use as the argument, or you can use the VerticaConnectionStringBuilder class to build a connection string for you.

To download the ADO.NET driver, go to the Client Drivers Downloads page .

This topic details the following:

- Manually building a connection string and connecting to Vertica
- Using VerticaConnectionStringBuilder to create the connection string and connecting to Vertica
- Closing the connection

To manually create a connection string:

See ADO.NET connection properties for a list of available properties to use in your connection string. At a minimum, you need to specify the Host, Database, and User.

1. For each property, provide a value and append the properties and values one after the other, separated by a semicolon. Assign this string to a variable. For example:
```
String connectString = "DATABASE=VMart;HOST=v_vmart_node0001;USER=dbadmin";
```
2. Build a Vertica connection object that specifies your connection string.
```
VerticaConnection _conn = new VerticaConnection(connectString)
```
3. Open the connection.
```
_conn.Open();
```
4. Create a command object and associate it with a connection. All VerticaCommand objects must be associated with a connection.
```
VerticaCommand command = _conn.CreateCommand();
```

To use the VerticaConnectionStringBuilder class to create a connection string and open a connection:

1. Create a new object of the VerticaConnectionStringBuilder class.
```
VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
```
2. Update your VerticaConnectionStringBuilder object with property values. See ADO.NET connection properties for a list of available properties to use in your connection string. At a minimum, you need to specify the Host, Database, and User.
```
builder.Host = "v_vmart_node0001";
builder.Database = "VMart";
builder.User = "dbadmin";
```
3. Build a Vertica connection object that specifies your connection VerticaConnectionStringBuilder object as a string.
```
VerticaConnection _conn = new VerticaConnection(builder.ToString());
```
4. Open the connection.
```
_conn.Open();
```
5. Create a command object and associate it with a connection. All VerticaCommand objects must be associated with a connection.
```
VerticaCommand command = _conn.CreateCommand;
```

> **Note**
> If your database is not in compliance with your Vertica license, the call to VerticaConnection.open() returns a warning message to the console and the log. See Managing licenses for more information.

To close the connection:

When you're finished with the database, close the connection. Failure to close the connection can deteriorate the performance and scalability of your application. It can also prevent other clients from obtaining locks.

```
_conn.Close();
```

Example usage:

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
   class Program
   {
      static void Main(string[] args)
      {
         VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
         builder.Host = "192.168.1.10";
         builder.Database = "VMart";
         builder.User = "dbadmin";
         VerticaConnection _conn = new VerticaConnection(builder.ToString());
         _conn.Open();
      //Perform some operations
         _conn.Close();
      }
   }
}
```

ADO.NET connection properties

To download the ADO.NET driver, go to the Client Drivers Downloads page .

You use connection properties to configure the connection between your ADO.NET client application and your Vertica database. The properties provide the basic information about the connections, such as the server name and port number, needed to connect to your database.

You can set a connection property in two ways:

- Include the property name and value as part of the connection string you pass to a VerticaConnection .
- Set the properties in a VerticaConnectionStringBuilder object, and then pass the object as a string to a VerticaConnection .

Property	Description	Default Value
Database	Name of the Vertica database to which you want to connect. For example, if you installed the example VMart database, the database is "VMart".	none
User	Name of the user to log into Vertica.	none
Port	Port on which Vertica is running.	5433
Host	The host name or IP address of the server on which Vertica is running. You can provide an IPv4 address, IPv6 address, or host name. In mixed IPv4/IPv6 networks, the DNS server configuration determines which IP version address is sent first. Use the PreferredAddressFamily option to force the connection to use either IPv4 or IPv6.	none

PreferredAddressFamily	The IP version to use if the client and server have both IPv4 and IPv6 addresses and you have provided a host name. Valid values are: • Ipv4—Connect to the server using IPv4. • Ipv6—Connect to the server using IPv6. • None—Use the IP address provided by the DNS server.	Vertica.Data.VerticaClient.AddressFamilyPreference.None
Password	The password associated with the user connecting to the server.	string.Empty
BinaryTransfer	Provides a Boolean value that, when set to true, uses binary transfer instead of text transfer. When set to false, the ADO.NET connection uses text transfer. Binary transfer provides faster performance in reading data from a server to an ADO.NET client. Binary transfer also requires less bandwidth than text transfer, although it sometimes uses more when transferring a large number of small values. Binary transfer mode is not backwards compatible to ADO.NET versions earlier than 3.8. If you are using an earlier version, set this value to false. The data output by both modes is identical with the following exceptions for certain data types: • FLOAT: Binary transfer has slightly better precision. • TIMESTAMPTZ: Binary transfer can fail to get the session time zone and default to the local time zone, while text transfer reliably uses the session time zone. • NUMERIC: Binary transfer is forcibly disabled for NUMERIC data by the server for Vertica 11.0.2+.	true
ConnSettings	SQL commands to run upon connection. Uses **%3B** for semicolons.	string.Empty
IsolationLevel	Sets the transaction isolation level for Vertica. See Transactions for a description of the different transaction levels. This value is either Serializable, ReadCommitted, or Unspecified. See Setting the transaction isolation level for an example of setting the isolation level using this keyword. **Note:** By default, this value is set to IsolationLevel.Unspecified, which means the connection uses the server's default transaction isolation level. Vertica's default isolation level is IsolationLevel.ReadCommitted.	System.Data. IsolationLevel.Unspecified
Label	A string to identify the session on the server.	string
DirectBatchInsert	Deprecated	true
ResultBufferSize	The size of the buffer to use when streaming results. A value of 0 means ResultBufferSize is turned off.	8192
ConnectionTimeout	Number seconds to wait for a connection. A value of 0 means no timeout.	0

ReadOnly	A Boolean value. If true, throw an exception on write attempts.	false
Pooling	A boolean value, whether to enable connection pooling. Connection pooling is useful for server applications because it allows the server to reuse connections. This saves resources and enhances the performance of executing commands on the database. It also reduces the amount of time a user must wait to establish a connection to the database	false
MinPoolSize	An integer that defines the minimum number of connections to pool. **Valid Values:** Cannot be greater than the number of connections that the server is configured to allow. Otherwise, an exception results. **Default:** 55	1
MaxPoolSize	An integer that defines the maximum number of connections to pool. **Valid Values:** Cannot be greater than the number of connections that the server is configured to allow. Otherwise, an exception results.	20
LoadBalanceTimeout	The amount of time, expressed in seconds, to timeout or remove unused pooled connections. **Disable: **Set to 0 (no timeouts) If you are using a cluster environment to load-balance the work, then pool is restricted to the servers in the cluster when the pool was created. If additional servers are added to the cluster, and the pool is not removed, then the new servers are never added to the connection pool unless LoadBalanceTimeout is set and exceeded or VerticaConnection.ClearAllPools() is called manually from an application. If you are using load balancing, then set this property to a value that considers when new servers are added to the cluster. However, do not set it so low that pools are frequently removed and rebuilt, doing so makes pooling ineffective.	0 (no timeout)
SSL	A Boolean value, indicating whether to use SSL for the connection.	false
IntegratedSecurity	Provides a Boolean value that, when set to true, uses the user's Windows credentials for authentication, instead of user/password in the connection string.	false
KerberosServiceName	Provides the service name portion of the Vertica Kerberos principal; for example: vertica/host@EXAMPLE.COM	vertica
KerberosHostname	Provides the instance or host name portion of the Vertica Kerberos principal; for example: vertica/host@EXAMPLE.COM	Value specified in the servername connection string property

Load balancing in ADO.NET

Native connection load balancing

Native connection load balancing helps spread the overhead caused by client connections on the hosts in the Vertica database. Both the server and the client must enable native connection load balancing. If enabled by both, then when the client initially connects to a host in the database, the host picks a host to handle the client connection from a list of the currently up hosts in the database, and informs the client which host it has chosen.

If the initially-contacted host does not choose itself to handle the connection, the client disconnects, then opens a second connection to the host selected by the first host. The connection process to this second host proceeds as usual—if SSL is enabled, then SSL negotiations begin, otherwise the client begins the authentication process. See About native connection load balancing for details.

To enable native load balancing on your client, set the ConnectionLoadBalance connection parameter to true either in the connection string or using the ConnectionStringBuilder() . The following example demonstrates connecting to the database several times with native connection load balancing enabled, and fetching the name of the node handling the connection from the V_MONITOR. CURRENT_SESSION system table.

```
using System;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;

namespace ConsoleApplication1 {
   class Program {
      static void Main(string[] args) {
         VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
         builder.Host = "v_vmart_node0001.example.com";
         builder.Database = "VMart";
         builder.User = "dbadmin";
         // Enable native client load balancing in the client,
         // must also be enabled on the server!
         builder.ConnectionLoadBalance = true;

         // Connect 3 times to verify a new node is connected
         // for each connection.
         for (int i = 1; i <= 4; i++) {
            try {
               VerticaConnection _conn = new VerticaConnection(builder.ToString());
               _conn.Open();
               if (i == 1) {
                  // On the first connection, check the server policy for load balance
                  VerticaCommand sqlcom = _conn.CreateCommand();
                  sqlcom.CommandText = "SELECT LOAD_BALANCE_POLICY FROM V_CATALOG.DATABASES";
                  var returnValue = sqlcom.ExecuteScalar();
                  Console.WriteLine("Status of load balancy policy
          on server: " + returnValue.ToString() + "\n");
               }
               VerticaCommand command = _conn.CreateCommand();
               command.CommandText = "SELECT node_name FROM V_MONITOR.CURRENT_SESSION";
               VerticaDataReader dr = command.ExecuteReader();
               while (dr.Read()) {
                  Console.Write("Connect attempt #" + i + "... ");
                  Console.WriteLine("Connected to node " + dr[0]);
               }
               dr.Close();
               _conn.Close();
               Console.WriteLine("Disconnecting.\n");
            }
            catch(Exception e) {
               Console.WriteLine(e.Message);
            }
         }
      }
   }
}
```

Running the above example produces the following output:

```
Status of load balancing policy on server: roundrobin

Connect attempt #1... Connected to node v_vmart_node0001
Disconnecting.

Connect attempt #2... Connected to node v_vmart_node0002
Disconnecting.

Connect attempt #3... Connected to node v_vmart_node0003
Disconnecting.

Connect attempt #4... Connected to node v_vmart_node0001
Disconnecting.
```

Hostname-based load balancing

You can also balance workloads by resolving a single hostname to multiple IP addresses. The ADO.NET client driver load balances by automatically resolving the hostname to one of the specified IP addresses at random.

For example, suppose the hostname verticahost.example.com has the following entries in C:\Windows\System32\drivers\etc\hosts :

```
192.0.2.0 verticahost.example.com
192.0.2.1 verticahost.example.com
192.0.2.2 verticahost.example.com
```

Specifying the hostname verticahost.example.com randomly resolves to one of the listed IP addresses.

ADO.NET connection failover

If a client application attempts to connect to a host in the Vertica cluster that is down, the connection attempt fails when using the default connection configuration. This failure usually returns an error to the user. The user must either wait until the host recovers and retry the connection or manually edit the connection settings to choose another host.

Due to Vertica Analytic Database's distributed architecture, you usually do not care which database host handles a client application's connection. You can use the client driver's connection failover feature to prevent the user from getting connection errors when the host specified in the connection settings is unreachable. The JDBC driver gives you several ways to let the client driver automatically attempt to connect to a different host if the one specified in the connection parameters is unreachable:

- Configure your DNS server to return multiple IP addresses for a host name. When you use this host name in the connection settings, the client attempts to connect to the first IP address from the DNS lookup. If the host at that IP address is unreachable, the client tries to connect to the second IP, and so on until it either manages to connect to a host or it runs out of IP addresses.
- Supply a list of backup hosts for the client driver to try if the primary host you specify in the connection parameters is unreachable.
- (JDBC only) Use driver-specific connection properties to manage timeouts before attempting to connect to the next node.

For all methods, the process of failover is transparent to the client application (other than specifying the list of backup hosts, if you choose to use the list method of failover). If the primary host is unreachable, the client driver automatically tries to connect to other hosts.

Failover only applies to the initial establishment of the client connection. If the connection breaks, the driver does not automatically try to reconnect to another host in the database.

Choosing a failover method

You usually choose to use one of the two failover methods. However, they do work together. If your DNS server returns multiple IP addresses and you supply a list of backup hosts, the client first tries all of the IPs returned by the DNS server, then the hosts in the backup list.

> **Note**
> If a host name in the backup host list resolves to multiple IP addresses, the client does not try all of them. It just tries the first IP address in the list.

The DNS method of failover centralizes the configuration client failover. As you add new nodes to your Vertica Analytic Database cluster, you can choose to add them to the failover list by editing the DNS server settings. All client systems that use the DNS server to connect to Vertica Analytic Database automatically use connection failover without having to change any settings. However, this method does require administrative access to the DNS server that all clients use to connect to the Vertica Analytic Database cluster. This may not be possible in your organization.

Using the backup server list is easier than editing the DNS server settings. However, it decentralizes the failover feature. You may need to update the application settings on each client system if you make changes to your Vertica Analytic Database cluster.

Using DNS failover

To use DNS failover, you need to change your DNS server's settings to map a single host name to multiple IP addresses of hosts in your Vertica Analytic Database cluster. You then have all client applications use this host name to connect to Vertica Analytic Database.

You can choose to have your DNS server return as many IP addresses for the host name as you want. In smaller clusters, you may choose to have it return the IP addresses of all of the hosts in your cluster. However, for larger clusters, you should consider choosing a subset of the hosts to return. Otherwise there can be a long delay as the client driver tries unsuccessfully to connect to each host in a database that is down.

Using the backup host list

To enable backup list-based connection failover, your client application has to specify at least one IP address or host name of a host in the BackupServerNode parameter. The host name or IP can optionally be followed by a colon and a port number. If not supplied, the driver defaults to the standard Vertica port number (5433). To list multiple hosts, separate them by a comma.

The following example demonstrates setting the BackupServerNode connection parameter to specify additional hosts for the connection attempt. The connection string intentionally has a non-existent node, so that the initial connection fails. The client driver has to resort to trying the backup hosts to establish a connection to Vertica.

```
using System;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;

namespace ConsoleApplication1
{
   class Program
   {
      static void Main(string[] args)
      {
         VerticaConnectionStringBuilder builder =
      new VerticaConnectionStringBuilder();
         builder.Host = "not.a.real.host:5433";
         builder.Database = "VMart";
         builder.User = "dbadmin";
         builder.BackupServerNode =
      "another.broken.node:5433,v_vmart_node0002.example.com:5433";
         try
         {
            VerticaConnection _conn =
         new VerticaConnection(builder.ToString());
            _conn.Open();
            VerticaCommand sqlcom = _conn.CreateCommand();
            sqlcom.CommandText = "SELECT node_name FROM current_session";
            var returnValue = sqlcom.ExecuteScalar();
            Console.WriteLine("Connected to node: " +
         returnValue.ToString() + "\n");
            _conn.Close();
            Console.WriteLine("Disconnecting.\n");
         }
         catch (Exception e)
         {
            Console.WriteLine(e.Message);
         }
      }
   }
}
```

Notes

- When native connection load balancing is enabled, the additional servers specified in the BackupServerNode connection parameter are only used for the initial connection to a Vertica host. If host redirects the client to another host in the database cluster to handle its connection request, the second connection does not use the backup node list. This is rarely an issue, since native connection load balancing is aware of which nodes are currently up in the database. See Load balancing in ADO.NET .
- Connections to a host taken from the BackupServerNode list are not pooled for ADO.NET connections.

Configuring log properties (ADO.Net)

Log properties for ADO.Net are configured differently than they are other client drivers. On the other client drivers, log properties can be configured as one of the connection properties. The ADO.Net driver user the VerticaLogProperties class to configure the properties.

VerticaLogProperties

VerticaLogProperties is a static class that allows you to set and get the log settings for the ADO.net driver. You can control the log level, log path, and log namespace using this class.

The log is created when the first connection is opened. Once the connection is opened, you cannot change the log path. It must be set prior to opening the connection. You can change the log level and log namespace at any time.

Setting log properties

Setting the log properties is done using the three methods in the VerticaLogProperties class. The three methods are:

- SetLogPath(String path, bool persist)
- SetLogNamespace(String lognamespace, bool persist)
- SetLogLevel(VerticaLogLevel loglevel, bool persist)

Each of the methods requires a boolean persist argument. When set to true, the persist argument causes the setting to be written to the client's Windows Registry, where it is used for all subsequent connections. If set to false, then the log property only applies to the current session.

SetLogPath

The SetLogPath method takes as its arguments a string containing the path to the log file and the persist argument. If the path string contains only a directory path, then the log file is created with the name vdp-driver-MM-dd_HH.mm.ss.log (where MM-dd_HH.mm.ss is the date and time the log was created). If the path ends in a filename, such as log.txt or log.log, then the log is created with that filename.

If SetLogPath is called with an empty string for the path argument, then the client executable's current directory is used as the log path.

If SetLogPath is not called and no registry entry exists for the log path, and you have called any of the other VerticaLogProperties methods, then the client executable's current directory is used as the log path.

When the persist argument is set to true, the path specified is copied to the registry verbatim. If no filename was specified, then the filename is not saved to the registry.

> **Note**
> Note: The path must exist on the client system prior to calling this method. The method does not create directories.

Example Usage:

```
//set the log path
string path = "C:\\log";
VerticaLogProperties.SetLogPath(path, false);
```

SetLogNamespace

The SetLogNamespace method takes as its arguments a string containing the namespace to log and the persist argument. The namespace string to log can be one of the following:

- Vertica
- Vertica.Data.VerticaClient
- Vertica.Data.Internal.IO
- Vertica.Data.Internal.DataEngine
- Vertica.Data.Internal.Core

Namespaces can be truncated to include multiple child namespaces. For example, you can specify "Vertica.Data.Internal" to log for all of the Vertica.Data.Internal namespaces.

If a log namespace is not set, and no value is stored in the registry, then the "Vertica" namespace is used for logging.

Example Usage:

```
        //set namespace to log
        string lognamespace = "Vertica.Data.VerticaClient";
        VerticaLogProperties.SetLogNamespace(lognamespace, false);
```

SetLogLevel

The SetLogLevel method takes as its arguments a VerticaLogLevel type and the persist argument. The VerticaLogLevel argument can be one of:

- VerticaLogLevel.None
- VerticaLogLevel.Fatal
- VerticaLogLevel.Error
- VerticaLogLevel.Warning
- VerticaLogLevel.Info
- VerticaLogLevel.Debug
- VerticaLogLevel.Trace

If a log level is not set, and no value is stored in the registry, then VerticaLogLevel.None is used.

Example Usage:

```
        //set log level
        VerticaLogLevel level = VerticaLogLevel.Debug;
        VerticaLogProperties.SetLogLevel(level, false);
```

Getting log properties

You can get the log property values using the getters included in the VerticaLogProperties class. The properties are:

- LogPath
- LogNamespace
- LogLevel

Example Usage:

```
        //get current log settings
        string logpath = VerticaLogProperties.LogPath;
        VerticaLogLevel loglevel = VerticaLogProperties.LogLevel;
        string logns = VerticaLogProperties.LogNamespace;
        Console.WriteLine("Current Log Settings:");
        Console.WriteLine("Log Path: " + logpath);
        Console.WriteLine("Log Level: " + loglevel);
        Console.WriteLine("Log Namespace: " + logns);
```

Setting and getting log properties example

This complete example shows how to set and get log properties:

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
   class Program
   {
      static void Main(string[] args)
      {
```

//configure connection properties

```
        VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
        builder.Host = "192.168.1.10";
        builder.Database = "VMart";
        builder.User = "dbadmin";
```

//get current log settings

```
        string logpath = VerticaLogProperties.LogPath;
        VerticaLogLevel loglevel = VerticaLogProperties.LogLevel;
        string logns = VerticaLogProperties.LogNamespace;
        Console.WriteLine("\nOld Log Settings:");
        Console.WriteLine("Log Path: " + logpath);
        Console.WriteLine("Log Level: " + loglevel);
        Console.WriteLine("Log Namespace: " + logns);
```

//set the log path

```
        string path = "C:\\log";
        VerticaLogProperties.SetLogPath(path, false);
```

//set log level

```
        VerticaLogLevel level = VerticaLogLevel.Debug;
        VerticaLogProperties.SetLogLevel(level, false);
```

//set namespace to log

```
        string lognamespace = "Vertica";
        VerticaLogProperties.SetLogNamespace(lognamespace, false);
```

//open the connection

```
        VerticaConnection _conn = new VerticaConnection(builder.ToString());
        _conn.Open();
```

//get new log settings

```
        logpath = VerticaLogProperties.LogPath;
        loglevel = VerticaLogProperties.LogLevel;
        logns = VerticaLogProperties.LogNamespace;
        Console.WriteLine("\nNew Log Settings:");
        Console.WriteLine("Log Path: " + logpath);
        Console.WriteLine("Log Level: " + loglevel);
        Console.WriteLine("Log Namespace: " + logns);
```

//close the connection

```
        _conn.Close();      }
    }
}
```

The example produces the following output:

```
Old Log Settings:
Log Path:
Log Level: None
Log Namespace:
New Log Settings:
Log Path: C:\log
Log Level: Debug
Log Namespace: Vertica
```

Querying the database using ADO.NET

This section describes how to create queries to do the following:

- Inserting data into the database
- Read data from the database
- Load data into the database

> **Note**
> The ExecuteNonQuery() method used to query the database returns an int32 with the number of rows affected by the query. The maximum size of an int32 type is a constant and is defined to be 2,147,483,547. If your query returns more results than the int32 max, then ADO.NET throws an exception because of the overflow of the int32 type. However the query is still processed by Vertica even when the reporting of the return value fails. This is a limitation in .NET, as ExecuteNonQuery() is part of the standard ADO.NET interface.

In this section

- Inserting data (ADO.NET)
- Reading data (ADO.Net)
- Loading data through ADO.Net

Inserting data (ADO.NET)

Inserting data can done using the VerticaCommand class. VerticaCommand is an implementation of DbCommand. It allows you to create and send a SQL statement to the database. Use the CommandText method to assign a SQL statement to the command and then execute the SQL by calling the ExecuteNonQuery method. The ExecuteNonQuery method is used for executing statements that do not return result sets.

To insert a single row of data:

1. Create a connection to the database .
2. Create a command object using the connection.
   ```
   VerticaCommand command = _conn.CreateCommand();
   ```
3. Insert data using an INSERT statement. The following is an example of a simple insert. Note that is does not contain a COMMIT statement because the Vertica ADO.NET driver operates in autocommit mode.
   ```
   command.CommandText =
       "INSERT into test values(2, 'username', 'email', 'password')";
   ```
4. Execute the query. The rowsAdded variable contains the number of rows added by the insert statement.
   ```
   Int32 rowsAdded = command.ExecuteNonQuery();
   ```

   The ExecuteNonQuery() method returns the number of rows affected by the command for UPDATE, INSERT, and DELETE statements. For all other types of statements it returns -1. If a rollback occurs then it is also set to -1.

Example usage:

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
   class Program
   {
      static void Main(string[] args)
      {
         VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
         builder.Host = "192.168.1.10";
         builder.Database = "VMart";
         builder.User = "dbadmin";
         VerticaConnection _conn = new VerticaConnection(builder.ToString());
         _conn.Open();
      VerticaCommand command = _conn.CreateCommand();
      command.CommandText =
            "INSERT into test values(2, 'username', 'email', 'password')";
      Int32 rowsAdded = command.ExecuteNonQuery();
      Console.WriteLine( rowsAdded + " rows added!");
         _conn.Close();
      }
   }
}
```

In this section

- Using parameters
- Creating and rolling back transactions

Using parameters

You can use parameters to execute similar SQL statements repeatedly and efficiently.

Using parameters

VerticaParameters are an extension of the System.Data.DbParameter base class in ADO.NET and are used to set parameters in commands sent to the server. Use Parameters in all queries (SELECT/INSERT/UPDATE/DELETE) for which the values in the WHERE clause are not static; that is for all queries that have a known set of columns, but whose filter criteria is set dynamically by an application or end user. Using parameters in this way greatly decreases the chances of a SQL injection issue that can occur when simply creating a SQL query from a number of variables.

Parameters require that a valid DbType, VerticaDbType, or System type be assigned to the parameter. See Data types and ADO.NET data types for a mapping of System, Vertica, and DbTypes.

To create a parameter placeholder, place either the at sign (@) or a colon (:) character in front of the parameter name in the actual query string. Do not insert any spaces between the placeholder indicator (@ or :) and the placeholder.

> **Note**
> The @ character is the preferred way to identify parameters. The colon (:) character is supported for backward compatibility.

For example, the following typical query uses the string 'MA' as a filter.

```
SELECT customer_name, customer_address, customer_city, customer_state
FROM customer_dimension WHERE customer_state = 'MA';
```

Instead, the query can be written to use a parameter. In the following example, the string MA is replaced by the parameter placeholder @STATE.

```
SELECT customer_name, customer_address, customer_city, customer_state
FROM customer_dimension WHERE customer_state = @STATE;
```

For example, the ADO.net code for the prior example would be written as:

```
VerticaCommand command = _conn.CreateCommand();
command.CommandText = “SELECT customer_name, customer_address, customer_city, customer_state
   FROM customer_dimension WHERE customer_state = @STATE”;
command.Parameters.Add(new VerticaParameter( “STATE”, VerticaType.VarChar));
command.Parameters["STATE"].Value = "MA";
```

> **Note**
> Although the VerticaCommand class supports a Prepare() method, you do not need to call the Prepare() method for parameterized statements because Vertica automatically prepares the statement for you.

Creating and rolling back transactions

Creating transactions

Transactions in Vertica are atomic, consistent, isolated, and durable. When you connect to a database using the Vertica ADO.NET Driver, the connection is in autocommit mode and each individual query is committed upon execution. You can collect multiple statements into a single transaction and commit them at the same time by using a transaction. You can also choose to rollback a transaction before it is committed if your code determines that a transaction should not commit.

Transactions use the VerticaTransaction object, which is an implementation of DbTransaction. You must associate the transaction with the VerticaCommand object.

The following code uses an explicit transaction to insert one row each into to tables of the VMart schema.

To create a transaction in Vertica using the ADO.NET driver:

1. Create a connection to the database .
2. Create a command object using the connection.
   ```
   VerticaCommand command = _conn.CreateCommand();
   ```
3. Start an explicit transaction, and associate the command with it.
   ```
   VerticaTransaction txn = _conn.BeginTransaction();
   command.Connection = _conn;
   command.Transaction = txn;
   ```
4. Execute the individual SQL statements to add rows.
   ```
   command.CommandText =
      "insert into product_dimension values( ... )";
   command.ExecuteNonQuery();
   command.CommandText =
      "insert into store_orders_fact values( ... )";
   ```
5. Commit the transaction.
   ```
   txn.Commit();
   ```

Rolling back transactions

If your code checks for errors, then you can catch the error and rollback the entire transaction.

```
VerticaTransaction txn = _conn.BeginTransaction();
VerticaCommand command = new
      VerticaCommand("insert into product_dimension values( 838929, 5, 'New item 5' )", _conn);
// execute the insert
command.ExecuteNonQuery();
command.CommandText = "insert into product_dimension values( 838929, 6, 'New item 6' )";
// try insert and catch any errors
bool error = false;
try
{
   command.ExecuteNonQuery();
}
catch (Exception e)
{
   Console.WriteLine(e.Message);
   error = true;
}
if (error)
{
   txn.Rollback();
   Console.WriteLine("Errors. Rolling Back.");
}
else
{
   txn.Commit();
   Console.WriteLine("Queries Successful. Committing.");
}
```

Commit and rollback example

This example details how you can commit or rollback queries during a transaction.

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
   class Program
   {
      static void Main(string[] args)
      {
         VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
         builder.Host = "192.168.1.10";
         builder.Database = "VMart";
         builder.User = "dbadmin";
         VerticaConnection _conn = new VerticaConnection(builder.ToString());
         _conn.Open();
         bool error = false;
            VerticaCommand command = _conn.CreateCommand();
            VerticaCommand command2 = _conn.CreateCommand();
            VerticaTransaction txn = _conn.BeginTransaction();
            command.Connection = _conn;
            command.Transaction = txn;
            command.CommandText =
            "insert into test values(1, 'test', 'test', 'test' )";
            Console.WriteLine(command.CommandText);
            try
            {
               command.ExecuteNonQuery();
            }
```

```
            }
            catch (Exception e)
            {
                Console.WriteLine(e.Message);
                error = true;
            }
            command.CommandText =
            "insert into test values(2, 'ear', 'eye', 'nose', 'extra' )";
            Console.WriteLine(command.CommandText);
            try
            {
                command.ExecuteNonQuery();
            }
            catch (Exception e)
            {
                Console.WriteLine(e.Message);
                error = true;
            }
            if (error)
            {
                txn.Rollback();
                Console.WriteLine("Errors. Rolling Back.");
            }
            else
            {
                txn.Commit();
                Console.WriteLine("Queries Successful. Committing.");
            }
        _conn.Close();
    }
  }
}
```

The example displays the following output on the console:

```
insert into test values(1, 'test', 'test', 'test' )
insert into test values(2, 'ear', 'eye', 'nose', 'extra' )
[42601]ERROR: INSERT has more expressions than target columns
Errors. Rolling Back.
```

- Setting the transaction isolation level

In this section

- Setting the transaction isolation level

Setting the transaction isolation level

You can set the transaction isolation level on a per-connection and per-transaction basis. See Transaction for an overview of the transaction isolation levels supported in Vertica. To set the default transaction isolation level for a connection, use the *IsolationLevel* keyword in the VerticaConnectionStringBuilder string (see Connection String Keywords for details). To set the isolation level for an individual transaction, pass the isolation level to the VerticaConnection.BeginTransaction() method call to start the transaction.

To set the isolation level on a connection-basis:

1. Use the VerticaConnectionStringBuilder to build the connection string.
2. Provide a value for the IsolationLevel builder string. It can take one of two values: IsolationLevel.ReadCommited (default) or IsolationLevel.Serializeable. For example:

```
VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
builder.Host = "192.168.1.100";
builder.Database = "VMart";
builder.User = "dbadmin";
builder.IsolationLevel = System.Data.IsolationLevel.Serializeable
VerticaConnection _conn1 = new VerticaConnection(builder.ToString());
_conn1.Open();
```

To set the isolation level on a transaction basis:

1. Set the IsolationLevel on the BeginTransaction method, for example

```
VerticaTransaction txn = _conn.BeginTransaction(IsolationLevel.Serializable);
```

Example usage:

The following example demonstrates:

- getting the connection's transaction isolation level.
- setting the connection's isolation level using connection property.
- setting the transaction isolation level for a new transaction.

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
   class Program
   {
      static void Main(string[] args)
      {
         VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
         builder.Host = "192.168.1.10";
         builder.Database = "VMart";
         builder.User = "dbadmin";
         VerticaConnection _conn1 = new VerticaConnection(builder.ToString());
          _conn1.Open();
         VerticaTransaction txn1 = _conn1.BeginTransaction();
         Console.WriteLine("\n Transaction 1 Transaction Isolation Level: " +
          txn1.IsolationLevel.ToString());
         txn1.Rollback();
         VerticaTransaction txn2 = _conn1.BeginTransaction(IsolationLevel.Serializable);
         Console.WriteLine("\n Transaction 2 Transaction Isolation Level: " +
          txn2.IsolationLevel.ToString());
         txn2.Rollback();
         VerticaTransaction txn3 = _conn1.BeginTransaction(IsolationLevel.ReadCommitted);
         Console.WriteLine("\n Transaction 3 Transaction Isolation Level: " +
          txn3.IsolationLevel.ToString());
         _conn1.Close();
      }
   }
}
```

When run, the example code prints the following to the system console:

```
Transaction 1 Transaction Isolation Level: ReadCommitted
Transaction 2 Transaction Isolation Level: Serializable
Transaction 3 Transaction Isolation Level: ReadCommitted
```

Reading data (ADO.Net)

To read data from the database use VerticaDataReader, an implementation of DbDataReader. This implementation is useful for moving large volumes of data quickly off the server where it can be run through analytic applications.

> **Note**
> A VerticaCommand cannot execute anything else while it has an open VerticaDataReader associated with it. To execute something else, close the data reader or use a different VerticaCommand object.

To read data from the database using VerticaDataReader:

1. Create a connection to the database .
2. Create a command object using the connection.
```
VerticaCommand command = _conn.CreateCommand();
```
3. Create a query. This query works with the example VMart database.
```
command.CommandText =
"SELECT fat_content, product_description " +
"FROM (SELECT DISTINCT fat_content, product_description" +
"      FROM product_dimension " +
"      WHERE department_description " +        "      IN ('Dairy') " +
"      ORDER BY fat_content) AS food " +
"LIMIT 10;";
```
4. Execute the reader to return the results from the query. The following command calls the ExecuteReader method of the VerticaCommand object to obtain the VerticaDataReader object.
```
VerticaDataReader dr = command.ExecuteReader();
```
5. Read the data. The data reader returns results in a sequential stream. Therefore, you must read data from tables row-by-row. The following example uses a while loop to accomplish this:
```
Console.WriteLine("\n\n Fat Content\t  Product Description");
   Console.WriteLine("------------\t  -------------------");
   int rows = 0;
   while (dr.Read())
   {
     Console.WriteLine("     " + dr[0] + "    \t  " + dr[1]);
     ++rows;
   }
   Console.WriteLine("------------\n  (" + rows + " rows)\n");
```
6. When you're finished, close the data reader to free up resources.
```
dr.Close();
```

Example usage:

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
   class Program
   {
      static void Main(string[] args)
      {
         VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
         builder.Host = "192.168.1.10";
         builder.Database = "VMart";
         builder.User = "dbadmin";
         VerticaConnection _conn = new VerticaConnection(builder.ToString());
         _conn.Open();
      VerticaCommand command = _conn.CreateCommand();
         command.CommandText =
            "SELECT fat_content, product_description " +
            "FROM (SELECT DISTINCT fat_content, product_description" +
            "      FROM product_dimension " +
            "      WHERE department_description " +
            "      IN ('Dairy') " +
            "      ORDER BY fat_content) AS food " +
            "LIMIT 10;";
       VerticaDataReader dr = command.ExecuteReader();

       Console.WriteLine("\n\n Fat Content\t  Product Description");
       Console.WriteLine("------------\t  --------------------");
       int rows = 0;
       while (dr.Read())
       {
            Console.WriteLine("     " + dr[0] + "    \t  " + dr[1]);
            ++rows;
       }
       Console.WriteLine("------------\n  (" + rows + " rows)\n");
           dr.Close();
         _conn.Close();
      }
   }
}
```

Loading data through ADO.Net

This section details the different ways that you can load data in Vertica using the ADO.NET client driver:

- Using the Vertica Data Adapter
- Using batch inserts and prepared statements
- Streaming data via ADO.NET

In this section

- Using the Vertica data adapter
- Using batch inserts and prepared statements
- Streaming data via ADO.NET

Using the Vertica data adapter

The Vertica data adapter (VerticaDataAdapter) enables a client to exchange data between a data set and a Vertica database. It is an implementation of DbDataAdapter. You can use VerticaDataAdapter to simply read data, or, for example, read data from a database into a data set, and then write changed data from the data set back to the database.

Batching updates

When using the Update() method to update a dataset, you can optionally use the UpdateBatchSize() method prior to calling Update() to reduce the number of times the client communicates with the server to perform the update. The default value of UpdateBatchSize is 1. If you have multiple rows.Add() commands for a data set, then you can change the batch size to an optimal size to speed up the operations your client must perform to complete the update.

Reading data from Vertica using the data adapter:

The following example details how to perform a select query on the VMart schema and load the result into a DataTable, then output the contents of the DataTable to the console.

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using System.Data.SqlClient;
Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
   class Program
   {
      static void Main(string[] args)
      {
         VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
         builder.Host = "192.168.1.10";
         builder.Database = "VMart";
         builder.User = "dbadmin";
         VerticaConnection _conn = new VerticaConnection(builder.ToString());
         _conn.Open();

         // Try/Catch any exceptions
               try
         {
            using (_conn)
            {
               // Create the command
               VerticaCommand command = _conn.CreateCommand();
               command.CommandText = "select product_key, product_description " +
                  "from product_dimension where product_key < 10";

                  // Associate the command with the connection
                  command.Connection = _conn;

                  // Create the DataAdapter
                  VerticaDataAdapter adapter = new VerticaDataAdapter();
                  adapter.SelectCommand = command;

                  // Fill the DataTable
                  DataTable table = new DataTable();
                  adapter.Fill(table);

                  //  Display each row and column value.
                  int i = 1;
                  foreach (DataRow row in table.Rows)
                  {
                     foreach (DataColumn column in table.Columns)
                     {
                        Console.Write(row[column] + "\t");
                     }
                     Console.WriteLine();
                     i++;
                  }
```

```
                }
                Console.WriteLine(i + " rows returned.");
            }
        }
        catch (Exception e)
        {
            Console.WriteLine(e.Message);
        }
        _conn.Close();
    }
  }
}
```

Reading data from Vertica into a data set and changing data:

The following example shows how to use a data adapter to read from and insert into a dimension table of the VMart schema.

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using System.Data.SqlClient;
using Vertica.Data.VerticaClient
namespace ConsoleApplication
{
  class Program
  {
    static void Main(string[] args)
    {
      VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
      builder.Host = "192.168.1.10";
      builder.Database = "VMart";
      builder.User = "dbadmin";
      VerticaConnection _conn = new VerticaConnection(builder.ToString());
      _conn.Open();

        // Try/Catch any exceptions
        try
      {
        using (_conn)
        {

            //Create a data adapter object using the connection
            VerticaDataAdapter da = new VerticaDataAdapter();

            //Create a select statement that retrieves data from the table
            da.SelectCommand = new
          VerticaCommand("select * from product_dimension where product_key < 10",
          _conn);
            //Set up the insert command for the data adapter, and bind variables for some of the columns
            da.InsertCommand = new
          VerticaCommand("insert into product_dimension values( :key, :version, :desc )",
          _conn);
        da.InsertCommand.Parameters.Add(new VerticaParameter("key", VerticaType.BigInt));
        da.InsertCommand.Parameters.Add(new VerticaParameter("version", VerticaType.BigInt));
        da.InsertCommand.Parameters.Add(new VerticaParameter("desc", VerticaType.VarChar));
        da.InsertCommand.Parameters[0].SourceColumn = "product_key";
        da.InsertCommand.Parameters[1].SourceColumn = "product_version";
        da.InsertCommand.Parameters[2].SourceColumn = "product_description";
        da.TableMappings.Add("product_key", "product_key");
        da.TableMappings.Add("product_version", "product_version");
```

```
            da.TableMappings.Add("product_description", "product_description");

                //Create and fill a Data set for this dimension table, and get the resulting DataTable.
                DataSet ds = new DataSet();
            da.Fill(ds, 0, 0, "product_dimension");
            DataTable dt = ds.Tables[0];

                //Bind parameters and add two rows to the table.
                DataRow dr = dt.NewRow();
            dr["product_key"] = 838929;
            dr["product_version"] = 5;
            dr["product_description"] = "New item 5";
            dt.Rows.Add(dr);
            dr = dt.NewRow();
            dr["product_key"] = 838929;
            dr["product_version"] = 6;
            dr["product_description"] = "New item 6";
            dt.Rows.Add(dr);
            //Extract the changes for the added rows.
                DataSet ds2 = ds.GetChanges();

                //Send the modifications to the server.
                int updateCount = da.Update(ds2, "product_dimension");

               //Merge the changes into the original Data set, and mark it up to date.
                ds.Merge(ds2);
            ds.AcceptChanges();
            Console.WriteLine(updateCount + " updates made!");
          }
        }
        catch (Exception e)
        {
            Console.WriteLine(e.Message);
        }
        _conn.Close();
    }
  }
}
```

Using batch inserts and prepared statements

You can load data in batches using a prepared statement with parameters. You can also use transactions to rollback the batch load if any errors are encountered.

If you are loading large batches of data (more than 100MB), then consider using a direct batch insert.

The following example details using data contained in arrays, parameters, and a transaction to batch load data.

The test table used in the example is created with the command:

```
=> CREATE TABLE test (id INT, username VARCHAR(24), email VARCHAR(64), password VARCHAR(8));
```

Example batch insert using parameters and transactions

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
  class Program
```

```
{
    static void Main(string[] args)
    {
        VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
        builder.Host = "192.168.1.10";
        builder.Database = "VMart";
        builder.User = "dbadmin";
        VerticaConnection _conn = new VerticaConnection(builder.ToString());
        _conn.Open();
        // Create arrays for column data
            int[] ids = {1, 2, 3, 4};
        string[] usernames = {"user1", "user2", "user3", "user4"};
        string[] emails = { "user1@example.com", "user2@example.com","user3@example.com","user4@example.com" };
        string[] passwords = { "pass1", "pass2", "pass3", "pass4" };
        // create counters for accepted and rejected rows
            int rows = 0;
        int rejRows = 0;
        bool error = false;
        // Create the transaction
            VerticaTransaction txn = _conn.BeginTransaction();
        // Create the parameterized query and assign parameter types
            VerticaCommand command = _conn.CreateCommand();
        command.CommandText = "insert into TEST values (@id, @username, @email, @password)";
        command.Parameters.Add(new VerticaParameter("id", VerticaType.BigInt));
        command.Parameters.Add(new VerticaParameter("username", VerticaType.VarChar));
        command.Parameters.Add(new VerticaParameter("email", VerticaType.VarChar));
        command.Parameters.Add(new VerticaParameter("password", VerticaType.VarChar));
        // Prepare the statement
            command.Prepare();

            // Loop through the column arrays and insert the data
            for (int i = 0; i < ids.Length; i++)            {
          command.Parameters["id"].Value = ids[i];
          command.Parameters["username"].Value = usernames[i];
          command.Parameters["email"].Value = emails[i];
          command.Parameters["password"].Value = passwords[i];
          try
          {
              rows += command.ExecuteNonQuery();
          }
          catch (Exception e)
          {
              Console.WriteLine("\nInsert failed - \n  " + e.Message + "\n");
              ++rejRows;
              error = true;
          }
        }
        if (error)
        {
          // Roll back if errors
                Console.WriteLine("Errors. Rolling Back Transaction.");
          Console.WriteLine(rejRows + " rows rejected.");
          txn.Rollback();
        }
        else
        {
          // Commit if no errors
                Console.WriteLine("No Errors. Committing Transaction.");
          txn.Commit();
          Console.WriteLine("Inserted " + rows + " rows. ");
        }
```

```
        _conn.Close();
      }
   }
}
```

Streaming data via ADO.NET

There are two options to stream data from a file on the client to your Vertica database through ADO.NET:

- Use the VerticaCopyStream ADO.NET class to stream data in an object-oriented manner
- Execute a COPY LOCAL SQL statement to stream the data

The topics in this section explain how to use these options.

In this section

- Streaming from the client via VerticaCopyStream
- Using copy with ADO.NET

Streaming from the client via VerticaCopyStream

The VerticaCopyStream class lets you stream data from the client system to a Vertica database. It lets you use the SQL COPY statement directly without having to copy the data to a host in the database cluster first by substituting one or more data stream(s) for STDIN.

Notes:

- Use Transactions and disable auto commit on the copy command for better performance.
- Disable auto commit using the copy command with the 'no commit' modifier. You must explicitly disable commits. Enabling transactions does not disable autocommit when using VerticaCopyStream.
- The copy command used with VerticaCopyStream uses copy syntax.
- VerticaCopyStream.rejects is zeroed every time execute is called. If you want to capture the number of rejects, assign the value of VerticaCopyStream.rejects to another variable before calling execute again.
- You can add multiple streams using multiple AddStream() calls.

Example usage:

The following example demonstrates using VerticaCopyStream to copy a file stream into Vertica.

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using System.IO;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
   class Program
   {
      static void Main(string[] args)
      {
         // Configure connection properties
               VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
         builder.Database = "VMart";
         builder.User = "dbadmin";
         //open the connection
         VerticaConnection _conn = new VerticaConnection(builder.ToString());
         _conn.Open();
         try
         {
            using (_conn)
            {
               // Start a transaction
                     VerticaTransaction txn = _conn.BeginTransaction();
```

```
                // Create a table for this example
                VerticaCommand command = new VerticaCommand("DROP TABLE IF EXISTS copy_table", _conn);
        command.ExecuteNonQuery();
           command.CommandText = "CREATE TABLE copy_table (Last_Name char(50), "
                    + "First_Name char(50),Email char(50), "
                    + "Phone_Number char(15))";
           command.ExecuteNonQuery();
           // Create a new filestream from the data file
                string filename = "C:/customers.txt";
         Console.WriteLine("\n\nLoading File: " + filename);
           FileStream inputfile = File.OpenRead(filename);
           // Define the copy command
                string copy = "copy copy_table from stdin record terminator E'\n' delimiter '|'" + " enforcelength "
              + " no commit";
           // Create a new copy stream instance with the connection and copy statement
                VerticaCopyStream vcs = new VerticaCopyStream(_conn, copy);

                // Start the VerticaCopyStream process
                vcs.Start();
                // Add the file stream
                vcs.AddStream(inputfile, false);

                // Execute the copy
                vcs.Execute();

                // Finish stream and write out the list of inserted and rejected rows
                long rowsInserted = vcs.Finish();
        IList<long> rowsRejected = vcs.Rejects;
        // Does not work when rejected or exceptions defined
           Console.WriteLine("Number of Rows inserted: " + rowsInserted);
           Console.WriteLine("Number of Rows rejected: " + rowsRejected.Count);
           if (rowsRejected.Count > 0)
           {
              for (int i = 0; i < rowsRejected.Count; i++)
              {
                 Console.WriteLine("Rejected row #{0} is row {1}", i, rowsRejected[i]);
              }
           }

                // Commit the changes
                txn.Commit();
        }
        }
        catch (Exception e)
        {
           Console.WriteLine(e.Message);
        }

           //close the connection
           _conn.Close();
   }
   }
}
```

Using copy with ADO.NET

To use COPY with ADO.NET, just execute a COPY statement and the path to the source file on the client system. This method is simpler than using the VerticaCopyStream class. However, you may prefer using VerticaCopyStream if you have many files to copy to the database or if your data comes from a source other than a local file (streamed over a network connection, for example).

The following example code demonstrates using COPY to copy a file from the client to the database. It is the same as the code shown in Bulk Loading Using the COPY Statement and the path to the data file is on the client system, rather than on the server.

To load data that is stored on a database node, use a VerticaCommand object to create a COPY command:

1. Create a connection to the database through the node on which the data file is stored.
2. Create a command object using the connection.
   ```
   VerticaCommand command = _conn.CreateCommand();
   ```
3. Copy data. The following is an example of using the COPY command to load data. It uses the LOCAL modifier to copy a file local to the client issuing the command.
   ```
   command.CommandText = "copy lcopy_table from '/home/dbadmin/customers.txt'"
    + " record terminator E'\n' delimiter '|'"
    + " enforcelength ";

   Int32 insertedRows = command.ExecuteNonQuery();
   Console.WriteLine(insertedRows + " inserted.");
   ```

Example usage:

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using System.IO;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
   class Program
   {
      static void Main(string[] args)
      {
         // Configure connection properties
         VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
    builder.Host = "192.168.1.10";
      builder.Database = "VMart";
      builder.User = "dbadmin";

               // Open the connection
                VerticaConnection _conn = new VerticaConnection(builder.ToString());
         _conn.Open();
         try
         {
            using (_conn)
            {

                     // Start a transaction
                     VerticaTransaction txn = _conn.BeginTransaction();

                     // Create a table for this example
                     VerticaCommand command = new VerticaCommand("DROP TABLE IF EXISTS lcopy_table", _conn);
               command.ExecuteNonQuery();
               command.CommandText = "CREATE TABLE IF NOT EXISTS lcopy_table (Last_Name char(50), "
                           + "First_Name char(50),Email char(50), "
                           + "Phone_Number char(15))";
               command.ExecuteNonQuery();
               // Define the copy command
                     command.CommandText = "copy lcopy_table from '/home/dbadmin/customers.txt'"
         + " record terminator E'\n' delimiter '|'"
                  + " enforcelength "
            + " no commit";
                     // Execute the copy
      Int32 insertedRows = command.ExecuteNonQuery();
Console.WriteLine(insertedRows + " inserted.");
                     // Commit the changes
                     txn.Commit();
            }
         }
         catch (Exception e)
         {
            Console.WriteLine("Exception: " + e.Message);
         }

                // Close the connection
                _conn.Close();
      }
   }
}
```

Canceling ADO.NET queries

You can cancel a running vsql query by calling the .Cancel() method of any Command object. The SampleCancelTests class demonstrates how to cancel a query after reading a specified number of rows. It implements the following methods:

- SampleCancelTest() executes the Setup() function to create a test table. Then, it calls RunQueryAndCancel() and RunSecondQuery() to demonstrate how to cancel a query after it reads a specified number of rows. Finally, it runs the Cleanup() function to drop the test table.
- Setup() creates a database for the example queries.
- Cleanup() drops the database.
- RunQueryAndCancel() reads exactly 100 rows from a query that returns more than 100 rows.
- RunSecondQuery() reads all rows from a query.

```
using System;
using Vertica.Data.VerticaClient;

class SampleCancelTests
{
    // Creates a database table, executes a query that cancels during a read loop,
    // executes a query that does not cancel, then drops the test database table.
    // connection: A connection to a Vertica database.

    public static void SampleCancelTest(VerticaConnection connection)
    {
        VerticaCommand command = connection.CreateCommand();

        Setup(command);

        try
        {
            Console.WriteLine("Running query that will cancel after reading 100 rows...");
            RunQueryAndCancel(command);
            Console.WriteLine("Running a second query...");
            RunSecondQuery(command);
            Console.WriteLine("Finished!");
        }
        finally
        {
            Cleanup(command);
        }
    }

    // Set up the database table for the example.
    // command: A Command object used to execute the query.
    private static void Setup(VerticaCommand command)
    {
        // Create table used for test.
        Console.WriteLine("Creating and loading table...");
        command.CommandText = "DROP TABLE IF EXISTS adocanceltest";
        command.ExecuteNonQuery();
        command.CommandText = "CREATE TABLE adocanceltest(id INTEGER, time TIMESTAMP)";
        command.ExecuteNonQuery();
        command.CommandText = @"INSERT INTO adocanceltest
        SELECT row_number() OVER(), slice_time
            FROM(
                SELECT slice_time FROM(
                SELECT '2021-01-01'::timestamp s UNION ALL SELECT '2022-01-01'::timestamp s
                ) sq TIMESERIES slice_time AS '1 second' OVER(ORDER BY s)
            ) sq2";
        command.ExecuteNonQuery();
    }
```

```
// Clean up the database after running the example.
// command: A Command object used to execute the query.
private static void Cleanup(VerticaCommand command)
{
    command.CommandText = "DROP TABLE IF EXISTS adocanceltest";
    command.ExecuteNonQuery();
}

// Execute a query that returns many rows and cancels after reading 100.
// command: A Command object used to execute the query.
private static void RunQueryAndCancel(VerticaCommand command)
{
    command.CommandText = "SELECT COUNT(id) from adocanceltest";
    int fullRowCount = Convert.ToInt32(command.ExecuteScalar());

    command.CommandText = "SELECT id, time FROM adocanceltest";
    VerticaDataReader dr = command.ExecuteReader();
    int nCount = 0;
    try
    {
        while (dr.Read())
        {
            nCount++;
            if (nCount == 100)
            {
                // After reaching 100 rows, cancel the command
                // Note that it is not necessary to read the remaining rows
                command.Cancel();
                return;
            }
        }
    }
    catch (Exception e)
    {
        Console.WriteLine(e.Message);
    }
    finally
    {
        dr.Close();
        // Verify that the cancel stopped the query
        Console.WriteLine((fullRowCount - nCount) + " rows out of " + fullRowCount + " discarded by cancel");
    }
}

// Execute a simple query and read all results.
// command: A Command object used to execute the query.
private static void RunSecondQuery(VerticaCommand command)
{
    command.CommandText = "SELECT 1 FROM dual";
    VerticaDataReader dr = command.ExecuteReader();
    try
    {
        while (dr.Read())
        {
            ;
        }
    }
    catch (Exception e)
    {
        Console.WriteLine(e.Message);
        Console.WriteLine("Warning: no exception should be thrown on query after cancel");
```

```
        }
        finally
        {
            dr.Close();
        }
    }
}
```

Handling messages (ADO.NET)

You can capture info and warning messages that Vertica provides to the ADO.NET driver by using the InfoMessage event on the VerticaConnection delegate class. This class captures messages that are not severe enough to force an exception to be triggered, but might still provide information that can benefit your application.

To use the VerticaInfoMessageEventHander class:

1. Create a method to handle the message sent from the even handler:
   ```
   static void conn_InfoMessage(object sender, VerticaInfoMessageEventArgs e)
   {
       Console.WriteLine(e.SqlState + ": " + e.Message);
   }
   ```
2. Create a connection and register a new VerticaInfoMessageHandler delegate for the InfoMessage event:
   ```
   _conn.InfoMessage += new VerticaInfoMessageEventHandler(conn_InfoMessage);
   ```
3. Execute your queries. If a message is generated, then the event handle function is run.
4. You can unsubscribe from the event with the following command:
   ```
   _conn.InfoMessage -= new VerticaInfoMessageEventHandler(conn_InfoMessage);
   ```

Example usage:

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
    class Program
    {
```

// define message handler to deal with messages

```
        static void conn_InfoMessage(object sender, VerticaInfoMessageEventArgs e)
        {
            Console.WriteLine(e.SqlState + ": " + e.Message);
        }
        static void Main(string[] args)
        {
```

//configure connection properties

```
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";
```

//open the connection

```
            VerticaConnection _conn = new VerticaConnection(builder.ToString());
            _conn.Open();
```

//create message handler instance by subscribing it to the InfoMessage event of the connection

```
            _conn.InfoMessage += new VerticaInfoMessageEventHandler(conn_InfoMessage);
```

//create and execute the command

```
        VerticaCommand cmd = _conn.CreateCommand();
        cmd.CommandText = "drop table if exists fakeTable";
        cmd.ExecuteNonQuery();
```

//close the connection

```
        _conn.Close();
    }
  }
}
```

This examples displays the following when run:

```
00000: Nothing was dropped
```

Getting table metadata (ADO.Net)

You can get the table metadata by using the GetSchema() method on a connection and loading the metadata into a DataTable:

- *database_name* , *schema_name* , and *table_name* can be set to null , a specific name, or use a LIKE pattern.
- *table_type* can be one of:
  - "SYSTEM TABLE"
  - "TABLE"
  - "GLOBAL TEMPORARY"
  - "LOCAL TEMPORARY"
  - "VIEW"
  - null
- If *table_type* is null , then the metadata for all metadata tables is returned.

For example:

```
DataTable table = _conn.GetSchema("Tables", new string[] { null, null, null, "SYSTEM TABLE" });
```

Examples

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
   class Program
   {
      static void Main(string[] args)
      {
         // configure connection properties
         VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
         builder.Host = "192.168.1.10";
         builder.Database = "VMart";
         builder.User = "dbadmin";

         // open the connection
         VerticaConnection _conn = new VerticaConnection(builder.ToString());
         _conn.Open();

         // create a new data table containing the schema
         // the last argument can be "SYSTEM TABLE", "TABLE", "GLOBAL TEMPORARY",
         // "LOCAL TEMPORARY", "VIEW", or null for all types
         DataTable table = _conn.GetSchema("Tables", new string[] { null, null, null, "SYSTEM TABLE" });

         // print out the schema
         foreach (DataRow row in table.Rows) {
            foreach (DataColumn col in table.Columns)
            {
               Console.WriteLine("{0} = {1}", col.ColumnName, row[col]);
            }
            Console.WriteLine("============================");
         }
```

//close the connection

```
         _conn.Close();
      }
   }
}
```

Programming Python client applications

To use Python with Vertica, you must either install the Vertica Open Source Python Client or install the pyodbc module and a Vertica ODBC driver on the machine where Python is installed. See Python prerequisites .

Python on Linux

Most Linux distributions come with Python preinstalled. If you want a more recent version, you can download and build it from the source code, though sometimes RPMs are also available. See the Python Web site and click an individual release for details. See also Python documentation .

To determine the Python version on your Linux operating systems, type the following at a command prompt:

```
# python -V
```

The system returns the version; for example:

```
Python 3.3.4
```

Python on Windows

Windows operating systems do not include Python by default. There are several different distributions of Python for windows:

- The ActiveState Web site distributes a free Windows installer for Python called ActivePython .
- The official Python.org site has installer packages for several versions of Python.

If you need installation instructions for Windows, see Using Python on Windows at python.org.

Python and unicode

When you are using Python, be sure that all of your components are using the same unicode text encoding. By default, the DSN Parameter ColumnsAsChar causes the ODBC driver to report CHAR and VARCHAR values as SQL_WCHAR. The driver returns these values to the driver manager in the encoding expected by the driver manager, as controlled by the DriverManagerEncoding parameter in vertica.ini. Similarly, your Python application must use the encoding expected by the driver manager. If any of these components use different encodings, your output can become garbled.

The Vertica Python client

The Vertica Python client is open source and available at https://github.com/vertica/vertica-python .

Using pyodbc and Vertica

Before you can connect to Vertica using pyodbc, you need to download the pyodbc module, which communicates with iODBC/unixODBC driver on UNIX operating systems and the ODBC Driver Manager for Windows operating systems.

The pyodbc module is an open source , MIT-licensed Python module, letting you use ODBC to connect to almost any database from Windows, Linux, Mac OS/X, and other operating systems.

Vertica supports multiple versions of pyodbc. See Python prerequisites for additional details.

Download the source distribution from the pyodbc Web site , unpack it and build it. Note that you need the unixODBC development package (in addition to the regular build tools) to build pyodbc. For example, on RedHat/CentOS run: yum install unixODBC-devel , and on Ubuntu run: sudo apt-get install unixodbc-dev . See the pyodbc wiki for detailed instructions.

Python clients and the UUID data type

Both the Vertica Python client and Vertica ODBC driver (that pyodbc interacts with) do not support Vertica's native UUID data type. Values retrieved using these drivers from a UUID column are converted to strings. When your client queries the metadata for a UUID column, the drivers report its data type as a string. Convert any UUID values that you want to insert into a UUID column to strings. Vertica automatically converts these values into the native UUID data type before inserting them into a table.

- Configuring the ODBC run-time environment on Linux
- Querying the database using Python and pyodbc

Open source Python client

The Vertica Python client is now open source. You can download it at https://github.com/vertica/vertica-python .

Configuring the ODBC run-time environment on Linux

To configure the ODBC run-time environment on Linux:

1. Create the odbc.ini file if it does not already exist.
2. Add the ODBC driver directory to the LD_LIBRARY_PATH system environment variable:
   ```
   export LD_LIBRARY_PATH=/path-to-vertica-odbc-driver:$LD_LIBRARY_PATH
   ```

   Important
   If you skip Step 2, the ODBC manager cannot find the driver in order to load it.

These steps are relevant only for unixODBC and iODBC. See their respective documentation for details on odbc.ini .

Querying the database using Python and pyodbc

The example session below uses pyodbc with the Vertica ODBC driver to connect Python to the Vertica database.

> **Note**
> SQLFetchScroll and SQLFetch functions cannot be mixed together in iODBC code. When using pyodbc with the iODBC driver manager, skip cannot be used with the fetchall, fetchone, and fetchmany functions.

Example script

The following example script shows how to query Vertica using Python 3, pyodbc, and an ODBC DSN.

```
import pyodbc
cnxn = pyodbc.connect("DSN=VerticaDSN", ansi=True)
cursor = cnxn.cursor()
# create table
cursor.execute("CREATE TABLE TEST("
   "C_ID  INT,"
   "C_FP  FLOAT,"
   "C_VARCHAR VARCHAR(100),"
   "C_DATE DATE, C_TIME TIME,"
   "C_TS TIMESTAMP,"
   "C_BOOL BOOL)")
cursor.execute("INSERT INTO test VALUES(1,1.1,'abcdefg1234567890','1901-01-01','23:12:34','1901-01-01 09:00:09','t')")
cursor.execute("INSERT INTO test VALUES(2,3.4,'zxcasdqwe09876543','1991-11-11','00:00:01','1981-12-31 19:19:19','f')")
cursor.execute("SELECT * FROM TEST")
rows = cursor.fetchall()
for row in rows:
   print(row, end='\n')
cursor.execute("DROP TABLE TEST CASCADE")
cursor.close()
cnxn.close()
```

The resulting output displays:

```
(2, 3.4, 'zxcasdqwe09876543', datetime.date(1991, 11, 11), datetime.time(0, 0, 1), datetime.datetime(1981, 12, 31, 19, 19, 19), False)
(1, 1.1, 'abcdefg1234567890', datetime.date(1901, 1, 1), datetime.time(23, 12, 34), datetime.datetime(1901, 1, 1, 9, 0, 9), True)
```

Notes

SQLPrimaryKeys returns the table name in the primary (pk_name) column for unnamed primary constraints. For example:

- Unnamed primary key:
  ```
  CREATE TABLE schema.test(c INT PRIMARY KEY);

  SQLPrimaryKeys
  "TABLE_CAT", "TABLE_SCHEM", "TABLE_NAME", "COLUMN_NAME", "KEY_SEQ", "PK_NAME" <Null>, "SCHEMA", "TEST", "C", 1, "TEST"
  ```
- Named primary key:
  ```
  CREATE TABLE schema.test(c INT CONSTRAINT pk_1 PRIMARY KEY);

  SQLPrimaryKeys
  "TABLE_CAT", "TABLE_SCHEM", "TABLE_NAME", "COLUMN_NAME", "KEY_SEQ", "PK_NAME" <Null>, "SCHEMA", "TEST", "C", 1, "PK_1"
  ```

OpenText recommends that you name your constraints.

Programming Perl client applications

The Perl programming language has a Database Interface module (DBI) that creates a standard interface for Perl scripts to interact with databases. The interface module relies on Database Driver modules (DBDs) to handle all of the database-specific communication tasks. The result is an interface that provides a consistent way for Perl scripts to interact with many different types of databases.

Your Perl script can interact with Vertica using the Perl DBI module along with the DBD::ODBC database driver to interface to Vertica's ODBC driver. See the CPAN pages for Perl's DBI and DBD::ODBC modules for detailed documentation.

Important

With Perl ODBC clients, Vertica allows a forked process (a child process) to drop the parent connection to the Vertica server when the child process completes and exits. Vertica allows this behavior regardless of the setting of the Perl DBI AutoInactiveDestroy attribute. To change the default setting so that Vertica honors the setting of the Perl DBI AutoInactiveDestroy attribute, add the parameter CleanupInForkChild to your vertica.ini file, and set its value to 1. When the Perl DBI AutoInactiveDestroy attribute is set to 1, and the Vertica parameter CleanupInForkChild is set to 1, Vertica does not drop the parent connection upon child process completion.

In this section

- Perl client prerequisites
- Connecting to Vertica using Perl
- Executing statements using Perl
- Batch loading data using Perl
- Using COPY LOCAL to load data in Perl
- Querying using Perl
- Conversions between Perl and Vertica data types
- Perl unicode support

Perl client prerequisites

In order run a Perl client script that connects to Vertica, your client system must have:

- The Vertica ODBC drivers installed and configured. See Installing the Vertica Client Drivers for details.
- A Data Source Name (DSN) containing the connection parameters for your Vertica. See Creating an ODBC Data Source Name. (Optionally, your Perl script can connect to Vertica without using a DSN as described in Connecting from Perl without a DSN).
- A supported version of Perl installed
- The DBI and DBD::ODBC Perl modules (see below)

Supported Perl versions

Vertica supports Perl versions 5.8 and 5.10. Versions later than 5.10 may also work.

Perl on Linux

Most Linux distributions come with Perl preinstalled. See your Linux distribution's documentation for details of installing and configuring its Perl package is it is not already installed.

To determine the Perl version on your Linux operating systems, type the following at a command prompt:

```
# perl -v
```

The system returns the version; for example:

```
This is perl, v5.10.0 built for x86_64-linux-thread-multi
```

Perl on Windows

Perl is not installed by default on Windows platforms. There are several different Perl packages you can download and install on your Windows system:

- ActivePerl by Activestate is a commercially-supported version of Perl for Windows platforms.
- Strawberry Perl is an open-source port of Perl for Windows.

The Perl driver modules (DBI and DBD::ODBC)

Before you can connect to Vertica using Perl, your Perl installation needs to have the Perl Database Interface module (DBI) and the Database Driver for ODBC (DBD::ODBC). These modules communicate with iODBC/unixODBC driver on UNIX operating systems or the ODBC Driver Manager for Windows operating systems.

Vertica supports the following Perl modules:

- DBI version 1.609 (DBI-1.609.tar.gz)
- DBD::ODBC version 1.22 (DBD-ODBC-1.22.tar.gz)

Later versions of DBI and DBD::ODBC may also work.

DBI is installed by default with many Perl installations. You can test whether it is installed by executing the following command on the Linux or Windows command line:

```
# perl -e "use DBI;"
```

If the command exits without printing anything, then DBI is installed. If it prints an error, such as:

```
Can't locate DBI.pm in @INC (@INC contains: /usr/local/lib64/perl5/usr/local/share/perl5
 /usr/lib64/perl5/vendor_perl /usr/share/perl5/vendor_perl
/usr/lib64/perl5 /usr/share/perl5 .) at -e line 1.
BEGIN failed--compilation aborted at -e line 1.
```

then DBI is not installed.

Similarly, you can see if DBD::ODBC is installed by executing the command:

```
# perl -e "use DBD::ODBC;"
```

You can also run the following Perl script to determine if DBI and DBD::ODBC are installed. If they are, the script lists any available DSNs.

```
#!/usr/bin/perl
use strict;
# Attempt to load the DBI module in an eval using require. Prevents
# script from erroring out if DBI is not installed.
eval
{
    require DBI;
    DBI->import();
};
if ($@) {
    # The eval failed, so DBI must not be installed
    print "DBI module is not installed\n";
} else {
    # Eval was successful, so DBI is installed
    print "DBI Module is installed\n";
    # List the drivers that DBI knows about.
    my @drivers = DBI->available_drivers;
    print "Available Drivers: \n";
    foreach my $driver (@drivers) {
        print "\t$driver\n";
    }
    # See if DBD::ODBC is installed by searching driver array.
    if (grep {/ODBC/i} @drivers) {
        print "\nDBD::ODBC is installed.\n";
        # List the ODBC data sources (DSNs) defined on the system
        print "Defined ODBC Data Sources:\n";
        my @dsns = DBI->data_sources('ODBC');
        foreach my $dsn (@dsns) {
            print "\t$dsn\n";
        }
    } else {
        print "DBD::ODBC is not installed\n";
    }
}
```

The exact output of the above code will depend on the configuration of your system. The following is an example of running the code on a Windows computer:

```
DBI Module is installed
Available Drivers:
        ADO
        DBM
        ExampleP
        File
        Gofer
        ODBC
        Pg
        Proxy
        SQLite
        Sponge
        mysql
DBD::ODBC is installed.
Defined ODBC Data Sources:
        dbi:ODBC:dBASE Files
        dbi:ODBC:Excel Files
        dbi:ODBC:MS Access Database
        dbi:ODBC:VerticaDSN
```

Installing missing Perl modules

If Perl's DBI or DBD::ODBC modules are not installed on your client system, you must install them before your Perl scripts can connect to Vertica. How you install modules depends on your Perl configuration:

- For most Perl installations, you use the cpan command to install modules. If the cpan command alias isn't installed on your system, you can try to start CPAN by using the command:

```
perl -MCPAN -e shell
```

- Some Linux distributions provide Perl modules as packages that can be installed with the system package manager (such as yum or apt). See your Linux distribution's documentation for details.
- On ActiveState Perl for Windows, you use the Perl Package Manager (PPM) program to install Perl modules. See the Activestate's PPM documentation for details.

> **Note**
> Installing Perl modules usually requires administrator or root privileges. If you do not have these permissions on your client system, you need to ask your system administrator to install these modules for you.

Connecting to Vertica using Perl

You use the Perl DBI module's connect function to connect to Vertica. This function takes a required data source string argument and optional arguments for the username, password, and connection attributes.

The data source string must start with "dbi:ODBC:", which tells the DBI module to use the DBD::ODBC driver to connect to Vertica. The remainder of the string is interpreted by the DBD::ODBC driver. It usually contains the name of a DSN that contains the connection information needed to connect to your Vertica database. For example, to tell the DBD::ODBC driver to use the DSN named VerticaDSN, you use the data source string:

```
"dbi:ODBC:VerticaDSN"
```

The username and password parameters are optional. However, if you do not supply them (or just the username for a passwordless account) and they are not set in the DSN, attempting to connect always fails.

The connect function returns a database handle if it connects to Vertica. If it does not, it returns undef . In that case, you can access the DBI module's error string property ($DBI::errstr) to get the error message.

> **Note**
> By default, the DBI module prints an error message to STDERR whenever it encounters an error. If you prefer to display your own error messages or handle errors in some other manner, you may want to disable these automatic messages by setting DBI's PrintError connection attribute to false. See Setting Perl DBI connection attributes for details. Otherwise, users may see two error messages: the one that DBI prints automatically, and the one that your script prints on its own.

The following example demonstrates connecting to Vertica using a DSN named VerticaDSN. The call to connect supplies a username and password. After connecting, it calls the database handle's disconnect function, which closes the connection.

```
#!/usr/bin/perl -w
use strict;
use DBI;
# Open a connection using a DSN. Supply the username and password.
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN","ExampleUser","password123");
unless (defined $dbh) {
   # Conection failed.
   die "Failed to connect: $DBI::errstr";
}
print "Connected!\n";
$dbh->disconnect();
```

In this section

- Setting ODBC connection parameters in Perl
- Setting Perl DBI connection attributes
- Connecting from Perl without a DSN

Setting ODBC connection parameters in Perl

To set ODBC connection parameters, replace the DSN name with a semicolon delimited list of parameter name and value pairs in the source data string. Use the DSN parameter to tell DBD::ODBC which DSN to use, then add in other the other ODBC parameters you want to set. For example, the following code connects using a DSN named VerticaDSN and sets the connection's locale to en_GB.

```
#!/usr/bin/perl -w
use strict;
use DBI;
# Instead of just using the DSN name, use name and value pairs.
my $dbh = DBI->connect("dbi:ODBC:DSN=VerticaDSN;Locale=en_GB@collation=binary","ExampleUser","password123");
unless (defined $dbh) {
   # Conection failed.
   die "Failed to connect: $DBI::errstr";
}
print "Connected!\n";
$dbh->disconnect();
```

See Data source name (DSN) connection properties for a list of the connection parameters you can set in the source data string.

Setting Perl DBI connection attributes

The Perl DBI module has attributes that you can use to control the behavior of its database connection. These attributes are similar to the ODBC connection parameters (in several cases, they duplicate each other's functionality). The DBI connection attributes are a cross-platform way of controlling the behavior of the database connection.

You can set the DBI connection attributes when establishing a connection by passing the DBI connect function a hash containing attribute and value pairs. For example, to set the DBI connection attribute AutoCommit to false, you would use:

```
# Create a hash that holds attributes for the connection
my $attr = {AutoCommit => 0};
# Open a connection using a DSN. Supply the username and password.
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN","ExampleUser","password123",
   $attr);
```

See the DBI documentation's Database Handle Attributes section for a full description of the attributes you can set on the database connection.

After your script has connected, it can access and modify the connection attributes through the database handle by using it as a hash reference. For example:

```
print "The AutoCommit attribute is: " . $dbh->{AutoCommit} . "\n";
```

The following example demonstrates setting two connection attributes:

- RaiseError controls whether the DBI driver generates a Perl error if it encounters a database error. Usually, you set this to true (1) if you want your Perl script to exit if there is a database error.
- AutoCommit controls whether statements automatically commit their transactions when they complete. DBI defaults to Vertica's default AutoCommit value of true. Always set AutoCommit to false (0) when bulk loading data to increase database efficiency.

```
#!/usr/bin/perl
use strict;
use DBI;
# Create a hash that holds attributes for the connection
 my $attr = {
            RaiseError => 1, # Make database errors fatal to script
            AutoCommit => 0, # Prevent statements from committing
                        # their transactions.
          };
# Open a connection using a DSN. Supply the username and password.
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN","ExampleUser","password123",
    $attr);

if (defined $dbh->err) {
    # Connection failed.
    die "Failed to connect: $DBI::errstr";
}
print "Connected!\n";
# The database handle lets you access the connection attributes directly:
print "The AutoCommit attribute is: " . $dbh->{AutoCommit} . "\n";
print "The RaiseError attribute is: " . $dbh->{RaiseError} . "\n";
# And you can change values, too...
$dbh->{AutoCommit} = 1;
print "The AutoCommit attribute is now: " . $dbh->{AutoCommit} . "\n";
$dbh->disconnect();
```

The example outputs the following when run:

```
Connected!The AutoCommit attribute is: 0
The RaiseError attribute is: 1
The AutoCommit attribute is now: 1
```

Connecting from Perl without a DSN

If you do not want to set up a Data Source Name (DSN) for your database, you can supply all of the information Perl's DBD::ODBC driver requires to connect to your Vertica database in the data source string. This source string must the DRIVER= parameter that tells DBD::ODBC which driver library to use in order to connect. The value for this parameter is the name assigned to the driver by the client system's driver manager:

- On Windows, the name assigned to the Vertica ODBC driver by the driver manager is Vertica.
- On Linux and other UNIX-like operating systems, the Vertica ODBC driver's name is assigned in the system's odbcinst.ini file. For example, if your /etc/odbcint.ini contains the following:

  ```
  [Vertica]
  Description = Vertica ODBC Driver
  Driver = /opt/vertica/lib64/libverticaodbc.so
  ```

  you would use the name Vertica. See Creating an ODBC DSN for Linux for more information about the odbcinst.ini file.

You can take advantage of Perl's variable expansion within strings to use variables for most of the connection properties as the following example demonstrates.

```
#!/usr/bin/perl
use strict;
use DBI;
my $server='VerticaHost';
my $port = '5433';
my $database = 'VMart';
my $user = 'ExampleUser';
my $password = 'password123';
# Connect without a DSN by supplying all of the information for the connection.
# The DRIVER value on UNIX platforms depends on the entry in the odbcinst.ini
# file.
my $dbh = DBI->connect("dbi:ODBC:DRIVER={Vertica};Server=$server;" .
      "Port=$port;Database=$database;UID=$user;PWD=$password")
      or die "Could not connect to database: " . DBI::errstr;
print "Connected!\n";
$dbh->disconnect();
```

Note
Surrounding the driver name with braces ({ and }) in the source string is optional.

Executing statements using Perl

Once your Perl script has connected to Vertica (see Connecting to Vertica Using Perl), it can execute simple statements that return a value rather than a result set by using the Perl DBI module's do function. You usually use this function to execute DDL statements or data loading statements such as COPY (see Using COPY LOCAL to load data in Perl).

```
#!/usr/bin/perl
use strict;
use DBI;
# Disable autocommit
 my $attr = {AutoCommit => 0};
# Open a connection using a DSN.
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN","ExampleUser","password123",
   $attr);
unless (defined $dbh) {
   # Conection failed.
   die "Failed to connect: $DBI::errstr";
}
# You can use the do function to perform DDL commands.
# Drop any existing table.
$dbh->do("DROP TABLE IF EXISTS TEST CASCADE;");
# Create a table to hold data.
$dbh->do("CREATE TABLE TEST( \
            C_ID  INT, \
            C_FP  FLOAT,\
            C_VARCHAR VARCHAR(100),\
            C_DATE DATE, C_TIME TIME,\
            C_TS TIMESTAMP,\
            C_BOOL BOOL)");
# Commit changes and exit.
$dbh->commit();
$dbh->disconnect();
```

Note
The do function returns the number of rows that were affected by the statement (or -1 if the count of rows doesn't apply or is unavailable). Usually, the only time you need to consult this value is after you deleted a number of rows or if you used a bulk load command such as COPY . You use other DBI functions instead of do to perform batch inserts and selects (see Batch loading data using Perl and Querying using Perl for details).

Batch loading data using Perl

To load large batches of data into Vertica using Perl:

1. Set DBI's AutoCommit connection attribute to false to improve the batch load speed. See Setting Perl DBI connection attributes for an example of disabling AutoCommit.
2. Call the database handle's prepare function to prepare a SQL INSERT statement that contains placeholders for the data values you want to insert. For example:

   ```
   # Prepare an INSERT statement for the test table
   $sth = $dbh->prepare("INSERT into test values(?,?,?,?,?,?,?)");
   ```

   The prepare function returns a statement handle that you will use to insert the data.
3. Assign data to the placeholders. There are several ways to do this. The easiest is to populate an array with a value for each placeholder in your INSERT statement.
4. Call the statement handle's execute function to insert a row of data into Vertica. The return value of this function call lets you know whether Vertica accepted or rejected the row.
5. Repeat steps 3 and 4 until you have loaded all of the data you need to load.
6. Call the database handle's commit function to commit the data you inserted.

The following example demonstrates inserting a small batch of data by populating an array of arrays with data, then looping through it and inserting each row.

```
#!/usr/bin/perl
use strict;
use DBI;
# Create a hash reference that holds a hash of parameters for the
# connection.
 my $attr = {AutoCommit => 0, # Turn off autocommit
            PrintError => 0   # Turn off automatic error printing.
                              # This is handled manually.
            };
# Open a connection using a DSN. Supply the username and password.
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN","ExampleUser","password123",
    $attr);
if (defined DBI::err) {
    # Conection failed.
    die "Failed to connect: $DBI::errstr";
}
print "Connection AutoCommit state is: " . $dbh->{AutoCommit} . "\n";
# Create table to hold inserted data
$dbh->do("DROP TABLE IF EXISTS TEST CASCADE;") or die "Could not drop table";
$dbh->do("CREATE TABLE TEST( \
              C_ID  INT, \
              C_FP  FLOAT,\
              C_VARCHAR VARCHAR(100),\
              C_DATE DATE, C_TIME TIME,\
              C_TS TIMESTAMP,\
              C_BOOL BOOL)") or die "Could not create table";
# Populate an array of arrays with values. One of these rows contains
# data that will not be sucessfully inserted. Another contains an
# undef value, which gets inserted into the database as a NULL.
my @data = (
              [1,1.111,'Hello World!','2001-01-01','01:01:01'
                 ,'2001-01-01 01:01:01','t'],
              [2,2.22222,'How are you?','2002-02-02','02:02:02'
                 ,'2002-02-02 02:02:02','f'],
              ['bad value',2.22222,'How are you?','2002-02-02','02:02:02'
                 ,'2002-02-02 02:02:02','f'],
              [4,4.22222,undef,'2002-02-02','02:02:02'
                 ,'2002-02-02 02:02:02','f'],
```

```
                , 2002-02-02 02:02:02 , 1],
        );
# Create a prepared statement to use parameters for inserting values.
my $sth = $dbh->prepare_cached("INSERT into test values(?,?,?,?,?,?,?)");
my $rowcount = 0; # Count # of rows
# Loop through the arrays to insert values
foreach my $tuple (@data) {
   $rowcount++;
   # Insert the row
   my $retval = $sth->execute(@$tuple);

   # See if the row was successfully inserted.
   if ($retval == 1) {
      # Value of 1 means the row was inserted (1 row was affected by insert)
      print "Row $rowcount successfully inserted\n";
   } else {
      print "Inserting row $rowcount failed";
      # Error message is not set on some platforms/versions of DBUI. Check to
      # ensure a message exists to avoid getting an unitialized var warning.
      if ($sth->err()) {
            print ": " . $sth->errstr();
      }
      print "\n";
   }
}
# Commit changes. With AutoCommit off, you need to use commit for batched
# data to actually be committed into the database. If your Perl script exits
# without committing its data, Vertica rolls back the transaction and the
# data is not committed.
$dbh->commit();
$dbh->disconnect();
```

The previous example displays the following when successfully run:

```
Connection AutoCommit state is: 0
Row 1 successfully inserted
Row 2 successfully inserted
Inserting row 3 failed with error 01000 [Vertica][VerticaDSII] (20) An
error occurred during query execution: Row rejected by server; see
server log for details (SQL-01000)
Row 4 successfully inserted
```

Note that one of the rows was not inserted because it contained a string value that could not be stored in an integer column. See Conversions between Perl and Vertica Data Types for details of data type handling in Perl scripts that communicate with Vertica.

Using COPY LOCAL to load data in Perl

You can use COPY LOCAL to load delimited files on your client system—for example, a file with comma-separated values—into Vertica. Rather than use Perl to read, parse, and then batch insert the file data, COPY LOCAL directly loads the file data from the local file system into Vertica. When execution completes, COPY LOCAL returns the number of rows that it successfully inserted.

> **Note**
> COPY LOCAL must be the first statement in a query,otherwise Vertica returns an error.

The following example uses COPY LOCAL to load into Vertica local file data.txt , which is located in the same directory as the Perl file.

```
#!/usr/bin/perl
use strict;
use DBI;
# Filesystem path handling module
use File::Spec;
# Create a hash reference that holds a hash of parameters for the
# connection.
 my $attr = {AutoCommit => 0}; # Turn off AutoCommit
# Open a connection using a DSN. Supply the username and password.
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN","ExampleUser","password123",
    $attr) or die "Failed to connect: $DBI::errstr";
print "Connected!\n";
# Drop any existing table.
$dbh->do("DROP TABLE IF EXISTS Customers CASCADE;");
# Create a table to hold data.
$dbh->do("CREATE TABLE Customers( \
            ID  INT, \
            FirstName  VARCHAR(100),\
            LastName   VARCHAR(100),\
            Email      VARCHAR(100),\
            Birthday   DATE)");
# Find the absolute path to the data file located in the current working
# directory and named data.txt
my $currDir = File::Spec->rel2abs(File::Spec->curdir());
my $dataFile = File::Spec->catfile($currDir, 'data.txt');
print "Loading file $dataFile\n";
# Load local file using copy local. Return value is the # of rows affected
# which equates to the number of rows inserted.
my $rows = $dbh->do("COPY Customers FROM LOCAL '$dataFile' DIRECT")
    or die $dbh->errstr;
print "Copied $rows rows into database.\n";
$dbh->commit();
# Prepare a query to get the first 15 rows of the results
my $sth = $dbh->prepare("SELECT * FROM Customers WHERE ID < 15 \
                         ORDER BY ID");

$sth->execute() or die "Error querying table: " . $dbh->errstr;
my @row; # Pre-declare variable to hold result row used in format statement.
# Use Perl formats to pretty print the output. Declare the heading for the
# form.
format STDOUT_TOP =
ID  First          Last         EMail                    Birthday
==  =====          ====         =====                    ========
.
# The Perl write statement will output a formatted line with values from the
# @row array. See http://perldoc.perl.org/perlform.html for details.
format STDOUT =
@>  @<<<<<<<<<<<<<  @<<<<<<<<<<<  @<<<<<<<<<<<<<<<<<<<<<<<<<<<<<  @<<<<<<<<<<
@row
.
# Loop through result rows while we have them
while (@row = $sth->fetchrow_array()) {
        write; # Format command does the work of extracting the columns from
               # the @row array and writing them out to STDOUT.
}
# Call commit to prevent Perl from complaining about uncommitted transactions
# when disconnecting
$dbh->commit();
$dbh->disconnect();
```

data.txt is a text file with a row of data on each line. The columns are delimited by pipe (|) characters. This is the default COPY delimiter for command accepts, which simplifies the COPY LOCAL statement.

Here is an example of the file content:

```
1|Georgia|Gomez|Rhiannon@magna.us|1937-10-03

```

> **Note**
> Loading a single, large data file into Vertica through a single data connection is less efficient than loading a number of smaller files onto multiple nodes in parallel. Loading onto multiple nodes prevents any one node from becoming a bottleneck.

Querying using Perl

To query Vertica using Perl:

1. Prepare a query statement using the Perl DBI module's prepare function. This function returns a statement handle that you use to execute the query and get the result set.
2. Execute the prepared statement by calling the execute function on the statement handle.
3. Retrieve the results of the query from the statement handle using one of several methods, such as calling the statement handle's fetchrow_array function to retrieve a row of data, or fetchall_array to get an array of arrays containing the entire result set (not a good idea if your result set may be very large!).

The following example demonstrates querying the table created by the example shown in Batch loading data using Perl . It executes a query to retrieve all of the content of the table, then repeatedly calls the statement handle's fetchrow_array function to get rows of data in an array. It repeats this process until fetchrow_array returns undef, which means that there are no more rows to be read.

```
#!/usr/bin/perl
use strict;
use DBI;
my $attr = {RaiseError => 1 }; # Make errors fatal to the Perl script.
# Open a connection using a DSN. Supply the username and password.
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN","ExampleUser","password123",
                       $attr);
# Prepare a query to get the content of the table
my $sth = $dbh->prepare("SELECT * FROM TEST ORDER BY C_ID ASC");
# Execute the query by calling execute on the statement handle
$sth->execute();
# Loop through result rows while we have them, getting each row as an array
while (my @row = $sth->fetchrow_array()) {
   # The @row array contains the column values for this row of data
   # Loop through the column values
   foreach my $column (@row) {
      if (!defined $column) {
         # NULLs are signaled by undefs. Set to NULL for clarity
         $column = "NULL";
      }
      print "$column\t"; # Output the column separated by a tab
   }
   print "\n";
}
$dbh->disconnect();
```

The example prints the following when run:

```
1    1.111    Hello World!    2001-01-01    01:01:01    2001-01-01 01:01:01    1
2    2.22222    How are you?    2002-02-02    02:02:02    2002-02-02 02:02:02    0
4    4.22222    NULL    2002-02-02    02:02:02    2002-02-02 02:02:02    0
```

Binding variables to column values

Another method of retrieving the query results is to bind variables to columns in the result set using the statement handle's bind_columns function. You may find this method convenient if you need to perform extensive processing on the returned data, since your code can use variables rather than array references to access the data. The following example demonstrates binding variables to the result set, rather than looping through the row and column values.

```
#!/usr/bin/perl
use strict;
use DBI;
my $attr = {RaiseError => 1 }; # Make SQL errors fatal to the Perl script.
# Open a connection using a DSN. Supply the username and password.
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN32","ExampleUser","password123",
                       $attr);
# Prepare a query to get the content of the table
my $sth = $dbh->prepare("SELECT * FROM TEST ORDER BY C_ID ASC");
$sth->execute();
# Create a set of variables to bind to the column values.
my ($C_ID, $C_FP, $C_VARCHAR, $C_DATE, $C_TIME, $C_TS, $C_BOOL);
# Bind the variable references to the columns in the result set.
$sth->bind_columns(\$C_ID, \$C_FP, \$C_VARCHAR, \$C_DATE, \$C_TIME,
                   \$C_TS, \$C_BOOL);

# Now, calling fetch() to get a row of data updates the values of the bound
# variables. Continue calling fetch until it returns undefined.
while ($sth->fetch()) {
   # Note, you should always check that values are defined before using them,
   # since NULL values are translated into Perl as undefined. For this
   # example, just check the VARCHAR column for undefined values.
   if (!defined $C_VARCHAR) {
      $C_VARCHAR = "NULL";
   }
   # Just print values separated by tabs.
   print "$C_ID\t$C_FP\t$C_VARCHAR\t$C_DATE\t$C_TIME\t$C_TS\t$C_BOOL\n";
}
$dbh->disconnect();
```

The output of this example is identical to the output of the previous example.

Preparing, querying, and returning a single row

If you expect a single row as the result of a query (for example, when you execute a COUNT (*) query), you can use the DBI module's selectrow_array function to combine executing a statement and retrieving an array as a result.

The following example shows using selectrow_array to execute and get the results of the SHOW LOCALE statement. It also demonstrates changing the locale using the do function.

```
#!/usr/bin/perl
use strict;
use DBI;
my $attr = {RaiseError => 1 }; # Make SQL errors fatal to the Perl script.
# Open a connection using a DSN. Supply the username and password.
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN","ExampleUser","password123",
                       $attr);
# Demonstrate setting/getting locale.
# Use selectrow_array to combine preparing a statement, executing it, and
# getting an array as a result.
my @localerv = $dbh->selectrow_array("SHOW LOCALE;");
# The locale name is the 2nd column (array index 1) in the result set.
print "Locale: $localerv[1]\n";
# Use do() to execute a SQL statement to set the locale.
$dbh->do("SET LOCALE TO en_GB");
# Get the locale again.
@localerv = $dbh->selectrow_array("SHOW LOCALE;");
print "Locale is now: $localerv[1]\n";
$dbh->disconnect();
```

The result of running the example is:

```
Locale: en_US@collation=binary (LEN_KBINARY)
Locale is now: en_GB (LEN)
```

Executing queries and ResultBufferSize settings

When you call the execute() function on a prepared statement, the client library retrieves results up to the size of the result buffer. The result buffer size is set using ODBC's ResultBufferSize setting.

Vertica does not allow multiple active queries per connection. However, you can simulate multiple active queries by setting the result buffer to be large enough to accommodate the entire results from the first query. To ensure that the ODBC client driver's buffer is large enough to store result set for first query you can set ResultBufferSize to 0. Setting this parameter to 0 makes the result buffer size unlimited. The ODBC driver allocates enough memory to read the entire result set. With the entire result set from the first query stored in the result set buffer, the database connection is free to perform another query. Your client can execute this second query even though it has not processed the entire result set from the first query.

However, if you set the ResultBufferSize to 0, you may find that your calls to execute() result in the operating system killing your Perl client script. The operating system may terminate your script if the ODBC driver allocates too much memory to store a large result set.

A workaround for this behavior is limit the number of rows returned by your query. Then you can set the ResultBufferSize to a value that accommodates this limited result set. For example, you can estimate the amount of memory needed to store a single row of your query result. Then use the LIMIT and OFFSET clauses to get a specific number of rows that will fit into the space you allocated using ResultBufferSize. If the results of your query is able to fit within the limited result set buffer, you can then perform additional queries with the same database connection. This solution makes your code more complex as you will need to perform multiple queries to get the entire result set. Also, it is not appropriate in cases where you need to operate on an entire result set at once, rather than just a portion of it at a time.

A better solution is to use separate database connections for each query you want to perform. The overhead of the additional database connection is small compared to the resources needed to process large data sets.

Conversions between Perl and Vertica data types

Perl is a loosely-typed programming language that does not assign specific data types to values. It converts between string and numeric values based on the operations being performed on the values. For this reason, Perl has little problem extracting most string and numeric data types from Vertica. All interval data types (DATE, TIMESTAMP, etc.) are converted to strings. You can use several different date and time handling Perl modules to manipulate these values in your scripts.

Vertica NULL values translate to Perl's undefined (undef) value. When reading data from columns that can contain NULL values, you should always test whether a value is defined before using it.

When inserting data into Vertica, Perl's DBI module attempts to coerce the data into the correct format. By default, it assumes column values are VARCHAR unless it can determine that they are some other data type. If given a string value to insert into a column that has an integer or numeric data type, DBI attempts to convert the string's contents to the correct data type. If the entire string can be converted to a value of the appropriate data type, it inserts the value into the column. If not, inserting the row of data fails.

DBI transparently converts integer values into numeric or float values when inserting into column of FLOAT, NUMERIC, or similar data types. It converts numeric or floating values to integers only when there would be no loss of precision (the value to the right of the decimal point is 0). For example, it can insert the value 3.0 into an INTEGER column since there is no loss of precision when converting the value to an integer. It cannot insert 3.1 into an INTEGER column, since that would result in a loss of precision. It returns an error instead of truncating the value to 3.

The following example demonstrates some of the conversions that the DBI module performs when inserting data into Vertica.

```
#!/usr/bin/perl
use strict;
use DBI;
# Create a hash reference that holds a hash of parameters for the
# connection.
 my $attr = {AutoCommit => 0, # Turn off autocommit
             PrintError => 0   # Turn off print error. Manually handled
             };
# Open a connection using a DSN. Supply the username and password.
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN","ExampleUser","password123",
    $attr);
if (defined DBI::err) {
    # Conection failed.
    die "Failed to connect: $DBI::errstr";
}
print "Connection AutoCommit state is: " . $dbh->{AutoCommit} . "\n";
```

```
# Create table to hold inserted data
$dbh->do("DROP TABLE IF EXISTS TEST CASCADE;");
$dbh->do("CREATE TABLE TEST( \
            C_ID  INT, \
            C_FP  FLOAT,\
            C_VARCHAR VARCHAR(100),\
            C_DATE DATE, C_TIME TIME,\
            C_TS TIMESTAMP,\
            C_BOOL BOOL)");
# Populate an array of arrays with values.
my @data = (
             # Start with matching data types
             [1,1.111,'Matching datatypes','2001-01-01','01:01:01'
                ,'2001-01-01 01:01:01','t'],
             # Force floats -> int and int -> float.
             [2.0,2,"Ints <-> floats",'2002-02-02','02:02:02'
                ,'2002-02-02 02:02:02',1],
             # Float -> int *only* works when there is no loss of precision.
             # this row will fail to insert:
             [3.1,3,"float -> int with trunc?",'2003-03-03','03:03:03'
                ,'2003-03-03 03:03:03',1],
             # String values are converted into numbers
             ["4","4.4","Strings -> numbers", '2004-04-04','04:04:04',
                ,'2004-04-04 04:04:04',0],
             # String -> numbers only works if the entire string can be
             # converted into a number
             ["5 and a half","5.5","Strings -> numbers", '2005-05-05',
                '05:05:05', ,'2005-05-05 05:05:05',0],
             # Number are converted into string values automatically,
             # assuming they fit into the column width.
             [6,6.6,3.14159, '2006-06-06','06:06:06',
                ,'2006-06-06 06:06:06',0],
             # There are some variations in the accepted date strings
             [7,7.7,'Date/time formats', '07/07/2007','07:07:07',
                ,'07-07-2007 07:07:07',1],
           );
# Create a prepared statement to use parameters for inserting values.
my $sth = $dbh->prepare_cached("INSERT into test values(?,?,?,?,?,?,?)");
my $rowcount = 0; # Count # of rows
# Loop through the arrays to insert values
foreach my $tuple (@data) {
   $rowcount++;
   # Insert the row
   my $retval = $sth->execute(@$tuple);

   # See if the row was successfully inserted.
   if ($retval == 1) {
      # Value of 1 means the row was inserted (1 row was affected by insert)
      print "Row $rowcount successfully inserted\n";
   } else {
      print "Inserting row $rowcount failed with error " .
            $sth->state . " " . $sth->errstr . "\n";
   }
}
# Commit the data
$dbh->commit();
# Prepare a query to get the content of the table
$sth = $dbh->prepare("SELECT * FROM TEST ORDER BY C_ID ASC");
$sth->execute() or die "Error: " . $dbh->errstr;
my @row; # Need to pre-declare to use in the format statement.
# Use Perl formats to pretty print the output.
```

```
format STDOUT_TOP =
Int  Float       VarChar       Date      Time      Timestamp     Bool
===  =====  ==================  ==========  ========  ================  ====
.
format STDOUT =
@>>  @<<<<  @<<<<<<<<<<<<<<<<<  @<<<<<<<<<  @<<<<<<<  @<<<<<<<<<<<<<<<  @<<<<
@row
.
# Loop through result rows while we have them
while (@row = $sth->fetchrow_array()) {
        write; # Format command does the work of extracting the columsn from
               # the array.
}
# Commit to stop Perl complaining about in-progress transactions.
$dbh->commit();
$dbh->disconnect();
```

The example produces the following output when run:

```
Connection AutoCommit state is: 0
Row 1 successfully inserted
Row 2 successfully inserted
Inserting row 3 failed with error 01000 [Vertica][VerticaDSII] (20) An error
occurred during query execution: Row rejected by server; see server log for
details (SQL-01000)
Row 4 successfully inserted
Inserting row 5 failed with error 01000 [Vertica][VerticaDSII] (20) An error
occurred during query execution: Row rejected by server; see server log for
details (SQL-01000)
Row 6 successfully inserted
Row 7 successfully inserted

```

Perl unicode support

Perl supports Unicode data with some caveats. See the perlunicode and the perlunitut (Perl Unicode tutorial) manual pages for details. (Be sure to see the copies of these manual pages included with the version of Perl installed on your client system, as the support for Unicode has changed in recent versions of Perl.) Perl DBI and DBD::ODBC also support Unicode, however DBD::ODBC must be compiled with Unicode support. See the DBD::ODBC documentation for details. You can check the DBD::ODBC-specific connection attribute named odbc_has_unicode to see if Unicode support is enabled in the driver.

The following example Perl script demonstrates directly inserting UTF-8 strings into Vertica and then reading them back. The example writes a text file with the output, since there are may problems displaying Unicode characters in terminal windows or consoles.

```
#!/usr/bin/perl
use strict;
use DBI;
# Open a connection using a DSN.
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN","ExampleUser","password123");
unless (defined $dbh) {
   # Conection failed.
   die "Failed to connect: $DBI::errstr";
}
# Output to a file. Displaying Unicode characters to a console or terminal
# window has many problems. This outputs a UTF-8 text file that can
# be handled by many Unicode-aware text editors:
open OUTFILE, '>:utf8', "unicodeout.txt";
# See if the DBD::ODBC driver was compiled with Unicode support. If this returns
# 1, your Perl script will get get strings from the driver with the UTF-8
# flag set on them, ensuring that Perl handles them correctly.
print OUTFILE "Was DBD::ODBC compiled with Unicode support? " .
   $dbh->{odbc_has_unicode} . "\n";

# Create a table to hold VARCHARs
$dbh->do("DROP TABLE IF EXISTS TEST CASCADE;");

# Create a table to hold data. Remember that the width of the VARCHAR column
# is the number of bytes set aside to store strings, which often does not equal
# the number of characters it can hold when it comes to Unicode!
$dbh->do("CREATE TABLE test( C_VARCHAR VARCHAR(100) )");
print OUTFILE "Inserting data...\n";
# Use Do to perform simple inserts
$dbh->do("INSERT INTO test VALUES('Hello')");
# This string contains several non-latin accented characters and symbols, encoded
# with Unicode escape notation. They are converted by Perl into UTF-8 characters
$dbh->do("INSERT INTO test VALUES('My favorite band is " .
   "\N{U+00DC}ml\N{U+00E4}\N{U+00FC}t \N{U+00D6}v\N{U+00EB}rk\N{U+00EF}ll" .
   " \N{U+263A}')");
# Some Chinese (Simplified) characters. This again uses escape sequence
# that Perl translates into UTF-8 characters.
$dbh->do("INSERT INTO test VALUES('\x{4F60}\x{597D}')");
print OUTFILE "Getting data...\n";
# Prepare a query to get the content of the table
my $sth = $dbh->prepare_cached("SELECT * FROM test");
# Execute the query by calling execute on the statement handle
$sth->execute();
# Loop through result rows while we have them
while (my @row = $sth->fetchrow_array()) {
   # Loop through the column values
   foreach my $column (@row) {
      print OUTFILE "$column\t";
   }
   print OUTFILE "\n";
}
close OUTFILE;
$dbh->disconnect();
```

Viewing the unicodeout.txt file in a UTF-8-capable text editor or viewer displays:

```
Was DBD::ODBC compiled with Unicode support? 1
Inserting data...
Getting data...
My favorite band is Ümläüt Övërkïll ☺
你好
Hello
```

Note
Terminal windows and consoles often have problems properly displaying Unicode characters. That is why the example writes the output to a text file. With some text editors, you may need to manually set the encoding of the text file to UTF-8 in order for the characters to properly appear (and the font used to display text must have a full Unicode character set). If the character still do not show up, it may be that your version of DBD::ODBC was not compiled with UTF-8 support.

- Locale and UTF-8 support
- Required ODBC driver configuration settings for Linux and UNIX

Programming PHP client applications

You can connect to Vertica through PHP-ODBC using the Unix ODBC or iODBC library.

In order to use PHP with Vertica, you must install the following packages (and their dependencies):

- php
- php-odbc
- php-pdo
- UnixODBC (if you are using the Unix ODBC driver)
- libiodbc (if you are using the iODBC driver)

PHP on Linux

PHP is available with most Linux operating systems as a module for the Apache web server. Check your particular Linux repository for PHP RPMs or Debian packages. You can also build PHP from source. See the PHP web site for documentation and source downloads.

PHP on Windows

PHP is available for windows for both the Apache and IIS web servers. You can download PHP for Windows and view installation instructions at the PHP web site.

The PHP ODBC drivers

PHP supports both the UnixODBC drivers and iODBC drivers. Both drivers use PHP's ODBC database abstraction layer.

Setup

You must read Programming ODBC client applications before connecting to Vertica through PHP. The following example ODBC configuration entries detail the typical settings required for PHP ODBC connections. The driver location assumes you have copied the Vertica drivers to /usr/lib64 .

Example odbc.ini

```
[ODBC Data Sources]
VerticaDSNunixodbc = exampledb
VerticaDNSiodbc = exampledb2
[VerticaDSNunixodbc]
Description = VerticaDSN Unix ODBC driver
Driver = /usr/lib64/libverticaodbc.so
Database = Telecom
Servername = localhost
UserName = dbadmin
Password =
Port = 5433
[VerticaDSNiodbc]
Description = VerticaDSN iODBC driver
Driver = /usr/lib64/libverticaodbc.so
Database = Telecom
Servername = localhost
UserName = dbadmin
Password =
Port = 5433
```

Example odbcinst.ini

```
# Vertica
[VerticaDSNunixodbc]
Description = VerticaDSN Unix ODBC driver
Driver = /usr/lib64/libverticaodbc.so
[VerticaDNSiodbc]
Description = VerticaDSN iODBC driver
Driver = /usr/lib64/libverticaodbc.so
[ODBC]
Threading = 1
```

Verify the Vertica UnixODBC or iODBC library

Verify the Vertica UnixODBC library can load all dependant libraries with the following command (assuming you have copies the libraries to /usr/lib64):

For example:

```
ldd /usr/lib64/libverticaodbc.so
```

You must resolve any "not found" libraries before continuing.

Test your ODBC connection

Test your ODBC connection with the following.

```
isql -v VerticaDSN
```

In this section

- PHP unicode support
- Querying the database using PHP

PHP unicode support

PHP does not offer native Unicode support. PHP only supports a 256-character set. However, PHP provides the UTF-8 functions utf8_encode() and utf8_decode() to provide some basic Unicode functionality.

See the PHP manual for strings for more details about PHP and Unicode.

Querying the database using PHP

The example script below details the use of PHP ODBC functions to connect to the Vertica Analytics Platform.

```
<?php
# Turn on error reporting
error_reporting(E_ERROR | E_WARNING | E_PARSE | E_NOTICE);
# A simple function to trap errors from queries
function errortrap_odbc($conn, $sql) {
   if(!$rs = odbc_exec($conn,$sql)) {
      echo "<br/>Failed to execute SQL: $sql<br/>" . odbc_errormsg($conn);
   } else {
      echo "<br/>Success: " . $sql;
   }
   return $rs;
}
# Connect to the Database
$dsn = "VerticaDSNunixodbc";
$conn = odbc_connect($dsn,'','') or die ("<br/>CONNECTION ERROR");
echo "<p>Connected with DSN: $dsn</p>";
# Create a table
$sql = "CREATE TABLE TEST(
      C_ID INT,
      C_FP FLOAT,
      C_VARCHAR VARCHAR(100),
      C_DATE DATE, C_TIME TIME,
      C_TS TIMESTAMP,
      C_BOOL BOOL)";
$result = errortrap_odbc($conn, $sql);
# Insert data into the table with a standard SQL statement
$sql = "INSERT into test values(1,1.1,'abcdefg1234567890','1901-01-01','23:12:34
','1901-01-01 09:00:09','t')";

} else {
         echo "<br/>Success: odbc_execute.";
}
# Get the data from the table and display it
$sql = "SELECT * FROM TEST";
if($result = errortrap_odbc($conn, $sql)) {
   echo "<pre>";
   while($row = odbc_fetch_array($result) ) {
         print_r($row);
   }
   echo "</pre>";
}
# Drop the table and projection
$sql = "DROP TABLE TEST CASCADE";
$result = errortrap_odbc($conn, $sql);
# Close the ODBC connection
odbc_close($conn);
?>
```

Example output

The following is the example output from the script.

```
Success: CREATE TABLE TEST( C_ID INT, C_FP FLOAT, C_VARCHAR VARCHAR(100), C_DATE DATE, C_TIME TIME, C_TS TIMESTAMP, C_BOOL BOOL)
Success: INSERT into test values(1,1.1,'abcdefg1234567890','1901-01-01','23:12:34 ','1901-01-01 09:00:09','t')
Success: odbc_execute.
Success: SELECT * FROM TEST
Array
(
    [C_ID] => 1
    [C_FP] => 1.1
    [C_VARCHAR] => abcdefg1234567890
    [C_DATE] => 1901-01-01
    [C_TIME] => 23:12:34
    [C_TS] => 1901-01-01 09:00:09
    [C_BOOL] => 1
)
Array
(
    [C_ID] => 2
    [C_FP] => 2.28
    [C_VARCHAR] => abcdefg1234567890
    [C_DATE] => 1901-01-01
    [C_TIME] => 23:12:34
    [C_TS] => 1901-01-01 23:12:34
    [C_BOOL] => 1
)
Success: DROP TABLE TEST CASCADE
```

Managing query execution between the client and Vertica

The following topics describe techniques that help you manage query execution between your client and your Vertica database.

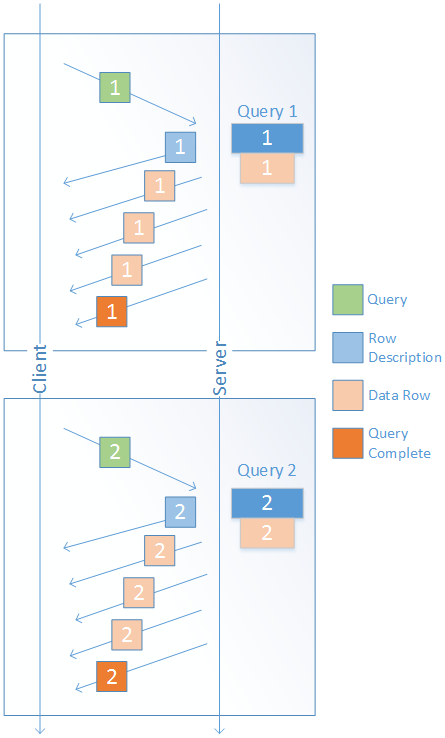
In this section

- ResultBufferSize
- Multiple active result sets (MARS)

ResultBufferSize

By default, Vertica uses the ResultBufferSize parameter to determine the maximum size (in bytes) of a result set that a client can retrieve from a server. When ResultBufferSize is enabled, Vertica sends rows of data directly to the client making the query. The number of rows returned to the client at each fetch of data depends on the size (in bytes) of the ResultBufferSize parameter.

Sometimes, the size of the result set requested by the client is greater than what the ResultBufferSize parameter allows. In such cases, Vertica retrieves only a portion of the result set at a time. Each fetch of data returns the amount of data equal to the size set by the ResultBufferSize parameter. Ultimately, as the client iterates over the individual fetches of data, the entire result set is returned.



Benefits of ResultBufferSize

If you are concerned with the effect of your queries on network latency, ResultBufferSize may provide an advantage over MARS. MARS requires that the client wait until all rows of data are written to the server before the client can retrieve the data. This delay may cause latency issues for your network while waiting for the results to be stored.

In addition, MARS requires that you send two separate requests to return rows of data. The first request performs the query execution which stores the result set on the server. The second request retrieves the data rows that are stored on the server. With ResultBufferSize, you only need to send one request. This request both executes and retrieves the data rows of interest.

Query execution with ResultBufferSize

The following graphic shows how Vertica returns rows of data from a database to the client with ResultBufferSize enabled:

The query execution performs the following steps:

1. The client sends a query, such as a SELECT statement, to the server. In the preceding graphic, the first query is named Query 1.
2. The server receives the client's request and begins to send both a description of the result set and the requested rows of data back to the client.
3. After all possible rows are returned to the client, the execution is complete. The size of the data set returned equals either that of the data that was requested or the maximum amount of data that ResultBufferSize parameter can retrieve. If the ResultBufferSize maximum size is not yet reached, Vertica can execute Query 2.

The server can accept Query 2 and perform the same steps that it did for Query 1. If the results for Query 1 had reached the maximum ResultBufferSize allowable, Vertica could not execute Query 2 until the client freed the results from Query 1.

After Query 2 runs, you cannot view the results you retrieved for Query 1, unless you execute Query 1 again.

Setting an unlimited buffer size

Setting ResultBufferSize to 0 tells the client driver to use an unlimited result set buffer. With this setting, the client library allocates as much memory as it needs to read the entire result set of a query. You may choose to set ResultBufferSize to 0 of you want to simulate having multiple active queries over a single database connection at the same time. With an unlimited buffer size, your client can run a query and have its entire result set stored in memory. This ends the first query, so your client can execute a second query before it fully processes the results of the first query.

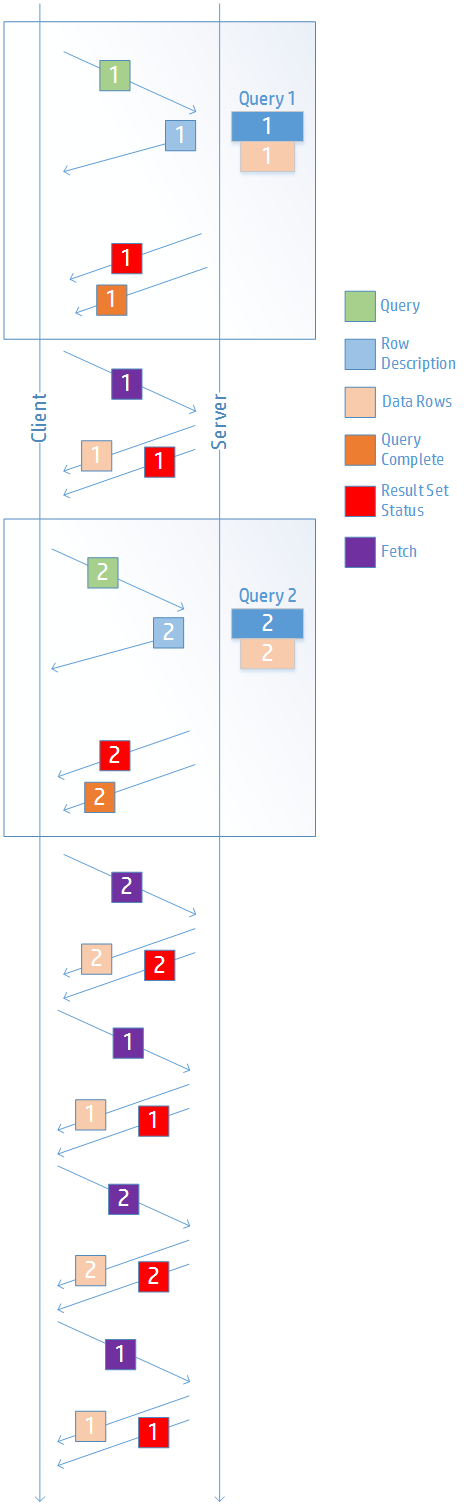
A drawback of this method is that your query may consume too much memory if your queries return large result sets. This over-allocation of memory can result in the operating system terminating your client. Due to this risk, consider using multiple database connections instead of trying to reuse a single connection for multiple queries. The overhead of multiple database connections is small compared to the overall amount of resources required to process a large data set.

Multiple active result sets (MARS)

You can only enable MARS when you connect to Vertica using a JDBC client connection. MARS allows the execution of multiple queries on a single connection. While ResultBufferSize sends the results of a query directly to the client, MARS stores the results first on the server. Once query execution has finished and all of the results have been stored, you can make a retrieval request to the server to have rows returned to the client.

MARS is set at the session level and must be enabled for every new session. When MARS is enabled, ResultBufferSize is disabled. No error is returned, however the ResultBufferSize parameter is ignored.

Benefits of MARS



In comparison with ResultBufferSize, MARS enables you to store multiple result sets from different queries at the same time. You can also send new queries before all of the results of a previous result set have been returned to the client. This allows applications to decouple query execution from result retrieval so that, on a single connection, you can process different results at the same time.

When you enable ResultBufferSize, you must wait until all result sets have been returned to the client before a new query can be executed.

Another benefit of MARS is that it allows you to free up query resources faster than ResultBufferSize allows. While a query is running, resources are held by that query session. When ResultBufferSize is enabled, a client that is performing slowly might read a single row of a result set and then have to stop to retrieve the next row. This prevents the query from finishing quickly and, therefore, prevents the resources used from being freed up for other applications. With MARS, the speed of the client is irrelevant to the reading of rows. As soon as the results are written to the MARS storage, the resources are freed and the speed at which the client retrieves rows no longer matters.

Query execution with MARS

The following graphic demonstrates how multiple queries to the server are handled when MARS is enabled:

Query 1:

1. Query 1 is sent to the server.
2. Query 1's row description and the status of its result set are returned to the client. However, no results are returned to the client at this time.
3. Query 1 completes and its results are saved on the server.
    1. You can now send commands to retrieve the rows of Query 1's result set. These rows are stored on the server. Retrieved rows are sent to the client along with the status of the result set. By keeping track of the status of the result set, Vertica is able to keep track of which rows have been retrieved from the server.

4. Now that Query 1 has successfully completed, and its result sets are being stored on the server, Query 2 can be executed.

Query 2:

1. Query 2 is sent to the server.
2. Query 2's row description and the status of its result set are returned to the client. However, no results are returned to the client at this time.
3. Query 2 completes and its results are stored on the server. Both Query 1 and Query 2 now have result sets stored on the server.
4. You can now send retrieval requests to both Query 1 and Query 2's result sets that are stored on the server. Whenever a retrieval request is made for rows from Query 1, the request is sent and rows and the result set status are sent to the client. The same occurs for Query 2.

Once all rows have been read by the client, the MARS storage on the server closes the active results session. The MARS storage on the server is then freed to store more data. The MARS storage also closes and frees once your session is finished.

Enabling and disabling MARS

You can enable and disable MARS in two different ways:

1. To enable MARS using the JDBC client connection properties, see JDBC connection properties .
2. To enable MARS using the SET SESSION command, see SET SESSION MULTIPLEACTIVERESULTSETS .

Management API

The Management API is a REST API that you can use to view and manage Vertica databases with scripts or applications that accept REST and JSON. The response format for all requests is JSON.

In this section

- cURL
- General API information
- Rest APIs for the agent
- Rest APIs for the Management Console

cURL

cURL is a command-line tool and application library used to transfer data to or from a server. It uses URL syntax, such as HTTP and HTTPS. All API requests sent to a Vertica server must be made using HTTPS. A request made using HTTP will fail.

There are four HTTP requests that can be passed using cURL to call API methods:

Request	Description
GET	Retrieves data.
PUT	Updates data.
POST	Creates new data.
DELETE	Deletes data.

Syntax

```
curl https://<NODE>:5444/
```

Options

-h --help	Lists all available command-line options.
-H --header	Allows you to use custom headers in your command. This is useful for sending a request that requires a VerticaAPIKEY. `curl -H "VerticaApiKey: ValidAPIKey" https://<NODE>:5444/`

-k --insecure	Allows SSL connections without certificate validation. `curl -k https://<NODE>:5444/`
-X --request	Specifies the custom request used when communicating with a server. `curl -X REQUEST https://<NODE>:5444/` Can be one of the following values: • GET • PUT • POST • DELETE **Note** If no request is specified, cURL automatically defaults to the GET request.

There are many more options available to add to your cURL query. For a comprehensive list with descriptions, visit the cURL Documentation Website .

General API information

These API calls can interact with either standard Vertica nodes or Management Console nodes.

GET /	Returns the agent-specific information useful for version checking and service discovery.
GET api	Returns a list of api objects and properties.

In this section

- GET /
- GET api

GET /

Returns API version information and a list of links to child resources for the Management API.

Resource URL

`https://<NODE>:5444/`

Authentication

Not required.

Parameters

None.

Example request

GET	https://<NODE>:5444/

Response:

```
{

  }
]
```

Rest APIs for the agent

These API calls interact with standard Vertica nodes.

Backup and restore

GET backups	Returns all the backups that have been created for all vbr configuration files (*.ini) that are located in the /opt/vertica/config directory.
POST backups/:config_script_base	Creates a new backup as defined by the given vbr configuration script base (filename without the .ini extension).
GET backups/:config_script_base/:archive_id	Returns details for a specific backup archive.
POST restore/:archive_id	Restores a backup.

Databases

GET databases	Returns a list of databases, their properties, and current status.
POST databases	Creates a new database by supplying a valid set of parameters.
GET databases/:database_name	Returns details about a specific database.
PUT databases/:database_name	Starts, stops, rebalances, or runs Workload Analyzer on a database.
DELETE databases/:database_name	Deletes an existing database.
GET databases/:database_name/configuration	Returns the current configuration parameters from the database.
PUT databases/:database_name/configuration	Sets one or more configuration parameters in the database.
GET databases/:database_name/hosts	Returns hosts details for a specific database.
POST databases/:database_name/hosts	Adds a new host to the database.
DELETE databases/:database_name/hosts/:host_id	Removes a host from the database.
POST databases/:database_name/hosts/:host_id/process	Starts the database process on a specific host.
DELETE databases/:database_name/hosts/:host_id/process	Stops the database on a specific host.
POST databases/:database_name/hosts/:host_id/replace_with/:host_id_new	Replaces a host with a standby host in the database.
GET databases/:database_name/license	Returns the Vertica license that the specified database is using.
PUT databases/:database_name/license	Upgrades the license in the database.
GET databases/:database_name/licenses	Returns all the feature licenses that the specified database is using.

GET databases/:database_name/nodes	Returns a list of nodes for the specified database.
GET databases/:database_name/nodes/:node_id	Returns details on a specific node for the specified database.
POST databases/:database_name/process	Starts the specified database.
GET databases/:database_name/process	Returns the state of the database as either UP or DOWN.
DELETE databases/:database_name/process	Stops the specified database on all hosts.
POST databases/:database_name/rebalance/process	Rebalances the specified database. This option can have a long run time.
POST databases/:database_name/Workload Analyzer/process	Runs the analyze workload action against the specified database.This option can have a long run time.

Hosts

GET hosts	Returns a list of hosts in this cluster.
GET hosts/:hostid	Returns details for a specific host in this cluster.

Jobs

GET jobs	Returns a list of jobs the agent is tracking, along with their current status and exit codes.
GET jobs/:id	Returns the details (the saved output) for a specific job.

Licenses

POST licenses	Uploads and applies a new license to this cluster.
GET licenses	Returns the license field that databases created on this cluster use.

Nodes

GET nodes	Returns a list of nodes in this cluster.
GET nodes/:nodeid	Returns details for a specific node in this cluster.

Webhooks

GET webhooks	Returns a list of active webhooks.
POST webhooks/subscribe	Creates a new webhook.
DELETE webhooks/:subscriber_id	Deletes an existing webhook.

VerticaAPIKey

The Management API requires an authentication key, named VerticaAPIKEY, to access some API resources. You can manage API keys by using the **apikeymgr** command-line tool.

```
usage: apikeymgr [-h] [--user REQUESTOR] [--app APPLICATION] [--delete]
                 [--create] [--update] [--migrate]
                 [--secure {restricted,normal,admin}] [--list]

API key management tool

optional arguments:
  -h, --help            show this help message and exit
  --user REQUESTOR      The name of the person requesting the key
  --app APPLICATION     The name of the application that will use the key
  --delete              Delete the key for the given R & A
  --create              Create a key for the given R & A
  --update              Update a key for the given R & A
  --migrate             migrate the keyset to the latest format
  --secure {restricted,normal,admin}
                        Set the keys security level
  --list                List all the keys known
```

Example request

To create a new VerticaAPIKEY for the dbadmin user with admin access, enter the following:

```
$ apikeymgr --user dbadmin --app vertica --create --secure admin
```

Response:

```
Requestor  : dbadmin
Application: vertica
API Key    : ValidAPIKey
Synchronizing cluster...
```

Backup and restore

You can use these API calls to perform backup and restore tasks for your database.

GET backups	Returns all the backups that have been created for all vbr configuration files (*.ini) that are located in the /opt/vertica/config directory.
POST backups/:config_script_base	Creates a new backup as defined by the given vbr configuration script base (filename without the .ini extension).
GET backups/:config_script_base/:archive_id	Returns details for a specific backup archive.
POST restore/:archive_id	Restores a backup.

In this section

- GET backups
- POST backups/:config_script_base
- GET backups/:config_script_base/:archive_id
- POST restore/:archive_id

GET backups

Returns a list of all backups created for vbr configuration (*.ini) files that reside in /opt/vertica/config and provides details about each backup.

Resource URL

```
https://<NODE>:5444/backups
```

The API key must have **restricted** level security or higher.

Parameters

None.

Example request

GET	https://<NODE>:5444/backups

Response:

```
{
   "data": [
      {
         "backups": [

}
```

POST backups/:config_script_base

Creates a new backup job for the backup defined in the vbr configuration script :config_script_base . The vbr configuration script must reside in /opt/vertica/configuration . The :config_script_base value does not include the .ini filename extention.

To determine valid :config_script_base values, see GET backups .

Returns a job ID that you can use to determine the status of the job.

Resource URL

```
https://<NODE>:5444/backups/:config_script_base
```

The API key must have **restricted** level security or higher.

Parameters

None.

Example request

POST	https://<NODE>:5444/backups/backup3

Response:

```
{
   "id": "CreateBackup-VMart-1404750602.03",
   "url": "/jobs/CreateBackup-VMart-1404750602.03"
}
```

GET backups/:config_script_base/:archive_id

Returns details on a specific backup. You must provide the :config_script_base . This value is the name of a vbr config file (without the .ini filename extension) that resides in /opt/vertica/config . The :archive_id is the value of the *backup* field that the GET backups command returns.

Resource URL

```
https://<NODE>:5444/backups/:config_script_base/:archive_id
```

The API key must have **restricted** level security or higher.

Parameters

None.

Example request

GET	https://<NODE>:5444/backups/fullbk/v_vdb_bk_snapshot_20190304_204814

Response:

```
{
   "archive_id": "v_vdb_bk_snapshot_20190304_204814",
   "config_file": "/opt/vertica/config/fullbk.ini",
   "objects": "",
   "href": "/backups/fullbk/v_vdb_bk_snapshot_20190304_204814",
   "exclude_patterns": "",
   "epoch": "16",
   "include_patterns": "",
   "backup_type": "full",
   "version": "v9.2.1-20190304",
   "hosts": "v_vdb_bk_node0001(10.20.91.240),
         v_vdb_bk_node0002(10.20.91.241),
         v_vdb_bk_node0003(10.20.91.242),
         v_vdb_bk_node0004(10.20.91.243),
         v_vdb_bk_node0005(10.20.91.244)"
}
```

POST restore/:archive_id

Creates a new restore job to restore the database from the backup archive identified by :archive_id . The :archive_id is the value of a *backup* field that the GET backups command returns.

Returns a job ID that you can use to determine the status of the job. See GET jobs .

Resource URL

```
https://<NODE>:5444/restore/:archive_id
```

The API key must have **restricted** level security or higher.

Parameters

None.

Example request

POST	https://<NODE>:5444/restore/backup3_20140707_132904

Response:

```
{
   "id": "RestoreBackup-VMart-1404760113.71",
   "url": "/jobs/RestoreBackup-VMart-1404760113.71"
}
```

Databases

You can use these API calls to interact with your database.

GET databases	Returns a list of databases, their properties, and current status.
POST databases	Creates a new database by supplying a valid set of parameters.
GET databases/:database_name	Returns details about a specific database.
PUT databases/:database_name	Starts, stops, rebalances, or runs Workload Analyzer on a database.
DELETE databases/:database_name	Deletes an existing database.
GET databases/:database_name/configuration	Returns the current configuration parameters from the database.
PUT databases/:database_name/configuration	Sets one or more configuration parameters in the database.
GET databases/:database_name/hosts	Returns hosts details for a specific database.
POST databases/:database_name/hosts	Adds a new host to the database.
DELETE databases/:database_name/hosts/:host_id	Removes a host from the database.
POST databases/:database_name/hosts/:host_id/process	Starts the database process on a specific host.
DELETE databases/:database_name/hosts/:host_id/process	Stops the database on a specific host.
POST databases/:database_name/hosts/:host_id/replace_with/:host_id_new	Replaces a host with a standby host in the database.
GET databases/:database_name/license	Returns the Vertica license that the specified database is using.
PUT databases/:database_name/license	Upgrades the license in the database.
GET databases/:database_name/licenses	Returns all the feature licenses that the specified database is using.
GET databases/:database_name/nodes	Returns a list of nodes for the specified database.
GET databases/:database_name/nodes/:node_id	Returns details on a specific node for the specified database.
POST databases/:database_name/process	Starts the specified database.
GET databases/:database_name/process	Returns the state of the database as either UP or DOWN.
DELETE databases/:database_name/process	Stops the specified database on all hosts.
POST databases/:database_name/rebalance/process	Rebalances the specified database. This option can have a long run time.

POST databases/:database_name/Workload Analyzer/process	Runs the analyze workload action against the specified database.This option can have a long run time.

GET databases

Returns a list of databases, their current status, and database properties.

Resource URL

```
https://<NODE>:5444/databases
```

The API key must have **restricted** level security or higher.

Parameters

None.

Example request

GET	https://<NODE>:5444/databases

An example of the full request using cURL:

```
curl -H "VerticaApiKey: ValidAPIKey" https://<NODE>:5444/databases
```

Response:

```
{
   "body": [
      {
         "href": "/databases/VMart",
         "mime-type": [
            "application/vertica.database.json-v2"
         ],
         "name": "VMart",
         "port": "5433",
         "status": "UP"
      },
      {
         "href": "/databases/testDB",
         "mime-type": [
            "application/vertica.database.json-v2"
         ],
         "name": "testDB",
         "port": "5433",
         "status": "DOWN"
      }
   ],
   "href": "/databases",
   "links": [
      "/:database_name"
   ],
   "mime-type": "application/vertica.databases.json-v2"
}
```

POST databases

Creates a job to create a new database with the provided parameters.

Important
You must stop any running databases on the nodes on which you want to create the new database. If you do not, database creation fails.

Returns a job ID that can be used to determine the status of the job. See GET jobs .

Resource URL

```
https://<NODE>:5444/databases
```

The API key must have **admin** level security.

Parameters

name	Name of the database to create.
passwd	Password for the new database.
only	Optional list of hostnames to include in the database. By default, all nodes in the cluster are added to the database.
exclude	Optional list of hostnames to exclude from the database.
catalog	Path of the catalog directory.
data	Path of the data directory.
port	Port where the database listens for client connections. Default is 5433.

Example request

POST	https://:5444/databases?passwd=*db_password*&name=*db_name*& catalog=%2F*path*%2F*to*%2F*catalog*&data=%2F*path*%2F*to*%2F*data_directory*

Response:

```
{
   "jobid": "CreateDatabase-testDB-2014-07-07 15:49:53.219445",
   "resource": "/jobs/CreateDatabase-testDB-2014-07-07 15:49:53.219445",
   "userid": "dbadmin"
}
```

GET databases/:database_name

Returns details about a specific database. The :database_name is the value of the *name* field that the GET databases command returns.

Resource URL

```
https://<NODE>:5444/databases/:database_name
```

The API key must have **restricted** level security or higher.

Parameters

None.

Example request

GET	https://<NODE>:5444/databases/VMart

Response:

```
{
   "body": {
      "database_id": "VMart",
      "id": "VMart",
      "nodes": "v_vmart_node0001,v_vmart_node0002,v_vmart_node0003",
      "nodes_new": [
         {
            "catalog_base": "/home/dbadmin",
            "data_base": "/home/dbadmin",
            "host": "10.20.100.247",
            "id": "v_vmart_node0001"
         },
         {
            "catalog_base": "/home/dbadmin",
            "data_base": "/home/dbadmin",
            "host": "10.20.100.248",
            "id": "v_vmart_node0002"
         },
         {
            "catalog_base": "/home/dbadmin",
            "data_base": "/home/dbadmin",
            "host": "10.20.100.249",
            "id": "v_vmart_node0003"
         }
      ],
      "path": "/home/dbadmin/VMart",
      "port": "5433",
      "restartpolicy": "ksafe",
      "status": "UP"
   },
   "href": "/databases/VMart",
   "links": [
      "/configuration",
      "/hosts",
      "/license",
      "/nodes",
      "/process",
      "/rebalance/process",
      "/status",
      "/Workload Analyzer/process"
   ],
   "mime-type": "application/vertica.database.json-v2"
}
```

PUT databases/:database_name

Creates a job to run the action specified by the *action* parameter against the database identified by :database_name . The :database_name is the value of the *name* field that the GET databases command returns.

Returns a job ID that you can use to determine the status of the job. See GET jobs .

Resource URL

```
https://<NODE>:5444/databases/:database_name
```

The API key must have **normal** level security or higher.

Parameters

user_id	A database username.
passwd	A password for the username.

action	Can be one of the following values: • start — Start the database. • stop — Stop the database. • rebalance — Rebalance the database. • Workload Analyzer — Run Work Load Analyzer against the database.

Example request

PUT	https://<NODE>:5444/databases/testDB?user_id= *username* &passwd= *username_password* &action=stop

Response:

```
{
   "id": "StopDatabase-testDB-2014-07-20 13:28:49.321744",
   "url": "/jobs/StopDatabase-testDB-2014-07-20 13:28:49.321744"
}
```

DELETE databases/:database_name

Creates a job to delete (drop) an existing database on the cluster. To perform this operation, you must first stop the database. The :database_name is the value of the *name* field that the GET databases command returns.

Returns a job ID that you can use to determine the status of the job. See GET jobs .

Resource URL

```
https://<NODE>:5444/databases/:database_name
```

The API key must have **admin** level security.

Parameters

None.

Example request

DELETE	https://<NODE>:5444/databases/TestDB

Response:

```
{
   "id": "DropDatabase-TestDB-2014-07-18 12:50:33.332383",
   "url": "/jobs/DropDatabase-TestDB-2014-07-18 12:50:33.332383"
}
```

GET databases/:database_name/configuration

Returns a list of configuration parameters for the database identified by :database_name . The :database_name is the value of the *name* field that the GET databases command returns.

Resource URL

```
https://<NODE>:5444/databases/:database_name/configuration
```

The API key must have **restricted** level security or higher.

Parameters

user_id	A database username.
passwd	The password for the username.

Example request

GET	https://<NODE>:5444/databases/testDB/configuration?user_id= *username* &passwd= *username_password*

Response:

This API call returns over 100 configuration parameters.. The following response is a small subset of the total amount returned.

```
[

```

PUT databases/:database_name/configuration

Sets one or more configuration parameters for the database identified by :database_name . The :database_name is the value of the *name* field that the GET databases command returns.

Returns the parameter name, the requested value, and the result of the attempted change (Success or Failed).

Resource URL

```
https://<NODE>:5444/databases/:database_name/configuration
```

The API key must have **admin** level security.

Parameters

user_id	A database username.
passwd	The password for the username.
parameter_name	A parameter name and value combination for the parameter to be changed. Values must be URL encoded. You can include multiple name/value pairs to set multiple parameters with a single API call.

Example request

PUT	https://:5444/databases/testDB/configuration?user_id=*username*&passwd=*username_password* &JavaBinaryForUDx=%2F*usr*%2F*bin*%2F*java*&TransactionIsolationLevel=SERIALIZABLE

Response:

```
[
   {
      "key": "JavaBinaryForUDx",
      "result": "Success",
      "value": "/usr/bin/java"
   },
   {
      "key": "TransactionIsolationLevel",
      "result": "Success",
      "value": "SERIALIZABLE"
   }
]
```

GET databases/:database_name/hosts

Returns the hostname/IP address, node name, and UP/DOWN status of each host associated with the database identified by :database_name . The :database_name is the value of the *name* field that the GET databases command returns.

Resource URL

```
https://<NODE>:5444/databases/:database_name/hosts
```

The API key must have **restricted** level security or higher.

Parameters

None.

Example request

GET	https://<NODE>:5444/databases/VMart/hosts

Response:

```
{
   "body": [
      {
         "hostname": "10.20.100.247",
         "nodename": "v_vmart_node0001",
         "status": "UP",
         "ts": "2014-07-18T13:12:31.904191"
      },
      {
         "hostname": "10.20.100.248",
         "nodename": "v_vmart_node0002",
         "status": "UP",
         "ts": "2014-07-18T13:12:31.904209"
      },
      {
         "hostname": "10.20.100.249",
         "nodename": "v_vmart_node0003",
         "status": "UP",
         "ts": "2014-07-18T13:12:31.904215"
      }
   ],
   "href": "/databases/VMart/hosts",
   "links": [],
   "mime-type": "application/vertica.hosts.json-v2"
}
```

POST databases/:database_name/hosts

Creates a job to add a host to the database identified by :database_name . This host must already be part of the cluster. The :database_name is the value of the *name* field that the GET databases command returns.

Returns a job ID that you can use to determine the status of the job. See GET jobs .

Resource URL

```
https://<NODE>:5444/databases/:database_name/hosts
```

The API key must have **admin** level security.

Parameters

user_id	A database username.
passwd	The password for the username.
hostname	The hostname to add to the database. This host must already be part of the cluster.

Example request

POST	https://<NODE>:5444/databases/testDB/hosts?hostname=192.168.232.181&user_id= *username* &passwd= *username_password*

Response:

```
{
   "id": "AddHostToDatabase-testDB-2014-07-20 12:24:04.088812",
   "url": "/jobs/AddHostToDatabase-testDB-2014-07-20 12:24:04.088812"
}
```

DELETE databases/:database_name/hosts/:host_id

Creates a job to remove the host identified by :host_id from the database identified by :database_name . The :database_name is the value of the *name* field that the GET databases command returns. The :host_id is the value of the *host* field returned by GET databases/:database_name .

Returns a job ID that you can use to determine the status of the job. See GET jobs .

Resource URL

https://<NODE>:5444/databases/:database_name/hosts/:host_id

The API key must have **admin** level security.

Parameters

user_id	A database username.
passwd	A password for the username.

Example request

DELETE	https://<NODE>:5444/databases/testDB/hosts/192.168.232.181?user_id= *username* &passwd= *username_password*

Response:

```
{
   "id": "RemoveHostFromDatabase-testDB-2014-07-20 13:41:15.646235",
   "url": "/jobs/RemoveHostFromDatabase-testDB-2014-07-20 13:41:15.646235"
}
```

POST databases/:database_name/hosts/:host_id/process

Creates a job to start the vertica process for the database identified by :database_name on the host identified by :host_id . The :database_name is the value of the *name* field that the GET databases command returns. The :host_id is the value of the *host* field returned by GET databases/:database_name .

Returns a job ID that you can use to determine the status of the job. See GET jobs .

Resource URL

https://<NODE>:5444/databases/:database_name/hosts/:host_id/process

The API key must have **restricted** level security or higher.

Parameters

None.

Example request

POST	https://<NODE>:5444/databases/testDB/hosts/192.168.232.181/process

Response:

```
{
   "id": "StartDatabase-testDB-2014-07-20 13:14:03.968340",
   "url": "/jobs/StartDatabase-testDB-2014-07-20 13:14:03.968340"
}
```

GET databases/:database_name/license

Returns details about the database license being used by the database identified by :database_name . The :database_name is the value of the *name* field that the GET databases command returns.

Resource URL

https://<NODE>:5444/:database_name/license

The API key must have **restricted** level security or higher.

Parameters

user_id	A database username.

passwd	The password for the username.

Example request

GET	https://<NODE>:5444/VMart/license?user_id= *username* &passwd= *username_password*

Response:

```
{
   "body": {
      "details": {
         "assigned_to": "Vertica Systems, Inc.",
         "grace_period": 0,
         "is_ce": false,
         "is_unlimited": false,
         "name": "vertica",
         "not_after": "Perpetual",
         "not_before": "2007-08-03"
      },
      "last_audit": {
         "audit_date": "2014-07-18 13:49:22.530105-04",
         "database_size_bytes": "814060522",
         "license_size_bytes": "536870912000",
         "usage_percent": "0.00151630588248372"
      }
   },
   "href": "/databases/VMart/license",
   "links": [],
   "mime-type": "application/vertica.license.json-v2"
}
```

GET databases/:database_name/licenses

Returns details about all license being used by the database identified by :database_name . The :database_name is the value of the *name* field that the GET databases command returns.

Resource URL

```
https://<NODE>:5444/:database_name/licenses
```

The API key must have **restricted** level security or higher.

Parameters

user_id	A database username.
passwd	The password for the username.

Example request

GET	https://<NODE>:5444/VMart/licenses?user_id= *username* &passwd= *username_password*

Response:

```
{
   "body": [
      {
         "details": {
            "assigned_to": "Vertica Systems, Inc.",
            "audit_date": "2014-07-19 21:35:25.111312",

            "license_size_bytes": 536870912000,
            "usage_percent": 0
         }
      }
   ],
   "href": "/databases/VMart/licenses",
   "links": [],
   "mime-type": "application/vertica.features.json-v2"
}
```

DELETE databases/:database_name/hosts/:host_id/process

Creates a job to stop the vertica process for the database identified by :database_name on the host identified by :host_id . The :database_name is the value of the *name* field that the GET databases command returns. The :host_id is the value of the *host* field returned by GET databases/:database_name .

Returns a job ID that can be used to determine the status of the job. See GET jobs .

> **Note**
> If stopping the database on the hosts causes the database to no longer be k-safe, then the all database nodes may shut down.

Resource URL

```
https://<NODE>:5444/databases/:database_name/hosts/:host_id/process
```

The API key must have **restricted** level security or higher.

Parameters

None.

Example request

DELETE	https://<NODE>:5444/databases/testDB/hosts/192.168.232.181/process

Response:

```
{
   "id": "StopDatabase-testDB-2014-07-20 13:02:08.453547",
   "url": "/jobs/StopDatabase-testDB-2014-07-20 13:02:08.453547"
}
```

POST databases/:database_name/hosts/:host_id/replace_with/:host_id_new

Creates a job to replace the host identified by hosts/:host_id with the host identified by replace_with/:host_id . Vertica performs these operations for the database identified by :database_name . The :database_name is the value of the *name* field that the GET databases command returns. The :host_id is the value of the *host* field as returned by GET databases/:database_name . You can find valid replacement hosts using GET hosts . The replacement host cannot already be part of the database. You must stop the vertica process on the host being replaced.

Returns a job ID that you can use to determine the status of the job. See GET jobs .

Resource URL

```
https://<NODE>:5444/databases/:database_name/hosts/:host_id/replace_with/:host_id_new
```

The API key must have **admin** level security.

Parameters

user_id	A database username.
passwd	A password for the username.

Example request

POST	https://<NODE>:5444/databases/testDB/hosts/192.168.232.180/replace_with/192.168.232.181?user_id= *username* &passwd= *username_password*

Response:

```
{
   "id": "ReplaceNode-testDB-2014-07-20 13:50:28.423509",
   "url": "/jobs/ReplaceNode-testDB-2014-07-20 13:50:28.423509"
}
```

GET databases/:database_name/nodes

Returns a comma-separated list of node IDs for the database identified by :database_name . The :database_name is the value of the *name* field that the GET databases command returns.

Resource URL

```
https://<NODE>:5444/:database_name/nodes
```

The API key must have **restricted** level security or higher.

Parameters

None.

Example request

GET	https://<NODE>:5444/VMart/nodes

Response:

```
[
   {
      "database_id": "VMart",
      "node_id": "v_vmart_node0001,v_vmart_node0002,v_vmart_node0003",
      "status": "Unknown"
   }
]
```

GET databases/:database_name/nodes/:node_id

Returns details about the node identified by :node_id . The :node_id is one of the node IDs returned by GET databases/:database_name/nodes .

Resource URL

```
https://<NODE>:5444/:database_name/nodes/:node_id
```

The API key must have **restricted** level security or higher.

Parameters

None.

Example request

GET	https://<NODE>:5444/databases/VMart/nodes/v_vmart_node0001

Response:

```
{
   "db": "VMart",
   "host": "10.20.100.247",
   "name": "v_vmart_node0001",
   "state": "UP"
}
```

POST databases/:database_name/process

Creates a job to start the database identified by :database_name . The :database_name is the value of the *name* field that the GET databases command returns.

Returns a job ID that can be used to determine the status of the job. See GET jobs .

Resource URL

```
https://<NODE>:5444/databases/:database_name/process
```

The API key must have **restricted** level security or higher.

Parameters

epoch	Start the database from this epoch.
include	Include only these hosts when starting the database. Use a comma-separated list of hostnames.

Example request

POST	https://<NODE>:5444/databases/:testDB/process

An example of the full request using cURL:

```
curl -d "epoch=epoch_number&include=host1,host2" -X POST -H "VerticaApiKey: ValidAPIKey" https://<NODE>:5444/:testDB/process
```

Response:

```
{
   "id": "StartDatabase-testDB-2014-07-20 12:41:46.061408",
   "url": "/jobs/StartDatabase-testDB-2014-07-20 12:41:46.061408"
}
```

GET databases/:database_name/process

Returns a state of UP or DOWN for the database identified by :database_name . The :database_name is the value of the *name* field that the GET databases command returns.

Resource URL

```
https://<NODE>:5444/databases/:database_name/process
```

The API key must have **restricted** level security or higher.

Parameters

None.

Example request

GET	https://<NODE>:5444/databases/VMart/process

Response:

```
{
   "state": "UP"
}
```

DELETE databases/:database_name/process

Creates a job to stop the database identified by :database_name . The :database_name is the value of the *name* field that the GET databases command returns.

Returns a job ID that you can useto determine the status of the job. See GET jobs .

Resource URL

```
https://<NODE>:5444/databases/:database_name/process
```

The API key must have **restricted** level security or higher.

Parameters

user_id	A database username.
passwd	The password for the username.

Example request

DELETE	https://<NODE>:5444/databases/testDB/process?user_id= *username* &passwd= *username_password*

An example of the full request using cURL:

```
curl -X DELETE -H "VerticaApiKey: ValidAPIKey" https://<NODE>:5444/:testDB/process?user_id=dbadmin"&"passwd=vertica
```

Response:

```
{
   "id": "StopDatabase-testDB-2014-07-20 12:46:04.406637",
   "url": "/jobs/StopDatabase-testDB-2014-07-20 12:46:04.406637"
}
```

POST databases/:database_name/rebalance/process

Creates a job to run a rebalance on the database identified by host identified by :database_name . The :database_name is the value of the *name* field that the GET databases command returns.

Returns a job ID that you can use to determine the status of the job. See GET jobs .

Resource URL

```
https://<NODE>:5444/databases/:database_name/rebalance/process
```

The API key must have **restricted** level security or higher.

Parameters

user_id	A database username.
passwd	A password for the username.

Example request

POST	https://<NODE>:5444/databases/testDB/rebalance/process?user_id= *username* &passwd= *username_password*

Response:

```
{
   "id": "RebalanceData-testDB-2014-07-20 21:42:45.731038",
   "url": "/jobs/RebalanceData-testDB-2014-07-20 21:42:45.731038"
}
```

POST databases/:database_name/Workload analyzer/process

Creates a job to run Workload Analyzer on the database identified by host identified by :database_name . The :database_name is the value of the *name* field that the GET databases command returns.

Returns a job ID that you can use to determine the status of the job. See GET jobs .

Resource URL

```
https://<NODE>:5444/databases/:database_name/Workload Analyzer/process
```

The API key must have **restricted** level security or higher.

Parameters

user_id	A database username.
passwd	A password for the username.

Example request

POST	https://<NODE>:5444/databases/testDB/Workload Analyzer/process?user_id= *username* &passwd= *username_password*

Response:

```
{
   "id": "AnalyzeWorkLoad-testDB-2014-07-20 21:48:27.972989",
   "url": "/jobs/AnalyzeWorkLoad-testDB-2014-07-20 21:48:27.972989"
}
```

Hosts

You can use these API calls to get information on the hosts in your cluster.

GET hosts	Returns a list of hosts in this cluster.
GET hosts/:hostid	Returns details for a specific host in this cluster.

In this section

- GET hosts
- GET hosts/:hostid

GET hosts

Returns a list of the hosts in the cluster and the hardware, software, and network details about each host.

Resource URL

https://<NODE>:5444/hosts

The API key must have **restricted** level security or higher.

Parameters

None.

Example request

GET	https://<NODE>:5444/hosts

Response:

```
{
   "body": [
      {
         "cpu_info": {
            "cpu_type": " Intel(R) Xeon(R) CPU E5-2695 v2 @ 2.40GHz",

```

GET hosts/:hostid

Returns hardware, software, and network details about the host identified by :host_id . You can find :host_id for each host using GET hosts .

Resource URL

```
https://<NODE>:5444/hosts/:hostid
```

The API key must have **restricted** level security or higher.

Parameters

None.

Example request

GET	https://<NODE>:5444/hosts/:10.20.100.247

Response:

```
{
  "body": {
    "cpu_info": {
      "cpu_type": " Intel(R) Xeon(R) CPU E5-2695 v2 @ 2.40GHz",
      "number_of_cpus": 2
    },
    "hostname": "v_vmart_node0001.example.com",
    "max_user_proc": "3833",
    "nics": [
      {
        "broadcast": "10.20.100.255",
        "ipaddr": "10.20.100.247",
        "name": "eth0",
        "netmask": "255.255.255.0",
        "speed": "unknown"
      },
      {
        "broadcast": "255.255.255.255",
        "ipaddr": "127.0.0.1",
        "name": "lo",
        "netmask": "255.0.0.0",
        "speed": "locallink"
      }
    ],
    "total_memory": 3833,
    "vertica": {
      "arch": "x86_64",
      "brand": "vertica",
      "release": "20140716",
      "version": "11.1.x0"
    }
  },
  "href": "/hosts/10.20.100.247",
  "links": [],
  "mime-type": "application/vertica.host.json-v2"
}
```

Jobs

You can use these API calls to get information on your database's jobs.

GET jobs	Returns a list of jobs the agent is tracking, along with their current status and exit codes.
GET jobs/:id	Returns the details (the saved output) for a specific job.

In this section

- GET jobs
- GET jobs/:id

GET jobs

Returns a list of jobs being tracked by the agent and job details.

Jobs always start immediately. The is_running field is a Boolean value. If is_running is false, then the job is complete.

The exit_code details the status of the job. The exit_code is different for certain types of jobs:

- For Backup jobs:
  - 0 indicates success.
  - Any other number indicates a failure.
- For all other jobs:
  - -9 indicates success.
  - Any other number indicates a failure.

You can see details about failures in /opt/vertica/log/agentStdMsg.log .

Resource URL

```
https://<NODE>:5444/jobs
```

The API key must have **restricted** level security or higher.

Parameters

None.

Example request

GET	https://<NODE>:5444/jobs

Response:

```
{
   "body": [
      {
         "exit_code": 0,
         "id": "CreateBackup-VMart-1405012447.75",
         "is_running": false,
         "status": "unused",
         "ts": "1405012461.18"
      },
      {
         "exit_code": 1,
         "id": "CreateBackup-VMart-1405012454.88",
         "is_running": false,
         "status": "unused",
         "ts": "1405012455.18"
      }
   ],
   "href": "/jobs",
   "links": [
      "/:jobid"
   ],
   "mime-type": "application/vertica.jobs.json-v2"
}
```

GET jobs/:id

Gets the details for a specific job with the provided :id . You can determine the list of job :ids using GET jobs .

Details for a specific job are the same as the details provided for all jobs by GET jobs .

> **Note**
> You must URL encode the :id as some IDs may contain spaces or other special characters.

Resource URL

```
https://<NODE>:5444/jobs/:id
```

The API key must have **restricted** level security or higher.

Parameters

None.

Example request

GET	https://<NODE>:5444/jobs/CreateBackup-VMart-1405012454.88

Licenses

You can use these API calls to manage licenses for your database.

POST licenses	Uploads and applies a new license to this cluster.
GET licenses	Returns the license field that databases created on this cluster use.

In this section

- POST licenses
- GET licenses

POST licenses

Uploads and applies a license file to this cluster.

You must provide the license file as an HTTP POST form upload, identified by the name *license* . For example, you can use cURL:

```
curl -k --request POST -H "VerticaApiKey:ValidAPIKey" \
https://v_vmart_node0001:5444/licenses --form "license=@vlicense.dat"
```

Resource URL

```
https://<NODE>:5444/licenses
```

The API key must have **admin** level security.

Parameters

None.

Example request

POST	https://<NODE>:5444/licenses

Response:

There is no HTTP body response for successful uploads. A successful upload returns an HTTP 200/OK header.

GET licenses

Returns any license files that are used by this cluster when creating databases. License files must reside in /opt/vertica/config/share .

Resource URL

https://<NODE>:5444/licenses

The API key must have **restricted** level security or higher.

Parameters

None.

Example request

GET	https://<NODE>:5444/licenses

Response:

```
{
   "body": [
      {
         "comment": "Vertica license is valid",
         "end": "Perpetual",
         "grace": "0",
         "size": "1TB CE Nodes 3",
         "start": "2011-11-22",
         "status": true,
         "vendor": "Vertica Community Edition"
      }
   ],
   "href": "/license",
   "links": [],
   "mime-type": "application/vertica.license.json-v2"
}
```

Nodes

You can use these API calls to retrieve information on the nodes in your cluster.

GET nodes	Returns a list of nodes in this cluster.
GET nodes/:nodeid	Returns details for a specific node in this cluster.

In this section

- GET nodes
- GET nodes/:nodeid

GET nodes

Returns a list of nodes associated with this cluster.

Resource URL

https://<NODE>:5444/nodes

The API key must have **restricted** level security or higher.

Parameters

None.

Example request

GET	https://<NODE>:5444/nodes

Response:

```
{
   "body": [
      "node0001",
      "node0002",
      "node0003",
      "v_testdb_node0001",
      "v_testdb_node0002",
      "v_testdb_node0003",
      "v_vmart_node0001",
      "v_vmart_node0002",
      "v_vmart_node0003"
   ],
   "href": "/nodes",
   "links": [
      "/:nodeid"
   ],
   "mime-type": "application/vertica.nodes.json-v2"
}
```

GET nodes/:nodeid

Returns details about the node identified by :node_id . You can find the :node_id for each node using GET nodes .

In the body field, the following information is detailed in comma-separated format:

- Node Name
- Host Address
- Catalog Directory
- Data Directory

Resource URL

```
https://<NODE>:5444/nodes/:node_id
```

The API key must have **restricted** level security or higher.

Parameters

None.

Example request

GET	https://<NODE>:5444/nodes/v_vmart_node0001

Response:

```
{
   "body": [
      "v_vmart_node0001",
      "10.20.100.247,/home/dbadmin,/home/dbadmin"
   ],
   "href": "/nodes/v_vmart_node0001",
   "links": [],
   "mime-type": "application/vertica.node.json-v2"
}
```

Webhooks

You can use these API calls to obtain information on, create, or delete webhooks.

GET webhooks	Returns a list of active webhooks.
POST webhooks/subscribe	Creates a new webhook.

DELETE webhooks/:subscriber_id	Deletes an existing webhook.

In this section

- GET webhooks
- POST webhooks/subscribe
- DELETE webhooks/:subscriber_id

GET webhooks

Returns a list of active webhooks for this cluster.

Resource URL

```
https://<NODE>:5444/webhooks
```

The API key must have **restricted** level security or higher.

Parameters

None.

Example request

GET	https://<NODE>:5444/webhooks

Response:

```
{
   "body": [
      {
         "host": "192.168.232.1",
         "id": "79c1c8a18be02804b3d2f48ea6462909",
         "port": 80,
         "timestamp": "2014-07-20 22:54:09.829642",
         "url": "/gettest.htm"
      },
      {
         "host": "192.168.232.1",
         "id": "9c32cb0f3d2f9a7cb10835f1732fd4a7",
         "port": 80,
         "timestamp": "2014-07-20 22:54:09.829707",
         "url": "/getwebhook.php"
      }
   ],
   "href": "/webhooks",
   "links": [
      "/subscribe",
      "/:subscriber_id"
   ],
   "mime-type": "application/vertica.webhooks.json-v2"
}
```

POST webhooks/subscribe

Creates a subscription for a webhook.

Resource URL

```
https://<NODE>:5444/webhooks/subscribe
```

The API key must have **restricted** level security or higher.

Parameters

url	A URL to an application that accepts JSON messages from this cluster.

Example request

POST	https://<NODE>:5444//webhooks/subscribe?url=http%3A%2F%2F *example.com* %2F *getwebhook.php*

Response:

The response is not JSON encoded. The only text response is the ID of the webhook subscription. Additionally, an HTTP 200/OK header indicates success.

```
79c1c8a18be02804b3d2f48ea6462909
```

DELETE webhooks/:subscriber_id

Deletes the webhook identified by :subscriber_id . The :subscriber_id is the value of the *id* field that the GET webhooks command returns.

Resource URL

```
https://<NODE>:5444/webhooks/:subscriber_id
```

The API key must have **restricted** level security or higher.

Parameters

None.

Example request

DELETE	https://<NODE>:5444/webhooks/79c1c8a18be02804b3d2f48ea6462909

Response:

There is no HTTP body response for successful deletes. A successful delete returns an HTTP 200/OK header.

Rest APIs for the Management Console

These API calls interact with Management Console nodes.

Alerts

GET alerts	Returns alerts for the current user.

Time information

GET mcTimeInfo	Returns the current time for the MC server and the timezone of the location where the MC server is located.

In this section

- MC-User-ApiKey
- GET alerts
- GET mcTimeInfo
- Thresholds category filter
- Database name category filter
- Combining sub-category filters with category filters

MC-User-ApiKey

The MC-User-ApiKey is a user-specific key used with Management Console. Users must have an MC-User-ApiKey to interact with MC using the Rest API. All users with roles other than None automatically receive an MC-User-ApiKey.

This key grants users the same rights through the API that they have available through their MC roles. To interact with the MC, users pass the key in the request header for the API.

View the MC-User-ApiKey

If you are the database administrator, you can view the MC-User-ApiKey for all users. Individual users can view their own keys.

1. Connect to MC and go to MC Settings > User Management.
2. Select the user to view and click Edit. The user's key appears in the User API Key field.

GET alerts

Returns a list of MC alerts, their current status, and database properties.

Resource URL

```
https://<MC_NODE>:5450/webui/api/alerts
```

Authentication

Requires an MC-User-Apikey in the request header.

Filter parameters

types	The type of alert to retrieve. Valid values are: • info • notice • warning • error • critical • alert • emergency
category	For information, see Thresholds category filter .
db_name	For information, see Database name category filter .
limit	The maximum number of alerts to retrieve. If the limit is lower than the number of existing alerts, Vertica retrieves the most recent alerts. Used with the type parameter, Vertica retrieves up to the limit for each type. For example, for a limit of five and types of critical and emergency, you could receive up to ten total alerts.
time_from	The timestamp start point from which to retrieve alerts. You can use this parameter in combination with the time_to parameter to retrieve alerts for a specific time range. Values must be passed in the following format: yyyy-MM-ddTHH:mm . If you provide only the time_from parameter, and omit the time_to parameter, the response contains all alerts generated from the time_from parameter to the current time.
time_to	The timestamp end point from which to retrieve alerts. You can use this parameter in combination with the time_from parameter to retrieve alerts for a specific time range. Values must be passed in the following format: yyyy-MM-ddTHH:mm . If you provide only the time_to parameter, and omit the time_from parameter , the response contains all alerts generated from the earliest possible time to the time passed in time_to .

Example request

GET	https://<MC_NODE>:5450/webui/api/alerts?types=critical

Request alerts using cURL

This example shows how you can request alerts using cURL. In this example, the limit parameter is set to '2' and the types parameters is set to info and notice :

```
curl -H "MC-User-ApiKey: ValidUserKey" https://<MC_NODE>:5450/webui/api/alerts?limit=2&types=info,notice
```

Response:

```
[
  {
    "alerts":[
      {
        "id":5502,
        "markedRead":false,
        "eventTypeCode":0,
        "create_time":"2016-02-02 05:12:10.0",
        "updated_time":"2016-02-02 15:50:20.511",
        "severity":"warning",
        "status":1,
        "nodeName":"v_vmart_node0001",
        "databaseName":"VMart",
        "databaseId":1,
        "clusterName":"1449695416208_cluster",
        "description":"Warning: Low disk space detected (73% in use)",
        "summary":"Low Disk Space",
        "internal":false,
        "count":3830
      },
      {
        "id":5501,
        "markedRead":false,
        "eventTypeCode":2,
        "create_time":"2016-02-02 05:12:02.31",
        "updated_time":"2016-02-02 05:12:02.31",
        "severity":"notice",
        "status":1,
        "databaseName":"VMart",
        "databaseId":1,
        "clusterName":"1449695416208_cluster",
        "description":"Analyze Workload operation started on Database",
        "summary":"Analyze Workload operation started on Database",
        "internal":false,
        "count":1
      }
    ],
    "total_alerts":190,
    "request_query":"limit=2",
    "request_time":"2016-02-02 15:50:26 -0500"
  }
]
```

Request alerts within a time range

These examples show various ways in which you can request the same alert as in the preceding example, but within specified time ranges.

Request the alert within a specific time range, using the time_from and time_to parameters:

```
curl -H "MC-User-ApiKey: ValidUserKey" https://<MC_NODE>:5450/webui/api/alerts?types=info,notice&time_from=2016-01-01T12:12&time_to=2016-02-01T12:12
```

Request the alert from a specific start time to the present using the time_from parameter:

```
curl -H "MC-User-ApiKey: ValidUserKey" https://<MC_NODE>:5450/webui/api/alerts?types=info,notice&time_from=2016-01-01T12:12
```

Request the alert to a specific end point using the time_to parameter. When you use the time_to parameter without the time_from parameter, the time_from parameter defaults to the oldest alerts your MC contains:

```
curl -H "MC-User-ApiKey: ValidUserKey" https://<MC_NODE>:5450/webui/api/alerts?types=info,notice&time_to=2016-01-01T12:12
```

GET mcTimeInfo

Returns the current time for the MC server and the timezone where the MC server is located.

Resource URL

```
https://<MC_NODE>:5450/webui/api/mcTimeInfo
```

Authentication

Requires an MC-User-Apikey in the request header.

Parameters

None.

Example request

GET	https://<MC_NODE>:5450/webui/api/mcTimeInfo

This example shows how you can request MC time information using cURL:

```
curl -H "MC-User-ApiKey: ValidUserKey" https://<MC_NODE>:5450/webui/api/mcTimeInfo
```

Response:

```
{"mc_current_time":"Tue, 2000-01-01 01:02:03 -0500","mc_timezone":"US/Eastern"}
```

Thresholds category filter

Returns a list of alerts related to threshold settings in MC.

Resource URL

```
https://<MC_NODE>:5450/webui/api/alerts?category=thresholds
```

Authentication

Requires an MC-User-Apikey in the request header.

Example request

GET	https://<MC_NODE>:5450/webui/api/alerts?category=thresholds

This example shows how you can request alerts on thresholds using cURL:

```
curl -H "MC-User-ApiKey: ValidUserKey" https://<MC_NODE>:5450/webui/api/alerts?category=thresholds
```

Response:

```
[
  {
    "alerts":[
      {
        "id":33,
        "markedRead":false,
        "eventTypeCode":2,
        "create_time":"2015-11-10 10:28:41.332",
        "updated_time":"2015-11-10 10:28:41.332",
        "severity":"warning",
        "status":1,
        "databaseName":"mydb",

  }
]
```

See also

- Combining sub-category filters with category filters

Database name category filter

Returns a list of MC alerts for a specific database.

Resource URL

```
https://<MC_NODE>:5450/webui/api/alerts?db_name=
```

Authentication

Requires an MC-User-Apikey in the request header.

Example request

GET	https://<MC_NODE>:5450/webui/api/alerts?db_name= *database_name*

This example shows how you can view alerts on a specific database using cURL:

```
curl -H "MC-User-ApiKey: ValidUserKey" https://<MC_NODE>:5450/webui/api/alerts?db_name="mydb"
```

Response:

```
[
  {
    "alerts":[
      {
        "id":9,
        "markedRead":false,
        "eventTypeCode":2,

Combining sub-category filters with category filters

You can combine category filters with sub-category filters, to obtain alert messages for specific thresholds you set in MC. You can also use sub-category filters to obtain information about alerts on specific resource pools in your database.

Sub-category filters

You can use the following sub-category filters with the category filters. Sub-category filters are case sensitive and must be lowercase.

Sub-Category Filter	Alerts Related to Threshold Value Set For:
THRESHOLD_NODE_CPU	Node CPU
THRESHOLD_NODE_MEMORY	Node Memory
THRESHOLD_NODE_DISK_USAGE	Node Disk Usage
THRESHOLD_NODE_DISKIO	Node Disk I/O
THRESHOLD_NODE_CPUIO	Node CPU I/O Wait
THRESHOLD_NODE_REBOOTRATE	Node Reboot Rate
THRESHOLD_NETIO	Network I/O Error
THRESHOLD_QUERY_QUEUED	Queued Query Number
THRESHOLD_QUERY_FAILED	Failed Query Number
THRESHOLD_QUERY_SPILLED	Spilled Query Number
THRESHOLD_QUERY_RETRIED	Retried Query Number
THRESHOLD_QUERY_RUNTIME	Query Running Time

Resource pool-specific sub-category filters

To retrieve alerts for a specific resource pool, you can use sub-category filters in combination with the following category filters:

- thresholds
- rp_name

If you use these sub-category filters without the RP_NAME filter, the query retrieves alerts for all resource pools in your database.

Sub-Category Filter	Alerts Related to Threshold Value Set For:
THRESHOLD_RP_QUERY_MAX_TIME	Queries reaching the maximum allowed execution time.
THRESHOLD_RP_QUERY_RESOURCE_REJECT	The number of queries with resource rejections.
THRESHOLD_RP_QUERY_QUEUE_TIME	The number of queries that ended because of queue time exceeding a limit.
THRESHOLD_RP_QUERY_RUN_TIME	The number of queries that ended because of run time exceeding a limit.
THRESHOLD_RP_MEMORY	The minimum allowed resource pool size.
THRESHOLD_RP_MAX_MEMORY	The maximum allowed resource pool size.

Authentication

Requires an MC-User-Apikey in the request header.

Example request

GET	https://<MC_NODE>:5450/webui/api/alerts?category=thresholds&subcategory= *<subcategory_filter>*

Combine the thresholds category filter with a sub-category filter

This example shows how you can request alerts using cURL with the thresholds category filter and a sub-category filter. You apply the following filters:

- THRESHOLDS
- THRESHOLD_NODE_CPU

```
curl -H "MC-User-ApiKey: ValidUserKey" https://<MC_NODE>:5450/webui/api/alerts?category=thresholds&subcategory=threshold_node_cpu
```

Response:

```
[
  {
    "alerts":[
      {

Connect with an SSH tunnel

You can set up an SSH tunnel to connect to Vertica through a proxy server. This can be useful in cases where the client or Vertica server is on a private network.

Server on private network

If the Vertica server is on a private network, run ssh -R to configure remote port forwarding on the Vertica server host. For example, to let the client connect to Vertica through a proxy hosted on proxy.example.com:9595 :

1. On the proxy server, add GatewayPorts yes to /etc/ssh/sshd_config .
2. On the proxy server, restart the SSH service:
   ```
   $ sudo systemctl restart ssh
   ```
3. On the Vertica server host, run:
   ```
   $ ssh -N -R 9595:localhost:5433 user@proxy.example.com
   ```
4. On the client host, run the following to connect to Vertica through the proxy server:

```
$ vsql -h proxy.example.com -p 9595
```

Client on private network

If the client machine is on a private network, run `ssh -L` on the client to configure local port forwarding. For example, to let the client use `localhost:9595` to connect to Vertica hosted on `vertica.example.com:5433` through a proxy on `proxy.example.com` :

```
$ ssh -N -L 9595:vertica.example.com:5433 user@proxy.example.com
```

You can then connect to Vertica from the client:

```
$ vsql -p 9595
```

Extending Vertica

You can extend Vertica to perform new operations or handle new types of data. There are several types of extensions:

- **External procedures:** external scripts or programs that are installed on a host in your database cluster.
- **User-defined SQL functions:** Frequently-used SQL expressions, which help you simplify and standardize your SQL scripts.
- **Stored Procedures:** SQL procedures that are stored in the database (as opposed to external procedures). Stored procedures can communicate and interact with your database directly to perform maintenance, execute queries, and update tables.
- **User-defined extensions (UDxs):** functions or data-load steps written in the C++, Python, Java, and R programming languages. They are useful when the type of data processing you want to perform is difficult or slow using SQL. User-defined extensions explains how to use them and Developing user-defined extensions (UDxs) explains how to create them.

In this section

- External procedures
- User-defined SQL functions
- Stored procedures
- User-defined extensions
- Developing user-defined extensions (UDxs)

External procedures

Enterprise Mode only

An external procedure is a script or executable program on a host in your database cluster that you can call from within Vertica. External procedures cannot communicate back to Vertica.

To implement an external procedure:

1. Create an external procedure executable file. See Requirements for external procedures .
2. Enable the set-user-ID(SUID), user execute, and group execute attributes for the file. Either the file must be readable by the dbadmin or the file owner's password must be given with the Administration tools `install_procedure` command.
3. Install the external procedure executable file .
4. Create the external procedure in Vertica .

After a procedure is created in Vertica, you can execute or drop it, but you cannot alter it.

In this section

- Requirements for external procedures
- Installing external procedure executable files
- Creating external procedures
- Executing external procedures
- Dropping external procedures

Requirements for external procedures

Enterprise Mode only

External procedures have requirements regarding their attributes, where you store them, and how you handle their output. You should also be cognizant of their resource usage.

Procedure file attributes

The procedure file cannot be owned by root. It must have the set-user-ID (SUID), user execute, and group execute attributes set. If it is not readable by the Linux database administrator user, then the owner's password will have to be specified when installing the procedure.

Handling procedure output

Vertica does not provide a facility for handling procedure output. Therefore, you must make your own arrangements for handling procedure output, which should include writing error, logging, and program information directly to files that you manage.

Handling resource usage

The Vertica resource manager is unaware of resources used by external procedures. Additionally, Vertica is intended to be the only major process running on your system. If your external procedure is resource intensive, it could affect the performance and stability of Vertica. Consider the types of external procedures you create and when you run them. For example, you might run a resource-intensive procedure during off hours.

Sample procedure file

```
#!/bin/bash
echo "hello planet argument: $1" >> /tmp/myprocedure.log
```

Installing external procedure executable files

Enterprise Mode only

To install an external procedure, use the Administration Tools through either menu or the command line.

Using the admin tools menus

1. Run the Administration tools.

   ```
   $ /opt/vertica/bin/adminTools
   ```

2. On the AdminTools **Main Menu**, click **Configuration Menu**, and then click **OK**.

3. On the **Configuration Menu**, click **Install External Procedure** and then click **OK**.

4. Select the database on which you want to install the external procedure.

5. Either select the file to install or manually type the complete file path, and then click **OK**.

6. If you are not the superuser, you are prompted to enter your password and click **OK**.

   The Administration Tools automatically create the <database_catalog_path>/procedures directory on each node in the database and installs the external procedure in these directories for you.

7. Click **OK** in the dialog that indicates that the installation was successful.

Command line

If you use the command line, be sure to specify the full path to the procedure file and the password of the Linux user who owns the procedure file.

For example:

```
$ admintools -t install_procedure -d vmartdb -f /scratch/helloworld.sh -p ownerpassword
Installing external procedure...
External procedure installed
```

Once you have installed an external procedure, you need to make Vertica aware of it. To do so, use the CREATE PROCEDURE statement, but review Creating external procedures first.

Creating external procedures

Enterprise Mode only

After you install an external procedure, you must make Vertica aware of it with CREATE PROCEDURE (external) .

Only superusers can create an external procedure, and by default, only they have execute privileges. However, superusers can grant users and roles EXECUTE privilege on the stored procedure.

After you create a procedure, its metadata is stored in system table USER_PROCEDURES . Users can see only those procedures that they have been granted the privilege to execute.

Example

The following example creates a procedure named helloplanet for external procedure file helloplanet.sh . This file accepts one VARCHAR argument. The sample code is provided in Requirements for external procedures .

```
=> CREATE PROCEDURE helloplanet(arg1 VARCHAR) AS 'helloplanet.sh' LANGUAGE 'external'
  USER 'dbadmin';
```

The next example creates a procedure named proctest for the script copy_vertica_database.sh . This script copies a database from one cluster to another; it is included in the server RPM located in directory /opt/vertica/scripts .

```
=> CREATE PROCEDURE proctest(shosts VARCHAR, thosts VARCHAR, dbdir VARCHAR)
  AS 'copy_vertica_database.sh' LANGUAGE 'external' USER 'dbadmin';
```

Overloading external procedures

You can create multiple external procedures with the same name if they have different signatures—that is, accept a different set of arguments. For example, you can overload the helloplanet external procedure to also accept an integer value:

```
=> CREATE PROCEDURE helloplanet(arg1 INT) AS 'helloplanet.sh' LANGUAGE 'external'
  USER 'dbadmin';
```

After executing this statement, the database catalog stores two external procedures named helloplanet —one that accepts a VARCHAR argument and one that accepts an integer. When you call the external procedure, Vertica evaluates the arguments in the procedure call to determine which procedure to call.

See also

- CREATE PROCEDURE (external)
- GRANT (procedure)

Executing external procedures

Enterprise Mode only

After you define a procedure using the CREATE PROCEDURE (external) statement, you can use it as a meta command in a SELECT statement. Vertica does not support using procedures in more complex statements or in expressions.

The following example runs a procedure named helloplanet :

```
=> SELECT helloplanet('earthlings');
 helloplanet
-------------
           0
(1 row)
```

The following example runs a procedure named proctest . This procedure references the copy_vertica_database.sh script that copies a database from one cluster to another. It is installed by the server RPM in the /opt/vertica/scripts directory.

```
=> SELECT proctest(
   '-s qa01',
   '-t rbench1',
   '-D /scratch_b/qa/PROC_TEST' );
```

> **Note**
> External procedures have no direct access to database data. Use ODBC or JDBC for this purpose.

Procedures are executed on the initiating node. Vertica runs the procedure by forking and executing the program. Each procedure argument is passed to the executable file as a string. The parent fork process waits until the child process ends.

If the child process exits with status 0, Vertica reports the operation took place by returning one row as shown in the helloplanet example. If the child process exits with any other status, Vertica reports an error like the following:

```
ERROR 7112: Procedure reported: Procedure execution error: exit status = code
```

To stop execution, cancel the process by sending a cancel command (for example, CTRL+C) through the client. If the procedure program exits with an error, an error message with the exit status is returned.

Permissions

To execute an external procedure, the user needs:

- EXECUTE privilege on procedure
- USAGE privilege on schema that contains the procedure

Dropping external procedures

Enterprise Mode only

Only a superuser can drop an external procedure. To drop the definition for an external procedure from Vertica, use the DROP PROCEDURE (external) statement. Only the reference to the procedure is removed. The external file remains in the <database>/procedures directory on each node in the database.

> **Note**
> The definition Vertica uses for a procedure cannot be altered; it can only be dropped.

Example

```
=> DROP PROCEDURE helloplanet(arg1 varchar);
```

See also

- DROP PROCEDURE (external)

User-defined SQL functions

User-defined SQL functions let you define and store commonly-used SQL expressions as a function. User-defined SQL functions are useful for executing complex queries and combining Vertica built-in functions. You simply call the function name you assigned in your query.

A user-defined SQL function can be used anywhere in a query where an ordinary SQL expression can be used, except in a table partition clause or the projection segmentation clause.

For syntax and parameters for the commands and system table discussed in this section, see the following topics:

- CREATE FUNCTION
- ALTER FUNCTION (scalar)
- DROP FUNCTION
- GRANT (user defined extension)
- REVOKE (user defined extension)

- V_CATALOG.USER_FUNCTIONS

In this section

- Creating user-defined SQL functions
- Altering and dropping user-defined SQL functions
- Managing access to SQL functions
- Viewing information about user-defined SQL functions
- Migrating built-in SQL functions

Creating user-defined SQL functions

A user-defined SQL function can be used anywhere in a query where an ordinary SQL expression can be used, except in the table partition clause or the projection segmentation clause.

To create a SQL function, the user must have CREATE privileges on the schema. To use a SQL function, the user must have USAGE privileges on the schema and EXECUTE privileges on the defined function.

This following statement creates a SQL function called myzeroifnull that accepts an INTEGER argument and returns an INTEGER result.

```
=> CREATE FUNCTION myzeroifnull(x INT) RETURN INT
  AS BEGIN
    RETURN (CASE WHEN (x IS NOT NULL) THEN x ELSE 0 END);
  END;
```

You can use the new SQL function (myzeroifnull) anywhere you use an ordinary SQL expression. For example, create a simple table:

```
=> CREATE TABLE tabwnulls(col1 INT);
=> INSERT INTO tabwnulls VALUES(1);
=> INSERT INTO tabwnulls VALUES(NULL);
=> INSERT INTO tabwnulls VALUES(0);
=> SELECT * FROM tabwnulls;
 a
---
 1
 0
(3 rows)
```

Use the myzeroifnull function in a SELECT statement, where the function calls col1 from table tabwnulls:

```
=> SELECT myzeroifnull(col1) FROM tabwnulls;
 myzeroifnull
--------------
            1
            0
            0
(3 rows)
```

Use the myzeroifnull function in the GROUP BY clause:

```
=> SELECT COUNT(*) FROM tabwnulls GROUP BY myzeroifnull(col1);
 count
-------
     2
     1
(2 rows)
```

If you want to change a user-defined SQL function's body, use the CREATE OR REPLACE syntax. The following command modifies the CASE expression:

```
=> CREATE OR REPLACE FUNCTION myzeroifnull(x INT) RETURN INT
  AS BEGIN
    RETURN (CASE WHEN (x IS NULL) THEN 0 ELSE x END);
  END;
```

To see how this information is stored in the Vertica catalog, see Viewing Information About SQL Functions .

See also

- CREATE FUNCTION (SQL)
- USER_FUNCTIONS

Altering and dropping user-defined SQL functions

Vertica allows multiple functions to share the same name with different argument types. Therefore, if you try to alter or drop a SQL function without specifying the argument data type, the system returns an error message to prevent you from dropping the wrong function:

```
=> DROP FUNCTION myzeroifnull();
ROLLBACK:  Function with specified name and parameters does not exist: myzeroifnull
```

> **Note**
> Only a superuser or owner can alter or drop a SQL Function.

Altering a user-defined SQL function

The ALTER FUNCTION (scalar) command lets you assign a new name to a user-defined function, as well as move it to a different schema.

In the previous topic, you created a SQL function called myzeroifnull . The following command renames the myzeroifnull function to zerowhennull :

```
=> ALTER FUNCTION myzeroifnull(x INT) RENAME TO zerowhennull;
ALTER FUNCTION
```

This next command moves the renamed function into a new schema called macros :

```
=> ALTER FUNCTION zerowhennull(x INT) SET SCHEMA macros;
ALTER FUNCTION
```

Dropping a SQL function

The DROP FUNCTION command drops a SQL function from the Vertica catalog.

Like with ALTER FUNCTION, you must specify the argument data type or the system returns the following error message:

```
=> DROP FUNCTION zerowhennull();
ROLLBACK:  Function with specified name and parameters does not exist: zerowhennull
```

Specify the argument type:

```
=> DROP FUNCTION macros.zerowhennull(x INT);
DROP FUNCTION
```

Vertica does not check for dependencies, so if you drop a SQL function where other objects reference it (such as views or other SQL Functions), Vertica returns an error when those objects are used, not when the function is dropped.

> **Tip**
> To view a list of all user-defined SQL functions on which you have EXECUTE privileges, (which also returns their argument types), query the V_CATALOG.USER_FUNCTIONS system table.

See also

- ALTER FUNCTION (scalar)
- DROP FUNCTION

Managing access to SQL functions

Before a user can execute a user-defined SQL function, he or she must have USAGE privileges on the schema and EXECUTE privileges on the defined function. Only the superuser or owner can grant/revoke EXECUTE usage on a function.

To grant EXECUTE privileges to user Fred on the myzeroifnull function:

```
=> GRANT EXECUTE ON FUNCTION myzeroifnull (x INT) TO Fred;
```

To revoke EXECUTE privileges from user Fred on the myzeroifnull function:

```
=> REVOKE EXECUTE ON FUNCTION myzeroifnull (x INT) FROM Fred;
```

See also

- GRANT (user defined extension)
- REVOKE (user defined extension)

Viewing information about user-defined SQL functions

You can access information about user-defined SQL functions on which you have EXECUTE privileges. This information is available in system table USER_FUNCTIONS and from the vsql meta-command \df .

To view all user-defined SQL functions on which you have EXECUTE privileges, query USER_FUNCTIONS:

```
=> SELECT * FROM USER_FUNCTIONS;
-[ RECORD 1 ]----------+--------------------------------------------------
schema_name            | public
function_name          | myzeroifnull
function_return_type   | Integer
function_argument_type | x Integer
function_definition    | RETURN CASE WHEN (x IS NOT NULL) THEN x ELSE 0 END
volatility             | immutable
is_strict              | f
```

If you want to change the body of a user-defined SQL function, use the CREATE OR REPLACE syntax. The following command modifies the CASE expression:

```
=> CREATE OR REPLACE FUNCTION myzeroifnull(x INT) RETURN INT
  AS BEGIN
    RETURN (CASE WHEN (x IS NULL) THEN 0 ELSE x END);
  END;
```

Now when you query USER_FUNCTIONS, you can see the changes in the function_definition column:

```
=> SELECT * FROM USER_FUNCTIONS;
-[ RECORD 1 ]----------+--------------------------------------------------
schema_name            | public
function_name          | myzeroifnull
function_return_type   | Integer
function_argument_type | x Integer
function_definition    | RETURN CASE WHEN (x IS NULL) THEN 0 ELSE x END
volatility             | immutable
is_strict              | f
```

If you use CREATE OR REPLACE syntax to change only the argument name or argument type (or both), the system maintains both versions of the function. For example, the following command tells the function to accept and return a numeric data type instead of an integer for the myzeroifnull function:

```
=> CREATE OR REPLACE FUNCTION myzeroifnull(z NUMERIC) RETURN NUMERIC
  AS BEGIN
    RETURN (CASE WHEN (z IS NULL) THEN 0 ELSE z END);
  END;
```

Now query the USER_FUNCTIONS table, and you can see the second instance of myzeroifnull in Record 2, as well as the changes in the function_return_type , function_argument_type , and function_definition columns.

> **Note**
> Record 1 still holds the original definition for the myzeroifnull function:

```
=> SELECT * FROM USER_FUNCTIONS;
-[ RECORD 1 ]----------+-----------------------------------------------------------
schema_name            | public
function_name          | myzeroifnull
function_return_type   | Integer
function_argument_type | x Integer
function_definition    | RETURN CASE WHEN (x IS NULL) THEN 0 ELSE x END
volatility             | immutable
is_strict              | f
-[ RECORD 2 ]----------+-----------------------------------------------------------
schema_name            | public
function_name          | myzeroifnull
function_return_type   | Numeric
function_argument_type | z Numeric
function_definition    | RETURN (CASE WHEN (z IS NULL) THEN (0) ELSE z END)::numeric
volatility             | immutable
is_strict              | f
```

Because Vertica allows functions to share the same name with different argument types, you must specify the argument type when you alter or drop a function. If you do not, the system returns an error message:

```
=> DROP FUNCTION myzeroifnull();
ROLLBACK:  Function with specified name and parameters does not exist: myzeroifnull
```

Migrating built-in SQL functions

If you have built-in SQL functions from another RDBMS that do not map to a Vertica-supported function, you can migrate them into your Vertica database by using a user-defined SQL function.

The example scripts below show how to create user-defined functions for the following DB2 built-in functions:

- UCASE()
- LCASE()
- LOCATE()
- POSSTR()

UCASE()

This script creates a user-defined SQL function for the UCASE() function:

```
=> CREATE OR REPLACE FUNCTION UCASE (x VARCHAR)
  RETURN VARCHAR
  AS BEGIN
  RETURN UPPER(x);
  END;
```

LCASE()

This script creates a user-defined SQL function for the LCASE() function:

```
=> CREATE OR REPLACE FUNCTION LCASE (x VARCHAR)
  RETURN VARCHAR
  AS BEGIN
  RETURN LOWER(x);
  END;
```

LOCATE()

This script creates a user-defined SQL function for the LOCATE() function:

```
=> CREATE OR REPLACE FUNCTION LOCATE(a VARCHAR, b VARCHAR)
  RETURN INT
  AS BEGIN
  RETURN POSITION(a IN b);
  END;
```

POSSTR()

This script creates a user-defined SQL function for the POSSTR() function:

```
=> CREATE OR REPLACE FUNCTION POSSTR(a VARCHAR, b VARCHAR)
  RETURN INT
  AS BEGIN
  RETURN POSITION(b IN a);
  END;
```

Stored procedures

You can condense complex database tasks and routines into stored procedures. Unlike external procedures , stored procedures live and can be executed from inside your database; this lets them communicate and interact with your database directly to perform maintenance, execute queries, and update tables.

Best practices

Many other databases are optimized for online transaction processing (OLTP), which focuses on frequent transactions. In contrast, Vertica is optimized for online analytical processing (OLAP), which instead focuses on storing and analyzing large amounts of data and delivering the fastest responses to the most complex queries on that data.

This architecture difference means that the recommended use cases and best practices for stored procedures in Vertica differ slightly from stored procedures in other databases.

While stored procedures in OLTP-oriented databases are often used to perform small transactions, stored procedures in OLAP-oriented databases like Vertica should instead be used to enhance analytical workloads. Vertica can handle isolated transactions, but frequent small transactions can potentially hinder performance.

Some recommended use cases for stored procedures in Vertica include information lifecycle management (ILM) activities such as extract, transform, and load (ETL), and data preparation for tasks like machine learning. For example:

- Swapping partitions according to age
- Exporting data at end-of-life and dropping the partitions
- Saving inputs, outputs, and metadata from a machine learning model—who ran the model, the version of the model, how many times the model was run, and who received the results

Stored procedures in Vertica can also operate on objects that require higher privileges than that of the caller. An optional parameter allows procedures to run using the privileges of the definer, allowing callers to perform sensitive operations in a controlled way.

Known issues and workarounds

- You cannot use PERFORM CREATE FUNCTION to create a SQL macro.
  Workaround
  Use EXECUTE to make SQL macros inside a stored procedure:

  ```
  CREATE PROCEDURE procedure_name()
  LANGUAGE PLvSQL AS $$
  BEGIN
    EXECUTE 'macro';
  end;
  $$;
  ```

  where *macro* is the creation statement for a SQL macro. For example, this procedure creates the argmax macro:

  ```
  => CREATE PROCEDURE make_argmax() LANGUAGE PLvSQL AS $$
  BEGIN
    EXECUTE
      'CREATE FUNCTION
      argmax(x int) RETURN int AS
      BEGIN
        RETURN (CASE WHEN (x IS NOT NULL) THEN x ELSE 0 END);
      END';
  END;
  $$;
  ```

- Non-error exceptions in embedded SQL statements are not reported.
- DECIMAL, NUMERIC, NUMBER, MONEY, and UUID data types cannot yet be used for arguments.

- Cursors should capture the variable context at declaration time, but they currently capture the variable context at open time.
- DML queries on tables with key constraints cannot yet return a value.
  Workaround
  Rather than:

```
DO $$
DECLARE
   y int;
BEGIN
   y := UPDATE tbl WHERE col1 = 3 SET col2 = 4;
END;
$$
```

  Check the result of the DML query with SELECT:

```
DO $$
DECLARE
   y int;
BEGIN
   y := SELECT COUNT(*) FROM tbl WHERE col1 = 3;
   PERFORM UPDATE tbl SET col2 = 4 WHERE col1 = 3;
END;
$$;
```

PL/vSQL

PL/vSQL is a powerful and expressive procedural language for creating reusable procedures, manipulating data, and simplifying otherwise complex database routines.

Vertica PL/vSQL is largely compatible with PostgreSQL PL/pgSQL, with minor semantic differences. For details on migrating your PostgreSQL PL/pgSQL stored procedures to Vertica, see the PL/pgSQL to PL/vSQL migration guide .

For real-world, practical examples of PL/vSQL usage, see Stored procedures: use cases and examples .

In this section

- Supported types
- Scope and structure
- Embedded SQL
- Control flow
- Errors and diagnostics
- Cursors
- PL/pgSQL to PL/vSQL migration guide

Supported types

Vertica PL/vSQL supports non-complex data types . The following types are supported as variables only and not as arguments:

- DECIMAL
- NUMERIC
- NUMBER
- MONEY
- UUID

Scope and structure

PL/vSQL uses block scope, where a block has the following structure:

```
[ <<label>> ]
[ DECLARE
   declarations ]
BEGIN
   statements
   ...
END [ label ];
```

Declarations

Variable *declarations* in the DECLARE block are structured as:

```
variable_name [ CONSTANT ] data_type [ NOT NULL ] [:= { expression | statement } ];
```

variable_name	Variable names must meet the following requirements: • Must be SQL identifiers • Cannot be reserved keywords • Cannot duplicate those in previous declarations inside the same block.
CONSTANT	Defines the variable as a constant (immutable). You can only set a constant variable's value during initialization.
data_type	The variable data type. PL/vSQL supports non-complex data types , with the following exceptions: • GEOMETRY • GEOGRAPHY You can optionally reference a particular column's data type: *variable_name table_name.column_name%TYPE ;*
NOT NULL	Specifies that the variable cannot hold a NULL value. If declared with NOT NULL, the variable must be initialized (otherwise, throws ERRCODE_SYNTAX_ERROR) and cannot be assigned NULL (otherwise, throws ERRCODE_WRONG_OBJECT_TYPE).

:= *expression*	Initializes a variable with *expression* or statement.
	If the variable is declared with NOT NULL , *expression* is required.
	Variable declarations in a given block execute sequentially, so old declarations can be referenced by newer ones. For example:
	`DECLARE`
	`  x int := 3;`
	`  y int := x;`
	Default (uninitialized): NULL

Aliases

Aliases are alternate names for the same variable. An alias of a variable is not a copy, and changes made to either reference affect the same underlying variable.

```
new_name ALIAS FOR variable;
```

Here, the identifier y is now an alias for variable x , and changes to y are reflected in x .

```
DO $$
DECLARE
   x int := 3;
   y ALIAS FOR x;
BEGIN
   y := 5; -- since y refers to x, x = 5
   RAISE INFO 'x = %, y = %', x, y;
END;
$$;

INFO 2005:  x = 5, y = 5
```

BEGIN and nested blocks

BEGIN contains *statements* . A *statement* is defined as a line or block of PL/vSQL.

Variables declared in inner blocks shadow those declared in outer blocks. To unambiguously specify a variable in a particular block, you can name the block with a *label* (case-insensitive), and then reference the variable declared in that block with:

```
label.variable_name
```

For example, specifying the variable x from inside the inner block implicitly refers to inner_block.x rather than outer_block.x because of shadowing:

```
<<outer_block>>
DECLARE
   x int;
BEGIN
   <<inner_block>>
   DECLARE
      x int;
   BEGIN
      x := 1000; -- implicitly specifies x in inner_block because of shadowing
      OUTER_BLOCK.x := 0; -- specifies x in outer_block; labels are case-insensitive
   END inner_block;
END outer_block;
```

NULL statement

The NULL statement does nothing. This can be useful as a placeholder statement or a way to show that a code block is intentionally empty. For example:

```
DO $$
BEGIN
   NULL;
END;
$$
```

Comments

Comments have the following syntax. You cannot nest comments.

```
-- single-line comment

/* multi-line
comment
*/
```

Embedded SQL

You can embed and execute SQL statements and expressions from within stored procedures.

Assignment

To save the value of an expression or returned value, you can assign it to a variable:

```
variable_name := expression;
variable_name := statement;
```

For example, this procedure assigns 3 into i and 'message' into v .

```
=> CREATE PROCEDURE performless_assignment() LANGUAGE PLvSQL AS $$
DECLARE
   i int;
   v varchar;
BEGIN
   i := SELECT 3;
   v := 'message';
END;
$$;
```

This type of assignment will fail if the query returns no rows or more than one row. For returns of multiple rows, use LIMIT or truncating assignment :

```
=> SELECT * FROM t1;
 b
---
 t
 f
 f
(3 rows)

=> CREATE PROCEDURE more_than_one_row() LANGUAGE PLvSQL as $$
DECLARE
   x boolean;
BEGIN
   x := SELECT * FROM t1;
END;
$$;
CREATE PROCEDURE

=> CALL more_than_one_row();
ERROR 10332:  Query returned multiple rows where 1 was expected
```

Truncating assignment

Truncating assignment stores in a variable the first row returned by a query. Row order is nondeterministic unless you specify an ORDER BY clause :

```
variable_name <- expression;
variable_name <- statement;
```

The following procedure takes the first row of the results returned by the specified query and assigns it to x :

```
=> CREATE PROCEDURE truncating_assignment() LANGUAGE PLvSQL AS $$
DECLARE
   x boolean;
BEGIN
   x <- SELECT * FROM t1 ORDER BY b DESC; -- x is now assigned the first row returned by the SELECT query
END;
$$;
```

PERFORM

The PERFORM keyword runs a SQL statement or expression and discards the returned result.

```
PERFORM statement;
PERFORM expression;
```

For example, this procedure inserts a value into a table. INSERT returns the number of rows inserted, so you must pair it with PERFORM.

```
=> DO $$
BEGIN
   PERFORM INSERT INTO coordinates VALUES(1,2,3);
END;
$$;
```

> **Note**
> If a SQL statement has no return value or you don't assign the return value to a variable, you must use PERFORM.

EXECUTE

EXECUTE allows you to dynamically construct a SQL query during execution:

```
EXECUTE command_expression [ USING expression [, ... ] ];
```

command_expression is a SQL expression that can reference PL/vSQL variables and evaluates to a string literal. The string literal is executed as a SQL statement, and $1, $2, ... are substituted with the corresponding * expression *s.

Constructing your query with PL/vSQL variables can be dangerous and expose your system to SQL injection, so wrap them with QUOTE_IDENT , QUOTE_LITERAL , and QUOTE_NULLABLE .

The following procedure constructs a query with a WHERE clause:

```
DO $$
BEGIN
   EXECUTE 'SELECT * FROM t1 WHERE x = $1' USING 10; -- becomes WHERE x = 10
END;
$$;
```

The following procedure creates a user with a password from the username and password arguments. Because the constructed CREATE USER statement uses variables, use the functions QUOTE_IDENT and QUOTE_LITERAL, concatenating them with ||.

```
=> CREATE PROCEDURE create_user(username varchar, password varchar) LANGUAGE PLvSQL AS $$
BEGIN
   EXECUTE 'CREATE USER ' || QUOTE_IDENT(username) || ' IDENTIFIED BY ' || QUOTE_LITERAL(password);
END;
$$;
```

EXECUTE is a SQL statement, so you can assign it to a variable or pair it with PERFORM:

```
variable_name:= EXECUTE command_expression;
PERFORM EXECUTE command_expression;
```

FOUND (special variable)

The special boolean variable FOUND is initialized as false and assigned true or false based on whether:

- A statement (but not expression) returns results with non-zero number of rows, or
- A FOR loop iterates at least once

You can use FOUND to distinguish between a NULL and 0-row return.

Special variables exist between the scope of a procedure's argument and the outermost block of its definition. This means that:

- Special variables shadow procedure arguments
- Variables declared in the body of the stored procedure will shadow the special variable

The following procedure demonstrates how FOUND changes. Before the SELECT statement, FOUND is false; after the SELECT statement, FOUND is true.

```
=> DO $$
BEGIN
   RAISE NOTICE 'Before SELECT, FOUND = %', FOUND;
   PERFORM SELECT 1; -- SELECT returns 1
   RAISE NOTICE 'After SELECT, FOUND = %', FOUND;
END;
$$;

NOTICE 2005:  Before SELECT, FOUND = f
NOTICE 2005:  After SELECT, FOUND = t
```

Similarly, UPDATE, DELETE, and INSERT return the number of rows affected. In the next example, UPDATE doesn't change any rows, but returns the value 0 to indicate that no rows were affected, so FOUND is set to true:

```
=> SELECT * t1;
 a  |  b
-----+-----
 100 | abc
(1 row)

DO $$
BEGIN
   PERFORM UPDATE t1 SET a=200 WHERE b='efg'; -- no rows affected since b doesn't contain 'efg'
   RAISE INFO 'FOUND = %', FOUND;
END;
$$;

INFO 2005:  FOUND = t
```

FOUND starts as false and is set to true if the loop iterates at least once:

```
=> DO $$
BEGIN
   RAISE NOTICE 'FOUND = %', FOUND;
   FOR i IN RANGE 1..1 LOOP -- RANGE is inclusive, so iterates once
      RAISE NOTICE 'i = %', i;
   END LOOP;
   RAISE NOTICE 'FOUND = %', FOUND;
END;
$$;

NOTICE 2005:  FOUND = f
NOTICE 2005:  FOUND = t

DO $$
BEGIN
   RAISE NOTICE 'FOUND = %', FOUND;
   FOR i IN RANGE 1..0 LOOP
      RAISE NOTICE 'i = %', i;
   END LOOP;
   RAISE NOTICE 'FOUND = %', FOUND;
END;
$$;

NOTICE 2005:  FOUND = f
NOTICE 2005:  FOUND = f
```

Control flow

Control flow constructs give you control over how many times and under what conditions a block of statements should run.

Conditionals

IF/ELSIF/ELSE

IF/ELSIF/ELSE statements let you perform different actions based on a specified condition.

```
IF condition_1 THEN
  statement_1;
[ ELSIF condition_2 THEN
  statement_2 ]
...
[ ELSE
  statement_n; ]
END IF;
```

Vertica successively evaluates each condition as a boolean until it finds one that's true, then executes the block of statements and exits the IF statement. If no conditions are true, it executes the ELSE block, if one exists.

```
IF i = 3 THEN...
ELSIF 0 THEN...
ELSIF true THEN...
ELSIF x <= 4 OR x >= 10 THEN...
ELSIF y = 'this' AND z = 'THAT' THEN...
```

For example, this procedure demonstrates a simple IF...ELSE branch. Because b is declared to be true, Vertica executes the first branch.

```
=> DO LANGUAGE PLvSQL $$
DECLARE
   b bool := true;
BEGIN
   IF b THEN
      RAISE NOTICE 'true branch';
   ELSE
      RAISE NOTICE 'false branch';
   END IF;
END;
$$;

NOTICE 2005:  true branch
```

CASE

CASE expressions are often more readable than IF...ELSE chains. After executing a CASE expression's branch, control jumps to the statement after the enclosing END CASE.

PL/vSQL CASE expressions are more flexible and powerful than SQL case expressions , but the latter are more efficient; you should favor SQL case expressions when possible.

```
CASE [ search_expression ]
  WHEN expression_1 [, expression_2, ...] THEN
     when_statements
 [ ... ]
 [ ELSE
     else_statements ]
END CASE;
```

search_expression is evaluated once and then compared with *expression_n* in each branch from top to bottom. If *search_expression* and a given *expression_n* are equal, then Vertica executes the WHEN block for *expression_n* and exits the CASE block. If no matching expression is found, the ELSE branch is executed, if one exists.

Case expressions must have either a matching case or an ELSE branch, otherwise Vertica throws a CASE_NOT_FOUND error.

If you omit *search_expression* , its value defaults to true .

For example, this procedure plays the game FizzBuzz, printing Fizz if the argument is divisible by 3, Buzz if the argument is divisible by 5, FizzBuzz if the if the argument is divisible by 3 and 5.

```
=> CREATE PROCEDURE fizzbuzz(IN x int) LANGUAGE PLvSQL AS $$
DECLARE
   fizz int := x % 3;
   buzz int := x % 5;
BEGIN
   CASE fizz
      WHEN 0 THEN -- if fizz = 0, execute WHEN block
         CASE buzz
            WHEN 0 THEN -- if buzz = 0, execute WHEN block
               RAISE INFO 'FizzBuzz';
            ELSE -- if buzz != 0, execute WHEN block
               RAISE INFO 'Fizz';
         END CASE;
      ELSE -- if fizz != 0, execute ELSE block
         CASE buzz
            WHEN 0 THEN
               RAISE INFO 'Buzz';
            ELSE
               RAISE INFO '';
         END CASE;
   END CASE;
END;
$$;

=> CALL fizzbuzz(3);
INFO 2005:  Fizz

=> CALL fizzbuzz(5);
INFO 2005:  Buzz

=> CALL fizzbuzz(15);
INFO 2005:  FizzBuzz
```

Loops

Loops repeatedly execute a block of code until a given condition is satisfied.

WHILE

A WHILE loop checks a given condition and, if the condition is true, it executes the loop body, after which the condition is checked again: if true, the loop body executes again; if false, control jumps to the end of the loop body.

```
[ <<label>> ]
WHILE condition LOOP
  statements;
END LOOP;
```

For example, this procedure computes the factorial of the argument:

```
=> CREATE PROCEDURE factorialSP(input int) LANGUAGE PLvSQL AS $$
DECLARE
   i int := 1;
   output int := 1;
BEGIN
   WHILE i <= input loop
      output := output * i;
      i := i + 1;
   END LOOP;
   RAISE INFO '%! = %', input, output;
END;
$$;

=> CALL factorialSP(5);
INFO 2005:  5! = 120
```

LOOP

This type of loop is equivalent to WHILE true and only terminates if it encounters a RETURN or EXIT statement, or if an exception is thrown.

```
[ <<label>> ]
LOOP
  statements;
END LOOP;
```

For example, this procedure prints the integers from counter up to upper_bound , inclusive:

```
DO $$
DECLARE
   counter int := 1;
   upper_bound int := 3;
BEGIN
   LOOP
      RAISE INFO '%', counter;
      IF counter >= upper_bound THEN
         RETURN;
      END IF;
      counter := counter + 1;
   END LOOP;
END;
$$;

INFO 2005:  1
INFO 2005:  2
INFO 2005:  3
```

FOR

FOR loops iterate over a collection, which can be an integral range, query, or cursor.

If a FOR loop iterates at least once, the special FOUND variable is set to true after the loop ends. Otherwise, FOUND is set to false.

The FOUND variable can be useful for distinguishing between a NULL and 0-row return, or creating an IF branch if a LOOP didn't run.

FOR (RANGE)

A FOR (RANGE) loop iterates over a range of integers specified by the expressions *left* and *right* .

```
[ <<label>> ]
FOR loop_counter IN RANGE [ REVERSE ] left..right [ BY step ] LOOP
   statements
END LOOP [ label ];
```

loop_counter :

- does not have to be declared and is initialized with the value of *left*
- is only available within the scope of the FOR loop

loop_counter iterates from *left* to *right* (inclusive), incrementing by *step* at the end of each iteration.

The REVERSE option instead iterates from *right* to *left* (inclusive), decrementing by *step* .

For example, here is a standard ascending FOR loop with *step* = 1:

```
=> DO $$
BEGIN
   FOR i IN RANGE 1..4 LOOP -- loop_counter i does not have to be declared
      RAISE NOTICE 'i = %', i;
   END LOOP;
   RAISE NOTICE 'after loop: i = %', i; -- fails
END;
$$;

NOTICE 2005:  i = 1
NOTICE 2005:  i = 2
NOTICE 2005:  i = 3
NOTICE 2005:  i = 4
ERROR 2624:  Column "i" does not exist -- loop_counter i is only available inside the FOR loop
```

Here, the *loop_counter* i starts at 4 and decrements by 2 at the end of each iteration:

```
=> DO $$
BEGIN
   FOR i IN RANGE REVERSE 4..0 BY 2 LOOP
      RAISE NOTICE 'i = %', i;
   END LOOP;
END;
$$;

NOTICE 2005:  i = 4
NOTICE 2005:  i = 2
NOTICE 2005:  i = 0
```

FOR (query)

A FOR (QUERY) loop iterates over the results of a query.

```
[ <<label>> ]
FOR target IN QUERY statement LOOP
   statements
END LOOP [ label ];
```

You can include an ORDER BY clause in the query to make the ordering deterministic.

Unlike FOR (RANGE) loops, you must declare the *target* variables. The values of these variables persist after the loop ends.

For example, suppose given the table tuple :

```
=> SELECT * FROM tuples ORDER BY x ASC;
 x | y | z
---+---+---
 1 | 2 | 3
 4 | 5 | 6
 7 | 8 | 9
(3 rows)
```

This procedure retrieves the tuples in each row and stores them in the variables a , b , and c , and prints them after each iteration:

```
=>
=> DO $$
DECLARE
   a int; -- target variables must be declared
   b int;
   c int;
   i int := 1;
BEGIN
   FOR a,b,c IN QUERY SELECT * FROM tuples ORDER BY x ASC LOOP
      RAISE NOTICE 'iteration %: a = %, b = %, c = %', i,a,b,c;
      i := i + 1;
   END LOOP;
   RAISE NOTICE 'after loop: a = %, b = %, c = %', a,b,c;
END;
$$;

NOTICE 2005:  iteration 1: a = 1, b = 2, c = 3
NOTICE 2005:  iteration 2: a = 4, b = 5, c = 6
NOTICE 2005:  iteration 3: a = 7, b = 8, c = 9
NOTICE 2005:  after loop: a = 7, b = 8, c = 9
```

You can also use a query constructed dynamically with EXECUTE :

```
[ <<label>> ]
FOR target IN EXECUTE 'statement' [ USING expression [, ... ] ] LOOP
   statements
END LOOP [ label ];
```

The following procedure uses EXECUTE to construct a FOR (QUERY) loop and stores the results of that SELECT statement in the variables x and y . The result set of a statement like this has only one row, so it only iterates once.

```
=> SELECT 'first string', 'second string';
  ?column?   |   ?column?
-------------+---------------
 first string | second string
(1 row)

=> DO $$
DECLARE
   x varchar; -- target variables must be declared
   y varchar;
BEGIN
   -- substitute the placeholders $1 and $2 with the strings
   FOR x, y IN EXECUTE 'SELECT $1, $2' USING 'first string', 'second string' LOOP
      RAISE NOTICE '%', x;
      RAISE NOTICE '%', y;
   END LOOP;
END;
$$;

NOTICE 2005:  first string
NOTICE 2005:  second string
```

FOR (cursor)

A FOR (CURSOR) loop iterates over a bound, unopened cursor , executing some set of *statements* for each iteration.

```
[ <<label>> ]
FOR loop_variable [, ...] IN CURSOR bound_unopened_cursor [ ( [ arg_name := ] arg_value [, ...] ) ] LOOP
   statements
END LOOP [ label ];
```

This type of FOR loop opens the cursor at start of the loop and closes at the end.

For example, this procedure creates a cursor c . The procedure passes 6 as an argument to the cursor, so the cursor only retrieves rows where the y-coordinate is 6, storing the coordinates in the variables x_ , y_ , and z_ and printing them at the end of each iteration:

```
=> SELECT * FROM coordinates;
 x  | y | z
----+---+----
 14 | 6 | 19
  1 | 6 |  2
 10 | 6 | 39
 10 | 2 | 1
  7 | 1 | 10
 67 | 1 | 77
(6 rows)

DO $$
DECLARE
   c CURSOR (key int) FOR SELECT * FROM coordinates WHERE y=key;
   x_ int;
   y_ int;
   z_ int;
BEGIN
   FOR x_,y_,z_ IN CURSOR c(6) LOOP
      RAISE NOTICE 'cursor returned %,%,% FOUND=%', x_,y_,z_,FOUND;
   END LOOP;
   RAISE NOTICE 'after loop: %,%,% FOUND=%', x_,y_,z_,FOUND;
END;
$$;

NOTICE 2005:  cursor returned 14,6,19 FOUND=f -- FOUND is only set after the loop ends
NOTICE 2005:  cursor returned 1,6,2 FOUND=f
NOTICE 2005:  after loop: 10,6,39 FOUND=t -- x_, y_, and z_ retain their values, FOUND is now true because the FOR loop iterated at least once
```

Manipulating loops

RETURN

You can exit the entire procedure (and therefore the loop) with RETURN. RETURN is an optional statement and can be added to signal to readers the end of a procedure.

```
RETURN;
```

EXIT

Similar to a break or labeled break in other programming languages, EXIT statements let you exit a loop early, optionally specifying:

- *loop_label* : the name of the loop to exit from
- *condition* : if the *condition* is true , execute the EXIT statement

```
EXIT [ loop_label ] [ WHEN condition ];
```

CONTINUE

CONTINUE skips to the next iteration of the loop without executing statements that follow the CONTINUE itself. You can specify a particular loop with *loop_label* :

```
CONTINUE [loop_label] [ WHEN condition ];
```

For example, this procedure doesn't print during its first two iterations because the CONTINUE statement executes and moves on to the next iteration of the loop before control reaches the RAISE NOTICE statement:

```
=> DO $$
BEGIN
   FOR i IN RANGE 1..5 LOOP
      IF i < 3 THEN
         CONTINUE;
      END IF;
      RAISE NOTICE 'i = %', i;
   END LOOP;
END;
$$;

NOTICE 2005:  i = 3
NOTICE 2005:  i = 4
NOTICE 2005:  i = 5
```

Errors and diagnostics

ASSERT

ASSERT is a debugging feature that checks whether a condition is true . If the condition is false , ASSERT raises an ASSERT_FAILURE exception with an optional error message.

To escape a ' (single quote) character, use '' . Similarly, to escape a " (double quote) character, use "" .

```
ASSERT condition [ , message ];
```

For example, this procedure checks the number of rows in the products table and uses ASSERT to check that the table is populated. If the table is empty, Vertica raises an error:

```
=> CREATE TABLE products(id UUID, name VARCHARE, price MONEY);
CREATE TABLE

=> SELECT * FROM products;
 id | name | price
----+------+-------
(0 rows)

DO $$
DECLARE
   prod_count INT;
BEGIN
   prod_count := SELECT count(*) FROM products;
   ASSERT prod_count > 0, 'products table is empty';
END;
$$;

ERROR 2005:  products table is empty
```

To stop Vertica from checking ASSERT statements, you can set the boolean session-level parameter PLpgSQLCheckAsserts .

RAISE

RAISE can throw errors or print a user-specified error message, one of the following:

```
RAISE [ level ] 'format' [, arg_expression [, ... ]] [ USING option = expression [, ... ] ];
RAISE [ level ] condition_name [ USING option = expression [, ... ] ];
RAISE [ level ] SQLSTATE 'sql-state' [ USING option = expression [, ... ] ];
RAISE [ level ] USING option = expression [, ... ];
```

level	VARCHAR, one of the following: • LOG: Sends the *format* to vertica.log • INFO: Prints an INFO message in VSQL • NOTICE: Prints a NOTICE in VSQL • WARNING: Prints a WARNING in VSQL • EXCEPTION: Throws catchable exception **Default:** EXCEPTION
format	VARCHAR, a string literal error message where the percent character % is substituted with the * arg_expression *s. %% escapes the substitution and results in a single % in plaintext. If the number of % characters doesn't equal the number of arguments, Vertica throws an error. To escape a ' (single quote) character, use '' . Similarly, to escape a " (double quote) character, use "" .
arg_expression	An expression that substitutes for the percent character (%) in the *format* string.
option = *expression*	*option* must be one of the following and paired with an *expression* that elaborates on the *option* :

option	***expression* content**
MESSAGE	An error message. **Default:** the ERRCODE associated with the exception
DETAIL	Details about the error.
HINT	A hint message.
ERRCODE	The error code to report, one of the following: • A condition name specified in the description column of the SQL state list (with optional ERRCODE_ prefix) • A code that satisfies the SQLSTATE formatting: 5-character sequence of numbers and capital letters (not necessarily on the SQL State List) **Default:** ERRCODE_RAISE_EXCEPTION (V0002)
COLUMN	A column name relevant to the error
CONSTRAINT	A constraint relevant to the error
DATATYPE	A data type relevant to the error
TABLE	A table name relevant to the error
SCHEMA	A schema name relevant to the error

This procedure demonstrates various RAISE levels:

```
=> DO $$
DECLARE
   logfile varchar := 'vertica.log';
BEGIN
   RAISE LOG 'this message was sent to %', logfile;
   RAISE INFO 'info';
   RAISE NOTICE 'notice';
   RAISE WARNING 'warning';
   RAISE EXCEPTION 'exception';

   RAISE NOTICE 'exception changes control flow; this is not printed';
END;
$$;

INFO 2005:  info
NOTICE 2005:  notice
WARNING 2005:  warning
ERROR 2005:  exception

$ grep 'this message was sent to vertica.log' v_vmart_node0001_catalog/vertica.log
<LOG> @v_vmart_node0001: V0002/2005: this message is sent to vertica.log
```

Exceptions

EXCEPTION blocks let you catch and handle exceptions that might get thrown from *statements* :

```
[ <<label>> ]
[ DECLARE
   declarations ]
BEGIN
   statements
EXCEPTION
   WHEN exception_condition [ OR exception_condition ... ] THEN
      handler_statements
   [ WHEN exception_condition [ OR exception_condition ... ] THEN
      handler_statements
     ... ]
END [ label ];
```

exception_condition has one of the following forms:

```
WHEN errcode_division_by_zero THEN ...
WHEN division_by_zero THEN ...
WHEN SQLSTATE '22012' THEN ...
WHEN OTHERS THEN ...
```

OTHERS is a special condition that catches all exceptions except QUERY_CANCELLED , ASSERT_FAILURE , and FEATURE_NOT_SUPPORTED .

When an exception is thrown, Vertica checks the list of exceptions for a matching *exception_condition* from top to bottom. If it finds a match, it executes the *handler_statements* and then leaves the exception block's scope.

If Vertica can't find a match, it propagates the exception up to the next enclosing block. You can do this manually within an exception handler with RAISE:

```
RAISE;
```

For example, the following procedure divides 3 by 0 in the inner_block , which is an illegal operation that throws the exception division_by_zero with SQL state 22012. Vertica checks the inner EXCEPTION block for a matching condition:

1. The first condition checks for SQL state 42501, so Vertica, so Vertica moves to the next condition.
2. WHEN OTHERS THEN catches all exceptions, so it executes that block.
3. The bare RAISE then propagates the exception to the outer_block .
4. The outer EXCEPTION block successfully catches the exception and prints a message.

```
=> DO $$
<<outer_block>>
BEGIN
   <<inner_block>>
   DECLARE
      x int;
   BEGIN
      x := 3 / 0; -- throws exception division_by_zero, SQLSTATE 22012
   EXCEPTION -- this block is checked first for matching exceptions
      WHEN SQLSTATE '42501' THEN
         RAISE NOTICE 'caught insufficient_privilege exception';
      WHEN OTHERS THEN -- catches all exceptions
         RAISE; -- manually propagate the exception to the next enclosing block
   END inner_block;
EXCEPTION -- exception is propagated to this block
   WHEN division_by_zero THEN
      RAISE NOTICE 'caught division_by_zero exception';
END outer_block;
$$;

NOTICE 2005:  caught division_by_zero exception
```

SQLSTATE and SQLERRM variables

When handling an exception, you can use the following variables to retrieve error information:

- SQLSTATE contains the SQL state
- SQLERRM contains the error message

For details, see SQL state list .

This procedure catches the exception thrown by attempting to assign NULL to a NOT NULL variable and prints the SQL state and error message:

```
DO $$
DECLARE
   i int NOT NULL := 1;
BEGIN
   i := NULL; -- illegal, i was declared with NOT NULL
EXCEPTION
   WHEN OTHERS THEN
      RAISE WARNING 'SQL State: %', SQLSTATE;
      RAISE WARNING 'Error message: %', SQLERRM;
END;
$$;

WARNING 2005:  SQLSTATE: 42809
WARNING 2005:  SQLERRM: Cannot assign null into NOT NULL variable
```

Retrieving exception information

You can retrieve information about exceptions inside exception handlers with GET STACKED DIAGNOSTICS:

```
GET STACKED DIAGNOSTICS variable_name { = | := } item [, ... ];
```

Where *item* can be any of the following:

item	**Description**
RETRUNED_SQLSTATE	SQLSTATE error code of the exception
COLUMN_NAME	Name of the column related to exception
CONSTRAINT_NAME	Name of the constraint related to exception

DATATYPE_NAME	Name of the data type related to exception
MESSAGE_TEXT	Text of the exception's primary message
TABLE_NAME	Name of the table related to exception
SCHEMA_NAME	Name of the schema related to exception
DETAIL_TEXT	Text of the exception's detail message, if any
HINT_TEXT	Text of the exception's hint message, if any
EXCEPTION_CONTEXT	Description of the call stack at the time of the exception

For example, this procedure has an EXCEPTION block that catches the division_by_zero error and prints SQL state, error message, and the exception context:

```
=> DO $$
DECLARE
   message_1 varchar;
   message_2 varchar;
   message_3 varchar;
   x int;
BEGIN
   x := 5 / 0;
EXCEPTION
   WHEN OTHERS THEN -- OTHERS catches all exceptions
   GET STACKED DIAGNOSTICS message_1 = RETURNED_SQLSTATE,
                           message_2 = MESSAGE_TEXT,
                           message_3 = EXCEPTION_CONTEXT;

   RAISE INFO 'SQLSTATE: %', message_1;
   RAISE INFO 'MESSAGE: %', message_2;
   RAISE INFO 'EXCEPTION_CONTEXT: %', message_3;
END;
$$;

INFO 2005:  SQLSTATE: 22012
INFO 2005:  MESSAGE: Division by zero
INFO 2005:  EXCEPTION_CONTEXT: PL/vSQL procedure inline_code_block line 8 at static SQL
```

Cursors

A cursor is a reference to the result set of a query and allows you to view the results one row at a time. Cursors remember their positions in result sets, which can be one of the following:

- a result row
- before the first row
- after the last row

You can also iterate over unopened, bound cursors with a FOR loop. See Control Flow for more information.

Declaring cursors

Bound cursors

To bind a cursor to a *statement* on declaration, use the FOR keyword:

```
cursor_name CURSOR [ ( arg_name arg_type [, ...] ) ] FOR statement;
```

The arguments to a cursor give you more control over which rows to process. For example, suppose you have the following table:

```
=> SELECT * FROM coordinates_xy;
 x | y
---+----
 1 |  2
 9 |  5
 7 | 13
...
(100000 rows)
```

If you're only interested in the rows where y is 6, you might declare the following cursor and then provide the argument 6 when you OPEN the cursor:

```
c CURSOR (key int) FOR SELECT * FROM coordinates_xy WHERE y=key;
```

Unbound cursors

To declare a cursor without binding it to a particular query, use the refcursor type:

```
cursor_name refcursor;
```

You can bind an unbound cursor at any time with OPEN .

For example, to declare the cursor my_unbound_cursor :

```
my_unbound_cursor refcursor;
```

Opening and closing cursors

OPEN

Opening a cursor executes the query with the given arguments, and puts the cursor before the first row of the result set. The ordering of query results (and therefore, the start of the result set) is non-deterministic, unless you specify an ORDER BY clause .

OPEN a bound cursor

To open a cursor that was bound during declaration:

```
OPEN bound_cursor [ ( [ arg_name := ] arg_value [, ...] ) ];
```

For example, given the following declaration:

```
c CURSOR (key int) FOR SELECT * FROM t1 WHERE y=key;
```

You can open the cursor with one of the following:

```
OPEN c(5);
OPEN c(key := 5);
```

CLOSE

Open cursors are automatically closed when the cursor leaves scope, but you can close the cursor preemptively with CLOSE. Closed cursors can be reopened later, which re-executes the query and prepares a new result set.

```
CLOSE cursor;
```

OPEN an unbound cursor

To bind an unbound cursor and then open it:

```
OPEN unbound_cursor FOR statement;
```

You can also use EXECUTE because it's a statement:

```
OPEN unbound_cursor FOR EXECUTE statement_string [ USING expression [, ... ] ];
```

For example, to bind the cursor c to a query to a table product_data :

```
OPEN c for SELECT * FROM product_data;
```

FETCH rows

FETCH statements:

1. Retrieve the row that the specified cursor currently points to and stores it in some variable.
2. Advance the cursor to the next position.

```
variable [, ...] := FETCH opened_cursor;
```

The retrieved value is stored in *variable* . Rows typically have more than one value, so you can use one variable for each.

If FETCH successfully retrieves a value, the special variable FOUND is set to true . Otherwise, if you call FETCH when the cursor is past the final row of the result set, it returns NULL and the special variable FOUND is set to false .

The following procedure creates a cursor c , binding it to a SELECT query on the coordinates table. The procedures passes the argument 1 to the cursor, so the cursor only retrieves rows where the y-coordinate is 1, storing the coordinates in the variables x_ , y_ , and z_ .

Only two rows have a y-coordinate of 1, so after using FETCH twice, the third FETCH starts to return NULL values and FOUND is set to false :

```
=> SELECT * FROM coordinates;
 x  | y | z
----+---+----
 14 | 6 | 19
  1 | 6 |  2
 10 | 6 | 39
 10 | 2 |  1
  7 | 1 | 10
 67 | 1 | 77
(6 rows)

DO $$
DECLARE
   c CURSOR (key int) FOR SELECT * FROM coordinates WHERE y=key;
   x_ int;
   y_ int;
   z_ int;
BEGIN
   OPEN c(1); -- only retrieve rows where y=1
   x_,y_,z_ := FETCH c;
   RAISE NOTICE 'cursor returned %, %, %, FOUND=%',x_, y_, z_, FOUND;
   x_,y_,z_ := FETCH c; -- fetches the last set of results and moves to the end of the result set
   RAISE NOTICE 'cursor returned %, %, %, FOUND=%',x_, y_, z_, FOUND;
   x_,y_,z_ := FETCH c; -- cursor has advanced past the final row
   RAISE NOTICE 'cursor returned %, %, %, FOUND=%',x_, y_, z_, FOUND;
END;
$$;

NOTICE 2005:  cursor returned 7, 1, 10, FOUND=t
NOTICE 2005:  cursor returned 67, 1, 77, FOUND=t
NOTICE 2005:  cursor returned <NULL>, <NULL>, <NULL>, FOUND=f
```

MOVE cursors

MOVE advances an open cursor to the next position without retrieving the row. The special FOUND variable is set to true if the cursor's position (before MOVE) was not past the final row—that is, if calling FETCH instead of MOVE would have retrieved the row.

```
MOVE bound_cursor;
```

For example, this cursor only retrieves rows where the y-coordinate is 2. The result set is only one row, so using MOVE twice advances past the first (and last) row, setting FOUND to false:

```
=> SELECT * FROM coordinates WHERE y=2;
 x  | y | z
----+---+---
 10 | 2 | 1
(1 row)

DO $$
DECLARE
   c CURSOR (key int) FOR SELECT * FROM coordinates WHERE y=key;
BEGIN
   OPEN c(2); -- only retrieve rows where y=2, cursor starts before the first row
   MOVE c; -- cursor advances to the first (and last) row
   RAISE NOTICE 'FOUND=%', FOUND; -- FOUND is true because the cursor points to a row in the result set
   MOVE c; -- cursor advances past the final row
   RAISE NOTICE 'FOUND=%', FOUND; -- FOUND is false because the cursor is past the final row
END;
$$;

NOTICE 2005:  FOUND=t
NOTICE 2005:  FOUND=f
```

PL/pgSQL to PL/vSQL migration guide

While Vertica PL/vSQL is largely compatible with PostgreSQL PL/pgSQL, there are some easily-resolved semantic and SQL-level differences when migrating from PostgreSQL PL/pgSQL.

Language-level differences

The following is a list of notable differences between Vertica PL/vSQL and PostgreSQL PL/pgSQL. In Vertica PL/vSQL:

- You must use the PERFORM statement for SQL statements that return no value.
- UPDATE/DELETE WHERE CURRENT OF is not supported.
- FOR loops have additional keywords:
  - FOR (RANGE) loops: RANGE keyword
  - FOR (QUERY) loops: QUERY keyword
  - FOR (CURSOR) loops: CURSOR keyword
- By default, NULL cannot be coerced to FALSE.

Workaround: coercing NULL to FALSE

Unlike PostgreSQL PL/pgSQL, in Vertica PL/vSQL NULLs are not coercible to false, and expressions that expect a boolean value throw an exception when given a NULL:

```
=> DO $$
BEGIN
   IF NULL THEN -- boolean value expected for IF
   END IF;
END;
$$;

ERROR 10268:  Query returned null where a value was expected
```

To enable NULL-to-false coercion, enable the configuration parameter PLvSQLCoerceNull:

```
=> ALTER DATABASE DEFAULT SET PLvSQLCoerceNull = 1;
```

Planned features

Support for the following features is planned for a future release:

- Full transaction and session semantics. Currently, stored procedures commit the transaction before executing, and each embedded SQL statement executes in its own auto-committed transaction. This has the following implications: * You cannot ROLLBACK. * Session-level changes like creating directed queries or setting session-level parameters will succeed, but have no effect.
- OUT/INOUT parameter modes .
- FOREACH (ARRAY) loops .
- Using the following types as arguments: * DECIMAL * NUMERIC * NUMBER * MONEY * UUID

- Non-forward moving cursors .
- CONTEXT/EXCEPTION_CONTEXT for diagnostics .
- The special variable ROW_COUNT.

> **Note**
> As a workaround, you can rely on INSERT, UPDATE, and DELETE to return the number of rows affected:

```
=> CREATE TABLE t1(i int);
CREATE TABLE
=> DO $$
DECLARE
x int;
BEGIN
x := INSERT INTO t1 VALUES (200);
RAISE INFO 'rows inserted: %', x;
END;
$$;

INFO 2005:  rows inserted: 1
```

SQL-level differences

The following list notes significant architectural, SQL-level differences between Vertica and PostgreSQL. In Vertica:

- Some data types are different sizes—for example, the standard INTEGER type in Vertica is 8 bytes, but 4 bytes in PostgreSQL.
- INSERT, UPDATE, and DELETE to return the number of rows affected.
- Certain SQLSTATE codes are different, which affects exception handling .

Parameter modes

Stored procedures support IN parameters. OUT and INOUT parameters are currently not supported.

If unspecified, a parameter's mode defaults to IN.

IN

IN parameters specify the name and type of an argument. These parameters determine a procedure's signature. When an overloaded procedure is called , Vertica runs the procedure whose signature matches the types of the arguments passed in the invocation.

For example, the caller of this procedure must pass in an INT and a VARCHAR value. Both x and y are IN parameters:

```
=> CREATE PROCEDURE raiseXY(IN x INT, y VARCHAR) LANGUAGE PLvSQL AS $$
BEGIN
   RAISE NOTICE 'x = %', x;
   RAISE NOTICE 'y = %', y;
   -- some processing statements
END;
$$;

CALL raiseXY(3, 'some string');
NOTICE 2005:  x = 3
NOTICE 2005:  y = some string
```

For more information on RAISE NOTICE, see Errors and diagnostics .

Executing stored procedures

If you have EXECUTE privileges on a stored procedure, you can execute it with a CALL statement that specifies the procedure and its IN arguments.

Syntax

```
CALL stored_procedure_name();
```

For example, the stored procedure raiseXY() is defined as:

```
=> CREATE PROCEDURE raiseXY(IN x INT, y VARCHAR) LANGUAGE PLvSQL AS $$
BEGIN
   RAISE NOTICE 'x = %', x;
   RAISE NOTICE 'y = %', y;
   -- some processing statements
END;
$$;

CALL raiseXY(3, 'some string');
NOTICE 2005:  x = 3
NOTICE 2005:  y = some string
```

For more information on RAISE NOTICE, see Errors and diagnostics .

You can execute an anonymous (unnamed) procedure with DO . This requires no privileges:

```
=> DO $$
BEGIN
   RAISE NOTICE '% ran an anonymous procedure', current_user();
END;
$$;

NOTICE 2005:  Bob ran an anonymous procedure
```

Limiting runtime

You can set the maximum runtime of a procedure with session parameter RUNTIMECAP.

This example sets the runtime of all stored procedures to one second for duration of session and runs an anonymous procedure with an infinite loop . Vertica terminates the procedure after it runs for more than one second:

```
=> SET SESSION RUNTIMECAP '1 SECOND';

=> DO $$
BEGIN
   LOOP
   END LOOP;
END;
$$;

ERROR 0:  Query exceeded maximum runtime
HINT:  Change the maximum runtime using SET SESSION RUNTIMECAP
```

Execution security and privileges

By default, stored procedures execute with the privileges of the caller (invoker), so callers must have the necessary privileges on the catalog objects accessed by the stored procedure. You can allow callers to execute the procedure with the privileges, default roles , user parameters , and user attributes (RESOURCE_POOL, MEMORY_CAP_KB, TEMP_SPACE_CAP_KB, RUNTIMECAP) of the definer by specifying DEFINER for the SECURITY option .

For example, the following procedure inserts a value into table s1.t1 . If the DEFINER has the required privileges (USAGE on the schema and INSERT on table), this requirement is waived for callers.

```
=> CREATE PROCEDURE insert_into_s1_t1(IN x int, IN y int)
LANGUAGE PLvSQL
SECURITY DEFINER AS $$
BEGIN
   PERFORM INSERT INTO s1.t1 VALUES(x,y);
END;
$$;
```

A procedure with SECURITY DEFINER effectively executes the procedure as that user, so changes to the database appear to be performed by the procedure's definer rather than its caller.

> **Caution**
> Improper use of SECURITY DEFINER can lead to the confused deputy problem and introduce vulnerabilities into your system like SQL injection.

Examples

In this example, this table:

```
records(i INT, updated_date TIMESTAMP DEFAULT sysdate, updated_by VARCHAR(128) DEFAULT current_user())
```

Contains the following content:

```
=> SELECT * FROM records;
 i |        updated_date        | updated_by
---+----------------------------+------------
 1 | 2021-08-27 15:54:05.709044 | Bob
 2 | 2021-08-27 15:54:07.051154 | Bob
 3 | 2021-08-27 15:54:08.301704 | Bob
(3 rows)
```

Bob creates a procedure to update the table and uses the SECURITY DEFINER option and grants EXECUTE on the procedure to Alice. Alice can now use the procedure to update the table without any additional privileges:

```
=> GRANT EXECUTE ON PROCEDURE update_records(int,int) to Alice;
GRANT PRIVILEGE

=> \c - Alice
You are now connected as user "Alice".

=> CALL update_records(99,1);
 update_records
----------------
              0
(1 row)
```

Because calls to update_records() effectively run the procedure as Bob, Bob is listed as the updater of the table rather than Alice:

```
=> SELECT * FROM records;
 i |        updated_date        | updated_by
----+----------------------------+------------
 99 | 2021-08-27 15:55:42.936404 | Bob
  2 | 2021-08-27 15:54:07.051154 | Bob
  3 | 2021-08-27 15:54:08.301704 | Bob
(3 rows)
```

Altering stored procedures

You can alter a stored procedure and retain its grants with ALTER PROCEDURE .

Examples

The examples below use the following procedure:

```
=> CREATE PROCEDURE echo_integer(IN x int) LANGUAGE PLvSQL AS $$
BEGIN
   RAISE INFO 'x is %', x;
END;
$$;
```

By default, stored procedures execute with the privileges of the caller (invoker), so callers must have the necessary privileges on the catalog objects accessed by the stored procedure. You can allow callers to execute the procedure with the privileges, default roles , user parameters , and user attributes (RESOURCE_POOL, MEMORY_CAP_KB, TEMP_SPACE_CAP_KB, RUNTIMECAP) of the definer by specifying DEFINER for the SECURITY option .

To execute the procedure with privileges of the...

- Definer (owner):
```
=> ALTER PROCEDURE echo_integer(int) SECURITY DEFINER;
```
- Invoker:
```
=> ALTER PROCEDURE echo_integer(int) SECURITY INVOKER;
```

To change a procedure's source code:

```
=> ALTER PROCEDURE echo_integer(int) SOURCE TO $$
   BEGIN
      RAISE INFO 'the integer is: %', x;
   END;
$$;
```

To change a procedure's owner (definer):

```
=> ALTER PROCEDURE echo_integer(int) OWNER TO u1;
```

To change a procedure's schema:

```
=> ALTER PROCEDURE echo_integer(int) SET SCHEMA s1;
```

To rename a procedure:

```
=> ALTER PROCEDURE echo_integer(int) RENAME TO echo_int;
```

Stored procedures: use cases and examples

Stored procedures in Vertica are best suited for complex, analytical workflows rather than small, transaction-heavy ones. Some recommended use cases include information lifecycle management (ILM) activities like extract, transform, and load (ETL), and data preparation for more complex analytical tasks like machine learning. For example:

- Swapping partitions according to age
- Exporting data at end-of-life and dropping the partitions
- Saving inputs, outputs, and metadata from a machine learning model (e.g. who ran the model, the version of the model, how many times the model was run, who received the results, etc.) for auditing purposes

Searching for a value

The find_my_value() procedure searches for a user-specified value in any table column in a given schema and stores the locations of instances of the value in a user-specified table:

```
=> CREATE PROCEDURE find_my_value(p_table_schema VARCHAR(128), p_search_value VARCHAR(1000), p_results_schema VARCHAR(128),
p_results_table VARCHAR(128)) AS $$
DECLARE
   sql_cmd VARCHAR(65000);
   sql_cmd_result VARCHAR(65000);
   results VARCHAR(65000);
BEGIN
   IF p_table_schema IS NULL OR p_table_schema = '' OR
      p_search_value IS NULL OR p_search_value = '' OR
      p_results_schema IS NULL OR p_results_schema = '' OR
      p_results_table IS NULL OR p_results_table = '' THEN
      RAISE EXCEPTION 'Please provide a schema to search, a search value, a results table schema, and a results table name.';
      RETURN;
   END IF;

   sql_cmd := 'CREATE TABLE IF NOT EXISTS ' || QUOTE_IDENT(p_results_schema) || '.' || QUOTE_IDENT(p_results_table) ||
      '(found_timestamp TIMESTAMP, found_value VARCHAR(1000), table_name VARCHAR(128), column_name VARCHAR(128));';

   sql_cmd_result := EXECUTE 'SELECT LISTAGG(c USING PARAMETERS max_length=1000000, separator="") 
      FROM (SELECT ''
      (SELECT ''''' || NOW() || '''''::TIMESTAMP , ''''' || QUOTE_IDENT(p_search_value) || ''''','''''' || table_name || '''''', '''''' || column_name || ''''''
         FROM '' || table_schema || ''.'' || table_name || ''
         WHERE '' || column_name || ''::'' ||
         CASE
            WHEN data_type_id IN (17, 115, 116, 117) THEN data_type
            ELSE ''VARCHAR('' || LENGTH('''' || QUOTE_IDENT(p_search_value)|| '''') || '')'' END || '' = '''''' || QUOTE_IDENT(p_search_value) || '''''''' ||
DECODE(LEAD(column_name) OVER(ORDER BY table_schema, table_name, ordinal_position), NULL, '' LIMIT 1);'', '' LIMIT 1)

      UNION ALL '') c
         FROM (SELECT table_schema, table_name, column_name, ordinal_position, data_type_id, data_type
         FROM columns WHERE NOT is_system_table AND table_schema ILIKE ''' || QUOTE_IDENT(p_table_schema) || ''' AND data_type_id < 1000
         ORDER BY table_schema, table_name, ordinal_position) foo) foo;';

   results := EXECUTE 'INSERT INTO ' || QUOTE_IDENT(p_results_schema) || '.' || QUOTE_IDENT(p_results_table) || ' ' || sql_cmd_result;

   RAISE INFO 'Matches Found: %', results;
END;
$$;
```

For example, to search the public schema for instances of the string ' dog ' and then store the results in public.table_list :

```
=> CALL find_my_value('public', 'dog', 'public', 'table_list');
 find_my_value
---------------
             0
(1 row)

=> SELECT * FROM public.table_list;
     found_timestamp       | found_value |  table_name   | column_name
---------------------------+-------------+---------------+-------------
 2021-08-25 22:13:20.147889 | dog         | another_table | b
 2021-08-25 22:13:20.147889 | dog         | some_table    | c
(2 rows)
```

Optimizing tables

You can automate loading data from Parquet files and optimizing your queries with the create_optimized_table() procedure. This procedure:

1. Creates an external table whose structure is built from Parquet files using the Vertica INFER_TABLE_DDL function.
2. Creates a native Vertica table, like the external table, resizing all VARCHAR columns to the MAX length of the data to be loaded.
3. Creates a super projection using the optional segmentation/order by columns passed in as a parameter.
4. Adds an optional primary key to the native table passed in as a parameter.
5. Loads a sample data set (1 million rows) from the external table into the native table.

6. Drops the external table.
7. Runs the ANALYZE_STATISTICS function on the native table.
8. Runs the DESIGNER_DESIGN_PROJECTION_ENCODINGS function to get a properly encoded super projection for the native table.
9. Truncates the now-optimized native table (we will load the entire data set in a separate script/stored procedure).

```
=> CREATE OR REPLACE PROCEDURE create_optimized_table(p_file_path VARCHAR(1000), p_table_schema VARCHAR(128), p_table_name
VARCHAR(128), p_seg_columns VARCHAR(1000), p_pk_columns VARCHAR(1000)) LANGUAGE PLvSQL AS $$
DECLARE
   command_sql VARCHAR(1000);
   seg_columns VARCHAR(1000);
   BEGIN

-- First 3 parms are required.
-- Segmented and PK columns names, if present, must be Unquoted Identifiers
   IF p_file_path IS NULL OR p_file_path = '' THEN
      RAISE EXCEPTION 'Please provide a file path.';
   ELSEIF p_table_schema IS NULL OR p_table_schema = '' THEN
      RAISE EXCEPTION 'Please provide a table schema.';
   ELSEIF p_table_name IS NULL OR p_table_name = '' THEN
      RAISE EXCEPTION 'Please provide a table name.';
   END IF;

-- Pass optional segmented columns parameter as null or empty string if not used
   IF p_seg_columns IS NULL OR p_seg_columns = '' THEN
      seg_columns := '';
   ELSE
      seg_columns := 'ORDER BY ' || p_seg_columns || ' SEGMENTED BY HASH(' || p_seg_columns || ') ALL NODES';
   END IF;

-- Add '_external' to end of p_table_name for the external table and drop it if it already exists
   EXECUTE 'DROP TABLE IF EXISTS ' || QUOTE_IDENT(p_table_schema) || '.' || QUOTE_IDENT(p_table_name) || '_external CASCADE;';

-- Execute INFER_TABLE_DDL to generate CREATE EXTERNAL TABLE from the Parquet files
   command_sql := EXECUTE 'SELECT infer_table_ddl(' || QUOTE_LITERAL(p_file_path) || ' USING PARAMETERS format = "parquet", table_schema = "' ||

```

Pivoting tables dynamically

The stored procedure unpivot() takes as input a source table and target table. It unpivots the source table and outputs it into a target table.

This example uses the following table:

```
=> SELECT * FROM make_the_columns_into_rows;
c1  | c2  |                  c3                  |            c4             |    c5    | c6
-----+-----+--------------------------------------+---------------------------+----------+----
123 | ABC | cf470c5b-50e3-492a-8483-b9e4f20d195a | 2021-08-24 18:49:40.835802 |  1.72964 | t
567 | EFG | 25ea7636-d924-4b4f-81b5-1e1c884b06e3 | 2021-08-04 18:49:40.835802 | 41.46100 | f
890 | XYZ | f588935a-35a4-4275-9e7f-ebb3986390e3 | 2021-08-29 19:53:39.465778 |  8.58207 | t
(3 rows)
```

This table contains the following columns:

```
=> \d make_the_columns_into_rows
                                  List of Fields by Tables
Schema |          Table           | Column |     Type      | Size | Default | Not Null | Primary Key | Foreign Key
--------+--------------------------+--------+---------------+------+---------+----------+-------------+-------------
public | make_the_columns_into_rows | c1     | int           |    8 |         | f        | f           |
public | make_the_columns_into_rows | c2     | varchar(80)   |   80 |         | f        | f           |
public | make_the_columns_into_rows | c3     | uuid          |   16 |         | f        | f           |
public | make_the_columns_into_rows | c4     | timestamp     |    8 |         | f        | f           |
public | make_the_columns_into_rows | c5     | numeric(10,5) |    8 |         | f        | f           |
public | make_the_columns_into_rows | c6     | boolean       |    1 |         | f        | f           |
(6 rows)
```

The target table has columns from the source table pivoted into rows as key/value pairs. It also has a ROWID column to tie the key/value pairs back to their original row from the source table:

```
=> CREATE PROCEDURE unpivot(p_source_table_schema VARCHAR(128), p_source_table_name VARCHAR(128), p_target_table_schema
VARCHAR(128), p_target_table_name VARCHAR(128)) AS $$
DECLARE
   explode_command VARCHAR(10000);
BEGIN
   explode_command := EXECUTE 'SELECT "explode(string_to_array(""[" || " || LISTAGG("NVL(" || column_name || "::VARCHAR, """")" USING
PARAMETERS separator=" || ""","" || ") || " || "]""")) OVER (PARTITION BY rn)" explode_command FROM (SELECT table_schema, table_name,
column_name, ordinal_position FROM columns ORDER BY table_schema, table_name, ordinal_position LIMIT 10000000) foo WHERE table_schema = ''' ||
QUOTE_IDENT(p_source_table_schema) || ''' AND table_name = ''' || QUOTE_IDENT(p_source_table_name) || ''';';

   EXECUTE 'CREATE TABLE ' || QUOTE_IDENT(p_target_table_schema) || '.' || QUOTE_IDENT(p_target_table_name) || '
      AS SELECT rn rowid, column_name key, value FROM (SELECT (ordinal_position - 1) op, column_name
         FROM columns WHERE table_schema = ''' || QUOTE_IDENT(p_source_table_schema) || '''
         AND table_name = ''' || QUOTE_IDENT(p_source_table_name) || ''') a
         JOIN (SELECT rn, ' || explode_command || '
         FROM (SELECT ROW_NUMBER() OVER() rn, *
         FROM ' || QUOTE_IDENT(p_source_table_schema) || '.' || QUOTE_IDENT(p_source_table_name) || ') foo) b ON b.position = a.op';
END;
$$;
```

Call the procedure:

```
=> CALL unpivot('public', 'make_the_columns_into_rows', 'public', 'columns_into_rows');
 unpivot
---------
       0
(1 row)

=> SELECT * FROM columns_into_rows ORDER BY rowid, key;
rowid | key |                value
-------+-----+--------------------------------------
     1 | c1  | 123
     1 | c2  | ABC
     1 | c3  | cf470c5b-50e3-492a-8483-b9e4f20d195a
     1 | c4  | 2021-08-24 18:49:40.835802
     1 | c5  | 1.72964
     1 | c6  | t
     2 | c1  | 890
     2 | c2  | XYZ
     2 | c3  | f588935a-35a4-4275-9e7f-ebb3986390e3
     2 | c4  | 2021-08-29 19:53:39.465778
     2 | c5  | 8.58207
     2 | c6  | t
     3 | c1  | 567
     3 | c2  | EFG
     3 | c3  | 25ea7636-d924-4b4f-81b5-1e1c884b06e3
     3 | c4  | 2021-08-04 18:49:40.835802
     3 | c5  | 41.46100
     3 | c6  | f
(18 rows)
```

The unpivot() procedure can handle new columns in the source table as well.

Add a new column z to the source table, and then unpivot the table with the same procedure:

```
=> ALTER TABLE make_the_columns_into_rows ADD COLUMN z VARCHAR;
ALTER TABLE

=> UPDATE make_the_columns_into_rows SET z = 'ZZZ' WHERE c1 IN (123, 890);
OUTPUT
--------
      2
(1 row)

=> CALL unpivot('public', 'make_the_columns_into_rows', 'public', 'columns_into_rows');
unpivot
---------
       0
(1 row)

=> SELECT * FROM columns_into_rows;
rowid | key |                value
-------+-----+--------------------------------------
     1 | c1  | 567
     1 | c2  | EFG
     1 | c3  | 25ea7636-d924-4b4f-81b5-1e1c884b06e3
     1 | c4  | 2021-08-04 18:49:40.835802
     1 | c5  | 41.46100
     1 | c6  | f
     1 | z   |   -- new column
     2 | c1  | 123
     2 | c2  | ABC
     2 | c3  | cf470c5b-50e3-492a-8483-b9e4f20d195a
     2 | c4  | 2021-08-24 18:49:40.835802
     2 | c5  | 1.72964
     2 | c6  | t
     2 | z   | ZZZ   -- new column
     3 | c1  | 890
     3 | c2  | XYZ
     3 | c3  | f588935a-35a4-4275-9e7f-ebb3986390e3
     3 | c4  | 2021-08-29 19:53:39.465778
     3 | c5  | 8.58207
     3 | c6  | t
     3 | z   | ZZZ   -- new column
(21 rows)
```

Machine learning: optimizing AUC estimation

The ROC function can approximate the AUC (area under the curve), the accuracy of which depends on the num_bins parameter; greater values of num_bins give you more precise approximations, but may impact performance.

You can use the stored procedure accurate_auc() to approximate the AUC, which automatically determines the optimal num_bins value for a given epsilon (error term):

```
=> CREATE PROCEDURE accurate_auc(relation VARCHAR, observation_col VARCHAR, probability_col VARCHAR, epsilon FLOAT) AS $$
DECLARE
    auc_value FLOAT;
    previous_auc FLOAT;
    nbins INT;
BEGIN
    IF epsilon > 0.25 THEN
        RAISE EXCEPTION 'epsilon must not be bigger than 0.25';
    END IF;
    IF epsilon < 1e-12 THEN
        RAISE EXCEPTION 'epsilon must be bigger than 1e-12';
    END IF;
    auc_value := 0.5;
    previous_auc := 0; -- epsilon and auc should be always less than 1
    nbins := 100;
    WHILE abs(auc_value - previous_auc) > epsilon and nbins < 1000000 LOOP
        RAISE INFO 'auc_value: %', auc_value;
        RAISE INFO 'previous_auc: %', previous_auc;
        RAISE INFO 'nbins: %', nbins;
        previous_auc := auc_value;
        auc_value := EXECUTE 'SELECT auc FROM (select roc(' || QUOTE_IDENT(observation_col) || ',' || QUOTE_IDENT(probability_col) || ' USING
parameters num_bins=$1, auc=true) over() FROM ' || QUOTE_IDENT(relation) || ') subq WHERE auc IS NOT NULL' USING nbins;
        nbins := nbins * 2;
    END LOOP;
    RAISE INFO 'Result_auc_value: %', auc_value;
END;
$$;
```

For example, given the following data in test_data.csv :

```
1,0,0.186
1,1,0.993
1,1,0.9
1,1,0.839
1,0,0.367
1,0,0.362
0,1,0.6
1,1,0.726
...
```

(see test_data.csv for the complete set of data)

You can load the data into table categorical_test_data as follows:

```
=> \set datafile '\'/data/test_data.csv\''
=> CREATE TABLE categorical_test_data(obs INT, pred INT, prob FLOAT);
CREATE TABLE

=> COPY categorical_test_data FROM :datafile DELIMITER ',';
```

Call accurate_auc() . For this example, the approximated AUC will be within the an epsilon of 0.01:

```
=> CALL accurate_auc('categorical_test_data', 'obs', 'prob', 0.01);
INFO 2005:  auc_value: 0.5
INFO 2005:  previous_auc: 0
INFO 2005:  nbins: 100
INFO 2005:  auc_value: 0.749597423510467
INFO 2005:  previous_auc: 0.5
INFO 2005:  nbins: 200
INFO 2005:  Result_auc_value: 0.750402576489533
```

User-defined extensions

A user-defined extension (UDx) is a component that expands Vertica functionality—for example, new types of data analysis and the ability to parse and load new types of data.

This section provides an overview of how to install and use a UDx. If you are using a UDx developed by a third party, consult its documentation for detailed installation and usage instructions.

In this section

- Loading UDxs
- Installing Java on Vertica hosts
- UDx restrictions
- Fenced and unfenced modes
- Updating UDx libraries
- Listing the UDxs contained in a library
- Using wildcards in your UDx

Loading UDxs

User-defined extensions (UDxs) are contained in libraries. A library can contain multiple UDxs. To add UDxs to Vertica, you must:

1. Deploy the library (once per library).
2. Create each UDx (once per UDx).

If you are using UDxs written in Java, you must also set up a Java runtime environment. See Installing Java on Vertica hosts .

Deploying libraries

To deploy a library to your Vertica database:

1. Copy the UDx shared library file (.so), Python file, Java JAR file, or R functions file that contains your function to a node on your Vertica cluster. You do not need to copy it to every node.
2. Connect to the node where you copied the library (for example, using vsql).
3. Add your library to the database catalog using the CREATE LIBRARY statement.

```
=> CREATE LIBRARY libname AS '/path_to_lib/filename'
  LANGUAGE 'language';
```

libname is the name you want to use to reference the library. *path_to_lib/filename* is the fully-qualified path to the library or JAR file you copied to the host. *language* is the implementation language.

For example, if you created a JAR file named TokenizeStringLib.jar and copied it to the dbadmin account's home directory, you would use this command to load the library:

```
=> CREATE LIBRARY tokenizelib AS '/home/dbadmin/TokenizeStringLib.jar'
  LANGUAGE 'Java';
```

You can load any number of libraries into Vertica.

Privileges

Superusers can create, modify, and drop any library. Users with the UDXDEVELOPER role or explicit grants can also act on libraries, as shown in the following table:

Operation	**Requires**
CREATE LIBRARY	UDXDEVELOPER
Replace a library (CREATE OR REPLACE LIBRARY)	UDXDEVELOPER and one of: • owner of library being replaced • DROP privilege on the target library
DROP LIBRARY	UDXDEVELOPER and one of: • owner of library being dropped • DROP privilege on the target library
ALTER LIBRARY	UDXDEVELOPER and owner

Creating UDx functions

After the library is loaded, define individual UDxs using SQL statements such as CREATE FUNCTION and CREATE SOURCE . These statements assign SQL function names to the extension classes in the library. They add the UDx to the database catalog and remain available after a database restart.

The statement you use depends on the type of UDx you are declaring, as shown in the following table:

UDx Type	**SQL Statement**
Aggregate Function (UDAF)	CREATE AGGREGATE FUNCTION
Analytic Function (UDAnF)	CREATE ANALYTIC FUNCTION
Scalar Function (UDSF)	CREATE FUNCTION (scalar)
Transform Function (UDTF)	CREATE TRANSFORM FUNCTION
Load (UDL): Source	CREATE SOURCE
Load (UDL): Filter	CREATE FILTER

Load (UDL): Parser	CREATE PARSER

If a UDx of the given name already exists, you can replace it or instruct Vertica to not replace it. To replace it, use the OR REPLACE syntax, as in the following example:

```
=> CREATE OR REPLACE TRANSFORM FUNCTION tokenize
   AS LANGUAGE 'C++' NAME 'TokenFactory' LIBRARY TransformFunctions;
CREATE TRANSFORM FUNCTION
```

You might want to replace an existing function to change between fenced and unfenced modes.

Alternatively, you can use IF NOT EXISTS to prevent the function from being created again if it already exists. You might want to use this in upgrade or test scripts that require, and therefore load, UDxs. By using IF NOT EXISTS, you preserve the original definition including fenced status. The following example shows this syntax:

```
--- original creation:
=> CREATE TRANSFORM FUNCTION tokenize
   AS LANGUAGE 'C++' NAME 'TokenFactory' LIBRARY TransformFunctions NOT FENCED;
CREATE TRANSFORM FUNCTION

--- function is not replaced (and is still unfenced):
=> CREATE TRANSFORM FUNCTION IF NOT EXISTS tokenize
   AS LANGUAGE 'C++' NAME 'TokenFactory' LIBRARY TransformFunctions FENCED;
CREATE TRANSFORM FUNCTION
```

After you add the UDx to the database, you can use your extension within SQL statements. The database superuser can grant access privileges to the UDx for users. See GRANT (user defined extension) for details.

When you call a UDx, Vertica creates an instance of the UDx class on each node in the cluster and provides it with the data it needs to process.

Installing Java on Vertica hosts

If you are using UDxs written in Java, follow the instructions in this section.

You must install a Java Virtual Machine (JVM) on every host in your cluster in order for Vertica to be able to execute your Java UDxs.

Installing Java on your Vertica cluster is a two-step process:

1. Install a Java runtime on all of the hosts in your cluster.
2. Set the JavaBinaryForUDx configuration parameter to tell Vertica the location of the Java executable.

Installing a Java runtime

For Java-based features, Vertica requires a 64-bit Java 6 (Java version 1.6) or later Java runtime. Vertica supports runtimes from either Oracle or OpenJDK. You can choose to install either the Java Runtime Environment (JRE) or Java Development Kit (JDK), since the JDK also includes the JRE.

Many Linux distributions include a package for the OpenJDK runtime. See your Linux distribution's documentation for information about installing and configuring OpenJDK.

To install the Oracle Java runtime, see the Java Standard Edition (SE) Download Page. You usually run the installation package as root in order to install it. See the download page for instructions.

Once you have installed a JVM on each host, ensure that the java command is in the search path and calls the correct JVM by running the command:

```
$ java -version
```

This command should print something similar to:

```
java version "1.8.0_102"
Java(TM) SE Runtime Environment (build 1.8.0_102-b14)
Java HotSpot(TM) 64-Bit Server VM (build 25.102-b14, mixed mode)
```

> **Note**
> Any previously installed Java VM on your hosts may interfere with a newly installed Java runtime. See your Linux distribution's documentation for instructions on configuring which JVM is the default. Unless absolutely required, you should uninstall any incompatible version of Java before

installing the Java 6 or Java 7 runtime.

Setting the JavaBinaryForUDx configuration parameter

The JavaBinaryForUDx configuration parameter tells Vertica where to look for the JRE to execute Java UDxs. After you have installed the JRE on all of the nodes in your cluster, set this parameter to the absolute path of the Java executable. You can use the symbolic link that some Java installers create (for example /usr/bin/java). If the Java executable is in your shell search path, you can get the path of the Java executable by running the following command from the Linux command line shell:

```
$ which java
/usr/bin/java
```

If the java command is not in the shell search path, use the path to the Java executable in the directory where you installed the JRE. Suppose you installed the JRE in /usr/java/default (which is where the installation package supplied by Oracle installs the Java 1.6 JRE). In this case the Java executable is /usr/java/default/bin/java .

You set the configuration parameter by executing the following statement as a database superuser :

```
=> ALTER DATABASE DEFAULT SET PARAMETER JavaBinaryForUDx = '/usr/bin/java';
```

See ALTER DATABASE for more information on setting configuration parameters.

To view the current setting of the configuration parameter, query the CONFIGURATION_PARAMETERS system table:

```
=> \x
Expanded display is on.
=> SELECT * FROM CONFIGURATION_PARAMETERS WHERE parameter_name = 'JavaBinaryForUDx';
-[ RECORD 1 ]----------------+-----------------------------------------------------------
node_name                    | ALL
parameter_name               | JavaBinaryForUDx
current_value                | /usr/bin/java
default_value                |
change_under_support_guidance | f
change_requires_restart      | f
description                  | Path to the java binary for executing UDx written in Java
```

Once you have set the configuration parameter, Vertica can find the Java executable on each node in your cluster.

> **Note**
> Since the location of the Java executable is set by a single configuration parameter for the entire cluster, you must ensure that the Java executable is installed in the same path on all of the hosts in the cluster.

UDx restrictions

You cannot use any UDx on inputs containing complex types (see Complex types). For example, you cannot transform or aggregate a ROW column. UDSFs, but not other UDxs, can return ROWs.

Some UDx types have special considerations or restrictions.

Aggregate functions

You cannot use the DISTINCT clause in queries with more than one aggregate function.

Analytic functions

UDAnFs do not support framing windows using ROWS .

As with Vertica's built-in analytic functions, UDAnFs cannot be used with Pattern matching functions .

Scalar functions

If the result of applying a UDSF is an invalid record, COPY aborts the load even if CopyFaultTolerantExpressions is set to true.

A ROW returned from a UDSF cannot be used as an argument to COUNT.

Transform functions

A query that includes a UDTF cannot:

- Include statements other than the SELECT statement that calls this UDTF and a PARTITION BY expression
- Call an analytic function
- Call another UDTF
- Include one of the following clauses:
  - TIMESERIES
  - Pattern matching
  - Gap filling and interpolation

Load functions

Installing an untrusted UDL function can compromise the security of the server. UDxs can contain arbitrary code. In particular, user-defined source functions can read data from any arbitrary location. It is up to the developer of the function to enforce proper security limitations. Superusers must not grant access to UDxs to untrusted users.

You cannot ALTER UDL functions.

Fenced and unfenced modes

User-defined extensions (UDxs) written in the C++ programming language have the option of running in fenced or unfenced mode. Fenced mode runs the UDx code outside of the main Vertica process in a separate zygote process. UDxs that use unfenced mode run directly within the Vertica process.

Fenced mode

You can run most C++ UDxs in fenced mode. Fenced mode uses a separate zygote process, so fenced UDx crashes do not impact the core Vertica process. There is a small performance impact when running UDx code in fenced mode. On average, using fenced mode adds about 10% more time to execution compared to unfenced mode.

Fenced mode is currently available for all C++ UDxs with the exception of user-defined aggregates. All UDxs developed in the Python, R, and Java programming languages must run in fenced mode, since the Python, R, and Java runtimes cannot run directly within the Vertica process.

Using fenced mode does not affect the development of your UDx. Fenced mode is enabled by default for UDxs that support fenced mode. Optionally, you can issue the CREATE FUNCTION command with the NOT FENCED modifier to disable fenced mode for the function. Additionally, you can enable or disable fenced mode on any fenced mode-supported C++ UDx by using the ALTER FUNCTION command.

Unfenced mode

Unfenced UDxs run within Vertica, so they have little overhead, and can perform almost as fast as Vertica's own built-in functions. However, because they run within Vertica directly, any bugs in their code (memory leaks, for example) can destabilize the main Vertica process and bring one or more database nodes down.

Important

Always carefully review code downloaded from third-party sources and test UDxs in a test or staging environment before deciding to run them in unfenced mode in production.

About the zygote process

The Vertica zygote process starts when Vertica starts. Each node has a single zygote process. Side processes are created "on demand". The zygote listens for requests and spawns a UDx side session that runs the UDx in fenced mode when a UDx is called by the user.

About fenced mode logging:

UDx code that runs in fenced mode is logged in the UDxZygote.log and is stored in the UDxLogs directory in the catalog directory of Vertica. Log entries for the side process are denoted by the UDx language (for example, C++), node, zygote process ID, and the UDxSideProcess ID.

For example, for the following query returns the current fenced processes:

```
=> SELECT * FROM UDX_FENCED_PROCESSES;
   node_name     |   process_type   |            session_id            |  pid  | port  | status
-----------------+------------------+----------------------------------+-------+-------+--------
 v_vmart_node0001 | UDxZygoteProcess |                                  | 27468 | 51900 | UP
 v_vmart_node0001 | UDxSideProcess   | localhost.localdoma-27465:0x800b |  5677 | 44123 | UP
```

Below is the corresponding log file for the fenced processes returned in the previous query:

```
2016-05-16 11:24:43.990 [C++-localhost.localdoma-27465:0x800b-5677]  0x2b3ff17e7fd0 UDx side process started
 11:24:43.996 [C++-localhost.localdoma-27465:0x800b-5677]  0x2b3ff17e7fd0 Finished setting up signal handlers.
 11:24:43.996 [C++-localhost.localdoma-27465:0x800b-5677]  0x2b3ff17e7fd0 My port: 44123
 11:24:43.996 [C++-localhost.localdoma-27465:0x800b-5677]  0x2b3ff17e7fd0 My address: 0.0.0.0
 11:24:43.996 [C++-localhost.localdoma-27465:0x800b-5677]  0x2b3ff17e7fd0 Vertica port: 51900
 11:24:43.996 [C++-localhost.localdoma-27465:0x800b-5677]  0x2b3ff17e7fd0 Vertica address: 127.0.0.1
 11:25:19.749 [C++-localhost.localdoma-27465:0x800b-5677]  0x41837940 Setting memory resource limit to -1
 11:30:11.523 [C++-localhost.localdoma-27465:0x800b-5677]  0x41837940 Exiting UDx side process
```

The last line indicates that the side process was killed. In this case it was killed when the user session (vsql) closed.

About fenced mode configuration parameters

Fenced mode supports the following configuration parameters :

- FencedUDxMemoryLimitMB : The maximum memory size, in MB, to use for fenced mode processes. The default is -1 (no limit). The side process is killed if this limit is exceeded.
- ForceUDxFencedMode : When set to 1 , force all UDx's that support fenced mode to run in fenced mode even if their definition specified NOT FENCED. The default is 0 (disabled).
- UDxFencedBlockTimeout : The maximum time, in seconds, that the Vertica server waits for a UDx to return before aborting with ERROR 3399. The default is 60 .

Updating UDx libraries

There are two cases where you need to update libraries that you have already deployed:

- When you have upgraded Vertica to a new version that contains changes to the SDK API. For your libraries to work with the new server version, you need to recompile them with new version of the SDK. See UDx library compatibility with new server versions for more information.
- When you have made changes to your UDxs and you want to deploy these changes. Before updating your UDx library, you need to determine if you have changed the signature of any of the functions contained in the library. If you have, you need to drop the functions from the Vertica catalog before you update the library.

In this section

- UDx library compatibility with new server versions
- Determining if a UDx signature has changed
- Deploying a new version of your UDx library

UDx library compatibility with new server versions

The Vertica SDK defines an application programming interface (API) that UDxs use to interact with the database. When developers compile their UDx code, it is linked to the SDK code to form a library. This library is only compatible with Vertica servers that support the version of the SDK API used to compile the code. The library and servers that share the same API version are compatible on a binary level (referred to as "binary compatible").

The Vertica server returns an error message if you attempt to load a library that is not binary compatible with it. Similarly, if you upgrade your Vertica server to a version that supports a new SDK API, any existing UDx that relies on newly-incompatible libraries returns an error messages when you call it:

```
ERROR 2858:  Could not find function definition
HINT:
This usually happens due to missing or corrupt libraries, libraries built
with the wrong SDK version, or due to a concurrent session dropping the library
or function. Try recreating the library and function
```

To resolve this issue, you must install UDx libraries that have been recompiled with the correct version of the SDK.

New versions of the Vertica server do not always change the SDK API version. The SDK API version changes whenever OpenText changes the components that make up the SDK. If the SDK API does not change in a new version of the server, then the old libraries remain compatible with the new server.

The SDK API almost always changes in Vertica releases (major, minor, service pack) as OpenText expands the SDK's features. Vertica will never change the API in a hotfix patch.

These policies mean that you must update UDx libraries when you upgrade between major versions. For example, if you upgrade from version 10.0 to 10.1, you must update your UDx libraries.

> **Note**
> A UDx written in a scripting language has no compiled binary, and so does not need to maintain binary compatibility from one version to another. UDxs written in scripting languages only become incompatible if the APIs used in the SDK actually change. For example, if the number of arguments to an API call changes, a UDx has to be changed to use the new number of arguments.

Pre-upgrade steps

Before upgrading your Vertica server, consider whether you have any UDx libraries that may be incompatible with the new version. Consult the release notes of the new server version to determine whether the SDK API has changed between the version of Vertica server you currently have installed and the new version. As mentioned previously, only upgrades from a previous major version or from the initial release of a major version to a service pack release can cause your currently-loaded UDx libraries to become incompatible with the server.

Any UDx libraries that are incompatible with the new version of the Vertica server must be recompiled. If you got the UDx library from a third party, you need to see if a new version has been released. If so, deploy the new version after you have upgraded the server (see Deploying a new version of your UDx library).

If you developed the UDx yourself (or if you have the source code) you must:

1. Recompile your UDx library using the new version of the Vertica SDK. See Compiling your C++ library or Compiling and packaging a Java library for more information.
2. Deploy the new version of your library. See Deploying a new version of your UDx library .

Determining if a UDx signature has changed

You need to be careful when making changes to UDx libraries that contain functions you have already deployed in your Vertica database. When you deploy a new version of your UDx library, Vertica does not ensure that the signatures of the functions that are defined in the library match the signature of the function that is already defined in the Vertica catalog. If you have changed the signature of a UDx in the library then update the library in the Vertica database, calls to the altered UDx will produce errors.

Making any of the following changes to a UDx alters its signature:

- Changing the number of arguments accepted or the data type of any argument accepted by your function (not including polymorphic functions).
- Changing the number or data types of any return values or output columns.
- Changing the name of the factory class that Vertica uses to create an instance of your function code.
- Changing the null handling or volatility behavior of your function.
- Removed the function's factory class from the library completely.

The following changes do not alter the signature of your function, and do not require you to drop the function before updating the library:

- Changing the number or type of arguments handled by a polymorphic function. Vertica does not process the arguments the user passes to a polymorphic function.
- Changing the name, data type, or number of parameters accepted by your function. The parameters your function accepts are not determined by the function signature. Instead, Vertica passes all of the parameters the user included in the function call, and your function processes them at runtime. See UDx parameters for more information about parameters.
- Changing any of the internal processing performed by your function.
- Adding new UDxs to the library.

After you drop any functions whose signatures have changed, you load the new library file, then re-create your altered functions. If you have not made any changes to the signature of your UDxs, you can just update the library file in your Vertica database without having to drop or alter your function definitions. As long as the UDx definitions in the Vertica catalog match the signatures of the functions in your library, function calls will work transparently after you have updated the library. See Deploying a new version of your UDx library .

Deploying a new version of your UDx library

You need to deploy a new version of your UDx library if:

- You have made changes to the library that you now want to roll out to your Vertica database.
- You have upgraded Vertica to a new version whose SDK is incompatible with the previous version.

The process of deploying a new version of your library is similar to deploying it initially.

1. If you are deploying a UDx library developed in C++ or Java, you must compile it with the current version of the Vertica SDK.
2. Copy your UDx's library file (a .so file for libraries developed in C++, a .py file for libraries developed in Python, or a .jar file for libraries developed in Java) or R source file to a host in your Vertica database.
3. Connect to the host using vsql .
4. If you have changed the signature of any of the UDxs in the shared library, you must drop them using DROP statements such as DROP FUNCTION or DROP SOURCE . If you are unsure whether any of the signatures of your functions have changed, see Determining if a UDx signature has changed .

   > **Note**
   > If all of the UDx signatures in your library have changed, you may find it more convenient to drop the library using the DROP LIBRARY statement with the CASCADE option to drop the library and all of the functions and loaders that reference it. Droping the library can save you the time it would take to drop each UDx individually. You can then reload the library and recreate all of the extensions using the same process you used to deploy the library in the first place. See CREATE LIBRARY .

5. Use the ALTER LIBRARY statement to update the UDx library definition with the file you copied in step 1. For example, if you want to update the library named ScalarFunctions with a file named ScalarFunctions-2.0.so in the dbadmin user's home directory, you could use the command:

   ```
   => ALTER LIBRARY ScalarFunctions AS '/home/dbadmin/ScalarFunctions-2.0.so';
   ```

   After you have updated the UDx library definition to use the new version of your shared library, the UDxs that are defined using classes in your UDx library begin using the new shared library file without any further changes.
6. If you had to drop any functions in step 4, recreate them using the new signature defined by the factory classes in your library. See CREATE FUNCTION statements .

Listing the UDxs contained in a library

Once a library has been loaded using the CREATE LIBRARY statement, you can find the UDxs and UDLs it contains by querying the USER_LIBRARY_MANIFEST system table:

```
=> CREATE LIBRARY ScalarFunctions AS '/home/dbadmin/ScalarFunctions.so';
CREATE LIBRARY
=> \x
Expanded display is on.
=> SELECT * FROM USER_LIBRARY_MANIFEST WHERE lib_name = 'ScalarFunctions';
-[ RECORD 1 ]-------------------
schema_name | public
lib_name    | ScalarFunctions
lib_oid     | 45035996273792402
obj_name    | RemoveSpaceFactory
obj_type    | Scalar Function
arg_types   | Varchar
return_type | Varchar
-[ RECORD 2 ]-------------------
schema_name | public
lib_name    | ScalarFunctions
lib_oid     | 45035996273792402
obj_name    | Div2intsInfo
obj_type    | Scalar Function
arg_types   | Integer, Integer
return_type | Integer
-[ RECORD 3 ]-------------------
schema_name | public
lib_name    | ScalarFunctions
lib_oid     | 45035996273792402
obj_name    | Add2intsInfo
obj_type    | Scalar Function
arg_types   | Integer, Integer
return_type | Integer
```

The obj_name column lists the factory classes contained in the library. These are the names you use to define UDxs and UDLs in the database catalog using statements such as CREATE FUNCTION and CREATE SOURCE .

Using wildcards in your UDx

Vertica supports wildcard * characters in the place of column names in user-defined functions.

You can use wildcards when:

- Your query contains a table in the FROM clause
- You are using a Vertica-supported development language
- Your UDx is running in fenced or unfenced mode

Supported SQL statements

The following SQL statements can accept wildcards:

- DELETE
- INSERT
- SELECT
- UPDATE

Unsupported configurations

The following situations do not support wildcards:

- You cannot pass a wildcard in the OVER clause of a query
- You cannot us a wildcard with a DROP statement
- You cannot use wildcards with any other arguments

Examples

These examples show wildcards and user-defined functions in a range of data manipulation operations.

DELETE statements:

```
=> DELETE FROM tablename WHERE udf(tablename.*) = 5;
```

INSERT statements:

```
=> INSERT INTO table1 SELECT udf(*) FROM table2;
```

SELECT statements:

```
=> SELECT udf(*) FROM tablename;
=> SELECT udf(tablename.*) FROM tablename;
=> SELECT udf(f.*) FROM table f;
=> SELECT udf(*) FROM table1,table2;
=> SELECT udf1( udf2(*) ) FROM table1,table2;
=> SELECT udf( db.schema.table.*) FROM tablename;
=> SELECT udf(sub.*) FROM (select col1, col2 FROM table) sub;
=> SELECT x FROM tablename WHERE udf(*) = y;
=> WITH sub as (SELECT * FROM tablename) select x, udf(*) FROM sub;
=> SELECT udf( * using parameters x=1) FROM tablename;
=> SELECT udf(table1.*, table2.col2) FROM table1,table2;
```

UPDATE statements:

```
=> UPDATE tablename set col1 = 4 FROM tablename WHERE udf(*) = 3;
```

Developing user-defined extensions (UDxs)

User-defined extensions (UDxs) are functions contained in external libraries that are developed in C++, Python, Java, or R using the Vertica SDK. The external libraries are defined in the Vertica catalog using the CREATE LIBRARY statement. They are best suited for analytic operations that are difficult to perform in SQL, or that need to be performed frequently enough that their speed is a major concern.

The primary strengths of UDxs are:

- They can be used anywhere an internal function can be used.
- They take full advantage of Vertica's distributed computing features. The extensions usually execute in parallel on each node in the cluster.
- They are distributed to all nodes by Vertica. You only need to copy the library to the initiator node.
- All of the complicated aspects of developing a distributed piece of analytic code are handled for you by Vertica. Your main programming task is to read in data, process it, and then write it out using the Vertica SDK APIs.

There are a few things to keep in mind about developing UDxs:

- UDxs can be developed in the programming languages C++, Python, Java, and R. (Not all UDx types support all languages.)
- UDxs written in Java always run in fenced mode, because the Java Virtual Machine that executes Java programs cannot run directly within the Vertica process.
- UDxs written in Python and R always run in fenced mode.
- UDxs developed in C++ have the option of running in unfenced mode, which means they load and run directly in the Vertica database process. This option provides the lowest overhead and highest speed. However, any bugs in the UDx's code can cause database instability. You must thoroughly test any UDxs you intend to run in unfenced mode before deploying them in a live environment. Consider whether the performance boost of running a C++ UDx unfenced is worth the potential database instability that a buggy UDx can cause.
- Because a UDx runs on the Vertica cluster, it can take processor time and memory away from the database processes. A UDx that consumes large amounts of computing resources can negatively impact database performance.

Types of UDxs

Vertica supports five types of user-defined extensions:

- User-defined scalar functions (UDSFs) take in a single row of data and return a single value. These functions can be used anywhere a native function can be used, except CREATE TABLE BY PARTITION and SEGMENTED BY expressions. UDSFs can be developed in C++, Python, Java, and R.
- User-defined aggregate functions (UDAF) allow you to create custom Aggregate functions specific to your needs. They read one column of data, and return one output column. UDAFs can be developed in C++.
- User-defined analytic functions (UDAnF) are similar to UDSFs, in that they read a row of data and return a single row. However, the function can read input rows independently of outputting rows, so that the output values can be calculated over several input rows. The function can be used with the query's OVER() clause to partition rows. UDAnFs can be developed in C++ and Java.
- User-defined transform functions (UDTFs) operate on table partitions (as specified by the query's OVER() clause) and return zero or more rows of data. The data they return can be an entirely new table, unrelated to the schema of the input table, with its own ordering and segmentation expressions. They can only be used in the SELECT list of a query. UDTFs can be developed in C++, Python, Java, and R.
  To optimize query performance, you can use live aggregate projections to pre-aggregate the data that a UDTF returns. For more information, see Pre-aggregating UDTF results.

- User-defined load allows you to create custom sources , filters , and parsers to load data. These extensions can be used in COPY statements. UDLs can be developed C++, Java and Python.

While each UDx type has a unique base class, developing them is similar in many ways. Different UDx types can also share the same library.

Structure

Each UDx type consists of two primary classes. The main class does the actual work (a transformation, an aggregation, and so on). The class usually has at least three methods: one to set up, one to tear down (release reserved resources), and one to do the work. Sometimes additional methods are defined.

The main processing method receives an instance of the ServerInterface class as an argument. This object is used by the underlying Vertica SDK code to make calls back into the Vertica process, for example to allocate memory. You can use this class to write to the server log during UDx execution.

The second class is a singleton factory. It defines one method that produces instances of the first class, and might define other methods to manage parameters.

When implementing a UDx you must subclass both classes.

Conventions

The C++, Python, and Java APIs are nearly identical. Where possible, this documentation describes these interfaces without respect to language. Documentation specific to C++, Python, or Java is covered in language-specific sections.

Because some documentation is language-independent, it is not always possible to use ideal, language-based terminology. This documentation uses the term "method" to refer to a Java method or a C++ member function.

Developing with the Vertica SDK

Before you can write a user-defined extension you must set up a development environment. After you do so, a good test is to download, build, and run the published examples.

In addition to covering how to set up your environment, this section covers general information about working with the Vertica SDK, including language-specific considerations.

In this section

- Setting up a development environment
- Downloading and running UDx example code
- C++ SDK
- Java SDK
- Python SDK
- R SDK
- Debugging tips

Setting up a development environment

Before you start developing your UDx, you need to configure your development and test environments. Development and test environments must use the same operating system and Vertica version as the production environment.

For additional language-specific requirements, see the following topics:

- Setting up the C++ SDK

- Setting up the Java SDK
- Python SDK
- Installing/upgrading the R language pack for Vertica

Development environment options

The language that you use to develop your UDx determines the setup options and requirements for your development environment. C++ developers can use the C++ UDx container , and all developers can use a non-production Vertica environment .

C++ UDx container

C++ developers can develop with the C++ UDx container. The UDx-container GitHub repository provides the tools to build a container that packages the binaries, libraries, and compilers required to develop C++ Vertica extensions. The C++ UDx container has the following build options:

- CentOS or Ubuntu base image
- Vertica 10.x and 11.x versions

For requirement, build, and test details, see the repository README .

Non-production Vertica environments

You can use a node in a non-production Vertica database or another machine that runs the same operating system and Vertica version as your production environment. For specific requirements and dependencies, refer to Operating System Requirements and Language Requirements .

Test environment options

To test your UDx, you need access to a non-production Vertica database. You have the following options:

- Install a single-node Vertica database on your development machine.
- Download and build a containerized test environment.

Containerized test environments

Vertica provides the following containerized options to simplify your test environment setup:

- Vertica Community Edition (CE) container image from the Vertica DockerHub registry . See the Overview for base image and Vertica version details.
  For details about Vertica CE, see Vertica community edition (CE) .
- Custom CE image with the one-node-ce GitHub repository . You can build CentOS- and Debian-based containers that are compatible with Vertica 10.x and 11.x versions.

Operating system requirements

Develop your UDx code on the same Linux platform that you use for your production Vertica database cluster. Centos- and Debian-based operating systems each require that you download additional packages.

CentOS-Based operating systems

Installations on the following CentOS-based operating systems require the devtoolset-7 package:

- CentOS
- Red Hat Enterprise Linux
- Oracle Enterprise Linux

Consult the documentation for your operating system for the specific installation command.

Debian-based operating systems

Installations on the following Debian-based operating systems require the GCC-7 package :

- Debian
- Ubuntu
- SUSE
- OpenSUSE
- Amazon Linux (The GCC package is pre-installed on Amazon Linux)

Consult the documentation for your operating system for the specific installation command.

Downloading and running UDx example code

You can download all of the examples shown in this documentation, and many more, from the Vertica GitHub repository . This repository includes examples of all types of UDxs.

You can download the examples in either of two ways:

- Download the ZIP file. Extract the contents of the file into a directory.
- Clone the repository. Using a terminal window, run the following command:

```
$ git clone https://github.com/vertica/UDx-Examples.git
```

The repository includes a makefile that you can use to compile the C++ and Java examples. It also includes .sql files that load and use the examples. See the README file for instructions on compiling and running the examples. To compile the examples you will need g++ or a JDK and make. See Setting up a development environment for related information.

Running the examples not only helps you understand how a UDx works, but also helps you ensure your development environment is properly set up to compile UDx libraries.

C++ SDK

The Vertica SDK supports writing both fenced and unfenced UDxs in C++ 11. You can download, compile, and run the examples; see Downloading and running UDx example code . Running the examples is a good way to verify that your development environment has all needed libraries.

If you do not have access to a Vertica test environment, you can install Vertica on your development machine and run a single node. Each time you rebuild your UDx library, you need to re-install it into Vertica. The following diagram illustrates the typical development cycle.

This section covers C++-specific topics that apply to all UDx types. For information that applies to all languages, see Arguments and return values , UDx parameters , Errors, warnings, and logging , Handling cancel requests and the sections for specific UDx types. For full API documentation, see the C++ SDK Documentation .

In this section

- Setting up the C++ SDK
- Compiling your C++ library
- Adding metadata to C++ libraries
- C++ SDK data types
- Resource use for C++ UDxs

Setting up the C++ SDK

The Vertica C++ Software Development Kit (SDK) is distributed as part of the server installation. It contains the source and header files you need to create your UDx library. For examples that you can compile and run, see Downloading and running UDx example code .

Requirements

At a minimum, install the following on your development machine:

- devtoolset-7 package (CentOS) or GCC-7 package (Debian), including gcc version 7 and an up-to-date libstdc++ package.
- [g++](http://gcc.gnu.org/ GCC homepage) and its associated toolchain, such as ld . Some Linux distributions package g++ separately from gcc .
- A copy of the Vertica SDK.

> **Note**
> The Vertica binaries are compiled using the default version of g++ installed on the supported Linux platforms.

You must compile with the flag -std=c++11 . The Vertica SDK uses features of C++ 11.

The following optional software packages can simplify development:

- make , or some other build-management tool.

- gdb , or some other debugger.
- Valgrind, or similar tools that detect memory leaks.

If you want to use any third-party libraries, such as statistical analysis libraries, you need to install them on your development machine. If you do not statically link these libraries into your UDx library, you must install them on every node in the cluster. See Compiling your C++ library for details.

SDK files

The SDK files are located in the sdk subdirectory under the root Vertica server directory (usually, /opt/vertica/sdk). This directory contains a subdirectory, include , which contains the headers and source files needed to compile UDx libraries.

There are two files in the include directory you need when compiling your UDx:

- Vertica.h is the main header file for the SDK. Your UDx code needs to include this file in order to find the SDK's definitions.
- Vertica.cpp contains support code that needs to be compiled into the UDx library.

Much of the Vertica SDK API is defined in the VerticaUDx.h header file (which is included by the Vertica.h file). If you're curious, you might want to review the contents of this file in addition to reading the API documentation.

Finding the current SDK version

You must develop your UDx using the same SDK version as the database in which you plan to use it. To display the SDK version currently installed on your system, run the following command in vsql:

```
=> SELECT sdk_version();
```

Running the examples

You can download the examples from the GitHub repository (see Downloading and running UDx example code). Compiling and running the examples helps you to ensure that your development environment is properly set up.

To compile all of the examples, including the Java examples, issue the following command in the Java-and-C++ directory under the examples directory:

```
$ make
```

> **Note**
> To compile the examples, you must have a g++ development environment installed. To install a g++ development environment on Red Hat systems, run yum install gcc gcc-c++ make.

Compiling your C++ library

GNU g++ is the only supported compiler for compiling UDx libraries. Always compile your UDx code on the same version of Linux that you use on your Vertica cluster.

When compiling your library, you must always:

- Compile with the -std=c++11 flag.
- Pass the -shared and -fPIC flags to the linker. The simplest method is to just pass these flags to g++ when you compile and link your library.
- Use the -Wno-unused-value flag to suppress warnings when macro arguments are not used. If you do not use this flag, you may get "left-hand operand of comma has no effect" warnings.
- Compile sdk/include/Vertica.cpp and link it into your library. This file contains support routines that help your UDx communicate with Vertica. The easiest way to do this is to include it in the g++ command to compile your library. Vertica supplies this file as C++ source rather than a library to limit library compatibility issues.
- Add the Vertica SDK include directory in the include search path using the g++ -I flag.

The SDK examples include a working makefile. See Downloading and running UDx example code .

Example of compiling a UDx

The following command compiles a UDx contained in a single source file named MyUDx.cpp into a shared library named MyUDx.so :

```
g++ -I /opt/vertica/sdk/include -Wall -shared -Wno-unused-value \
    -fPIC -o MyUDx.so MyUDx.cpp /opt/vertica/sdk/include/Vertica.cpp
```

Important

Vertica only supports UDx development on 64-bit architectures.

After you debug your UDx, you are ready to deploy it. Recompile your UDx using the -O3 flag to enable compiler optimization.

You can add additional source files to your library by adding them to the command line. You can also compile them separately and then link them together.

> **Tip**
> The examples subdirectory in the Vertica SDK directory contains a make file that you can use as starting point for your own UDx project.

Handling external libraries

You must link your UDx library to any supporting libraries that your UDx code relies on.These libraries might be either ones you developed or others provided by third parties. You have two options for linking:

- Statically link the support libraries into your UDx. The benefit of this method is that your UDx library does not rely on external files. Having a single UDx library file simplifies deployment because you just transfer a single file to your Vertica cluster. This method's main drawback is that it increases the size of your UDx library file.
- Dynamically link the library to your UDx. You must sometimes use dynamic linking if a third-party library does not allow static linking. In this case, you must copy the libraries to your Vertica cluster in addition to your UDx library file.

Adding metadata to C++ libraries

You can add metadata, such as author name, the version of the library, a description of your library, and so on to your library. This metadata lets you track the version of your function that is deployed on a Vertica Analytic Database cluster and lets third-party users of your function know who created the function. Your library's metadata appears in the USER_LIBRARIES system table after your library has been loaded into the Vertica Analytic Database catalog.

You declare the metadata for your library by calling the RegisterLibrary() function in one of the source files for your UDx. If there is more than one function call in the source files for your UDx, whichever gets interpreted last as Vertica Analytic Database loads the library is used to determine the library's metadata.

The RegisterLibrary() function takes eight string parameters:

```
RegisterLibrary(author,
                library_build_tag,
                library_version,
                library_sdk_version,
                source_url,
                description,
                licenses_required,
                signature);
```

- author contains whatever name you want associated with the creation of the library (your own name or your company's name for example).
- library_build_tag is a string you want to use to represent the specific build of the library (for example, the SVN revision number or a timestamp of when the library was compiled). This is useful for tracking instances of your library as you are developing them.
- library_version is the version of your library. You can use whatever numbering or naming scheme you want.
- library_sdk_version is the version of the Vertica Analytic Database SDK Library for which you've compiled the library.

  > **Note**
  > This field isn't used to determine whether a library is compatible with a version of the Vertica Analytic Database server. The version of the Vertica Analytic Database SDK you use to compile your library is embedded in the library when you compile it. It is this information that Vertica Analytic Database server uses to determine if your library is compatible with it.

- source_url is a URL where users of your function can find more information about it. This can be your company's website, the GitHub page hosting your library's source code, or whatever site you like.
- description is a concise description of your library.
- licenses_required is a placeholder for licensing information. You must pass an empty string for this value.
- signature is a placeholder for a signature that will authenticate your library. You must pass an empty string for this value.

For example, the following code demonstrates adding metadata to the Add2Ints example (see C++ example: Add2Ints).

```
// Register the factory with Vertica
RegisterFactory(Add2IntsFactory);

// Register the library's metadata.
RegisterLibrary("Whizzo Analytics Ltd.",
                "1234",
                "2.0",
                "7.0.0",
                "http://www.example.com/add2ints",
                "Add 2 Integer Library",
                "",
                "");
```

Loading the library and querying the USER_LIBRARIES system table shows the metadata supplied in the call to RegisterLibrary() :

```
=> CREATE LIBRARY add2intslib AS '/home/dbadmin/add2ints.so';
CREATE LIBRARY
=> \x
Expanded display is on.
=> SELECT * FROM USER_LIBRARIES WHERE lib_name = 'add2intslib';
-[ RECORD 1 ]-----+----------------------------------------
schema_name       | public
lib_name          | add2intslib

```

C++ SDK data types

The Vertica SDK has typedefs and classes for representing Vertica data types within your UDx code. Using these typedefs ensures data type compatibility between the data your UDx processes and generates and the Vertica database. The following table describes some of the typedefs available. Consult the C++ SDK Documentation for a complete list, as well as lists of helper functions to convert and manipulate these data types.

For information about SDK support for complex data types, see Complex Types as Arguments and Return Values .

Type Definition	Description
Interval	A Vertica interval
IntervalYM	A Vertica year-to-month interval.
Timestamp	A Vertica timestamp
vint	A standard Vertica 64-bit integer
vbool	A Boolean value in Vertica
vbool_null	A null value for a Boolean data types

vfloat	A Vertica floating point value
VString	String data types (such as varchar and char) **Note:** Do not use a VString object to hold an intermediate result. Use a std::string or char[] instead.
VNumeric	Fixed-point data types from Vertica
VUuid	A Vertica universally unique identifier

Notes

- When making some Vertica SDK API calls (such as VerticaType::getNumericLength()) on objects, make sure they have the correct data type. To minimize overhead and improve performance, most of the APIs do not check the data types of the objects on which they are called. Calling a function on an incorrect data type can result in an error.
- You cannot create instances of VString or VNumeric yourself. You can manipulate the values of existing objects of these classes that Vertica passes to your UDx, and extract values from them. However, only Vertica can instantiate these classes.

Resource use for C++ UDxs

Your UDxs consume at least a small amount of memory by instantiating classes and creating local variables. This basic memory usage by UDxs is small enough that you do not need to be concerned about it.

If your UDx needs to allocate more than one or two megabytes of memory for data structures, or requires access to additional resources such as files, you must inform Vertica about its resource use. Vertica can then ensure that the resources your UDx requires are available before running a query that uses it. Even moderate memory use (10MB per invocation of a UDx, for example) can become an issue if there are many simultaneous queries that call it.

> **Note**
> If your UDx allocates its own memory, you must make **absolutely sure** it properly frees it. Failing to free even a single byte of allocated memory can have significant consequences at scale. Instead of having your code allocate its own memory, you should use the C++ vt_alloc macro, which uses Vertica's own memory manager to allocate and track memory. This memory is guaranteed to be properly disposed of when your UDx completes execution. See Allocating resources for UDxs for more information.

In this section

- Allocating resources for UDxs
- Allocating resources with the SDK macros
- Informing Vertica of resource requirements
- Setting memory limits for fenced-mode UDxs
- How resource limits are enforced

Allocating resources for UDxs

You have two options for allocating memory and file handles for your user-defined extensions (UDxs):

- Use Vertica SDK macros to allocate resources. This is the best method, since it uses Vertica's own resource manager, and guarantees that resources used by your UDx are reclaimed. See Allocating resources with the SDK macros .
- While not the recommended option, you can allocate resources in your UDxs yourself using standard C++ methods (instantiating objects using new , allocating memory blocks using malloc() , etc.). You must manually free these resources before your UDx exits.

> **Note**
> You must be extremely careful if you choose to allocate your own resources in your UDx. Failing to free resources properly will have significant negative impact, especially if your UDx is running in unfenced mode.

Whichever method you choose, you usually allocate resources in a function named setup() in your UDx class. This function is called after your UDx function object is instantiated, but before Vertica calls it to process data.

If you allocate memory on your own in the setup() function, you must free it in a corresponding function named destroy() . This function is called after your UDx has performed all of its processing. This function is also called if your UDx returns an error (see Handling errors).

> **Note**
> Always use the setup() and destroy() functions to allocate and free resources instead of your own constructors and destructors. The memory for your UDx object is allocated from one of Vertica's own memory pools. Vertica always calls your UDx's destroy() function before it deallocates the object's memory. There is no guarantee that your UDx's destructor is will be called before the object is deallocated. Using the destroy() function ensures that your UDx has a chance to free its allocated resources before it is destroyed.

The following code fragment demonstrates allocating and freeing memory using a setup() and destroy() function.

```
class MemoryAllocationExample : public ScalarFunction
{
public:
  uint64* myarray;
  // Called before running the UDF to allocate memory used throughout
  // the entire UDF processing.
  virtual void setup(ServerInterface &srvInterface, const SizedColumnTypes
                     &argTypes)
  {
    try
    {
      // Allocate an array. This memory is directly allocated, rather than
      // letting Vertica do it. Remember to properly calculate the amount
      // of memory you need based on the data type you are allocating.
      // This example divides 500MB by 8, since that's the number of
      // bytes in a 64-bit unsigned integer.
      myarray = new uint64[1024 * 1024 * 500 / 8];
    }
    catch (std::bad_alloc &ba)
    {
      // Always check for exceptions caused by failed memory
      // allocations.
      vt_report_error(1, "Couldn't allocate memory :[%s]", ba.what());
    }

  }

  // Called after the UDF has processed all of its information. Use to free
  // any allocated resources.
  virtual void destroy(ServerInterface &srvInterface, const SizedColumnTypes
                       &argTypes)
  {
    // srvInterface.log("RowNumber processed %d records", *count_ptr);
    try
    {
      // Properly dispose of the allocated memory.
      delete[] myarray;
    }
    catch (std::bad_alloc &ba)
    {
      // Always check for exceptions caused by failed memory
      // allocations.
      vt_report_error(1, "Couldn't free memory :[%s]", ba.what());
    }

  }
```

Allocating resources with the SDK macros

The Vertica SDK provides three macros to allocate memory:

- vt_alloc allocates a block of memory to fit a specific data type (vint, struct, etc.).
- vt_allocArray allocates a block of memory to hold an array of a specific data type.
- vt_allocSize allocates an arbitrarily-sized block of memory.

All of these macros allocate their memory from memory pools managed by Vertica. The main benefit of allowing Vertica to manage your UDx's memory is that the memory is automatically reclaimed after your UDx has finished. This ensures there is no memory leaks in your UDx.

Because Vertica frees this memory automatically, do not attempt to free any of the memory you allocate through any of these macros. Attempting to free this memory results in run-time errors.

Informing Vertica of resource requirements

When you run your UDx in fenced mode, Vertica monitors its use of memory and file handles. If your UDx uses more than a few megabytes of memory or any file handles, it should tell Vertica about its resource requirements. Knowing the resource requirements of your UDx allows Vertica to determine whether it can run the UDx immediately or needs to queue the request until enough resources become available to run it.

Determining how much memory your UDx requires can be difficult in some cases. For example, if your UDx extracts unique data elements from a data set, there is potentially no bound on the number of data items. In this case, a useful technique is to run your UDx in a test environment and monitor its memory use on a node as it handles several differently-sized queries, then extrapolate its memory use based on the worst-case scenario it may face in your production environment. In all cases, it's usually a good idea to add a safety margin to the amount of memory you tell Vertica your UDx uses.

> **Note**
> The information on your UDx's resource needs that you pass to Vertica is used when planning the query execution. There is no way to change the amount of resources your UDx requests from Vertica while the UDx is actually running.

Your UDx informs Vertica of its resource needs by implementing the getPerInstanceResources() function in its factory class (see Vertica::UDXFactory::getPerInstanceResources() in the SDK documentation). If your UDx's factory class implements this function, Vertica calls it to determine the resources your UDx requires.

The getPerInstanceResources() function receives an instance of the Vertica::VResources struct. This struct contains fields that set the amount of memory and the number of file handles your UDx needs. By default, the Vertica server allocates zero bytes of memory and 100 file handles for each instance of your UDx.

Your implementation of the getPerInstanceResources() function sets the fields in the VResources struct based on the maximum resources your UDx may consume for each instance of the UDx function. So, if your UDx's processBlock() function creates a data structure that uses at most 100MB of memory, your UDx must set the VResources.scratchMemory field to at least 104857600 (the number of bytes in 100MB). Leave yourself a safety margin by increasing the number beyond what your UDx should normally consume. In this example, allocating 115000000 bytes (just under 110MB) is a good idea.

The following ScalarFunctionFactory class demonstrates calling getPerInstanceResources() to inform Vertica about the memory requirements of the MemoryAllocationExample class shown in Allocating resources for UDxs. It tells Vertica that the UDSF requires 510MB of memory (which is a bit more than the UDSF actually allocates, to be on the safe size).

```
class MemoryAllocationExampleFactory : public ScalarFunctionFactory
{
  virtual Vertica::ScalarFunction *createScalarFunction(Vertica::ServerInterface
                                                         &srvInterface)
  {
    return vt_createFuncObj(srvInterface.allocator, MemoryAllocationExample);
  }
  virtual void getPrototype(Vertica::ServerInterface &srvInterface,
                            Vertica::ColumnTypes &argTypes,
                            Vertica::ColumnTypes &returnType)
  {
    argTypes.addInt();
    argTypes.addInt();
    returnType.addInt();
  }
  // Tells Vertica the amount of resources that this UDF uses.
  virtual void getPerInstanceResources(ServerInterface &srvInterface,
                                       VResources &res)
  {
    res.scratchMemory += 1024LL * 1024 * 510; // request 510MB of memory
  }
};
```

Setting memory limits for fenced-mode UDxs

Vertica calls a fenced-mode UDx's implementation of Vertica::UDXFactory::getPerInstanceResources() to determine if there are enough free resources to run the query containing the UDx (see Informing Vertica of Resource Requirements). Since these reports are not generated by actual memory use, they can be inaccurate. Once started by Vertica, a UDx could allocate far more memory or file handles than it reported it needs.

The FencedUDxMemoryLimitMB configuration parameter lets you create an absolute memory limit for UDxs. Any attempt by a UDx to allocate more memory than this limit results in a bad_alloc exception. For more information on configuration parameters, see Configuration parameters . For an example of setting FencedUDxMemoryLimitMB, see How resource limits are enforced .

How resource limits are enforced

Before running a query, Vertica determines how much memory it requires to run. If the query contains a fenced-mode UDx which implements the getPerInstanceResources() function in its factory class, Vertica calls it to determine the amount of memory the UDx needs and adds this to the total required for the query. Based on these requirements, Vertica decides how to handle the query:

- If the total amount of memory required (including the amount that the UDxs report that they need) is larger than the session's MEMORYCAP or resource pool's MAXMEMORYSIZE setting, Vertica rejects the query. For more information about resource pools, see Resource pool architecture .
- If the amount of memory is below the limit set by the session and resource pool limits, but there is currently not enough free memory to run the query, Vertica queues it until enough resources become available.
- If there are enough free resources to run the query, Vertica executes it.

> **Note**
> Vertica has no other way to determine the amount of resources a UDx requires other than the values it reports using the getPerInstanceResources() function. A UDx could use more resources than it claims, which could cause performance issues for other queries that are denied resources. You can set an absolute limit on the amount of memory UDxs can allocate. See Setting memory limits for fenced-mode UDxs for more information.

If the process executing your UDx attempts to allocate more memory than the limit set by the FencedUDxMemoryLimitMB configuration parameter, it receives a bad_alloc exception. For more information about FencedUDxMemoryLimitMB, see Setting memory limits for fenced-mode UDxs .

Below is the output of loading a UDSF that consumes 500MB of memory, then changing the memory settings to cause out-of-memory errors. The MemoryAllocationExample UDSF in the following example is just the Add2Ints UDSF example altered as shown in Allocating resources for UDxs and Informing Vertica of resource requirements to allocate 500MB of RAM.

```
=> CREATE LIBRARY mylib AS '/home/dbadmin/MemoryAllocationExample.so';
CREATE LIBRARY
=> CREATE FUNCTION usemem AS NAME 'MemoryAllocationExampleFactory' LIBRARY mylib
-> FENCED;
CREATE FUNCTION
=> SELECT usemem(1,2);
 usemem
--------
      3
(1 row)
```

The following statements demonstrate setting the session's MEMORYCAP to lower than the amount of memory that the UDSF reports it uses. This causes Vertica to return an error before it executes the UDSF.

```
=> SET SESSION MEMORYCAP '100M';
SET
=> SELECT usemem(1,2);
ERROR 3596:  Insufficient resources to execute plan on pool sysquery
[Request exceeds session memory cap: 520328KB > 102400KB]
=> SET SESSION MEMORYCAP = default;
SET
```

The resource pool can also prevent a UDx from running if it requires more memory than is available in the pool. The following statements demonstrate the effect of creating and using a resource pool that has too little memory for the UDSF to run. Similar to the session's MAXMEMORYCAP limit, the pool's MAXMEMORYSIZE setting prevents Vertica from executing the query containing the UDSF.

```
=> CREATE RESOURCE POOL small MEMORYSIZE '100M' MAXMEMORYSIZE '100M';
CREATE RESOURCE POOL
=> SET SESSION RESOURCE POOL small;
SET
=> CREATE TABLE ExampleTable(a int, b int);
CREATE TABLE
=> INSERT /*+direct*/ INTO ExampleTable VALUES (1,2);
 OUTPUT
--------
      1
(1 row)
=> SELECT usemem(a, b) FROM ExampleTable;
ERROR 3596:  Insufficient resources to execute plan on pool small
[Request Too Large:Memory(KB) Exceeded: Requested = 523136, Free = 102400 (Limit = 102400, Used = 0)]
=> DROP RESOURCE POOL small; --Dropping the pool resets the session's pool
DROP RESOURCE POOL
```

Finally, setting the FencedUDxMemoryLimitMB configuration parameter to lower than the UDx actually allocates results in the UDx throwing an exception. This is a different case than either of the previous two examples, since the query actually executes. The UDx's code needs to catch and handle the exception. In this example, it uses the vt_report_error macro to report the error back to Vertica and exit.

```
=> ALTER DATABASE DEFAULT SET FencedUDxMemoryLimitMB = 300;

=> SELECT usemem(1,2);
   ERROR 3412:  Failure in UDx RPC call InvokeSetup(): Error calling setup() in
   User Defined Object [usemem] at [MemoryAllocationExample.cpp:32], error code:
    1, message: Couldn't allocate memory :[std::bad_alloc]

=> ALTER DATABASE DEFAULT SET FencedUDxMemoryLimitMB = -1;

=> SELECT usemem(1,2);
 usemem
--------
      3
(1 row)
```

- SET SESSION MEMORYCAP

Java SDK

The Vertica SDK supports writing Java UDxs of all types except aggregate functions. All Java UDxs are fenced.

You can download, compile, and run the examples; see Downloading and running UDx example code . Running the examples is a good way to verify that your development environment has all needed libraries.

If you do not have access to a Vertica test environment, you can install Vertica on your development machine and run a single node. Each time you rebuild your UDx library, you need to re-install it into Vertica. The following diagram illustrates the typical development cycle.

This section covers Java-specific topics that apply to all UDx types. For information that applies to all languages, see Arguments and return values , UDx parameters , Errors, warnings, and logging , Handling cancel requests and the sections for specific UDx types. For full API documentation, see the Java SDK Documentation .

In this section

- Setting up the Java SDK
- Compiling and packaging a Java library
- Handling Java UDx dependencies
- Java and Vertica data types
- Handling NULL values
- Adding metadata to Java UDx libraries
- Java UDx resource management

Setting up the Java SDK

The Vertica Java Software Development Kit (SDK) is distributed as part of the server installation. It contains the source and JAR files you need to create your UDx library. For examples that you can compile and run, see Downloading and running UDx example code .

Requirements

At a minimum, install the following on your development machine:

- The Java Development Kit (JDK) version that matches the Java version you have installed on your database hosts (see Installing Java on Vertica Hosts).
- A copy of the Vertica SDK.

Optionally, you can simplify development with a build-management tool, such as make .

SDK files

To use the SDK you need two files from the Java support package:

- /opt/vertica/bin/VerticaSDK.jar contains the Vertica Java SDK and other supporting files.
- /opt/vertica/sdk/BuildInfo.java contains version information about the SDK. You must compile this file and include it within your Java UDx JAR files.

If you are not doing your development on a database node, you can copy these two files from one of the database nodes to your development system.

The BuildInfo.java and VerticaSDK.jar files that you use to compile your UDx must be from the same SDK version. Both files must also match the version of the SDK files on your Vertica hosts. Versioning is only an issue if you are not compiling your UDxs on a Vertica host. If you are compiling on a separate development system, always refresh your copies of these two files and recompile your UDxs just before deploying them.

Finding the current SDK version

You must develop your UDx using the same SDK version as the database in which you plan to use it. To display the SDK version currently installed on your system, run the following command in vsql:

```
=> SELECT sdk_version();
```

Compiling BuildInfo.java

You need to compile the BuildInfo.java file into a class file, so you can include it in your Java UDx JAR library. If you are using a Vertica node as a development system, you can either:

- Copy the BuildInfo.java file to another location on your host.
- If you have root privileges, compile the BuildInfo.java file in place. (Only the root user has privileges to write files to the /opt/vertica/sdk directory.)

Compile the file using the following command. Replace *path* with the path to the file and *output-directory* with the directory where you will compile your UDxs.

```
$ javac -classpath /opt/vertica/bin/VerticaSDK.jar \
    /path/BuildInfo.java -d output-directory
```

If you use an IDE such as Eclipse, you can include the BuildInfo.java file in your project instead of compiling it separately. You must also add the VerticaSDK.jar file to the project's build path. See your IDE's documentation for details on how to include files and libraries in your projects.

Running the examples

You can download the examples from the GitHub repository (see Downloading and running UDx example code). Compiling and running the examples helps you to ensure that your development environment is properly set up.

If you have not already done so, set the JAVA_HOME environment variable to your JDK (not JRE) directory.

To compile all of the examples, including the Java examples, issue the following command in the Java-and-C++ directory under the examples directory:

```
$ make
```

To compile only the Java examples, issue the following command in the Java-and-C++ directory under the examples directory:

```
$ make JavaFunctions
```

Compiling and packaging a Java library

Before you can use your Java UDx, you need to compile it and package it into a JAR file.

The SDK examples include a working makefile. See Downloading and running UDx example code .

Compile your Java UDx

You must include the SDK JAR file in the CLASSPATH when you compile your Java UDx source files so the Java compiler can resolve the Vertica API calls. If you are using the command-line Java compiler on a host in your database cluster, enter this command:

```
$ javac -classpath /opt/vertica/bin/VerticaSDK.jar factorySource.java \
    [functionSource.java...] -d output-directory
```

If all of your source files are in the same directory, you can use *.java on the command line instead of listing the files individually.

If you are using an IDE, verify that a copy of the VerticaSDK.jar file is in the build path.

UDx class file organization

After you compile your UDx, you must package its class files and the BuildInfo.class file into a JAR file.

> **Note**
> You can package as many UDxs as you want into the same JAR file. Bundling your UDxs together saves you from having to load multiple libraries.

To use the jar command packaged as part of the JDK, you must organize your UDx class files into a directory structure matching your class package structure. For example, suppose your UDx's factory class has a fully-qualified name of com.mycompany.udfs.Add2ints . In this case, your class files must be in the directory hierarchy com/mycompany/udfs relative to your project's base directory. In addition, you must have a copy of the BuildInfo.class file in the path com/vertica/sdk so that it can be included in the JAR file. This class must appear in your JAR file to indicate the SDK version that was used to compile your Java UDx.

The JAR file for the Add2ints UDSF example has the following directory structure after compilation:

```
com/vertica/sdk/BuildInfo.class
com/mycompany/example/Add2intsFactory.class
com/mycompany/example/Add2intsFactory$Add2ints.class
```

Package your UDx into a JAR file

To create a JAR file from the command line:

1. Change to the root directory of your project.
2. Use the jar command to package the BuildInfo.class file and all of the classes in your UDx:

   ```
   # jar -cvf libname.jar com/vertica/sdk/BuildInfo.class \
       packagePath/*.class
   ```

   When you type this command, *libname* is the filename you have chosen for your JAR file (choose whatever name you like), and *packagePath* is the path to the directory containing your UDx's class files.
   - For example, to package the files from the Add2ints example, you use the command:

     ```
     # jar -cvf Add2intsLib.jar com/vertica/sdk/BuildInfo.class \
     com/mycompany/example/*.class
     ```

   - More simply, if you compiled BuildInfo.class and your class files into the same root directory, you can use the following command:

     ```
     # jar -cvf Add2intsLib.jar .
     ```

   You must include all of the class files that make up your UDx in your JAR file. Your UDx always consists of at least two classes (the factory class and the function class). Even if you defined your function class as an inner class of your factory class, Java generates a separate class file for the inner class.

After you package your UDx into a JAR file, you are ready to deploy it to your Vertica database.

Handling Java UDx dependencies

If your Java UDx relies on one or more external libraries, you can handle the dependencies in one of three ways:

- Bundle the JAR files into your UDx JAR file using a tool such as One-JAR or Eclipse Runnable JAR Export Wizard.
- Unpack the JAR file and then repack its contents in your UDx's JAR file.
- Copy the libraries to your Vertica cluster in addition to your UDx library.Then, use the DEPENDS keyword of the CREATE LIBRARY statement to tell Vertica that the UDx library depends on the external libraries. This keyword acts as a library-specific CLASSPATH setting. Vertica distributes the support libraries to all of the nodes in the cluster and sets the class path for the UDx so it can find them.
  If your UDx depends on native libraries (SO files), use the DEPENDS keyword to specify their path. When you call System.loadLibrary in your UDx (which you must do before using a native library), this function uses the DEPENDS path to find them. You do not need to also set the LD_LIBRARY_PATH environment variable.

External library example

The following example demonstrates using an external library with a Java UDx.

The following sample code defines a simple class, named VowelRemover . It contains a single method, named removevowels , that removes all of the vowels (the letters *a* , *e* , *i* , *o u* , and *y*) from a string.

```
package com.mycompany.libs;

public class VowelRemover {
    public String removevowels(String input) {
        return input.replaceAll("(?i)[aeiouy]", "");
    }
}
```

You can compile this class and package it into a JAR file with the following commands:

```
$ javac -g com/mycompany/libs/VowelRemover.java
$ jar cf mycompanylibs.jar com/mycompany/libs/VowelRemover.class
```

The following code defines a Java UDSF, named DeleteVowels , that uses the library defined in the preceding example code. DeleteVowels accepts a single VARCHAR as input, and returns a VARCHAR.

```
package com.mycompany.udx;
// Import the support class created earlier
import com.mycompany.libs.VowelRemover;
// Import the Vertica SDK
import com.vertica.sdk.*;

public class DeleteVowelsFactory extends ScalarFunctionFactory {

    @Override
    public ScalarFunction createScalarFunction(ServerInterface arg0) {
        return new DeleteVowels();
    }

    @Override
    public void getPrototype(ServerInterface arg0, ColumnTypes argTypes,
            ColumnTypes returnTypes) {
        // Accept a single string and return a single string.
        argTypes.addVarchar();
        returnTypes.addVarchar();
    }

    @Override
    public void getReturnType(ServerInterface srvInterface,
            SizedColumnTypes argTypes,
            SizedColumnTypes returnType){
        returnType.addVarchar(
        // Output will be no larger than the input.
        argTypes.getColumnType(0).getStringLength(), "RemovedVowels");
    }

    public class DeleteVowels extends ScalarFunction
    {
        @Override
        public void processBlock(ServerInterface arg0, BlockReader argReader,
                BlockWriter resWriter) throws UdfException, DestroyInvocation {

            // Create an instance of the  VowelRemover object defined in
            // the library.
            VowelRemover remover = new VowelRemover();

            do {
                String instr = argReader.getString(0);
                // Call the removevowels method defined in the library.
                resWriter.setString(remover.removevowels(instr));
                resWriter.next();
            } while (argReader.next());
        }
    }

}
```

Use the following commands to build the example UDSF and package it into a JAR:

- The first javac command compiles the SDK's BuildInfo class. Vertica requires all UDx libraries to contain this class. The javac command's -d option outputs the class file in the directory structure of your UDSF's source.
- The second javac command compiles the UDSF class. It adds the previously-created mycompanylibs.jar file to the class path so compiler can find the the VowelRemover class.
- The jar command packages the BuildInfo and the classes for the UDx library together.

```
$ javac -g -cp /opt/vertica/bin/VerticaSDK.jar\
  /opt/vertica/sdk/com/vertica/sdk/BuildInfo.java -d .
$ javac -g -cp mycompanylibs.jar:/opt/vertica/bin/VerticaSDK.jar\
 com/mycompany/udx/DeleteVowelsFactory.java
$ jar cf DeleteVowelsLib.jar com/mycompany/udx/*.class \
  com/vertica/sdk/*.class
```

To install the UDx library, you must copy both of the JAR files to a node in the Vertica cluster. Then, connect to the node to execute the CREATE LIBRARY statement.

The following example demonstrates how to load the UDx library after you copy the JAR files to the home directory of the dbadmin user. The DEPENDS keyword tells Vertica that the UDx library depends on the mycompanylibs.jar file.

```
=> CREATE LIBRARY DeleteVowelsLib AS
  '/home/dbadmin/DeleteVowelsLib.jar' DEPENDS '/home/dbadmin/mycompanylibs.jar'
  LANGUAGE 'JAVA';
CREATE LIBRARY
=> CREATE FUNCTION deleteVowels AS language 'java' NAME
 'com.mycompany.udx.DeleteVowelsFactory' LIBRARY DeleteVowelsLib;
CREATE FUNCTION
=> SELECT deleteVowels('I hate vowels!');
 deleteVowels
--------------
 ht vwls!
(1 row)
```

Java and Vertica data types

The Vertica Java SDK converts Vertica's native data types into the appropriate Java data type. The following table lists the Vertica data types and their corresponding Java data types.

Vertica Data Type	Java Data Type
INTEGER	long
FLOAT	double
NUMERIC	com.vertica.sdk.VNumeric
DATE	java.sql.Date
CHAR, VARCHAR, LONG VARCHAR	com.vertica.sdk.VString
BINARY, VARBINARY, LONG VARBINARY	com.vertica.sdk.VString
TIMESTAMP	java.sql.Timestamp

> **Note**
> Some Vertica data types are not supported.

Setting BINARY, VARBINARY, and LONG VARBINARY values

The Vertica BINARY, VARBINARY, and LONG VARBINARY data types are converted as the Java UDx SDK 's VString class. You can also set the value of a column with one of these data types with a ByteBuffer object (or a byte array wrapped in a ByteBuffer) using the PartitionWriter.setStringBytes() method. See the Java API UDx entry for PartitionWriter.setStringBytes() for more information.

Timestamps and time zones

When the SDK converts a Vertica timestamp into a Java timestamp, it uses the time zone of the JVM. If the JVM is running in a different time zone than the one used by Vertica, the results can be confusing.

Vertica stores timestamps in the database in UTC. (If a database time zone is set, the conversion is done at query time.) To prevent errors from the JVM time zone, add the following code to the processing method of your UDx:

```
TimeZone.setDefault(TimeZone.getTimeZone("UTC"));
```

Strings

The Java SDK contains a class named StringUtils that assists you when manipulating string data. One of its more useful features is its getStringBytes() method. This method extracts bytes from a String in a way that prevents the creation of invalid strings. If you attempt to extract a substring that would split part of a multi-byte UTF-8 character, getStringBytes() truncates it to the nearest whole character.

Handling NULL values

Your UDxs must be prepared to handle NULL values. These values usually must be handled separately from regular values.

Reading NULL values

Your UDx reads data from instances of the the BlockReader or PartitionReader classes. If the value of a column is NULL, the methods you use to get data (such as getLong) return a Java null reference. If you attempt to use the value without checking for NULL, the Java runtime will throw a null pointer exception.

You can test for null values before reading columns by using the data-type-specific methods (such as isLongNull , isDoubleNull , and isBooleanNull). For example, to test whether the INTEGER first column of your UDx's input is a NULL, you would use the statement:

```
// See if the Long value in column 0 is a NULL
if (inputReader.isLongNull(0)) {
  // value is null
  . . .
```

Writing NULL values

You output NULL values using type-specific methods on the BlockWriter and PartitionWriter classes (such as setLongNull and setStringNull). These methods take the column number to receive the NULL value. In addition, the PartitionWriter class has data-type specific set value methods (such as setLongValue and setStringValue). If you pass these methods a value, they set the output column to that value. If you pass them a Java null reference, they set the output column to NULL.

Adding metadata to Java UDx libraries

You can add metadata, such as author name, the version of the library, a description of your library, and so on to your library. This metadata lets you track the version of your function that is deployed on a Vertica Analytic Database cluster and lets third-party users of your function know who created the function. Your library's metadata appears in the USER_LIBRARIES system table after your library has been loaded into the Vertica Analytic Database catalog.

To add metadata to your Java UDx library, you create a subclass of the UDXLibrary class that contains your library's metadata. You then include this class within your JAR file. When you load your class into the Vertica Analytic Database catalog using the CREATE LIBRARY statement, looks for a subclass of UDXLibrary for the library's metadata.

In your subclass of UDXLibrary , you need to implement eight getters that return String values containing the library's metadata. The getters in this class are:

- getAuthor() returns the name you want associated with the creation of the library (your own name or your company's name for example).
- getLibraryBuildTag() returns whatever String you want to use to represent the specific build of the library (for example, the SVN revision number or a timestamp of when the library was compiled). This is useful for tracking instances of your library as you are developing them.
- getLibraryVersion() returns the version of your library. You can use whatever numbering or naming scheme you want.
- getLibrarySDKVersion() returns the version of the Vertica Analytic Database SDK Library for which you've compiled the library.

> **Note**
> This field isn't used to determine whether a library is compatible with a version of the Vertica Analytic Database server. The version of the Vertica Analytic Database SDK you use to compile your library is embedded in the library when you compile it. It is this information that Vertica Analytic Database server uses to determine if your library is compatible with it.

- getSourceUrl() returns a URL where users of your function can find more information about it. This can be your company's website, the GitHub page hosting your library's source code, or whatever site you like.

- getDescription() returns a concise description of your library.
- getLicensesRequired() returns a placeholder for licensing information. You must pass an empty string for this value.
- getSignature() returns a placeholder for a signature that will authenticate your library. You must pass an empty string for this value.

For example, the following code demonstrates creating a UDXLibrary subclass to be included in the Add2Ints UDSF example JAR file (see /opt/vertica/sdk/examples/JavaUDx/ScalarFunctions on any Vertica node).

```
// Import the UDXLibrary class to hold the metadata
import com.vertica.sdk.UDXLibrary;

public class Add2IntsLibrary extends UDXLibrary
{
    // Return values for the metadata about this library.

    @Override public String getAuthor() {return "Whizzo Analytics Ltd.";}
    @Override public String getLibraryBuildTag() {return "1234";}
    @Override public String getLibraryVersion() {return "1.0";}
    @Override public String getLibrarySDKVersion() {return "7.0.0";}
    @Override public String getSourceUrl() {
        return "http://example.com/add2ints";
    }
    @Override public String getDescription() {
        return "My Awesome Add 2 Ints Library";
    }
    @Override public String getLicensesRequired() {return "";}
    @Override public String getSignature() {return "";}
}
```

When the library containing the Add2IntsLibrary class loaded, the metadata appears in the USER_LIBRARIES system table:

```
=> CREATE LIBRARY JavaAdd2IntsLib AS :libfile LANGUAGE 'JAVA';
CREATE LIBRARY
=> CREATE FUNCTION JavaAdd2Ints as LANGUAGE 'JAVA'  name 'com.mycompany.example.Add2IntsFactory' library JavaAdd2IntsLib;
CREATE FUNCTION
=> \x
Expanded display is on.
=> SELECT * FROM USER_LIBRARIES WHERE lib_name = 'JavaAdd2IntsLib';
-[ RECORD 1 ]-----+-------------------------------------------

Java UDx resource management

Java Virtual Machines (JVMs) allocate a set amount of memory when they start. This set memory allocation complicates memory management for Java UDxs, because memory cannot be dynamically allocated and freed by the UDx as it is processing data. This is differs from C++ UDxs which can dynamically allocate resources.

To control the amount of memory consumed by Java UDxs, Vertica has a memory pool named jvm that it uses to allocate memory for JVMs. If this memory pool is exhausted, queries that call Java UDxs block until enough memory in the pool becomes free to start a new JVM.

By default, the jvm pool has:

- no memory of its own assigned to it, so it borrows memory from the GENERAL pool.
- its MAXMEMORYSIZE set to either 10% of system memory or 2GB, whichever is smaller.
- its PLANNEDCONCURRENCY set to AUTO, so that it inherits the GENERAL pool's PLANNEDCONCURRENCY setting.

You can view the current settings for the jvm pool by querying the RESOURCE_POOLS table:

```
=> SELECT MAXMEMORYSIZE,PLANNEDCONCURRENCY FROM V_CATALOG.RESOURCE_POOLS WHERE NAME = 'jvm';
 MAXMEMORYSIZE | PLANNEDCONCURRENCY
---------------+--------------------
10%            | AUTO
```

When a SQL statement calls a Java UDx, Vertica checks if the jvm memory pool has enough memory to start a new JVM instance to execute the function call. Vertica starts each new JVM with its heap memory size set to approximately the jvm pool's MAXMEMORYSIZE parameter divided by its PLANNEDCONCURRENCY parameter. If the memory pool does not contain enough memory, the query blocks until another JVM exits and return their memory to the pool.

If your Java UDx attempts to consume more memory than has been allocated to the JVM's heap size, it exits with a memory error. You can attempt to resolve this issue by:

- increasing the jvm pool's MAXMEMORYSIZE parameter.
- decreasing the jvm pool's PLANNEDCONCURRENCY parameter.
- changing your Java UDx's code to consume less memory.

Adjusting the jvm pool

When adjusting the jvm pool to your needs, you must consider two factors:

- the amount of RAM your Java UDx requires to run
- how many concurrent Java UDx functions you expect your database to run

You can learn the amount of memory your Java UDx needs using several methods. For example, your code can use Java's Runtime class to get an estimate of the total memory it has allocated and then log the value using ServerInterface.log() . (An instance of this class is passed to your UDx.) If you have multiple Java UDxs in your database, set the jvm pool memory size based on the UDx that uses the most memory.

The number of concurrent sessions that need to run Java UDxs may not be the same as the global PLANNEDCONCURRENCY setting. For example, you may have just a single user who runs a Java UDx, which means you can lower the jvm pool's PLANNEDCONCURRENCY setting to 1.

When you have an estimate for the amount of RAM and the number of concurrent user sessions that need to run Java UDXs, you can adjust the jvm pool to an appropriate size. Set the pool's MAXMEMORYSIZE to the maximum amount of RAM needed by the most demanding Java UDx multiplied by the number of concurrent user sessions that need to run Java UDxs. Set the pool's PLANNEDCONCURENCY to the numebr of simultaneous user sessions that need to run Java UDxs.

For example, suppose your Java UDx requires up to 4GB of memory to run and you expect up to two user sessions use Java UDx's. You would use the following command to adjust the jvm pool:

```
=> ALTER RESOURCE POOL jvm MAXMEMORYSIZE '8G' PLANNEDCONCURRENCY 2;
```

The MEMORYSIZE is set to 8GB, which is the 4GB maximum memory use by the Java UDx multiplied by the 2 concurrent user sessions.

> **Note**
> The PLANNEDCONCURRENCY value is **not** the number of calls to Java UDx that you expect to happen simultaneously. Instead, it is the number of concurrently open user sessions that call Java UDxs at any time during the session. See below for more information.

See Managing workloads for more information on tuning the jvm and other resource pools.

Freeing JVM memory

The first time users call a Java UDx during their session, Vertica allocates memory from the jvm pool and starts a new JVM. This JVM remains running for as long as the user's session is open so it can process other Java UDx calls. Keeping the JVM running lowers the overhead of executing multiple Java UDxs by the same session. If the JVM did not remain open, each call to a Java UDx would require additional time for Vertica to allocate resources and

start a new JVM. However, having the JVM remain open means that the JVM's memory remains allocated for the life of the session whether or not it will be used again.

If the jvm memory pool is depleted, queries containing Java UDxs either block until memory becomes available or eventually fail due a lack of resources. If you find queries blocking or failing for this reason, you can allocate more memory to the jvm pool and increase its PLANNEDCONCURRENCY. Another option is to ask users to call the RELEASE_JVM_MEMORY function when they no longer need to run Java UDxs. This function closes any JVM belonging to the user's session and returns its allocated memory to the jvm memory pool.

The following example demonstrates querying V_MONITOR.SESSIONS to find the memory allocated to JVMs by all sessions. It also demonstrates how the memory is allocated by a call to a Java UDx, and then freed by calling RELEASE_JVM_MEMORY.

```
=> SELECT USER_NAME,EXTERNAL_MEMORY_KB FROM V_MONITOR.SESSIONS;
 user_name | external_memory_kb
-----------+--------------------
 dbadmin   |                  0
(1 row)

=> -- Call a Java UDx
=> SELECT add2ints(123,456);
 add2ints
----------
      579
(1 row)
=> -- JVM is now running and memory is allocated to it.
=> SELECT USER_NAME,EXTERNAL_MEMORY_KB FROM V_MONITOR.SESSIONS;
 USER_NAME | EXTERNAL_MEMORY_KB
-----------+--------------------
 dbadmin   |              79705
(1 row)

=> -- Shut down the JVM and deallocate memory
=> SELECT RELEASE_JVM_MEMORY();
           RELEASE_JVM_MEMORY
-----------------------------------------
 Java process killed and memory released
(1 row)

=> SELECT USER_NAME,EXTERNAL_MEMORY_KB FROM V_MONITOR.SESSIONS;
 USER_NAME | EXTERNAL_MEMORY_KB
-----------+--------------------
 dbadmin   |                  0
(1 row)
```

In rare cases, you may need to close all JVMs. For example, you may need to free memory for an important query, or several instances of a Java UDx may be taking too long to complete. You can use the RELEASE_ALL_JVM_MEMORY to close all of the JVMs in all user sessions:

```
=> SELECT USER_NAME,EXTERNAL_MEMORY_KB FROM V_MONITOR.SESSIONS;
 USER_NAME  | EXTERNAL_MEMORY_KB
------------+--------------------
ExampleUser |              79705
dbadmin     |              79705
(2 rows)

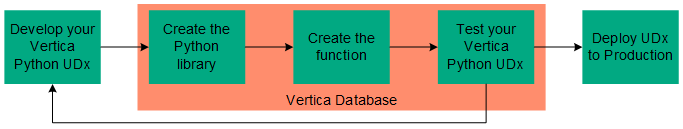
=> SELECT RELEASE_ALL_JVM_MEMORY();
                        RELEASE_ALL_JVM_MEMORY
-------------------------------------------------------------------------------
 Close all JVM sessions command sent. Check v_monitor.sessions for progress.
(1 row)

=> SELECT USER_NAME,EXTERNAL_MEMORY_KB FROM V_MONITOR.SESSIONS;
 USER_NAME | EXTERNAL_MEMORY_KB
-----------+--------------------
 dbadmin   |                  0
(1 row)
```

Caution

This function terminates all JVMs, including ones that are currently executing Java UDXs. This will cause any query that is currently executing a Java UDx to return an error.

Notes



- The jvm resource pool is used only to allocate memory for the Java UDx function calls in a statement. The rest of the resources required by the SQL statement come from other memory pools.
- The first time a Java UDx is called, Vertica starts a JVM to execute some Java methods to get metadata about the UDx during the query planning phase. The memory for this JVM is also taken from the jvm memory pool.

Python SDK

The Vertica SDK supports writing UDxs of some types in Python 3.

The Python SDK does not require any additional system configuration or header files. This low overhead allows you to develop and deploy new capabilities to your Vertica cluster in a short amount of time.

The following workflow is typical for the Python SDK:

Because Python has an interpreter, you do not have to compile your program before loading the UDx in Vertica. However, you should expect to do some debugging of your code after you create your function and begin testing it in Vertica.

When Vertica calls your UDx, it starts a side process that manages the interaction between the server and the Python interpreter.

This section covers Python-specific topics that apply to all UDx types. For information that applies to all languages, see Arguments and return values , UDx parameters , Errors, warnings, and logging , Handling cancel requests and the sections for specific UDx types. For full API documentation, see the Python SDK .

Important

Your UDx must be able to run with the version of Python bundled with Vertica. You can find this with `/opt/vertica/sbin/python3 --version` . You cannot change the version used by the Vertica Python interpreter.

In this section

- Python libraries
- Python and Vertica data types

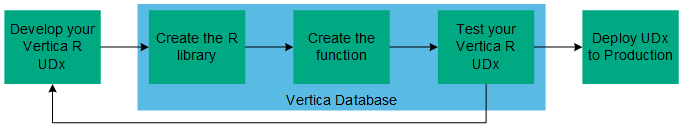
Python libraries

Before you can use your Python UDx, you need to verify that it meets the following library requirements:

- Your UDx must import the vertica_sdk package in your code. You do not need to download this package. It is included as a part of the Vertica server.
  ```
  python import vertica_sdk
  ```
- The Vertica Python SDK includes the Python Standard Library. If your UDx depends on other libraries, you must add them as dependencies using CREATE LIBRARY. You cannot simply import them.

Python and Vertica data types

The Vertica Python SDK converts native Vertica data types into the appropriate Python data types, as follows:



Vertica Data Type	Python Data Type
INTEGER	int
FLOAT	float
NUMERIC	decimal.Decimal
DATE	datetime.date
CHAR, VARCHAR, LONG VARCHAR	string (UTF-8 encoded)
BINARY, VARBINARY, LONG VARBINARY	binary
TIMESTAMP	datetime.datetime
TIME	datetime.time

> **Note**
> Some Vertica Analytic Database data types are not supported in Python.

R SDK

The Vertica R SDK extends the capabilities of the Vertica Analytic Database so you can leverage additional R libraries. Before you can begin developing User Defined Extensions (UDxs) in R, you must install the R Language Pack for Vertica on each of the nodes in your cluster. The R SDK supports scalar and transform functions in fenced mode. Other UDx types are not supported.

The following workflow is typical for the R SDK:

You can find detailed documentation of all of the classes in the Vertica R SDK.

In this section

- Installing/upgrading the R language pack for Vertica
- R packages
- R and Vertica data types
- Adding metadata to R libraries
- Setting null input and volatility behavior for R functions

Installing/upgrading the R language pack for Vertica

To create R UDxs in Vertica, install the R Language Pack package that matches your server version. The R Language Pack includes the R runtime and associated libraries for interfacing with Vertica. You must use this version of the R runtime; you cannot upgrade it.

You must install the R Language Pack on each node in the cluster. The Vertica R Language Pack must be the only R Language Pack installed on the node.

Vertica R language pack prerequisites

The R Language Pack package requires a number of packages for installation and execution. The names of these dependencies vary among Linux distributions. For Vertica-supported Linux platforms the packages are:

- RHEL/CentOS: libfortran , xz-libs , libgomp
- SUSE Linux Enterprise Server: libfortran3 , liblzma5 , libgomp1
- Debian/Ubuntu: libfortran3 , liblzma5 , libgomp1
- Amazon Linux 2.0: compat-gcc-48-libgfortran , xz-libs , libgomp

Vertica requires a version of the libgfortran4 library later than 7.1 to create R extensions. The libgfortran library is included by default with the devtool and gcc packages.

Installing the Vertica R language pack

If you use your operating systems package manager, rather than the rpm or dpkg command, for installation, you do not need to manually install the R Language Pack. The native package managers for each supported Linux version are:

- RHEL/CentOS: yum
- SUSE Linux Enterprise Server: zypper
- Debian/Ubuntu: apt-get
- Amazon Linux 2.0: yum

1. Download the R language package by browsing to the Vertica website .
2. On the **Support** tab, select **Customer Downloads** .
3. When prompted, log in using your Micro Focus credentials.
4. Located and select the vertica-R-lang_ *version* .rpm or vertica-R-lang_ *version* .deb file for your server version. The R language package version must match your server version to three decimal points.
5. Install the package as root or using sudo:
   - RHEL/CentOS
     ```
     $ yum install vertica-R-lang-<version>.rpm
     ```
   - SUSE Linux Enterprise Server
     ```
     $ zypper install vertica-R-lang-<version>.rpm
     ```
   - Debian
     ```
     $ apt-get install ./vertica-R-lang_<version>.deb
     ```
   - Amazon Linux 2.0
     ```
     $ yum install vertica-R-lang-<version>.AMZN.rpm
     ```

The installer puts the R binary in /opt/vertica/R .

Upgrading the Vertica R language pack

When upgrading, some R packages you have manually installed may not work and may have to be reinstalled. If you do not update your package(s), then R returns an error if the package cannot be used. Instructions for upgrading these packages are below.

> **Note**
> The R packages provided in the R Language Pack are automatically upgraded and do not need to be reinstalled.

1. You must uninstall the R Language package before upgrading Vertica. Any additional R packages you manually installed remain in /opt/vertica/R and are not removed when you uninstall the package.
2. Upgrade your server package as detailed in Upgrading Vertica to a New Version .
3. After the server package has been updated, install the new R Language package on each host.

If you have installed additional R packages, on each node:

1. As root run /opt/vertica/R/bin/R and issue the command:
   ```
   > update.packages(checkBuilt=TRUE)
   ```
2. Select a CRAN mirror from the list displayed.

3. You are prompted to update each package that has an update available for it. You must update any packages that you manually installed and are not compatible with the current version of R in the R Language Pack.
   Do **NOT** update:
   - Rcpp
   - Rinside
   The packages you selected to be updated are installed. Quit R with the command:

```
> quit()
```

Vertica UDx functions written in R do not need to be compiled and you do not need to reload your Vertica-R libraries and functions after an upgrade.

R packages

The Vertica R Language Pack includes the following R packages in addition to the default packages bundled with R:

- Rcpp
- RInside
- lpSolve
- lpSolveAPI

You can install additional R packages not included in the Vertica R Language Pack by using one of two methods. You must install the same packages on all nodes.

Installing R packages

You can install additional R packages by using one of the two following methods.

Using the install.packages() R command:

```
$ sudo /opt/vertica/R/bin/R
> install.packages("Zelig");
```

Using CMD INSTALL:

```
/opt/vertica/R/bin/R CMD INSTALL <path-to-package-tgz>
```

The installed packages are located in: /opt/vertica/R/library .

R and Vertica data types

The following data types are supported when passing data to/from an R UDx:

Vertica Data Type	**R Data Type**
BOOLEAN	logical
DATE, DATETIME, SMALLDATETIME, TIME, TIMESTAMP, TIMESTAMPTZ, TIMETZ	numeric
DOUBLE PRECISION, FLOAT, REAL	numeric
BIGINT, DECIMAL, INT, NUMERIC, NUMBER, MONEY	numeric
BINARY, VARBINARY	character
CHAR, VARCHAR	character

NULL values in Vertica are translated to R NA values when sent to the R function. R NA values are translated into Vertica null values when returned from the R function to Vertica.

Important

When specifying LONG VARCHAR or LONG VARBINARY data types, include the space between the two words. For example, datatype = c("long varchar")
.

Adding metadata to R libraries

You can add metadata, such as author name, the version of the library, a description of your library, and so on to your library. This metadata lets you track the version of your function that is deployed on a Vertica Analytic Database cluster and lets third-party users of your function know who created the function. Your library's metadata appears in the USER_LIBRARIES system table after your library has been loaded into the Vertica Analytic Database catalog.

You declare the metadata for your library by calling the RegisterLibrary() function in one of the source files for your UDx. If there is more than one function call in the source files for your UDx, whichever gets interpreted last as Vertica Analytic Database loads the library is used to determine the library's metadata.

The RegisterLibrary() function takes eight string parameters:

```
RegisterLibrary(author,
                library_build_tag,
                library_version,
                library_sdk_version,
                source_url,
                description,
                licenses_required,
                signature);
```

- author contains whatever name you want associated with the creation of the library (your own name or your company's name for example).
- library_build_tag is a string you want to use to represent the specific build of the library (for example, the SVN revision number or a timestamp of when the library was compiled). This is useful for tracking instances of your library as you are developing them.
- library_version is the version of your library. You can use whatever numbering or naming scheme you want.
- library_sdk_version is the version of the Vertica Analytic Database SDK Library for which you've compiled the library.

> **Note**
> This field isn't used to determine whether a library is compatible with a version of the Vertica Analytic Database server. The version of the Vertica Analytic Database SDK you use to compile your library is embedded in the library when you compile it. It is this information that Vertica Analytic Database server uses to determine if your library is compatible with it.

- source_url is a URL where users of your function can find more information about it. This can be your company's website, the GitHub page hosting your library's source code, or whatever site you like.
- description is a concise description of your library.
- licenses_required is a placeholder for licensing information. You must pass an empty string for this value.
- signature is a placeholder for a signature that will authenticate your library. You must pass an empty string for this value.

The following example shows how to add metadata to an R UDx.

```
RegisterLibrary("Speedy Analytics Ltd.",
                "1234",
                "1.0",
                "8.1.0",
                "http://www.example.com/sales_tax_calculator.R",
                "Sales Tax R Library",
                "",
                "")
```

Loading the library and querying the USER_LIBRARIES system table shows the metadata supplied in the call to RegisterLibrary :

```
=> CREATE LIBRARY rLib AS '/home/dbadmin/sales_tax_calculator.R' LANGUAGE 'R';
CREATE LIBRARY
=> SELECT * FROM USER_LIBRARIES WHERE lib_name = 'rLib';
-[ RECORD 1 ]-----+-------------------------------------------------------
schema_name       | public
lib_name          | rLib
lib_oid           | 45035996273708350
author            | Speedy Analytics Ltd.

```

Setting null input and volatility behavior for R functions

Vertica supports defining volatility and null-input settings for UDxs written in R. Both settings aid in the performance of your R function.

Volatility settings

Volatility settings describe the behavior of the function to the Vertica optimizer. For example, if you have identical rows of input data and you know the UDx is immutable, then you can define the UDx as IMMUTABLE. This tells the Vertica optimizer that it can return a cached value for subsequent identical rows on which the function is called rather than having the function run on each identical row.

To indicate your UDx's volatility, set the volatility parameter of your R factory function to one of the following values:

Value	Description
VOLATILE	Repeated calls to the function with the same arguments always result in different values. Vertica always calls volatile functions for each invocation.
IMMUTABLE	Calls to the function with the same arguments always results in the same return value.
STABLE	Repeated calls to the function with the same arguments *within the same statement* returns the same output. For example, a function that returns the current user name is stable because the user cannot change within a statement. The user name could change between statements.
DEFAULT_VOLATILITY	The default volatility. This is the same as VOLATILE.

If you do not define a volatility, then the function is considered to be VOLATILE.

The following example sets the volatility to STABLE in the multiplyTwoIntsFactory function:

```
multiplyTwoIntsFactory <- function() {
list(name                = multiplyTwoInts,
     udxtype             = c("scalar"),
     intype              = c("float","float"),
     outtype             = c("float"),
     volatility          = c("stable"),
     parametertypecallback = multiplyTwoIntsParameters)
}
```

Null input behavior

Null input setting determine how to respond to rows that have null input. For example, you can choose to return null if any inputs are null rather than calling the function and having the function deal with a NULL input.

To indicate how your UDx reacts to NULL input, set the strictness parameter of your R factory function to one of the following values:

Value	Description
CALLED_ON_NULL_INPUT	The function must be called, even if one or more arguments are NULL.
RETURN_NULL_ON_NULL_INPUT	The function always returns a NULL value if any of its arguments are NULL.
STRICT	A synonym for RETURN_NULL_ON_NULL_INPUT
DEFAULT_STRICTNESS	The default strictness setting. This is the same as CALLED_ON_NULL_INPUT.

If you do not define a null input behavior, then the function is called on every row of data regardless of the presence of NULL values.

The following example sets the NULL input behavior to STRICT in the multiplyTwoIntsFactory function:

```
multiplyTwoIntsFactory <- function() {
list(name                = multiplyTwoInts,
     udxtype             = c("scalar"),
     intype              = c("float","float"),
     outtype             = c("float"),
     strictness          = c("strict"),
     parametertypecallback = multiplyTwoIntsParameters)
}
```

Debugging tips

The following tips can help you debug your UDx before deploying it in a production environment.

Use a single node for initial debugging

You can attach to the Vertica process using a debugger such as gdb to debug your UDx code. Doing this in a multi-node environment, however, is very difficult. Therefore, consider setting up a single-node Vertica test environment to initially debug your UDx.

Use logging

Each UDx has an associated ServerInterface instance. The ServerInterface provides functions to write to the Vertica log and, in the C++ API only, a system table. See Logging for more information.

Arguments and return values

For all UDx types except load (UDL), the factory class declares the arguments and return type of the associated function. Factories have two methods for this purpose:

- getPrototype() (required): declares input and output types
- getReturnType() (sometimes required): declares the return types, including length and precision, when applicable

The getPrototype() method receives two ColumnTypes parameters, one for input and one for output. The factory in C++ example: string tokenizer takes a single input string and returns a string:

```
virtual void getPrototype(ServerInterface &srvInterface,
                          ColumnTypes &argTypes, ColumnTypes &returnType)
{
    argTypes.addVarchar();
    returnType.addVarchar();
}
```

The ColumnTypes class provides "add" methods for each supported type, like addVarchar() . This class supports complex types with the addArrayType() and addRowType() methods; see Complex Types as Arguments . If your function is polymorphic, you can instead call addAny() . You are then responsible for validating your inputs and outputs. For more information about implementing polymorphic UDxs, see Creating a polymorphic UDx .

The getReturnType() method computes a maximum length for the returned value. If your UDx returns a sized column (a return data type whose length can vary, such as a VARCHAR), a value that requires precision, or more than one value, implement this factory method. (Some UDx types require you to implement it.)

The input is a SizedColumnTypes containing the input argument types along with their lengths. Depending on the input types, add one of the following to the output types:

- CHAR, (LONG) VARCHAR, BINARY, and (LONG) VARBINARY: return the maximum length.
- NUMERIC types: specify the precision and scale.
- TIME and TIMESTAMP values (with or without timezone): specify precision.
- INTERVAL YEAR TO MONTH: specify range.
- INTERVAL DAY TO SECOND: specify precision and range.

In the case of the string tokenizer, the output is a VARCHAR and the function determines its maximum length:

```
// Tell Vertica what our return string length will be, given the input
// string length
virtual void getReturnType(ServerInterface &srvInterface,
                           const SizedColumnTypes &inputTypes,
                           SizedColumnTypes &outputTypes)
{
  // Error out if we're called with anything but 1 argument
  if (inputTypes.getColumnCount() != 1)
    vt_report_error(0, "Function only accepts 1 argument, but %zu provided", inputTypes.getColumnCount());

  int input_len = inputTypes.getColumnType(0).getStringLength();

  // Our output size will never be more than the input size
  outputTypes.addVarchar(input_len, "words");
}
```

Complex types as arguments and return values

The ColumnTypes class supports ARRAY and ROW types. Arrays have elements and rows have fields, both of which have types that you need to describe. To work with complex types, you build ColumnTypes objects for the array or row and then add them to the ColumnTypes objects representing the function inputs and outputs.

In the following example, the input to a transform function is an array of orders, which are rows, and the output is the individual rows with their positions in the array. An order consists of a shipping address (VARCHAR) and an array of product IDs (INT). The factory's getPrototype() method first creates ColumnTypes for the array and row elements and then calls addArrayType() and addRowType() using them:

```
void getPrototype(ServerInterface &srv,
        ColumnTypes &argTypes,
        ColumnTypes &retTypes)
  {
    // item ID (int), to be used in an array
    ColumnTypes itemIdProto;
    itemIdProto.addInt();

    // row: order = address (varchar) + array of previously-created item IDs
    ColumnTypes orderProto;
    orderProto.addVarchar();                /* address */
    orderProto.addArrayType(itemIdProto);   /* array of item ID */

    /* argument (input) is array of orders */
    argTypes.addArrayType(orderProto);

    /* return values: index in the array, order */
    retTypes.addInt();                      /* index of element */
    retTypes.addRowType(orderProto);        /* element return type */
  }
```

The arguments include a sized type (the VARCHAR). The getReturnType() method uses a similar approach, using the Fields class to build the two fields

in the order.

```
void getReturnType(ServerInterface &srv,
        const SizedColumnTypes &argTypes,
        SizedColumnTypes &retTypes)
{
    Fields itemIdElementFields;
    itemIdElementFields.addInt("item_id");

    Fields orderFields;
    orderFields.addVarchar(32, "address");
    orderFields.addArrayType(itemIdElementFields[0], "item_id");
                // optional third arg: max length, default unbounded

    /* declare return type */
    retTypes.addInt("index");
    static_cast<Fields &>(retTypes).addRowType(orderFields, "element");

    /* NOTE: presumably we have verified that the arguments match the prototype, so really we could just do this: */
    retTypes.addInt("index");
    retTypes.addArg(argTypes.getColumnType(0).getElementType(), "element");
}
```

To access complex types in the UDx processing method, use the ArrayReader , ArrayWriter , StructReader , and StructWriter classes.

See C++ example: using complex types for a polymorphic function that uses arrays.

Handling different numbers and types of arguments

You can create UDxs that handle multiple signatures, or even accept all arguments supplied to them by the user, using either overloading or polymorphism.

You can overload your UDx by assigning the same SQL function name to multiple factory classes, each of which defines a unique function signature. When a user uses the function name in a query, Vertica tries to match the signature of the function call to the signatures declared by the factory's getPrototype() method. This is the best technique to use if your UDx needs to accept a few different signatures (for example, accepting two required and one optional argument).

Alternatively, you can write a polymorphic function, writing one factory method instead of several and declaring that it accepts any number and type of arguments. When a user uses the function name in a query, Vertica calls your function regardless of the signature. In exchange for this flexibility, your UDx's main "process" method has to determine whether it can accept the arguments and emit errors if not.

All UDx types can use polymorphic inputs. Transform functions and analytic functions can also use polymorphic outputs. This means that getPrototype() can declare a return type of "any" and set the actual return type at runtime. For example, a function that returns the largest value in an input would return the same type as the input type.

In this section

- Overloading your UDx
- Creating a polymorphic UDx

Overloading your UDx

You may want your UDx to accept several different signatures (sets of arguments). For example, you might want your UDx to accept:

- One or more optional arguments.
- One or more arguments that can be one of several data types.
- Completely distinct signatures (either all INTEGER or all VARCHAR, for example).

You can create a function with this behavior by creating several factory classes, each of which accepts a different signature (the number and data types of arguments). You can then associate a single SQL function name with all of them. You can use the same SQL function name to refer to multiple factory classes as long as the signature defined by each factory is unique. When a user calls your UDx, Vertica matches the number and types of arguments supplied by the user to the arguments accepted by each of your function's factory classes. If one matches, Vertica uses it to instantiate a function class to process the data.

Multiple factory classes can instantiate the same function class, so you can re-use one function class that is able to process multiple sets of arguments and then create factory classes for each of the function signatures. You can also create multiple function classes if you want.

See the C++ example: overloading your UDx and Java example: overloading your UDx examples.

In this section

- C++ example: overloading your UDx
- Java example: overloading your UDx

C++ example: overloading your UDx

The following example code demonstrates creating a user-defined scalar function (UDSF) that adds two or three integers together. The Add2or3ints class is prepared to handle two or three arguments. The processBlock() function checks the number of arguments that have been passed to it, and adds all two or three of them together. It also exits with an error message if it has been called with less than 2 or more than 3 arguments. In theory, this should never happen, since Vertica only calls the UDSF if the user's function call matches a signature on one of the factory classes you create for your function. In practice, it is a good idea to perform this sanity checking, in case your (or someone else's) factory class inaccurately reports a set of arguments your function class cannot handle.

```
#include "Vertica.h"
using namespace Vertica;
using namespace std;
// a ScalarFunction that accepts two or three
// integers and adds them together.
class Add2or3ints : public Vertica::ScalarFunction
{
public:
  virtual void processBlock(Vertica::ServerInterface &srvInterface,
                            Vertica::BlockReader &arg_reader,
                            Vertica::BlockWriter &res_writer)
  {
    const size_t numCols = arg_reader.getNumCols();

    // Ensure that only two or three parameters are passed in
    if ( numCols < 2 || numCols > 3)
      vt_report_error(0, "Function only accept 2 or 3 arguments, "
                      "but %zu provided", arg_reader.getNumCols());
    // Add two integers together
    do {
      const vint a = arg_reader.getIntRef(0);
      const vint b = arg_reader.getIntRef(1);
      vint c = 0;
    // Check for third argument, add it in if it exists.
      if (numCols == 3)
        c = arg_reader.getIntRef(2);
      res_writer.setInt(a+b+c);
      res_writer.next();
    } while (arg_reader.next());
  }
};
// This factory accepts function calls with two integer arguments.
class Add2intsFactory : public Vertica::ScalarFunctionFactory
{
  virtual Vertica::ScalarFunction *createScalarFunction(Vertica::ServerInterface
          &srvInterface)
  { return vt_createFuncObj(srvInterface.allocator, Add2or3ints); }
  virtual void getPrototype(Vertica::ServerInterface &srvInterface,
                            Vertica::ColumnTypes &argTypes,
                            Vertica::ColumnTypes &returnType)
  {  // Accept 2 integer values
    argTypes.addInt();
    argTypes.addInt();
    returnType.addInt();
  }
};
RegisterFactory(Add2intsFactory);
```

```
// This factory defines a function that accepts 3 ints.
class Add3intsFactory : public Vertica::ScalarFunctionFactory
{
   virtual Vertica::ScalarFunction *createScalarFunction(Vertica::ServerInterface
         &srvInterface)
   { return vt_createFuncObj(srvInterface.allocator, Add2or3ints); }
   virtual void getPrototype(Vertica::ServerInterface &srvInterface,
                             Vertica::ColumnTypes &argTypes,
                             Vertica::ColumnTypes &returnType)
   {   // accept 3 integer values
      argTypes.addInt();
      argTypes.addInt();
      argTypes.addInt();
      returnType.addInt();
   }
};
RegisterFactory(Add3intsFactory);
```

The example has two ScalarFunctionFactory classes, one for each signature that the function accepts (two integers and three integers). There is nothing unusual about these factory classes, except that their implementation of ScalarFunctionFactory::createScalarFunction() both create Add2or3ints objects.

The final step is to bind the same SQL function name to both factory classes. You can assign multiple factories to the same SQL function, as long as the signatures defined by each factory's getPrototype() implementation are different.

```
=> CREATE LIBRARY add2or3IntsLib AS '/home/dbadmin/Add2or3Ints.so';
CREATE LIBRARY
=> CREATE FUNCTION add2or3Ints as NAME 'Add2intsFactory' LIBRARY add2or3IntsLib FENCED;
CREATE FUNCTION
=> CREATE FUNCTION add2or3Ints as NAME 'Add3intsFactory' LIBRARY add2or3IntsLib FENCED;
CREATE FUNCTION
=> SELECT add2or3Ints(1,2);

need to add explicit type casts
```

The error message in response to the final call to the add2or3Ints function was generated by Vertica, since it could not find a factory class associated with add2or3Ints that accepted four integer arguments. To expand add2or3Ints further, you could create another factory class that accepted this signature, and either change the Add2or3ints ScalarFunction class or create a totally different class to handle adding more integers together. However, adding more classes to accept each variation in the arguments quickly becomes overwhelming. In that case, you should consider creating a polymorphic UDx.

Java example: overloading your UDx

The following example code demonstrates creating a user-defined scalar function (UDSF) that adds two or three integers together. The Add2or3ints class is prepared to handle two or three arguments. It checks the number of arguments that have been passed to it, and adds all two or three of them together. The processBlock() method checks whether it has been called with less than 2 or more than 3 arguments. In theory, this should never happen, since Vertica only calls the UDSF if the user's function call matches a signature on one of the factory classes you create for your function. In practice, it is a good idea to perform this sanity checking, in case your (or someone else's) factory class reports that your function class accepts a set of arguments that it actually does not.

```
// You need to specify the full package when creating functions based on
// the classes in your library.
package com.mycompany.multiparamexample;
// Import the entire Vertica SDK
import com.vertica.sdk.*;
// This ScalarFunction accepts two or three integer arguments. It tests
// the number of input columns to determine whether to read two or three
// arguments as input.
public class Add2or3ints extends ScalarFunction
{
  @Override
  public void processBlock(ServerInterface srvInterface,
                           BlockReader argReader,
                           BlockWriter resWriter)
          throws UdfException, DestroyInvocation
  {
    // See how many arguments were passed in
    int numCols = argReader.getNumCols();

    // Return an error if less than two or more than 3 aerguments
    // were given. This error only occurs if a Factory class that
    // accepts the wrong number of arguments instantiates this
    // class.
    if (numCols < 2 || numCols > 3) {
      throw new UdfException(0,
          "Must supply 2 or 3 integer arguments");
    }

    // Process all of the rows of input.
    do {
      // Get the first two integer arguments from the BlockReader
      long a = argReader.getLong(0);
      long b = argReader.getLong(1);

      // Assume no third argument.
      long c = 0;

      // Get third argument value if it exists
      if (numCols == 3) {
        c = argReader.getLong(2);
      }

      // Process the arguments and come up with a result. For this
      // example, just add the three arguments together.
      long result = a+b+c;

      // Write the integer output value.
      resWriter.setLong(result);

      // Advance the output BlockWriter to the next row.
      resWriter.next();

      // Continue processing input rows until there are no more.
    } while (argReader.next());
  }
```

The main difference between the Add2ints class and the Add2or3ints class is the inclusion of a section that gets the number of arguments by calling BlockReader.getNumCols() . This class also tests the number of columns it received from Vertica to ensure it is in the range it is prepared to handle. This test will only fail if you create a ScalarFunctionFactory whose getPrototype() method defines a signature that accepts less than two or more than

three arguments. This is not really necessary in this simple example, but for a more complicated class it is a good idea to test the number of columns and data types that Vertica passed your function class.

Within the do loop, Add2or3ints uses a default value of zero if Vertica sent it two input columns. Otherwise, it retrieves the third value and adds that to the other two. Your own class needs to use default values for missing input columns or alter its processing in some other way to handle the variable columns.

You must define your function class in its own source file, rather than as an inner class of one of your factory classes since Java does not allow the instantiation of an inner class from outside its containing class. You factory class has to be available for instantiation by multiple factory classes.

Once you have created a function class or classes, you create a factory class for each signature you want your function class to handle. These factory classes can call individual function classes, or they can all call the same class that is prepared to accept multiple sets of arguments.

The following example's createScalarFunction() method instantiates a member of the Add2or3ints class.

```
// You will need to specify the full package when creating functions based on
// the classes in your library.
package com.mycompany.multiparamexample;
// Import the entire Vertica SDK
import com.vertica.sdk.*;
public class Add2intsFactory extends ScalarFunctionFactory
{

  @Override
  public void getPrototype(ServerInterface srvInterface,
                           ColumnTypes argTypes,
                           ColumnTypes returnType)
  {
    // Accept two integers as input
    argTypes.addInt();
    argTypes.addInt();
    // writes one integer as output
    returnType.addInt();
  }
  @Override
  public ScalarFunction createScalarFunction(ServerInterface srvInterface)
  {
    // Instantiate the class that can handle either 2 or 3 integers.
    return new Add2or3ints();
  }
```

The following ScalarFunctionFactory subclass accepts three integers as input. It, too, instantiates a member of the Add2or3ints class to process the function call:

```
// You will need to specify the full package when creating functions based on
// the classes in your library.
package com.mycompany.multiparamexample;
// Import the entire Vertica SDK
import com.vertica.sdk.*;
public class Add3intsFactory extends ScalarFunctionFactory
{
   @Override
   public void getPrototype(ServerInterface srvInterface,
                            ColumnTypes argTypes,
                            ColumnTypes returnType)
   {
      // Accepts three integers as input
      argTypes.addInt();
      argTypes.addInt();
      argTypes.addInt();
      // Returns a single integer
      returnType.addInt();
   }
   @Override
   public ScalarFunction createScalarFunction(ServerInterface srvInterface)
   {
      // Instantiates the Add2or3ints ScalarFunction class, which is able to
      // handle eitehr 2 or 3 integers as arguments.
      return new Add2or3ints();
   }
}
```

The factory classes and the function class or classes they call must be packaged into the same JAR file (see Compiling and packaging a Java library for details). If a host in the database cluster has the JDK installed on it, you could use the following commands to compile and package the example:

```
$ cd pathToJavaProject$ javac -classpath /opt/vertica/bin/VerticaSDK.jar \
> com/mycompany/multiparamexample/*.java
$ jar -cvf Add2or3intslib.jar com/vertica/sdk/BuildInfo.class \
> com/mycompany/multiparamexample/*.class
added manifest
adding: com/vertica/sdk/BuildInfo.class(in = 1202) (out= 689)(deflated 42%)
adding: com/mycompany/multiparamexample/Add2intsFactory.class(in = 677) (out= 366)(deflated 45%)
adding: com/mycompany/multiparamexample/Add2or3ints.class(in = 919) (out= 601)(deflated 34%)
adding: com/mycompany/multiparamexample/Add3intsFactory.class(in = 685) (out= 369)(deflated 46%)
```

Once you have packaged your overloaded UDx, you deploy it the same way as you do a regular UDx, except you use multiple CREATE FUNCTION statements to define the function, once for each factory class.

```
=> CREATE LIBRARY add2or3intslib as '/home/dbadmin/Add2or3intslib.jar'
-> language 'Java';
CREATE LIBRARY
=> CREATE FUNCTION add2or3ints as LANGUAGE 'Java' NAME 'com.mycompany.multiparamexample.Add2intsFactory' LIBRARY add2or3intslib;
CREATE FUNCTION
=> CREATE FUNCTION add2or3ints as LANGUAGE 'Java' NAME 'com.mycompany.multiparamexample.Add3intsFactory' LIBRARY add2or3intslib;
CREATE FUNCTION
```

You call the overloaded function the same way you call any other function.

```
=> SELECT add2or3ints(2,3);
 add2or3ints
-------------
           5
(1 row)
=> SELECT add2or3ints(2,3,4);
 add2or3ints
-------------
           9
(1 row)
=> SELECT add2or3ints(2,3,4,5);
ERROR 3457:  Function add2or3ints(int, int, int, int) does not exist, or permission is denied for add2or3ints(int, int, int, int)
HINT:  No function matches the given name and argument types. You may need to add explicit type casts
```

The last error was generated by Vertica, not the UDx code. It returns an error if it cannot find a factory class whose signature matches the function call's signature.

Creating an overloaded UDx is useful if you want your function to accept a limited set of potential arguments. If you want to create a more flexible function, you can create a polymorphic function.

Creating a polymorphic UDx

Polymorphic UDxs accept any number and type of argument that the user supplies. Transform functions (UDTFs) and analytic functions (UDAnFs) can define their output return types at runtime, usually based on the input arguments. For example, a UDTF that adds two numbers could return an integer or a float, depending on the input types.

Vertica does not check the number or types of argument that the user passes to the UDx—it just passes the UDx all of the arguments supplied by the user. It is up to your polymorphic UDx's main processing function (for example, processBlock() in user-defined scalar functions) to examine the number and types of arguments it received and determine if it can handle them. UDxs support up to 9800 arguments.

Polymorphic UDxs are more flexible than using multiple factory classes for your function (see Overloading your UDx). They also allow you to write more concise code, instead of writing versions for each data type. The tradeoff is that your polymorphic function needs to perform more work to determine whether it can process its arguments.

Your polymorphic UDx declares that it accepts any number of arguments in its factory's getPrototype() function by calling the addAny() function on the ColumnTypes object that defines its arguments, as follows:

```
// C++ example
void getPrototype(ServerInterface &srvInterface,
                  ColumnTypes &argTypes,
                  ColumnTypes &returnType)
{
    argTypes.addAny(); // Must be only argument type.
    returnType.addInt(); // or whatever the function returns
}
```

This "any parameter" argument type is the only one that your function can declare. You cannot define required arguments and then call addAny() to declare the rest of the signature as optional. If your function has requirements for the arguments it accepts, your process() function must enforce them.

The getPrototype() example shown previously accepts any type and declares that it returns an integer. The following example shows a version of the method that defers resolving the return type until runtime. You can only use the "any" return type for transform and analytic functions.

```
void getPrototype(ServerInterface &srvInterface,
                  ColumnTypes &argTypes,
                  ColumnTypes &returnType)
{
    argTypes.addAny();
    returnType.addAny(); // type determined at runtime
}
```

If you use polymorphic return types, you must also define getReturnType() in your factory. This function is called at runtime to determine the actual return type. See C++ example: PolyNthValue for an example.

Polymorphic UDxs and schema search paths

If a user does not supply a schema name as part of a UDx call, Vertica searches each schema in the schema search path for a function whose name and signature match the function call. See Setting search paths for more information about schema search paths.

Because polymorphic UDxs do not have specific signatures associated with them, Vertica initially skips them when searching for a function to handle the function call. If none of the schemas in the search path contain a UDx whose name and signature match the function call, Vertica searches the schema search path again for a polymorphic UDx whose name matches the function name in the function call.

This behavior gives precedence to a UDx whose signature exactly matches the function call. It allows you to create a "catch-all" polymorphic UDx that Vertica calls only when none of the non-polymorphic UDxs with the same name have matching signatures.

This behavior may cause confusion if your users expect the first polymorphic function in the schema search path to handle a function call. To avoid confusion, you should:

- Avoid using the same name for different UDxs. You should always uniquely name UDxs unless you intend to create an overloaded UDx with multiple signatures.
- When you cannot avoid having UDxs with the same name in different schemas, always supply the schema name as part of the function call. Using the schema name prevents ambiguity and ensures that Vertica uses the correct UDx to process your function calls.

In this section

- C++ example: PolyNthValue
- Java example: AddAnyInts
- R example: kmeansPoly

C++ example: PolyNthValue

The PolyNthValue example is an analytic function that returns the value in the Nth row in each partition in its input. This function is a generalization of FIRST_VALUE [analytic] and LAST_VALUE [analytic] .

The values can be of any primitive data type.

For the complete source code, see PolymorphicNthValue.cpp in the examples (in /opt/vertica/sdk/examples/AnalyticFunctions/).

Loading and using the example

Load the library and create the function as follows:

```
=> CREATE LIBRARY AnalyticFunctions AS '/home/dbadmin/AnalyticFns.so';
CREATE LIBRARY

=> CREATE ANALYTIC FUNCTION poly_nth_value AS LANGUAGE 'C++'
   NAME 'PolyNthValueFactory' LIBRARY AnalyticFunctions;
CREATE ANALYTIC FUNCTION
```

Consider a table of scores for different test groups:

```
=> SELECT cohort, score FROM trials;
 cohort | score
--------+-------
   1    | 9
   1    | 8
   1    | 7
   3    | 3
   3    | 2
   3    | 1
   2    | 4
   2    | 5
   2    | 6
(9 rows)
```

Call the function in a query that uses an OVER clause to partition the data. This example returns the second-highest score in each cohort:

```
=> SELECT cohort, score, poly_nth_value(score USING PARAMETERS n=2) OVER (PARTITION BY cohort) AS nth_value
FROM trials;
 cohort | score | nth_value
--------+-------+-----------
  1   | 9   |         8
  1   | 8   |         8
  1   | 7   |         8
  3   | 3   |         2
  3   | 2   |         2
  3   | 1   |         2
  2   | 4   |         5
  2   | 5   |         5
  2   | 6   |         5
(9 rows)
```

Factory implementation

The factory declares that the class is polymorphic, and then sets the return type based on the input type. Two factory methods specify the argument and return types.

Use the getPrototype() method to declare that the analytic function takes and returns any type:

```
void getPrototype(ServerInterface &srvInterface, ColumnTypes &argTypes, ColumnTypes &returnType)
{
    // This function supports any argument data type
    argTypes.addAny();

    // Output data type will be the same as the argument data type
    // We will specify that in getReturnType()
    returnType.addAny();
}
```

The getReturnType() method is called at runtime. This is where you set the return type based on the input type:

```
void getReturnType(ServerInterface &srvInterface, const SizedColumnTypes &inputTypes,
                   SizedColumnTypes &outputTypes)
{
    // This function accepts only one argument
    // Complain if we find a different number
    std::vector<size_t> argCols;
    inputTypes.getArgumentColumns(argCols); // get argument column indices

    if (argCols.size() != 1)
    {
        vt_report_error(0, "Only one argument is expected but %s provided",
                        argCols.size()? std::to_string(argCols.size()).c_str() : "none");
    }

    // Define output type the same as argument type
    outputTypes.addArg(inputTypes.getColumnType(argCols[0]), inputTypes.getColumnName(argCols[0]));
}
```

Function implementation

The analytic function itself is type-agnostic:

```
void processPartition(ServerInterface &srvInterface, AnalyticPartitionReader &inputReader,
                      AnalyticPartitionWriter &outputWriter)
{
    try {
        const SizedColumnTypes &inTypes = inputReader.getTypeMetaData();
        std::vector<size_t> argCols; // Argument column indexes.
        inTypes.getArgumentColumns(argCols);

        vint currentRow = 1;
        bool nthRowExists = false;

        // Find the value of the n-th row
        do {
            if (currentRow == this->n) {
                nthRowExists = true;
                break;
            } else {
                currentRow++;
            }
        } while (inputReader.next());

        if (nthRowExists) {
            do {
                // Return n-th value
                outputWriter.copyFromInput(0 /*dest column*/, inputReader,
                                           argCols[0] /*source column*/);
            } while (outputWriter.next());
        } else {
            // The partition has less than n rows
            // Return NULL value
            do {
                outputWriter.setNull(0);
            } while (outputWriter.next());
        }
    } catch(std::exception& e) {
        // Standard exception. Quit.
        vt_report_error(0, "Exception while processing partition: [%s]", e.what());
    }
}
};
```

Java example: AddAnyInts

The following example shows an implementation of a Java ScalarFunction that adds together two or more integers.

For the complete source code, see AddAnyIntsInfo.java in the examples (in /opt/vertica/sdk/examples/JavaUDx/ScalarFunctions).

Loading and using the example

Load the library and create the function as follows:

```
=> CREATE LIBRARY JavaScalarFunctions AS '/home/dbadmin/JavaScalarLib.jar' LANGUAGE 'JAVA';
CREATE LIBRARY

=> CREATE FUNCTION addAnyInts AS LANGUAGE 'Java' NAME 'com.vertica.JavaLibs.AddAnyIntsInfo'
   LIBRARY JavaScalarFunctions;
CREATE FUNCTION
```

Call the function with two or more integer arguments:

```
=> SELECT addAnyInts(1,2);
 addAnyInts
------------
          3
(1 row)

=> SELECT addAnyInts(1,2,3,40,50,60,70,80,900);
 addAnyInts
------------
       1206
(1 row)
```

Calling the function with too few arguments, or with non-integer arguments, produces errors that are generated from the processBlock() method. It is up to your UDx to ensure that the user supplies the correct number and types of arguments to your function and exit with an error if it cannot process them.

Function implementation

Most of the work in the example is done by the processBlock() method. It performs two checks on the arguments that have been passed in through the BlockReader object:

- There are at least two arguments.
- The data types of all arguments are integers.

It is up to your polymorphic UDx to determine that all of the input passed to it is valid.

Once the processBlock() method validates its arguments, it loops over them, adding them together.

```
    @Override
    public void processBlock(ServerInterface srvInterface,
                             BlockReader arg_reader,
                             BlockWriter res_writer)
                throws UdfException, DestroyInvocation
    {
    SizedColumnTypes inTypes = arg_reader.getTypeMetaData();
    ArrayList<Integer> argCols = new ArrayList<Integer>(); // Argument column indexes.
    inTypes.getArgumentColumns(argCols);
    // While we have inputs to process
        do {
    long sum = 0;
    for (int i = 0; i < argCols.size(); ++i){
        long a = arg_reader.getLong(i);
        sum += a;
    }
            res_writer.setLong(sum);
            res_writer.next();
        } while (arg_reader.next());
    }
}
```

Factory implementation

The factory declares the number and type of arguments in the getPrototype() function.

```
  @Override
  public void getPrototype(ServerInterface srvInterface,
                           ColumnTypes argTypes,
                           ColumnTypes returnType)
  {
  argTypes.addAny();
    returnType.addInt();
  }
```

R example: kmeansPoly

The following example shows an implementation of a Transform Function (UDTF) that performs kmeans clustering on one or more input columns.

```
kmeansPoly <- function(v.data.frame,v.param.list) {
  # Computes clusters using the kmeans algorithm.
  #
  # Input: A dataframe and a list of parameters.
  # Output: A dataframe with one column that tells the cluster to which each data
  #         point belongs.
  # Args:
  #  v.data.frame: The data from Vertica cast as an R data frame.
  #  v.param.list: List of function parameters.
  #
  # Returns:
  #  The cluster associated with each data point.
  # Ensure k is not null.
  if(!is.null(v.param.list['k'])) {
    number_of_clusters <- as.numeric(v.param.list['k'])
  } else {
    stop("k cannot be NULL! Please use a valid value.")
  }
  # Run the kmeans algorithm.
  kmeans_clusters <- kmeans(v.data.frame, number_of_clusters)
  final.output <- data.frame(kmeans_clusters$cluster)
  return(final.output)
}

kmeansFactoryPoly <- function() {
  # This function tells Vertica the name of the R function,
  # and the polymorphic parameters.
  list(name=kmeansPoly, udxtype=c("transform"), intype=c("any"),
       outtype=c("int"), parametertypecallback=kmeansParameters)
}

kmeansParameters <- function() {
  # Callback function for the parameter types.
  function.parameters <- data.frame(datatype=rep(NA, 1), length=rep(NA,1),
                                    scale=rep(NA,1), name=rep(NA,1))
  function.parameters[1,1] = "int"
  function.parameters[1,4] = "k"
  return(function.parameters)
}
```

The polymorphic R function declares it accepts any number of arguments in its factory function by specifying "any" as the argument to the intype parameter and optionally the outtype parameter. If you define "any" argument for intype or outtype , then it is the only type that your function can declare for the respective parameter. You cannot define required arguments and then call "any" to declare the rest of the signature as optional. If your function has requirements for the arguments it accepts, your process function must enforce them.

The outtypecallback method is used to indicate the argument types and sizes it has been called with, and is expected to indicate the types and sizes that the function returns. The outtypecallback method can also be used to check for unsupported types and/or number of arguments. For example, the function may require only integers, with no more than 10 of them.

You assign a SQL name to your polymorphic UDx using the same statement you use to assign one to a non-polymorphic UDx. The following statements show how you load and call the polymorphic function from the example.

```
=> CREATE LIBRARY rlib2 AS '/home/dbadmin/R_UDx/poly_kmeans.R' LANGUAGE 'R';
CREATE LIBRARY
=> CREATE TRANSFORM FUNCTION kmeansPoly AS LANGUAGE 'R' name 'kmeansFactoryPoly' LIBRARY rlib2;
CREATE FUNCTION
=> SELECT spec, kmeansPoly(sl,sw,pl,pw USING PARAMETERS k = 3)
   OVER(PARTITION BY spec) AS Clusters
    FROM iris;
    spec       | Clusters
---------------+----------
 Iris-setosa   |        1
 Iris-setosa   |        1
 Iris-setosa   |        1
 Iris-setosa   |        1
.
.
.
(150 rows)
```

UDx parameters

Parameters let you define arguments for your UDxs that remain constant across all of the rows processed by the SQL statement that calls your UDx. Typically, your UDxs accept arguments that come from columns in a SQL statement. For example, in the following SQL statement, the arguments a and b to the add2ints UDSF change value for each row processed by the SELECT statement:

```
=> SELECT a, b, add2ints(a,b) AS 'sum' FROM example;
a | b  | sum
---+----+-----
1 |  2 |   3
3 |  4 |   7
5 |  6 |  11
7 |  8 |  15
9 | 10 |  19
(5 rows)
```

Parameters remain constant for all the rows your UDx processes. You can also make parameters optional so that if the user does not supply it, your UDx uses a default value. For example, the following example demonstrates calling a UDSF named add2intsWithConstant that has a single parameter value named constant whose value is added to each the arguments supplied in each row of input:

```
=> SELECT a, b, add2intsWithConstant(a, b USING PARAMETERS constant=42)
   AS 'a+b+42' from example;
a | b  | a+b+42
---+----+--------
1 |  2 |     45
3 |  4 |     49
5 |  6 |     53
7 |  8 |     57
9 | 10 |     61
(5 rows)
```

> **Note**
> When calling a UDx with parameters, there is no comma between the last argument and the USING PARAMETERS clause.

The topics in this section explain how to develop UDxs that accept parameters.

In this section

- Defining the parameters your UDx accepts
- Getting parameter values in UDxs
- Calling UDxs with parameters
- Specifying the behavior of passing unregistered parameters
- User-defined session parameters

- C++ example: defining parameters
- C++ example: using session parameters
- Java example: defining parameters
- Java example: using session parameters

Defining the parameters your UDx accepts

You define the parameters that your UDx accepts in its factory class (ScalarFunctionFactory , AggregateFunctionFactory , and so on) by implementing getParameterType() . This method is similar to getReturnType() : you call data-type-specific methods on a SizedColumnTypes object that is passed in as a parameter. Each function call sets the name, data type, and width or precision (if the data type requires it) of the parameter.

Setting parameter properties (C++ only)

When you add parameters to the getParameterType() function using the C++ API, you can also set properties for each parameter. For example, you can define a parameter as being required by the UDx. Doing so lets the Vertica server know that every UDx invocation must provide the specified parameter, or the query fails.

By passing an object to the SizedColumnTypes::Properties class, you can define the following four parameter properties:

Parameter	Type	Description
visible	BOOLEAN	If set to TRUE, the parameter appears in the USER_FUNCTION_PARAMETERS table. You may want to set this to FALSE to declare a parameter for internal use only.
required	BOOLEAN	If set to TRUE: • The parameter is required when invoking the UDx. • Invoking the UDx without supplying the parameter results in an error, and the UDx does not run.
canBeNull	BOOLEAN	If set to TRUE, the parameter can have a NULL value. If set to FALSE, make sure that the supplied parameter does not contain a NULL value when invoking the UDx. Otherwise, an error results, and the UDx does not run.
comment	VARCHAR(128)	A comment to describe the parameter. If you exceed the 128 character limit, Vertica generates an error when you run the CREATE_FUNCTION command. Additionally, if you replace the existing function definition in the comment parameter, make sure that the new definition does not exceed 128 characters. Otherwise, you delete all existing entries in the USER_FUNCTION_PARAMETERS table related to the UDx.

Setting parameter properties (R only)

When using parameters in your R UDx, you must specify a field in the factory function called parametertypecallback . This field points to the callback function that defines the parameters expected by the function. The callback function defines a four-column data frame with the following properties:

Parameter	Type	Description
datatype	VARCHAR(128)	The data type of the parameter.
length	INTEGER	The dimension of the parameter.
scale	INTEGER	The proportional dimensions of the parameter.
name	VARCHAR(128)	The name of the parameter.

If any of the columns are left blank (or the parametertypecallback function is omitted), then Vertica uses default values.

For more information, see Parametertypecallback function .

Getting parameter values in UDxs

Your UDx uses the parameter values it declared in its factory class (see Defining the parameters your UDx accepts) in its function class's processing method (for example, processBlock() or processPartition()). It gets its parameter values from a ParamReader object, which is available from the ServerInterface object that is passed to your processing method. Reading parameters from this object is similar to reading argument values from BlockReader or PartitionReader objects: you call a data-type-specific function with the name of the parameter to retrieve its value. For example, in C++:

```
// Get the parameter reader from the ServerInterface to see if there are supplied parameters.
ParamReader paramReader = srvInterface.getParamReader();
// Get the value of an int parameter named constant.
const vint constant = paramReader.getIntRef("constant");
```

> **Note**
> String data values do not have any of their escape characters processed before they are passed to your function. Therefore, your function may need to process the escape sequences itself if it needs to operate on unescaped character values.

Using parameters in the factory class

In addition to using parameters in your UDx function class, you can also access the parameters in the factory class. You may want to access the parameters to let the user control the input or output values of your function in some way. For example, your UDx can have a parameter that lets the user choose to have your UDx return a single- or double-precision value. The process of accessing parameters in the factory class is the same as accessing it in the function class: get a ParamReader object from the ServerInterface 's getParamReader() method, them read the parameter values.

Testing whether the user supplied parameter values

Unlike its handling of arguments, Vertica does not immediately return an error if a user's function call does not include a value for a parameter defined by your UDx's factory class. This means that your function can attempt to read a parameter value that the user did not supply. If it does so, by default Vertica returns a non-existent parameter warning to the user, and the query containing the function call continues.

If you want your parameter to be optional, you can test whether the user supplied a value for the parameter before attempting to access its value. Your function determines if a value exists for a particular parameter by calling the ParamReader 's containsParameter() method with the parameter's name. If this call returns true, your function can safely retrieve the value. If this call returns false, your UDx can use a default value or change its processing in some other way to compensate for not having the parameter value. As long as your UDx does not try to access the non-existent parameter value, Vertica does not generate an error or warning about missing parameters.

> **Note**
> If the user passes your UDx a parameter that it has not defined, by default Vertica issues a warning that the parameter is not used. It still executes the SQL statement, ignoring the parameter. You can change this behavior by altering the `StrictUDxParameterChecking` configuration parameter.

See C++ example: defining parameters for an example.

Calling UDxs with parameters

You pass parameters to a UDx by adding a USING PARAMETERS clause in the function call after the last argument.

- Do *not* insert a comma between the last argument and the USING PARAMETERS clause.
- After the USING PARAMETERS clause, add one or more parameter definitions, in the following form:
  <parameter name> = <parameter value>
- Separate parameter definitions by commas.

Parameter values can be a constant expression (for example 1234 + SQRT(5678)). You cannot use volatile functions (such as RANDOM) in the expression, because they do not return a constant value. If you do supply a volatile expression as a parameter value, by default, Vertica returns an incorrect parameter type warning. Vertica then tries to run the UDx without the parameter value. If the UDx requires the parameter, it returns its own error, which cancels the query.

Calling a UDx with a single parameter

The following example demonstrates how you can call the Add2intsWithConstant UDSF example shown in C++ example: defining parameters :

```
=> SELECT a, b, Add2intsWithConstant(a, b USING PARAMETERS constant=42) AS 'a+b+42' from example;
 a | b  | a+b+42
---+----+--------
 1 |  2 |     45
 3 |  4 |     49
 5 |  6 |     53
 7 |  8 |     57
 9 | 10 |     61
(5 rows)
```

To remove the first instance of the number 3, you can call the RemoveSymbol UDSF example:

```
=> SELECT '3re3mo3ve3sy3mb3ol' original_string, RemoveSymbol('3re3mo3ve3sy3mb3ol' USING PARAMETERS symbol='3');
  original_string   |    RemoveSymbol
--------------------+--------------------
 3re3mo3ve3sy3mb3ol | re3mo3ve3sy3mb3ol
(1 row)
```

Calling a UDx with multiple parameters

The following example shows how you can call a version of the tokenize UDTF. This UDTF includes parameters to limit the shortest allowed word and force the words to be output in uppercase. Separate multiple parameters with commas.

```
=> SELECT url, tokenize(description USING PARAMETERS minLength=4, uppercase=true) OVER (partition by url) FROM T;
       url       |   words
-----------------+-----------
 www.amazon.com  | ONLINE
 www.amazon.com  | RETAIL
 www.amazon.com  | MERCHANT
 www.amazon.com  | PROVIDER
 www.amazon.com  | CLOUD
 www.amazon.com  | SERVICES
 www.dell.com    | LEADING
 www.dell.com    | PROVIDER
 www.dell.com    | COMPUTER
 www.dell.com    | HARDWARE
 www.vertica.com | WORLD'S
 www.vertica.com | FASTEST
 www.vertica.com | ANALYTIC
 www.vertica.com | DATABASE
(16 rows)
```

The following example calls the RemoveSymbol UDSF. By changing the value of the optional parameter, n , you can remove all instances of the number 3:

```
=> SELECT '3re3mo3ve3sy3mb3ol' original_string, RemoveSymbol('3re3mo3ve3sy3mb3ol' USING PARAMETERS symbol='3', n=6);
  original_string   | RemoveSymbol
--------------------+--------------
 3re3mo3ve3sy3mb3ol | removesymbol
(1 row)
```

Calling a UDx with optional or incorrect parameters

You can optionally add the Add2intsWithConstant UDSF's constant parameter. Calling this constraint without the parameter does not return an error or warning:

```
=> SELECT a,b,Add2intsWithConstant(a, b) AS 'sum' FROM example;
 a | b  | sum
---+----+-----
 1 |  2 |   3
 3 |  4 |   7
 5 |  6 |  11
 7 |  8 |  15
 9 | 10 |  19
(5 rows)
```

Although calling a UDx with incorrect parameters generates a warning, by default, the query still runs. For further information on setting the behavior of your UDx when you supply incorrect parameters, see Specifying the behavior of passing unregistered parameters .

```
=> SELECT a, b,  add2intsWithConstant(a, b USING PARAMETERS wrongparam=42) AS 'result' from example;
WARNING 4332:  Parameter wrongparam was not registered by the function and cannot
be coerced to a definite data type
 a | b  | result
---+----+--------
 1 |  2 |      3
 3 |  4 |      7
 5 |  6 |     11
 7 |  8 |     15
 9 | 10 |     19
(5 rows)
```

Specifying the behavior of passing unregistered parameters

By default, Vertica issues a warning message when you pass a UDx an unregistered parameter. An *unregistered parameter* is one that you did not declare in the getParameterType() method.

You can control the behavior of your UDx when you pass it an unregistered parameter by altering the StrictUDxParameterChecking configuration parameter.

Unregistered parameter behavior settings

You can specify the behavior of your UDx in response to one or more unregistered parameters. To do so, set the StrictUDxParameterChecking configuration parameter to one of the following values:

Value	Description
0	Allows unregistered parameters to be accessible to the UDx. The ParamReader class's getType() method determines the data type of the unregistered parameter. Vertica does not display any warning or error message.
1	[Default Value] Ignores the unregistered parameter and allows the function to run. Vertica displays a warning message.
2	Returns an error and does not allow the function to run.

Examples

The following examples demonstrate the behavior you can specify using different values with the StrictUDxParameterChecking parameter.

View the current value of StrictUDxParameterChecking

To view the current value of the StrictUDxParameterChecking configuration parameter, run the following query:

```
=> \x
Expanded display is on.
=> SELECT * FROM configuration_parameters WHERE parameter_name = 'StrictUDxParameterChecking';
-[ RECORD 1 ]----------------+--------------------------------------------------------------------
node_name                    | ALL
parameter_name               | StrictUDxParameterChecking
current_value                | 1
restart_value                | 1
database_value               | 1
default_value                | 1
current_level                | DATABASE
restart_level                | DATABASE
is_mismatch                  | f
groups                       |
allowed_levels               | DATABASE
superuser_only               | f
change_under_support_guidance | f
change_requires_restart      | f
description                  | Sets the behavior to deal with undeclared UDx function parameters
```

Change the value of StrictUDxParameterChecking

You can change the value of the StrictUDxParameterChecking configuration parameter at the database, node, or session level. For example, you can change the value to '0' to specify that unregistered parameters can pass to the UDx without displaying a warning or error message:

```
=> ALTER DATABASE DEFAULT SET StrictUDxParameterChecking = 0;
ALTER DATABASE
```

Invalid parameter behavior with RemoveSymbol

The following example demonstrates how to call the RemoveSymbol UDSF example. The RemoveSymbol UDSF has a required parameter, symbol , and an optional parameter, n . In this case, you do not use the optional parameter.

If you pass both symbol and an additional parameter called wrongParam , which is not declared in the UDx, the behavior of the UDx changes corresponding to the value of StrictUDxParameterChecking .

When you set StrictUDxParameterChecking to '0', the UDx runs normally without a warning. Additionally, wrongParam becomes accessible to the UDx through the ParamReader object of the ServerInterface object:

```
=> ALTER DATABASE DEFAULT SET StrictUDxParameterChecking = 0;
ALTER DATABASE

=> SELECT '3re3mo3ve3sy3mb3ol' original_string, RemoveSymbol('3re3mo3ve3sy3mb3ol' USING PARAMETERS symbol='3', wrongParam='x');
  original_string   |   RemoveSymbol
--------------------+-------------------
 3re3mo3ve3sy3mb3ol | re3mo3ve3sy3mb3ol
(1 row)
```

When you set StrictUDxParameterChecking to '1', the UDx ignores wrongParam and runs normally. However, it also issues a warning message:

```
=> ALTER DATABASE DEFAULT SET StrictUDxParameterChecking = 1;
ALTER DATABASE

=> SELECT '3re3mo3ve3sy3mb3ol' original_string, RemoveSymbol('3re3mo3ve3sy3mb3ol' USING PARAMETERS symbol='3', wrongParam='x');
WARNING 4320:  Parameter wrongParam was not registered by the function and cannot be coerced to a definite data type
  original_string   |   RemoveSymbol
--------------------+-------------------
 3re3mo3ve3sy3mb3ol | re3mo3ve3sy3mb3ol
(1 row)
```

When you set StrictUDxParameterChecking to '2', the UDx encounters an error when it tries to call wrongParam and does not run. Instead, it generates an error message:

```
=> ALTER DATABASE DEFAULT SET StrictUDxParameterChecking = 2;
ALTER DATABASE

=> SELECT '3re3mo3ve3sy3mb3ol' original_string, RemoveSymbol('3re3mo3ve3sy3mb3ol' USING PARAMETERS symbol='3', wrongParam='x');
ERROR 0:  Parameter wrongParam was not registered by the function
```

Managing configuration parameters: VSQL

User-defined session parameters

User-defined session parameters allow you to write more generalized parameters than what Vertica provides. You can configure user-defined session parameters in these ways:

- From the client—for example, with ALTER SESSION
- Through the UDx itself

A user-defined session parameter can be passed into any type of UDx supported by Vertica. You can also set parameters for your UDx at the session level. By specifying a user-defined session parameter, you can have the state of a parameter saved continuously. Vertica saves the state of the parameter even when the UDx is invoked multiple times during a single session.

The RowCount example uses a user-defined session parameter. This parameter counts the total number of rows processed by the UDx each time it runs. RowCount then displays the aggregate number of rows processed for all executions. See C++ example: using session parameters and Java example: using session parameters for implementations.

Viewing the user-defined session parameter

Enter the following command to see the value of all session parameters:

```
=> SHOW SESSION UDPARAMETER all;
schema | library | key | value
--------+---------+-----+-------
(0 rows)
```

No value has been set, so the table is empty. Now, execute the UDx:

```
=> SELECT RowCount(5,5);
RowCount
----------
10
(1 row)
```

Again, enter the command to see the value of the session parameter:

```
=> SHOW SESSION UDPARAMETER all;
schema |  library  |   key    | value
--------+-----------+----------+-------
public | UDSession | rowcount | 1
(1 row)
```

The library column shows the name of the library containing the UDx. This is the name set with CREATE LIBRARY. Because the UDx has processed one row, the value of the rowcount session parameter is now 1. Running the UDx two more times should increment the value twice.

```
=> SELECT RowCount(10,10);
RowCount
----------
20
(1 row)
=> SELECT RowCount(15,15);
RowCount
----------
30
(1 row)
```

You have now executed the UDx three times, obtaining the sum of 5 + 5, 10 + 10, and 15 + 15. Now, check the value of rowcount.

```
=> SHOW SESSION UDPARAMETER all;
schema |  library  |   key    | value
--------+-----------+----------+-------
public | UDSession | rowcount | 3
(1 row)
```

Altering the user-defined session parameter

You can also manually alter the value of rowcount. To do so, enter the following command:

```
=> ALTER SESSION SET UDPARAMETER FOR UDSession rowcount = 25;
ALTER SESSION
```

Check the value of RowCount:

```
=> SHOW SESSION UDPARAMETER all;
schema |  library  |   key    | value
--------+-----------+----------+-------
public | UDSession | rowcount | 25
(1 row)
```

Clearing the user-defined session parameter

From the client :

To clear the current value of rowcount, enter the following command:

```
=> ALTER SESSION CLEAR UDPARAMETER FOR UDSession rowcount;
ALTER SESSION
```

Verify that rowcount has been cleared:

```
=> SHOW SESSION UDPARAMETER all;
schema | library | key | value
--------+---------+-----+-------
(0 rows)
```

Through the UDx in C++ :

You can set the session parameter to clear through the UDx itself. For example, to clear rowcount when its value reaches 10 or greater, do the following:

1. Remove the following line from the destroy() method in the RowCount class:
   ```
   udParams.getUDSessionParamWriter("library").getStringRef("rowCount").copy(i_as_string);
   ```
2. Replace the removed line from the destroy() method with the following code:
   ```
   if (rowCount < 10)
   {
   udParams.getUDSessionParamWriter("library").getStringRef("rowCount").copy(i_as_string);
   }
   else
   {
   udParams.getUDSessionParamWriter("library").clearParameter("rowCount");
   }
   ```
3. To see the UDx clear the session parameter, set rowcount to a value of 9:
   ```
   => ALTER SESSION SET UDPARAMETER FOR UDSession rowcount = 9;
   ALTER SESSION
   ```
4. Check the value of rowcount:

```
=> SHOW SESSION UDPARAMETER all;
 schema |  library  |   key    | value
--------+-----------+----------+-------
 public | UDSession | rowcount | 9
 (1 row)
```

5. Invoke RowCount so that its value becomes 10:

```
=> SELECT RowCount(15,15);
RowCount
----------
      30
 (1 row)
```

6. Check the value of rowcount again. Because the value has reached 10, the threshold specified in the UDx, expect that rowcount is cleared:

```
=> SHOW SESSION UDPARAMETER all;
 schema | library | key | value
--------+---------+-----+-------
 (0 rows)
```

As expected, RowCount is cleared.

Through the UDx in Java :

1. Remove the following lines from the destroy() method in the RowCount class:

```
udParams.getUDSessionParamWriter("library").setString("rowCount", Integer.toString(rowCount));
srvInterface.log("RowNumber processed %d records", count);
```

2. Replace the removed lines from the destroy() method with the following code:

```

if (rowCount < 10)
{
udParams.getUDSessionParamWriter("library").setString("rowCount", Integer.toString(rowCount));
srvInterface.log("RowNumber processed %d records", count);
}
else
{
udParams.getUDSessionParamWriter("library").clearParameter("rowCount");
}
```

3. To see the UDx clear the session parameter, set rowcount to a value of 9:

```
=> ALTER SESSION SET UDPARAMETER FOR UDSession rowcount = 9;
ALTER SESSION
```

4. Check the value of rowcount:

```
=> SHOW SESSION UDPARAMETER all;
 schema |  library  |   key    | value
--------+-----------+----------+-------
 public | UDSession | rowcount | 9
 (1 row)
```

5. Invoke RowCount so that its value becomes 10:

```
=> SELECT RowCount(15,15);
RowCount
----------
      30
 (1 row)
```

6. Check the value of rowcount. Since the value has reached 10, the threshold specified in the UDx, expect that rowcount is cleared:

```
=> SHOW SESSION UDPARAMETER all;
 schema | library | key | value
--------+---------+-----+-------
 (0 rows)
```

As expected, rowcount is cleared.

Read-only and hidden session parameters

If you don't want a parameter to be set anywhere except in the UDx, you can make it read-only. If, additionally, you don't want a parameter to be visible in the client, you can make it hidden.

To make a parameter read-only, meaning that it cannot be set in the client, but can be viewed, add a single underscore before the parameter's name. For example, to make rowCount read-only, change all instances in the UDx of "rowCount" to "_rowCount".

To make a parameter hidden, meaning that it cannot be viewed in the client nor set, add two underscores before the parameter's name. For example, to make rowCount hidden, change all instances in the UDx of "rowCount" to "__rowCount".

Kafka user-defined session parameters

C++ example: defining parameters

The following code fragment demonstrates adding a single parameter to the C++ add2ints UDSF example. The getParameterType() function defines a single integer parameter that is named constant .

```
class Add2intsWithConstantFactory : public ScalarFunctionFactory
{
    // Return an instance of Add2ints to perform the actual addition.
    virtual ScalarFunction *createScalarFunction(ServerInterface &interface)
    {
        // Calls the vt_createFuncObj to create the new Add2ints class instance.
        return vt_createFuncObj(interface.allocator, Add2intsWithConstant);
    }
    // Report the argument and return types to Vertica.
    virtual void getPrototype(ServerInterface &interface,
                              ColumnTypes &argTypes,
                              ColumnTypes &returnType)
    {
        // Takes two ints as inputs, so add ints to the argTypes object.
        argTypes.addInt();
        argTypes.addInt();
        // Returns a single int.
        returnType.addInt();
    }
    // Defines the parameters for this UDSF. Works similarly to defining arguments and return types.
    virtual void getParameterType(ServerInterface &srvInterface,
                                  SizedColumnTypes &parameterTypes)
    {
        // One int parameter named constant.
        parameterTypes.addInt("constant");
    }
};
RegisterFactory(Add2intsWithConstantFactory);
```

See the Vertica SDK entry for SizedColumnTypes for a full list of the data-type-specific functions you can call to define parameters.

The following code fragment demonstrates using the parameter value. The Add2intsWithConstant class defines a function that adds two integer values. If the user supplies it, the function also adds the value of the optional integer parameter named constant.

```
/**
 * A UDSF that adds two numbers together with a constant value.
 *
 */
class Add2intsWithConstant : public ScalarFunction
{
public:
    // Processes a block of data sent by Vertica.
    virtual void processBlock(ServerInterface &srvInterface,
                              BlockReader &arg_reader,
                              BlockWriter &res_writer)
    {
        try
            {
                // The default value for the constant parameter is 0.
                vint constant = 0;

                // Get the parameter reader from the ServerInterface to see if there are supplied parameters.
                ParamReader paramReader = srvInterface.getParamReader();
                // See if the user supplied the constant parameter.
                if (paramReader.containsParameter("constant"))
                    // There is a parameter, so get its value.
                    constant = paramReader.getIntRef("constant");
                // While we have input to process:
                do
                    {
                        // Read the two integer input parameters by calling the BlockReader.getIntRef class function.
                        const vint a = arg_reader.getIntRef(0);
                        const vint b = arg_reader.getIntRef(1);
                        // Add arguments plus constant.
                        res_writer.setInt(a+b+constant);
                        // Finish writing the row, and advance to the next output row.
                        res_writer.next();
                        // Continue looping until there are no more input rows.
                    }
                while (arg_reader.next());
            }
        catch (exception& e)
            {
                // Standard exception. Quit.
                vt_report_error(0, "Exception while processing partition: %s",
                    e.what());
            }
    }
};
```

C++ example: using session parameters

The RowCount example uses a user-defined session parameter, also called RowCount. This parameter counts the total number of rows processed by the UDx each time it runs. RowCount then displays the aggregate number of rows processed for all executions.

```
#include <string>
#include <sstream>
#include <iostream>
#include "Vertica.h"
#include "VerticaUDx.h"

using namespace Vertica;

class RowCount : public Vertica::ScalarFunction
{
private:
```

```
private:
  int rowCount;
  int count;

public:

  virtual void setup(Vertica::ServerInterface &srvInterface, const Vertica::SizedColumnTypes &argTypes) {
    ParamReader pSessionParams = srvInterface.getUDSessionParamReader("library");
    std::string rCount = pSessionParams.containsParameter("rowCount")?
      pSessionParams.getStringRef("rowCount").str(): "0";
    rowCount=atoi(rCount.c_str());

  }
  virtual void processBlock(Vertica::ServerInterface &srvInterface, Vertica::BlockReader &arg_reader, Vertica::BlockWriter &res_writer) {

    count = 0;
    if(arg_reader.getNumCols() != 2)
      vt_report_error(0, "Function only accepts two arguments, but %zu provided", arg_reader.getNumCols());

    do {
      const Vertica::vint a = arg_reader.getIntRef(0);
      const Vertica::vint b = arg_reader.getIntRef(1);
      res_writer.setInt(a+b);
      count++;
      res_writer.next();
    } while (arg_reader.next());

    srvInterface.log("count %d", count);

    }

    virtual void destroy(ServerInterface &srvInterface, const SizedColumnTypes &argTypes, SessionParamWriterMap &udParams) {
      rowCount = rowCount + count;

      std:ostringstream s;
      s << rowCount;
      const std::string i_as_string(s.str());

      udParams.getUDSessionParamWriter("library").getStringRef("rowCount").copy(i_as_string);

    }
};

class RowCountsInfo : public Vertica::ScalarFunctionFactory {
  virtual Vertica::ScalarFunction *createScalarFunction(Vertica::ServerInterface &srvInterface)
  { return Vertica::vt_createFuncObject<RowCount>(srvInterface.allocator);
  }

  virtual void getPrototype(Vertica::ServerInterface &srvInterface, Vertica::ColumnTypes &argTypes, Vertica::ColumnTypes &returnType)
  {
    argTypes.addInt();
    argTypes.addInt();
    returnType.addInt();
  }
};

RegisterFactory(RowCountsInfo);
```

Java example: defining parameters

The following code fragment demonstrates adding a single parameter to the Java add2ints UDSF example. The getParameterType() method defines a single integer parameter that is named constant.

```
package com.mycompany.example;
import com.vertica.sdk.*;
public class Add2intsWithConstantFactory extends ScalarFunctionFactory
{

  @Override
  public void getPrototype(ServerInterface srvInterface,
                           ColumnTypes argTypes,
                           ColumnTypes returnType)
  {
    argTypes.addInt();
    argTypes.addInt();
    returnType.addInt();
  }

  @Override
  public void getReturnType(ServerInterface srvInterface,
                            SizedColumnTypes argTypes,
                            SizedColumnTypes returnType)
  {
    returnType.addInt("sum");
  }

  // Defines the parameters for this UDSF. Works similarly to defining
  // arguments and return types.
  public void getParameterType(ServerInterface srvInterface,
                               SizedColumnTypes parameterTypes)
  {
    // One INTEGER parameter named constant
    parameterTypes.addInt("constant");
  }

  @Override
  public ScalarFunction createScalarFunction(ServerInterface srvInterface)
  {
    return new Add2intsWithConstant();
  }
```

See the Vertica Java SDK entry for SizedColumnTypes for a full list of the data-type-specific methods you can call to define parameters.

Java example: using session parameters

The RowCount example uses a user-defined session parameter, also called RowCount. This parameter counts the total number of rows processed by the UDx each time it runs. RowCount then displays the aggregate number of rows processed for all executions.

```
package com.mycompany.example;

import com.vertica.sdk.*;

public class RowCountFactory extends ScalarFunctionFactory {

   @Override
   public void getPrototype(ServerInterface srvInterface, ColumnTypes argTypes, ColumnTypes returnType)
   {
      argTypes.addInt();
      argTypes.addInt();
    returnType.addInt();
   }

public class RowCount extends ScalarFunction {

   private Integer count;
   private Integer rowCount;

   // In the setup method, you look for the rowCount parameter. If it doesn't exist, it is created.
   // Look in the default namespace which is "library," but it could be anything else, most likely "public" if not "library".
   @Override
      public void setup(ServerInterface srvInterface, SizedColumnTypes argTypes) {
   count = new Integer(0);
   ParamReader pSessionParams = srvInterface.getUDSessionParamReader("library");
   String rCount = pSessionParams.containsParameter("rowCount")?
   pSessionParams.getString("rowCount"): "0";
   rowCount = Integer.parseInt(rCount);

   }

   @Override
   public void processBlock(ServerInterface srvInterface, BlockReader arg_reader, BlockWriter res_writer)
      throws UdfException, DestroyInvocation {
      do {
      ++count;
      long a = arg_reader.getLong(0);
      long b = arg_reader.getLong(1);

      res_writer.setLong(a+b);
      res_writer.next();
      } while (arg_reader.next());
   }

   @Override
   public void destroy(ServerInterface srvInterface, SizedColumnTypes argTypes, SessionParamWriterMap udParams){
      rowCount = rowCount+count;
      udParams.getUDSessionParamWriter("library").setString("rowCount", Integer.toString(rowCount));
      srvInterface.log("RowNumber processed %d records", count);
      }
   }

   @Override
   public ScalarFunction createScalarFunction(ServerInterface srvInterface){
      return new RowCount();
   }
```

Errors, warnings, and logging

The SDK provides several ways for a UDx to report errors, warnings, and other messages. For a UDx written in C++ or Python, use the messaging APIs described in Sending messages . UDxs in all languages can halt execution with an error, as explained in Handling errors .

UDxs can also write messages to the Vertica log , and UDxs written in C++ can write messages to a system table.

In this section

- Sending messages
- Handling errors
- Logging

Sending messages

A UDx can handle a problem by reporting an error and terminating execution, but in some cases you might want to send a warning and proceed. For example, a UDx might ignore or use a default for an unexpected input and report that it did so. The C++ and Python messaging APIs support reporting messages at different severity levels.

A UDx has access to a ServerInterface instance. This class has the following methods for reporting messages, in order of severity:

- reportError (also terminates execution)
- reportWarning
- reportNotice
- reportInfo

Each method produces messages with the following components:

- ID code: an identification code, any integer. This code does not interact with Vertica error codes.
- Message string: a succinct description of the issue.
- Optional details string: provides more contextual information.
- Optional hint string: provides other guidance.

Duplicate messages are condensed into a single report if they have the same code and message string, even if the details and hint strings differ.

Constructing messages

The UDx should report errors immediately, usually during a process call. For all other message types, record information during processing and call the reporting methods from the UDx's destroy method. The other reporting methods do not produce output if called during processing.

The process of constructing messages is language-specific.

C++

Each ServerInterface reporting method takes a ClientMessage argument. The ClientMessage class has the following methods to set the code and message, detail, and hint:

- makeMessage: sets the ID code and message string.
- setDetail: sets the optional detail string.
- setHint: sets the optional hint string.

These method calls can be chained to simplify creating and passing the message.

All strings support printf -style arguments and formatting.

In the following example, a function records issues in processBlock and reports them in destroy :

```
class PositiveIdentity : public Vertica::ScalarFunction
{
public:
    using ScalarFunction::destroy;
    bool hitNotice = false;

    virtual void processBlock(Vertica::ServerInterface &srvInterface,
                              Vertica::BlockReader &arg_reader,
                              Vertica::BlockWriter &res_writer)
    {
        do {
            const Vertica::vint a = arg_reader.getIntRef(0);
            if (a < 0 && a != vint_null) {
                hitNotice = true;
                res_writer.setInt(null);
            } else {
                res_writer.setInt(a);
            }
            res_writer.next();
        } while (arg_reader.next());
    }

    virtual void destroy(ServerInterface &srvInterface,
                         const SizedColumnTypes &argTypes) override
    {
        if (hitNotice) {
            ClientMessage msg = ClientMessage::makeMessage(100, "Passed negative argument")
                                .setDetail("Value set to null");
            srvInterface.reportNotice(msg);
        }
    }
```

Python

Each ServerInterface reporting method has the following positional and keyword arguments:

- *idCode* : integer ID code, positional argument.
- *message* : message text, positional argument.
- *hint* : optional hint text, keyword argument.
- *detail* : optional detail text, keyword argument.

All arguments support str.format() and f-string formatting.

In the following example, a function records issues in processBlock and reports them in destroy :

```
class PositiveIdentity(vertica_sdk.ScalarFunction):
  def __init__(self):
    self.hitNotice = False

  def processBlock(self, server_interface, arg_reader, res_writer):
    while True:
      arg = arg_reader.getInt(0)
      if arg < 0 and arg is not None:
        self.hitNotice = True
        res_writer.setNull()
      else:
        res_writer.setInt(arg)
      res_writer.next()
      if not arg_reader.next():
        break

  def destroy(self, srv, argType):
    if self.hitNotice:
      srv.reportNotice(100, "Passed negative arguement", detail="Value set to null")
    return
```

API

C++

Python

Before calling a ServerInterface reporting method, construct and populate a message with the ClientMessage class.

The ServerInterface API provides the following methods for reporting messages:

```
// ClientMessage methods
template<typename... Argtypes>
static ClientMessage makeMessage(int errorcode, const char *fmt, Argtypes&&... args);

template <typename... Argtypes>
ClientMessage & setDetail(const char *fmt, Argtypes&&... args);

template <typename... Argtypes>
ClientMessage & setHint(const char *fmt, Argtypes&&... args);

// ServerInterface reporting methods
virtual void reportError(ClientMessage msg);

virtual void reportInfo(ClientMessage msg);

virtual void reportNotice(ClientMessage msg);

virtual void reportWarning(ClientMessage msg);
```

Handling errors

If your UDx encounters an unrecoverable error, it should report the error and terminate. How you do this depends on the language:

- C++: Consider using the API described in Sending messages , which is more expressive than the error-handling described in this topic. Alternatively, you can use the vt_report_error macro to report an error and exit. The macro takes two parameters: an error number and an error message string. Both the error number and message appear in the error that Vertica reports to the user. The error number is not defined by Vertica. You can use whatever value that you wish.

- Java: Instantiate and throw a UdfException , which takes a numeric code and a message string to report to the user.
- Python: Consider using the API described in Sending messages , which is more expressive than the error-handling described in this topic. Alternatively, raise an exception built into the Python language; the SDK does not include a UDx-specific exception.
- R: Use stop to halt execution with a message.

An exception or halt causes the transaction containing the function call to be rolled back.

The following examples demonstrate error-handling:

C++

Java

Python

R

The following function divides two integers. To prevent division by zero, it tests the second parameter and fails if it is zero:

```
class Div2ints : public ScalarFunction
{
public:
  virtual void processBlock(ServerInterface &srvInterface,
                            BlockReader &arg_reader,
                            BlockWriter &res_writer)
  {
    // While we have inputs to process
    do
      {
        const vint a = arg_reader.getIntRef(0);
        const vint b = arg_reader.getIntRef(1);
        if (b == 0)
          {
            vt_report_error(1,"Attempted divide by zero");
          }
        res_writer.setInt(a/b);
        res_writer.next();
      }
    while (arg_reader.next());
  }
};
```

Loading and invoking the function demonstrates how the error appears to the user. Fenced and unfenced modes use different error numbers.

```
=> CREATE LIBRARY Div2IntsLib AS '/home/dbadmin/Div2ints.so';
CREATE LIBRARY
=> CREATE FUNCTION div2ints AS LANGUAGE 'C++' NAME 'Div2intsInfo' LIBRARY Div2IntsLib;
CREATE FUNCTION
=> SELECT div2ints(25, 5);
 div2ints
----------
        5
(1 row)
=> SELECT * FROM MyTable;
 a  | b
----+---
 12 | 6
  7 | 0
 12 | 2
 18 | 9
(4 rows)
=> SELECT * FROM MyTable WHERE div2ints(a, b) > 2;
ERROR 3399:  Error in calling processBlock() for User Defined Scalar Function
div2ints at Div2ints.cpp:21, error code: 1, message: Attempted divide by zero
```

To report additional diagnostic information about the error, you can write messages to a log file before throwing the exception (see Logging).

Your UDx must not consume exceptions that it did not throw. Intercepting server exceptions can lead to database instability.

Logging

Each UDx written in C++, Java, or Python has an associated instance of ServerInterface . The ServerInterface class provides a function to write to the Vertica log, and the C++ implementation also provides a function to log events in a system table.

Writing messages to the Vertica log

You can write to log files using the ServerInterface.log() function. The function acts similarly to printf() , taking a formatted string and an optional set of values and writing the string to the log file. Where the message is written depends on whether your function runs in fenced mode or unfenced mode:

- Functions running in unfenced mode write their messages into the vertica.log file in the catalog directory.
- Functions running in fenced mode write their messages into a log file named UDxLogs/UDxFencedProcesses.log in the catalog directory.

To help identify your function's output, Vertica adds the SQL function name bound to your UDx to the log message.

The following example logs a UDx's input values:

C++

Java

Python

```
virtual void processBlock(ServerInterface &srvInterface,
                          BlockReader &argReader,
                          BlockWriter &resWriter)
{
    try {
        // While we have inputs to process
        do {
            if (argReader.isNull(0) || argReader.isNull(1)) {
                resWriter.setNull();
            } else {
                const vint a = argReader.getIntRef(0);
                const vint b = argReader.getIntRef(1);
                <span class="code-input">srvInterface.log("got a: %d and b: %d", (int) a, (int) b);</span>
                resWriter.setInt(a+b);
            }
            resWriter.next();
        } while (argReader.next());
    } catch(std::exception& e) {
        // Standard exception. Quit.
        vt_report_error(0, "Exception while processing block: [%s]", e.what());
    }
}
```

The log() function generates entries in the log file like the following:

```
$ tail /home/dbadmin/py_db/v_py_db_node0001_catalog/UDxLogs/UDxFencedProcesses.log
 07:52:12.862 [Python-v_py_db_node0001-7524:0x206c-40575]  0x7f70eee2f780 PythonExecContext::processBlock
 07:52:12.862 [Python-v_py_db_node0001-7524:0x206c-40575]  0x7f70eee2f780 [UserMessage] add2ints - Python UDx - Adding 2 ints!
 07:52:12.862 [Python-v_py_db_node0001-7524:0x206c-40575]  0x7f70eee2f780 [UserMessage] add2ints - Values: first_int is 100 second_int is 100
```

For details on viewing the Vertica log files, see Monitoring log files .

Writing messages to the UDX_EVENTS table (C++ only)

In the C++ API, you can write messages to the UDX_EVENTS system table instead of or in addition to writing to the log. Writing to a system table allows you to collect events from all nodes in one place.

You can write to this table using the ServerInterface.logEvent() function. The function takes one argument, a map. The map is written into the __RAW__ column of the table as a Flex VMap. The following example shows how the Parquet exporter creates and logs this map.

```
// Log exported parquet file details to v_monitor.udx_events
std::map<std::string, std::string> details;
details["file"] = escapedPath;
details["created"] = create_timestamp_;
details["closed"] = close_timestamp_;
details["rows"] = std::to_string(num_rows_in_file);
details["row_groups"] = std::to_string(num_row_groups_in_file);
details["size_mb"] = std::to_string((double)outputStream->Tell()/(1024*1024));
srvInterface.logEvent(details);
```

You can select individual fields from the VMap as in the following example.

```
=> SELECT __RAW__['file'] FROM UDX_EVENTS;
                          __RAW__
------------------------------------------------------------------------------
 /tmp/export_tmpzLkrKq3a/450c4213-v_vmart_node0001-139770732459776-0.parquet
 /tmp/export_tmpzLkrKq3a/9df1c797-v_vmart_node0001-139770860660480-0.parquet
(2 rows)
```

Alternatively, you can define a view to make it easier to query fields directly, as columns. See Monitoring exports for an example.

Handling cancel requests

Users of your UDx might cancel the operation while it is running. How Vertica handles the cancellation of the query and your UDx depends on whether your UDx is running in fenced or unfenced mode:

- If your UDx is running in unfenced mode, Vertica either stops the function when it requests a new block of input or output, or waits until your function completes running and discards the results.
- If your UDx is running in Fenced and unfenced modes , Vertica kills the zygote process that is running your function if it continues processing past a timeout.

In addition, you can implement the cancel() method in any UDx to perform any necessary additional work. Vertica calls your function when a query is canceled. This cancellation can occur at any time during your UDx's lifetime, from setup() through destroy() .

You can check for cancellation before starting an expensive operation by calling isCanceled() .

In this section

- Implementing the cancel callback
- Checking for cancellation during execution
- C++ example: cancelable UDSource

Implementing the cancel callback

Your UDx can implement a cancel() callback function. Vertica calls this function if the query that invoked the UDx has been canceled.

You usually implement this function to perform an orderly shutdown of any additional processing that your UDx spawned. For example, you can have your cancel() function shut down threads that your UDx has spawned or signal a third-party library that it needs to stop processing and exit. Your cancel() function should leave your UDx's function class ready to be destroyed, because Vertica calls the UDx's destroy() function after the cancel() function has exited.

A UDx's default cancel() behavior is to do nothing.

The contract for cancel() is:

- Vertica will call cancel() at most once per UDx instance.
- Vertica can call cancel() concurrently with any other method of the UDx object except the constructor and destructor.
- Vertica can call cancel() from another thread, so implementations should be thread-safe.
- Vertica will call cancel() for either an explicit user cancellation or an error in the query.
- Vertica does not guarantee that cancel() will run to completion. Long-running cancellations might be aborted.

The call to cancel() is not synchronized in any way with your UDx's other functions. If you need your processing function to exit before your cancel() function performs some action (killing threads, for example), you must have the two function synchronize their actions.

Vertica always calls destroy() if it called setup() . Cancellation does not prevent destruction.

See C++ example: cancelable UDSource for an example that implements cancel() .

Checking for cancellation during execution

You can call the isCanceled() method to check for user cancellation. Typically you check for cancellation from the method that does the main processing in your UDx before beginning expensive operations. If isCanceled() returns true, the query has been canceled and your method should exit immediately to prevent it from wasting CPU time. If your UDx is not running fenced mode, Vertica cannot halt your function and has to wait for it to finish. If it is running in fenced mode, Vertica eventually kills the side process running it.

See C++ example: cancelable UDSource for an example that uses isCanceled() .

C++ example: cancelable UDSource

The FifoSource example, found in filelib.cpp in the SDK examples, demonstrates use of cancel() and isCanceled() . This source reads from a named pipe. Unlike reads from files, reads from pipes can block. Therefore, we need to be able to cancel a load from this source.

To manage cancellation, the UDx uses a pipe , a data channel used for inter-process communication. A process can write data to the write end of the pipe, and it remains available until another process reads it from the read end of the pipe. This example doesn't pass data through this pipe; rather, it uses the pipe to manage cancellation, as explained further below. In addition to the pipe's two file descriptors (one for each end), the UDx creates a file descriptor for the file to read from. The setup() function creates the pipe and then opens the file.

```
virtual void setup(ServerInterface &srvInterface) {
 // cancelPipe is a pipe used only for checking cancellation
 if (pipe(cancelPipe)) {
  vt_report_error(0, "Error opening control structure");
 }

 // handle to the named pipe from which we read data
 namedPipeFd = open(filename.c_str(), O_RDONLY | O_NONBLOCK);
 if (namedPipeFd < 0) {
  vt_report_error(0, "Error opening fifo [%s]", filename.c_str());
 }
}
```

We now have three file descriptors: `namedPipeFd` , `cancelPipe[PIPE_READ]` , and `cancelPipe[PIPE_WRITE]` . Each of these must eventually be closed.

This UDx uses the `poll()` system call to wait either for data to arrive from the named pipe (`namedPipeFd`) or for a cancellation (`cancelPipe[PIPE_READ]`). The `process()` function polls, checks for results, checks for cancellation, writes output if needed, and returns.

```
virtual StreamState process(ServerInterface &srvInterface, DataBuffer &output) {
 struct pollfd pollfds[2] = {
  { namedPipeFd,          POLLIN, 0 },
  { cancelPipe[PIPE_READ], POLLIN, 0 }
 };

 if (poll(pollfds, 2, -1) < 0) {
  vt_report_error(1, "Error reading [%s]", filename.c_str());
 }

 if (pollfds[1].revents & (POLLIN | POLLHUP)) {
  /* This can only happen after cancel() has been called */
  VIAssert(isCanceled());
  return DONE;
 }

 VIAssert(pollfds[PIPE_READ].revents & (POLLIN | POLLHUP));

 const ssize_t amount = read(namedPipeFd, output.buf + output.offset, output.size - output.offset);
 if (amount < 0) {
  vt_report_error(1, "Error reading from fifo [%s]", filename.c_str());
 }

 if (amount == 0 || isCanceled()) {
  return DONE;
 } else {
  output.offset += amount;
  return OUTPUT_NEEDED;
 }
}
```

If the query is canceled, the `cancel()` function closes the write end of the pipe. The next time `process()` polls for input, it finds no input on the read end of the pipe and exits. Otherwise, it continues. The function also calls `isCanceled()` to check for cancellation before returning `OUTPUT_NEEDED` , the signal that it has filled its buffer and is waiting for it to be processed downstream.

The `cancel()` function does only the work needed to interrupt a call to `process()` . Cleanup that is always needed, not just for cancellation, is instead done in `destroy()` or the destructor. The `cancel()` function closes the write end of the pipe. (The helper function will be shown later.)

```
virtual void cancel(ServerInterface &srvInterface) {
 closeIfNeeded(cancelPipe[PIPE_WRITE]);
```

It is not safe to close the named pipe in cancel() , because closing it could create a race condition if another process (like another query) were to reuse the file descriptor number for a new descriptor before the UDx finishes. Instead we close it, and the read end of the pipe, in destroy() .

```
virtual void destroy(ServerInterface &srvInterface) {
 closeIfNeeded(namedPipeFd);
 closeIfNeeded(cancelPipe[PIPE_READ]);
```

It is not safe to close the write end of the pipe in destroy() , because cancel() closes it and can be called concurrently with destroy() . Therefore, we close it in the destructor.

```
~FifoSource() {
 closeIfNeeded(cancelPipe[PIPE_WRITE]);
```

The UDx uses a helper function, closeIfNeeded() , to make sure each file descriptor is closed exactly once.

```
void closeIfNeeded(int &fd) {
 if (fd >= 0) {
  close(fd);
  fd = -1;
 }
```

Aggregate functions (UDAFs)

Aggregate functions perform an operation on a set of values and return one value. Vertica provides standard built-in aggregate functions such as AVG , MAX , and MIN . User-defined aggregate functions (UDAFs) provide similar functionality:

- Support a single input column (or set) of values and provide a single output column.
- Support RLE decompression. RLE input is decompressed before it is sent to a UDAF.
- Support use with GROUP BY and HAVING clauses. Only columns appearing in the GROUP BY clause can be selected.

Restrictions

The following restrictions apply to UDAFs:

- Available for C++ only.
- Cannot be run in fenced mode.
- Cannot be used with correlated subqueries.

In this section

- AggregateFunction class
- AggregateFunctionFactory class
- UDAF performance in statements containing a GROUP BY clause
- C++ example: average

AggregateFunction class

The AggregateFunction class performs the aggregation. It computes values on each database node where relevant data is stored and then combines the results from the nodes. You must implement the following methods:

- initAggregate() - Initializes the class, defines variables, and sets the starting value for the variables. This function must be idempotent.
- aggregate() - The main aggregation operation, executed on each node.
- combine() - If multiple invocations of aggregate() are needed, Vertica calls combine() to combine all the sub-aggregations into a final aggregation. Although this method might not be called, you must define it.
- terminate() - Terminates the function and returns the result as a column.

Important

The aggregate() function might not operate on the complete input set all at once. For this reason, initAggregate() must be idempotent.

The AggregateFunction class also provides optional methods that you can implement to allocate and free resources: setup() and destroy() . You should use these methods to allocate and deallocate resources that you do not allocate through the UDAF API (see Allocating resources for UDxs for details).

API

Aggregate functions are supported for C++ only.

The AggregateFunction API provides the following methods for extension by subclasses:

```
virtual void setup(ServerInterface &srvInterface,
    const SizedColumnTypes &argTypes);

virtual void initAggregate(ServerInterface &srvInterface, IntermediateAggs &aggs)=0;

void aggregate(ServerInterface &srvInterface, BlockReader &arg_reader,
    IntermediateAggs &aggs);

virtual void combine(ServerInterface &srvInterface, IntermediateAggs &aggs_output,
    MultipleIntermediateAggs &aggs_other)=0;

virtual void terminate(ServerInterface &srvInterface, BlockWriter &res_writer,
    IntermediateAggs &aggs);

virtual void cancel(ServerInterface &srvInterface);

virtual void destroy(ServerInterface &srvInterface, const SizedColumnTypes &argTypes);
```

AggregateFunctionFactory class

The AggregateFunctionFactory class specifies metadata information such as the argument and return types of your aggregate function. It also instantiates your AggregateFunction subclass. Your subclass must implement the following methods:

- getPrototype() - Defines the number of parameters and data types accepted by the function. There is a single parameter for aggregate functions.
- getIntermediateTypes() - Defines the intermediate variable(s) used by the function. These variables are used when combining the results of aggregate() calls.
- getReturnType() - Defines the type of the output column.

Your function may also implement getParameterType() , which defines the names and types of parameters that this function uses.

Vertica uses this data when you call the CREATE AGGREGATE FUNCTION SQL statement to add the function to the database catalog.

API

Aggregate functions are supported for C++ only.

The AggregateFunctionFactory API provides the following methods for extension by subclasses:

```
virtual AggregateFunction *
    createAggregateFunction ServerInterface &srvInterface)=0;

virtual void getPrototype(ServerInterface &srvInterface,
    ColumnTypes &argTypes, ColumnTypes &returnType)=0;

virtual void getIntermediateTypes(ServerInterface &srvInterface,
    const SizedColumnTypes &inputTypes, SizedColumnTypes &intermediateTypeMetaData)=0;

virtual void getReturnType(ServerInterface &srvInterface,
    const SizedColumnTypes &argTypes, SizedColumnTypes &returnType)=0;

virtual void getParameterType(ServerInterface &srvInterface,
    SizedColumnTypes &parameterTypes);
```

UDAF performance in statements containing a GROUP BY clause

You may see slower-than-expected performance from your UDAF if the SQL statement calling it also contains a GROUP BY clause . For example:

```
=> SELECT a, MYUDAF(b) FROM sampletable GROUP BY a;
```

In statements like this one, Vertica does not consolidate row data together before calling your UDAF's aggregate() method. Instead, it calls aggregate() once for each row of data. Usually, the overhead of having Vertica consolidate the row data is greater than the overhead of calling aggregate() for each row of data. However, if your UDAF's aggregate() method has significant overhead, then you might notice an impact on your UDAF's performance.

For example, suppose aggregate() allocates memory. When called in a statement with a GROUP BY clause, it performs this memory allocation for each row of data. Because memory allocation is a relatively expensive process, this allocation can impact the overall performance of your UDAF and the query.

There are two ways you can address UDAF performance in a statement containing a GROUP BY clause:

- Reduce the overhead of each call to aggregate() . If possible, move any allocation or other setup operations to the UDAF's setup() function.
- Declare a special parameter that tells Vertica to group row data together when calling a UDAF. This technique is explained below.

Using the _minimizeCallCount parameter

Your UDAF can tell Vertica to always batch row data together to reduce the number of calls to its aggregate() method. To trigger this behavior, your UDAF must declare an integer parameter named _minimizeCallCount . You do not need to set a value for this parameter in your SQL statement. The fact that your UDAF declares this parameter triggers Vertica to group row data together when calling aggregate() .

You declare the _minimizeCallCount parameter the same way you declare other UDx parameters. See UDx parameters for more information.

Important

Always test the performance of your UDAF before and after implementing the _minimizeCallCount parameter to ensure that it improves performance. You might find that the overhead of having Vertica group row data for your UDAF is greater than the cost of the repeated calls to aggregate() .

C++ example: average

The Average aggregate function created in this example computes the average of values in a column.

You can find the source code used in this example on the Vertica GitHub page .

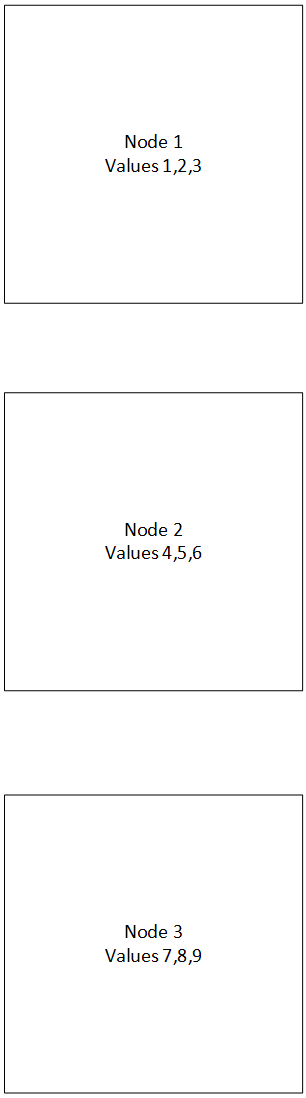
Loading the example

Use CREATE LIBRARY and CREATE AGGREGATE FUNCTION to declare the function:

```
=> CREATE LIBRARY AggregateFunctions AS
'/opt/vertica/sdk/examples/build/AggregateFunctions.so';
CREATE LIBRARY
=> CREATE aggregate function ag_avg AS LANGUAGE 'C++'
name 'AverageFactory' library AggregateFunctions;
CREATE AGGREGATE FUNCTION
```

Using the example

Use the function as part of a SELECT statement:



```
=> SELECT * FROM average;
id | count
----+---------
A  |     8
B  |     3
C  |     6
D  |     2
E  |     9
F  |     7
G  |     5
H  |     4
I  |     1
(9 rows)
=> SELECT ag_avg(count) FROM average;
ag_avg
--------
  5
(1 row)
```

AggregateFunction implementation

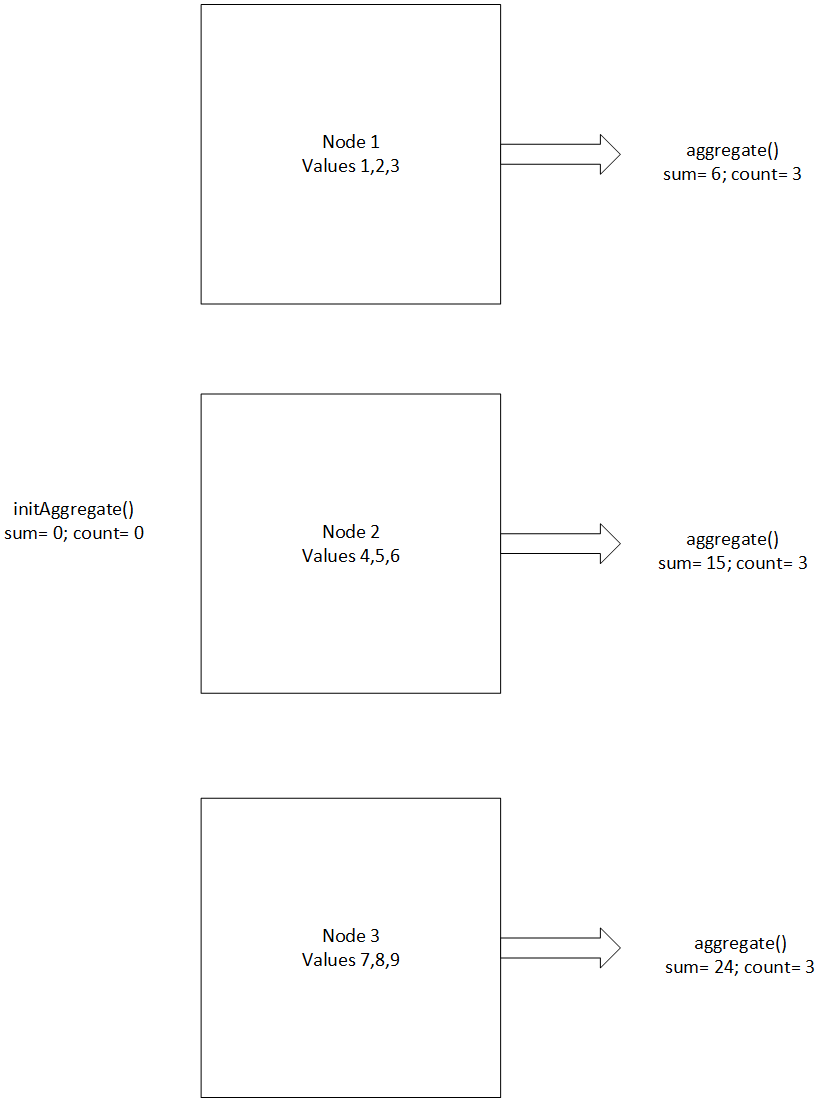
This example adds the input argument values in the aggregate() method and keeps a counter of the number of values added. The server runs aggregate() on every node and different data chunks, and combines all the individually added values and counters in the combine() method. Finally, the average value is computed in the terminate() method by dividing the total sum by the total number of values processed.

For this discussion, assume the following environment:

- A three-node Vertica cluster
- A table column that contains nine values that are evenly distributed across the nodes. Schematically, the nodes look like the following figure:

The function uses sum and count variables. *Sum* contains the sum of the values, and *count* contains the count of values.

First, initAggregate() initializes the variables and sets their values to zero.



```
virtual void initAggregate(ServerInterface &srvInterface,
                           IntermediateAggs &aggs)
{
 try {
  VNumeric &sum = aggs.getNumericRef(0);
  sum.setZero();

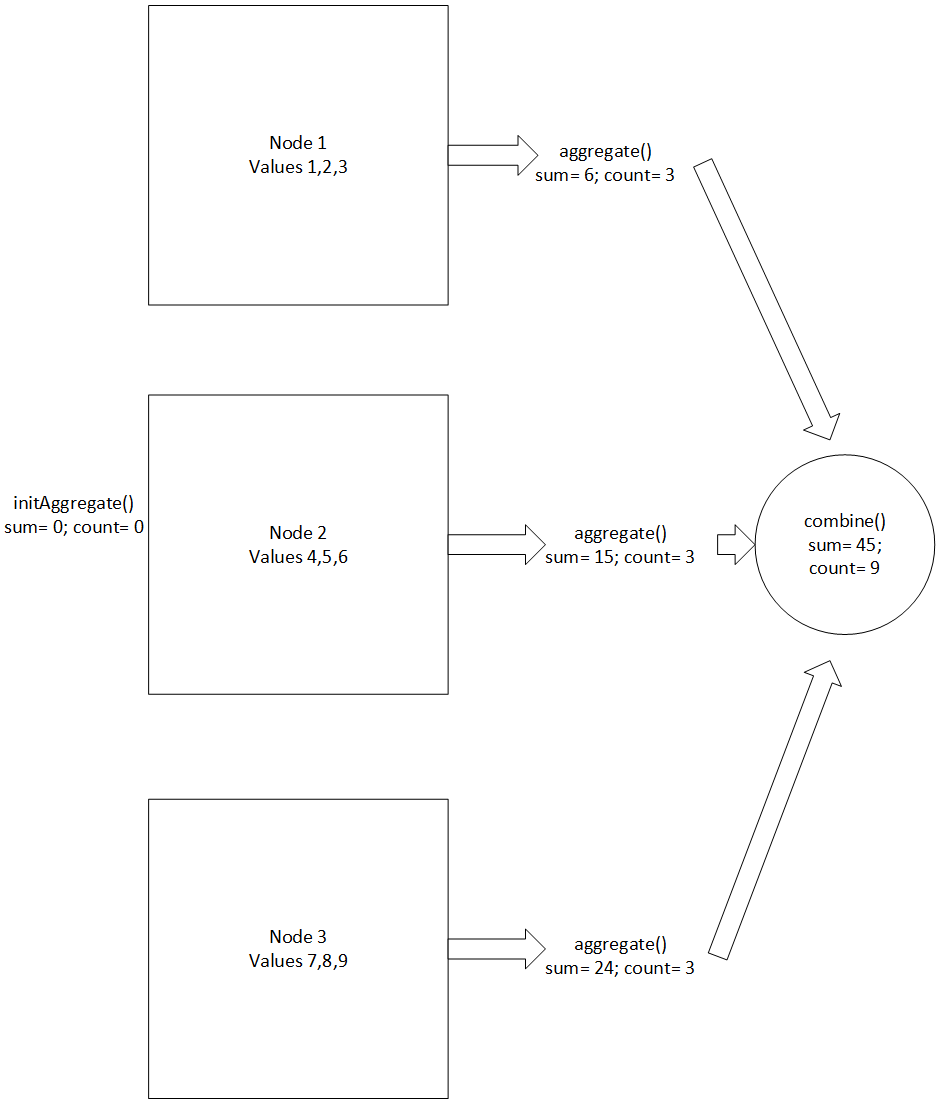
  vint &count = aggs.getIntRef(1);
  count = 0;
 }
 catch(std::exception &e) {
  vt_ report_ error(0, "Exception while initializing intermediate aggregates: [% s]", e.what());
 }
}
```

The aggregate() function reads the block of data on each node and calculates partial aggregates.

```
void aggregate(ServerInterface &srvInterface,
               BlockReader &argReader,
               IntermediateAggs &aggs)
{
  try {
      VNumeric &sum = aggs.getNumericRef(0);
      vint     &count = aggs.getIntRef(1);
      do {
          const VNumeric &input = argReader.getNumericRef(0);
          if (!input.isNull()) {
           sum.accumulate(&input);
       count++;
          }
      } while (argReader.next());
  } catch(std::exception &e) {
    vt_report_ error(0, " Exception while processing aggregate: [%s]", e.what());
  }
```

Each completed instance of the aggregate() function returns multiple partial aggregates for sum and count. The following figure illustrates this process using the aggregate() function:

The combine() function puts together the partial aggregates calculated by each instance of the average function.

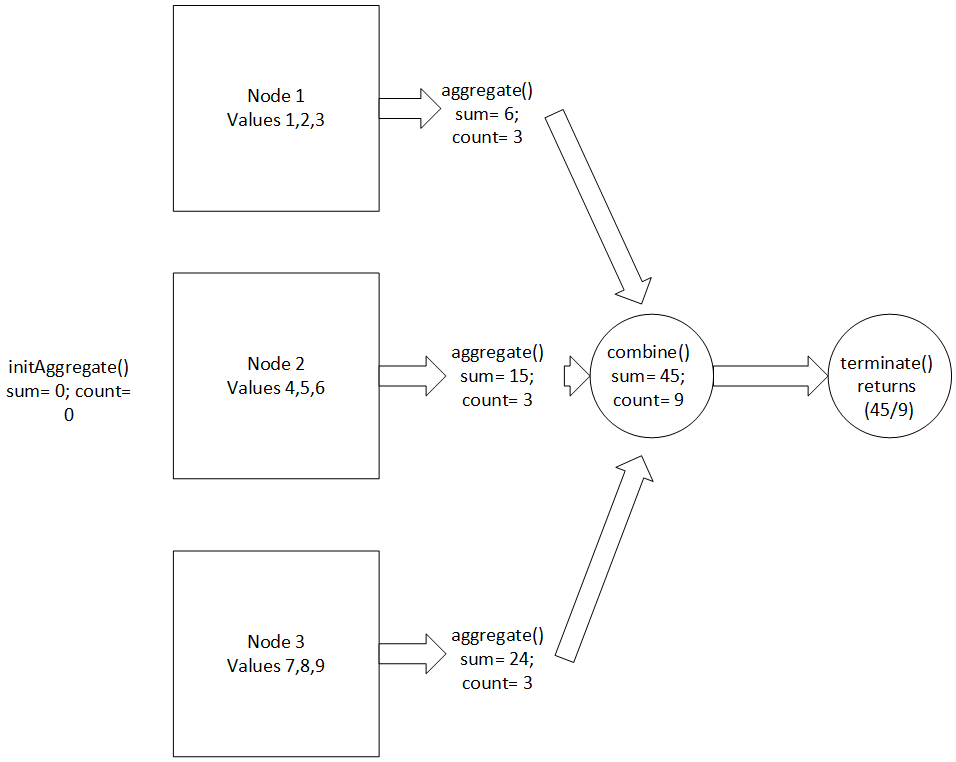


```
virtual void combine(ServerInterface &srvInterface,
                     IntermediateAggs &aggs,
                     MultipleIntermediateAggs &aggsOther)
{
  try {
    VNumeric      &mySum      = aggs.getNumericRef(0);
    vint          &myCount    = aggs.getIntRef(1);

    // Combine all the other intermediate aggregates
    do {
      const VNumeric &otherSum   = aggsOther.getNumericRef(0);
      const vint     &otherCount = aggsOther.getIntRef(1);

      // Do the actual accumulation
      mySum.accumulate(&otherSum);
      myCount += otherCount;

    } while (aggsOther.next());
  } catch(std::exception &e) {
    // Standard exception. Quit.
    vt_report_error(0, "Exception while combining intermediate aggregates: [%s]", e.what());
  }
```



The following figure shows how each partial aggregate is combined:

After all input has been evaluated by the aggregate() function Vertica calls the terminate() function. It returns the average to the caller.

```
virtual void terminate(ServerInterface &srvInterface,
                       BlockWriter &resWriter,
                       IntermediateAggs &aggs)
{
  try {
    const int32 MAX_INT_PRECISION = 20;
    const int32 prec = Basics::getNumericWordCount(MAX_INT_PRECISION);
    uint64 words[prec];
    VNumeric count(words,prec,0/*scale*/);
    count.copy(aggs.getIntRef(1));
    VNumeric &out = resWriter.getNumericRef();
    if (count.isZero()) {
      out.setNull();
    } else
      const VNumeric &sum = aggs.getNumericRef(0);
      out.div(&sum, &count);
  }
```

The following figure shows the implementation of the terminate() function:

AggregateFunctionFactory implementation

The getPrototype() function allows you to define the variables that are sent to your aggregate function and returned to Vertica after your aggregate function runs. The following example accepts and returns a numeric value:

```
virtual void getPrototype(ServerInterface &srvInterface,
                          ColumnTypes &argTypes,
                          ColumnTypes &returnType)
{
  argTypes.addNumeric();
  returnType.addNumeric();
}
```

The getIntermediateTypes() function defines any intermediate variables that you use in your aggregate function. *Intermediate variables* are values used to pass data among multiple invocations of an aggregate function. They are used to combine results until a final result can be computed. In this example, there are two results - total (numeric) and count (int).

```
virtual void getIntermediateTypes(ServerInterface &srvInterface,
                                  const SizedColumnTypes &inputTypes,
                                  SizedColumnTypes &intermediateTypeMetaData)
{
    const VerticaType &inType = inputTypes.getColumnType(0);
    intermediateTypeMetaData.addNumeric(interPrec, inType.getNumericScale());
    intermediateTypeMetaData.addInt();
}
```

The getReturnType() function defines the output data type:

```
virtual void getReturnType(ServerInterface &srvfloaterface,
                           const SizedColumnTypes &inputTypes,
                           SizedColumnTypes &outputTypes)
{
    const VerticaType &inType = inputTypes.getColumnType(0);
    outputTypes.addNumeric(inType.getNumericPrecision(),
    inType.getNumericScale());
}
```

Analytic functions (UDAnFs)

User-defined analytic functions (UDAnFs) are used for analytics. See SQL analytics for an overview of Vertica's built-in analytics. Like user-defined scalar functions (UDSFs), UDAnFs must output a single value for each row of data read and can have no more than 9800 arguments.

Unlike UDSFs, the UDAnF's input reader and output reader can be advanced independently. This feature lets you create analytic functions where the output value is calculated over multiple rows of data. By advancing the reader and writer independently, you can create functions similar to the built-in analytic functions such as LAG , which uses data from prior rows to output a value for the current row.

In this section

- AnalyticFunction class
- AnalyticFunctionFactory class
- C++ example: rank

AnalyticFunction class

The AnalyticFunction class performs the analytic processing. Your subclass must define the processPartition() method to perform the operation. It may define methods to set up and tear down the function.

Performing the operation

The processPartition() method reads a partition of data, performs some sort of processing, and outputs a single value for each input row.

Vertica calls processPartition() once for each partition of data. It supplies the partition using an AnalyticPartitionReader object from which you read its input data. In addition, there is a unique method on this object named isNewOrderByKey() , which returns a Boolean value indicating whether your function has seen a row with the same ORDER BY key (or keys). This method is very useful for analytic functions (such as the example RANK function) which need to handle rows with identical ORDER BY keys differently than rows with different ORDER BY keys.

> **Note**
> You can specify multiple ORDER BY columns in the SQL query you use to call your UDAnF. The isNewOrderByKey method returns true if any of the ORDER BY keys are different than the previous row.

Once your method has finished processing the row of data, you advance it to the next row of input by calling next() on AnalyticPartitionReader .

Your method writes its output value using an AnalyticPartitionWriter object that Vertica supplies as a parameter to processPartition() . This object has data-type-specific methods to write the output value (such as setInt()). After setting the output value, call next() on AnalyticPartitionWriter to advance to the next row in the output.

> **Note**
> You must be sure that your function produces a row of output for each row of input in the partition. You must also not output more rows than are in the partition, otherwise the zygote size process (if running in Fenced and unfenced modes) or Vertica itself could generate an out of

bounds error.

Setting up and tearing down

The AnalyticFunction class defines two additional methods that you can optionally implement to allocate and free resources: setup() and destroy() . You should use these methods to allocate and deallocate resources that you do not allocate through the UDx API (see Allocating resources for UDxs for details).

API

C++

Java

The AnalyticFunction API provides the following methods for extension by subclasses:

```
virtual void setup(ServerInterface &srvInterface,
    const SizedColumnTypes &argTypes);

virtual void processPartition (ServerInterface &srvInterface,
    AnalyticPartitionReader &input_reader,
    AnalyticPartitionWriter &output_writer)=0;

virtual void cancel(ServerInterface &srvInterface);

virtual void destroy(ServerInterface &srvInterface, const SizedColumnTypes &argTypes);
```

AnalyticFunctionFactory class

The AnalyticFunctionFactory class tells Vertica metadata about your UDAnF: its number of parameters and their data types, as well as the data type of its return value. It also instantiates a subclass of AnalyticFunction .

Your AnalyticFunctionFactory subclass must implement the following methods:

- getPrototype() describes the input parameters and output value of your function. You set these values by calling functions on two ColumnTypes objects that are passed to your method.
- createAnalyticFunction() supplies an instance of your AnalyticFunction that Vertica can call to process a UDAnF function call.
- getReturnType() provides details about your function's output. This method is where you set the width of the output value if your function returns a variable-width value (such as VARCHAR) or the precision of the output value if it has a settable precision (such as TIMESTAMP).

API

C++

Java

The AnalyticFunctionFactory API provides the following methods for extension by subclasses:

```
virtual AnalyticFunction * createAnalyticFunction (ServerInterface &srvInterface)=0;

virtual void getPrototype(ServerInterface &srvInterface,
    ColumnTypes &argTypes, ColumnTypes &returnType)=0;

virtual void getReturnType(ServerInterface &srvInterface,
    const SizedColumnTypes &argTypes, SizedColumnTypes &returnType)=0;

virtual void getParameterType(ServerInterface &srvInterface,
    SizedColumnTypes &parameterTypes);
```

C++ example: rank

The Rank analytic function ranks rows based on how they are ordered. A Java version of this UDx is included in /opt/vertica/sdk/examples .

Loading and using the example

The following example shows how to load the function into Vertica. It assumes that the AnalyticFunctions.so library that contains the function has been copied to the dbadmin user's home directory on the initiator node.

```
=> CREATE LIBRARY AnalyticFunctions AS '/home/dbadmin/AnalyticFunctions.so';
CREATE LIBRARY
=> CREATE ANALYTIC FUNCTION an_rank AS LANGUAGE 'C++'
   NAME 'RankFactory' LIBRARY AnalyticFunctions;
CREATE ANALYTIC FUNCTION
```

An example of running this rank function, named an_rank , is:

```
=> SELECT * FROM hits;
     site       |    date    | num_hits
----------------+------------+----------
 www.example.com | 2012-01-02 |       97
 www.vertica.com | 2012-01-01 |   343435
 www.example.com | 2012-01-01 |      123
 www.example.com | 2012-01-04 |      112
 www.vertica.com | 2012-01-02 |   503695
 www.vertica.com | 2012-01-03 |   490387
 www.example.com | 2012-01-03 |      123
(7 rows)
=> SELECT site,date,num_hits,an_rank()
   OVER (PARTITION BY site ORDER BY num_hits DESC)
   AS an_rank FROM hits;
     site       |    date    | num_hits | an_rank
----------------+------------+----------+---------
 www.example.com | 2012-01-03 |      123 |       1
 www.example.com | 2012-01-01 |      123 |       1
 www.example.com | 2012-01-04 |      112 |       3
 www.example.com | 2012-01-02 |       97 |       4
 www.vertica.com | 2012-01-02 |   503695 |       1
 www.vertica.com | 2012-01-03 |   490387 |       2
 www.vertica.com | 2012-01-01 |   343435 |       3
(7 rows)
```

As with the built-in RANK analytic function, rows that have the same value for the ORDER BY column (num_hits in this example) have the same rank, but the rank continues to increase, so that the next row that has a different ORDER BY key gets a rank value based on the number of rows that preceded it.

AnalyticFunction implementation

The following code defines an AnalyticFunction subclass named Rank . It is based on example code distributed in the examples directory of the SDK.

```
/**
 * User-defined analytic function: Rank - works mostly the same as SQL-99 rank
 * with the ability to define as many order by columns as desired
 *
 */
class Rank : public AnalyticFunction
{
  virtual void processPartition(ServerInterface &srvInterface,
                                AnalyticPartitionReader &inputReader,
                                AnalyticPartitionWriter &outputWriter)
  {
    // Always use a top-level try-catch block to prevent exceptions from
    // leaking back to Vertica or the fenced-mode side process.
    try {
      rank = 1; // The rank to assign a row
      rowCount = 0; // Number of rows processed so far
      do {
        rowCount++;
        // Do we have a new order by row?
        if (inputReader.isNewOrderByKey()) {
          // Yes, so set rank to the total number of rows that have been
          // processed. Otherwise, the rank remains the same value as
          // the previous iteration.
          rank = rowCount;
        }
        // Write the rank
        outputWriter.setInt(0, rank);
        // Move to the next row of the output
        outputWriter.next();
      } while (inputReader.next()); // Loop until no more input
    } catch(exception& e) {
      // Standard exception. Quit.
      vt_report_error(0, "Exception while processing partition: %s", e.what());
    }
  }
private:
  vint rank, rowCount;
};
```

In this example, the processPartition() method does not actually read any of the data from the input row; it just advances through the rows. It does not need to read data; it just counts the rows that have been read and determine whether those rows have the same ORDER BY key as the previous row. If the current row is a new ORDER BY key, then the rank is set to the total number of rows that have been processed. If the current row has the same ORDER BY value as the previous row, then the rank remains the same.

Note that the function has a top-level try-catch block. All of your UDx functions should always have one to prevent stray exceptions from being passed back to Vertica (if you run the function unfenced) or the side process.

AnalyticFunctionFactory implementation

The following code defines the AnalyticFunctionFactory that corresponds with the Rank analytic function.

```
class RankFactory : public AnalyticFunctionFactory
{
  virtual void getPrototype(ServerInterface &srvInterface,
                            ColumnTypes &argTypes, ColumnTypes &returnType)
  {
    returnType.addInt();
  }
  virtual void getReturnType(ServerInterface &srvInterface,
                             const SizedColumnTypes &inputTypes,
                             SizedColumnTypes &outputTypes)
  {
    outputTypes.addInt();
  }
  virtual AnalyticFunction *createAnalyticFunction(ServerInterface
                                                   &srvInterface)
  { return vt_createFuncObj(srvInterface.allocator, Rank); }
};
```

The first method defined by the RankFactory subclass, getPrototype() , sets the data type of the return value. Because the Rank UDAnF does not read input, it does not define any arguments by calling methods on the ColumnTypes object passed in the argTypes parameter.

The next method is getReturnType() . If your function returns a data type that needs to define a width or precision, your implementation of the getReturnType() method calls a method on the SizedColumnType object passed in as a parameter to tell Vertica the width or precision. Rank returns a fixed-width data type (an INTEGER) so it does not need to set the precision or width of its output; it just calls addInt() to report its output data type.

Finally, RankFactory defines the createAnalyticFunction() method that returns an instance of the AnalyticFunction class that Vertica can call. This code is mostly boilerplate. All you need to do is add the name of your analytic function class in the call to vt_createFuncObj() , which takes care of allocating the object for you.

Scalar functions (UDSFs)

A user-defined scalar function (UDSF) returns a single value for each row of data it reads. You can use a UDSF anywhere you can use a built-in Vertica function. You usually develop a UDSF to perform data manipulations that are too complex or too slow to perform using SQL statements and functions. UDSFs also let you use analytic functions provided by third-party libraries within Vertica while still maintaining high performance.

A UDSF returns a single column. You can automatically return multiple values in a ROW . A ROW is a group of property-value pairs. In the following example, div_with_rem is a UDSF that performs a division operation, returning the quotient and remainder as integers:

```
=> SELECT div_with_rem(18,5);
      div_with_rem
------------------------------
 {"quotient":3,"remainder":3}
(1 row)
```

A ROW returned from a UDSF cannot be used as an argument to COUNT.

Alternatively, you can construct a complex return value yourself, as described in Complex Types as Arguments .

Your UDSF must return a value for every input row (unless it generates an error; see Handling errors for details). Failure to return a value for an input row results in incorrect results and potentially destabilizes the Vertica server if not run in Fenced and unfenced modes .

A UDSF can have up to 9800 arguments.

ScalarFunction class

The ScalarFunction class is the heart of a UDSF. Your subclass must define the processBlock() method to perform the scalar operation. It may define methods to set up and tear down the function.

For scalar functions written in C++, you can provide information that can help with query optimization. See Improving query performance (C++ only) .

Performing the operation

The processBlock() method carries out all of the processing that you want your UDSF to perform. When a user calls your function in a SQL statement, Vertica bundles together the data from the function parameters and passes it to processBlock() .

The input and output of the processBlock() method are supplied by objects of the BlockReader and BlockWriter classes. They define methods that you use to read the input data and write the output data for your UDSF.

The majority of the work in developing a UDSF is writing processBlock() . This is where all of the processing in your function occurs. Your UDSF should follow this basic pattern:

- Read in a set of arguments from the BlockReader object using data-type-specific methods.
- Process the data in some manner.
- Output the resulting value using one of the BlockWriter class's data-type-specific methods.
- Advance to the next row of output and input by calling BlockWriter.next() and BlockReader.next() .

This process continues until there are no more rows of data to be read (BlockReader.next() returns false).

You must make sure that processBlock() reads all of the rows in its input and outputs a single value for each row. Failure to do so can corrupt the data structures that Vertica reads to get the output of your UDSF. The only exception to this rule is if your processBlock() function reports an error back to Vertica (see Handling errors). In that case, Vertica does not attempt to read the incomplete result set generated by the UDSF.

Setting up and tearing down

The ScalarFunction class defines two additional methods that you can optionally implement to allocate and free resources: setup() and destroy() . You should use these methods to allocate and deallocate resources that you do not allocate through the UDx API (see Allocating resources for UDxs for details).

Notes

- While the name you choose for your ScalarFunction subclass does not have to match the name of the SQL function you will later assign to it, Vertica considers making the names the same a best practice.
- Do not assume that your function will be called from the same thread that instantiated it.
- The same instance of your ScalarFunction subclass can be called on to process multiple blocks of data.
- The rows of input sent to processBlock() are not guaranteed to be any particular order.
- Writing too many output rows can cause Vertica to emit an out-of-bounds error.

API

C++

Java

Python

R

The ScalarFunction API provides the following methods for extension by subclasses:

```
virtual void setup(ServerInterface &srvInterface,
    const SizedColumnTypes &argTypes);

virtual void processBlock(ServerInterface &srvInterface,
    BlockReader &arg_reader, BlockWriter &res_writer)=0;

virtual void getOutputRange (ServerInterface &srvInterface,
    ValueRangeReader &inRange, ValueRangeWriter &outRange)

virtual void cancel(ServerInterface &srvInterface);

virtual void destroy(ServerInterface &srvInterface, const SizedColumnTypes &argTypes);
```

ScalarFunctionFactory class

The ScalarFunctionFactory class tells Vertica metadata about your UDSF: its number of parameters and their data types, as well as the data type of its return value. It also instantiates a subclass of ScalarFunction .

Methods

You must implement the following methods in your ScalarFunctionFactory subclass:

- createScalarFunction() instantiates a ScalarFunction subclass. If writing in C++, you can call the vt_createFuncObj macro with the name of the ScalarFunction subclass. This macro takes care of allocating and instantiating the class for you.
- getPrototype() tells Vertica about the parameters and return type(s) for your UDSF. In addition to a ServerInterface object, this method gets two ColumnTypes objects. All you need to do in this function is to call class functions on these two objects to build the list of parameters and the return value type(s). If you return more than one value, the results are packaged into a ROW type.

After defining your factory class, you need to call the RegisterFactory macro. This macro instantiates a member of your factory class, so Vertica can interact with it and extract the metadata it contains about your UDSF.

Declaring return values

If your function returns a sized column (a return data type whose length can vary, such as a VARCHAR), a value that requires precision, or more than one value, you must implement getReturnType() . This method is called by Vertica to find the length or precision of the data being returned in each row of the results. The return value of this method depends on the data type your processBlock() method returns:

- CHAR, (LONG) VARCHAR, BINARY, and (LONG) VARBINARY return the maximum length.
- NUMERIC types specify the precision and scale.
- TIME and TIMESTAMP values (with or without timezone) specify precision.
- INTERVAL YEAR TO MONTH specifies range.
- INTERVAL DAY TO SECOND specifies precision and range.

If your UDSF does not return one of these data types and returns a single value, it does not need a getReturnType() method.

The input to the getReturnType() method is a SizedColumnTypes object that contains the input argument types along with their lengths. This object will be passed to an instance of your processBlock() function. Your implementation of getReturnType() must extract the data types and lengths from this input and determine the length or precision of the output rows. It then saves this information in another instance of the SizedColumnTypes class.

API

C++

Java

Python

R

The ScalarFunctionFactory API provides the following methods for extension by subclasses:

```
virtual ScalarFunction * createScalarFunction(ServerInterface &srvInterface)=0;

virtual void getPrototype(ServerInterface &srvInterface,
      ColumnTypes &argTypes, ColumnTypes &returnType)=0;

virtual void getReturnType(ServerInterface &srvInterface,
      const SizedColumnTypes &argTypes, SizedColumnTypes &returnType);

virtual void getParameterType(ServerInterface &srvInterface,
      SizedColumnTypes &parameterTypes);
```

Setting null input and volatility behavior

Normally, Vertica calls your UDSF for every row of data in the query. There are some cases where Vertica can avoid executing your UDSF. You can tell Vertica when it can skip calling your function and just supply a return value itself by changing your function's volatility and strictness settings.

- Your function's **volatility** indicates whether it always returns the same output value when passed the same arguments. Depending on its behavior, Vertica can cache the arguments and the return value. If the user calls the UDSF with the same set of arguments, Vertica returns the cached value instead of calling your UDSF.
- Your function's **strictness** indicates how it reacts to NULL arguments. If it always returns NULL when *any* argument is NULL, Vertica can just return NULL without having to call the function. This optimization also saves you work, because you do not need to test for and handle null arguments in your UDSF code.

You indicate the volatility and null handling of your function by setting the vol and strict fields in your ScalarFunctionFactory class's constructor.

Volatility settings

To indicate your function's volatility, set the vol field to one of the following values:

Value	Description
VOLATILE	Repeated calls to the function with the same arguments always result in different values. Vertica always calls volatile functions for each invocation.
IMMUTABLE	Calls to the function with the same arguments always results in the same return value.
STABLE	Repeated calls to the function with the same arguments *within the same statement* returns the same output. For example, a function that returns the current user name is stable because the user cannot change within a statement. The user name could change between statements.
DEFAULT_VOLATILITY	The default volatility. This is the same as VOLATILE.

Example

C++

Java

The following example shows a version of the Add2ints example factory class that makes the function immutable.

```
class Add2intsImmutableFactory : public Vertica::ScalarFunctionFactory
{
    virtual Vertica::ScalarFunction *createScalarFunction(Vertica::ServerInterface &srvInterface)
    { return vt_createFuncObj(srvInterface.allocator, Add2ints); }
    virtual void getPrototype(Vertica::ServerInterface &srvInterface,
                              Vertica::ColumnTypes &argTypes,
                              Vertica::ColumnTypes &returnType)
    {
        argTypes.addInt();
        argTypes.addInt();
        returnType.addInt();
    }

public:
    Add2intsImmutableFactory() {vol = IMMUTABLE;}
};
RegisterFactory(Add2intsImmutableFactory);
```

Null input behavior

To indicate how your function reacts to NULL input, set the strictness field to one of the following values.

Value	Description
CALLED_ON_NULL_INPUT	The function must be called, even if one or more arguments are NULL.
RETURN_NULL_ON_NULL_INPUT	The function always returns a NULL value if any of its arguments are NULL.
STRICT	A synonym for RETURN_NULL_ON_NULL_INPUT
DEFAULT_STRICTNESS	The default strictness setting. This is the same as CALLED_ON_NULL_INPUT.

Example

The following C++ example demonstrates setting the null behavior of Add2ints so Vertica does not call the function with NULL values.

```
class Add2intsNullOnNullInputFactory : public Vertica::ScalarFunctionFactory
{
    virtual Vertica::ScalarFunction *createScalarFunction(Vertica::ServerInterface &srvInterface)
    { return vt_createFuncObj(srvInterface.allocator, Add2ints); }
    virtual void getPrototype(Vertica::ServerInterface &srvInterface,
                              Vertica::ColumnTypes &argTypes,
                              Vertica::ColumnTypes &returnType)
    {
        argTypes.addInt();
        argTypes.addInt();
        returnType.addInt();
    }

public:
    Add2intsNullOnNullInputFactory() {strict = RETURN_NULL_ON_NULL_INPUT;}
};
RegisterFactory(Add2intsNullOnNullInputFactory);
```

Improving query performance (C++ only)

When evaluating a query, Vertica can take advantage of available information about the ranges of values. For example, if data is partitioned and a query restricts output by the partitioned value, Vertica can ignore partitions that cannot possibly contain data that would satisfy the query. Similarly, for a scalar function, Vertica can skip processing rows in the data where the value returned from the function cannot possibly affect the results.

Consider a table with millions of rows of data on customer orders and a scalar function that computes the total price paid for everything in an order. A query uses a WHERE clause to restrict results to orders above a given value. A scalar function is called on a block of data; if no rows within that block could produce the target value, skipping the processing of the block could improve query performance.

A scalar function written in C++ can implement the getOutputRange method. Before calling processBlock , Vertica calls getOutputRange to determine the minimum and maximum return values from this block given the input ranges. It then decides whether to call processBlock to perform the computations.

The Add2Ints example implements this function. The minimum output value is the sum of the smallest values of each of the two inputs, and the maximum output is the sum of the largest values of each of the inputs. This function does not consider individual rows. Consider the following inputs:

```
 a  | b
----+----
 21 | 92
500 | 19
111 | 11
```

The smallest values of the two inputs are 21 and 11, so the function reports 32 as the low end of the output range. The largest input values are 500 and 92, so it reports 592 as the high end of the output range. 592 is larger than the value returned for any of the input rows and 32 is smaller than any row's return value.

The purpose of getOutputRange is to quickly eliminate calls where outputs would definitely be out of range. For example, if the query included "WHERE Add2Ints(a,b) > 600", this block of data could be skipped. There can still be cases where, after calling getOutputRange , processBlock returns no results. If the query included "WHERE Add2Ints(a,b) > 500", getOutputRange would not eliminate this block of data.

Add2Ints implements getOutputRange as follows:

```
/*
 * This method computes the output range for this scalar function from
 *   the ranges of its inputs in a single invocation.
 *
 * The input ranges are retrieved via inRange
 * The output range is returned via outRange
 */
virtual void getOutputRange(Vertica::ServerInterface &srvInterface,
                            Vertica::ValueRangeReader &inRange,
                            Vertica::ValueRangeWriter &outRange)
{
    if (inRange.hasBounds(0) && inRange.hasBounds(1)) {
        // Input ranges have bounds defined
        if (inRange.isNull(0) || inRange.isNull(1)) {
            // At least one range has only NULL values.
            // Output range can only have NULL values.
            outRange.setNull();
            outRange.setHasBounds();
            return;
        } else {
            // Compute output range
            const vint& a1LoBound = inRange.getIntRefLo(0);
            const vint& a2LoBound = inRange.getIntRefLo(1);
            outRange.setIntLo(a1LoBound + a2LoBound);

            const vint& a1UpBound = inRange.getIntRefUp(0);
            const vint& a2UpBound = inRange.getIntRefUp(1);
            outRange.setIntUp(a1UpBound + a2UpBound);
        }
    } else {
        // Input ranges are unbounded. No output range can be defined
        return;
    }

    if (!inRange.canHaveNulls(0) && !inRange.canHaveNulls(1)) {
        // There cannot be NULL values in the output range
        outRange.setCanHaveNulls(false);
    }

    // Let Vertica know that the output range is bounded
    outRange.setHasBounds();
}
```

If getOutputRange produces an error, Vertica issues a warning and does not call the method again for the current query.

C++ example: Add2Ints

The following example shows a basic subclass of ScalarFunction called Add2ints . As the name implies, it adds two integers together, returning a single integer result.

For the complete source code, see /opt/vertica/sdk/examples/ScalarFunctions/Add2Ints.cpp . Java and Python versions of this UDx are included in /opt/vertica/sdk/examples .

Loading and using the example

Use CREATE LIBRARY to load the library containing the function, and then use CREATE FUNCTION (scalar) to declare the function as in the following example:

```
=> CREATE LIBRARY ScalarFunctions AS '/home/dbadmin/examples/ScalarFunctions.so';

=> CREATE FUNCTION add2ints AS LANGUAGE 'C++' NAME 'Add2IntsFactory' LIBRARY ScalarFunctions;
```

The following example shows how to use this function:

```
=> SELECT Add2Ints(27,15);
 Add2ints
----------
       42
(1 row)
=> SELECT * FROM MyTable;
 a  | b
-----+----
  7 |  0
 12 |  2
 12 |  6
 18 |  9
  1 |  1
 58 |  4
450 | 15
(7 rows)
=> SELECT * FROM MyTable WHERE Add2ints(a, b) > 20;
 a  | b
-----+----
 18 |  9
 58 |  4
450 | 15
(3 rows)
```

Function implementation

A scalar function does its computation in the processBlock method:

```
class Add2Ints : public ScalarFunction
{
  public:
  /*
   * This method processes a block of rows in a single invocation.
   *
   * The inputs are retrieved via argReader
   * The outputs are returned via resWriter
   */
  virtual void processBlock(ServerInterface &srvInterface,
                            BlockReader &argReader,
                            BlockWriter &resWriter)
  {
    try {
      // While we have inputs to process
      do {
        if (argReader.isNull(0) || argReader.isNull(1)) {
          resWriter.setNull();
        } else {
          const vint a = argReader.getIntRef(0);
          const vint b = argReader.getIntRef(1);
          resWriter.setInt(a+b);
        }
        resWriter.next();
      } while (argReader.next());
    } catch(std::exception& e) {
      // Standard exception. Quit.
      vt_report_error(0, "Exception while processing block: [%s]", e.what());
    }
  }

// ...
};
```

Implementing getOutputRange , which is optional, allows your function to skip rows where the result would not be within a target range. For example, if a WHERE clause restricts the query results to those in a certain range, calling the function for cases that could not possibly be in that range is unnecessary.

```
/*
 * This method computes the output range for this scalar function from
 *   the ranges of its inputs in a single invocation.
 *
 * The input ranges are retrieved via inRange
 * The output range is returned via outRange
 */
virtual void getOutputRange(Vertica::ServerInterface &srvInterface,
                            Vertica::ValueRangeReader &inRange,
                            Vertica::ValueRangeWriter &outRange)
{
    if (inRange.hasBounds(0) && inRange.hasBounds(1)) {
        // Input ranges have bounds defined
        if (inRange.isNull(0) || inRange.isNull(1)) {
            // At least one range has only NULL values.
            // Output range can only have NULL values.
            outRange.setNull();
            outRange.setHasBounds();
            return;
        } else {
            // Compute output range
            const vint& a1LoBound = inRange.getIntRefLo(0);
            const vint& a2LoBound = inRange.getIntRefLo(1);
            outRange.setIntLo(a1LoBound + a2LoBound);

            const vint& a1UpBound = inRange.getIntRefUp(0);
            const vint& a2UpBound = inRange.getIntRefUp(1);
            outRange.setIntUp(a1UpBound + a2UpBound);
        }
    } else {
        // Input ranges are unbounded. No output range can be defined
        return;
    }

    if (inRange.canHaveNulls(0) && inRange.canHaveNulls(1)) {
        // There cannot be NULL values in the output range
        outRange.setCanHaveNulls(false);
    }

    // Let Vertica know that the output range is bounded
    outRange.setHasBounds();
}
```

Factory implementation

The factory instantiates a member of the class (createScalarFunction), and also describes the function's inputs and outputs (getPrototype):

```
class Add2IntsFactory : public ScalarFunctionFactory
{
  // return an instance of Add2Ints to perform the actual addition.
  virtual ScalarFunction *createScalarFunction(ServerInterface &interface)
  { return vt_createFuncObject<Add2Ints>(interface.allocator); }

  // This function returns the description of the input and outputs of the
  // Add2Ints class's processBlock function.  It stores this information in
  // two ColumnTypes objects, one for the input parameters, and one for
  // the return value.
  virtual void getPrototype(ServerInterface &interface,
                            ColumnTypes &argTypes,
                            ColumnTypes &returnType)
  {
    argTypes.addInt();
    argTypes.addInt();

    // Note that ScalarFunctions *always* return a single value.
    returnType.addInt();
  }
};
```

The RegisterFactory macro

Use the RegisterFactory macro to register a UDx. This macro instantiates the factory class and makes the metadata it contains available for Vertica to access. To call this macro, pass it the name of your factory class:

```
RegisterFactory(Add2IntsFactory);
```

Python example: currency_convert

The currency_convert scalar function reads two values from a table, a currency and a value. It then converts the item's value to USD, returning a single float result.

You can find more UDx examples in the Vertica Github repository, https://github.com/vertica/UDx-Examples .

UDSF Python code

```
import vertica_sdk
import decimal

rates2USD = {'USD': 1.000,
             'EUR': 0.89977,
             'GBP': 0.68452,
             'INR': 67.0345,
             'AUD': 1.39187,
             'CAD': 1.30335,
             'ZAR': 15.7181,
             'XXX': -1.0000}

class currency_convert(vertica_sdk.ScalarFunction):
    """Converts a money column to another currency

    Returns a value in USD.

    """
    def __init__(self):
        pass

    def setup(self, server_interface, col_types):
        pass

    def processBlock(self, server_interface, block_reader, block_writer):
        while(True):
            currency = block_reader.getString(0)
            try:
                rate = decimal.Decimal(rates2USD[currency])

            except KeyError:
                server_interface.log("ERROR: {} not in dictionary.".format(currency))
                # Scalar functions always need a value to move forward to the
                # next input row. Therefore, we need to assign it a value to
                # move beyond the error.
                currency = 'XXX'
                rate = decimal.Decimal(rates2USD[currency])

            starting_value = block_reader.getNumeric(1)
            converted_value = decimal.Decimal(starting_value  / rate)
            block_writer.setNumeric(converted_value)
            block_writer.next()
            if not block_reader.next():
                break

    def destroy(self, server_interface, col_types):
        pass

class currency_convert_factory(vertica_sdk.ScalarFunctionFactory):

    def createScalarFunction(self, srv):
        return currency_convert()

    def getPrototype(self, srv_interface, arg_types, return_type):
        arg_types.addVarchar()
        arg_types.addNumeric()
        return_type.addNumeric()

    def getReturnType(self, srv_interface, arg_types, return_type):
        return_type.addNumeric(9,4)
```

Load the function and library

Create the library and the function.

```
=> CREATE LIBRARY pylib AS '/home/dbadmin/python_udx/currency_convert/currency_convert.py' LANGUAGE 'Python';
CREATE LIBRARY
=> CREATE FUNCTION currency_convert AS LANGUAGE 'Python' NAME 'currency_convert_factory' LIBRARY pylib fenced;
CREATE FUNCTION
```

Querying data with the function

The following query shows how you can run a query with the UDSF.

```
=> SELECT product, currency_convert(currency, value) AS cost_in_usd
    FROM items;
   product    | cost_in_usd
--------------+-------------
 Shoes        |    133.4008
 Soccer Ball  |    110.2817
 Coffee       |     13.5190
 Surfboard    |    176.2593
 Hockey Stick |     76.7177
 Car          |  17000.0000
 Software     |     10.4424
 Hamburger    |      7.5000
 Fish         |    130.4272
 Cattle       |    269.2367
(10 rows)
```

Python example: validate_url

The validate_url scalar function reads a string from a table, a URL. It then validates if the URL is responsive, returning a status code or a string indicating the attempt failed.

You can find more UDx examples in the Vertica Github repository, https://github.com/vertica/UDx-Examples .

UDSF Python code

```
import vertica_sdk
import urllib.request
import time

class validate_url(vertica_sdk.ScalarFunction):
    """Validates HTTP requests.

    Returns the status code of a webpage. Pages that cannot be accessed return
    "Failed to load page."

    """

    def __init__(self):
        pass

    def setup(self, server_interface, col_types):
        pass

    def processBlock(self, server_interface, arg_reader, res_writer):
        # Writes a string to the UDx log file.
        server_interface.log("Validating webpage accessibility - UDx")

        while(True):
            url = arg_reader.getString(0)
            try:
                status = urllib.request.urlopen(url).getcode()
                # Avoid overwhelming web servers -- be nice.
                time.sleep(2)
            except (ValueError, urllib.error.HTTPError, urllib.error.URLError):
                status = 'Failed to load page'
            res_writer.setString(str(status))
            res_writer.next()
            if not arg_reader.next():
                # Stop processing when there are no more input rows.
                break

    def destroy(self, server_interface, col_types):
        pass

class validate_url_factory(vertica_sdk.ScalarFunctionFactory):

    def createScalarFunction(self, srv):
        return validate_url()

    def getPrototype(self, srv_interface, arg_types, return_type):
        arg_types.addVarchar()
        return_type.addChar()

    def getReturnType(self, srv_interface, arg_types, return_type):
        return_type.addChar(20)
```

Load the function and library

Create the library and the function.

```
=> CREATE OR REPLACE LIBRARY pylib AS 'webpage_tester/validate_url.py' LANGUAGE 'Python';
=> CREATE OR REPLACE FUNCTION validate_url AS LANGUAGE 'Python' NAME 'validate_url_factory' LIBRARY pylib fenced;
```

Querying data with the function

The following query shows how you can run a query with the UDSF.

```
=> SELECT url, validate_url(url) AS url_status FROM webpages;
                    url                    |      url_status
-------------------------------------------------+----------------------
 http://www.vertica.com/documentation/vertica/ | 200
 http://www.google.com/                         | 200
 http://www.mass.gov.com/                       | Failed to load page
 http://www.espn.com                            | 200
 http://blah.blah.blah.blah                     | Failed to load page
 http://www.vertica.com/                        | 200
(6 rows)
```

R example: SalesTaxCalculator

The SalesTaxCalculator scalar function reads a float and a varchar from a table, an item's price and the state abbreviation. It then uses the state abbreviation to find the sales tax rate from a list and calculates the item's price including the state's sales tax, returning the total cost of the item.

You can find more UDx examples in the Vertica Github repository, https://github.com/vertica/UDx-Examples .

Load the function and library

Create the library and the function.

```
=> CREATE OR REPLACE LIBRARY rLib AS 'sales_tax_calculator.R' LANGUAGE 'R';
CREATE LIBRARY
=> CREATE OR REPLACE FUNCTION SalesTaxCalculator AS LANGUAGE 'R' NAME 'SalesTaxCalculatorFactory' LIBRARY rLib FENCED;
CREATE FUNCTION
```

Querying data with the function

The following query shows how you can run a query with the UDSF.

```
=> SELECT item, state_abbreviation,
        price, SalesTaxCalculator(price, state_abbreviation) AS Price_With_Sales_Tax
    FROM inventory;
    item     | state_abbreviation | price | Price_With_Sales_Tax
-------------+--------------------+-------+----------------------
 Scarf       | AZ                 |  6.88 |              7.53016
 Software    | MA                 | 88.31 |             96.655295
 Soccer Ball | MS                 | 12.55 |             13.735975
 Beads       | LA                 |  0.99 |              1.083555
 Baseball    | TN                 | 42.42 |             46.42869
 Cheese      | WI                 | 20.77 |             22.732765
 Coffee Mug  | MA                 |  8.99 |              9.839555
 Shoes       | TN                 | 23.99 |             26.257055
(8 rows)
```

UDSF R code

```
SalesTaxCalculator <- function(input.data.frame) {
  # Not a complete list of states in the USA, but enough to get the idea.
  state.sales.tax <- list(ma = 0.0625,
                          az = 0.087,
                          la = 0.0891,
                          tn = 0.0945,
                          wi = 0.0543,
                          ms = 0.0707)
  for ( state_abbreviation in input.data.frame[, 2] ) {
    # Ensure state abbreviations are lowercase.
    lower_state <- tolower(state_abbreviation)
    # Check if the state is in our state.sales.tax list.
    if (is.null(state.sales.tax[[lower_state]])) {
      stop("State is not in our small sample!")
    } else {
      sales.tax.rate <- state.sales.tax[[lower_state]]
      item.price <- input.data.frame[, 1]
      # Calculate the price including sales tax.
      price.with.sales.tax <- (item.price) + (item.price * sales.tax.rate)
    }
  }
  return(price.with.sales.tax)
}

SalesTaxCalculatorFactory <- function() {
  list(name    = SalesTaxCalculator,
       udxtype = c("scalar"),
       intype  = c("float", "varchar"),
       outtype = c("float"))
}
```

R example: kmeans

The KMeans_User scalar function reads any number of columns from a table, the observations. It then uses the observations and the two parameters when applying the kmeans clustering algorithm to the data, returning an integer value associated with the cluster of the row.

You can find more UDx examples in the Vertica Github repository, https://github.com/vertica/UDx-Examples .

Load the function and library

Create the library and the function:

```
=> CREATE OR REPLACE LIBRARY rLib AS 'kmeans.R' LANGUAGE 'R';
CREATE LIBRARY
=> CREATE OR REPLACE FUNCTION KMeans_User AS LANGUAGE 'R' NAME 'KMeans_UserFactory' LIBRARY rLib FENCED;
CREATE FUNCTION
```

Querying data with the function

The following query shows how you can run a query with the UDSF:

```
=> SELECT spec,
        KMeans_User(sl, sw, pl, pw USING PARAMETERS clusters = 3, nstart = 20)
   FROM iris;
     spec       | KMeans_User
----------------+-------------
 Iris-setosa    |           2
 Iris-setosa    |           2
 Iris-setosa    |           2
 Iris-setosa    |           2
 Iris-setosa    |           2
 Iris-setosa    |           2
 Iris-setosa    |           2
 Iris-setosa    |           2
 Iris-setosa    |           2
 Iris-setosa    |           2
 Iris-setosa    |           2
.
.
.
(150 rows)
```

UDSF R code

```
KMeans_User <- function(input.data.frame, parameters.data.frame) {
  # Take the clusters and nstart parameters passed by the user and assign them
  # to variables in the function.
  if ( is.null(parameters.data.frame[['clusters']]) ) {
    stop("NULL value for clusters! clusters cannot be NULL.")
  } else {
    clusters.value <- parameters.data.frame[['clusters']]
  }
  if ( is.null(parameters.data.frame[['nstart']]) ) {
    stop("NULL value for nstart! nstart cannot be NULL.")
  } else {
    nstart.value <- parameters.data.frame[['nstart']]
  }
  # Apply the algorithm to the data.
  kmeans.clusters <- kmeans(input.data.frame[, 1:length(input.data.frame)],
                            clusters.value, nstart = nstart.value)
  final.output <- data.frame(kmeans.clusters$cluster)
  return(final.output)
}

KMeans_UserFactory <- function() {
  list(name       = KMeans_User,
       udxtype = c("scalar"),
       # Since this is a polymorphic function the intype must be any
       intype  = c("any"),
       outtype = c("int"),
       parametertypecallback=KMeansParameters)
}

KMeansParameters <- function() {
  parameters <- list(datatype = c("int", "int"),
                     length   = c("NA", "NA"),
                     scale    = c("NA", "NA"),
                     name     = c("clusters", "nstart"))
  return(parameters)
}
```

C++ example: using complex types

UDxs can accept and return complex types. The ArraySlice example takes an array and two indices as inputs and returns an array containing only the values in that range. Because array elements can be of any type, the function is polymorphic.

The complete source code is in /opt/vertica/sdk/examples/ScalarFunctions/ArraySlice.cpp .

Loading and using the example

Load the library and create the function as follows:

```
=> CREATE OR REPLACE LIBRARY ScalarFunctions AS '/home/dbadmin/examplesUDSF.so';

=> CREATE FUNCTION ArraySlice AS
LANGUAGE 'C++' NAME 'ArraySliceFactory' LIBRARY ScalarFunctions;
```

Create some data and call the function on it as follows:

```
=> CREATE TABLE arrays (id INTEGER, aa ARRAY[INTEGER]);
COPY arrays FROM STDIN;
1|[]
2|[1,2,3]
3|[5,4,3,2,1]
\.

=> CREATE TABLE slices (b INTEGER, e INTEGER);
COPY slices FROM STDIN;
0|2
1|3
2|4
\.

=> SELECT id, b, e, ArraySlice(aa, b, e) AS slice FROM arrays, slices;
 id | b | e | slice
----+---+---+-------
  1 | 0 | 2 | []
  1 | 1 | 3 | []
  1 | 2 | 4 | []
  2 | 0 | 2 | [1,2]
  2 | 1 | 3 | [2,3]
  2 | 2 | 4 | [3]
  3 | 0 | 2 | [5,4]
  3 | 1 | 3 | [4,3]
  3 | 2 | 4 | [3,2]
(9 rows)
```

Factory implementation

Because the function is polymorphic, getPrototype() declares that the inputs and outputs can be of any type, and type enforcement must be done elsewhere:

```
void getPrototype(ServerInterface &srvInterface,
                  ColumnTypes &argTypes,
                  ColumnTypes &returnType) override

{
  /*
   * This is a polymorphic function that accepts any array
   * and returns an array of the same type
   */
  argTypes.addAny();
  returnType.addAny();
}
```

The factory validates input types and determines the return type in getReturnType() :

```
void getReturnType(ServerInterface &srvInterface,
                   const SizedColumnTypes &argTypes,
                   SizedColumnTypes &returnType) override
{
  /*
   * Three arguments: (array, slicebegin, sliceend)
   * Validate manually since the prototype accepts any arguments.
   */
  if (argTypes.size() != 3) {
    vt_report_error(0, "Three arguments (array, slicebegin, sliceend) expected");
  } else if (!argTypes[0].getType().isArrayType()) {
    vt_report_error(1, "Argument 1 is not an array");
  } else if (!argTypes[1].getType().isInt()) {
    vt_report_error(2, "Argument 2 (slicebegin) is not an integer)");
  } else if (!argTypes[2].getType().isInt()) {
    vt_report_error(3, "Argument 3 (sliceend) is not an integer)");
  }

  /* return type is the same as the array arg type, copy it over */
  returnType.push_back(argTypes[0]);
}
```

Function implementation

The processBlock() method is called with a BlockReader and a BlockWriter . The first argument is an array. To access elements of the array, the method uses an ArrayReader . Similarly, it uses an ArrayWriter to construct the output.

```
void processBlock(ServerInterface &srvInterface,
    BlockReader &argReader,
    BlockWriter &resWriter) override
{
  do {
    if (argReader.isNull(0) || argReader.isNull(1) || argReader.isNull(2)) {
      resWriter.setNull();
    } else {
      Array::ArrayReader argArray  = argReader.getArrayRef(0);
      const vint slicebegin = argReader.getIntRef(1);
      const vint sliceend   = argReader.getIntRef(2);

      Array::ArrayWriter outArray = resWriter.getArrayRef(0);
      if (slicebegin < sliceend) {
        for (int i = 0; i < slicebegin && argArray->hasData(); i++) {
          argArray->next();
        }
        for (int i = slicebegin; i < sliceend && argArray->hasData(); i++) {
          outArray->copyFromInput(*argArray);
          outArray->next();
          argArray->next();
        }
      }
      outArray.commit();  /* finalize the written array elements */
    }
    resWriter.next();
  } while (argReader.next());
}
```

C++ example: returning multiple values

When writing a UDSF, you can specify more than one return value. If you specify multiple values, Vertica packages them into a single ROW as a return value. You can query fields in the ROW or the entire ROW.

The following example implements a function named div (division) that returns two integers, the quotient and the remainder.

This example shows one way to return a ROW from a UDSF. Returning multiple values and letting Vertica build the ROW is convenient when inputs and outputs are all of primitive types. You can also work directly with the complex types, as described in Complex Types as Arguments and illustrated in C++ example: using complex types .

Loading and using the example

Load the library and create the function as follows:

```
=> CREATE OR REPLACE LIBRARY ScalarFunctions AS '/home/dbadmin/examplesUDSF.so';

=> CREATE FUNCTION div AS
LANGUAGE 'C++' NAME 'DivFactory' LIBRARY ScalarFunctions;
```

Create some data and call the function on it as follows:

```
=> CREATE TABLE D (a INTEGER, b INTEGER);
COPY D FROM STDIN DELIMITER ',';
10,0
10,1
10,2
10,3
10,4
10,5
\.

=> SELECT a, b, Div(a, b), (Div(a, b)).quotient, (Div(a, b)).remainder FROM D;
 a  | b |                  Div                  | quotient | remainder
----+---+---------------------------------------+----------+-----------
 10 | 0 | {"quotient":null,"remainder":null} |          |
 10 | 1 | {"quotient":10,"remainder":0}      |       10 |         0
 10 | 2 | {"quotient":5,"remainder":0}       |        5 |         0
 10 | 3 | {"quotient":3,"remainder":1}       |        3 |         1
 10 | 4 | {"quotient":2,"remainder":2}       |        2 |         2
 10 | 5 | {"quotient":2,"remainder":0}       |        2 |         0
(6 rows)
```

Factory implementation

The factory declares the two return values in getPrototype() and in getReturnType() . The factory is otherwise unremarkable.

```
void getPrototype(ServerInterface &interface,
        ColumnTypes &argTypes,
        ColumnTypes &returnType) override
{
    argTypes.addInt();
    argTypes.addInt();
    returnType.addInt(); /* quotient  */
    returnType.addInt(); /* remainder */
}

void getReturnType(ServerInterface &srvInterface,
        const SizedColumnTypes &argTypes,
        SizedColumnTypes &returnType) override
{
    returnType.addInt("quotient");
    returnType.addInt("remainder");
}
```

Function implementation

The function writes two output values in processBlock() . The number of values here must match the factory declarations.

```
class Div : public ScalarFunction {
  void processBlock(Vertica::ServerInterface &srvInterface,
                    Vertica::BlockReader &argReader,
                    Vertica::BlockWriter &resWriter) override
  {
    do {
      if (argReader.isNull(0) || argReader.isNull(1) || (argReader.getIntRef(1) == 0)) {
        resWriter.setNull(0);
        resWriter.setNull(1);
      } else {
        const vint dividend = argReader.getIntRef(0);
        const vint divisor  = argReader.getIntRef(1);
        resWriter.setInt(0, dividend / divisor);
        resWriter.setInt(1, dividend % divisor);
      }
      resWriter.next();
    } while (argReader.next());
  }
};
```

C++ example: calling a UDSF from a check constraint

This example shows you the C++ code needed to create a UDSF that can be called by a check constraint. The name of the sample function is LargestSquareBelow . The sample function determines the largest number whose square is less than the number in the subject column. For example, if the number in the column is 1000, the largest number whose square is less than 1000 is 31 (961).

Important
A UDSF used within a check constraint must be immutable, and the constraint must handle null values properly. Otherwise, the check constraint might not work as you intended. In addition, Vertica evaluates the predicate of an enabled check constraint on every row that is loaded or updated, so consider performance in writing your function.

For information on check constraints, see Check constraints .

Loading and using the example

The following example shows how you can create and load a library named MySqLib, using CREATE LIBRARY . Adjust the library path in this example to the absolute path and file name for the location where you saved the shared object LargestSquareBelow .

Create the library:

```
=> CREATE OR REPLACE LIBRARY MySqLib AS '/home/dbadmin/LargestSquareBelow.so';
```

1. After you create and load the library, add the function to the catalog using the CREATE FUNCTION (scalar) statement:

```
=> CREATE OR REPLACE FUNCTION largestSqBelow AS LANGUAGE 'C++' NAME 'LargestSquareBelowInfo' LIBRARY MySqLib;
```

1. Next, include the UDSF in a check constraint:

```
=> CREATE TABLE squaretest(
   ceiling INTEGER UNIQUE,
   CONSTRAINT chk_sq CHECK (largestSqBelow(ceiling) < ceiling*ceiling)
);
```

1. Add data to the table, squaretest :

```
=> COPY squaretest FROM stdin DELIMITER ','NULL'null';
-1
null
0
1
1000
1000000
1000001
\.
```

Your output should be similar to the following sample, based upon the data you use:

```
SELECT ceiling, largestSqBelow(ceiling)
FROM squaretest ORDER BY ceiling;

ceiling  | largestSqBelow
---------+----------------
         |
      -1 |
       0 |
       1 |              0
    1000 |             31
 1000000 |            999
 1000001 |           1000
(7 rows)
```

ScalarFunction implementation

This ScalarFunction implementation does the processing work for a UDSF that determines the largest number whose square is less than the number input.

```
#include "Vertica.h"
/*
 * ScalarFunction implementation for a UDSF that
 * determines the largest number whose square is less than
 * the number input.
 */
class LargestSquareBelow : public Vertica::ScalarFunction
{
public:
  /*
   * This function does all of the actual processing for the UDSF.
   * The inputs are retrieved via arg_reader
   * The outputs are returned via arg_writer
   *
   */
    virtual void processBlock(Vertica::ServerInterface &srvInterface,
                              Vertica::BlockReader &arg_reader,
                              Vertica::BlockWriter &res_writer)
    {
        if (arg_reader.getNumCols() != 1)
            vt_report_error(0, "Function only accept 1 argument, but %zu provided", arg_reader.getNumCols());
// While we have input to process
        do {
            // Read the input parameter by calling the
            // BlockReader.getIntRef class function
            const Vertica::vint a = arg_reader.getIntRef(0);
            Vertica::vint res;
            //Determine the largest square below the number
            if ((a != Vertica::vint_null) && (a > 0))
            {
                res = (Vertica::vint)sqrt(a - 1);
            }
            else
                res = Vertica::vint_null;
            //Call BlockWriter.setInt to store the output value,
            //which is the largest square
            res_writer.setInt(res);
            //Write the row and advance to the next output row
            res_writer.next();
            //Continue looping until there are no more input rows
        } while (arg_reader.next());
    }
};
```

ScalarFunctionFactory implementation

This ScalarFunctionFactory implementation does the work of handling input and output, and marks the function as immutable (a requirement if you plan to use the UDSF within a check constraint).

```
class LargestSquareBelowInfo : public Vertica::ScalarFunctionFactory
{
  //return an instance of LargestSquareBelow to perform the computation.
  virtual Vertica::ScalarFunction *createScalarFunction(Vertica::ServerInterface &srvInterface)
  //Call the vt_createFuncObj to create the new LargestSquareBelow class instance.
  { return Vertica::vt_createFuncObject<LargestSquareBelow>(srvInterface.allocator); }

  /*
   * This function returns the description of the input and outputs of the
   * LargestSquareBelow class's processBlock function.  It stores this information in
   * two ColumnTypes objects, one for the input parameter, and one for
   * the return value.
   */
  virtual void getPrototype(Vertica::ServerInterface &srvInterface,
                            Vertica::ColumnTypes &argTypes,
                            Vertica::ColumnTypes &returnType)
  {
      // Takes one int as input, so adds int to the argTypes object
      argTypes.addInt();
      // Returns a single int, so add a single int to the returnType object.
      // ScalarFunctions always return a single value.
      returnType.addInt();
  }
public:
  // the function cannot be called within a check constraint unless the UDx author
  // certifies that the function is immutable:
  LargestSquareBelowInfo() { vol = Vertica::IMMUTABLE; }
};
```

The RegisterFactory macro

Use the RegisterFactory macro to register a ScalarFunctionFactory subclass. This macro instantiates the factory class and makes the metadata it contains available for Vertica to access. To call this macro, pass it the name of your factory class.

```
RegisterFactory(LargestSquareBelowInfo);
```

Transform functions (UDTFs)

A user-defined transform function (UDTF) lets you transform a table of data into another table. It reads one or more arguments (treated as a row of data), and returns zero or more rows of data consisting of one or more columns. A UDTF can produce any number of rows as output. However, each row it outputs must be complete. Advancing to the next row without having added a value for each column produces incorrect results.

The schema of the output table does not need to correspond to the schema of the input table—they can be totally different. The UDTF can return any number of output rows for each row of input.

UDTFs can only be used in the SELECT list that contains just the UDTF call and a required OVER clause. A multi-phase UDTF can make use of partition columns (PARTITION BY), but other UDTFs cannot.

UDTFs are run after GROUP BY, but before the final ORDER BY, when used in conjunction with GROUP BY and ORDER BY in a statement. The ORDER BY clause may contain only columns or expressions that are in a window partition clause (see Window partitioning).

UDTFs can take up to 9800 parameters (input columns). Attempts to pass more parameters to a UDTF return an error.

TransformFunction class

The TransformFunction class is where you perform the data-processing, transforming input rows into output rows. Your subclass must define the processPartition() method. It may define methods to set up and tear down the function.

Performing the transformation

The processPartition() method carries out all of the processing that you want your UDTF to perform. When a user calls your function in a SQL statement, Vertica bundles together the data from the function parameters and passes it to processPartition() .

The input and output of the processPartition() method are supplied by objects of the PartitionReader and PartitionWriter classes. They define methods that you use to read the input data and write the output data for your UDTF.

A UDTF does not necessarily operate on a single row the way a UDSF does. A UDTF can read any number of rows and write output at any time.

Consider the following guidelines when implementing processPartition() :

- Extract the input parameters by calling data-type-specific functions in the PartitionReader object to extract each input parameter. Each of these functions takes a single parameter: the column number in the input row that you want to read. Your function might need to handle NULL values.
- When writing output, your UDTF must supply values for all of the output columns you defined in your factory. Similarly to reading input columns, the PartitionWriter object has functions for writing each type of data to the output row.
- Use PartitionReader.next() to determine if there is more input to process, and exit when the input is exhausted.
- In some cases, you might want to determine the number and types of parameters using PartitionReader 's getNumCols() and getTypeMetaData() functions, instead of just hard-coding the data types of the columns in the input row. This is useful if you want your TransformFunction to be able to process input tables with different schemas. You can then use different TransformFunctionFactory classes to define multiple function signatures that call the same TransformFunction class. See Overloading your UDx for more information.

Setting up and tearing down

The TransformFunction class defines two additional methods that you can optionally implement to allocate and free resources: setup() and destroy() . You should use these methods to allocate and deallocate resources that you do not allocate through the UDx API (see Allocating resources for UDxs for details).

API

C++

Java

Python

R

The TransformFunction API provides the following methods for extension by subclasses:

```
virtual void setup(ServerInterface &srvInterface,
    const SizedColumnTypes &argTypes);

virtual void processPartition(ServerInterface &srvInterface,
    PartitionReader &input_reader, PartitionWriter &output_writer)=0;

virtual void cancel(ServerInterface &srvInterface);

virtual void destroy(ServerInterface &srvInterface,
    const SizedColumnTypes &argTypes);
```

The PartitionReader and PartitionWriter classes provide getters and setters for column values, along with next() to iterate through partitions. See the API reference documentation for details.

TransformFunctionFactory class

The TransformFunctionFactory class tells Vertica metadata about your UDTF: its number of parameters and their data types, as well as the data type of its return value. It also instantiates a subclass of TransformFunction .

You must implement the following methods in your TransformFunctionFactory :

- getPrototype() returns two ColumnTypes objects that describe the columns your UDTF takes as input and returns as output.
- getReturnType() tells Vertica details about the output values: the width of variable-sized data types (such as VARCHAR) and the precision of data types that have settable precision (such as TIMESTAMP). You can also set the names of the output columns using this function. While this method is optional for UDxs that return single values, you must implement it for UDTFs.
- createTransformFunction() instantiates your TransformFunction subclass.

For transform functions written in C++, you can provide information that can help with query optimization. See Improving query performance (C++ only) .

API

C++

Java

Python

R

The TransformFunctionFactory API provides the following methods for extension by subclasses:

```
virtual TransformFunction *
    createTransformFunction (ServerInterface &srvInterface)=0;

virtual void getPrototype(ServerInterface &srvInterface,
            ColumnTypes &argTypes, ColumnTypes &returnType)=0;

virtual void getReturnType(ServerInterface &srvInterface,
            const SizedColumnTypes &argTypes,
            SizedColumnTypes &returnType)=0;

virtual void getParameterType(ServerInterface &srvInterface,
            SizedColumnTypes &parameterTypes);
```

MultiPhaseTransformFunctionFactory class

Multi-phase UDTFs let you break your data processing into multiple steps. Using this feature, your UDTFs can perform processing in a way similar to Hadoop or other MapReduce frameworks. You can use the first phase to break down and gather data, and then use subsequent phases to process the data. For example, the first phase of your UDTF could extract specific types of user interactions from a web server log stored in the column of a table, and subsequent phases could perform analysis on those interactions.

Multi-phase UDTFs also let you decide where processing should occur: locally on each node, or throughout the cluster. If your multi-phase UDTF is like a MapReduce process, you want the first phase of your multi-phase UDTF to process data that is stored locally on the node where the instance of the UDTF is running. This prevents large segments of data from being copied around the Vertica cluster. Depending on the type of processing being performed in later phases, you may choose to have the data segmented and distributed across the Vertica cluster.

Each phase of the UDTF is the same as a traditional (single-phase) UDTF: it receives a table as input, and generates a table as output. The schema for each phase's output does not have to match its input, and each phase can output as many or as few rows as it wants.

You create a subclass of TransformFunction to define the processing performed by each stage. If you already have a TransformFunction from a single-phase UDTF that performs the processing you want a phase of your multi-phase UDTF to perform, you can easily adapt it to work within the multi-phase UDTF.

What makes a multi-phase UDTF different from a traditional UDTF is the factory class you use. You define a multi-phase UDTF using a subclass of MultiPhaseTransformFunctionFactory , rather than the TransformFunctionFactory . This special factory class acts as a container for all of the phases in your multi-step UDTF. It provides Vertica with the input and output requirements of the entire multi-phase UDTF (through the getPrototype() function), and a list of all the phases in the UDTF.

Within your subclass of the MultiPhaseTransformFunctionFactory class, you define one or more subclasses of TransformFunctionPhase . These classes fill the same role as the TransformFunctionFactory class for each phase in your multi-phase UDTF. They define the input and output of each phase and create instances of their associated TransformFunction classes to perform the processing for each phase of the UDTF. In addition to these subclasses, your MultiPhaseTransformFunctionFactory includes fields that provide a handle to an instance of each of the TransformFunctionPhase subclasses.

API

C++

Java

Python

The MultiPhaseTransformFunctionFactory class extends TransformFunctionFactory The API provides the following additional methods for extension by subclasses:

```
virtual void getPhases(ServerInterface &srvInterface,
        std::vector< TransformFunctionPhase * > &phases)=0;
```

If using this factory you must also extend TransformFunctionPhase . See the SDK reference documentation.

Improving query performance (C++ only)

When evaluating a query, the Vertica optimizer might sort its input to improve performance. If a function already returns sorted data, this means the optimizer is doing extra work. A transform function written in C++ can declare how the data it returns is sorted, and the optimizer can take advantage of that information.

A transform function does the actual sorting in the function's processPartition() method. To take advantage of this optimization, sorts must be ascending. You need not sort all columns, but you must return the sorted column or columns first.

You can declare how the function sorts its output in the factory's getReturnType() method.

Caution
If the sorting declared in the factory does not match the sorting provided by the function, query results can be incorrect.

The PolyTopKPerPartition example sorts input columns and returns a given number of rows:

```
=> SELECT polykSort(14, a, b, c) OVER (ORDER BY a, b, c)
   AS (sort1,sort2,sort3) FROM observations ORDER BY 1,2,3;
 sort1 | sort2 | sort3
-------+-------+-------
     1 |     1 |     1
     1 |     1 |     2
     1 |     1 |     3
     1 |     2 |     1
     1 |     2 |     2
     1 |     3 |     1
     1 |     3 |     2
     1 |     3 |     3
     1 |     3 |     4
     2 |     1 |     1
     2 |     1 |     2
     2 |     2 |     3
     2 |     2 |    34
     2 |     3 |     5
(14 rows)
```

The factory declares this sorting in getReturnType() by setting the isSortedBy property on each column. Each SizedColumnType has an associated Properties object where this value can be set:

```
virtual void getReturnType(ServerInterface &srvInterface, const SizedColumnTypes &inputTypes, SizedColumnTypes &outputTypes)
{
   vector<size_t> argCols; // Argument column indexes.
   inputTypes.getArgumentColumns(argCols);
   size_t colIdx = 0;

   for (vector<size_t>::iterator i = argCols.begin() + 1; i < argCols.end(); i++)
   {
      SizedColumnTypes::Properties props;
      props.isSortedBy = true;
      std::stringstream cname;
      cname << "col" << colIdx++;
      outputTypes.addArg(inputTypes.getColumnType(*i), cname.str(), props);
   }
}
```

You can see the effects of this optimization by reviewing the EXPLAIN plans for queries with and without this setting. The following output shows the query plan for polyk , the unsorted version. Note the cost for sorting:

```
=> EXPLAN SELECT polyk(14, a, b, c) OVER (ORDER BY a, b, c)
   FROM observations ORDER BY 1,2,3;

 Access Path:
 +-SORT [Cost: 2K, Rows: 10K] (PATH ID: 1)
 |  Order: col0 ASC, col1 ASC, col2 ASC
 | +---> ANALYTICAL [Cost: 2K, Rows: 10K] (PATH ID: 2)
 | |      Analytic Group
 | |       Functions: polyk()
 | |       Group Sort: observations.a ASC NULLS LAST, observations.b ASC NULLS LAST, observations.c ASC NULLS LAST
 | | +---> STORAGE ACCESS for observations [Cost: 2K, Rows: 10K]
 (PATH ID: 3)
 | | |      Projection: public.observations_super
 | | |      Materialize: observations.a, observations.b, observations.c
```

The query plan for the sorted version omits this step (and cost) and starts with the analytical step (the second step in the previous plan):

```
=> EXPLAN SELECT polykSort(14, a, b, c) OVER (ORDER BY a, b, c)
   FROM observations ORDER BY 1,2,3;

Access Path:
 +-ANALYTICAL [Cost: 2K, Rows: 10K] (PATH ID: 2)
 |  Analytic Group
 |   Functions: polykSort()
 |   Group Sort: observations.a ASC NULLS LAST, observations.b ASC NULLS LAST, observations.c ASC NULLS LAST
 | +---> STORAGE ACCESS for observations [Cost: 2K, Rows: 10K] (PATH ID: 3)
 | |      Projection: public.observations_super
 | |      Materialize: observations.a, observations.b, observations.c
```

Partitioning options for processing local data

UDTFs typically process data that is partitioned in a specific way. For example, a UDTF that processes a web server log file to count the number of hits referred by each partner web site needs to have its input partitioned by a referrer column. Each instance of the UDTF sees the hits referred by a particular partner site so it can count them.

In cases like this, the window partitioning clause should use a PARTITION BY clause. Each node in the cluster partitions the data it stores, sends some of these partitions off to other nodes, and then consolidates the partitions it receives from other nodes and runs an instance of the UDTF to process them.

In other cases, a UDTF might not need to partition input data in a particular way—for example, a UDTF that parses data out of an Apache log file. In this case, you can specify that each UDTF instance process only the data that is stored locally by the node on which it is running. By eliminating the overhead of partitioning data, processing can be much more efficient.

You can tell a UDTF to process only local data with one of the following window partitioning options:

- PARTITION BEST : For thread-safe UDTFs only, optimizes performance through multi-threaded queries across multiple nodes.
- PARTITION NODES : Optimizes performance of single-threaded queries across multiple nodes.

The query must specify a source table that is replicated across all nodes and contains a single row (similar to the DUAL table). For example, the following statements call a UDTF that parses locally-stored Apache log files:

```
=> CREATE TABLE rep (dummy INTEGER) UNSEGMENTED ALL NODES;
CREATE TABLE
=> INSERT INTO rep VALUES (1);
 OUTPUT
--------
      1
(1 row)
=> SELECT ParseLogFile('/data/apache/log*') OVER (PARTITION BEST) FROM rep;
```

C++ example: string tokenizer

The following example shows a subclass of TransformFunction named StringTokenizer . It defines a UDTF that reads a table containing an INTEGER ID column and a VARCHAR column. It breaks the text in the VARCHAR column into tokens (individual words). It returns a table containing each token, the row it occurred in, and its position within the string.

Loading and using the example

The following example shows how to load the function into Vertica. It assumes that the TransformFunctions.so library that contains the function has been copied to the dbadmin user's home directory on the initiator node.

```
=> CREATE LIBRARY TransformFunctions AS
   '/home/dbadmin/TransformFunctions.so';
CREATE LIBRARY
=> CREATE TRANSFORM FUNCTION tokenize
   AS LANGUAGE 'C++' NAME 'TokenFactory' LIBRARY TransformFunctions;
CREATE TRANSFORM FUNCTION
```

You can then use it from SQL statements, for example:

```
=> CREATE TABLE T (url varchar(30), description varchar(2000));
CREATE TABLE
=> INSERT INTO T VALUES ('www.amazon.com','Online retail merchant and provider of cloud services');
 OUTPUT
--------
      1
(1 row)
=> INSERT INTO T VALUES ('www.vertica.com','World"s fastest analytic database');
 OUTPUT
--------
      1
(1 row)
=> COMMIT;
COMMIT

=> -- Invoke the UDTF
=> SELECT url, tokenize(description) OVER (partition by url) FROM T;
       url       |   words
-----------------+-----------
 www.amazon.com  | Online
 www.amazon.com  | retail
 www.amazon.com  | merchant
 www.amazon.com  | and
 www.amazon.com  | provider
 www.amazon.com  | of
 www.amazon.com  | cloud
 www.amazon.com  | services
 www.vertica.com | World's
 www.vertica.com | fastest
 www.vertica.com | analytic
 www.vertica.com | database
(12 rows)
```

Notice that the number of rows and columns in the result table are different than the input table. This is one of the strengths of a UDTF.

TransformFunction implementation

The following code shows the StringTokenizer class.

```
class StringTokenizer : public TransformFunction
{
 virtual void processPartition(ServerInterface &srvInterface,
                               PartitionReader &inputReader,
                               PartitionWriter &outputWriter)
 {
  try {
   if (inputReader.getNumCols() != 1)
    vt_report_error(0, "Function only accepts 1 argument, but %zu provided", inputReader.getNumCols());

   do {
    const VString &sentence = inputReader.getStringRef(0);

    // If input string is NULL, then output is NULL as well
    if (sentence.isNull())
     {
      VString &word = outputWriter.getStringRef(0);
      word.setNull();
      outputWriter.next();
     }
    else
     {
      // Otherwise, let's tokenize the string and output the words
      std::string tmp = sentence.str();
      std::istringstream ss(tmp);

      do
       {
        std::string buffer;
        ss >> buffer;

        // Copy to output
        if (!buffer.empty()) {
         VString &word = outputWriter.getStringRef(0);
         word.copy(buffer);
         outputWriter.next();
        }
       } while (ss);
     }
   } while (inputReader.next() && !isCanceled());
  } catch(std::exception& e) {
   // Standard exception. Quit.
   vt_report_error(0, "Exception while processing partition: [%s]", e.what());
  }
 }
};
```

The processPartition() function in this example follows a pattern that you will follow in your own UDTF: it loops over all rows in the table partition that Vertica sends it, processing each row and checking for cancellation before advancing. For UDTFs you do not have to actually process every row. You can exit your function without having read all of the input without any issues. You may choose to do this if your UDTF is performing some sort search or some other operation where it can determine that the rest of the input is unneeded.

In this example, processPartition() first extracts the VString containing the text from the PartitionReader object. The VString class represents a Vertica string value (VARCHAR or CHAR). If there is input, it then tokenizes it and adds it to the output using the PartitionWriter object.

Similarly to reading input columns, the PartitionWriter class has functions for writing each type of data to the output row. In this case, the example calls the PartitionWriter object's getStringRef() function to allocate a new VString object to hold the token to output for the first column, and then copies the token's value into the VString .

TranformFunctionFactory implementation

The following code shows the factory class.

```
class TokenFactory : public TransformFunctionFactory
{
 // Tell Vertica that we take in a row with 1 string, and return a row with 1 string
 virtual void getPrototype(ServerInterface &srvInterface, ColumnTypes &argTypes, ColumnTypes &returnType)
 {
  argTypes.addVarchar();
  returnType.addVarchar();
 }

 // Tell Vertica what our return string length will be, given the input
 // string length
 virtual void getReturnType(ServerInterface &srvInterface,
                            const SizedColumnTypes &inputTypes,
                            SizedColumnTypes &outputTypes)
 {
  // Error out if we're called with anything but 1 argument
  if (inputTypes.getColumnCount() != 1)
   vt_report_error(0, "Function only accepts 1 argument, but %zu provided", inputTypes.getColumnCount());

  int input_len = inputTypes.getColumnType(0).getStringLength();

  // Our output size will never be more than the input size
  outputTypes.addVarchar(input_len, "words");
 }

 virtual TransformFunction *createTransformFunction(ServerInterface &srvInterface)
 { return vt_createFuncObject<StringTokenizer>(srvInterface.allocator); }

};
```

In this example:

- The UDTF takes a VARCHAR column as input. To define the input column, getPrototype() calls addVarchar() on the ColumnTypes object that represents the input table.
- The UDTF returns a VARCHAR as output. The getPrototype() function calls addVarchar() to define the output table.

This example must return the maximum length of the VARCHAR output column. It sets the length to the length of the input string. This is a safe value, because the output will never be longer than the input string. It also sets the name of the VARCHAR output column to "words".

> **Note**
> You are not required to supply a name for an output column in this function. However, it is a best practice to do so. If you do not name an output column, getReturnType() sets the column name to "". The SQL statements that call your UDTF must provide aliases for any unnamed columns to access them or else they return an error. From a usability standpoint, it is easier for you to supply the column names here once. The alternative is to force all of the users of your function to supply their own column names for each call to the UDTF.

The implementation of the createTransformFunction() function in the example is boilerplate code. It just calls the vt_returnFuncObj macro with the name of the TransformFunction class associated with this factory class. This macro takes care of instantiating a copy of the TransformFunction class that Vertica can use to process data.

The RegisterFactory macro

The final step in creating your UDTF is to call the RegisterFactory macro. This macro ensures that your factory class is instantiated when Vertica loads the shared library containing your UDTF. Having your factory class instantiated is the only way that Vertica can find your UDTF and determine what its inputs and outputs are.

The RegisterFactory macro just takes the name of your factory class:

```
RegisterFactory(TokenFactory);
```

Python example: string tokenizer

The following example shows a transform function that breaks an input string into tokens (based on whitespace). It is similar to the tokenizer examples for C++ and Java.

Loading and using the example

Create the library and function:

```
=> CREATE LIBRARY pyudtf AS '/home/dbadmin/udx/tokenize.py' LANGUAGE 'Python';
CREATE LIBRARY
=> CREATE TRANSFORM FUNCTION tokenize AS NAME 'StringTokenizerFactory' LIBRARY pyudtf;
CREATE TRANSFORM FUNCTION
```

You can then use the function in SQL statements, for example:

```
=> CREATE TABLE words (w VARCHAR);
CREATE TABLE
=> COPY words FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> this is a test of the python udtf
>> \.

=> SELECT tokenize(w) OVER () FROM words;
  token
----------
 this
 is
 a
 test
 of
 the
 python
 udtf
(8 rows)
```

Setup

All Python UDxs must import the Vertica SDK.

```
import vertica_sdk
```

UDTF Python code

The following code defines the tokenizer and its factory.

```
class StringTokenizer(vertica_sdk.TransformFunction):
    """
    Transform function which tokenizes its inputs.
    For each input string, each of the whitespace-separated tokens of that
    string is produced as output.
    """
    def processPartition(self, server_interface, input, output):
        while True:
            for token in input.getString(0).split():
                output.setString(0, token)
                output.next()
            if not input.next():
                break

class StringTokenizerFactory(vertica_sdk.TransformFunctionFactory):
    def getPrototype(self, server_interface, arg_types, return_type):
        arg_types.addVarchar()
        return_type.addVarchar()
    def getReturnType(self, server_interface, arg_types, return_type):
        return_type.addColumn(arg_types.getColumnType(0), "tokens")
    def createTransformFunction(cls, server_interface):
        return StringTokenizer()
```

R example: log tokenizer

The LogTokenizer transform function reads a varchar from a table, a log message. It then tokenizes each of the log messages, returning each of the tokens.

You can find more UDx examples in the Vertica Github repository, https://github.com/vertica/UDx-Examples .

Load the function and library

Create the library and the function.

```
=> CREATE OR REPLACE LIBRARY rLib AS 'log_tokenizer.R' LANGUAGE 'R';
CREATE LIBRARY
=> CREATE OR REPLACE TRANSFORM FUNCTION LogTokenizer AS LANGUAGE 'R' NAME 'LogTokenizerFactory' LIBRARY rLib FENCED;
CREATE FUNCTION
```

Querying data with the function

The following query shows how you can run a query with the UDTF.

```
=> SELECT machine,
          LogTokenizer(error_log USING PARAMETERS spliton = ' ') OVER(PARTITION BY machine)
     FROM error_logs;
 machine |  Token
---------+---------
 node001 | ERROR
 node001 | 345
 node001 | -
 node001 | Broken
 node001 | pipe
 node001 | WARN
 node001 | -
 node001 | Nearly
 node001 | filled
 node001 | disk
 node002 | ERROR
 node002 | 111
 node002 | -
 node002 | Flooded
 node002 | roads
 node003 | ERROR
 node003 | 222
 node003 | -
 node003 | Plain
 node003 | old
 node003 | broken
(21 rows)
```

UDTF R code

```
LogTokenizer <- function(input.data.frame, parameters.data.frame) {
  # Take the spliton parameter passed by the user and assign it to a variable
  # in the function so we can use that as our tokenizer.
  if ( is.null(parameters.data.frame['spliton']) ) {
    stop("NULL value for spliton! Token cannot be NULL.")
  } else {
    split.on <- as.character(parameters.data.frame['spliton'])
  }
  # Tokenize the string.
  tokens <- vector(length=0)
  for ( string in input.data.frame[, 1] ) {
    tokenized.string <- strsplit(string, split.on)
    for ( token in tokenized.string ) {
      tokens <- append(tokens, token)
    }
  }
  final.output <- data.frame(tokens)
  return(final.output)
}

LogTokenizerFactory <- function() {
  list(name     = LogTokenizer,
       udxtype = c("transform"),
       intype  = c("varchar"),
       outtype = c("varchar"),
       outtypecallback=LogTokenizerReturn,
       parametertypecallback=LogTokenizerParameters)
}

LogTokenizerParameters <- function() {
  parameters <- list(datatype = c("varchar"),
                     length   = c("NA"),
                     scale    = c("NA"),
                     name     = c("spliton"))
  return(parameters)
}

LogTokenizerReturn <- function(arg.data.frame, parm.data.frame) {
  output.return.type <- data.frame(datatype = rep(NA,1),
                                   length   = rep(NA,1),
                                   scale    = rep(NA,1),
                                   name     = rep(NA,1))
  output.return.type$datatype <- c("varchar")
  output.return.type$name <- c("Token")
  return(output.return.type)
}
```

C++ example: multi-phase indexer

The following code fragment is from the InvertedIndex UDTF example distributed with the Vertica SDK. It demonstrates subclassing the MultiPhaseTransformFunctionFactory including two TransformFunctionPhase subclasses that define the two phases in this UDTF.

```
class InvertedIndexFactory : public MultiPhaseTransformFunctionFactory

public:
  /**
   * Extracts terms from documents.
   */
  class ForwardIndexPhase : public TransformFunctionPhase
  {
```

```
{
  virtual void getReturnType(ServerInterface &srvInterface,
                             const SizedColumnTypes &inputTypes,
                             SizedColumnTypes &outputTypes)
  {
    // Sanity checks on input we've been given.
    // Expected input: (doc_id INTEGER, text VARCHAR)
    vector<size_t> argCols;
    inputTypes.getArgumentColumns(argCols);
    if (argCols.size() < 2 ||
        !inputTypes.getColumnType(argCols.at(0)).isInt() ||
        !inputTypes.getColumnType(argCols.at(1)).isVarchar())
        vt_report_error(0, "Function only accepts two arguments"
                        "(INTEGER, VARCHAR)");
    // Output of this phase is:
    //   (term_freq INTEGER) OVER(PBY term VARCHAR OBY doc_id INTEGER)
    // Number of times term appears within a document.
    outputTypes.addInt("term_freq");
    // Add analytic clause columns: (PARTITION BY term ORDER BY doc_id).
    // The length of any term is at most the size of the entire document.
    outputTypes.addVarcharPartitionColumn(
        inputTypes.getColumnType(argCols.at(1)).getStringLength(),
        "term");
    // Add order column on the basis of the document id's data type.
    outputTypes.addOrderColumn(inputTypes.getColumnType(argCols.at(0)),
                               "doc_id");
  }
  virtual TransformFunction *createTransformFunction(ServerInterface
      &srvInterface)
  { return vt_createFuncObj(srvInterface.allocator, ForwardIndexBuilder); }
};
/**
 * Constructs terms' posting lists.
 */
class InvertedIndexPhase : public TransformFunctionPhase
{
  virtual void getReturnType(ServerInterface &srvInterface,
                             const SizedColumnTypes &inputTypes,
                             SizedColumnTypes &outputTypes)
  {
    // Sanity checks on input we've been given.
    // Expected input:
    //   (term_freq INTEGER) OVER(PBY term VARCHAR OBY doc_id INTEGER)
    vector<size_t> argCols;
    inputTypes.getArgumentColumns(argCols);
    vector<size_t> pByCols;
    inputTypes.getPartitionByColumns(pByCols);
    vector<size_t> oByCols;
    inputTypes.getOrderByColumns(oByCols);
    if (argCols.size() != 1 || pByCols.size() != 1 || oByCols.size() != 1 ||
        !inputTypes.getColumnType(argCols.at(0)).isInt() ||
        !inputTypes.getColumnType(pByCols.at(0)).isVarchar() ||
        !inputTypes.getColumnType(oByCols.at(0)).isInt())
        vt_report_error(0, "Function expects an argument (INTEGER) with "
                        "analytic clause OVER(PBY VARCHAR OBY INTEGER)");
    // Output of this phase is:
    //   (term VARCHAR, doc_id INTEGER, term_freq INTEGER, corp_freq INTEGER).
    outputTypes.addVarchar(inputTypes.getColumnType(
                           pByCols.at(0)).getStringLength(),"term");
    outputTypes.addInt("doc_id");
    // Number of times term appears within the document.
    outputTypes.addInt("term_freq");
```

```
        // Number of documents where the term appears in.
        outputTypes.addInt("corp_freq");
    }

    virtual TransformFunction *createTransformFunction(ServerInterface
            &srvInterface)
    { return vt_createFuncObj(srvInterface.allocator, InvertedIndexBuilder); }
};
ForwardIndexPhase fwardIdxPh;
InvertedIndexPhase invIdxPh;
virtual void getPhases(ServerInterface &srvInterface,
     std::vector<TransformFunctionPhase *> &phases)
{
    fwardIdxPh.setPrepass(); // Process documents wherever they're originally stored.
    phases.push_back(&fwardIdxPh);
    phases.push_back(&invIdxPh);
}
virtual void getPrototype(ServerInterface &srvInterface,
                          ColumnTypes &argTypes,
                          ColumnTypes &returnType)
{
    // Expected input: (doc_id INTEGER, text VARCHAR).
    argTypes.addInt();
    argTypes.addVarchar();
    // Output is: (term VARCHAR, doc_id INTEGER, term_freq INTEGER, corp_freq INTEGER)
    returnType.addVarchar();
    returnType.addInt();
    returnType.addInt();
    returnType.addInt();
}
};
RegisterFactory(InvertedIndexFactory);
```

Most of the code in this example is similar to the code in a TransformFunctionFactory class:

- Both TransformFunctionPhase subclasses implement the getReturnType() function, which describes the output of each stage. This is the similar to the getReturnType() function from the TransformFunctionFactory class. However, this function also lets you control how the data is partitioned and ordered between each phase of your multi-phase UDTF.
  The first phase calls SizedColumnTypes::addVarcharPartitionColumn() (rather than just addVarcharColumn()) to set the phase's output table to be partitioned by the column containing the extracted words. It also calls SizedColumnTypes::addOrderColumn() to order the output table by the document ID column. It calls this function instead of one of the data-type-specific functions (such as addIntOrderColumn()) so it can pass the data type of the original column through to the output column.

  > **Note**
  > Any order by column or partition by column set by the final phase of the UDTF in its getReturnType() function is ignored. Its output is returned to the initiator node rather than partitioned and reordered then sent to another phase.

- The MultiPhaseTransformFunctionFactory class implements the getPrototype() function, that defines the schemas for the input and output of the multi-phase UDTF. This function is the same as the TransformFunctionFactory::getPrototype() function.

The unique function implemented by the MultiPhaseTransformFunctionFactory class is getPhases() . This function defines the order in which the phases are executed. The fields that represent the phases are pushed into this vector in the order they should execute.

The MultiPhaseTransformFunctionFactory.getPhases() function is also where you flag the first phase of the UDTF as operating on data stored locally on the node (called a "pre-pass" phase) rather than on data partitioned across all nodes. Using this option increases the efficiency of your multi-phase UDTF by avoiding having to move significant amounts of data around the Vertica cluster.

> **Note**

> Only the first phase of your UDTF can be a pre-pass phase. You cannot have multiple pre-pass phases, and no later phase can be a pre-pass phase.

To mark the first phase as pre-pass, you call the TransformFunctionPhase::setPrepass() function of the first phase's TransformFunctionPhase instance from within the getPhase() function.

Notes

- You need to ensure that the output schema of each phase matches the input schema expected by the next phase. In the example code, each TransformFunctionPhase::getReturnType() implementation performs a sanity check on its input and output schemas. Your TransformFunction subclasses can also perform these checks in their processPartition() function.
- There is no built-in limit on the number of phases that your multi-phase UDTF can have. However, more phases use more resources. When running in fenced mode, Vertica may terminate UDTFs that use too much memory. See Resource use for C++ UDxs .

Python example: multi-phase calculation

The following example shows a multi-phase transform function that computes the average value on a column of numbers in an input table. It first defines two transform functions, and then defines a factory that creates the phases using them.

See AvgMultiPhaseUDT.py in the examples distribution for the complete code.

Loading and using the example

Create the library and function:

```
=> CREATE LIBRARY pylib_avg AS '/home/dbadmin/udx/AvgMultiPhaseUDT.py' LANGUAGE 'Python';
CREATE LIBRARY
=> CREATE TRANSFORM FUNCTION myAvg AS NAME 'MyAvgFactory' LIBRARY pylib_avg;
CREATE TRANSFORM FUNCTION
```

You can then use the function in SELECT statements:

```
=> CREATE TABLE IF NOT EXISTS numbers(num FLOAT);
CREATE TABLE

=> COPY numbers FROM STDIN delimiter ',';
1
2
3
4
\.

=> SELECT myAvg(num) OVER() FROM numbers;
 average | ignored_rows | total_rows
---------+--------------+------------
     2.5 |            0 |          4
(1 row)
```

Setup

All Python UDxs must import the Vertica SDK. This example also imports another library.

```
import vertica_sdk
import math
```

Component transform functions

A multi-phase transform function must define two or more TransformFunction subclasses to be used in the phases. This example uses two classes: LocalCalculation , which does calculations on local partitions, and GlobalCalculation , which aggregates the results of all LocalCalculation instances to calculate a final result.

In both functions, the calculation is done in the processPartition() function:

```
class LocalCalculation(vertica_sdk.TransformFunction):
    """
    This class is the first phase and calculates the local values for sum, ignored_rows and total_rows.
    """

    def setup(self, server_interface, col_types):
        server_interface.log("Setup: Phase0")
        self.local_sum = 0.0
        self.ignored_rows = 0
        self.total_rows = 0

    def processPartition(self, server_interface, input, output):
        server_interface.log("Process Partition: Phase0")

        while True:
            self.total_rows += 1

            if input.isNull(0) or math.isinf(input.getFloat(0)) or math.isnan(input.getFloat(0)):
                # Null, Inf, or Nan is ignored
                self.ignored_rows += 1
            else:
                self.local_sum += input.getFloat(0)

            if not input.next():
                break

        output.setFloat(0, self.local_sum)
        output.setInt(1, self.ignored_rows)
        output.setInt(2, self.total_rows)
        output.next()

class GlobalCalculation(vertica_sdk.TransformFunction):
    """
    This class is the second phase and aggregates the values for sum, ignored_rows and total_rows.
    """

    def setup(self, server_interface, col_types):
        server_interface.log("Setup: Phase1")
        self.global_sum = 0.0
        self.ignored_rows = 0
        self.total_rows = 0

    def processPartition(self, server_interface, input, output):
        server_interface.log("Process Partition: Phase1")

        while True:
            self.global_sum += input.getFloat(0)
            self.ignored_rows += input.getInt(1)
            self.total_rows += input.getInt(2)

            if not input.next():
                break

        average = self.global_sum / (self.total_rows - self.ignored_rows)

        output.setFloat(0, average)
        output.setInt(1, self.ignored_rows)
        output.setInt(2, self.total_rows)
        output.next()
```

Multi-phase factory

A MultiPhaseTransformFunctionFactory ties together the individual functions as phases. The factory defines a TransformFunctionPhase for each function. Each phase defines createTransformFunction() , which calls the constructor for the corresponding TransformFunction , and getReturnType() .

The first phase, LocalPhase , follows.

```
class MyAvgFactory(vertica_sdk.MultiPhaseTransformFunctionFactory):
    """ Factory class """

    class LocalPhase(vertica_sdk.TransformFunctionPhase):
        """ Phase 1 """
        def getReturnType(self, server_interface, input_types, output_types):
            # sanity check
            number_of_cols = input_types.getColumnCount()
            if (number_of_cols != 1 or not input_types.getColumnType(0).isFloat()):
                raise ValueError("Function only accepts one argument (FLOAT)")

            output_types.addFloat("local_sum");
            output_types.addInt("ignored_rows");
            output_types.addInt("total_rows");

        def createTransformFunction(cls, server_interface):
            return LocalCalculation()
```

The second phase, GlobalPhase , does not check its inputs because the first phase already did. As with the first phase, createTransformFunction merely constructs and returns the corresponding TransformFunction .

```
    class GlobalPhase(vertica_sdk.TransformFunctionPhase):
        """ Phase 2 """
        def getReturnType(self, server_interface, input_types, output_types):
            output_types.addFloat("average");
            output_types.addInt("ignored_rows");
            output_types.addInt("total_rows");

        def createTransformFunction(cls, server_interface):
            return GlobalCalculation()
```

After defining the TransformFunctionPhase subclasses, the factory instantiates them and chains them together in getPhases() .

```
    ph0Instance = LocalPhase()
    ph1Instance = GlobalPhase()

    def getPhases(cls, server_interface):
        cls.ph0Instance.setPrepass()
        phases = [cls.ph0Instance, cls.ph1Instance]
        return phases
```

User-defined load (UDL)

COPY offers extensive options and settings to control how to load data. However, you may find that these options do not suit the type of data load that you want to perform. The user-defined load (UDL) feature lets you develop one or more functions that change how the COPY statement operates. You can create custom libraries using the Vertica SDK to handle various steps in the loading process. .

You use three types of UDL functions during development, one for each stage of the data-load process:

- User-defined source (UDSource): Controls how COPY obtains the data it loads into the database. For example, COPY might obtain data by fetching it through HTTP or cURL. Up to one UDSource reads data from a file or input stream. Your UDSource can read from more than one source, but COPY invokes only one UDSource.
  API support: C++, Java.
- User-defined filter (UDFilter): Preprocesses the data. For example, a filter might unzip a file or convert UTF-16 to UTF-8. You can chain multiple user-defined filters together, for example unzipping and then converting.
  API support: C++, Java, Python.

- User-defined parser (UDParser): Up to one parser parses the data into tuples that are ready to be inserted into a table. For example, a parser could extract data from an XML-like format. You can optionally define a user-defined chunker (UDChunker, C++ only), to have the parser perform parallel parsing.
  API support: C++, Java, Python.

After the final step, COPY inserts the data into a table, or rejects it if the format is incorrect.

In this section

- User-defined source
- User-defined filter
- User-defined parser
- Load parallelism
- Continuous load
- Buffer classes

User-defined source

A user-defined source allows you to process a source of data using a method that is not built into Vertica. For example, you can write a user-defined source to access the data from an HTTP source using cURL. While a given COPY statement can use specify only one user-defined source statement, the source function itself can pull data from multiple sources.

The UDSource class acquires data from an external source. It reads data from an input stream and produces an output stream to be filtered and parsed. If you implement a UDSource , you must also implement a corresponding SourceFactory .

In this section

- UDSource class
- SourceFactory class
- C++ example: CurlSource
- C++ example: concurrent load
- Java example: FileSource

UDSource class

You can subclass the UDSource class when you need to load data from a source type that COPY does not already support.

Each instance of your UDSource subclass reads from a single data source. Examples of a single data source are a single file or the results of a single function call to a RESTful web application.

UDSource methods

Your UDSource subclass must override process() or processWithMetadata() :

> **Note**
> processWithMetadata() is available only for user-defined extensions (UDxs) written in the C++ programming language.

- process() reads the raw input stream as one large file. If there are any errors or failures, the entire load fails.
- processWithMetadata() is useful when the data source has metadata about record boundaries available in some structured format that's separate from the data payload. With this interface, the source emits a record length for each record in addition to the data.
  By implementing processWithMetadata() instead of process() in each phase, you can retain this record length metadata throughout the load stack, which enables a more efficient parse that can recover from errors on a per-message basis, rather than a per-file or per-source basis. KafkaSource and the Kafka parsers (KafkaAvroParser , KafkaJSONParser , and KafkaParser) use this mechanism to support per-Kafka-message rejections when individual Kafka messages are cannot be parsed.

  > **Note**
  > To implement processWithMetadata() , you must override useSideChannel() to return true .

Additionally, you can override the other UDSource class methods.

Source execution

The following sections detail the execution sequence each time a user-defined source is called. The following example overrides the process() method.

Setting Up
COPY calls setup() before the first time it calls process() . Use setup() to perform any necessary setup steps to access the data source. This method establishes network connections, opens files, and similar tasks that need to be performed before the UDSource can read data from the data source. Your object might be destroyed and re-created during use, so make sure that your object is restartable.

Processing a Source
COPY calls process() repeatedly during query execution to read data and write it to the DataBuffer passed as a parameter. This buffer is then passed to the first filter.

If the source runs out of input, or fills the output buffer, it must return the value StreamState.OUTPUT_NEEDED . When Vertica gets this return value, it will call the method again. This second call occurs after the output buffer has been processed by the next stage in the data-load process. Returning StreamState.DONE indicates that all of the data from the source has been read.

The user can cancel the load operation, which aborts reading.

Tearing Down
COPY calls destroy() after the last time that process() is called. This method frees any resources reserved by the setup() or process() methods, such as file handles or network connections that the setup() method allocated.

Accessors
A source can define two accessors, getSize() and getUri() .

COPY might call getSize() to estimate the number of bytes of data to be read before calling process() . This value is an estimate only and is used to indicate the file size in the LOAD_STREAMS table. Because Vertica can call this method before calling setup() , getSize() must not rely on any resources allocated by setup() .

This method should not leave any resources open. For example, do not save any file handles opened by getSize() for use by the process() method. Doing so can exhaust the available resources, because Vertica calls getSize() on all instances of your UDSource subclass before any data is loaded. If many data sources are being opened, these open file handles could use up the system's supply of file handles. Thus, none would remain available to perform the actual data load.

Vertica calls getUri() during execution to update status information about which resources are currently being loaded. It returns the URI of the data source being read by this UDSource .

API

C++

Java

The UDSource API provides the following methods for extension by subclasses:

```
virtual void setup(ServerInterface &srvInterface);

virtual bool useSideChannel();

virtual StreamState process(ServerInterface &srvInterface, DataBuffer &output)=0;

virtual StreamState processWithMetadata(ServerInterface &srvInterface, DataBuffer &output, LengthBuffer &output_len

virtual void cancel(ServerInterface &srvInterface);

virtual void destroy(ServerInterface &srvInterface);

virtual vint getSize();

virtual std::string getUri();
```

SourceFactory class

If you write a source, you must also write a source factory. Your subclass of the SourceFactory class is responsible for:

- Performing the initial validation of the parameters passed to your UDSource .
- Setting up any data structures your UDSource instances need to perform their work. This information can include recording which nodes will read which data source.
- Creating one instance of your UDSource subclass for each data source (or portion thereof) that your function reads on each host.

The simplest source factory creates one UDSource instance per data source per executor node. You can also use multiple concurrent UDSource instances on each node. This behavior is called *concurrent load* . To support both options, SourceFactory has two versions of the method that creates the sources. You must implement exactly one of them.

Source factories are singletons. Your subclass must be stateless, with no fields containing data. The subclass also must not modify any global variables.

SourceFactory methods

The SourceFactory class defines several methods. Your class must override prepareUDSources() ; it may override the other methods.

Setting up

Vertica calls plan() once on the initiator node to perform the following tasks:

- Check the parameters the user supplied to the function call in the COPY statement and provide error messages if there are any issues. You can read the parameters by getting a ParamReader object from the instance of ServerInterface passed into the plan() method.
- Decide which hosts in the cluster will read the data source. How you divide up the work depends on the source your function is reading. Some sources can be split across many hosts, such as a source that reads data from many URLs. Others, such as an individual local file on a host's file system, can be read only by a single specified host.
  You store the list of hosts to read the data source by calling the setTargetNodes() method on the NodeSpecifyingPlanContext object. This object is passed into your plan() method.
- Store any information that the individual hosts need to process the data sources in the NodeSpecifyingPlanContext instance passed to the plan() method. For example, you could store assignments that tell each host which data sources to process. The plan() method runs only on the initiator node, and the prepareUDSources() method runs on each host reading from a data source. Therefore, this object is the only means of communication between them.
  You store data in the NodeSpecifyingPlanContext by getting a ParamWriter object from the getWriter() method. You then write parameters by calling methods on the ParamWriter such as setString() .

  > **Note**
  > ParamWriter offers the ability to store only simple data types. For complex types, you must serialize the data in some manner and store it as a string or long string.

Creating sources

Vertica calls prepareUDSources() on all hosts that the plan() method selected to load data. This call instantiates and returns a list of UDSource subclass instances. If you are not using concurrent load, return one UDSource for each of the sources that the host is assigned to process. If you are using concurrent load, use the version of the method that takes an ExecutorPlanContext as a parameter, and return as many sources as you can use. Your factory must implement exactly one of these methods.

> **Note**
> In the C++ API, the function that supports concurrent load is named prepareUDSourcesExecutor() . In the Java API the class provides two overloads of prepareUDSources() .

For concurrent load, you can find out how many threads are available on the node to run UDSource instances by calling getLoadConcurrency() on the ExecutorPlanContext that is passed in.

Defining parameters

Implement getParameterTypes() to define the names and types of parameters that your source uses. Vertica uses this information to warn callers about unknown or missing parameters. Vertica ignores unknown parameters and uses default values for missing parameters. While you should define the types and parameters for your function, you are not required to override this method.

Requesting threads for concurrent load

When a source factory creates sources on an executor node, by default, it creates one thread per source. If your sources can use multiple threads, implement getDesiredThreads() . Vertica calls this method before it calls prepareUDSources() , so you can also use it to decide how many sources to create. Return the number of threads your factory can use for sources. The maximum number of available threads is passed in, so you can take that into account. The value your method returns is a hint, not a guarantee; each executor node determines the number of threads to allocate. The FilePortionSourceFactory example implements this method; see C++ example: concurrent load .

You can allow your source to have control over parallelism, meaning that it can divide a single input into multiple load streams, by implementing isSourceApportionable() . Returning true from this method does not guarantee that the source *will* apportion the load. However, returning false indicates that it will not try to do so. See Apportioned load for more information.

Often, a SourceFactory that implements getDesiredThreads() also uses apportioned load. However, using apportioned load is not a requirement. A source reading from Kafka streams, for example, could use multiple threads without ssapportioning.

API

C++

Java

The SourceFactory API provides the following methods for extension by subclasses:

```
virtual void plan(ServerInterface &srvInterface, NodeSpecifyingPlanContext &planCtxt);

// must implement exactly one of prepareUDSources() or prepareUDSourcesExecutor()
virtual std::vector< UDSource * > prepareUDSources(ServerInterface &srvInterface,
        NodeSpecifyingPlanContext &planCtxt);

virtual std::vector< UDSource * > prepareUDSourcesExecutor(ServerInterface &srvInterface,
        ExecutorPlanContext &planCtxt);

virtual void getParameterType(ServerInterface &srvInterface,
        SizedColumnTypes &parameterTypes);

virtual bool isSourceApportionable();

ssize_t getDesiredThreads(ServerInterface &srvInterface,
        ExecutorPlanContext &planContext);
```

After creating your SourceFactory , you must register it with the RegisterFactory macro.

C++ example: CurlSource

The CurlSource example allows you to use cURL to open and read in a file over HTTP. The example provided is part of: /opt/vertica/sdk/examples/SourceFunctions/cURL.cpp .

Source implementation

This example uses the helper library available in /opt/vertica/sdk/examples/HelperLibraries/ .

CurlSource loads the data in chunks. If the parser encounters an EndOfFile marker, then the process() method returns DONE. Otherwise, the method returns OUTPUT_NEEDED and processes another chunk of data. The functions included in the helper library (such as url_fread() and url_fopen()) are based on examples that come with the libcurl library. For an example, see http://curl.haxx.se/libcurl/c/fopen.html .

The setup() function opens a file handle and the destroy() function closes it. Both use functions from the helper library.

```
class CurlSource : public UDSource {private:
   URL_FILE *handle;
   std::string url;
   virtual StreamState process(ServerInterface &srvInterface, DataBuffer &output) {
      output.offset = url_fread(output.buf, 1, output.size, handle);
      return url_feof(handle) ? DONE : OUTPUT_NEEDED;
   }
public:
   CurlSource(std::string url) : url(url) {}
   void setup(ServerInterface &srvInterface) {
      handle = url_fopen(url.c_str(),"r");
   }
   void destroy(ServerInterface &srvInterface) {
      url_fclose(handle);
   }
};
```

Factory implementation

CurlSourceFactory produces CurlSource instances.

```
class CurlSourceFactory : public SourceFactory {public:
   virtual void plan(ServerInterface &srvInterface,
         NodeSpecifyingPlanContext &planCtxt) {
      std::vector<std::string> args = srvInterface.getParamReader().getParamNames();
      /* Check parameters */
      if (args.size() != 1 || find(args.begin(), args.end(), "url") == args.end()) {
         vt_report_error(0, "You must provide a single URL.");
      }
      /* Populate planData */
      planCtxt.getWriter().getStringRef("url").copy(
                        srvInterface.getParamReader().getStringRef("url"));

      /* Assign Nodes */
      std::vector<std::string> executionNodes = planCtxt.getClusterNodes();
      while (executionNodes.size() > 1) executionNodes.pop_back();
      // Only run on the first node in the list.
      planCtxt.setTargetNodes(executionNodes);
   }
   virtual std::vector<UDSource*> prepareUDSources(ServerInterface &srvInterface,
         NodeSpecifyingPlanContext &planCtxt) {
      std::vector<UDSource*> retVal;
      retVal.push_back(vt_createFuncObj(srvInterface.allocator, CurlSource,
            planCtxt.getReader().getStringRef("url").str()));
      return retVal;
   }
   virtual void getParameterType(ServerInterface &srvInterface,
                        SizedColumnTypes &parameterTypes) {
      parameterTypes.addVarchar(65000, "url");
   }
};
RegisterFactory(CurlSourceFactory);
```

C++ example: concurrent load

The FilePortionSource example demonstrates the use of concurrent load. This example is a refinement of the FileSource example. Each input file is divided into portions and distributed to FilePortionSource instances. The source accepts a list of offsets at which to break the input into portions; if offsets are not provided, the source divides the input dynamically.

Concurrent load is handled in the factory, so this discussion focuses on FilePortionSourceFactory . The full code for the example is located in /opt/vertica/sdk/examples/ApportionLoadFunctions . The distribution also includes a Java version of this example.

Loading and using the example

Load and use the FilePortionSource example as follows.

```
=> CREATE LIBRARY FilePortionLib AS '/home/dbadmin/FP.so';

=> CREATE SOURCE FilePortionSource AS LANGUAGE 'C++'
-> NAME 'FilePortionSourceFactory' LIBRARY FilePortionLib;

=> COPY t WITH SOURCE FilePortionSource(file='g1/*.dat', nodes='initiator,e0,e1', offsets = '0,380000,820000');

=> COPY t WITH SOURCE FilePortionSource(file='g2/*.dat', nodes='e0,e1,e2', local_min_portion_size = 2097152);
```

Implementation

Concurrent load affects the source factory in two places, getDesiredThreads() and prepareUDSourcesExecutor() .

getDesiredThreads()

The getDesiredThreads() member function determines the number of threads to request. Vertica calls this member function on each executor node before calling prepareUDSourcesExecutor() .

The function begins by breaking an input file path, which might be a glob, into individual paths. This discussion omits those details. If apportioned load is not being used, then the function allocates one source per file.

```
virtual ssize_t getDesiredThreads(ServerInterface &srvInterface,
    ExecutorPlanContext &planCtxt) {
  const std::string filename = srvInterface.getParamReader().getStringRef("file").str();

  std::vector<std::string> paths;
  // expand the glob - at least one thread per source.
  ...

  // figure out how to assign files to sources
  const std::string nodeName = srvInterface.getCurrentNodeName();
  const size_t nodeId = planCtxt.getWriter().getIntRef(nodeName);
  const size_t numNodes = planCtxt.getTargetNodes().size();

  if (!planCtxt.canApportionSource()) {
    /* no apportioning, so the number of files is the final number of sources */
    std::vector<std::string> *expanded =
        vt_createFuncObject<std::vector<std::string> >(srvInterface.allocator, paths);
    /* save expanded paths so we don't have to compute expansion again */
    planCtxt.getWriter().setPointer("expanded", expanded);
    return expanded->size();
  }

  // ...
```

If the source can be apportioned, then getDesiredThreads() uses the offsets that were passed as arguments to the factory to divide the file into portions. It then allocates portions to available nodes. This function does not actually assign sources directly; this work is done to determine how many threads to request.

```
else if (srvInterface.getParamReader().containsParameter("offsets")) {

  // if the offsets are specified, then we will have a fixed number of portions per file.
  // Round-robin assign offsets to nodes.
  // ...

  /* Construct the portions that this node will actually handle.
   * This isn't changing (since the offset assignments are fixed),
   * so we'll build the Portion objects now and make them available
   * to prepareUDSourcesExecutor() by putting them in the ExecutorContext.
   *
   * We don't know the size of the last portion, since it depends on the file
   * size.  Rather than figure it out here we will indicate it with -1 and
   * defer that to prepareUDSourcesExecutor().
   */
  std::vector<Portion> *portions =
    vt_createFuncObject<std::vector<Portion>>(srvInterface.allocator);

  for (std::vector<size_t>::const_iterator offset = offsets.begin();
       offset != offsets.end(); ++offset) {
    Portion p(*offset);
    p.is_first_portion = (offset == offsets.begin());
    p.size = (offset + 1 == offsets.end() ? -1 : (*(offset + 1) - *offset));

    if ((offset - offsets.begin()) % numNodes == nodeId) {
      portions->push_back(p);
      srvInterface.log("FilePortionSource: assigning portion %ld: [offset = %lld, size = %lld]",
                       offset - offsets.begin(), p.offset, p.size);
    }
  }
```

The function now has all the portions and thus the number of portions:

```
  planCtxt.getWriter().setPointer("portions", portions);

  /* total number of threads we want is the number of portions per file, which is fixed */
  return portions->size() * expanded->size();
} // end of "offsets" parameter
```

If offsets were not provided, the function divides the file into portions dynamically, one portion per thread. This discussion omits the details of this computation. There is no point in requesting more threads than are available, so the function calls getMaxAllowedThreads() on the PlanContext (an argument to the function) to set an upper bound:

```
if (portions->size() >= planCtxt.getMaxAllowedThreads()) {
  return paths.size();
}
```

See the full example for the details of how this function divides the file into portions.

This function uses the vt_createFuncObject template to create objects. Vertica calls the destructors of returned objects created using this macro, but it does not call destructors for other objects like vectors. You must call these destructors yourself to avoid memory leaks. In this example, these calls are made in prepareUDSourcesExecutor() .

prepareUDSourcesExecutor()

The prepareUDSourcesExecutor() member function, like getDesiredThreads() , has separate blocks of code depending on whether offsets are provided. In both cases, the function breaks input into portions and creates UDSource instances for them.

If the function is called with offsets, prepareUDSourcesExecutor() calls prepareCustomizedPortions() . This function follows.

```
/* prepare portions as determined via the "offsets" parameter */
void prepareCustomizedPortions(ServerInterface &srvInterface,
                               ExecutorPlanContext &planCtxt,
                               std::vector<UDSource *> &sources,
                               const std::vector<std::string> &expandedPaths,
                               std::vector<Portion> &portions) {
  for (std::vector<std::string>::const_iterator filename = expandedPaths.begin();
       filename != expandedPaths.end(); ++filename) {
    /*
     * the "portions" vector contains the portions which were generated in
     * "getDesiredThreads"
     */
    const size_t fileSize = getFileSize(*filename);
    for (std::vector<Portion>::const_iterator portion = portions.begin();
         portion != portions.end(); ++portion) {
      Portion fportion(*portion);
      if (fportion.size == -1) {
        /* as described above, this means from the offset to the end */
        fportion.size = fileSize - portion->offset;
        sources.push_back(vt_createFuncObject<FilePortionSource>(srvInterface.allocator,
                          *filename, fportion));
      } else if (fportion.size > 0) {
        sources.push_back(vt_createFuncObject<FilePortionSource>(srvInterface.allocator,
                          *filename, fportion));
      }
    }
  }
```

If prepareUDSourcesExecutor() is called without offsets, then it must decide how many portions to create.

The base case is to use one portion per source. However, if extra threads are available, the function divides the input into more portions so that a source can process them concurrently. Then prepareUDSourcesExecutor() calls prepareGeneratedPortions() to create the portions. This function begins by calling getLoadConcurrency() on the plan context to find out how many threads are available.

```
void prepareGeneratedPortions(ServerInterface &srvInterface,
                              ExecutorPlanContext &planCtxt,
                              std::vector<UDSource *> &sources,
                              std::map<std::string, Portion> initialPortions) {

  if ((ssize_t) initialPortions.size() >= planCtxt.getLoadConcurrency()) {
  /* all threads will be used, don't bother splitting into portions */

    for (std::map<std::string, Portion>::const_iterator file = initialPortions.begin();
         file != initialPortions.end(); ++file) {
      sources.push_back(vt_createFuncObject<FilePortionSource>(srvInterface.allocator,
                        file->first, file->second));
    } // for
    return;
  } // if

  // Now we can split files to take advantage of potentially-unused threads.
  // First sort by size (descending), then we will split the largest first.

  // details elided...
```

For more information

See the source code for the full implementation of this example.

Java example: FileSource

The example shown in this section is a simple UDL Source function named FileSource , This function loads data from files stored on the host's file system (similar to the standard COPY statement). To call FileSource , you must supply a parameter named file that contains the absolute path to one or more files on the host file system. You can specify multiple files as a comma-separated list.

The FileSource function also accepts an optional parameter, named nodes , that indicates which nodes should load the files. If you do not supply this parameter, the function defaults to loading data on the initiator node only. Because this example is simple, the nodes load only the files from their own file systems. Any files in the file parameter must exist on all of the hosts in the nodes parameter. The FileSource UDSource attempts to load all of the files in the file parameter on all of the hosts in the nodes parameter.

Generating files

You can use the following Python script to generate files and distribute them to hosts in your Vertica cluster. With these files, you can experiment with the example UDSource function. Running the function requires passwordless-SSH logins to copy the files to the other hosts. Therefore, you must run the script using the database administrator account on one of your database hosts.

```
#!/usr/bin/python
# Save this file as UDLDataGen.py
import string
import random
import sys
import os

# Read in the dictionary file to provide random words. Assumes the words
# file is located in /usr/share/dict/words
wordFile = open("/usr/share/dict/words")
wordDict = []
for line in wordFile:
    if len(line) > 6:
        wordDict.append(line.strip())

MAXSTR = 4 # Maximum number of words to concatentate
NUMROWS = 1000 # Number of rows of data to generate
#FILEPATH = '/tmp/UDLdata.txt' # Final filename to use for UDL source
TMPFILE = '/tmp/UDLtemp.txt'  # Temporary filename.

# Generate a random string by concatenating several words together. Max
# number of words set by MAXSTR
def randomWords():
    words = [random.choice(wordDict) for n in xrange(random.randint(1, MAXSTR))]
    sentence = " ".join(words)
    return sentence

# Create a temporary data file that will be moved to a node. Number of
# rows for the file is set by NUMROWS. Adds the name of the node which will
# get the file, to show which node loaded the data.
def generateFile(node):
    outFile = open(TMPFILE, 'w')
    for line in xrange(NUMROWS):
        outFile.write('{0}|{1}|{2}\n'.format(line,randomWords(),node))
    outFile.close()

# Copy the temporary file to a node. Only works if passwordless SSH login
# is enabled, which it is for the database administrator account on
# Vertica hosts.
def copyFile(fileName,node):
    os.system('scp "%s" "%s:%s"' % (TMPFILE, node, fileName) )

# Loop through the comma-separated list of nodes given in the first
# parameter, creating and copying data files whose full comma-separated
# paths are passed in the second parameter
for node in [x.strip() for x in sys.argv[1].split(',')]:
    for fileName in [y.strip() for y in sys.argv[2].split(',')]:
        print "generating file", fileName, "for", node
        generateFile(node)
        print "Copying file to",node
        copyFile(fileName,node)
```

You call this script by giving it a comma-separated list of hosts to receive the files and a comma-separated list of absolute paths of files to generate. For example:

```
python UDLDataGen.py v_vmart_node0001,v_vmart_node0002,v_vmart_node0003 /tmp/UDLdata01.txt,/tmp/UDLdata02.txt,\
UDLdata03.txt
```

This script generates files that contain a thousand rows of columns delimited with the pipe character (|). These columns contain an index value, a set of random words, and the node for which the file was generated, as shown in the following output sample:

```
0|megabits embanks|v_vmart_node0001
1|unneatly|v_vmart_node0001
2|self-precipitation|v_vmart_node0001
3|antihistamine scalados Vatter|v_vmart_node0001
```

Loading and using the example

Load and use the FileSource UDSource as follows:

```
=> --Load library and create the source function
=> CREATE LIBRARY JavaLib AS '/home/dbadmin/JavaUDlLib.jar'
-> LANGUAGE 'JAVA';
CREATE LIBRARY
=> CREATE SOURCE File as LANGUAGE 'JAVA' NAME
-> 'com.mycompany.UDL.FileSourceFactory' LIBRARY JavaLib;
CREATE SOURCE FUNCTION
=> --Create a table to hold the data loaded from files
=> CREATE TABLE t (i integer, text VARCHAR, node VARCHAR);
CREATE TABLE
=> -- Copy a single file from the currently host using the FileSource
=> COPY t SOURCE File(file='/tmp/UDLdata01.txt');
 Rows Loaded
-------------
        1000
(1 row)

=> --See some of what got loaded.
=> SELECT * FROM t WHERE i < 5 ORDER BY i;
 i |             text              |  node
---+-------------------------------+-----------------
 0 | megabits embanks              | v_vmart_node0001
 1 | unneatly                      | v_vmart_node0001
 2 | self-precipitation            | v_vmart_node0001
 3 | antihistamine scalados Vatter | v_vmart_node0001
 4 | fate-menaced toilworn         | v_vmart_node0001
(5 rows)

=> TRUNCATE TABLE t;
TRUNCATE TABLE
=> -- Now load a file from three hosts. All of these hosts must have a file
=> -- named /tmp/UDLdata01.txt, each with different data
=> COPY t SOURCE File(file='/tmp/UDLdata01.txt',
-> nodes='v_vmart_node0001,v_vmart_node0002,v_vmart_node0003');
 Rows Loaded
-------------
        3000
(1 row)

=> --Now see what has been loaded
=> SELECT * FROM t WHERE i < 5 ORDER BY i,node ;

```

Parser implementation

The following code shows the source of the FileSource class that reads a file from the host file system. The constructor, which is called by FileSourceFactory.prepareUDSources() , gets the absolute path for the file containing the data to be read. The setup() method opens the file and the destroy() method closes it. The process() method reads from the file into a buffer provided by the instance of the DataBuffer class passed to it as a parameter. If the read operation filled the output buffer, it returns OUTPUT_NEEDED . This value tells Vertica to call the method again after the next stage of the load has processed the output buffer. If the read did not fill the output buffer, then process() returns DONE to indicate it has finished processing the data source.

```
package com.mycompany.UDL;

import java.io.File;
import java.io.FileNotFoundException;
import java.io.FileReader;
import java.io.IOException;
import java.io.RandomAccessFile;

import com.vertica.sdk.UdfException;

public class FileSource extends UDSource {

    private String filename;  // The file for this UDSource to read
    private RandomAccessFile reader;   // handle to read from file

    // The constructor just stores the absolute filename of the file it will
```

```
// The constructor just stores the absolute filename of the file it will
// read.
public FileSource(String filename) {
    super();
    this.filename = filename;
}

// Called before Vertica starts requesting data from the data source.
// In this case, setup needs to open the file and save to the reader
// property.
@Override
public void setup(ServerInterface srvInterface ) throws UdfException{
    try {
        reader = new RandomAccessFile(new File(filename), "r");
    } catch (FileNotFoundException e) {
        // In case of any error, throw a UDfException. This will terminate
        // the data load.
         String msg = e.getMessage();
         throw new UdfException(0, msg);
    }
}

// Called after data has been loaded. In this case, close the file handle.
@Override
public void destroy(ServerInterface srvInterface ) throws UdfException {
    if (reader != null) {
        try {
            reader.close();
        } catch (IOException e) {
            String msg = e.getMessage();
             throw new UdfException(0, msg);
        }
    }
}

@Override
public StreamState process(ServerInterface srvInterface, DataBuffer output)
                           throws UdfException {

    // Read up to the size of the buffer provided in the DataBuffer.buf
    // property. Here we read directly from the file handle into the
    // buffer.
    long offset;
    try {
        offset = reader.read(output.buf,output.offset,
                             output.buf.length-output.offset);
    } catch (IOException e) {
        // Throw an exception in case of any errors.
        String msg = e.getMessage();
        throw new UdfException(0, msg);
    }

    // Update the number of bytes processed so far by the data buffer.
    output.offset +=offset;

    // See end of data source has been reached, or less data was read
    // than can fit in the buffer
    if(offset == -1 || offset < output.buf.length) {
        // No more data to read.
        return StreamState.DONE;
    }else{
        // Tell Vertica to call again when buffer has been emptied
```

```
            return StreamState.OUTPUT_NEEDED;
        }
    }
}
```

Factory implementation

The following code is a modified version of the example Java UDsource function provided in the Java UDx support package. You can find the full example in /opt/vertica/sdk/examples/JavaUDx/UDLFuctions/com/vertica/JavaLibs/FileSourceFactory.java . Its override of the plan() method verifies that the user supplied the required file parameter. If the user also supplied the optional nodes parameter, this method verifies that the nodes exist in the Vertica cluster. If there is a problem with either parameter, the method throws an exception to return an error to the user. If there are no issues with the parameters, the plan() method stores their values in the plan context object.

```
package com.mycompany.UDL;

import java.util.ArrayList;
import java.util.Vector;
import com.vertica.sdk.NodeSpecifyingPlanContext;
import com.vertica.sdk.ParamReader;
import com.vertica.sdk.ParamWriter;
import com.vertica.sdk.ServerInterface;
import com.vertica.sdk.SizedColumnTypes;
import com.vertica.sdk.SourceFactory;
import com.vertica.sdk.UDSource;
import com.vertica.sdk.UdfException;

public class FileSourceFactory extends SourceFactory {

    // Called once on the initiator host to do initial setup. Checks
    // parameters and chooses which nodes will do the work.
    @Override
    public void plan(ServerInterface srvInterface,
            NodeSpecifyingPlanContext planCtxt) throws UdfException {

        String nodes; // stores the list of nodes that will load data

        // Get  copy of the parameters the user supplied to the UDSource
        // function call.
        ParamReader args =  srvInterface.getParamReader();

        // A list of nodes that will perform work. This gets saved as part
        // of the plan context.
        ArrayList<String> executionNodes = new ArrayList<String>();

        // First, ensure the user supplied the file parameter
        if (!args.containsParameter("file")) {
            // Withut a file parameter, we cannot continue. Throw an
            // exception that will be caught by the Java UDx framework.
            throw new UdfException(0, "You must supply a file parameter");
        }

        // If the user specified nodes to read the file, parse the
        // comma-separated list and save. Otherwise, assume just the
        // initiator node has the file to read.
        if (args.containsParameter("nodes")) {
            nodes = args.getString("nodes");

            // Get list of nodes in cluster, to ensure that the node the
            // user specified actually exists. The list of nodes is available
            // from the planCTxt (plan context) object.
            ArrayList<String> clusterNodes = planCtxt.getClusterNodes();
```

```
        // Parse the string parameter "nodes" which
        // is a comma-separated list of node names.
        String[] nodeNames = nodes.split(",");

        for (int i = 0; i < nodeNames.length; i++){
            // See if the node the user gave us actually exists
            if(clusterNodes.contains(nodeNames[i]))
                // Node exists. Add it to list of nodes.
                executionNodes.add(nodeNames[i]);
            else{
                // User supplied node that doesn't exist. Throw an
                // exception so the user is notified.
                String msg = String.format("Specified node '%s' but no" +
                    " node by that name is available.  Available nodes " +
                    "are \"%s\".",
                    nodeNames[i], clusterNodes.toString());
                throw new UdfException(0, msg);
            }
        }
    } else {
        // User did not supply a list of node names. Assume the initiator
        // is the only host that will read the file. The srvInterface
        // instance passed to this method has a getter for the current
        // node.
        executionNodes.add(srvInterface.getCurrentNodeName());
    }

    // Set the target node(s) in the plan context
    planCtxt.setTargetNodes(executionNodes);

    // Set parameters for each node reading data that tells it which
    // files it will read. In this simple example, just tell it to
    // read all of the files the user passed in the file parameter
    String files = args.getString("file");

    // Get object to write parameters into the plan context object.
    ParamWriter nodeParams = planCtxt.getWriter();

    // Loop through list of execution nodes, and add a parameter to plan
    // context named for each node performing the work, which tells it the
    // list of files it will process. Each node will look for a
    // parameter named something like "filesFor_vmart_node0002" in its
    // prepareUDSources() method.
    for (int i = 0; i < executionNodes.size(); i++) {
        nodeParams.setString("filesFor" + executionNodes.get(i), files);
    }
}

// Called on each host that is reading data from a source. This method
// returns an array of UDSource objects that process each source.
@Override
public ArrayList<UDSource> prepareUDSources(ServerInterface srvInterface,
        NodeSpecifyingPlanContext planCtxt) throws UdfException {

    // An array to hold the UDSource subclasses that we instaniate
    ArrayList<UDSource> retVal = new ArrayList<UDSource>();

    // Get the list of files this node is supposed to process. This was
    // saved by the plan() method in the plancontext
    String myName = srvInterface.getCurrentNodeName();
    ParamReader params = planCtxt.getReader();
```

```
    String fileNames = params.getString("filesFor" + myName);

    // Note that you can also be lazy and directly grab the parameters
    // the user passed to the UDSource functon in the COPY statement directly
    // by getting parameters from the ServerInterface object. I.e.:

    //String fileNames = srvInterface.getParamReader().getString("file");

    // Split comma-separated list into a single list.
    String[] fileList = fileNames.split(",");
    for (int i = 0; i < fileList.length; i++){
        // Instantiate a FileSource object (which is a subclass of UDSource)
        // to read each file. The constructor for FileSource takes the
        // file name of the
        retVal.add(new FileSource(fileList[i]));
    }

    // Return the collection of FileSource objects. They will be called,
    // in turn, to read each of the files.
    return retVal;
}

// Declares which parameters that this factory accepts.
@Override
public void getParameterType(ServerInterface srvInterface,
                             SizedColumnTypes parameterTypes) {
    parameterTypes.addVarchar(65000, "file");
    parameterTypes.addVarchar(65000, "nodes");
}
```

User-defined filter

User-defined filter functions allow you to manipulate data obtained from a source in various ways. For example, a filter can:

- Process a compressed file in a compression format not natively supported by Vertica.
- Take UTF-16-encoded data and transcode it to UTF-8 encoding.
- Perform search-and-replace operations on data before it is loaded into Vertica.

You can also process data through multiple filters before it is loaded into Vertica. For instance, you could unzip a file compressed with GZip, convert the content from UTF-16 to UTF-8, and finally search and replace certain text strings.

If you implement a UDFilter , you must also implement a corresponding FilterFactory .

See UDFilter class and FilterFactory class for API details.

In this section

- UDFilter class
- FilterFactory class
- Java example: ReplaceCharFilter
- C++ example: converting encoding

UDFilter class

The UDFilter class is responsible for reading raw input data from a source and preparing it to be loaded into Vertica or processed by a parser. This preparation may involve decompression, re-encoding, or any other sort of binary manipulation.

A UDFilter is instantiated by a corresponding FilterFactory on each host in the Vertica cluster that is performing filtering for the data source.

UDFilter methods

Your UDFilter subclass must override process() or processWithMetadata() :

> **Note**
> processWithMetadata() is available only for user-defined extensions (UDxs) written in the C++ programming language.

- process() reads the raw input stream as one large file. If there are any errors or failures, the entire load fails.
  You can implement process() when the upstream source implements processWithMetadata() , but it might result in parsing errors.
- processWithMetadata() is useful when the data source has metadata about record boundaries available in some structured format that's separate from the data payload. With this interface, the source emits a record length for each record in addition to the data.
  By implementing processWithMetadata() instead of process() in each phase, you can retain this record length metadata throughout the load stack, which enables a more efficient parse that can recover from errors on a per-message basis, rather than a per-file or per-source basis. KafkaSource and the Kafka parsers (KafkaAvroParser , KafkaJSONParser , and KafkaParser) use this mechanism to support per-Kafka-message rejections when individual Kafka messages are corrupted.
  Using processWithMetadata() with your UDFilter subclass enables you to write an internal filter that integrates the record length metadata from the source into the data stream, producing a single byte stream with boundary information to help parsers extract and process individual messages. KafkaInsertDelimeters and KafkaInsertLengths use this mechanism to insert message boundary information into Kafka data streams.

  > **Note**
  > To implement processWithMetadata() , you must override useSideChannel() to return true .

Optionally, you can override other UDFilter class methods.

Filter execution

The following sections detail the execution sequence each time a user-defined filter is called. The following example overrides the process() method.

Setting Up

COPY calls setup() before the first time it calls process() . Use setup() to perform any necessary setup steps that your filter needs to operate, such as initializing data structures to be used during filtering. Your object might be destroyed and re-created during use, so make sure that your object is restartable.

Filtering Data

COPY calls process() repeatedly during query execution to filter data. The method receives two instances of the DataBuffer class among its parameters, an input and an output buffer. Your implementation should read from the input buffer, manipulate it in some manner (such as decompressing it), and write the result to the output. A one-to-one correlation between the number of bytes your implementation reads and the number it writes might not exist. The process() method should process data until it either runs out of data to read or runs out of space in the output buffer. When one of these conditions occurs, your method should return one of the following values defined by StreamState :

- OUTPUT_NEEDED if the filter needs more room in its output buffer.
- INPUT_NEEDED if the filter has run out of input data (but the data source has not yet been fully processed).
- DONE if the filter has processed all of the data in the data source.
- KEEP_GOING if the filter cannot proceed for an extended period of time. The method will be called again, so do not block indefinitely. If you do, then you prevent your user from canceling the query.

Before returning, your process() method must set the offset property in each DataBuffer . In the input buffer, set it to the number of bytes that the method successfully read. In the output buffer, set it to the number of bytes the method wrote. Setting these properties allows the next call to process() to resume reading and writing data at the correct points in the buffers.

Your process() method also needs to check the InputState object passed to it to determine if there is more data in the data source. When this object is equal to END_OF_FILE, then the data remaining in the input data is the last data in the data source. Once it has processed all of the remaining data, process() must return DONE.

Tearing Down

COPY calls destroy() after the last time it calls process() . This method frees any resources reserved by the setup() or process() methods. Vertica calls this method after the process() method indicates it has finished filtering all of the data in the data stream.

If there are still data sources that have not yet been processed, Vertica may later call setup() on the object again. On subsequent calls Vertica directs the method to filter the data in a new data stream. Therefore, your destroy() method should leave an object of your UDFilter subclass in a state where the setup() method can prepare it to be reused.

API

C++

Java

Python

The UDFilter API provides the following methods for extension by subclasses:

```
virtual void setup(ServerInterface &srvInterface);

virtual bool useSideChannel();

virtual StreamState process(ServerInterface &srvInterface, DataBuffer &input, InputState input_state, DataBuffer &outpu

virtual StreamState processWithMetadata(ServerInterface &srvInterface, DataBuffer &input,
    LengthBuffer &input_lengths, InputState input_state, DataBuffer &output, LengthBuffer &output_lengths)=0;

virtual void cancel(ServerInterface &srvInterface);

virtual void destroy(ServerInterface &srvInterface);
```

FilterFactory class

If you write a filter, you must also write a filter factory to produce filter instances. To do so, subclass the FilterFactory class.

Your subclass performs the initial validation and planning of the function execution and instantiates UDFilter objects on each host that will be filtering data.

Filter factories are singletons. Your subclass must be stateless, with no fields containing data. The subclass also must not modify any global variables.

FilterFactory methods

The FilterFactory class defines the following methods. Your subclass must override the prepare() method. It may override the other methods.

Setting up

Vertica calls plan() once on the initiator node, to perform the following tasks:

- Check any parameters that have been passed from the function call in the COPY statement and error messages if there are any issues. You read the parameters by getting a ParamReader object from the instance of ServerInterface passed into your plan() method.
- Store any information that the individual hosts need in order to filter data in the PlanContext instance passed as a parameter. For example, you could store details of the input format that the filter will read and output the format that the filter should produce. The plan() method runs only on the initiator node, and the prepare() method runs on each host reading from a data source. Therefore, this object is the only means of communication between them.
  You store data in the PlanContext by getting a ParamWriter object from the getWriter() method. You then write parameters by calling methods on the ParamWriter such as setString .

  > **Note**
  > ParamWriter offers only the ability to store simple data types. For complex types, you need to serialize the data in some manner and store it as a string or long string.

Creating filters

Vertica calls prepare() to create and initialize your filter. It calls this method once on each node that will perform filtering. Vertica automatically selects the best nodes to complete the work based on available resources. You cannot specify the nodes on which the work is done.

Defining parameters

Implement getParameterTypes() to define the names and types of parameters that your filter uses. Vertica uses this information to warn callers about unknown or missing parameters. Vertica ignores unknown parameters and uses default values for missing parameters. While you should define the types and parameters for your function, you are not required to override this method.

API

C++

Java

Python

The FilterFactory API provides the following methods for extension by subclasses:

```
virtual void plan(ServerInterface &srvInterface, PlanContext &planCtxt);

virtual UDFilter * prepare(ServerInterface &srvInterface, PlanContext &planCtxt)=0;

virtual void getParameterType(ServerInterface &srvInterface, SizedColumnTypes &parameterTypes);
```

After creating your FilterFactory , you must register it with the RegisterFactory macro.

Java example: ReplaceCharFilter

The example in this section demonstrates creating a UDFilter that replaces any occurrences of a character in the input stream with another character in the output stream. This example is highly simplified and assumes the input stream is ASCII data.

Always remember that the input and output streams in a UDFilter are actually binary data. If you are performing character transformations using a UDFilter , convert the data stream from a string of bytes into a properly encoded string. For example, your input stream might consist of UTF-8 encoded text. If so, be sure to transform the raw binary being read from the buffer into a UTF string before manipulating it.

Loading and using the example

The example UDFilter has two required parameters. The from_char parameter specifies the character to be replaced, and the to_char parameter specifies the replacement character. Load and use the ReplaceCharFilter UDFilter as follows:

```
=> CREATE LIBRARY JavaLib AS '/home/dbadmin/JavaUDlLib.jar'
->LANGUAGE 'JAVA';
CREATE LIBRARY
=> CREATE FILTER ReplaceCharFilter as LANGUAGE 'JAVA'
->name 'com.mycompany.UDL.ReplaceCharFilterFactory' library JavaLib;
CREATE FILTER FUNCTION
=> CREATE TABLE t (text VARCHAR);
CREATE TABLE
=> COPY t FROM STDIN WITH FILTER ReplaceCharFilter(from_char='a', to_char='z');
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> Mary had a little lamb
>> a man, a plan, a canal, Panama
>> \.

=> SELECT * FROM t;
             text
--------------------------------
 Mzry hzd z little lzmb
 z mzn, z plzn, z cznzl, Pznzmz
(2 rows)

=> --Calling the filter with incorrect parameters returns errors
=> COPY t from stdin with filter ReplaceCharFilter();
ERROR 3399:  Failure in UDx RPC call InvokePlanUDL(): Error in User Defined Object [
ReplaceCharFilter], error code: 0

```

Parser implementation

The ReplaceCharFilter class reads the data stream, replacing each occurrence of a user-specified character with another character.

```
package com.vertica.JavaLibs;

import com.vertica.sdk.DataBuffer;
import com.vertica.sdk.ServerInterface;
import com.vertica.sdk.State.InputState;
import com.vertica.sdk.State.StreamState;
import com.vertica.sdk.UDFilter;

public class ReplaceCharFilter extends UDFilter {

    private byte[] fromChar;
    private byte[] toChar;

    public ReplaceCharFilter(String fromChar, String toChar){
        // Stores the from char and to char as byte arrays. This is
        // not a robust method of doing this, but works for this simple
        // example.
        this.fromChar= fromChar.getBytes();
        this.toChar=toChar.getBytes();
    }
    @Override
    public StreamState process(ServerInterface srvInterface, DataBuffer input,
            InputState input_state, DataBuffer output) {

        // Check if there is no more input and the input buffer has been completely
        // processed. If so, filtering is done.
        if (input_state == InputState.END_OF_FILE && input.buf.length == 0) {
            return StreamState.DONE;
        }

        // Get current position in the input buffer
        int offset = output.offset;

        // Determine how many bytes to process. This is either until input
        // buffer is exhausted or output buffer is filled
        int limit = Math.min((input.buf.length - input.offset),
                (output.buf.length - output.offset));

        for (int i = input.offset; i < limit; i++) {
            // This example just replaces each instance of from_char
            // with to_char. It does not consider things such as multi-byte
            // UTF-8 characters.
            if (input.buf[i] == fromChar[0]) {
                output.buf[i+offset] = toChar[0];
            } else {
                // Did not find from_char, so copy input to the output
                output.buf[i+offset]=input.buf[i];
            }
        }

        input.offset += limit;
        output.offset += input.offset;

        if (input.buf.length - input.offset < output.buf.length - output.offset) {
            return StreamState.INPUT_NEEDED;
        } else {
            return StreamState.OUTPUT_NEEDED;
        }
    }
```

Factory implementation

ReplaceCharFilterFactory requires two parameters (from_char and to_char). The plan() method verifies that these parameters exist and are single-character strings. The method then stores them in the plan context. The prepare() method gets the parameter values and passes them to the ReplaceCharFilter objects, which it instantiates, to perform the filtering.

```
package com.vertica.JavaLibs;

import java.util.ArrayList;
import java.util.Vector;

import com.vertica.sdk.FilterFactory;
import com.vertica.sdk.PlanContext;
import com.vertica.sdk.ServerInterface;
import com.vertica.sdk.SizedColumnTypes;
import com.vertica.sdk.UDFilter;
import com.vertica.sdk.UdfException;

public class ReplaceCharFilterFactory extends FilterFactory {

    // Run on the initiator node to perform varification and basic setup.
    @Override
    public void plan(ServerInterface srvInterface,PlanContext planCtxt)
            throws UdfException {
        ArrayList<String> args =
                srvInterface.getParamReader().getParamNames();

        // Ensure user supplied two arguments
        if (!(args.contains("from_char") && args.contains("to_char"))) {
            throw new UdfException(0, "You must supply two parameters" +
                    " to ReplaceChar: 'from_char' and 'to_char'");
        }

        // Verify that the from_char is a single character.
        String fromChar = srvInterface.getParamReader().getString("from_char");
        if (fromChar.length() != 1) {
            String message =  String.format("Replacechar expects a single " +
                "character in the 'from_char' parameter. Got length %d",
                fromChar.length());
            throw new UdfException(0, message);
        }

        // Save the from character in the plan context, to be read by
        // prepare() method.
        planCtxt.getWriter().setString("fromChar",fromChar);

        // Ensure to character parameter is a single characater
        String toChar = srvInterface.getParamReader().getString("to_char");
        if (toChar.length() != 1) {
            String message =  String.format("Replacechar expects a single "
                + "character in the 'to_char' parameter. Got length %d",
                toChar.length());
            throw new UdfException(0, message);
        }
        // Save the to character in the plan data
        planCtxt.getWriter().setString("toChar",toChar);
    }

    // Called on every host that will filter data. Must instantiate the
    // UDFilter subclass.
    @Override
    public UDFilter prepare(ServerInterface srvInterface, PlanContext planCtxt)
```

```
                    throws UdfException {
    // Get data stored in the context by the plan() method.
    String fromChar = planCtxt.getWriter().getString("fromChar");
    String toChar = planCtxt.getWriter().getString("toChar");

    // Instantiate a filter object to perform filtering.
    return new ReplaceCharFilter(fromChar, toChar);
  }

  // Describe the parameters accepted by this filter.
  @Override
  public void getParameterType(ServerInterface srvInterface,
          SizedColumnTypes parameterTypes) {
    parameterTypes.addVarchar(1, "from_char");
    parameterTypes.addVarchar(1, "to_char");
  }
```

C++ example: converting encoding

The following example shows how you can convert encoding for a file from one type to another by converting UTF-16 encoded data to UTF-8. You can find this example in the SDK at /opt/vertica/sdk/examples/FilterFunctions/IConverter.cpp .

Filter implementation

```
class Iconverter : public UDFilter{
private:
  std::string fromEncoding, toEncoding;
  iconv_t cd; // the conversion descriptor opened
  uint converted; // how many characters have been converted
protected:
  virtual StreamState process(ServerInterface &srvInterface, DataBuffer &input,
                              InputState input_state, DataBuffer &output)
  {
    char *input_buf = (char *)input.buf + input.offset;
    char *output_buf = (char *)output.buf + output.offset;
    size_t inBytesLeft = input.size - input.offset, outBytesLeft = output.size - output.offset;
    // end of input
    if (input_state == END_OF_FILE && inBytesLeft == 0)
    {
      // Gnu libc iconv doc says, it is good practice to finalize the
      // outbuffer for stateful encodings (by calling with null inbuffer).
      //
      // http://www.gnu.org/software/libc/manual/html_node/Generic-Conversion-Interface.html
      iconv(cd, NULL, NULL, &output_buf, &outBytesLeft);
      // output buffer can be updated by this operation
      output.offset = output.size - outBytesLeft;
      return DONE;
    }
    size_t ret = iconv(cd, &input_buf, &inBytesLeft, &output_buf, &outBytesLeft);
    // if conversion is successful, we ask for more input, as input has not reached EOF.
    StreamState retStatus = INPUT_NEEDED;
    if (ret == (size_t)(-1))
    {
      // seen an error
      switch (errno)
      {
      case E2BIG:
        // input size too big, not a problem, ask for more output.
        retStatus = OUTPUT_NEEDED;
        break;
      case EINVAL:
```

```
            // input stops in the middle of a byte sequence, not a problem, ask for more input
            retStatus = input_state == END_OF_FILE ? DONE : INPUT_NEEDED;
            break;
        case EILSEQ:
            // invalid sequence seen, throw
            // TODO: reporting the wrong byte position
            vt_report_error(1, "Invalid byte sequence when doing %u-th conversion", converted);
        case EBADF:
            // something wrong with descriptor, throw
            vt_report_error(0, "Invalid descriptor");
        default:
            vt_report_error(0, "Uncommon Error");
            break;
        }
    }
    else converted += ret;
    // move position pointer
    input.offset = input.size - inBytesLeft;
    output.offset = output.size - outBytesLeft;
    return retStatus;
  }
public:
  Iconverter(const std::string &from, const std::string &to)
  : fromEncoding(from), toEncoding(to), converted(0)
  {
    // note "to encoding" is first argument to iconv...
    cd = iconv_open(to.c_str(), from.c_str());
    if (cd == (iconv_t)(-1))
    {
        // error when creating converters.
        vt_report_error(0, "Error initializing iconv: %m");
    }
  }
  ~Iconverter()
  {
    // free iconv resources;
    iconv_close(cd);
  }
};
```

Factory implementation

```
class IconverterFactory : public FilterFactory{
public:
  virtual void plan(ServerInterface &srvInterface,
        PlanContext &planCtxt) {
    std::vector<std::string> args = srvInterface.getParamReader().getParamNames();
    /* Check parameters */
    if (!(args.size() == 0 ||
          (args.size() == 1 && find(args.begin(), args.end(), "from_encoding")
                != args.end()) || (args.size() == 2
                && find(args.begin(), args.end(), "from_encoding") != args.end()
                && find(args.begin(), args.end(), "to_encoding") != args.end()))) {
      vt_report_error(0, "Invalid arguments.  Must specify either no arguments,  or "
                      "'from_encoding' alone, or 'from_encoding' and 'to_encoding'.");
    }
    /* Populate planData */
    // By default, we do UTF16->UTF8, and x->UTF8
    VString from_encoding = planCtxt.getWriter().getStringRef("from_encoding");
    VString to_encoding = planCtxt.getWriter().getStringRef("to_encoding");
    from_encoding.copy("UTF-16");
    to_encoding.copy("UTF-8");
    if (args.size() == 2)
    {
      from_encoding.copy(srvInterface.getParamReader().getStringRef("from_encoding"));
      to_encoding.copy(srvInterface.getParamReader().getStringRef("to_encoding"));
    }
    else if (args.size() == 1)
    {
      from_encoding.copy(srvInterface.getParamReader().getStringRef("from_encoding"));
    }
    if (!from_encoding.length()) {
      vt_report_error(0, "The empty string is not a valid from_encoding value");
    }
    if (!to_encoding.length()) {
      vt_report_error(0, "The empty string is not a valid to_encoding value");
    }
  }
  virtual UDFilter* prepare(ServerInterface &srvInterface,
        PlanContext &planCtxt) {
    return vt_createFuncObj(srvInterface.allocator, Iconverter,
          planCtxt.getReader().getStringRef("from_encoding").str(),
          planCtxt.getReader().getStringRef("to_encoding").str());
  }
  virtual void getParameterType(ServerInterface &srvInterface,
                        SizedColumnTypes &parameterTypes) {
    parameterTypes.addVarchar(32, "from_encoding");
    parameterTypes.addVarchar(32, "to_encoding");
  }
};
RegisterFactory(IconverterFactory);
```

User-defined parser

A parser takes a stream of bytes and passes a corresponding sequence of tuples to the Vertica load process. You can use user-defined parser functions to parse:

- Data in formats not understood by the Vertica built-in parser.
- Data that requires more specific control than the built-in parser supplies.

For example, you can load a CSV file using a specific CSV library. See the Vertica SDK for two CSV examples.

COPY supports a single user-defined parser that you can use with a user-defined source and zero or more instances of a user-defined filter . If you implement a UDParser class , you must also implement a corresponding ParserFactory .

Sometimes, you can improve the performance of your parser by adding a *chunker* . A chunker divides up the input and uses multiple threads to parse it. Chunkers are available only in the C++ API. For details, see Cooperative parse and UDChunker class . Under special circumstances you can further improve performance by using *apportioned load* , an approach where multiple Vertica nodes parse the input.

In this section

- UDParser class
- UDChunker class
- ParserFactory class
- C++ example: BasicIntegerParser
- C++ example: ContinuousIntegerParser
- Java example: numeric text
- Java example: JSON parser
- C++ example: delimited parser and chunker

UDParser class

You can subclass the UDParser class when you need to parse data that is in a format that the COPY statement's native parser cannot handle.

During parser execution, Vertica always calls three methods: setup() , process() , and destroy() . It might also call getRejectedRecord() .

UDParser constructor

The UDParser class performs important initialization required by all subclasses, including initializing the StreamWriter object used by the parser. Therefore, your constructor must call super() .

UDParser methods

Your UDParser subclass must override process() or processWithMetadata() :

> **Note**
> processWithMetadata() is available only for user-defined extensions (UDxs) written in the C++ programming language.

- process() reads the raw input stream as one large file. If there are any errors or failures, the entire load fails. You can implement process() with a source or filter that implements processWithMetadata() , but it might result in parsing errors.
  You can implement process() when the upstream source or filter implements processWithMetadata() , but it might result in parsing errors.
- processWithMetadata() is useful when the data source has metadata about record boundaries available in some structured format that's separate from the data payload. With this interface, the source emits a record length for each record in addition to the data.
  By implementing processWithMetadata() instead of process() in each phase, you can retain this record length metadata throughout the load stack, which enables a more efficient parse that can recover from errors on a per-message basis, rather than a per-file or per-source basis. KafkaSource and Kafka parsers (KafkaAvroParser , KafkaJSONParser , and KafkaParser) use this mechanism to support per-Kafka-message rejections when individual Kafka messages are corrupted.

  > **Note**
  > To implement processWithMetadata() , you must override useSideChannel() to return true .

Additionally, you must override getRejectedRecord() to return information about rejected records.

Optionally, you can override the other UDParser class methods.

Parser execution

The following sections detail the execution sequence each time a user-defined parser is called. The following example overrides the process() method.

Setting up

COPY calls setup() before the first time it calls process() . Use setup() to perform any initial setup tasks that your parser needs to parse data. This setup includes retrieving parameters from the class context structure or initializing data structures for use during filtering. Vertica calls this method before calling the process() method for the first time. Your object might be destroyed and re-created during use, so make sure that your object is restartable.

Parsing

COPY calls process() repeatedly during query execution. Vertica passes this method a buffer of data to parse into columns and rows and one of the following input states defined by InputState :

- OK : currently at the start of or in the middle of a stream
- END_OF_FILE : no further data is available.
- END_OF_CHUNK : the current data ends on a record boundary and the parser should consume all of it before returning. This input state only occurs when using a chunker.
- START_OF_PORTION : the input does not start at the beginning of a source. The parser should find the first end-of-record mark. This input state only occurs when using apportioned load.You can use the getPortion() method to access the offset and size of the portion.
- END_OF_PORTION : the source has reached the end of its portion. The parser should finish processing the last record it started and advance no further. This input state only occurs when using apportioned load.

The parser must reject any data that it cannot parse, so that Vertica can report the rejection and write the rejected data to files.

The process() method must parse as much data as it can from the input buffer. The buffer might not end on a row boundary. Therefore, it might have to stop parsing in the middle of a row of input and ask for more data. The input can contain null bytes, if the source file contains them, and is *not* automatically null-terminated.

A parser has an associated StreamWriter object, which performs the actual writing of the data. When your parser extracts a column value, it uses one of the type-specific methods on StreamWriter to write that value to the output stream. See Writing Data for more information about these methods.

A single call to process() might write several rows of data. When your parser finishes processing a row of data, it must call next() on its StreamWriter to advance the output stream to a new row. (Usually a parser finishes processing a row because it encounters an end-of-row marker.)

When your process() method reaches the end of the buffer, it tells Vertica its current state by returning one of the following values defined by StreamState :

- INPUT_NEEDED : the parser has reached the end of the buffer and needs more data to parse.
- DONE : the parser has reached the end of the input data stream.
- REJECT : the parser has rejected the last row of data it read (see Rejecting Rows).

Tearing down

COPY calls destroy() after the last time that process() is called. It frees any resources reserved by the setup() or process() method.

Vertica calls this method after the process() method indicates it has completed parsing the data source. However, sometimes data sources that have not yet been processed might remain. In such cases, Vertica might later call setup() on the object again and have it parse the data in a new data stream. Therefore, write your destroy() method so that it leaves an instance of your UDParser subclass in a state where setup() can be safely called again.

Reporting rejections

If process() rejects a row, Vertica calls getRejectedRecord() to report it. Usually, this method returns an instance of the RejectedRecord class with details of the rejected row.

Writing data

A parser has an associated StreamWriter object, which you access by calling getStreamWriter() . In your process() implementation, use the set *Type* () methods on the StreamWriter object to write values in a row to specific column indexes. Verify that the data types you write match the data types expected by the schema.

The following example shows how you can write a value of type long to the fourth column (index 3) in the current row:

```
StreamWriter writer = getStreamWriter();
...
writer.setLongValue(3, 98.6);
```

StreamWriter provides methods for all the basic types, such as setBooleanValue() , setStringValue() , and so on. See the API documentation for a complete list of StreamWriter methods, including options that take primitive types or explicitly set entries to null.

Rejecting rows

If your parser finds data it cannot parse, it should reject the row by:

1. Saving details about the rejected row data and the reason for the rejection. These pieces of information can be directly stored in a RejectedRecord object, or in fields on your UDParser subclass, until they are needed.
2. Updating the row's position in the input buffer by updating input.offset so it can resume parsing with the next row.
3. Signaling that it has rejected a row by returning with the value StreamState.REJECT .
4. Returning an instance of the RejectedRecord class with the details about the rejected row.

Breaking up large loads

Vertica provides two ways to break up large loads. Apportioned load allows you to distribute a load among several database nodes. Cooperative parse (C++ only) allows you to distribute a load among several threads on one node.

API

C++

Java

Python

The UDParser API provides the following methods for extension by subclasses:

```
virtual void setup(ServerInterface &srvInterface, SizedColumnTypes &returnType);

virtual bool useSideChannel();

virtual StreamState process(ServerInterface &srvInterface, DataBuffer &input, InputState input_state)=0;

virtual StreamState processWithMetadata(ServerInterface &srvInterface, DataBuffer &input,
                    LengthBuffer &input_lengths, InputState input_state)=0;

virtual void cancel(ServerInterface &srvInterface);

virtual void destroy(ServerInterface &srvInterface, SizedColumnTypes &returnType);

virtual RejectedRecord getRejectedRecord();
```

UDChunker class

You can subclass the UDChunker class to allow your parser to support Cooperative parse . This class is available only in the C++ API.

Fundamentally, a UDChunker is a very simplistic parser. Like UDParser , it has the following three methods: setup() , process() , and destroy() . You must override process() ; you may override the others. This class has one additional method, alignPortion() , which you must implement if you want to enable Apportioned load for your UDChunker .

Setting up and tearing down

As with UDParser , you can define initialization and cleanup code for your chunker. Vertica calls setup() before the first call to process() and destroy() after the last call to process() . Your object might be reused among multiple load sources, so make sure that setup() completely initializes all fields.

Chunking

Vertica calls process() to divide an input into chunks that can be parsed independently. The method takes an input buffer and an indicator of the input state:

- OK : the input buffer begins at the start of or in the middle of a stream.
- END_OF_FILE : no further data is available.
- END_OF_PORTION : the source has reached the end of its portion. This state occurs only when using apportioned load.

If the input state is END_OF_FILE , the chunker should set the input.offset marker to input.size and return DONE . Returning INPUT_NEEDED is an error.

If the input state is OK , the chunker should read data from the input buffer and find record boundaries. If it finds the end of at least one record, it should align the input.offset marker with the byte after the end of the last record in the buffer and return CHUNK_ALIGNED . For example, if the input is "abc~def" and "~" is a record terminator, this method should set input.offset to 4, the position of "d". If process() reaches the end of the input without finding a record boundary, it should return INPUT_NEEDED .

You can divide the input into smaller chunks, but consuming all available records in the input can have better performance. For example, a chunker could scan backwards from the end of the input to find a record terminator, which might be the last of many records in the input, and return it all as one chunk without scanning through the rest of the input.

If the input state is END_OF_PORTION , the chunker should behave as it does for an input state of OK , except that it should also set a flag. When called again, it should find the first record in the next portion and align the chunk to that record.

The input data can contain null bytes, if the source file contains them. The input argument is not automatically null-terminated.

The process() method must not block indefinitely. If this method cannot proceed for an extended period of time, it should return KEEP_GOING . Failing to return KEEP_GOING has several consequences, such as preventing your user from being able to cancel the query.

See C++ example: delimited parser and chunker for an example of the process() method using chunking.

Aligning portions

If your chunker supports apportioned load, implement the alignPortion() method. Vertica calls this method one or more times, before calling process() , to align the input offset with the beginning of the first complete chunk in the portion. The method takes an input buffer and an indicator of the input state:

- START_OF_PORTION : the beginning of the buffer corresponds to the start of the portion. You can use the getPortion() method to access the offset and size of the portion.
- OK : the input buffer is in the middle of a portion.
- END_OF_PORTION : the end of the buffer corresponds to the end of the portion or beyond the end of a portion.
- END_OF_FILE : no further data is available.

The method should scan from the beginning of the buffer to the start of the first complete record. It should set input.offset to this position and return one of the following values:

- DONE , if it found a chunk. input.offset is the first byte of the chunk.
- INPUT_NEEDED , if the input buffer does not contain the start of any chunk. It is an error to return this from an input state of END_OF_FILE .
- REJECT , if the portion (not buffer) does not contain the start of any chunk.

API

The UDChunker API provides the following methods for extension by subclasses:

```
virtual void setup(ServerInterface &srvInterface,
        SizedColumnTypes &returnType);

virtual StreamState alignPortion(ServerInterface &srvInterface,
        DataBuffer &input, InputState state);

virtual StreamState process(ServerInterface &srvInterface,
        DataBuffer &input, InputState input_state)=0;

virtual void cancel(ServerInterface &srvInterface);

virtual void destroy(ServerInterface &srvInterface,
        SizedColumnTypes &returnType);
```

ParserFactory class

If you write a parser, you must also write a factory to produce parser instances. To do so, subclass the ParserFactory class.

Parser factories are singletons. Your subclass must be stateless, with no fields containing data. Your subclass also must not modify any global variables.

The ParserFactory class defines the following methods. Your subclass must override the prepare() method. It may override the other methods.

Setting up

Vertica calls plan() once on the initiator node to perform the following tasks:

- Check any parameters that have been passed from the function call in the COPY statement and error messages if there are any issues. You read the parameters by getting a ParamReader object from the instance of ServerInterface passed into your plan() method.
- Store any information that the individual hosts need in order to parse the data. For example, you could store parameters in the PlanContext instance passed in through the planCtxt parameter. The plan() method runs only on the initiator node, and the prepareUDSources() method runs on each host reading from a data source. Therefore, this object is the only means of communication between them.

You store data in the PlanContext by getting a ParamWriter object from the getWriter() method. You then write parameters by calling methods on the ParamWriter such as setString .

> **Note**
> ParamWriter offers only the ability to store simple data types. For complex types, you need to serialize the data in some manner and store it as a string or long string.

Creating parsers

Vertica calls prepare() on each node to create and initialize your parser, using data stored by the plan() method.

Defining parameters

Implement getParameterTypes() to define the names and types of parameters that your parser uses. Vertica uses this information to warn callers about unknown or missing parameters. Vertica ignores unknown parameters and uses default values for missing parameters. While you should define the types and parameters for your function, you are not required to override this method.

Defining parser outputs

Implement getParserReturnType() to define the data types of the table columns that the parser outputs. If applicable, getParserReturnType() also defines the size, precision, or scale of the data types. Usually, this method reads data types of the output table from the argType and perColumnParamReader arguments and verifies that it can output the appropriate data types. If getParserReturnType() is prepared to output the data types, it calls methods on the SizedColumnTypes object passed in the returnType argument. In addition to the data type of the output column, your method should also specify any additional information about the column's data type:

- For binary and string data types (such as CHAR, VARCHAR, and LONG VARBINARY), specify its maximum length.
- For NUMERIC types, specify its precision and scale.
- For Time/Timestamp types (with or without time zone), specify its precision (-1 means unspecified).
- For all other types, no length or precision specification is required.

Supporting cooperative parse

To support Cooperative parse , implement prepareChunker() and return an instance of your UDChunker subclass. If isChunkerApportionable() returns true , then it is an error for this method to return null.

Cooperative parse is currently supported only in the C++ API.

Supporting apportioned load

To support Apportioned load , your parser, chunker, or both must support apportioning. To indicate that the parser can apportion a load, implement isParserApportionable() and return true . To indicate that the chunker can apportion a load, implement isChunkerApportionable() and return true .

The isChunkerApportionable() method takes a ServerInterface as an argument, so you have access to the parameters supplied in the COPY statement. You might need this information if the user can specify a record delimiter, for example. Return true from this method if and only if the factory can create a chunker for this input.

API

C++

Java

Python

The ParserFactory API provides the following methods for extension by subclasses:

```
virtual void plan(ServerInterface &srvInterface, PerColumnParamReader &perColumnParamReader, PlanContext &plan

virtual UDParser * prepare(ServerInterface &srvInterface, PerColumnParamReader &perColumnParamReader,
        PlanContext &planCtxt, const SizedColumnTypes &returnType)=0;

virtual void getParameterType(ServerInterface &srvInterface, SizedColumnTypes &parameterTypes);

virtual void getParserReturnType(ServerInterface &srvInterface, PerColumnParamReader &perColumnParamReader,
        PlanContext &planCtxt, const SizedColumnTypes &argTypes,
        SizedColumnTypes &returnType);

virtual bool isParserApportionable();

// C++ API only:
virtual bool isChunkerApportionable(ServerInterface &srvInterface);

virtual UDChunker * prepareChunker(ServerInterface &srvInterface, PerColumnParamReader &perColumnParamRead
        PlanContext &planCtxt, const SizedColumnTypes &returnType);
```

If you are using Apportioned load to divide a single input into multiple load streams, implement isParserApportionable() and/or isChunkerApportionable() and return true . Returning true from these methods does not guarantee that Vertica *will* apportion the load. However, returning false from both indicates that it will not try to do so.

If you are using Cooperative parse , implement prepareChunker() and return an instance of your UDChunker subclass. Cooperative parse is supported only for the C++ API.

Vertica calls the prepareChunker() method *only* for unfenced functions. This method is not available when you use the function in fenced mode.

If you want your chunker to be available for apportioned load, implement isChunkerApportionable() and return true .

After creating your ParserFactory , you must register it with the RegisterFactory macro.

C++ example: BasicIntegerParser

The BasicIntegerParser example parses a string of integers separated by non-numeric characters. For a version of this parser that uses continuous load, see C++ example: ContinuousIntegerParser .

Loading and using the example

Load and use the BasicIntegerParser example as follows.

```
=> CREATE LIBRARY BasicIntegerParserLib AS '/home/dbadmin/BIP.so';

=> CREATE PARSER BasicIntegerParser AS
LANGUAGE 'C++' NAME 'BasicIntegerParserFactory' LIBRARY BasicIntegerParserLib;

=> CREATE TABLE t (i integer);

=> COPY t FROM stdin WITH PARSER BasicIntegerParser();
0
1
2
3
4
5
\.
```

Implementation

The BasicIntegerParser class implements only the process() method from the API. (It also implements a helper method for type conversion.) This method processes each line of input, looking for numbers on each line. When it advances to a new line it moves the input.offset marker and checks the input state. It then writes the output.

```
virtual StreamState process(ServerInterface &srvInterface, DataBuffer &input,
        InputState input_state) {
    // WARNING: This implementation is not trying for efficiency.
    // It is trying for simplicity, for demonstration purposes.

    size_t start = input.offset;
    const size_t end = input.size;

    do {
        bool found_newline = false;
        size_t numEnd = start;
        for (; numEnd < end; numEnd++) {
            if (input.buf[numEnd] < '0' || input.buf[numEnd] > '9') {
                found_newline = true;
                break;
            }
        }

        if (!found_newline) {
            input.offset = start;
            if (input_state == END_OF_FILE) {
                // If we're at end-of-file,
                // emit the last integer (if any) and return DONE.
                if (start != end) {
                    writer->setInt(0, strToInt(input.buf + start, input.buf + numEnd));
                    writer->next();
                }
                return DONE;
            } else {
                // Otherwise, we need more data.
                return INPUT_NEEDED;
            }
        }

        writer->setInt(0, strToInt(input.buf + start, input.buf + numEnd));
        writer->next();

        start = numEnd + 1;
    } while (true);
}
};
```

In the factory, the plan() method is a no-op; there are no parameters to check. The prepare() method instantiates the parser using the macro provided by the SDK:

```
virtual UDParser* prepare(ServerInterface &srvInterface,
        PerColumnParamReader &perColumnParamReader,
        PlanContext &planCtxt,
        const SizedColumnTypes &returnType) {

    return vt_createFuncObject<BasicIntegerParser>(srvInterface.allocator);
}
```

The getParserReturnType() method declares the single output:

```
    virtual void getParserReturnType(ServerInterface &srvInterface,
                                     PerColumnParamReader &perColumnParamReader,
                                     PlanContext &planCtxt,
                                     const SizedColumnTypes &argTypes,
                                     SizedColumnTypes &returnType) {
        // We only and always have a single integer column
        returnType.addInt(argTypes.getColumnName(0));
    }
```

As for all UDxs written in C++, the example ends by registering its factory:

```
RegisterFactory(BasicIntegerParserFactory);
```

C++ example: ContinuousIntegerParser

The ContinuousIntegerParser example is a variation of BasicIntegerParser . Both examples parse integers from input strings. ContinuousIntegerParser uses Continuous load to read data.

Loading and using the example

Load the ContinuousIntegerParser example as follows.

```
=> CREATE LIBRARY ContinuousIntegerParserLib AS '/home/dbadmin/CIP.so';

=> CREATE PARSER ContinuousIntegerParser AS
LANGUAGE 'C++' NAME 'ContinuousIntegerParserFactory'
LIBRARY ContinuousIntegerParserLib;
```

Use it in the same way that you use BasicIntegerParser . See C++ example: BasicIntegerParser .

Implementation

ContinuousIntegerParser is a subclass of ContinuousUDParser . Subclasses of ContinuousUDParser place the processing logic in the run() method.

```
    virtual void run() {

        // This parser assumes a single-column input, and
        // a stream of ASCII integers split by non-numeric characters.
        size_t pos = 0;
        size_t reserved = cr.reserve(pos+1);
        while (!cr.isEof() || reserved == pos + 1) {
            while (reserved == pos + 1 && isdigit(*ptr(pos))) {
                pos++;
                reserved = cr.reserve(pos + 1);
            }

            std::string st(ptr(), pos);
            writer->setInt(0, strToInt(st));
            writer->next();

            while (reserved == pos + 1 && !isdigit(*ptr(pos))) {
                pos++;
                reserved = cr.reserve(pos + 1);
            }
            cr.seek(pos);
            pos = 0;
            reserved = cr.reserve(pos + 1);
        }
    }
};
```

For a more complex example of a ContinuousUDParser , see ExampleDelimitedParser in the examples. (See Downloading and running UDx example code .) ExampleDelimitedParser uses a chunker; see C++ example: delimited parser and chunker .

Java example: numeric text

This NumericTextParser example parses integer values spelled out in words rather than digits (for example "one two three" for one-hundred twenty three). The parser:

- Accepts a single parameter to set the character that separates columns in a row of data. The separator defaults to the pipe (|) character.
- Ignores extra spaces and the capitalization of the words used to spell out the digits.
- Recognizes the digits using the following words: zero, one, two, three, four, five, six, seven, eight, nine.
- Assumes that the words spelling out an integer are separated by at least one space.
- Rejects any row of data that cannot be completely parsed into integers.
- Generates an error, if the output table has a non-integer column.

Loading and using the example

Load and use the parser as follows:

```
=> CREATE LIBRARY JavaLib AS '/home/dbadmin/JavaLib.jar' LANGUAGE 'JAVA';
CREATE LIBRARY

=> CREATE PARSER NumericTextParser AS LANGUAGE 'java'
->    NAME 'com.myCompany.UDParser.NumericTextParserFactory'
->    LIBRARY JavaLib;
CREATE PARSER FUNCTION
=> CREATE TABLE t (i INTEGER);
CREATE TABLE
=> COPY t FROM STDIN WITH PARSER NumericTextParser();
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.

Parser implementation

The following code implements the parser.

```
package com.myCompany.UDParser;

import java.util.Arrays;
import java.util.List;
import java.util.regex.Pattern;

import com.vertica.sdk.DataBuffer;
import com.vertica.sdk.DestroyInvocation;
import com.vertica.sdk.RejectedRecord;
import com.vertica.sdk.ServerInterface;
import com.vertica.sdk.State.InputState;
import com.vertica.sdk.State.StreamState;
import com.vertica.sdk.StreamWriter;
import com.vertica.sdk.UDParser;
import com.vertica.sdk.UdfException;

public class NumericTextParser extends UDParser {

    private String separator; // Holds column separator character

    // List of strings that we accept as digits.
    private List<String> numbers = Arrays.asList("zero", "one",
            "two", "three", "four", "five", "six", "seven",
            "eight", "nine");

    // Hold information about the last rejected row.
    private String rejectedReason;
    private String rejectedRow;

    // Constructor gets the separator character from the Factory's prepare()
    // method.
    public NumericTextParser(String sepparam) {
        super();
        this.separator = sepparam;
    }

    // Called to perform the actual work of parsing. Gets a buffer of bytes
    // to turn into tuples.
    @Override
    public StreamState process(ServerInterface srvInterface, DataBuffer input,
            InputState input_state) throws UdfException, DestroyInvocation {

        int i=input.offset; // Current position in the input buffer
        // Flag to indicate whether we just found the end of a row.
        boolean lastCharNewline = false;
        // Buffer to hold the row of data being read.
        StringBuffer line = new StringBuffer();

        //Continue reading until end of buffer.
        for(; i < input.buf.length; i++){
            // Loop through input until we find a linebreak: marks end of row
            char inchar = (char) input.buf[i];
            // Note that this isn't a robust way to find rows. It should
            // accept a user-defined row separator. Also, the following
            // assumes ASCII line break metheods, which isn't a good idea
            // in the UTF world. But it is good enough for this simple example.
            if (inchar != '\n' && inchar != '\r') {
                // Keep adding to a line buffer until a full row of data is read
                line.append(inchar);
                lastCharNewline = false; // Last character not a new line
            } else {
                // Found a line break. Process the row
```

```
            // Found a line break. Process the row.
            lastCharNewline = true; // indicate we got a complete row
            // Update the position in the input buffer. This is updated
            // whether the row is successfully processed or not.
            input.offset = i+1;
            // Call procesRow to extract values and write tuples to the
            // output. Returns false if there was an error.
            if (!processRow(line)) {
                // Processing row failed. Save bad row to rejectedRow field
                // and return to caller indicating a rejected row.
                rejectedRow = line.toString();
                // Update position where we processed the data.
                return StreamState.REJECT;
            }
            line.delete(0, line.length()); // clear row buffer
        }
    }

    // At this point, process() has finished processing the input buffer.
    // There are two possibilities: need to get more data
    // from the input stream to finish processing, or there is
    // no more data to process. If at the end of the input stream and
    // the row was not terminated by a linefeed, it may need
    // to process the last row.

    if (input_state == InputState.END_OF_FILE && lastCharNewline) {
        // End of input and it ended on a newline. Nothing more to do
        return StreamState.DONE;
    } else if (input_state == InputState.END_OF_FILE && !lastCharNewline) {
        // At end of input stream but didn't get a final newline. Need to
        // process the final row that was read in, then exit for good.
        if (line.length() == 0) {
            // Nothing to process. Done parsing.
            return StreamState.DONE;
        }
        // Need to parse the last row, not terminated by a linefeed. This
        // can occur if the file being read didn't have a final line break.
        if (processRow(line)) {
            return StreamState.DONE;
        } else {
            // Processing last row failed. Save bad row to rejectedRow field
            // and return to caller indicating a rejected row.
            rejectedRow = line.toString();
            // Tell Vertica the entire buffer was processed so it won't
            // call again to have the line processed.
            input.offset = input.buf.length;
            return StreamState.REJECT;
        }
    } else {
        // Stream is not fully read, so tell Vertica to send more. If
        // process() didn't get a complete row before it hit the end of the
        // input buffer, it will end up re-processing that segment again
        // when more data is added to the buffer.
        return StreamState.INPUT_NEEDED;
    }
}

// Breaks a row into columns, then parses the content of the
// columns. Returns false if there was an error parsing the
// row, in which case it sets the rejected row to the input
// line. Returns true if the row was successfully read.
private boolean processRow(StringBuffer line)
```

```
private boolean processRow(StringBuffer line)
                    throws UdfException, DestroyInvocation {
   String[] columns = line.toString().split(Pattern.quote(separator));
   // Loop through the columns, decoding their contents
   for (int col = 0; col < columns.length; col++) {
      // Call decodeColumn to extract value from this column
      Integer colval = decodeColumn(columns[col]);
      if (colval == null) {
         // Could not parse one of the columns. Indicate row should
         // be rejected.
         return false;
      }
      // Column parsed OK. Write it to the output. writer is a field
      // provided by the parent class. Since this parser only accepts
      // integers, there is no need to verify that data type of the parsed
      // data matches the data type of the column being written. In your
      // UDParsers, you may want to perform this verification.
      writer.setLong(col,colval);
   }
   // Done with the row of data. Advance output to next row.

   // Note that this example does not verify that all of the output columns
   // have values assigned to them. If there are missing values at the
   // end of a row, they get automatically get assigned a default value
   // (0 for integers). This isn't a robust solution. Your UDParser
   // should perform checks here to handle this situation and set values
   // (such as null) when appropriate.
   writer.next();
   return true; // Successfully processed the row.
}

// Gets a string with text numerals, i.e. "One Two Five Seven" and turns
// it into an integer value, i.e. 1257. Returns null if the string could not
// be parsed completely into numbers.
private Integer decodeColumn(String text) {
   int value = 0; // Hold the value being parsed.

   // Split string into individual words. Eat extra spaces.
   String[] words = text.toLowerCase().trim().split("\\s+");

   // Loop through the words, matching them against the list of
   // digit strings.
   for (int i = 0; i < words.length; i++) {
      if (numbers.contains(words[i])) {
         // Matched a digit. Add the it to the value.
         int digit = numbers.indexOf(words[i]);
         value = (value * 10) + digit;
      } else {
         // The string didn't match one of the accepted string values
         // for digits. Need to reject the row. Set the rejected
         // reason string here so it can be incorporated into the
         // rejected reason object.
         //
         // Note that this example does not handle null column values.
         // In most cases, you want to differentiate between an
         // unparseable column value and a missing piece of input
         // data. This example just rejects the row if there is a missing
         // column value.
         rejectedReason = String.format(
               "Could not parse '%s' into a digit",words[i]);
         return null;
      }
```

```
        }
        return value;
    }

    // Vertica calls this method if the parser rejected a row of data
    // to find out what went wrong and add to the proper logs. Just gathers
    // information stored in fields and returns it in an object.
    @Override
    public RejectedRecord getRejectedRecord() throws UdfException {
        return new RejectedRecord(rejectedReason,rejectedRow.toCharArray(),
                rejectedRow.length(), "\n");
    }
}
```

ParserFactory implementation

The following code implements the parser factory.

NumericTextParser accepts a single optional parameter named separator . This parameter is defined in the getParameterType() method, and the plan() method stores its value. NumericTextParser outputs only integer values. Therefore, if the output table contains a column whose data type is not integer, the getParserReturnType() method throws an exception.

```
package com.myCompany.UDParser;

import java.util.regex.Pattern;

import com.vertica.sdk.ParamReader;
import com.vertica.sdk.ParamWriter;
import com.vertica.sdk.ParserFactory;
import com.vertica.sdk.PerColumnParamReader;
import com.vertica.sdk.PlanContext;
import com.vertica.sdk.ServerInterface;
import com.vertica.sdk.SizedColumnTypes;
import com.vertica.sdk.UDParser;
import com.vertica.sdk.UdfException;
import com.vertica.sdk.VerticaType;

public class NumericTextParserFactory extends ParserFactory {

    // Called once on the initiator host to check the parameters and set up the
    // context data that hosts performing processing will need later.
    @Override
    public void plan(ServerInterface srvInterface,
            PerColumnParamReader perColumnParamReader,
            PlanContext planCtxt) {

        String separator = "|"; // assume separator is pipe character

        // See if a parameter was given for column separator
        ParamReader args = srvInterface.getParamReader();
        if (args.containsParameter("separator")) {
            separator = args.getString("separator");
            if (separator.length() > 1) {
                throw new UdfException(0,
                        "Separator parameter must be a single character");
            }
            if (Pattern.quote(separator).matches("[a-zA-Z]")) {
                throw new UdfException(0,
                        "Separator parameter cannot be a letter");
            }
        }
```

```
    // Save separator character in the Plan Data
    ParamWriter context = planCtxt.getWriter();
    context.setString("separator", separator);
  }

  // Define the data types of the output table that the parser will return.
  // Mainly, this just ensures that all of the columns in the table which
  // is the target of the data load are integer.
  @Override
  public void getParserReturnType(ServerInterface srvInterface,
          PerColumnParamReader perColumnParamReader,
          PlanContext planCtxt,
          SizedColumnTypes argTypes,
          SizedColumnTypes returnType) {

    // Get access to the output table's columns
    for (int i = 0; i < argTypes.getColumnCount(); i++ ) {
      if (argTypes.getColumnType(i).isInt()) {
          // Column is integer... add it to the output
          returnType.addInt(argTypes.getColumnName(i));
      } else {
          // Column isn't an int, so throw an exception.
          // Technically, not necessary since the
          // UDx framework will automatically error out when it sees a
          // Discrepancy between the type in the target table and the
          // types declared by this method. Throwing this exception will
          // provide a clearer error message to the user.
          String message = String.format(
              "Column %d of output table is not an Int", i + 1);
          throw new UdfException(0, message);
      }
    }
  }

  // Instantiate the UDParser subclass named NumericTextParser. Passes the
  // separator characetr as a paramter to the constructor.
  @Override
  public UDParser prepare(ServerInterface srvInterface,
      PerColumnParamReader perColumnParamReader, PlanContext planCtxt,
      SizedColumnTypes returnType) throws UdfException {
    // Get the separator character from the context
    String separator = planCtxt.getReader().getString("separator");
    return new NumericTextParser(separator);
  }

  // Describe the parameters accepted by this parser.
  @Override
  public void getParameterType(ServerInterface srvInterface,
          SizedColumnTypes parameterTypes) {
    parameterTypes.addVarchar(1, "separator");
  }
```

Java example: JSON parser

The JSON Parser consumes a stream of JSON objects. Each object must be well formed and on a single line in the input. Use line breaks to delimit the objects. The parser uses the field names as keys in a map, which become column names in the table. You can find the code for this example in /opt/vertica/packages/flextable/examples. This directory also contains an example data file.

This example uses the setRowFromMap() method to write data.

Loading and using the example

1. Load the library and define the JSON parser, using the third-party library (gson-2.2.4.jar). See the comments in JsonParser.java for a download URL.

```
=> CREATE LIBRARY json
-> AS '/opt/vertica/packages/flextable/examples/java/output/json.jar'
-> DEPENDS '/opt/vertica/bin/gson-2.2.4.jar' language 'java';
CREATE LIBRARY

=> CREATE PARSER JsonParser AS LANGUAGE 'java'
-> NAME 'com.vertica.flex.JsonParserFactory' LIBRARY json;
CREATE PARSER FUNCTION
```

1. Define a table, and then use the JSON parser to load data into that table.

```
=> CREATE TABLE mountains(name varchar(64), type varchar(32), height integer);
CREATE TABLE

=> COPY mountains FROM '/opt/vertica/packages/flextable/examples/mountains.json'
-> WITH PARSER JsonParser();
-[ RECORD 1 ]--
Rows Loaded | 2

=> SELECT * from mountains;
-[ RECORD 1 ]--------
name   | Everest
type   | mountain
height | 29029
-[ RECORD 2 ]--------
name   | Mt St Helens
type   | volcano
height |
```

The data file contains a value (hike_safety) that was not loaded because the table definition did not include that column. The data file follows:

```
{ "name": "Everest", "type":"mountain", "height": 29029, "hike_safety": 34.1  }
{ "name": "Mt St Helens", "type": "volcano", "hike_safety": 15.4 }
```

Implementation

The following code shows the process() method from JsonParser.java. The parser attempts to read the input into a Map. If the read is successful, the JSON Parser calls setRowFromMap() :

```
    @Override
    public StreamState process(ServerInterface srvInterface, DataBuffer input,
            InputState inputState) throws UdfException, DestroyInvocation {
        clearReject();
        StreamWriter output = getStreamWriter();

        while (input.offset < input.buf.length) {
            ByteBuffer lineBytes = consumeNextLine(input, inputState);

            if (lineBytes == null) {
                return StreamState.INPUT_NEEDED;
            }

            String lineString = StringUtils.newString(lineBytes);

            try {
                Map map = gson.fromJson(lineString, parseType);

                if (map == null) {
                    continue;
                }

                output.setRowFromMap(map);
                // No overrides needed, so just call next() here.
            output.next();
            } catch (Exception ex) {
                setReject(lineString, ex);
                return StreamState.REJECT;
            }
        }
```

The factory, JsonParserFactory.java, instantiates and returns a parser in the prepare() method. No additional setup is required.

C++ example: delimited parser and chunker

The ExampleDelimitedUDChunker class divides an input at delimiter characters. You can use this chunker with any parser that understands delimited input. ExampleDelimitedParser is a ContinuousUDParser subclass that uses this chunker.

Loading and using the example

Load and use the example as follows.

```
=> CREATE LIBRARY ExampleDelimitedParserLib AS '/home/dbadmin/EDP.so';

=> CREATE PARSER ExampleDelimitedParser AS
   LANGUAGE 'C++' NAME 'DelimitedParserFrameworkExampleFactory'
   LIBRARY ExampleDelimitedParserLib;

=> COPY t FROM stdin WITH PARSER ExampleDelimitedParser();
0
1
2
3
4
5
6
7
8
9
\.
```

Chunker implementation

This chunker supports apportioned load. The alignPortion() method finds the beginning of the first complete record in the current portion and aligns

the input buffer with it. The record terminator is passed as an argument and set in the constructor.

```
StreamState ExampleDelimitedUDChunker::alignPortion(
        ServerInterface &srvInterface,
        DataBuffer &input, InputState state)
{
  /* find the first record terminator.  Its record belongs to the previous portion */
  void *buf = reinterpret_cast<void *>(input.buf + input.offset);
  void *term = memchr(buf, recordTerminator, input.size - input.offset);

  if (term) {
    /* record boundary found.  Align to the start of the next record */
    const size_t chunkSize = reinterpret_cast<size_t>(term) - reinterpret_cast<size_t>(buf);
    input.offset += chunkSize
        + sizeof(char) /* length of record terminator */;

    /* input.offset points at the start of the first complete record in the portion */
    return DONE;
  } else if (state == END_OF_FILE || state == END_OF_PORTION) {
    return REJECT;
  } else {
    VIAssert(state == START_OF_PORTION || state == OK);
    return INPUT_NEEDED;
  }
```

The process() method has to account for chunks that span portion boundaries. If the previous call was at the end of a portion, the method set a flag. The code begins by checking for and handling that condition. The logic is similar to that of alignPortion() , so the example calls it to do part of the division.

```
StreamState ExampleDelimitedUDChunker::process(
        ServerInterface &srvInterface,
        DataBuffer &input,
        InputState input_state)
{
  const size_t termLen = 1;
  const char *terminator = &recordTerminator;

  if (pastPortion) {
    /*
     * Previous state was END_OF_PORTION, and the last chunk we will produce
     * extends beyond the portion we started with, into the next portion.
     * To be consistent with alignPortion(), that means finding the first
     * record boundary, and setting the chunk to be at that boundary.
     * Fortunately, this logic is identical to aligning the portion (with
     * some slight accounting for END_OF_FILE)!
     */
    const StreamState findLastTerminator = alignPortion(srvInterface, input);

    switch (findLastTerminator) {
      case DONE:
        return DONE;
      case INPUT_NEEDED:
        if (input_state == END_OF_FILE) {
          /* there is no more input where we might find a record terminator */
          input.offset = input.size;
          return DONE;
        }
        return INPUT_NEEDED;
      default:
        VIAssert("Invalid return state from alignPortion()");
    }
    return findLastTerminator;
  }
```

Now the method looks for the delimiter. If the input began at the end of a portion, it sets the flag.

```
  size_t ret = input.offset, term_index = 0;
  for (size_t index = input.offset; index < input.size; ++index) {
    const char c = input.buf[index];
    if (c == terminator[term_index]) {
      ++term_index;
      if (term_index == termLen) {
        ret = index + 1;
        term_index = 0;
      }
      continue;
    } else if (term_index > 0) {
      index -= term_index;
    }

    term_index = 0;
  }

  if (input_state == END_OF_PORTION) {
    /*
     * Regardless of whether or not a record was found, the next chunk will extend
     * into the next portion.
     */
    pastPortion = true;
  }
```

Finally, process() moves the input offset and returns.

```
    // if we were able to find some rows, move the offset to point at the start of the next (potential) row, or end of block
    if (ret > input.offset) {
        input.offset = ret;
        return CHUNK_ALIGNED;
    }

    if (input_state == END_OF_FILE) {
        input.offset = input.size;
        return DONE;
    }

    return INPUT_NEEDED;
}
```

Factory implementation

The file ExampleDelimitedParser.cpp defines a factory that uses this UDChunker . The chunker supports apportioned load, so the factory implements isChunkerApportionable() :

```
    virtual bool isChunkerApportionable(ServerInterface &srvInterface) {
        ParamReader params = srvInterface.getParamReader();
        if (params.containsParameter("disable_chunker") && params.getBoolRef("d\
isable_chunker")) {
            return false;
        } else {
            return true;
        }
    }
```

The prepareChunker() method creates the chunker:

```
    virtual UDChunker* prepareChunker(ServerInterface &srvInterface,
                                      PerColumnParamReader &perColumnParamReade\
r,
                                      PlanContext &planCtxt,
                                      const SizedColumnTypes &returnType)
    {
        ParamReader params = srvInterface.getParamReader();
        if (params.containsParameter("disable_chunker") && params.getBoolRef("d\
isable_chunker")) {
            return NULL;
        }

        std::string recordTerminator("\n");

        ParamReader args(srvInterface.getParamReader());
        if (args.containsParameter("record_terminator")) {
            recordTerminator = args.getStringRef("record_terminator").str();
        }

        return vt_createFuncObject<ExampleDelimitedUDChunker>(srvInterface.allo\
cator,
                recordTerminator[0]);
    }
```

Load parallelism

Vertica can divide the work of loading data, taking advantage of parallelism to speed up the operation. Vertica supports several types of parallelism:

- Distributed load: Vertica distributes files in a multi-file load to several nodes to load in parallel, instead of loading all of them on a single node. Vertica manages distributed load; you do not need to do anything special in your UDL.

- Cooperative parse: A source being loaded on a single node uses multi-threading to parallelize the parse. Cooperative parse divides a load at execution time, based on how threads are scheduled. You must enable cooperative parse in your parser. See Cooperative parse .
- Apportioned load: Vertica divides a single large file or other single source into segments, which it assigns to several nodes to load in parallel. Apportioned load divides the load at planning time, based on available nodes and cores on each node. You must enable apportioned load in your source and parser. See Apportioned load .

You can support both cooperative parse and apportioned load in the same UDL. Vertica decides which to use for each load operation and might use both. See Combining cooperative parse and apportioned load .

In this section

- Cooperative parse
- Apportioned load
- Combining cooperative parse and apportioned load

Cooperative parse

By default, Vertica parses a data source in a single thread on one database node. You can optionally use *cooperative parse* to parse a source using multiple threads on a node. More specifically, data from a source passes through a *chunker* that groups blocks from the source stream into logical units. These chunks can be parsed in parallel. The chunker divides the input into pieces that can be individually parsed, and the parser then parses them concurrently. Cooperative parse is available only for unfenced UDxs. (See Fenced and unfenced modes .)

To use cooperative parse, a chunker must be able to locate end-of-record markers in the input. Locating these markers might not be possible in all input formats.

Chunkers are created by parser factories. At load time, Vertica first calls the UDChunker to divide the input into chunks and then calls the UDParser to parse each chunk.

You can use cooperative parse and apportioned load independently or together. See Combining cooperative parse and apportioned load .

How Vertica divides a load

When Vertica receives data from a source, it calls the chunker's process() method repeatedly. A chunker is, essentially, a lightweight parser; instead of parsing, the process() method divides the input into chunks.

After the chunker has finished dividing the input into chunks, Vertica sends those chunks to as many parsers as are available, calling the process() method on the parser.

Implementing cooperative parse

To implement cooperative parse, perform the following actions:

- Subclass UDChunker and implement process() .
- In your ParserFactory , implement prepareChunker() to return a UDChunker .

See C++ example: delimited parser and chunker for a UDChunker that also supports apportioned load.

Apportioned load

A parser can use more than one database node to load a single input source in parallel. This approach is referred to as *apportioned load* . Among the parsers built into Vertica, the default (delimited) parser supports apportioned load.

Apportioned load, like cooperative parse, requires an input that can be divided at record boundaries. The difference is that cooperative parse does a sequential scan to find record boundaries, while apportioned load first jumps (seeks) to a given position and then scans. Some formats, like generic XML, do not support seeking.

To use apportioned load, you must ensure that the source is reachable by all participating database nodes. You typically use apportioned load with distributed file systems.

It is possible for a parser to not support apportioned load directly but to have a chunker that supports apportioning.

You can use apportioned load and cooperative parse independently or together. See Combining cooperative parse and apportioned load .

How Vertica apportions a load

If both the parser and its source support apportioning, then you can specify that a single input is to be distributed to multiple database nodes for loading. The SourceFactory breaks the input into portions and assigns them to execution nodes. Each Portion consists of an offset into the input and a size. Vertica distributes the portions and their parameters to the execution nodes. A source factory running on each node produces a UDSource for the given portion.

The UDParser first determines where to start parsing:

- If the portion is the first one in the input, the parser advances to the offset and begins parsing.
- If the portion is not the first, the parser advances to the offset and then scans until it finds the end of a record. Because records can break across portions, parsing begins after the first record-end encountered.

The parser must complete a record, which might require it to read past the end of the portion. The parser is responsible for parsing all records that *begin* in the assigned portion, regardless of where they end. Most of this work occurs within the process() method of the parser.

Sometimes, a portion contains nothing to be parsed by its assigned node. For example, suppose you have a record that begins in portion 1, runs through all of portion 2, and ends in portion 3. The parser assigned to portion 1 parses the record, and the parser assigned to portion 3 starts after that record. The parser assigned to portion 2, however, has no record starting within its portion.

If the load also uses Cooperative parse , then after apportioning the load and before parsing, Vertica divides portions into chunks for parallel loading.

Implementing apportioned load

To implement apportioned load, perform the following actions in the source, the parser, and their factories.

In your SourceFactory subclass:

- Implement isSourceApportionable() and return true .
- Implement plan() to determine portion size, designate portions, and assign portions to execution nodes. To assign portions to particular executors, pass the information using the parameter writer on the plan context (PlanContext::getWriter()).
- Implement prepareUDSources() . Vertica calls this method on each execution node with the plan context created by the factory. This method returns the UDSource instances to be used for this node's assigned portions.
- If sources can take advantage of parallelism, you can implement getDesiredThreads() to request a number of threads for each source. See SourceFactory class for more information about this method.

In your UDSource subclass, implement process() as you would for any other source, using the assigned portion. You can retrieve this portion with getPortion() .

In your ParserFactory subclass:

- Implement isParserApportionable() and return true .
- If your parser uses a UDChunker that supports apportioned load, implement isChunkerApportionable() .

In your UDParser subclass:

- Write your UDParser subclass to operate on portions rather than whole sources. You can do so by handling the stream states PORTION_START and PORTION_END , or by using the ContinuousUDParser API. Your parser must scan for the beginning of the portion, find the first record boundary after that position, and parse to the end of the last record beginning in that portion. Be aware that this behavior might require that the parser read beyond the end of the portion.
- Handle the special case of a portion containing no record start by returning without writing any output.

In your UDChunker subclass, implement alignPortion() . See Aligning Portions .

Example

The SDK provides a C++ example of apportioned load in the ApportionLoadFunctions directory:

- FilePortionSource is a subclass of UDSource .
- DelimFilePortionParser is a subclass of ContinuousUDParser .

Use these classes together. You could also use FilePortionSource with the built-in delimited parser.

The following example shows how you can load the libraries and create the functions in the database:

```
=> CREATE LIBRARY FilePortionSourceLib as '/home/dbadmin/FP.so';

=> CREATE LIBRARY DelimFilePortionParserLib as '/home/dbadmin/Delim.so';

=> CREATE SOURCE FilePortionSource AS
LANGUAGE 'C++' NAME 'FilePortionSourceFactory' LIBRARY FilePortionSourceLib;

=> CREATE PARSER DelimFilePortionParser AS
LANGUAGE 'C++' NAME 'DelimFilePortionParserFactory' LIBRARY DelimFilePortionParserLib;
```

The following example shows how you can use the source and parser to load data:

```
=> COPY t WITH SOURCE FilePortionSource(file='g1/*.dat') PARSER DelimFilePortionParser(delimiter = '|',
   record_terminator = '~');
```

Combining cooperative parse and apportioned load

You can enable both Cooperative parse and Apportioned load in the same parser, allowing Vertica to decide how to load data.

Deciding how to divide a load

Vertica uses apportioned load, where possible, at query-planning time. It decides whether to also use cooperative parse at execution time.

Apportioned load requires SourceFactory support. Given a suitable UDSource , at planning time Vertica calls the isParserApportionable() method on the ParserFactory . If this method returns true , Vertica apportions the load.

If isParserApportionable() returns false but isChunkerApportionable() returns true , then a chunker is available for cooperative parse and that chunker supports apportioned load. Vertica apportions the load.

If neither of these methods returns true , then Vertica does not apportion the load.

At execution time, Vertica first checks whether the load is running in unfenced mode and proceeds only if it is. Cooperative parse is not supported in fenced mode.

If the load is not apportioned, and more than one thread is available, Vertica uses cooperative parse.

If the load is apportioned, and exactly one thread is available, Vertica uses cooperative parse if and only if the parser is not apportionable. In this case, the chunker is apportionable but the parser is not.

If the load is apportioned, and more than one thread is available, and the chunker is apportionable, Vertica uses cooperative parse.

If Vertica uses cooperative parse but prepareChunker() does not return a UDChunker instance, Vertica reports an error.

Executing apportioned, cooperative loads

If a load uses both apportioned load and cooperative parse, Vertica uses the SourceFactory to break the input into portions. It then assigns the portions to execution nodes. See How Vertica Apportions a Load .

On the execution node, Vertica calls the chunker's alignPortion() method to align the input with portion boundaries. (This step is skipped for the first portion, which by definition is already aligned at the beginning.) This step is necessary because a parser using apportioned load sometimes has to read beyond the end of the portion, so a chunker needs to find the end point.

After aligning the portion, Vertica calls the chunker's process() method repeatedly. See How Vertica Divides a Load .

The chunks found by the chunker are then sent to the parser's process() method for processing in the usual way.

Continuous load

The ContinuousUDSource , ContinuousUDFilter , and ContinuousUDParser classes allow you to write and process data as needed instead of having to iterate through the data. The Python API does not support continuous load.

Each class includes the following functions:

- initialize() - Invoked before run() . You can optionally override this function to perform setup and initialization.
- run() - Processes the data.

- deinitialize() - Invoked after run() has returned. You can optionally override this function to perform tear-down and destruction.

Do not override the setup() , process() , and destroy() functions that are inherited from parent classes.

You can use the yield() function to yield control back to the server during idle or busy loops so the server can check for status changes or query cancellations.

These three classes use associated ContinuousReader and ContinuousWriter classes to read input data and write output data.

ContinuousUDSource API (C++)

The ContinuousUDSource class extends UDSource and adds the following methods for extension by subclasses:

```
virtual void initialize(ServerInterface &srvInterface);

virtual void run();

virtual void deinitialize(ServerInterface &srvInterface);
```

ContinuousUDFilter API (C++)

The ContinuousUDFilter class extends UDFilter and adds the following methods for extension by subclasses:

```
virtual void initialize(ServerInterface &srvInterface);

virtual void run();

virtual void deinitialize(ServerInterface &srvInterface);
```

ContinuousUDParser API

C++

Java

The ContinuousUDParser class extends UDParser and adds the following methods for extension by subclasses:

```
virtual void initialize(ServerInterface &srvInterface);

virtual void run();

virtual void deinitialize(ServerInterface &srvInterface);
```

See the API documentation for additional utility methods.

Buffer classes

Buffer classes are used as handles to the raw data stream for all UDL functions. The C++ and Java APIs use a single DataBuffer class for both input and output. The Python API has two classes, InputBuffer and OutputBuffer .

DataBuffer API

API

C++

Java

The DataBuffer class has a pointer to a buffer and size, and an offset indicating how much of the stream has been consumed.

```
/**
* A contiguous in-memory buffer of char *
*/
  struct DataBuffer {
   /// Pointer to the start of the buffer
   char * buf;

   /// Size of the buffer in bytes
   size_t size;

   /// Number of bytes that have been processed by the UDL
   size_t offset;
};
```

InputBuffer and OutputBuffer APIs

The Python InputBuffer and OutputBuffer classes replace the DataBuffer class in the C++ and Java APIs.

InputBuffer class

The InputBuffer class decodes and translates raw data streams depending on the specified encoding. Python natively supports a wide range of languages and codecs . The InputBuffer is an argument to the process() method for both UDFilters and UDParsers. A user interacts with the UDL's data stream by calling methods of the InputBuffer

If you do not specify a value for setEncoding() , Vertica assumes a value of NONE.

```
class InputBuffer:
    def getSize(self):
        ...
    def getOffset(self):
        ...

    def setEncoding(self, encoding):
        """
        Set the encoding of the data contained in the underlying buffer
        """
        pass

    def peek(self, length = None):
        """
        Copy data from the input buffer into Python.
        If no encoding has been specified, returns a Bytes object containing raw data.
        Otherwise, returns data decoded into an object corresponding to the specified encoding
        (for example, 'utf-8' would return a string).
        If length is None, returns all available data.
        If length is not None then the length of the returned object is at most what is requested.
        This method does not advance the buffer offset.
        """
        pass

    def read(self, length = None):
        """
        See peek().
        This method does the same thing as peek(), but it also advances the
        buffer offset by the number of bytes consumed.
        """
        pass

        # Advances the DataBuffer offset by a number of bytes equal to the result
        # of calling "read" with the same arguments.
        def advance(self, length = None):
        """
        Advance the buffer offset by the number of bytes indicated by
        the length and encoding arguments.  See peek().
    Returns the new offset.
        """
        pass
```

OutputBuffer class

The OutputBuffer class encodes and outputs data from Python to Vertica. The OutputBuffer is an argument to the process() method for both UDFilters and UDParsers. A user interacts with the UDL's data stream by calling methods of the OutputBuffer to manipulate and encode data.

The write() method transfers all data from the Python client to Vertica. The output buffer can accept any size object. If a user writes an object to the OutputBuffer larger than Vertica can immediately process, Vertica stores the overflow. During the next call to process() ,Vertica checks for leftover data. If there is any, Vertica copies it to the DataBuffer before determining whether it needs to call process() from the Python UDL.

If you do not specify a value for setEncoding() , Vertica assumes a value of NONE.

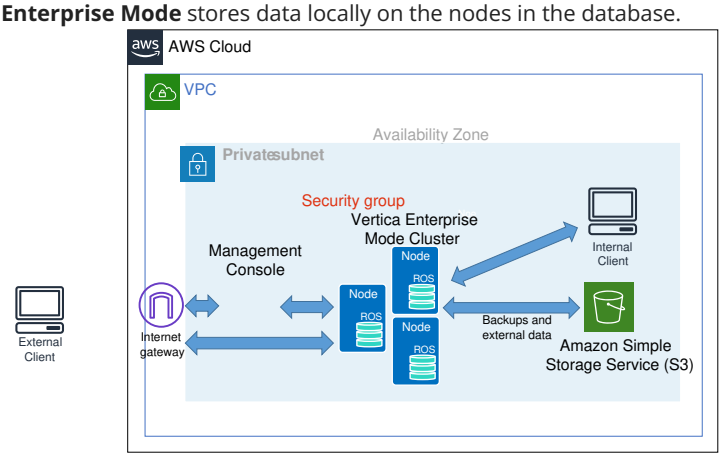
```
class OutputBuffer:
def setEncoding(self, encoding):
"""
Specify the encoding of the data which will be written to the underlying buffer
"""
pass
def write(self, data):
"""
Transfer bytes from the data object into Vertica.
If an encoding was specified via setEncoding(), the data object will be converted to bytes using the specified encoding.
Otherwise, the data argument is expected to be a Bytes object and is copied to the underlying buffer.
"""
pass
```

Using Vertica on the cloud

Welcome to the Vertica on the Cloud guide. This section explains how you can create Vertica clusters running on different cloud platforms. It does not cover working with existing data stored in the cloud. For information about loading data, see Data load .

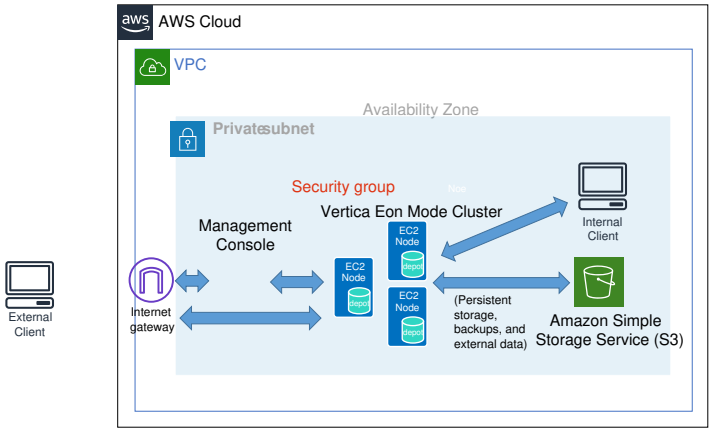
This document assumes that you are familiar with the cloud environment on which you will create your Vertica cluster.

In this section



- Vertica on Amazon Web Services
- Vertica on Microsoft Azure
- Vertica on Google Cloud Platform
- Moving a cloud installation from by the hour (BTH) to bring your own license (BYOL)
- Adjusting Spread Daemon timeouts for virtual environments

Vertica on Amazon Web Services



This section explains how to create and manage Vertica clusters on AWS.

When you launch a cluster on AWS resources and are ready to create your database, consider whether to run it in Eon Mode or Enterprise Mode . The differences in these two modes lay in their architecture, deployment, and scalability:

- **Enterprise Mode** stores data locally on the nodes in the database.

- **Eon Mode** stores its data in an S3 bucket.

Eon Mode separates the computational processes from the communal storage layer of your database. This separation lets you elastically vary the number of nodes in your database cluster to adjust to varying workloads.
Vertica provides CloudFormation Templates (CFTs) through the AWS Marketplace. These CFTs also deploy the Management Console.

> **Note**
> For detailed information about which CFT to use, see Creating a database in Eon Mode .

See Architecture for more about the differences between the two database modes.

In this section

- Overview of Vertica on Amazon Web Services (AWS)
- Installing Vertica with CloudFormation templates
- Install Vertica with manually deployed AWS resources
- Export data to Amazon S3 using the AWS library
- Add nodes to a running cluster on the cloud
- Remove nodes from a running AWS cluster
- Upgrade Vertica on AWS
- Copying and exporting data on AWS: what you need to know

Overview of Vertica on Amazon Web Services (AWS)

Vertica clusters on AWS can operate on EC2 instances automatically provisioned using a CloudFormation Template, or manually deployed from Amazon Machine Images (AMIs).

You can create a database in either Eon Mode or Enterprise Mode in a Vertica cluster in AWS.

For more information about Amazon cluster instances and their limitations, see the Amazon documentation .

- CloudFormation templates
- Vertica offerings on AWS
- Vertica AMI operating systems for AWS
- Supported AWS instance types
- Choosing AWS Eon Mode instance types
- Vertica AMI sleep c-states
- AWS features supported by Vertica
- AWS authentication

CloudFormation templates

Vertica provides Cloud Formation Templates (CFTs) through the AWS Marketplace . After you provide a few parameters to the template, create a stack to automatically provision the AWS resources for your Vertica system.

After creating the stack, in the Management Console (MC) you can create and manage your clusters and databases. See Creating an Eon Mode database in AWS with MC or Creating an Enterprise Mode database in AWS with MC .

Vertica offerings on AWS

Using the license models and CFTs described in CloudFormation template (CFT) overview , you can install the following Vertica products:

- Vertica BYOL, Amazon Linux 2.0
- Vertica by the Hour, Amazon Linux 2.0
- Vertica BYOL, Red Hat
- Vertica by the Hour, Red Hat

See Launch MC and AWS resources with a CloudFormation template for information on installing these products

Vertica AMI operating systems for AWS

Vertica provides Vertica and Management Console AMIs in the following operating systems.

- Red Hat 7.4 and later
- Amazon Linux 2.0 and later

You can use the AMI to deploy MC hosts or cluster hosts.

Important
When using Amazon Linux 2.0, you must compile C++ UDX libraries with a supported gcc version. For more information see Setting up a development environment .

Supported AWS instance types

Vertica supports a range of Amazon Web Services instance types, each optimized for different purposes. Choose the instance type that best matches your requirements. The two tables below list the AWS instance types that Vertica supports for Vertica cluster hosts, and for use in MC. For more information, see the Amazon Web Services documentation on instance types and volumes .

Instance types for Vertica cluster hosts

Each Amazon EC2 Instance type natively provides one of the following storage options:

- Elastic Block Store (EBS) provides durable storage: Data files stored on instance persist after instance is stopped.
- Instance Store provides temporary storage: Data files stored on instance are lost when instance is stopped.

Important
Instance types that support EBS volumes support encrypting.

Optimization	**Instance Types Using *Only* EBS Volumes (Durable)**	**Instance Types Using Instance Store Volumes (Temporary)**
General purpose	m4.4xlarge m4.10xlarge m5.4xlarge m5.8xlarge m5.12xlarge	m5d.4xlarge m5d.8xlarge m5d.12xlarge
Compute	c4.4xlarge c4.8xlarge c5.4xlarge c5.9xlarge	c3.4xlarge c3.8xlarge c5d.4xlarge c5d.9xlarge

Memory	r4.4xlarge r4.8xlarge r4.16xlarge r5.4xlarge r5.8xlarge r5.12xlarge	r3.4xlarge r3.8xlarge r5d.4xlarge r5d.8xlarge r5d.12xlarge
Storage		d2.4xlarge d2.8xlarge i3.4xlarge i3.8xlarge i3.16xlarge i3en.3xlarge i3en.6xlarge i3en.12xlarge

Instance types available for MC hosts

Optimization	Type	Supports EBS Storage (Durable)	Supports Ephemeral Storage (Temporary)
Computing	c4.large	Yes	No
	c4.xlarge	Yes	No
	c5.large	Yes	No
	c5.xlarge	Yes	No

More information

For more information about Amazon cluster instances and their limitations, see Manage Clusters in the Amazon Web Services documentation.

Choosing AWS Eon Mode instance types

This topic lists the recommended instance types to use in an Eon Mode database running in AWS.

Choose instance types that support ephemeral instance storage or EBS volumes for your depot, depending on cost and availability. It is not mandatory to have an EBS-backed depot, because in Eon Mode, a copy of the data is safely stored in communal storage. Vertica recommends either r4 or i3 instances for production clusters.

The following table provides information to help you make a decision on how to pick instances with ephemeral instance storage or EBS only storage. Check with AWS for the latest cost per hour.

Storage Type	Instance Type	Pros/Cons
Instance storage	i3.8xlarge	Instance storage offers better performance than EBS attached storage through multiple EBS volumes. Instance storage can be striped (RAIDed) together to increase throughput and load balance I/O. Data stored in instance-store volumes is not persistent through instance stops, terminations, or hardware failures.

EBS-only storage	r4.8xlarge with 600 GB EBS volume attached	Newer instance types from AWS have only the EBS option. In most AWS regions, it's easier to provision a large number of instances. You can terminate an instance but leave the EBS volume around for faster revive. Perserving the EBS will preserve the depot. While some of the cached files might have become stale, they will be ignored and evicted. Much of the cached data will not be stale. It will save time when the node revives and warms its depot. Take advantage of full-volume encryption.

Important
If you select instances that use instance store, if you then terminate those instances there is the potential for data loss. For Eon mode, MC displays an alert to inform the user of the potential data loss when terminating instances that support instance store.

Vertica AMI sleep c-states

By default, the following instances have their processor C-states set to a value of 1 in the Vertica AMI:

- c4.8xlarge
- d2.8xlarge
- m4.10xlarge

This measure is meant to improve performance by limiting the sleep states that an instance running Vertica uses.

For more information about sleep states, visit the AWS Documentation .

AWS features supported by Vertica

Vertica supports the following AWS features:

- **Enhanced Networking** : Vertica recommends that you use the AWS enhanced networking for optimal performance. For more information, see Enabling Enhanced Networking on Linux Instances in a VPC in the AWS documentation.
- **Command Line Interface** : Use the Amazon command-line Interface (CLI) with your Vertica AMIs. For more information, see What Is the AWS Command Line Interface? .
- **Elastic Load Balancing** : Use elastic load balancing (ELB) for queries up to one hour. When enabling ELB, configure the timer to 3600 seconds. For more information see Elastic Load Balancing in the AWS documentation.

AWS authentication

Amazon defines two ways to control access to AWS resources such as S3: IAM roles and the combination of id, secrets, and (optionally) session tokens. For long-term access to non-communal storage buckets, you should use IAM roles for access control centralization. You do not need to change your application's configuration if you want to change its access settings. You just alter the IAM role applied to your EC2 instances.

However, for one-time tasks like backing up and restoring the database or loading data to and from non-communal storage buckets, you should use an AWS access key .

Vertica uses both of these authentication methods to support different features and use cases:

- An Eon Mode database's access to S3 for communal and catalog storage must always use IAM role authentication. IAM roles are the default access control method for AWS resources. Vertica uses this method if you do not configure the legacy access control session parameters.
- Individual users can read data from S3 storage locations other than the ones Vertica uses for communal storage. For example, users can use COPY to load data into Vertica from an S3 bucket or query an external table stored on S3. If the IAM role assigned to the Vertica nodes does not have access to this external S3 data, the user must set an id, secret, and optionally an access token in session variables to authorize access to it. These session variables override the IAM role set on the server. See S3 parameters for a list of these session parameters.
- Individual users can export data to S3 using the Vertica Library for AWS. This library cannot use IAM authorization. Users who want to export data to S3 using this library must set id, secret, and optionally access token values in session variables. See Configure the Vertica library for Amazon Web Services for details.

Important
If the database is running in Eon Mode, using id and secret authentication is more complex. In addition to having access to the external S3 data, any id that a user sets must be authorized to read from and write to the S3 storage locations that Vertica uses to store communal and catalog data. The queries that the user executes uses this id for all storage requests, not just those for accessing external S3 data. If the id does not have access to the catalog and communal storage, the user cannot execute queries.

Configuring an IAM role

To configure an IAM role to grant Vertica to access AWS resources you must:

1. Create an IAM role to allow EC2 instances to access the specific resources.
2. Grant that role permission to access your resources.
3. Attach this IAM role to each EC2 instance in the Vertica cluster.

To see an example of IAM roles for a Vertica cluster, look at the roles defined in one of the Cloud Formation Templates provided by Vertica. You can download these templates from any of the Vertica entries in the Amazon Marketplace . Under each entry's Usage Information section, click the View CloudFormation Template link, then click Download CloudFormation Template.

For more information about IAM roles, see IAM Roles for Amazon EC2 in the AWS documentation.

Installing Vertica with CloudFormation templates

Vertica provides CloudFormation Templates (CFTs) on the AWS Marketplace that allow you to get a cluster up and running quickly. Using the template allows you to automatically provision your AWS resources and launch a Vertica cluster and Management Console, with minimal configuration required.

If you prefer to deploy a VPC, instances, and related resources manually, see Install Vertica with manually deployed AWS resources .

For details about creating an Eon Mode or Enterprise Mode database after you create a cluster with CFTs, see Amazon Web Services in MC .

In this section

- CloudFormation template (CFT) overview
- Prerequisites for using CFTs
- Launch MC and AWS resources with a CloudFormation template
- Access Management Console
- Creating a virtual private cloud

CloudFormation template (CFT) overview

With Vertica on AWS, use CloudFormation Templates (CFTs) to easily manage provisioning the AWS resources with a running Vertica system.

To access Vertica CFTs, go to the AWS Marketplace . Licensing models for CFTs are:

- **Bring Your Own License (BYOL)** : By default, free CE license is installed with 3 nodes and 1 TB. To extend nodes or size, you can purchase the Vertica BYOL license.
  Outside of the BYOL license on CFTs, you can also access the Community Edition without a license file:
  - If you are using Management Console, simply leave the license field blank.
  - If you are using a command line (see Installing Vertica with the installation script), specify CE in the --license parameter during installation.
- **By the Hour** : A pay-as-you-go model where you pay for only the number of hours you use for each node. One advantage of using the Paid Listing is that all charges appear on your Amazon AWS bill. This offers an alternative to purchasing a full Vertica license. This eliminates the need to compute potential storage needs in advance.

Available Vertica CFTs are:

- **Management Console with 3 Vertica nodes** : The easiest way to deploy Vertica. This CFT deploys an Eon Mode database by default. However, this environment can also be used to create an Enterprise Mode database. For more information, see Creating a database .
- **Deploy Management Console into new VPC** : This CFT deploys all required AWS resources and installs the Vertica Management Console (MC). After stack creation completes, log in to the MC to provision a Vertica database cluster.
- **Deploy Management Console into existing VPC** : This CFT deploys the Vertica Management Console (MC) in an already-existing VPC and subnet. After stack creation completes, the MC is available. Log in to MC to provision either a Vertica database cluster or an Eon Mode database cluster. For this CFT, you must first set up the VPC, subnet, and related network resources. For more information about the correct configuration of these resources for Vertica, see the following topics in the AWS documentation: * Creating a virtual private cloud * Configuring the network

For more information

For supported operating systems for these CFTs, see Vertica AMI operating systems for AWS .

For Vertica products available on AWS, see Vertica offerings on AWS .

Prerequisites for using CFTs

Before you can install Vertica on AWS using CloudFormation Templates (CFTs), verify that you have:

- AWS account with permissions to create a VPC, subnet, security group, EC2 instances, and IAM roles (For more information about AWS accounts, see the AWS documentation)
- Amazon key pair for SSH access to an EC2 instance. (See the AWS documentation for key pairs .)

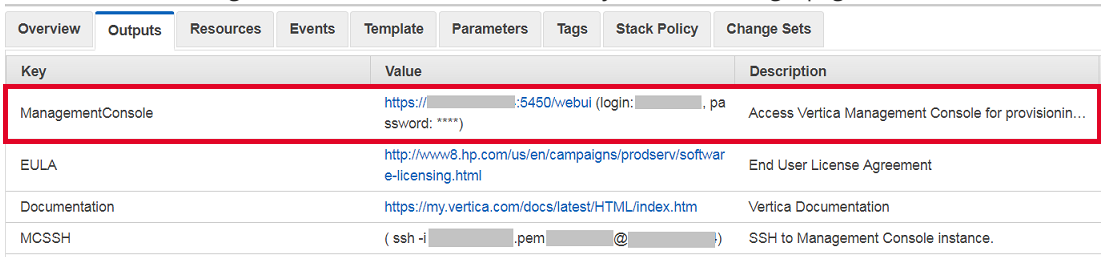
Launch MC and AWS resources with a CloudFormation template

Launch Management Console (MC) and its associated AWS resources using CloudFormation templates (CFTs) that are available through the AWS Marketplace. For a list of available CFTs, see CloudFormation template (CFT) overview .

Starting in the AWS Marketplace, launch the provisioning instance from which you can install Vertica.:

1. Log in to the AWS Marketplace with an AWS account (see the **Prerequisites** section above).
2. Search for "Vertica" in the AWS Marketplace.
3. Select a Vertica CFT. Each CFT leads you to a product overview page, with pricing estimates. (Also see CloudFormation template (CFT) overview for an overview of available templates and products).
4. Click Continue to Subscribe.
5. On the next page, select your launch settings based on your requirements for deployment.
6. If you have not agreed to Vertica EULA terms on the AWS Marketplace before, click Accept Software Terms to subscribe.
7. Click **Launch with CloudFormation Console** . The CloudFormation Console opens.
8. The CloudFormation Console automatically supplies the URL in the **Specify an Amazon S3 template URL field** . Click **Next** .
9. Follow the CloudFormation workflow and enter the parameters (collectively called a stack).

> **Note**
> **Important:** Take note of the username and password you set for Management Console during this step. You cannot recover or reset these credentials after you create the stack.



10. After confirming the details you have provided for your new stack, click **Create** . The AWS console brings you to the Stacks page, where you can view the progress of the creation process. The process takes several minutes.
11. The **Outputs** tab displays information about accessing your environment after the process completes.

Next, access the Management Console (MC) to deploy your cluster instances and create a database, as described in Access Management Console .

Access Management Console

You use MC to deploy Vertica cluster instances and create a database. You can also use MC to manage and monitor your databases. You will use Management Console to provision a Vertica cluster and database on the AWS resources you just launched.

1. On the AWS CloudFormation Stacks page, select your new stack and view the **Outputs** tab. This tab provides information about accessing your environment, as well as documentation and licensing resources.
2. Click the **Access** Management Console URL. This link takes you to the MC login page.

3. To log in, enter the MC username and password that you created using the CloudFormation Console.
   After login, MC displays the home page, with options to provision a new cluster or database or import existing ones. If you chose a CFT that also creates a database, your new database is also displayed on the home page.
   This page also provides a Resources section with links to online training, blogs, community, and help resources.

You have successfully launched Management Console on AWS resources.

If you have not yet provisioned a Vertica cluster and database, complete the steps in one of the following:

- Creating an Eon Mode database in AWS with MC
- Creating an Enterprise Mode database in AWS with MC

Creating a virtual private cloud

A Vertica cluster on AWS must be logically located in the same network. This is similar to placing the nodes of an on-premises cluster within the same network. Create a virtual private cloud (VPC) to ensure the nodes in your cluster will be able to communicate with each other within AWS.

Create a single public subnet VPC with the following configurations:

- Assign a Network Access Control List (ACL) that is appropriate to your situation. The default ACL does not provide a high level of security.
- Enable DNS resolution and enable DNS hostname support for instances launched in this VPC.
- Add the required network inbound and outbound rules to the Network ACL associated to the VPC .

> **Note**
> A Vertica cluster must be operated within a single availability zone.

For information about VPCs, including how to create one, visit the AWS documentation .

Install Vertica with manually deployed AWS resources

Vertica provides an AMI that you can install on AWS resources that you manually deploy. This section will guide you through configuring your network settings on AWS, launching and preparing EC2 instances using the Vertica AMI, and creating a Vertica cluster on those EC2 instances.

Choose this method of installation if you are familiar with configuring AWS and have many specific AWS configuration needs. (To automatically deploy AWS resources and a Vertica cluster instead, see Installing Vertica with CloudFormation templates .

In this section

- Configure your network
- Deploy AWS instances for your Vertica database cluster

Configure your network

Before you create your cluster, you must configure the network on which Vertica will run. Vertica requires a number of specific network configurations to operate on AWS. You may also have specific network configuration needs beyond the default Vertica settings.

Important
You can create a Vertica database that uses IPv6 for internal communications running on AWS. However, if you do so, you must identify the hosts in your cluster using IP addresses rather than host names. The AWS DNS resolution service is incompatible with IPv6.

The following sections explain which Amazon EC2 features you need to configure for instance creation.

In this section

- Create a placement group, key pair, and VPC
- Network ACL settings
- Configure TCP keepalive with AWS network load balancer
- Create and assign an internet gateway
- Assign an elastic IP address
- Create a security group

Create a placement group, key pair, and VPC

Part of configuring your network for AWS is to create the following:

- Placement Group
- Key Pair
- Virtual Private Cloud (VPC)

Create a placement group

A placement group is a logical grouping of instances in a single Availability Zone . Placement Groups are required for clusters and all Vertica nodes must be in the same Placement Group.

Vertica recommends placement groups for applications that benefit from low network latency, high network throughput, or both. To provide the lowest latency, and the highest packet-per-second network performance for your Placement Group, choose an instance type that supports enhanced networking.

For information on creating placement groups, see Placement Groups in the AWS documentation.

Create a key pair

You need a key pair to access your instances using SSH. Create the key pair using the AWS interface and store a copy of your key (*.pem) file on your local machine. When you access an instance, you need to know the local path of your key.

Use a key pair to:

- Authenticate your connection as dbadmin to your instances from outside your cluster.
- Install and configure Vertica on your AWS instances.

for information on creating a key pair, see Amazon EC2 Key Pairs in the AWS documentation.

Create a virtual private cloud (VPC)

You create a Virtual Private Cloud (VPC) on Amazon so that you can create a network of your EC2 instances. Your instances in the VPC all share the same network and security settings.

A Vertica cluster on AWS must be logically located in the same network. Create a VPC to ensure the nodes in you cluster can communicate with each other in AWS.

Create a single public subnet VPC with the following configurations:

- Assign a Network Access Control List (ACL) that is appropriate to your situation.
- Enable DNS resolution and enable DNS hostname support for instances launched in this VPC.
- Add the required network inbound and outbound rules to the Network ACL associated to the VPC.

> **Note**
> A Vertica cluster must be operated in a single availability zone.

For information on creating a VPC, see Create a Virtual Private Cloud (VPC) in the AWS documentation.

Network ACL settings

Vertica requires the following basic network access control list (ACL) settings on an AWS instance running the Vertica AMI. Vertica recommends that you secure your network with additional ACL settings that are appropriate to your situation.

Inbound Rules

Type	Protocol	Port Range	Use	Source	Allow/Deny
SSH	TCP (6)	22	SSH (Optional—for access to your cluster from outside your VPC)	User Specific	Allow
Custom TCP Rule	TCP (6)	5450	MC (Optional—for MC running outside of your VPC)	User Specific	Allow
Custom TCP Rule	TCP (6)	5433	SQL Clients (Optional—for access to your cluster from SQL clients)	User Specific	Allow
Custom TCP Rule	TCP (6)	50000	Rsync (Optional—for backup outside of your VPC)	User Specific	Allow
Custom TCP Rule	TCP (6)	1024-65535	Ephemeral Ports (Needed if you use any of the above)	User Specific	Allow
ALL Traffic	ALL	ALL	N/A	0.0.0.0/0	Deny

Outbound Rules

Type	Protocol	Port Range	Use	Source	Allow/Deny
Custom TCP Rule	TCP (6)	0–65535	Ephemeral Ports	0.0.0.0/0	Allow

You can use the entire port range specified in the previous table, or find your specific ephemeral ports by entering the following command:

```
$ cat /proc/sys/net/ipv4/ip_local_port_range
```

More information

For detailed information on network ACLs within AWS, refer to Network ACLs in the Amazon documentation.

For detailed information on ephemeral ports within AWS, refer to Ephemeral Ports in the Amazon documentation.

Configure TCP keepalive with AWS network load balancer

AWS supports three types of elastic load balancers (ELBs):

• Classic Load Balancers

• Application Load Balancers

• Network Load Balancers

Vertica strongly recommends the AWS Network Load Balancer (NLB), which provides the best performance with your Vertica database. The Network Load Balancer acts as a proxy between clients (such as JDBC) and Vertica servers. The Classic and Application Load Balancers do not work with Vertica, in Enterprise Mode or Eon Mode.

To avoid timeouts and hangs when connecting to Vertica through the NLB, it is important to understand how AWS NLB handles idle timeouts for connections. For the NLB, AWS sets the idle timeout value to 350 seconds and you cannot change this value. The timeout applies to both connection points.

For a long-running query, if either the client or the server fails to send a timely keepalive, that side of the connection is terminated. This can lead to situations where a JDBC client hangs waiting for results that would never be returned because the server fails to send a keepalive within 350 seconds.

To identify an idle timeout/keepalive issue, run a query like this via a client such as JDBC:

```
=> SELECT SLEEP(355);
```

If there's a problem, one of the following situations occurs:

- The client connection terminates before 355 seconds. In this case, lower the JDBC keepalive setting so that keepalives are sent less than 350 seconds apart.
- The client connection doesn't return a result after 355 seconds. In this case, you need to adjust the server keepalive settings (tcp_keepalive_time and tcp_keepalive_intvl) so that keepalives are sent less than 350 seconds apart.

For detailed information about AWS Network Load Balancers, see What is a Network Load Balancer? in the AWS documentation.

Create and assign an internet gateway

When you create a VPC, an Internet gateway is automatically assigned to it. You can use that gateway, or you can assign your own. If you are using the default Internet gateway, continue with the procedure described in Create a security group .

Otherwise, create an Internet gateway specific to your needs. Associate that internet gateway with your VPC and subnet.

For information about how to create an Internet Gateway, see Internet Gateways in the AWS documentation.

Assign an elastic IP address

An elastic IP address is an unchanging IP address that you can use to connect to your cluster externally. Vertica recommends you assign a single elastic IP to a node in your cluster. You can then connect to other nodes in your cluster from your primary node using their internal IP addresses dictated by your VPC settings.

Create an elastic IP address. For information, see Elastic IP Addresses in the AWS documentation.

Create a security group

The Vertica AMI has specific security group requirements. When you create a Virtual Private Cloud (VPC), AWS automatically creates a default security group and assigns it to the VPC. You can use the default security group, or you can name and assign your own.

Create and name your own security group using the following basic security group settings. You may make additional modifications based on your specific needs.

Inbound

Type	Use	Protocol	Port Range	IP

SSH		TCP	22	The CIDR address range of administrative systems that require SSH access to the Vertica nodes. Make this range as restrictive as possible. You can add multiple rules for separate network ranges, if necessary.
DNS (UDP)		UDP	53	Your private subnet address range (for example, 10.0.0.0/24).
Custom UDP	Spread	UDP	4803 and 4804	Your private subnet address range (for example, 10.0.0.0/24).
Custom TCP	Spread	TCP	4803	Your private subnet address range (for example, 10.0.0.0/24).
Custom TCP	VSQL/SQL	TCP	5433	The CIDR address range of client systems that require access to the Vertica nodes. This range should be as restrictive as possible. You can add multiple rules for separate network ranges, if necessary.
Custom TCP	Inter-node Communication	TCP	5434	Your private subnet address range (for example, 10.0.0.0/24).
Custom TCP		TCP	5444	Your private subnet address range (for example, 10.0.0.0/24).
Custom TCP	MC	TCP	5450	The CIDR address of client systems that require access to the management console. This range should be as restrictive as possible. You can add multiple rules for separate network ranges, if necessary.
Custom TCP	Rsync	TCP	50000	Your private subnet address range (for example, 10.0.0.0/24).
ICMP	Installer	Echo Reply	N/A	Your private subnet address range (for example, 10.0.0.0/24).
ICMP	Installer	Traceroute	N/A	Your private subnet address range (for example, 10.0.0.0/24).

Note
In Management Console (MC), the Java IANA discovery process uses port 7 once to detect if an IP address is reachable before the database import operation. Vertica tries port 7 first. If port 7 is blocked, Vertica switches to port 22.

Outbound

Type	Protocol	Port Range	Destination	IP
All TCP	TCP	0-65535	Anywhere	0.0.0.0/0
All ICMP	ICMP	0-65535	Anywhere	0.0.0.0/0
All UDP	UDP	0-65535	Anywhere	0.0.0.0/0

For information about what a security group is, as well as how to create one, see Amazon EC2 Security Groups for Linux Instances in the AWS documentation.

Deploy AWS instances for your Vertica database cluster

Once you have configured your network, you are ready to create your AWS instances and install Vertica. Follow these procedures to install and run Vertica on AWS.

In this section

- Configure and launch an instance
- Connect to an instance
- Prepare instances for cluster formation
- Change instances on AWS
- Configure storage
- Create a cluster
- Use Management Console (MC) on AWS

Configure and launch an instance

After you configure your network settings on AWS, configure and launch the instances onto which you will install Vertica. An Elastic Compute Cloud (EC2) instance without a Vertica AMI is similar to a traditional host. Just like with an on-premises cluster, you must prepare and configure your cluster and network at the hardware level before you can install Vertica.

When you create an EC2 instance on AWS using a Vertica AMI, the instance includes the Vertica software and the recommended configuration. The Vertica AMI acts as a template, requiring fewer configuration steps. Vertica recommends that you use the Vertica AMI as is—without modification.

Configure EC2 instances in AWS

1. Select the Vertica AMI from the AWS marketplace.
2. Select the desired fulfillment method.
3. Configure the following:
   - A supported instance type
   - The number of instances you want to launch. A Vertica cluster usually uses identically configured instances of the same type.
   - A VPC
   - Placement Group

Add storage to your instances

Consider the following issues when you add storage to your instances:

- Add a number of drives equal to the number of physical cores in your instance. For example, for a c3.8xlarge instance, 16 drives. For an r3.4xlarge, add 8 drives.
- Do not store your information on the root volume.
- Amazon EBS provides durable, block-level storage volumes that you can attach to running instances. For guidance on selecting and configuring an Amazon EBS volume type, see Amazon EBS Volume Types in the Amazon Web Services documentation.

Decide whether to configure EBS volumes as a RAID array

You can choose to configure your EBS volumes into a RAID 0 array to improve disk performance. Before doing so, use the vioperf utility to determine whether the performance of the EBS volumes is fast enough without using them in a RAID array. Pass vioperf the path to a mount point for an EBS volume. In this example, an EBS volume is mounted on a directory named /vertica/data:

```
[dbadmin@ip-10-11-12-13 ~]$ /opt/vertica/bin/vioperf /vertica/data

The minimum required I/O is 20 MB/s read and write per physical processor core on
each node, in full duplex i.e. reading and writing at this rate simultaneously,
concurrently on all nodes of the cluster. The recommended I/O is 40 MB/s per
physical core on each node. For example, the I/O rate for a server node with 2
hyper-threaded six-core CPUs is 240 MB/s required minimum, 480 MB/s recommended.

Using direct io (buffer size=1048576, alignment=512) for directory "/vertica/data"

test      | directory     | counter name         | counter | counter   | counter       | counter       | thread | %CPU  | %IO Wait  | elapsed | remaining
          |               |                      | value   | value (10 | value/core    | value/core    | count  |       |           | time (s)| time (s)
          |               |                      |         | sec avg)  |               | (10 sec avg)  |        |       |           |         |
----------------------------------------------------------------------------------------------------------------------------------------------------------
Write     | /vertica/data | MB/s                 | 259     | 259       | 32.375        | 32.375        | 8      | 4     | 11        | 10      | 65
Write     | /vertica/data | MB/s                 | 248     | 232       | 31            | 29            | 8      | 4     | 11        | 20      | 55
Write     | /vertica/data | MB/s                 | 240     | 234       | 30            | 29.25         | 8      | 4     | 11        | 30      | 45
Write     | /vertica/data | MB/s                 | 240     | 233       | 30            | 29.125        | 8      | 4     | 13        | 40      | 35
Write     | /vertica/data | MB/s                 | 240     | 233       | 30            | 29.125        | 8      | 4     | 13        | 50      | 25
Write     | /vertica/data | MB/s                 | 240     | 232       | 30            | 29            | 8      | 4     | 12        | 60      | 15
Write     | /vertica/data | MB/s                 | 240     | 238       | 30            | 29.75         | 8      | 4     | 12        | 70      | 5
Write     | /vertica/data | MB/s                 | 240     | 235       | 30            | 29.375        | 8      | 4     | 12        | 75      | 0

```

If the EBS volume read and write performance (the entries with Read and Write in column 1 of the output) is greater than 20MB/s per physical processor core (columns 6 and 7), you do not need to configure the EBS volumes as a RAID array to meet the minimum requirements to run Vertica. You may still consider configuring your EBS volumes as a RAID array if the performance is less than the optimal 40MB/s per physical core (as is the case in this example).

> **Note**
> If your EC2 instance has hyper-threading enabled, vioperf may incorrectly count the number of cores in your system. The 20MB/s throughput per core requirement only applies to physical cores, rather than virtual cores. If your EC2 instance has hyper-threading enabled, divide the counter value (column 4 in the output) by the number of physical cores. See CPU Cores and Threads Per CPU Core Per Instance Type section in the AWS documentation topic Optimizing CPU Options for a list of physical cores in each instance type.

If you determine you need to configure your EBS volumes as a RAID 0 array, see the AWS documentation topic RAID Configuration on Linux the steps you need to take.

Security group and access

1. Choose between your previously configured security group or the default security group.
2. Configure S3 access for your nodes by creating and assigning an IAM role to your EC2 instance. See AWS authentication for more information.

Launch instances

Verify that your instances are running.

Connect to an instance

Using your private key, take these steps to connect to your cluster through the instance to which you attached an elastic IPaddress:

1. As the dbadmin user, type the following command, substituting your ssh key:
   ```
   $ ssh --ssh-identity <ssh key> dbadmin@elasticipaddress
   ```
2. Select **Instances** from the Navigation panel.
3. Select the instance that is attached to the Elastic IP.
4. Click **Connect** .
5. On **Connect to Your Instance** , choose one of the following options:
   - **A Java SSH Client directly from my browser** —Add the path to your private key in the field **Private key path** , andclick **Launch SSH Client** .
   - **Connect with a standalone SSH client** **—**Follow the steps required by your standalone SSH client.

Connect to an instance from windows using putty

If you connect to the instance from the Windows operating system, and plan to use Putty:

1. Convert your key file using PuTTYgen.
2. Connect with Putty or WinSCP (connect via the elastic IP), using your converted key (i.e., the *ppk file).
3. Move your key file (the *pem file) to the root dir using Putty or WinSCP.

Prepare instances for cluster formation

After you create your instances, you need to prepare them for cluster formation. Prepare your instances by adding your AWS .pem key and your Vertica license.

By default, each AMI includes a Community Edition license. Once Vertica is installed, you can find the license at this location:

```
/opt/vertica/config/licensing/vertica_community_edition.license.key
```

1. As the dbadmin user, copy your *pem file (from where you saved it locally) onto your primary instance.
   Depending upon the procedure you use to copy the file, the permissions on the file may change. If permissions change, the install_vertica script fails with a message similar to the following:
   ```
   FATAL (19): Failed Login Validation 10.0.3.158, cannot resolve or connect to host as root.
   ```
   If you receive a failure message, enter the following command to correct permissions on your *pem file:
   ```
   $ chmod 600 /<name-of-pem>.pem
   ```
2. Copy your Vertica license over to your primary instance, placing it in your home directory or other known location.

Change instances on AWS

You can change instance types on AWS. For example, you can downgrade a c3.8xlarge instance to c3.4xlarge. See Supported AWS instance types for a list of valid AWS instances.

When you change AWS instances you may need to:

- Reconfigure memory settings
- Reset memory size in a resource pool
- Reset number of CPUs in a resource pool

Reconfigure memory settings

If you change to an AWS instance type that requires a different amount of memory, you may need to recompute the following and then reset the values:

- min_free_kbytes setting
- max_map_count

> **Note**
> You may need root user permissions to reset these values.

Reset memory size in a resource pool

If you used absolute memory in a resource pool, you may need to reconfigure the memory using the MEMORYSIZE parameter in ALTER RESOURCE POOL .

> **Note**
> If you set memory size as a percentage when you created the original resource pool, you do not need to change it here.

Reset number of CPUs in a resource pool

If your new instance requires a different number of CPUs, you may need to reset the CPUAFFINITYSET parameter in ALTER RESOURCE POOL .

Configure storage

Vertica recommends that you store information — especially your data and catalog directories — on dedicated Amazon EBS volumes formatted with a supported file system . The /opt/vertica/sbin/configure_software_raid.sh script automates the storage configuration process.

> **Caution**
> Do not store information on the root volume because it might result in data loss.

Vertica performance tests Eon Mode with a per-node EBS volume of up to 2TB. For best performance, combine multiple EBS volumes into a RAID 0 array.

For more information about RAID 0 arrays and EBS volumes, see RAID configuration on Linux .

Determining volume names

Because the storage configuration script requires the volume names that you want to configure, you must identify the volumes on your machine. The following command lists the contents of the /dev directory. Search for the volumes that begin with xvd :

```
$ ls /dev
```

Important
Ignore the root volume. Do not include any of your root volumes in the RAID creation process.

Combining volumes for storage

The configure_software_raid.sh shell script combines your EBS volumes into a RAID 0 array.

> **Caution**
> Run configure_software_raid.sh in the default setting only if you have a fresh configuration with no existing RAID settings.
>
> If you have existing RAID settings, open the script in a text editor and manually edit the raid_dev value to reflect your current RAID settings. If you have existing RAID settings and you do not edit the script, the script deletes important operating system device files.
>
> Alternately, use the Management Console (MC) console to add storage nodes without unwanted changes to operating system device files. For more information, see Managing database clusters .

The following steps combine your EBS volumes into RAID 0 with the configure_software_raid.sh script:

1. Edit the /opt/vertica/sbin/configure_software_raid.sh shell file as follows:
    1. Comment out the safety exit command at the beginning .

2. Change the sample volume names to your own volume names, which you noted previously. Add more volumes, if necessary.
2. Run the /opt/vertica/sbin/configure_software_raid.sh shell file. Running this file creates a RAID 0 volume and mounts it to /vertica/data .
3. Change the owner of the newly created volume to dbadmin with chown .
4. Repeat steps 1-3 for each node on your cluster.

Create a cluster

On AWS, use the install_vertica script to combine instances and create a cluster. Check your **My Instances** page on AWS for a list of current instances and their associated IP addresses. You need these IP addresses when you run install_vertica .

Create a cluster as follows:

1. While connected to your primary instance, enter the following command to combine your instances into a cluster. Substitute the IP addresses for your instances and include your root *.pem file name.

```
$ sudo /opt/vertica/sbin/install_vertica --hosts 10.0.11.164,10.0.11.165,10.0.11.166 \
 --dba-user-password-disabled --point-to-point --data-dir /vertica/data \
 --ssh-identity ~/name-of-pem.pem --license license.file
```

Note

```
*  If you are using Vertica Community Edition, which limits you to three instances, you can specify `-L CE` with no license file.

* When you issue install_vertica or update_vertica on a Vertica AMI script, --point-to-point is the default. This parameter configures <a class="glosslink" href="/glossary/spread.html" title="An open source toolkit used in Vertica to provide a high performance messaging service that is resilient to network faults.">Spread</a> to use direct point-to-point communication between all Vertica nodes, which is a requirement for clusters on AWS.

* If you are using IPv6 network addresses to identify the hosts in your cluster, use the --ipv6 flag in your `install_vertica` command. You must also use IP addresses instead of host names, as the AWS DNS server cannot resolve host names to IPv6 addresses.
```

2. After combining your instances, Vertica recommends deleting your *.pem key from your cluster to reduce security risks. The example below uses the shred command to delete the file:

```
$ shred name-of-pem.pem
```

3. After creating one or more clusters, create your database .

For complete information on the install_vertica script and its parameters, see Installing Vertica with the installation script .

Important

Stopping or rebooting an instance or cluster without first shutting down the database down, may result in disk or database corruption. To safely shut down and restart your cluster, see Operating the database .

Check open ports manually using the netcat utility

Once your cluster is up and running, you can check ports manually through the command line using the netcat (nc) utility. What follows is an example using the utility to check ports.

Before performing the procedure, choose the private IP addresses of two nodes in your cluster.

The examples given below use nodes with the private IPs:

```
10.0.11.60 10.0.11.61
```

Install the nc utility on your nodes. Once installed, you can issue commands to check the ports on one node from another node.

1. To check a TCP port:
    1. Put one node in listen mode and specify the port. The following sample shows how to put IP 10.0.11.60 into listen mode for port 4804.

    ```
    [root@ip-10-0-11-60 ~]# nc -l 4804
    ```

    2. From the other node, run nc specifying the IP address of the node you just put in listen mode, and the same port number.

    ```
    [root@ip-10-0-11-61 ~]# nc 10.0.11.60 4804
    ```

3. Enter sample text from either node and it should show up on the other node. To cancel after you have checked a port, enter **Ctrl+C** .

> **Note**
> **Note** : To check a UDP port, use the same nc commands with the –u option.

```
[root@ip-10-0-11-60 ~]# nc -u -l 4804
[root@ip-10-0-11-61 ~]# nc -u 10.0.11.60 4804
```

Use Management Console (MC) on AWS

Management Console (MC) is a database management tool that allows you to view and manage aspects of your cluster. Vertica provides an MC AMI, which you can use with AWS. The MC AMI allows you to create an instance, dedicated to running MC, that you can attach to a new or existing Vertica cluster on AWS. You can create and attach an MC instance to your Vertica on AWS cluster at any time.

For information on requirements and installing MC, see Installing Management Console .

See also

- Network ACL settings

In this section

- Log in to MC and managing your cluster

Log in to MC and managing your cluster

After you launch your MC instance and configure your security group settings, log in to your database. To do so, use the elastic IP you specified during instance creation.

From this elastic IP, you can manage your Vertica database on AWS using standard MC procedures.

Considerations when using MC on AWS

- Because MC is already installed on the MC AMI, the MC installation process does not apply.
- To uninstall MC on AWS, follow the procedures provided in Uninstalling Management Console before terminating the MC Instance.

Export data to Amazon S3 using the AWS library

> **Deprecated**
> The AWS library is deprecated. To export delimited data to S3 or any other destination, use EXPORT TO DELIMITED .

The Vertica library for Amazon Web Services (AWS) is a set of functions and configurable session parameters. These parameters allow you to export delimited data from Vertica to Amazon S3 storage without any third-party scripts or programs.

To use the AWS library, you must have access to an Amazon S3 storage account.

In this section

- Configure the Vertica library for Amazon Web Services
- Export data to Amazon S3 from Vertica

Configure the Vertica library for Amazon Web Services

You use the Vertica library for Amazon Web Services (AWS) to export data from Vertica to S3. This library does not support IAM authentication. You must configure it to authenticate with S3 by using session parameters containing your AWS access key credentials. You can set your session parameters directly, or you can store your credentials in a table and set them with the AWS_SET_CONFIG function.

Because the AWS library uses session parameters, you must reconfigure the library with each new session.

> **Note**
> **Important:** Your AWS access key ID and secret access key are different from your account access credentials. For more information about AWS access keys, visit the Managing Access Keys for IAM Users in the AWS documentation.

Set AWS authentication parameters

The following AWS authentication parameters allow you to access AWS and work with the data in your Vertica database:

- aws_id: The 20-character AWS access key used to authenticate your account.
- aws_secret: The 40-character AWS secret access key used to authenticate your account.
- aws_session_token: The AWS temporary security token generated by running the AWS STS command get-session-token . This AWS STS command generates temporary credentials you can use to implement multi-factor authentication for security purposes. See Implementing Multi-factor Authentication .

Implement multi-factor authentication

Implement multi-factor authentication as follows:

1. Run the AWS STS command get-session-token , this returns the following:

```
$ Credentials": {
"SecretAccessKey": "bQid6jNuSWRqUzkIJCFG7c71gDHZY3h7aDSW2DU6",
"SessionToken":
"FQoDYXdzEBcaDKM1mWpeu88nDTTFICKsAbaiIDTWe4BTh33tnUvo9F/8mZicKKLLy7WIcpT4FLfr6ltIm242/U2CI9G/
XdC6eoysUi3UGH7cxdhjxAW4fjgCKKYuNL764N2xn0issmIuJOku3GTDyc4U4iNlWyEng3SlshdiqVlk1lt2Mk0isEQXKtx
F9VgfncDQBxjZUCkYIzseZw5pULa9YQcJOzl+Q2JrdUCWu0iFspSUJPhOguH+wTqiM2XdHL5hcUcomqm41gU=",
"Expiration": "2018-04-12T01:58:50Z",
"AccessKeyId": "ASIAJ4ZYGTOSVSLUIN7Q"
 }
}
```

   For more information on get-session-token, see the AWS documentation .
2. Using the SecretAccessKey returned from get-sessiontoken, set your temporary aws_secret:

```
=> ALTER SESSION SET UDPARAMETER FOR awslib aws_secret='bQid6jNuSWRqUzkIJCFG7c71gDHZY3h7aDSW2DU6';
```

3. Using the SessionToken returned from get-session-token, set your temporary aws_session_token:

```
=> ALTER SESSION SET UDPARAMETER FOR awslib aws_session_token='FQoDYXdzEBcaDKM1mWpeu88nDTTFICKsAbaiIDTWe4B
Th33tnUvo9F/8mZicKKLLy7WIcpT4FLfr6ltIm242/U2CI9G/XdC6eoysUi3UGH7cxdhjxAW4fjgCKKYuNL764N2xn0issmIuJOku3GTDy
c4U4iNlWyEng3SlshdiqVlk1lt2Mk0isEQXKtxF9VgfncDQBxjZUCkYIzseZw5pULa9YQcJOzl+Q2JrdUCWu0iFspSUJPhOguH+wTq
iM2XdHL5hcUcomqm41gU=';
```

4. Using the AccessKeyID returned from get-session-token, set your temporary aws_id:

```
=> ALTER SESSION SET UDPARAMETER FOR awslib aws_id='ASIAJ4ZYGTOSVSLUIN7Q';
```

The Expiration value returned indicates when the temporary credentials expire. In this example expiration occurs April 12, 2018 at 01:58:50.

These examples show how to implement multifactor authentication using session parameters. You can use either of the following methods to securely set and store your AWS account credentials:

- Configure Session Parameters Directly
- Configure Session Parameters Using Credentials Stored in a Table

> **Note**
> **Note:** To increase security, avoid directly setting the plain text value of your key directly in the aws_set_config parameter. Instead, store the value in a table protected with a access policy as described in Configure Session Parameters Using Credentials Stored in a Table .

AWS access key requirements

To communicate with AWS, your access key must have the following permissions:

- s3:GetObject
- s3:PutObject
- s3:ListBucket

For security purposes, Vertica recommends that you create a separate access key with limited permissions specifically for use with the Vertica Library for AWS.

Configure session parameters directly

These examples show how to set the session parameters for AWS using your own credentials. Parameter values are case sensitive:

- aws_id : This value is your AWS access key ID.
  ```
  => ALTER SESSION SET UDPARAMETER FOR awslib aws_id='AKABCOEXAMPLEPKPXYZQ';
  ```
- aws_secret : This value is your AWS secret access key.
  ```
  => ALTER SESSION SET UDPARAMETER FOR awslib aws_secret='CEXAMPLE3tEXAMPLE1wEXAMPLEFrFEXAMPLE6+Yz';
  ```
- aws_region : This value is the AWS region associated with the S3 bucket you intend to access. Left unconfigured, aws_region will default to us-east-1. It identifies the default server used by Amazon S3.
  ```
  => ALTER SESSION SET UDPARAMETER FOR awslib aws_region='us-east-1';
  ```

When using ALTER SESSION :

- Using ALTER SESSION to change the values of S3 parameters also changes the values of corresponding UDParameters.
- Setting a UDParameter changes only the UDParameter.
- Setting a configuration parameter changes both the AWS parameter and UDParameter.

Configure session parameters using credentials stored in a table

You can place your credentials in a table and secure them with a row-level access policy . You can then call your credentials with the AWS_SET_CONFIG scalar meta-function. This approach allows you to store your credentials on your cluster for future session parameter configuration. You must have dbadmin access to create access policies.

1. Create a table with rows or columns corresponding with your credentials:
   ```
   => CREATE TABLE keychain(accesskey varchar, secretaccesskey varchar);
   ```
2. Store your credentials in the corresponding columns:
   ```
   => COPY keychain FROM STDIN;
   Enter data to be copied followed by a newline.
   End with a backslash and a period on a line by itself.
   >> AEXAMPLEI5EXAMPLEYXQ|CCEXAMPLEtFjTEXAMPLEiEXAMPLE6+Yz
   >> \.
   ```
3. Set a row-level access policy appropriate to your security situation.
4. With each new session, configure your session parameters by calling the AWS_SET_CONFIG parameter in a SELECT statement:
   ```
   => SELECT AWS_SET_CONFIG('aws_id', accesskey), AWS_SET_CONFIG('aws_secret', secretaccesskey)
     FROM keychain;
   aws_set_config | aws_set_config
   ----------------+----------------
   aws_id         | aws_secret
   (1 row)
   ```
5. After you have configured your session parameters, verify them:
   ```
   => SHOW SESSION UDPARAMETER ALL;
   ```

- AWS_GET_CONFIG

Export data to Amazon S3 from Vertica

After you configure the library for Amazon Web Services (AWS), you can export Vertica data to Amazon S3 by calling the S3EXPORT() transform function. S3EXPORT() writes data to files, based on the URL you provide. Vertica performs all communication over HTTPS, regardless of the URL type you use.Vertica does not support virtual host style URLs. If you use HTTPS URL constructions, you must use path style URLs.

> **Note**
> If your S3 bucket contains a period in its path, set the prepend_hash parameter to True.

You can control the output of S3EXPORT() in the following ways:

- Adjust the base query provided to S3EXPORT
- Adjust the partition of your result set with the OVER() clause

Adjust the query provided to S3EXPORT

By adjusting the query given to S3EXPORT(), you can export anything from tables to reporting queries.

This example exports a whole table:

```
=> SELECT S3EXPORT( * USING PARAMETERS url='s3://exampleBucket/object') OVER(PARTITION BEST)
   FROM exampleTable;
 rows | url
------+-------------------------------
  606 | https://exampleBucket/object
(1 row)
```

This example exports the results of a query:

```
=> SELECT S3EXPORT(customer_name, annual_income USING PARAMETERS url='s3://exampleBucket/object') OVER()
    FROM public.customer_dimension
     WHERE (customer_gender, annual_income) IN
       (SELECT customer_gender, MAX(annual_income)
        FROM public.customer_dimension
        GROUP BY customer_gender);

 rows | url
------+-------------------------------
   25 | https://exampleBucket/object
(1 row)
```

Adjust the partition of your result set with the OVER clause

Use the OVER clause to control your export partitions. Using the OVER() clause without qualification results in a single partition processed by the initiator for all of the query data. This example shows how to call the function with an unqualified OVER() clause:

```
=> SELECT S3EXPORT(name, company USING PARAMETERS url='s3://exampleBucket/object',
                                        delimiter=',') OVER()
    FROM exampleTable WHERE company='Vertica';
 rows | url
------+-------------------------------
   10 | https://exampleBucket/object
(1 row)
```

You can also use window clauses, such as window partition clauses and window order clauses, to manage exported objects.

This example shows how you can use a window partition clause to partition S3 objects based on company values:

```
=> SELECT S3EXPORT(name, company
                USING PARAMETERS url='s3://exampleBucket/object',
                                 delimiter=',') OVER(PARTITION BY company) AS MEDIAN
    FROM exampleTable;
```

Adjusting the export chunk size for wide tables

You may encounter the following error when exporting extremely wide tables or tables with long data types such as LONG VARCHAR or LONG VARBINARY:

```
=> SELECT S3EXPORT( * USING PARAMETERS url='s3://exampleBucket/object') OVER(PARTITION BEST)
   FROM veryWideTable;
ERROR 5861: Error calling setup() in User Function s3export
at [/data/.../S3.cpp:787],
error code: 0, message: The specified buffer of 10485760 bytesRead is too small,
it should be at least 11279701 bytesRead.
```

Vertica returns this error if the data for a single row overflows the buffer storing the data before export. By default, this buffer is 10MB. You can increase the size of this buffer using the chunksize parameter, which sets the size of the buffer in bytes. This example sets it to around 60MB:

```
=> SELECT S3EXPORT( * USING PARAMETERS url='s3://exampleBucket/object', chunksize=60485760)
   OVER(PARTITION BEST) FROM veryWideTable;
 rows | url
------+-------------------------------
  606 | https://exampleBucket/object
(1 row)
```

Add nodes to a running cluster on the cloud

There are two ways to add nodes to an AWS cluster:

- Using Management Console
- Using admintools

When you use MC to add nodes to a cluster in the cloud, MC provisions the instances, adds the new instances to the existing Vertica cluster, and then adds those hosts to the database. However, when you add nodes to a cluster using admintools, you need to execute those steps yourself, as explained in Adding Nodes Using admintools .

Adding nodes using Management Console

In the Vertica Management Console, you can add nodes in several ways, depending on your database mode.

For Eon Mode databases, MC supports actions for subcluster and node management for the following public and private cloud providers:

- Amazon Web Services (AWS)
- Google Cloud Platform (GCP)
- Microsoft Azure
- Pure Storage FlashBlade

> **Note**
> Enterprise Mode does not support subclusters.

For Enterprise Mode databases, MC supports these actions:

- In the cloud on AWS: Add Node action, Add Instance action.
- On-premises: Add Node action.

> **Note**
> In the cloud on GCP, Enterprise Mode databases are not supported.

Adding nodes in an Eon Mode database

In an Eon Mode database, every node must belong to a subcluster . To add nodes, you always add them to one of the subclusters in the database:

- By scaling up an existing subcluster by one or more nodes.
- By adding a new subcluster of one or more nodes.

Adding nodes in an Enterprise Mode database on AWS

In an Enterprise Mode database on AWS, to add an instance to your cluster:

1. On the MC Home page, click **View Infrastructure** to go to the Infrastructure page . This page lists all the clusters the MC is monitoring.
2. Click any cluster shown on the Infrastructure page.
3. Select **View** or **Manage** from the dialog that displays, to view its Cluster page. (In a cloud environment, if MC was deployed from a cloud template the button says "Manage". Otherwise, the button says "View".)

   > **Note**
   > You can click the pencil icon beside the cluster name to rename the cluster. Enter a name that is unique within MC.

1. Click the Add (**+**) icon on the **Instance List** on the **Cluster Management** page.
   MC adds a node to the selected cluster.

Adding nodes using admintools

This section gives an overview on how to add nodes if you are managing your cluster using admintools. Each main step points to another topic with the complete instructions.

Step 1: before you start

Before you add nodes to a cluster, verify that you have an AWS cluster up and running and that you have:

- Created a database.
- Defined a database schema.
- Loaded data.
- Run the Database Designer.
- Connected to your database.

Step 2: launch new instances to add to an existing cluster

Perform the procedure in Configure and launch an instance to create new instances (hosts) that you then will add to your existing cluster. Be sure to choose the same details you chose when you created the original instances (VPC, placement group, subnet, and security group).

Step 3: include new instances as cluster nodes

You need the IP addresses when you run the install_vertica script to include new instances as cluster nodes.

If you are configuring Amazon Elastic Block Store (EBS) volumes, be sure to configure the volumes on the node before you add the node to your cluster.

To add the new instances as nodes to your existing cluster:

1. Configure and launch your new instances .
2. Connect to the instance that is assigned to the Elastic IP. See Connect to an instance if you need more information.
3. Run the Vertica installation script to add the new instances as nodes to your cluster. Specify the internal IP addresses for your instances and your *.pem file name.

```
$ sudo /opt/vertica/sbin/install_vertica --add-hosts instance-ip --dba-user-password-disabled \
 --point-to-point --data-dir /vertica/data --ssh-identity ~/name-of-pem.pem
```

Step 4: add the nodes

After you have added the new instances to your existing cluster, add them as nodes to your cluster, as described in Adding nodes to a database .

Step 5: rebalance the database

After you add nodes to a database, always rebalance the database.

Remove nodes from a running AWS cluster

Use the following procedures to remove instances/nodes from an AWS cluster.

To avoid data loss, Vertica strongly recommends that you back up your database before removing a node. For details, see Backing up and restoring the database .

In this section

In this section

- Remove hosts from the database
- Remove nodes from the cluster
- Stop the AWS instances (optional)

Remove hosts from the database

Before you remove hosts from the database, verify that you have:

- Backed up the database.
- Lowered the K-safety of the database.

> **Note**
> Do not stop the database.

To remove a host from the database:

1. While logged on as dbadmin, launch Administration Tools.
   $ /opt/vertica/bin/admintools
2. From the **Main Menu** , select **Advanced Menu** .
3. From **Advanced Menu** , select **Cluster Management** . Click **OK** .
4. From **Cluster Management** , select **Remove Host(s)** . Click **OK** .
5. From **Select Database** , choose the database from which you plan to remove hosts. Click **OK** .
6. Select the host(s) to remove. Click **OK** .
7. Click **Yes** to confirm removal of the hosts.

   > **Note**
   > Enter a password if necessary. Leave blank if there is no password.

8. Click **OK** . The system displays a message telling you that the hosts have been removed. Automatic rebalancing also occurs.
9. Click **OK** to confirm. Administration Tools brings you back to the **Cluster Management** menu.

Remove nodes from the cluster

To remove nodes from a cluster, run the update_vertica script and specify:

- The option --remove-hosts , followed by the IP addresses of the nodes you are removing.
- The option --ssh-identity , followed by the location and name of your *pem file.
- The option --dba-user-password-disabled .

The following example removes one node from the cluster:

```
$ sudo /opt/vertica/sbin/update_vertica  --remove-hosts 10.0.11.165  --point-to-point  \
 --ssh-identity ~/name-of-pem.pem --dba-user-password-disabled
```

Stop the AWS instances (optional)

After you have removed one or more nodes from your cluster, to save costs associated with running instances, you can choose to stop the AWS instances that were previously part of your cluster.

To stop an instance in AWS:

1. On AWS, navigate to your **Instances** page.
2. Right-click the instance, and choose **Stop** .

This step is optional because, after you have removed the node from your Vertica cluster, Vertica no longer sees the node as part of the cluster, even though it is still running within AWS.

Upgrade Vertica on AWS

Before you upgrade to the latest Vertica version, do the following:

1. Back up your existing database.
2. Download the Vertica install packages described in Download and Install the Vertica Install Package .

Upgrade to the latest version of Vertica on AWS

To upgrade to the latest version of Vertica on AWS, follow the instructions in Upgrading Vertica .

If you are setting up a Vertica cluster on AWS for the first time, follow the procedure for installing and running on AWS .

Upgrade Vertica running on AWS

Vertica supports upgrades of Vertica server running on AWS instances created from the Vertica AMI. To upgrade Vertica, follow the instructions provided in Upgrading Vertica .

Make sure to add the following arguments to the upgrade script:

- --dba-user-password-disabled
- --point-to-point

Copying and exporting data on AWS: what you need to know

There are common issues that occur when exporting or copying on AWS clusters, as described below. Except for these specific issues as they relate to AWS, copying and exporting data works as documented in Database export and import .

To copy or export data on AWS:

1. **Verify that all nodes in source and destination clusters have their own elastic IPs (or public IPs) assigned.**
   If your destination cluster is located within the same VPC as your source cluster, proceed to step 3. Each node in one cluster must be able to communicate with each node in the other cluster. Thus, each source and destination node needs an elastic IP (or public IP) assigned.
2. (For non-CloudFormation Template installs) Create an S3 gateway endpoint.
   If you aren't using a CloudFormation Template (CFT) to install Vertica, you must create an S3 gateway endpoint in your VPC. For more information, see the AWS documentation .
   For example, the Vertica CFT has the following VPC endpoint:

```
"S3Enpoint" : {
   "Type" : "AWS::EC2::VPCEndpoint",
   "Properties" : {
   "PolicyDocument" : {
      "Version":"2012-10-17",
      "Statement":[{
      "Effect":"Allow",
      "Principal": "*",
      "Action":["*"],
      "Resource":["*"]
      }]
   },
   "RouteTableIds" : [ {"Ref" : "RouteTable"} ],
   "ServiceName" : { "Fn::Join": [ "", [ "com.amazonaws.", { "Ref": "AWS::Region" }, ".s3" ] ] },
   "VpcId" : {"Ref" : "VPC"}
}
```

3. **Verify that your security group allows the AWS clusters to communicate.**
   Check your security groups for both your source and destination AWS clusters. Verify that ports 5433 and 5434 are open. If one of your AWS clusters is on a separate VPC, verify that your network access control list (ACL) allows communication on port 5434.

   > **Note**
   > **Note:** This communication method exports and copies (imports) data across the Internet. You can alternatively use non-public IPs and gateways, or VPN to connect the source and destination clusters.

4. If there are one or more elastic load balancers (ELBs) between the clusters, verify that port 5433 is open between the ELBs and clusters.

5. If you use the Vertica client to connect to one or more ELBs, the ELBs only distribute incoming connections. The data transmission path occurs between clusters.

Vertica on Microsoft Azure

You can deploy a Vertica database on the Microsoft Azure Cloud running in either Enterprise Mode or Eon Mode . In Eon Mode, Vertica stores its data communally using Azure block blob storage.

This section explains how to deploy a Vertica database to Microsoft Azure.

For more information about Azure, see the Azure documentation .

In this section

- Deploying Vertica from the Azure Marketplace
- Manually deploy Vertica on Microsoft Azure
- Eon Mode databases on Azure
- page_title

Deploying Vertica from the Azure Marketplace

Deploy Vertica in the Microsoft Azure Cloud using the Vertica Analytics Platform entry in the Azure Marketplace. Vertica provides the following deployment options:

- Eon Mode : Deploy a Management Console (MC) instance, and then provision and create an Eon Mode database from the MC. For cluster and storage requirements, see Eon Mode on Azure prerequisites .
- Enterprise Mode : Deploy a four-node Enterprise Mode database comprised of one MC instance and three database nodes. This requires an Azure subscription with a minimum of 12 cores for the Vertica Marketplace solution.
  The Enterprise Mode deployment uses the MC primarily as a monitoring tool. For example, you cannot provision and create a database with an Enterprise Mode MC. For information about creating and managing an Enterprise Mode database, see Create a database using administration tools .

Creating a deployment

Eon Mode and Enterprise Mode require much of the same information for deployment. Any information that is not required for both deployment types is clearly marked.

1. selecting the deployment type

1. Sign in to your Microsoft Azure account. From the **Home** screen, select **Create a resource** under **Azure services** .
2. Search for **Vertica Analytics Platform** and select it from the search results.
3. On the **Vertica Analytics Platform** page, select one of the following:
   - To deploy an MC instance that can manage an Eon Mode database, select Vertica **Data Warehouse, Eon BYOL** .
   - To deploy an Enterprise Mode database, select Vertica **Analytics Platform** .
4. On the next screen, select **Create** .

After you select your deployment type, the **Basics** tab on the **Create** Vertica **Analytics Platform** page displays.

2. adding project and instance details on the basics tab

Provide the following information in the **Project details** and **Instance details** sections:

1. **Subscription** : Azure bills this subscription for the cluster resources.
2. **Resource group** : The location to save all of the Azure resources. Create a new resource group or choose an existing one from the dropdown list.
3. **Region** : The location where the virtual machine running your MC instance is deployed.
4. VerticaManagement Console **User** : Eon Mode only. The administrator username for the MC.
5. **SSH public key for OS Access** : Provide the SSH public key associated with the Vertica **User** , for command line access to the virtual machine.
6. **Password for MC Access** : Enter a password to log in to Management Console. Note that Management Console requires that you change your password after the initial login.
7. **Confirm password** : Reenter the value you entered in **Password for MC Access** .
8. Select **Next: Virtual Machine Settings >** .

3. selecting virtual machine settings

Provide the following information on the **Virtual Machine Settings** tab:

1. Management Console **VM size** : Select Change size to customize the VM settings or select the default. For a list of VM types recommended by use case, see Recommended Azure VM types .
2. **Storage account of Eon DB** : Eon Mode only. The storage account associated with the database deployment.

3. **Number of** Vertica **Cluster nodes** : Enterprise Mode only. The number of nodes to deploy in the cluster, in addition to the MC instance.
   The Community Edition (CE) license is automatically applied to the cluster. This license is limited to 1 TB of RAW data 3 Vertica nodes. If you select more than 3 nodes with a CE license, the initial database is created on the first 3 nodes. For information about upgrading your license, see Managing licenses .
4. Vertica **Node VM size** : Enterprise Mode only. Select the VM type to deploy in your cluster. Use the default or select **Change size** to customize the VM settings. For a list of VM types recommended by use case, see Recommended Azure VM types .
5. **Total RAW storage per node** : Enterprise Mode only. Select the amount of storage per node from the dropdown list. Each VM has a set of premium data disks that are configured and presented as a single storage location.
6. Select **Next: Network Settings >** .

4. selecting network settings

Provide the following information on the **Network Settings** tab:

1. **Virtual Network** : The virtual network that hosts the Vertica cluster. Create a new virtual network or select an existing one from the dropdown list.
   If you select an existing virtual network, Vertica recommends that you already created a subnet to use for the deployment.
2. **First subnet** : The subnet for the associated **Virtual Network** . Create a new subnet or select an existing one from the dropdown list.
3. **Public IP Address Resource Name** : Each VM is configured with a publicly accessible IP address. This field allows you to specify the resource name for those IP addresses, and whether they are static or dynamic. The first public IP address resource is created exactly as entered, and associated with the VerticaManagement Console. Azure appends a number from 1 to 16 to the resource name for each additional Vertica cluster node created. This number associates each VM with a resource.
4. **Domain Name Label for** Management Console: Because each VM has a public IP address, each node requires a DNS name. Enter a prefix for the name. The first DNS name is created exactly as entered, and associated with the VerticaManagement Console. Azure appends a number from 1 to 16 to the DNS name for each Vertica cluster node created. That number associates each VM with a resource. Azure adds the remaining part of the fully qualified domain name based on the location where you created the cluster.
5. Select **Next: Review + create >** .

5. verifying on review + create

As the **Review + create** page loads, Azure validates your settings. After it passes validation, review your settings. When you are satisfied with your selections, select **Create** .

Accessing the MC after deployment

After your resources are successfully deployed, you are brought to the **Overview** page on **Home** > *resources-name* > **Deployments** . You must retrieve your Management Console IP address and username to log in.

1. From the **Overview** page, select **Outputs** in the left navigation.
2. Copy the **vertica management console URL** and **vertica management console user name** .
3. Paste the **vertica management console URL** in the browser address bar and press **Enter** .
4. Depending on your browser, you might receive a warning of a security risk. If you receive the warning, select the **Advanced** button and follow the browsers instructions to proceed to the Management Console.
5. On the VerticaManagement Console log in page, paste the **vertica management console user name** , and enter the **Password for MC Access** that you entered on **Basics** > **Project details** when you were deploying your MC instance.

Deleting a resource group

For details about the Azure Resource Manager and deleting a resource group, see the Azure documentation .

Manually deploy Vertica on Microsoft Azure

Manually creating a database cluster for your Vertica deployment lets you customize your VMs to meet your specific needs. You often want to manually configure your VMs when deploying a Vertica cluster to host an Eon Mode database.

To start creating your Vertica cluster in Azure using manual steps, you first need to create a VM. During the VM creation process, you create and configure the other resources required for your cluster, which are then available for any additional VMs that you create.

The topics in this section explain how to manually deploy Vertica on Azure.

In this section

- Recommended Azure VM types
- Supported Azure operating systems
- Configuring and launching a new instance
- Connect to a virtual machine
- Prepare the virtual machines
- Configure storage

- Download Vertica
- Form a cluster and install Vertica
- After your cluster is up and running

Recommended Azure VM types

Vertica supports a range of Microsoft Azure virtual machine (VM) types, each optimized for different purposes. Choose the VM type that best matches your performance and price needs as a user.

> **Note**
> The GS VMs are not available in all regions, or from the Azure Marketplace.
>
> You can use them by following the manual deployment steps described in Manually deploy Vertica on Microsoft Azure .

For the best performance in most common scenarios, use one of the following VMs:

Virtual Machine Types	Virtual Machine Size
Memory optimized	DS13_v2 DS14_v2 DS15_v2 D8s_v3 D16s_v3 D32s_v3
High memory and I/O throughput	GS3 GS4 GS5 E8s_v3 E16s_v3 E32s_v3 L8s L16s L32s

Supported Azure operating systems

For best performance, use one of the following operating systems when deploying Vertica on Azure:

- Red Hat 7.3 or later
- CentOS 7.3 or later. The Azure Marketplace solution as of this writing (June 2017) is based on CentOS 7.3.1611.

For more information, see Supported platforms .

Configuring and launching a new instance

An Azure VM is similar to a traditional host. Just as with an on-premises cluster, you must prepare and configure the hardware settings for your cluster and network before you install Vertica.

The first steps are:

1. From the Azure marketplace, select an operating system that Vertica supports.
2. Select a VM type.See Recommended Azure VM types .
3. Choose a deployment model. For best results, choose the resource manager deployment model.

Configure network security group

Vertica has specific network security group requirements, as described in page_title .

Create and name your own network security group, following these guidelines.

You must configure SSH as:

- Protocol: TCP
- Source port range: Any
- Destination port range: 22
- Source: Any
- Destination: Any

You can make additional modifications, based on your specific requirements.

Add disk containers

Create an Azure storage account, which later contains your cluster storage disk containers.

For optimal throughput, select Premium storage and align the storage to your chosen VM type.

For more information about what a storage account is, and how to create one, refer to About Azure storage accounts .

For an Enterprise Mode database deployment, provision enough space

Configure credentials

Create a password or assign an SSH key pair to use with Vertica.

For information about how to use key pairs in Azure, see How to create and use an SSH public and private key pair for Linux VMs in Azure .

Assign a public IP address

A public IP is an IP address that you can use to connect to your cluster externally. For best results, assign a single static public IP to a node in your cluster. You can then connect to other nodes in your cluster from your primary node using the internal IP addresses that Azure generated when you specified your virtual network settings.

By default, a public IP address is dynamic; it changes every time you shut down the server. You can choose a static IP address, but doing so can add cost to your deployment.

During a VM installation, you cannot set a DNS name. If you use dynamic public IPs, set the DNS name in the public IP resource for each VM after deployment.

For information about public IP addresses, refer to IP address types and allocation methods in Azure .

Create additional VMs

If needed, to create additional VMs, repeat the previous instructions in this document.

Connect to a virtual machine

Before you can connect to any of the VMs you created, you must first make your virtual network externally accessible. To do so, you must attach the public IP address you created during network configuration to one of your VMs.

Connect to your VM

To connect to your VM, complete the following tasks:

1. Connect to your VM using SSH with the public IP address you created in the configuration steps.
2. Authenticate using the credentials and authentication method you specified during the VM creation process.

Connect to other VMs

Connect to other virtual machines in your virtual network by first using SSH to connect to your publicly connected VM. Then, use SSH again from that VM to connect through the private IP addresses of your other VMs.

If you are using private key authentication, you may need to move your key file to the root directory of your publicly connected VM. Then, use PuTTY or WinSCP to connect to other VMs in your virtual network.

Prepare the virtual machines

After you create your VMs, you need to prepare them for cluster formation.

Add the Vertica license and private key

Prepare your nodes by adding your private key (if you are using one) to each node and to your Vertica license. These steps assume that the initial user you configured is the DBADMIN user.

1. As the dbadmin user, copy your private key file from where you saved it locally onto your primary node.
   Depending upon the procedure you use to copy the file, the permissions on the file may change. If permissions change, the install_vertica script fails with a message similar to the following:
   ```
   Failed Login Validation 10.0.2.158, cannot resolve or connect to host as root.
   ```
   If you receive a failure message, enter the following command to correct permissions on your private key file:
   ```
   $ chmod 600 /<name-of-key>.pem
   ```
2. Copy your Vertica license to your primary VM. Save it in your home directory or other known location.

Install software dependencies for Vertica on Azure

In addition to the Vertica standard Package dependencies , as the root user, you must install the following packages before you install Vertica on Azure:

- pstack
- mcelog
- sysstat
- dialog

Configure storage

Use a dedicated Azure storage account for node storage.

> **Caution**
> **Caution:** Do *not* store your information on the root volume, especially your data and catalog directories. Storing information on the root volume may result in data loss.

When configuring your storage, make sure to use a supported file system. For details, see Recommended storage format types .

Attach disk containers to virtual machines (VMs)

Using your previously created storage account, attach disk containers to your VMs that are appropriate to your needs.

For best performance, combine multiple storage volumes into RAID-0. For most RAID-0 implementations, attach 6 storage disk containers per VM.

Combine disk containers for storage

If you are using RAID, follow these steps to create a RAID-0 drive on your VMs. The following example shows how you can create a RAID-0 volume named md10 from 6 individual volumes named:

- sdc
- sdd
- sde
- sdf
- sdg
- sdh

1. Form a RAID-0 volume using the mdadm utility:
   ```
   $ mdadm --create /dev/md10 --level 0 --raid-devices=6 \
     /dev/sdc /dev/sdd /dev/sde /dev/sdf /dev/sdg /dev/sdh
   ```
2. Format the file system to be one that Vertica supports:
   ```
   $ mkfs.ext4 /dev/md10
   ```
3. Find the UUID on the newly-formed RAID volume using the blkid command. In the output, look for the device you assigned to the RAID volume:

```
$ blkid
. . .
/dev/md10 : UUID="e7510a6f-2922-4413-b5fa-9dcd725967fd" TYPE="ext4" PARTUUID="fb9b7449-08c3-4231-9ee5-086f7b0c9001"
. . .
```

4. The RAID device can be renamed after a reboot. To ensure the filesystem is mounted in a predictable location on your VM, create a directory to use as the mount point to mount the filesystem. For example, you can choose to create a mount point named /data that you will use to store your database's catalog and data (or depot, if you are running Vertica in Eon Mode).

   ```
   $ mkdir /data
   ```

5. Using a text editor, add an entry to the /etc/fstab file for the UUID of the filesystem and your mount point so it is mounted when the system boots:

   ```
   UUID=RAID_UUID mountpoint      ext4    defaults,nofail,nobarrier    0   2
   ```

   For example, if you have the UUID shown in the previous example and the mount point /data , add the following line to the /etc/fstab file:

   ```
   UUID=e7510a6f-2922-4413-b5fa-9dcd725967fd  /data      ext4    defaults,nofail,nobarrier    0   2
   ```

6. Mount the RAID filesystem you added to the fstab file. For example, to mount a mount point named /data use the command:

   ```
   $ mount /data
   ```

7. Create folders for your Vertica data and catalog under your mount point.

   ```
   $ mkdir /data/vertica
   $ mkdir /data/vertica/data
   ```

   If you are planning to run Vertica in Eon Mode, create a directory for the depot instead of data:

   ```
   $ mkdir /data/vertica/depot
   ```

Create a swap file

In addition to storage volumes to store your data, Vertica requires a swap volume or swap file to operate.

Create a swap file or swap volume of at least 2 GB. The following steps show how to create a swap file within Vertica on Azure:

1. Install devnull and swapfile:

   ```
   $ install -o root -g root -m 0600 /dev/null /swapfile
   ```

2. Create the swap file:

   ```
   $ dd if=/dev/zero of=/swapfile bs=1024 count=2048k
   ```

3. Prepare the swap file using mkswap :

   ```
   $ mkswap /swapfile
   ```

4. Use swapon to instruct Linux to swap on the swap file:

   ```
   $ swapon /swapfile
   ```

5. Persist the swapfile in FSTAB:

   ```
   $ echo "/swapfile       swap    swap    auto      0       0" >> /etc/fstab
   ```

Repeat the volume attachment, combination, and swap file creation procedures for each VM in your cluster.

For more information

- About Azure storage accounts
- Prepare disk storage locations

Download Vertica

To download the Vertica server appropriate for your operating system and license type, go to www.vertica.com/download/vertica .

Run the rpm to extract the files.

After you complete the download and extraction, the next section describes how to use the install_vertica script to form a cluster and install the Vertica database software.

Form a cluster and install Vertica

Use the install_vertica script to combine two or more individual VMs to form a cluster and install the Vertica database.

Before you start

Before you run the install_vertica script:

- Check the **Virtual Network** page for a list of current VMs and their associated private IP addresses.
- Identify your storage location. The installer assumes that you have mounted your storage to /vertica/data . To specify another location, use the --data-dir argument.
- Identify your storage location. To create your database's data directory on mounted RAID drive, when you run the install_vertica script, provide /vertica/data as the value of the --data-dir option .

> **Caution**
> **Caution:** Do *not* store your data on the root drive.

Combine virtual machines (VMs)

The following example shows how to combine VMs using the install_vertica script.

1. While connected to your primary node, construct the following command to combine your nodes into a cluster.
   ```
   $ sudo /opt/vertica/sbin/install_vertica --hosts 10.2.0.164,10.2.0.165,10.2.0.166 --dba-user-password-disabled --point-to-point --data-dir /vertica/data --ssh-identity ~/<name-of-private-key>.pem --license <license.file>
   ```
2. Substitute the IP addresses for your VMs and include your root key file name, if applicable.
3. Include the --point-to-point parameter to configure spread to use direct point-to-point communication between all Vertica nodes, as required for clusters on Azure when installing or updating Vertica.
4. If you are using Vertica Community Edition, which limits you to three nodes, specify -L CE with no license file.
5. After you combine your nodes, to reduce security risks, keep your key file in a secure place—separate from your cluster—and delete your on-cluster key with the **shred** command:
   ```
   $ shred examplekey.pem
   ```

   Important
   You need your key file to perform future Vertica updates.

6. Reboot your cluster to complete the cluster formation and Vertica installation.

For complete information on the install_vertica script and its parameters, see Installing Vertica with the installation script .

After your cluster is up and running

Now that your cluster is configured and running, take these steps:

1. Log into one of the database nodes using the database administrator account (named dbadmin by default).
2. Create and start a database:
   - To create an Enterprise Mode database, see Create a database using administration tools .
   - To create an Eon Mode database, see Manually creating an Eon Mode database on Azure .
3. Configure your database. See Configuring the database .

Eon Mode databases on Azure

You can create an Eon Mode database on a cluster that is hosted on Azure. In this configuration, your database stores its data communally in Azure Blob storage. See Eon Mode to learn more about this database mode.

Eon Mode databases on Azure support some of the encryption features built into Azure Storage. You can use its encryption at rest feature transparently—you do not need to configure Vertica to take advantage of it. You can use Microsoft-managed or customer-managed keys for storage encryption. Vertica does not support Azure Storage's client-side encryption and encryption using customer-provided keys. See the Azure Data Encryption at rest page in the Azure documentation for more information about the encryption at rest features in Azure Storage.

> **Note**
> If you have an existing Enterprise Mode database, you can migrate it to an to Eon Mode database running on Azure. See Migrating an enterprise database to Eon Mode .

This section explains how you create an Eon Mode database running on Azure cloud.

In this section

- Eon Mode on Azure prerequisites
- Manually creating an Eon Mode database on Azure

Eon Mode on Azure prerequisites

Before you can create an Eon Mode database on Azure, you must have a database cluster and an Azure blob storage container to store your database's data.

Cluster requirements

Before you can create an Eon Mode database on Azure, you must provision a cluster to host it. See Configuring your Vertica cluster for Eon Mode for suggestions on choosing VM configurations and the number of nodes your cluster should start with.

Storage requirements

An Eon Mode database on Azure stores its data communally in Azure blob storage. Vertica only supports block blob storage for communal data storage, not append or page blob storage.

You must create a storage path for Vertica to use exclusively. This path can be a blob container or a folder within a blob container. This path must not contain any files. If you attempt to create an Eon Mode database with a container or folder that contains files, admintools returns an error.

You pass Vertica a URI for the storage path using the azb:// schema. See Azure Blob Storage object store for the format of this URI.

You must also configure the storage container so Vertica is authorized to access it. Depending on authentication method you use, you may need to supply Vertica the with credentials to access the container. Vertica can use one of following methods to authenticate with the blob storage container:

- Using Azure managed identities. This authentication method is transparent—you do not need to add any authentication configuration information to Vertica. Vertica automatically uses the managed identity bound to the VMs it runs on to authenticate with the blob storage container. See the Azure AD-managed identities for Azure resources documentation page in the Azure documentation for more information.
  If you provide credentials for either of the other two supported authentication methods, Vertica uses them instead of authenticating using a managed identity bound to your VM.

  > **Note**
  > If your Azure VMs have more than one managed identity bound to them, you must tell Vertica which identity to use when authenticating with the blob storage container. Vertica gets the identity to use from a tag set on the VMs that it is running on.
  >
  > On your VMs, create a tag with its key named VerticaManagedIdentityClientId and its value to the name of a managed identity bound to your VMs. See the Use tags to organize your Azure resources and management hierarchy page in the Azure documentation for more information.

- Using an account name and access key credentials for a service account that has full access to the blob storage container. In this case, you provide Vertica with the credentials when you create the Eon Mode database. See Creating an Authentication File for details.
- Using a shared access signature (SAS) that grants Vertica access to the storage container. See Grant limited access to Azure Storage resources using shared access signatures (SAS) in the Azure documentation. See Creating an Authentication File for details.

For details on how Vertica accesses Azure blob storage, see Azure Blob Storage object store .

Manually creating an Eon Mode database on Azure

Once you have met the cluster and storage requirements for using an Eon Mode database on Azure, you are ready to create an Eon Mode database. Use the admintools create_db tool to create your Eon Mode database.

Creating an authentication file

If your database will use a managed identity to authenticate with the Azure storage container, you do not need to supply any additional configuration information to the create_db tool.

If your database will not use a managed identity, you must supply create_db with authentication information in a configuration file. It must contain at least the AzureStorageCredentials parameter that defines one or more account names and keys Vertica will use to access blob storage. It can also contain an AzureStorageEnpointConfig parameter that defines an alternate endpoint to use instead of the the default Azure host name. This option is useful if you are creating a test environment using an Azure storage emulator such as Azurite.

Important
Vertica does not officially support Azure storage emulators as a communal storage location.

The following table defines the values that can be set in these two parameters.

AzureStorageCredentials

Collection of JSON objects, each of which specifies connection credentials for one endpoint. This parameter takes precedence over Azure managed identities.

The collection must contain at least one object and may contain more. Each object must specify at least one of accountName or blobEndpoint , and at least one of accountKey or sharedAccessSignature .

- accountName : If not specified, uses the label of blobEndpoint .
- blobEndpoint : Host name with optional port (host:port). If not specified, uses *account* .blob.core.windows.net .
- accountKey : Access key for the account or endpoint.
- sharedAccessSignature : Access token for finer-grained access control, if being used by the Azure endpoint.

AzureStorageEndpointConfig

Collection of JSON objects, each of which specifies configuration elements for one endpoint. Each object must specify at least one of accountName or blobEndpoint .

- accountName : If not specified, uses the label of blobEndpoint .
- blobEndpoint : Host name with optional port (host:port). If not specified, uses *account* .blob.core.windows.net .
- protocol : HTTPS (default) or HTTP.
- isMultiAccountEndpoint : true if the endpoint supports multiple accounts, false otherwise (default is false). To use multiple-account access, you must include the account name in the URI. If a URI path contains an account, this value is assumed to be true unless explicitly set to false.

The authentication configuration file is a text file containing the configuration parameter names and their values. The values are in a JSON format. The name of this file is not important. The following examples use the file name auth_params.conf .

The following example is a configuration file for a storage account hosted on Azure. The storage account name is mystore, and the key value is a placeholder. In your own configuration file, you must provide the storage account's access key. You can find this value by right-clicking the storage account in the Azure Storage Explorer and selecting **Copy Primary Key** .

```
AzureStorageCredentials=[{"accountName": "mystore", "accountKey": "access-key"}]
```

The following example shows a configuration file that defines an account for a storage container hosted on the local system using the Azurite storage system. The user account and key are the "well-known" account provided by Azurite by default. Because this configuration uses an alternate storage endpoint, it also defines the AzureStorageEndpointConfig parameter. In addition to reiterating the account name and endpoint definition, this example sets the protocol to the non-encrypted HTTP.

Important
This example wraps the contents of the JSON values for clarity. In an actual configuration file, you **cannot wrap these values** . They must be on a single line.

```
AzureStorageCredentials=[{"accountName": "devstoreaccount1", "blobEndpoint": "127.0.0.1:10000 ",
                          "accountKey":
"Eby8vdM02xNOcqFlqUwJPLlmEtlCDXJ1OUzFT50uSRZ6IFsuFq2UVErCz4I6tq/K1SZFPTOtr/KBHBeksoGMGw=="
                        }]

AzureStorageEndpointConfig=[{"accountName": "devstoreaccount1",
                             "blobEndpoint": "127.0.0.1:10000", "protocol": "http"}]
```

Creating the Eon Mode database

Use the admintools create_db tool to create your Eon Mode database. The required arguments you pass to this tool are:

Argument	Description
--communal-storage-location	The URI for the storage container Vertica will use for communal storage. This URI must use the azb:// schema. See Azure Blob Storage object store for the format of this URI.

-x	The path to the file containing the authentication parameters Vertica needs to access the communal storage location. This argument is only required if your database will use a storage account name and key to authenticate with the storage container. If it is using a managed identity, you do not need to specify this argument.
--depot-path	The absolute path to store the depot on the nodes in the cluster.
--shard-count	The number of shards for the database. This is an integer number that is usually either a multiple of the number of nodes in your cluster, or an even divisor. See Planning for Scaling Your Cluster for more information.
-s	A comma-separated list of the nodes in your database.
-d	The name for your database.

Some other common optional arguments for create_db are:

Argument	Description
-l	The absolute path to the Vertica license file to apply to the new database.
-p	The password for the new database.
--depot-size	The maximum size for the depot. Defaults to 60% of the filesystem containing the depot path. You can specify the size in two ways: • *integer* % : Percentage of filesystem's disk space to allocate. • *integer* {K|M|G|T} : Amount of disk space to allocate for the depot in kilobytes, megabytes, gigabytes, or terabytes. However you specify this value, the depot size cannot be more than 80 percent of disk space of the file system where the depot is stored.

To view all arguments for the create_db tool, run the command:

```
admintools -t create_db --help
```

The following example demonstrates creating an Eon Mode database with the following settings:

- Vertica will use a storage account named mystore.
- The communal data will be stored in a directory named verticadb located in a storage container named db_blobs .
- The authentication information Vertica needs to access the storage container is in the file named auth_params.conf in the current directory. The contents of this file are shown in the first example under Creating an Authentication File .
- The hostnames of the nodes in the cluster are node01 through node03.

```
$ admintools -t create_db \
        --communal-storage-location=azb://mystore/db_blobs/verticadb \
        -x auth_params.conf -s node01,node02,node03  \
        -d verticadb --depot-path /vertica/depot --shard-count 3 \
        -p 'mypassword'
```

page_title

Vertica has the following network security group requirements.

For details on security groups and how to create one, see the Azure documentation .

Inbound settings

Name	Protocol	Source port range	Destination port range	Source	Destination

SSH	TCP	•	22	Any	Any
HTTP	TCP	•	80	Any	Any
HTTPS	TCP	•	80	Any	Any
HTTPS	TCP	•	443	Any	Any

All UDP	UDP	0-65535	•	Any	Any

Vertica on Google Cloud Platform

Welcome to the Vertica on Google Cloud Platform guide.

Vertica provides two templates to help you deploy a Vertica database running in either Enterprise Mode or Eon Mode . See Architecture for more information about these modes.

The following topics describe several deployment methods to run Vertica on Google Cloud Platform.

In this section

- Supported GCP machine types
- Deploy Vertica from the Google cloud marketplace

- Manually deploying an Enterprise Mode database on GCP

Supported GCP machine types

Vertica Analytic Database supports a range of machine types, each optimized for different workloads. When you deploy your Vertica Analytic Database cluster to the Google Cloud Platform (GCP), different machine types are available depending on how you provision your database.

> **Note**
> Some machine types are not available across all regions.

The sections below list the GCP machine types that Vertica supports for Vertica cluster hosts, and for use in Management Console. For details on the configuration of the machine type options, see the Google Cloud documentation's Machine types page.

Machine types available for MC hosts

Vertica supports all N1, N2, E2, M1, M2, and C2 machine types to deploy an instance for running the Vertica Management Console.

> **Tip**
> In most cases, 8 vCPUs are sufficient when selecting a machine type for running the Management Console.

Machine types available for Vertica database cluster hosts

Vertica supports all N1, N2, E2, M1, M2, and C2 machine types to deploy cluster hosts.

Machine types for Vertica database cluster hosts provisioned from MC

The table below lists the GCP machine types that Vertica supports when you provision your cluster from Management Console.

Machine Type	Machine Name
N1 standard	n1-standard-16 n1-standard-32 n1-standard-64
N1 high-memory	n1-highmem-16 n1-highmem-32 n1-highmem-64
N2 standard	n2-standard-16 n2-standard-32 n2-standard-48 n2-standard-64
N2 high-memory	n2-highmem-16 n2-highmem-32 n2-highmem-48 n2-highmem-64

Deploy Vertica from the Google cloud marketplace

The Vertica entries in the Google Cloud Launcher Marketplace let you quickly deploy a Vertica cluster in the Google Cloud Platform (GCP). Currently, three entries let you select the database mode and the license you want to use:

- The Enterprise Mode launcher deploys a Vertica database with 3 or more nodes, plus an additional VM running the Management Console (MC). See Deploying an Enterprise Mode database in GCP from the marketplace for more information.
- The Eon Mode BYOL (bring your own license) launcher deploys a single instance running the MC. You use this MC instance to deploy a Vertica database running on Eon Mode. This database has a community license applied to it initially. You can later upgrade it to a license you have obtained from Vertica. See Deploying an Eon Mode database on GCP for more information.
- The Eon Mode BTH (by the hour) launcher also deploys a single instance running the MC that you use to deploy a database. This database has a by-the-hour license applied to it. Instead of paying for a license up front, you pay an hourly fee that covers both Vertica and running your instances. The BTH license is automatically applied to all clusters you create using a BTH MC instance. See Deploying an Eon Mode database on GCP for more information. If you choose, you can upgrade this hourly license to a longer-term license you purchase from Vertica. To move a BTH cluster to a BYOL license, follow the instructions in Moving a cloud installation from by the hour (BTH) to bring your own license (BYOL) for more information.

> **Note**
> Vertica clusters that use IPv6 to identify hosts have not been tested on GCP. Vertica recommends you use IPv4 addresses to identify the hosts in your cluster on GCP.

In this section

- Deploying an Enterprise Mode database in GCP from the marketplace
- Eon Mode databases on GCP

Deploying an Enterprise Mode database in GCP from the marketplace

The Vertica Cloud Launcher solution creates a Vertica Enterprise Mode database. The solution includes the Vertica Management Console (MC) as the primary UI for you to get started.

The launcher automatically creates a database named vdb using the Community Edition (CE) license. The CE license is limited to a maximum of 3 nodes. You can tell the launcher to add more than 3 nodes to your deployment. In this case, it uses the first three nodes in the cluster to create the database. The remaining nodes are not part of the database, but are added to your cluster. To add these nodes to your database, you must replace the Community Edition license with a license key you receive from the Software Entitlement support site. See Managing licenses for more information.

After the launcher creates the initial database, it configures the MC to attach to that database automatically.

Configure the Vertica cloud launcher solution

To get started with a deployment of Vertica from the Google Cloud Launcher , search for the Vertica Data Warehouse, Enterprise Mode entry.

Follow these steps:

1. Verify that your user account has the **Editor** role and the runtimeconfig.waiters.getIamPolicy permission.
2. From the listing page, click **LAUNCH** .
3. On the New Vertica Analytics Platform deployment page, enter the following information:
   - **Deployment name** : Each deployment must have a unique name. That name is used as the prefix for the names of all VMs created during the deployment. The deployment name can only contain lowercase characters, numbers, and dashes. The name must start with a lowercase letter and cannot end with a dash.
   - **Zone** : GCP breaks its cloud data centers into regions and zones. *Regions* are a collection of zones in the same geographical location. *Zones* are collections of compute resources, which vary from zone to zone.
     For best results, pick the zone in your designated region that supports the latest Intel CPUs. For a complete listing of regions and zones, including supported processors, see Regions and Zones .
   - **Service Account** : Service accounts allow automated processes to authenticate with GCP. Select the default service account, identified by *project_number* -compute@developer.gserviceaccount.com .
   - Under **Vertica Management Console** , choose the configuration for the virtual machine that will run the Management Console. The Vertica Analytics Platform in Cloud Launcher always deploys the Vertica Management Console (MC) as part of the solution.
     The default machine type for MC is sufficient for most deployments. You can choose another machine type that better suits any additional purposes, such serving as a target node for backups, data transformation, or additional management tools.
   - **Node count for Vertica Cluster** : The total number of VMs you want to deploy in the Vertica Cluster. The default is 3.

     > **Note**

> As mentioned above, the Cloud Launcher automatically deploys the Vertica Community Edition license, which limits the database to 3 nodes and up to 1 TB in raw data. Any additional nodes will be part of your database cluster, but will not be part of your database.
>
> If you intend to use the Community Edition license for your database, leave the setting at 3. Otherwise, you would add nodes that will sit idle and cost you money without being part of your database.

- **Machine type for Vertica Cluster nodes** : The Cloud Launcher builds each node in the cluster using the same machine type. Modify the machine type for your nodes based on the workloads you expect your database to handle. See Supported GCP machine types for more information.
- **Data disk type** : GCP offers two types of persistent disk storage: Standard and SSD. The costs associated with Standard are less, but the performance of SSD storage is much better. Vertica recommends you use SSD storage. For more information on Standard and SSD persistent disks, see Storage Options .
- **Disk size in GB** : Disk performance is directly tied to the disk size in GCP. The default value of 2000 GBs (2 TB) is the minimum disk size for SSD persistent disks that allows maximum throughput.
  If you select a smaller disk size, the throughput performance decreases. If you select a large disk size, the performance remains the same as the 2 TB option.
- **Network** : VMs in GCP must exist on a virtual private cloud (VPC). When you created your GCP account, a default VPC was created. Create additional VPCs to isolate solutions or projects from one another. The Vertica Analytics Plaform creates all the nodes in the same VPC.
- **Subnetwork** : Just as a GCP account may have multiple VPCs, each VPC may also have multiple subnets. Use additional subnets to group or isolate solutions within the same VPC.
- **Firewall** : If you want your MC to be accessible via the internet, check the Allow access to the Management Console from the Internet box. Vertica recommends you protect your MC using a firewall that restricts access to just the IP addresses of users that need to access it. You can enter one or more comma-separated CIDR address ranges.

After you have entered all the required information, click **Deploy** to begin the deployment process.

Monitor the deployment

After the deployment begins, Google Cloud Launcher automatically opens the Deployment Manager page that displays the status of the deployment. Items that are still being processed have a spinning circle to the left of them and the text is a light gray color. Items that have been created are dark gray in color, with an icon designating that resource type on the left.

After the deployment completes, a green check mark appears next to the deployment name in the upper left-hand section of the screen.

Accessing the cluster after deployment

After the deployment completes, the right-hand section of the screen displays the following information:

- dbadmin password: A randomly generated password for the dbadmin account on the nodes. For security reasons, change the dbadmin password when you first log in to one of the Vertica cluster nodes.
- mcadmin password: A randomly generated password for the mcadmin account for accessing the Management Console. For security reasons, change the mcadmin password after you first log in to the MC.
- Vertica Node 1 IP address: The external IP address for the first node in the Vertica cluster is exposed here so that you can connect to the VM using a standard SSH client.To access the MC, press the **Access Vertica MC** button in the **Get Started** section of the dialog box. Copy the mcadmin password and paste it when asked.

For more information on using the MC, see Management Console .

Access the cluster nodes

There are two ways to access the cluster nodes directly:

- Use GCP's integrated SSH shell by selecting the SSH button in the **Get Started** section. This shell opens a pop-up in your browser that runs GCP's web-based SSH client. You are automatically logged on as the user you authenticated as in the GCP environment.
  After you have access to the first Vertica cluster node, execute the su dbadmin command, and authenticate using the dbadmin password.
- In addition, use other standard SSH clients to connect directly to the first Vertica cluster node. Use the Vertica Node 1 IP address listed on the screen as the dbadmin user, and authenticate with the dbadmin password.
  Follow the on-screen directions to log in using the mcadmin account and accept the EULA. After you've been authenticated, access the initial database by clicking the vdb icon (looks like a green cylinder) in the **Recent Databases** section.

Using a custom service account

In general, you should use the default service account created by the GCP deployment (*project_number* -compute@developer.gserviceaccount.com), but if you want to use a custom service account:

- The custom service account must have the **Editor** role.

- Individual user accounts must have the **Service Account User** role on the custom service account.

Eon Mode databases on GCP

You deploy an Eon Mode database to GCP using Google Cloud Platform Launcher to deploy a Management Console (MC) instance. You then use the MC instance to provision and deploy an Eon Mode database.

In this section

- GCP Eon Mode instance recommendations
- Eon Mode on GCP prerequisites
- Deploying an Eon Mode database on GCP

GCP Eon Mode instance recommendations

When you use the MC to deploy an Eon Mode database to the Google Cloud Platform (GCP), you choose the instance type to deploy as the database's nodes. The default instance settings in the MC are the more conservative option (currently, n1-standard-16). They are sufficient for most workloads. However, you may choose instances with more memory (such as n1-highmem-16) if your queries perform complex joins that may otherwise spill to disk. You can also choose instances with more cores (such as n1-standard-32), if you perform highly-complex compute-intensive analysis. The following links provide additional information about GCP machine type instances and Vertica:

- Machine types : Google Cloud's documentation that describes configuration details for each instance option.
- Supported GCP machine types : Available machine types when deploying Vertica to GCP.
- Eon Mode volume configuration defaults for GCP : Details about Vertica's default volume configurations.

The more powerful instance you choose, the higher the cost per hour. You need to balance whether you want to use fewer, higher-powered but more expensive instances vs. relying on more lower-powered instances that cost less. Thanks to Eon Mode's elasticity, if you choose to use the less-powerful instances, you can always add more nodes to meet peak demands. When you reduce the number of instances to a minimum during off-peak times, you'll spend less than if you had a similar number of more-powerful instances.

Storage options

The MC's deployment wizard also asks you to select the type of local storage for your instances. You can select different options for each type of local storage that Vertica uses: the catalog, the depot, and temporary space. For all of these storage locations, you choose the type of disks to use (standard vs. SSD). You will see the best performance with SSD disks. However, SSD disks cost more.

For the depot, you also choose whether to use local or persistent disks. The local option is faster, as it resides directly on the virtual machine host. However, whenever you shut down the node, this storage is wiped clean. The persistent storage is slower than the local option, as it is not stored directly on the machine hosting the instance. However, it is not wiped out whenever you shut down the instance. See the Google Cloud documentation's Storage options page for more information.

Which of these options you choose depends on how much depot warming the nodes must perform when starting. If the content of your node's depots change little over time (or you tend to frequently start and stop instances), using persistent storage makes sense. In this case, the depot's warming period will be shorter because most of the data the node needs to participate in queries may still be in its depot when it starts. It will perform fewer fetches of data from communal storage while participating in queries.

If your working data set is rapidly changing or you tend to leave nodes stopped for extended periods of time, your best choice is usually to use local storage. In this scenario, the data in the node's depot when it restarts is usually stale. To participate in queries, the node must fetch much of the data it needs from communal storage, resulting in slower performance until it has warmed its depot. Using local ephemeral storage makes sense here, because you will get the benefit of having faster depot storage. Because your nodes have to warm their depots anyhow, there is less of a downside of having the depot on ephemeral storage.

For general guidelines on scaling your cluster for Eon Mode database, see Configuring your Vertica cluster for Eon Mode .

Eon Mode on GCP prerequisites

Before deploying an Eon Mode database on GCP, you must take several steps:

- Review the default service account's permissions for your GCP project.
- Create an HMAC key to use when creating your cluster.
- Create a communal storage location.

Service account permissions

Service accounts allow automated processes to authenticate with GCP. The Eon Mode database deployment process uses the project's service account for your GCP project to deploy instances. When you create a new project, GCP automatically creates a default service account (identified by *project_number* -compute@developer.gserviceaccount.com) for the project and grants it the IAM role Editor. See the Google Cloud documentation's

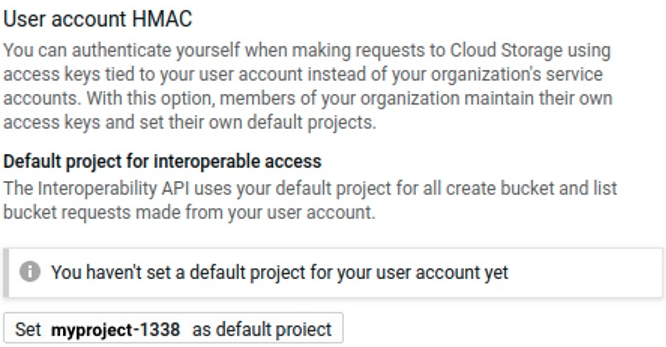
Understanding roles for details about this and other IAM roles.

The Editor role lets the service account create resources from the Marketplace. When you create an instance of the Management Console (MC), the MC uses the account to deploy further resources, such as provisioning instances for an database.

For details, see the Google Cloud documentation's Understanding service accounts page.

Permissions and roles

To deploy Vertica on GCP, your user account must have the:



- **Editor** role.
- runtimeconfig.waiters.getIamPolicy permission.

Creating an HMAC key

Vertica uses a hash-based message authentication code (HMAC) key to authenticate requests to access the communal storage location. This key has two parts: an access ID and a secret. When you create an Eon Mode database in GCP, you provide both parts of an HMAC key for the nodes to use to access communal storage.

To create an HMAC key:

1. Log in to your Google Cloud account.
2. If the name of the project you will use to create your database does not appear in the top banner, click the dropdown and select the correct project.
3. In the navigation menu in the upper-left corner, under the Storage heading, click **Storage** and select **Settings** .
4. In the Settings page, click **Interoperability** .
5. Scroll to the bottom of the page and find the User account HMAC heading.
6. Unless you have already set a default project, you will see the message stating you haven't set a default project for your user account yet. Click the **Set *project-id* as default project** button to choose the current project as your default for interoperability.

> **Note**
> The project ID appears in the button label, not the project name.

7. Under Access keys for your user account, click **Create a key** .
8. Your new access key and secret appear in the HMAC key list. You will need them when you create your Eon Mode database. You can copy them to a handy location (such as a text editor) or leave a browser tab open to this page while you use another tab or window to create your database. These keys remain available on this page, so you do not need to worry about saving them elsewhere.

> **Caution**
> It is vital that you protect the security of your HMAC key. It can grant others access to your Eon Mode database's communal storage location. This means they could access all of the data in your database. Do not write the HMAC key anyplace where it may be exposed, such as email, shared folders, or similar insecure locations.

Creating a communal storage location

Your Eon Mode database needs a storage location for its communal storage. Eon Mode databases running on GCP use Google Cloud Storage (GCS) for their communal storage location. When you create your new Eon Mode database, you will supply the MC's wizard with a GCS URL for the storage location.

This location needs to meet the following criteria:

- The URL must include at least a bucket name. You can use one or more levels of folders, as well. For example, the following GCS URLs are valid:
  - gs://verticabucket/mydatabase
  - gs://verticabucket/databases/mydatabase
  - gs://verticabucket

  Multiple databases can share the same bucket, as long as each has its own folder.
- If provided, the lowest-level folder in the URL must not already exist. For example, in the GCS URL gs://verticabucket/databases/mydatabase , the bucket named verticabucket and the directory named databases must exist. The subdirectory named mydatabase must not exist. The Vertica install process expects to create the final folder itself. If the folder already exists, the installation process fails.

> **Note**
> If you have a communal storage location that already contains data from a previous Eon Mode database that you want to access, use the revive process, rather than installing a new database. See Stopping, starting, terminating, and reviving Eon Mode database clusters for details.

- The permissions on the bucket must be set to allow the service account read, write, and delete privileges on the bucket. The best role to assign to the user to gain these permissions is Storage Object Admin .
- To prevent performance issues, the bucket must be in the same region as all of the nodes running the Eon Mode database.
- If you create the database through the admintools UI, you must set gcsauth as a bootstrap parameter in admintools.conf . For more information on this and other GCP parameters, see Google Cloud Storage parameters .

```
[BootstrapParameters]
gcsauth = ID:secret
```

Deploying an Eon Mode database on GCP

Once you have taken the steps listed in Eon Mode on GCP prerequisites , you are ready to deploy an Eon Mode database in GCP. This process has two steps: deploy a single-node MC instance, then use the MC to provision and deploy a database. The following topics explain these steps.

In this section

- Deploying an MC instance to GCP for Eon Mode
- Using the MC to provision and create an Eon Mode database in GCP

Deploying an MC instance to GCP for Eon Mode

To deploy an MC instance that is able to deploy Eon Mode databases to GCP:

1. Log into your GCP account, if you are not currently logged in.
2. Verify that your user account has the **Editor** role and the runtimeconfig.waiters.getIamPolicy permission.
3. Verify that the name of the GCP project you want to use for the deployment appears in the top banner. If it does not, click the down arrow next to the project name and select the correct project.
4. Click the navigation menu icon in the top left of the page and select **Marketplace** .
5. In the **Search for solutions** box, type Vertica Eon Mode and press enter.
6. Click the search result for Vertica **Data Warehouse,** Eon Mode. There are two license options: by the hour (BTH) and bring your own license (BYOL). See Deploy Vertica from the Google cloud marketplace for more information on this license choice.
7. Click **Launch** on the license option you prefer.
8. On the following page, fill in the fields to configure your MC instance:
   - **Deployment name** identifies your MC deployment in the GCP Deployments page.
   - **Zone** is the location where the virtual machine running your MC instance will be deployed. Make this the same location where your communal storage bucket is located.
   - **Service Account** : Service accounts allow automated processes to authenticate with GCP. Select the default service account, identified by *project_number* -compute@developer.gserviceaccount.com .
   - **Machine Type** is the virtual hardware configuration of the instance that will run the MC. The default values here are "middle of the road" settings which are sufficient for most use cases. If you are doing a small proof-of-concept deployment, you can choose a less powerful instance to save some money. If you are planning on deploying multiple large databases, consider increasing the count of virtual CPUs and RAM.
     For details about Vertica's default volume configurations, see Eon Mode volume configuration defaults for GCP .
   - **User Name for Access to MC** is the administrator username for the MC. You can customize this if you want.
   - **Network** and **Subnetwork** are the virtual private cloud (VPC) network and subnet within that network you want your MC instance and your Vertica nodes to use. This setting does not affect your MC's external network address. If you want to isolate your Vertica cluster from other GCP instances in your project, create a custom VPC network and optionally a subnet in your GCP project and select them in these fields. See

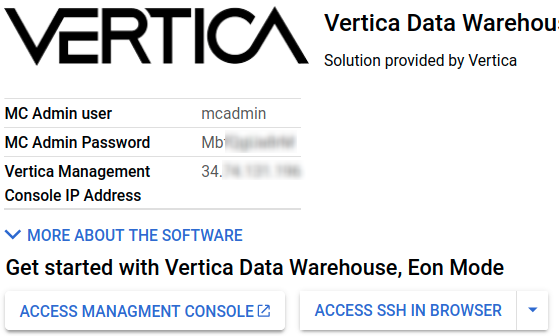
the Google Cloud documentation's VPC network overview page for more information.

- **Firewall** enables access to the MC from the internet by opening port 5450 in the firewall. You can choose to not open this port by clearing the **I accept opening a port in the firewall (5450) for Vertica** box. However, if you do not open the port in the firewall, your MC instance will only be accessible from within the VPC network. Not opening the port will make accessing your MC instance much harder.
- **Source IP ranges for MC traffic** : If you choose to open the MC for external access, add one or more or more CIDR address ranges to this box for network addresses that you want to be able to access to the MC.

> **Caution**
> Make the address ranges as limited as possible to reduce the chances of unauthorized access to your MC instance.

9. Click the **Deploy** button to start the deployment of your MC instance.

The deployment process will take several minutes.



Using a custom service account

In general, you should use the default service account created by the GCP deployment (*project_number* -compute@developer.gserviceaccount.com), but if you want to use a custom service account:

- The custom service account must have the **Editor** role.
- Individual user accounts must have the **Service Account User** role on the custom service account.

Connect and log into the MC instance

After the deployment process is finished, the Deployment Manager page for your MC instance contains links to connect to the MC via your browser or ssh.

To connect to the MC instance:

1. The MC administrator user has a randomly-generated password that you need to log into the MC. Copy the password in the **MC Admin Password** field to the clipboard.
2. Click **Access Management Console** .
3. A new browser tab or window opens, showing you a page titled Redirection Notice. Click the link for the MC URL to continue to the MC login page.
4. Your browser will likely show you a security warning. The MC instance uses a self-signed security certificate. Most browsers treat these certificates as a security hazard because they cannot verify their origin. You can safely ignore this warning and continue. In most browsers, click the **Advanced** button on the warning page, and select the option to proceed. In Chrome, this is a link titled **Proceed to** *xxx.xxx.xxx.xxx* **(unsafe)** . In Firefox, it is a button labeled **Accept the Risk and Continue** .
5. At the login screen, enter the MC administrator user name into the **Username** box. This user name is mcadmin, unless you changed the user name in the MC deployment form.
6. Paste the automatically-generated password you copied from the MC Admin Password field earlier into the **Password** box.
7. Click **Log In** .

Once you have logged into the MC, change the MC administrator account's password.

> **Caution**
> The automatically-generated password appears on the MC instance's deployment page and can be revealed in several locations in the deployment logs. Failure to change this password can lead to unauthorized access to your MC instance.

To change the password:

1. On the home page of the MC, under the MC Tools section, click **MC Settings.**
2. In the left-hand menu, click **User Management** .
3. Select the entry for the MC administrator account and click **Edit** .
4. Click either the **Generate new** or **Edit password** button to change the password. If you click the **Generate new** button, be sure to save the automatically-generated password in a safe location. If you click **Edit password** , you are prompted to enter a new password twice.
5. Click **Save** to update the password.

Now that you have created your MC instance, you are ready to deploy a Vertica Eon Mode cluster. See Using the MC to provision and create an Eon Mode database in GCP .

Using the MC to provision and create an Eon Mode database in GCP

After you deploy an MC instance to GCP, use it to deploy an Eon Mode database.

> **Note**
> Currently, the admintools menu-based interface does not support creating an Eon Mode database on GCP.

To use the MC to provision and deploy a new Eon Mode database on GCP:

1. From the MC home screen, click **Create new database** to launch the Create a Vertica Cluster on Google Cloud wizard.
2. On the first page of the wizard enter the following information:
   - **Google Cloud Storage HMAC Access Key** and **HMAC Secret Key** : Copy and paste the HMAC access key and secret you created earlier. You find these values on the Interoperability tab of the of the Storage Settings page. See Eon Mode on GCP prerequisites for details.
   - **Zone** : This value defaults to the zone containing your MC instance. Make this value the same as the zone containing the Google Cloud Storage bucket that your database will use for communal storage.
   - > **Caution**
     > You will see significant performance issues if you choose different zones for cluster instances, storage, or the MC.
   - **CIDR Range** : The IP address range for clients to whom you want to grant access to your database. Make this range as restrictive as possible to limit access to your database.
3. Click **Next** , and supply the following information:
   - **Vertica Database Name** : the name for your new database. See Creating a database name and password for database name requirements.
   - **Vertica Version** : select the desired Vertica database version. You can select from the latest hotfix of recent Vertica releases. For each database version, you can also select the operating system.
   - **Vertica Database User Name** : the name of the database superuser . This name defaults to dbadmin, but you can enter another user name here.
   - **Password** and **Confirm Password** : Enter a password for the database superuser account.
   - **Database Size** : The number of nodes in your initial database. If you specify more than three nodes here, you must supply a valid Vertica license file in the Vertica License field (below).
   - **Vertica License** : Click **Browse** to locate and upload your Vertica license key file. If you do not supply a license key file here, the wizard deploys your database with a Vertica Community Edition license. This license has a three node limit, so the value in the Database Size filed cannot be larger than 3 if you do not supply a license. If you use a Community Edition license for your deployment, you can upgrade the license later to expand your cluster load more than 1TB of data. See Managing licenses form more information.

     > **Note**
     > This field does not appear if you created your MC instance using a by-the-hour (BTH) launcher. The BTH license is automatically applied to all clusters you create using a BTH MC instance. For a by-the-hour license, cloud vendors charge the customer for licensed Vertica usage along with their cloud infrastructure charges.
   - **Load example data** : Check this box if you want your deployed database to load some example clickstream data. This option is useful if you are testing features and just want some preloaded data in the database to query.
4. Click **Next** and supply the following information:
   - **Instance Type** : the specifications of the virtual machine instances the MC will use to deploy your database nodes. See the Google Cloud documentation's Machine types page for details of each instance type. Also see GCP Eon Mode instance recommendations .

- **Database Depot Path** and **Disk Type** : the local mount point for the depot, and the type and number of local disks dedicated to the depot for each node. You cannot change the mount path for the depot. The disks you select in the **Disk Type** field are only used to store the depot. On the next page of the wizard, you will configure disks for the catalog and temporary disk space. You will see the best performance when using SSD disks, although at a higher cost. You can choose to use faster local storage for your depot. However, local storage is ephemeral—GCP wipes the disk clean whenever you stop the instance. This means each time you start a node, it will have to warm its depot from scratch, rather than taking advantage of any still-current data in its depot. See the Google Cloud documentation's Storage options page for more information about the local disk options.
- **Volume Size** : the amount of disk space available on each disk attached to each node in your cluster. This field shows you the total disk space available per node in your cluster. For the best practices on choosing the amount of disk space for your nodes, see Configuring your Vertica cluster for Eon Mode .
- **Data Segmentation Shards** : sets the number of shards in your database. After you set this value, you cannot change it later. See Configuring your Vertica cluster for Eon Mode for recommendations. The default value is based on the number of nodes you entered in the Database size you specified earlier. It is usually sufficient, unless you anticipate greatly expanding your cluster beyond your initial node count.
- **Communal Location** : a Google Cloud Storage URL that specifies where to store your database's communal data. See Eon Mode on GCP prerequisites for requirements.
- **Instance IP settings** : specify whether the nodes in your database will have static or ephemeral network addresses that are accessible from the internet, or addresses that are only accessible from within the internal virtual network.

5. Click **Next** . The wizard validates your communal storage location URL. If there is an problem with the URL you entered, it displays an error message and prompts you to fix the URL.
   After your communal storage URL passes validation, fill in the following information:
   - **Database Catalog Path** , **Disk Type** , and **Size (GB) per Available Node** : the mount point disk type, and disk size for the local copy of the database catalog on each node. You cannot edit the mount point. You choose the type of local disk to use for the catalog, and its size. You can only choose persistent disk storage for the catalog. SSD drives are faster, but more expensive than standard disks. The default setting for the disk size is adequate for most medium size databases. Increase the size if you anticipate maintaining a large database.
   - **Database Temp Path** , **Disk Type** , and **Size (GB) per Available Node** : the mount point disk type, and disk size for the temporary storage space on each node. You cannot edit the mount point. You choose the type of local disk to use, and its size. You can only choose persistent disk storage for the temporary disk space. SSD drives are faster, but more expensive than standard disks. The default setting is adequate for most databases. Consider increasing the temporary space if you perform many complex merges that spill to disk.
   - **Label Instances** : check this box to enable adding labels to your node's instances. Many organizations use labels to organize, track responsibility, and assign costs for instances. See the Google Cloud documentation's Labeling resources page for more information. If you choose to add labels, enter the label name and value, and click **Add** .
6. Click **Next** . Review the summary of all your database settings. If you need to make a correction, use the Back button to step back to previous pages of the wizard.
7. When you are satisfied with the database settings, check **Accept terms and conditions** and click **Create** .

The process of provisioning and creating the database takes several minutes. After it completes successfully, the MC displays a **Get Started** button. This button leads to a page of useful links for getting started with your new database.

Manually deploying an Enterprise Mode database on GCP

Before you create your Vertica cluster in Google Cloud Platform (GCP) using manual steps, you must create a virtual machine (VM) instance from the Compute Engine section of GCP.

Configure and launch a new instance

All VM instances that you create should be launched in the same virtual public cloud (VPC).

To configure and launch a new VM instance, follow these instructions:

1. From within the Compute Engine section of GCP, from the menu on the left-hand site of the screen, select **VM Instances** .
   GCP displays all the VM instances that you have created so far.
2. Select the **CREATE INSTANCE** link.
3. Enter a name for the new instance.
4. Select the zone where you plan to deploy the instance.
   GCP breaks its cloud data centers down by regions and zones. *Regions* are a collection of zones that are all in the same geographical location. Zones are collections of compute resources, which vary from zone to zone. Always pick the zone in your designated region that supports the latest Intel CPUs.
   For a complete listing of regions and zones, including supported processors, see Regions and Zones .

5. Select a machine type.
   GCE offers many different types of VM instances. For best results, only deploy Vertica on VM instances with 8 vCPus or more and at least 30 GB of RAM.
6. Select the boot disk (image).
   You create VM instances from a public or custom image. If you are starting with Vertica in GCP for the first time, select either the CentOS 7 or RHEL 7 public image. Those images have been tested thoroughly with Vertica.
   For more information about deploying a VM instance, see Creating and Starting an Instance .

After you have configured the VM instance to be used as a Vertica cluster node, GCP allows you to convert that instance into a custom image. Doing so allows you to deploy multiple versions of that VM instance; each VM instance is identical except for the node name and IP address.

For more information about creating a custom image, see Creating, Deleting, and Deprecating Custom Images .

Connect to a virtual machine

Before you can connect to any of the VMs you created, you must first identify the external IP address. The VM instance section of GCP contains a list of all currently deployed VMs and their associated external IP addresses.

Connect to your VM

To connect to your VM, complete the following tasks:

1. Connect to your VM using SSH with the external IP address you created in the configuration steps.
2. Authenticate using the credentials and SSH key that you provided to your GCP account upon creation.

Connect to other VMs

To connect to other virtual machines in your virtual network:

1. Use SSH to connect to your publicly connected VM.
2. Use SSH again from that VM to connect through the private IP addresses of your other VMs.

Because GCP forces the use of private key authentication, you may need to move your key file to the root directory of your publicly connected VM. Then, use SSH to connect to other VMs in your virtual network.

Prepare the virtual machines

After you create your VMs, you need to prepare them for cluster formation.

Add the Vertica license and private key

Prepare your nodes by adding your private key (if you are using one) to each node and to your Vertica license. The following steps assume that the initial user you configured is the DBADMIN user:

1. As the DBADMIN user, copy your private key file from where you saved it locally onto your primary node.
   Depending upon the procedure you use to copy the file, the permissions on the file may change. If permissions change, the install_vertica script fails with a message similar to the following:

   ```
   Failed Login Validation 10.0.2.158, cannot resolve or connect to host as root.
   ```

   If you see the previous failure message, enter the following command to correct permissions on your private key file:

   ```
   $ chmod 600 /<name-of-key>.pem
   ```

2. Copy your Vertica license to your primary VM. Save it in your home directory or other known location.

Install software dependencies for Vertica on GCP

In addition to the Vertica standard package dependencies, as the root user, you must install the following packages before you install Vertica:

- pstack
- mcelog
- sysstat
- dialog

Configure storage

For best disk performance in GCP, Vertica recommends customers use SSD persistent storage, configured to at least 2TB (2000 GB) in size. Disk performance is directly tied to the disk size in GCP. 2000 GBs (2TB) is the minimum disk size for SSD persistent disks that allows maximum throughput.

> **Caution**
> Do not store your information on the root volume, especially in your data and catalog directories. Storing information on the root volume may

result in data loss.

When configuring your storage, make sure to use a supported file system. See Recommended storage format types for details.

Create a swap file

In addition to storage volumes to store your data, Vertica requires a swap volume or swap file for the setup script to complete.

Create a swap file or swap volume of at least 2 GB. The following steps show how to create a swap file within Vertica on GCP:

1. Install the devnull and swapfile files:
```
$ install -o root -g root -m 0600 /dev/null /swapfile
```
2. Create the swap file:
```
$ dd if=/dev/zero of=/swapfile bs=1024 count=2048k
```
3. Prepare the swap file using mkswap :
```
$ mkswap /swapfile
```
4. Use swapon to instruct Linux to swap on the swap file:
```
$ swapon /swapfile
```
5. Persist the swapfile in FSTAB:
```
$ echo "/swapfile swap swap auto 0 0" >> /etc/fstab
```
6. Repeat the volume attachment, combination, and swap file creation procedures for each VM in your cluster.

Download Vertica

To download the Vertica server appropriate for your operating system and license type, follow the steps in described in Download and install the Vertica server package .

After you complete the download and extraction, use the install_vertica script to form a cluster and install the Vertica database software, as described in the next section.

Form a cluster and install Vertica

Use the install_vertica script to combine two or more individual VMs to form a cluster and install your Vertica database.

Before you run the install_vertica script, follow these steps:

1. Check the **VM Instances** page of the Compute Engine section on GCP to locate a list of current VMs and their associated internal IP addresses.
2. Identify your storage location on your VMs. The installer assumes that you have mounted your storage to /home/dbadmin . To specify another location, use the --data-dir argument.

Caution

Do not store your data on the root drive.

The following steps show how to combine virtual machines (VMs) into a cluster using the install_vertica script:

1. While connected to your primary node, construct the following command to combine your nodes into a cluster.
```
$ sudo /opt/vertica/sbin/install_vertica --hosts 10.2.0.164,10.2.0.165,10.2.0.166 --dba-user-password-disabled --point-to-point --data-dir /vertica/data --ssh-identity ~/.pem --license
```
2. Substitute the IP addresses for your VMs, and include your root key file name, if applicable.
3. Include the --point-to-point parameter to configure spread to use direct point-to-point communication among all Vertica nodes, as required for clusters on GCP when installing or updating Vertica.
4. If you are using Vertica Community Edition, which limits you to three nodes, specify -L CE with no license file.
5. After you combine your nodes, to reduce security risks, keep your key file in a secure place—separate from your cluster—and delete your on-cluster key with the shred command:
```
$ shred examplekey.pem
```

Important

You need your key file to perform future Vertica updates.

For complete information about the install_vertica script and its parameters, see Installing Vertica with the installation script .

After your cluster is up and running

Now that your cluster is configured and running, and Vertica is running, take these steps:

1. Create a database. See Creating a database for details.
2. When you installed Vertica, a database administrator user was created with the DBADMIN role (usually named dbadmin). Use this account to create and start a database.
3. See Configuring the database for important database configuration steps.

Moving a cloud installation from by the hour (BTH) to bring your own license (BYOL)

Vertica offers two licensing options for some of the entries in the Amazon Web Services Marketplace and Google Cloud Marketplace:

- **Bring Your Own License (BYOL)** : a long-term license that you obtain through an online licensing portal . These deployments also work with a free Community Edition license. Vertica uses a community license automatically if you do not install a license that you purchased. (For more about Vertica licenses, see Managing licenses and Understanding Vertica licenses .)
- Vertica **by the Hour (BTH)** : a pay-as-you-go environment where you are charged an hourly fee for both the use of Vertica and the cost of the instances it runs on. The Vertica by the hour deployment offers an alternative to purchasing a term license. If you want to crunch large volumes of data within a short period of time, this option might work better for you. The BTH license is automatically applied to all clusters you create using a BTH MC instance.

If you start out with an hourly license, you can later decide to use a long-term license for your database. The support for an hourly versus a long-term license is built into the instances running your database. To move your database from an hourly license to a long-term license, you must create a new database cluster with a new set of instances.

To move from an hourly to a long-term license, follow these steps:

1. Purchase a BYOL license. Follow the process described in Obtaining a license key file .
2. Apply the new license to your database.
3. Shut down your database.
4. Create a new database cluster using a BYOL marketplace entry.
5. Revive your database onto the new cluster.

The exact steps you must take depend on your database mode and your preferred tool for managing your database:

- **Eon Mode databases:** Use either the command line or Management Console .
- **Enterprise Mode databases:** Use the command line to switch licenses.

Moving an Eon Mode database from BTH to BYOL using the command line

Follow these steps to move an Eon Mode database from an hourly to a long-term license.

Obtain a long-term BYOL license from the online licensing portal, described in Obtaining a license key file .Upload the license file to a node in your database. Note the absolute path in the node's filesystem, as you will need this later when installing the license.Connect to the node you uploaded the license file to in the previous step. Connect to your database using vsql and view the licenses table:

```
=> SELECT * FROM licenses;
```

Note the name of the hourly license listed in the NAME column, so you can check if it is still present later.

Install the license in the database using the INSTALL_LICENSE function with the absolute path to the license file you uploaded in step 2:

```
=> SELECT install_license('absolute path to BYOL license');
```

View the licenses table again:

```
=> SELECT * FROM licenses;
```

If only the new BYOL license appears in the table, skip to step 8. If the hourly license whose name you noted in step 4 is still in the table, copy the name and proceed to step 7.

Call the DROP_LICENSE function to drop the hourly license:

```
=> SELECT drop_license('hourly license name');
```

1. You will need the path for your cluster's communal storage in a later step. If you do not already know the path, you can find this information by executing this query:

```
=> SELECT location_path FROM V_CATALOG.STORAGE_LOCATIONS
  WHERE sharing_type = 'COMMUNAL';
```

2. Synchronize your database's metadata. See Synchronizing metadata .
3. Shut down the database by calling the SHUTDOWN function:

```
=> SELECT SHUTDOWN();
```

4. You now need to create a new BYOL cluster onto which you will revive your database. Deploy a new cluster including a new MC instance using a BYOL entry in the marketplace of your chosen cloud platform. See:
   - Launch MC and AWS resources with a CloudFormation template
   - Deploying an Eon Mode database on GCP

   Important
   Your new BYOL cluster must have the same number of primary nodes as your existing hourly license cluster.

5. Revive your database onto the new cluster. For instructions, see Reviving an Eon Mode database cluster . Because you created the new cluster using a BYOL entry in the marketplace, the database uses the BYOL you applied earlier.
6. After reviving the database on your new BYOL cluster, terminate the instances for your hourly license cluster and MC. For instructions, see your cloud provider's documentation.

Moving an Eon Mode database from BTH to BYOL using the MC

Follow this procedure to move to BYOL and revive your database using MC:

1. Purchase a long-term BYOL license from the online licensing portal, following the steps detailed in Obtaining a license key file . Save the file to a location on your computer.
2. You now need to install the new license on your database. Log into MC and click your database in the Recent Databases list.
3. At the bottom of your database's Overview page, click the **License** tab.
4. Under the Installed Licenses list, note the name of the BTH license in the License Name column. You will need this later to check whether it is still present after installing the new long-term license.
5. In the ribbon at the top of the License History page, click the **Install New License** button. The Settings: License page opens.
6. Click the **Browse** button next to the **Upload a new license box** .
7. Locate the license file you obtained in step 1, and click **Open** .
8. Click the **Apply** button on the top right of the page.
9. Select the checkbox to agree to the EULA terms and click **OK** .
10. After Vertica installs the license, click the **Close** button.
11. Click the **License** tab at the bottom of the page.
12. If only the new long-term license appears in the **Installed Licenses** list, skip to Step 16. If the by-the-hour license also appears in the list, copy down its name from the **License Name** column.
13. You must drop the by-the-hour license before you can proceed. At the bottom of the page, click the **Query Execution** tab.
14. In the query editor, enter the following statement:

```
SELECT DROP_LICENSE('hourly license name');
```

15. Click **Execute Query** . The query should complete indicating that the license has been dropped.
16. You will need the path for your cluster's communal storage in a later step. If you do not already know the path, you can find this information by executing this query in the Query Execution tab:

```
SELECT location_path FROM V_CATALOG.STORAGE_LOCATIONS
  WHERE sharing_type = 'COMMUNAL';
```

17. Synchronize your database's metadata. See Synchronizing metadata .
18. You must now stop your by-the-hour database cluster. At the bottom of the page, click the **Manage** tab.
19. In the banner at the top of the page, click **Stop Database** and then click **OK** to confirm.
20. From the Amazon Web Services Marketplace or the Google Cloud Marketplace , deploy a new Vertica Management Console using a BYOL entry. Do not deploy a full cluster. You just need an MC deployment.
21. Log into your new MC instance and revive the database. See Reviving an Eon Mode database on AWS in MC for detailed instructions.
22. After reviving the database on your new environment, terminate the instances for your hourly license environment. To do so, on the AWS CloudFormation Stacks page , select the hourly environment's stack (its collection of AWS resources) and click **Actions** > **Delete Stack** .

Moving an Enterprise Mode database from hourly to BYOL using backup and restore

> **Note**
> Currently, AWS is the only platform supported for Enterprise Mode databases using hourly licenses.

In an Enterprise Mode database, follow this procedure to move to BYOL, and then back up and restore your database:

Obtain a long-term BYOL license from the online licensing portal, described in Obtaining a license key file .Upload the license file to a node in your database. Note the absolute path in the node's filesystem, as you will need this later when installing the license.Connect to the node you uploaded the license file to in the previous step. Connect to your database using vsql and view the licenses table:

```
=> SELECT * FROM licenses;
```

Note the name of the hourly license listed in the NAME column, so you can check if it is still present later.

Install the license in the database using the INSTALL_LICENSE function with the absolute path to the license file you uploaded in step 2:

```
=> SELECT install_license('absolute path to BYOL license');
```

View the licenses table again:

```
=> SELECT * FROM licenses;
```

If only the new BYOL license appears in the table, skip to step 8. If the hourly license whose name you noted in step 4 is still in the table, copy the name and proceed to step 7.

Call the DROP_LICENSE function to drop the hourly license:

```
=> SELECT drop_license('hourly license name');
```

1. Back up the database. See Backing up and restoring the database .
2. Deploy a new cluster for your database using one of the BYOL entries in the Amazon Web Services Marketplace .
3. Restore the database from the backup you created earlier. See Backing up and restoring the database . When you restore the database, it will use the BYOL you loaded earlier.
4. After restoring the database on your new environment, terminate the instances for your hourly license environment. To do so, on the AWS CloudFormation Stacks page , select the hourly environment's stack (its collection of AWS resources) and click **Actions** > **Delete Stack** .

After completing one of these procedures, see Viewing your license status to confirm the license drop and install were successful.

Adjusting Spread Daemon timeouts for virtual environments

You may see Vertica nodes leave the database even though they are still running. This issue can happen on networks that are prone to spikes in latency or in virtual environments where a node's VM may be paused for a short period of time. You can adjust a setting in Vertica to help prevent this issue from occurring.

Vertica relies on spread daemons to pass messages between database nodes. When a node fails to respond to a spread message after a timeout period, Vertica assumes the node is down and starts to remove it from the database.

The default Spread timeout depends on the number of configured Spread segments:

Configured Spread segments	Default timeout
1	8 seconds
> 1	25 seconds

If network delays or temporary pauses of a VM last longer than the spread timeout period, you may see UP nodes leave the database. In these cases, you can increase the spread timeout to reduce or eliminate instances where UP nodes leave the database.

Azure's memory-preserving updates and spread timeouts

In Azure, you might see running nodes leave the database due to scheduled maintenance. Azure's maintenance down time is usually well-defined. For example, Azure's memory-preserving updates can pause a VM for up to 30 seconds while performing maintenance on the system hosting the VM. This pause does not disrupt the node. It continues normal operation once Azure resumes it. See the Azure documentation's topic on Maintenance for virtual machines in Azure for more information about updates. If Azure pauses a node for longer than the spread timeout period, Vertica interprets the node's inability to respond to a spread message as the node going down, even though it will resume running normally.

> **Note**
> If you deploy your Vertica cluster using the Azure Marketplace, the spread timeout defaults to 35 seconds. If you manually create your cluster in Azure, the spread timeout defaults to 8 or 25 seconds, as described earlier.

Setting the spread timeout

When you know your network or nodes may be unable to respond for a specific amount of time, you can increase the spread timeout period to longer than this time. Adjust the timeout to the period of time the node may be unable to respond, plus an additional 5 seconds as a safety margin.

For example, if you know Azure's memory-preserving maintenance can pause your VMs for up to 30 seconds, set the spread timeout to 35 seconds.

If you do not know exactly how long network or node disruptions can last, you can try increasing the spread timeout gradually, until you see reduced instances of UP nodes leaving the database. Be as conservative with this setting as you can.

Important
Vertica cannot react to a node going down or being shut down improperly before the timeout period has elapsed. Changing spread's timeout to a value too high can result in longer query restarts if a node goes down.

You can see the current setting of the spread timeout by querying system table SPREAD_STATE :

```
=> SELECT * FROM V_MONITOR.SPREAD_STATE;
    node_name     | token_timeout
------------------+---------------
 v_vmart_node0003 |          8000
 v_vmart_node0001 |          8000
 v_vmart_node0002 |          8000
(3 rows)
```

You change the spread timeout calling the meta-function SET_SPREAD_OPTION to set the token timeout to a new value. This value is a string, and sets the timeout in milliseconds.

Important
Changing spread settings with SET_SPREAD_OPTION has minor impact on your cluster as it pauses while the new settings are propagated across the entire cluster.

This example sets the timeout to 35 seconds (35000ms):

```
=> SELECT SET_SPREAD_OPTION( 'TokenTimeout', '35000');
NOTICE 9003:  Spread has been notified about the change
                SET_SPREAD_OPTION
-------------------------------------------------------
 Spread option 'TokenTimeout' has been set to '35000'.

(1 row)

=> SELECT * FROM V_MONITOR.SPREAD_STATE;
    node_name     | token_timeout
------------------+---------------
 v_vmart_node0001 |         35000
 v_vmart_node0002 |         35000
 v_vmart_node0003 |         35000
(3 rows);
```

Note
The changes you make to the spread timeout might not take effect immediately. It might take some time before you see the settings change in system table V_MONITOR.SPREAD_STATE table.

Apache Hadoop integration

Apache™ Hadoop™, like Vertica, uses a cluster of nodes for distributed processing. The primary component of interest is HDFS, the Hadoop Distributed File System.

You can use Vertica with HDFS in several ways:

- You can import HDFS data into locally-stored ROS files.
- You can access HDFS data in place using external tables. You can define the tables yourself or get schema information from Hive, a Hadoop component.
- You can use HDFS as a storage location for ROS files.
- You can export data from Vertica to share with other Hadoop components using a Hadoop columnar format. See File export for more information.

Hadoop file paths are expressed as URLs in the webhdfs or hdfs URL scheme. For more about using these schemes, see HDFS file system .

Hadoop distributions

Vertica can be used with Hadoop distributions from Hortonworks, Cloudera, and MapR. See Hadoop integrations for the specific versions that are supported.

If you are using Cloudera, you can manage your Vertica cluster using Cloudera Manager. See Integrating with Cloudera Manager .

If you are using MapR, see Integrating Vertica with the MapR distribution of Hadoop .

WebHDFS requirement

By default, if you use a URL in the hdfs scheme, Vertica uses the (deprecated) Libhdfs++ library instead of WebHDFS. However, it falls back to WebHDFS for features not available in Libhdfs++, such as encryption zones, wire encryption, or writes. Even if you always use URLs in the hdfs scheme to choose Libhdfs++, you must still have a WebHDFS service available to handle these fallback cases. In addition, for some uses, such as Eon Mode communal storage, you must use WebHDFS directly with the webhdfs scheme.

> **Deprecated**
> Support for LibHDFS++ is deprecated. In the future, URLs in the hdfs scheme will be automatically converted to the webhdfs scheme. To make this change in your database, set the HDFSUseWebHDFS configuration parameter to 1 (enabled).

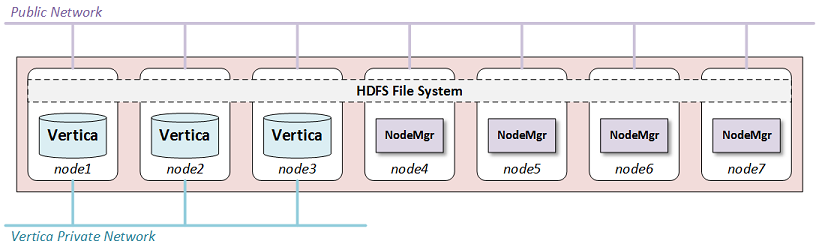
In this section

- Cluster layout
- Configuring HDFS access
- Accessing kerberized HDFS data
- Using HDFS storage locations
- Using the HCatalog Connector
- Integrating with Cloudera Manager
- Integrating Vertica with the MapR distribution of Hadoop

Cluster layout

Vertica supports two cluster architectures for Hadoop integration. Which architecture you use affects the decisions you make about integration with HDFS. These options might also be limited by license terms.

- You can co-locate Vertica on some or all of your Hadoop nodes. Vertica can then take advantage of data locality.
- You can build a Vertica cluster that is separate from your Hadoop cluster. In this configuration, Vertica can fully use each of its nodes; it does not share resources with Hadoop.



With either architecture, if you are using the hdfs scheme to read ORC or Parquet files, you must do some additional configuration. See Configuring HDFS access .

In this section

- Co-located clusters
- Configuring Hadoop for co-located clusters
- Configuring rack locality
- Separate clusters

Co-located clusters

With co-located clusters, Vertica is installed on some or all of your Hadoop nodes. The Vertica nodes use a private network in addition to the public network used by all Hadoop nodes, as the following figure shows:

You might choose to place Vertica on all of your Hadoop nodes or only on some of them. If you are using HDFS Storage Locations you should use at least three Vertica nodes, the minimum number for K-safety in an Enterprise Mode database .

Using more Vertica nodes can improve performance because the HDFS data needed by a query is more likely to be local to the node.

You can place Hadoop and Vertica clusters within a single rack, or you can span across many racks and nodes. If you do not co-locate Vertica on every node, you can improve performance by co-locating it on at least one node in each rack. See Configuring rack locality .

Normally, both Hadoop and Vertica use the entire node. Because this configuration uses shared nodes, you must address potential resource contention in your configuration on those nodes. See Configuring Hadoop for co-located clusters for more information. No changes are needed on Hadoop-only nodes.

Hardware recommendations

Hadoop clusters frequently do not have identical provisioning requirements or hardware configurations. However, Vertica nodes should be equivalent in size and capability, per the best-practice standards recommended in General hardware and OS requirements and recommendations .

Because Hadoop cluster specifications do not always meet these standards, Vertica recommends the following specifications for Vertica nodes in your Hadoop cluster.

Specifications for…	**Recommendation**
Processor	For best performance, run: • Two-socket servers with 8–14 core CPUs, clocked at or above 2.6 GHz for clusters over 10 TB • Single-socket servers with 8–12 cores clocked at or above 2.6 GHz for clusters under 10 TB
Memory	Distribute the memory appropriately across all memory channels in the server: • **Minimum** —8 GB of memory per physical CPU core in the server • **High-performance applications** —12–16 GB of memory per physical core • **Type** —at least DDR3-1600, preferably DDR3-1866
Storage	Read/write: • **Minimum** —40 MB/s per physical core of the CPU • **For best performance** —60–80 MB/s per physical core Storage post RAID: Each node should have 1–9 TB. For a production setting, Vertica recommends RAID 10. In some cases, RAID 50 is acceptable. Because Vertica performs heavy compression and encoding, SSDs are not required. In most cases, a RAID of more, less-expensive HDDs performs just as well as a RAID of fewer SSDs. If you intend to use RAID 50 for your data partition, you should keep a spare node in every rack, allowing for manual failover of a Vertica node in the case of a drive failure. A Vertica node recovery is faster than a RAID 50 rebuild. Also, be sure to never put more than 10 TB compressed on any node, to keep node recovery times at an acceptable rate.

Network	10 GB networking in almost every case. With the introduction of 10 GB over cat6a (Ethernet), the cost difference is minimal.

Configuring Hadoop for co-located clusters

If you are co-locating Vertica on any HDFS nodes, there are some additional configuration requirements.

Hadoop configuration parameters

For best performance, set the following parameters with the specified minimum values:

Parameter	Minimum Value
HDFS block size	512MB
Namenode Java Heap	1GB
Datanode Java Heap	2GB

WebHDFS

Hadoop has two services that can provide web access to HDFS:

- WebHDFS
- httpFS

For Vertica, you must use the WebHDFS service.

YARN

The YARN service is available in newer releases of Hadoop. It performs resource management for Hadoop clusters. When co-locating Vertica on YARN-managed Hadoop nodes you must make some changes in YARN.

Vertica recommends reserving at least 16GB of memory for Vertica on shared nodes. Reserving more will improve performance. How you do this depends on your Hadoop distribution:

- If you are using Hortonworks, create a "Vertica" node label and assign this to the nodes that are running Vertica.
- If you are using Cloudera, enable and configure static service pools.

Consult the documentation for your Hadoop distribution for details. Alternatively, you can disable YARN on the shared nodes.

Hadoop balancer

The Hadoop Balancer can redistribute data blocks across HDFS. For many Hadoop services, this feature is useful. However, for Vertica this can reduce performance under some conditions.

If you are using HDFS storage locations, the Hadoop load balancer can move data away from the Vertica nodes that are operating on it, degrading performance. This behavior can also occur when reading ORC or Parquet files if Vertica is not running on all Hadoop nodes. (If you are using separate Vertica and Hadoop clusters, all Hadoop access is over the network, and the performance cost is less noticeable.)

To prevent the undesired movement of data blocks across the HDFS cluster, consider excluding Vertica nodes from rebalancing. See the Hadoop documentation to learn how to do this.

Replication factor

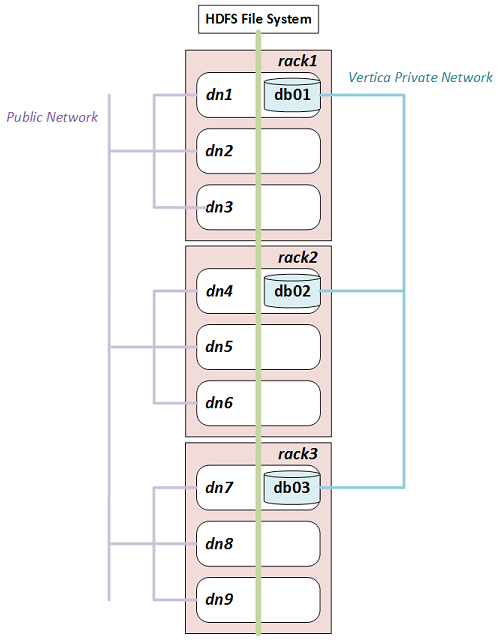
By default, HDFS stores three copies of each data block. Vertica is generally set up to store two copies of each data item through K-Safety. Thus, lowering the replication factor to 2 can save space and still provide data protection.

To lower the number of copies HDFS stores, set HadoopFSReplication, as explained in Troubleshooting HDFS storage locations .

Disk space for Non-HDFS use

You also need to reserve some disk space for non-HDFS use. To reserve disk space using Ambari, set dfs.datanode.du.reserved to a value in the hdfs-site.xml configuration file.

Setting this parameter preserves space for non-HDFS files that Vertica requires.



Configuring rack locality

Note
This feature is supported only for reading ORC and Parquet data on co-located clusters. It is only meaningful on Hadoop clusters that span multiple racks.

When possible, when planning a query Vertica automatically uses database nodes that are co-located with the HDFS nodes that contain the data. Moving query execution closer to the data reduces network latency and can improve performance. This behavior, called node locality, requires no additional configuration.

When Vertica is co-located on only a subset of HDFS nodes, sometimes there is no database node that is co-located with the data. However, performance is usually better if a query uses a database node in the same rack. If configured with information about Hadoop rack structure, Vertica attempts to use a database node in the same rack as the data to be queried.

For example, the following diagram illustrates a Hadoop cluster with three racks each containing three data nodes. (Typical production systems have more data nodes per rack.) In each rack, Vertica is co-located on one node.

If you configure rack locality, Vertica uses db01 to query data on dn1, dn2, or dn3, and uses db02 and db03 for data on rack2 and rack3 respectively. Because HDFS replicates data, any given data block can exist in more than one rack. If a data block is replicated on dn2, dn3, and dn6, for example, Vertica uses either db01 or db02 to query it.

Hadoop components are rack-aware, so configuration files describing rack structure already exist in the Hadoop cluster. To use this information in Vertica, configure fault groups that describe this rack structure. Vertica uses fault groups in query planning.

Configuring fault groups

Vertica uses Fault groups to describe physical cluster layout. Because your database nodes are co-located on HDFS nodes, Vertica can use the information about the physical layout of the HDFS cluster.

Tip
For best results, ensure that each Hadoop rack contains at least one co-located Vertica node.

Hadoop stores its cluster-layout data in a topology mapping file in HADOOP_CONF_DIR. On HortonWorks the file is typically named topology_mappings.data. On Cloudera it is typically named topology.map. Use the data in this file to create an input file for the fault-group script. For more information about the format of this file, see Creating a fault group input file .

Following is an example topology mapping file for the cluster illustrated previously:

```
[network_topology]
dn1.example.com=/rack1
10.20.41.51=/rack1
dn2.example.com=/rack1
10.20.41.52=/rack1
dn3.example.com=/rack1
10.20.41.53=/rack1
dn4.example.com=/rack2
10.20.41.71=/rack2
dn5.example.com=/rack2
10.20.41.72=/rack2
dn6.example.com=/rack2
10.20.41.73=/rack2
dn7.example.com=/rack3
10.20.41.91=/rack3
dn8.example.com=/rack3
10.20.41.92=/rack3
dn9.example.com=/rack3
10.20.41.93=/rack3
```

From this data, you can create the following input file describing the Vertica subset of this cluster:

```
/rack1 /rack2 /rack3
/rack1 = db01
/rack2 = db02
/rack3 = db03
```

This input file tells Vertica that the database node "db01" is on rack1, "db02" is on rack2, and "db03" is on rack3. In creating this file, ignore Hadoop data nodes that are not also Vertica nodes.

After you create the input file, run the fault-group tool:

```
$ python /opt/vertica/scripts/fault_group_ddl_generator.py dbName input_file > fault_group_ddl.sql
```

The output of this script is a SQL file that creates the fault groups. Execute it following the instructions in Creating fault groups .

You can review the new fault groups with the following statement:

```
=> SELECT member_name,node_address,parent_name FROM fault_groups
INNER JOIN nodes ON member_name=node_name ORDER BY parent_name;

 member_name  | node_address  | parent_name
--------------------------+--------------+-------------
db01          | 10.20.41.51   | /rack1
db02          | 10.20.41.71   | /rack2
db03          | 10.20.41.91   | /rack3

(3 rows)
```

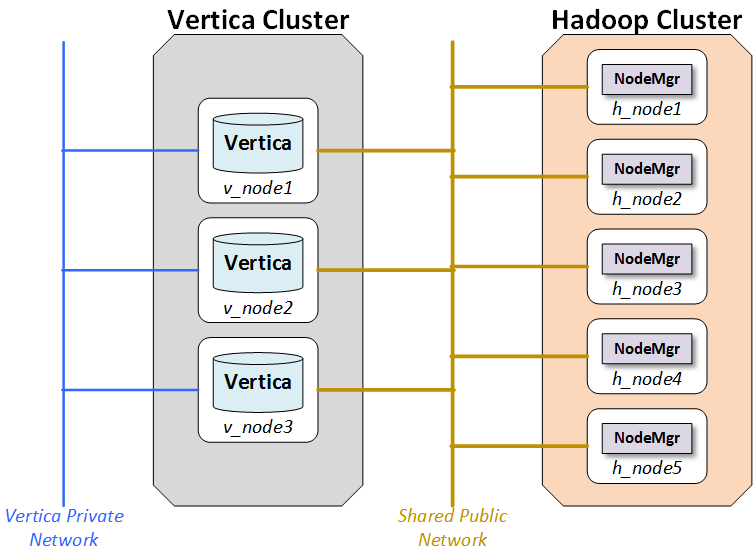
Working with multi-level racks

A Hadoop cluster can use multi-level racks. For example, /west/rack-w1, /west/rack-2, and /west/rack-w3 might be served from one data center, while /east/rack-e1, /east/rack-e2, and /east/rack-e3 are served from another. Use the following format for entries in the input file for the fault-group script:

```
/west /east
/west = /rack-w1 /rack-w2 /rack-w3
/east = /rack-e1 /rack-e2 /rack-e3
/rack-w1 = db01
/rack-w2 = db02
/rack-w3 = db03
/rack-e1 = db04
/rack-e2 = db05
/rack-e3 = db06
```

Do not create entries using the full rack path, such as /west/rack-w1.

Auditing results



To see how much data can be loaded with rack locality, use EXPLAIN with the query and look for statements like the following in the output:

```
100% of ORC data including co-located data can be loaded with rack locality.
```

Separate clusters

With separate clusters, a Vertica cluster and a Hadoop cluster share no nodes. You should use a high-bandwidth network connection between the two clusters.

The following figure illustrates the configuration for separate clusters::

Network

The network is a key performance component of any well-configured cluster. When Vertica stores data to HDFS it writes and reads data across the network.

The layout shown in the figure calls for two networks, and there are benefits to adding a third:

- Database Private Network: Vertica uses a private network for command and control and moving data between nodes in support of its database functions. In some networks, the command and control and passing of data are split across two networks.
- Database/Hadoop Shared Network: Each Vertica node must be able to connect to each Hadoop data node and the NameNode. Hadoop best practices generally require a dedicated network for the Hadoop cluster. This is not a technical requirement, but a dedicated network improves Hadoop performance. Vertica and Hadoop should share the dedicated Hadoop network.
- Optional Client Network: Outside clients may access the clustered networks through a client network. This is not an absolute requirement, but the use of a third network that supports client connections to either Vertica or Hadoop can improve performance. If the configuration does not support a client network, than client connections should use the shared network.

Hadoop configuration parameters

For best performance, set the following parameters with the specified minimum values:

Parameter	Minimum Value
HDFS block size	512MB
Namenode Java Heap	1GB
Datanode Java Heap	2GB

Configuring HDFS access

Vertica uses information from the Hadoop cluster configuration to support reading data (COPY or external tables). In Eon Mode, it also uses this information to access communal storage on HDFS. Vertica nodes therefore must have access to certain Hadoop configuration files.

For both co-located and separate clusters that use Kerberos authentication, configure Vertica for Kerberos as explained in Configure Vertica for Kerberos Authentication .

Vertica requires access to the WebHDFS service and ports on all name nodes and data nodes. For more information about WebHDFS ports, see HDFS Ports in the Cloudera documentation .

Accessing Hadoop configuration files

Your Vertica nodes need access to certain Hadoop configuration files:

- If Vertica is co-located on HDFS nodes, then those configuration files are already present.
- If Vertica is running on a separate cluster, you must copy the required files to all database nodes. A simple way to do so is to configure your Vertica nodes as Hadoop edge nodes. Client applications run on *edge nodes* ; from Hadoop's perspective, Vertica is a client application. You can use Ambari or Cloudera Manager to configure edge nodes. For more information, see the documentation from your Hadoop vendor.

Verify that the value of the HadoopConfDir configuration parameter (see Apache Hadoop parameters) includes a directory containing the core-site.xml and hdfs-site.xml files. If you do not set a value, Vertica looks for the files in /etc/hadoop/conf. For all Vertica users, the directory is accessed by the Linux user under which the Vertica server process runs.

Vertica uses several properties defined in these configuration files. These properties are listed in HDFS file system .

Using a cluster with high availability NameNodes

If your Hadoop cluster uses High Availability (HA) Name Nodes, verify that the dfs.nameservices parameter and the individual name nodes are defined in hdfs-site.xml .

Using more than one Hadoop cluster

In some cases, a Vertica cluster requires access to more than one HDFS cluster. For example, your business might use separate HDFS clusters for separate regions, or you might need data from both test and deployment clusters.

To support multiple clusters, perform the following steps:

1. Copy the configuration files from all HDFS clusters to your database nodes. You can place the copied files in any location readable by Vertica. However, as a best practice, you should place them all in the same directory tree, with one subdirectory per HDFS cluster. The locations must be the same on all database nodes.
2. Set the HadoopConfDir configuration parameter. The value is a colon-separated path containing the directories for all of your HDFS clusters.
3. Use an explicit name node or name service in the URL when creating an external table or copying data. Do not use hdfs:/// because it could be ambiguous. For more information about URLs, see HDFS file system .

Vertica connects directly to a name node or name service; it does not otherwise distinguish among HDFS clusters. Therefore, names of HDFS name nodes and name services must be globally unique.

Verifying the configuration

Use the VERIFY_HADOOP_CONF_DIR function to verify that Vertica can find configuration files in HadoopConfDir.

Use the HDFS_CLUSTER_CONFIG_CHECK function to test access through the hdfs scheme.

For more information about testing your configuration, see Verifying HDFS configuration .

Updating configuration files

If you update the configuration files after starting Vertica, use the following statement to refresh them:

```
=> SELECT CLEAR_HDFS_CACHES();
```

The CLEAR_HDFS_CACHES function also flushes information about which name node is active in a High Availability (HA) Hadoop cluster. Therefore, the first request after calling this function is slow, because the initial connection to the name node can take more than 15 seconds.

In this section

- Verifying HDFS configuration
- Troubleshooting reads from HDFS

Verifying HDFS configuration

Use the EXTERNAL_CONFIG_CHECK function to test access to HDFS. This function calls several others. If you prefer to test individual components, or if some tests do not apply to your configuration, you can instead call the functions individually. For example, if you are not using the HCatalog Connector then you do not need to call that function. The functions are:

- KERBEROS_CONFIG_CHECK : tests the Vertica keytab and the user's Kerberos credential.
- HADOOP_IMPERSONATION_CONFIG_CHECK : shows the delegation tokens that are in use. This function does not test them.
- HDFS_CLUSTER_CONFIG_CHECK : tests access to the HDFS clusters found in HadoopConfDir, including using Kerberos and impersonation (delegation tokens).
- HCATALOGCONNECTOR_CONFIG_CHECK : tests HCatalog Connector access to HiveServer2.

To run all tests, call EXTERNAL_CONFIG_CHECK with no arguments:

```
=> SELECT EXTERNAL_CONFIG_CHECK();
```

To test only some authorities, nameservices, or Hive schemas, pass a single string argument. The format is a comma-separated list of "key=value" pairs, where keys are "authority", "nameservice", and "schema". The value is passed to all of the sub-functions; see those reference pages for details on how values are interpreted.

The following example tests the configuration of only the nameservice named "ns1":

```
=> SELECT EXTERNAL_CONFIG_CHECK('nameservice=ns1');
```

Troubleshooting reads from HDFS

You might encounter the following issues when accessing data in HDFS.

Queries using [web]hdfs:/// show unexpected results

If you are using the /// shorthand to query external tables and see unexpected results, such as production data in your test cluster, verify that HadoopConfDir is set to the value you expect. The HadoopConfDir configuration parameter defines a path to search for the Hadoop configuration files that Vertica needs to resolve file locations. The HadoopConfDir parameter can be set at the session level, overriding the permanent value set in the database.

To debug problems with /// URLs, try replacing the URLs with ones that use an explicit nameservice or name node. If the explicit URL works, then the problem is with the resolution of the shorthand. If the explicit URL also does not work as expected, then the problem is elsewhere (such as your nameservice).

Queries take a long time to run when using HA

The High Availability Name Node feature in HDFS allows a name node to fail over to a standby name node. The dfs.client.failover.max.attempts configuration parameter (in hdfs-site.xml) specifies how many attempts to make when failing over. Vertica uses a default value of 4 if this parameter is not set. After reaching the maximum number of failover attempts, Vertica concludes that the HDFS cluster is unavailable and aborts the operation. Vertica uses the dfs.client.failover.sleep.base.millis and dfs.client.failover.sleep.max.millis parameters to decide how long to wait between retries. Typical ranges are 500 milliseconds to 15 seconds, with longer waits for successive retries.

A second parameter, ipc.client.connect.retry.interval , specifies the time to wait between attempts, with typical values being 10 to 20 seconds.

Cloudera and Hortonworks both provide tools to automatically generate configuration files. These tools can set the maximum number of failover attempts to a much higher number (50 or 100). If the HDFS cluster is unavailable (all name nodes are unreachable), Vertica can appear to hang for an extended period (minutes to hours) while trying to connect.

Failover attempts are logged in the QUERY_EVENTS system table. The following example shows how to query this table to find these events:

```
=> SELECT event_category, event_type, event_description, operator_name,
   event_details, count(event_type) AS count
   FROM query_events
   WHERE event_type ilike 'WEBHDFS FAILOVER RETRY'
   GROUP BY event_category, event_type, event_description, operator_name, event_details;
-[ RECORD 1 ]-----+---------------------------------------
event_category    | EXECUTION
event_type        | WEBHDFS FAILOVER RETRY
event_description | WebHDFS Namenode failover and retry.
operator_name     | WebHDFS FileSystem
event_details     | WebHDFS request failed on ns
count             | 4
```

You can either wait for Vertica to complete or abort the connection, or set the dfs.client.failover.max.attempts parameter to a lower value.

WebHDFS error when using LibHDFS++

When creating an external table or loading data and using the hdfs scheme, you might see errors from WebHDFS failures. Such errors indicate that Vertica was not able to use the hdfs scheme and fell back to webhdfs , but that the WebHDFS configuration is incorrect.

First verify the value of the HadoopConfDir configuration parameter, which can be set at the session level. Then verify that the HDFS configuration files found there have the correct WebHDFS configuration for your Hadoop cluster. See Configuring HDFS access for information about use of these files. See your Hadoop documentation for information about WebHDFS configuration.

Vertica places too much load on the name node (LibHDFS++)

Large HDFS clusters can sometimes experience heavy load on the name node when clients, including Vertica, need to locate data. If your name node is sensitive to this load and if you are using LibHDFS++, you can instruct Vertica to distribute metadata about block locations to its nodes so that they do not have to contact the name node as often. Distributing this metadata can degrade database performance somewhat in deployments where the name node isn't contended. This performance effect is because the data must be serialized and distributed.

If protecting your name node from load is more important than query performance, set the EnableHDFSBlockInfoCache configuration parameter to 1 (true). Usually this applies to large HDFS clusters where name node contention is already an issue.

This setting applies to access through LibHDFS++ (hdfs scheme). Sometimes LibHDFS++ falls back to WebHDFS, which does not use this setting. If you have enabled this setting and you are still seeing high traffic on your name node from Vertica, check the QUERY_EVENTS system table for LibHDFS++ UNSUPPORTED OPERATION events.

Kerberos authentication errors

Kerberos authentication can fail even though a ticket is valid if Hadoop expires tickets frequently. It can also fail due to clock skew between Hadoop and Vertica nodes. For details, see Troubleshooting Kerberos authentication .

Accessing kerberized HDFS data

If your Hortonworks or Cloudera Hadoop cluster uses Kerberos authentication to restrict access to HDFS, Vertica must be granted access. If you use Kerberos authentication for your Vertica database, and database users have HDFS access, then you can configure Vertica to use the same principals to authenticate. However, not all Hadoop administrators want to grant access to all database users, preferring to manage access in other ways. In addition, not all Vertica databases use Kerberos.

Vertica provides the following options for accessing Kerberized Hadoop clusters:

- Using Vertica Kerberos principals.
- Using Hadoop proxy users combined with Vertica users.
- Using a user-specified delegation token which grants access to HDFS. Delegation tokens are issued by the Hadoop cluster.

Proxy users and delegation tokens both use a session parameter to manage identities. Vertica need not be Kerberized when using either of these methods.

Vertica does not support Kerberos for MapR.

To test your Kerberos configuration, see Verifying HDFS configuration .

In this section

- Using Kerberos with Vertica
- Proxy users and delegation tokens
- Token expiration

Using Kerberos with Vertica

If you use Kerberos for your Vertica cluster and your principals have access to HDFS, then you can configure Vertica to use the same credentials for HDFS.

Vertica authenticates with Hadoop in two ways that require different configurations:

- **User Authentication** —On behalf of the user, by passing along the user's existing Kerberos credentials. This method is also called user impersonation. Actions performed on behalf of particular users, like executing queries, generally use user authentication.
- Vertica **Authentication** —On behalf of system processes that access ROS data or the catalog, by using a special Kerberos credential stored in a keytab file.

> **Note**
> Vertica and Hadoop must use the same Kerberos server or servers (KDCs).

Vertica can interact with more than one Kerberos realm. To configure multiple realms, see Multi-realm Support .

Vertica attempts to automatically refresh Hadoop tokens before they expire. See Token expiration .

User authentication

To use Vertica with Kerberos and Hadoop, the client user first authenticates with one of the Kerberos servers (Key Distribution Center, or KDC) being used by the Hadoop cluster. A user might run kinit or sign in to Active Directory, for example.

A user who authenticates to a Kerberos server receives a Kerberos ticket. At the beginning of a client session, Vertica automatically retrieves this ticket. Vertica then uses this ticket to get a Hadoop token, which Hadoop uses to grant access. Vertica uses this token to access HDFS, such as when executing a query on behalf of the user. When the token expires, Vertica automatically renews it, also renewing the Kerberos ticket if necessary.

The user must have been granted permission to access the relevant files in HDFS. This permission is checked the first time Vertica reads HDFS data.

Vertica can use multiple KDCs serving multiple Kerberos realms, if proper cross-realm trust has been set up between realms.

Vertica authentication

Automatic processes, such as the Tuple Mover or the processes that access Eon Mode communal storage, do not log in the way users do. Instead, Vertica uses a special identity (principal) stored in a keytab file on every database node. (This approach is also used for Vertica clusters that use Kerberos but do not use Hadoop.) After you configure the keytab file, Vertica uses the principal residing there to automatically obtain and maintain a Kerberos ticket, much as in the client scenario. In this case, the client does not interact with Kerberos.

Each Vertica node uses its own principal; it is common to incorporate the name of the node into the principal name. You can either create one keytab per node, containing only that node's principal, or you can create a single keytab containing all the principals and distribute the file to all nodes. Either way, the node uses its principal to get a Kerberos ticket and then uses that ticket to get a Hadoop token.

When creating HDFS storage locations Vertica uses the principal in the keytab file, not the principal of the user issuing the CREATE LOCATION statement. The HCatalog Connector sometimes uses the principal in the keytab file, depending on how Hive authenticates users.

Configuring users and the keytab file

If you have not already configured Kerberos authentication for Vertica, follow the instructions in Configure Vertica for Kerberos authentication . Of particular importance for Hadoop integration:

1. Create one Kerberos principal per node.
2. Place the keytab files in the same location on each database node and set configuration parameter KerberosKeytabFile to that location.
3. Set KerberosServiceName to the name of the principal. (See Inform Vertica about the Kerberos principal .)

If you are using the HCatalog Connector, follow the additional steps in Configuring security in the HCatalog Connector documentation.

If you are using HDFS storage locations, give all node principals read and write permission to the HDFS directory you will use as a storage location.

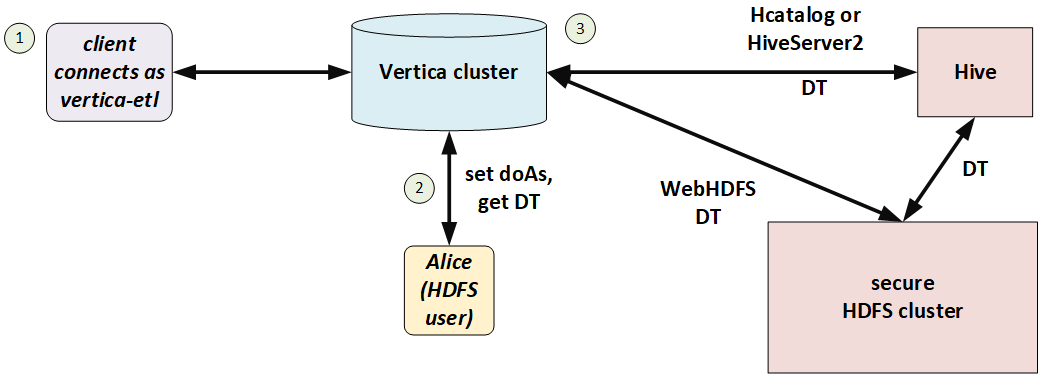
Proxy users and delegation tokens

An alternative to granting HDFS access to individual Vertica users is to use delegation tokens, either directly or with a proxy user. In this configuration, Vertica accesses HDFS on behalf of some other (Hadoop) user. The Hadoop users need not be Vertica users at all.

In Vertica, you can either specify the name of the Hadoop user to act on behalf of (doAs), or you can directly use a Kerberos delegation token that you obtain from HDFS (Bring Your Own Delegation Token). In the doAs case, Vertica obtains a delegation token for that user, so both approaches ultimately use delegation tokens to access files in HDFS.

Use the HadoopImpersonationConfig session parameter to specify a user or delegation token to use for HDFS access. Each session can use a different user and can use either doAs or a delegation token. The value of HadoopImpersonationConfig is a set of JSON objects.

To use delegation tokens of either type (more specifically, when HadoopImpersonationConfig is set), you must access HDFS through WebHDFS.



In this section

- User impersonation (doAs)
- Bring your own delegation token
- Getting a HiveServer2 delegation token
- HadoopImpersonationConfig format

User impersonation (doAs)

You can use user impersonation to access data in an HDFS cluster from Vertica. This approach is called "doAs" (for "do as") because Vertica uses a single proxy user on behalf of another (Hadoop) user. The impersonated Hadoop user does not need to also be a Vertica user.

In the following illustration, Alice is a Hadoop user but not a Vertica user. She connects to Vertica as the proxy user, vertica-etl. In her session, Vertica obtains a delegation token (DT) on behalf of the doAs user (Alice), and uses that delegation token to access HDFS.

You can use doAs with or without Kerberos, so long as HDFS and Vertica match. If HDFS uses Kerberos then Vertica must too.

User configuration

The Hadoop administrator must create a proxy user and allow it to access HDFS on behalf of other users. Set values in core-site.xml as in the following example:

```
<name>hadoop.proxyuser.vertica-etl.users</name>
<value>*</value>
<name>hadoop.proxyuser.vertica-etl.hosts</name>
<value>*</value>
```

In Vertica, create a corresponding user.

Session configuration

To make requests on behalf of a Hadoop user, first set the HadoopImpersonationConfig session parameter to specify the user and HDFS cluster. Vertica will access HDFS as that user until the session ends or you change the parameter.

The value of this session parameter is a collection of JSON objects. Each object specifies an HDFS cluster and a Hadoop user. For the cluster, you can specify either a name service or an individual name node. If you are using HA name node, then you must either use a name service or specify all name nodes. HadoopImpersonationConfig format describes the full JSON syntax.

The following example shows access on behalf of two different users. The users "stephanie" and "bob" are Hadoop users, not Vertica users. "vertica-etl" is a Vertica user.

```
$ vsql -U vertica-etl

=> ALTER SESSION SET
   HadoopImpersonationConfig = '[{"nameservice":"hadoopNS", "doAs":"stephanie"}]';
=> COPY nation FROM 'webhdfs:///user/stephanie/nation.dat';

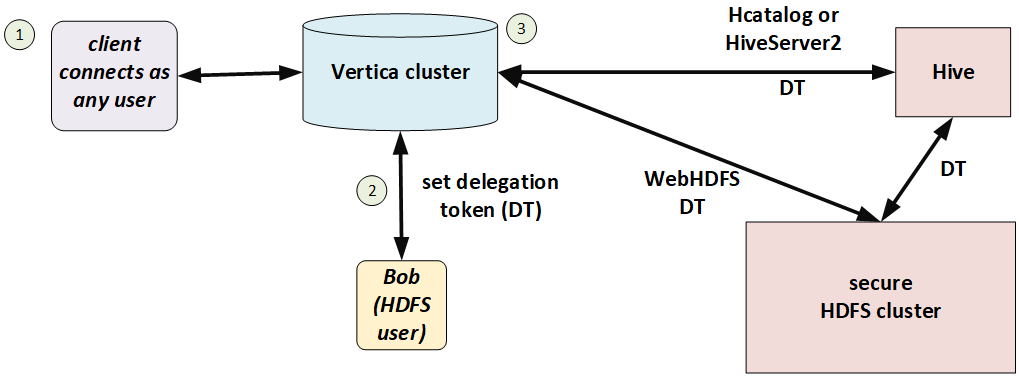
=> ALTER SESSION SET
   HadoopImpersonationConfig = '[{"nameservice":"hadoopNS", "doAs":"bob"}, {"authority":"hadoop2:50070", "doAs":"rob"}]';
=> COPY nation FROM 'webhdfs:///user/bob/nation.dat';
```

Vertica uses Hadoop delegation tokens, obtained from the name node, to impersonate Hadoop users. In a long-running session, a token could expire. Vertica attempts to renew tokens automatically; see Token expiration .

Testing the configuration

You can use the HADOOP_IMPERSONATION_CONFIG_CHECK function to test your HDFS delegation tokens and HCATALOGCONNECTOR_CONFIG_CHECK to test your HCatalog Connector delegation token.

Bring your own delegation token



Instead of creating a proxy user and giving it access to HDFS for use with doAs, you can give Vertica a Hadoop delegation token to use. You must obtain this delegation token from the Hadoop name node. In this model, security is handled entirely on the Hadoop side, with Vertica just passing along a token. Vertica may or may not be Kerberized.

A typical workflow is:

- In an ETL front end, a user submits a query.
- The ETL system uses authentication and authorization services to verify that the user has sufficient permission to run the query.
- The ETL system requests a delegation token for the user from the name node.
- The ETL system makes a client connection to Vertica, sets the delegation token for the session, and runs the query.

When using a delegation token, clients can connect as any Vertica user. No proxy user is required.

In the following illustration, Bob has a Hadoop-issued delegation token. He connects to Vertica and Vertica uses that delegation token to access files in HDFS.

Session configuration

Set the HadoopImpersonationConfig session parameter to specify the delegation token and HDFS cluster. Vertica will access HDFS using that delegation token until the session ends, the token expires, or you change the parameter.

The value of this session parameter is a collection of JSON objects. Each object specifies a delegation token ("token") in WebHDFS format and an HDFS name service or name node. HadoopImpersonationConfig format describes the full JSON syntax.

The following example shows access on behalf of two different users. The users "stephanie" and "bob" are Hadoop users, not Vertica users. "dbuser1" is a Vertica user with no special privileges.

```
$ vsql -U dbuser1

=> ALTER SESSION SET
   HadoopImpersonationConfig ='[{"authority":"hadoop1:50070","token":"JAAGZGJldGwxBmRiZXRsMQCKAWDXJgB9igFg-
zKEfY4gao4BmhSJYtXiWqrhBHbbUn4VScNg58HWQxJXRUJIREZTIGRlbGVnYXRpb24RMTAuMjAuMTAwLjU0OjgwMjA"}]';
=> COPY nation FROM 'webhdfs:///user/stephanie/nation.dat';

=> ALTER SESSION SET
   HadoopImpersonationConfig ='[{"authority":"hadoop1:50070","token":"HgADdG9tA3RvbQCKAWDXJgAoigFg-
zKEKI4gaI4BmhRoOUpq_jPxrVhZ1NSMnodAQnhUthJXRUJIREZTIGRlbGVnYXRpb24RMTAuMjAuMTAwLjU0OjgwMjA"}]';
=> COPY nation FROM 'webhdfs:///user/bob/nation.dat';
```

You can use the WebHDFS REST API to get delegation tokens:

```
$ curl -s --noproxy "*" --negotiate -u: -X GET "http://hadoop1:50070/webhdfs/v1/?op=GETDELEGATIONTOKEN"
```

Vertica does not, and cannot, renew delegation tokens when they expire. You must either keep sessions shorter than token lifetime or implement a renewal scheme.

Delegation tokens and the HCatalog Connector

HiveServer2 uses a different format for delegation tokens. To use the HCatalog Connector, therefore, you must set two delegation tokens, one as usual (authority) and one for HiveServer2 (schema). The HCatalog Connector uses the schema token to access metadata and the authority token to access data. The schema name is the same Hive schema you specified in CREATE HCATALOG SCHEMA. The following example shows how to use these two delegation tokens.

```
$ vsql -U dbuser1

-- set delegation token for user and HiveServer2
=> ALTER SESSION SET
   HadoopImpersonationConfig='[
    {"nameservice":"hadoopNS","token":"JQAHcmVsZWFzZQdyZWxlYXNlAIoBYVJKrYSKAWF2VzGEjgmzj_IUCIrI9b8Dqu6awFTHk5nC-
fHB8xsSV0VCSERGUyBkZWxlZ2F0aW9uETEwLjIwLjQyLjEwOTo4MDIw"},

{"schema":"access","token":"UwAHcmVsZWFzZQdyZWxlYXNlL2hpdmUvZW5nLWc5LTEwMC52ZXJ0aWNhY29ycC5jb21AVkVSVElDQUNPUlAuQ09NigFhU
kmyTooBYXZWNk4BjgETFKN2xPURn19Yq9tf-0nekoD51TZvFUhJVkVfREVMRUdBVElPTl9UT0tFThZoaXZlc2VydmVyMkNsaWVudFRva2Vu"}]';

-- uses HiveServer2 token to get metadata
=> CREATE HCATALOG SCHEMA access WITH hcatalog_schema 'access';

-- uses both tokens
=> SELECT * FROM access.t1;

--uses only HiveServer2 token
=> SELECT * FROM hcatalog_tables;
```

HiveServer2 does not provide a REST API for delegation tokens like WebHDFS does. See Getting a HiveServer2 delegation token for some tips.

Testing the configuration

You can use the HADOOP_IMPERSONATION_CONFIG_CHECK function to test your HDFS delegation tokens and HCATALOGCONNECTOR_CONFIG_CHECK to test your HCatalog Connector delegation token.

Getting a HiveServer2 delegation token

To acccess Hive metadata using HiveServer2, you need a special delegation token. (See Bring your own delegation token .) HiveServer2 does not provide an easy way to get this token, unlike the REST API that grants HDFS (data) delegation tokens.

The following utility code shows a way to get this token. You will need to modify this code for your own cluster; in particular, change the value of the connectURL static.

```
import java.io.FileWriter;
import java.io.PrintStream;
import java.io.PrintWriter;
import java.io.StringWriter;
import java.io.Writer;

```

HadoopImpersonationConfig format

The value of the HadoopImpersonationConfig session parameter is a set of one or more JSON objects. Each object describes one doAs user or delegation token for one Hadoop destination. You must use WebHDFS, not LibHDFS++, to use impersonation.

Syntax

```
[ { ("doAs" | "token"): value,
    ("nameservice" | "authority" | "schema"): value} [,...]
]
```

Properties

doAs	The name of a Hadoop user to impersonate.
token	A delegation token to use for HDFS access.
nameservice	A Hadoop name service. All access to this name service uses the doAs user or delegation token.
authority	A name node authority. All access to this authority uses the doAs user or delegation token. If the name node fails over to another name node, the doAs user or delegation token does *not* automatically apply to the failover name node. If you are using HA name node, use nameservice instead of authority or include objects for every name node.
schema	A Hive schema, for use with the HCatalog Connector. Vertica uses this object's doAs user or token to access Hive metadata only. For data access you must also specify a name service or authority object, just like for all other data access.

Examples

In the following example of doAs, Bob is a Hadoop user and vertica-etl is a Kerberized proxy user.

```
$ kinit vertica-etl -kt /home/dbadmin/vertica-etl.keytab
$ vsql -U vertica-etl

=> ALTER SESSION SET
   HadoopImpersonationConfig = '[{"nameservice":"hadoopNS", "doAs":"Bob"}]';
=> COPY nation FROM 'webhdfs:///user/bob/nation.dat';
```

In the following example, the current Vertica user (it doesn't matter who that is) uses a Hadoop delegation token. This token belongs to Alice, but you never specify the user name here. Instead, you use it to get the delegation token from Hadoop.

```
$ vsql -U dbuser1

=> ALTER SESSION SET
   HadoopImpersonationConfig ='[{"nameservice":"hadoopNS","token":"JAAGZGJldGwxBmRiZXRsMQCKAWDXJgB9igFg-
zKEfY4gao4BmhSJYtXiWqrhBHbbUn4VScNg58HWQxJXRUJIREZTIGRlbGVnYXRpb24RMTAuMjAuMTAwLjU0OjgwMjA"}]';
=> COPY nation FROM 'webhdfs:///user/alice/nation.dat';
```

In the following example, "authority" specifies the (single) name node on a Hadoop cluster that does not use high availability.

```
$ vsql -U dbuser1

=> ALTER SESSION SET
   HadoopImpersonationConfig ='[{"authority":"hadoop1:50070", "doAs":"Stephanie"}]';
=> COPY nation FROM 'webhdfs://hadoop1:50070/user/stephanie/nation.dat';
```

To access data in Hive you need to specify two delegation tokens. The first, for a name service or authority, is for data access as usual. The second is for the HiveServer2 metadata for the schema. HiveServer2 requires a delegation token in WebHDFS format. The schema name is the Hive schema you specify with CREATE HCATALOG SCHEMA.

```
$ vsql -U dbuser1

-- set delegation token for user and HiveServer2
=> ALTER SESSION SET
   HadoopImpersonationConfig='[
     {"nameservice":"hadoopNS","token":"JQAHcmVsZWFzZQdyZWxlYXNlAIoBYVJKrYSKAWF2VzGEjgmzj_IUCIrI9b8Dqu6awFTHk5nC-
fHB8xsSV0VCSERGUyBkZWxlZ2F0aW9uETEwLjIwLjQyLjEwOTo4MDIw"},

{"schema":"access","token":"UwAHcmVsZWFzZQdyZWxlYXNlL2hpdmUvZW5nLWc5LTEwMC52ZXJ0aWNhY29ycC5jb21AVkVSVElDQUNPUlAuQ09NigFhU
kmyTooBYXZWNk4BjgETFKN2xPURn19Yq9tf-0nekoD51TZvFUhJVkVfREVMRUdBVElPTl9UT0tFThZoaXZlc2VydmVyMkNsaWVudFRva2Vu"}]';

-- uses HiveServer2 token to get metadata
=> CREATE HCATALOG SCHEMA access WITH hcatalog_schema 'access';

-- uses both tokens
=> SELECT * FROM access.t1;

--uses only HiveServer2 token
=> SELECT * FROM hcatalog_tables;
```

Each object in the HadoopImpersonationConfig collection specifies one connection to one Hadoop cluster. You can add as many connections as you like, including to more than one Hadoop cluster. The following example shows delegation tokens for two different Hadoop clusters. Vertica uses the correct token for each cluster when connecting.

```
$ vsql -U dbuser1

=> ALTER SESSION SET
   HadoopImpersonationConfig ='[
    {"nameservice":"productionNS","token":"JAAGZGJldGwxBmRiZXRsMQCKAWDXJgB9igFg-
zKEfY4gao4BmhSJYtXiWqrhBHbbUn4VScNg58HWQxJXRUJIREZTIGRlbGVnYXRpb24RMTAuMjAuMTAwLjU0OjgwMjA"},
    {"nameservice":"testNS", "token":"HQAHcmVsZWFzZQdyZWxlYXNlAIoBYVJKrYSKAWF2VzGEjgmzj_IUCIrI9b8Dqu6awFTHk5nC-
fHB8xsSV0VCSERGUyBkZWxlZ2F0aW9uETEwLjIwLjQyLjEwOTo4MDIw"}]';

=> COPY clicks FROM 'webhdfs://productionNS/data/clickstream.dat';
=> COPY testclicks FROM 'webhdfs://testNS/data/clickstream.dat';
```

Token expiration

Vertica uses Hadoop tokens when using Kerberos tickets (Using Kerberos with Vertica) or doAs (User impersonation (doAs)). Vertica attempts to automatically refresh Hadoop tokens before they expire, but you can also set a minimum refresh frequency if you prefer. Use the HadoopFSTokenRefreshFrequency configuration parameter to specify the frequency in seconds:

```
=> ALTER DATABASE exampledb SET HadoopFSTokenRefreshFrequency = '86400';
```

If the current age of the token is greater than the value specified in this parameter, Vertica refreshes the token before accessing data stored in HDFS.

Vertica does not refresh delegation tokens (Bring your own delegation token).

Using HDFS storage locations

Vertica stores data in its native format, ROS, in storage locations. You can place storage locations on the local Linux file system or in HDFS. If you place storage locations on HDFS, you must perform additional configuration in HDFS to be able to manage them. These are in addition to the requirements in Vertica for managing storage locations and backup/restore .

If you use HDFS storage locations, the HDFS data must be available when you start Vertica. Your HDFS cluster must be operational, and the ROS files must be present. If you moved data files, or they are corrupted, or your HDFS cluster is not responsive, Vertica cannot start.

In this section

- Hadoop configuration for backup and restore
- Removing HDFS storage locations

Hadoop configuration for backup and restore

If your Vertica cluster uses storage locations on HDFS, and you want to be able to back up and restore those storage locations using vbr , you must enable snapshotting in HDFS.

The Vertica backup script uses HDFS's snapshotting feature to create a backup of HDFS storage locations. A directory must allow snapshotting before HDFS can take a snapshot. Only a Hadoop superuser can enable snapshotting on a directory. Vertica can enable snapshotting automatically if the database administrator is also a Hadoop superuser.

If HDFS is unsecured, the following instructions apply to the database administrator account, usually dbadmin. If HDFS uses Kerberos security, the following instructions apply to the principal stored in the Vertica keytab file, usually vertica. The instructions below use the term "database account" to refer to this user.

We recommend that you make the database administrator or principal a Hadoop superuser. If you are not able to do so, you must enable snapshotting on the directory before configuring it for use by Vertica.

The steps you need to take to make the Vertica database administrator account a superuser depend on the distribution of Hadoop you are using. Consult your Hadoop distribution's documentation for details.

Manually enabling snapshotting for a directory

If you cannot grant superuser status to the database account, you can instead enable snapshotting of each directory manually. Use the following command:

```
$ hdfs dfsadmin -allowSnapshot path
```

Issue this command for each directory on each node. Remember to do this each time you add a new node to your HDFS cluster.

Nested snapshottable directories are not allowed, so you cannot enable snapshotting for a parent directory to automatically enable it for child directories. You must enable it for each individual directory.

Additional requirements for Kerberos

If HDFS uses Kerberos, then in addition to granting the keytab principal access, you must give Vertica access to certain Hadoop configuration files. See Configuring Kerberos .

Testing the database account's ability to make HDFS directories snapshottable

After making the database account a Hadoop superuser, verify that the account can set directories snapshottable:

1. Log into the Hadoop cluster as the database account (dbadmin by default).
2. Determine a location in HDFS where the database administrator can create a directory. The /tmp directory is usually available. Create a test HDFS directory using the command:
   ```
   $ hdfs dfs -mkdir /path/testdir
   ```
3. Make the test directory snapshottable using the command:

```
$ hdfs dfsadmin -allowSnapshot /path/testdir
```

The following example demonstrates creating an HDFS directory and making it snapshottable:

```
$ hdfs dfs -mkdir /tmp/snaptest
$ hdfs dfsadmin -allowSnapshot /tmp/snaptest
Allowing snaphot on /tmp/snaptest succeeded
```

Removing HDFS storage locations

The steps to remove an HDFS storage location are similar to standard storage locations:

1. Remove any existing data from the HDFS storage location by using SET_OBJECT_STORAGE_POLICY to change each object's storage location. Alternatively, you can use CLEAR_OBJECT_STORAGE_POLICY . Because the Tuple Mover runs infrequently, set the *enforce-storage-move* parameter to true to make the change immediately.
2. Retire the location on each host that has the storage location defined using RETIRE_LOCATION . Set *enforce-storage-move* to true .
3. Drop the location on each node using DROP_LOCATION .
4. Optionally remove the snapshots and files from the HDFS directory for the storage location.
5. Perform a full database backup.

For more information about changing storage policies, changing usage, retiring locations, and dropping locations, see Managing storage locations .

Important
If you have backed up the data in the HDFS storage location you are removing, you must perform a full database backup after you remove the location. If you do not and restore the database to a backup made before you removed the location, the location's data is restored.

Removing storage location files from HDFS

Dropping an HDFS storage location does not automatically clean the HDFS directory that stored the location's files. Any snapshots of the data files created when backing up the location are also not deleted. These files consume disk space on HDFS and also prevent the directory from being reused as an HDFS storage location. Vertica cannot create a storage location in a directory that contains existing files or subdirectories.

You must log into the Hadoop cluster to delete the files from HDFS. An alternative is to use some other HDFS file management tool.

Removing backup snapshots

HDFS returns an error if you attempt to remove a directory that has snapshots:

```
$ hdfs dfs -rm -r -f -skipTrash /user/dbadmin/v_vmart_node0001
rm: The directory /user/dbadmin/v_vmart_node0001 cannot be deleted since
/user/dbadmin/v_vmart_node0001 is snapshottable and already has snapshots
```

The Vertica backup script creates snapshots of HDFS storage locations as part of the backup process. If you made backups of your HDFS storage location, you must delete the snapshots before removing the directories.

HDFS stores snapshots in a subdirectory named .snapshot . You can list the snapshots in the directory using the standard HDFS ls command:

```
$ hdfs dfs -ls /user/dbadmin/v_vmart_node0001/.snapshot
Found 1 items
drwxrwx---   - dbadmin supergroup          0 2014-09-02 10:13 /user/dbadmin/v_vmart_node0001/.snapshot/s20140902-101358.629
```

To remove snapshots, use the command:

```
$ hdfs dfs -removeSnapshot directory snapshotname
```

The following example demonstrates the command to delete the snapshot shown in the previous example:

```
$ hdfs dfs -deleteSnapshot /user/dbadmin/v_vmart_node0001 s20140902-101358.629
```

You must delete each snapshot from the directory for each host in the cluster. After you have deleted the snapshots, you can delete the directories in the storage location.

Important
Each snapshot's name is based on a timestamp down to the millisecond. Nodes independently create their own snapshots. They do not synchronize snapshot creation, so their snapshot names differ. You must list each node's snapshot directory to learn the names of the snapshots it contains.

See Apache's HDFS Snapshot documentation for more information about managing and removing snapshots.

Removing the storage location directories

You can remove the directories that held the storage location's data by either of the following methods:

- Use an HDFS file manager to delete directories. See your Hadoop distribution's documentation to determine if it provides a file manager.
- Log into the Hadoop Name Node using the database administrator's account and use HDFS's rmr command to delete the directories. See Apache's File System Shell Guide for more information.

The following example uses the HDFS rmr command from the Linux command line to delete the directories left behind in the HDFS storage location directory /user/dbamin . It uses the -skipTrash flag to force the immediate deletion of the files:

```
$ hdfsp dfs -ls /user/dbadmin
Found 3 items
drwxrwx---   - dbadmin supergroup          0 2014-08-29 15:11 /user/dbadmin/v_vmart_node0001
drwxrwx---   - dbadmin supergroup          0 2014-08-29 15:11 /user/dbadmin/v_vmart_node0002
drwxrwx---   - dbadmin supergroup          0 2014-08-29 15:11 /user/dbadmin/v_vmart_node0003

$ hdfs dfs -rmr -skipTrash /user/dbadmin/*
Deleted /user/dbadmin/v_vmart_node0001
Deleted /user/dbadmin/v_vmart_node0002
Deleted /user/dbadmin/v_vmart_node0003
```

Using the HCatalog Connector

The Vertica HCatalog Connector lets you access data stored in Apache's Hive data warehouse software the same way you access it within a native Vertica table.

If your files are in the Optimized Columnar Row (ORC) or Parquet format and do not use complex types, the HCatalog Connector creates an external table and uses the ORC or Parquet reader instead of using the Java SerDe. See ORC (parser) and PARQUET (parser) for more information about these readers.

The HCatalog Connector performs predicate pushdown to improve query performance. Instead of reading all data across the network to evaluate a query, the HCatalog Connector moves the evaluation of predicates closer to the data. Predicate pushdown applies to Hive partition pruning, ORC stripe pruning, and Parquet row-group pruning. The HCatalog Connector supports predicate pushdown for the following predicates: >, >=, =, <>, <=, <.

In this section

- Overview
- How the HCatalog Connector works

- Synchronizing an HCatalog schema or table with a local schema or table
- Data type conversions from Hive to Vertica
- Using nonstandard SerDes
- Troubleshooting HCatalog Connector problems

Overview

There are several Hadoop components that you need to understand to use the HCatalog connector:

- Apache Hive lets you query data stored in a Hadoop Distributed File System (HDFS) the same way you query data stored in a relational database. Behind the scenes, Hive uses a set of serializer and deserializer (SerDe) classes to extract data from files stored in HDFS and break it into columns and rows. Each SerDe handles data files in a specific format. For example, one SerDe extracts data from comma-separated data files while another interprets data stored in JSON format.
- Apache HCatalog is a component of the Hadoop ecosystem that makes Hive's metadata available to other Hadoop components (such as Pig).
- HiveServer2 makes HCatalog and Hive data available via JDBC. Through it, a client can make requests to retrieve data stored in Hive, as well as information about the Hive schema. HiveServer2 can use authorization services (Sentry or Ranger). HiverServer2 can use Hive LLAP (Live Long And Process).

The Vertica HCatalog Connector lets you transparently access data that is available through HiveServer2. You use the connector to define a schema in Vertica that corresponds to a Hive database or schema. When you query data within this schema, the HCatalog Connector transparently extracts and formats the data from Hadoop into tabular data. Vertica supports authorization services and Hive LLAP.

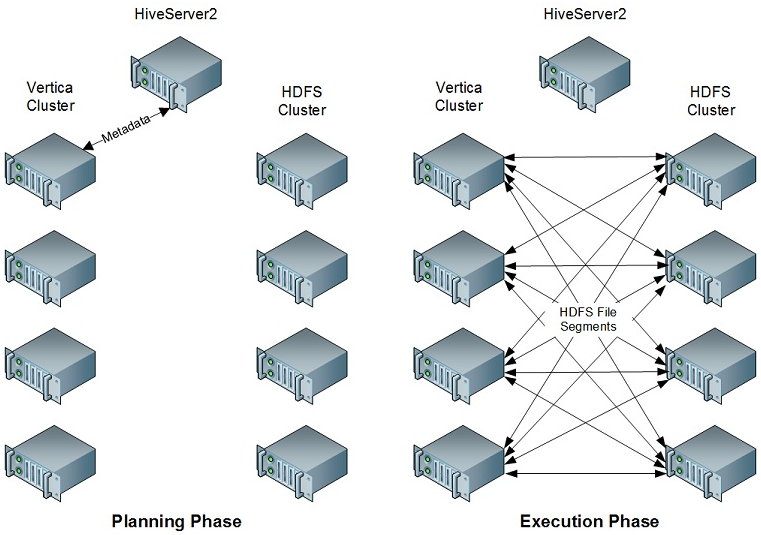
> **Note**
> You can use the WebHCat service instead of HiveServer2, but performance is usually better with HiveServer2. Support for WebHCat is deprecated. To use WebHCat, set the HCatalogConnectorUseHiveServer2 configuration parameter to 0. See Apache Hadoop parameters . WebHCat does not support authorization services.

HCatalog connection features

The HCatalog Connector lets you query data stored in Hive using the Vertica native SQL syntax. Some of its main features are:

- The HCatalog Connector always reflects the current state of data stored in Hive.
- The HCatalog Connector uses the parallel nature of both Vertica and Hadoop to process Hive data. The result is that querying data through the HCatalog Connector is often faster than querying the data directly through Hive.
- Because Vertica performs the extraction and parsing of data, the HCatalog Connector does not significantly increase the load on your Hadoop cluster.
- The data you query through the HCatalog Connector can be used as if it were native Vertica data. For example, you can execute a query that joins data from a table in an HCatalog schema with a native table.

HCatalog Connector considerations



There are a few things to keep in mind when using the HCatalog Connector:

- Hive's data is stored in flat files in a distributed file system, requiring it to be read and deserialized each time it is queried. This deserialization causes Hive performance to be much slower than that of Vertica. The HCatalog Connector has to perform the same process as Hive to read the data. Therefore, querying data stored in Hive using the HCatalog Connector is much slower than querying a native Vertica table. If you need to perform extensive analysis on data stored in Hive, you should consider loading it into Vertica. Vertica optimization often makes querying data through the HCatalog Connector faster than directly querying it through Hive.
- If Hive uses Kerberos security, the HCatalog Connector uses the querying user's credentials in queries by default. If Hive uses Sentry or Ranger to enforce security, then you must either disable this behavior in Vertica by setting EnableHCatImpersonation to 0 or grant users access to the underlying data in HDFS. (Sentry supports ACL synchronization to automatically grant access.) Alternatively, you can specify delegation tokens for data and metadata access. See Configuring security .
- Hive supports complex data types such as lists, maps, and structs that Vertica does not support. Columns containing these data types are converted to a JSON representation of the data type and stored as a VARCHAR. See Data type conversions from Hive to Vertica .

> **Note**
> The HCatalog Connector is read-only. It cannot insert data into Hive.

How the HCatalog Connector works

When planning a query that accesses data from a Hive table, the Vertica HCatalog Connector on the initiator node contacts HiveServer2 (or WebHCat) in your Hadoop cluster to determine if the table exists. If it does, the connector retrieves the table's metadata from the metastore database so the query planning can continue. When the query executes, all nodes in the Vertica cluster directly retrieve the data necessary for completing the query from HDFS. They then use the Hive SerDe classes to extract the data so the query can execute. When accessing data in ORC or Parquet format, the HCatalog Connector uses Vertica's internal readers for these formats instead of the Hive SerDe classes.

This approach takes advantage of the parallel nature of both Vertica and Hadoop. In addition, by performing the retrieval and extraction of data directly, the HCatalog Connector reduces the impact of the query on the Hadoop cluster.

For files in the Optimized Columnar Row (ORC) or Parquet format that do not use complex types, the HCatalog Connector creates an external table and uses the ORC or Parquet reader instead of using the Java SerDe. You can direct these readers to access custom Hive partition locations if Hive used them when writing the data. By default these extra checks are turned off to improve performance.

HCatalog Connector requirements

Before you can use the HCatalog Connector, both your Vertica and Hadoop installations must meet the following requirements.

Vertica requirements

All of the nodes in your cluster must have a Java Virtual Machine (JVM) installed. You must use the same Java version that the Hadoop cluster uses. See Installing the Java Runtime on Your Vertica Cluster .

You must also add certain libraries distributed with Hadoop and Hive to your Vertica installation directory. See Configuring Vertica for HCatalog .

Hadoop requirements

Your Hadoop cluster must meet several requirements to operate correctly with the Vertica Connector for HCatalog:

- It must have Hive, HiveServer2, and HCatalog installed and running. See Apache's HCatalog page for more information.
- The HiveServer2 server and all of the HDFS nodes that store HCatalog data must be directly accessible from all of the hosts in your Vertica database. Verify that any firewall separating the Hadoop cluster and the Vertica cluster will pass HiveServer2, metastore database, and HDFS traffic.
- The data that you want to query must be in an internal or external Hive table.
- If a table you want to query uses a non-standard SerDe, you must install the SerDe's classes on your Vertica cluster before you can query the data. See Using nonstandard SerDes .

Installing the Java runtime on your Vertica cluster

The HCatalog Connector requires a 64-bit Java Virtual Machine (JVM). The JVM must support Java 6 or later, and must be the same version as the one installed on your Hadoop nodes.

> **Note**
> If your Vertica cluster is configured to execute User Defined Extensions (UDxs) written in Java, it already has a correctly-configured JVM installed. See Developing user-defined extensions (UDxs) for more information.

Installing Java on your Vertica cluster is a two-step process:

1. Install a Java runtime on all of the hosts in your cluster.
2. Set the JavaBinaryForUDx configuration parameter to tell Vertica the location of the Java executable.

Installing a Java runtime

For Java-based features, Vertica requires a 64-bit Java 6 (Java version 1.6) or later Java runtime. Vertica supports runtimes from either Oracle or OpenJDK . You can choose to install either the Java Runtime Environment (JRE) or Java Development Kit (JDK), since the JDK also includes the JRE.

Many Linux distributions include a package for the OpenJDK runtime. See your Linux distribution's documentation for information about installing and configuring OpenJDK.

To install the Oracle Java runtime, see the Java Standard Edition (SE) Download Page . You usually run the installation package as root in order to install it. See the download page for instructions.

Once you have installed a JVM on each host, ensure that the java command is in the search path and calls the correct JVM by running the command:

```
$ java -version
```

This command should print something similar to:

```
java version "1.8.0_102"
Java(TM) SE Runtime Environment (build 1.8.0_102-b14)
Java HotSpot(TM) 64-Bit Server VM (build 25.102-b14, mixed mode)
```

Note
Any previously installed Java VM on your hosts may interfere with a newly installed Java runtime. See your Linux distribution's documentation for instructions on configuring which JVM is the default. Unless absolutely required, you should uninstall any incompatible version of Java before installing the Java 6 or Java 7 runtime.

Setting the JavaBinaryForUDx configuration parameter

The JavaBinaryForUDx configuration parameter tells Vertica where to look for the JRE to execute Java UDxs. After you have installed the JRE on all of the nodes in your cluster, set this parameter to the absolute path of the Java executable. You can use the symbolic link that some Java installers create (for example /usr/bin/java). If the Java executable is in your shell search path, you can get the path of the Java executable by running the following command from the Linux command line shell:

```
$ which java
/usr/bin/java
```

If the java command is not in the shell search path, use the path to the Java executable in the directory where you installed the JRE. Suppose you installed the JRE in /usr/java/default (which is where the installation package supplied by Oracle installs the Java 1.6 JRE). In this case the Java executable is /usr/java/default/bin/java .

You set the configuration parameter by executing the following statement as a database superuser :

```
=> ALTER DATABASE DEFAULT SET PARAMETER JavaBinaryForUDx = '/usr/bin/java';
```

See ALTER DATABASE for more information on setting configuration parameters.

To view the current setting of the configuration parameter, query the CONFIGURATION_PARAMETERS system table:

```
=> \x
Expanded display is on.
=> SELECT * FROM CONFIGURATION_PARAMETERS WHERE parameter_name = 'JavaBinaryForUDx';
-[ RECORD 1 ]----------------+-----------------------------------------------------------
node_name                    | ALL
parameter_name               | JavaBinaryForUDx
current_value                | /usr/bin/java
default_value                |
change_under_support_guidance | f
change_requires_restart      | f
description                  | Path to the java binary for executing UDx written in Java
```

Once you have set the configuration parameter, Vertica can find the Java executable on each node in your cluster.

Note
Since the location of the Java executable is set by a single configuration parameter for the entire cluster, you must ensure that the Java executable is installed in the same path on all of the hosts in the cluster.

Configuring Vertica for HCatalog

Before you can use the HCatalog Connector, you must add certain Hadoop and Hive libraries to your Vertica installation. You must also copy the Hadoop configuration files that specify various connection properties. Vertica uses the values in those configuration files to make its own connections to Hadoop.

You need only make these changes on one node in your cluster. After you do this you can install the HCatalog connector.

Copy Hadoop libraries and configuration files

Vertica provides a tool, hcatUtil, to collect the required files from Hadoop. This tool copies selected libraries and XML configuration files from your Hadoop cluster to your Vertica cluster. This tool might also need access to additional libraries:

- If you plan to use Hive to query files that use Snappy compression, you need access to the Snappy native libraries, libhadoop*.so and libsnappy*.so.
- If you plan to use Hive to query files that use LZO compression, you need access to the hadoop-lzo-*.jar and libgplcompression.so* libraries. In core-site.xml you must also edit the io.compression.codecs property to include com.hadoop.compression.lzo.LzopCodec .
- If you plan to use a JSON SerDe with a Hive table, you need access to its library. This is the same library that you used to configure Hive; for example:

```
hive> add jar /home/release/json-serde-1.3-jar-with-dependencies.jar;

hive> create external table nationjson (id int,name string,rank int,text string)
    ROW FORMAT SERDE 'org.openx.data.jsonserde.JsonSerDe'
    LOCATION '/user/release/vt/nationjson';
```

- If you are using any other libraries that are not standard across all supported Hadoop versions, you need access to those libraries.

If any of these cases applies to you, do one of the following:

- Include the path(s) in the path you specify as the value of --hcatLibPath, or
- Copy the file(s) to a directory already on that path.

If Vertica is not co-located on a Hadoop node, you should do the following:

1. Copy /opt/vertica/packages/hcat/tools/hcatUtil to a Hadoop node and run it there, specifying a temporary output directory. Your Hadoop, HIVE, and HCatalog lib paths might be different. In newer versions of Hadoop the HCatalog directory is usually a subdirectory under the HIVE directory, and Cloudera creates a new directory for each revision of the configuration files. Use the values from your environment in the following command:

   ```
   hcatUtil --copyJars
       --hadoopHiveHome="$HADOOP_HOME/lib;$HIVE_HOME/lib;/hcatalog/dist/share"
        --hadoopHiveConfPath="$HADOOP_CONF_DIR;$HIVE_CONF_DIR;$WEBHCAT_CONF_DIR"
       --hcatLibPath="/tmp/hadoop-files"
   ```

   If you are using Hive LLAP, specify the hive2 directories.
2. Verify that all necessary files were copied:

   ```
   hcatUtil --verifyJars --hcatLibPath=/tmp/hadoop-files
   ```

3. Copy that output directory (/tmp/hadoop-files, in this example) to /opt/vertica/packages/hcat/lib on the Vertica node you will connect to when installing the HCatalog connector. If you are updating a Vertica cluster to use a new Hadoop cluster (or a new version of Hadoop), first remove all JAR files in /opt/vertica/packages/hcat/lib except vertica-hcatalogudl.jar.
4. Verify that all necessary files were copied:

   ```
   hcatUtil --verifyJars --hcatLibPath=/opt/vertica/packages/hcat
   ```

If Vertica is co-located on some or all Hadoop nodes, you can do this in one step on a shared node. Your Hadoop, HIVE, and HCatalog lib paths might be different; use the values from your environment in the following command:

```
hcatUtil --copyJars
    --hadoopHiveHome="$HADOOP_HOME/lib;$HIVE_HOME/lib;/hcatalog/dist/share"
    --hadoopHiveConfPath="$HADOOP_CONF_DIR;$HIVE_CONF_DIR;$WEBHCAT_CONF_DIR"
    --hcatLibPath="/opt/vertica/packages/hcat/lib"
```

The hcatUtil script has the following arguments:

-c, --copyJars	Copy the required JAR files from hadoopHiveHome and configuration files from hadoopHiveConfPath.
-v, --verifyJars	Verify that the required files are present in hcatLibPath. Check the output of hcatUtil for error and warning messages.
--hadoopHiveHome= *"value1;value2;..."*	Paths to the Hadoop, Hive, and HCatalog home directories. Separate directories by semicolons (;). Enclose paths in double quotes. **Note** Always place $HADOOP_HOME on the path before $HIVE_HOME. In some Hadoop distributions, these two directories contain different versions of the same library.
--hadoopHiveConfPath= *"value1;value2;..."*	Paths of the following configuration files: • hive-site.xml • core-site.xml • yarn-site.xml • webhcat-site.xml (optional with the default configuration; required if you use WebHCat instead of HiveServer2) • hdfs-site.xml Separate directories by semicolons (;). Enclose paths in double quotes. In previous releases of Vertica this parameter was optional under some conditions. It is now required.
--hcatLibPath= *"value"*	Output path for the libraries and configuration files. On a Vertica node, use /opt/vertica/packages/hcat/lib. If you have previously run hcatUtil with a different version of Hadoop, first remove the old JAR files from the output directory (all except vertica-hcatalogudl.jar).

After you have copied the files and verified them, install the HCatalog connector.

Install the HCatalog Connector

On the same node where you copied the files from hcatUtil, install the HCatalog connector by running the install.sql script. This script resides in the ddl/ folder under your HCatalog connector installation path. This script creates the library and VHCatSource and VHCatParser.

Note
The data that was copied using hcatUtil is now stored in the database. If you change any of those values in Hadoop, you need to rerun hcatUtil and install.sql. The following statement returns the names of the libraries and configuration files currently being used:

```
=> SELECT dependencies FROM user_libraries WHERE lib_name='VHCatalogLib';
```

Now you can create HCatalog schema parameters, which point to your existing Hadoop services, as described in Defining a schema using the HCatalog Connector .

Upgrading to a new version of Vertica

After upgrading to a new version of Vertica, perform the following steps:

1. Uninstall the HCatalog Connector using the uninstall.sql script. This script resides in the ddl/ folder under your HCatalog connector installation path.
2. Delete the contents of the hcatLibPath directory except for vertica-hcatalogudl.jar .
3. Rerun hcatUtil.
4. Reinstall the HCatalog Connector using the install.sql script.

For more information about upgrading Vertica, see Upgrade Vertica .

Additional options for Hadoop columnar file formats

When reading Hadoop columnar file formats (ORC or Parquet), the HCatalog Connector attempts to use the built-in readers. When doing so, it uses the hdfs scheme by default. In order to use the hdfs scheme, you must perform the configuration described in Configuring HDFS access .

To have the HCatalog Connector use the webhdfs scheme instead, use ALTER DATABASE to set HDFSUseWebHDFS to 1. This setting applies to all HDFS access, not just the HCatalog Connector.

Configuring security

You can use any of the security options described in Accessing kerberized HDFS data to access Hive data. This topic describes additional steps needed specifically for using the HCatalog Connector.

If you use Kerberos from Vertica, the HCatalog Connector can use an authorization service (Sentry or Ranger). If you use delegation tokens, you must manage authorization yourself.

Kerberos

You can use Kerberos from Vertica as described in Using Kerberos with Vertica .

How you configure the HCatalog Connector depends on how Hive manages authorization.

- If Hive uses Sentry to manage authorization, and if Sentry uses ACL synchronization, then the HCatalog Connector must access HDFS as the current user. Verify that the EnableHCatImpersonation configuration parameter is set to 1 (the default). ACL synchronization automatically provides authorized users with read access to the underlying HDFS files.
- If Hive uses Sentry without ACL synchronization, then the HCatalog Connector must access HDFS data as the Vertica principal. (The user still authenticates and accesses metadata normally.) Set the EnableHCatImpersonation configuration parameter to 0. The Vertica principal must have read access to the underlying HDFS files.
- If Hive uses Ranger to manage authorization, and the Vertica users have read access to the underlying HDFS files, then you can use user impersonation. Verify that the EnableHCatImpersonation configuration parameter is set to 1 (the default). You can, instead, disable user impersonation and give the Vertica principal read access to the HDFS files.
- If Hive uses either Sentry or Ranger, the HCatalog Connector must use HiveServer2 (the default). WebHCat does not support authorization services.
- If Hive does not use an authorization service, or if you are connecting to Hive using WebHCat instead of HiveServer2, then the HCatalog Connector accesses Hive as the current user. Verify that EnableHCatImpersonation is set to 1. All users must have read access to the underlying HDFS files.

In addition, in your Hadoop configuration files (core-site.xml in most distributions), make sure that you enable all Hadoop components to impersonate the Vertica user. The easiest way to do so is to set the proxyuser property using wildcards for all users on all hosts and in all groups. Consult your Hadoop documentation for instructions. Make sure you set this property before running hcatUtil (see Configuring Vertica for HCatalog).

Delegation tokens

You can use delegation tokens for a session as described in Bring your own delegation token . When using the HCatalog Connector you specify two delegation tokens, one for the data and one for the metadata. The metadata token is tied to a Hive schema. See HadoopImpersonationConfig format for information about how to specify these two delegation tokens.

Verifying security configuration

To verify that the HCatalog Connector can access Hive data, use the HCATALOGCONNECTOR_CONFIG_CHECK function.

For more information about testing your configuration, see Verifying HDFS configuration .

Defining a schema using the HCatalog Connector

After you set up the HCatalog Connector, you can use it to define a schema in your Vertica database to access the tables in a Hive database. You define the schema using the CREATE HCATALOG SCHEMA statement.

When creating the schema, you must supply the name of the schema to define in Vertica. Other parameters are optional. If you do not supply a value, Vertica uses default values. Vertica reads some default values from the HDFS configuration files; see Configuration Parameters .

To create the schema, you must have read access to all Hive data. Verify that the user creating the schema has been granted access, either directly or through an authorization service such as Sentry or Ranger. The dbadmin user has no automatic special privileges.

After you create the schema, you can change many parameters using the ALTER HCATALOG SCHEMA statement.

After you define the schema, you can query the data in the Hive data warehouse in the same way you query a native Vertica table. The following example demonstrates creating an HCatalog schema and then querying several system tables to examine the contents of the new schema. See Viewing Hive schema and table metadata for more information about these tables.

```
=> CREATE HCATALOG SCHEMA hcat WITH HOSTNAME='hcathost' PORT=9083
   HCATALOG_SCHEMA='default' HIVESERVER2_HOSTNAME='hs.example.com'
   SSL_CONFIG='/etc/hadoop/conf/ssl-client.xml' HCATALOG_USER='admin';
CREATE SCHEMA
=> \x
Expanded display is on.

=> SELECT * FROM v_catalog.hcatalog_schemata;

```

Configuration parameters

The HCatalog Connector uses the following values from the Hadoop configuration files if you do not override them when creating the schema.

File	Properties
hive-site.xml	hive.server2.thrift.bind.host (used for HIVESERVER2_HOSTNAME)

	hive.server2.thrift.port
	hive.server2.transport.mode
	hive.server2.authentication
	hive.server2.authentication.kerberos.principal
	hive.server2.support.dynamic.service.discovery
	hive.zookeeper.quorum (used as HIVESERVER2_HOSTNAME if dynamic service discovery is enabled)
	hive.zookeeper.client.port
	hive.server2.zookeeper.namespace
	hive.metastore.uris (used for HOSTNAME and PORT)
ssl-client.xml	ssl.client.truststore.location
	ssl.client.truststore.password

Using partitioned data

Hive supports partitioning data, as in the following example:

```
hive> create table users (name varchar(64), address string, city varchar(64))
   partitioned by (state varchar(64)) stored as orc;
```

Vertica takes advantage of partitioning information for formats that provide it in metadata (ORC and Parquet). Queries can skip irrelevant partitions entirely (partition pruning), and Vertica does not need to materialize partition columns. For more about use of partitions, see Improving query performance and Using partition columns .

By default Hive stores partition information under the path for the table definition, which might be local to Hive. However, a Hive user can choose to store partition information elsewhere, such as in a shared location like S3, as in the following example:

```
hive> alter table users add partition (state='MA')
   location 's3a://DataLake/partitions/users/state=MA';
```

During query execution, therefore, Vertica must query Hive for the location of a table's partition information.

Because the additional Hive queries can be expensive, Vertica defaults to looking for partition information only in Hive's default location. If your Hive table specified a custom location, use the CUSTOM_PARTITIONS parameter:

```
=> CREATE HCATALOG SCHEMA hcat WITH HOSTNAME='hcathost' PORT=9083
   HCATALOG_SCHEMA='default' HIVESERVER2_HOSTNAME='hs.example.com'
   SSL_CONFIG='/etc/hadoop/conf/ssl-client.xml' HCATALOG_USER='admin'
   CUSTOM_PARTITIONS='yes';
```

Vertica can access partition locations in the S3 and S3a schemes, and does not support the S3n scheme.

The HIVE_CUSTOM_PARTITIONS_ACCESSED system table records all custom partition locations that have been used in queries.

Using the HCatalog Connector with WebHCat

By default the HCatalog Connector uses HiveServer2 to access Hive data. If you are instead using WebHCat, set the HCatalogConnectorUseHiveServer2 configuration parameter to 0 before creating the schema as in the following example.

```
=> ALTER DATABASE DEFAULT SET PARAMETER HCatalogConnectorUseHiveServer2 = 0;
=> CREATE HCATALOG SCHEMA hcat WITH WEBSERVICE_HOSTNAME='webhcat.example.com';
```

If you have previously used WebHCat, you can switch to using HiveServer2 by setting the configuration parameter to 1 and using ALTER HCATALOG SCHEMA to set HIVESERVER2_HOSTNAME. You do not need to remove the WebHCat values; the HCatalog Connector uses the value of HCatalogConnectorUseHiveServer2 to determine which parameters to use.

Querying Hive tables using HCatalog Connector

Once you have defined the HCatalog schema, you can query data from the Hive database by using the schema name in your query.

```
=> SELECT * from hcat.messages limit 10;
 messageid |   userid   |        time         |             message
-----------+------------+---------------------+---------------------------------
         1 | nPfQ1ayhi  | 2013-10-29 00:10:43 | hymenaeos cursus lorem Suspendis
         2 | N7svORIoZ  | 2013-10-29 00:21:27 | Fusce ad sem vehicula morbi
         3 | 4VvzN3d    | 2013-10-29 00:32:11 | porta Vivamus condimentum
         4 | heojkmTmc  | 2013-10-29 00:42:55 | lectus quis imperdiet
         5 | coROws3OF  | 2013-10-29 00:53:39 | sit eleifend tempus a aliquam mauri
         6 | oDRP1i     | 2013-10-29 01:04:23 | risus facilisis sollicitudin sceler
         7 | AU7a9Kp    | 2013-10-29 01:15:07 | turpis vehicula tortor
         8 | ZJWg185DkZ | 2013-10-29 01:25:51 | sapien adipiscing eget Aliquam tor
         9 | E7ipAsYC3  | 2013-10-29 01:36:35 | varius Cum iaculis metus
        10 | kStCv      | 2013-10-29 01:47:19 | aliquam libero nascetur Cum mal
(10 rows)
```

Since the tables you access through the HCatalog Connector act like Vertica tables, you can perform operations that use both Hive data and native Vertica data, such as a join:

```
=> SELECT u.FirstName, u.LastName, d.time, d.Message from UserData u
-> JOIN hcat.messages d ON u.UserID = d.UserID LIMIT 10;
FirstName | LastName |        time         |                Message
----------+----------+---------------------+---------------------------------

Chelsea   | Malone   | 2013-10-29 02:08:47 | pede tempor dignissim Sed luctus
(10 rows)
```

Viewing Hive schema and table metadata

When using Hive, you access metadata about schemas and tables by executing statements written in HiveQL (Hive's version of SQL) such as SHOW TABLES . When using the HCatalog Connector, you can get metadata about the tables in the Hive database through several Vertica system tables.

There are four system tables that contain metadata about the tables accessible through the HCatalog Connector:

- HCATALOG_SCHEMATA lists all of the schemas that have been defined using the HCatalog Connector.
- HCATALOG_TABLE_LIST contains an overview of all of the tables available from all schemas defined using the HCatalog Connector. This table only shows the tables that the user querying the table can access. The information in this table is retrieved using a single call to HiveServer2 for each schema defined using the HCatalog Connector, which means there is a little overhead when querying this table.
- HCATALOG_TABLES contains more in-depth information than HCATALOG_TABLE_LIST.
- HCATALOG_COLUMNS lists metadata about all of the columns in all of the tables available through the HCatalog Connector. As for HCATALOG_TABLES, querying this table results in one call to HiveServer2 per table, and therefore can take a while to complete.

The following example demonstrates querying the system tables containing metadata for the tables available through the HCatalog Connector.

```
=> CREATE HCATALOG SCHEMA hcat WITH hostname='hcathost'
-> HCATALOG_SCHEMA='default' HCATALOG_DB='default' HCATALOG_USER='hcatuser';
CREATE SCHEMA
=> SELECT * FROM HCATALOG_SCHEMATA;
-[ RECORD 1 ]--------+---------------------------
schema_id            | 45035996273864536
schema_name          | hcat
schema_owner_id      | 45035996273704962
schema_owner         | dbadmin
```

```
create_time          | 2013-11-05 10:19:54.70965-05
hostname             | hcathost

Synchronizing an HCatalog schema or table with a local schema or table

Querying data from an HCatalog schema can be slow due to Hive performance issues. This slow performance can be especially annoying when you want to examine the structure of the tables in the Hive database. Getting this information from Hive requires you to query the HCatalog schema's metadata using the HCatalog Connector.

To avoid this performance problem you can use the SYNC_WITH_HCATALOG_SCHEMA function to create a snapshot of the HCatalog schema's metadata within a Vertica schema. You supply this function with the name of a pre-existing Vertica schema, typically the one created through CREATE HCATALOG SCHEMA, and a Hive schema available through the HCatalog Connector. You must have permission both in Vertica to write the data and in Hive and HDFS to read it.

> **Note**
> To synchronize a schema, you must have read permission for the underlying files in HDFS. If Hive uses Sentry to manage authorization, then you can use ACL synchronization to manage HDFS access. Otherwise, the user of this function must have read access in HDFS.

The function creates a set of external tables within the Vertica schema that you can then use to examine the structure of the tables in the Hive database. Because the metadata in the Vertica schema is local, query planning is much faster. You can also use standard Vertica statements and system-table queries to examine the structure of Hive tables in the HCatalog schema.

> **Caution**
> The SYNC_WITH_HCATALOG_SCHEMA function overwrites tables in the Vertica schema whose names match a table in the HCatalog schema. Do not use the Vertica schema to store other data.

When SYNC_WITH_HCATALOG_SCHEMA creates tables in Vertica, it matches Hive's STRING and BINARY types to Vertica's VARCHAR(65000) and VARBINARY(65000) types. You might want to change these lengths, using ALTER TABLE SET DATA TYPE, in two cases:

- If the value in Hive is larger than 65000 bytes, increase the size and use LONG VARCHAR or LONG VARBINARY to avoid data truncation. If a Hive string uses multi-byte encodings, you must increase the size in Vertica to avoid data truncation. This step is needed because Hive counts string length in characters while Vertica counts it in bytes.
- If the value in Hive is much smaller than 65000 bytes, reduce the size to conserve memory in Vertica.

The Vertica schema is just a snapshot of the HCatalog schema's metadata. Vertica does not synchronize later changes to the HCatalog schema with the local schema after you call SYNC_WITH_HCATALOG_SCHEMA. You can call the function again to re-synchronize the local schema to the HCatalog schema. If you altered column data types, you will need to repeat those changes because the function creates new external tables.

By default, SYNC_WITH_HCATALOG_SCHEMA does not drop tables that appear in the local schema that do not appear in the HCatalog schema. Thus, after the function call the local schema does not reflect tables that have been dropped in the Hive database since the previous call. You can change this behavior by supplying the optional third Boolean argument that tells the function to drop any table in the local schema that does not correspond to a table in the HCatalog schema.

Instead of synchronizing the entire schema, you can synchronize individual tables by using SYNC_WITH_HCATALOG_SCHEMA_TABLE . If the table already exists in Vertica the function overwrites it. If the table is not found in the HCatalog schema, this function returns an error. In all other respects this function behaves in the same way as SYNC_WITH_HCATALOG_SCHEMA.

If you change the settings of any HCatalog Connector configuration parameters (Apache Hadoop parameters), you must call this function again.

Examples

The following example demonstrates calling SYNC_WITH_HCATALOG_SCHEMA to synchronize the HCatalog schema in Vertica with the metadata in Hive. Because it synchronizes the HCatalog schema directly, instead of synchronizing another schema with the HCatalog schema, both arguments are the same.

```
=> CREATE HCATALOG SCHEMA hcat WITH hostname='hcathost' HCATALOG_SCHEMA='default'
   HCATALOG_USER='hcatuser';
CREATE SCHEMA
=> SELECT sync_with_hcatalog_schema('hcat', 'hcat');
sync_with_hcatalog_schema
-----------------------------------------
Schema hcat synchronized with hcat
tables in hcat = 56
tables altered in hcat = 0
tables created in hcat = 56
stale tables in hcat = 0
table changes erred in hcat = 0
(1 row)

=> -- Use vsql's \d command to describe a table in the synced schema

=> \d hcat.messages
List of Fields by Tables
 Schema  |  Table  | Column |      Type      | Size  | Default | Not Null | Primary Key | Foreign Key
---------+---------+--------+----------------+-------+---------+----------+-------------+-------------
hcat     | messages | id     | int            |     8 |         | f        | f           |
hcat     | messages | userid | varchar(65000) | 65000 |         | f        | f           |
hcat     | messages | "time" | varchar(65000) | 65000 |         | f        | f           |
hcat     | messages | message | varchar(65000) | 65000 |        | f        | f           |
(4 rows)
```

This example shows synchronizing with a schema created using CREATE HCATALOG SCHEMA. Synchronizing with a schema created using CREATE SCHEMA is also supported.

You can query tables in the local schema that you synchronized with an HCatalog schema. However, querying tables in a synchronized schema isn't much faster than directly querying the HCatalog schema, because SYNC_WITH_HCATALOG_SCHEMA only duplicates the HCatalog schema's metadata. The data in the table is still retrieved using the HCatalog Connector.

Data type conversions from Hive to Vertica

The data types recognized by Hive differ from the data types recognized by Vertica. The following table lists how the HCatalog Connector converts Hive data types into data types compatible with Vertica.

Hive Data Type	**Vertica Data Type**
TINYINT (1-byte)	TINYINT (8-bytes)
SMALLINT (2-bytes)	SMALLINT (8-bytes)
INT (4-bytes)	INT (8-bytes)

BIGINT (8-bytes)	BIGINT (8-bytes)
BOOLEAN	BOOLEAN
FLOAT (4-bytes)	FLOAT (8-bytes)
DECIMAL (precision, scale)	DECIMAL (precision, scale)
DOUBLE (8-bytes)	DOUBLE PRECISION (8-bytes)
CHAR (length in characters)	CHAR (length in bytes)
VARCHAR (length in characters)	VARCHAR (length in bytes), if length <= 65000 LONG VARCHAR (length in bytes), if length > 65000
STRING (2 GB max)	VARCHAR (65000)
BINARY (2 GB max)	VARBINARY (65000)
DATE	DATE
TIMESTAMP	TIMESTAMP
LIST/ARRAY	VARCHAR (65000) containing a JSON-format representation of the list.
MAP	VARCHAR (65000) containing a JSON-format representation of the map.
STRUCT	VARCHAR (65000) containing a JSON-format representation of the struct.

Data-width handling differences between Hive and Vertica

The HCatalog Connector relies on Hive SerDe classes to extract data from files on HDFS. Therefore, the data read from these files are subject to Hive's data width restrictions. For example, suppose the SerDe parses a value for an INT column into a value that is greater than 2^{32} -1 (the maximum value for a 32-bit integer). In this case, the value is rejected even if it would fit into a Vertica's 64-bit INTEGER column because it cannot fit into Hive's 32-bit INT.

Hive measures CHAR and VARCHAR length in characters and Vertica measures them in bytes. Therefore, if multi-byte encodings are being used (like Unicode), text might be truncated in Vertica.

Once the value has been parsed and converted to a Vertica data type, it is treated as native data. This treatment can result in some confusion when comparing the results of an identical query run in Hive and in Vertica. For example, if your query adds two INT values that result in a value that is larger than 2^{32} -1, the value overflows its 32-bit INT data type, causing Hive to return an error. When running the same query with the same data in Vertica using the HCatalog Connector, the value will probably still fit within Vertica's 64-int value. Thus the addition is successful and returns a value.

Using nonstandard SerDes

Hive stores its data in unstructured flat files located in the Hadoop Distributed File System (HDFS). When you execute a Hive query, it uses a set of serializer and deserializer (SerDe) classes to extract data from these flat files and organize it into a relational database table. For Hive to be able to extract data from a file, it must have a SerDe that can parse the data the file contains. When you create a table in Hive, you can select the SerDe to be used for the table's data.

Hive has a set of standard SerDes that handle data in several formats such as delimited data and data extracted using regular expressions. You can also use third-party or custom-defined SerDes that allow Hive to process data stored in other file formats. For example, some commonly-used third-party SerDes handle data stored in JSON format.

The HCatalog Connector directly fetches file segments from HDFS and uses Hive's SerDes classes to extract data from them. The Connector includes all Hive's standard SerDes classes, so it can process data stored in any file that Hive natively supports. If you want to query data from a Hive table that uses a custom SerDe, you must first install the SerDe classes on the Vertica cluster.

Determining which SerDe you need

If you have access to the Hive command line, you can determine which SerDe a table uses by using Hive's SHOW CREATE TABLE statement. This statement shows the HiveQL statement needed to recreate the table. For example:

```
hive> SHOW CREATE TABLE msgjson;
OK
CREATE EXTERNAL TABLE msgjson(
messageid int COMMENT 'from deserializer',
userid string COMMENT 'from deserializer',
time string COMMENT 'from deserializer',
message string COMMENT 'from deserializer')
ROW FORMAT SERDE
'org.apache.hadoop.hive.contrib.serde2.JsonSerde'
STORED AS INPUTFORMAT
'org.apache.hadoop.mapred.TextInputFormat'
OUTPUTFORMAT
'org.apache.hadoop.hive.ql.io.HiveIgnoreKeyTextOutputFormat'
LOCATION
'hdfs://hivehost.example.com:8020/user/exampleuser/msgjson'
TBLPROPERTIES (
'transient_lastDdlTime'='1384194521')
Time taken: 0.167 seconds
```

In the example, ROW FORMAT SERDE indicates that a special SerDe is used to parse the data files. The next row shows that the class for the SerDe is named org.apache.hadoop.hive.contrib.serde2.JsonSerde .You must provide the HCatalog Connector with a copy of this SerDe class so that it can read the data from this table.

You can also find out which SerDe class you need by querying the table that uses the custom SerDe. The query will fail with an error message that contains the class name of the SerDe needed to parse the data in the table. In the following example, the portion of the error message that names the missing SerDe class is in bold.

```
=> SELECT * FROM hcat.jsontable;
ERROR 3399:  Failure in UDx RPC call InvokePlanUDL(): Error in User Defined

at com.vertica.udxfence.UDxExecContext.planUDSource(UDxExecContext.java:898)
. . .
```

Installing the SerDe on the Vertica cluster

You usually have two options to getting the SerDe class file the HCatalog Connector needs:

- Find the installation files for the SerDe, then copy those over to your Vertica cluster. For example, there are several third-party JSON SerDes available from sites like Google Code and GitHub. You may find the one that matches the file installed on your Hive cluster. If so, then download the package and copy it to your Vertica cluster.
- Directly copy the JAR files from a Hive server onto your Vertica cluster. The location for the SerDe JAR files depends on your Hive installation. On some systems, they may be located in /usr/lib/hive/lib .

Wherever you get the files, copy them into the /opt/vertica/packages/hcat/lib directory on every node in your Vertica cluster.

Important

If you add a new host to your Vertica cluster, remember to copy every custom SerDer JAR file to it.

Troubleshooting HCatalog Connector problems

You may encounter the following issues when using the HCatalog Connector.

Connection errors

The HCatalog Connector can encounter errors both when you define a schema and when you query it. The types of errors you get depend on which CREATE HCATALOG SCHEMA parameters are incorrect. Suppose you have incorrect parameters for the metastore database, but correct parameters for HiveServer2. In this case, HCatalog-related system table queries succeed, while queries on the HCatalog schema fail. The following example demonstrates creating an HCatalog schema with the correct default HiveServer2 information. However, the port number for the metastore database is incorrect.

```
=> CREATE HCATALOG SCHEMA hcat2 WITH hostname='hcathost'
-> HCATALOG_SCHEMA='default' HCATALOG_USER='hive' PORT=1234;
CREATE SCHEMA
=> SELECT * FROM HCATALOG_TABLE_LIST;
-[ RECORD 1 ]------+--------------------
table_schema_id    | 45035996273864536
table_schema       | hcat2
hcatalog_schema    | default
table_name         | test
hcatalog_user_name | hive

=> SELECT * FROM hcat2.test;
ERROR 3399:  Failure in UDx RPC call InvokePlanUDL(): Error in User Defined
 Object [VHCatSource], error code: 0
com.vertica.sdk.UdfException: Error message is [
org.apache.hcatalog.common.HCatException : 2004 : HCatOutputFormat not
initialized, setOutput has to be called. Cause : java.io.IOException:
MetaException(message:Could not connect to meta store using any of the URIs
provided. Most recent failure: org.apache.thrift.transport.TTransportException:
java.net.ConnectException:
Connection refused
at org.apache.thrift.transport.TSocket.open(TSocket.java:185)
at org.apache.hadoop.hive.metastore.HiveMetaStoreClient.open(
HiveMetaStoreClient.java:277)
. . .
```

To resolve these issues, you must drop and recreate the schema or alter the schema to correct the parameters. If you still have issues, determine whether there are connectivity issues between your Vertica cluster and your Hadoop cluster. Such issues can include a firewall that prevents one or more Vertica hosts from contacting the HiveServer2, metastore, or HDFS hosts.

UDx failure when querying data: error 3399

You might see an error message when querying data (as opposed to metadata like schema information). This might be accompanied by a ClassNotFoundException in the log. This can happen for the following reasons:

- You are not using the same version of Java on your Hadoop and Vertica nodes. In this case you need to change one of them to match the other.
- You have not used hcatUtil to copy all Hadoop and Hive libraries and configuration files to Vertica, or you ran hcatutil and then changed your version of Hadoop or Hive.
- You upgraded Vertica to a new version and did not rerun hcatutil and reinstall the HCatalog Connector.
- The version of Hadoop you are using relies on a third-party library that you must copy manually.
- You are reading files with LZO compression and have not copied the libraries or set the io.compression.codecs property in core-site.xml .
- You are reading Parquet data from Hive, and columns were added to the table after some data was already present in the table. Adding columns does not update existing data, and the ParquetSerDe provided by Hive and used by the HCatalog Connector does not handle this case. This error is due to a limitation in Hive and there is no workaround.
- The query is taking too long and is timing out. If this is a frequent problem, you can increase the value of the UDxFencedBlockTimeout configuration parameter. See General parameters .

If you did not copy the libraries or configure LZO compression, follow the instructions in Configuring Vertica for HCatalog .

If the Hive jars that you copied from Hadoop are out of date, you might see an error message like the following:

```
ERROR 3399: Failure in UDx RPC call InvokePlanUDL(): Error in User Defined Object [VHCatSource],
error code: 0 Error message is [ Found interface org.apache.hadoop.mapreduce.JobContext, but
class was expected ]
HINT hive metastore service is thrift://localhost:13433 (check UDxLogs/UDxFencedProcessesJava.log
in the catalog directory for more information)
```

This error usually signals a problem with hive-hcatalog-core jar . Make sure you have an up-to-date copy of this file. Remember that if you rerun hcatUtil you also need to re-create the HCatalog schema.

You might also see a different form of this error:

```
ERROR 3399: Failure in UDx RPC call InvokePlanUDL(): Error in User Defined Object [VHCatSource],
error code: 0 Error message is [ javax/servlet/Filter ]
```

This error can be reported even if hcatUtil reports that your libraries are up to date. The javax.servlet.Filter class is in a library that some versions of Hadoop use but that is not usually part of the Hadoop installation directly. If you see an error mentioning this class, locate servlet-api-*.jar on a Hadoop node and copy it to the hcat/lib directory on all database nodes. If you cannot locate it on a Hadoop node, locate and download it from the Internet. (This case is rare.) The library version must be 2.3 or higher.

After you have copied the jar to the hcat/lib directory, reinstall the HCatalog connector as explained in Configuring Vertica for HCatalog .

Authentication error when querying data

You might have successfully created a schema using CREATE HCATALOG SCHEMA but get errors at query time such as the following:

```
=> SELECT * FROM hcat.clickdata;
ERROR 6776:  Failed to glob [hdfs:///user/hive/warehouse/click-*.parquet]
because of error: hdfs:///user/hive/warehouse/click-12214.parquet: statAll failed;
error: AuthenticationFailed
```

You might see this error if Hive uses an authorization service. If the permissions on the underlying files in HDFS match those in the authorization service, then Vertica must use user impersonation when accessing that data. To enable user impersonation, set the EnableHCatImpersonation configuration parameter to 1.

Vertica uses the database principal to access HDFS. Therefore, if EnableHCatImpersonation is 0, the Vertica database principal must have access to the data inside the hive warehouse on HDFS. If it does not, you might see the following error:

```
=> SELECT * FROM hcat.salesdata;
ERROR 6776:  Failed to glob [vertica-hdfs:///hive/warehouse/sales/*/*]
because of error: vertica-hdfs:///hive/warehouse/sales/: listStat failed;
error: Permission denied: user=vertica, access=EXECUTE, inode="/hive/warehouse/sales":hdfs:hdfs:d---------
```

The URL scheme in this error message has been changed from hdfs to vertica-hdfs . This is an internal scheme and is not valid in URLs outside of Vertica. You cannot use this scheme when specifying paths in HDFS.

Differing results between Hive and Vertica queries

Sometimes, running the same query on Hive and on Vertica through the HCatalog Connector can return different results. There are a few common causes of this problem.

This discrepancy is often caused by the differences between the data types supported by Hive and Vertica. See Data type conversions from Hive to Vertica for more information about supported data types.

If Hive string values are being truncated in Vertica, this might be caused by multi-byte character encodings in Hive. Hive reports string length in characters, while Vertica records it in bytes. For a two-byte encoding such as Unicode, you need to double the column size in Vertica to avoid truncation.

Discrepancies can also occur if the Hive table uses partition columns of types other than string.

If the Hive table stores partition data in custom locations instead of the default, you will see different query results if you do not specify the CUSTOM_PARTITIONS parameter when creating the Vertica schema. See Using Partitioned Data . Further, even when using custom partitions, there are differences between Vertica and Hive:

- If a custom partition is unavailable at query time, Hive ignores it and returns the rest of the results. Vertica reports an error.
- If a partition is altered in Hive to use a custom location after table creation, Hive reads data from only the new location while Vertica reads data from both the default and the new locations.
- If a partition value and its corresponding directory name disagree, Hive uses the value in its metadata while Vertica uses the value in the directory name.

The following example illustrates these differences. A table in Hive, partitioned on the state column, starts with the following data:

```
hive> select * from inventory;
+--------------+----------------+----------------+--+
| inventory.ID | inventory.quant | inventory.state |
+--------------+----------------+----------------+--+
| 2            | 300            | CA             |
| 4            | 400            | CA             |
| 5            | 500            | DC             |
| 1            | 100            | PA             |
| 2            | 200            | PA             |
+--------------+----------------+----------------+--+
```

The partition for one state, CA, is then moved. This directory contains some data already. Note that the query now returns different results for the CA partitions.

```
hive> ALTER TABLE inventory PARTITION (state='CA') SET LOCATION 'hdfs:///partitions/inventory/state=MD';
hive> select * from inventory;
+--------------+----------------+----------------+--+
| inventory.ID | inventory.quant | inventory.state |
+--------------+----------------+----------------+--+
| 20           | 30000          | CA             |
| 40           | 40000          | CA             |
| 5            | 500            | DC             |
| 1            | 100            | PA             |
| 2            | 200            | PA             |
+--------------+----------------+----------------+--+
5 rows selected (0.399 seconds)
```

The CA partitions were moved to a directory named state=MD. Vertica reports the state for the first two rows, the ones in the new partition location, as MD because of the directory name. It also reports the CA values from the original location in addition to the new one:

```
=> SELECT * FROM hcat.inventory;
 ID | quant | state
----+----------+------
 20 | 30000 | MD
 40 | 40000 | MD
  2 | 300   | CA
  4 | 400   | CA
  1 | 100   | PA
  2 | 200   | PA
  5 | 500   | DC
(7 rows)
```

HCatalog Connector installation fails on MapR

If you mount a MapR file system as an NFS mount point and then install the HCatalog Connector, it could fail with a message like the following:

```
ROLLBACK 2929: Couldn't create new UDx side process,
failed to get UDx side process info from zygote: Broken pipe
```

This might be accompanied by an error like the following in dbLog :

```
java.io.IOException: Couldn't get lock for /home/dbadmin/node02_catalog/UDxLogs/UDxFencedProcessesJava.log
    at java.util.logging.FileHandler.openFiles(FileHandler.java:389)
    at java.util.logging.FileHandler.<init>(FileHandler.java:287)
    at com.vertica.udxfence.UDxLogger.setup(UDxLogger.java:78)
    at com.vertica.udxfence.UDxSideProcess.go(UDxSideProcess.java:75)
    ...
```

This error occurs if you locked your NFS mount point when creating it. Locking is the default. If you use the HCatalog Connector with MapR mounted as an NFS mount point, you must create the mount point with the -o nolock option. For example:

```
sudo mount -o nolock -t nfs MaprCLDBserviceHostname:/mapr/ClusterName/vertica/$(hostname -f)/ vertica
```

You can use the HCatalog Connector with MapR without mounting the MapR file system. If you mount the MapR file system, you must do so without a lock.

Excessive query delays

Network issues or high system loads on the HiveServer2 server can cause long delays while querying a Hive database using the HCatalog Connector. While Vertica cannot resolve these issues, you can set parameters that limit how long Vertica waits before canceling a query on an HCatalog schema. You can set these parameters globally using Vertica configuration parameters. You can also set them for specific HCatalog schemas in the CREATE HCATALOG SCHEMA statement. These specific settings override the settings in the configuration parameters.

The HCatConnectionTimeout configuration parameter and the CREATE HCATALOG SCHEMA statement's HCATALOG_CONNECTION_TIMEOUT parameter control how many seconds the HCatalog Connector waits for a connection to the HiveServer2 server. A value of 0 (the default setting for the configuration parameter) means to wait indefinitely. If the server does not respond by the time this timeout elapses, the HCatalog Connector breaks the connection and cancels the query. If you find that some queries on an HCatalog schema pause excessively, try setting this parameter to a timeout value, so the query does not hang indefinitely.

The HCatSlowTransferTime configuration parameter and the CREATE HCATALOG SCHEMA statement's HCATALOG_SLOW_TRANSFER_TIME parameter specify how long the HCatlog Connector waits for data after making a successful connection to the server. After the specified time has elapsed, the HCatalog Connector determines whether the data transfer rate from the server is at least the value set in the HCatSlowTransferLimit configuration parameter (or by the CREATE HCATALOG SCHEMA statement's HCATALOG_SLOW_TRANSFER_LIMIT parameter). If it is not, then the HCatalog Connector terminates the connection and cancels the query.

You can set these parameters to cancel queries that run very slowly but do eventually complete. However, query delays are usually caused by a slow connection rather than a problem establishing the connection. Therefore, try adjusting the slow transfer rate settings first. If you find the cause of the issue is connections that never complete, you can alternately adjust the Linux TCP socket timeouts to a suitable value instead of relying solely on the HCatConnectionTimeout parameter.

SerDe errors

Errors can occur if you attempt to query a Hive table that uses a nonstandard SerDe. If you have not installed the SerDe JAR files on your Vertica cluster, you receive an error similar to the one in the following example:

```
=> SELECT * FROM hcat.jsontable;
ERROR 3399:  Failure in UDx RPC call InvokePlanUDL(): Error in User Defined
Object [VHCatSource], error code: 0
com.vertica.sdk.UdfException: Error message is [

. . .
```

In the error message, you can see that the root cause is a missing SerDe class (shown in bold). To resolve this issue, install the SerDe class on your Vertica cluster. See Using nonstandard SerDes for more information.

This error may occur intermittently if just one or a few hosts in your cluster do not have the SerDe class.

Integrating with Cloudera Manager

The Cloudera distribution of Hadoop includes Cloudera Manager, a web-based tool for managing a Hadoop cluster. Cloudera Manager can manage any service for which a service description is available, including Vertica.

You can use Cloudera Manager to start, stop, and monitor individual database nodes or the entire database. You can manage both co-located and separate Vertica clusters—Cloudera can manage services on nodes that are not part of the Hadoop cluster.

You must install and configure your Vertica database before proceeding; you cannot use Cloudera Manager to create the database.

Installing the service

> **Note**
> Because the service has to send the database password over the network, you should enable encryption on your Hadoop cluster before

proceeding.

A Cloudera Service Description (CSD) file describes a service that Cloudera can manage. The Vertica CSD is in /opt/vertica/share/CSD on a database node.

To install the Vertica CSD, follow these steps:

1. On a Vertica node, follow the instructions in VerticaAPIKey to generate an API key. You need this key to finish the installation of the CSD.
2. On the Hadoop node that hosts Cloudera Manager, copy the CSD file into /opt/cloudera/csd.
3. Restart Cloudera Manager:
   ```
   $ service cloudera-scm-server restart
   ```
4. In a web browser, go to Cloudera Manager and restart the Cloudera Management Service.
5. If your Vertica cluster is separate from your Hadoop cluster (not co-located on it): Use Cloudera Manager to add the hosts for your database nodes. If your cluster is co-located, skip this step.
6. Use Cloudera Manager to add the Vertica service.
7. On the "Role Assignment" page, select the hosts that are database nodes.
8. On the "Configuration" page, specify values for the following fields:
   - database name
   - agent port (accept the default if you're not sure)
   - API key
   - database user to run as (usually dbadmin) and password

About the agent

When you manage Vertica through Cloudera Manager, you are actually interacting with the Vertica Agent, not the database directly. The Agent runs on all database nodes and interacts with the database on your behalf. Management Console uses the same agent. Most of the time this extra indirection is transparent to you.

A Cloudera-managed service contains one or more roles. In this case the service is "Vertica" and the single role is "Vertica Node".

Available operations

Cloudera Manager shows two groups of operations. Service-level operations apply to the service on all nodes, while role-level operations apply only to a single node.

You can perform the following service-level operations on all nodes:

- Start: Starts the agent and, if it is not already running, the database.
- Stop: Stops the database and agent.
- Restart: Calls Stop and then Start.
- Add Role Instances: Adds new database nodes to Cloudera Manager. The nodes must already be part of the Vertica cluster, and the hosts must already be known to Cloudera Manager.
- Enter Maintenance Mode: Suppresses health alerts generated by Cloudera Manager.
- Exit Maintenance Mode: Resumes normal reporting.
- Update Memory Pool Size: Applies memory-pool settings from the Static Service Pools configuration page.

You can perform all of these operations except Add Role Instances on individual nodes as role-level operations.

Managing memory pools

Cloudera Manager allows you to change resource allocations, such as memory and CPU, for the nodes it manages. If you are using co-located clusters, centrally managing resources can simplify your cluster management. If you are using separate Hadoop and Vertica clusters, you might prefer to manage Vertica separately as described in Managing the database .

Use the Cloudera Manager "Static Service Pools" configuration page to configure resource allocations. The "Vertica Memory Pool" value, specified in GB, is the maximum amount of memory to allocate to the database on each node. If the configuration page includes "Cgroup Memory Hard Limit", set it to the same value as "Vertica Memory Pool".

After you have set these values, you can use the "Update Memory Pool Size" operation to apply the value to the managed nodes. This operation is equivalent to ALTER RESOURCE POOL GENERAL MAXMEMORYSIZE. Configuration changes in "Static Service Pools" do not take effect in Vertica until you perform this operation.

Uninstalling the service

To uninstall the Vertica CSD, follow these steps:

1. Stop the Vertica service and then remove it from Cloudera Manager.
2. Remove the CSD file from /opt/cloudera/csd.
3. From the command line, restart the Cloudera Manager server.
4. In Cloudera Manager, restart the Cloudera Management Service.

Integrating Vertica with the MapR distribution of Hadoop

MapR is a distribution of Apache Hadoop produced by MapR Technologies that extends the standard Hadoop components with its own features. Vertica can integrate with MapR in the following ways:

- You can read data from MapR through an NFS mount point. After you mount the MapR file system as an NFS mount point, you can use CREATE EXTERNAL TABLE AS COPY or COPY to access the data as if it were on the local file system. This option provides the best performance for reading data.
- You can use the HCatalog Connector to read Hive data. Do not use the HCatalog Connector with ORC or Parquet data in MapR for performance reasons. Instead, mount the MapR file system as an NFS mount point and create external tables without using the Hive schema. For more about reading Hive data, see Using the HCatalog Connector .
- You can create a storage location to store data in MapR using the native Vertica format (ROS). Mount the MapR file system as an NFS mount point and then use CREATE LOCATION ...ALL NODES SHARED to create a storage location. (CREATE LOCATION does not support NFS mount points in general, but does support them for MapR.)

> **Note**
> If you create a Vertica database and place its initial storage location on MapR, Vertica designates the storage location for both DATA and TEMP usage. Vertica does not support TEMP storage locations on MapR, so after you create the location, you must alter it to store only DATA files. See Altering location use . Ensure that you have a TEMP location on the Linux file system.

Other Vertica integrations for Hadoop are not available for MapR.

For information on mounting the MapR file system as an NFS mount point, see Accessing Data with NFS and Configuring Vertica Analytics Platform with MapR on the MapR website. In particular, you must configure MapR to add Vertica as a MapR service.

Examples

In the following examples, the MapR file system has been mounted as /mapr.

The following statement creates an external table from ORC data:

```
=> CREATE EXTERNAL TABLE t (a1 INT, a2 VARCHAR(20))
  AS COPY FROM '/mapr/data/file.orc' ORC;
```

The following statement creates an external table from Parquet data and takes advantage of partition pruning (see Using partition columns):

```
=> CREATE EXTERNAL TABLE t2 (id int, name varchar(50), created date, region varchar(50))
  AS COPY FROM '/mapr/*/*/*' PARQUET(hive_partition_cols='created,region');
```

The following statement loads ORC data from MapR into Vertica:

```
=> COPY t FROM '/mapr/data/*.orc' ON ANY NODE ORC;
```

The following statements create a storage location to hold ROS data in the MapR file system:

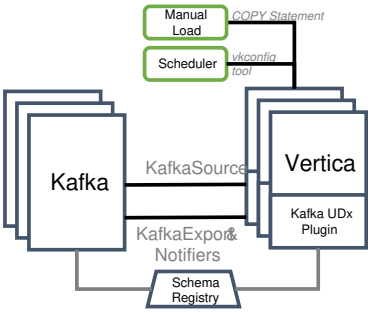
```
=> CREATE LOCATION '/mapr/my.cluster.com/data' SHARED USAGE 'DATA' LABEL 'maprfs';

=> SELECT ALTER_LOCATION_USE('/mapr/my.cluster.com/data', '', 'DATA');
```

Apache Kafka integration

Vertica provides a high-performance mechanism for integrating with Apache Kafka, an open-source distributed real-time streaming platform. Because Vertica can both consume data from and produce data for Kafka, you can use Vertica as part of an automated analytics workflow: Vertica can retrieve data from Kafka, perform analytics on the data, and then send the results back to Kafka for consumption by other applications.

Prerequisites



- Install Vertica .
- Configure the database .

- Install and configure Apache Kafka .

Architecture overview

The Vertica and Kafka integration provides the following features:

- A UDx library containing functions that load and parse data from Kafka topics into Vertica
- A job scheduler that uses the UDL library to continuously consume data from Kafka with exactly-once semantics
- Push-based notifiers that send data collector messages from Vertica to Kafka
- A KafkaExport function that sends Vertica data to Kafka

Vertica as a Kafka consumer

A Kafka consumer reads messages written to Kafka by other data streams. Because Vertica can read messages from Kafka, you can store and analyze data from any application that sends data to Kafka without configuring each individual application to connect to Vertica. Vertica provides tools to automatically or manually consume data loads from Kafka.

Manual loads

Manually load a finite amount of data from Kafka by directly executing a COPY statement. This is useful if you want to analyze, test, or perform additional processing on a set of messages.

For more information, see Consuming data from Kafka .

Automatic loads

Automatically load data from Kafka with a job scheduler. A scheduler constantly loads data and ensures that each Kafka message is loaded exactly once.

You must install Java 8 on each Vertica node that runs the scheduler. For more information, see Automatically consume data from Kafka with the scheduler .

Vertica as a Kafka producer

A Kafka producer sends data to Kafka, which is then available to Kafka consumers for processing. You can send the following types of data to Kafka:

- Vertica anayltics results. Use KafkaExport to export Vertica tables and queries.
- Health and performance data from Data Collector tables. Create push-based notifiers to send this data for consumption for third-party monitoring tools.
- Ad hoc messages. Use NOTIFY to signal that tasks such as stored procedures are complete.

For more information, see Producing data for Kafka .

- Data streaming schema tables
- Avro schema registry with Vertica

Data streaming integration terms

Vertica uses the following terms to describe its streaming feature. These are general terms, which may differ from each specific streaming platform's terminology.

Terminology

Host
: A data streaming server.

Source
: A feed of messages in a common category which streams into the same Vertica target tables. In Apache Kafka, a source is known as a topic.

Partition
: Unit of parallelism within data streaming. Data streaming splits a source into multiple partitions, which can each be served in parallel to consumers such as a Vertica database. Within a partition, messages are usually ordered chronologically.

Offset
: An index into a partition. This index is the position within an ordered queue of messages, not an index into an opaque byte stream.

Message
: A unit of data within data streaming. The data is typically in JSON or Avro format. Messages are loaded as rows into Vertica tables, and are uniquely identified by their source, partition, and offset.

Data loader terminology

Scheduler
: An external tool that schedules data loads from a streaming data source into Vertica.

Microbatch
: A microbatch represents a single segment of a data load from a streaming data source. It encompasses all of the information the scheduler needs to perform a load from a streaming data source into Vertica.

Frame
: The window of time during which a Scheduler executes microbatches to load data. This window controls the duration of each COPY statement the scheduler runs as a part of the microbatch. During the frame, the scheduler gives an active microbatch from each source an opportunity to load data. It gives priority to microbatches that need more time to load data based on the history of previous microbatches.

Stream
: A feed of messages that is identified by a source and partition.

  The offset uniquely identifies the position within a particular source-partition stream.

Lane
: A thread within a job scheduler instance that issues microbatches to perform the load.

  The number of lanes available is based on the PlannedConcurrency of the job scheduler's resource pool. Multiple lanes allow the scheduler to run microbatches for different sources in parallel during a frame.

Configuring Vertica and Kafka

Both Vertica and Kafka have settings you can use to optimize your streaming data loads. The topics in this section explain these settings.

In this section

- Kafka and Vertica configuration settings
- Directly setting Kafka library options
- Configuring Vertica for Apache Kafka version 0.9 and earlier
- Changes to the message.max.bytes setting in Kafka version 0.11 and later

Kafka and Vertica configuration settings

You can fine-tune configuration settings for Vertica and Kafka that optimize performance.

The Vertica and Kafka integration uses rdkafka version 0.11.6. Unless otherwise noted, the following configuration settings use the default librdkafka configuration properties values. For instructions on how to override the default values, see Directly setting Kafka library options .

Vertica producer settings

These settings change how Vertica produces data for Kafka with the KafkaExport function and notifiers .

queue.buffering.max.messages
: Size of the Vertica producer queue. If Vertica generates too many messages too quickly, the queue can fill, resulting in dropped messages.

Increasing this value consumes more memory, but reduces the chance of lost messages.

Defaults :

- KafkaExport: 1000
- Notifiers: 10000

queue.buffering.max.ms

Frequency with which Vertica flushes the producer message queue. Lower values decrease latency at the cost of throughput. Higher values increase throughput, but can cause the producer queue (set by queue.buffering.max.messages) to fill more frequently, resulting in dropped messages.

Default: 100 ms

message.max.bytes

Maximum size of a Kafka protocol request message batch. This value should be the same on your sources, brokers, and producers.

message.send.max.retries

Number of attempts the producer makes to deliver the message to a broker. Higher values increase the chance of success.

retry.backoff.ms

Interval Vertica waits before resending a failed message.

request.required.acks

Number of broker replica acknowledgments Kafka requires before it considers message delivery successful. Requiring acknowledgments increases latency. Removing acknowledgments increases the risk of message loss.

request.timeout.ms

Interval that the producer waits for a response from the broker. Broker response time is affected by server load and the number of message acknowledgments you require.
Higher values increase latency.

compression.type

Compression algorithm used to encode data before sending it to a broker. Compression helps to reduce the network footprint of your Vertica producers and increase disk utilization. Vertica supports gzip and snappy .

Kafka broker settings

Kafka brokers receive messages from producers and distribute them among Kafka consumers. Configure these settings on the brokers themselves. These settings function independently of your producer and consumer settings. For detailed information on Apache Kafka broker settings, refer to the Apache Kafka documentation .

message.max.bytes

Maximum size of a Kafka protocol request message batch.This value should be the same on your sources, brokers, and producers.

num.io.threads

Number of network threads the broker uses to receive and process requests. More threads can increase your concurrency.

num.network.threads

Number of network threads the broker uses to accept network requests. More threads can increase your concurrency.

Vertica consumer settings

The following settings changes how Vertica acts when it consumes data from Kafka. You can set this value using the kafka_conf parameter on the KafkaSource UDL when directly executing a COPY statement. For schedulers, use the --message_max_bytes settings in the scheduler tool .

message.max.bytes

Maximum size of a Kafka protocol request message batch. Set this value to a high enough value to prevent the overhead of fetching batches of messages interfering with loading data. Defaults to 24MB for newly-created load specs.
Important
The meaning of this setting changed between Kafka version 0.10 and 0.11. If you have a scheduler that uses Vertica version 9.1.0 or earlier, see Changes to the message.max.bytes setting in Kafka version 0.11 and later for settings that you might need to change.

Directly setting Kafka library options

Vertica relies on the open source rdkafka library to communicate with Apache Kafka. This library contains many options for controlling how Vertica and Kafka interact. You set the most common rdkafka library options through the settings in the vkconfig utility and the Kafka integration functions such as KafkaSource.

There are some rdkafka settings that cannot be directly set from within the Vertica. Under normal circumstances, you do not need to change them. However, if you find that you need to set a specific rdkafka setting that is not directly available from Vertica, you can directly pass options to the rdkafka library through the kafka_conf options.

The kafka_conf argument is supported when using a scheduler to load data from Kafka. You can set the values in the following ways (listed in order of lower to higher precedence):

- The Linux environment variable VERTICA_RDKAFKA_CONF set on the host where you run the vkconfig utility.
- The Linux environment variable VERTICA_RDKAFKA_CONF_ *KAFKA_CLUSTER* set on the host where you run the vkconfig utility. The *KAFKA_CLUSTER* portion of the variable name is the name of a Kafka cluster you have defined using vkconfig's cluster utility . The settings in this environment variable only affect the specific Kafka cluster you name in *KAFKA_CLUSTER* .
- The --kafka_conf option of the vkconfig utility. This option can be set in the cluster , source , launch , and sync tools. Note that the setting only applies to each vkconfig utility call—it does not carry over to other vkconfig utility calls. For example, if you need to supply an option to the cluster and source tool, you must supply the kafka_conf option to both of them.

> **Note**
> Using an environment variable to set your rdkafka options helps to keep your settings consistent. It is easy to forget to set the --kafka_conf option for each call to the vkconfig script.

All of these options cascade, so setting an option using the --kafka_conf argument to the cluster tool overrides the same option that was set in the environment variables.

You can also directly set rdkafka options when directly calling KafkaExport, KafkaSource, and several other Kafka integration functions. These functions accept a parameter named kafka_conf .

The kafka_conf option settings

The kafka_conf vkconfig option accepts a JSON object with settings in the following formats:

- One or more option/value pairs:
  ```
  --kafka_conf '{"option1":value1[, "option2":value2...]}'
  ```
- A single option with multiple values:
  ```
  --kafka_conf '{"option1":"value1[;value2...]"}'
  ```

See the rdkafka project on GitHub for a list of the configuration options supported by the rdkafka library.

Important

Arbitrarily setting options via kafka_conf can result in errors or unpredictable behavior. If you encounter a problem loading messages after setting an rdkafka option using the kafka_conf option, roll back your change to see if that was the source of the problem.

To prevent confusion, never set options via the kafka_conf parameter that can be set directly through scheduler options. For example, do not use the kafka_conf option to set Kafka's message.max.bytes setting. Instead, use the load-spec tool's --message-max-bytes option.

Example

The following example demonstrates disabling rdkafka's api.version.request option when manually loading messages using KafkaSource. You should always disable this option when accessing Kafka cluster running version 0.9 or earlier. See Configuring Vertica for Apache Kafka version 0.9 and earlier for more information.

```
=> CREATE FLEX TABLE iot_data();
CREATE TABLE
=> COPY public.iot_data SOURCE KafkaSource(stream='iot_json|0|-2',
                                brokers='kafka-01.example.com:9092',
                                stop_on_eof=True,
                                kafka_conf='{"api.version.request":false}')
      PARSER KafkaJSONParser();
 Rows Loaded
-------------
      5000
(1 row)
```

This example demonstrates setting two options with a JSON object when calling the cluster tool. It disables the api.version.request option and enables CRC checks of messages from Kafka using the check.crcs option:

```
$ vkconfig cluster --create --cluster StreamCluster1 \
                   --hosts kafka01.example.com:9092,kafka02.example.com:9092 \
                   --conf myscheduler.config \
                   --kafka_conf '{"api.version.request":false, "check.crcs":true}'
```

The following example demonstrates setting the same options using an environment variable:

```
$ export VERTICA_RDKAFKA_CONF='{"api.version.request":false, "check.crcs":true}'
$ vkconfig cluster --create --cluster StreamCluster1 \
                   --hosts kafka01.example.com:9092,kafka02.example.com:9092 \
                   --conf myscheduler.config
```

Important
Setting the check.crc option is just an example. Vertica does not suggest you enable the CRC check in your schedulers under normal circumstances. It adds additional overhead and can result in slower performance.

Configuring Vertica for Apache Kafka version 0.9 and earlier

Apache Kafka version 0.10 introduced a new feature that allows consumers to determine which version of the Kafka API the Kafka brokers support. Consumers that support this feature send an initial API version query to the Kafka broker to determine the API version to use when communicating with them. Kafka brokers running version 0.9.0 or earlier cannot respond to the API query. If the consumer does not receive a reply from the Kafka broker within a timeout period (set to 10 seconds by default) the consumer can assume the Kafka broker is running Kafka version 0.9.0 or earlier.

The Vertica integration with Kafka supports this API query feature starting in version 9.1.1. This API check can cause problems if you are connecting Vertica to a Kafka cluster running 0.9.0 or earlier. You may notice poorer performance loading messages from Kafka and may experience errors as the 10 second API request timeout can cause parts of the Kafka integration feature to time out and report errors.

For example, if you run the vkconfig source utility to configure a source on a Kafka 0.9 cluster, you may get the following error:

```
$ vkconfig source --create --conf weblog.conf --cluster kafka_weblog --source web_hits
Exception in thread "main" com.vertica.solutions.kafka.exception.ConfigurationException:

```

Disabling the API version request when using the streaming job scheduler

To avoid these problems, you must disable the API version request feature in the rdkafka library that Vertica uses to communicate with Kafka. The easiest way to disable this setting when using the scheduler is to set a Linux environment variable on the host on which you run the vkconfig script. Using the environment variable ensures that each call to vkconfig includes the setting to disable the API version request. The vkconfig script checks two variables:

- VERTICA_RDKAFKA_CONF applies to all Kafka clusters that the scheduler running on the host communicates with.
- VERTICA_RDKAFKA_CONF_ *CLUSTER_NAME* applies to just the Kafka cluster named *CLUSTER_NAME* . Use this variable if your scheduler communicates with several Kafka clusters, some of which are not running version 0.9 or earlier.

If you set both variables, the cluster-specific one takes precedence. This feature is useful if most of the clusters your scheduler connects to are running Kafka 0.9 or earlier, but a few run 0.10 or later. This case, you can disable the API version check for most clusters using the VERTICA_RDKAFKA_CONF variable and re-enable the check for specific clusters using VERTICA_RDKAFKA_CONF_ *CLUSTER_NAME* .

If just a few of your Kafka clusters run version 0.9 or earlier, you can just set the cluster-specific variables for them, and leave the default values in place for the majority of your clusters.

The contents of the environment variable is a JSON object that tells the rdkafka library whether to query the Kafka cluster for the API version it supports:

```
'{"api.version.request":false}'
```

To set the environment variable in BASH, use the export command:

```
$ export VERTICA_RDKAFKA_CONF='{"api.version.request":false}'
```

If you wanted the setting to just affect a cluster named kafka_weblog, the command is:

```
$ export VERTICA_RDKAFKA_CONF_kafka_weblog='{"api.version.request":false}'
```

You can add the command to any of the common user environment configuration files such as ~/.bash_profile or the system-wide files such as /etc/profile . You must ensure that the same setting is used for all users who may run the vkconfig script, including any calls made by daemon processes such as init. You can also directly include this command in any script you use to set configure or start your scheduler.

Disabling the API version request when directly loading messages

You can disable the API request when you directly call KafkaSource to load messages by using the kafka_conf parameter:

```
=> CREATE FLEX TABLE iot_data();
CREATE TABLE
=> COPY public.iot_data SOURCE KafkaSource(stream='iot_json|0|-2',
                                brokers='kafka-01.example.com:9092',
                                stop_on_eof=True,
                                kafka_conf='{"api.version.request":false}')
      PARSER KafkaJSONParser();
 Rows Loaded
-------------
      5000
(1 row)
```

- Directly setting Kafka library options
- Automatically consume data from Kafka with the scheduler
- Manually consume data from Kafka

Changes to the message.max.bytes setting in Kafka version 0.11 and later

In Kafka version 0.10 and earlier, the message.max.bytes setting configured the maximum allowable size for an individual message. Starting in version 0.11, Kafka began grouping messages into batches. This version changed the meaning of this setting to be the largest allowable size of a message batch.

This change can have a significant impact on how fast your Vertica database loads messages from Kafka 0.11 and later. If you created your streaming job scheduler using Vertica version 9.1.0 or earlier, you might find that its load spec's message.max.bytes value is set too low. Upgrading your scheduler does not adjust this setting automatically.

To prevent slow throughput when using Vertica with Kafka 0.11 and later, manually adjust the message.max.bytes setting in scheduler's load spec. Testing by Vertica suggests the best value for this setting is 25165824 (24 × 1024 × 1024) bytes.

The following example demonstrates updating the message.max.bytes setting in the load spec named weblog_load of an existing scheduler that is defined using the configuration file named weblog.conf:

```
$ /opt/vertica/packages/kafka/bin/vkconfig load-spec --update \
    --load-spec weblog_load --conf weblog.conf --message-max-bytes 25165824
```

Vertica Eon Mode and Kafka

You can use the Vertica integration with Apache Kafka when Vertica is running in Eon Mode . For Eon Mode running in a cloud environment, consider using a larger frame duration for schedulers in clusters. Cloud infrastructures lead to larger latencies overall, especially when storage layers are separated from compute layers. If you do not account for the added latency, you can experience a lower data throughput, as more of the frame's time is lost to overhead caused by the cloud environment. Using a longer frame length can also help prevent Vertica from creating many small ROS containers when loading data from Kafka. The trade off when you use a larger frame length is that your data load experiences more latency. See Choosing a frame duration for more information.

Consuming data from Kafka

A Kafka consumer subscribes to one or more topics managed by a Kafka cluster. Each topic is a data stream, an unbounded dataset that is represented as an ordered sequence of messages. Vertica can manually or automatically consume Kafka topics to perform analytics on your streaming data.

Manually consume data

Manually consume data from Kafka with a COPY statement that calls a KafkaSource function and parser. Manual loads are helpful when you want to:

- Populate a table one time with the messages currently in Kafka.
- Analyze a specific set of messages. You can choose the subset of data to load from the Kafka stream.
- Explore the data in a Kafka stream before you set up a scheduler to continuously stream the data into Vertica.
- Control the data load in ways not possible with the scheduler. For example, you cannot perform business logic or custom rejection handling during the data load from Kafka because the scheduler does not support additional processing during its transactions. Instead, you can periodically run a transaction that executes a COPY statement to load data from Kafka, and then perform additional processing.

For a detailed example, see Manually consume data from Kafka .

Automatically consume data

Automatically consume streaming data from Kafka into Vertica with a scheduler , a command-line tool that loads data as it arrives. The scheduler loads data in segments defined by a microbatch, a unit of work that processes the partitions of a single Kafka topic for a specified duration of time. You can manage scheduler configuration and options using the vkconfig tool .

For details, see Automatically consume data from Kafka with the scheduler .

Monitoring consumption

You must monitor message consumption to ensure that Kafka and Vertica are communicating effectively. You can use native Kafka tools to monitor consumer groups, or you can use vkconfig tool to view consumption details.

For additional information, see Monitoring message consumption .

Parsing data with Kafka filters

Your data stream might encode data that the Kafka parser functions cannot parse by default. Use Kafka filters to delimit messages in your stream to improve data consumption.

For details, see Parsing custom formats .

In this section

- Manually consume data from Kafka
- Automatically consume data from Kafka with the scheduler
- Monitoring message consumption
- Parsing custom formats

Manually consume data from Kafka

You can manually load streaming data from Kafka into Vertica using a COPY statement, just as you can load a finite set of data from a file or other source. Unlike a standard data source, Kafka data arrives continuously as a stream of messages that you must parse before loading into Vertica. Use Kafka functions in the COPY statement to prepare the data stream.

This example incrementally builds a COPY statement that manually loads JSON-encoded data from a Kafka topic named web_hits. The web_hits topic streams server logs of web site requests.

For information about loading data into Vertica, see Data load .

Creating the target table

To determine the target table schema, you must identify the message structure. The following is a sample of the web_hits stream:

```
{"url": "list.jsp", "ip": "144.177.38.106", "date": "2017/05/02 20:56:00",
"user-agent": "Mozilla/5.0 (compatible; MSIE 6.0; Windows NT 6.0; Trident/5.1)"}
{"url": "search/wp-content.html", "ip": "215.141.172.28", "date": "2017/05/02 20:56:01",
"user-agent": "Opera/9.53.(Windows NT 5.2; sl-SI) Presto/2.9.161 Version/10.00"}
```

This topic streams JSON-encoded data. Because JSON data is inconsistent and might contain unpredictable added values, store this data stream in a flex table. Flex tables dynamically accept additional fields that appear in the data.

The following statement creates a flex table named web_table to store the data stream:

```
=> CREATE FLEX TABLE web_table();
```

To begin the COPY statement, add the web_table as the target table:

```
COPY web_table
```

For more information about flex tables, see Flex tables .

Note
If you are copying data containing default values into a flex table, you must identify the default value column as __raw__ . For more information, see Bulk Loading Data into Flex Tables .

Defining KafkaSource

The source of your COPY statement is always KafkaSource . KafkaSource accepts details about the data stream, Kafka brokers, and additional processing options to continuously load data until an end condition is met.

Stream details

The stream parameter defines the data segment that you want to load from one or more topic partitions. Each Kafka topic splits its messages into different partitions to get scalable throughput. Kafka keeps a backlog of messages for each topic according to rules set by the Kafka administrator. You can choose to load some or all of the messages in the backlog, or just load the currently streamed messages.

For each partition, the stream parameter requires the topic name, topic partition, and the partition offset as a list delimited by a pipe character (|). Optionally, you can provide and end offset as an end condition to stop loading from the data stream:

'stream=' *topic_name* | *partition* | *start_offset* [| *end_offset*]'

To load the entire backlog from a single partition of the web_hits topic, use the SOURCE keyword to append KafkaSource with the following stream parameter values:

```
COPY ...
SOURCE KafkaSource(stream='web_hits|0|-2', ...
```

In the previous example:

- web_hits is the name of the topic to load data from.
- 0 is the topic partition to load data from. Topic partitions are 0-indexed, and web_hits contains only one partition.
- -2 loads the entire backlog. This is a special offset value that tells KafkaSource to start loading at the earliest available message offset.

Loading multiple partitions

This example loads from only one partition, but it is important to understand how to load from multiple partitions in a single COPY statement.

To load from additional partitions in the same topic, or even additional topics, supply a comma-separated list of topic name, partition number, and offset values delimited by pipe characters. For example, the following stream argument loads the entire message backlog from partitions 0 through 2 of the web_hits topic:

```
KafkaSource(stream='web_hits|0|-2,web_hits|1|-2,web_hits|2|-2'...
```

Note
While you can load messages from different Kafka topics in the same COPY statement, you must ensure the data from the different topics is compatible with the target table's schema. The schema is less of a concern if you are loading data into a flex table, which can accommodate almost any data you want to load.

When you load multiple partitions in the same COPY statement, you can set the executionparallelism parameter to define the number of threads created for the COPY statement. Ideally, you want to use one thread per partition. You can choose to not specify a value and let Vertica determine the number of threads based on the number of partitions and the resources available in the resource pool. In this example, there is only one partition, so there's no need for additional threads to load data.

> **Note**
> The EXECUTIONPARALLELISM setting on the resource pool assigned is the upper limit on the number of threads your COPY statement can use. Setting executionparallelism on the KafkaSource function call to a value that is higher than that of the resource pool's EXECUTIONPARALLELISM setting does not increase the number of threads Vertica uses beyond the limits of the resource pool.

Adding the Kafka brokers

KafkaSource requires the host names (or IP addresses) and port numbers of the brokers in your Kafka cluster. The Kafka brokers are the service Vertica accesses in order to retrieve the Kafka data. In this example, the Kafka cluster has one broker named kafka01.example.com, running on port 9092. Append the brokers parameter and value to the COPY statement:

```
COPY ...
SOURCE KafkaSource(stream='web_hits|0|-2',
                   brokers='kafka01.example.com:9092', ...
```

Choosing the end condition

Because data continuously arrives from Kafka, manual loads from Kafka require that you define an end condition that indicates when to stop loading data. In addition to the end offset described in Stream Details , you can choose to:

- Copy as much data as possible for a set duration of time.
- Load data until no new data arrives within a timeout period.
- Load all available data, and not wait for any further data to arrive.

This example runs COPY for 10000 milliseconds (10 seconds) to get a sample of the data. If the COPY statement is able to load the entire backlog of data in under 10 seconds, it spends the remaining time loading streaming data as it arrives. This values is set in the duration parameter. Append the duration value to complete the KafkaSource definition:

```
COPY ...
SOURCE KafkaSource(stream='web_hits|0|-2',
                   brokers='kafka01.example.com:9092',
                   duration=interval '10000 milliseconds')
```

If you start a long-duration COPY statement from Kafka and need to stop it, you can call one of the functions that closes its session, such as CLOSE_ALL_SESSIONS .

Important
The duration that you set for your data load is not exact. The duration controls how long the KafkaSource process runs.

Selecting a parser

Kafka does not enforce message formatting on its data streams. Messages are often in Avro or JSON format, but they could be in any format. Your COPY statement usually uses one of three Kafka-specific parsers:

- KafkaParser
- KafkaJSONParser
- KafkaAvroParser

Because the Kafka parsers can recognize record boundaries in streaming data, the other parsers (such as the Flex parsers) are not directly compatible with the output of KafkaSource. You must alter the KafkaSource output using filters before other parsers can process the data. See Parsing custom formats for more information.

In this example, the data in the web_hits is encoded in JSON format, so it uses the KafkaJSONParser. This value is set in the COPY statement's PARSER clause:

```
COPY ...
SOURCE ...
PARSER KafkaJSONParser()
```

Storing rejected data

Vertica saves raw Kafka messages that the parser cannot parse to a rejects table, along with information on why it was rejected. This table is created by the COPY statement. This example saves rejects to the table named web_hits_rejections. This value is set in the COPY statement's REJECTED DATA AS TABLE clause:

```
COPY ...
SOURCE ...
PARSER ...
REJECTED DATA AS TABLE public.web_hits_rejections;
```

Loading the data stream into Vertica

The following steps load JSON data from the web_hits topic for 10 seconds using the COPY statement that was incrementally built in the previous sections:

1. Execute the COPY statement:

```
=> COPY web_table
   SOURCE KafkaSource(stream='web_hits|0|-2',
                      brokers='kafka01.example.com:9092',
                      duration=interval '10000 milliseconds')
   PARSER KafkaJSONParser()
   REJECTED DATA AS TABLE public.web_hits_rejections;
 Rows Loaded
-------------
         800
(1 row)
```

2. Compute the flex table keys:

```
=> SELECT compute_flextable_keys('web_table');
               compute_flextable_keys
-----------------------------------------------------
 Please see public.web_table_keys for updated keys
(1 row)
```

   For additional details, see Computing flex table keys .

3. Query web_table_keys to return the keys:

```
=> SELECT * FROM web_table_keys;
  key_name  | frequency | data_type_guess
------------+-----------+-----------------
 date       |       800 | Timestamp
 user_agent |       800 | Varchar(294)
 ip         |       800 | Varchar(30)
 url        |       800 | Varchar(88)
(4 rows)
```

4. Query web_table to return the data loaded from the web_hits Kafka topic:

```
=> SELECT date, url, ip FROM web_table LIMIT 10;
        date         |                 url                  |       ip
---------------------+--------------------------------------+-----------------

Automatically consume data from Kafka with the scheduler

Vertica offers a scheduler that loads streamed messages from one or more Kafka topics. Automatically loading streaming data has a number of advantages over manually using COPY:

- The streamed data automatically appears in your database. The frequency with which new data appears in your database is governed by the scheduler's frame duration.
- The scheduler provides an exactly-once consumption process. The schedulers manage offsets for you so that each message sent by Kafka is consumed once.
- You can configure backup schedulers to provide high-availability. Should the primary scheduler fail for some reason, the backup scheduler automatically takes over loading data.
- The scheduler manages resources for the data load. You control its resource usage through the settings on the resource pool you assign to it . When loading manually, you must take into account the resources your load consumes.

There are a few drawbacks to using a scheduler which may make it unsuitable for your needs. You may find that schedulers do not offer the flexibility you need for your load process. For example, schedulers cannot perform business logic during the load transaction. If you need to perform this sort of processing, you are better off creating your own load process. This process would periodically run COPY statements to load data from Kafka. Then it would perform the business logic processing you need before committing the transaction.

For information on job scheduler requirements, refer to Apache Kafka integrations .

What the job scheduler does

The scheduler is responsible for scheduling loads of data from Kafka. The scheduler's basic unit of processing is a frame, which is a period of time. Within each frame, the scheduler assigns a slice of time for each active microbatch to run. Each microbatch is responsible for loading data from a single source. Once the frame ends, the scheduler starts the next frame. The scheduler continues this process until you stop it.

The anatomy of a scheduler

Each scheduler has several groups of settings, each of which control an aspect of the data load. These groups are:

- The scheduler itself, which defines the configuration schema, frame duration, and resource pool.
- Clusters, which define the hosts in the Kafka cluster that the scheduler contacts to load data. Each scheduler can contain multiple clusters, allowing you to load data from multiple Kafka clusters with a single scheduler.
- Sources, which define the Kafka topics and partitions in those topics to read data from.
- Targets, which define the tables in Vertica that will receive the data. These tables can be traditional Vertica database tables, or they can be flex tables.
- Load specs, which define setting Vertica uses while loading the data. These settings include the parsers and filters Vertica needs to use to load the data. For example, if you are reading a Kafka topic that is in Avro format, your load spec needs to specify the Avro parser and schema.
- Microbatches, which represent an individual segment of a data load from a Kafka stream. They combine the definitions for your cluster, source, target, and load spec that you create using the other vkconfig tools. The scheduler uses all of the information in the microbatch to execute COPY statements using the KafkaSource UDL function to transfer data from Kafka to Vertica. The statistics on each microbatch's load is stored in the stream_microbatch_history table.

The vkconfig script

You use a Linux command-line script named vkconfig to create, configure, and run schedulers. This script is installed on your Vertica hosts along with the Vertica server in the following path:

```
/opt/vertica/packages/kafka/bin/vkconfig
```

> **Note**
> You can install and use the vkconfig utility on a non-Vertica host. You may want to do this if:
>
> - You do not want the scheduler to use Vertica host resources.
> - You want users who do not have shell accounts on the Vertica hosts to be able to set up and alter schedulers.
>
> The easiest way to install vkconfig on a host is to install the Vertica server RPM. You must use the RPM that matches the version of Vertica installed on your database cluster. Do not create a database after installing the RPM. The vkconfig utility and its associated files will be in the /opt/vertica/packages/kafka/bin directory on the host.

The vkconfig script contains multiple tools. The first argument to the vkconfig script is always the tool you want to use. Each tool performs one function, such as changing one group of settings (such as clusters or sources) or starting and stopping the scheduler. For example, to create or configure a scheduler, you use the command:

```
$ /opt/vertica/packages/kafka/bin/vkconfig scheduler other options...
```

What happens when you create a scheduler

When you create a new scheduler, the vkconfig script takes the following steps:

- Creates a new Vertica schema using the name you specified for the scheduler. You use this name to identify the scheduler during configuration.
- Creates the tables needed to manage the Kafka data load in the newly-created schema. See Data streaming schema tables for more information.

Validating schedulers

When you create or configure a scheduler, it validates the following settings:

- Confirms that all brokers in the specified cluster exist.
- Connects to the specified host or hosts and retrieves the list of all brokers in the Kafka cluster. Getting this list always ensures that the scheduler has an up-to-date list of all the brokers. If the host is part of a cluster that has already been defined, the scheduler cancels the configuration.
- Confirms that the specified source exists. If the source no longer exists, the source is disabled.
- Retrieves the number of partitions in the source. If the number of partitions retrieved from the source is different than the partitions value saved by the scheduler, Vertica updates the scheduler with the number of partitions retrieved from the source in the cluster.

You can disable validation using the --validation-type option in the vkconfig script's scheduler tool. See Scheduler tool options for more information.

Synchronizing schedulers

By default, the scheduler automatically synchronizes its configuration and source information with Kafka host clusters. You can configure the synchronization interval using the --config-refresh scheduler utility option. Each interval, the scheduler:

- Checks for updates to the scheduler's configuration by querying its settings in its Vertica configuration schema.
- Performs all of the checks listed in Validating Schedulers .

You can configure synchronization settings using the --auto-sync option using the vkconfig script's scheduler tool. Scheduler tool options for details.

Launching a scheduler

You use the vkconfig script's launch tool to launch a scheduler.

When you launch a scheduler, it collects data from your sources, starting at the specified offset. You can view the stream_microbatch_history table to see what the scheduler is doing at any given time.

To learn how to create, configure, and launch a scheduler, see Setting up a scheduler in this guide.

You can also choose to bypass the scheduler. For example, you might want to do a single load with a specific range of offsets. For more information, see Manually consume data from Kafka in this guide.

If the Vertica cluster goes down, the scheduler attempts to reconnect and fails. You must relaunch the scheduler when the cluster is restarted.

Managing a running scheduler

When you launch a scheduler from the command line, it runs in the foreground. It will run until you kill it (or the host shuts down). Usually, you want to start the scheduler as a daemon process that starts it when the host operating system starts, or after the Vertica database has started.

You shut down a running scheduler using the vkconfig script's shutdown tool. See Shutdown tool options for details.

You can change most of a scheduler's settings (adding or altering clusters, sources, targets, and microbatches for example) while it is running. The scheduler automatically acts on the configuration updates.

Launching multiple job schedulers for high availability

For high availability, you can launch two or more identical schedulers that target the same configuration schema. You differentiate the schedulers using the launch tool's --instance-name option (see Launch tool options).

The active scheduler loads data and maintains an S lock on the stream_lock table. The scheduler not in use remains in stand-by mode until the active scheduler fails or is disabled. If the active scheduler fails, the backup scheduler immediately obtains the lock on the stream_lock table, and takes over loading data from Kafka where the failed scheduler left off.

Managing messages rejected during automatic loads

Vertica rejects messages during automatic loads using the parser definition, which is required in the microbatch load spec .

The scheduler creates a rejection table to store rejected messages for each microbatch automatically. To manually specify a rejection table, use the --rejection-schema and --rejection-table microbatch utility options when creating the microbatch. Query the stream_microbatches table to return the rejection schema and table for a microbatch.

For additional details about how Vertica handles rejected data, see Handling messy data .

Passing options to the scheduler's JVM

The scheduler uses a Java Virtual Machine to connect to Vertica via JDBC. You can pass command-line options to the JVM through a Linux environment variable named VKCONFIG_JVM_OPTS. This option is useful when configuring a scheduler to use TLS/SSL encryption when connecting to Vertica. See Configuring your scheduler for TLS connections for more information.

Viewing schedulers from the MC

You can view the status of Kafka jobs from the MC. For more information, refer to Viewing load history .

In this section

- Setting up a scheduler
- Choosing a frame duration
- Managing scheduler resources and performance
- Using connection load balancing with the Kafka scheduler
- Limiting loads using offsets
- Updating schedulers after Vertica upgrades

Setting up a scheduler

You set up a scheduler using the Linux command line. Usually you perform the configuration on the host where you want your scheduler to run. It can be one of your Vertica hosts, or a separate host where you have installed the vkconfig utility (see The vkconfig Script for more information).

Follow these steps to set up and start a scheduler to stream data from Kafka to Vertica:

1. Create a Config File (Optional)
2. Add the Kafka Bin Directory to Your Path (Optional)
3. Create a Resource Pool for Your Scheduler
4. Create the Scheduler
5. Create a Cluster
6. Create a Data Table
7. Create a Source
8. Create a Target
9. Create a Load-Spec
10. Create a Microbatch
11. Launch the Scheduler

These steps are explained in the following sections. These sections will use the example of loading web log data (hits on a web site) from Kafka into a Vertica table.

Create a config file (optional)

Many of the arguments you supply to the vkconfig script while creating a scheduler do not change. For example, you often need to pass a username and password to Vertica to authorize the changes to be made in the database. Adding the username and password to each call to vkconfig is tedious and error-prone.

Instead, you can pass the vkconfig utility a configuration file using the --conf option that specifies these arguments for you. It can save you a lot of typing and frustration.

The config file is a text file with a *keyword* = *value* pair on each line. Each keyword is a vkconfig command-line option, such as the ones listed in Common vkconfig script options .

The following example shows a config file named weblog.conf that will be used to define a scheduler named weblog_sched. This config file is used throughout the rest of this example.

```
# The configuraton options for the weblog_sched scheduler.
username=dbadmin
password=mypassword
dbhost=vertica01.example.com
dbport=5433
config-schema=weblog_sched
```

Add the vkconfig directory to your path (optional)

The vkconfig script is located in the /opt/vertica/packages/kafka/bin directory. Typing this path for each call to vkconfig is tedious. You can add vkconfig to your search path for your current Linux session using the following command:

```
$ export PATH=/opt/vertica/packages/kafka/bin:$PATH
```

For the rest of your session, you are able to call vkconfig without specifying its entire path:

```
$ vkconfig
Invalid tool
Valid options are scheduler, cluster, source, target, load-spec, microbatch, sync, launch,
shutdown, help
```

If you want to make this setting permanent, add the export statement to your ~/.profile file. The rest of this example assumes that you have added this directory to your shell's search path.

Create a resource pool for your scheduler

Vertica recommends you always create a resource pool specifically for each scheduler. Schedulers assume they have exclusive use of the resource pool they are assigned. Using a separate pool for a scheduler lets you fine-tune its impact on your Vertica cluster's performance. You create resource pools within Vertica using the CREATE RESOURCE POOL statement.

The following resource pool settings play an important role when creating your scheduler's resource pool:

- PLANNEDCONCURRENCY determines the number of microbatches (COPY statements) that the scheduler sends to Vertica simultaneously.
- EXECUTIONPARALLELISM determines the maximum number of threads that each node creates to process a microbatch's partitions.
- QUEUETIMEOUT provides manual control over resource timings. Set this to 0 to allow the scheduler to manage timings.

See Managing scheduler resources and performance for detailed information about these settings and how to fine-tune a resource pool for your scheduler.

The following CREATE RESOURCE POOL statement creates a resource pool that loads 1 microbatch and processes 1 partition:

```
=> CREATE RESOURCE POOL weblog_pool
   MEMORYSIZE '10%'
   PLANNEDCONCURRENCY 1
   EXECUTIONPARALLELISM 1
   QUEUETIMEOUT 0;
```

If you do not create and assign a resource pool for your scheduler, it uses a portion of the GENERAL resource pool. Vertica suggests you do not use the GENERAL pool for schedulers used in production environments. This fallback to using the GENERAL pool is intended as a convenience during testing your scheduler configuration. When you are ready to deploy your scheduler, create a resource pool that you have tuned to its specific needs. Each time you start a scheduler that is using the GENERAL pool, the vkconfig utility will display a warning message.

Not allocating enough resources to your schedulers can result in errors. For example, you may get OVERSHOT DEADLINE FOR FRAME errors if the scheduler is not able to load data from all of the topics it is supposed to in a data frame.

See Resource pool architecture for more information about resource pools.

Create the scheduler

Vertica includes a default scheduler named stream_config. You can use this scheduler or create a new scheduler using the vkconfig script's scheduler tool with the --create and --config-schema options:

```
$ vkconfig scheduler --create --config-schema scheduler_name --conf conf_file
```

The --create and --config-schema options are the only ones required to add a scheduler with default options. This command creates a new schema in Vertica that holds the scheduler's configuration. See What Happens When You Create a Scheduler for details on the creation of the scheduler's schema.

You can use additional configuration parameters to further customize your scheduler. See Scheduler tool options for more information.

The following example:

- Creates a scheduler named weblog_sched using the -- config-schema option.
- Grants privileges to configure and run the scheduler to the Vertica user named kafka_user with the --operator option. The dbadmin user must specify additional privileges separately.
- Specifies a frame duration of seven minutes with the --frame-duration option. For more information about picking a frame duration, see Choosing a frame duration .
- Sets the resource pool that the scheduler uses to the weblog_pool created earlier:

```
$ vkconfig scheduler --create --config-schema weblog_sched --operator kafka_user \
  --frame-duration '00:07:00' --resource-pool weblog_pool --conf weblog.conf
```

> **Note**
> Technically, the previous example doesn't need to supply the --config-schema argument because it is set in the weblog.conf file. It appears in this example for clarity. There's no harm in supplying it on the command line as well as in the configuration file, as long as the values match. If they do not match, the value given on the command line takes priority.

Create a cluster

You must associate at least one Kafka cluster with your scheduler. Schedulers can access more than one Kafka cluster. To create a cluster, you supply a name for the cluster and host names and ports the Kafka cluster's brokers.

When you create a cluster, the scheduler attempts to validate it by connecting to the Kafka cluster. If it successfully connects, the scheduler automatically retrieves the list of all brokers in the cluster. Therefore, you do not have to list every single broker in the --hosts parameter.

The following example creates a cluster named kafka_weblog, with two Kafka broker hosts: kafka01 and kafka03 in the example.com domain. The Kafka brokers are running on port 9092.

```
$ vkconfig cluster --create --cluster kafka_weblog \
  --hosts kafka01.example.com:9092,kafka03.example.com:9092 --conf weblog.conf
```

See Cluster tool options for more information.

Create a source

Next, create at least one source for your scheduler to read. The source defines the Kafka topic the scheduler loads data from as well as the number of partitions the topic contains.

To create and associate a source with a configured scheduler, use the source tool. When you create a source, Vertica connects to the Kafka cluster to verify that the topic exists. So, before you create the source, make sure that the topic already exists in your Kafka cluster. Because Vertica verifies the existence of the topic, you must supply the previously-defined cluster name using the --cluster option.

The following example creates a source for the Kafka topic named web_hits on the cluster created in the previous step. This topic has a single partition.

```
$ vkconfig source --create --cluster kafka_weblog --source web_hits --partitions 1 --conf weblog.conf
```

> **Note**
> The --partitions parameter is the number of partitions to load, not a list of individual partitions. For example, if you set this parameter to 3, the scheduler will load data from partitions 0, 1, and 2.

See Source tool options for more information.

Create a data table

Before you can create a target for your scheduler, you must create a target table in your Vertica database. This is the table Vertica uses to store the data the scheduler loads from Kafka. You must decide which type of table to create for your target:

- A standard Vertica database table, which you create using the CREATE TABLE statement. This type of table stores data efficiently. However, you must ensure that its columns match the data format of the messages in Kafka topic you are loading. You cannot load complex types of data into a standard Vertica table.
- A flex table, which you create using CREATE FLEXIBLE TABLE . A flex table is less efficient than a standard Vertica database table. However, it is flexible enough to deal with data whose schema varies and changes. It also can load most complex data types that (such as maps and lists) that standard Vertica tables cannot.

Important

Avoid having columns with primary key restrictions in your target table. The scheduler stops loading data if it encounters a row that has a value which violates this restriction. If you must have a primary key restricted column, try to filter out any redundant values for that column in the streamed data before is it loaded by the scheduler.

The data in this example is in a set format, so the best table to use is a standard Vertica table. The following example creates a table named web_hits to hold four columns of data. This table is located in the public schema.

```
=> CREATE TABLE web_hits (ip VARCHAR(16), url VARCHAR(256), date DATETIME, user_agent VARCHAR(1024));
```

> **Note**
> You do not need to create a rejection table to store rejected messages. The scheduler creates the rejection table automatically.

Create a target

Once you have created your target table, you can create your scheduler's target. The target tells your scheduler where to store the data it retrieves from Kafka. This table must exist when you create your target. You use the vkconfig script's target tool with the --target-schema and --target_table options to specify the Vertica target table's schema and name. The following example adds a target for the table created in the previous step.

```
$ vkconfig target --create --target-schema public --target-table web_hits --conf weblog.conf
```

See Target tool options for more information.

Create a load spec

The scheduler's load spec provides parameters that Vertica uses when parsing the data loaded from Kafka. The most important option is --parser which sets the parser that Vertica uses to parse the data. You have three parser options:

- KafkaAvroParser for data in Avro format.
- KafkaJSONParser for data in JSON format.
- KafkaParser to load each message into a single VARCHAR field. See Parsing custom formats for more information.

In this example, the data being loaded from Kafka is in JSON format. The following command creates a load spec named weblog_load and sets the parser to KafkaJSONParser.

```
$ vkconfig load-spec --create --parser KafkaJSONParser --load-spec weblog_load --conf weblog.conf
```

See Load spec tool options for more information.

Create a microbatch

The microbatch combines all of the settings added to the scheduler so far to define the individual COPY statements that the scheduler uses to load data from Kafka.

The following example uses all of the settings created in the previous examples to create a microbatch called weblog.

```
$ vkconfig microbatch --create --microbatch weblog --target-schema public --target-table web_hits \
      --add-source web_hits --add-source-cluster kafka_weblog --load-spec weblog_load \
      --conf weblog.conf
```

For microbatches that might benefit from a reduced transaction size, consider using the --max-parallelism option when creating the microbatch. This option splits a single microbatch with multiple partitions into the specified number of simultaneous COPY statements consisting of fewer partitions.

See Microbatch tool options for more information about --max-parallelism and other options.

Launch the scheduler

Once you've created at least one microbatch, you can run your scheduler. You start your scheduler using the launch tool, passing it the name of the scheduler's schema. The scheduler begins scheduling microbatch loads for every enabled microbatch defined in its schema.

The following example launches the weblog scheduler defined in the previous steps. It uses the nohup command to prevent the scheduler being killed when the user logs out, and redirects stdout and stderr to prevent a nohup.out file from being created.

```
$ nohup vkconfig launch --conf weblog.conf >/dev/null 2>&1 &
```

Important

Vertica does not recommend specifying a password on the command line. Passwords on the command line can be exposed by the system's list of processes, which shows the command line for each process. Instead, put the password in a configuration file. Make sure the configuration file's permissions only allow it to be read by the user.

See Launch tool options for more information.

Checking that the scheduler is running

Once you have launched your scheduler, you can verify that it is running by querying the stream_microbatch_history table in the scheduler's schema. This table lists the results of each microbatch the scheduler has run.

For example, this query lists the microbatch name, the start and end times of the microbatch, the start and end offset of the batch, and why the batch ended. The results are ordered to start from when the scheduler was launched:

```
=> SELECT microbatch, batch_start, batch_end, start_offset,
        end_offset, end_reason
        FROM weblog_sched.stream_microbatch_history
        ORDER BY batch_start DESC LIMIT 10;

 microbatch |       batch_start          |         batch_end          | start_offset | end_offset |  end_reason

Choosing a frame duration

One key setting for your scheduler is its frame duration. The duration sets the amount of time the scheduler has to run all of the microbatches you have defined for it. This setting has significant impact on how data is loaded from Apache Kafka.

What happens during each frame

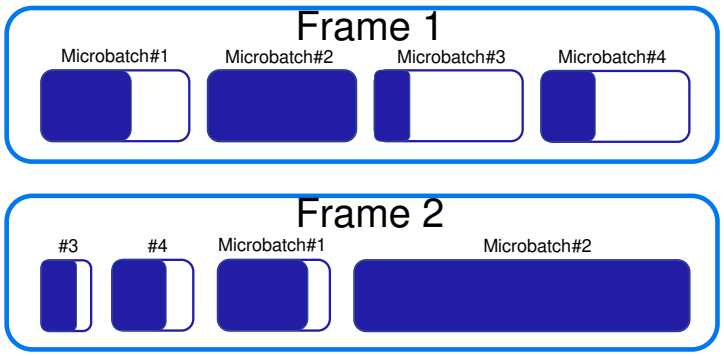
To understand the right frame duration, you first need to understand what happens during each frame.

The frame duration is split among the microbatches you add to your scheduler. In addition, there is some overhead in each frame that takes some time away from processing the microbatches. Within each microbatch, there is also some overhead which reduces the time the microbatch spends loading data from Kafka. The following diagram shows roughly how each frame is divided:

As you can see, only a portion of the time in the frame is spent actually loading the streaming data.

How the scheduler prioritizes microbatches

To start with, the scheduler evenly divides the time in the frame among the microbatches. It then runs each microbatch in turn.



In each microbatch, the bulk of the time is dedicated to loading data using a COPY statement. This statement loads data using the KafkaSource UDL. It runs until one of two conditions occurs:

- It reaches the ends of the data streams for the topics and partitions you defined for the microbatch. In this case, the microbatch completes processing early.
- It reaches a timeout set by the scheduler.

As the scheduler processes frames, it notes which microbatches finish early. It then schedules them to run first in the next frame. Arranging the microbatches in this manner lets the scheduler allocate more of the time in the frame to the microbatches that are spending the most time loading data (and perhaps have not had enough time to reach the end of their data streams).

For example, consider the following diagram. During the first frame, the scheduler evenly divides the time between the microbatches. Microbatch #2 uses all of the time allocated to it (as indicated by the filled-in area), while the other microbatches do not. In the next frame, the scheduler rearranges the microbatches so that microbatches that finished early go first. It also allocates less time to the microbatches that ran for a shorter period.

Assuming these microbatches finish early again, the scheduler is able to give the rest of the time in the frame to microbatch #2. This shifting of priorities continues while the scheduler runs. If one topic sees a spike in traffic, the scheduler compensates by giving the microbatch reading from that topic more time.

What happens if the frame duration is too short

If you make the scheduler's frame duration too short, microbatches may not have enough time to load all of the data in the data streams they are responsible for reading. In the worst case, a microbatch could fall further behind when reading a high-volume topic during each frame. If left unaddressed, this issue could result in messages never being loaded, as they age out of the data stream before the microbatch has a chance to read them.

In extreme cases, the scheduler may not be able to run each microbatch during each frame. This problem can occur if the frame duration is so short that much of is spent in overhead tasks such committing data and preparing to run microbatches. The COPY statement that each microbatch runs to load data from Kafka has a minimum duration of 1 second. Add to this the overhead of processing data loads. In general, if the frame duration is shorter than 2 seconds times the number of microbatches in the scheduler, then some microbatches may not get a chance to run in each frame.

If the scheduler runs out of time during a frame to run each microbatch, it compensates during the next frame by giving priority to the microbatches that didn't run in the prior frame. This strategy makes sure each microbatch gets a chance to load data. However, it cannot address the root cause of the problem. Your best solution is to increase the frame duration to give each microbatch enough time to load data during each frame.

What happens if the frame duration is too long

One downside of a long frame duration is increased data latency. This latency is the time between when Kafka sends data out and when that data becomes available for queries in your database. A longer frame duration means that there is more time between each execution of a microbatch. That translates into more time between the data in your database being updated.

Depending on your application, this latency may not be important. When determining your frame duration, consider whether having the data potentially delayed up to the entire length of the frame duration will cause an issue.

Another issue to consider when using a long frame duration is the time it takes to shut down the scheduler. The scheduler does not shut down until the current COPY statement completes. Depending on the length of your frame duration, this process might take a few minutes.

The minimum frame duration

At a minimum, allocate two seconds for each microbatch you add to your scheduler. The vkconfig utility warns you if your frame duration is shorter than this lower limit. In most cases, you want your frame duration to be longer. Two seconds per microbatch leaves little time for data to actually load.

Balancing frame duration requirements

To determine the best frame duration for your deployment, consider how sensitive you are to data latency. If you are not performing time-sensitive queries against the data streaming in from Kafka, you can afford to have the default 5 minute or even longer frame duration. If you need a shorter data latency, then consider the volume of data being read from Kafka. High volumes of data, or data that has significant spikes in traffic can cause problems if you have a short frame duration.

Using different schedulers for different needs

Suppose you are loading streaming data from a few Kafka topics that you want to query with low latency and other topics that have a high volume but which you can afford more latency. Choosing a "middle of the road" frame duration in this situation may not meet either need. A better solution is to use multiple schedulers: create one scheduler with a shorter frame duration that reads just the topics that you need to query with low latency. Then create another scheduler that has a longer frame duration to load data from the high-volume topics.

For example, suppose you are loading streaming data from an Internet of Things (IOT) sensor network via Kafka into Vertica. You use the most of this data to periodically generate reports and update dashboard displays. Neither of these use cases are particularly time sensitive. However, three of the topics you are loading from do contain time-sensitive data (system failures, intrusion detection, and loss of connectivity) that must trigger immediate alerts.

In this case, you can create one scheduler with a frame duration of 5 minutes or more to read most of the topics that contain the non-critical data. Then create a second scheduler with a frame duration of at least 6 seconds (but preferably longer) that loads just the data from the three time-sensitive topics. The volume of data in these topics is hopefully low enough that having a short frame duration will not cause problems.

Managing scheduler resources and performance

Your scheduler's performance is impacted by the number of microbatches in your scheduler, partitions in each microbatch, and nodes in your Vertica cluster. Use resource pools to allocate a subset of system resources for your scheduler, and fine-tune those resources to optimize automatic loads into Vertica.

The following sections provide details about scheduler resource pool configurations and processing scenarios:

- Schedulers and Resource Pools
- Key Resource Pool Settings
- Loading Multiple Microbatches Concurrently
- Parallel Processing within Vertica
- Loading Partitioned Topics Concurrently

Schedulers and resource pools

Vertica recommends you always create a resource pool specifically for each scheduler. Schedulers assume they have exclusive use of the resource pool they are assigned. Using a separate pool for a scheduler lets you fine-tune its impact on your Vertica cluster's performance. You create resource pools within Vertica using the CREATE RESOURCE POOL statement.

If you do not create and assign a resource pool for your scheduler, it uses a portion of the GENERAL resource pool. Vertica suggests you do not use the GENERAL pool for schedulers used in production environments. This fallback to using the GENERAL pool is intended as a convenience during testing your scheduler configuration. When you are ready to deploy your scheduler, create a resource pool that you have tuned to its specific needs. Each time you start a scheduler that is using the GENERAL pool, the vkconfig utility will display a warning message.

Not allocating enough resources to your schedulers can result in errors. For example, you may get OVERSHOT DEADLINE FOR FRAME errors if the scheduler is not able to load data from all of the topics it is supposed to in a data frame.

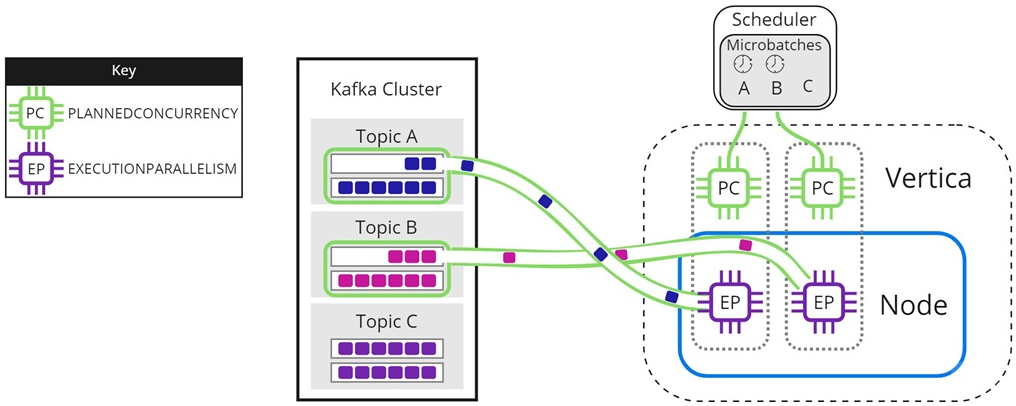
See Resource pool architecture for more information about resource pools.

Key resource pool settings

A microbatch is a unit of work that processes the partitions of a single Kafka topic within the duration of a frame . The following resource pool settings play an important role in how Vertica loads microbatches and processes partitions:

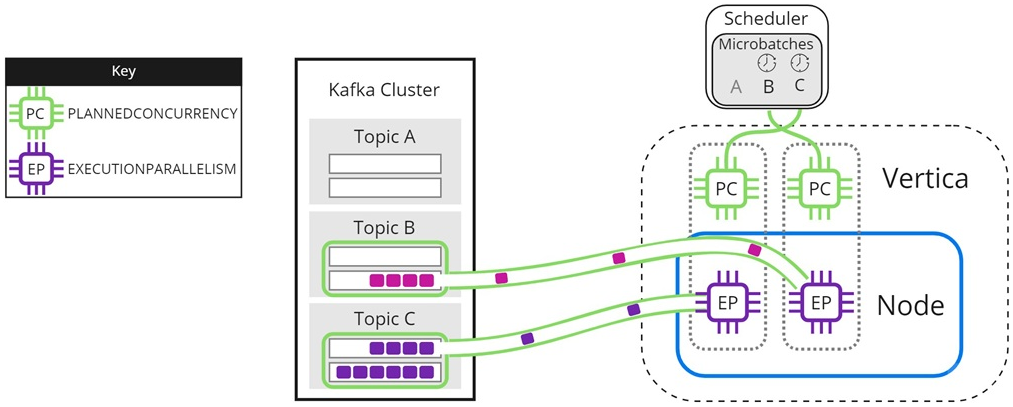
- PLANNEDCONCURRENCY determines the number of microbatches (COPY statements) the scheduler sends to Vertica simultaneously. At the start of each frame, the scheduler creates the number of scheduler threads specified by PLANNEDCONCURRENCY. Each scheduler thread connects to Vertica and loads one microbatch at a time. If there are more microbatches than scheduler threads, the scheduler queues the extra microbatches and loads them as threads become available.
- EXECUTIONPARALLELISM determines the maximum number of threads each node creates to process a microbatch's partitions. When a microbatch is loaded into Vertica, its partitions are distributed evenly among the nodes in the cluster. During each frame, a node creates a maximum of one thread for each partition. Each thread reads from one partition at a time until processing completes, or the frame ends. If there are more partitions than threads across all nodes, remaining partitions are processed as threads become available.
- QUEUETIMEOUT provides manual control over resource timings. Set the resource pool parameter QUEUETIMEOUT to 0 to allow the scheduler to manage timings. After all of the microbatches are processed, the scheduler waits for the remainder of the frame to process the next microbatch. A properly sized configuration includes rest time to plan for traffic surges. See Choosing a frame duration for information about the impacts of frame duration size.

For example, the following CREATE RESOURCE POOL statement creates a resource pool named weblogs_pool that loads 2 microbatches simultaneously. Each node in the Vertica cluster creates 10 threads per microbatch to process partitions:



```
=> CREATE RESOURCE POOL weblogs_pool
   MEMORYSIZE '10%'
   PLANNEDCONCURRENCY 2
   EXECUTIONPARALLELISM 10
   QUEUETIMEOUT 0;
```

For a three-node Vertica cluster, weblogs_pool provides resources for each node to create up to 10 threads to process partitions, or 30 total threads per microbatch.

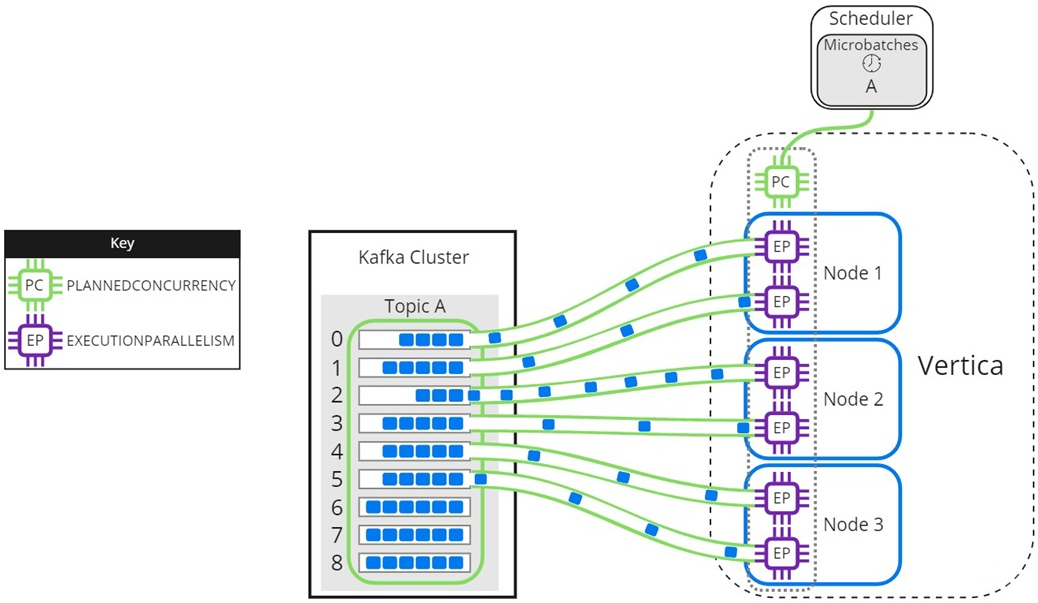


Loading multiple microbatches concurrently

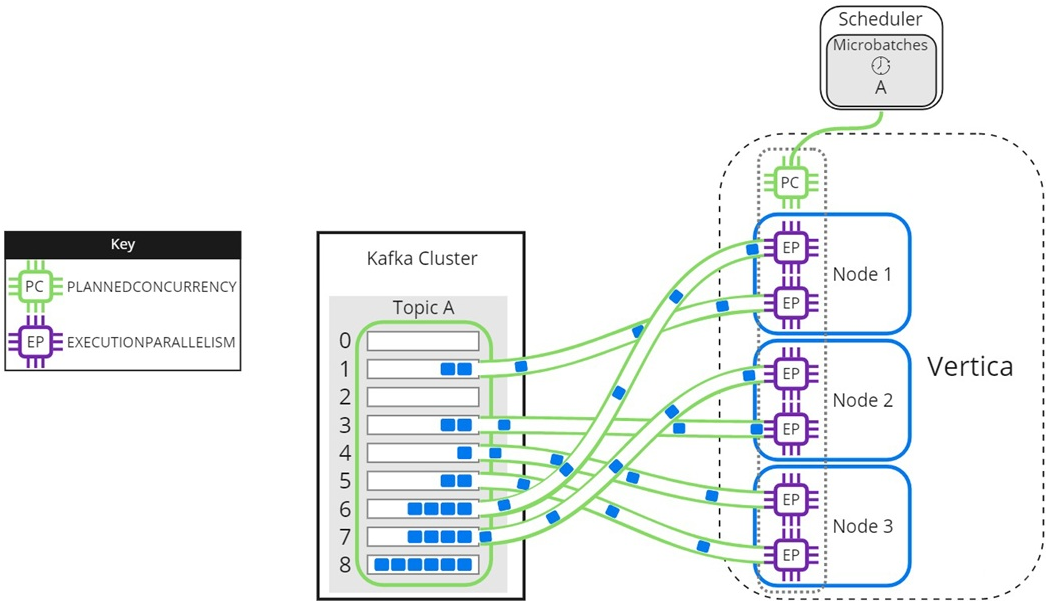
In some circumstances, you might have more microbatches in your scheduler than available PLANNEDCONCURRENCY . The following images illustrate how the scheduler loads microbatches into a single Vertica node when there are not enough scheduler threads to load each microbatch simultaneously. The resource pool's PLANNEDCONCURRENCY (PC) is set to 2, but the scheduler must load three microbatches: A, B, and C. For simplicity, EXECUTIONPARALLELISM (EP) is set to 1.

To begin, the scheduler loads microbatch A and microbatch B, while microbatch C waits:

When either microbatch finishes loading, the scheduler loads any remaining microbatches. In the following image, microbatch A is completely loaded into Vertica. The scheduler continues to load microbatch B, and uses the newly available scheduler thread to load microbatch C:



The scheduler continues sending data until all microbatches are loaded into Vertica, or the frame ends.

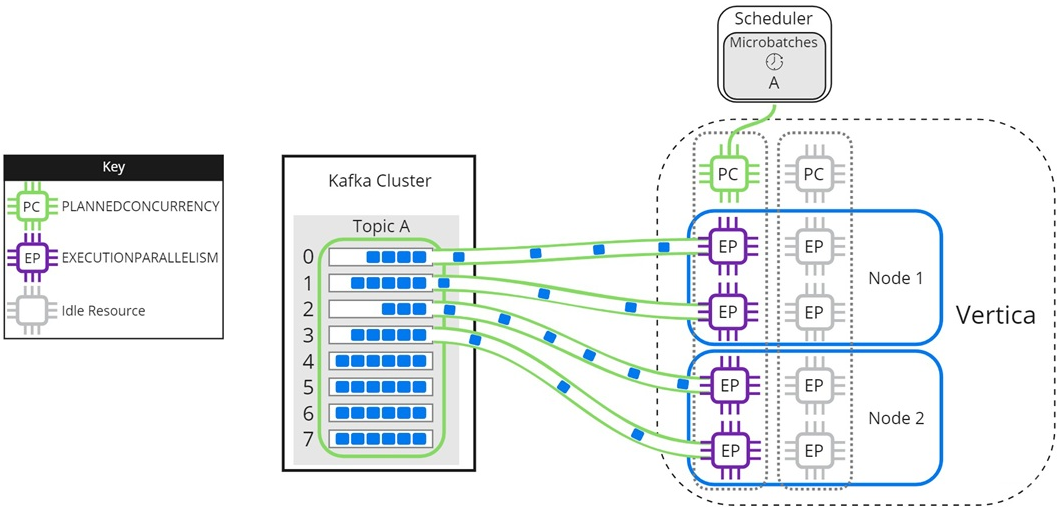


Experiment with PLANNEDCONCURRENCY to optimize performance. Note that setting it too high might create too many connections at the beginning of each frame, resulting in scalability stress on Vertica or Kafka. Setting PLANNEDCONCURRENCY too low does not take full advantage of the multiprocessing power of Vertica.

Parallel processing within Vertica

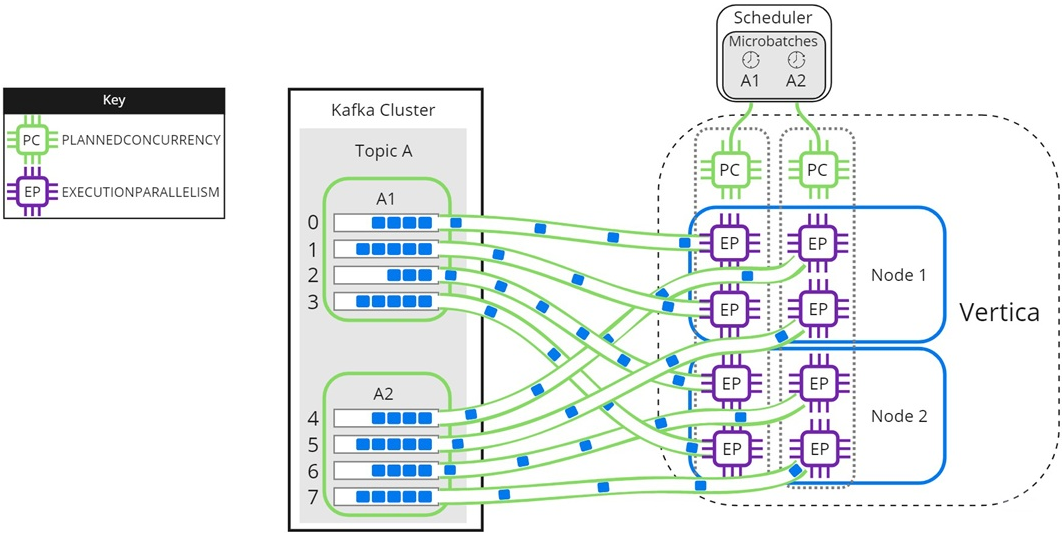
The resource pool setting EXECUTIONPARALLELISM limits the number of threads each Vertica node creates to process partitions. The following image illustrates how a three-node Vertica cluster processes a topic with nine partitions, when there is not enough EXECUTIONPARALLELISM to create one thread per partition. The partitions are distributed evenly among Node 1, Node 2, and Node 3 in the Vertica cluster. The scheduler's resource pool has PLANNEDCONCURRENCY (PC) set to 1 and EXECUTIONPARALLELISM (EP) set to 2, so each node creates a maximum of 2 threads when the scheduler loads microbatch A. Each thread reads from one partition at a time. Partitions that are not assigned a thread must wait for processing:

As threads finish processing their assigned partitions, the remaining partitions are distributed to threads as they become available:



When setting the EXECUTIONPARALLELISM on your scheduler's resource pool, consider the number of partitions across all microbatches in the scheduler.

Loading partitioned topics concurrently



Single topics with multiple partitions might benefit from increased parallel loading or a reduced transaction size. The --max-parallelism microbatch utility option enables you to dynamically split a topic with multiple partitions into multiple, load-balanced microbatches that each consist of a subset of the original microbatch's partitions. The scheduler loads the dynamically split microbatches simultaneously using the PLANNEDCONCURRENCY available in its resource pool.

The EXECUTIONPARALLELISM setting in the scheduler's resource pool determines the maximum number of threads each node creates to process its portion of a single microbatch's partitions. Splitting a microbatch enables each node to create more threads for the same unit of work. When there is enough PLANNEDCONCURRENCY and the number of partitions assigned per node is greater than the EXECUTIONPARALLELISM setting in the scheduler's resource pool, use --max-parallelism to split the microbatch and create more threads per node to process more partitions in parallel.

The following image illustrates how a two-node Vertica cluster loads and processes microbatch A using a resource pool with PLANNEDCONCURRENCY (PC) set to 2, and EXECUTIONPARALLELISM (EP) set to 2. Because the scheduler is loading only one microbatch, there is 1 scheduler thread left unused. Each node creates 2 threads per scheduler thread to process its assigned partitions:

Setting microbatch A's --max-parallelism option to 2 enables the scheduler to dynamically split microbatch A into 2 smaller microbatches, A1 and A2. Because there are 2 available scheduler threads, the subset microbatches are loaded into Vertica simultaneously. Each node creates 2 threads per scheduler thread to process partitions for microbatches A1 and A2:

Use --max-parallelism to prevent bottlenecks in microbatches consisting of high-volume Kafka topics. It also provides faster loads for microbatches that require additional processing, such as text indexing.

Using connection load balancing with the Kafka scheduler

You supply the scheduler with the name of a Vertica node in the --dbhost option or the dbhost entry in your configuration file. The scheduler connects to this node to initiate all of the statements it executes to load data from Kafka. For example, each time it executes a microbatch, the scheduler connects to the same node to run the COPY statement. Having a single node act as the initiator node for all of the scheduler's actions can affect the performance of the node, and in turn the database as a whole.

To avoid a single node becoming a bottleneck, you can use connection load balancing to spread the load of running the scheduler's statements across multiple nodes in your database. Connection load balancing distributes client connections among the nodes in a load balancing group. See About native connection load balancing for an overview of this feature.

Enabling connection load balancing for a scheduler is a two-step process:

1. Choose or create a load balancing policy for your scheduler.
2. Enable load balancing in the scheduler.

Choosing or creating a load balancing policy for the scheduler

A connecting load balancing policy redirects incoming connections in from a specific set of network addresses to a group of nodes. If your database already defines a suitable load balancing policy, you can use it instead of creating one specifically for your scheduler.

If your database does not have a suitable policy, create one. Have your policy redirect connections coming from the IP addresses of hosts running Kafka schedulers to a group of nodes in your database. The group of nodes that you select will act as the initiators for the statements that the scheduler executes.

Important
In an Eon Mode database, only include nodes that are part of a primary subcluster in the scheduler's load balancing group. These nodes are the most efficient for loading data.

The following example demonstrates setting up a load balancing policy for all three nodes in a three-node database. The scheduler runs on node 1 in the database, so the source address range (192.168.110.0/24) of the routing rule covers the IP addresses of the nodes in the database. The last step of the example verifies that connections from the first node (IP address 10.20.110.21) are load balanced.

```
=> SELECT node_name,node_address,node_address_family FROM v_catalog.nodes;
    node_name     | node_address | node_address_family
------------------+--------------+---------------------
 v_vmart_node0001 | 10.20.110.21 | ipv4
 v_vmart_node0002 | 10.20.110.22 | ipv4
 v_vmart_node0003 | 10.20.110.23 | ipv4
(4 rows)

=> CREATE NETWORK ADDRESS node01 ON v_vmart_node0001 WITH '10.20.110.21';
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS node02 ON v_vmart_node0002 WITH '10.20.110.22';
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS node03 on v_vmart_node0003 WITH '10.20.110.23';
CREATE NETWORK ADDRESS
```

```
=> CREATE LOAD BALANCE GROUP kafka_scheduler_group WITH ADDRESS node01,node02,node03;
CREATE LOAD BALANCE GROUP
=> CREATE ROUTING RULE kafka_scheduler_rule ROUTE
   '10.20.110.0/24' TO kafka_scheduler_group;
CREATE ROUTING RULE
=> SELECT describe_load_balance_decision('10.20.110.21');
                    describe_load_balance_decision
-------------------------------------------------------------------------------
  Describing load balance decision for address [10.20.110.21]
Load balance cache internal version id (node-local): [2]
Considered rule [kafka_scheduler_rule] source ip filter [10.20.110.0/24]...
input address matches this rule
Matched to load balance group [kafka_scheduler_group] the group has policy [ROUNDROBIN]
number of addresses [3]
(0) LB Address: [10.20.110.21]:5433
(1) LB Address: [10.20.110.22]:5433
(2) LB Address: [10.20.110.23]:5433
Chose address at position [1]
Routing table decision: Success. Load balance redirect to: [10.20.110.23] port [5433]

(1 row)
```

Important
Be careful if you run your scheduler on a Vertica node and have either set its dbhost name to localhost or are not specifying a value (which means dbhost defaults to localhost). Connections to localhost use the loopback IP address 127.0.0.1 instead of the node's primary network address. If you create a load balancing routing rule that redirects incoming connections from the node's IP address range, it will not apply to connections made using localhost. The best solution is to use the node's IP address or FQDN as the dbhost setting.

If your scheduler connects to Vertica from an IP address that no routing rule applies to, you will see messages similar to the following in the vertica.log:

```
[Session] <INFO> Load balance request from client address ::1 had decision:
   Classic load balancing considered, but either the policy was NONE or no target was
   available. Details: [NONE or invalid]
<LOG> @v_vmart_node0001: 00000/5789: Connection load balance request
   refused by server
```

Enabling load balancing in the scheduler

Clients must opt-in to load balancing for Vertica to apply the connection load balancing policies to the connection. For example, you must pass the -C flag to the vsql command for your interactive session to be load balanced.

The scheduler uses the Java JDBC library to connect to Vertica. To have the scheduler opt-in to load balancing, you must set the JDBC library's ConnectionLoadBalance option to 1. See Load balancing in JDBC for details.

Use the vkconfig script's --jdbc-opt option, or add the jdbc-opt option to your configuration file to set the ConnectionLoadBalance option. For example, to start the scheduler from the command line using a configuration file named weblog.conf, use the command:

```
$ nohup vkconfig launch --conf weblog.conf --jdbc-opt ConnectionLoadBalance=1 >/dev/null 2>&1 &
```

To permanently enable load balancing, you can add the load balancing option to your configuration file. The following example shows the weblog.conf file from the example in Setting up a scheduler configured to use connection load balancing.

```
username=dbadmin
password=mypassword
dbhost=10.20.110.21
dbport=5433
config-schema=weblog_sched
jdbc-opt=ConnectionLoadBalance=1
```

You can check whether the scheduler's connections are being load balanced by querying the SESSIONS table:

```
=> SELECT node_name, user_name, client_label FROM V_MONITOR.SESSIONS;
   node_name     | user_name |              client_label
-----------------+-----------+-----------------------------------------
 v_vmart_node0001 | dbadmin   | vkstream_weblog_sched_leader_persistent_4
 v_vmart_node0001 | dbadmin   |
 v_vmart_node0002 | dbadmin   | vkstream_weblog_sched_lane-worker-0_0_8
 v_vmart_node0003 | dbadmin   | vkstream_weblog_sched_VDBLogger_0_9
(4 rows)
```

In the client_labels column, the scheduler's connections have labels starting with vkstream (the row without a client label is an interactive session). You can see that the three connections the scheduler has opened all go to different nodes.

Limiting loads using offsets

Kafka maintains a user-configurable backlog of messages. By default, a newly-created scheduler reads all of the messages in a Kafka topic, including all of the messages in the backlog, not just the messages that are streamed out after the scheduler starts. Often, this is what you want.

In some cases, however, you may want to stream just a section of a source into a table. For example, suppose you want to analyze the web traffic of your e-commerce site starting at specific date and time. However, your Kafka topic contains web access records from much further back in time than you want to analyze. In this case, you can use an offset to stream just the data you want into Vertica for analysis.

Another common use case is when you have already loaded data some from Kafka manually (see Manually consume data from Kafka). Now you want to stream all of the newly-arriving data. By default, your scheduler ill reload all of the previously loaded data (assuming it is still available from Kafka). You can use an offset to tell your scheduler to start automatically loading data at the point where your manual data load left off.

Configuring a scheduler to start streaming from an offset

The vkconfig script's microbatch tool has an --offset option that lets you specify the index of the message in the source where you want the scheduler to begin loading. This option accepts a comma-separated list of index values. You must supply one index value for each partition in the source unless you use the --partition option. This option lets you choose the partitions the offsets apply to. The scheduler cannot be running when you set an offset in the microbatch.

If your microbatch defines more than one cluster, use the --cluster option to select which one the offset option applies to. Similarly, if your microbatch has more than one source, you must select one using the --source option.

For example, suppose you want to load just the last 1000 messages from a source named web_hits. To make things easy, suppose the source contains just a single partition, and the microbatch defines just a single cluster and single topic.

Your first task is to determine the current offset of the end of the stream. You can do this on one of the Kafka nodes by calling the GetOffsetShell class with the time parameter set to -1 (the end of the topic):

```
$ path to kafka/bin/kafka-run-class.sh kafka.tools.GetOffsetShell \
                                --broker-list kafka01:9092,kafka03:9092 --time -1 \
                                --topic web_hits

{metadata.broker.list=kafka01:9092,kafka03:9092, request.timeout.ms=1000,
 client.id=GetOffsetShell, security.protocol=PLAINTEXT}
web_hits:0:8932
```

You can also use GetOffsetShell to find the offset in the stream that occurs before a timestamp.

In the above example, the web_hits topic's single partition has an ending offset of 8932. If we want to load the last 1000 messages from the source, we need to set the microbatch's offset to 8932 - 1001 or 7931.

> **Note**
> The start of an offset is inclusive in the Vertica COPY statement. Kafka's native starting offset is exclusive. Therefore, you must add one to the offset to get the correct number of messages.

With the offset calculated, you are ready to set it in the microbatch's configuration. The following example:

- Shuts down the scheduler whose configuration information stored in the weblog.conf file.
- Sets the starting offset using the microbatch utility.
- Restarts the scheduler.

```
$ vkconfig shutdown --conf weblog.conf
$ vkconfig microbatch --microbatch weblog --update --conf weblog.conf --offset 7931
$ nohup vkconfig launch --conf weblog.conf >/dev/null 2>&1 &
```

If the target table was empty or truncated before the scheduler started, it will have 1000 rows in the table in it (until more messages are streamed through the source):

```
=> select count(*) from web_hits;
 count
-------
  1000
(1 row)
```

> **Note**
> The last example assumes that the offset values for the last 1000 messages in the Kafka topic were assigned consecutively. This assumption is not always be true. A Kafka topic can have gaps in its offset numbering for a variety of reasons. Offsets refer to the key value assigned to a message by Kafka, not its position in the topic.

Updating schedulers after Vertica upgrades

A scheduler is only compatible with the version of Vertica that created it. Between Vertica versions, the scheduler's configuration schema or the UDx function the scheduler calls may change. After you upgrade Vertica, you must update your schedulers to account for these changes.

When you upgrade Vertica to a new major version or service pack, use the vkconfig scheduler tool's --upgrade option to update your scheduler. If you do not update a scheduler, you receive an error message if you try to launch it. For example:

```
$ nohup vkconfig launch --conf weblog.conf >/dev/null 2>&1 &
com.vertica.solutions.kafka.exception.FatalException: Configured scheduler schema and current
scheduler configuration schema version do not match. Upgrade configuration by running:
vkconfig scheduler --upgrade
    at com.vertica.solutions.kafka.scheduler.StreamCoordinator.assertVersion(StreamCoordinator.java:64)
    at com.vertica.solutions.kafka.scheduler.StreamCoordinator.run(StreamCoordinator.java:125)
    at com.vertica.solutions.kafka.Launcher.run(Launcher.java:205)
    at com.vertica.solutions.kafka.Launcher.main(Launcher.java:258)
Scheduler instance failed. Check log file. Check log file.
$ vkconfig scheduler --upgrade --conf weblog.conf
Checking if UPGRADE necessary...
UPGRADE required, running UPGRADE...
UPGRADE completed successfully, now the scheduler configuration schema version is v8.1.1
$ nohup vkconfig launch --conf weblog.conf >/dev/null 2>&1 &
                . . .
```

Monitoring message consumption

You can monitor the progress of your data streaming from Kafka several ways:

- Monitoring the consumer groups to which Vertica reports its progress. This technique is best if the tools you want to use to monitor your data load work with Kafka.
- Use the monitoring APIs built into the vkconfig tool. These APIs report the configuration and consumption of your streaming scheduler in JSON format. These APIs are useful if you are developing your own monitoring scripts, or your monitoring tools can consume status information in JSON format.

In this section

- Monitoring Vertica message consumption with consumer groups
- Getting configuration and statistics information from vkconfig

Monitoring Vertica message consumption with consumer groups

Apache Kafka has a feature named consumer groups that helps distribute message consumption loads across sets of consumers. When using consumer groups, Kafka evenly divides up messages based on the number of consumers in the group. Consumers report back to the Kafka broker which messages it read successfully. This reporting helps Kafka to manage message offsets in the topic's partitions, so that no consumer in the group is sent the same message twice.

Vertica does not rely on Kafka's consumer groups to manage load distribution or preventing duplicate loads of messages. The streaming job scheduler manages topic partition offsets on its own.

Even though Vertica does not need consumer groups to manage offsets, it does report back to the Kafka brokers which messages it consumed. This feature lets you use third-party tools to monitor the Vertica cluster's progress as it loads messages. By default, Vertica reports its progress to a consumer group named vertica- *databaseName* , where *databaseName* is the name of the Vertica database. You can change the name of the consumer group that Vertica reports its progress to when defining a scheduler or during manual loads of data. Third party tools can query the Kafka brokers to monitor the Vertica cluster's progress when loading data.

For example, you can use Kafka's kafka-consumer-groups.sh script (located in the bin directory of your Kafka installation) to view the status of the Vertica consumer group. The following example demonstrates listing the consumer groups available defined in the Kafka cluster and showing the details of the Vertica consumer group:

```
$ cd /path/to/kafka/bin
$ ./kafka-consumer-groups.sh --list --bootstrap-server localhost:9092
Note: This will not show information about old Zookeeper-based consumers.

vertica-vmart
$ ./kafka-consumer-groups.sh --describe --group vertica-vmart \
  --bootstrap-server localhost:9092
Note: This will not show information about old Zookeeper-based consumers.

Consumer group 'vertica-vmart' has no active members.

TOPIC                PARTITION  CURRENT-OFFSET  LOG-END-OFFSET  LAG       CONSUMER-ID                           HOST
CLIENT-ID
web_hits             0          24500           30000           5500      -                                     -               -
```

From the output, you can see that Vertica reports its consumption of messages back to the vertica-vmart consumer group. This group is the default consumer group when Vertica has the example VMart database loaded. The second command lists the topics being consumed by the vertica-vmart consumer group. You can see that the Vertica cluster has read 24500 of the 30000 messages in the topic's only partition. Later, running the same command will show the Vertica cluster's progress:

```
$ cd /path/to/kafka/bin
$ ./kafka-consumer-groups.sh --describe --group vertica-vmart \
   --bootstrap-server localhost:9092
Note: This will not show information about old Zookeeper-based consumers.

Consumer group 'vertica-vmart' has no active members.

TOPIC                PARTITION  CURRENT-OFFSET  LOG-END-OFFSET  LAG       CONSUMER-ID                           HOST
CLIENT-ID
web_hits             0          30000           30000           0         -
```

Changing the consumer group where Vertica reports its progress

You can change the consumer group that Vertica reports its progress to when consuming messages.

Changing for automatic loads with the scheduler

When using a scheduler, you set the consumer group by setting the --consumer-group-id argument to the vkconfig script's scheduler or microbatch utilities. For example, suppose you want the example scheduler shown in Setting up a scheduler to report its consumption to the consumer group name vertica-database. Then you could use the command:

```
$ /opt/vertica/packages/kafka/bin/vkconfig microbatch --update \
   --conf weblog.conf --microbatch weblog --consumer-group-id vertica-database
```

When the scheduler begins loading data, it will start updating the new consumer group. You can see this on a Kafka node using kafka-consumer-groups.sh .

Use the --list option to return the consumer groups:

```
$ /path/to/kafka/bin/kafka-consumer-groups.sh --list --bootstrap-server localhost:9092
Note: This will not show information about old Zookeeper-based consumers.

vertica-database
vertica-vmart
```

Use the --describe and --group options to return details about a specific consumer group:

```
$ /path/to/kafka/bin/kafka-consumer-groups.sh --describe --group vertica-database \
                              --bootstrap-server localhost:9092
Note: This will not show information about old Zookeeper-based consumers.

Consumer group 'vertica-database' has no active members.

TOPIC                PARTITION  CURRENT-OFFSET  LOG-END-OFFSET  LAG        CONSUMER-ID                                HOST
CLIENT-ID
web_hits             0          30300           30300           0          -                                          -                    -
```

Changing for manual loads

To change the consumer group when manually loading data, use the group_id parameter of KafkaSource function:

```
=> COPY web_hits SOURCE KafkaSource(stream='web_hits|0|-2',
                                    brokers='kafka01.example.com:9092',
                                    stop_on_eof=True,
                                    group_id='vertica_database')
                 PARSER KafkaJSONParser();
 Rows Loaded
-------------
       50000
(1 row)
```

Using consumer group offsets when loading messages

You can choose to have your scheduler, manual load, or custom loading script start loading messages from the consumer group's offset. To load messages from the last offset stored in the consumer group, use the special -3 offset.

Automatic load with the scheduler example

To instruct your scheduler to load messages from the consumer group's saved offset, use the vkconfig script microbatch tool's --offset argument.

1. Stop the scheduler using the shutdown command and the configuration file that you used to create the scheduler:
   ```
   $ /opt/vertica/packages/kafka/bin/vkconfig microbatch shutdown --conf weblog.conf
   ```
2. Set the microbatch --offset option to -3:
   ```
   $ /opt/vertica/packages/kafka/bin/vkconfig microbatch --update --conf weblog.conf --microbatch weblog --offset -3
   ```

This sets the offset to -3 for all topic partitions that your scheduler reads from. The scheduler begins the next load with the consumer group's saved offset, and all subsequent loads use the offset saved in stream_microbatch_history .

Manual load example

This example loads messages from the web_hits topic that has one partition consisting of 51,000 messages. For details about manual loads with KafkaSource , see Manually consume data from Kafka .

1. The first COPY statement creates a consumer group named vertica_manual, and loads the first 50,000 messages from the first partition in the web_hits topic:
   ```
   => COPY web_hits
     SOURCE KafkaSource(stream='web_hits|0|0|50000',
                                    brokers='kafka01.example.com:9092',
                                    stop_on_eof=True,
                                    group_id='vertica_manual')
     PARSER KafkaJSONParser()
     REJECTED DATA AS TABLE public.web_hits_rejections;
    Rows Loaded
   -------------
         50000
   (1 row)
   ```
2. The next COPY statement passes -3 as the start_offset stream parameter to load from the consumer group's saved offset:

```
=> COPY web_hits
  SOURCE KafkaSource(stream='web_hits|0|-3',
                     brokers='kafka01.example.com:9092',
                     stop_on_eof=True,
                     group_id='vertica_manual')
  PARSER KafkaJSONParser()
  REJECTED DATA AS TABLE public.web_hits_rejections;
 Rows Loaded
-------------
        1000
(1 row)
```

Disabling consumer group reporting

Vertica reports the offsets of the messages it consumes to Kafka by default. If you do not specifically configure a consumer group for Vertica, it still reports its offsets to a consumer group named vertica_ *database-name* (where *database-name* is the name of the database Vertica is currently running).

If you want to completely disable having Vertica report its consumption back to Kafka, you can set the consumer group to an empty string or NULL. For example:

```
=> COPY web_hits SOURCE KafkaSource(stream='web_hits|0|-2',
                     brokers='kafka01.example.com:9092',
                     stop_on_eof=True,
                     group_id=NULL)
             PARSER KafkaJsonParser();
 Rows Loaded
-------------
      60000
(1 row)
```

Getting configuration and statistics information from vkconfig

The vkconfig tool has two features that help you examine your scheduler's configuration and monitor your data load:

- The vkconfig tools that configure your scheduler (scheduler, cluster, source, target, load-spec, and microbatch) have a --read argument that has them output their current settings in the scheduler.
- The vkconfig statistics tool lets you get statistics on your microbatches. You can filter the microbatch records based on a date and time range, cluster, partition, and other criteria.

Both of these features output their data in JSON format. You can use third-party tools that can consume JSON data or write your own scripts to process the configuration and statics data.

You can also access the data provided by these vkconfig options by querying the configuration tables in the scheduler's schema. However, you may find these options easier to use as they do not require you to connect to the Vertica database.

Getting configuration information

You pass the --read option to vkconfig's configuration tools to get the current settings for the options that the tool can set. This output is in JSON format. This example demonstrates getting the configuration information from the scheduler and cluster tools for the scheduler defined in the weblog.conf configuration file:

```
$ vkconfig scheduler --read --conf weblog.conf
{"version":"v9.2.0", "frame_duration":"00:00:10", "resource_pool":"weblog_pool",
 "config_refresh":"00:05:00", "new_source_policy":"FAIR",
 "pushback_policy":"LINEAR", "pushback_max_count":5, "auto_sync":true,
 "consumer_group_id":null}

$ vkconfig cluster --read --conf weblog.conf
{"cluster":"kafka_weblog", "hosts":"kafak01.example.com:9092,kafka02.example.com:9092"}
```

The --read option lists all of values created by the tool in the scheduler schema. For example, if you have defined multiple targets in your scheduler, the --read option lists all of them.

```
$ vkconfig target --list --conf weblog.conf
{"target_schema":"public", "target_table":"health_data"}
{"target_schema":"public", "target_table":"iot_data"}
{"target_schema":"public", "target_table":"web_hits"}
```

You can filter the --read option output using the other arguments that the vkconfig tools accept. For example, in the cluster tool, you can use the --host argument to limit the output to just show clusters that contain a specific host. These arguments support LIKE-predicate wildcards, so you can match partial values. See LIKE predicate for more information about using wildcards.

The following example demonstrates how you can filter the output of the --read option of the cluster tool using the --host argument. The first call shows the unfiltered output. The second call filters the output to show only those clusters that start with "kafka":

```
$ vkconfig cluster --read --conf weblog.conf
{"cluster":"some_cluster", "hosts":"host01.example.com"}
{"cluster":"iot_cluster",
 "hosts":"kafka-iot01.example.com:9092,kafka-iot02.example.com:9092"}
{"cluster":"weblog",
 "hosts":"web01.example.com.com:9092,web02.example.com:9092"}
{"cluster":"streamcluster1",
 "hosts":"kafka-a-01.example.com:9092,kafka-a-02.example.com:9092"}
{"cluster":"test_cluster",
 "hosts":"test01.example.com:9092,test02.example.com:9092"}

$ vkconfig cluster --read --conf weblog.conf --hosts kafka%
{"cluster":"iot_cluster",
 "hosts":"kafka-iot01.example.com:9092,kafka-iot02.example.com:9092"}
{"cluster":"streamcluster1",
 "hosts":"kafka-a-01.example.com:9092,kafka-a-02.example.com:9092"}
```

See the Cluster tool options , Load spec tool options , Microbatch tool options , Scheduler tool options , Target tool options , and Source tool options for more information.

Getting streaming data load statistics

The vkconfig script's statistics tool lets you view the history of your scheduler's microbatches. You can filter the results using any combination of the following criteria:

- The name of the microbatch
- The Kafka cluster that was the source of the data load
- The name of the topic
- The partition within the topic
- The Vertica schema and table targeted by the data load
- A date and time range
- The latest microbatches

See Statistics tool options for all of the options available in this tool.

This example gets the last two microbatches that the scheduler ran:

```
$ vkconfig statistics --last 2 --conf weblog.conf
{"microbatch":"weblog", "target_schema":"public", "target_table":"web_hits",
 "source_name":"web_hits", "source_cluster":"kafka_weblog", "source_partition":0,
 "start_offset":73300, "end_offset":73399, "end_reason":"END_OF_STREAM",
 "end_reason_message":null, "partition_bytes":19588, "partition_messages":100,
 "timeslice":"00:00:09.807000", "batch_start":"2018-11-02 13:22:07.825295",
 "batch_end":"2018-11-02 13:22:08.135299", "source_duration":"00:00:00.219619",
 "consecutive_error_count":null, "transaction_id":45035996273976123,
 "frame_start":"2018-11-02 13:22:07.601", "frame_end":null}
{"microbatch":"weblog", "target_schema":"public", "target_table":"web_hits",
 "source_name":"web_hits", "source_cluster":"kafka_weblog", "source_partition":0,
 "start_offset":73200, "end_offset":73299, "end_reason":"END_OF_STREAM",
 "end_reason_message":null, "partition_bytes":19781, "partition_messages":100,
 "timeslice":"00:00:09.561000", "batch_start":"2018-11-02 13:21:58.044698",
 "batch_end":"2018-11-02 13:21:58.335431", "source_duration":"00:00:00.214868",
 "consecutive_error_count":null, "transaction_id":45035996273976095,
 "frame_start":"2018-11-02 13:21:57.561", "frame_end":null}
```

This example gets the microbatches from the source named web_hits between 13:21:00 and 13:21:20 on November 2nd 2018:

```
$ vkconfig statistics --source "web_hits" --from-timestamp \
        "2018-11-02 13:21:00" --to-timestamp "2018-11-02 13:21:20"  \
        --conf weblog.conf
{"microbatch":"weblog", "target_schema":"public", "target_table":"web_hits",
 "source_name":"web_hits", "source_cluster":"kafka_weblog", "source_partition":0,
 "start_offset":72800, "end_offset":72899, "end_reason":"END_OF_STREAM",
 "end_reason_message":null, "partition_bytes":19989, "partition_messages":100,
 "timeslice":"00:00:09.778000", "batch_start":"2018-11-02 13:21:17.581606",
 "batch_end":"2018-11-02 13:21:18.850705", "source_duration":"00:00:01.215751",
 "consecutive_error_count":null, "transaction_id":45035996273975997,
 "frame_start":"2018-11-02 13:21:17.34", "frame_end":null}
{"microbatch":"weblog", "target_schema":"public", "target_table":"web_hits",
 "source_name":"web_hits", "source_cluster":"kafka_weblog", "source_partition":0,
 "start_offset":72700, "end_offset":72799, "end_reason":"END_OF_STREAM",
 "end_reason_message":null, "partition_bytes":19640, "partition_messages":100,
 "timeslice":"00:00:09.857000", "batch_start":"2018-11-02 13:21:07.470834",
 "batch_end":"2018-11-02 13:21:08.737255", "source_duration":"00:00:01.218932",
 "consecutive_error_count":null, "transaction_id":45035996273975978,
 "frame_start":"2018-11-02 13:21:07.309", "frame_end":null}
```

See Statistics tool options for more examples of using this tool.

Parsing custom formats

To process a Kafka data stream, the parser must identify the boundary between each message. Vertica provides Kafka parsers that can identify boundaries for Avro , JSON , and raw data formats, but your data stream might use a custom format. To parse custom formats, Vertica provides filters that insert boundary information in the data stream before it reaches the parser.

Kafka filters

Vertica provides the following filters:

- KafkaInsertDelimiters: Inserts a user-specified delimiter between each message in the data stream. The delimiter can contain any characters and be of any length. This parser uses the following syntax:
  KafkaInsertDelimiters(delimiter = ' *delimiter* ')
- KafkaInsertLengths: Inserts the message length in bytes at the beginning of the message. Vertica writes the length as a 4-byte uint32 value in big-endian network byte order. For example, a 100-byte message is preceded by 0x00000064. This parser uses the following syntax:
  KafkaInsertLengths()

> **Note**
> Because each Kafka filter requires input from a stream source and outputs a non-stream source, you cannot use both Kafka filters in the same COPY statement to process a Kafka data stream.

In addition to one of the Kafka filters, you can include one or more user-defined filters in a single COPY statement. Specify multiple filters as a comma-separated list, and list the Vertica filter first. If you use a non-Kafka parser, you must use at least one filter to prepare the data stream for the parser, or the parser fails and returns an error.

Examples

The following COPY statement loads comma-separated values from two partitions in a topic named iot-data . The load exits after it processes all messages in both partitions. The KafkaInsertDelimiters filter inserts newlines between the Kafka messages to convert them into traditional rows of data. The statement uses the standard COPY parser to delimit CSV values with a comma:

```
=> COPY kafka_iot SOURCE KafkaSource(stream='iot-data|0|-2,iot-data|1|-2',
                                     brokers='kafka01:9092',
                                     stop_on_eof=True)
              FILTER KafkaInsertDelimiters(delimiter = E'\n')
              DELIMITER ',';
 Rows Loaded
-------------
        3430
(1 row)
```

Producing data for Kafka

In addition to consuming data from Kafka, Vertica can produce data for Kafka. Stream the following data from Vertica for consumption by other Kafka consumers:

- Vertica anayltics results. Use KafkaExport to export Vertica tables and queries.
- Health and performance data from Data Collector tables. Create push-based notifiers to send this data for consumption for third-party monitoring tools.
- Ad hoc messages. Use NOTIFY to signal that tasks such as stored procedures are complete.

In this section

- Producing data using KafkaExport
- Producing Kafka messages using notifiers

Producing data using KafkaExport

The KafkaExport function lets you stream data from Vertica to Kafka. You pass this function three arguments and two or three parameters:

```
SELECT KafkaExport(partitionColumn, keyColumn, valueColumn
   USING PARAMETERS brokers='host[:port][,host...]',
   topic='topicname'
   [,kafka_conf='kafka_configuration_setting']
   [,fail_on_conf_parse_error=Boolean])
OVER (partition_clause) FROM table;
```

The *partitionColumn* and *keyColumn* arguments set the Kafka topic's partition and key value, respectively. You can set either or both of these values to NULL. If you set the partition to NULL, Kafka uses its default partitioning scheme (either randomly assigning partitions if the key value is NULL, or based on the key value if it is not).

The *valueColumn* argument is a LONG VARCHAR containing message data that you want to send to Kafka. Kafka does not impose structure on the message content. Your only restriction on the message format is what the consumers of the data are able to parse.

You are free to convert your data into a string in any way you like. For simple messages (such as a comma-separated list), you can use functions such as CONCAT to assemble your values into a message. If you need a more complex data format, such as JSON, consider writing a UDx function that accepts columns of data and outputs a LONG VARCHAR containing the data in the format you require. See Developing user-defined extensions (UDxs) for more information.

See KafkaExport for detailed information about KafkaExport's syntax.

Export example

This example shows you how to perform a simple export of several columns of a table. Suppose you have the following table containing a simple set of Internet of things (IOT) data:

```
=> SELECT * FROM iot_report LIMIT 10;
 server |        date         |       location        |    id
--------+---------------------+-----------------------+----------
      1 | 2016-10-11 04:09:28 | -14.86058, 112.75848  | 70982027
      1 | 2017-07-02 12:37:48 | -21.42197, -127.17672 | 49494918
      1 | 2017-10-19 14:04:33 | -71.72156, -36.27381  | 94328189
      1 | 2018-07-11 19:35:18 | -9.41315, 102.36866   | 48366610
      1 | 2018-08-30 08:09:45 | 83.97962, 162.83848   |   967212
      2 | 2017-01-20 03:05:24 | 37.17372, 136.14026   | 36670100
      2 | 2017-07-29 11:38:37 | -38.99517, 171.72671  | 52049116
      2 | 2018-04-19 13:06:58 | 69.28989, 133.98275   | 36059026
      2 | 2018-08-28 01:09:51 | -59.71784, -144.97142 | 77310139
      2 | 2018-09-14 23:16:15 | 58.07275, 111.07354   |  4198109
(10 rows)

=> \d iot_report

 Schema |   Table    |  Column |     Type     | Size | Default | Not Null | Primary Key | Foreign Key
--------+------------+---------+--------------+------+---------+----------+-------------+-------------
 public | iot_report | server  | int          |    8 |         | f        | f           |
 public | iot_report | date    | timestamp    |    8 |         | f        | f           |
 public | iot_report | location | varchar(40) |   40 |         | f        | f           |
 public | iot_report | id      | int          |    8 |         | f        | f           |
(4 rows)
```

You want to send the data in this table to a Kafka topic named iot_results for consumption by other applications. Looking at the data and the structure of the iot_report, you may decide the following:

- The server column is a good match for the partitions in iot_report. There are three partitions in the Kafka topic, and the values in server column are between 1 and 3. Suppose the partition column had a larger range of values (for example, between 1 and 100). Then you could use the modulo operator (%) to coerce the values into the same range as the number of partitions (server % 3).
  A complication with these values is that the values in the server are 1-based (the lowest value in the column is 1). Kafka's partition numbering scheme is zero-based. So, you must adjust the values in the server column by subtracting 1 from them.
- The id column can act as the key. This column has a data type of INTEGER. The KafkaExport function expects the key value to be a VARCHAR. Vertica does not automatically cast INTEGER values to VARCHAR, so you must explicitly cast the value in your function call.
- The consumers of the iot_report topic expect values in comma-separated format. You can combine the values from the date and location columns into a single VARCHAR using nested calls to the CONCAT function.

The final piece of information you need to know is the host names and port numbers of the brokers in your Kafka cluster. In this example, there are two brokers named kafka01 and kafka03, running on port 6667 (the port that Hortonworks clusters use). Once you have all of this information, you are ready to export your data.

The following example shows how you might export the contents of iot_report:

```
=> SELECT KafkaExport(server - 1, id::VARCHAR,
   CONCAT(CONCAT(date, ', '), location)
   USING PARAMETERS brokers='kafka01:6667,kafka03:6667',
   topic='iot_results') OVER (PARTITION BEST) FROM iot_report;
 partition | key | message | failure_reason
-----------+-----+---------+----------------
(0 rows)
```

KafkaExport returned 0 rows which means Vertica was able to send all of your data to Kafka without any errors.

Other things to note about the example:

- The CONCAT function automatically converts the date column's DATETIME value to a VARCHAR for you, so you do not need to explicitly cast it.
- Two nested CONCAT functions are necessary to concatenate the date field with a comma, and the resulting string with the location field.
- Adding a third column to the message field would require *two* additional CONCAT function calls (one to concatenate a comma after the location column, and one to concatenate the additional column's value). Using CONCAT becomes messy after just a few column's worth of data.

On the Kafka side, you will see whatever you sent as the valueColumn (third) argument of the KafkaExport function. In the above example, this is a CSV list. If you started a console consumer for iot_results topic before running the example query, you would see the following output when the query runs:

```
$ /opt/kafka/bin/kafka-console-consumer.sh --topic iot_results --zookeeper localhost
2017-10-10 12:08:33, 78.84883, -137.56584
2017-12-06 16:50:57, -25.33024, -157.91389
2018-01-12 21:27:39, 82.34027, 116.66703
2018-08-19 00:02:18, 13.00436, 85.44815
2016-10-11 04:09:28, -14.86058, 112.75848
2017-07-02 12:37:48, -21.42197, -127.17672
2017-10-19 14:04:33, -71.72156, -36.27381
2018-07-11 19:35:18, -9.41315, 102.36866
2018-08-30 08:09:45, 83.97962, 162.83848
2017-01-20 03:05:24, 37.17372, 136.14026
2017-07-29 11:38:37, -38.99517, 171.72671
2018-04-19 13:06:58, 69.28989, 133.98275
2018-08-28 01:09:51, -59.71784, -144.97142
2018-09-14 23:16:15, 58.07275, 111.07354
```

KafkaExport's return value

KafkaExport outputs any rows that Kafka rejected. For example, suppose you forgot to adjust the partition column to be zero-based in the previous example. Then some of the rows exported to Kafka would specify a partition that does not exist. In this case, Kafka rejects these rows, and KafkaExport reports them in table format:

```
=> SELECT KafkaExport(server, id::VARCHAR,
   CONCAT(CONCAT(date, ', '), location)
   USING PARAMETERS brokers='kafka01:6667,kafka03:6667',
   topic='iot_results') OVER (PARTITION BEST) FROM iot_report;
 partition |   key    |                 message                  |      failure_reason
-----------+----------+------------------------------------------+--------------------------
         3 | 40492866 | 2017-10-10 12:08:33, 78.84883, -137.56584,  | Local: Unknown partition
         3 | 73846006 | 2017-12-06 16:50:57, -25.33024, -157.91389, | Local: Unknown partition
         3 | 45020829 | 2018-01-12 21:27:39, 82.34027, 116.66703,   | Local: Unknown partition
         3 | 27462612 | 2018-08-19 00:02:18, 13.00436, 85.44815,    | Local: Unknown partition
(4 rows)
```

> **Note**
> Another common reason for Kafka rejecting a row is that its message value is longer than Kafka's message.max.bytessetting.

You can capture this output by creating a table to hold the rejects. Then use an INSERT statement to insert KafkaExport's results:

```
=> CREATE TABLE export_rejects (partition INTEGER, key VARCHAR, message LONG VARCHAR, failure_reason VARCHAR);
CREATE TABLE
=> INSERT INTO export_rejects SELECT KafkaExport(server, id::VARCHAR,
   CONCAT(CONCAT(date, ', '), location)
   USING PARAMETERS brokers='kafka01:6667,kafka03:6667',
   topic='iot_results') OVER (PARTITION BEST) FROM iot_report;
 OUTPUT
--------
      4
(1 row)
=> SELECT * FROM export_rejects;
 partition |   key    |                 message                  |      failure_reason
-----------+----------+------------------------------------------+--------------------------
         3 | 27462612 | 2018-08-19 00:02:18, 13.00436, 85.44815    | Local: Unknown partition
         3 | 40492866 | 2017-10-10 12:08:33, 78.84883, -137.56584  | Local: Unknown partition
         3 | 73846006 | 2017-12-06 16:50:57, -25.33024, -157.91389 | Local: Unknown partition
         3 | 45020829 | 2018-01-12 21:27:39, 82.34027, 116.66703   | Local: Unknown partition
(4 rows)
```

Producing Kafka messages using notifiers

You can use notifiers to help you monitor your Vertica database using third-party Kafka-aware tools by producing messages to a Kafka topic. You can directly publish messages (for example, from a SQL script to indicate a long-running query has finished). Notifiers can also automatically send messages when a component in the data collector tables is updated.

In this section

- Creating a Kafka notifier
- Sending individual messages via a Kafka notifier
- Monitoring DC tables with Kafka notifiers

Creating a Kafka notifier

The following procedure creates a Kafka notifier. At a minimum, a notifier defines:

- A unique name.
- A message protocol. This is kafka:// when sending messages to Kafka.
- The server to communicate with. For Kafka, this is the address and port number of a Kafka broker.
- The maximum message buffer size. If the queue of messages to be sent via the notifier exceed this limit, messages are dropped.

You create the notifier with CREATE NOTIFIER . This example creates a notifier named load_progress_notifier that sends messages via the Kafka broker running on kafka01.example.com on port 9092:

```
=> CREATE NOTIFIER load_progress_notifier
   ACTION 'kafka://kafka01.example.com:9092'
   MAXMEMORYSIZE '10M';
```

While not required, it's best practice to create notifiers that use an encrypted connection. The following example creates a notifier that uses an encrypted connection and verifies the Kafka server's certificate with the provided CA bundle :

```
=> CREATE NOTIFIER encrypted_notifier
   ACTION 'kafka://127.0.0.1:9092'
   MAXMEMORYSIZE '10M'
   TLSMODE 'verify-ca'
   CA BUNDLE ca_bundle;
```

Follow this procedure to create or alter notifiers for Kafka endpoints that use SASL_SSL. Note that you must repeat this procedure whenever you change the TLSMODE, certificates, or CA bundle for a given notifier.

1. Use CREATE or ALTER to disable the notifier while setting the TLSMODE, certificate, and CA bundle.
   ```
   => ALTER NOTIFIER encrypted_notifier
      DISABLE
      TLSMODE 'verify-ca'
      CA BUNDLE ca_bundle2;
   ```
2. ALTER the notifier and set the proper rdkafka adapter parameters for SASL_SSL.
   ```
   => ALTER NOTIFIER encrypted_notifier PARAMETERS
    'sasl.username=user;sasl.password=password;sasl.mechanism=PLAIN;security.protocol=SASL_SSL';
   ```
3. Enable the notifier.
   ```
   => ALTER NOTIFIER encrypted_notifier ENABLE;
   ```

Sending individual messages via a Kafka notifier

You can send an individual message via a Kafka notifier using the NOTIFY function. This feature is useful for reporting the progress of SQL scripts such as ETL tasks to third-party reporting tools.

You pass this function three string values:

- The message to send.
- The name of the notifier to send the message.
- The Kafka topic to receive the message.

For example, suppose you want to send the message "Daily load finished" to the vertica_notifications topic of the Kafka cluster defined in the load_progress_notifier notifier created earlier. Then you could execute the following statement:

```
=> SELECT NOTIFY('Daily load finished.',
                 'load_progress_notifier',
                 'vertica_notifications');
 NOTIFY
--------
 OK
(1 row)
```

The message the notifier sends to Kafka is in JSON format. You can see the resulting message by using the console consumer on a Kafka node. For example:

```
$ /opt/kafka/bin/kafka-console-consumer.sh --bootstrap-server localhost:9092 \
                                           --from-beginning \
                                           --topic vertica_notifications \
                                           --max-messages 1

{"_db":"vmart","_schema":"v_internal","_table":"dc_notifications",
"channel":"vertica_notifications","message":"Daily load finished.",
"node_name":"v_vmart_node0001","notifier":"load_progress_notifier",
"request_id":2,"session_id":"v_vmart_node0001-463079:0x4ba6f",
"statement_id":-1,"time":"2018-06-19 09:48:42.314181-04",
"transaction_id":45035996275565458,"user_id":45035996273704962,
"user_name":"dbadmin"}

Processed a total of 1 messages
```

Monitoring DC tables with Kafka notifiers

The Vertica Data collector (DC) tables monitor many different database functions. You can have a notifier automatically send a message to a Kafka endpoint when a DC component updates. You can query the DATA_COLLECTOR table to get a list of the DC components.

You configure the notifier to send DC component updates to Kafka using the function SET_DATA_COLLECTOR_NOTIFY_POLICY .

To be notified of failed login attempts, you can create a notifier that sends a notification when the DC component LoginFailures updates. The TLSMODE 'verify-ca' verifies that the server's certificate is signed by a trusted CA.

```
=> CREATE NOTIFIER vertica_stats ACTION 'kafka://kafka01.example.com:9092' MAXMEMORYSIZE '10M' TLSMODE 'verify-ca';
CREATE NOTIFIER
=> SELECT SET_DATA_COLLECTOR_NOTIFY_POLICY('LoginFailures','vertica_stats', 'vertica_notifications', true);
SET_DATA_COLLECTOR_NOTIFY_POLICY
-----------------------------------
 SET
(1 row)
```

Like the messages sent via the NOTIFY function, the data sent to Kafka from the DC components is in JSON format. The previous example results in messages like the following being sent to the vertica_notifications Kafka topic:

```
{"_db":"vmart","_schema":"v_internal","_table":"dc_login_failures",
"authentication_method":"Reject","client_authentication_name":"",
"client_hostname":"::1","client_label":"","client_os_user_name":"dbadmin",
"client_pid":481535,"client_version":"","database_name":"alice",
"effective_protocol":"3.8","node_name":"v_vmart_node0001",
"reason":"INVALID USER","requested_protocol":"3.8","ssl_client_fingerprint":"",
"time":"2018-06-19 14:51:22.437035-04","user_name":"alice"}
```

Viewing notification policies for a DC component

Use the GET_DATA_COLLECTOR_NOTIFY_POLICY function to list the policies set for a DC component.

```
=> SELECT GET_DATA_COLLECTOR_NOTIFY_POLICY('LoginFailures');
                GET_DATA_COLLECTOR_NOTIFY_POLICY
-------------------------------------------------------------------------
 Notifiable;  Notifier: vertica_stats; Channel: vertica_notifications
(1 row)
```

Disabling a notification policy

You can call SET_DATA_COLLECTOR_NOTIFY_POLICY function with its fourth argument set to FALSE to disable a notification policy. The following example disables the notify policy for the LoginFailures component:

```
=> SELECT SET_DATA_COLLECTOR_NOTIFY_POLICY('LoginFailures','vertica_stats', 'vertica_notifications', false);
 SET_DATA_COLLECTOR_NOTIFY_POLICY
----------------------------------
 SET
(1 row)
```

```
=> SELECT GET_DATA_COLLECTOR_NOTIFY_POLICY('LoginFailures');
 GET_DATA_COLLECTOR_NOTIFY_POLICY
----------------------------------
 Not notifiable;
(1 row)
```

TLS/SSL encryption with Kafka

You can use TLS/SSL encryption between Vertica, your scheduler, and Kakfa. This encryption prevents others from accessing the data that is sent between Kafka and Vertica. It can also verify the identity of all parties involved in data streaming, so no impostor can pose as your Vertica cluster or a Kafka broker.

> **Note**
> Many people often confuse the terms TLS and SSL. SSL is an older encryption protocol that has been largely replace with the newer and more secure TLS standard. However, many people still use the term SSL to refer to encryption between servers and applications , even when that encryption is actually TLS. For example, Java and Kafka use the term SSL exclusively, even when dealing with TLS. This document uses SSL/TLS and SSL interchangeably.

Some common cases where you want to use SSL encryption between Vertica and Kafka are:

- Your Vertica database and Kafka communicate over an insecure network. For example, suppose your Kafka cluster is located in a cloud service and your Vertica cluster is within your internal network. In this case, any data you read from Kafka travels over an insecure connection across the Internet.
- You are required by security policies, laws, or other requirements to encrypt all of your network traffic.

For more information about TLS/SSL encryption in Vertica, see TLS protocol .

Using TLS/SSL between the scheduler and Vertica

The scheduler connects to Vertica the same way other client applications do. There are two ways you can configure Vertica to use SSL/TLS authentication and encryption with clients:

- If Vertica is configured to use SSL/TLS server authentication, you can choose to have your scheduler confirm the identity of the Vertica server.
- If Vertica is configured to use mutual SSL/TLS authentication, you can configure your scheduler identify itself to Vertica as well as have it verify the identity of the Vertica server. Depending on your database's configuration, the Vertica server may require your scheduler to use TLS when connecting. See Implementing client self-authentication for more information.

For information on encrypted client connections with Vertica, refer to TLS protocol .

The scheduler runs on a Java Virtual Machine (JVM) and uses JDBC to connect to Vertica. It acts like any other JDBC client when connecting to Vertica. To use TLS/SSL encryption for the scheduler's connection to Vertica, use the Java keystore and truststore mechanism to hold the keys and certificates the scheduler uses to identify itself and Vertica.

- The keystore contains your scheduler's private encryption key and its certificate (public key).
- The truststore contains CAs that you trust. If you enable authentication, the scheduler uses these CAs to verify the identity of the Vertica cluster it connects to. If one of the CAs in the trust store was used to sign the server's certificate, then the Scheduler knows it can trust the identity of the Vertica server.

You can pass options to the JVM that executes the scheduler through the Linux environment variable named VKCONFIG_JVM_OPTS. You add the parameters to this variable that alter the scheduler's JDBC settings (such as the truststore and keystore for the scheduler's JDBC connection). See Step 2: Set the VKCONFIG_JVM_OPTS Environment Variable for an example.

You can also use the --jdbc-url scheduler option to alter the JDBC configuration. See Common vkconfig script options for more information about the scheduler options and JDBC connection properties for more information about the properties they can alter.

Using TLS/SSL between Vertica and Kafka

You can stream data from Kafka into Vertica two ways: manually using a COPY statement and the KafkaSource UD source function, or automatically using the scheduler.

To directly copy data from Kafka via an SSL connection, you set session variables containing an SSL key and certificate. When KafkaSource finds that you have set these variables, it uses the key and certificate to create a secure connection to Kafka. See Kafka TLS/SSL Example Part 4: Loading Data Directly From Kafka for details.

When automatically streaming data from Kafka to Vertica, you configure the scheduler the same way you do to use an SSL connection to Vertica. When the scheduler executes COPY statements to load data from Kafka, it uses its own keystore and truststore to create an SSL connection to Kafka.

To use an SSL connection when producing data from Vertica to Kafka, you set the same session variables you use when directly streaming data from Kafka via an SSL connection. The KafkaExport function uses these variables to establish a secure connection to Kafka.

> **Note**
> Notifiers do not currently support using TLS/SSL connections.

See the Apache Kafka documentation for more information about using SSL/TLS authentication with Kafka .

In this section

- Planning TLS/SSL encryption between Vertica and Kafka
- Configuring your scheduler for TLS connections
- Using TLS/SSL when directly loading data from Kafka
- Configure Kafka for TLS
- Troubleshooting Kafka TLS/SSL connection issues

Planning TLS/SSL encryption between Vertica and Kafka

Some things to consider before you begin configuring TLS/SSL:

- Which connections between the scheduler, Vertica, and Kafka needs to be encrypted? In some cases, you may only need to enable encryption between Vertica and Kafka. This scenario is common when Vertica and the Kafka cluster are on different networks. For example, suppose Kafka is hosted in a cloud provider and Vertica is hosted in your internal network. Then the data must travel across the unsecured Internet between the two. However, if Vertica and the scheduler are both in your local network, you may decide that configuring them to use SSL/TLS is unnecessary. In other cases, you will want all parts of the system to be encrypted. For example, you want to encrypt all traffic when Kafka, Vertica, and the scheduler are all hosted in a cloud provider whose network may not be secure.
- Which connections between the scheduler, Vertica, and Kafka require trust? You can opt to have any of these connections fail if one system cannot verify the identity of another. See Verifying Identities below.
- Which CAs will you be using to sign each certificate? The simplest way to configure the scheduler, Kafka, and Vertica is to use the same CA to sign all of the certificates you will use when setting up TLS/SSL. Using the same root CA to sign the certificates requires you to be able to edit the configuration of Kafka, Vertica, and the scheduler. If you cannot use the same CA to sign all certificates, all truststores must contain the entire chain of CAs used to sign the certificates, all the way up to the root CA. Including the entire chain of trust ensures each system can verify each other's identities.

Verifying identities

Your primary challenge when configuring TLS/SSL encryption between Vertica, the scheduler, and Kafka is making sure the scheduler, Kafka, and Vertica can all verify each other's identity. The most common problem people have encountered when setting up TLS/SSL encryption is ensuring the remote system can verify the authenticity of a system's certificate. The best way to prevent this problem is to ensure that the all systems have their certificates signed by a CA that all of the systems explicitly trust.

When a system attempts to start an encrypted connection with another system, it sends its certificate to the remote system. This certificate can be signed by one or more Certificate Authorities (CA) that help identify the system making the connection. These signatures form a "chain of trust." A certificate is signed by a CA. That CA, in turn, could have been signed by another CA, and so forth. Often, the chain ends with a CA (referred to as the root CA) from a well-known commercial provider of certificates, such as Comodo SSL or DigiCert, that are trusted by default on many platforms such as operating systems and web browsers.

If the remote system finds a CA in the chain that it trusts, it verifies the identity of the system making the connection, and the connection can continue. If the remote system cannot find the signature of a CA it trusts, it may block the connection, depending on its configuration. Systems can be configured to only allow connections from systems whose identity has been verified.

Note
Verifying the identity of another system making a TLE/SSL connection is often referred to as "authentication." Do not confuse this use of authentication with other forms of authentication used with Vertica. For example, TLS/SSL's authentication of a client connection has nothing to do with Vertica user authentication. Even if you successfully establish a TLS/SSL connection to Vertica using a client, Vertica still requires you to provide a user name and password before you can interact with it.

Configuring your scheduler for TLS connections

The scheduler can use TLS for two different connections: the one it makes to Vertica, and the connection it creates when running COPY statements to retrieve data from Kafka. Because the scheduler is a Java application, you supply the TLS key and the certificate used to sign it in a keystore. You also supply a truststore that contains in the certificates that the scheduler should trust. Both the connection to Vertica and to Kafka can use the same keystore and truststore. You can also choose to use separate keystores and truststores for these two connections by setting different JDBC settings for the scheduler. See JDBC connection properties for a list of these settings.

See Kafka TLS-SSL Example Part 5: Configure the Scheduler for detailed steps on configuring your scheduler to use SSL.

Important
If you choose to use a file format other than the standard Java Keystore (JKS) format for your keystore or truststore files, you must use the correct file extension in the filename. For example, suppose you choose to use a keystore and truststore saved in PKCS#12 format. Then your keystore and trustore files must end with the .pfx or .p12 extension.

If the scheduler does not recognize the file's extension (or there is no extension in the file name), it assumes that the file is in JKS format. If the file is not in JKS format, you will see an error message when starting the scheduler, similar to "Failed to create an SSLSocketFactory when setting up TLS: keystore not found."

Note that if the Kafka server's parameter client.ssl.auth is set to none or requested , you do not need to create a keystore.

Using TLS/SSL when directly loading data from Kafka

You can manually load data from Kafka using the COPY statement and the KafkaSource user-defined load function (see Manually consume data from Kafka). To have KafkaSource open a secure connection to Kafka, you must supply it with an SSL key and other information.

When starting, the KafkaSource function checks if several user session variables are defined. These variables contain the SSL key, the certificate used to sign the key, and other information that the function needs to create the SSL connection. See Kafka user-defined session parameters for a list of these variables. If KafkaSource finds these variables are defined, it uses them to create an SSL connection to Kafka.

See Kafka TLS/SSL Example Part 4: Loading Data Directly From Kafka for a step-by-step guide on configuring and using an SSL connection when directly copying data from Kafka.

These variables are also used by the KafkaExport function to establish a secure connection to Kafka when exporting data.

Configure Kafka for TLS

This page covers procedures for configuring TLS connections Vertica, Kafka, and the scheduler.

Note that the following example configures TLS for a Kafka server where ssl.client.auth=required , which requires the following:

- kafka_SSL_Certificate
- kafka_SSL_PrivateKey_secret
- kafka_SSL_PrivateKeyPassword_secret
- A keystore for the Scheduler

If your configuration uses ssl.client.auth=none or ssl.client.auth=requested , these parameters and the scheduler keystore are optional.

Creating certificates for Vertica and clients

The CA certificate in this example is self-signed. In a production environment, you should instead use a trusted CA.

This example uses the same self-signed root CA to sign all of the certificates used by the scheduler, Kafka brokers, and Vertica. If you cannot use the same CA to sign the keys for all of these systems, make sure you include the entire chain of trust in your keystores.

For more information, see Generating TLS certificates and keys .

1. Generate a private key, root.key .

```
$ openssl genrsa -out root.key
Generating RSA private key, 2048 bit long modulus
.....................................................................
.........................+++
.............+++
e is 65537 (0x10001)
```

2. Generate a self-signed CA certificate.

```
$ openssl req -new -x509 -key root.key -out root.crt
You are about to be asked to enter information that will be incorporated
into your certificate request.
What you are about to enter is what is called a Distinguished Name or a DN.
There are quite a few fields but you can leave some blank
For some fields there will be a default value,
If you enter '.', the field will be left blank.
-----
Country Name (2 letter code) [AU]:US
State or Province Name (full name) [Some-State]:MA
Locality Name (eg, city) []:Cambridge
Organization Name (eg, company) [Internet Widgits Pty Ltd]:My Company
Organizational Unit Name (eg, section) []:
Common Name (e.g. server FQDN or YOUR name) []:*.mycompany.com
Email Address []:myemail@mycompany.com
```

3. Restrict to the owner read/write permissions for root.key and root.crt . Grant read permissions to other groups for root.crt .

```
$ ls
root.crt  root.key
$ chmod 600 root.key
$ chmod 644 root.crt
```

4. Generate the server private key, *server.key* .

```
$ openssl genrsa -out server.key
Generating RSA private key, 2048 bit long modulus
.....................................................................+++
.....................................+++
e is 65537 (0x10001)
```

5. Create a certificate signing request (CSR) for your CA. Be sure to set the "Common Name" field to a wildcard (asterisk) so the certificate is accepted for all Vertica nodes in the cluster:

```
$ openssl req -new -key server.key -out server_reqout.txt
You are about to be asked to enter information that will be incorporated
into your certificate request.
What you are about to enter is what is called a Distinguished Name or a DN.
There are quite a few fields but you can leave some blank
For some fields there will be a default value,
If you enter '.', the field will be left blank.
-----
Country Name (2 letter code) [AU]:US
State or Province Name (full name) [Some-State]:MA
Locality Name (eg, city) []:Cambridge
Organization Name (eg, company) [Internet Widgits Pty Ltd]:My Company
Organizational Unit Name (eg, section) []:
Common Name (e.g. server FQDN or YOUR name) []:*.mycompany.com
Email Address []:myemail@mycompany.com

Please enter the following 'extra' attributes
to be sent with your certificate request
A challenge password []: server_key_password
An optional company name []:
```

6. Sign the server certificate with your CA. This creates the server certificate server.crt .

```
$ openssl x509 -req -in server_reqout.txt -days 3650 -sha1 -CAcreateserial -CA root.crt \
  -CAkey root.key -out server.crt
  Signature ok
  subject=/C=US/ST=MA/L=Cambridge/O=My Company/CN=*.mycompany.com/emailAddress=myemail@mycompany.com
  Getting CA Private Key
```

7. Set the appropriate permissions for the key and certificate.

```
$ chmod 600 server.key
$ chmod 644 server.crt
```

Create a client key and certificate (mutual mode only)

In **Mutual Mode** , clients and servers verify each other's certificates before establishing a connection. The following procedure creates a client key and certificate to present to Vertica. The certificate must be signed by a CA that Vertica trusts.

The steps for this are identical to those above for creating a server key and certificate for Vertica.

```
$ openssl genrsa -out client.key
Generating RSA private key, 2048 bit long modulus
.....................................................................+++
.............................+++
e is 65537 (0x10001)

$ openssl req -new -key client.key -out client_reqout.txt
You are about to be asked to enter information that will be incorporated
into your certificate request.
What you are about to enter is what is called a Distinguished Name or a DN.
There are quite a few fields but you can leave some blank
For some fields there will be a default value,
If you enter '.', the field will be left blank.
-----
Country Name (2 letter code) [AU]:US
State or Province Name (full name) [Some-State]:MA
Locality Name (eg, city) []:Cambridge
Organization Name (eg, company) [Internet Widgits Pty Ltd]:My Company
Organizational Unit Name (eg, section) []:
Common Name (e.g. server FQDN or YOUR name) []:*.mycompany.com
Email Address []:myemail@mycompany.com

Please enter the following 'extra' attributes
to be sent with your certificate request
A challenge password []: server_key_password
An optional company name []:

$ openssl x509 -req -in client_reqout.txt -days 3650 -sha1 -CAcreateserial -CA root.crt \
  -CAkey root.key -out client.crt
Signature ok
subject=/C=US/ST=MA/L=Cambridge/O=My Company/CN=*.mycompany.com/emailAddress=myemail@mycompany.com
Getting CA Private Key

$ chmod 600 client.key
$ chmod 644 client.crt
```

Set up mutual mode client-server TLS

Configure Vertica for mutual mode

The following keys and certificates must be imported and then distributed to the nodes on your Vertica cluster with TLS CONFIGURATION for **Mutual Mode** :

- root.key
- root.crt
- server.key
- server.crt

You can view existing keys and certificates by querying CRYPTOGRAPHIC_KEYS and CERTIFICATES .

1. Import the server and root keys and certificates into Vertica with CREATE KEY and CREATE CERTIFICATE . See Generating TLS certificates and keys for details.

```
=> CREATE KEY imported_key TYPE 'RSA' AS '-----BEGIN PRIVATE KEY-----...-----END PRIVATE KEY-----';
=> CREATE CA CERTIFICATE imported_ca AS '-----BEGIN CERTIFICATE-----...-----END CERTIFICATE-----';
=> CREATE CERTIFICATE imported_cert AS '-----BEGIN CERTIFICATE-----...-----END CERTIFICATE-----';
```

   In this example, \set is used to retrieve the contents of root.key , root.crt , server.key , and server.crt .

```
=> \set ca_cert '''`cat root.crt`'''
=> \set serv_key '''`cat server.key`'''
=> \set serv_cert '''`cat server.crt`'''

=> CREATE CA CERTIFICATE root_ca AS :ca_cert;
CREATE CERTIFICATE
=> CREATE KEY server_key TYPE 'RSA' AS :serv_key;
CREATE KEY
=> CREATE CERTIFICATE server_cert AS :serv_cert;
CREATE CERTIFICATE
```

2. Follow the steps for **Mutual Mode** in Configuring client-server TLS to set the proper TLSMODE and TLS CONFIGURATION parameters.

Configure a client for mutual mode

Clients must have their private key, certificate, and CA certificate. The certificate will be presented to Vertica when establishing a connection, and the CA certificate will be used to verify the server certificate from Vertica.

This example configures the vsql client for mutual mode.

1. Create a .vsql directory in the user's home directory.

```
$ mkdir ~/.vsql
```

2. Copy client.key , client.crt , and root.crt to the vsql directory.

```
$ cp client.key client.crt root.crt ~/.vsql
```

3. Log into Vertica with vsql and query the SESSIONS system table to verify that the connection is using mutual mode:

```
$ vsql
Password: user-password
Welcome to vsql, the Vertica Analytic Database interactive terminal.

Type:  \h or \? for help with vsql commands
       \g or terminate with semicolon to execute query
       \q to quit

SSL connection (cipher: DHE-RSA-AES256-GCM-SHA384, bits: 256, protocol: TLSv1.2)

=> select user_name,ssl_state from sessions;
 user_name | ssl_state
-----------+-----------
 dbadmin   | Mutual
(1 row)
```

Configure Kafka for TLS

Configure the Kafka brokers

This procedure configures Kafka to use TLS with client connections. You can also configure Kafka to use TLS to communicate between brokers. However, inter-broker TLS has no impact on establishing an encrypted connection between Vertica and Kafka.

1. Create a truststore file for all of your Kafka brokers, importing your CA certificate. This example uses the self-signed root.crt created above.

```
=> $ keytool -keystore kafka.truststore.jks -alias CARoot -import \
            -file root.crt
Enter keystore password: some_password
Re-enter new password: some_password
Owner: EMAILADDRESS=myemail@mycompany.com, CN=*.mycompany.com, O=MyCompany, L=Cambridge, ST=MA, C=US
Issuer: EMAILADDRESS=myemail@mycompany.com, CN=*.mycompany.com, O=MyCompany, L=Cambridge, ST=MA, C=US
Serial number: c3f02e87707d01aa
Valid from: Fri Mar 22 13:37:37 EDT 2019 until: Sun Apr 21 13:37:37 EDT 2019
Certificate fingerprints:
        MD5:  73:B1:87:87:7B:FE:F1:6E:94:55:FD:AF:5D:D0:C3:0C
        SHA1: C0:69:1C:93:54:21:87:C7:03:93:FE:39:45:66:DE:22:18:7E:CD:94

0010: E5 3D 78 16                                        .=x.
]
]

Trust this certificate? [no]:  yes
Certificate was added to keystore
```

2. Create a keystore file for the Kafka broker named kafka01 . Each broker's keystore should be unique.
   The keytool command adds the a Subject Alternative Name (SAN) used as a fallback when establishing a TLS connection. Use your Kafka' broker's fully-qualified domain name (FQDN) as the value for the SAN and "What is your first and last name?" prompt.
   In this example, the FQDN is kafka01.example.com . The alias for keytool is set to localhost , so local connections to the broker use TLS.

```
$ keytool -keystore kafka01.keystore.jks -alias localhost -validity 365 -genkey -keyalg RSA \
    -ext SAN=DNS:kafka01.mycompany.com
Enter keystore password: some_password
Re-enter new password: some_password
What is your first and last name?
  [Unknown]:  kafka01.mycompany.com
What is the name of your organizational unit?
  [Unknown]:
What is the name of your organization?
  [Unknown]: MyCompany
What is the name of your City or Locality?
  [Unknown]:  Cambridge
What is the name of your State or Province?
  [Unknown]:  MA
What is the two-letter country code for this unit?
  [Unknown]:  US
Is CN=Database Admin, OU=MyCompany, O=Unknown, L=Cambridge, ST=MA, C=US correct?
  [no]:  yes

Enter key password for <localhost>
      (RETURN if same as keystore password):
```

3. Export the Kafka broker's certificate. In this example, the certificate is exported as kafka01.unsigned.crt .

```
$ keytool -keystore kafka01.keystore.jks -alias localhost \
            -certreq -file kafka01.unsigned.crt
 Enter keystore password: some_password
```

4. Sign the broker's certificate with the CA certificate.

```
$ openssl x509 -req -CA root.crt -CAkey root.key -in kafka01.unsigned.crt \
          -out kafka01.signed.crt -days 365 -CAcreateserial
Signature ok
subject=/C=US/ST=MA/L=Cambridge/O=Unknown/OU=MyCompany/CN=Database Admin
Getting CA Private Key
```

5. Import the CA certificate into the broker's keystore.

> **Note**
> If you use different CAs to sign the certificates in your environment, you must add the entire chain of CAs you used to sign your certificate to the keystore, all the way up to the root CA. Including the entire chain of trust helps other systems verify the identity of your Kafka broker.

```
$ keytool -keystore kafka01.keystore.jks -alias CARoot -import -file root.crt
Enter keystore password: some_password
Owner: EMAILADDRESS=myemail@mycompany.com, CN=*.mycompany.com, O=MyCompany, L=Cambridge, ST=MA, C=US

Signature algorithm name: SHA256withRSA
Subject Public Key Algorithm: 2048-bit RSA key
Version: 1
Trust this certificate? [no]:  yes
Certificate was added to keystore
```

7. If you are not logged into the Kafka broker for which you prepared the keystore, copy the truststore and keystore to it using scp. If you have already decided where to store the keystore and truststore files in the broker's filesystem, you can directly copy them to their final destination. This example just copies them to the root user's home directory temporarily. The next step moves them into their final location.

```
$ scp kafka.truststore.jks kafka01.keystore.jks root@kafka01.mycompany.com:
root@kafka01.mycompany.com's password: root_password
kafka.truststore.jks                          100% 1048     1.0KB/s   00:00
kafka01.keystore.jks                          100% 3277     3.2KB/s   00:00
```

8. Repeat steps 2 through 7 for the remaining Kafka brokers.

Allow Kafka to read the keystore and truststore

If you did not copy the truststore and keystore to directory where Kafka can read them in the previous step, you must copy them to a final location on the broker. You must also allow the user account you use to run Kafka to read these files. The easiest way to ensure the user's access is to give this user ownership of these files.

In this example, Kafka is run by a Linux user kafka . If you use another user to run Kafka, be sure to set the permissions on the truststore and keystore files appropriately.

1. Log into the Kafka broker as root.
2. Copy the truststore and keystore to a directory where Kafka can access them. There is no set location for these files: you can choose a directory under /etc, or some other location where configuration files are usually stored. This example copies them from root's home directory to Kafka's configuration directory named /opt/kafka/config/. In your own system, this configuration directory may be in a different location depending on how you installed Kafka.
3. Copy the truststore and keystore to a directory where Kafka can access them. There is no set location for these files: you can choose a directory under /etc , or some other location where configuration files are usually stored. This example copies them from root's home directory to Kafka's configuration directory named /opt/kafka/config/ . In your own system, this configuration directory may be in a different location depending on how you installed Kafka.

```
~# cd /opt/kafka/config/
/opt/kafka/config# cp /root/kafka01.keystore.jks /root/kafka.truststore.jks .
```

4. If you aren't logged in as a user account that runs Kafka, change the ownership of the truststore and keystore files. This example changes the ownership from root (which is the user currently logged in) to the kafka user:

```
/opt/kafka/config# ls -l
total 80
...
-rw-r--r-- 1 kafka nogroup 1221 Feb 21  2018 consumer.properties
-rw------- 1 root  root    3277 Mar 27 08:03 kafka01.keystore.jks
-rw-r--r-- 1 root  root    1048 Mar 27 08:03 kafka.truststore.jks
-rw-r--r-- 1 kafka nogroup 4727 Feb 21  2018 log4j.properties
...
/opt/kafka/config# chown kafka kafka01.keystore.jks kafka.truststore.jks
/opt/kafka/config# ls -l
total 80
...
-rw-r--r-- 1 kafka nogroup 1221 Feb 21  2018 consumer.properties
-rw------- 1 kafka root    3277 Mar 27 08:03 kafka01.keystore.jks
-rw-r--r-- 1 kafka root    1048 Mar 27 08:03 kafka.truststore.jks
-rw-r--r-- 1 kafka nogroup 4727 Feb 21  2018 log4j.properties
...
```

5. Repeat steps 1 through 3 for the remaining Kafka brokers.

Configure Kafka to use TLS

With the truststore and keystore in place, your next step is to edit the Kafka's server.properties configuration file to tell Kafka to use TLS/SSL encryption. This file is usually stored in the Kafka config directory. The location of this directory depends on how you installed Kafka. In this example, the file is located in /opt/kafka/config .

When editing the files, be sure you do not change their ownership. The best way to ensure Linux does not change the file's ownership is to use su to become the user account that runs Kafka, assuming you are not already logged in as that user:

```
$ /opt/kafka/config# su -s /bin/bash kafka
```

> **Note**
> The previous command lets you start a shell as the kafka system user even if that user cannot log in.

The server.properties file contains Kafka broker settings in a *property* = *value* format. To configure the Kafka broker to use SSL, alter or add the following property settings:

listeners
Host names and ports on which the Kafka broker listens. If you are not using SSL for connections between brokers, you must supply both a PLANTEXT and SSL option. For example:

listeners=PLAINTEXT:// *hostname* :9092,SSL:// *hostname* :9093

ssl.keystore.location
Absolute path to the keystore file.

ssl.keystore.password
Password for the keystore file.

ssl.key.password
Password for the Kafka broker's key in the keystore. You can make this password different than the keystore password if you choose.

ssl.truststore.location
Location of the truststore file.

ssl.truststore.password
Password to access the truststore.

ssl.enabled.protocols
TLS/SSL protocols that Kafka allows clients to use.

ssl.client.auth
Specifies whether SSL authentication is required or optional. The most secure setting for this setting is required to verify the client's identity.

Important
These settings vary depending on your version of Kafka. Always consult the Apache Kafka documentation for your version of Kafka before making changes to server.properties . In particular, be aware that Kafka version 2.0 and later enables host name verification for clients and inter-broker communications by default.

This example configures Kafka to verify client identities via SSL authentication. It does not use SSL to communicate with other brokers, so the server.properties file defines both SSL and PLAINTEXT listener ports. It does not supply a host name for listener ports which tells Kafka to listen on the default network interface.

The lines added to the kafka01 broker's copy of server.properties for this configuration are:

```
listeners=PLAINTEXT://:9092,SSL://:9093
ssl.keystore.location=/opt/kafka/config/kafka01.keystore.jks
ssl.keystore.password=vertica
ssl.key.password=vertica
ssl.truststore.location=/opt/kafka/config/kafka.truststore.jks
ssl.truststore.password=vertica
ssl.enabled.protocols=TLSv1.2,TLSv1.1,TLSv1
ssl.client.auth=required
```

You must make these changes to the server.properties file on all of your brokers.

After making your changes to your broker's server.properties files, restart Kafka. How you restart Kafka depends on your installation:

- If Kafka is running as part of a Hadoop cluster, you can usually restart it from within whatever interface you use to control Hadoop (such as Ambari).
- If you installed Kafka directly, you can restart it either by directly running the kafka-server-stop.sh and kafka-server-start.sh scripts or via the Linux system's service control commands (such as systemctl). You must run this command on each broker.

Test the configuration
If you have not configured client authentication, you can quickly test whether Kafka can access its keystore by running the command:

```
$ openssl s_client -debug -connect broker_host_name:9093 -tls1
```

If Kafka is able to access its keystore, this command will output a dump of the broker's certificate (exit with CTRL+C):

```
=> # openssl s_client -debug -connect kafka01.mycompany.com:9093 -tls1
CONNECTED(00000003)
write to 0xa4e4f0 [0xa58023] (197 bytes => 197 (0xC5))

00c0 - 00 0f 00 01 01                                    .....
read from 0xa4e4f0 [0xa53ad3] (5 bytes => 5 (0x5))
0000 - 16 03 01 08 fc                                    .....
           . . .
```

The above method is not conclusive, however; it only tells you if Kafka is able to find its keystore.

The best test of whether Kafka is able to accept TLS connections is to configure the command-line Kafka producer and consumer. In order to configure these tools, you must first create a client keystore. These steps are identical to creating a broker keystore.

> **Note**
> This example assumes that Kafka has a topic named test that you can send test messages to.

1. Create the client keystore:
   ```
   keytool -keystore client.keystore.jks -alias localhost -validity 365 -genkey -keyalg RSA -ext SAN=DNS:fqdn_of_client_system
   ```
2. Respond to the "What is your first and last name?" with the FQDN of the system you will use to run the producer and/or consumer. Answer the rest of the prompts with the details of your organization.
3. Export the client certificate so it can be signed:
   ```
   keytool -keystore client.keystore.jks -alias localhost -certreq -file client.unsigned.cert
   ```
4. Sign the client certificate with the root CA:
   ```
   openssl x509 -req -CA root.crt -CAkey root.key -in client.unsigned.cert -out client.signed.cert \
         -days 365 -CAcreateserial
   ```
5. Add the root CA to keystore:
   ```
   keytool -keystore client.keystore.jks -alias CARoot -import -file root.crt
   ```
6. Add the signed client certificate to the keystore:
   ```
   keytool -keystore client.keystore.jks -alias localhost -import -file client.signed.cert
   ```
7. Copy the keystore to a location where you will use it. For example, you could choose to copy it to the same directory where you copied the keystore for the Kafka broker. If you choose to copy it to some other location, or intend to use some other user to run the command-line clients, be sure to add a copy of the truststore file you created for the brokers. Clients can reuse this truststore file for authenticating the Kafka brokers because the same CA is used to sign all of the certificates. Also set the file's ownership and permissions accordingly.

Next, you must create a properties file (similar to the broker's server.properties file) that configures the command-line clients to use TLS. For a client running on the Kafka broker named kafka01, your configuration file could would look like this:

```
security.protocol=SSL
ssl.truststore.location=/opt/kafka/config/kafka.truststore.jks
ssl.truststore.password=trustore_password
ssl.keystore.location=/opt/kafka/config/client.keystore.jks
ssl.keystore.password=keystore_password
ssl.key.password=key_password
ssl.enabled.protocols=TLSv1.2,TLSv1.1,TLSv1
ssl.client.auth=required
```

This property file assumes the keystore file is located in the Kafka configuration directory.

Finally, you can run the command line producer or consumer to ensure they can connect and process data. You supply these clients the properties file you just created. The following example assumes you stored the properties file in the Kafka configuration directory, and that Kafka is installed in /opt/kafka :

```
~# cd /opt/kafka

/opt/kafka# bin/kafka-console-producer.sh --broker-list kafka01.mycompany.com:9093  \
                              --topic test --producer.config config/client.properties
>test
>test again
>More testing. These messages seem to be getting through!
^D
/opt/kafka# bin/kafka-console-consumer.sh --bootstrap-server kafaka01.mycompany.com:9093  --topic test \
                              --consumer.config config/client.properties --from-beginning
test
test again
More testing. These messages seem to be getting through!

Loading data from Kafka

After you configure Kafka to accept TLS connections, verify that you can directly load data from it into Vertica. You should perform this step even if you plan to create a scheduler to automatically stream data.

You can choose to create a separate key and certificate for directly loading data from Kafka. This example re-uses the key and certificate created for the Vertica server in part 2 of this example.

You directly load data from Kafka by using the KafkaSource data source function with the COPY statement (see Manually consume data from Kafka). The KafkaSource function creates the connection to Kafka, so it needs a key, certificate, and related passwords to create an encrypted connection. You pass this information via session parameters. See Kafka user-defined session parameters for a list of these parameters.

The easiest way to get the key and certificate into the parameters is by first reading them into vsql variables . You get their contents by using back quotes to read the file contents via the Linux shell. Then you set the session parameters from the variables. Before setting the session parameters, increase the MaxSessionUDParameterSize session parameter to add enough storage space in the session variables for the key and the certificates. They can be larger than the default size limit for session variables (1000 bytes).

The following example reads the server key and certificate and the root CA from the a directory named /home/dbadmin/SSL . Because the server's key password is not saved in a file, the example sets it in a Linux environment variable named KVERTICA_PASS before running vsql. The example sets MaxSessionUDParameterSize to 100000 before setting the session variables. Finally, it enables TLS for the Kafka connection and streams data from the topic named test.

```
$ export KVERTICA_PASS=server_key_password
$ vsql
Password:
Welcome to vsql, the Vertica Analytic Database interactive terminal.

Type:  \h or \? for help with vsql commands
       \g or terminate with semicolon to execute query

Configure the scheduler

The final piece of the configuration is to set up the scheduler to use SSL when communicating with Kafka (and optionally with Vertica). When the scheduler runs a COPY command to get data from Kafka, it uses its own key and certificate to authenticate with Kafka. If you choose to have the scheduler use TLS/SSL to connect to Vertica, it can reuse the same keystore and truststore to make this connection.

Create a truststore and keystore for the scheduler

Because the scheduler is a separate component, it must have its own key and certificate. The scheduler runs in Java and uses the JDBC interface to connect to Vertica. Therefore, you must create a keystore (when ssl.client.auth=required) and truststore for it to use when making a TLS-encrypted connection to Vertica.

Keep in mind that creating a keystore is optional if your Kafka server sets ssl.client.auth to none or requested .

This process is similar to creating the truststores and keystores for Kafka brokers. The main difference is using the the -dname option for keytool to set the Common Name (CN) for the key to a domain wildcard. Using this setting allows the key and certificate to match any host in the network. This option is especially useful if you run multiple schedulers on different servers to provide redundancy. The schedulers can use the same key and certificate, no matter which server they are running on in your domain.

1. Create a truststore file for the scheduler. Add the CA certificate that you used to sign the keystore of the Kafka cluster and Vertica cluster. If you are using more than one CA to sign your certificates, add all of the CAs you used.

```
$ keytool -keystore scheduler.truststore.jks -alias CARoot -import \
            -file root.crt
Enter keystore password: some_password
Re-enter new password: some_password
Owner: EMAILADDRESS=myemail@mycompany.com, CN=*.mycompany.com, O=MyCompany, L=Cambridge, ST=MA, C=US
Issuer: EMAILADDRESS=myemail@mycompany.com, CN=*.mycompany.com, O=MyCompany, L=Cambridge, ST=MA, C=US

]
]

Trust this certificate? [no]:  yes
Certificate was added to keystore
```

2. Initialize the keystore, passing it a wildcard host name as the Common Name. The alias parameter in this command is important, as you use it later to identify the key the scheduler must use when creating SSL conections:

```
keytool -keystore scheduler.keystore.jks -alias vsched -validity 365 -genkey \
      -keyalg RSA  -dname CN=*.mycompany.com
```

Important
If you choose to use a file format other than the standard Java Keystore (JKS) format for your keystore or truststore files, you must use the correct file extension in the filename. For example, suppose you choose to use a keystore and truststore saved in PKCS#12 format. Then your keystore and trustore files must end with the .pfx or .p12 extension.

If the scheduler does not recognize the file's extension (or there is no extension in the file name), it assumes that the file is in JKS format. If the file is not in JKS format, you will see an error message when starting the scheduler, similar to "Failed to create an SSLSocketFactory when setting up TLS: keystore not found."

3. Export the scheduler's key so you can sign it with the root CA:

```
$ keytool -keystore scheduler.keystore.jks -alias vsched -certreq \
    -file scheduler.unsigned.cert
```

4. Sign the scheduler key with the root CA:

```
$ openssl x509 -req -CA root.crt -CAkey root.key -in scheduler.unsigned.cert \
    -out scheduler.signed.cert -days 365 -CAcreateserial
```

5. Re-import the scheduler key into the keystore:

```
$ keytool -keystore scheduler.keystore.jks -alias localhost -import -file scheduler.signed.cert
```

Set environment variable VKCONFIG_JVM_OPTS

You must pass several settings to the JDBC interface of the Java Virtual Machine (JVM) that runs the scheduler. These settings tell the JDBC driver where to find the keystore and truststore, as well as the key's password. The easiest way to pass in these settings is to set a Linux environment variable named VKCONFIG_JVM_OPTS. As it starts, the scheduler checks this environment variable and passes any properties defined in it to the JVM.

The properties that you need to set are:

- javax.net.ssl.keystore: the absolute path to the keystore file to use.
- javax.net.ssl.keyStorePassword: the password for the scheduler's key.
- javax.net.ssl.trustStore: The absolute path to the truststore file.

The Linux command line to set the environment variable is:

```
export VKCONFIG_JVM_OPTS="$VKCONFIG_JVM_OPTS -Djavax.net.ssl.trustStore=/path/to/truststore \
                -Djavax.net.ssl.keyStore=/path/to/keystore \
                -Djavax.net.ssl.keyStorePassword=keystore_password"
```

Note
The previous command preserves any existing contents of the VKCONFIG_JVM_OPTS variable. If you find the variable has duplicate settings, remove the $VKCONFIG_JVM_OPTS from your statement so you override the existing values in the variable.

For example, suppose the scheduler's truststore and keystore are located in the directory /home/dbadmin/SSL . Then you could use the following command to set the VKCONFIG_JVM_OPTS variable:

```
$ export VKCONFIG_JVM_OPTS="$VKCONFIG_JVM_OPTS \
                -Djavax.net.ssl.trustStore=/home/dbadmin/SSL/scheduler.truststore.jks \
                -Djavax.net.ssl.keyStore=/home/dbadmin/SSL/scheduler.keystore.jks \
                -Djavax.net.ssl.keyStorePassword=key_password"
```

Important
The Java property names are case sensitive.

To ensure that this variable is always set, add the command to the ~/.bashrc or other startup file of the user account that runs the scheduler.

If you require TLS on the JDBC connection to Vertica, add TLSmode=require to the JDBC URL that the scheduler uses. The easiest way to add this is to use the scheduler's --jdbc-url option. Assuming that you use a configuration file for your scheduler, you can add this line to it:

```
--jdbc-url=jdbc:vertica://VerticaHost:portNumber/databaseName?user=username&password=password&TLSmode=require
```

For more information about using the JDBC with Vertica, see Programming JDBC client applications .

Enable TLS in the scheduler configuration

Lastly, enable TLS. Every time you run vkconfig , you must pass it the following options:

--enable-ssl

true , to enable the scheduler to use SSL when connecting to Kafka.

--ssl-ca-alias

Alias for the CA you used to sign your Kafka broker's keys. This must match the value you supplied to the -alias argument of the keytool command to import the CA into the truststore.

> **Note**
> If you used more than one CA to sign keys, omit this option to import all of the CAs into the truststore.

--ssl-key-alias

Alias assigned to the schedule key. This value must match the value you supplied to the -alias you supplied to the keytool command when creating the scheduler's keystore.

--ssl-key-password

Password for the scheduler key.

See Common vkconfig script options for details of these options. For convenience and security, add these options to a configuration file that you pass to vkconfig. Otherwise, you run the risk of exposing the key password via the process list which can be viewed by other users on the same system. See Configuration File Format for more information on setting up a configuration file.

Add the following to the scheduler configuration file to allow it to use the keystore and truststore and enable TLS when connecting to Vertica:

```
enable-ssl=true
ssl-ca-alias=CAroot
ssl-key-alias=vsched
ssl-key-password=vertica
jdbc-url=jdbc:vertica://VerticaHost:portNumber/databaseName?user=username&password=password&TLSmode=require
```

Start the scheduler

Once you have configured the scheduler to use SSL, start it and verify that it can load data. For example, to start the scheduler with a configuration file named weblog.conf , use the command:

```
$ nohup vkconfig launch --conf weblog.conf >/dev/null 2>&1 &
```

Troubleshooting Kafka TLS/SSL connection issues

After configuring Vertica, Kafka, and your scheduler to use TLS/SSL authentication and encryption, you may encounter issues with data streaming. This section explains some of the more common errors you may encounter, and how to trouble shoot them.

Errors when launching the scheduler

You may see errors like this when launching the scheduler:

```
$ vkconfig launch --conf weblog.conf
java.sql.SQLNonTransientException: com.vertica.solutions.kafka.exception.ConfigurationException:
      No keystore system property found: null
   at com.vertica.solutions.kafka.util.SQLUtilities.getConnection(SQLUtilities.java:181)
   at com.vertica.solutions.kafka.cli.CLIUtil.assertDBConnectionWorks(CLIUtil.java:40)
   at com.vertica.solutions.kafka.Launcher.run(Launcher.java:135)
   at com.vertica.solutions.kafka.Launcher.main(Launcher.java:263)
Caused by: com.vertica.solutions.kafka.exception.ConfigurationException: No keystore system property found: null
   at com.vertica.solutions.kafka.security.KeyStoreUtil.loadStore(KeyStoreUtil.java:77)
   at com.vertica.solutions.kafka.security.KeyStoreUtil.<init>(KeyStoreUtil.java:42)
   at com.vertica.solutions.kafka.util.SQLUtilities.getConnection(SQLUtilities.java:179)
   ... 3 more
```

The scheduler throws these errors when it cannot locate or read the keystore or truststore files. To resolve this issue:

- Verify you have set the VKCONFIG_JVM_OPTS Linux environment variable. Without this variable, the scheduler will not know where to find the truststore and keystore to use when creating TLS/SSL connections. See Step 2: Set the VKCONFIG_JVM_OPTS Environment Variable for more information.
- Verify that the keystore and truststore files are located in the path you set in the VKCONFIG_JVM_OPTS environment variable.
- Verify that the user account that runs the scheduler has read access to the trustore and keystore files.
- Verify that the key password you provide in the scheduler configuration is correct. Note that you must supply the password for the key, not the keystore.

Another possible error message is a failure to set up a TLS Keystore:

```
Exception in thread "main" java.sql.SQLRecoverableException: [Vertica][VJDBC](100024) IOException while communicating with server: java.io.IOException: Failed to create an SSLSocketFactory when setting up TLS: keystore not found.
    at com.vertica.io.ProtocolStream.logAndConvertToNetworkException(Unknown Source)
    at com.vertica.io.ProtocolStream.enableSSL(Unknown Source)
    at com.vertica.io.ProtocolStream.initSession(Unknown Source)
    at com.vertica.core.VConnection.tryConnect(Unknown Source)
    at com.vertica.core.VConnection.connect(Unknown Source)
    . . .
```

This error can be caused by using a keystore or truststore file in a format other than JKS and not supplying the correct file extension. If the scheduler does not recognize the file extension of your keystore or truststore file name, it assumes the file is in JKS format. If the file isn't in this format, the scheduler will exit with the error message shown above. To correct this error, rename the keystore and truststore files to use the correct file extension. For example, if your files are in PKCS 12 filemat, change their file extension to .p12 or .pks .

Data does not load

If you find that scheduler is not loading data into your database, you should first query the stream_microbatch_history table to determine whether the scheduler is executing microbatches, and if so, what their results are. A faulty TLS/SSL configuration usually results in a status of NETWORK_ISSUE:

```
=> SELECT frame_start, end_reason, end_reason_message FROM weblog_sched.stream_microbatch_history;
     frame_start       |  end_reason   | end_reason_message
-------------------------+---------------+--------------------
 2019-04-05 11:35:18.365 | NETWORK_ISSUE |
 2019-04-05 11:35:38.462 | NETWORK_ISSUE |
```

If you suspect an SSL issue, you can verify that Vertica is establishing a connection to Kafka by looking at Kafka's server.log file. Failed SSL connection attempts can appear in this log like this example:

```
java.io.IOException: Unexpected status returned by SSLEngine.wrap, expected
    CLOSED, received OK. Will not send close message to peer.
    at org.apache.kafka.common.network.SslTransportLayer.close(SslTransportLayer.java:172)
    at org.apache.kafka.common.utils.Utils.closeAll(Utils.java:703)
    at org.apache.kafka.common.network.KafkaChannel.close(KafkaChannel.java:61)
    at org.apache.kafka.common.network.Selector.doClose(Selector.java:739)
    at org.apache.kafka.common.network.Selector.close(Selector.java:727)
    at org.apache.kafka.common.network.Selector.pollSelectionKeys(Selector.java:520)
    at org.apache.kafka.common.network.Selector.poll(Selector.java:412)
    at kafka.network.Processor.poll(SocketServer.scala:551)
    at kafka.network.Processor.run(SocketServer.scala:468)
    at java.lang.Thread.run(Thread.java:748)
```

If you do not see errors of this sort, you likely have a network problem between Kafka and Vertica. If you do see these errors, consider the following debugging steps:

- Verify that the configuration of your Kafka cluster is uniform. For example, you may see connection errors if some Kafka nodes are set to require client authentication and others aren't.
- Verify that the Common Names (CN) in the certificates and keys match the host name of the system.
- Verify that the Kafka cluster is accepting connections on the ports and host names you specify in the server.properties file's listeners property. For example, suppose you use IP addresses in this setting, but use host names when defining the cluster in the scheduler's configuration. Then Kafka may reject the connection attempt by Vertica or Vertica may reject the Kafka node's identity.
- If you are using client authentication in Kafka, try turning it off to see if the scheduler can connect. If disabling authentication allows the scheduler to stream data, then you can isolate the problem to client authentication. In this case, review the certificates and CAs of both the Kafka cluster and the scheduler. Ensure that the truststores include all of the CAs used to sign the key, up to and including the root CA.

Avro schema registry and KafkaAvroParser

At minimum, the KafkaAvroParser requires the following parameters to create a TLS connection between the Avro Schema Registry and Vertica:

- schema_registry_url with the https scheme
- schema_registry_ssl_ca_path

If and only if TLS access fails, determine what TLS schema registry information Vertica requires from the following:

- Certificate Authority (CA)

- TLS server certificate
- TLS key

Provide only the necessary TLS schema registry information with KafkaAvroParser parameters. The TLS information must be accessible in the filesystem of each Vertica node that processes Avro data.

The following example shows how to pass these parameters to KafkaAvroParser:

```
KafkaAvroParser(
   schema_registry_url='https://localhost:8081'
   schema_registry_ssl_ca_path='path/to/certificate-authority',
   schema_registry_ssl_cert_path='path/to/tls-server-certificate',
   schema_registry_ssl_key_path='path/to/private-tls-key',
   schema_registry_ssl_key_password_path='path/to/private-tls-key-password'
)
```

Authenticating with Kafka using SASL

Kafka supports using Simple Authentication and Security Layer (SASL) to authenticate producers and consumers. You can use SASL to authenticate Vertica with Kafka when using most of the Kafka-related functions such as KafkaSource .

Vertica supports using the SASL_PLAINTEXT and SASL_SSL protocols with the following authentication mechanisms:

- PLAIN
- SCRAM-SHA-256
- SCRAM-SHA-512

You must configure your Kafka cluster to enable SASL authentication. See the Kafka documentation for your Kafka version to learn how to configure SASL authentication.

> **Note**
> KafkaExport does not support using TLS/SSL with SASL authentication at this time.

To use SASL authentication between Vertica and Kafka, directly set SASL-related configuration options in the rdkafka library using the kafka_conf parameter. Vertica uses this library to connect to Kafka. See Directly setting Kafka library options for more information on directly setting configuration options in the rdkafka library.

Among the relevant configuration options are:

- security.protocol sets the security protocol to use to authenticate with Kafka.
- sasl.mechanism sets the security mechanism.
- sasl.username sets the SASL user to use for authentication.
- sasl.password sets the password to use for SASL authentication.

See the rdkafka configuration documentation for a list of all the SASL-related settings.

The following example demonstrates calling KafkaCheckBrokers using the SASL_PLAINTEXT security protocol:

```
=> SELECT KafkaCheckBrokers(USING PARAMETERS
    brokers='kafka01.example.com:9092',
    kafka_conf='{"sasl.username":"dbadmin", "sasl.password":"pword", "sasl.mechanism":"PLAIN", "security.protocol":"SASL_PLAINTEXT"}'
  ) OVER ();
```

This example demonstrates using SASL authentication when copying data from Kafka via an SSL connection. This example assumes that Vertica and Kafka have been configures to use TLS/SSL encryption as described in TLS/SSL encryption with Kafka :

```
=> COPY mytopic_table
    SOURCE KafkaSource(
      stream='mytopic|0|-2',
      brokers='kafka01.example.com:9092',
      stop_on_eof=true,
      kafka_conf='{"sasl.username":"dbadmin", "sasl.password":"pword", "sasl.mechanism":"PLAIN", "security.protocol":"SASL_SSL"}'
    )
    FILTER KafkaInsertDelimiters(delimiter = E'\n')
    DELIMITER ','
    ENCLOSED BY '"';
```

For more information about using SASL with the rfkafka library, see Using SASL with librdkafka on the rdkafka github site.

Troubleshooting Kafka integration issues

The following topics can help you troubleshoot issues integrating Vertica with Apache Kafka.

In this section

- Using kafkacat to troubleshoot Kafka integration issues
- Troubleshooting slow load speeds
- Troubleshooting missing messages

Using kafkacat to troubleshoot Kafka integration issues

Kafkacat is a third-party open-source utility that lets you connect to Kafka from the Linux command line. It uses the same underlying library that the Vertica integration for Apache Kafka uses to connect to Kafka. This shared library makes kafkcat a useful tool for testing and debugging your Vertica integration with Kafka.

You may find kafkacat useful for:

- Testing connectivity between your Vertica and Kafka clusters.
- Examining Kafka data for anomalies that may prevent some of it from loading into Vertica.
- Producing data for test loads into Vertica.
- Listing details about a Kafka topic.

For more information about kafkacat, see its project page at Github .

Running kafkacat on Vertica nodes

The kafkacat utility is bundled in the Vertica install package, so it is available on all nodes of your Vertica cluster in the /opt/vertica/packages/kafka/bin directory. This is the same directory containing the vkconfig utility, so if you have added it to your path, you can use the kafkacat utility without specifying its full path. Otherwise, you can add this path to your shell's environment variable using the command:

```
set PATH=/opt/vertica/packages/kafka/bin:$PATH
```

> **Note**
> On Debian and Ubuntu systems, you must tell kafkacat to use Vertica's own copy of the SSL libraries by setting the LD_LIBRARY_PATH environment variable:
>
> ```
> $ export LD_LIBRARY_PATH=/opt/vertica/lib
> ```
>
> If you do not set this environment variable, the kafkcat utility exits with the error:
>
> ```
> kafkacat: error while loading shared libraries: libcrypto.so.10:
>       cannot open shared object file: No such file or directory
> ```

Executing kafkacat without any arguments gives you a basic help message:

```
$ kafkacat
Error: -b <broker,..> missing

Usage: kafkacat <options> [file1 file2 .. | topic1 topic2 ..]]
kafkacat - Apache Kafka producer and consumer tool
```

https://github.com/edenhill/kafkacat

General options:
 -C | -P | -L   Mode: Consume, Produce or metadata List
 -G <group-id>   Mode: High-level KafkaConsumer (Kafka 0.9 balanced consumer groups)
                    Expects a list of topics to subscribe to
 -t <topic>   Topic to consume from, produce to, or list
 -p <partition>   Partition
 -b <brokers,..>   Bootstrap broker(s) (host[:port])
 -D <delim>   Message delimiter character:
                    a-z.. | \r | \n | \t | \xNN
                    Default: \n
 -K <delim>   Key delimiter (same format as -D)
 -c <cnt>   Limit message count
 -X list   List available librdkafka configuration properties
 -X prop=val   Set librdkafka configuration property.
                    Properties prefixed with "topic." are
                    applied as topic properties.
 -X dump   Dump configuration and exit.
 -d <dbg1,...>   Enable librdkafka debugging:
                    all,generic,broker,topic,metadata,queue,msg,protocol,cgrp,security,fetch,feature
 -q   Be quiet (verbosity set to 0)
 -v   Increase verbosity
 -V   Print version

Producer options:
 -z snappy|gzip   Message compression. Default: none
 -p -1   Use random partitioner
 -D <delim>   Delimiter to split input into messages
 -K <delim>   Delimiter to split input key and message
 -l   Send messages from a file separated by
                    delimiter, as with stdin.
                    (only one file allowed)
 -T   Output sent messages to stdout, acting like tee.
 -c <cnt>   Exit after producing this number of messages
 -Z   Send empty messages as NULL messages
 file1 file2..   Read messages from files.
                    With -l, only one file permitted.
                    Otherwise, the entire file contents will
                    be sent as one single message.

Consumer options:
 -o <offset>   Offset to start consuming from:
                    beginning | end | stored |
                    <value> (absolute offset) |
                    -<value> (relative offset from end)
 -e   Exit successfully when last message received
 -f <fmt..>   Output formatting string, see below.
                    Takes precedence over -D and -K.
 -D <delim>   Delimiter to separate messages on output
 -K <delim>   Print message keys prefixing the message
                    with specified delimiter.
 -O   Print message offset using -K delimiter
 -c <cnt>   Exit after consuming this number of messages
 -Z   Print NULL messages and keys as "NULL"(instead of empty)
 -u   Unbuffered output

```
Metadata options:
 -t <topic>      Topic to query (optional)

Format string tokens:
 %s              Message payload
 %S              Message payload length (or -1 for NULL)
 %R              Message payload length (or -1 for NULL) serialized
                 as a binary big endian 32-bit signed integer
 %k              Message key
 %K              Message key length (or -1 for NULL)
 %t              Topic
 %p              Partition
 %o              Message offset
 \n \r \t        Newlines, tab
 \xXX \xNNN      Any ASCII character
Example:
 -f 'Topic %t [%p] at offset %o: key %k: %s\n'

Consumer mode (writes messages to stdout):
 kafkacat -b <broker> -t <topic> -p <partition>
or:
 kafkacat -C -b ...

High-level KafkaConsumer mode:
 kafkacat -b <broker> -G <group-id> topic1 top2 ^aregex\d+

Producer mode (reads messages from stdin):
 ... | kafkacat -b <broker> -t <topic> -p <partition>
or:
 kafkacat -P -b ...

Metadata listing:
 kafkacat -L -b <broker> [-t <topic>]
```

Testing connectivity to a Kafka cluster and getting metadata

One basic troubleshooting step you often need to perform is verifying that Vertica nodes can connect to the Kafka cluster. Successfully executing just about any kafkacat command will prove the Vertica node you are logged into is able to reach the Kafka cluster. One simple command you can execute to verify connectivity is to get the metadata for all of the topics the Kafka cluster has defined. The following example demonstrates using kafkacat's metadata listing command to connect to the broker named kafka01 running on port 6667 (the Kafka broker port used by Hortonworks Hadoop clusters).

```
$ kafkacat -L -b kafka01:6667
Metadata for all topics (from broker -1: kafka01:6667/bootstrap):
 2 brokers:
  broker 1001 at kafka03.example.com:6667
  broker 1002 at kafka01.example.com:6667
 4 topics:
  topic "iot-data" with 3 partitions:
    partition 2, leader 1002, replicas: 1002, isrs: 1002
    partition 1, leader 1001, replicas: 1001, isrs: 1001
    partition 0, leader 1002, replicas: 1002, isrs: 1002
  topic "__consumer_offsets" with 50 partitions:
    partition 23, leader 1001, replicas: 1002,1001, isrs: 1001,1002
    partition 41, leader 1001, replicas: 1002,1001, isrs: 1001,1002
    partition 32, leader 1002, replicas: 1002,1001, isrs: 1001,1002
    partition 8, leader 1002, replicas: 1002,1001, isrs: 1001,1002
    partition 17, leader 1001, replicas: 1002,1001, isrs: 1001,1002
    partition 44, leader 1002, replicas: 1002,1001, isrs: 1001,1002
    partition 35, leader 1001, replicas: 1002,1001, isrs: 1001,1002
    partition 26, leader 1002, replicas: 1002,1001, isrs: 1001,1002
```

```
  partition 11, leader 1001, replicas: 1002,1001, isrs: 1001,1002
  partition 29, leader 1001, replicas: 1002,1001, isrs: 1001,1002
  partition 38, leader 1002, replicas: 1002,1001, isrs: 1001,1002
  partition 47, leader 1001, replicas: 1002,1001, isrs: 1001,1002
  partition 20, leader 1002, replicas: 1002,1001, isrs: 1001,1002
  partition 2, leader 1002, replicas: 1002,1001, isrs: 1001,1002
  partition 5, leader 1001, replicas: 1002,1001, isrs: 1001,1002
  partition 14, leader 1002, replicas: 1002,1001, isrs: 1001,1002
  partition 46, leader 1002, replicas: 1002,1001, isrs: 1001,1002
  partition 49, leader 1001, replicas: 1002,1001, isrs: 1001,1002
  partition 40, leader 1002, replicas: 1002,1001, isrs: 1001,1002
  partition 4, leader 1002, replicas: 1002,1001, isrs: 1001,1002
  partition 13, leader 1001, replicas: 1002,1001, isrs: 1001,1002
  partition 22, leader 1002, replicas: 1002,1001, isrs: 1001,1002
  partition 31, leader 1001, replicas: 1002,1001, isrs: 1001,1002
  partition 16, leader 1002, replicas: 1002,1001, isrs: 1001,1002
  partition 7, leader 1001, replicas: 1002,1001, isrs: 1001,1002
  partition 43, leader 1001, replicas: 1002,1001, isrs: 1001,1002
  partition 25, leader 1001, replicas: 1002,1001, isrs: 1001,1002
  partition 34, leader 1002, replicas: 1002,1001, isrs: 1001,1002
  partition 10, leader 1002, replicas: 1002,1001, isrs: 1001,1002
  partition 37, leader 1001, replicas: 1002,1001, isrs: 1001,1002
  partition 1, leader 1001, replicas: 1002,1001, isrs: 1001,1002
  partition 19, leader 1001, replicas: 1002,1001, isrs: 1001,1002
  partition 28, leader 1002, replicas: 1002,1001, isrs: 1001,1002
  partition 45, leader 1001, replicas: 1002,1001, isrs: 1001,1002
  partition 36, leader 1002, replicas: 1002,1001, isrs: 1001,1002
  partition 27, leader 1001, replicas: 1002,1001, isrs: 1001,1002
  partition 9, leader 1001, replicas: 1002,1001, isrs: 1001,1002
  partition 18, leader 1002, replicas: 1002,1001, isrs: 1001,1002
  partition 21, leader 1001, replicas: 1002,1001, isrs: 1001,1002
  partition 48, leader 1002, replicas: 1002,1001, isrs: 1001,1002
  partition 12, leader 1002, replicas: 1002,1001, isrs: 1001,1002
  partition 3, leader 1001, replicas: 1002,1001, isrs: 1001,1002
  partition 30, leader 1002, replicas: 1002,1001, isrs: 1001,1002
  partition 39, leader 1001, replicas: 1002,1001, isrs: 1001,1002
  partition 15, leader 1001, replicas: 1002,1001, isrs: 1001,1002
  partition 42, leader 1002, replicas: 1002,1001, isrs: 1001,1002
  partition 24, leader 1002, replicas: 1002,1001, isrs: 1001,1002
  partition 33, leader 1001, replicas: 1002,1001, isrs: 1001,1002
  partition 6, leader 1002, replicas: 1002,1001, isrs: 1001,1002
  partition 0, leader 1002, replicas: 1002,1001, isrs: 1001,1002
topic "web_hits" with 1 partitions:
  partition 0, leader 1001, replicas: 1001, isrs: 1001
topic "ambari_kafka_service_check" with 1 partitions:
  partition 0, leader 1002, replicas: 1002, isrs: 1002
```

You can also use this output to verify the topics defined by your Kafka cluster, as well as the number of partitions each topic defines. You need this information when copying data between Kafka and Vertica.

Retrieving messages from a Kafka topic

When you are troubleshooting issues with streaming messages from Kafka in Vertica, you often want to look at the raw data that Kafka sent. For example, you may want to verify that the messages are in the format that your expect. Or, you may want to review specific messages to see if some of them weren't in the right format for Vertica to parse. You can use kafkacat to read messages from a topic using its consume command (-C). At the very least, you must pass kafkacat the brokers (-b argument) and the topic you want to read from (-t). You can also choose to read messages from a specific offset (-o) and partition (-p). You will usually also want kafkacat to exit after completing the data read (-e) instead continuing to wait for more messages.

This example gets the last message in the topic named web_hits. The offset argument uses a negative value, which tells kafkacat to read from the end of the topic.

```
$ kafkacat -C -b kafka01:6667 -t web_hits -o -1 -e
{"url": "wp-content/list/search.php", "ip": "132.74.240.52",
"date": "2018/03/28 14:12:34",
"user_agent": "Mozilla/5.0 (iPod; U; CPU iPhone OS 4_2 like
Mac OS X; sl-SI) AppleWebKit/532.22.4 (KHTML, like Gecko) Version/3.0.5
Mobile/8B117 Safari/6532.22.4"}
% Reached end of topic web_hits [0] at offset 54932: exiting
```

You can also read a specific range of messages by specifying an offset and a limit (-c argument). For example, you may want to look at a specific range of data to determine why Vertica could not load it. The following example reads 10 messages from the topic iot-data starting at offset 3280:

```
$ kafkacat -C -b kafka01:6667 -t iot-data -o 3280 -c 10 -e
63680, 19, 24.439323, 26.0128725
43510, 71, 162.319805, -37.4924025
91113, 53, 139.764857, -74.735731
88508, 14, -85.821967, -7.236280
20419, 31, -129.583988, 13.995481
79365, 79, 153.184594, 51.1583485
26283, 25, -168.911020, 35.331027
32111, 56, -157.930451, 82.2676385
56808, 17, 19.603286, -0.7698495
9118, 73, 97.365445, -74.8593245
```

Generating data for a Kafka topic

If you are preparing to stream data from a Kafka topic that is not yet active, you may want a way to stream test messages. You can then verify that the topic's messages load into Vertica without worrying that you will miss actual data.

To send data to Kafka, use kafkacat's produce command (-P). The easiest way to supply it with messages is to pipe them in via STDIN, one message per line. You can choose a specific partition for the data, or have kafkacat randomly assign each message to a random partition by setting the partition number to -1. For example, suppose you have a file named iot-data.csv that you wanted to produce to random partitions of a Kafka topic named iot-data. Then you could use the following command:

```
$ cat iot_data.csv | kafkacat -P -p -1 -b kafka01:6667 -t iot-data
```

Troubleshooting slow load speeds

Here are some potential issues that could cause messages to load slowly from Kafka.

Verify you have disabled the API version check when communicating with Kafka 0.9 or earlier

If your Kafka cluster is running 0.9 or earlier, be sure you have disable the rdkafka library's api.version.request option. If you do not, every Vertica connection to Kafka will pause for 10 seconds until the API version request times out. Depending on the frame size of your load or other timeout settings, this delay can either reduce the throughput of your data loads. It can even totally prevent messages from being loaded. See Configuring Vertica for Apache Kafka version 0.9 and earlier for more information.

Update the message-max-bytes setting of schedulers created before Vertica version 9.1.1

If you find that a scheduler is loading data slowly after upgrading to Vertica Version 9.1.1 or later, consider updating its load spec's message-max-bytes parameter. The meaning of this setting changed in Kafka 0.11. See Changes to the message.max.bytes setting in Kafka version 0.11 and later for more information.

Eon Mode and cloud latency

Eon Mode separates compute from storage in a Vertica cluster, which can cause a small amount of latency when Vertica loads and saves data. Cloud computing infrastructure can also cause latency. This latency can eat into the frame duration for your schedulers, causing them to load less data in each frame. For this reason, you should consider increasing frame durations when loading data from Kafka in an Eon Mode database. See Vertica Eon Mode and Kafka for more information.

Troubleshooting missing messages

Kafka producers that emit a high data volume might overwhelm Vertica, possibly resulting in messages expiring in Kafka before the scheduler loads them into Vertica. This is more common when Vertica performs additional processing on the loaded messages, such as text indexing.

If you see that you are missing messages from a topic with multiple partitions, consider configuring the --max-parallelism microbatch utility option . The --max-parallelism option splits a microbatch into multiple subset microbatches. This enables you to use PLANNEDCONCURRENCY available in the scheduler's resource pool to create more scheduler threads for simultaneous loads of a single microbatch. Each node uses the resource pool

EXECUTIONPARALLELISM setting to determine the number of threads created to process partitions. Because EXECUTIONPARALLELISM threads are created per scheduler thread, using more PLANNEDCONCURRENCY per microbatch enables you to process more partitions in parallel for a single unit of work.

For details, see Managing scheduler resources and performance .

vkconfig script options

Vertica includes the vkconfig script that lets you configure your schedulers. This script contains multiple tools that set groups of options in the scheduler, as well as starting and shutting it down. You supply the tool you want to use as the first argument in your call to the vkconfig script.

The topics in this section explain each of the tools available in the vkconfig script as well as their options. You can use the options in the Common vkconfig script options topic with any of the utilities. Utility-specific options appear in their respective tables.

In this section

- Common vkconfig script options
- Scheduler tool options
- Cluster tool options
- Source tool options
- Target tool options
- Load spec tool options
- Microbatch tool options
- Launch tool options
- Shutdown tool options
- Statistics tool options
- Sync tool options

Common vkconfig script options

These options are available across the different tools available in the vkconfig script.

--conf ***filename***

A text file containing configuration options for the vkconfig script. See Configuration File Format below.

--config-schema ***schema_name***

The name of the scheduler's Vertica schema. This value is the same as the name of the scheduler. You use this name to identify the scheduler during configuration.

Default:
stream_config

--dbhost ***host name***

The host name or IP address of the Vertica node acting as the initiator node for the scheduler.

Default:
localhost

--dbport ***port_number***

The port to use to connect to a Vertica database.

Default:
5433

--enable-ssl

Enables the vkconfig script to use SSL to connect to Vertica or between Vertica and Kafka. See Configuring your scheduler for TLS connections for more information.

--help

Prints out a help menu listing available options with a description.

--jdbc-opt ***option*** **=** ***value*** **[&** ***option2*** **=** ***value2*** **...]**

One or more options to add to the standard JDBC URL that vkconfig uses to connect to Vertica. Cannot be combined with --jdbc-url .

--jdbc-url ***url***

A complete JDBC URL that vkconfig uses instead of standard JDBC URL string to connect to Vertica.

--password ***password***

Password for the database user.

--ssl-ca-alias ***alias_name***

The alias of the root certificate authority in the truststore. When set, the scheduler loads only the certificate associated with the specified alias. When omitted, the scheduler loads all certificates into the truststore.

--ssl-key-alias ***alias_name***

The alias of the key and certificate pairs within the keystore. Must be set when Vertica uses SSL to connect to Kafka.

--ssl-key-password ***password***

The password for the SSL key. Must be set when Vertica uses SSL to connect to Kafka.

> **Caution**
> Specifying this option on the command line can expose it to other users logged into the host. Always use a configuration file to set this option.

--username ***username***

The Vertica database user used to alter the configuration of the scheduler. This use must have create privileges on the scheduler's schema.

Default:
Current user

--version

Displays the version number of the scheduler.

Configuration file format

You can use a configuration file to store common parameters you use in your calls to the vkconfig utility. The configuration file is a text file containing one option setting per line in the format:

```
option=value
```

You can also include comments in the option file by prefixing them with a hash mark (#).

```
#config.properties:
username=myuser
password=mypassword
dbhost=localhost
dbport=5433
```

You tell vkconfig to use the configuration file using the --conf option:

```
$ /opt/vertica/packages/kafka/bin/vkconfig source --update --conf config.properties
```

You can override any stored parameter from the command line:

```
$ /opt/vertica/packages/kafka/bin/vkconfig source --update --conf config.properties --dbhost otherVerticaHost
```

Examples

These examples show how you can use the shared utility options.

Display help for the scheduler utility:

```
$ vkconfig scheduler --help
This command configures a Scheduler, which can run and load data from configured
sources and clusters into Vertica tables. It provides options for changing the
'frame duration' (time given per set of batches to resolve), as well as the
dedicated Vertica resource pool the Scheduler will use while running.

Available Options:
PARAMETER             #ARGS    DESCRIPTION
conf                  1        Allow the use of a properties file to associate
                               parameter keys and values. This file enables
                               command string reuse and cleaner command strings.
help                  0        Outputs a help context for the given subutility.
version               0        Outputs the current Version of the scheduer.
```

```
skip-validation      0      [Depricated] Use --validation-type.
validation-type      1      Determine what happens when there are
                            configuration errors. Accepts: ERROR - errors
                            out, WARN - prints out a message and continues,
                            SKIP - skip running validations
dbhost               1      The Vertica database hostname that contains
                            metadata and configuration information. The
                            default value is 'localhost'.
dbport               1      The port at the hostname to connect to the
                            Vertica database. The default value is '5433'.
username             1      The user to connect to Vertica. The default
                            value is the current system user.
password             1      The password for the user connecting to Vertica.
                            The default value is empty.
jdbc-url             1      A JDBC URL that can override Vertica connection
                            parameters and provide additional JDBC options.
jdbc-opt             1      Options to add to the JDBC URL used to connect
                            to Vertica ('&'-separated key=value list).
                            Used with generated URL (i.e. not with
                            '--jdbc-url' set).
enable-ssl           1      Enable SSL between JDBC and Vertica and/or
                            Vertica and Kafka.
ssl-ca-alias         1      The alias of the root CA within the provided
                            truststore used when connecting between
                            Vertica and Kafka.
ssl-key-alias        1      The alias of the key and certificate pair
                            within the provided keystore used when
                            connecting between Vertica and Kafka.
ssl-key-password     1      The password for the key used when connecting
                            between Vertica and Kafka. Should be hidden
                            with file access (see --conf).
config-schema        1      The schema containing the configuration details
                            to be used, created or edited. This parameter
                            defines the scheduler. The default value is
                            'stream_config'.
create               0      Create a new instance of the supplied type.
read                 0      Read an instance of the supplied type.
update               0      Update an instance of the supplied type.
delete               0      Delete an instance of the supplied type.
drop                 0      Drops the specified configuration schema.
                            CAUTION: this command will completely delete
                            and remove all configuration and monitoring
                            data for the specified scheduler.
dump                 0      Dump the config schema query string used to
                            answer this command in the output.
operator             1      Specifies a user designated as an operator for
                            the created configuration. Used with --create.
add-operator         1      Add a user designated as an operator for the
                            specified configuration. Used with --update.
remove-operator      1      Removes a user designated as an operator for
                            the specified configuration. Used with
                            --update.
upgrade              0      Upgrade the current scheduler configuration
                            schema to the current version of this
                            scheduler. WARNING: if upgrading between
                            EXCAVATOR and FRONTLOADER be aware that the
                            Scheduler is not backwards compatible. The
                            upgrade procedure will translate your kafka
                            model into the new stream model.
upgrade-to-schema    1      Used with upgrade: will upgrade the
                            configuration to a new given schema instead of
```

		upgrading within the same schema.
fix-config	0	Attempts to fix the configuration (ex: dropped tables) before doing any other updates. Used with --update.
frame-duration	1	The duration of the Scheduler's frame, in which every configured Microbatch runs. Default is 300 seconds: '00:05:00'
resource-pool	1	The Vertica resource pool to run the Scheduler on. Default is 'general'.
config-refresh	1	The interval of time between Scheduler configuration refreshes. Default is 5 minutes: '00:05'
new-source-policy	1	The policy for new Sources to be scheduled during a frame. Options are: START, END, and FAIR. Default is 'FAIR'.
pushback-policy	1	
pushback-max-count	1	
auto-sync	1	Automatically update configuration based on metadata from the Kafka cluster
consumer-group-id	1	The Kafka consumer group id to report offsets to.
eof-timeout-ms	1	[DEPRECATED] This option has no effect.

Scheduler tool options

The vkconfig script's scheduler tool lets you configure schedulers that continuously loads data from Kafka into Vertica. Use the scheduler tool to create, update, or delete a scheduler, defined by config-schema . If you do not specify a scheduler, commands apply to the default stream_config scheduler.

Syntax

```
vkconfig scheduler {--create | --read | --update | --drop} other_options...
```

--create

Creates a new load spec, cannot be used with --delete , --read , or --update .

--read

Outputs the current setting of the scheduler in JSON format. Cannot be used with --create , --delete , or --update .

--update

Updates an existing Set Snippet Variable Value in Topic. Cannot be used with --create , --delete , or --read .

--drop

Drops the scheduler's schema. Dropping its schema deletes the scheduler. After you drop the scheduler's schema, you cannot recover it.

--add-operator *user_name*

Grants a Vertica user account or role access to use and alter the scheduler. Requires the --update shared utility option.

--auto-sync {TRUE|FALSE}

When TRUE, Vertica automatically synchronizes scheduler source information at the interval specified in --config-refresh .

For details about what the scheduler synchronizes at each interval, see the "Validating Schedulers" and "Synchronizing Schedulers" sections in Automatically consume data from Kafka with the scheduler .

Default: TRUE

--config-refresh *HH:MM:SS*

The interval of time that the scheduler runs before synchronizing its settings and updating its cached metadata (such as changes made by using the --update option).

Default: 00:05:00

--consumer-group-id *id_name*

The name of the Kafka consumer group to which Vertica reports its progress consuming messages. Set this value to disable progress reports to a Kafka consumer group. For details, see Monitoring Vertica message consumption with consumer groups .

Default: vertica_ *database-name*

--dump

When you use this option along with the --read option, vkconfig outputs the Vertica query it would use to retrieve the data, rather than outputting the data itself. This option is useful if you want to access the data from within Vertica without having to go through vkconfig. This option has no effect if not used with --read .

--eof-timeout-ms ***number of milliseconds***

If a COPY command does not receive any messages within the eof-timeout-ms interval, Vertica responds by ending that COPY statement.

See Manually consume data from Kafka for more information.
Default: 1 second

--fix-config

Repairs the configuration and re-creates any missing tables. Valid only with the --update shared configuration option.

--frame-duration ***HH:MM:SS***

The interval of time that all individual frames last with this scheduler. The scheduler must have enough time to run each microbatch (each of which execute a COPY statement). You can approximate the average available time per microbatch using the following equation:

TimePerMicrobatch=(*FrameDuration* Parallelism*)/*Microbatches*

This is just a rough estimate as there are many factors that impact the amount of time that each microbatch will be able to run.
The vkconfig utility warns you if the time allocated per microbatch is below 2 seconds. You usually should allocate more than two seconds per microbatch to allow the scheduler to load all of the data in the data stream.

> **Note**
> In versions of Vertica earlier than 10.0, the default frame duration was 10 seconds. In version 10.0, this default value was increased to 5 minutes in part to compensate for the removal of WOS. If you created your scheduler with the default frame duration in a version prior to 10.0, the frame duration is not updated to the new default value. In this case, consider adjusting the frame duration manually. See Choosing a frame duration for more information.

Default: 00:05:00

--message_max_bytes ***max_message_size***

Specifies the maximum size, in bytes, of a Kafka protocol batch message.
Important
You may need to manually update this value if you created a scheduler using Vertica 9.1.0 or earlier. The meaning of Kafka's max.message.bytes setting changed between version 0.10 and 0.11. See Changes to the message.max.bytes setting in Kafka version 0.11 and later for more information.

Default:25165824

--new-source-policy {FAIR|START|END}

Determines how Vertica allocates resources to the newly added source, one of the following:

- FAIR: Takes the average length of time from the previous batches and schedules itself appropriately.
- START: All new sources start at the beginning of the frame. The batch receives the minimal amount of time to run.
- END: All new sources start at the end of the frame. The batch receives the maximum amount of time to run.

Default: FAIR

--operator ***username***

Allows the dbadmin to grant privileges to a previously created Vertica user or role.

This option gives the specified user all privileges on the scheduler instance and EXECUTE privileges on the libkafka library and all its UDxs. Granting operator privileges gives the user the right to read data off any source in any cluster that can be reached from the Vertica node.

The dbadmin must grant the user separate permission for them to have write privileges on the target tables.

Requires the --create shared utility option. Use the --add-operator option to grant operate privileges after the scheduler has been created.

To revoke privileges, use the --remove-operator option.

--remove-operator ***user_name***

Removes access to the scheduler from a Vertica user account. Requires the --update shared utility option.

--resource-pool ***pool_name***

The resource pool to be used by all queries executed by this scheduler. You must create this pool in advance.

Default: GENERAL pool

> **Note**
> The scheduler can use only one-fourth of GENERAL pool's PLANNEDCONCURRENCY .

--upgrade

Upgrades the existing scheduler and configuration schema to the current Vertica version. The upgraded version of the scheduler is not backwards compatible with earlier versions. To upgrade a scheduler to an alternate schema, use the upgrade-to-schema parameter. See Updating schedulers after Vertica upgrades for more information.

--upgrade-to-schema ***schema name***

Copies the scheduler's schema to a new schema specified by *schema name* and then upgrades it to be compatible with the current version of Vertica. Vertica does not alter the old schema. Requires the --upgrade scheduler utility option.

--validation-type {ERROR|WARN|SKIP}

Renamed from --skip-validation , specifies the level of validation performed on the scheduler. Invalid SQL syntax and other errors can cause invalid microbatches. Vertica supports the following validation types:

- ERROR: Cancel configuration or creation if validation fails.
- WARN: Proceed with task if validation fails, but display a warning.
- SKIP: Perform no validation.

For more information on validation, refer to Automatically consume data from Kafka with the scheduler .
Default: ERROR

See Common vkconfig script options for options that are available in all of the vkconfig tools.

Examples

These examples show how you can use the scheduler utility options.

Give a user, Jim, privileges on the StreamConfig scheduler. Specify that you are making edits to the stream_config scheduler with the --config-schema option:

```
$ /opt/vertica/packages/kafka/bin/vkconfig scheduler --update --config-schema stream_config --add-operator Jim
```

Edit the default stream_config scheduler so that every microbatch waits for data for one second before ending:

```
$ /opt/vertica/packages/kafka/bin/vkconfig scheduler --update --eof-timeout-ms 1000
```

Upgrade the scheduler named iot_scheduler_8.1 to a new scheduler named iot_scheduler_9.0 that is compatible with the current version of Vertica:

```
$ /opt/vertica/packages/kafka/bin/vkconfig scheduler --upgrade --config-schema iot_scheduler_8.1 \
                                    --upgrade-to-schema iot_scheduler_9.0
```

Drop the schema scheduler219a:

```
$ /opt/vertica/packages/kafka/bin/vkconfig scheduler --drop --config-schema  scheduler219a --username dbadmin
```

Read the current setting of the options you can set using the scheduler tool for the scheduler defined in weblogs.conf.

```
$ vkconfig scheduler --read --conf weblog.conf
{"version":"v9.2.0", "frame_duration":"00:00:10", "resource_pool":"weblog_pool",
"config_refresh":"00:05:00", "new_source_policy":"FAIR",
"pushback_policy":"LINEAR", "pushback_max_count":5, "auto_sync":true,
"consumer_group_id":null}
```

Cluster tool options

The vkconfig script's cluster tool lets you define the streaming hosts your scheduler connects to.

Syntax

```
vkconfig cluster {--create | --read | --update | --delete} [--cluster cluster_name] [other_options...]
```

--create

Creates a new load spec, cannot be used with --delete , --read , or --update .

--read

Outputs the settings of all clusters defined in the scheduler. This output is in JSON format. Cannot be used with --create , --delete , or --update .

You can limit the output to specific clusters by supplying one or more cluster names in the --cluster option. You an also limit the output to clusters that contain one or more specific hosts using the --hosts option. Use commas to separate multiple values.
You can use LIKE wildcards in these options. See LIKE predicate for more information about using wildcards.

--update

Updates an existing Set Snippet Variable Value in Topic. Cannot be used with --create , --delete , or --read .

--delete

Deletes a Set Snippet Variable Value in Topic. Cannot be used with --create , --read , or --update .

--dump

When you use this option along with the --read option, vkconfig outputs the Vertica query it would use to retrieve the data, rather than outputting the data itself. This option is useful if you want to access the data from within Vertica without having to go through vkconfig. This option has no effect if not used with --read .

--cluster *cluster_name*

A unique, case-insensitive name for the cluster to operate on. This option is required for --create , --update , and --delete .

--hosts *b1* : *port* [, *b2* : *port* ...]

Identifies the broker hosts that you want to add, edit, or remove from a Kafka cluster. To identify multiple hosts, use a comma delimiter.

--kafka_conf ' *kafka_configuration_setting* '

A JSON-formatted object of option/value pairs to pass directly to the rdkafka library. This is the library Vertica uses to communicate with Kafka. You can use this parameter to directly set configuration options that are not available through the Vertica integration with Kafka. See Directly setting Kafka library options for details.

--new-cluster *cluster_name*

The updated name for the cluster. Requires the --update shared utility option.

--validation-type {ERROR|WARN|SKIP}

Specifies the level of validation performed on a created or updated cluster:

- ERROR - Cancel configuration or creation if vkconfig cannot validate that the cluster exists. This is the default setting.
- WARN - Proceed with task if validation fails, but display a warning.
- SKIP - Perform no validation.

Renamed from --skip-validation .

See Common vkconfig script options for options that are available in all of the vkconfig tools.

Examples

This example shows how you can create the cluster, StreamCluster1, and assign two hosts:

```
$ /opt/vertica/packages/kafka/bin/vkconfig cluster --create --cluster StreamCluster1 \
                                    --hosts 10.10.10.10:9092,10.10.10.11:9092
                                    --conf myscheduler.config
```

This example shows how you can list all of the clusters associated with the scheduler defined in the weblogs.conf file:

```
$ vkconfig cluster --read --conf weblog.conf
{"cluster":"kafka_weblog",
"hosts":"kafka01.example.com:9092,kafka02.example.com:9092"}
```

Source tool options

Use the vkconfig script's source tool to create, update, or delete a source.

Syntax

```
vkconfig source {--create | --read | --update | --delete} --source source_name [other_options...]
```

--create

Creates a new load spec, cannot be used with --delete , --read , or --update .

--read

Outputs the current setting of the sources defined in the scheduler. The output is in JSON format. Cannot be used with --create , --delete , or --update .

By default this option outputs all of the sources defined in the scheduler. You can limit the output by using the --cluster , --enabled , --partitions , and --source options. The output will only contain sources that match the values in these options. The --enabled option can only have a true or false value. The --source option is case-sensitive.
You can use LIKE wildcards in these options. See LIKE predicate for more information about using wildcards.

--update

Updates an existing Set Snippet Variable Value in Topic. Cannot be used with --create , --delete , or --read .

--delete

Deletes a Set Snippet Variable Value in Topic. Cannot be used with --create , --read , or --update .

--source *source_name*

Identifies the source to create or alter in the scheduler's configuration. This option is case-sensitive. You can use any name you like for a new source. Most people use the name of the Kafka topic the scheduler loads its data from. This option is required for --create , --update , and --delete .

--cluster *cluster_name*

Identifies the cluster containing the source that you want to create or edit. You must have already defined this cluster in the scheduler.

--dump

When you use this option along with the --read option, vkconfig outputs the Vertica query it would use to retrieve the data, rather than outputting the data itself. This option is useful if you want to access the data from within Vertica without having to go through vkconfig. This option has no effect if not used with --read .

--enabled TRUE|FALSE

When TRUE, the source is available for use.

--new-cluster *cluster_name*

Changes the cluster this source belongs to.

All sources referencing the old cluster source now target this cluster.
Requires: --update and --source options

--new-source *source_name*

Updates the name of an existing source to the name specified by this parameter.

Requires: --update shared utility option

--partitions *count*

Sets the number of partitions in the source.

Default:
The number of partitions defined in the cluster.

Requires: --create and --source options

You must keep this consistent with the number of partitions in the Kafka topic.

Renamed from --num-partitions .

--validation-type{ERROR|WARN|SKIP}

Controls the validation performed on a created or updated source:

- ERROR - Cancel configuration or creation if vkconfig cannot validate the source. This is the default setting.

- WARN - Proceed with task if validation fails, but display a warning.
- SKIP - Perform no validation.

Renamed from --skip-validation .

See Common vkconfig script options for options that are available in all of the vkconfig tools.

Examples

The following examples show how you can create or update SourceFeed.

Create the source SourceFeed and assign it to the cluster, StreamCluster1 in the scheduler defined by the myscheduler.conf config file:

```
$ /opt/vertica/packages/kafka/bin/vkconfig source --create --source SourceFeed \
                                  --cluster StreamCluster1 --partitions 3
                                  --conf myscheduler.conf
```

Update the existing source SourceFeed to use the existing cluster, StreamCluster2 in the scheduler defined by the myscheduler.conf config file:

```
$ /opt/vertica/packages/kafka/bin/vkconfig source --update --source SourceFeed \
                                  --new-cluster StreamCluster2
                                  --conf myscheduler.conf
```

The following example reads the sources defined in the scheduler defined by the weblogs.conf file.

```
$ vkconfig source --read --conf weblog.conf
{"source":"web_hits", "partitions":1, "src_enabled":true,
"cluster":"kafka_weblog",
"hosts":"kafka01.example.com:9092,kafka02.example.com:9092"}
```

Target tool options

Use the target tool to configure a Vertica table to receive data from your streaming data application.

Syntax

```
vkconfig target {--create | --read | --update | --delete} [--target-table table --table_schema schema] [other_options...]
```

--create

Creates a new load spec, cannot be used with --delete , --read , or --update .

--read

Outputs the targets defined in the scheduler. This output is in JSON format. Cannot be used with --create , --delete , or --update .

By default this option outputs all of the targets defined in the configuration schema. You can limit the output to specific targets by using the --target-schema and --target-table options. The vkconfig script only outputs targets that match the values you set in these options.
You can use LIKE wildcards in these options. See LIKE predicate for more information about using wildcards.

--update

Updates an existing Set Snippet Variable Value in Topic. Cannot be used with --create , --delete , or --read .

--delete

Deletes a Set Snippet Variable Value in Topic. Cannot be used with --create , --read , or --update .

--target-table *table*

The name of a Vertica table receive data from the scheduler. This option is required for --create , --update , and --delete .

--target-schema *schema*

The existing Vertica schema containing the target table. This option is required for --create , --update , and --delete .

--dump

When you use this option along with the --read option, vkconfig outputs the Vertica query it would use to retrieve the data, rather than outputting the data itself. This option is useful if you want to access the data from within Vertica without having to go through vkconfig. This option has no effect if not used with --read .

--new-target-schema *schema_name*

Changes the Vertica schema associated with this schema to a new, already created schema.

Requires: --update option.

--new-target-table *schema_name*

Changes the Vertica target table associated with this schema to a new, already created table.

Requires: --update option.

--validation-type{ERROR|WARN|SKIP}

Controls validation performed on a created or updated target:

- ERROR - Cancel configuration or creation if vkconfig cannot validate that the table exists. This is the default setting.
- WARN - Creates or updates the target if validation fails, but display a warning.
- SKIP - Perform no validation.

Renamed from --skip-validation .

Important
Avoid having columns with primary key restrictions in your target table. The scheduler stops loading data if it encounters a row that has a value which violates this restriction. If you must have a primary key restricted column, try to filter out any redundant values for that column in the streamed data before is it loaded by the scheduler.

See Common vkconfig script options for options that are available in all of the vkconfig tools.

Examples

This example shows how you can create a target for the scheduler defined in the myscheduler.conf configuration file from public.streamtarget table:

```
$ /opt/vertica/packages/kafka/bin/vkconfig target --create --target-table streamtarget --conf myscheduler.conf
```

This example lists all of the targets in the scheduler defined in the weblogs.conf configuration file.

```
$ vkconfig target --read --conf weblog.conf
{"target_schema":"public", "target_table":"web_hits"}
```

Load spec tool options

The vkconfig script's load spec tool lets you provide parameters for a COPY statement that loads streaming data.

Syntax

```
$ vkconfig load-spec {--create | --read | --update | --delete} [--load-spec spec-name] [other-options...]
```

--create

Creates a new load spec, cannot be used with --delete , --read , or --update .

--read

Outputs the current settings of the load specs defined in the scheduler. This output is in JSON format. Cannot be used with --create , --delete , or --update .

By default, this option outputs all load specs defined in the scheduler. You can limit the output by supplying a single value or a comma-separated list of values to these options:

- --load-spec
- --filters
- --uds-kv-parameters
- --parser
- --message-max-bytes
- --parser-parameters

The vkconfig script only outputs the configuration of load specs that match the values you supply.

You can use LIKE wildcards in these options. See LIKE predicate for more information about using wildcards.

--update

Updates an existing Set Snippet Variable Value in Topic. Cannot be used with --create , --delete , or --read .

--delete

Deletes a Set Snippet Variable Value in Topic. Cannot be used with --create , --read , or --update .

--load-spec ***spec-name***

A unique name for copy load spec to operate on. This option is required for --create , --update , and --delete .

--dump

When you use this option along with the --read option, vkconfig outputs the Vertica query it would use to retrieve the data, rather than outputting the data itself. This option is useful if you want to access the data from within Vertica without having to go through vkconfig. This option has no effect if not used with --read .

--filters " *filter-name* "

A Vertica FILTER chain containing all of the UDFilters to use in the COPY statement. For more information on filters, refer to Parsing custom formats .

--message-max-bytes ***max-size***

Specifies the maximum size, in bytes, of a Kafka protocol batch message.
Important
You may need to manually update this value if you created a scheduler using Vertica 9.1.0 or earlier. The meaning of Kafka's max.message.bytes setting changed between version 0.10 and 0.11. See Changes to the message.max.bytes setting in Kafka version 0.11 and later for more information.

Default:25165824

--new-load-spec ***new-name***

A new, unique name for an existing load spec. Requires the --update parameter.

--parser-parameters " *key* = *value* [,...]"

A list of parameters to provide to the parser specified in the --parser parameter. When you use a Vertica native parser, the scheduler passes these parameters to the COPY statement where they are in turn passed to the parser.

--parser ***parser-name***

Identifies a Vertica UDParser to use with a specified target.This parser is used within the COPY statement that the scheduler runs to load data. If you are using a Vertica native parser, the values supplied to the --parser-parameters option are passed through to the COPY statement.

Default: KafkaParser

--uds-kv-parameters ***key*** **=** ***value*** **[,...]**

A comma separated list of key value pairs for the user-defined source.

--validation-type {ERROR|WARN|SKIP}

Specifies the validation performed on a created or updated load spec, to one of the following:

- ERROR : Cancel configuration or creation if vkconfig cannot validate the load spec. This is the default setting.
- WARN : Proceed with task if validation fails, but display a warning.
- SKIP : Perform no validation.

Renamed from --skip-validation .

See Common vkconfig script options for options that are available in all of the vkconfig tools.

Examples

These examples show how you can use the Load Spec utility options.

Create load spec Streamspec1 :

```
$ /opt/vertica/packages/kafka/bin/vkconfig load-spec --create --load-spec Streamspec1 --conf myscheduler.conf
```

Rename load spec Streamspec1 to Streamspec2 :

```
$ /opt/vertica/packages/kafka/bin/vkconfig load-spec --update --load-spec Streamspec1 \
                                    --new-load-spec Streamspec2 \
                                    --conf myscheduler.conf
```

Update load spec Filterspec to use the KafkaInsertLengths filter and a custom decryption filter:

```
$ /opt/vertica/packages/kafka/bin/vkconfig load-spec --update --load-spec Filterspec \
                                        --filters "KafkaInsertLengths() DecryptFilter(parameter=Key)" \
                                        --conf myscheduler.conf
```

Read the current settings for load spec streamspec1 :

```
$ vkconfig load-spec --read --load-spec streamspec1 --conf weblog.conf
{"load_spec":"streamspec1", "filters":null, "parser":"KafkaParser",
"parser_parameters":null, "load_method":"TRICKLE", "message_max_bytes":null,
"uds_kv_parameters":null}
```

Microbatch tool options

The vkconfig script's microbatch tool lets you configure a scheduler's microbatches.

Syntax

```
vkconfig microbatch {--create | --read | --update | --delete} [--microbatch name] [other_options...]
```

--create

Creates a new load spec, cannot be used with --delete , --read , or --update .

--read

Outputs the current settings of all microbatches defined in the scheduler. This output is in JSON format. Cannot be used with --create , --delete , or --update .

You can limit the output to specific microbatches by using the --consumer-group-id , --enabled , --load-spec , --microbatch , --rejection-schema , --rejection-table , --target-schema , --target-table , and --target-columns options. The --enabled option only accepts a true or false value.
You can use LIKE wildcards in these options. See LIKE predicate for more information about using wildcards.

--update

Updates an existing Set Snippet Variable Value in Topic. Cannot be used with --create , --delete , or --read .

--delete

Deletes a Set Snippet Variable Value in Topic. Cannot be used with --create , --read , or --update .

--microbatch *name*

A unique, case insensitive name for the microbatch. This option is required for --create , --update , and --delete .

--add-source-cluster *cluster_name*

The name of a cluster to assign to the microbatch you specify with the --microbatch option. You can use this parameter once per command. You can also use it with --update to add sources to a microbatch. You can only add sources from the same cluster to a single microbatch. Requires --add-source .

--add-source *source_name*

The name of a source to assign to this microbatch. You can use this parameter once per command. You can also use it with --update to add sources to a microbatch. Requires --add-source-cluster .

--cluster *cluster_name*

The name of the cluster to which the --offset option applies. Only required if the microbatch defines more than one cluster or the --source parameter is supplied. Requires the --offset option.

--consumer-group-id *id_name*

The name of the Kafka consumer group to which Vertica reports its progress consuming messages. Set this value to disable progress reports to a Kafka consumer group. For details, see Monitoring Vertica message consumption with consumer groups .
Default: vertica_ *database-name*

--dump

When you use this option along with the --read option, vkconfig outputs the Vertica query it would use to retrieve the data, rather than outputting the data itself. This option is useful if you want to access the data from within Vertica without having to go through vkconfig. This option has no effect if not used with --read .

--enabled TRUE|FALSE

When TRUE, allows the microbatch to execute.

--load-spec ***loadspec_name***

The load spec to use while processing this microbatch.

--max-parallelism ***max_num_loads***

The maximum number of simultaneous COPY statements created for the microbatch. The scheduler dynamically splits a single microbatch with multiple partitions into *max_num_loads* COPY statements with fewer partitions.

This option allows you to:

- Control the transaction size.
- Optimize your loads according to your scheduler's scheduler's resource pool settings, such as PLANNEDCONCURRENCY .

--new-microbatch ***updated_name***

The updated name for the microbatch. Requires the --update option.

--offset ***partition_offset*** **[,...]**

The offset of the message in the source where the microbatch starts its load. If you use this parameter, you must supply an offset value for each partition in the source or each partition you list in the --partition option.

You can use this option to skip some messages in the source or reload previously read messages.
See Special Starting Offset Values below for more information.

Important
You cannot set an offset for a microbatch while the scheduler is running. If you attempt to do so, the vkconfig utility returns an error. Use the shutdown utility to shut the scheduler down before setting an offset for a microbatch.

--partition ***partition*** **[,...]**

One or more partitions to which the offsets given in the --offset option apply. If you supply this option, then the offset values given in the --offset option applies to the partitions you specify. Requires the --offset option.

--rejection-schema ***schema_name***

The existing Vertica schema that contains a table for storing rejected messages.

--rejection-table ***table_name***

The existing Vertica table that stores rejected messages.

--remove-source-cluster ***cluster_name***

The name of a cluster to remove from this microbatch. You can use this parameter once per command. Requires --remove-source .

--remove-source ***source_name***

The name of a source to remove from this microbatch. You can use this parameter once per command. You can also use it with --update to remove multiple sources from a microbatch. Requires --remove-source-cluster .

--source ***source_name***

The name of the source to which the offset in the --offset option applies. Required when the microbatch defines more than one source or the --cluster parameter is given. Requires the --offset option.

--target-columns ***column_expression***

A column expression for the target table, where *column_expression* can be a comma-delimited list of columns or a complete expression.

See the COPY statement Parameters for a description of column expressions.

--target-schema ***schema_name***

The existing Vertica target schema associated with this microbatch.

--target-table ***table_name***

The name of a Vertica table corresponding to the target. This table must belong to the target schema.

--validation-type{ERROR|WARN|SKIP}

Controls the validation performed on a created or updated microbatch:

- ERROR - Cancel configuration or creation if vkconfig cannot validate the microbatch. This is the default setting.
- WARN - Proceed with task if validation fails, but display a warning.
- SKIP - Perform no validation.

Renamed from --skip-validation .

See Common vkconfig script options for options that are available in all of the vkconfig tools.

Special starting offset values

The *start_offset* portion of the stream parameter lets you start loading messages from a specific point in the topic's partition. It also accepts one of two special offset values:

- -2 tells Set Snippet Variable Value in Topic to start loading at the earliest available message in the topic's partition. This value is useful when you want to load as many messages as you can from the Kafka topic's partition.
- -3 tells Set Snippet Variable Value in Topic to start loading from the consumer group's saved offset. If the consumer group does not have a saved offset, it starts loading from the earliest available message in the topic partition. See Monitoring Vertica message consumption with consumer groups for more information.

Examples

This example shows how you can create the microbatch, mbatch1. This microbatch identifies the schema, target table, load spec, and source for the microbatch:

```
$ /opt/vertica/packages/kafka/bin/vkconfig microbatch --create --microbatch mbatch1 \
                                        --target-schema public \
                                        --target-table BatchTarget \
                                        --load-spec Filterspec \
                                        --add-source SourceFeed \
                                        --add-source-cluster StreamCluster1 \
                                        --conf myscheduler.conf
```

This example demonstrates listing the current settings for the microbatches in the scheduler defined in the weblog.conf configuration file.

```
$ vkconfig microbatch --read --conf weblog.conf
{"microbatch":"weblog", "target_columns":null, "rejection_schema":null,
"rejection_table":null, "enabled":true, "consumer_group_id":null,
"load_spec":"weblog_load", "filters":null, "parser":"KafkaJSONParser",
"parser_parameters":null, "load_method":"TRICKLE", "message_max_bytes":null,
"uds_kv_parameters":null, "target_schema":"public", "target_table":"web_hits",
"source":"web_hits", "partitions":1, "src_enabled":true, "cluster":"kafka_weblog",
"hosts":"kafka01.example.com:9092,kafka02.example.com:9092"}
```

Launch tool options

Use the vkconfig script's launch tool to assign a name to a scheduler instance.

Syntax

```
vkconfig launch [options...]
```

--enable-ssl {true|false}

(Optional) Enables SSL authentication between Kafka and Vertica . For more information, refer to TLS/SSL encryption with Kafka .

--ssl-ca-alias *alias*

The user-defined alias of the root certifying authority you are using to authenticate communication between Vertica and Kafka. This parameter is used only when SSL is enabled.

--ssl-key-alias *alias*

The user-defined alias of the key/certificate pair you are using to authenticate communication between Vertica and Kafka. This parameter is used only when SSL is enabled.

--ssl-key-password *password*

The password used to create your SSL key. This parameter is used only when SSL is enabled.

--instance-name *name*

(Optional) Allows you to name the process running the scheduler. You can use this command when viewing the scheduler_history table, to find which instance is currently running.

--refresh-interval *hours*

(Optional) The time interval at which the connection between Vertica and Kafka is refreshed (24 hours by default).

--kafka_conf ' *kafka_configuration_setting* '

A JSON-formatted object of option/value pairs to pass directly to the rdkafka library. This is the library Vertica uses to communicate with Kafka. You can use this parameter to directly set configuration options that are not available through the Vertica integration with Kafka. See Directly setting Kafka library options for details.

See Common vkconfig script options for options that are available in all of the vkconfig tools.

Examples

This example shows how you can launch the scheduler defined in the myscheduler.conf config file and give it the instance name PrimaryScheduler:

```
$ nohup /opt/vertica/packages/kafka/bin/vkconfig launch --instance-name PrimaryScheduler \
 --conf myscheduler.conf >/dev/null 2>&1 &
```

This example shows how you can launch an instance named SecureScheduler with SSL enabled:

```
$ nohup /opt/vertica/packages/kafka/bin/vkconfig launch --instance-name SecureScheduler --enable-SSL true \
                                    --ssl-ca-alias authenticcert --ssl-key-alias ourkey \
                                    --ssl-key-password secret \
                                    --conf myscheduler.conf \
                                    >/dev/null 2>&1 &
```

Shutdown tool options

Use the vkconfig script's shutdown tool to terminate one or all Vertica schedulers running on a host. Always run this command before restarting a scheduler to ensure the scheduler has shutdown correctly.

Syntax

```
vkconfig shutdown [options...]
```

See Common vkconfig script options for options that are available in all vkconfig tools.

Examples

To terminate all schedulers running on a host, use the shutdown command with no options:

```
$ /opt/vertica/packages/kafka/bin/vkconfig shutdown
```

Use the --conf or --config-schema option to specify a scheduler to shut down. The following command terminates the scheduler that was launched with the same --conf myscheduler.conf option:

```
$ /opt/vertica/packages/kafka/bin/vkconfig shutdown --conf myscheduler.conf
```

Statistics tool options

The statistics tool lets you access the history of microbatches that your scheduler has run. This tool outputs the log of the microbatches in JSON format to the standard output. You can use its options to filter the list of microbatches to get just the microbatches that interest you.

> **Note**
> The statistics tool can sometimes produce confusing output if you have altered the scheduler configuration over time. For example, suppose you have microbatch-a target a table. Later, you change the scheduler's configuration so that microbatch-b targets the table. Afterwards, you run the statistics tool and filter the microbatch log based on target table. Then the log output will show entries from both microbatch-a and microbatch-b.

Syntax

```
vkconfig statistics [options]
```

--cluster " *cluster* "[," *cluster2* "...]

Only return microbatches that retrieved data from a cluster whose name matches one in the list you supply.

--dump

Instead of returning microbatch data, return the SQL query that vkconfig would execute to extract the data from the scheduler tables. You can use this option if you want use a Vertica client application to get the microbatch log instead of using vkconfig's JSON output.

--from-timestamp " *timestamp* "

Only return microbatches that began after *timestamp* . The timestamp value is in *yyyy* -[*m*] *m* -[*d*] *d hh* : *mm* : *ss* format.

Cannot be used in conjunction with --last .

--last *number*

Returns the *number* most recent microbatches that meet all other filters. Cannot be used in conjunction with --from-timestamp or --to-timestamp .

--microbatch " *name* "[," *name2* "...]

Only return microbatches whose name matches one of the names in the comma-separated list.

--partition *partition#* [, *partition#2* ...]

Only return microbatches that accessed data from the topic partition that matches ones of the values in the partition list.

--source " *source* "[," *source2* "...]

Only return microbatches that accessed data from a source whose name matches one of the names in the list you supply to this argument.

--target-schema "schema"[,"schema2"...]

Only return microbatches that wrote data to the Vertica schemas whose name matches one of the names in the target schema list argument.

--target-table "table"[,"table2"...]

Only return microbatches that wrote data to Vertica tables whose name match one of the names in the target schema list argument.

--to-timestamp " *timestamp* "

Only return microbatches that began before *timestamp* . The timestamp value is in *yyyy* -[*m*] *m* -[*d*] *d hh* : *mm* : *ss* format.

Cannot be used in conjunction with --last .

See Common vkconfig script options for options that are available in all of the vkconfig tools.

Usage considerations

- You can use LIKE wildcards in the values you supply to the --cluster , --microbatch , --source , --target-schema , and --target-table arguments. This feature lets you match partial strings in the microbatch data. See LIKE predicate for more information about using wildcards.
- The string comparisons for the --cluster , --microbatch , --source , --target-schema , and --target-table arguments are case-insensitive.
- The date and time values you supply to the --from-timestamp and --to-timestamp arguments use the java.sql.timestamp format for parsing the value. This format's parsing can accept values that you may consider invalid and would expect it to reject. For example, if you supply a timestamp of 01-01-2018 24:99:99, the Java timestamp parser silently converts the date to 2018-01-02 01:40:39 instead of returning an error.

Examples

This example gets the last microbatch that the scheduler defined in the weblog.conf file ran:

```
$ /opt/vertica/packages/kafka/bin/vkconfig statistics --last 1 --conf weblog.conf
{"microbatch":"weblog", "target_schema":"public", "target_table":"web_hits",
"source_name":"web_hits", "source_cluster":"kafka_weblog", "source_partition":0,
"start_offset":80000, "end_offset":79999, "end_reason":"END_OF_STREAM",
"end_reason_message":null, "partition_bytes":0, "partition_messages":0,
"timeslice":"00:00:09.793000", "batch_start":"2018-11-06 09:42:00.176747",
"batch_end":"2018-11-06 09:42:00.437787", "source_duration":"00:00:00.214314",
"consecutive_error_count":null, "transaction_id":45035996274513069,
"frame_start":"2018-11-06 09:41:59.949", "frame_end":null}
```

If your scheduler is reading from more than partition, the --last 1 option lists the last microbatch from each partition:

```
$ /opt/vertica/packages/kafka/bin/vkconfig statistics --last 1 --conf iot.conf
{"microbatch":"iotlog", "target_schema":"public", "target_table":"iot_data",
"source_name":"iot_data", "source_cluster":"kafka_iot", "source_partition":0,
"start_offset":-2, "end_offset":-2, "end_reason":"DEADLINE",
"end_reason_message":null, "partition_bytes":0, "partition_messages":0,
"timeslice":"00:00:09.842000", "batch_start":"2018-11-06 12:52:49.387567",
"batch_end":"2018-11-06 12:52:59.400219", "source_duration":"00:00:09.950127",
"consecutive_error_count":null, "transaction_id":45035996274537015,
"frame_start":"2018-11-06 12:52:49.213", "frame_end":null}
{"microbatch":"iotlog", "target_schema":"public", "target_table":"iot_data",
"source_name":"iot_data", "source_cluster":"kafka_iot", "source_partition":1,
"start_offset":1604, "end_offset":1653, "end_reason":"END_OF_STREAM",
"end_reason_message":null, "partition_bytes":4387, "partition_messages":50,
"timeslice":"00:00:09.842000", "batch_start":"2018-11-06 12:52:49.387567",
"batch_end":"2018-11-06 12:52:59.400219", "source_duration":"00:00:00.220329",
"consecutive_error_count":null, "transaction_id":45035996274537015,
"frame_start":"2018-11-06 12:52:49.213", "frame_end":null}
{"microbatch":"iotlog", "target_schema":"public", "target_table":"iot_data",
"source_name":"iot_data", "source_cluster":"kafka_iot", "source_partition":2,
"start_offset":1603, "end_offset":1652, "end_reason":"END_OF_STREAM",
"end_reason_message":null, "partition_bytes":4383, "partition_messages":50,
"timeslice":"00:00:09.842000", "batch_start":"2018-11-06 12:52:49.387567",
"batch_end":"2018-11-06 12:52:59.400219", "source_duration":"00:00:00.318997",
"consecutive_error_count":null, "transaction_id":45035996274537015,
"frame_start":"2018-11-06 12:52:49.213", "frame_end":null}
{"microbatch":"iotlog", "target_schema":"public", "target_table":"iot_data",
"source_name":"iot_data", "source_cluster":"kafka_iot", "source_partition":3,
"start_offset":1604, "end_offset":1653, "end_reason":"END_OF_STREAM",
"end_reason_message":null, "partition_bytes":4375, "partition_messages":50,
"timeslice":"00:00:09.842000", "batch_start":"2018-11-06 12:52:49.387567",
"batch_end":"2018-11-06 12:52:59.400219", "source_duration":"00:00:00.219543",
"consecutive_error_count":null, "transaction_id":45035996274537015,
"frame_start":"2018-11-06 12:52:49.213", "frame_end":null}
```

You can use the --partition argument to get just the partitions you want:

```
$ /opt/vertica/packages/kafka/bin/vkconfig statistics --last 1 --partition 2 --conf iot.conf
{"microbatch":"iotlog", "target_schema":"public", "target_table":"iot_data",
"source_name":"iot_data", "source_cluster":"kafka_iot", "source_partition":2,
"start_offset":1603, "end_offset":1652, "end_reason":"END_OF_STREAM",
"end_reason_message":null, "partition_bytes":4383, "partition_messages":50,
"timeslice":"00:00:09.842000", "batch_start":"2018-11-06 12:52:49.387567",
"batch_end":"2018-11-06 12:52:59.400219", "source_duration":"00:00:00.318997",
"consecutive_error_count":null, "transaction_id":45035996274537015,
"frame_start":"2018-11-06 12:52:49.213", "frame_end":null}
```

If your scheduler reads from more than one source, the --last 1 option outputs the last microbatch from each source:

```
$ /opt/vertica/packages/kafka/bin/vkconfig statistics --last 1 --conf weblog.conf
{"microbatch":"weberrors", "target_schema":"public", "target_table":"web_errors",
"source_name":"web_errors", "source_cluster":"kafka_weblog",
"source_partition":0, "start_offset":10000, "end_offset":9999,
"end_reason":"END_OF_STREAM", "end_reason_message":null,
"partition_bytes":0, "partition_messages":0, "timeslice":"00:00:04.909000",
"batch_start":"2018-11-06 10:58:02.632624",
"batch_end":"2018-11-06 10:58:03.058663", "source_duration":"00:00:00.220618",
"consecutive_error_count":null, "transaction_id":45035996274523991,
"frame_start":"2018-11-06 10:58:02.394", "frame_end":null}
{"microbatch":"weblog", "target_schema":"public", "target_table":"web_hits",
"source_name":"web_hits", "source_cluster":"kafka_weblog", "source_partition":0,
"start_offset":80000, "end_offset":79999, "end_reason":"END_OF_STREAM",
"end_reason_message":null, "partition_bytes":0, "partition_messages":0,
"timeslice":"00:00:09.128000", "batch_start":"2018-11-06 10:58:03.322852",
"batch_end":"2018-11-06 10:58:03.63047", "source_duration":"00:00:00.226493",
"consecutive_error_count":null, "transaction_id":45035996274524004,
"frame_start":"2018-11-06 10:58:02.394", "frame_end":null}
```

You can use wildcards to enable partial matches. This example demonstrates getting the last microbatch for all microbatches whose names end with "log":

```
~$ /opt/vertica/packages/kafka/bin/vkconfig statistics --microbatch "%log" \
                                    --last 1 --conf weblog.conf
{"microbatch":"weblog", "target_schema":"public", "target_table":"web_hits",
"source_name":"web_hits", "source_cluster":"kafka_weblog", "source_partition":0,
"start_offset":80000, "end_offset":79999, "end_reason":"END_OF_STREAM",
"end_reason_message":null, "partition_bytes":0, "partition_messages":0,
"timeslice":"00:00:04.874000", "batch_start":"2018-11-06 11:37:16.17198",
"batch_end":"2018-11-06 11:37:16.460844", "source_duration":"00:00:00.213129",
"consecutive_error_count":null, "transaction_id":45035996274529932,
"frame_start":"2018-11-06 11:37:15.877", "frame_end":null}
```

To get microbatches from a specific period of time, use the --from-timestamp and --to-timestamp arguments. This example gets the microbatches that read from partition #2 between 12:52:30 and 12:53:00 on 2018-11-06 for the scheduler defined in iot.conf.

```
$ /opt/vertica/packages/kafka/bin/vkconfig statistics  --partition 1 \
                    --from-timestamp "2018-11-06 12:52:30" \
                    --to-timestamp "2018-11-06 12:53:00" --conf iot.conf
{"microbatch":"iotlog", "target_schema":"public", "target_table":"iot_data",
"source_name":"iot_data", "source_cluster":"kafka_iot", "source_partition":1,
"start_offset":1604, "end_offset":1653, "end_reason":"END_OF_STREAM",
"end_reason_message":null, "partition_bytes":4387, "partition_messages":50,
"timeslice":"00:00:09.842000", "batch_start":"2018-11-06 12:52:49.387567",
"batch_end":"2018-11-06 12:52:59.400219", "source_duration":"00:00:00.220329",
"consecutive_error_count":null, "transaction_id":45035996274537015,
"frame_start":"2018-11-06 12:52:49.213", "frame_end":null}
{"microbatch":"iotlog", "target_schema":"public", "target_table":"iot_data",
"source_name":"iot_data", "source_cluster":"kafka_iot", "source_partition":1,
"start_offset":1554, "end_offset":1603, "end_reason":"END_OF_STREAM",
"end_reason_message":null, "partition_bytes":4371, "partition_messages":50,
"timeslice":"00:00:09.788000", "batch_start":"2018-11-06 12:52:38.930428",
"batch_end":"2018-11-06 12:52:48.932604", "source_duration":"00:00:00.231709",
"consecutive_error_count":null, "transaction_id":45035996274536981,
"frame_start":"2018-11-06 12:52:38.685", "frame_end":null}
```

This example demonstrates using the --dump argument to get the SQL statement vkconfig executed to retrieve the output from the previous example:

```
$ /opt/vertica/packages/kafka/bin/vkconfig statistics  --dump --partition 1 \
                --from-timestamp "2018-11-06 12:52:30" \
                --to-timestamp "2018-11-06 12:53:00" --conf iot.conf
SELECT microbatch, target_schema, target_table, source_name, source_cluster,
source_partition, start_offset, end_offset, end_reason, end_reason_message,
partition_bytes, partition_messages, timeslice, batch_start, batch_end,
last_batch_duration AS source_duration, consecutive_error_count, transaction_id,
frame_start, frame_end FROM "iot_sched".stream_microbatch_history WHERE
(source_partition = '1') AND (frame_start >= '2018-11-06 12:52:30.0') AND
(frame_start < '2018-11-06 12:53:00.0') ORDER BY frame_start DESC, microbatch,
source_cluster, source_name, source_partition;
```

Sync tool options

The sync utility immediately updates all source definitions by querying the Kafka cluster's brokers defined by the source. By default, it updates all of the sources defined in the target schema. To update just specific sources, use the --source and --cluster options to specify which sources to update.

Syntax

```
vkconfig sync [options...]
```

--source ***source_name***

The name of the source sync. This source must already exist in the target schema.

--cluster ***cluster_name***

Identifies the cluster containing the source that you want to sync. You must have already defined this cluster in the scheduler.

--kafka_conf ' ***kafka_configuration_setting*** **'**

A JSON-formatted object of option/value pairs to pass directly to the rdkafka library. This is the library Vertica uses to communicate with Kafka. You can use this parameter to directly set configuration options that are not available through the Vertica integration with Kafka. See Directly setting Kafka library options for details.

See the Common vkconfig script options for options available in all of the vkconfig tools..

Kafka function reference

This section lists the functions that make up Vertica's Kafka integration feature.

In this section

- KafkaAvroParser
- KafkaCheckBrokers
- KafkaExport
- KafkaJSONParser
- KafkaListManyTopics
- KafkaListTopics
- KafkaOffsets
- KafkaParser
- KafkaSource
- KafkaTopicDetails

KafkaAvroParser

The KafkaAvroParser parses Avro-formatted Kafka messages and loads them into a regular Vertica table or a Vertica flex table.

Syntax

```
KafkaAvroParser(param=value[,...])
```

enforce_length

When set to TRUE, rejects the row if any value is too wide to fit into its column. When using the default setting (FALSE) , the parser truncates any value that is too wide to fit within the column's maximum width.

reject_on_materialized_type_error

When set to TRUE, rejects the row if it contains a materialized column value that cannot be mapped into the materialized column's data type.

flatten_maps

If set to TRUE, flattens all Avro maps.

flatten_arrays

If set to TRUE, flattens Avro arrays.

flatten_records

If set to TRUE, flattens all Avro records.

external_schema

The schema of the Avro file as a JSON string. If this parameter is not specified, the parser assumes that each message has the schema on it. If you are using a schema registry, do not use this parameter.

codec

The codec in which the Avro file was written. Valid values are:

- default : Data is not compressed and codec is not needed
- deflate : Data is compressed using the deflate codec
- snappy : Snappy compression

> **Note**
> This option is mainly provided for backwards compatibility. You usually have Kafka compress data at the message level, and have KafkaSource decompress the message for you.

with_metadata

If set to TRUE, messages include Avro datum, schema, and object metadata. By default, the KafkaAvroParser parses messages without including schema and metadata. If you enable this parameter, write your messages using the Avro API and confirm they contain only Avro datum. The default value is FALSE.

schema_registry_url

Required, the URL of the Confluent schema registry. This parameter is required to load data based on a schema registry version. If you are using an external schema, do not use this parameter. For more information, refer to Avro schema registry with Vertica .

> **Note**
> TLS connections must use the HTTPS protocol.

schema_registry_ssl_ca_path

Required for TLS connections, the path on the Vertica node's file system to a directory containing one or more hashed certificate authority (CA) certificates that signed the schema registry's server certificate. Each Vertica node must store hashed CA certificates on the same path.

For details on hashed CA certificates, see Hashed CA Certificates .

schema_registry_ssl_cert_path

Path on the Vertica node's file system to a client certificate issued by a certificate authority (CA) that the schema registry trusts.

schema_registry_ssl_key_path

Path on the Vertica server file system to the private key for the client certificate defined with schema_registry_ssl_cert_path .

schema_registry_ssl_key_password_path

Path on the Vertica server file system to the optional password for the private key defined with schema_registry_ssl_key_path .

schema_registry_subject

In the schema registry, the subject of the schema to use for data loading.

schema_registry_version

In the schema registry, the version of the schema to use for data loading.

key_separator

Sets the character to use as the separator between keys.

Data types

KafkaAvroParser supports the same data types as the favroparser . For details, see Avro data .

Example

The following example demonstrates loading data from Kafka in an Avro format. The statement:

- Loads data into an existing flex table named weather_logs.
- Copies data from the default Kafka broker (running on the local system on port 9092).
- The source is named temperature.
- The source has a single partition.
- The load starts from offset 0.
- The load ends either after 10 seconds or the load reaches the end of the source, whichever occurs first.
- The KafkaAvroParser does not flatten any arrays, maps, or records it finds in the source.
- The schema for the data is provided in the statement as a JSON string. It defines a record type named Weather that contains fields for a station name, a time, and a temperature.
- Rejected rows of data are saved to a table named t_rejects1.

```
=> COPY weather_logs
  SOURCE KafkaSource(stream='temperature|0|0', stop_on_eof=true,
                     duration=interval '10 seconds')
  PARSER KafkaAvroParser(flatten_arrays=False, flatten_maps=False, flatten_records=False,
                         external_schema=E'{"type":"record","name":"Weather","fields":'
                                         '[{"name":"station","type":"string"},'
                                         '{"name":"time","type":"long"},'
                                         '{"name":"temp","type":"int"}]}')
  REJECTED DATA AS TABLE "t_rejects1";
```

Hashed CA certificates

Some parameters like schema_registry_ssl_ca_path require hashed CA certificates rather than the CA certificates themselves. A hashed CA certificate is a symbolic link to the original CA certificate. This symbolic link must have the following naming scheme:

```
CA_hash.0
```

For example, if the hash for ca_cert.pem is 9741086f , the hashed CA certificate would be 9741086f.0 , a symbolic link to ca_cert.pem .

For details, see the OpenSSL 1.1 or 1.0 documentation.

Hashing CA certificates

The procedure for hashing CA certificates varies between versions of openssl . You can find your version of openssl with:

```
$ openssl version
```

For openssl 1.1 or higher, use openssl rehash . For example, if the directory /my_ca_certs/ contains ca_cert.pem , you can hash and symbolically link to it with:

```
$ openssl rehash /my_ca_certs/
```

This adds the hashed CA certificate to the directory:

```
$ ls -l
total 8
lrwxrwxrwx 1 ver ver    8 Mar 13 14:41 9da13359.0 -> ca_cert.pem
-rw-r--r-- 1 ver ver 1245 Mar 13 14:41 ca_cert.pem
```

For openssl 1.0, you can use openssl x509 -hash -noout -in *ca_cert* .pem to retrieve the hash and then create a symbolic link to the CA certificate. For example:

1. Run the following command to retrieve the hash of the CA certificate ca_cert.pem :
   ```
   $ openssl x509 -hash -noout -in /my_ca_certs/ca_cert.pem
   9741086f
   ```
2. Create a symbolic link to /my_ca_certs/ca_cert.pem :
   ```
   $ ln /my_ca_certs/ca_cert.pem /my_ca_certs/9741086f.0
   ```

This adds the hashed CA certificate to the directory:

```
$ ls -l
total 8
-rw-r--r-- 2 ver ver 1220 Mar 13 13:41 9741086f.0 -> ca_cert.pem
-rw-r--r-- 2 ver ver 1220 Mar 13 13:41 ca_cert.pem
```

KafkaCheckBrokers

Retrieves information about the brokers in a Kafka cluster. This function is intended mainly for internal use—it used by the streaming job scheduler to get the list of brokers in the Kafka cluster. You can call the function to determine which brokers Vertica knows about.

Syntax

```
KafkaCheckBrokers(USING PARAMETERS brokers='hostname:port[,hostname2:port...]'
                                [, kafka_conf='kafka_configuration_setting']
                                [, timeout=timeout_sec])
```

brokers

The host name and port number of a broker in the Kafka cluster used to retrieve the list of brokers. You can supply more than one broker as a comma-separated list. If the list includes brokers from more than one Kafka cluster, the cluster containing the last host in the list is queried.

kafka_conf

A JSON-formatted object of option/value pairs to pass directly to the rdkafka library. This is the library Vertica uses to communicate with Kafka. You can use this parameter to directly set configuration options that are not available through the Vertica integration with Kafka. See Directly setting Kafka library options for details.

timeout

Integer number of seconds to wait for a response from the Kafka cluster.

Example

```
=> SELECT KafkaCheckBrokers(USING PARAMETERS brokers='kafka01.example.com:9092')
        OVER ();
 broker_id |       hostname      | port
-----------+---------------------+------
         2 | kafka03.example.com | 9092
         1 | kafka02.example.com | 9092
         3 | kafka04.example.com | 9092
         0 | kafka01.example.com | 9092
(4 rows)
```

KafkaExport

Sends Vertica data to Kafka.

If Vertica successfully exports all of the rows of data to Kafka, this function returns zero rows. You can use the output of this function to copy failed messages to a secondary table for evaluation and reprocessing.

Syntax

```
SELECT KafkaExport(partitionColumn, keyColumn, valueColumn
   USING PARAMETERS brokers='host[:port][,host...]',
   topic='topicname'
   [,kafka_conf='kafka_configuration_setting']
   [,fail_on_conf_parse_error=Boolean])
OVER (partition_clause) FROM table;
```

Parameters

partitionColumn

The target partition for the export. If you set this value to NULL, Vertica uses the default partitioning scheme. You can use the partition argument to send messages to partitions that map to Vertica segments.

keyColumn

The user defined key value associated with the valueColumn. Use NULL to skip this argument.

valueColumn

The message itself. The column is a LONG VARCHAR, allowing you to send up to 32MB of data to Kafka. However, Kafka may impose its own limits on message size.

brokers

A string containing a comma-separated list of one or more host names or IP addresses (with optional port number) of brokers in the Kafka cluster.

topic

The Kafka topic to which you are exporting.

kafka_conf

A JSON-formatted object of option/value pairs to pass directly to the rdkafka library. This is the library Vertica uses to communicate with Kafka. You can use this parameter to directly set configuration options that are not available through the Vertica integration with Kafka. See Directly setting Kafka library options for details.

fail_on_conf_parse_error

Determines whether the function fails when kafka_conf contains incorrectly formatted options and values, or invalid configuration properties.
Default Value : FALSE

For accepted option and value formats, see Directly setting Kafka library options .

For a list of valid configuration properties, see the rdkafka GitHub repository .

Example

The following example converts each row from the iot_report table into a JSON object, and exports it to a Kafka topic named iot-report.

The iot_report table contains the following columns and data:

```
=> SELECT * FROM iot_report;
 server |        date         |        location         |    id
--------+---------------------+-------------------------+----------
      1 | 2016-10-11 04:09:28 |  -14.86058, 112.75848   | 70982027
      1 | 2017-07-02 12:37:48 |  -21.42197, -127.17672  | 49494918
      2 | 2017-01-20 03:05:24 |  37.17372, 136.14026    | 36670100
      2 | 2017-07-29 11:38:37 |  -38.99517, 171.72671   | 52049116
      1 | 2017-10-19 14:04:33 |  -71.72156, -36.27381   | 94328189
(5 rows)
```

To build the KafkaExport function, provide the following values to define the Kafka message:

- *partitionColumn* : Use the server column. Because the server column values are one-based and Kafka partitions are zero-based, subtract 1 from the server value.
- *keyColumn* : Use the id column. This requires that you explicitly cast the id value to a VARCHAR type.
- *valueColumn* : Each message formats the date and location columns as the key/value pairs in the exported JSON object.
  To convert these rows to JSON format, use the ROW function to convert the date and location columns to structured data. Then, pass the ROW function to the TO_JSON function to encode the data structure as a JSON object.

Complete the remaining required function arguments and execute the KafkaExport function. If it succeeds, it returns 0 rows:

```
=> SELECT KafkaExport(server - 1, id::VARCHAR, TO_JSON(ROW(date, location))
                      USING PARAMETERS brokers='broker01:9092,broker02:9092',
                      topic='iot-results')
  OVER (PARTITION BEST)
  FROM iot_report;
 partition | key | message | failure_reason
-----------+-----+---------+----------------
(0 rows)
```

Use kafkacat to verify that the consumer contains the JSON-formatted data in the iot-results topic:

```
$ /opt/vertica/packages/kafka/bin/kafkacat -C -t iot-results -b broker01:9092,broker02:9092
{"date":"2017-01-20 03:05:24","location":" 37.17372, 136.14026   "}
{"date":"2017-07-29 11:38:37","location":" -38.99517, 171.72671  "}
{"date":"2016-10-11 04:09:28","location":" -14.86058, 112.75848  "}
{"date":"2017-10-19 14:04:33","location":" -71.72156, -36.27381  "}
{"date":"2017-07-02 12:37:48","location":" -21.42197, -127.17672 "}
```

See also

Producing data using KafkaExport
KafkaJSONParser

The KafkaJSONParser parses JSON-formatted Kafka messages and loads them into a regular Vertica table or a Vertica flex table.

Syntax

```
KafkaJSONParser(
    [enforce_length=Boolean]
    [, flatten_maps=Boolean]
    [, flatten_arrays=Boolean]
    [, start_point=string]
    [, start_point_occurrence=integer]
    [, omit_empty_keys=Boolean]
    [, reject_on_duplicate=Boolean]
    [, reject_on_materialized_type_error=Boolean]
    [, reject_on_empty_key=Boolean]
    [, key_separator=char]
    [, suppress_nonalphanumeric_key_chars=Boolean]
    )
```

enforce_length

If set to TRUE, rejects the row if data being loaded is too wide to fit into its column. Defaults to FALSE, which truncates any data that is too wide to fit into its column.

flatten_maps

If set to TRUE, flattens all JSON maps.

flatten_arrays

If set to TRUE, flattens JSON arrays.

start_point

Specifies the key in the JSON data that the parser should parse. The parser only extracts data that is within the value associated with the start_point key. It parses the values of all instances of the start_point key within the data.

start_point_occurrence

Integer value indicating which the occurrence of the key specified by the start_point parameter where the parser should begin parsing. For example, if you set this value to 4, the parser will only begin loading data from the fifth occurrence of the start_point key. Only has an effect if you also supply the start_point parameter.

omit_empty_keys

If set to TRUE, omits any key from the load data that does not have a value set.

reject_on_duplicate

If set to TRUE, rejects the row that contains duplicate key names. Key names are case-insensitive, so the keys "mykey" and "MyKey" are considered duplicates.

reject_on_materialized_type_error

If set to TRUE, rejects the row if the data includes keys matching an existing materialized column and has a key that cannot be mapped into the materialized column's data type.

reject_on_empty_key

If set to TRUE, rejects any row containing a key without a value.

key_separator

A single character to use as the separator between key values instead of the default period (.) character.

suppress_nonalphanumeric_key_chars

If set to TRUE, replaces all non-alphanumeric characters in JSON key values with an underscore (_) character.

See JSON data for more information.

The following example demonstrates loading JSON data from Kafka. The parameters in the statement define to the load to:

- Load data into the pre-existing table named logs.
- The KafkaSource streams the data from a single partition in the source called server_log.
- The Kafka broker for the data load is running on the host named kafka01 on port 9092.
- KafkaSource stops loading data after either 10 seconds or on reaching the end of the stream, whichever happens first.
- The KafkJSONParser flattens any arrays or maps in the JSON data.

```
=> COPY logs SOURCE KafkaSource(stream='server_log|0|0',
                        stop_on_eof=true,
                        duration=interval '10 seconds',
                        brokers='kafka01:9092')
  PARSER KafkaJSONParser(flatten_arrays=True, flatten_maps=True);
```

KafkaListManyTopics

Retrieves information about all topics from a Kafka broker. This function lists all of the topics defined in the Kafka cluster as well the number of partitions it contains and which brokers serve the topic.

Syntax

```
KafkaListManyTopics('broker:port[;...]'
                [USING PARAMETERS
                   [kafka_conf='kafka_configuration_setting'
                   [, timeout=timeout_sec]])
```

broker

The hostname (or ip address) of a broker in the Kafka cluster

port

The port number on which the broker is running.

kafka_conf

A JSON-formatted object of option/value pairs to pass directly to the rdkafka library. This is the library Vertica uses to communicate with Kafka. You can use this parameter to directly set configuration options that are not available through the Vertica integration with Kafka. See Directly setting Kafka library options for details.

timeout

Integer number of seconds to wait for a response from the Kafka cluster.

Example

```
=> \x
Expanded display is on.
=> SELECT KafkaListManyTopics('kafka01.example.com:9092')
   OVER (PARTITION AUTO);
-[ RECORD 1 ]--+-------------------------------------------------
brokers        | kafka01.example.com:9092,kafka02.example.com:9092
topic          | __consumer_offsets
num_partitions | 50
-[ RECORD 2 ]--+-------------------------------------------------
brokers        | kafka01.example.com:9092,kafka02.example.com:9092
topic          | iot_data
num_partitions | 1
-[ RECORD 3 ]--+-------------------------------------------------
brokers        | kafka01.example.com:9092,kafka02.example.com:9092
topic          | test
num_partitions | 1
```

KafkaListTopics

Gets the list of topics available from a Kafka broker.

Syntax

```
KafkaListTopics(USING PARAMETERS brokers='hostname:port[,hostname2:port2...]'
                        [, kafka_conf='kafka_configuration_setting']
                        [, timeout=timeout_sec])
```

brokers

The host name and port number of the broker to query for a topic list. You can supply more than one broker as a comma-separated list. However, the returned list will only contains the topics served by the last broker in the list.

kafka_conf

A JSON-formatted object of option/value pairs to pass directly to the rdkafka library. This is the library Vertica uses to communicate with Kafka. You can use this parameter to directly set configuration options that are not available through the Vertica integration with Kafka. See Directly setting Kafka library options for details.

timeout

Integer number of seconds to wait for a response from the Kafka cluster.

Example

```
=> SELECT KafkaListTopics(USING PARAMETERS brokers='kafka1-01.example.com:9092')
        OVER ();
       topic        | num_partitions
----------------------+----------------
 test                |              1
 iot_data            |              1
 __consumer_offsets  |             50
 vertica_notifications |            1
 web_hits            |              1
(5 rows)
```

KafkaOffsets

The KafkaOffsets user-defined transform function returns load operation statistics generated by the most recent invocation of KafkaSource. Query KafkaOffsets to see the metadata produced by your most recent load operation. You can query KafkaOffsets after each KafkaSource invocation to view information about that load. If you are using the scheduler, you can also view historical load information in the stream_microbatch_history table.

For each load operation, KafkaOffsets returns the following:

- source kafka topic
- source kafka partition
- starting offset
- ending offset
- number of messages loaded
- number of bytes read
- duration of the load operation
- end message
- end reason

The following example demonstrates calling KafkaOffsets to show partition information that was loaded using KafkaSource:

```
=> SELECT kpartition, start_offset, end_offset, msg_count, ending FROM (select KafkaOffsets() over()) AS stats ORDER BY kpartition;
 kpartition | start_offset | end_offset | msg_count |   ending
------------+--------------+------------+-----------+------------
          0 |           -2 |       9999 |      1068 | END_OFFSET
```

The output shows that KafkaSource loaded 1068 messages (rows) from Kafka in a single partition. The KafkaSource ended the data load because it reached the ending offset.

> **Note**
> The values shown in the start_offset column are exclusive (the message with the shown offset was not loaded) and the values in the end_offset column are inclusive (the message with the shown offset was loaded). This is the opposite of the values specified in the KafkaSource's stream parameter. The difference between the inclusiveness of KafkaSource's and KafkaOffset's start and end offsets are based on the needs of the job scheduler. KafkaOffset is primarily intended for the job scheduler's use, so the start and end offset values are defined so the scheduler can easily start streaming from where left off.

KafkaParser

The KafkaParser does not parse data loaded from Kafka. Instead, it passes the messages through as LONG VARCHAR values. Use this parser when you want to load raw Kafka messages into Vertica for further processing. You can use this parser as a catch-all for unsupported formats.

KafkaParser does not take any parameters.

Example

The following example loads raw messages from a Kafka topic named iot-data into a table named raw_iot.

```
=> CREATE TABLE raw_iot(message LONG VARCHAR);
CREATE TABLE
=> COPY raw_iot SOURCE KafkaSource(stream='iot-data|0|-2,iot-data|1|-2,iot-data|2|-2',
                                   brokers='docd01:6667,docd03:6667', stop_on_eof=TRUE)
             PARSER KafkaParser();
 Rows Loaded
-------------
        5000
(1 row)

=> select * from raw_iot limit 10;
              message
-------------------------------------
 10039, 59, -68.951406, -19.270126
 10042, 40, -82.688712, 4.7187705
 10054, 6, -153.805268, -10.5173935
 10054, 71, -135.613150, 58.286458
 10081, 44, 130.288419, -77.344405
 10104, -5, 77.882598, -56.600744
 10132, 87, 103.530616, -69.672863
 10135, 6, -121.420382, 15.3229855
 10166, 77, -179.592211, 42.0477075
 10183, 62, 17.225394, -55.6644765
(10 rows)
```

KafkaSource

The KafkaSource UDL accesses data from a Kafka cluster. All Kafka parsers must use KafkaSource. Messages processed by KafkaSource must be at least one byte in length. KafkaSource writes an error message to vertica.log for zero-length messages.

The output of KafkaSource does not work directly with any of the non-Kafka parsers in Vertica (such as the FCSVPARSER). The KafkaParser produces additional metadata about the stream that parsers need to use in order to correctly parse the data. You must use filters such as KafkaInsertDelimiters to transform the data into a format that can be processed by other parsers. See Parsing custom formats for more an example.

You can cancel a running KafkaSource data load by using a close session function such as CLOSE_ALL_SESSIONS .

Syntax

```
KafkaSource(stream='topic_name|partition|start_offset[|end_offset]'[, param=value [,...] ] )
```

stream

Required. Defines the data to be loaded as a comma-separated list of one or more partitions. Each partition is defined by three required values and one optional value separated by pipe characters (|) :

- *topic_name* : the name of the Kafka topic to load data from. You can read from different Kafka topics in the same stream parameter, with some limitations. See Loading from Multiple Topics in the Same Stream Parameter below for more information.
- *partition* : the partition in the Kafka topic to copy.
- *start_offset* : the offset in the Kafka topic where the load will begin. This offset is inclusive (the message with the offset *start_offset* is loaded). See Special Starting Offset Values below for additional options.
- *end_offset* : the optional offset where the load should end. This offset is exclusive (the message with the offset end_offset will not be loaded). To end a load using *end_offset* , you must supply an ending offset value for all partitions in the stream parameter. Attempting to set an ending offset for some partitions and not set offset values for others results in an error.
  If you do not specify an ending offset, you must supply at least one other ending condition using stop_on_eof or duration .

brokers

A comma-separated list of host:port pairs of the brokers in the Kafka cluster. Vertica recommends running Kafka on a different machine than Vertica.

Default: localhost:9092

duration

An INTERVAL that specifies the duration of the frame. After this specified amount of time, KafkaSource terminates the COPY statements. If this

parameter is not set, you must set at least one other ending condition by using stop_on_eof or specify an ending offset instead. See Duration Note below for more information.

executionparallelism

The number of threads to use when loading data. Normally, you set this to an integer value between 1 and the number of partitions the node is loading from. Setting this parameter to a reduced value limits the number of threads used to process any COPY statement. It also increases the throughput of short queries issued in the pool, especially if the queries are executed concurrently.

If you do not specify this parameter, Vertica automatically creates a thread for every partition, up to the limit allowed by the resource pool. If the value you specify for the KafkaSource is lower than the value specified for the scheduler resource pool, the KafkaSource value applies. This value cannot exceed the value specified for the scheduler's resource pool.

stop_on_eof

Determines whether KafkaSource should terminate the COPY statement after it reaches the end of a file. If this value is not set, you must set at least one other ending condition using duration or by supplying ending offsets instead.

Default: FALSE

group_id

The name of the Kafka consumer group to which Vertica reports its progress consuming messages. Set this value to disable progress reports to a Kafka consumer group. For details, see Monitoring Vertica message consumption with consumer groups .
Default: vertica_ *database-name*

kafka_conf

A JSON-formatted object of option/value pairs to pass directly to the rdkafka library. This is the library Vertica uses to communicate with Kafka. You can use this parameter to directly set configuration options that are not available through the Vertica integration with Kafka. See Directly setting Kafka library options for details.

fail_on_conf_parse_error

Determines whether the function fails when kafka_conf contains incorrectly formatted options and values, or invalid configuration properties.
Default Value : FALSE

For accepted option and value formats, see Directly setting Kafka library options .

For a list of valid configuration properties, see the rdkafka GitHub repository .

Special starting offset values

The *start_offset* portion of the stream parameter lets you start loading messages from a specific point in the topic's partition. It also accepts one of two special offset values:

- -2 tells Set Snippet Variable Value in Topic to start loading at the earliest available message in the topic's partition. This value is useful when you want to load as many messages as you can from the Kafka topic's partition.
- -3 tells Set Snippet Variable Value in Topic to start loading from the consumer group's saved offset. If the consumer group does not have a saved offset, it starts loading from the earliest available message in the topic partition. See Monitoring Vertica message consumption with consumer groups for more information.

Loading from multiple topics in the same stream parameter

You can load from multiple Kafka topics in a single stream parameter as long as you follow these guidelines:

- The data for the topics must be in the same format because you pass the data from KafkaSource to a single parser. For example, you cannot load data from one topic that is in Avro format and another in JSON format.
- Similarly, you need to be careful if you are loading Avro data and specifying an external schema from a registry. The Avro parser accepts a single schema per data load. If the data from the separate topics have different schemas, then all of the data from one of the topics will be rejected.
- The data in the different topics should have the same (or very similar) schemas, especially if you are loading data into a traditional Vertica table. While you can load data with different schemas into a flex table, there are only a few scenarios where it makes sense to combine dissimilar data into a single table.

Duration note

The duration parameter applies to the length of time that Vertica allows the KafkaSource function to run. It usually reflects the amount of time the overall load statement takes. However, if KafkaSource is loading a large volume of data or the data needs extensive processing and parsing, the overall runtime of the query can exceed the amount of time specified in duration .

Example

The following example demonstrates calling KafkaSource to load data from Kafka into an existing flex table named web_table with the following options:

- The stream is named web_hits which has a single partition.
- The load starts at the earliest message in the stream (identified by passing -2 as the start offset).
- The load ends when it reaches the message with offset 1000.
- The Kafka cluster's brokers are kafka01 and kafka03 in the example.com domain.
- The brokers are listening on port 9092.
- The load ends if it reaches the end of the stream before reaching the message with offset 1000. If you do not supply this option, the connector waits until Kafka sends a message with offset 1000.
- The loaded data is sent to the KafkaJSONParser for processing.

```
=> COPY web_table
   SOURCE KafkaSource(stream='web_hits|0|-2|1000',
                      brokers='kafka01.example.com:9092,kafka03.example.com:9092',
                      stop_on_eof=true)
   PARSER KafkaJSONParser();
 Rows Loaded
-------------
        1000
(1 row)
```

To view details about this load operation, query KafkaOffsets . KafkaOffsets returns metadata about the messages that Vertica consumed from Kafka during the most recent KafkaSource invocation:

```
=> SELECT KafkaOffsets() OVER();
  ktopic  | kpartition | start_offset | end_offset | msg_count | bytes_read |    duration     |  ending  |      end_msg
----------+------------+--------------+------------+-----------+------------+-----------------+----------+-------------------
 web_hits |          0 |            0 |        999 |      1000 |     197027 | 00:00:00.385365 | END_OFFSET | Last message read
(1 row)
```

The msg_count column verifies that Vertica loaded 1000 messages, and the ending column indicates that Vertica stopped consuming messages when it reached the message with the offset 1000.

KafkaTopicDetails

Retrieves information about the specified topic from one or more Kafka brokers. This function lists details about the topic partitions, and the Kafka brokers that serve each partition in the Kafka cluster.

Syntax

```
KafkaTopicDetails(USING PARAMETERS brokers='hostname:port[,hostname2:port2...]'
                                  , topic=topic_name
                                 [, kafka_conf='option=value[;option2=value2...]']
                                 [, timeout=timeout_sec])
```

brokers
The hostname (or IP address) of a broker in the Kafka cluster.

port
The port number on which the broker is running.

topic
Kafka topic that you want details for.

kafka_conf
A semicolon-delimited list of *option* = *value* pairs to pass directly to the rdkafka library. This is the library Vertica uses to communicate with Kafka. You can use this parameter to directly set configuration options that are not available through the Vertica integration with Kafka. See Directly setting Kafka library options for details.

timeout
Integer number of seconds to wait for a response from the Kafka cluster.

Example

```
=> SELECT KafkaTopicDetails(USING PARAMETERS brokers='kafka1-01.example.com:9092',topic='iot_data') OVER();
 partition_id | lead_broker | replica_brokers | in_sync_replica_brokers
--------------+-------------+-----------------+-------------------------
            0 |           0 | 0               | 0
            1 |           1 | 1               | 1
            2 |           0 | 0               | 0
            3 |           1 | 1               | 1
            4 |           0 | 0               | 0
(5 rows)
```

Data streaming schema tables

Every time you create a scheduler (--create), Vertica creates a schema for that scheduler with the name you specify or the default stream_config . Each schema has the following tables:

- stream_clusters
- stream_events
- stream_load_specs
- stream_microbatch_history
- stream_microbatch_source_map
- stream_microbatches
- stream_scheduler
- stream_scheduler_history
- stream_sources
- stream_targets

Caution
Vertica recommends that you do not alter these tables except in consultation with support.

In this section

- stream_clusters
- stream_events
- stream_load_specs
- stream_lock
- stream_microbatch_history
- stream_microbatch_source_map
- stream_microbatches
- stream_scheduler
- stream_scheduler_history
- stream_sources
- stream_targets

stream_clusters

This table lists clusters and hosts. You change settings in this table using the vkconfig cluster tool. See Cluster tool options for more information.

Column	Data Type	Description
id	INTEGER	The identification number assigned to the cluster.
cluster	VARCHAR	The name of the cluster.
hosts	VARCHAR	A comma-separated list of hosts associated with the cluster.

Examples

This example shows a cluster and its associated hosts.

```
=> SELECT * FROM stream_config.stream_clusters;

   id    |    cluster     |               hosts
---------+----------------+-----------------------------------
 2250001 | streamcluster1 | 10.10.10.10:9092,10.10.10.11:9092
(1 rows)
```

stream_events

This table logs microbatches and other important events from the scheduler in an internal log table.

This table was renamed from kafka_config.kafka_events.

Column	Data Type	Description
event_time	TIMESTAMP	The time the event was logged.
log_level	VARCHAR	The type of event that was logged. **Valid Values:** • TRACE • DEBUG • FATAL • ERROR • WARN • INFO **Default:** INFO
frame_start	TIMESTAMP	The time when the frame executed.
frame_end	TIMESTAMP	The time when the frame completed.
microbatch	INTEGER	The identification number of the associated microbatch.
message	VARCHAR	A description of the event.
exception	VARCHAR	If this log is in the form of a stack trace, this column lists the exception.

Examples

This example shows typical rows from the stream_events table.

```
=> SELECT * FROM stream_config.stream_events;
-[ RECORD 1 ]-+-------------
event_time    | 2016-07-17 13:28:35.548-04
log_level     | INFO
frame_start   |
frame_end     |
microbatch    |
message       | New leader registered for schema stream_config. New ID: 0, new Host: 10.20.30.40
exception     |
-[ RECORD 2 ]-+-------------
event_time    | 2016-07-17 13:28:45.643-04
log_level     | INFO
frame_start   | 2015-07-17 12:28:45.633
frame_end     | 2015-07-17 13:28:50.701-04
microbatch    |
message       | Generated tuples: test3|2|-2,test3|1|-2,test3|0|-2
exception     |
-[ RECORD 3 ]-+----------------
event_time    | 2016-07-17 14:28:50.701-04
log_level     | INFO
frame_start   | 2016-07-17 13:28:45.633
frame_end     | 2016-07-17 14:28:50.701-04
microbatch    |
message       | Total rows inserted: 0
exception     |
```

stream_load_specs

This table describes user-created load specs. You change the entries in this table using the vkconfig utility's load spec tool .

Column	Data Type	Description
id	INTEGER	The identification number assigned to the cluster.
load_spec	VARCHAR	The name of the load spec.
filters	VARCHAR	A comma-separated list of UDFilters for the scheduler to include in the COPY statement it uses to load data from Kafka.
parser	VARCHAR	A Vertica UDParser to use with a specified target. If you are using a Vertica native parser, parser parameters serve as a COPY statement parameters.
parser_parameters	VARCHAR	A list of parameters to provide to the parser.
load_method	VARCHAR	The COPY load method to use for all loads with this scheduler. **Deprecated** In Vertica 10.0, load methods are no longer used due to the removal of the WOS. The value shown in this column has no effect.
message_max_bytes	INTEGER	The maximum size, in bytes, of a message.
uds_kv_parameters	VARCHAR	A list of parameters that are supplied to the KafkaSource statement. If the value in this column is in the format *key* = *value* , the scheduler it to the COPY statement's KafkaSource call.

Examples

This example shows the load specs that you can use with a Vertica instance.

```
SELECT * FROM stream_config.stream_load_specs;
-[ RECORD 1 ]-----+------------
id                | 1
load_spec         | loadspec2
filters           |
parser            | KafkaParser
parser_parameters |
load_method       | direct
message_max_bytes | 1048576
uds_kv_parameters |
-[ RECORD 2 ]-----+------------
id                | 750001
load_spec         | streamspec1
filters           |
parser            | KafkaParser
parser_parameters |
load_method       | TRICKLE
message_max_bytes | 1048576
uds_kv_parameters |
```

stream_lock

This table is locked by the scheduler. This locks prevent multiple schedulers from running at the same time. The scheduler that locks this table updates it with its own information.

Important
Do not use this table in a serializable transaction that locks this table. Locking this table can interfere with the operation of the scheduler.

Column	Data Type	Description
scheduler_id	INTEGER	A unique ID for the scheduler instance that is currently running.
update_time	TIMESTAMP	The time the scheduler took ownership of writing to the schema.
process_info	VARCHAR	Information about the scheduler process. Currently unused.

Example

```
=> SELECT * FROM weblog_sched.stream_lock;
 scheduler_id |       update_time       | process_info
--------------+-------------------------+--------------
            2 | 2018-11-08 10:12:36.033 |
(1 row)
```

stream_microbatch_history

This table contains a history of every microbatch executed within this scheduler configuration.

Column	Data Type	Description
source_name	VARCHAR	The name of the source.
source_cluster	VARCHAR	The name of the source cluster. The clusters are defined in stream_clusters .
source_partition	INTEGER	The number of the data streaming partition.
start_offset	INTEGER	The starting offset of the microbatch.

end_offset	INTEGER	The ending offset of the microbatch.
end_reason	VARCHAR	An explanation for why the batch ended.The following are valid end reasons: • DEADLINE - The batch ran out of time. • END_OFFSET - The load reached the ending offset specified in the KafkaSource. This reason is never used by the scheduler, as it does specify an end offset. • END_OF_STREAM - There are no messages available to the scheduler or the eof_timeout has been reached. • NETWORK_ERROR - The scheduler could not connect to Kafka. • RESET_OFFSET - The start offset was changed using the --update and --offset parameters to the KafkaSource. This state does not occur during normal scheduler operations. • SOURCE_ISSUE - The Kafka service returned an error. • UNKNOWN - The batch ended for an unknown reason.
end_reason_message	VARCHAR	If the end reason is a network or source issue, this column contains a brief description of the issue.
partition_bytes	INTEGER	The number of bytes transferred from a source partition to a Vertica target table.
partition_messages	INTEGER	The number of messages transferred from a source partition to a Vertica target table.
microbatch_id	INTEGER	The Vertica transaction id for the batch session.
microbatch	VARCHAR	The name of the microbatch.
target_schema	VARCHAR	The name of the target schema.
target_table	VARCHAR	The name of the target table.
timeslice	INTERVAL	The amount of time spent in the KafkaSource operator.
batch_start	TIMESTAMP	The time the batch executed.
batch_end	TIMESTAMP	The time the batch completed.
last_batch_duration	INTERVAL	The length of time required to run the complete COPY statement.
last_batch_parallelism	INTEGER	The number of parallel COPY statements generated to process the microbatch during the last frame.
microbatch_sub_id	INTEGER	The identifier for the COPY statement that processed the microbatch.
consecutive_error_count	INTEGER	(Currently not used.) The number of times a microbatch has encountered an error on an attempt to load. This value increases over multiple attempts.
transaction_id	INTEGER	The identifier for the transaction within the session.
frame_start	TIMESTAMP	The time the frame started. A frame can contain multiple microbatches.
frame_end	TIMESTAMP	The time the frame completed.

Examples

This example shows typical rows from the stream_microbatch_history table.

```
=> SELECT * FROM stream_config.stream_microbatch_history;

-[ RECORD 1 ]--+--------------------------
source_name              | streamsource1
source_cluster           | kafka-1
source_partition         | 0
start_offset             | 196
end_offset               | 196
end_reason               | END_OF_STREAM
partition_bytes          | 0
partition_messages       | 0
microbatch_id            | 1
microbatch               | mb_0
target_schema            | public
target_table             | kafka_flex_0
timeslice                | 00:00:09.892
batch_start              | 2016-07-28 11:31:25.854221
batch_end                | 2016-07-28 11:31:26.357942
last_batch_duration      | 00:00:00.379826
last_batch_parallelism   | 1
microbatch_sub_id        | 0
consecutive_error_count |
transaction_id           | 45035996275130064
frame_start              | 2016-07-28 11:31:25.751
frame_end                |
end_reason_message       |

-[ RECORD 2 ]--+--------------------------
source_name              | streamsource1
source_cluster           | kafka-1
source_partition         | 1
start_offset             | 197
end_offset               | 197
end_reason               | NETWORK_ISSUE

batch_end                | 2016-07-28 11:31:46.253367
last_batch_duration      | 000:00:00.377796
last_batch_parallelism   | 1
microbatch_sub_id        | 0
consecutive_error_count |
transaction_id           | 45035996275130109
frame_start              | 2016-07-28 11:31:45.751
frame_end                |
end_reason_message       | Local: All brokers are down
```

stream_microbatch_source_map

This table maps microbatches to the their associated sources.

Column	Data Type	Description
microbatch	INTEGER	The identification number of the microbatch.

source	INTEGER	The identification number of the associated source.

Examples

This example shows typical rows from the stream_microbatch table.

```
SELECT * FROM stream_config.stream_microbatch_source_map;
microbatch | source
-----------+--------
         1 |      4
         3 |      2
(2 rows)
```

stream_microbatches

This table contains configuration data related to microbatches.

Column	Data Type	Description
id	INTEGER	The identification number of the microbatch.
microbatch	VARCHAR	The name of the microbatch.
target	INTEGER	The identification number of the target associated with the microbatch.
load_spec	INTEGER	The identification number of the load spec associated with the microbatch.
target_columns	VARCHAR	The table columns associated with the microbatch.
rejection_schema	VARCHAR	The schema that contains the rejection table.
rejection_table	VARCHAR	The table where Vertica stores messages that are rejected by the database.
max_parallelism	INTEGER	The number of parallel COPY statements the scheduler uses to process the microbatch.
enabled	BOOLEAN	When TRUE, the microbatch is enabled for use.
consumer_group_id	VARCHAR	The name of the Kafka consumer group to report loading progress to. This value is NULL if the microbatch reports its progress to the default consumer group for the scheduler. See Monitoring Vertica message consumption with consumer groups for more information.

Examples

This example shows a row from a typical stream_microbatches table.

```
=> select * from weblog_sched.stream_microbatches;
-[ RECORD 1 ]-----+----------
id                | 750001
microbatch        | weberrors
target            | 750001
load_spec         | 2250001
target_columns    |
rejection_schema  |
rejection_table   |
max_parallelism   | 1
enabled           | t
consumer_group_id |
-[ RECORD 2 ]-----+----------
id                | 1
microbatch        | weblog
target            | 1
load_spec         | 1
target_columns    |
rejection_schema  |
rejection_table   |
max_parallelism   | 1
enabled           | t
consumer_group_id | weblog_group
```

stream_scheduler

This table contains metadata related to a single scheduler.

This table was renamed from kafka_config.kafka_scheduler. This table used to contain a column named eof_timeout_ms. It has been removed.

Column	Data Type	Description
version	VARCHAR	The version of the scheduler.
frame_duration	INTERVAL	The length of time of the frame. The default is 00:00:10.
resource_pool	VARCHAR	The resource pool associated with this scheduler.
config_refresh	INTERVAL	The interval of time that the scheduler runs before applying any changes to its metadata, such as, changes made using the --update option. For more information, refer to --config-refresh in Scheduler tool options .
new_source_policy	VARCHAR	When during the frame that the source runs. Set this value with the --new-source-policy in Source tool options . **Valid Values:** • FAIR: Takes the average length of time from the previous batches and schedules itself appropriately. • START: Runs all new sources at the beginning of the frame. In this case, Vertica gives the minimal amount of time to run. • END: Runs all new sources starting at the end of the frame. In this case, Vertica gives the maximum amount of time to run. **Default:** FAIR

pushback_policy	VARCHAR	(Not currently used.) How Vertica handles delays for microbatches that continually fail. **Valid Values:** • FLAT • LINEAR • EXPONENTIAL **Default:** LINEAR
pushback_max_count	INTEGER	(Currently not used.) The maximum number of times a microbatch can fail before Vertica terminates it.
auto_sync	BOOLEAN	When TRUE, the scheduler automatically synchronizes source information with host clusters. For more information, refer to Automatically consume data from Kafka with the scheduler . **Default:** TRUE
consumer_group_id	VARCHAR	The name of the Kafka consumer group to which the scheduler reports its progress in consuming messages. This value is NULL if the scheduler reports to the default consumer group named vertica- *database_name* . See Monitoring Vertica message consumption with consumer groups for more information.

Examples

This example shows a typical row in the stream_scheduler table.

```
=> SELECT * FROM weblog_sched.stream_scheduler;
-[ RECORD 1 ]------+----------------------
version            | v9.2.1
frame_duration     | 00:05:00
resource_pool      | weblog_pool
config_refresh     | 00:05
new_source_policy  | FAIR
pushback_policy    | LINEAR
pushback_max_count | 5
auto_sync          | t
consumer_group_id  | vertica-consumer-group
```

stream_scheduler_history

This table shows the history of launched scheduler instances.

This table was renamed from kafka_config.kafka_scheduler_history.

Column	Data Type	Description
elected_leader_time	TIMESTAMP	The time when this instance took began scheduling operations.
host	VARCHAR	The host name of the machine running the scheduler instance.
launcher	VARCHAR	The name of the currently active scheduler instance. **Default:** NULL
scheduler_id	INTEGER	The identification number of the scheduler.
version	VARCHAR	The version of the scheduler.

Examples

This example shows typical rows from the stream_scheduler_history table.

```
SELECT * FROM stream_config.stream_scheduler_history;
  elected_leader_time   |     host     |     launcher      | scheduler_id | version
------------------------+--------------+-------------------+--------------+---------
2016-07-26 13:19:42.692 | 10.20.100.62 |                   |            0 | v8.0.0
2016-07-26 13:54:37.715 | 10.20.100.62 |                   |            1 | v8.0.0
2016-07-26 13:56:06.785 | 10.20.100.62 |                   |            2 | v8.0.0
2016-07-26 13:56:56.033 | 10.20.100.62 | SchedulerInstance |            3 | v8.0.0
2016-07-26 15:51:20.513 | 10.20.100.62 | SchedulerInstance |            4 | v8.0.0
2016-07-26 15:51:35.111 | 10.20.100.62 | SchedulerInstance |            5 | v8.0.0
  (6 rows)
```

stream_sources

This table contains metadata related to data streaming sources.

This table was formerly named kafka_config.kafka_scheduler.

Column	Data Type	Description
id	INTEGER	The identification number of the source
source	VARCHAR	The name of the source.
cluster	INTEGER	The identification number of the cluster associated with the source.
partitions	INTEGER	The number of partitions in the source.
enabled	BOOLEAN	When TRUE, the source is enabled for use.

Examples

This example shows a typical row from the stream_sources table.

```
select * from  stream_config.stream_sources;
-[ RECORD 1 ]----------
  id         | 1
  source     | SourceFeed1
  cluster    | 1
  partitions | 1
  enabled    | t
-[ RECORD 2 ]----------
  id         | 250001
  source     | SourceFeed2
  cluster    | 1
  partitions | 1
  enabled    | t
```

stream_targets

This table contains the metadata for all Vertica target tables.

The table was formerly named kafka_config.kafka_targets.

Column	Data Type	Description
id	INTEGER	The identification number of the target table
target_schema	VARCHAR	The name of the schema for the target table.
target_table	VARCHAR	The name of the target table.

Examples

This example shows typical rows from the stream_tables table.

```
=> SELECT * FROM stream_config.stream_targets;
-[ RECORD 1 ]-----+--------------------
id                | 1
target_schema     | public
target_table      | stream_flex1
-[ RECORD 2 ]-----+--------------------
id                | 2
target_schema     | public
target_table      | stream_flex2
```

Avro schema registry with Vertica

Vertica supports the use of a Confluent schema registry for Avro schemas with the Manually consume data from Kafka . By using a schema registry, you enable the Avro parser to parse and decode messages written by the registry and to retrieve schemas stored in the registry. In addition, a schema registry enables Vertica to process streamed data without sending a copy of the schema with each record. Vertica can access a schema registry in the following ways:

- schema ID
- subject and version

> **Note**
> If you use the compatibility config resource in your schema registry, you should specify a value of at least BACKWARD. You may also choose to use a stricter compatibility setting. For more information on installing and configuring a schema registry, refer to the Confluent documentation .

Schema ID loading

In schema ID based loading, the Avro parser checks the schema ID associated with each message to identify the correct schema to use. A single COPY statement can reference multiple schemas. Because each message is not validated, Vertica recommends that you use a flex table as the target table for schema ID based loading.

The following example shows a COPY statement that refers to a schema registry located on the same host:

```
=> COPY logs source kafkasource(stream='simple|0|0', stop_on_eof=true,
duration=interval '10 seconds') parser
KafkaAvroParser(schema_registry_url='http://localhost:8081/')
```

Subject and version loading

In subject and version loading, you specify a subject and version in addition to the schema registry URL. The addition of the subject and version identifies a single schema to use for all messages in the COPY. If any message in the statement is incompatible with the schema, the COPY fails. Because all messages are validated prior to loading, Vertica recommends that you use a standard Vertica table as the target for subject and version loading.

The following example shows a COPY statement that identifies a schema subject and schema version as well as a schema registry.

```
=> COPY t source kafkasource(stream='simpleEvolution|0|0',
stop_on_eof=true, duration=interval '10 seconds') parser
KafkaAvroParser(schema_registry_url='http://repository:8081/schema-repo/',
schema_registry_subject='simpleEvolution-value',schema_registry_version='1')
REJECTED DATA AS TABLE "t_rejects";
```

Apache Spark integration

Apache Spark is an open-source, general-purpose cluster-computing framework. See the Apache Spark website for more information. Vertica provides a Spark connector that you install into Spark that lets you transfer data between Vertica and Spark.

Using the connector, you can:

- Copy large volumes of data from Spark DataFrames to Vertica tables. This feature lets you save your Spark analytics in Vertica.

- Copy data from Vertica to Spark RDDs or DataFrames for use with Python, R, Scala and Java. The connector efficiently pushes down column selection and predicate filtering to Vertica before loading the data.

The connector lets you use Spark to preprocess data for Vertica and to use Vertica data in your Spark application. You can even round-trip data from Vertica to Spark—copy data from Vertica to Spark for analysis, and then save the results of that analysis back to Vertica.

See the spark-connector project on GitHub for more information about the connector.

How the connector works

The Spark connector is a library that you incorporate into your Spark applications to read data from and write data to Vertica. When transferring data, the connector uses an intermediate storage location as a buffer between the Vertica and Spark clusters. Using the intermediate storage location lets both Vertica and Spark use all of the nodes in their clusters to transfer data in parallel.

When transferring data from Vertica to Spark, the connector tells Vertica to write the data as Parquet files in the intermediate storage location. As part of this process, the connector pushes down the required columns and any Spark data filters into Vertica as SQL. This push down lets Vertica pre-filter the data so it only copies the data that Spark needs. Once Vertica finishes copying the data, the connector has Spark load it into DataFrames from the intermediate location.

When transferring data from Spark to Vertica, the process is reversed. Spark writes data into the intermediate storage location. It then connects to Vertica and runs a COPY statement to load the data from the intermediate location into a table.

Getting the connector

The Spark connector is an open source project. For the latest information on it, visit the spark-connector project on GitHub. To get an alert when there are updates to the connector, you can log into a GitHub account and click the **Notifications** button on any of the project's pages.

You have three options to get the Spark connector:

- Get the connector from Maven Central . If you use Gradle, Maven, or SBT to manage your Spark applications, you can add a dependency to your project to automatically get the connector and its dependencies and add them into your Spark application. See Getting the Connector from Maven Central below.
- Download a precompiled assembly from the GitHub project's releases page . Once you have downloaded the connector, you must configure Spark to use it. See Deploy the Connector to the Spark Cluster below.
- Clone the connector project and compile it. This option is useful if you want features or bugfixes that have not been released yet. See Compiling the Connector below.

See the Spark connector project on GitHub for detailed instructions on deploying and using the connector.

Getting the connector from maven central

The Vertica Spark connector is available from the Maven Central Repository. Using Maven Central is the easiest method of getting the connector if your build tool supports downloading dependencies from it.

If your Spark project is managed by Gradle, Maven, or SBT you can add the Spark connector to it by listing it as a dependency in its configuration file. You may also have to enable Maven Central if your build tool does not automatically do so.

For example, suppose you use SBT to manage your Spark application. In this case, the Maven Central repository is enabled by default. All you need to do is add the com.vertica.spark dependency to your build.sbt file.

See the com.vertica.spark page on the Maven Repository site for more information on the available Spark connector versions and dependency information for your build system.

Compiling the connector

You may choose to compile the Spark connector if you want to test new features or bugfixes that have not yet been released. Compiling the connector is necessary if you plan on contributing your own features.

To compile the connector, you need:

- The SBT build tool. In order to compile the connector, you must install SBT and all of its dependencies (including a version of the Java SDK). See the SBT documentation for requirements and installation instructions.
- git to clone the Spark connector V2 source from the GitHub.

As a quick overview, executing the following commands on a Linux command line will download the source and compile it into an assembly file:

```
$ git clone https://github.com/vertica/spark-connector.git
$ cd spark-connector/connector
$ sbt assembly
```

Once compiled, the connector is located at target/scala- *n.n* /spark-vertica-connector-assembly- *x.x* .jar . The *n.n* is the currently-supported version of Scala and *x.x* is the current version of the Spark connector.

See the CONTRIBUTING document in the connector's GitHub project for detailed requirements and compiling instructions.

Once you compile the connector, you must deploy it to your Spark cluster. See the next section for details.

Deploy the connector to the Spark cluster

If you downloaded the Spark connector from GitHub or compiled it yourself, you must deploy it to your Spark cluster before you can use it. Two options include copying it to a Spark node and including it in a spark-submit or spark-shell command or deploying it to the entire cluster and having it loaded automatically.

Loading the Spark connector from the command line

The quickest way to use the connector is to include it in the --jars argument when executing a spark-submit or spark-shell command. To be able to use the connector in the command line, you must first copy its assembly JAR to the Spark node on which you will run the commands. Then add the path to the assembly JAR file as part of the --jars command line argument.

For example, suppose you copied the assembly file to your current directory on a Spark node. Then you could load the connector when starting spark-shell with the command:

```
spark-shell --jars spark-vertica-connector-assembly-x.x.jar
```

You could also enable the connector when submitting a Spark job using spark-submit with the command:

```
spark-submit --jars spark-vertica-connector-assembly-x.x.jar
```

Configure Spark to automatically load the connector

You can configure your Spark cluster to automatically load the connector. Deploying the connector this way ensures that the Spark connector is available to all Spark applications on your cluster.

To have Spark automatically load the Spark connector:

1. Copy the Spark connector's assembly JAR file to the same path on all of the nodes in your Spark cluster. For example, on Linux you could copy the spark-vertica-connector-assembly- *x.x* .jar file to the /usr/local/lib directory on every Spark node. The file must be in the same location on each node.
2. In your Spark installation directories on each node in your cluster, edit the conf/spark-defaults.conf file to add or alter the following line:

   ```
   spark.jars /path_to_assembly/spark-vertica-connector-assembly-x.x.jar
   ```

   For example, if you copied the assembly JAR file to /usr/local/lib , you would add:

   ```
   spark.jars /usr/local/lib/spark-vertica-connector-assembly-x.x.jar
   ```

   > **Note**
   > If the spark.jars line already exists in the configuration file, add a comma to the end of the line, then add the path to the assembly file. Do not add a space between the comma and the surrounding values.
   >
   > If you have the JAR files for the Spark connector V1 in your configuration file, you do not need to remove them. Both connector versions can be loaded into Spark at the same time without a conflict.

3. Test your configuration by starting a Spark shell and entering the statement:

   ```
   import com.vertica.spark._
   ```

   If the statement completes successfully, then Spark was able to locate and load the Spark connector library correctly.

Prior connector versions

The Vertica Spark connector is an open source project available from GitHub. It is released on a separate schedule than the Vertica server.

Versions of Vertica prior to 11.0.2 distributed a closed-source proprietary version of the Spark connector. This legacy version is no longer supported, and is not distributed with the Vertica server install package.

The newer open source Spark connector differs from the old one in the following ways:

- The new connector uses the Spark V2 API. Using this newer API makes it more future-proof than the legacy connector, which uses an older Spark API.

- The primary class name has changed. Also, the primary class has several renamed configuration options and a few removed options. See Migrating from the legacy Vertica Spark connector for a list of these changes.
- It supports more features than the older connector, such as Kerberos authentication and S3 intermediate storage.
- It comes compiled as an assembly which contains supporting libraries such as the Vertica JDBC library.
- It is distributed separate from the Vertica server. You can directly download it from the GitHub project. It is also available from the Maven Central Repository, making it easier for you to integrate it into your Gradle, Maven, or SBT workflows.
- It is an open-source project that is not tied to the Vertica server release cycle. New features and bug fixes do not have to wait for a Vertica release. You can also contribute your own features and fixes.

If you have Spark applications that used the previous version of the Spark connector, see Migrating from the legacy Vertica Spark connector for instructions on how to update your Spark code to work with the new connector.

If you are still using a version of Spark earlier than 3.0, you must use the legacy version of the Spark connector. The new open source version is incompatible with older versions of Spark. You can get the older connector by downloading and extracting a Vertica installation package earlier than version 11.0.2.

In this section

- Migrating from the legacy Vertica Spark connector

Migrating from the legacy Vertica Spark connector

If you have existing Spark applications that used the closed-source Vertica Spark connector, you must update them to work with the newer open-source connector. The new connector offers new features, better performance, and is under ongoing development. The old connector has been removed from service.

Deployment changes between the old and connectors

The legacy connector was only distributed with the Vertica server install. The new connector is distributed via several channels giving you more ways to deploy it.

The new Spark connector is available from Maven Central. If you use Gradle, Maven, or SBT to manage your Spark applications, you may find it more convenient to deploy the Spark connector using a dependency rather than manually installing it on your Spark cluster. Integrating the connector into your Spark project as a dependency makes updating to newer versions of the connector easy—just update the required version in the dependency. See Getting the Connector from Maven Central for more information.

You can also download the precompiled connector assembly or build it from source. In this case, you must deploy the connector to your Spark cluster. The legacy connector depended on the Vertica JDBC driver and required that you separately include it. The new connector is an assembly that incorporates all of its dependencies, including the JDBC driver. You only need to deploy a single JAR file containing the Spark connector to your Spark cluster.

You can have Spark load both the legacy and new connector at the same time because the new connector's primary class name is different (see below). This renaming lets you add the new connector to your Spark configuration files without having to immediately port all of your Spark applications that use the legacy connector to the new API. You can just add the new assembly JAR file to spark-jars list in the spark-defaults.conf file.

API changes

There are several API changes from the legacy connector to the new connector require changes to your Spark application.

VerticaRDD class no longer supported

The legacy connector supported a class named VerticaRDD to load data from Vertica using the Spark resilient distributed dataset (RDD) feature. The new connector does not support this separate class. Instead, if you want to directly manipulate an RDD, access it through the DataFrame object you create using the DataSource API.

DefaultSource class renamed VerticaSource

The primary class in the legacy connector is named DataSource . In the new connector, this class has been renamed to VerticaSource . This renaming lets both connectors coexist, allowing you to gradually transition your Spark applications.

For your existing Spark application to use the new connector, you must change calls to the DataSource class to the VerticaSource class. For example, suppose your Spark application has this method call to read data from the legacy connector:

```
spark.read.format("com.vertica.spark.datasource.DefaultSource").options(opts).load()
```

Then to have it use the new connector, use this method call:

```
spark.read.format("com.vertica.spark.datasource.VerticaSource").options(opts).load()
```

Changed API options

In addition to renaming of the DataSource class to VerticaSource , some of the names for options for the primary connector class have changed. Other options are no longer supported. If you are porting a Spark application from the legacy to the new connector that uses one of the following options, you must update your code:

Legacy DataSource Option	New VerticaSource Option	Description
fileformat	none	The new connector does not support the fileformat option. The files that Vertica and Spark write to the intermediate storage location are always in parquet format.
hdfs_url	staging_fs_url	The location of the intermediate storage location that Vertica and Spark use to exchange data. Renamed to be more general, as the new connector supports storage platforms in addition to HDFS.
logging_level	none	The connector no longer supports setting a logging level. Instead, set the logging level in Spark.
numpartitions	num_partitions	The number of Spark partitions to use when reading data from Vertica.
target_table_ddl	target_table_sql	A SQL statement for Vertica to execute before loading data from Spark.
web_hdfs_url	staging_fs_url	Use the same option for a web HDFS URL as you would for an S3 or HDFS storage location.

In addition, the new connector has added options to support new features such as Kerberos authentication. For details on the connector's VerticaSource options API, see the Vertica Spark connector GitHub project .

Take advantage of new features

The new Vertica Spark connector offers new features that you may want to take advantage of.

Currently, the most notable new features are:

- Kerberos authentication. This feature lets you configure the connector for passwordless connections to Vertica. See the Kerberos documentation in the Vertica Spark connector GitHub project for details of using this feature.
- Support for using S3 for intermediate storage. This option lets you avoid having to set up a Hadoop cluster solely to host an HDFS storage location. See the S3 user guide at the connector GitHub site.

Voltage SecureData integration

Voltage SecureData is a suite of encryption technologies that let you integrate end-to-end data encryption into other applications. It uses Format-Preserving Encryption (FPE): the encrypted values have the same overall format as the unencrypted data. This feature means you do not have to change the data types of table columns that you want to encrypt. It also preserves reference integrity: the encrypted values have the same sort order as unencrypted data, and encrypted values can be cross-referenced between tables, as long as each instance of the value is encrypted with the same key.

See the Voltage web site for more about SecureData.

This section explains how you can integrate the SecureData encryption feature into Vertica.

In this section

- How Vertica and SecureData work together
- Requirements for integrating with SecureData
- Best practices for safe unicode FPE
- Verifying the Vertica server's access to the SecureData CA certificate
- Configuring access to SecureData
- Encrypting, decrypting, and hashing data
- Encapsulating encryption business logic with SQL macros
- Granting users access to the Voltage SecureData integration functions
- Automating encryption and decryption with access policies
- Querying eFPE encrypted columns
- Voltage SecureData integration function reference

How Vertica and SecureData work together

Vertica provides functions to encrypt and decrypt data using SecureData.

Voltage SecureData supplies a number of interfaces for applications to use its encryption: web-based APIs, command-line tools, and SDKs for C, C#, and Java. Vertica has developed a connector that calls the SecureData API that lets you:

- Encrypt sensitive data as it is being loaded into Vertica using SecueData's FPE feature. You can ensure data is stored in Vertica in its encrypted state (referred to as "encrypted at rest"). Authorized users can decrypt the data as needed. Unauthorized users only see the encrypted values. Decryption for authorized users can be automated using views or access policies. The data is transparently decrypted for them.
- Encrypt semi-sensitive data that is stored unencrypted in Vertica so unauthorized users only see a masked version of the data. You an also automate this on-the-fly encryption using access policies.

The encryption method you choose depends in the data you are processing. For example, regulations or contracts may require you to encrypt specific pieces of data. In these cases, use SecureData to encrypt your data as it is loaded, so it is never stored in an unencrypted format within Vertica.

In other cases, you may have semi-sensitive data that you can choose between the two options. In these cases, choose the method that requires the least number encryptions or decryptions (and therefore of calls to SecureData). If most of the queries on the data need to be masked from users who should not see the unencrypted values, then encrypt the data at rest. Alternatively, if the most of the queries will be from authorized users, with only occasional queries where the data should be masked, then store the data in an unencrypted format and use on-the-fly encryption to mask the data.

Requirements for integrating with SecureData

Before you can use SecureData with Vertica, you must verify the following:

- You are using version 6.0 or later of SecureData. The Vertica integration functions use APIs introduced in version 6.0 of SecureData.
- All of the nodes in your Vertica cluster are able to communicate with all of your SecureData appliance hosts. Any firewalls between your Vertica cluster and your SecureData appliance must allow connections on the ports that SecureData uses for communications. See "Ensuring Access to SecureData Services" in the *SecureData Appliance Installation Guide* for a list of the ports that SecureData uses.
- Your Vertica database is not using Federal information processing standard (FIPS) mode. FIPS is incompatible with the Voltage SecureData integration. When FIPS mode is active, the SecureData integration library is not installed by default. Do not manually install this library if you are using FIPS.
- You are following the best practices when using Safe Unicode FPE formats.

Best practices for safe unicode FPE

Starting with Voltage SecureData Simple API 6.0, you can use Safe Unicode Format Preserving Encryption (FPE) formats to encrypt and decrypt Unicode strings.

When encrypting Unicode with Safe Unicode FPE formats, the plaintext passed into the VoltageSecureProtect function is first encrypted with an alphabet of all Unicode code points, and then encoded with the Base32K-encoding to produce encrypted text in Unicode Normalization Form C (NFC). The encrypted text will generally consist of 3-byte Chinese and Japanese characters, as they account for a significant portion of the NFC-stable alphabet. VoltageSecureAccess reverses this process.

Unlike regular FPE, which handles ASCII strings consisting of single bytes, Safe Unicode FPE handles strings consisting of variable-length code points. This variability introduces an important complication: Safe Unicode FPE formats like UNICODE_BASE32K are not length-preserving. The encryption algorithm guarantees that the encrypted text will be larger than the original, and failing to account for this expansion can lead to truncated or otherwise improperly stored encrypted text, making decryption impossible.

Additionally, Unicode allows semantically equivalent characters to be encoded in different ways, which means that unnormalized, semantically equivalent plaintexts can have different forms when encrypted, compromising referential integrity. To prevent this, you should always normalize your plaintext strings into their NFC forms before encryption. For more information on Unicode normalization, see the Unicode Consortium's Normalization FAQ.

The encrypted text is guaranteed to be larger than the plaintext in the following ways:

- 16/15ths longer in character-length (rounded up)
- up to 4-times larger (in bytes)

For a list of predefined formats for Safe Unicode FPE, consult your copy of the Voltage SecureData Simple API documentation.

Checklist for safe unicode FPE

Before using Safe Unicode FPE:

- Normalize your plaintext to its NFC form before encryption.
- For fixed-length data types : remove any padding from the plaintext string.
- To store the encrypted text, ensure that the columns storing the encrypted text can handle:
  - strings 16/15ths times longer than your longest plaintext string
  - strings up to 4-times larger (in bytes) than your largest plaintext string

Verifying the Vertica server's access to the SecureData CA certificate

Before you can use SecureData with Vertica, you must verify that the root certificate authority (CA) and any intermediate certificate authority used to sign the SecureData Appliance's certificate is in the Vertica server's trust store (/opt/vertica/packages/voltagesecure/trustStore/). Vertica supplies many standard root certificates in this directory. If your SecureData Appliance uses a certificate signed by a standard CA authority, it is likely already in the trust store.

If your SecureData Appliance is using a certificate signed by your own internal CA authority , you must add this CA Certificate to the Vertica trust store.

If you are unsure whether your CA Certificate is in the Vertica trust store, follow the steps under Troubleshooting Certificate Problems to test whether the Vertica already has the CA certificate. If you are able to retrieve the client policy XML file from the SecureData Appliance, then your Vertica cluster has the correct CA certificate to access SecureData.

Adding the CA certificate to Vertica

You must add the CA to Vertica trust store before using the SecureData Integration if you used:

- Your own CA certificate to sign your SecureData Appliance's certificate.
- A third-party CA that is not in the Vertica trust store.

To add the CA certificate to the Vertica trust store, you need:

- The certificate authority (CA) file used to sign the SecureData Appliance's certificate. This file must be in Privacy Enhanced Mail (.pem) format. The file name does not matter, as long as it has the .pem extension.
- Access to the dbadmin account on the Vertica nodes. This access is required in order to copy the certificate file to trust store directory in the Vertica installation.

To add the necessary CA file to Vertica:

1. Login to one of the Vertica nodes as the dbadmin user.
2. Copy the .pem file to the /opt/vertica/packages/voltagesecure/trustStore/ directory. You only need to copy this file to a single node. Vertica takes care of distributing the file to the rest of the nodes in the cluster.
3. On the Linux command line, execute the following command to reinstall the SecureData integration library:

```
$ admintools -t install_package -d database_name -p 'password' --package voltagesecure --force-reinstall
```

When Vertica reinstalls the SecureData integration library, it copies the CA authority file to the all nodes in the cluster. After the file is distributed, all Vertica nodes can authenticate with the SecureData Appliance.

For example, suppose:

- Your certificate file is named my_ca.cert.pem , and you have copied it to the dbadmin home directory on node in your cluster.
- Your database is named VMart.

Then the process of installing the CA file would look like this:

```
$ cp my_ca.cert.pem /opt/vertica/packages/voltagesecure/trustStore/
$ admintools -t install_package -d VMart -p dbadminpassword --package voltagesecure --force-reinstall
Installing package voltagesecure...
...Success!
```

Troubleshooting certificate problems

You can test whether the Vertica trust store has the correct certificate by executing the following statement from the Linux command line:

```
curl --capath /vertica_catalog_directory/Libraries/\
$(vsql -A -t -c "SELECT sal_storage_id from user_libraries WHERE lib_name = 'VoltageSecureLib';")\
https://SecureData_applicance_hostname/policy/clientPolicy.xml
```

Where:

- *vertica_catalog_directory* is the absolute path to the Vertica catalog directory. See Understanding the catalog directory for more information about the catalog directory.
- *SecureData_appliance_hostname* is the host name of your Voltage SecureData Appliance.

For example, suppose you are connected to node0001 of the example VMart database. Also, your Voltage SecureData appliance's host name is voltage-pp-0000.example.com. Then you would use the following command to test your certificate installation.

```
$ curl --capath /home/dbadmin/VMart/v_vmart_node0001_catalog/Libraries/\
$(vsql -A -t -c "SELECT sal_storage_id from user_libraries WHERE lib_name = 'VoltageSecureLib';") \
https://voltage-pp-0000.example.com/policy/clientPolicy.xml

<clientPolicy version="2">

<server name="SecureDataAppliance" version="6.4.2.232000" />

<localDomains>example.com</localDomains>

<userWhitelist></userWhitelist>

<defaultDistrict value="0" />

<sendUniversalReader value="1" />

<messageFooterGlobal></messageFooterGlobal>

<parameterAggressiveDistricts>example.com</parameterAggressiveDistricts>

<localPolicyLocked value="0" />

<trustedDistricts></trustedDistricts>

<fallThroughDistrict>example.com</fallThroughDistrict>
    .   .   .
```

The <clientPolicy>... output (which is the content of the clientPolicy.xml file) indicates that the Vertica node was able to use its CA certificate to connect to the SecureData Appliance.

> **Tip**
> If you are unsure which Format Preserving Encryption (FPE) formats are defined in your SecureData Appliance, examine the output of the curl command. Look for the tags with formatName attributes which describe each of the formats.

If the CA certificate you installed on Vertica does not match the certificate installed on the SecureData Appliance, you will see an error similar to the following:

```
$ curl --capath /home/dbadmin/VMart/v_vmart_node0001_catalog/Libraries/$(vsql\
 -A -t -c "SELECT sal_storage_id from user_libraries WHERE lib_name = 'VoltageSecureLib';")\
 https://voltage-pp-0000.example.com/policy/clientPolicy.xml

curl: (60) Peer certificate cannot be authenticated with known CA certificates
More details here: http://curl.haxx.se/docs/sslcerts.html
```

In this case, verify that you have installed the correct CA certificate in Vertica, and that its file name has a .pem extension.

If you see other errors, such as "couldn't connect to host," verify that your firewall configuration allows your Vertica nodes to access your SecureData Appliance.

Configuring access to SecureData

The Vertica integration functions require several pieces of information in order to connect to and authenticate with SecureData.

SecureData global configuration settings

The SecureData integration has one required setting and two optional settings that you set globally using the VoltageSecureConfigureGlobal function. This function saves the settings to a configuration file named /voltagesecure/conf.global stored in the Vertica Distributed File System (DFS). This file system is used by Vertica to store data that can be accessed by all nodes. You must use the function to create this file before you use any of the other SecureData integration functions. All users who have access to the SecureData functions are able to access the settings in this file.

The one required setting is the URL of the SecureData policy file. This file provides the SecureData integration library with details of how the SecureData Appliance is configured. The library also uses this URL to determine the address of the SecureData Appliance.

The two optional settings are:

- allow_short_fpe : When set to True, SecureData ignores the lower length limit for encoding FPE values. Usually, SecureData does not use FPE to encrypt data shorter than a lower limit (usually, 8 bits). See the *SecureData Architecture Guide* 's section on Data Length Restrictions for more information.
- enable_file_cache : When set to True, Vertica caches the SecureData policy file and encryption keys to disk, rather than just to memory. Defaults to false.

This example sets the policy URL globally to https://voltage-pp-0000.example.com/policy/clientPolicy.xml and the network timeout to 200 seconds.

```
=> SELECT VoltageSecureConfigureGlobal(USING PARAMETERS
                                policy_url='https://voltage-pp-0000.example.com/policy/clientPolicy.xml',
                                NETWORK_TIMEOUT=200)
                                OVER ();

                      policy_url                       | allow_short_fpe | enable_file_cache | network_timeout
-------------------------------------------------------+-----------------+-------------------+-----------------
 https://voltage-pp-0000.example.com/policy/clientPolicy.xml     |                 |                   | 200
(1 row)
```

Manually refresh the client policy across the nodes:

```
=> SELECT VoltageSecureRefreshPolicy() OVER ();
                            PolicyRefresh
-------------------------------------------------------------------------------
Successfully refreshed policy on node [v_sandbox_node0001]. Policy on other nodes
will be refreshed the next time a Voltage operation is run on them.
(1 row)
```

Important
The SecureData integration only supports one configuration for the SecureData Appliance at a time.

SecureData user configuration settings

The remaining SecureData settings define SecureData user information. They are usually specific to each user accessing the integration functions. However, you can have all Vertica users share the same SecureData user configuration. These settings are:

- Your authentication credentials for SecureData. The exact information you need depends on your SecureData Appliance's configuration. There are four potential settings you that you can use:
  - username : a username that you use to identify yourself. Your user name is either defined by LDAP (when using LDAP authentication) or by the SecureData appliance when using shared secret authentication.
  - identity : the SecureData identity to use. See the *SecureData Administrator Guide* for more information about identities in SecureData. The identity usually takes the form of an email address. When your SecureData Appliance uses LDAP authentication, your LDAP account must have access to this identity.
  - shared_secret : a password set in SecureData.
  - password : the LDAP password to use to authenticate with SecureData.

You can supply both a username and identity, depending on the SecureData Appliance's configuration. Your SecureData Appliance can be configured to supply the identity based on your SecureData username.

However, you can only use a shared_secret or a password. If you set both parameters, the Vertica SecureData functions exit with an error.

You have two options for setting these configuration values: setting them in user-defined session parameters , or saving the values in a configuration file stored in the Vertica distributed file system.

Setting SecureDate user session parameters

Use the ALTER SESSION statement to set parameters for the voltagesecurelib library. This library contains all of the SecureData functions. The following example demonstrates configuring the session to access SecureData using shared secret authentication.

```
=> ALTER SESSION SET UDPARAMETER FOR voltagesecurelib identity='alice@example.com';
ALTER SESSION
=> ALTER SESSION SET UDPARAMETER FOR voltagesecurelib username='alice';
ALTER SESSION
=> ALTER SESSION SET UDPARAMETER FOR voltagesecurelib shared_secret='my_shared_secret';
ALTER SESSION
```

Once set, these parameters only last for the duration of your session.

Saving parameters in configuration files

You can use the VoltageSecureConfigure function to save SecureData user parameters to a configuration file in the DFS. You must supply a file name for your configuration file. You can choose to store your SecureData parameters in a user-specific file by supplying just a file name, such as securedata.conf . Behind the scenes, your configuration file is stored in DFS under a directory named for your username. This directory prevents your configuration file from conflicting with other users' files. You do not use this directory name when accessing your configuration file.

You can also store the configuration parameters in an absolute file named /voltagesecure/conf . All users who have access to the SecureData integration functions can use this configuration file in their function calls. You can use this file if all of the users accessing the SecureData functions share the same SecureData user settings.

Important
All users that have access to the VoltageSecureConfigure function can write to the global /voltagesecure/conf file. Users do not need to be able to write to this file in order to use it in calls to the other SecureData integration functions. You will usually choose to either grant users access to VoltageSecureConfigure in order to save their own configuration files, or you will use the global /voltagesecure/conf file and not grant users access to VoltageSecureConfigure.

Values in the session parameters override values in configuration files.

You call VoltageSecureConfigure with the parameters you want to save to the configuration file. Values that you do not set in this function call are not set in the configuration file. You must supply those values to the other SecureData integration functions using session parameters.

If you choose to save either the password or shared secret to your configuration file, you do not directly pass them to the VoltageSecureConfigure function. Instead, you set the value in the appropriate session variable, and then set either VoltageSecureConfigure's store_password or store_shared_secret parameter to true. When either of these parameters are true, VoltageSecureConfigure reads the value from the session variable and saves it in the configuration file.

Caution
Under normal circumstances, users are not able to directly read data from files stored in DFS. However, all users who have access to UDx functions that read from the DFS could access these files from within Vertica.

In addition, these files are stored as plain text in every node's file system. Anyone with the proper file system access on the nodes can read the file's contents.

You should take both of these facts into consideration when deciding whether to store sensitive information such as passwords or shared secrets in either the shared or per-user configuration files.

Example: creating a user-specific configuration file

The following example shows how you can create a user-specific configuration file. This example does not store information such as the password or shared secret, so you must still set session parameters for these values before you can call the other SecureData integration functions.

```
=> \x
Expanded display is on.
=> SELECT VoltageSecureConfigure(USING PARAMETERS config_dfs_path='voltage.conf',
                                 username='alice', identity='alice@example.com', store_password=false
                                ) OVER ();
-[ RECORD 1 ]-----+-----------------------------------------------------------------
config_dfs_path   | voltage.conf
identity          | alice@example.com
username          | alice
```

Encrypting, decrypting, and hashing data

Once you have set up authentication with the SecureData Appliance (SDA), call the VoltageSecureProtect and VoltageSecureAccess functions to encrypt/hash or decrypt your data, respectively. At a minimum, you pass these functions the value to be encrypted, hashed, or decrypted and value's FPE format as defined in the Voltage SDA. You can also capture these parameters in SQL Macros and access policies .

Connecting Vertica to the SecureData appliance

The following example demonstrates how to fetch the SDA client policy with Vertica and then how to set the session parameters for authentication to the SDA.

1. Add the SecureData CA certificate to Vertica .
2. Set the client policy with VoltageSecureConfigureGlobal .

```
