The **vbr** log is separate from the Vertica log. Its location is set by the **vbr** configuration parameter [tempDir](#), by default `/tmp/vbr`.

If the log has no explanation for an error or unexpected results, try increasing the logging level with the **vbr** option `--debug`:

```
vbr -t backup -c config-file --debug debug-level
```

where `debug-level` is an integer between 0 (default) and 3 (verbose), inclusive. As you increase the logging level, the file size of the log increases. For example:

```
$ vbr -t backup -c full_backup.ini --debug 3
```

Note

Scrutinize reports do not include **vbr** logs.

Check status of backup nodes

Backups fail if you run out of disk space on the backup hosts or if `vbr` cannot reach them all. Check that you have sufficient space on each backup host and that you can reach each host via ssh.

Sometimes `vbr` leaves rsync processes running on the database or backup nodes. These processes can interfere with new ones. If you get an rsync error in the console, look for runaway processes and kill them.

Common errors

Object replication fails

If you do not exclude the DOWN node, replication fails with the following error:

```
Error connecting to a destination database node on the host <hostname> : <error> ...
```

Confirm that you excluded all DOWN nodes from the object replication operation.

Error restoring an archive

You might see an error like the following when restoring an archive:

```
$ vbr --task restore --archive prd_db_20190131_183111 --config-file /home/dbadmin/backup.ini
IOError: [Errno 2] No such file or directory: '/tmp/vbr/vbr_20190131_183111_s0rpYR/prd_db.info'
```

The problem is that the archive name is not in the correct format. Specify only the date/timestamp suffix of the directory name that identifies the archive to restore, as described in [Restoring an Archive](#). For example:

```
$ vbr --task restore --archive 20190131_183111 --config-file /home/dbadmin/backup.ini
```

Backup or restore fails when using an HDFS storage location

When performing a backup of a cluster that includes HDFS storage locations, you might see an error like the following:

```
ERROR 5127: Unable to create snapshot No such file /usr/bin/hadoop:
check the HadoopHome configuration parameter
```

This error is caused by the backup script not being able to back up the HDFS storage locations. You must configure Vertica and Hadoop to enable the backup script to back up these locations. See [Requirements for backing up and restoring HDFS storage locations](#).

Object-level backup and restore are not supported with HDFS storage locations. You must use full backup and restore.

Could not connect to endpoint URL

(Eon Mode) When performing a cross-endpoint operation, you can see a connection error if you failed to specify the endpoint URL for your communal storage (`VBR_COMMUNAL_STORAGE_ENDPOINT_URL`). When the endpoint is missing but you specify credentials for communal storage, `vbr` tries to use those credentials to access AWS. This access fails, because those credentials are for your on-premises storage, not AWS. When performing cross-endpoint operations, check that all environment variables described in [Cross-Endpoint Backups in Eon Mode](#) are set correctly.

vbr reference

`vbr` can back up and restore the full database, or specific schemas and tables. It also supports a number of other backup-related tasks—for example, list the history of all backups.

`vbr` is located in the Vertica binary directory—typically, `/opt/vertica/bin/vbr`.

Syntax

```
vbr { --help | -h }
| { --task | -t } task { --config-file | -c } configfile [ option[...]]
```

Global options

The following options apply to all `vbr` tasks. For additional options, see [Task-Specific Options](#).

Option	Description
<code>--help -h</code>	Display a brief <code>vbr</code> usage guide.

<p><code>{--task -t}</code> <i>task</i></p>	<p>The vbr task to execute, one of the following:</p> <ul style="list-style-type: none"> • backup: create a full or object-level backup • collect-garbage: rebuild the backup manifest and delete any unreferenced objects in the backup location • copycluster: copy the database to another cluster (Enterprise Mode only, invalid for HDFS) • full-check: verify all objects in the backup manifest and report missing or unreferenced objects • init: prepare a new backup location • listbackup: show available backups • quick-check: confirm that all backed-up objects are in the backup manifest and report discrepancies between objects in the backup location and objects listed in the backup manifest • quick-repair: build a replacement backup manifest based on storage locations and objects • remove: remove specified restore points • replicate: copy objects from one cluster to another • restore: restore a full or object-level backup <div style="background-color: #e6f2ff; padding: 10px; margin-top: 10px;"> <p>Note</p> <p>In general, tasks cannot run concurrently, with one exception: multiple replicate tasks can run concurrently with each other, and with backup.</p> </div>
<p><code>{--config-file -c}</code> <i>path</i></p>	<p>File path of the configuration file to use for the given task.</p>
<p><code>--debug level</code></p>	<p>Level of debug messaging to the vbr log, an integer from 0 to 3 inclusive, where 0 (default) turns off debug messaging, and 3 is the most verbose level of messaging.</p>
<p><code>--nodes nodeslist</code></p>	<p>(Enterprise Mode only) Comma-delimited list of nodes on which to perform a vbr task. Listed nodes must match names in the Mapping section of the configuration file. Use this option to exclude DOWN nodes from a task, so vbr does not return with an error.</p> <div style="background-color: #ffe6e6; padding: 10px; margin-top: 10px;"> <p>Caution</p> <p>If you use <code>--nodes</code> with a backup task, be sure that the nodes list includes all UP nodes; omitting any UP node can cause data loss in that backup.</p> </div>
<p><code>--showconfig</code></p>	<p>Displays the configuration values used to perform a specific task, displayed in raw JSON format before vbr starts task execution:</p> <pre>vbr -t task -c configfile --showconfig</pre> <p><code>--showconfig</code> can also show settings for a given configuration file:</p> <pre>vbr -c configfile --showconfig</pre>

Task-specific options

Some **vbr** tasks support additional options, described in the sections that follow.

The following **vbr** tasks have no task-specific options:

- **copycluster**
- **quick-check**
- **quick-repair**

Backup

Create a [full database](#) or [object-level](#) backup, depending on configuration file settings.

Option	Description
--------	-------------

<code>--dry-run</code>	Perform a test run to evaluate impact of the backup operation—for example, its size and potential overhead.
------------------------	---

Collect-garbage

[Rebuild the backup manifest](#) and delete any unreferenced objects in the backup location.

Option	Description
<code>--report-file</code>	Output results to a delimited JSON file.

Full-check

Produce a [full backup integrity check](#) that verifies all objects in the backup manifest against file system metadata, and then outputs missing and unreferenced objects.

Option	Description
<code>--report-file</code>	Output results to a delimited JSON file.

Init

[Create a backup directory](#) or prepare an existing one for use, and create backup manifests. This task must precede the first `vbr` backup operation.

Option	Description
<code>--cloud-force-init</code>	Qualifies the <code>--task init</code> command to force the <code>init</code> task to succeed on S3 or GS storage targets when an identity/lock file mismatch occurs.
<code>--report-file</code>	Output results to a delimited JSON file.

Listbackup

[Displays backups](#) associated with the specified configuration file. Use this task to get archive (restore point) identifiers for `restore` and `remove` tasks.

Option	Description
<code>--list-all</code>	List all backups stored on the hosts and paths in the configuration file.
<code>--list-output-file filename</code>	Redirect output to the specified file.
<code>--json</code>	Use JSON delimited format.

Remove

[Remove the backup restore points](#) specified by the `--archive` option.

Option	Description
<code>--archive</code>	<p>Restore points to remove, one of the following:</p> <ul style="list-style-type: none"> <code>timestamp</code> : A single restore point to remove. <code>timestamp : timestamp</code> : A range of contiguous restore points to remove. <code>all</code> : Remove all restore points. <p>You obtain timestamp identifiers for the target restore points with the <code>listbackup</code> task. For details, see vbr listbackup.</p>

Replicate

[Copy objects](#) from one cluster to an alternate cluster. This task can run concurrently with `backup` and other `replicate` tasks.

Option	Description
<code>--archive</code>	Timestamp of the backup restore point to replicate, obtained from the <code>listbackup</code> task.
<code>--dry-run</code>	Perform a test run to evaluate impact of the replicate operation—for example, its size and potential overhead.
<code>--target-namespace</code>	<p>Eon Mode only, the namespace in the target database to which objects are replicated.</p> <p><code>vbr</code> behaves differently depending on whether the target namespace exists:</p> <ul style="list-style-type: none"> Exists: <code>vbr</code> attempts to restore or replicate the objects to the existing namespace, which must have the same shard count, shard boundaries, and node subscriptions as the source namespace. If these conditions are not met, the <code>vbr</code> task fails. Nonexistent: <code>vbr</code> creates a namespace in the target database with the name specified in <code>--target-namespace</code> and the shard count of the source namespace, and then replicates or restores the objects to that namespace. <p>If no target namespace is specified, <code>vbr</code> attempts to restore or replicate objects to a namespace with the same name as the source namespace.</p>

Restore

[Restore](#) a full or object-level database backup.

Option	Description
<code>--archive</code>	Timestamp of the backup to restore, obtained from the <code>listbackup</code> task. If omitted, <code>vbr</code> restores the latest backup of the specified configuration.
<code>--restore-objects</code>	Comma-delimited list of objects—tables and schemas—to restore from a given backup.
<code>--include-objects</code>	Comma-delimited list of database objects or patterns of objects to include from a full or object-level backup.
<code>--exclude-objects</code>	Comma-delimited list of database objects or patterns of objects to exclude from the set specified by <code>--include-objects</code> . This option can only be used together with <code>--include-objects</code> .
<code>--dry-run</code>	Perform a test run to evaluate impact of the restore operation—for example, its size and potential overhead.
<code>--target-namespace</code>	<p>Eon Mode only, the namespace in the target database to which objects are restored.</p> <p><code>vbr</code> behaves differently depending on whether the target namespace exists:</p> <ul style="list-style-type: none"> Exists: <code>vbr</code> attempts to restore or replicate the objects to the existing namespace, which must have the same shard count, shard boundaries, and node subscriptions as the source namespace. If these conditions are not met, the <code>vbr</code> task fails. Nonexistent: <code>vbr</code> creates a namespace in the target database with the name specified in <code>--target-namespace</code> and the shard count of the source namespace, and then replicates or restores the objects to that namespace. <p>If no target namespace is specified, <code>vbr</code> attempts to restore or replicate objects to a namespace with the same name as the source namespace.</p>

Note

The `--restore-objects` option and the `--include-objects` / `exclude-objects` options are mutually exclusive. You can use `--include-objects` to specify a set of objects and combine it with `--exclude-objects` to remove objects from the set.

Interrupting vbr

To cancel a backup, use Ctrl+C or send a SIGINT to the `vbr` Python process. `vbr` stops the backup process after it completes copying the data. Canceling a `vbr` backup with Ctrl+C closes the session immediately.

The files generated by an interrupted backup process remain in the target backup location directory. The next backup process picks up where the interrupted process left off.

Backup operations are atomic, so interrupting a backup operation does not affect the previous backup. The latest backup replaces the previous backup only after all other backup steps are complete.

Caution

`restore` or `copycluster` operations overwrite the database catalog directory. Interrupting either of these processes leaves the database unusable until you restart the process and allow it to finish.

- [vbr configuration file reference](#)
- [Sample vbr configuration files](#)

vbr configuration file reference

`vbr` configuration files divide backup settings into sections, under section-specific headings such as `[Database]` and `[CloudStorage]`, which contain database access and cloud storage location settings, respectively. Sections can appear in any order and can be repeated—for example, multiple `[Database]` sections.

Important

Section headings are case-sensitive.

In this section

- [\[CloudStorage\]](#)
- [\[database\]](#)
- [\[mapping\]](#)
- [\[misc\]](#)
- [\[NodeMapping\]](#)
- [\[transmission\]](#)
- [Password configuration file](#)

`[CloudStorage]`

Eon Mode only

Sets options for storing backup data on in a [supported cloud storage](#) location.

The `[CloudStorage]` and `[Mapping]` configuration sections are mutually exclusive. If you include both, the backup fails with this error message:

```
Config has conflicting sections (Mapping, CloudStorage), specify only one of them.
```

Important

The `[CloudStorage]` section replaces the now-deprecated `[S3]` section of earlier releases. Likewise, cloud storage-specific configuration variables replace the equivalent S3 configuration variables.

Do not include `[S3]` and `[CloudStorage]` sections in the same configuration file; otherwise, `vbr` will use `[S3]` configuration settings and ignore `[CloudStorage]` settings, which can yield unexpected results.

Options

`cloud_storage_backup_file_system_path`

Host and path that you are using to handle file locking during the backup process. The format is `[host]: path`. `vbr` must be able to create a [passwordless ssh connection](#) to the location that you specify here.

To use a local NFS file system, omit the host: `[]: path`.

`cloud_storage_backup_path`

Backup location. For S3-compatible or cloud locations, provide the bucket name and backup path. For HDFS locations, provide the appropriate protocol and backup path.

When you back up to cloud storage, all nodes back up to the same cloud storage bucket. You must create the backup location in the cloud storage before performing a backup. The following example specifies the backup path for S3 storage:

```
cloud_storage_backup_path = s3:// backup-bucket / database-backup-path /
```

When you back up to an HDFS location, use the `swebhdfs` protocol if you use wire encryption. Use the `webhdfs` protocol if you do not use wire encryption. The following example uses encryption:

```
cloud_storage_backup_path = swebhdfs:// backup-nameservice / database-backup-path /
```

cloud_storage_ca_bundle

Path to an SSL server certificate bundle.

Note

The key (`*pem`) file must be on the same path on all nodes of the database cluster.

For example:

```
cloud_storage_ca_bundle = / home / user / ssl-folder / ca-bundle
```

cloud_storage_concurrency_backup

The maximum number of concurrent backup threads for backup to cloud storage. For very large data volumes (greater than 10TB), you might need to reduce this value to avoid vbr failures.

Default: 10

cloud_storage_concurrency_delete

The maximum number of concurrent delete threads for deleting files from cloud storage. If the vbr configuration file contains a [CloudStorage] section, this value is set to 10 by default.

Default: 10

cloud_storage_concurrency_restore

The maximum number of concurrent restore threads for restoring from cloud storage. For very large data volumes (greater than 10TB), you might need to reduce this value to avoid vbr failures.

Default: 10

cloud_storage_encrypt_at_rest

S3 storage only. To enable at-rest encryption of your backups to S3, specify a value of `sse` . For more information, see [Encrypting Backups on Amazon S3](#) .

This value takes the following form:

```
cloud_storage_encrypt_at_rest = sse
```

cloud_storage_encrypt_transport

Boolean. If true, uses SSL encryption to encrypt data moving between your Vertica cluster and your cloud storage instance.

You must set this parameter to true if backing up or restoring from:

- Amazon EC2 cluster
- Google Cloud Storage (GCS)
- Eon Mode on-premises database with communal storage on HDFS, to use wire encryption.

Default: true

cloud_storage_sse_kms_key_id

S3 storage only. If you use Amazon Key Management Security, use this parameter to provide your key ID. If you enable encryption and do not include this parameter, vbr uses SSE-S3 encryption.

This value takes the following form:

```
cloud_storage_sse_kms_key_id = key-id
```

[database]

Sets options for accessing the database and, for replication, the destination.

Database options

dbName

Name of the database to back up. If you do not supply a database name, vbr selects the current database to back up.

OpenText recommends that you provide a database name.

dbPromptForPassword

Boolean, whether vbr prompts for a password. If set to false (no prompt at runtime), then the [dbPassword](#) parameter in the [password configuration file](#) must provide the password; otherwise, vbr prompts for one at runtime.

As a best practice, set [dbPromptForPassword](#) to false if [dbUseLocalConnection](#) is set to true.

Default: true

dbUser

Vertica user that performs vbr operations on the database operations. In the case of replicate tasks, this user is the source database user. You must be logged on as the database administrator to back up the database. The user password can be stored in the [dbPassword](#) parameter of the [password configuration file](#); otherwise, vbr prompts for one at runtime.

Default: Current user name

dbUseLocalConnection

Boolean, whether vbr accesses the target database over a local connection with the user's Vertica password. If [dbUseLocalConnection](#) is enabled, vbr can operate on a local database without the user password being set in the vbr configuration. vbr ignores the [passwordFile](#) parameter and any settings in the [password configuration file](#), including [dbPassword](#).

If [dbUseLocalConnection](#) is enabled, then an [authentication method](#) must be granted to vbr users—typically a dbadmin—where method type is set to trust, and access is set to local:

```
=> CREATE AUTHENTICATION h1 method 'trust' local;  
=> GRANT AUTHENTICATION h1 to dbadmin;
```

Default: false

Destination options

Set destination database parameters only if replicating objects on alternate clusters:

dest_dbName

Name of the destination database.

dest_dbPromptForPassword

Boolean, whether vbr prompts for the destination database password. If set to false (no prompt at runtime), then [dest_dbPassword](#) parameter in the password configuration file must provide the password; otherwise, vbr prompts for one at runtime.

dest_dbUser

Vertica user name in the destination database to use for loading replicated data. This user must have superuser privileges.

[mapping]

Enterprise Mode only

Specifies all database nodes to include in an Enterprise Mode database backup. This section also specifies the backup host and directory of each node. If objects are replicated to an alternative database, the [Mapping] section maps target database nodes to the corresponding source database backup locations.

Note

[CloudStorage] and [Mapping] configuration sections are mutually exclusive. If you include both, the backup fails.

Format

Unlike other configuration file sections, the [Mapping] section does not use named parameters. Instead, it contains entries of the following format:

```
dbNode = backupHost:backupDir
```

dbNode

Name of the database node as recognized by Vertica. This value is not the node's host name; rather, it is the name Vertica uses internally to identify the node, typically in this format:

```
v_dbname_node000 int
```

To find database node names in your cluster, query the `node_name` column of the [NODES](#) system table.

backupHost

The target host name or IP address on which to store this node's backup. `backupHost` is different from `dbNode`. The `copycluster` command uses this value to identify the target database node host name.

IPv6 addresses must be enclosed by square brackets `[]`. For example:

```
v_backup_restore_node0001 = [fdfb:dbfa:0:2000::112]:/backupdir/backup_restore.2021-06-01T16:17:57
v_backup_restore_node0002 = [fdfb:dbfa:0:2000::113]:/backupdir/backup_restore.2021-06-01T16:17:57
v_backup_restore_node0003 = [fdfb:dbfa:0:2000::114]:/backupdir/backup_restore.2021-06-01T16:17:57
```

Important

Although supported, backups to an NFS host might perform poorly, particularly on networks shared with rsync operations.

backupDir

The full path to the directory on the backup host or node where the backup will be stored. The following requirements apply this directory:

- Already exists when you run `vbr` with `--task backup`
- Writable by the user account used to run `vbr`.
- Unique to the database you are backing up. Multiple databases cannot share the same backup directory.
- File system at this location supports `fcntl lockf` file locking.

For example:

```
[Mapping]
v_sec_node0001 = pri_bsrv01:/archive/backup
v_sec_node0002 = pri_bsrv02:/archive/backup
v_sec_node0003 = pri_bsrv03:/archive/backup
```

Mapping to the local host

`vbr` does not support using `localhost` to specify a backup host. To back up a database node to its own disk, specify the host name with empty square brackets. For example:

```
[Mapping]
NodeName = []:/backup/path
```

Mapping to the same database

The following example shows a `[Mapping]` section that specifies a single node to back up: `v_vmart_node0001`. The node is assigned to backup host `srv01` and backup directory `/home/dbadmin/backups`. Although a single-node cluster is backed up, and the backup host and the database node are the same system, they are specified differently.

Specify the backup host and directory using a colon (`:`) as a separator:

```
[Mapping]
v_vmart_node0001 = srv01:/home/dbadmin/backups
```

Mapping to an alternative database

Note

Replicating objects to an alternative database requires the `vbr` configuration file to include a `[NodeMapping]` section. This section points source nodes to their target database nodes.

To restore an alternative database, add mapping information as follows:

```
[Mapping]
targetNode = backupHost:backupDir
```

For example:

[Mapping]

v_sec_node0001 = pri_bsrv01:/archive/backup

v_sec_node0002 = pri_bsrv02:/archive/backup

v_sec_node0003 = pri_bsrv03:/archive/backup

[misc]

Configures basic backup settings.

Options

passwordFile

Path name of the [password configuration file](#), ignored if [dbUseLocalConnection](#) (under [Database]) is set to true.

restorePointLimit

Number of earlier backups to retain with the most recent backup. If set to 1 (the default), Vertica maintains two backups: the latest backup and the one before it.

Note

vbr saves multiple backups to the same location, which are shared through hard links. In such cases, the [listbackup](#) task displays the common backup prefix with unique time and date suffixes: `my_archive20111111_205841`

Default: 1

snapshotName

Base name of the backup used in the directory tree structure that **vbr** creates for each node, containing up to 240 characters limited to the following:

- a-z
- A-Z
- 0-9
- Hyphen (-)
- Underscore (_)

Each iteration in this series (up to [restorePointLimit](#)) consists of `snapshotName` and the backup timestamp. Each series of backups should have a unique and descriptive snapshot name. Full and object-level backups cannot share names. For most **vbr** tasks, `snapshotName` serves as a useful identifier in diagnostics and system tables. For object restore and replication tasks, `snapshotName` is used to build schema names in coexist mode operations.

Default: `snapshotName`

tempDir

Absolute path to a temporary storage area on the cluster nodes. This path must be the same on all database cluster nodes. **vbr** uses this directory as temporary storage for log files, lock files, and other bookkeeping information while it copies files from the source cluster node to the destination backup location. **vbr** also writes backup logs to this location.

The file system at this location must support [fcntl lockf](#) (POSIX) file locking.

Caution

Do not use the same location as your database's data or catalog directory. Unexpected files and directories in your data or catalog location can cause errors during database startup or restore.

Default: `/tmp/vbr`

drop_foreign_constraints

If true, all foreign key constraints are unconditionally dropped during object-level restore. You can then restore database objects independent of their foreign key dependencies.

Important

Vertica only uses this option if [objectRestoreMode](#) is set to `coexist`.

Default: false

enableFreeSpaceCheck

If true (default) or omitted, **vbr** confirms that the specified backup locations contain sufficient free space to allow a successful backup. If a backup location has insufficient resources, **vbr** displays an error message and cancels the backup. If **vbr** cannot determine the amount of available space or number of nodes in the [backup directory](#), it displays a warning and continues with the backup.

Default: true

excludeObjects

Database objects and [wildcard](#) patterns to exclude from the set specified by `includeObjects`. Unicode characters are case-sensitive; others are not.

This parameter can be set only if [includeObjects](#) is also set.

hadoop_conf_dir

(Eon Mode on HDFS with high availability (HA) nodes only) Directory path containing the XML configuration files copied from Hadoop.

If the **vbr** operation includes more than one HA HDFS cluster, use a colon-separated list to provide the directory paths to the XML configuration files for each HA HDFS cluster. For example:

```
hadoop_conf_dir = path / to / xml-config-hahdfs1 : path / to / xml-config-hahdfs2
```

This value must match the HadoopConfDir value set in the [bootstrapping file created during installation](#).

includeObjects

Database objects and [wildcard](#) patterns to include with a backup task. You can use this parameter together with [excludeObjects](#). Unicode characters are case-sensitive; others are not.

The [includeObjects](#) and [objects](#) parameters are mutually exclusive.

kerberos_keytab_file

(Eon Mode on HDFS only) Location of the keytab file that contains credentials for the Vertica Kerberos principal.

This value must match the KerberosKeytabFile value set in the [bootstrapping file created during installation](#).

kerberos_realm

(Eon Mode on HDFS only) Realm portion of the Vertica Kerberos principal.

This value must match the KerberosRealm value set in the [bootstrapping file created during installation](#).

kerberos_service_name

(Eon Mode on HDFS only) Service name portion of the Vertica Kerberos principal.

This value must match the KerberosServiceName value set in the [bootstrapping file created during installation](#).

Default: vertica

objectRestoreMode

How **vbr** handles objects of the same name when restoring schema or table backups, one of the following:

- **createOrReplace** : **vbr** creates any objects that do not exist. If an object does exist, **vbr** overwrites it with the version from the archive.
- **create** : **vbr** creates any objects that do not exist and does not replace existing objects. If an object being restored does exist, the restore fails.
- **coexist** : **vbr** creates the restored version of each object with a name formatted as follows: *backup_timestamp_objectname*

This approach allows existing and restored objects to exist simultaneously. If the appended information pushes the schema name past the maximum length of 128 characters, Vertica truncates the name. You can perform a reverse lookup of the original schema name by querying the system table [TRUNCATED_SCHEMATA](#).

Tables named in the COPY clauses of [data loaders](#) are not changed. You can use [ALTER DATA LOADER](#) to rename target tables.

In all modes, **vbr** restores data with the current epoch. Object restore mode settings do not apply to backups and full restores.

Default: createOrReplace

objects

For an object-level backup or object replication, object (schema or table) names to include. To specify more than one object, enter multiple names in a comma-delimited list. If you specify no objects, **vbr** creates a full backup.

Important

If your Eon Mode database has multiple [namespaces](#), you must specify the namespace to which the objects belong. For **vbr** tasks, namespace names are prefixed with a period. For example, `.n.s.t` refers to table `t` in schema `s` in namespace `n`. See [Eon Mode database requirements](#) for more information.

This parameter cannot be used together with the parameters [includeObjects](#) and [excludeObjects](#).
You specify objects as follows:

- Specify table names in the form *schema . objectname* . For example, to make backups of the table **customers** from the schema **finance** , enter: **finance.customers**
If a public table and a schema have the same name, **vbr** backs up only the schema. Use the *schema . objectname* convention to avoid confusion.
- Object names can include UTF-8 alphanumeric characters. Object names cannot include escape characters, single- (') or double-quote (") characters.
- Specify non-alphanumeric characters with a backslash (\) followed by a hex value. For instance, if the table name is **my table** (**my** followed by a space character, then **table**), enter the object name as follows:
objects=my\20table
- If an object name includes a period, enclose the name with double quotes.

Tip

To identify objects with [wildcards](#) , use the [includeObjects](#) / [excludeObjects](#) parameters.

[NodeMapping]

vbr uses the node mapping section exclusively to restore objects from a backup of one database to a different database. Be sure to update the [\[Mapping\]](#) section of your configuration file to point your target database nodes to their source backup locations. The target database must have at least as many UP nodes as the source database.

Use the following format to specify node mapping: **source_node = target_node** For example, you can use the following mapping to restore content from one 4-node database to an alternate 4-node database.

```
[NodeMapping]
v_sourcedb_node0001 = v_targetdb_node0001
v_sourcedb_node0002 = v_targetdb_node0002
v_sourcedb_node0003 = v_targetdb_node0003
v_sourcedb_node0004 = v_targetdb_node0004
```

See [Restoring a database to an alternate cluster](#) for a complete example.

[transmission]

Sets options for transmitting data when using backup hosts.

Options

concurrency_backup

Maximum number of backup TCP rsync connection threads per node. To improve local and remote backup, replication, and copy cluster performance, you can increase the number of threads available to perform backups.

Increasing the number of threads allocates more CPU resources to the backup task and can, for remote backups, increase the amount of bandwidth used. The optimal value for this setting depends greatly on your specific configuration and requirements. Values higher than 16 produce no additional benefit.

Default: 1

concurrency_delete

Maximum number of delete TCP rsync connections per node. To improve local and remote restore, replication, and copycluster performance, increase the number of threads available to delete files.

Increasing the number of threads allocates more CPU resources to the delete task and can increase the amount of bandwidth used for deletes on remote backups. The optimal value for this setting depends on your specific configuration and requirements.

Default: 16

concurrency_restore

Maximum number of restore TCP rsync connections per node. To improve local and remote restore, replication, and copycluster performance, increase the number of threads available to perform restores.

Increasing the number of threads allocates more CPU resources to the restore task and can increase the amount of bandwidth used for restores of remote backups. The optimal value for this setting depends greatly on your specific configuration and requirements. Values higher than 16 produce no additional benefit.

Default: 1

copyOnHardLinkFailure

If a hard-link local backup cannot create links, copy the data instead. Copying takes longer than linking, so the default behavior is to return an error if links cannot be created on any node.

Default: false

encrypt

Whether transmitted data is encrypted while it is copied to the target backup location. Set this parameter to true only if performing a backup over an untrusted network—for example, backing up to a remote host across the Internet.

Important

Encrypting data transmission causes significant processing overhead and slows transfer. One of the processor cores of each database node is consumed during the encryption process. Use this option only if you are concerned about the security of the network used when transmitting backup data.

Omit this parameter from the configuration file for hard-link local backups. If you set both `encrypt` and `hardLinkLocal` to true in the same configuration file, vbr issues a warning and ignores `encrypt`.

Default: false

hardLinkLocal

Whether to create a full- or object-level backup using hard file links on the local file system, rather than copying database files to a remote backup host. Add this configuration parameter manually to the Transaction section of the configuration file.

For details on usage, see [Full Hardlink Backup/Restore](#).

Default: false

port_rsync

Default port number for the rsync protocol. Change this value if the default rsync port is in use on your cluster, or you need rsync to use another port to avoid a firewall restriction.

Default: 50000

serviceAccessUser

User name used for simple authentication of rsync connections. This user is neither a Linux nor Vertica user name, but rather an arbitrary identifier used by the rsync protocol. If you omit setting this parameter, rsync runs without authentication, which can create a potential security risk. If you choose to save the password, store it in the [password configuration file](#).

total_bwlimit_backup

Total bandwidth limit in KBps for backup connections. Vertica distributes this bandwidth evenly among the number of connections set in `concurrency_backup`. The default value of 0 allows unlimited bandwidth.

The total network load allowed by this value is the number of nodes multiplied by the value of this parameter. For example, a three node cluster and a `total_bwlimit_backup` value of 100 would allow 300Kbytes/sec of network traffic.

Default: 0

total_bwlimit_restore

Total bandwidth limit in KBps for restore connections. distributes this bandwidth evenly among the number of connections set in `concurrency_restore`. The default value of 0 allows unlimited bandwidth.

The total network load allowed by this value is the number of nodes multiplied by the value of this parameter. For example, a three node cluster and a `total_bwlimit_restore` value of 100 would allow 300Kbytes/sec of network traffic.

Default: 0

Password configuration file

For improved security, store passwords in a password configuration file and then restrict read access to that file. Set the [passwordFile](#) parameter in your vbr configuration file to this file.

[passwords] password settings

All password configuration parameters are inside the file's [Passwords] section.

dbPassword

Database administrator's Vertica password, used if the [dbPromptForPassword](#) parameter is false. This parameter is ignored if [dbUseLocalConnection](#) is set to true.

dest_dbPassword

Password for the dest_dbuser Vertica account, for replication tasks only.

serviceAccessPass

Password for the rsync user account.

Examples

See [Password file](#).

Failure recovery

Hardware or software issues can force nodes in your cluster to fail. In this case, the node or nodes leave the database. You must recover these failed nodes before they can rejoin the cluster and resume normal operation.

Node failure's impact on the database

Having failed nodes in your database affects how your database operates. If you have an Enterprise Mode database with [K-safety 0](#), the loss of any node causes the database to shut down. Eon Mode databases usually do not have a K-safety of 0 (see [Data integrity and high availability in an Eon Mode database](#)).

In a database in either mode with K-safety of 1 or greater, your database continues to run normally after losing a node. However, its performance is affected:

- In Enterprise Mode, another node fills in for a down node, using its copy of the down node's data. This node must perform up to twice the amount of work it usually does. Operations such as queries will take longer because the rest of the cluster waits for the node to finish.
- In Eon Mode, another node fills in for the down node. Nodes in Eon Mode databases do not maintain buddy projections like nodes in Enterprise Mode databases. The node filling in for the down node retrieves the down node's data from communal storage to process queries. It does not store that data in the depot. Having to retrieve all of the data from communal storage slows down the processing of the query, in addition to the node having to perform more work. The performance impact of the down node is usually limited to the subcluster that contains it.

Because of these performance impacts, you should recover the failed nodes as soon as possible.

If too many database nodes fail, your database loses the ability to maintain [K-safety](#) or [quorum](#). In an Eon Mode database, loss of [primary nodes](#) can also result in loss of [primary shard coverage](#). In any of these cases, your database stops normal operations to prevent data corruption. How it responds to the loss of K-safety or quorum depends on its mode:

- In Enterprise Mode, the database shuts down because it does not have access to all of its data.
- In Eon Mode, the database continues running in read-only mode. Operations that change the global catalog such as inserting data or altering table schemas fail. However, queries can run on any subcluster that still has shard coverage. See [Read-Only Mode](#).

To return your database to normal operation, you must restore the failed nodes and recover the database.

Recovery scenarios

Vertica begins the database recovery process when you restart failed nodes or the database. The mode of recovery for a K-safe database depends on the type of failure:

- One or more nodes in the database failed, but the database continued to operate normally. See [Recovery of Failed Nodes](#).
- A database administrator shut down the database cleanly after losing one or more nodes. See [Recovery After Clean Shutdown](#).
- An Eon Mode database went into read-only mode after quorum or primary shard coverage loss. See [Recovery of a Read-Only Eon Mode Database](#).
- An Enterprise Mode database shut down uncleanly due to loss of quorum or K-safety, or a database in either mode shut down due to site-wide failures. See [Recovery After Unclean Shutdown](#).

In the first three cases, nodes automatically rejoin the database after you resolve their failure; in the fourth case (unclean shutdown), you must manually intervene to recover the database. The following sections discuss these cases in greater detail.

If a recovery causes a table or schema to exceed its disk quota, the recovery proceeds anyway. You must then either reduce disk usage or increase the quota before you can perform other operations that consume disk space. For more information, see [Disk quotas](#).

Recovery of failed nodes

One or more nodes in your database have failed. However, the database maintained quorum and K-safety so it continued running without interruption.

Recover the down nodes by restarting the Vertica process on them using:

- The admintools [Restart Vertica on Host](#) option.
- The start or restart buttons on the **Manage > Subcluster** page in the Management Console. See [Starting, stopping, and restarting nodes in MC](#).

While restarted nodes recover their data from other nodes, their status is set to RECOVERING . Except for a short period at the end, the recovery phase has no effect on database transaction processing. After recovery is complete, the restarted nodes status changes to UP .

Recovery after clean shutdown

An administrator shut down the database cleanly after the loss of nodes. To recover:

1. Resolve any hardware or system problems that caused the node's host to go down.
2. Restart the database. See [Starting the database](#).

On restart, all nodes whose status was UP before the shutdown resume a status of UP . If the database contained one or more failed nodes on shutdown and they are now available, they begin the recovery process as described in the previous section.

Recovery of a read-only Eon Mode database

A database in Eon Mode has lost enough [primary nodes](#) to cause it to go into read-only mode. To return the database to normal operation, restart the failed nodes. See [Recover from Read-Only Mode](#).

Recovery after unclean shutdown

In an unclean shutdown, Vertica was not able to complete a normal shutdown process. Reasons for unclean shutdown include:

- A critical node in an Enterprise Mode database failed, leaving part of the database's data unavailable. The database immediately shuts down to prevent potential data corruption.
- A site-wide event such as a power failure caused all nodes to reboot.
- Vertica processes on the nodes exited due to a software or hardware failure.

Unclean shutdown can put the database in an inconsistent state—for example, Vertica might have been in the middle of writing data to disk at the time of failure, and this process was left incomplete. When you restart the database, Vertica determines that normal startup is not possible and uses the [Last Good Epoch](#) to determine when data was last consistent on all nodes. Vertica prompts you to accept recovery with the suggested epoch. If you accept, the database recovers and all data changes after the Last Good Epoch are lost. If you do not accept, the database does not start.

Instead of accepting the recommended epoch, you can [recover from a backup](#). You can also choose an epoch that precedes the Last Good Epoch, through the Administration Tools Advanced Menu option Roll Back Database to Last Good Epoch. This is useful in special situations—for example the failure occurs during a batch of loads, where it is easier to restart the entire batch, even though some of the work must be repeated. In most cases, you should accept the recommended epoch.

Epochs and node recovery

The checkpoint epochs (CPEs) for both the source and target projections are updated as ROS containers are moved. The start and end epochs of all storage containers, such as ROS containers, are modified to the commit epoch. When this occurs, the epochs of all columns without an actual data file rewrite advance the CPE to the commit epoch of MOVE_PARTITIONS_TO_TABLE . If any nodes are down during the partition move operation, they detect that there is storage to recover. On rejoining the cluster, the restarted nodes recover from other nodes with the correct epoch.

See [Epochs](#) for additional information about how Vertica uses epochs.

Manual recovery notes

- You can manually recover a database where up to K nodes are offline—for example, they were physically removed for repair or were not reachable at the time of recovery. When the missing nodes are restored, they recover and rejoin the cluster as described in [Recovery Scenarios](#).
- You can manually recover a database if the nodes to be restarted can supply all partition segments, even if more than K nodes remain down at startup. In this case, all data is available from the remaining cluster nodes, so the database can successfully start.
- The default setting for the HistoryRetentionTime configuration parameter is 0, so Vertica only keeps historical data when nodes are down. This setting prevents use of the [Administration tools](#) Roll Back Database to Last Good Epoch option because the [AHM](#) remains close to the current epoch and a rollback is not permitted to an epoch that precedes the AHM. If you rely on the Roll Back option to remove recently loaded data, consider setting a day-wide window to remove loaded data. For example:

```
=> ALTER DATABASE DEFAULT SET HistoryRetentionTime = 86400;
```

For more information, see [Epoch management parameters](#).

- When a node is down and manual recovery is required, it can take a full minute or longer for Vertica processes to time out while the system tries to form a cluster. Wait approximately one minute until the system returns the manual recovery prompt. Do not press CTRL-C during database startup.

In this section

- [Restarting Vertica on a host](#)

- [Restarting the database](#)
- [Recovering the cluster from a backup](#)
- [Phases of a recovery](#)
- [Epochs](#)
- [Best practices for disaster recovery](#)
- [Recovery by table](#)

Restarting Vertica on a host

When one node in a running database cluster fails, or if any files from the catalog or data directories are lost from any one of the nodes, you can check the status of failed nodes using either the Administration Tools or the Management Console.

Restarting Vertica on a host using the administration tools

1. Run [Administration tools](#).
2. From the Main Menu, select **Restart Vertica on Host** and click **OK**.
3. Select the database host you want to recover and click **OK**.

Note

You might see additional nodes in the list, which are used internally by the Administration Tools. You can safely ignore these nodes.

4. Verify recovery state by selecting **View Database Cluster State** from the **Main Menu**.

After the database is fully recovered, you can check the status at any time by selecting **View Database Cluster State** from the Administration Tools **Main Menu**.

Restarting Vertica on a host using the Management Console

1. Connect to a cluster node (or the host on which MC is installed).
2. Open a browser and [connect to MC](#) as an MC administrator.
3. On the MC **Home** page, double-click the running database under the **Recent Databases** section.
4. Within the **Overview** page, look at the node status under the Database sub-section and see if all nodes are up. The status will indicate how many nodes are up, critical, down, recovering, or other.
5. If a node is down, click **Manage** at the bottom of the page and inspect the graph. A failed node will appear in red.
6. Click the failed node to select it and in the Node List, click the **Start node** button.

Restarting the database

If you lose the Vertica process on more than one node (for example, due to power loss), or if the servers are shut down without properly shutting down the Vertica database first, the database cluster indicates that it did not shut down gracefully the next time you start it.

The database automatically detects when the cluster was last in a consistent state and then shuts down, at which point an administrator can restart it.

From the Main Menu in the [Administration tools](#):

1. Verify that the database has been stopped by clicking **Stop Database**.
A message displays: No databases owned by < *dbadmin* > are running
2. Start the database by selecting **Start Database** from the Main Menu.
3. Select the database you want to restart and click **OK**.
If you are starting the database after an unclean shutdown, messages display, which indicate that the startup failed. Press **RETURN** to continue with the recovery process.
An [epoch](#) represents committed changes to the data stored in a database between two specific points in time. When starting the database, Vertica searches for [last good epoch](#).
4. Upon determining the last good epoch, you are prompted to verify that you want to start the database from the good epoch date. Select **Yes** to continue with the recovery.

Caution

If you do not want to start from the last good epoch, you may instead restore the data from a backup and attempt to restart the database. For this to be useful, the backup must be more current than the last good epoch.

Vertica continues to initialize and recover all data prior to the last good epoch.

If recovery takes more than a minute, you are prompted to answer <Yes> or <No> to "Do you want to continue waiting?" When all the nodes' status have changed to RECOVERING or UP, selecting <No> lets you exit this screen and monitor progress via the Administration Tools Main Menu. Selecting <Yes> continues to display the database recovery window.

Note

Be sure to reload any data that was added after the last good epoch date to which you have recovered.

Recovering the cluster from a backup

To recover a cluster from a backup, refer to the following topics:

- [Backing up and restoring the database](#)
- [Restoring a database from a full backup](#)

Phases of a recovery

The phases of a Vertica recovery are the same regardless of whether you are recovering by table or node. In the case of a [recovery by table](#), tables become individually available as they complete the final phase. In the case of a recovery by node, the database objects only become available after the entire node completes recovery.

When you perform a recovery in Vertica, each recovered table goes through the following phases:

Order	Phase	Description	Lock Type
1	Historical	Vertica copies any historical data it may have missed while in a state of DOWN or INITIALIZING.	none
2	Historical Dirty	Vertica recovers any DML transactions that committed after the node or table began recovery.	none
3	Current Replay Delete	Vertica replays any delete transactions that took place during the recovery.	T-lock
4	Aggregate Projections	Vertica recovers any aggregate projections.	T-lock

After a table completes the last phase, Vertica considers it fully recovered. At this point, the table can participate in DDL and DML operations.

Epochs

An epoch represents a cutoff point of historical data within the database. The timestamp of all commits within a given epoch are equal to or less than the epoch's timestamp. Understanding epochs is useful when you need to perform the following operations:

- [Database recovery](#): Vertica uses epochs to determine the last time data was consistent across all nodes in a database cluster.
- [Execute historical queries](#): A SELECT statement that includes an *AT epoch* clause only returns data that was committed on or before the specified epoch.
- [Purge deleted data](#): Deleted data is not removed from physical storage until it is purged from the database. You can purge deleted data from the database only if it precedes the ancient history marker (AHM) epoch.

Vertica has one open epoch and any number of closed epochs, depending on your system configuration. New and updated data is written into the open epoch, and each closed epoch represents a previous commit to your database. When data is committed with a DML operation (INSERT, UPDATE, MERGE, COPY, or DELETE), Vertica writes the data, closes the open epoch, and opens a new epoch. Each row committed to the database is associated with the epoch in which it was written.

The [EPOCHS](#) system table contains information about each available closed epoch. The [epoch_close_time](#) column stores the date and time of the commit. The [epoch_number](#) column stores the corresponding epoch number:

```
=> SELECT * FROM EPOCHS;
 epoch_close_time | epoch_number
-----+-----
2020-07-27 14:29:49.687106-04 | 91
2020-07-28 12:51:53.291795-04 | 92
(2 rows)
```

Epoch milestones

As an epoch progresses through its life cycle, it reaches milestones that Vertica uses it to perform a variety of operations and maintain the state of the database. The following image generally depicts these milestones within the epoch life cycle:

Vertica defines each milestone as follows:

- Current epoch (CE): The current, open epoch that you are presently writing data to.
- Latest epoch (LE): The most recently closed epoch.
- Checkpoint epoch: Enterprise Mode only. A node-level epoch that is the latest epoch in which data is consistent across all projections on that node.
- Last good epoch (LGE): The minimum checkpoint epoch in which data is consistent across all nodes.
- Ancient history mark (AHM): The oldest epoch that contains data that is accessible by historical queries.

See [Epoch life cycle](#) for detailed information about each stage.

In this section

- [Epoch life cycle](#)
- [Managing epochs](#)
- [Configuring epochs](#)

Epoch life cycle

The epoch life cycle consists of a sequence of milestones that enable you to perform a variety of operations and manage the state of your database.

Note

Depending on your configuration, a single epoch can represent the latest epoch, last good epoch, checkpoint epoch, and ancient history mark.

Vertica provides [epoch management parameters](#) and [functions](#) so that you can retrieve and adjust epoch values. Additionally, see [Configuring epochs](#) for recommendations on how to set epochs for specific use cases.

Current epoch (CE)

The open epoch that contains all uncommitted changes that you are presently writing to the database. The current epoch is stored in the **SYSTEM** system table:

```
=> SELECT CURRENT_EPOCH FROM SYSTEM;  
CURRENT_EPOCH  
-----  
71  
(1 row)
```

The following example demonstrates how the current epoch advances when you commit data:

1. Query the **SYSTEM** systems table to return the current epoch:

```
=> SELECT CURRENT_EPOCH FROM SYSTEM;  
CURRENT_EPOCH  
-----  
71  
(1 row)
```

The current epoch is open, which means it is the epoch that you are presently writing data to.

2. Insert a row into the `orders` table:

```
=> INSERT INTO orders VALUES ('123456789', 323426, 'custacct@example.com');
OUTPUT
-----
      1
(1 row)
```

Each row of data has an implicit epoch column that stores that row's commit epoch. The row that you just inserted into the table was not committed, so the `epoch` column is blank:

```
=> SELECT epoch, orderkey, custkey, email_addrs FROM orders;
epoch | orderkey | custkey | email_addrs
-----+-----+-----+-----
      | 123456789 | 323426 | custacct@example.com
(1 row)
```

3. Commit the data, then query the table again. The committed data is associated with epoch `71`, the current epoch that was previously returned from the `SYSTEM` systems table:

```
=> COMMIT;
COMMIT
=> SELECT epoch, orderkey, custkey, email_addrs FROM orders;
epoch | orderkey | custkey | email_addrs
-----+-----+-----+-----
    71 | 123456789 | 323426 | custacct@example.com
(1 row)
```

4. Query the `SYSTEMS` table again to return the current epoch. The current epoch is 1 integer higher:

```
=> SELECT CURRENT_EPOCH FROM SYSTEM;
CURRENT_EPOCH
-----
      72
(1 row)
```

Latest epoch (LE)

The most recently closed epoch. The current epoch becomes the latest epoch after a commit operation.

The LE is the most recent epoch stored in the `EPOCHS` system table:

```
=> SELECT * FROM EPOCHS;
epoch_close_time | epoch_number
-----+-----
2020-07-27 14:29:49.687106-04 |    91
2020-07-28 12:51:53.291795-04 |    92
(2 rows)
```

Checkpoint epoch (CPE)

Valid in Enterprise Mode only. Each node has a checkpoint epoch, which is the most recent epoch in which the data on that node is consistent across all projections. When the database runs optimally, the checkpoint epoch is equal to the LE, which is always one epoch older than the current epoch.

The checkpoint epoch is used during node failure and recovery. When a single node fails, that node attempts to rebuild data beyond its checkpoint epoch from other nodes. If the failed node cannot recover data using any of those epochs, then the failed node recovers data using the checkpoint epoch.

Use `PROJECTION_CHECKPOINT_EPOCHS` to query information about the checkpoint epochs. The following query returns information about the checkpoint epoch on nodes that store the `orders` projection:

```
=> SELECT checkpoint_epoch, node_name, projection_name, is_up_to_date, would_recover, is_behind_ahm
       FROM PROJECTION_CHECKPOINT_EPOCHS WHERE projection_name ILIKE 'orders_b%';
checkpoint_epoch | node_name      | projection_name | is_up_to_date | would_recover | is_behind_ahm
-----+-----+-----+-----+-----+-----
          92 | v_vmart_node0001 | orders_b1      | t             | f             | f
          92 | v_vmart_node0001 | orders_b0      | t             | f             | f
          92 | v_vmart_node0003 | orders_b1      | t             | f             | f
          92 | v_vmart_node0003 | orders_b0      | t             | f             | f
          92 | v_vmart_node0002 | orders_b0      | t             | f             | f
          92 | v_vmart_node0002 | orders_b1      | t             | f             | f
(6 rows)
```

This query confirms that the database epochs are advancing correctly. The `would_recover` column displays an `f` when the last good epoch (LGE) is equal to the CPE because Vertica gives precedence to the LGE for recovery when possible. The `is_behind_ahm` column shows whether the checkpoint epoch is behind the AHM. Any data in an epoch that precedes the ancient history mark (AHM) is unrecoverable in case of a database or node failure.

Last good epoch (LGE)

The minimum checkpoint epoch in which data is consistent across all nodes in the cluster. Each node has an LGE, and Vertica evaluates the LGE for each node to determine the cluster LGE. The cluster's LGE is stored in the `SYSTEM` system table:

```
=> SELECT LAST_GOOD_EPOCH FROM SYSTEM;
LAST_GOOD_EPOCH
-----
          70
(1 row)
```

You can retrieve the LGE for each node by querying the expected recovery epoch:

```
=> SELECT GET_EXPECTED_RECOVERY_EPOCH();
INFO 4544: Recovery Epoch Computation:
Node Dependencies:
011 - cnt: 21
101 - cnt: 21
110 - cnt: 21
111 - cnt: 9

001 - name: v_vmart_node0001
010 - name: v_vmart_node0002
100 - name: v_vmart_node0003
Nodes certainly in the cluster:
  Node 0(v_vmart_node0001), epoch 70
  Node 1(v_vmart_node0002), epoch 70
Filling more nodes to satisfy node dependencies:
Data dependencies fulfilled, remaining nodes LGEs don't matter:
  Node 2(v_vmart_node0003), epoch 70
--
GET_EXPECTED_RECOVERY_EPOCH
-----
          70
(1 row)
```

Because the LGE is a snapshot of all of the most recent data on the disk, it is used to recover from database failure. Administration Tools uses the LGE to [manually reset the database](#). If you are [recovering from database failure](#) after an unclean shutdown, Vertica prompts you to accept recovery using the LGE during restart.

Ancient history mark (AHM)

The oldest epoch that contains data that is accessible by [historical queries](#). The AHM is stored in the `SYSTEM` system table:

```
=> SELECT AHM_EPOCH FROM SYSTEM;
AHM_EPOCH
-----
      70
(1 row)
```

Epochs that precede the AHM are unavailable for historical queries. The following example returns the AHM, and then returns an error when executing a historical query that precedes the AHM:

```
=> SELECT GET_AHM_EPOCH();
GET_AHM_EPOCH
-----
      93
(1 row)

=> AT EPOCH 92 SELECT * FROM orders;
ERROR 3183: Epoch number out of range
HINT: Epochs prior to [93] do not exist. Epochs [94] and later have not yet closed
```

The AHM advances according to your [HistoryRetentionTime](#) , [HistoryRetentionEpochs](#) , and [AdvanceAHMInterval](#) [parameter settings](#) . By default, the AHM advances every 180 seconds until it is equal with the LGE. This helps reduce the number of epochs saved to the [epoch map](#) , which reduces the catalog size. The AHM cannot advance beyond the LGE.

The AHM serves as the cutoff epoch for purging data from physical disk. As the AHM advances, the Tuple Mover [mergeout process](#) purges any deleted data that belongs to an epoch that precedes the AHM. See [Purging deleted data](#) for details about automated or manual purges.

Managing epochs

Epochs are stored in the epoch map, a catalog object that contains a list of closed epochs beginning at ancient history mark (AHM) epoch and ending at the latest epoch (LE). As the epoch map increases in size, the catalog uses more memory. Additionally, the AHM is used to determine what data is purged from disk. It is important to monitor database epochs to verify that they are advancing correctly to optimize database performance.

Monitoring epochs

When Vertica is running properly using the default Vertica settings, the ancient history mark, last good epoch (LGE), and checkpoint epoch (CPE, Enterprise Mode only) are equal to the latest epoch, or 1 less than the current epoch. This maintains control on the size of the epoch map and catalog by making sure that disk space is not used storing data that is eligible for purging. The **SYSTEM** system table stores the current epoch, last good epoch, and ancient history mark:

```
=> SELECT CURRENT_EPOCH, LAST_GOOD_EPOCH, AHM_EPOCH FROM SYSTEM;
CURRENT_EPOCH | LAST_GOOD_EPOCH | AHM_EPOCH
-----+-----+-----
      88 |      87 |      87
(1 row)
```

Vertica provides [GET_AHM_EPOCH](#) , [GET_AHM_TIME](#) , [GET_CURRENT_EPOCH](#) , and [GET_LAST_GOOD_EPOCH](#) to retrieve these epochs individually.

In Enterprise Mode, you can query the checkpoint epoch using the [PROJECTION_CHECKPOINT_EPOCHS](#) table to return the checkpoint epoch for each node in your cluster. The following query returns the CPE for any node that stores the **orders** projection:

```
=> SELECT checkpoint_epoch, node_name, projection_name
FROM PROJECTION_CHECKPOINT_EPOCHS WHERE projection_name ILIKE 'orders_b%';
checkpoint_epoch | node_name | projection_name
-----+-----+-----
      87 | v_vmart_node0001 | orders_b1
      87 | v_vmart_node0001 | orders_b0
      87 | v_vmart_node0003 | orders_b1
      87 | v_vmart_node0003 | orders_b0
      87 | v_vmart_node0002 | orders_b0
      87 | v_vmart_node0002 | orders_b1
(6 rows)
```

Troubleshooting the ancient history mark

A properly functioning AHM is critical in determining how well your database utilizes disk space and executes queries. When you commit a DELETE or UPDATE (a combination of DELETE and INSERT) operation, the data is not deleted from disk immediately. Instead, Vertica marks the data for deletion so that you can retrieve it with historical queries. Deleted data takes up space on disk and impacts query performance because Vertica must read the deleted data during non-historical queries.

Epochs advance as you commit data, and any data that is marked for deletion is automatically purged by the Tuple Mover [mergeout process](#) when its epoch advances past the AHM. You can create an automated purge policy or manually purge any deleted data that was committed in an epoch that precedes the AHM. See [Setting a purge policy](#) for additional information.

By default, the AHM advances every 180 seconds until it is equal to the LGE. Monitor the **SYSTEM** system table to ensure that the AHM is advancing according properly:

```
=> SELECT CURRENT_EPOCH, LAST_GOOD_EPOCH, AHM_EPOCH FROM SYSTEM;
CURRENT_EPOCH | LAST_GOOD_EPOCH | AHM_EPOCH
-----+-----+-----
          94 |          93 |          86
(1 row)
```

If you notice that the AHM is not advancing correctly, it might be due to one or more of the following:

- Your database contains unrefreshed projections. This occurs when you create a projection for a table that already contains data. See [Refreshing projections](#) for details on how to refresh projections.
- A node is DOWN. When a node is DOWN, the AHM cannot advance. See [Restarting Vertica on a host](#) for information on how to resolve this issue.

Caution

You can use the [MAKE_AHM_NOW](#), [SET_AHM_EPOCH](#), or [SET_AHM_TIME](#) epoch management functions to manually set the AHM to a specific epoch. If the selected epoch is later than the DOWN node's LGE, the node must recover from scratch upon restart.

- Confirm that the **AHMBackupManagement** epoch parameter is set to 0 . If this parameter is set to 1, the AHM does not advance beyond the most recent full backup:

```
=> SELECT node_name, parameter_name, current_value FROM CONFIGURATION_PARAMETERS WHERE
parameter_name='AHMBackupManagement';
node_name | parameter_name | current_value
-----+-----+-----
ALL      | AHMBackupManagement | 0
(1 row)
```

Configuring epochs

Epoch configuration impacts how your database recovers from failure, handles historical data, and purges data from disk. Vertica provides [epoch management parameters](#) for system-wide epoch configuration. [Epoch management functions](#) enable you to make ad hoc adjustments to epoch values.

Important

Epoch configuration has a significant impact on how your database functions. Make sure that you understand how epochs work before you save any configurations.

Historical query and recovery precision

When you execute a historical query, Vertica returns an epoch within the amount of time specified by the [EpochMapInterval](#) configuration parameter. For example, when you execute a historical query using the **AT TIME *time*** epoch clause, Vertica returns an epoch within the parameter setting. By default, **EpochMapInterval** is set to 180 seconds. You must set **EpochMapInterval** to a value greater than or equal to the **AdvanceAHMInterval** parameter:

```
=> SELECT node_name, parameter_name, current_value FROM CONFIGURATION_PARAMETERS
WHERE parameter_name='EpochMapInterval' OR parameter_name='AdvanceAHMInterval';
node_name | parameter_name | current_value
-----+-----+-----
ALL      | EpochMapInterval | 180
ALL      | AdvanceAHMInterval | 180
(2 rows)
```

During [failure recovery](#), Vertica uses the **EpochMapInterval** setting to determine which epoch is reported as the last good epoch (LGE).

History retention and purge workflows

Vertica recommends that you configure your epoch parameters to create a purge policy that determines when deleted data is purged from disk. If you use [historical queries](#) often, then you need to find a balance between saving deleted historical data and purging it from disk. An aggressive purge policy increases disk utilization and improves query performance, but also limits your recovery options and narrows the window of data available for historical queries.

There are two strategies to creating a purge policy:

- Set **HistoryRetentionTime** to specify how long deleted data is saved (in seconds) as an historical reference.
- Set **HistoryRetentionEpochs** to specify the number of historical epochs to save.

See [Setting a purge policy](#) for details about configuring each workflow.

Setting **HistoryRetentionTime** is the preferred method for creating a purge policy. By default, Vertica sets this value to **0**, so the AHM is 1 less than the current epoch when the database is running properly. You cannot execute historical queries on epochs that precede the AHM, so you might want to adjust this setting to save more data between the present time and the AHM. Another reason to adjust this parameter is if you use the [Roll Back Database to Last Good Epoch](#) option for manual roll backs. For example, the following command sets **HistoryRetentionTime** to 1 day (in seconds) to provide a wider range of epoch roll back options:

```
=> ALTER DATABASE vmart SET HistoryRetentionTime = 86400;
```

Vertica checks the status of your retention settings using the **AdvanceAHMInterval** setting and advances the AHM as necessary. After the AHM advances, any deleted data in an epoch that precedes the AHM is purged automatically by the Tuple Mover [mergeout process](#).

If you want to disable any purge policy and preserve all historical data, set both **HistoryRetentionTime** and **HistoryRetentionEpochs** to **-1**:

```
=> ALTER DATABASE vmart SET HistoryRetentionTime = -1;  
=> ALTER DATABASE vmart SET HistoryRetentionEpochs = -1;
```

If you do not set a purge policy, you can use [epoch management functions](#) to adjust the AHM to manually purge deleted data as needed. Manual purges are useful if you need to update or delete data uploaded by mistake. See [Manually purging data](#) for details.

Best practices for disaster recovery

To protect your database from site failures caused by catastrophic disasters, maintain an off-site replica of your database to provide a standby. In case of disaster, you can switch database users over to the standby database. The amount of data loss between a disaster and fail over to the offsite replica depends on how frequently you save a full database backup.

The solution to employ for disaster recover depends upon two factors that you must determine for your application:

- **Recovery point objective (RPO)**: How much data loss can your organization tolerate upon a disaster recovery?
- **Recovery time objective (RTO)**: How quickly do you need to recover the database following a disaster?

Depending on your RPO and RTO, Vertica recommends choosing from the following solutions:

1. **Dual-load**: During each load process for the database, simultaneously load a second database. You can achieve this easily with off-the-shelf ETL software.
2. **Periodic Incremental Backups**: Use the procedure described in [Copying the database to another cluster](#) to periodically copy the data to the target database. Remember that the script copies only files that have changed.
3. **Replication solutions provided by Storage Vendors**: Although some users have had success with SAN storage, the number of vendors and possible configurations prevent Vertica from providing support for SANs.

The following table summarizes the RPO, RTO, and the pros and cons of each approach:

	Dual Load	Periodic Incremental	Storage Replication
RPO	Up to the minute data	Up to the last backup	Recover to the minute
RTO	Available at all times	Available except when backup in progress	Available at all times

Pros	<ul style="list-style-type: none"> Standby database can have different configuration Can use the standby database for queries 	<ul style="list-style-type: none"> Built-in scripts High performance due to compressed file transfers 	Transparent to the database
Cons	<ul style="list-style-type: none"> Possibly incur additional ETL licenses Requires application logic to handle errors 	Need identical standby system	<ul style="list-style-type: none"> More expensive Media corruptions are also replicated

Recovery by table

Vertica supports node recovery on a per-table basis. Unlike node-based recovery, recovering by table makes tables available as they recover, before the node itself is completely restored. You can [prioritize your most important tables](#) so they become available as soon as possible. Recovered tables support all DDL and DML operations.

To enhance recovery speed, Vertica recovers multiple tables in parallel. The maximum number of tables recoverable at one time is set by the `MAXCONCURRENCY` parameter in the [RECOVERY resource pool](#).

After a node has fully recovered, it enables full Vertica functionality.

In this section

- [Prioritizing table recovery](#)
- [Viewing table recovery status](#)

Prioritizing table recovery

You can specify the order in which Vertica recovers tables. This feature ensures that your most critical tables become available as soon as possible. To specify the recovery order of your tables, assign an integer priority value. Tables with higher priority values recover first. For example, a table with a priority of 1000 is recovered before a table with a value of 500. Table priorities have the maximum value of a 64-bit integer.

If you do not assign a priority, or if multiple tables have the same priority, Vertica restores tables by [OID](#) order. Assign a priority with a query such as this:

```
=> SELECT set_table_recover_priority('avro_basic', '1000');
      set_table_recover_priority
-----
Table recovery priority has been set.
(1 row)
```

View assigned priorities with a query using this form: `SELECT table_name, recover_priority FROM v_catalog.tables`; The next example shows prioritized tables from the VMart sample database. In this case, the table with the highest recovery priorities are listed first (DESC). The `shipping_dimension` table has the highest priority and will be recovered first. (Example has hard Returns for display purposes.)

```
=> SELECT table_name AS Name, recover_priority from v_catalog.tables WHERE recover_priority > 1
      ORDER BY recover_priority DESC;
      Name      | recover_priority
-----+-----
shipping_dimension |      60000
warehouse_dimension |      50000
employee_dimension |      40000
vendor_dimension  |      30000
date_dimension    |      20000
promotion_dimension |      10000
iris2             |       9999
product_dimension |         10
customer_dimension |         10
(9 rows)
```

Viewing table recovery status

View general information about a recovery querying the `V_MONITOR`. [TABLE_RECOVERY_STATUS](#) table. You can also view detailed information about

the status of the recovery the table being restored by querying the V_MONITOR. [TABLE_RECOVERIES](#) table.

Collecting database statistics

The Vertica cost-based query optimizer relies on data statistics to produce query plans. If statistics are incomplete or out-of-date, the optimizer is liable to use a sub-optimal plan to execute a query.

When you query a table, the Vertica optimizer checks for statistics as follows:

1. If the table is partitioned, the optimizer checks whether the partitions required by this query have recently been analyzed. If so, it retrieves those statistics and uses them to facilitate query planning.
2. Otherwise, the optimizer uses table-level statistics, if available.
3. If no valid partition- or table-level statistics are available, the optimizer assumes uniform distribution of data values and equal storage usage for all projections.

Statistics management functions

Vertica provides two functions that generate up-to-date statistics on table data: [ANALYZE_STATISTICS](#) and [ANALYZE_STATISTICS_PARTITION](#) collect table-level and partition-level statistics, respectively. After computing statistics, the functions store them in the database catalog.

Both functions perform the following operations:

- Collect statistics using [historical queries](#) (at epoch latest) without any locks.
- Perform fast data sampling, which expedites analysis of relatively small tables with a large number of columns.
- Recognize deleted data instead of ignoring delete markers.

Vertica also provides several functions that help you management database statistics—for example, to [export](#) and [import](#) statistics, [validate](#) statistics, and [drop](#) statistics.

After you collect the desired statistics, you can run [Workload Analyzer](#) to retrieve hints about under-performing queries and their root causes, and obtain tuning recommendations.

In this section

- [Collecting table statistics](#)
- [Collecting partition statistics](#)
- [Analyzing row counts](#)
- [Canceling statistics collection](#)
- [Getting data on table statistics](#)
- [Best practices for statistics collection](#)

Collecting table statistics

[ANALYZE_STATISTICS](#) collects and aggregates data samples and storage information from all nodes that store projections of the target tables.

You can set the scope of the collection at several levels:

- [Database](#)
- [Table](#)
- [Table columns](#)

[ANALYZE_STATISTICS](#) can also control the size of the data sample that it collects.

Analyze all database tables

If [ANALYZE_STATISTICS](#) specifies no table, it collects statistics for all database tables and their projections. For example:

```
=> SELECT ANALYZE_STATISTICS ("");
ANALYZE_STATISTICS
-----
          0
(1 row)
```

Analyze a single table

You can compute statistics on a single table as follows:

```
=> SELECT ANALYZE_STATISTICS ('public.store_orders_fact');
ANALYZE_STATISTICS
```

```
-----
0
```

```
(1 row)
```

When you query system table [PROJECTION_COLUMNS](#), it confirms that statistics have been collected on all table columns for all projections of [store_orders_fact](#) :

```
=> SELECT projection_name, statistics_type, table_column_name, statistics_updated_timestamp
FROM projection_columns WHERE projection_name ilike 'store_orders_fact%' AND table_schema='public';
```

```
projection_name | statistics_type | table_column_name | statistics_updated_timestamp
```

```
-----+-----+-----+-----
store_orders_fact_b0 | FULL          | product_key      | 2019-04-04 18:06:55.747329-04
store_orders_fact_b0 | FULL          | product_version  | 2019-04-04 18:06:55.747329-04
store_orders_fact_b0 | FULL          | store_key        | 2019-04-04 18:06:55.747329-04
store_orders_fact_b0 | FULL          | vendor_key       | 2019-04-04 18:06:55.747329-04
store_orders_fact_b0 | FULL          | employee_key     | 2019-04-04 18:06:55.747329-04
store_orders_fact_b0 | FULL          | order_number     | 2019-04-04 18:06:55.747329-04
store_orders_fact_b0 | FULL          | date_ordered     | 2019-04-04 18:06:55.747329-04
store_orders_fact_b0 | FULL          | date_shipped     | 2019-04-04 18:06:55.747329-04
store_orders_fact_b0 | FULL          | quantity_ordered | 2019-04-04 18:06:55.747329-04
store_orders_fact_b0 | FULL          | shipper_name     | 2019-04-04 18:06:55.747329-04
store_orders_fact_b1 | FULL          | product_key      | 2019-04-04 18:06:55.747329-04
store_orders_fact_b1 | FULL          | product_version  | 2019-04-04 18:06:55.747329-04
...
```

```
(20 rows)
```

Analyze table columns

Within a table, you can narrow scope of analysis to a subset of its columns. Doing so can save significant processing overhead for big tables that contain many columns. It is especially useful if you frequently query these tables on specific columns.

Important

If you collect statistics on specific columns, be sure to include all columns that you are likely to query. If a query includes other columns in that table, the query optimizer regards the statistics as incomplete for that query and ignores them in its plan.

For example, instead of collecting statistics on all columns in [store_orders_fact](#), you can select only those columns that are frequently queried: [product_key](#), [product_version](#), [order_number](#), and [quantity_shipped](#) :

```
=> SELECT DROP_STATISTICS('public.store_orders_fact');
=> SELECT ANALYZE_STATISTICS ('public.store_orders_fact', 'product_key, product_version, order_number, quantity_ordered');
ANALYZE_STATISTICS
```

```
-----
0
```

```
(1 row)
```

If you query [PROJECTION_COLUMNS](#) again, it returns the following results:

```
=> SELECT projection_name, statistics_type, table_column_name, statistics_updated_timestamp
FROM projection_columns WHERE projection_name ilike 'store_orders_fact%' AND table_schema='public';
projection_name | statistics_type | table_column_name | statistics_updated_timestamp
-----+-----+-----+-----
store_orders_fact_b0 | FULL          | product_key       | 2019-04-04 18:09:40.05452-04
store_orders_fact_b0 | FULL          | product_version   | 2019-04-04 18:09:40.05452-04
store_orders_fact_b0 | ROWCOUNT     | store_key         | 2019-04-04 18:09:40.05452-04
store_orders_fact_b0 | ROWCOUNT     | vendor_key        | 2019-04-04 18:09:40.05452-04
store_orders_fact_b0 | ROWCOUNT     | employee_key      | 2019-04-04 18:09:40.05452-04
store_orders_fact_b0 | FULL          | order_number      | 2019-04-04 18:09:40.05452-04
store_orders_fact_b0 | ROWCOUNT     | date_ordered      | 2019-04-04 18:09:40.05452-04
store_orders_fact_b0 | ROWCOUNT     | date_shipped      | 2019-04-04 18:09:40.05452-04
store_orders_fact_b0 | FULL          | quantity_ordered  | 2019-04-04 18:09:40.05452-04
store_orders_fact_b0 | ROWCOUNT     | shipper_name      | 2019-04-04 18:09:40.05452-04
store_orders_fact_b1 | FULL          | product_key       | 2019-04-04 18:09:40.05452-04
store_orders_fact_b1 | FULL          | product_version   | 2019-04-04 18:09:40.05452-04
store_orders_fact_b1 | ROWCOUNT     | store_key         | 2019-04-04 18:09:40.05452-04
store_orders_fact_b1 | ROWCOUNT     | vendor_key        | 2019-04-04 18:09:40.05452-04
store_orders_fact_b1 | ROWCOUNT     | employee_key      | 2019-04-04 18:09:40.05452-04
store_orders_fact_b1 | FULL          | order_number      | 2019-04-04 18:09:40.05452-04
store_orders_fact_b1 | ROWCOUNT     | date_ordered      | 2019-04-04 18:09:40.05452-04
store_orders_fact_b1 | ROWCOUNT     | date_shipped      | 2019-04-04 18:09:40.05452-04
store_orders_fact_b1 | FULL          | quantity_ordered  | 2019-04-04 18:09:40.05452-04
store_orders_fact_b1 | ROWCOUNT     | shipper_name      | 2019-04-04 18:09:40.05452-04
(20 rows)
```

In this case, columns statistics_type is set to **FULL** only for those columns on which you ran ANALYZE_STATISTICS. The remaining table columns are set to **ROWCOUNT**, indicating that only [row statistics](#) were collected for them.

Note

ANALYZE_STATISTICS always invokes ANALYZE_ROW_COUNT on all table columns, even if ANALYZE_STATISTICS specifies a subset of those columns.

Data collection percentage

By default, Vertica collects a fixed 10-percent sample of statistical data from disk. Specifying a percentage of data to read from disk gives you more control over deciding between sample accuracy and speed.

The percentage of data you collect affects collection time and accuracy:

- A smaller percentage is faster but returns a smaller data sample, which might compromise histogram accuracy.
- A larger percentage reads more data off disk. Data collection is slower, but *a larger data sample enables greater histogram accuracy*.

For example:

Collect data on all projections for **shipping_dimension** from 20 percent of the disk:

```
=> SELECT ANALYZE_STATISTICS ('shipping_dimension', 20);
ANALYZE_STATISTICS
-----
0
(1 row)
```

Collect data from the entire disk by setting the **percent** parameter to 100:

```
=> SELECT ANALYZE_STATISTICS ('shipping_dimension', 'shipping_key', 100);
ANALYZE_STATISTICS
-----
0
(1 row)
```

Sampling size

ANALYZE_STATISTICS constructs a column histogram from a set of rows that it randomly selects from all collected data. Regardless of the percentage setting, the function always creates a statistical sample that contains up to (approximately) the smaller of:

- 2^{17} (131,072) rows
- Number of rows that fit in 1 GB of memory

If a column has fewer rows than the maximum sample size, ANALYZE_STATISTICS reads all rows from disk and analyzes the entire column.

Note

The data collected in a sample range does not indicate how data should be distributed.

The following table shows how ANALYZE_STATISTICS, when set to different percentages, obtains a statistical sample from a given column:

Number of column rows	%	Number of rows read	Number of sampled rows
<i><= max-sample-size</i>	20	All	All
400K	10	<i>max-sample-size</i>	<i>max-sample-size</i>
4000K	10	400K	<i>max-sample-size</i>

Note

When a column specified for ANALYZE_STATISTICS is first in a projection's sort order, the function reads all data from disk to avoid a biased sample.

Collecting partition statistics

[ANALYZE_STATISTICS_PARTITION](#) collects and aggregates data samples and storage information for a range of partitions in the specified table. Vertica writes the collected statistics to the database catalog.

For example, the following table stores sales data and is partitioned by order dates:

```
CREATE TABLE public.store_orders_fact
(
  product_key int,
  product_version int,
  store_key int,
  vendor_key int,
  employee_key int,
  order_number int,
  date_ordered date NOT NULL,
  date_shipped date NOT NULL,
  quantity_ordered int,
  shipper_name varchar(32)
);

ALTER TABLE public.store_orders_fact PARTITION BY date_ordered::DATE GROUP BY CALENDAR_HIERARCHY_DAY(date_ordered::DATE, 2, 2)
REORGANIZE;

ALTER TABLE public.store_orders_fact ADD CONSTRAINT fk_store_orders_product FOREIGN KEY (product_key, product_version) references
public.product_dimension (product_key, product_version);

ALTER TABLE public.store_orders_fact ADD CONSTRAINT fk_store_orders_vendor FOREIGN KEY (vendor_key) references public.vendor_dimension
(vendor_key);

ALTER TABLE public.store_orders_fact ADD CONSTRAINT fk_store_orders_employee FOREIGN KEY (employee_key) references
public.employee_dimension (employee_key);
```

At the end of each business day you might call ANALYZE_STATISTICS_PARTITION and collect statistics on all data of the latest (today's) partition:

```
=> SELECT ANALYZE_STATISTICS_PARTITION('public.store_orders_fact', CURRENT_DATE::VARCHAR(10), CURRENT_DATE::VARCHAR(10));
ANALYZE_STATISTICS_PARTITION
```

```
0
```

```
(1 row)
```

The function produces a set of fresh statistics for the most recent partition in `store.store_sales_fact`. If you query this table each morning on yesterday's sales, the optimizer uses these statistics to generate an optimized query plan:

```
=> EXPLAIN SELECT COUNT(*) FROM public.store_orders_fact WHERE date_ordered = CURRENT_DATE-1;
```

```
QUERY PLAN
```

```
QUERY PLAN DESCRIPTION:
```

```
EXPLAIN SELECT COUNT(*) FROM public.store_orders_fact WHERE date_ordered = CURRENT_DATE-1;
```

```
Access Path:
```

```
+GROUPBY NOTHING [Cost: 2, Rows: 1] (PATH ID: 1)
```

```
| Aggregates: count(*)
```

```
| Execute on: All Nodes
```

```
| +---> STORAGE ACCESS for store_orders_fact [Cost: 1, Rows: 222(PARTITION-LEVEL STATISTICS)] (PATH ID: 2)
```

```
|| Projection: public.store_orders_fact_v1_b1
```

```
|| Filter: (store_orders_fact.date_ordered = '2019-04-01'::date)
```

```
|| Execute on: All Nodes
```

Narrowing the collection scope

Like [ANALYZE_STATISTICS](#), `ANALYZE_STATISTICS_PARTITION` lets you narrow the scope of analysis to a [subset of a table's columns](#). You can also control the size of the data sample that it collects. For details on these options, see [Collecting table statistics](#).

Collecting statistics on multiple partition ranges

If you specify multiple partitions, they must be continuous. Different collections of statistics can overlap. For example, the following table `t1` is partitioned on column `c1`:

```
=> SELECT export_tables(", 't1');
export_tables
```

```
CREATE TABLE public.t1
```

```
(
  a int,
  b int,
  c1 int NOT NULL
)
```

```
PARTITION BY (t1.c1);
```

```
=> SELECT * FROM t1 ORDER BY c1;
```

```
a | b | c1
```

```
-----+-----
```

```
1 | 2 | 3
```

```
4 | 5 | 6
```

```
7 | 8 | 9
```

```
10 | 11 | 12
```

```
(4 rows)
```

Given this dataset, you can call `ANALYZE_STATISTICS_PARTITION` on `t1` twice. The successive calls collect statistics for two overlapping ranges of partition keys, 3 through 9 and 6 through 12:

```
=> SELECT drop_statistics_partition('t1', ", ");
drop_statistics_partition
```

```
-----
0
```

```
(1 row)
```

```
=> SELECT analyze_statistics_partition('t1', '3', '9');
analyze_statistics_partition
```

```
-----
0
```

```
(1 row)
```

```
=> SELECT analyze_statistics_partition('t1', '6', '12');
analyze_statistics_partition
```

```
-----
0
```

```
(1 row)
```

```
=> SELECT table_name, min_partition_key, max_partition_key, row_count FROM table_statistics WHERE table_name = 't1';
table_name | min_partition_key | max_partition_key | row_count
```

```
-----+-----+-----
t1 | 3 | 9 | 3
t1 | 6 | 12 | 3
```

```
(2 rows)
```

If two statistics collections overlap, Vertica stores only the most recent statistics for each partition range. Thus, given the previous example, Vertica uses only statistics from the second collection for partition keys 6 through 9.

Statistics that are collected for a given range of partition keys always supersede statistics that were previously collected for a subset of that range. For example, given a call to `ANALYZE_STATISTICS_PARTITION` that specifies partition keys 3 through 12, the collected statistics are a superset of the two sets of statistics collected earlier, so it supersedes both:

```
=> SELECT analyze_statistics_partition('t1', '3', '12');
analyze_statistics_partition
```

```
-----
0
```

```
(1 row)
```

```
=> SELECT table_name, min_partition_key, max_partition_key, row_count FROM table_statistics WHERE table_name = 't1';
table_name | min_partition_key | max_partition_key | row_count
```

```
-----+-----+-----
t1 | 3 | 12 | 4
```

```
(1 row)
```

Finally, `ANALYZE_STATISTICS_PARTITION` collects statistics on partition keys 3 through 6. This collection is a subset of the previous collection, so Vertica retains both sets and uses the latest statistics from each:

```
=> SELECT analyze_statistics_partition('t1', '3', '6');
analyze_statistics_partition
```

```
-----
0
```

```
(1 row)
```

```
=> SELECT table_name, min_partition_key, max_partition_key, row_count FROM table_statistics WHERE table_name = 't1';
table_name | min_partition_key | max_partition_key | row_count
```

```
-----+-----+-----
t1 | 3 | 12 | 4
t1 | 3 | 6 | 2
```

```
(2 rows)
```

ANALYZE_STATISTICS_PARTITION can collect partition-level statistics on tables where the partition expression specifies one of the following date/time functions:

- [DATE](#)
- [DATE_PART](#)
- [DATE_TRUNC](#)
- [DAY](#)
- [DAYOFMONTH](#)
- [DAYOFYEAR](#)
- [DAYS](#)
- [EXTRACT](#)
- [HOUR](#)
- [MINUTE](#)
- [MONTH](#)
- [QUARTER](#)
- [WEEK](#)
- [WEEK_ISO](#)
- [YEAR](#)
- [YEAR_ISO](#)

Requirements and restrictions

The following requirements and restrictions apply to ANALYZE_STATISTICS_PARTITION:

- The table must be partitioned and cannot contain unpartitioned data.
- The table partition expression must specify a single column. The following expressions are supported:
 - Expressions that specify only the column—that is, partition on all column values. For example:

```
PARTITION BY ship_date GROUP BY CALENDAR_HIERARCHY_DAY(ship_date, 2, 2)
```
 - If the column is a [DATE](#) or [TIMESTAMP/TIMESTAMPTZ](#), the partition expression can specify a [supported date/time function](#) that returns that column or any portion of it, such as month or year. For example, the following partition expression specifies to partition on the year portion of column `order_date` :

```
PARTITION BY YEAR(order_date)
```
 - Expressions that perform addition or subtraction on the column. For example:

```
PARTITION BY YEAR(order_date) -1
```
- The table partition expression cannot coerce the specified column to another data type.
- Vertica collects no statistics from the following projections:
 - Live aggregate and Top-K projections
 - Projections that are defined to include an SQL function within an expression

Analyzing row counts

Vertica lets you obtain row counts for projections and for external tables, through [ANALYZE_ROW_COUNT](#) and [ANALYZE_EXTERNAL_ROW_COUNT](#), respectively.

Projection row count

ANALYZE_ROW_COUNT is a lightweight operation that collects a minimal set of statistics and aggregate row counts for a projection, and saves it in the database catalog. In many cases, this data satisfies many optimizer requirements for producing optimal query plans. This operation is invoked on the following occasions:

- At the time intervals specified by configuration parameter [AnalyzeRowCountInterval](#)—by default, once a day.
- During loads. Vertica updates the catalog with the current aggregate row count data for a given table when the percentage of difference between the last-recorded aggregate projection row count and current row count exceeds the setting in configuration parameter [ARCCommitPercentage](#).
- On calls to meta-functions [ANALYZE_STATISTICS](#) and [ANALYZE_STATISTICS_PARTITION](#).

You can explicitly invoke ANALYZE_ROW_COUNT through calls to [DO_TM_TASK](#). For example:

```
=> SELECT DO_TM_TASK('analyze_row_count', 'store_orders_fact_b0');
      do_tm_task
```

```
-----
Task: row count analyze
(Table: public.store_orders_fact) (Projection: public.store_orders_fact_b0)

(1 row)
```

You can change the intervals when Vertica regularly collects row-level statistics by setting configuration parameter `AnalyzeRowCountInterval`. For example, you can change the collection interval to 1 hour (3600 seconds):

```
=> ALTER DATABASE DEFAULT SET AnalyzeRowCountInterval = 3600;
ALTER DATABASE
```

External table row count

[ANALYZE_EXTERNAL_ROW_COUNT](#) calculates the exact number of rows in an external table. The optimizer uses this count to optimize for queries that access external tables. This is especially useful when an external table participates in a join. This function enables the optimizer to identify the smaller table to use as the inner input to the join, and facilitate better query performance.

The following query calculates the exact number of rows in the external table `loader_rejects` :

```
=> SELECT ANALYZE_EXTERNAL_ROW_COUNT('loader_rejects');
ANALYZE_EXTERNAL_ROW_COUNT
-----
0
```

Canceling statistics collection

To cancel statistics collection mid analysis, execute CTRL-C on [vsq](#) or call the [INTERRUPT_STATEMENT\(\)](#) function.

If you want to remove statistics for the specified table or type, call the [DROP_STATISTICS\(\)](#) function.

Caution

After you drop statistics, it can be time consuming to regenerate them.

Getting data on table statistics

Vertica provides information about statistics for a given table and its columns and partitions in two ways:

- The query optimizer notifies you about the availability of statistics to process a given query.
- System table [PROJECTION_COLUMNS](#) shows what types of statistics are available for the table columns, and when they were last updated.

Query evaluation

During predicate selectivity estimation, the query optimizer can identify when histograms are not available or are out of date. If the value in the predicate is outside the histogram's maximum range, the statistics are stale. If no histograms are available, then no statistics are available to the plan.

When the optimizer detects stale or no statistics, such as when it encounters a column predicate for which it has no histogram, the optimizer performs the following actions:

- Displays and logs a message that you should run [ANALYZE_STATISTICS](#).
- Annotates [EXPLAIN](#)-generated query plans with a statistics entry.
- Ignores stale statistics when it generates a query plan. The optimizer uses other considerations to create a query plan, such as FK-PK constraints.

For example, the following query plan fragment shows no statistics (histograms unavailable):

```
|| |-- Outer -> STORAGE ACCESS for fact [Cost: 604, Rows: 10K (NO STATISTICS)]
```

The following query plan fragment shows that the predicate falls outside the histogram range:

```
|| |-- Outer -> STORAGE ACCESS for fact [Cost: 35, Rows: 1 (PREDICATE VALUE OUT-OF-RANGE)]
```

Statistics data in PROJECTION_COLUMNS

Two columns in system table [PROJECTION_COLUMNS](#) show the status of each table column's statistics, as follows:

- **STATISTICS_TYPE** returns the type of statistics that are available for this column, one of the following: **NONE** , **ROWCOUNT** , or **FULL** .
- **STATISTICS_UPDATED_TIMESTAMP** returns the last time statistics were collected for this column.

For example, the following sample schema defines a table named `trades`, which groups the highly-correlated columns `bid` and `ask` and stores the `stock` column separately:

```
=> CREATE TABLE trades (stock CHAR(5), bid INT, ask INT);
=> CREATE PROJECTION trades_p (
  stock ENCODING RLE, GROUPED(bid ENCODING DELTAVAL, ask))
  AS (SELECT * FROM trades) ORDER BY stock, bid;
=> INSERT INTO trades VALUES('acme', 10, 20);
=> COMMIT;
```

Query the **PROJECTION_COLUMNS** table for table `trades` :

```
=> SELECT table_name AS table, projection_name AS projection, table_column_name AS column, statistics_type, statistics_updated_timestamp AS
last_updated
  FROM projection_columns WHERE table_name = 'trades';
table | projection | column | statistics_type | last_updated
-----+-----+-----+-----+-----
trades | trades_p_b0 | stock | NONE           |
trades | trades_p_b0 | bid   | NONE           |
trades | trades_p_b0 | ask   | NONE           |
trades | trades_p_b1 | stock | NONE           |
trades | trades_p_b1 | bid   | NONE           |
trades | trades_p_b1 | ask   | NONE           |
(6 rows)
```

The `statistics_type` column returns **NONE** for all columns in the `trades` table, while `statistics_updated_timestamp` is empty because statistics have not yet been collected on this table.

Now, run **ANALYZE_STATISTICS** on the `stock` column:

```
=> SELECT ANALYZE_STATISTICS ('public.trades', 'stock');
ANALYZE_STATISTICS
-----
          0
(1 row)
```

Now, when you query **PROJECTION_COLUMNS** , it returns the following results:

```
=> SELECT table_name AS table, projection_name AS projection, table_column_name AS column, statistics_type, statistics_updated_timestamp AS
last_updated
  FROM projection_columns WHERE table_name = 'trades';
table | projection | column | statistics_type | last_updated
-----+-----+-----+-----+-----
trades | trades_p_b0 | stock | FULL           | 2019-04-03 12:00:12.231564-04
trades | trades_p_b0 | bid   | ROWCOUNT      | 2019-04-03 12:00:12.231564-04
trades | trades_p_b0 | ask   | ROWCOUNT      | 2019-04-03 12:00:12.231564-04
trades | trades_p_b1 | stock | FULL           | 2019-04-03 12:00:12.231564-04
trades | trades_p_b1 | bid   | ROWCOUNT      | 2019-04-03 12:00:12.231564-04
trades | trades_p_b1 | ask   | ROWCOUNT      | 2019-04-03 12:00:12.231564-04
(6 rows)
```

This time, the query results contain several changes:

statistics_type

- Set to **FULL** for the `stock` column, confirming that full statistics were run on this column.
- Set to **ROWCOUNT** for the `bid` and `ask` columns, confirming that **ANALYZE_STATISTICS** always invokes **ANALYZE_ROW_COUNT** on all table columns, even if **ANALYZE_STATISTICS** specifies a subset of those columns.

`statistics_updated_timestamp`

Set to the same timestamp for all columns, confirming that statistics (either full or row count) were updated on all.

Best practices for statistics collection

You should call `ANALYZE_STATISTICS` or `ANALYZE_STATISTICS_PARTITION` when one or more of following conditions are true:

- Data is bulk loaded for the first time.
- A new projection is refreshed.
- The number of rows changes significantly.
- A new column is added to the table.
- Column minimum/maximum values change significantly.
- New primary key values with referential integrity constraints are added . The primary key and foreign key tables should be re-analyzed.
- Table size notably changes relative to other tables it is joined to—for example, a table that was 50 times larger than another table is now only five times larger.
- A notable deviation in data distribution necessitates recalculating histograms—for example, an event causes abnormally high levels of trading for a particular stock.
- The database is inactive for an extended period of time.

Overhead considerations

Running `ANALYZE_STATISTICS` is an efficient but potentially long-running operation. You can run it concurrently with queries and loads in a production environment. However, the function can incur considerable overhead on system resources (CPU and memory), at the expense of queries and load operations. To minimize overhead, consider calling `ANALYZE_STATISTICS_PARTITIONS` on those partitions that are subject to significant activity—typically, the most recently loaded partitions, including the table's active partition. You can further narrow the scope of both functions by specifying a subset of the table columns—generally, those that are queried most often.

Related tools

You can diagnose and resolve many statistics-related issues by calling [ANALYZE_WORKLOAD](#), which returns tuning recommendations. If you update statistics and find that a query still performs poorly, run it through the Database Designer and choose [incremental](#) as the design type.

Using diagnostic tools

In this section

- [Determining your version of Vertica](#)
- [Collecting diagnostics: scrutinize command](#)
- [Exporting a catalog](#)
- [Exporting profiling data](#)

Determining your version of Vertica

To determine which version of Vertica is installed on a host, log in to that host and type:

```
$ rpm -qa | grep vertica
```

The command returns the name of the installed package, which contains the version and build numbers. The following example indicates that both Vertica 9.3.x and Management Console 9.3.x are running on the targeted host:

```
$ rpm -qa | grep vertica
vertica-9.3.0-0
vertica-console-9.3.0-0.x86_64
```

When you are logged in to your Vertica Analytic Database database, you can also run a query for the version only, by running the following command:

```
=> SELECT version();
       version
-----
Vertica Analytic Database v9.3.0-0
```

Collecting diagnostics: scrutinize command

The diagnostics tool `scrutinize` collects a broad range of information from a Vertica cluster. It also supports a range of options that let you control the amount and type of data that is collected. Collected data can include but is not limited to:

- Host diagnostics and configuration data

- Run-time state (number of nodes up or down)
- Log files from the installation process, the database, and the administration tools (such as, [vertica.log](#), [dbLog](#), [/opt/vertica/log/adminTools.log](#))
- Error messages
- Database design
- System table information, such as system, resources, workload, and performance
- Catalog metadata, such as system configuration parameters
- Backup information

Requirements

[scrutinize](#) requires that a cluster be configured to support the Administration Tools utility. If Administration Tools cannot run on the initiating host, then [scrutinize](#) cannot run on that host.

In this section

- [Running scrutinize](#)
- [Informational options](#)
- [Redirecting scrutinize output](#)
- [Scrutinize security](#)
- [Data collection scope](#)
- [Uploading scrutinize results](#)
- [Troubleshooting scrutinize](#)

Running scrutinize

Important

This section details the implementation of [scrutinize](#) that executes commands with [Administration Tools \(admintools\)](#). For details about running [scrutinize](#) on Kubernetes, see [VerticaScrutinize custom resource definition](#).

You can run [scrutinize](#) with the following command:

```
$ /opt/vertica/bin/scrutinize
```

Unqualified, [scrutinize](#) collects a wide range of information from all cluster nodes. It stores the results in a [.tar](#) file ([VerticaScrutinize. NumericID .tar](#)), with minimal effect on database performance. [scrutinize](#) output can help diagnose most issues and yet reduces upload size by omitting fine-grained profiling data.

Note

[scrutinize](#) is designed to collect information for troubleshooting your database and cluster. Depending on your system configuration, logs generated from running [scrutinize](#) might contain proprietary information. If you are concerned with sharing proprietary information, please remove it from the [.tar](#) file before you send it to Vertica Customer Support for assistance.

Command options

[scrutinize](#) options support the following tasks:

- [Obtain version information](#) about [scrutinize](#) and Vertica, and online help.
- [Redirect output](#).
- [Access a password-protected database](#).
- [Control the scope of data collection](#).
- [Upload results](#) to Vertica Customer Support.

Privileges

In order for [scrutinize](#) to collect data from all system tables, you must have [superuser](#) or [SYSMONITOR](#) privileges; otherwise, [scrutinize](#) collects data only from the system tables that you have privileges to access. If you run [scrutinize](#) as root when the dbadmin user exists, Vertica returns an error.

Disk space requirements

[scrutinize](#) requires temporary disk space where it can collect data before posting the final compressed ([.tar](#)) output. How much space depends on variables such as the size of the Vertica log and extracted system tables, as well as user-specified options that limit the scope of information collected. Before [scrutinize](#) runs, it verifies that the temporary directory contains at least 1 GB of space; however, the actual amount needed can be much higher.

You can redirect [scrutinize](#) output to another directory. For details, see [Redirecting scrutinize output](#).

Database specification

If multiple databases are defined on the cluster and more than one is active, or none is active, you must run `scrutinize` with one of the following options:

```
$ /opt/vertica/bin/scrutinize [--database=database | -d database]
```

If you omit this option when these conditions are true, `scrutinize` returns with an error.

Informational options

`scrutinize` supports two informational options that cannot be combined with any other options:

`--version`

Obtains the version number of the Vertica server and the `scrutinize` version number, and then exits. For example:

```
$ scrutinize --version
Scrutinize Version 12.0.2-20221107
```

`--help -h`

Lists all `scrutinize` options to the console, and then exits:

```
$ scrutinize -h
Usage: scrutinize [options]

Options:
--version      show program's version number and exit
-h, --help    show this help message and exit
-X LIST, --exclude-tasks=LIST
               Skip tasks of a particular type. Provide a comma-
               separated lists of types to skip. Types are case-
               sensitive. Possible types are: Command, File,
               VerticalLog, DC, SystemTable, CatalogObject, Query,
               UdxLog, KafkaLog, MemoryReportLog, all.
-v, --vsqloff Does -X Query, SystemTable and skips vsqll checks.
               Useful if vertica is running, but slow to respond.
-s, --local_diags Gather diagnostics for local machine only
-d DB, --database=DB Only report on database <DB>
-n HOST_LIST, --hosts=HOST_LIST
               Gather diagnostics for these hosts only. Host list
               must be a comma-separated list. Ex. host1,host2,host3
               or 'host1, host2, host3'
-m MESSAGE, --message=MESSAGE
               Reason for gathering diagnostics
-o OUTPUT_DIR, --output_dir=OUTPUT_DIR
               redirect output to somewhere other than the current
               directory
-U USERNAME, --user=USERNAME
               Specify DB user
-P PASSWORD, --password=PASSWORD
               Specify DB user password
-W, --prompt-password
               Force Scrutinize to prompt for DB user password
...
```

Redirecting `scrutinize` output

By default, `scrutinize` uses the temporary directory `/opt/vertica/tmp` execution to compile output while it executes. On completing its collection, it saves the collection to a tar file to the current directory. You can redirect `scrutinize` output with two options:

`--tmpdir= path`

Directs temporary output to the specified path, where the following requirements apply to `path` :

- The directory must have at least 1 GB of free space.

- You must have write permission to it.

--output_dir= *path*

-o *path*

Saves `scrutinize` results to a tar file in *path* . For example:

```
$ scrutinize --output_dir="/my_diagnostics"
```

Scrutinize security

`scrutinize` can specify user names and passwords as follows:

--user= *username*

-U *username*

Specifies the dbadmin user name. By default, `scrutinize` uses the user name of the invoking user.

--password= *password* -P *password*

Sets the database password as an argument to the `scrutinize` command. Use this option if the administrator account (default dbadmin) has password authentication. If you omit this option on a password-protected database, `scrutinize` returns a warning, unless the environment variable `VSQL_PASSWORD` is set.

Passwords with special characters must be enclosed with single quotes. For example:

```
$ scrutinize -P '@passWord**'
```

```
$ scrutinize --password='$password1**'
```

`-prompt-password` `-W`

Specifies to prompt users for their database password before `scrutinize` begins to collect data.

Data collection scope

`scrutinize` options let you control the scope of the data collection. You can specify the scope of the data collection according to the following criteria:

- [Amount of data](#), including its level of granularity
- [Specific nodes](#)
- Types of data to [include](#) and [exclude](#)

You can use these options singly or in combination, to achieve the desired level of granularity.

Amount of collected data

Several options let you limit how much data `scrutinize` collects:

--by-second

Collect data every second. This is the highest level of granularity when collecting from Data Collector tables.

--by-minute= *boolean-value*

Collect data every minute (if the value is true) or every hour (if the value is false).

--get-files *file-list*

Collect the specified additional files, including globs, where *file-list* is a semicolon-delimited list of files.

--include_gzlogs= *num-files*

-z *num-files*

Number of rotated log files (`vertica.log*.gz`) to include in the `scrutinize` output, or `all` .

By default, `scrutinize` includes three rotated log files.

--log-limit= *limit*

-l *limit*

How much data to collect from Vertica logs, in gigabytes, starting from the most recent log entry. By default, `scrutinize` collects unlimited log data.

Node-specific collection

By default, `scrutinize` collects data from all cluster nodes. You can specify that `scrutinize` collect from individual nodes in two ways:

--local_diags

-s

Collect diagnostics only from the host on which `scrutinize` was invoked. To collect data from multiple nodes in the cluster, use the `--hosts` option.

--hosts= *host-list*

-n *host-list*

Collect diagnostics only from the hosts specified in *host-list*, a comma-separated list of IP addresses or host names.

For example:

```
$ scrutinize --hosts=127.0.0.1,host_3,host_1
```

Types of data to include

`scrutinize` provides several options that let you specify the type of data to collect:

--debug

Collects debug information for the log.

--diag-dump

Limits the collection to database design, system tables, and Data Collector tables. Use this option to collect data to analyze system performance.

--diagnostics

Limits the collection to log file data and output from commands that are run against Vertica and its host system. Use this option to collect data to evaluate unexpected behavior in your Vertica system.

--include-ros-info

Includes ROS related information from system tables.

--no-active-queries | --with-active-queries

Whether to exclude diagnostic information from system tables and Data Collector tables about currently running queries. By default, `scrutinize` collects this information (`--with-active-queries`).

--tasks= *tasks*

-T *tasks*

Gathers diagnostics on one or more tasks, as specified in a file or JSON list. This option is typically used together with `--exclude` .

Note

Use this option only in consultation with Vertica Customer Support

--type= *type*

-t *type*

Type of diagnostics collection to perform, one of the following:

- **profiling** : Gather profiling data.
- **context** : Gather summary information.

Types of data to exclude

`scrutinize` options also let you specify the types of data to exclude from its collection:

--exclude= *tasks*

-X *tasks*

Excludes one or more types of tasks from the diagnostics collection, where *tasks* is a comma-separated list of the tasks to exclude:

- **all** : All default tasks
- **DC** : Data Collector tables
- **File** : Log files from the installation process, the database, and Administration Tools, such as `vertica.log` , `dbLog` , and `adminTools.log`
- **VerticaLog** : Vertica logs
- **CatalogObject** : Vertica catalog metadata, such as system configuration parameters
- **SystemTable** : Vertica system tables that contain information about system, resources, workload, and performance
- **Query** : Vertica meta-functions that use `vsql` to connect to the database, such as `EXPORT_CATALOG()`
- **Command** : Operating system information, such as the length of time that a node has been up

Note

This option is typically used only in consultation with your Vertica Customer Support contact.

--no-active-queries

Omits diagnostic information from system tables and Data Collector tables about currently running queries. By default, **scrutinize** always collects active query information (**--with-active-queries**).

--vsql-off

-v

Excludes **Query** and **SystemTable** tasks, which are used to connect to the database. This option can help you deal with problems that occur during an upgrade, and is typically used in the following cases:

- Vertica is running but is slow to respond.
- You haven't yet created a database but need help troubleshooting other cluster issues.

Uploading scrutinize results

scrutinize provides several options for uploading data to Vertica customer support.

Upload packaging

When you use an upload option, **scrutinize** does not bundle all output in a single tar file. Instead, each node posts its output directly to the specified URL as follows:

1. Uploads a smaller, context file, enabling Customer Support to review high-level information.
2. On completion of **scrutinize** execution, uploads the complete diagnostics collection.

Upload prerequisites

Before you run **scrutinize** with an upload option:

- Install the **cURL** program in the path for the database administrator user who is running **scrutinize** .
- Verify each node in the cluster can make an HTTP or FTP connection directly to the Internet.

Upload options

Note

Two options upload **scrutinize** output to a Vertica support-provided URL or FTP address: **--auth-upload** and **--url** . Each option authenticates the upload differently, as noted below.

--auth-upload= *url*

-A *url*

Uses your Vertica license to authenticate with the Vertica server, by uploading your customer name. Customer Support uses this information to verify your identity on receiving your uploaded file. This option requires a valid Vertica license.

--url =*url*

-u *url*

Requires *url* to include a user name and password that is supplied by Vertica Customer Support.

--message= *message*

-m *message*

Includes a message with the **scrutinize** output, where *message* is a text string, a path to a text file, or **PROMPT** to open an input stream in which to compose a message. **scrutinize** reads input until you type a period (.) on a new line. This closes the input stream, and **scrutinize** writes the message to the collected output.

The message is written in the output directory in **reason.txt** . If no message is specified, **scrutinize** generates the default message **Unknown reason for collection** . Messages typically include the following information:

- Reason for gathering/submitting diagnostics.
- Support-supplied case number and other issue-specific information, to help Vertica Customer Support identify your case and analyze the problem.

Examples

The **--auth-upload** option uses your Vertica to identify yourself:

```
$ scrutinize -U username -P 'password' --auth-upload="support-provided-url"
```

The **--url** option includes the FTP username and password, supplied by support, in the URL:

```
$ scrutinize -U username -P 'password' --url='ftp://username/password@customers.vertica.com/'
```

You can supply a message as a text string or in a text file:

```
$ scrutinize --message="re: case number #ABC-12345"  
$ scrutinize --message="/path/to/msg.txt"
```

Alternatively, you can open an input stream and type a message:

```
$ scrutinize --message=PROMPT  
Enter reason for collecting diagnostics; end with '.' on a line by itself:  
Query performance degradation noticed around 9AM EST on Saturday  
.  
Vertica Scrutinize Report  
-----  
Result Dir:      /home/dbadmin/VerticaScrutinize.20131126083311  
...
```

Troubleshooting scrutinize

The troubleshooting advice in this section can help you resolve common issues that you might encounter when using [scrutinize](#) .

Collection time is too slow

To speed up collection time, omit system tables when running an instance of [scrutinize](#) . Be aware that collecting from fewer nodes does not necessarily speed up the collection process.

Output size is too large

Output size depends on system table size and vertica log size.

To create a smaller [scrutinize](#) output, omit some system tables or truncate the vertica log. For more information, see [Narrowing the Scope of scrutinize Data Collection](#).

System tables not collected on databases with password

Running [scrutinize](#) on a password-protected database might require you to supply a user name and password:

```
$ scrutinize -U username -P 'password'
```

Exporting a catalog

When you export a catalog you can quickly move a catalog to another cluster. Exporting a catalog transfers schemas, tables, constraints, projections, and views. System tables are not exported.

Exporting catalogs can also be useful for support purposes.

See the [EXPORT_CATALOG](#) function for details.

Exporting profiling data

The diagnostics audit script gathers system table contents, design, and planning objects from a running database and exports the data into a file named `./diag_dump_<timestamp>.tar.gz` , where `<timestamp>` denotes when you ran the script.

If you run the script without parameters, you will be prompted for a database password.

Syntax

```
/opt/vertica/scripts/collect_diag_dump.sh [ -U value ] [ -w value ] [ -c ]
```

Arguments

-U *value*

User name, typically the database administrator account, dbadmin.

-w *value*

Database password.

-c

Include a compression analysis, resulting in a longer script execution time.

Example

The following command runs the audit script with all arguments:

```
$ /opt/vertica/scripts/collect_diag_dump.sh -U dbadmin -w password -c
```

Profiling database performance

You can profile database operations to evaluate performance. Profiling can deliver information such as the following:

- How much memory and how many threads each operator is allocated.
- How data flows through each operator at different points in time during query execution.
- Whether a query is network bound.

Profiling data can help provide valuable input into database design considerations, such as how best to segment and sort projections, or facilitate better distribution of data processing across the cluster.

For example, profiling can show data skew, where some nodes process more data than others. The **rows produced** counter in system table [EXECUTION_ENGINE_PROFILES](#) shows how many rows were processed by each operator. Comparing **rows produced** across all nodes for a given operator can reveal whether a data skew problem exists.

The topics in this section focus on obtaining profile data with vsql statements. You can also view profiling data in the [Management Console](#).

In this section

- [Enabling profiling](#)
- [Profiling single statements](#)
- [Labeling statements](#)
- [Real-time profiling](#)
- [Profiling query resource consumption](#)
- [Profiling query plans](#)
- [Sample views for counter information](#)

Enabling profiling

You can enable profiling at three scopes:

- [Globally across all database sessions](#)
- [The current session](#)
- [Individual SQL statements](#)

Vertica meta-function [SHOW_PROFILING_CONFIG](#) shows whether profiling is enabled at global and session scopes. In the following example, the function shows that profiling is disabled across all categories for the current session, and enabled globally across all categories:

```
=> SELECT SHOW_PROFILING_CONFIG();
SHOW_PROFILING_CONFIG
-----
Session Profiling: Session off, Global on
EE Profiling:      Session off, Global on
Query Profiling:  Session off, Global on
(1 row)
```

Global profiling

When global profiling is enabled or disabled for a given category, that setting persists across all database sessions. You set global profiling with [ALTER DATABASE](#), as follows:

```
ALTER DATABASE db-spec SET profiling-category = {0 | 1}
```

profiling-category specifies a profiling category with one of the following arguments:

Argument	Data profiled
----------	---------------

GlobalQueryProfiling	Query-specific information, such as query string and duration of execution, divided between two system tables: <ul style="list-style-type: none"> • QUERY_PLAN_PROFILES : Real-time status for each query plan path. • QUERY_PROFILES : Query information.
GlobalSessionProfiling	General information about query execution on each node during the current session, stored in system table SESSION_PROFILES .
GlobalEETProfiling	Execution engine data, saved in system tables QUERY_CONSUMPTION and EXECUTION_ENGINE_PROFILES .

For example, the following statement globally enables query profiling on the current (**DEFAULT**) database:

```
=> ALTER DATABASE DEFAULT SET GlobalQueryProfiling = 1;
```

Session profiling

Session profiling can be enabled for the current session, and persists until you explicitly disable profiling, or the session ends. You set session profiling with the following Vertica meta-functions:

- [ENABLE_PROFILING](#) (*profiling-type*)
- [DISABLE_PROFILING](#) (*profiling-type*)

profiling-type specifies type of profiling data to enable or disable with one of the following arguments:

Argument	Data profiled
query	Query-specific information, such as query string and duration of execution, divided between two system tables: <ul style="list-style-type: none"> • QUERY_PLAN_PROFILES : Real-time status for each query plan path. • QUERY_PROFILES : Query information.
session	General information about query execution on each node during the current session, stored in system table SESSION_PROFILES .
ee	Execution engine data, saved in system tables QUERY_CONSUMPTION and EXECUTION_ENGINE_PROFILES .

For example, the following statement enables session-scoped profiling for the execution run of each query:

```
=> SELECT ENABLE_PROFILING('ee');
ENABLE_PROFILING
-----
EE Profiling Enabled
(1 row)
```

Statement profiling

You can enable profiling for individual SQL statements by prefixing them with the keyword [PROFILE](#). You can profile a **SELECT** statement, or any DML statement such as [INSERT](#), [UPDATE](#), [COPY](#), and [MERGE](#). For detailed information, see [Profiling single statements](#).

Precedence of profiling scopes

Vertica checks session and query profiling at the following scopes in descending order of precedence:

1. Statement profiling (highest)
2. Session profiling (ignored if global profiling is enabled)
3. Global profiling (lowest)

Regardless of query and session profiling settings, Vertica always saves a minimum amount of profiling data in the pertinent system tables: [QUERY_PROFILES](#), [QUERY_PLAN_PROFILES](#), and [SESSION_PROFILES](#).

For execution engine profiling, Vertica first checks the setting of configuration parameter [SaveDCEETProfileThresholdUS](#). If the query runs longer than the specified threshold (by default, 60 seconds), Vertica gathers execution engine data for that query and saves it to system tables [QUERY_CONSUMPTION](#) and [EXECUTION_ENGINE_PROFILES](#). Vertica uses profiling settings of other scopes (statement, session, global) only if the query's duration is below the threshold.

Important

To disable or minimize execution engine profiling:

- Set [SaveDCEEPProfileThresholdUS](#) to a very high value, up to its maximum value of 2147483647 ($2^{31} - 1$, or ~35.79 minutes).
- Disable profiling at session and global scopes.

Profiling single statements

To profile a single statement, prefix it with [PROFILE](#). You can profile a query ([SELECT](#)) statement, or any DML statement such as [INSERT](#), [UPDATE](#), [COPY](#), and [MERGE](#). The statement returns with a profile summary:

- Profile identifiers [transaction_id](#) and [statement_id](#)
- Initiator memory for the query
- Total memory required

For example:

```
=> PROFILE SELECT customer_name, annual_income FROM public.customer_dimension
  WHERE (customer_gender, annual_income) IN (SELECT customer_gender, MAX(annual_income)
  FROM public.customer_dimension GROUP BY customer_gender);NOTICE 4788: Statement is being profiled
HINT: Select * from v_monitor.execution_engine_profiles where transaction_id=45035996274760535 and statement_id=1;
NOTICE 3557: Initiator memory for query: [on pool general: 2783428 KB, minimum: 2312914 KB]
NOTICE 5077: Total memory required by query: [2783428 KB]
 customer_name | annual_income
-----+-----
James M. McNulty |    999979
Emily G. Vogel   |    999998
(2 rows)
```

You can use the profile identifiers [transaction_id](#) and [statement_id](#) to obtain detailed profile information for this query from system tables [EXECUTION_ENGINE_PROFILES](#) and [QUERY_PLAN_PROFILES](#). You can also use these identifiers to obtain resource consumption data from system table [QUERY_CONSUMPTION](#).

For example:

```
=> SELECT path_id, path_line::VARCHAR(68), running_time FROM v_monitor.query_plan_profiles
  WHERE transaction_id=45035996274760535 AND statement_id=1 ORDER BY path_id, path_line_index;
 path_id |          path_line          | running_time
-----+-----+-----
 1 | +-JOIN HASH [Semi] [Cost: 631, Rows: 25K (NO STATISTICS)] (PATH ID: | 00:00:00.052478
 1 | | Join Cond: (customer_dimension.customer_gender = VAL(2)) AND (cus |
 1 | | Materialize at Output: customer_dimension.customer_name      |
 1 | | Execute on: All Nodes                                         |
 2 | | +- Outer -> STORAGE ACCESS for customer_dimension [Cost: 30, Rows | 00:00:00.051598
 2 | | | Projection: public.customer_dimension_b0                    |
 2 | | | Materialize: customer_dimension.customer_gender, customer_d |
 2 | | | Execute on: All Nodes                                         |
 2 | | | Runtime Filters: (SIP1(HashJoin): customer_dimension.custom |
 4 | | +----> GROUPBY HASH (GLOBAL RESEGMENT GROUPS) (LOCAL RESEGMENT GR | 00:00:00.050566
 4 | | | Aggregates: max(customer_dimension.annual_income)          |
 4 | | | Group By: customer_dimension.customer_gender                |
 4 | | | Execute on: All Nodes                                         |
 5 | | | +----> STORAGE ACCESS for customer_dimension [Cost: 30, Rows: 5 | 00:00:00.09234
 5 | | | | Projection: public.customer_dimension_b0                  |
 5 | | | | Materialize: customer_dimension.customer_gender, custom |
 5 | | | | Execute on: All Nodes                                         |
(17 rows)
```

Labeling statements

To quickly identify queries and other operations for profiling and debugging purposes, include the [LABEL](#) hint.

LABEL hints are valid in the following statements:

- [COPY](#)
- [DELETE](#)
- EXPORT statements:
 - [EXPORT TO DELIMITED](#)
 - [EXPORT TO ORC](#)
 - [EXPORT TO PARQUET](#)
 - [EXPORT TO VERTICA](#)
- [INSERT](#)
- [MERGE](#)
- [SELECT](#)
- [UPDATE](#)
- [UNION](#): Valid in the UNION's first SELECT statement. Vertica ignores labels in subsequent SELECT statements.

For example:

```
SELECT /*+label(myselectquery)*/ COUNT(*) FROM t;  
INSERT /*+label(myinsertquery)*/ INTO t VALUES(1);
```

After you add a label to one or more statements, query the [QUERY_PROFILES](#) system table to see which queries ran with your supplied labels. The QUERY_PROFILES system table IDENTIFIER column returns the user-defined label that you previously assigned to a statement. You can also obtain other query-specific data that can be useful for querying other system tables, such as transaction IDs.

For example:

```
=> SELECT identifier, query FROM query_profiles;  
  identifier | query  
-----+-----  
myselectquery | SELECT /*+label(myselectquery)*/ COUNT(*) FROM t;  
myinsertquery | INSERT /*+label(myinsertquery)*/ INTO t VALUES(1);  
myupdatequery | UPDATE /*+label(myupdatequery)*/ t SET a = 2 WHERE a = 1;  
mydeletequery | DELETE /*+label(mydeletequery)*/ FROM t WHERE a = 1;  
              | SELECT identifier, query from query_profiles;  
(5 rows)
```

Real-time profiling

You can monitor long-running queries while they execute by querying system table [EXECUTION_ENGINE_PROFILES](#). This table contains available profiling counters for internal operations and user statements. You can use the Linux `watch` command to query this table at frequent intervals.

Queries for real-time profiling data require a transaction ID. If the transaction executes multiple statements, the query also requires a statement ID to identify the desired statement. If you [profile individual queries](#), the query returns with the statement's transaction and statement IDs. You can also obtain transaction and statement IDs from the [SYSTEM_SESSIONS](#) system table.

Profiling counters

The [EXECUTION_ENGINE_PROFILES](#) system table contains available profiling counters for internal operations and user statements. Real-time profiling counters are available for all statements while they execute, including internal operations such as [mergeout](#), [recovery](#), and [refresh](#). Unless you explicitly enable profiling using the keyword **PROFILE** on a specific SQL statement, or generally [enable profiling](#) for the database and/or the current session, profiling counters are unavailable after the statement completes.

Useful counters include:

- Execution time (μ s)
- Rows produced
- Total merge phases
- Completed merge phases
- Current size of temp files (bytes)

You can view all available counters by querying [EXECUTION_ENGINE_PROFILES](#):

```
=> SELECT DISTINCT(counter_name) FROM EXECUTION_ENGINE_PROFILES;
```

To monitor the profiling counters, you can run a command like the following using a retrieved transaction ID (`a00000000027`):

```
=> SELECT * FROM execution_engine_profiles
WHERE TO_HEX(transaction_id)='a00000000027'
AND counter_name = 'execution time (us)'
ORDER BY node_name, counter_value DESC;
```

The following example finds operators with the largest execution time on each node:

```
=> SELECT node_name, operator_name, counter_value execution_time_us FROM V_MONITOR.EXECUTION_ENGINE_PROFILES WHERE
counter_name='execution time (us)' LIMIT 1 OVER(PARTITION BY node_name ORDER BY counter_value DESC);
```

```
node_name | operator_name | execution_time_us
-----+-----+-----
v_vmart_node0001 | Join | 131906
v_vmart_node0002 | Join | 227778
v_vmart_node0003 | NetworkSend | 524080
(3 rows)
```

Linux watch command

You can use the Linux [watch](#) command to monitor long-running queries at frequent intervals. Common use cases include:

- Observing executing operators within a query plan on each Vertica cluster node.
- Monitoring workloads that might be unbalanced among cluster nodes—for example, some nodes become idle while others are active. Such imbalances might be caused by data skews or by hardware issues.

In the following example, [watch](#) queries operators with the largest execution time on each node. The command specifies to re-execute the query each second:

```
watch -n 1 -d "vsq1 VMart -c"SELECT node_name, operator_name, counter_value execution_time_us
FROM v_monitor.execution_engine_profiles WHERE counter_name='execution time (us)'
LIMIT 1 OVER(PARTITION BY node_name ORDER BY counter_value DESC);
```

Every 1.0s: vsq1 VMart -c"SELECT node_name, operator_name, counter_value execution_time_us FROM v_monitor.execu... Thu Jan 21 15:00:44 2016

```
node_name | operator_name | execution_time_us
-----+-----+-----
v_vmart_node0001 | Root | 110266
v_vmart_node0002 | UnionAll | 38932
v_vmart_node0003 | Scan | 22058
(3 rows)
```

Profiling query resource consumption

Vertica collects data on resource usage of all queries—including those that fail—and summarizes this data in system table [QUERY_CONSUMPTION](#).

This data includes the following information about each query:

- Wall clock duration
- CPU cycles consumed
- Memory reserved and allocated
- Network bytes sent and received
- Disk bytes read and written
- Bytes spilled
- Threads allocated
- Rows output to client
- Rows read and written

You can obtain information about individual queries through their transaction and statement IDs. Columns [TRANSACTION_ID](#) and [STATEMENT_ID](#) provide a unique key to each query statement.

Note

One exception applies: a query with multiple plans has a record for each plan.

For example, the following query is profiled:

```
=> PROFILE SELECT pd.category_description AS 'Category', SUM(sf.sales_quantity*sf.sales_dollar_amount) AS 'Total Sales'
FROM store.store_sales_fact sf
JOIN public.product_dimension pd ON pd.product_version=sf.product_version AND pd.product_key=sf.product_key
GROUP BY pd.category_description;
NOTICE 4788: Statement is being profiled
HINT: Select * from v_monitor.execution_engine_profiles where transaction_id=45035996274751822 and statement_id=1;
NOTICE 3557: Initiator memory for query: [on pool general: 256160 KB, minimum: 256160 KB]
NOTICE 5077: Total memory required by query: [256160 KB]
```

Category	Total Sales
Non-food	1147919813
Misc	1158328131
Medical	1155853990
Food	4038220327

(4 rows)

You can use the transaction and statement IDs that Vertica returns to get profiling data from [QUERY_CONSUMPTION](#) —for example, the total number of bytes sent over the network for a given query:

```
=> SELECT NETWORK_BYTES_SENT FROM query_consumption WHERE transaction_id=45035996274751822 AND statement_id=1;
NETWORK_BYTES_SENT
-----
757745
(1 row)
```

Note

[QUERY_CONSUMPTION](#) saves data from all queries, whether explicitly profiled or not.

QUERY_CONSUMPTION versus EXECUTION_ENGINE_PROFILES

[QUERY_CONSUMPTION](#) includes data that it rolls up from counters in [EXECUTION_ENGINE_PROFILES](#). In the previous example, [NETWORK_BYTES_SENT](#) rolls up data that is accessible through multiple counters in [EXECUTION_ENGINE_PROFILES](#). The equivalent query on [EXECUTION_ENGINE_PROFILES](#) looks like this:

```
=> SELECT operator_name, counter_name, counter_tag, SUM(counter_value) FROM execution_engine_profiles
WHERE transaction_id=45035996274751822 AND statement_id=1 AND counter_name='bytes sent'
GROUP BY ROLLUP (operator_name, counter_name, counter_tag) ORDER BY 1,2,3, GROUPING_ID();
operator_name | counter_name | counter_tag | SUM
-----+-----+-----+-----
NetworkSend | bytes sent | Net id 1000 - v_vmart_node0001 | 252471
NetworkSend | bytes sent | Net id 1000 - v_vmart_node0002 | 251076
NetworkSend | bytes sent | Net id 1000 - v_vmart_node0003 | 253717
NetworkSend | bytes sent | Net id 1001 - v_vmart_node0001 | 192
NetworkSend | bytes sent | Net id 1001 - v_vmart_node0002 | 192
NetworkSend | bytes sent | Net id 1001 - v_vmart_node0003 | 0
NetworkSend | bytes sent | Net id 1002 - v_vmart_node0001 | 97
NetworkSend | bytes sent | | 757745
NetworkSend | | | 757745
| | | 757745
(10 rows)
```

[QUERY_CONSUMPTION](#) and [EXECUTION_ENGINE_PROFILES](#) also differ as follows:

- [QUERY_CONSUMPTION](#) saves data from all queries, no matter their duration or whether they are explicitly profiled. It also includes data on unsuccessful queries.
- [EXECUTION_ENGINE_PROFILES](#) only includes data from queries whose length of execution exceeds a set threshold, or that you explicitly profile. It also excludes data of unsuccessful queries.

Profiling query plans

To monitor real-time flow of data through a query plan and its individual [paths](#), query the following system tables:

[EXECUTION_ENGINE_PROFILES](#) and [QUERY_PLAN_PROFILES](#). These tables provides data on how Vertica executed a query plan and its individual [paths](#):

- [EXECUTION_ENGINE_PROFILES](#) summarizes query execution runs.
- [QUERY_PLAN_PROFILES](#) shows the real-time flow of data, and the time and resources consumed for each query plan path.

Each query plan path has a unique ID, as shown in the following [EXPLAIN](#) output fragment.

Both tables provide path-specific data. For example, [QUERY_PLAN_PROFILES](#) provides high-level data for each path, which includes:

- Length of a query operation execution
- How much memory that path's operation consumed
- Size of data sent/received over the network

For example, you might observe that a **GROUP BY HASH** operation executed in 0.2 seconds using 100MB of memory.

Requirements

Real-time profiling minimally requires the ID of the transaction to monitor. If the transaction includes multiple statements, you also need the statement ID. You can get statement and transaction IDs by issuing [PROFILE](#) on the query to profile. You can then use these identifiers to query system tables [EXECUTION_ENGINE_PROFILES](#) and [QUERY_PLAN_PROFILES](#).

For more information, see [Profiling single statements](#).

In this section

- [Getting query plan status for small queries](#)
- [Getting query plan status for large queries](#)
- [Improving readability of QUERY_PLAN_PROFILES output](#)
- [Managing query profile data](#)
- [Analyzing suboptimal query plans](#)

Getting query plan status for small queries

Real-time profiling counters, stored in system table [EXECUTION_ENGINE_PROFILES](#), are available for all currently executing statements, including internal operations, such as a [mergeout](#).

Profiling counters are available after query execution completes, if any one of the following conditions is true:

- The query was run via the [PROFILE](#) command
- Systemwide profiling is enabled by Vertica meta-function [ENABLE_PROFILING](#).
- The query ran more than two seconds.

Profiling counters are saved in system table [EXECUTION_ENGINE_PROFILES](#) until the storage quota is exceeded.

For example:

1. Profile the query to get [transaction_id](#) and [statement_id](#) from from [EXECUTION_ENGINE_PROFILES](#). For example:

```

=> PROFILE SELECT * FROM t1 JOIN t2 ON t1.x = t2.y;
NOTICE 4788: Statement is being profiled
HINT: Select * from v_monitor.execution_engine_profiles where transaction_id=45035996273955065 and statement_id=4;
NOTICE 3557: Initiator memory for query: [on pool general: 248544 KB, minimum: 248544 KB]
NOTICE 5077: Total memory required by query: [248544 KB]
x | y | z
-----
3 | 3 | three
(1 row)
  
```

2. Query system table [QUERY_PLAN_PROFILES](#).

Note

For best results, sort on columns `transaction_id`, `statement_id`, `path_id`, and `path_line_index`.

```
=> SELECT ... FROM query_plan_profiles
WHERE transaction_id=45035996273955065 and statement_id=4;
ORDER BY transaction_id, statement_id, path_id, path_line_index;
```

Getting query plan status for large queries

Real-time profiling is designed to monitor large (long-running) queries. Take the following steps to monitor plans for large queries:

1. Get the statement and transaction IDs for the query plan you want to profile by querying system table [CURRENT_SESSION](#):

```
=> SELECT transaction_id, statement_id from current_session;
transaction_id | statement_id
-----+-----
45035996273955001 |      4
(1 row)
```

2. Run the query:

```
=> SELECT * FROM t1 JOIN t2 ON x=y JOIN ext on y=z;
```

3. Query system table [QUERY_PLAN_PROFILES](#), and sort on the `transaction_id`, `statement_id`, `path_id`, and `path_line_index` columns.

```
=> SELECT ... FROM query_plan_profiles WHERE transaction_id=45035996273955001 and statement_id=4
ORDER BY transaction_id, statement_id, path_id, path_line_index;
```

You can also use the Linux `watch` command to monitor long-running queries (see [Real-time profiling](#)).

Example

The following series of commands creates a table for a long-running query and then queries system table [QUERY_PLAN_PROFILES](#):

1. Create table `longq`:

```

=> CREATE TABLE longq(x int);
CREATE TABLE
=> COPY longq FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 1
>> 2
>> 3
>> 4
>> 5
>> 6
>> 7
>> 8
>> 9
>> 10
>> \.
=> INSERT INTO longq SELECT f1.x+f2.x+f3.x+f4.x+f5.x+f6.x+f7.x
  FROM longq f1
  CROSS JOIN longq f2
  CROSS JOIN longq f3
  CROSS JOIN longq f4
  CROSS JOIN longq f5
  CROSS JOIN longq f6
  CROSS JOIN longq f7;
OUTPUT
-----
10000000
(1 row)
=> COMMIT;
COMMIT

```

2. Suppress query output on the terminal window by using the vsq! \o command:

```

=> \o /home/dbadmin/longQprof

```

3. Query the new table:

```

=> SELECT * FROM longq;

```

4. Get the transaction and statement IDs:

```

=> SELECT transaction_id, statement_id from current_session;
 transaction_id | statement_id
-----+-----
45035996273955021 |      4
(1 row)

```

5. Turn off the \o command so Vertica continues to save query plan information to the file you specified. Alternatively, leave it on and examine the file after you query system table `QUERY_PLAN_PROFILES`.

```

=> \o

```

6. Query system table `QUERY_PLAN_PROFILES`:

```

=> SELECT
  transaction_id,
  statement_id,
  path_id,
  path_line_index,
  is_executing,
  running_time,
  path_line
FROM query_plan_profiles
WHERE transaction_id=45035996273955021 AND statement_id=4
ORDER BY transaction_id, statement_id, path_id, path_line_index;

```

Improving readability of QUERY_PLAN_PROFILES output

Output from the [QUERY_PLAN_PROFILES](#) table can be very wide because of the [path_line](#) column. To facilitate readability, query [QUERY_PLAN_PROFILES](#) using one or more of the following options:

- Sort output by [transaction_id](#) , [statement_id](#) , [path_id](#) , and [path_line_index](#) :

```
=> SELECT ... FROM query_plan_profiles
WHERE ...
ORDER BY transaction_id, statement_id, path_id, path_line_index;
```

- Use column aliases to decrease column width:

```
=> SELECT statement_id AS sid, path_id AS id, path_line_index AS order,
is_started AS start, is_completed AS end, is_executing AS exe,
running_time AS run, memory_allocated_bytes AS mem,
read_from_disk_bytes AS read, received_bytes AS rec,
sent_bytes AS sent, FROM query_plan_profiles
WHERE transaction_id=45035996273910558 AND statement_id=3
ORDER BY transaction_id, statement_id, path_id, path_line_index;
```

- Use the vsql [\o](#) command to redirect [EXPLAIN](#) output to a file:

```
=> \o /home/dbadmin/long-queries
=> EXPLAIN SELECT * FROM customer_dimension;
=> \o
```

Managing query profile data

Vertica retains data for queries until the storage quota for the table is exceeded, when it automatically purges the oldest queries to make room for new ones. You can also clear profiled data by calling one of the following functions:

- [CLEAR_PROFILING](#) clears profiled data from memory. For example, the following command clears profiling for general query-run information, such as the query strings used and the duration of queries.

```
=> SELECT CLEAR_PROFILING('query');
```

- [CLEAR_DATA_COLLECTOR](#) clears all memory and disk records on the Data Collector tables and functions and resets collection statistics in system table [DATA_COLLECTOR](#).
- [FLUSH_DATA_COLLECTOR](#) waits until memory logs are moved to disk and then flushes the Data Collector, synchronizing the DataCollector log with the disk storage.

Configuring data retention policies

Vertica [retains the historical data](#) it gathers as specified by the [configured](#) retention policies.

Analyzing suboptimal query plans

If profiling uncovers a suboptimal query, invoking one of the following functions might help:

- [ANALYZE_WORKLOAD](#) analyzes system information held in system tables and provides tuning recommendations that are based on a combination of statistics, system and [data collector](#) events, and database-table-projection design.
- [ANALYZE_STATISTICS](#) collects and aggregates data samples and storage information from all nodes that store projections associated with the specified table or column.

You can also run your query through the Database Designer. See [Incremental Design](#).

Sample views for counter information

The EXECUTION_ENGINE_PROFILES table contains the data for each profiling counter as a row within the table. For example, the execution time (us) counter is in one row, and the rows produced counter is in a second row. Since there are many different profiling counters, many rows of profiling data exist for each operator. Some sample views are installed by default to simplify the viewing of profiling counters.

Running scripts to create the sample views

The following script creates the [v_demo](#) schema and places the views in that schema.

```
/opt/vertica/scripts/demo_eeprof_view.sql
```

Viewing counter values using the sample views

There is one view for each of the profiling counters to simplify viewing of a single counter value. For example, to view the execution time for all operators, issue the following command from the database:

```
=> SELECT * FROM v_demo.eeprof_execution_time_us;
```

To view all counter values available for all profiled queries:

```
=> SELECT * FROM v_demo.eeprof_counters;
```

To select all distinct operators available for all profiled queries:

```
=> SELECT * FROM v_demo.eeprof_operators;
```

Combining sample views

These views can be combined:

```
=> SELECT * FROM v_demo.eeprof_execution_time_us  
NATURAL LEFT OUTER JOIN v_demo.eeprof_rows_produced;
```

To view the execution time and rows produced for a specific transaction and `statement_id` ranked by execution time on each node:

```
=> SELECT * FROM v_demo.eeprof_execution_time_us_rank  
WHERE transaction_id=45035996273709699  
AND statement_id=1  
ORDER BY transaction_id, statement_id, node_name, rk;
```

To view the top five operators by execution time on each node:

```
=> SELECT * FROM v_demo.eeprof_execution_time_us_rank  
WHERE transaction_id=45035996273709699  
AND statement_id=1 AND rk<=5  
ORDER BY transaction_id, statement_id, node_name, rk;
```

About locale

Locale specifies the user's language, country, and any special variant preferences, such as collation. Vertica uses locale to determine the behavior of certain string functions. Locale also determines the collation for various SQL commands that require ordering and comparison, such as aggregate `GROUP BY` and `ORDER BY` clauses, joins, and the analytic `ORDER BY` clause.

The default locale for a Vertica database is `en_US@collation=binary` (English US). You can define a new default locale that is used for all sessions on the database. You can also override the locale for individual sessions. However, projections are always collated using the default `en_US@collation=binary` collation, regardless of the session collation. Any locale-specific collation is applied at query time.

If you set the locale to null, Vertica sets the locale to `en_US_POSIX`. You can set the locale back to the default locale and collation by issuing the vsql meta-command `\locale`. For example:

Note

```
=> set locale to "";  
INFO 2567: Canonical locale: 'en_US_POSIX'  
Standard collation: 'LEN'  
English (United States, Computer)  
SET  
=> \locale en_US@collation=binary;  
INFO 2567: Canonical locale: 'en_US'  
Standard collation: 'LEN_KBINARY'  
English (United States)  
=> \locale  
en_US@collation=binary;
```

You can set locale through [ODBC](#), [JDBC](#), and [ADO.net](#).

Vertica locale specifications follow a subset of the [Unicode LDML](#) standard as implemented by the [ICU library](#).

In this section

- [Locale handling in Vertica](#)
- [Specifying locale: long form](#)
- [Specifying locale: short form](#)
- [Supported locales](#)
- [Locale and UTF-8 support](#)
- [Locale-aware string functions](#)

Locale handling in Vertica

The following sections describes how Vertica handles locale.

Session locale

Locale is session-scoped and applies only to queries executed in that session. You cannot specify locale for individual queries. When you start a session it obtains its locale from the configuration parameter `DefaultSessionLocale`.

Query restrictions

The following restrictions apply when queries are run with locale other than the default `en_US@collation=binary`:

- When one or more of the left-side **NOT IN** columns is **CHAR** or **VARCHAR**, multi-column **NOT IN** subqueries are not supported. For example:

```
=> CREATE TABLE test (x VARCHAR(10), y INT);
=> SELECT ... FROM test WHERE (x,y) NOT IN (SELECT ...);
ERROR: Multi-expression NOT IN subquery is not supported because a left
hand expression could be NULL
```

Note

Even if columns `test.x` and `test.y` have a NOT NULL constraint, an error occurs.

- If the outer query contains a **GROUP BY** clause on a **CHAR** or **VARCHAR** column, correlated **HAVING** clause subqueries are not supported. In the following example, the **GROUP BY x** in the outer query causes the error:

```
=> DROP TABLE test CASCADE;
=> CREATE TABLE test (x VARCHAR(10));
=> SELECT COUNT(*) FROM test t GROUP BY x HAVING x
  IN (SELECT x FROM test WHERE t.x||'a' = test.x||'a' );
ERROR: subquery uses ungrouped column "t.x" from outer query
```

- Subqueries that use analytic functions in the **HAVING** clause are not supported. For example:

```
=> DROP TABLE test CASCADE;
=> CREATE TABLE test (x VARCHAR(10));
=> SELECT MAX(x)OVER(PARTITION BY 1 ORDER BY 1) FROM test
  GROUP BY x HAVING x IN (SELECT MAX(x) FROM test);
ERROR: Analytics query with having clause expression that involves
aggregates and subquery is not supported
```

Collation and projections

Projection data is sorted according to the default `en_US@collation=binary` collation. Thus, regardless of the session setting, issuing the following command creates a projection sorted by `col1` according to the binary collation:

```
=> CREATE PROJECTION p1 AS SELECT * FROM table1 ORDER BY col1;
```

In such cases, `straße` and `strasse` are not stored near each other on disk.

Sorting by binary collation also means that sort optimizations do not work in locales other than binary. Vertica returns the following warning if you create tables or projections in a non-binary locale:

```
WARNING: Projections are always created and persisted in the default
Vertica locale. The current locale is de_DE
```

Non-binary locale input handling

When the locale is non-binary, Vertica uses the [COLLATION](#) function to transform input to a binary string that sorts in the proper order.

This transformation increases the number of bytes required for the input according to this formula:

```
result_column_width = input_octet_width * CollationExpansion + 4
```

The default value of configuration parameter [CollationExpansion](#) is 5.

Character data type handling

- **CHAR** fields are displayed as fixed length, including any trailing spaces. When **CHAR** fields are processed internally, they are first stripped of trailing spaces. For **VARCHAR** fields, trailing spaces are usually treated as significant characters; however, trailing spaces are ignored when sorting or comparing either type of character string field using a non-binary locale.
- The maximum length parameter for **VARCHAR** and **CHAR** data type refers to the number of octets (bytes) that can be stored in that field and not number of characters. When using multi-byte UTF-8 characters, the fields must be sized to accommodate from 1 to 4 bytes per character, depending on the data.

Specifying locale: long form

Vertica supports long forms that specify the [collation](#) keyword. Vertica extends long-form processing to accept collation arguments.

Syntax

```
[language][_script][_country][_variant][@collation-spec]
```

Note

The following syntax options apply:

- Locale specification strings are case insensitive. For example, `en_us` and `EN_US`, are equivalent.
- You can substitute underscores with hyphens. For example: `[-script]`

Parameters

language

A two- or three-letter lowercase code for a particular language. For example, Spanish is `es` English is `en` and French is `fr`. The two-letter language code uses the ISO-639 standard.

_script

An optional four-letter script code that follows the language code. If specified, it should be a valid script code as listed on the Unicode ISO 15924 Registry.

_country

A specific language convention within a generic language for a specific country or region. For example, French is spoken in many countries, but the currencies are different in each country. To allow for these differences among specific geographical, political, or cultural regions, locales are specified by two-letter, uppercase codes. For example, `FR` represents France and `CA` represents Canada. The two letter country code uses the ISO-3166 standard.

_variant

Differences may also appear in language conventions used within the same country. For example, the Euro currency is used in several European countries while the individual country's currency is still in circulation. To handle variations inside a language and country pair, add a third code, the variant code. The variant code is arbitrary and completely application-specific. ICU adds `_EURO` to its locale designations for locales that support the Euro currency. Variants can have any number of underscored key words. For example, `EURO_WIN` is a variant for the Euro currency on a Windows computer.

Another use of the variant code is to designate the Collation (sorting order) of a locale. For instance, the `es__TRADITIONAL` locale uses the traditional sorting order which is different from the default modern sorting of Spanish.

@ collation-spec

Vertica only supports the keyword [collation](#), as follows:

```
@collation=collation-type[;arg]...
```

Collation can specify one or more semicolon-delimited [arguments](#), described below.

[collation-type](#) is set to one of the following values:

- `big5han`: Pinyin ordering for Latin, big5 charset ordering for CJK characters (used in Chinese).

- **dict** : For a dictionary-style ordering (such as in Sinhala).
- **direct** : Hindi variant.
- **gb2312/gb2312han** : Pinyin ordering for Latin, gb2312han charset ordering for CJK characters (used in Chinese).
- **phonebook** : For a phonebook-style ordering (such as in German).
- **pinyin** : Pinyin ordering for Latin and for CJK characters; that is, an ordering for CJK characters based on a character-by-character transliteration into a pinyin (used in Chinese).
- **reformed** : Reformed collation (such as in Swedish).
- **standard** : The default ordering for each language. For root it is [UCA] order; for each other locale it is the same as UCA ([Unicode Collation Algorithm](#)) ordering except for appropriate modifications to certain characters for that language. The following are additional choices for certain locales; they have effect only in certain locales.
- **stroke** : Pinyin ordering for Latin, stroke order for CJK characters (used in Chinese) not supported.
- **traditional** : For a traditional-style ordering (such as in Spanish).
- **unihan** : Pinyin ordering for Latin, Unihan radical-stroke ordering for CJK characters (used in Chinese) not supported.
- **binary** : Vertica default, providing UTF-8 octet ordering.

Notes:

- Collations might default to root, the ICU default collation.
- Invalid values of the collation keyword and its synonyms do not cause an error. For example, the following does not generate an error. It simply ignores the invalid value:

```
=> \locale en_GB@collation=xyz
INFO 2567: Canonical locale: 'en_GB@collation=xyz'
Standard collation: 'LEN'
English (United Kingdom, collation=xyz)
```

For more about collation options, see [Unicode Locale Data Markup Language \(LDML\)](#).

Collation arguments

collation can specify one or more of the following arguments :

Parameter	Short form	Description
colstrength	S	<p>Sets the default strength for comparison. This feature is locale dependent.</p> <p>Set colstrength to one of the following:</p> <ul style="list-style-type: none"> • 1 primary : Ignores case and accents. Only primary differences are used during comparison—for example, a versus z . • 2 secondary : Ignores case. Only secondary and above differences are considered for comparison—for example, different accented forms of the same base letter such as a versus \u00E4 . • 3 tertiary (default): Only tertiary differences and higher are considered for comparison. Tertiary comparisons are typically used to evaluate case differences—for example, Z versus z . • 4 quarternary : For example, used with Hiragana.
colAlternate	A	<p>Sets alternate handling for variable weights, as described in UCA, one of the following:</p> <ul style="list-style-type: none"> • non-ignorable N D • shifted S

<code>colBackwards</code>	F	<p>For Latin with accents, this parameter determines which accents are sorted. It sets the comparison for the second level to be backwards.</p> <p>Note <code>colBackwards</code> is automatically set for French accents.</p> <p>Set <code>colBackwards</code> to one of the following:</p> <ul style="list-style-type: none"> • <code>on O</code> : The normal UCA algorithm is used. • <code>off X</code> : All strings that are in Fast C or D normalization form (FCD) sort correctly, but others do not necessarily sort correctly. Set to off if the strings to be compared are in FCD.
<code>colNormalization</code>	N	<p>Set to one of the following:</p> <ul style="list-style-type: none"> • <code>on O</code> : The normal UCA algorithm is used. • <code>off X</code> : All strings that are in Fast C or D normalization form (FCD) sort correctly, but others won't necessarily sort correctly. It should only be set off if the strings to be compared are in FCD.
<code>colCaseLevel</code>	E	<p>Set to one of the following:</p> <ul style="list-style-type: none"> • <code>on O</code> : A level consisting only of case characteristics is inserted in front of tertiary level. To ignore accents but take cases into account, set strength to primary and case level to on. • <code>off X</code> : This level is omitted.
<code>colCaseFirst</code>	C	<p>Set to one of the following:</p> <ul style="list-style-type: none"> • <code>upper U</code> : Upper case sorts before lower case. • <code>lower L</code> : Lower case sorts before upper case. This is useful for locales that have already supported ordering but require different order of cases. It affects case and tertiary levels. • <code>off short</code> : Tertiary weights unaffected
<code>colHiraganaQuarternary</code>	H	<p>Controls special treatment of Hiragana code points on quaternary level, one of the following:</p> <ul style="list-style-type: none"> • <code>on O</code> : Hiragana codepoints get lower values than all the other non-variable code points. The strength must be greater or equal than quaternary for this attribute to take effect. • <code>off X</code> : Hiragana letters are treated normally.
<code>colNumeric</code>	D	<p>If set to on, any sequence of Decimal Digits (General_Category = Nd in the [UCD]) is sorted at a primary level with its numeric value. For example, <code>A-21 < A-123</code> .</p>
<code>variableTop</code>	B	<p>Sets the default value for the variable top. All code points with primary weights less than or equal to the variable top will be considered variable, and are affected by the alternate handling.</p> <p>For example, the following command sets variableTop to be HYPHEN (<code>u2010</code>)</p> <pre>=> \locale en_US@colalternate=shifted;variabletop=u2010</pre>

Locale processing notes

- Incorrect locale strings are accepted if the prefix can be resolved to a known locale version.

For example, the following works because the language can be resolved:

```
=> \locale en_XX
INFO 2567: Canonical locale: 'en_XX'
Standard collation: 'LEN'
English (XX)
```

The following does not work because the language cannot be resolved:

```
=> \locale xx_XX
xx_XX: invalid locale identifier
```

- POSIX-type locales such as `en_US.UTF-8` work to some extent in that the encoding part "UTF-8" is ignored.
- Vertica uses the `icu4c-4_2_1` library to support basic locale/collation processing with some extensions. This does not currently meet [current standards for locale processing](https://tools.ietf.org/html/rfc5646) (<https://tools.ietf.org/html/rfc5646>).

Examples

Specify German locale as used in Germany (`de`), with `phonebook` -style collation:

```
=> \locale de_DE@collation=phonebook
INFO 2567: Canonical locale: 'de_DE@collation=phonebook'
Standard collation: 'KPHONEBOOK_LDE'
German (Germany, collation=Phonebook Sort Order)
Deutsch (Deutschland, Sortierung=Telefonbuch-Sortierregeln)
```

Specify German locale as used in Germany (`de`), with `phonebook` -style collation and strength set to secondary:

```
=> \locale de_DE@collation=phonebook;colStrength=secondary
INFO 2567: Canonical locale: 'de_DE@collation=phonebook'
Standard collation: 'KPHONEBOOK_LDE_S2'
German (Germany, collation=Phonebook Sort Order)
Deutsch (Deutschland, Sortierung=Telefonbuch-Sortierregeln)
```

Specifying locale: short form

Vertica accepts locales in short form. You can use the short form to specify the locale and keyname pair/value names.

To determine the short form for a locale, type in the long form and view the last line of INFO, as follows:

```
\locale fr
INFO: Locale: 'fr'
INFO: French
INFO: français
INFO: Short form: 'LFR'
```

Examples

Specify `en` (English) locale:

```
\locale LEN
INFO: Locale: 'en'
INFO: English
INFO: Short form: 'LEN'
```

Specify German locale as used in Germany (`de`), with `phonebook` -style collation:

```
\locale LDE_KPHONEBOOK
INFO: Locale: 'de@collation=phonebook'
INFO: German (collation=Phonebook Sort Order)
INFO: Deutsch (Sortierung=Telefonbuch-Sortierregeln)
INFO: Short form: 'KPHONEBOOK_LDE'
```

Specify German locale as used in Germany (`de`), with `phonebook` -style collation:

```
\locale LDE_KPHONEBOOK_S2
INFO: Locale: 'de@collation=phonebook'
INFO: German (collation=Phonebook Sort Order)
INFO: Deutsch (Sortierung=Telefonbuch-Sortierregeln)
INFO: Short form: 'KPHONEBOOK_LDE_S2'
```

Supported locales

The following are the supported locale strings for Vertica. Each locale can optionally have a list of key/value pairs (see [Specifying locale: long form](#)).

Locale Name	Language or Variant	Region
-------------	---------------------	--------

af	Afrikaans	
af_NA	Afrikaans	Namibian Afrikaans
af_ZA	Afrikaans	South Africa

zu	Zulu	
zu_ZA	Zulu	South Africa

Locale and UTF-8 support

Vertica supports Unicode Transformation Format-8, or UTF8, where 8 equals 8-bit. UTF-8 is a variable-length character encoding for Unicode created by Ken Thompson and Rob Pike. UTF-8 can represent any universal character in the Unicode standard. Initial encoding of byte codes and character assignments for UTF-8 coincides with ASCII. Thus, UTF8 requires little or no change for software that handles ASCII but preserves other values.

Vertica database servers expect to receive all data in UTF-8, and Vertica outputs all data in UTF-8. The ODBC API operates on data in UCS-2 on Windows systems, and normally UTF-8 on Linux systems. JDBC and ADO.NET APIs operate on data in UTF-16. Client drivers automatically convert data to and from UTF-8 when sending to and receiving data from Vertica using API calls. The drivers do not transform data loaded by executing a [COPY](#) or [COPY LOCAL](#) statement.

UTF-8 string functions

The following string functions treat **VARCHAR** arguments as UTF-8 strings (when **USING OCTETS** is not specified) regardless of locale setting.

String function	Description
-----------------	-------------

LOWER	Returns a VARCHAR value containing the argument converted to lowercase letters.
UPPER	Returns a VARCHAR value containing the argument converted to uppercase letters.
INITCAP	Capitalizes first letter of each alphanumeric word and puts the rest in lowercase.
INSTR	Searches string for substring and returns an integer indicating the position of the character in string that is the first character of this occurrence.
SPLIT_PART	Splits string on the delimiter and returns the location of the beginning of the given field (counting from one).
POSITION	Returns an integer value representing the character location of a specified substring with a string (counting from one).
STRPOS	Returns an integer value representing the character location of a specified substring within a string (counting from one).

Locale-aware string functions

Vertica provides string functions to support internationalization. Unless otherwise specified, these string functions can optionally specify whether **VARCHAR** arguments should be interpreted as octet (byte) sequences, or as (locale-aware) sequences of characters. Specify this information by adding the parameter **USING OCTETS** and **USING CHARACTERS** (default) to the function.

The following table lists all string functions that are locale-aware:

String function	Description
BTRIM	Removes the longest string consisting only of specified characters from the start and end of a string.
CHARACTER_LENGTH	Returns an integer value representing the number of characters or octets in a string.
GREATEST	Returns the largest value in a list of expressions.
GREATESTB	Returns its greatest argument, using binary ordering, not UTF-8 character ordering.
INITCAP	Capitalizes first letter of each alphanumeric word and puts the rest in lowercase.
INSTR	Searches string for substring and returns an integer indicating the position of the character in string that is the first character of this occurrence.
LEAST	Returns the smallest value in a list of expressions.
LEASTB	Returns its least argument, using binary ordering, not UTF-8 character ordering.
LEFT	Returns the specified characters from the left side of a string.
LENGTH	Takes one argument as an input and returns returns an integer value representing the number of characters in a string.
LTRIM	Returns a VARCHAR value representing a string with leading blanks removed from the left side (beginning).
OVERLAY	Returns a VARCHAR value representing a string having had a substring replaced by another string.
OVERLAYB	Returns an octet value representing a string having had a substring replaced by another string.
REPLACE	replaces all occurrences of characters in a string with another set of characters.

RIGHT	Returns the <i>length</i> right-most characters of string.
SUBSTR	Returns a VARCHAR value representing a substring of a specified string.
SUBSTRB	Returns a byte value representing a substring of a specified string.
SUBSTRING	Given a value, a position, and an optional length, returns a value representing a substring of the specified string at the given position.
TRANSLATE	Replaces individual characters in <i>string_to_replace</i> with other characters.
UPPER	Returns a VARCHAR value containing the argument converted to uppercase letters.

Appendix: creating native binary format files

Using [COPY](#) to load data with the NATIVE parser requires that the input data files conform to the requirements described in this appendix. All NATIVE files must contain:

- [File signature](#)
- [Column size definitions](#)
- [Rows of data](#)

The subsection [Loading a NATIVE file into a table: example](#) describes an example of loading data with the NATIVE parser.

Note

You cannot mix Binary and ASCII source files in the same COPY statement.

In this section

- [File signature](#)
- [Column definitions](#)
- [Row data](#)
- [Loading a NATIVE file into a table: example](#)

File signature

The first part of a NATIVE binary file consists of a file signature. The contents of the signature are fixed, and listed in the following table.

Byte Offset	0	1	2	3	4	5	6	7	8	9	10
Hex Value	4E	41	54	49	56	45	0A	FF	0D	0A	00
Text Literals	N	A	T	I	V	E	E'\n'	E'^317'	E'\r'	E'\n'	E'^000'

The signature ensures that the file has neither been corrupted by a non-8-bit file transfer, nor stripped of carriage returns, linefeeds, or null values. If the signature is intact, Vertica determines that the file has not been corrupted.

Column definitions

Following the file signature, the file must define the widths of each column in the file as follows.

Byte Offset	Length (bytes)	Description	Comments
11	4	Header area length	32-bit integer in little-endian format that contains the length in bytes of remaining in the header, not including itself. This is the number of bytes from the end of this value to the start of the row data.

15	2	NATIVE file version	16-bit integer in little-endian format containing the version number of the NATIVE file format. The only valid value is currently 1. Future changes to the format could be assigned different version numbers to maintain backward compatibility.
17	1	Filler	Always 0.
18	2	Number of columns	16-bit integer in little-endian format that contains the number of columns in each row in the file.
20+	4 bytes for each column of data in the table	Column widths	Array of 32-bit integers in little-endian format that define the width of each column in the row. Variable-width columns have a value of -1 (0xFF 0xFF 0xFF 0xFF).

Note

All integers in NATIVE files are in **little-endian format** (least significant byte first).

The width of each column is determined by the data type it contains. The following table explains the column width needed for each data type, along with the data encoding.

Data Type	Length (bytes)	Column Content
INTEGER	1, 2, 4, 8	8-, 16-, 32-, and 64-bit integers are supported. All multi-byte values are stored in little-endian format. Note: All values for a column must be the width you specify here. If you set the length of an INTEGER column to be 4 bytes, then all of the values you supply for that column must be 32-bit integers.
BOOLEAN	1	0 for false, 1 for true.
FLOAT	8	Encoded in IEEE-754 format.
CHAR	User-specified	<ul style="list-style-type: none"> • Strings shorter than the specified length must be right-padded with spaces (E'\040'). • Strings are not null-terminated. • Character encoding is UTF-8. • UTF-8 strings can contain multi-byte characters. Therefore, number of characters in the string may not equal the number of bytes.
VARCHAR	4-byte integer (length) + data	The column width for a VARCHAR column is always -1 to signal that it contains variable-length data. <ul style="list-style-type: none"> • Each VARCHAR column value starts with a 32-bit integer that contains the number of bytes in the string. • The string must not be null-terminated. • Character encoding must be UTF-8. • Remember that UTF-8 strings can contain multi-byte characters. Therefore, number of characters in the string may not equal the number of bytes.
DATE	8	64-bit integer in little-endian format containing the Julian day since Jan 01 2000 (J2451545)
TIME	8	64-bit integer in little-endian format containing the number of microseconds since midnight in the UTC time zone.

TIMETZ	8	<p>64-bit value where</p> <ul style="list-style-type: none"> Upper 40 bits contain the number of microseconds since midnight. Lower 24 bits contain time zone as the UTC offset in microseconds calculated as follows: Time zone is logically from -24hrs to +24hrs from UTC. Instead it is represented here as a number between 0hrs to 48hrs. Therefore, 24hrs should be added to the actual time zone to calculate it. <p>Each portion is stored in little-endian format (5 bytes followed by 3 bytes).</p>
TIMESTAMP	8	64-bit integer in little-endian format containing the number of microseconds since Julian day: Jan 01 2000 00:00:00.
TIMESTAMP TZ	8	A 64-bit integer in little-endian format containing the number of microseconds since Julian day: Jan 01 2000 00:00:00 in the UTC timezone.
INTERVAL	8	64-bit integer in little-endian format containing the number of microseconds in the interval.
BINARY	User-specified	Similar to CHAR. The length should be specified in the file header in the <i>Field Lengths</i> entry for the field. The field in the record must contain <i>length</i> number of bytes. If the value is smaller than the specified length, the remainder should be filled with nulls (E'\000').
VARBINARY	4-byte integer + data	Stored just like VARCHAR but data is interpreted as bytes rather than UTF-8 characters.
NUMERIC	(precision, scale) (precision , 19 + 1) ^ 8 rounded up	<p>A constant-length data type. Length is determined by the precision, assuming that a 64-bit unsigned integer can store roughly 19 decimal digits. The data consists of a sequence of 64-bit integers, each stored in little-endian format, with the most significant integer first. Data in the integers is stored in base 2^{64}. 2's complement is used for negative numbers.</p> <p>If there is a scale, then the numeric is stored as $\text{numeric} \cdot 10^{\text{scale}}$; that is, all real numbers are stored as integers, ignoring the decimal point. It is required that the scale matches that of the target column in the dataanchor table. Another option is to use FILLER columns to coerce the numeric to the scale of the target column.</p>

Row data

Following the file header is a sequence of records that contain the data for each row of data. Each record starts with a header:

Length (bytes)	Description	Comments
4	Row length	<p>A 32-bit integer in little-endian format containing the length of the row's data in bytes. It includes the size of data only, not the header.</p> <p>Note: The number of bytes in each row can vary not only because of variable-length data, but also because columns containing NULL values do not have any data in the row. If column 3 has a NULL value, then column 4's data immediately follows the end of column 2's data. See the next</p>
Number of columns , 8 rounded up (<code>CEILING(NumFields / (sizeof(uint8) * 8));</code>)	Null value bit field	A series of bytes whose bits indicate whether a column contains a NULL. The most significant bit of the first byte indicates whether the first column in this row contains a NULL, the next most significant bit indicates whether the next column contains a NULL, and so on. If a bit is 1 (true) then the column contains a NULL, and there is no value for the column in the data for the row.

Following the record header is the column values for the row. There is no separator characters for these values. Their location in the row of data is calculated based on where the previous column's data ended. Most data types have a fixed width, so their location is easy to determine. Variable-width values (such as VARCHAR and VARBINARY) start with a count of the number of bytes the value contains.

See the table in the previous section for details on how each data type's value is stored in the row's data.

Loading a NATIVE file into a table: example

The example below demonstrates creating a table and loading a NATIVE file that contains a single row of data. The table contains all possible data types.

```
=> CREATE TABLE allTypes (INTCOL INTEGER,
    FLOATCOL FLOAT,
    CHARCOL CHAR(10),
    VARCHARCOL VARCHAR,
    BOOLCOL BOOLEAN,
    DATECOL DATE,
    TIMESTAMPCOL TIMESTAMP,
    TIMESTAMPTZCOL TIMESTAMPTZ,
    TIMECOL TIME,
    TIMETZCOL TIMETZ,
    VARBINCOL VARBINARY,
    BINCOL BINARY,
    NUMCOL NUMERIC(38,0),
    INTERVALCOL INTERVAL
);
=> COPY allTypes FROM '/home/dbadmin/allTypes.bin' NATIVE;
=> \pset expanded
Expanded display is on.
=> SELECT * from allTypes;
-[ RECORD 1 ]--+-----
INTCOL      | 1
FLOATCOL    | -1.11
CHARCOL     | one
VARCHARCOL  | ONE
BOOLCOL     | t
DATECOL     | 1999-01-08
TIMESTAMPCOL | 1999-02-23 03:11:52.35
TIMESTAMPTZCOL | 1999-01-08 07:04:37-05
TIMECOL     | 07:09:23
TIMETZCOL   | 15:12:34-04
VARBINCOL   | \253\315
BINCOL      | \253
NUMCOL      | 1234532
INTERVALCOL | 03:03:03
```

The content of the [allTypes.bin](#) file appears below as a raw hex dump:

```
4E 41 54 49 56 45 0A FF 0D 0A 00 3D 00 00 00 01 00 00 0E 00
08 00 00 00 08 00 00 00 0A 00 00 00 FF FF FF FF 01 00 00 00
08 00 00 00 08 00 00 00 08 00 00 00 08 00 00 00 08 00 00 00
FF FF FF FF 03 00 00 00 18 00 00 00 08 00 00 00 73 00 00 00
00 00 01 00 00 00 00 00 00 00 C3 F5 28 5C 8F C2 F1 BF 6F 6E
65 20 20 20 20 20 20 03 00 00 00 4F 4E 45 01 9A FE FF FF
FF FF FF FF 30 85 B3 4F 7E E7 FF FF 40 1F 3E 64 E8 E3 FF FF
C0 2E 98 FF 05 00 00 00 D0 97 01 80 F0 79 F0 10 02 00 00 00
AB CD AB CD 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00
00 64 D6 12 00 00 00 00 00 C0 47 A3 8E 02 00 00 00
```

The following table breaks this file down into each of its components, and describes the values it contains.

Hex Values	Description	Value
4E 41 54 49 56 45 0A FF 0D 0A 00	Signature	NATIVE\n317\r\n\000
3D 00 00 00	Header area length	61 bytes

01 00	Native file format version	Version 1
00	Filler value	0
0E 00	Number of columns	14 columns
08 00 00 00	Width of column 1 (INTEGER)	8 bytes
08 00 00 00	Width of column 2 (FLOAT)	8 bytes
0A 00 00 00	Width of column 3 (CHAR(10))	10 bytes
FF FF FF FF	Width of column 4 (VARCHAR)	-1 (variable width column)
01 00 00 00	Width of column 5 (BOOLEAN)	1 bytes
08 00 00 00	Width of column 6 (DATE)	8 bytes
08 00 00 00	Width of column 7 (TIMESTAMP)	8 bytes
08 00 00 00	Width of column 8 (TIMESTAMPTZ)	8 bytes
08 00 00 00	Width of column 9 (TIME)	8 bytes
08 00 00 00	Width of column 10 (TIMETZ)	8 bytes
FF FF FF FF	Width of column 11 (VARBINARY)	-1 (variable width column)
03 00 00 00	Width of column 12 (BINARY)	3 bytes
18 00 00 00	Width of column 13 (NUMERIC)	24 bytes. The size is calculated by dividing 38 (the precision specified for the numeric column) by 19 (the number of digits each 64-bit chunk can represent) and adding 1. $38 / 19 + 1 = 3$. then multiply by eight to get the number of bytes needed. $3 * 8 = 24$ bytes.
08 00 00 00	Width of column 14 (INTERVAL). last portion of the header section.	8 bytes
73 00 00 00	Number of bytes of data for the first row. this is the start of the first row of data.	115 bytes
00 00	Bit field for the null values contained in the first row of data	The row contains no null values.
01 00 00 00 00 00 00 00	Value for 64-bit INTEGER column	1

C3 F5 28 5C 8F C2 F1 BF	Value for the FLOAT column	-1.11
6F 6E 65 20 20 20 20 20 20 20	Value for the CHAR(10) column	"one " (padded With 7 spaces to fill the full 10 characters for the column)
03 00 00 00	The number of bytes in the following VARCHAR value.	3 bytes
4F 4E 45	The value for the VARCHAR column	" ONE "
01	The value for the BOOLEAN column	True
9A FE FF FF FF FF FF FF	The value for the DATE column	1999-01-08
30 85 B3 4F 7E E7 FF FF	The value for the TIMESTAMP column	1999-02-23 03:11:52.35
40 1F 3E 64 E8 E3 FF FF	The value for the TIMESTAMPTZ column	1999-01-08 07:04:37-05
C0 2E 98 FF 05 00 00 00	The value for the TIME column	07:09:23
D0 97 01 80 F0 79 F0 10	The value for the TIMETZ column	15:12:34-05
02 00 00 00	The number of bytes in the following VARBINARY value	2 bytes
AB CD	The value for the VARBINARY column	Binary data (\253\315 as octal values)
AB CD	The value for the BINARY column	Binary data (\253\315 as octal values)
00 00 00 00 00 00 00 00 00 00 64 D6 12 00 00 00 00 00	The value for the NUMERIC column	1234532
C0 47 A3 8E 02 00 00 00	The value for the INTERVAL column	03:03:03

Security and authentication

Vertica provides tools and features that allow you to ensure your system is secure as well as to prevent unauthorized users from accessing sensitive information.

[Client authentication](#) establish the identity of the requesting client and determines whether that client is authorized to connect to the Vertica server.

In this section

- [Client authentication](#)

- [Internode TLS](#)
- [TLS protocol](#)
- [LDAP link service](#)
- [Connector framework service](#)
- [Federal information processing standard](#)
- [Database auditing](#)
- [System table restriction and access](#)

Client authentication

[Authentication records](#) and their associated methods define what credentials a user/client application must provide to access the database. For example, the `hash` authentication method requires users to provide a password, while the `oauth` authentication method requires users to provide an access token.

Client authentication overview

Vertica uses the following procedure to authenticate users:

1. If a client attempts to authenticate as the [dbadmin from a local connection](#) (that is, on the same node as the database):
 - If the dbadmin does not have a password, Vertica authenticates the client with the `trust` method.
 - If the dbadmin has a password, Vertica authenticates the client with the `hash` method.
2. If a client attempts to authenticate as a database user that does not have a password, and the only authentication records defined are the [defaults](#), then Vertica authenticates the client with the `trust` method. For details, see [Implicit authentication](#).
3. If a client specifies the credentials for a particular authentication method, Vertica [filters](#) for [granted](#) authentication records that use that method, skipping higher priority authentication records (except TRUST, which is not skippable). However, if the client sends credentials that correspond with an authentication record that they do not have, Vertica uses the record with the highest priority.
4. If a client attempts to authenticate as a user that has a password and an [authentication record](#), then Vertica attempts to authenticate the client with that record. If more than one authentication record exists for the user or role, Vertica chooses the one with the highest [priority](#).

Note

Typically, if no custom authentication records were defined with [CREATE AUTHENTICATION](#), the default authentication records take effect (unless they were deliberately dropped by the dbadmin), and clients are authenticated with the `password` method.

5. If the client fails to authenticate with the chosen authentication method and [authentication fallback](#) is enabled, Vertica attempts to authenticate the client with the authentication with the next highest priority. Otherwise, the client is rejected.
6. Otherwise, no authentication records exist and the default authentication records have been dropped; no users (other than the [dbadmin from a local connection](#).) can access the database.

Authentication management

Users with the `DBADMIN` role can perform the following authentication tasks:

- [Create](#) authentication records.
- [Drop](#) an authentication record from the database.
- Define parameters required by the following authentication methods:
 - [LDAP](#)
 - [Ident](#)
 - [Kerberos](#)
 - [OAuth](#)
- [Grant](#) (assign) or [revoke](#) an authentication record to a user.
- Use [ALTER AUTHENTICATION](#) to:
 - Enable/disable authentication methods.
 - Define a default authentication method to be used if a user has not been assigned a specific authentication method. To assign this as a default authentication method, use [GRANT \(authentication\)](#) to grant it to the PUBLIC role.
 - Change authentication record priority.
 - Enable [fallback authentication](#).

In this section

- [Default authentication records](#)
- [Configuring client authentication](#)
- [Fallback authentication](#)
- [Authentication filtering](#)

- [Ident authentication](#)
- [Kerberos authentication](#)
- [LDAP authentication](#)
- [OAuth 2.0 authentication](#)
- [TLS authentication](#)

Default authentication records

Vertica automatically creates the following default authentication records and grants them to the **public** role. These have the lowest possible priority (-1), so [user-created authentication records](#) take priority over these default records:

```
=> SELECT auth_name,is_auth_enabled,auth_host_type,auth_method,auth_priority,is_fallthrough_enabled FROM client_auth;
      auth_name      | is_auth_enabled | auth_host_type | auth_method | auth_priority | is_fallthrough_enabled
-----+-----+-----+-----+-----+-----
default_hash_network_ipv4 | True          | HOST          | PASSWORD   | -1           | False
default_hash_network_ipv6 | True          | HOST          | PASSWORD   | -1           | False
default_hash_local      | True          | LOCAL        | PASSWORD   | -1           | False
(3 rows)
```

Note

Do not use the **password** method for your custom authentication records. If you want to use password-based authentication for your custom authentication records, use **hash** instead.

If no authentication records are defined (and the default authentication records are dropped), only the dbadmin and users without passwords can access the database. For details, see [Implicit authentication](#).

Configuring client authentication

You can restrict how database users can connect with authentication records. The Vertica database uses client authentication to establish the identity of the connecting client and determines whether that client is authorized to connect to the Vertica database using the supplied credentials and from their host address.

Basic authentication configuration workflow

In general, the workflow for configuring client authentication is as follows:

1. [Create](#) an authentication record. Authentication records are enabled automatically after creation. For details, see [Creating authentication records](#).
2. [Grant](#) the authentication to a user or role.

To view existing authentication records, query the system table [CLIENT_AUTH](#).

IPv4 and IPv6 for client authentication

Vertica supports clients using either the IPv4 or the IPv6 protocol to connect to the database server. Internal communication between database servers must consistently use one address family (IPv4 or IPv6). The client, however, can connect to the database from either type of IP address.

If the client will be connecting from either IPv4 or IPv6, you must create two authentication methods, one for each address. Any authentication method that uses HOST authentication requires an IP address.

For example, the first statement allows users to connect from any IPv4 address. The second statement allows users to connect from any IPv6 address:

```
=> CREATE AUTHENTICATION <name> METHOD 'gss' HOST '0.0.0.0/0'; --IPv4
=> CREATE AUTHENTICATION <name> METHOD 'gss' HOST ':::0'; --IPv6
```

If you are using a literal IPv6 address in a URL, you must enclose the IPv6 address in square brackets as shown in the following examples:

```
=> ALTER AUTHENTICATION Ldap SET host='ldap://[1dfa:2bfa:3:45:5:6:7:877]';
=> ALTER AUTHENTICATION Ldap SET host='ldap://[fdb:dbfa:0:65::177]';
=> ALTER AUTHENTICATION Ldap SET host='ldap://[fdb::177]';
=> ALTER AUTHENTICATION Ldap SET host='ldap://[::1]';
=> ALTER AUTHENTICATION Ldap SET host='ldap://[1dfa:2bfa:3:45:5:6:7:877]:5678';
```

If you are working with a multi-node cluster, any IP/netmask settings in (HOST, HOST TLS, HOST NO TLS) must match all nodes in the cluster. This setup allows the database owner to authenticate with and administer every node in the cluster. For example, specifying 10.10.0.8/30 allows a CIDR address range of 10.10.0.8-10.10.0.11.

For detailed information about IPv6 addresses, see [RFC 1924](#) and [RFC 2732](#).

Supported client authentication methods

Vertica supports the following client authentication methods:

- **trust** : Users can authenticate with a valid username (that is, without a password).
- **reject** : Rejects the connection attempt.
- **hash** : Users must provide a valid username and password. For details, see [Hash authentication](#).
- **gss** : Authorizes clients that connect to Vertica with an MIT Kerberos implementation. The Key Distribution Center (KDC) must support Kerberos 5 using the GSS-API. Non-MIT Kerberos implementations must use the GSS-API. For details, see [Kerberos authentication](#).
- **ident** : Authenticates the client against a username on an Ident server. For details, see [Ident authentication](#).
- **ldap** : Authenticates a client and their username and password with an LDAP or Active Directory server. For details, see [LDAP authentication](#).
- **tls** : Authenticates clients that provide a certificate with a Common Name (CN) that specifies a valid database username. Vertica must be configured for [mutual mode TLS](#) to use this method. For details, see [TLS authentication](#).
- **oauth** : Authenticates a client with an access token. For details, see [OAuth 2.0 authentication](#).

Local and host authentication

You can define a client authentication method as:

- **Local**: Local connection to the database.
- **Host**: Remote connection to the database from different hosts, each with their own IPv4 or IPv6 address and host parameters. For more information see [IPv4 and IPv6 for Client Authentication](#) above.

Some authentication methods can only be designated as local or host, as listed in this table:

Authentication Method	Local?	Host?
gss (Kerberos)	No	Yes
ident	Yes	No
ldap	Yes	Yes
hash	Yes	Yes
reject	Yes	Yes
trust	Yes	Yes
tls	No	Yes
oauth	Yes	Yes

Authentication for chained users and roles

Vertica supports creating chained users and roles, where you can grant ROLE2 privileges to ROLE1. All users in ROLE1 use the same authentication assigned to ROLE2. For example:

```
=> CREATE USER user1;
=> CREATE ROLE role1;
=> CREATE ROLE role2;
=> CREATE AUTHENTICATION h1 METHOD 'hash' LOCAL;
=> GRANT AUTHENTICATION h1 to role2;
=> GRANT role2 to role1;
=> GRANT role1 to user1;
```

The user and role chain in the example above can be illustrated as follows:

auth1 -> role2 -> role1 -> user1

In this example, since role2 privileges are granted to role1 you only need to grant authentication to role2 to also enable it for role1.

Fallthrough authentication

Normally, if a user fails to authenticate with the first chosen authentication record, the user is rejected. However, certain authentication methods can be specified to instead, upon failure, "fall through" to an authentication record with a [lower priority](#). This can be useful, for example, for [using multiple LDAP search attributes](#).

Authentication fallthrough is disabled by default for new records.

Another way to bypass method priority or implement fallthrough authentication is to implement it on the client instead. For details, see [Authentication filtering](#).

Authentication method compatibility

The following table shows each authentication method's compatibility with fallthrough authentication. A value of "yes" indicates that the method in the column can fall through and validate the row method it falls through to. A value of "no" indicates that you cannot fall through to it and authentication ends.

A value of "-" (dash) indicates that while fallthrough works, it has no meaningful effect. For example, a [hash](#) authentication record can fall through to another [hash](#) authentication record, but authentication will always fail because you cannot fall through to a correct password:

Column falls through to row	ldap	hash	tls	ident	oauth	gss	trust	reject
ldap	yes	yes	yes	yes	no	no	no	no
hash	yes	-	yes	yes	no	no	no	no
tls	yes	yes	-	yes	no	no	no	no
ident	yes	yes	yes	yes	no	no	no	no
oauth	no	no	no	no	no	no	no	no
gss	no	no	no	no	no	no	no	no
trust	yes	yes	yes	yes	no	no	no	no
reject	yes	yes	yes	yes	no	no	no	no

For example, suppose the user [Bob](#) was granted the following authentication record with fallthrough enabled:

```
=> CREATE AUTHENTICATION v_tls_auth METHOD 'tls' HOST TLS '0.0.0.0/0' FALLTHROUGH;
```

In addition, [Bob](#) has the [public](#) role, and therefore has the [default authentication records](#):

```
=> SELECT auth_name,is_auth_enabled,auth_host_type,auth_method,auth_priority,is_fallthrough_enabled FROM client_auth;
      auth_name      | is_auth_enabled | auth_host_type | auth_method | auth_priority | is_fallthrough_enabled
-----+-----+-----+-----+-----+-----
default_hash_network_ipv4 | True           | HOST           | PASSWORD    | -1           | False
default_hash_network_ipv6 | True           | HOST           | PASSWORD    | -1           | False
default_hash_local       | True           | LOCAL          | PASSWORD    | -1           | False
(3 rows)
```

If **Bob** , connecting from a remote address, fails to authenticate with `v_tls_auth` , Vertica attempts to authenticate him with the next ([in order of priority](#)) authentication record, `default_hash_network_ipv4` .

Logging authentication failures

Login failures are only [logged](#) if the user is rejected after all granted authentication records have failed. Only the final failure is logged.

For example, suppose a user is granted both `tls` and `password` authentication records, and the `tls` record falls through to the `password` record.

If the user fails to authenticate with both the `tls` record and the `password` record, then only the `password` failure is logged in [LOGIN_FAILURES](#) .

However, if the user fails to authenticate with the `tls` record, but succeeds with the `password` record, then no failure is logged in [LOGIN_FAILURES](#) because the user was not rejected at the end of the record chain.

Examples

To enable fallthrough on a new authentication record, use [CREATE AUTHENTICATION](#) :

```
=> CREATE AUTHENTICATION v_tls_auth METHOD 'tls' HOST TLS '0.0.0.0/0' FALLTHROUGH;
```

To toggle fallthrough on an existing authentication record, use [ALTER AUTHENTICATION](#) :

```
=> ALTER AUTHENTICATION v_tls_auth NO FALLTHROUGH; -- disable
=> ALTER AUTHENTICATION v_tls_auth FALLTHROUGH; -- enable
```

Authentication filtering

You can filter for and authenticate with [authentication records](#) that use a particular method by specifying the credentials for that method. This process skips any [higher-priority](#) , non- `trust` authentication records.

If the selected record fails and [fallthrough](#) is enabled, Vertica uses to the record with the [next highest priority](#) .

If you provide the credentials for an authentication method for which you have not been [granted](#) , Vertica instead attempts to authenticate you with the highest priority authentication record.

The following table shows the credentials the client provides and the requested authentication method in descending filter priority. If you attempt to provide more than one type of credential, your client selects and sends the one with the higher priority:

Credentials sent by client	Requested authentication method
OAuthRefreshToken or OAuthAccessToken	<code>oauth</code>
Non-default KerberosServiceName or KerberosHostname	<code>gss</code>
Username, Password	<code>ldap</code> , <code>hash</code> , <code>ident</code> , <code>trust</code> , <code>tls</code>

For example, if a client provides a username and password for user Alice, and the Alice has `oauth` , `ldap` , and `hash` records, then Vertica attempts to authenticate the client with `ldap` or `hash` , whichever has the [higher priority](#) .

Similarly, if Alice instead provides an OAuthAccessToken, username, and password, then Vertica attempts to authenticate her with the `oauth` record because it has a higher filter priority.

However, if Alice provides a KerberosHostname, Vertica attempts to authenticate her with the highest priority authentication record between her `oauth` , `ldap` , and `hash` records.

Client-side fallthrough authentication

A workaround for the incompatibility of certain authentication methods with [fallthrough authentication](#) is to use authentication filtering to manually fall through to the proper authentication record by detecting the initial authentication failure, and then making a new connection attempt with a different set of credentials.

For example, `oauth` and `hash` cannot fall through to each other, so if a user is `granted` authentication records with these methods, they can only authenticate with the higher priority record. As a workaround, you can detect the authentication failure with `oauth` and then filter for `hash` in another connection attempt. Doing this programmatically depends on the client. In JDBC, you can catch `SQLException` and then try to reconnect in the exception handler. In ODBC, you can check the return value of `SQLDriverConnect()` :

```
// error checking omitted for brevity
SQLHENV hdlEnv;
SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hdlEnv);
SQLHDBC hdlDbc;
SQLSetEnvAttr(hdlEnv, SQL_ATTR_ODBC_VERSION,
              (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_UIINTEGER);
SQLAllocHandle(SQL_HANDLE_DBC, hdlEnv, &hdlDbc);
SQLRETURN ret = SQLDriverConnect(hdlDbc, NULL, (SQLCHAR *)("DSN=VerticaDSN;OAuthAccessToken=" + accessToken + ";OAuthRefreshToken="
+ refreshToken + ";OAuthClientSecret=" + clientSecret).c_str(), SQL_NTS, NULL, 0, NULL, false);

if (!SQL_SUCCEEDED(ret))
{
    std::cout << "Could not connect to database with OAuth, retrying with hash authentication" << std::endl;
    reportError <SQLHDBC>(SQL_HANDLE_DBC, hdlDbc);
    SQLAllocHandle(SQL_HANDLE_DBC, hdlEnv, &hdlDbc);
    const char* dsnName = "ExampleDB";
    const char* userID = "Alice";
    const char* passwd = "mypassword";
    SQLConnect(hdlDbc, (SQLCHAR*)dsnName, SQL_NTS, (SQLCHAR*)userID, SQL_NTS, (SQLCHAR*)passwd, SQL_NTS);
}
```

Examples

In the following example, the user Bob is `granted` two authentication records: one that uses Kerberos authentication (`gss`) and another that uses password authentication (`hash`):

```
=> SELECT auth_name, auth_host_type, auth_method FROM client_auth;
  auth_name | auth_host_type | auth_method
-----+-----+-----
v_hash     | HOST           | HASH
v_kerberos | HOST           | GSS
(2 rows)
```

1. Bob attempts to authenticate with Kerberos, but fails (the exact error message varies):

```
$ vsql -h vertica_db.example.com -K vcluster.example.com -U Bob
vsq: GSSAPI continuation error: Unspecified GSS failure. Minor code may provide more information
GSSAPI continuation error: No Kerberos credentials available (default cache: KEYRING:persistent:0)
```

2. Bob notices the failure. The steps involved in detecting this programmatically depend on your client.
3. An authentication record that uses `gss` cannot fall through to one that uses `hash` , so the only way for Bob to authenticate to the database is to filter for the `hash` by providing the username and password:

```
=> vsql -h vertica_db.example.com -U Bob -w 'mypassword'
```

To implement client-side fallthrough authentication, check the initial connection/authentication attempt for errors and then create a new connection in the error handler. For example, the user Alice is granted `oauth` and `hash` authentication records:

```
=> SELECT auth_name, auth_host_type, auth_method FROM client_auth;
  auth_name | auth_host_type | auth_method
-----+-----+-----
v_oauth    | HOST           | OAUTH
v_hash     | HOST           | HASH
(2 rows)
```

Implicit authentication

Vertica has implicit (that is, not reflected in the [CLIENT_AUTH](#) system table) authentication records reserved for the dbadmin and users without passwords. These records cannot be [dropped](#).

For the dbadmin user:

- The **trust** method is used if all of the following are true:
 - The dbadmin does not have a password.
 - The connection is local (that is, from a Vertica node).
- The **hash** method is used if all of the following are true:
 - The dbadmin has a password.
 - The connection is local (that is, from a Vertica node).

For a non-dbadmin user, the **trust** method is used if all of the following are true:

- The user does not have a password.
- No custom (that is, non-default) authentication methods are enabled.

Dbadmin authentication access

The dbadmin user must have access to the database at all times. Vertica automatically ensures that a client can authenticate as the dbadmin from a LOCAL connection.

If you need to authenticate as the dbadmin from a remote connection, the dbadmin must have a password. You can use the following methods:

- Use fallthrough authentication.
- Create a custom, dbadmin-specific authentication method.

Authenticating from a local connection

You can always implicitly authenticate as the dbadmin from a local connection. These dbadmin-specific authentication records are implicit, so they are not listed in the [CLIENT_AUTH](#) system table, and cannot be [dropped](#).

If the dbadmin user does not have a password, then Vertica authenticates them with the **trust** method. Otherwise, Vertica authenticates them with the **password** method.

In this example, the dbadmin did not have a password and connected to Vertica from a local connection:

```
=> SELECT authentication_method, client_authentication_name FROM vs_sessions;
authentication_method | client_authentication_name
-----+-----
ImpTrust              | default: Implicit Trust
```

Authenticating from a remote connection

Fallthrough authentication

Vertica automatically creates the following authentication records and grants them to the **public** role (for details, see [Client authentication](#)):

```
=> SELECT auth_name,is_auth_enabled,auth_host_type,auth_method,auth_priority,is_fallthrough_enabled FROM client_auth;
auth_name      | is_auth_enabled | auth_host_type | auth_method | auth_priority | is_fallthrough_enabled
-----+-----+-----+-----+-----+-----
default_hash_network_ipv4 | True          | HOST          | PASSWORD    | -1 | False
default_hash_network_ipv6 | True          | HOST          | PASSWORD    | -1 | False
default_hash_local      | True          | LOCAL         | PASSWORD    | -1 | False
(3 rows)
```

These default authentication records ensure that all users with the **public** role (which includes dbadmin) have access to the database, provided that any custom authentication records are set to [fall through](#) (disabled by default) to the default records.

For example, the following **ldap** authentication enables fallthrough, so if the LDAP server is down, users can still authenticate with **password** authentication (as defined by the default records).

```
=> CREATE AUTHENTICATION ldap1 METHOD 'ldap' LOCAL FALLTHROUGH;
=> ALTER AUTHENTICATION ldap1 SET host='ldap://localhost:5389',
    binddn='cn=Manager,dc=example,dc=com',
    bind_password='password',
    basedn='ou=dev,dc=example,dc=com',
    search_attribute='cn';
```

Custom authentication records

A dbadmin-specific authentication record should:

- Use the [hash](#) authentication method (so authentication is not dependent on some external service).
- Have a high [priority](#) (e.g. 10,000) so it supersedes all other authentication records.

The following example [creates](#) an authentication record `v_dbadmin_hash` and grants it to the dbadmin user. The `hash` method indicates that the dbadmin must provide a password when logging in. The `HOST '0.0.0.0/0'` access method indicates that the dbadmin can connect remotely from any IPv4 address:

```
=> CREATE AUTHENTICATION v_dbadmin_hash METHOD 'hash' HOST '0.0.0.0/0';
=> ALTER AUTHENTICATION v_dbadmin_hash PRIORITY 10000;
=> GRANT AUTHENTICATION v_dbadmin_hash TO dbadmin;
```

If you want to authenticate as the dbadmin from a local connection, but want to use an authentication record with the `HOST` access method, specify the `--host` option with the hostname or IP address of the database:

```
$ vsql database_name user --host hostname_or_ip;
```

Creating authentication records

You can manage client authentication records with `vsql`. You must be connected to the database as a superuser.

Important

You cannot modify client authentication records using the Administration Tools. The Administration Tools interface allows you to modify the contents of the `vertica.conf` file. However, Vertica ignores any client authentication information stored in that file.

1. [Create](#) an authentication records, specifying:

- The name of the authentication record.
- The authentication method, one of the following:
 - `trust`: Users can authenticate with a valid username (that is, without a password).
 - `reject`: Rejects the connection attempt.
 - `hash`: Users must provide a valid username and password. For details, see [Hash authentication](#).
 - `gss`: Authorizes clients that connect to Vertica with an MIT Kerberos implementation. The Key Distribution Center (KDC) must support Kerberos 5 using the GSS-API. Non-MIT Kerberos implementations must use the GSS-API. For details, see [Kerberos authentication](#).
 - `ident`: Authenticates the client against a username on an Ident server. For details, see [Ident authentication](#).
 - `ldap`: Authenticates a client and their username and password with an LDAP or Active Directory server. For details, see [LDAP authentication](#).
 - `tls`: Authenticates clients that provide a certificate with a Common Name (CN) that specifies a valid database username. Vertica must be configured for [mutual mode TLS](#) to use this method. For details, see [TLS authentication](#).
 - `oauth`: Authenticates a client with an access token. For details, see [OAuth 2.0 authentication](#).
- The access method, one of the following, which specify the allowed connection type:
 - `LOCAL`: Authenticates users or applications that attempt to connect from the same node that the database is running on.
 - `HOST`: Authentications users or applications that attempt to connect from a node that has a different IPv4 or IPv6 address than the database. You can use `TLS` or `NO TLS` to specify an encrypted or plaintext connection, respectively.
- Whether to enable [Fallthrough authentication](#) (disabled by default).

2. [Grant](#) the authentication record to a user or role.

Examples

The following examples show how to create authentication records.

Create authentication method `localpwd` to authenticate users who are trying to log in from a local host using a password:

```
=> CREATE AUTHENTICATION localpwd METHOD 'hash' LOCAL;
```

Create authentication method `v_ldap` that uses LDAP over TLS to authenticate users logging in from the host with the IPv4 address 10.0.0.0/23:

```
=> CREATE AUTHENTICATION v_ldap METHOD 'ldap' HOST TLS '10.0.0.0/23';
```

Create authentication method `v_kerberos` to authenticate users who are trying to connect from any host in the networks 2001:0db8:0001:12 xx :

```
=> CREATE AUTHENTICATION v_kerberos METHOD 'gss' HOST '2001:db8:1::1200/56';
```

The following [authentication record v_oauth](#) authenticates users from any IP address by contacting the identity provider to validate the OAuth token (rather than a username and password) and uses the following parameters:

- `validate_type` : The method used to validate the OAuth token. This should be set to `IDP` (default) to validate the OAuth token for confidential clients.
- `client_id` : The client in the identity provider.
- `client_secret` : The client secret generated by the identity provider. This is required if `validate_type` is `IDP` .
- `discovery_url` : Also known as the [OpenID Provider Configuration Document](#) , Vertica uses this endpoint to retrieve information about the identity provider's configuration and other endpoints (Keycloak only).
- `introspect_url` : Used by Vertica to introspect (validate) access tokens. You must specify the `introspect_url` if you do not specify the `discovery_url` and are not using `JWT` validation.

If `discovery_url` and `introspect_url` are both set, `discovery_url` takes precedence. The following example sets both for demonstration purposes; in general, you should prefer to set the `discovery_url` :

```
=> CREATE AUTHENTICATION v_oauth METHOD 'oauth' HOST '0.0.0.0/0';
=> ALTER AUTHENTICATION v_oauth SET validate_type = 'IDP';
=> ALTER AUTHENTICATION v_oauth SET client_id = 'vertica';
=> ALTER AUTHENTICATION v_oauth SET client_secret = 'client_secret';
=> ALTER AUTHENTICATION v_oauth SET discovery_url = 'https://203.0.113.1:8443/realms/myrealm/.well-known/openid-configuration';
=> ALTER AUTHENTICATION v_oauth SET introspect_url = 'https://203.0.113.1:8443/realms/myrealm/protocol/openid-connect/token/introspect';
```

Alternatively, if your identity provider supports the OpenID Connect protocol and your client is public, Vertica can use JWT validation, where Vertica validates OAuth tokens by verifying that it was signed by the identity provider's private key.

Vertica does not contact the identity provider for JWT validation.

JWT validation requires the following parameters:

- `validate_type` : The method used to validate the OAuth token. This should be set to `JWT` to validate the OAuth token for public clients.
- `jwt_rsa_public_key` : In PEM format, the public key used to sign the client's OAuth token. Vertica uses this to validate the OAuth token. If your identity provider does not natively provide PEM-formatted public keys, you must convert them to PEM format. For example, keys retrieved from an Okta endpoint are in JWK format and must be converted.
- `jwt_issuer` : The issuer of the OAuth token. For Keycloak, this is the [token endpoint](#) .
- `jwt_user_mapping` : The name of the Vertica user.

You can also specify the following parameters to define a whitelist based on fields of the OAuth token:

- `jwt_accepted_audience_list` : Optional, a comma-delimited list of values to accept from the client JWT's `aud` field. If set, tokens must include in `aud` one of the accepted audiences to authenticate.
- `jwt_accepted_scope_list` : Optional, a comma-delimited list of values to accept from the client JWT's `scope` field. If set, tokens must include in `scope` at least one of the accepted scopes to authenticate.

The following [authentication record v_oauth_jwt](#) authenticates users from any IP address by verifying that the client's OAuth token was signed by the identity provider's private key. It also requires the user to provide the proper values in the token's `aud` and `scope` fields:

```
=> CREATE AUTHENTICATION v_oauth_jwt METHOD 'oauth' HOST '0.0.0.0/0';
=> ALTER AUTHENTICATION v_oauth_jwt SET validate_type = 'JWT';
=> ALTER AUTHENTICATION v_oauth_jwt SET jwt_rsa_public_key = '-----BEGIN PUBLIC KEY-----public-key-value-----END PUBLIC KEY-----';
=> ALTER AUTHENTICATION v_oauth_jwt SET jwt_issuer = 'http://10.20.30.40:8080/realms/realm_name';
=> ALTER AUTHENTICATION v_oauth_jwt SET jwt_user_mapping = 'preferred_username';
=> ALTER AUTHENTICATION v_oauth_jwt SET jwt_accepted_audience_list = 'vertica,local';
=> ALTER AUTHENTICATION v_oauth_jwt SET jwt_accepted_scope_list = 'email,profile,user';
```

For example, to reject all plaintext client connections, specify the `reject` authentication method and the `HOST NO TLS` access method as follows:

```
=> CREATE AUTHENTICATION RejectNoSSL METHOD 'reject' HOST NO TLS '0.0.0.0/0'; --IPv4
=> CREATE AUTHENTICATION RejectNoSSL METHOD 'reject' HOST NO TLS ':::0'; --IPv6
```

- [Modifying authentication records](#)

Modifying authentication records

To modify existing authentication records, you must first be connected to your database. The following examples show how to make changes to your authentication records. For more information see [ALTER AUTHENTICATION](#).

Rename an authentication method

Rename the `v_kerberos` authentication method to `K5`, and enable it. All users who have been associated with the `v_kerberos` authentication method are now associated with the `K5` method granted instead.

```
=> ALTER AUTHENTICATION v_kerberos RENAME TO K5 ENABLE;
```

Specify a priority for an authentication method

Specify a priority of 10 for `K5` authentication:

```
=> ALTER AUTHENTICATION K5 PRIORITY 10;
```

For more information see [Authentication record priority](#).

Change a parameter

Set the `system_users` parameter for `ident1` authentication to `root`:

```
=> CREATE AUTHENTICATION ident1 METHOD 'ident' LOCAL;
=> ALTER AUTHENTICATION ident1 SET system_users='root';
```

Change the IP address and specify the parameters for an LDAP authentication method named `Ldap1`.

In this example, you specify the bind parameters for the LDAP server. Vertica connects to the LDAP server, which authenticates the Vertica client. If the authentication succeeds, Vertica authenticates any users who have been granted the `Ldap1` authentication method on the designated LDAP server:

```
=> CREATE AUTHENTICATION Ldap1 METHOD 'ldap' HOST '172.16.65.196';
=> ALTER AUTHENTICATION Ldap1 SET host='ldap://172.16.65.177',
  binddn_prefix='cn=', binddn_suffix=',dc=qa_domain,dc=com';
```

Change the IP address, and specify the parameters for an LDAP authentication method named `Ldap1`. Assume that Vertica does not have enough information to create the distinguished name (DN) for a user attempting to authenticate. Therefore, in this case, you must specify to use LDAP search and bind:

```
=> CREATE AUTHENTICATION LDAP1 METHOD 'ldap' HOST '172.16.65.196';
=> ALTER AUTHENTICATION Ldap1 SET host='ldap://172.16.65.177',
  basedn='dc=qa_domain,dc=com',binddn='cn=Manager,dc=qa_domain,
  dc=com',search_attribute='cn',bind_password='secret';
```

Change the associated method

Change the `localpwd` authentication from trust to hash:

```
=> CREATE AUTHENTICATION localpwd METHOD 'trust' LOCAL;
=> ALTER AUTHENTICATION localpwd METHOD 'hash';
```

`ALTER AUTHENTICATION` validates the parameters you enter. If there are errors, it disables the authentication method that you are trying to modify.

Using the administration tools

The advantages of using the Administration Tools are:

- You do not have to connect to the database
- The editor verifies that records are correctly formed
- The editor maintains records so they are available to you to edit later

Note

You must restart the database to implement your changes.

For information about using the Administration Tools to create and edit authentication records, see [Creating authentication records](#).

Deleting authentication records

To delete client authentication record, use [DROP AUTHENTICATION](#). To use this approach, you have to be connected to your database.

To delete an authentication record for md5_auth use the following command:

```
=> DROP AUTHENTICATION md5_auth;
```

To delete an authentication record for a method that has been granted to a user, use the CASCADE keyword:

```
=> CREATE AUTHENTICATION localpwd METHOD 'password' LOCAL;
=> GRANT AUTHENTICATION localpwd TO jsmith;
=> DROP AUTHENTICATION localpwd CASCADE;
```

See also

- [Creating authentication records](#)
- [Granting and revoking authentication methods](#)

Authentication record priority

Each authentication record has a [priority](#). If a user is [granted](#) more than one authentication record, Vertica attempts to authenticate the user with the authentication record with the highest priority and rejects the user if authentication fails.

There are two ways to authenticate with a record other than that with the highest priority:

- [Fallthrough authentication](#): If authentication fails, Vertica attempts to authenticate the client with the record with the next highest priority.
- [Authentication filtering](#): Clients can send the credentials required for a particular authentication method to authenticate with a record that uses that method.

Determining authentication priority

The following factors contribute to an authentication record's priority, as reflected in the [CLIENT_AUTH](#) system table:

```
=> SELECT auth_name, auth_method, auth_priority, method_priority, address_priority FROM client_auth;
```

```
auth_name | auth_method | auth_priority | method_priority | address_priority
-----+-----+-----+-----+-----
ldap_auth | LDAP       | 5           | 5             | 96
hash_auth | HASH       | 5           | 2             | 126
tls_auth  | TLS        | 0           | 5             | 96
oauth_auth | OAUTH      | 0           | 5             | 96
gss_auth  | GSS        | 0           | 5             | 96
trust_auth | TRUST      | 0           | 0             | 96
reject_auth | REJECT     | 0           | 10            | 96
(7 rows)
```

Note

Greater values indicate higher priorities. For example:

- A priority of 10 is higher than a priority of 5.
- A priority 0 is the lowest possible value.

Priorities are divided into tiers and listed in order of importance; in the event of a tie at one priority tier, Vertica checks the next priority tier. For example, if a user had both [ldap](#) and [hash](#) authentication records with an [auth_priority](#) of 5, Vertica would attempt to use the [ldap](#) authentication record because it has a greater [method_priority](#) value:

1. [auth_priority](#): The priority explicitly set with [ALTER AUTHENTICATION](#) (default: 0).
2. [method_priority](#): The priority specific to the authentication method. These priorities are as follows:

- `trust` : 0
 - `hash` : 2
 - `ldap` : 5
 - `tls` : 5
 - `oauth` : 5
 - `gss` : 5
 - `reject` : 10
3. `address_priority` : The priority for IP address specified in `HOST [TLS | NO TLS] ' host-ip-address '`. This priority is determined by the size of the netmask of the address; fewer zeros indicate greater specificity, and therefore higher priority. `LOCAL` has the lowest priority: 0.

Setting authentication priority

To set authentication priority:

```
=> ALTER AUTHENTICATION authentication_name PRIORITY value;
```

- [CLIENT_AUTH](#)
- [CLIENT_AUTH_PARAMS](#)
- [Client authentication](#)

Viewing information about client authentication records

For information about client authentication records that you have configured for your database, query the following system tables in the `V_CATALOG` schema:

- [CLIENT_AUTH](#)
- [CLIENT_AUTH_PARAMS](#)
- [PASSWORD_AUDITOR](#)
- [USER_CLIENT_AUTH](#)

To determine the details behind the client authentication used for a particular user session, query the following tables in the `V_MONITOR` schema:

- [SESSIONS](#)
- [USER_SESSIONS](#)

Enabling and disabling authentication methods

When you create an authentication method, Vertica stores it in the catalog and enables it automatically. To enable or disable an authentication method, use the [ALTER AUTHENTICATION](#) statement. To use this approach, you must be connected to your database.

If an authentication method has not been enabled, Vertica cannot use it to authenticate users and clients trying to connect to the database.

To enable an authentication method:

```
ALTER AUTHENTICATION v_kerberos ENABLE;
```

To disable this authentication method:

```
ALTER AUTHENTICATION v_kerberos DISABLE;
```

See also

- [Creating authentication records](#)
- [Deleting Authentication Records](#)
- [Granting and revoking authentication methods](#)
- [Modifying authentication records](#)

Granting and revoking authentication methods

Before Vertica can validate a user or client through an authentication method, you must first associate that authentication method with the user or role that requires it, with [GRANT \(authentication\)](#). When that user or role no longer needs to connect to Vertica using that method, you can disassociate that authentication from that user with `REVOKE AUTHENTICATION`.

Grant authentication methods

You can grant an authentication method to a specific user or role. You can also specify the default authentication method by granting an authentication method to **PUBLIC** , as in the following examples.

- Associate **v_ldap** authentication with user **jsmith** :

```
=> GRANT AUTHENTICATION v_ldap TO jsmith;
```

- Associate **v_gss** authentication to the role **DBprogrammer** :

```
=> CREATE ROLE DBprogrammer;  
=> GRANT AUTHENTICATION v_gss TO DBprogrammer;
```

- Associate client authentication method **v_localpwd** with role **PUBLIC** , which is assigned by default to all users:

```
=> GRANT AUTHENTICATION v_localpwd TO PUBLIC;
```

Revoke authentication methods

If you no longer want to authenticate a user or client with a given authentication method, use the [REVOKE \(authentication\)](#) statement as in the following examples.

- Revoke **v_ldap** authentication from user **jsmith** :

```
=> REVOKE AUTHENTICATION v_ldap FROM jsmith;
```

- Revoke **v_gss** authentication from the role **DBprogrammer** :

```
=> REVOKE AUTHENTICATION v_gss FROM DBprogrammer;
```

- Revoke **localpwd** as the default client authentication method:

```
=> REVOKE AUTHENTICATION localpwd FROM PUBLIC;
```

Hiding database usernames

If you want to keep certain database usernames a secret from connecting clients and your authentication records do not use [Fallthrough authentication](#) , then these two user groups must share the same single [authentication method](#) (not necessarily the same authentication record):

- Users whose usernames must be kept secret.
- Users with the **PUBLIC** role.

If your authentication records use fallthrough, then ensure that the first authentication method that prompts for a password in the authentication chain is the same for both the secret users and the **PUBLIC** role. The following methods prompt for a password:

- [hash](#)
- [ldap](#)

A simple way to satisfy this condition is by duplicating the fallthrough chain for both groups with the same methods. For example, a valid authentication chain would be **tls > ldap** for both the secret users and the **PUBLIC** role.

Another valid configuration would be **tls > ldap > hash** for secret users, and **ldap** for the **PUBLIC** role.

Hash authentication

The **hash** authentication method authenticates users with passwords.

In general, you should prefer [other authentication methods](#) over **hash** .

In this section

- [Password hashing algorithm](#)
- [Configuring hash authentication](#)
- [Passwords](#)

Password hashing algorithm

Note

Vertica strongly recommends that you use SHA-512 for **hash** authentication.

Vertica does not store user passwords for the **hash** authentication method. Rather, Vertica stores a hash of the password. The hashing algorithm is determined by two parameters:

- A system-level configuration parameter, **SecurityAlgorithm** :

```
=> ALTER DATABASE DEFAULT SET PARAMETER SecurityAlgorithm = 'hashing_algorithm';
```

- A user-level parameter, **SECURITY_ALGORITHM** :

```
=> ALTER USER username SECURITY_ALGORITHM 'hashing_algorithm' IDENTIFIED BY 'new_password';
```

The system-level parameter, **SecurityAlgorithm** , can have the following values:

- **SHA512** (default)
- **MD5**

The user-level parameter, **SECURITY_ALGORITHM** , can have the following values. Values other than **NONE** will take priority over the system-level parameter:

- **NONE** (default, uses algorithm specified by the system-level parameter **SecurityAlgorithm**)
- **SHA512**
- **MD5**

Note

If user's password is hashed with MD5, you cannot change their username with [ALTER USER](#).

A user's **EFFECTIVE_SECURITY_ALGORITHM** is determined by a combination of the system-level and user-level parameters. If the user-level parameter is set to **NONE** , the effective security algorithm will be that of the system-level parameter. You can override the system-level parameter for a particular user by setting the user-level parameter to a non- **NONE** value.

You can view these parameters and their effects on each user by querying the system table [PASSWORD_AUDITOR](#).

The following table shows the various combinations of the system-level and user-level parameters and the effective security algorithm for each.

FIPS mode forces the effective security algorithm to be SHA-512.

Parameter value		Effective Security Algorithm	
System level: SecurityAlgorithm	User-level: SECURITY_ALGORITHM	Algorithm Used	Algorithm Used (FIPS mode)
MD5	NONE	MD5	SHA-512
SHA512	NONE	SHA-512	SHA-512
MD5	MD5	MD5	SHA-512
SHA512	MD5	MD5	SHA-512
MD5	SHA512	SHA-512	SHA-512
SHA512	SHA512	SHA-512	SHA-512

Configuring hash authentication

The **hash** authentication method allows users to authenticate with a password.

Vertica stores hashes (SHA-512 [by default](#)) of passwords and not the passwords themselves. For details, see [Password hashing algorithm](#).

1. [Create an authentication record](#) with the **hash** method. Authentication records are automatically enabled after creation. For example, to create the authentication record **v_hash** for users that log in from the IP address 192.0.2.0/24:

```
=> CREATE AUTHENTICATION v_hash METHOD 'hash' HOST '192.0.2.0/24';
```

2. Associate the `v_hash` authentication method with the desired users or roles, using a GRANT statement:

```
=> GRANT AUTHENTICATION v_hash to user1, user2, ...;
```

Passwords

Assign a password to a user to allow that user to connect to the database using password authentication. When the user supplies the correct password a connection to the database occurs.

Vertica hashes passwords according to each user's [EFFECTIVE_SECURITY_ALGORITHM](#). However, the transmission of the hashed password from the client to Vertica is in plaintext. Thus, it is possible for a "man-in-the-middle" attack to intercept the plaintext password from the client.

Configuring [Hash authentication](#) ensures secure login using passwords.

About password creation and modification

You must be a [superuser](#) to create passwords for user accounts using the [CREATE USER](#) statement. A superuser can set any user account's password.

- To add a password, use the [ALTER USER](#) statement.
- To change a password, use [ALTER USER](#) or the vsql meta-command `\password` .

Users can also change their own passwords.

To make password authentication more effective, Vertica recommends that you enforce password policies that control how often users are forced to change passwords and the required content of a password. You set these policies using [Profiles](#) .

Default password authentication

When you have not specified any authentication methods, Vertica defaults to using password authentication for user accounts that have passwords.

If you create authentication methods, even for remote hosts, password authentication is disabled. In such cases, you must explicitly enable password authentication. The following commands create the `local_pwd` authentication method and make it the default for all users. When you create an authentication method, Vertica enables it automatically:

```
=> CREATE AUTHENTICATION local_pwd METHOD hash' LOCAL;  
=> GRANT AUTHENTICATION local_pwd To Public;
```

In this section

- [Profiles](#)
- [Password guidelines](#)
- [Password expiration](#)
- [Account locking](#)

Profiles

You can set password policies for users by assigning them profiles. You can create multiple profiles to manage the password policies for several categories of users. For example, you could create one profile for interactive users that requires frequent password changes and another profile for user accounts that never requires password changes.

Defining profiles

You create profiles with [CREATE PROFILE](#) and alter existing profiles with [ALTER PROFILE](#) . Both statements let you set one or more profile parameters which can control, among other things, the minimum lifetime of a password, password complexity, and password-reset rules.

Each profile can specify one or more of the following policies.

- How often users must change their passwords
- How long a password must be set before it can be reset
- How many times users must change their passwords before they can reuse an old password
- How many times a user can fail to log in before the account is locked
- The required length and content of the password:
 - Maximum and minimum number of characters
 - Minimum number of capital letters, lowercase letters, digits, and symbols required in a password
 - How different a new password must be from the old password

Assigning profiles

After you define a profile, you can assign it to new and existing users with [CREATE USER](#) and [ALTER USER](#) , respectively.

Changes to profile policies for password content—for example, `PASSWORD_MAX_LENGTH` and `PASSWORD_MIN_SYMBOLS`—affect users only when they change their passwords. Vertica does not test existing passwords to verify that they comply with new password requirements. To enforce immediate compliance with new profile requirements, use `ALTER USER...PASSWORD EXPIRE` to immediately expire the current user's password. The next time the user logs in, Vertica prompts them to supply a new password, which must comply with the current policy.

Default profile

Each database contains a `DEFAULT` profile. Vertica assigns the default profile to users who are not explicitly assigned a profile. The default profile also sets parameters of non-default profiles in two cases:

- Profile parameters that are not explicitly set by `CREATE PROFILE`
- Parameters that `ALTER PROFILE` sets to `DEFAULT`

All parameters in the default profile are initially set to `unlimited`. You can use `ALTER PROFILE` to change these settings. For example, the following statement modifies the default profile parameter `PASSWORD_MIN_SYMBOLS`. The change requires passwords to contain at least one symbol, such as \$, #, @. This change affects all profiles where `PASSWORD_MIN_SYMBOLS` is set to `default`:

```
ALTER PROFILE DEFAULT LIMIT PASSWORD_MIN_SYMBOLS 1;
```

Profile settings and client authentication

The following profile settings affect [client authentication methods](#), such as LDAP or GSS:

- `FAILED_LOGIN_ATTEMPTS`
- `PASSWORD_LOCK_TIME`

All other profile settings are used only by Vertica to manage its passwords.

See also

- [PROFILES](#)
- [Creating a database name and password](#)

Password guidelines

For passwords to be effective, they must be hard to guess. You need to protect passwords from:

- Dictionary-style, brute-force attacks
- Users who have knowledge of the password holder (family names, birth dates, etc.)

Use [Profiles](#) to enforce good password practices (password length and required content). Make sure database users know the password guidelines, and encourage them not to use personal information in their passwords.

For guidelines on creating strong passwords go to [Microsoft Tips for Creating a Strong Password](#).

See also

- [Creating a database name and password](#)

Password expiration

The following PROFILE parameters control the conditions for password expiration, new passwords, and minimum lifetime:

- `PASSWORD_LIFE_TIME` - The number of days a password remains valid
- `PASSWORD_MIN_LIFE_TIME` - The number of days a password must be set before it can be changed
- `PASSWORD_GRACE_TIME` - The number of days a password can be used after it expires
- `PASSWORD_REUSE_MAX` - The number of times you must change your password before you can reuse an earlier password
- `PASSWORD_REUSE_TIME` - The number of days that must pass after a password is set before you can reuse it
- `PASSWORD_MIN_CHAR_CHANGE` - Minimum number of characters that must be different from the previous password

For more details on these and other parameters, see [CREATE PROFILE](#) and [ALTER PROFILE](#).

Important

Password expiration has no effect on current sessions.

Password expiration and grace period behavior

The profile parameter `PASSWORD_LIFE_TIME` controls the life time of a password in days. By default, the DEFAULT profile sets `PASSWORD_LIFE_TIME` to `UNLIMITED`, which disables password expiration. You can change this for the DEFAULT and custom profiles with `ALTER PROFILE`.

Normally, when a password expires, Vertica forces users to change their passwords the next time they log in. However, you can set a `PASSWORD_GRACE_TIME` to allow users to log in after their password expires. If a user logs in during their grace period, Vertica warns the user that their password has expired. Once this grace period ends, Vertica will issue the standard prompt to change the user's password.

Expire a password

You can expire a user's password immediately using the `ALTER USER` statement's `PASSWORD EXPIRE` parameter. By expiring a password, you can:

- Force users to comply with a change to password policy.
- Set a new password when a user forgets the old password.

Account locking

In a profile, you can set a password policy for how many consecutive failed login attempts a user account is allowed before locking. This locking mechanism helps prevent dictionary-style brute-force attempts to guess users' passwords.

Set account locking

Set this value using the `FAILED_LOGIN_ATTEMPTS` parameter using the `CREATE PROFILE` or `ALTER PROFILE` statement.

Vertica locks any user account that has more consecutive failed login attempts than the value to which you set `FAILED_LOGIN_ATTEMPTS`. The user cannot log in to a locked account, even by supplying the correct password.

Unlock a locked account

You can unlock accounts in one of two ways, depending on your privileges.

- **Manually** : If you are a [superuser](#), you can manually unlock the account using the `ALTER USER` command.

Note

A superuser account cannot be locked, because it is the only user that can unlock accounts. For this reason, choose a very secure password for a superuser account. See [Password guidelines](#) for suggestions.

- **Password Lock Time Setting** : `PASSWORD_LOCK_TIME` specifies the number of days (units configurable with [PasswordLockTimeUnit](#)) an account is locked after a specified number of failed login attempts (configurable with `FAILED_LOGIN_ATTEMPTS`). Vertica automatically unlocks the account after the specified number of days has passed.

If you set this parameter to `UNLIMITED`, the user's account is never automatically unlocked and a superuser must manually unlock it.

Ident authentication

The Ident protocol, defined in [RFC 1413](#), authenticates a database user with a system user name. To see if that system user can log in without specifying a password, you configure Vertica client authentication to query an Ident server. With this feature, the DBADMIN user can run automated scripts to execute tasks on the Vertica server.

Caution

Ident responses can be easily spoofed by untrusted servers. Use Ident authentication only on local connections, where the Ident server is installed on the same computer as the Vertica database server.

Following the instructions in these topics to install, set up, and configure Ident authentication for your database:

- [Installing and setting up an ident server](#)
- [Configuring ident authentication for database users](#)

Examples

The following examples show several ways to configure Ident authentication.

Allow `system_user1` to connect to the database as Vertica `vuser1` :

```
=> CREATE AUTHENTICATION v_ident METHOD 'ident' LOCAL;
=> ALTER AUTHENTICATION v_ident SET system_users='system_user1';
=> GRANT AUTHENTICATION v_ident to vuser1;
=> ALTER AUTHENTICATION v_ident ENABLE;
```

Allow `system_user1` , `system_user2` , and `system_user3` to connect to the database as `vuser1` . Use colons (:) to separate the user names:

```
=> CREATE AUTHENTICATION v_ident METHOD 'ident' LOCAL;
=> ALTER AUTHENTICATION v_ident SET system_users='system_user1:system_user2:system_user3';
=> GRANT AUTHENTICATION v_ident TO vuser1;
=> ALTER AUTHENTICATION v_ident ENABLE;
```

Associate the authentication with `Public` using a GRANT AUTHENTICATION statement. The users, `system_user1` , `system_user2` , and `system_user3` can now connect to the database as any database user:

```
=> CREATE AUTHENTICATION v_ident METHOD 'ident' LOCAL;
=> ALTER AUTHENTICATION v_ident SET system_users='system_user1:system_user2:system_user3';
=> GRANT AUTHENTICATION v_ident to Public;
=> ALTER AUTHENTICATION v_ident ENABLE;
```

Set the `system_users` parameter to `*` to allow any system user to connect to the database as `vuser1` :

```
=> CREATE AUTHENTICATION v_ident METHOD 'ident' LOCAL;
=> ALTER AUTHENTICATION v_ident SET system_users='*';
=> GRANT AUTHENTICATION v_ident TO vuser1;
=> ALTER AUTHENTICATION v_ident ENABLE;
```

Using a GRANT statement, associate the `v_ident` authentication with `Public` to allow `system_user1` to log into the database as any database user:

```
=> CREATE AUTHENTICATION v_ident METHOD 'ident' LOCAL;
=> ALTER AUTHENTICATION v_ident SET system_users='system_user1';
=> GRANT AUTHENTICATION v_ident to Public;
=> ALTER AUTHENTICATION v_ident ENABLE;
```

In this section

- [Installing and setting up an ident server](#)
- [Configuring ident authentication for database users](#)

Installing and setting up an ident server

To use Ident authentication, you must install one or more packages, depending on your operating system, and enable the Ident server on your Vertica server. `oidentd` is an Ident daemon that is compatible with Vertica and compliant with [RFC 1413](#).

Note

You can find the source code and installation instructions for `oidentd` at the [oidentd website](#).

To install and configure Ident authentication for use with your Vertica database, follow the appropriate steps for your operating system.

Red hat 7.x/CentOS 7.x

Install an Ident server on Red Hat 7.x or CentOS 7.x by installing the `authd` and `xinetd` packages:

```
$ yum install authd
$ yum install xinetd
```

Ubuntu/debian

Install `oidentd` on Ubuntu or Debian by running this command:

```
$ sudo apt-get install oidentd
```

SUSE Linux enterprise server

Install the `pidentd` and `xinetd` RPMs from the following locations:

- https://www.suse.com/LinuxPackages/packageRouter.jsp?product=server&version=11&service_pack=&architecture=i386&package_name=pidentd
- https://www.suse.com/LinuxPackages/packageRouter.jsp?product=server&version=11&service_pack=&architecture=i386&package_name=xinetd

Post-installation steps for ubuntu/debian

After you install **oidentd** on your Ubuntu/Debian system, continue with the following steps:

1. Verify that the Ident server accepts IPv6 connections to prevent authentication failure. To do so, you must enable this capability. In the script `/etc/init.d/oidentd`, change the line from:

```
exec="/usr/sbin/oidentd"
```

to

```
exec="/usr/sbin/oidentd -a ::"
```

Then, at the Linux prompt, start **oidentd** with `-a ::`.

2. Restart the server with the following command:

```
$ /etc/init.d/oidentd restart
```

Post-installation steps for red hat 7.x/CentOS 7.x and SUSE Linux enterprise server

After you install the required packages on your Red Hat 7.x/CentOS 7.x or SUSE Linux Enterprise Server system, continue with the following steps:

1. Enable the **auth** service by setting `disable = no` in the configuration file `/etc/xinetd.d/auth`. If this file does not exist, create it. The following is a sample configuration file:

```
service auth
{
    disable = no
    socket_type = stream
    wait = no
    user = ident
    cps = 4096 10
    instances = UNLIMITED
    server = /usr/sbin/in.authd
    server_args = -t60 --xerror --os
}
```

2. Restart the **xinetd** service with the following command:

```
$ service xinetd restart
```

Configuring ident authentication for database users

To configure Ident authentication, take the following steps:

1. Create an authentication method that uses Ident.

The Ident server must be installed on the same computer as your database, so specify the keyword `LOCAL`. Vertica requires that the Ident server and database always be on the same computer as the database.

```
=> CREATE AUTHENTICATION v_ident METHOD 'ident' LOCAL;
```

2. Set the Ident authentication parameters, specifying the system users who should be allowed to connect to your database.

```
=> ALTER AUTHENTICATION v_ident SET system_users='user1:user2:user3';
```

3. Associate the authentication method with the Vertica user. Use a `GRANT` statement that allows the system user **user1** to log in using Ident authentication:

```
=> GRANT AUTHENTICATION v_ident TO user1;
```

Kerberos authentication

Kerberos authentication uses the following components to perform user authentication.

Client package

The Kerberos 5 client package communicates with the KDC server. This package is not included as part of the Vertica Analytics Platform installation. Kerberos software is built into Microsoft Windows. If you are using another operating system, you must obtain and install the client package.

If you do not already have the Kerberos 5 client package on your system, download it from the [MIT Kerberos Distribution page](#). Install the package on each Vertica server and client used in Kerberos authentication, except the KDC itself.

Refer to the [Kerberos documentation](#) for installation instructions.

Service principals

A service principal consists of a host name, a service name, and a realm to which a set of credentials gets assigned (service/hostname@REALM). These credentials connect to the service, which is a host that you connect to over your network and authenticate using the KDC.

See [Specify KDC information and configure realms](#) to create the realm name. The host name must match the value supplied by the operating system. Typically this is the fully qualified host name. If the host name part of your principal does not match the value supplied by the operating system, Kerberos authentication fails.

Some systems use a hosts file (/etc/hosts or /etc/hostnames) to define host names. A hosts file can define more than one name for a host. The operating system supplies the first entry, so use that in your principal. For example, if your hosts file contains:

```
192.168.1.101 v_vmart_node0001.example.com v_vmart_node0001
```

then use v_vmart_node0001.example.com as the hostname value.

Note

Depending on your configuration it may be safer to use the fully qualified domain name rather than the hostname.

Configure the following as Kerberos principals:

- Each client (users or applications that connects to Vertica)
- The Vertica server

See the following topics for more information:

- [Configure Vertica for Kerberos authentication](#)
- [Configure Clients for Kerberos Authentication](#)

Keytab files

Principals are stored in encrypted keytab files. The keytab file contains the credentials for the Vertica principal. The keytab allows the Vertica server to authenticate itself to the KDC. You need the keytab so that Vertica Analytic Database does not have to prompt for a password.

Create one service principal for each node in your cluster. You can then either create individual keytab files (one for each node containing only that node's principal) or create one keytab file containing all the principals.

- **Create one keytab file with all principals** to simplify setup: all nodes have the same file, making initial setup easier. If you add nodes later you either update (and redistribute) the global keytab file or make separate keytabs for the new nodes. If a principal is compromised it is compromised on all nodes where it is present in a keytab file.
- **Create separate keytab files on each node** to simplify maintenance. Initial setup is more involved as you must create a different file on each node, but no principals are shared across nodes. If you add nodes later you create keytabs on the new nodes. Each node's keytab contains only one principal, the one to use for that node.

Ticket-granting ticket

The Ticket-Granting Ticket (TGT) retrieves service tickets that authenticates users to servers in the domain. Future login requests use the cached HTTP Service Ticket for authentication, unless it has expired as set in the ticket_lifetime parameter in krb5.conf.

Multi-realm support

Note

When assigning multiple realms to an authentication record, keep in mind that Vertica cannot distinguish between users from one realm and users from the Vertica realm. This allows the same user to log in to Vertica from multiple realms at the same time.

Vertica provides multi-realm support for Kerberos authentication using the SET param=value parameter in [ALTER AUTHENTICATION](#) with REALM as the parameter:

```
=> ALTER AUTHENTICATION krb_auth_users set REALM='USERS.COM';  
=> ALTER AUTHENTICATION krb_auth_realmad set REALM='REALM_AD.COM';
```

This allows you to assign a different realm so that users from another realm can authenticate to Vertica.

Mutli-realm support applies to GSS authentication types only. You can have one realm per authentication method. If you have multiple authentication methods, each can have its own realm:

```
=> SELECT * FROM client_auth;
auth_oid | auth_name | is_auth_enabled | auth_host_type | auth_host_address | auth_method | auth_parameters | auth_priority
-----+-----+-----+-----+-----+-----+-----+-----
45035996 | krb001 | True | HOST | 0.0.0.0/0 | GSS | realm=USERS.COM | 0
45035997 | user_auth | True | LOCAL | | TRUST | | 1000
45035737 | krb002 | True | HOST | 0.0.0.0/0 | GSS | realm=REALM_AD.COM | 1
```

In this section

- [Configure Vertica for Kerberos authentication](#)
- [Configure clients for Kerberos authentication](#)
- [Troubleshooting Kerberos authentication](#)

Configure Vertica for Kerberos authentication

Kerberos provides a strong cryptographic authentication against the devices which lets the client & servers to communicate in a more secured manner. It addresses network security problems.

Your system must have one or more Kerberos Key Distribution Centers (KDC) installed and configured. The KDCs must be accessible from every node in your Vertica Analytic Database cluster.

The KDC must support Kerberos 5 using GSS-API. For details, see the [MIT Kerberos Distribution Page](#).

In this section

In this section

- [Create the Vertica principals and keytabs on Linux KDC](#)
- [Specify KDC information and configure realms](#)
- [Inform Vertica about the Kerberos principal](#)
- [Configure the authentication method for all clients](#)
- [Creating the principals and keytab on active directory](#)
- [Get the Kerberos ticket and authenticate Vertica](#)

Create the Vertica principals and keytabs on Linux KDC

Vertica uses service principals for system-level operations. These principals identify the Vertica service and are used as follows:

- Kerberized Vertica clients request access to this service when they authenticate to the database.
- System processes like the Tuple Mover use this identity when they authenticate to external services such as Hadoop.

Create principals and keys as follows:

1. Start the Kerberos 5 database administration utility (`kadmin` or `kadmin.local`) to create Vertica principals on a Linux KDC.
 - Use `kadmin` if you are accessing the KDC on a remote server. If you have access to the Kerberos administrator password, you can use `kadmin` on any machine where the Kerberos 5 client package is installed. When you start `kadmin` , the utility prompts you for the Kerberos administrator's password. You might need root privileges on the client to run `kadmin` .
 - Use `kadmin.local` if:
 - The KDC is on the machine that you are logging in to.
 - You have root privileges on that server.

`kadmin.local` does not require the administrators login credentials.

For more information about the `kadmin` and `kadmin.local` commands, see the [kadmin documentation](#) .

2. Create one service principal for Vertica on each node. The host name must match the value supplied by the operating system. The following example creates the service principal `vertica` for the node named `v_vmart_node0001.example.com` :

```
$ sudo /usr/kerberos/sbin/kadmin.local
kadmin.local add_principal vertica/v_vmart_node0001.example.com
```

Repeat the `ktadd` command once per principal. You can create separate keytabs for each principal user or add them all to a single keytab file (such as `krb5.keytab`). If you are using a single file, see the documentation for the `-glob` option in the [MIT Kerberos documentation](#) .

You must have a user principal for each Vertica Analytic Database user that uses Kerberos Authentication. For example:

```
$ sudo /usr/kerberos/sbin/kadmin.local
kadmin.local add_principal [options] VerticaUser1
```

3. Copy each keytab file to the `/etc` folder on the corresponding cluster node. Use the same path and file name on all nodes.
4. On each node, make the keytab file readable by the file owner who is running the database process (typically, the Linux `dbadmin` user). For example, you can change ownership of the files to `dbadmin` as follows:

```
$ sudo chown dbadmin *.keytab
```

Important

In a production environment, you must control who can access the keytab file to prevent unauthorized users from delegating your server. For more information about delegation (also known as impersonation), see [Technet.Microsoft.com](https://technet.microsoft.com).

After you create a keytab file, you can use the `klist` command to view keys stored in the file:

```
$ sudo /usr/kerberos/bin/klist -ke -t
Keytab name: FILE:/etc/krb5.keytab
KVNO  Timestamp      Principal
-----
4      08/15/2017 7:35:41  vertica/v_vmart_node0001.example.com@EXAMPLE.COM (aes256-cts-hmac-sha1-96)
4      08/15/2017 7:35:41  vertica/v_vmart_node0001.example.com@EXAMPLE.COM (aes128-cts-hmac-sha1-96)
```

5. On Vertica run the following to ensure the Kerberos parameters are set correctly:

```
=> select parameter_name, current_value from configuration_parameters where parameter_name like 'Ker%';
parameter_name | current_value
-----
KerberosHostname | v_vmart_node0001.example.com
KerberosKeytabFile | /etc/krb5.keytab
KerberosRealm | EXAMPLE.COM
KerberosTicketDuration | 0
KerberosServiceName | vertica
(5 rows)
```

6. Ensure that all clients use the gss authentication method.

From Vertica:

```
=> CREATE USER bob;
CREATE USER

=> CREATE AUTHENTICATION v_kerberos method 'gss' host '0.0.0.0/0';
CREATE AUTHENTICATION

=> ALTER AUTHENTICATION v_kerberos enable;
ALTER AUTHENTICATION

=> GRANT AUTHENTICATION v_kerberos to bob;
GRANT AUTHENTICATION
```

From the operating system command line:

```
$ kinit bob

$ vsql -U bob -k vertica -K v_vmart_node0001.example.com -h v_vmart_node0001 -c "select client_authentication_name,
authentication_method from sessions;"
client_authentication_name | authentication_method--
-----
v_kerberos | GSS-Kerberos
(1 row)
```

7. On Vertica, run [KERBEROS_CONFIG_CHECK](#) to verify the Kerberos configuration. `KERBEROS_CONFIG_CHECK` verifies the following:
 - o The existence of the `kinit` and `kb5.conf` files.
 - o Whether the keytab file exists and is set
 - o The Kerberos configuration parameters set in the database:
 - `KerberosServiceName`
 - `KerberosHostname`
 - `KerberosRealm`
 - Vertica Principal
 - o That Kerberos can read the Vertica keys

- That Kerberos can get the tickets for the Vertica principal
- That Vertica can initialize the keys with kinit

Specify KDC information and configure realms

Each client and Vertica Analytic Database server in the Kerberos realm must have a valid, identically configured Kerberos configuration ([krb5.conf](#)) file. Without this file, the client does not know how to reach the KDC.

If you use Microsoft Active Directory, you do not need to perform this step. Refer to the Kerberos documentation for your platform for more information about the Kerberos configuration file on Active Directory.

At a minimum, you must configure the following sections in the [krb5.conf](#) file.

- [[libdefaults](#)]—Settings used by the Kerberos 5 library
- [[realms](#)]—Realm-specific contact information and settings
- [[domain_realm](#)]—Maps server hostnames to Kerberos realms

See the Kerberos documentation for information about other sections in this configuration file.

You must update the [/etc/krb5.conf](#) file to reflect your site's Kerberos configuration. The simplest way to enforce consistency among all clients and servers in the Kerberos realm is to copy the [/etc/krb5.conf](#) file from the KDC. Then, place this file in the [/etc](#) directory on each Vertica cluster node.

Inform Vertica about the Kerberos principal

Follow these steps to inform Vertica about the principal name and keytab location.

For information about the parameters that you are setting in this procedure, see [Kerberos parameters](#).

1. Log in to the database as an administrator (typically dbadmin).
2. Set the [KerberosKeyTabFile](#) configuration parameter to point to the location of the keytab file:

```
=> ALTER DATABASE DEFAULT SET PARAMETER KerberosKeytabFile = '/etc/krb5.keytab';
```

The keytab file must be in the same location ([/etc/krb5.keytab](#) in this example) on all nodes.

3. Set the service name for the Vertica principal; for example, [vertica](#) :

```
=> ALTER DATABASE DEFAULT SET PARAMETER KerberosServiceName = 'vertica';
```

4. Provide the realm portion of the principal, for example, [EXAMPLE.COM](#) :

```
=> ALTER DATABASE DEFAULT SET PARAMETER KerberosRealm = 'EXAMPLE.COM'
```

Configure the authentication method for all clients

To make sure that all clients use the gss authentication method, run the following statements:

```
=> CREATE AUTHENTICATION <method_name> METHOD 'gss' HOST '0.0.0.0/0';
=> GRANT AUTHENTICATION <method_name> TO Public;
```

For more information, see [Implementing Client Authentication](#).

Creating the principals and keytab on active directory

Active Directory stores information about members of the Windows domain, including users and hosts.

Vertica uses the Kerberos protocol to access this information in order to authenticate Windows users to the Vertica database. The Kerberos protocol uses principals to identify users and keytab files to store their cryptographic information. You need to install the keytab files into Vertica to enable the Vertica database to cryptographically authenticate windows users.

This procedure describes:

- Creating a Vertica service principal.
- Exporting the keytab files for these principals
- Installing the keytab files in the Vertica database. This allows Vertica to authenticate Windows users and grant them access to the Vertica database.

1. Create a Windows account (principal) for the Vertica service and one Vertica host for each node/host in the cluster. This procedure creates Windows accounts for host [verticanode01](#) and service [vertica](#) running on this node.

When you create these accounts, select the following:

- User cannot change password
- Password never expires

Note

You can deselect **Password never expires**. However, if you change these user passwords, you must recreate the keytab files and reinstall them into Vertica. This includes repeating the entire procedure.

2. If you are using external tables on HDFS that are secured by Kerberos authentication, you *must* enable Delegation. To do so, access the Active Directory Users and Computers dialog, right-click the Windows account (principal) for the **Vertica** service, and select Delegation. Trust this user for delegation to any service.

3. Run the following command to create the keytab for the host **verticanode01.dc.com** node/host:

```
$ ktpass -out ./host.verticanode01.dc.com.keytab -princ host/verticanode01.dc.com@DC.COM -mapuser verticanode01 -mapop set -pass secret -ptype KRB5_NT_SRV_HST
```

4. Run the following command to create the keytab for the **vertica** service :

```
$ ktpass -out ./vertica.verticanode01dc.com.keytab -princ vertica/verticanode01.dc.com@DC.COM -mapuser vertica -mapop set -pass secret -ptype KRB5_NT_PRINCIPAL
```

For more information about keytab files, see Technet.Microsoft.com.

5. Run the following commands to verify that the service principal name is mapped correctly. You must run these commands for each node in your cluster:

```
$ setspn -L vertica
Registered ServicePrincipalNamefor CN=vertica,CN=Users,DC=dc,DC=com
vertica/verticanode01.dc.com

$ setspn -L verticanode01
Registered ServicePrincipalNamefor CN=verticanode01,CN=Users,DC=dc,DC=com
host/verticanode01.dc.com
```

6. Copy the keytabs you created above, **vertica.verticanode01.dc.com.keytab** and **host.verticanode01.dc.com.keytab** , to the Linux host **verticanode01.dc.com** .

7. Combine the keytab files into a single keytab:

```
[release@vertica krbTest]$ /usr/kerberos/sbin/ktutil
ktutil: rkt host.verticanode01.dc.com.keytab
ktutil: rkt vertica.verticanode01.dc.com.keytab
ktutil: list
slot KVNO Principal
-----
 1  3 host/verticanode01.dc.com@DC.COM
 2 16 vertica/verticanode01.dc.com@DC.COM
ktutil: wkt verticanode01.dc.com.keytab
ktutil: exit
```

This creates a single keytab file that contains the server principal for authentication.

8. Copy the new keytab file to the catalog directory. For example:

```
$ cp verticanode01.dc.com.keytab /home/dbadmin/VMart/v_vmart_nodennnn_catalog
```

9. Test the keytab file's ability to retrieve a ticket to ensure it works from the Vertica node:

```
$ kinit vertica/verticanode01.dc.com -k -t verticanode01.dc.com.keytab
$ klist

Ticket cache: KFILE:/tmp/krb_ccache_1003
Default principal: vertica/verticanode01.dc.com@DC.COM

Valid starting Expires Service principal
04/08/2017 13:35:25 04/08/2017 23:35:25 krbtgt/DC.COM@DC.COM
renew until 04/15/2017 14:35:25
```

When the ticket expires or not automatically retrieved you need to manually run the kinit command. See [Get the Kerberos ticket and authenticate Vertica](#).

10. Set the right permissions and ownership on the keytab files:

```
$ chmod 600 verticanode01.dc.com.keytab
$ chown dbadmin:verticadba verticanode01.dc.com.keytab
```

11. Set the following [Kerberos parameters](#) using [ALTER DATABASE](#) to inform Vertica about the Kerberos principal:

```
KerberosKeytabFile=<CATALOGDIR>/verticanode01.dc.com.keytab
KerberosRealm=DC.COM
KerberosServiceName=vertica
KerberosTicketDuration = 0
KerberosHostname=verticanode01.dc.com
```

12. Restart the Vertica server.

13. Test your Kerberos setup as follows to ensure that all clients use the gss authentication method.

From Vertica:

```
=> CREATE USER windowsuser1;
CREATE USER

=> CREATE AUTHENTICATION v_kerberos method 'gss' host '0.0.0.0/0';
CREATE AUTHENTICATION

=> ALTER AUTHENTICATION v_kerberos enable;
ALTER AUTHENTICATION

=> GRANT AUTHENTICATION v_kerberos to windowsuser1;
GRANT AUTHENTICATION
```

From the operating system command line:

```
$ kinit windowsuser1

$ vsql -U windowsuser1 -k vertica -K verticanode01.dc.com -h verticanode01.dc.com -c "select client_authentication_name,
authentication_method from sessions;"
client_authentication_name | authentication_method--
-----+-----
v_kerberos                | GSS-Kerberos

(1 row)
```

14. Run [KERBEROS_CONFIG_CHECK](#) to verify the Kerberos configuration. KERBEROS_CONFIG_CHECK verifies the following:

- The existence of the kinit and kb5.conf files.
- Whether the keytab file exists and is set
- The Kerberos configuration parameters set in the database:
 - KerberosServiceName
 - KerberosHostname
 - KerberosRealm
 - Vertica Principal
- That Kerberos can read the Vertica keys
- That Kerberos can get the tickets for the Vertica principal
- That Vertica can initialize the keys with kinit

Get the Kerberos ticket and authenticate Vertica

If your organization uses Kerberos as part of the login process, Kerberos tickets are automatically retrieved upon login. Otherwise, you need to run [kinit](#) to retrieve the Kerberos ticket.

The following example shows how to retrieve the ticket and authenticate Vertica Analytic Database with the KDC using the [kinit](#) command.

EXAMPLE.COM is the realm name. You must use the realm name with your username to retrieve a Kerberos ticket. See [Specify KDC information and configure realms](#).

```
$ kinit
Password for principal_user@EXAMPLE.COM: kpasswd
```

You are prompted for the password of the principal user name created when you created the principals and keytabs (see [Create the Vertica principals and keytabs on Linux KDC](#)).

The Kerberos ticket gets cached for a pre-determined length of time. See [Ticket Management](#) in the Kerberos documentation for more information on setting expiration parameters.

Upon expiration, you need to run the `kinit` command again to retrieve another Kerberos ticket.

Configure clients for Kerberos authentication

Each supported platform has a different security framework. Thus, the steps required to configure and authenticate against Kerberos differ among clients.

On the server side, you construct the Vertica Kerberos service name principal using this format:

```
Kerberos_Service_Name/Kerberos_Host_Name@Kerberos_Realm
```

For each client, the GSS libraries require the following format for the Vertica service principal:

```
Kerberos_Service_Name@Kerberos_Host_Name
```

You can omit the realm portion of the principal because GSS libraries use the realm name of the configured default (`Kerberos_Realm`) realm.

For information about client connection strings, see the following topics:

- [ODBC DSN connection properties](#)
- [JDBC connection properties](#)
- [ADO.NET connection properties](#)
- (vsq!) [Command-line options](#)

Note

A few scenarios exist in which the Vertica server principal name might not match the host name in the connection string. See [Troubleshooting Kerberos Authentication](#) for more information.

In this section

- [Configure ODBC and vsq! clients on non-windows platforms](#)
- [Configure ODBC and vsq! Clients on Windows and ADO.NET](#)
- [Configure JDBC Clients on all Platforms](#)

In this section

- [Configure ODBC and vsq! clients on non-windows platforms](#)
- [Configure ADO.NET, ODBC, and vsq! clients on Windows](#)
- [Configure JDBC clients on all platforms](#)

Configure ODBC and vsq! clients on non-windows platforms

To configure an ODBC or vsq! client on Linux or MAC OSX, you must first install the Kerberos 5 client package. See [Kerberos authentication](#).

After you install the Kerberos 5 client package, you must provide clients with a valid Kerberos configuration file (`krb5.conf`). To communicate with the KDC, each client participating in Kerberos authentication must have a valid, identically configured `krb5.conf` file. The default location for the Kerberos configuration file is `/etc/krb5.conf`.

Tip

To enforce consistency among clients, Vertica Analytic Database, and the KDC, copy the `/etc/krb5.conf` file from the KDC to the client's/etc directory.

The Kerberos configuration (`krb5.conf`) file contains Kerberos-specific information, including:

- How to reach the KDC
- Default realm name
- Domain
- Path to log files
- DNS lookup
- Encryption types to use
- Ticket lifetime

The default location for the Kerberos configuration file is `/etc/krb5.conf`.

When configured properly, the client can authenticate with Kerberos and retrieve a ticket through the `kinit` utility (see [Acquire an ODBC Authentication Request and Connection](#) below). Likewise, the server can then use `ktutil` to store its credentials in a keytab file

Authenticating ODBC and vsql clients requests and connections on non-windows platforms

ODBC and vsql use the client's ticket established by `kinit` to perform Kerberos authentication. These clients rely on the security library's default mechanisms to find the ticket file and the Kerberos configuration file.

To authenticate against Kerberos, call the `kinit` utility to obtain a ticket from the Kerberos KDC server. The following two examples show how to send the ticket request using ODBC and vsql clients.

Acquire an ODBC authentication request and connection

1. On an ODBC client, acquire a ticket for the `kuser` user by calling the `kinit` utility.

```
$ kinit kuser@EXAMPLE.COM
Password for kuser@EXAMPLE.COM:
```

2. Connect to Vertica, and provide the principals in the connection string:

```
char outStr[100];
SQLLEN len;
SQLDriverConnect(handle, NULL, "Database=VMart;User=kuser;
Server=myserver.example.com;Port=5433;KerberosHostname=vcluster.example.com",
SQL_NTS, outStr, &len);
```

Acquire a vsql authentication request connection

If the vsql client is on the same machine you are connecting to, vsql connects through a UNIX domain socket. This connection bypasses Kerberos authentication. When you authenticate with Kerberos, especially if the client authentication method is configured as 'local', you must include the `-h` hostname option. See [Command Line Options](#).

1. On the vsql client, call the `kinit` utility:

```
$ kinit kuser@EXAMPLE.COM
Password for kuser@EXAMPLE.COM:
```

2. Connect to Vertica, and provide the host and user principals in the connection string:

```
$ ./vsql -K vcluster.example.com -h myserver.example.com -U kuser
Welcome to vsql, the Vertica Analytic Database
interactive terminal.

Type: \h or \? for help with vsql commands
\g or terminate with semicolon to execute query
\q to quit
```

In the future, when you log in to vsql as `kuser`, vsql uses your cached ticket without prompting you for a password.

Verify the authentication method

You can verify the authentication method by querying the `SESSIONS` system table:

```
=> SELECT authentication_method FROM sessions;
authentication_method
-----
GSS-Kerberos
(1 row)
```

- [ODBC DSN connection properties](#)

- (vsq!) [Command-line options](#)

Configure ADO.NET, ODBC, and vsq! clients on Windows

The Vertica client drivers support the Windows SSPI library for Kerberos authentication. Windows Kerberos configuration is stored in the registry.

You can choose between two different setup scenarios for Kerberos authentication on ODBC and vsq! clients on Windows and ADO.NET:

- [Windows KDC on Active Directory with Windows Built-in Kerberos Client and](#)
- [Linux KDC with Windows Built-in Kerberos Client and](#)

Note

The procedures on this page are only relevant for [ADO.NET drivers 12.0.4 and below](#). Later versions of the ADO.NET driver do not currently support Kerberos authentication.

Windows KDC on active directory with Windows built-in Kerberos client and Vertica

Kerberos authentication on Windows is commonly used with Active Directory, Microsoft's enterprise directory service/Kerberos implementation. Typically your organization's network or IT administrator performs the setup.

Windows clients have Kerberos authentication built into the authentication process. You do not need any additional software.

Your login credentials authenticate you to the Kerberos server (KDC) when you:

- Log in to Windows from a client machine
- Use a Windows instance that has been configured to use Kerberos through Active Directory

To use Kerberos authentication on Windows clients, log in as REALM\user.

Important

When you use the ADO.NET driver to connect to Vertica, you can optionally specify [IntegratedSecurity=true](#) in the connection string. This informs the driver to authenticate the calling user against the user's Windows credentials. As a result, you do not need to include a user name or password in the connection string. Any `user=< username >` entry to the connection string is ignored.

Linux KDC with Windows built-in Kerberos client and Vertica

A simple, but less common scenario is to configure Windows to authenticate against a non-Windows KDC. In this implementation, you use the [ksetup](#) utility to point the Windows operating system native Kerberos capabilities at a non-Active Directory KDC. By logging in to Windows, you obtain a ticket-granting ticket, similar to the Active Directory implementation. However, in this case, Windows is internally communicating with a Linux KDC. See the Microsoft Windows Server [Ksetup page](#) for more information.

When a database/windows user logs into their Windows machine (or after performing a kinit on Windows) the Kerberos ticket MUST have `ok_as_delegate` and `forwardable` flag set to be able to access webhdfs based external tables as follows:

```
$ CMD \> klist
#2> Client: release @ VERT.LOCAL
Server: vertica/example.com @ VERT.LOCAL
KerbTicket Encryption Type: RSADSI RC4-HMAC(NT)
Ticket Flags 0x40a50000 forwardable renewable pre_authent ok_as_delegate name_canonicalize
Start Time: 9/27/2017 13:24:43 (local)
End Time: 9/27/2017 20:34:45 (local)
Renew Time: 10/3/2017 15:04:45 (local)
Session Key Type: RSADSI RC4-HMAC(NT)
Cache Flags: 0
Kdc Called: ADKDC01
```

Note

The Ticket Flags setting above must contain `ok_as_delegate` and `forwardable` entries. For information on these parameters see [Kerberos documentation](#).

Configure Windows clients for Kerberos authentication

Depending on which implementation you want to configure, refer to one of the following pages on the Microsoft Server website:

- To set up Windows clients with Active Directory, refer to [Step-by-Step Guide to Kerberos 5 \(krb5 1.0\) Interoperability](#).
- To set up Windows clients with the `ksetup` utility, refer to the [Ksetup page](#).

Authenticate and connect clients

The KDC can authenticate both an ADO.NET and a vsql client.

Note

Use the fully-qualified domain name as the server in your connection string; for example, use `host.example.com` instead of just `host`. That way, if the server moves location, you do not have to change your connection string.

Verify an ADO.NET authentication request and connection

This example shows how to use the `IntegratedSecurity=true`, setting to specify that the ADO.NET driver authenticates the calling user's Windows credentials:

```
VerticaConnection conn = new
VerticaConnection("Database=VMart;Server=host.example.com;
Port=5433;IntegratedSecurity=true;
KerberosServiceName=vertica;KerberosHostname=vcluster.example.com");
conn.open();
```

Verify a vsql authentication request and connection

1. Log in to your Windows client, for example, as `EXAMPLE\kuser`.
2. Run the vsql client and supply the connection string to Vertica:

```
C:\Users\kuser\Desktop>vsq.exe -h host.example.com -K vcluster -U kuser
```

```
Welcome to vsql, the Vertica Analytic Database interactive terminal.
```

```
Type: \h or \? for help with vsql commands
```

```
\g or terminate with semicolon to execute query
```

```
\q to quit
```

- [ADO.NET connection properties](#)

Configure JDBC clients on all platforms

Kerberos authentication on JDBC clients uses Java Authentication and Authorization Service (JAAS) to acquire the initial Kerberos credentials. JAAS is an API framework that hides platform-specific authentication details and provides a consistent interface for other applications.

You specify the client login process through the JAAS Login Configuration File. This file contains options that specify the authentication method and other settings to use for Kerberos. A class called the `LoginModule` defines valid options in the configuration file.

The JDBC client principal is crafted as `jdbc-username@server-from-connection-string`.

Implement the LoginModule

Vertica recommends that you use the JAAS public class `com.sun.security.auth.module.Krb5LoginModule` provided in the Java Runtime Environment (JRE).

The `Krb5LoginModule` authenticates users using Kerberos protocols and is implemented differently on non-Windows and Windows platforms:

- **On non-Windows platforms:** The `Krb5LoginModule` defers to a native Kerberos client implementation. Thus, you can use the same `/etc/krb5.conf` setup as you use to [configure ODBC and vsql clients](#) on Linux and MAC OSX platforms.
- **On Windows platforms:** The `Krb5LoginModule` uses a custom Kerberos client implementation bundled with the Java Runtime Environment (JRE). Windows settings are stored in a `%WINDIR%\krb5.ini` file, which has similar syntax and conventions to the non-Windows `krb5.conf` file. You can copy a `krb5.conf` from a non-Windows client to `%WINDIR%\krb5.ini`.

You can find documentation for the `LoginModules` in the `com.sun.security.auth` package, and on the [Krb5LoginModule](#) web page.

Create the JAAS login configuration

The [JAASConfigName connection property](#) identifies a specific configuration within a JAAS configuration that contains the [Krb5LoginModule](#) and its settings. The [JAASConfigName](#) setting lets multiple JDBC applications with different Kerberos settings coexist on a single host. The default configuration name is [verticajdbc](#).

Important

Carefully construct the JAAS login configuration file. If syntax is incorrect, authentication fails.

You can configure JAAS-related settings in the [java.security](#) master security properties file. This file resides in the [lib/security](#) directory of the JRE. For more information, see [Appendix A](#) in the Java™ Authentication and Authorization Service (JAAS) Reference Guide.

Create a JDBC login context

The following example shows how to create a login context for Kerberos authentication on a JDBC client. The client uses the default [JAASConfigName](#) of [verticajdbc](#) and specifies that:

- The ticket-granting ticket will be obtained from the ticket cache
- The user will not be prompted for a password if credentials cannot be obtained from the cache, keytab file, or through a shared state.

```
verticajdbc {
  com.sun.security.auth.module.Krb5LoginModule
  required
  useTicketCache=true
  doNotPrompt=true;
};
```

JDBC authentication request and connection

You can configure the [Krb5LoginModule](#) to use a cached ticket or keytab. The driver can also acquire a ticket or keytab automatically if the calling user provides a password.

In the preceding example, the login process uses a cached ticket and does not prompt for a password because both [useTicketCache](#) and [doNotPrompt](#) are set to [true](#). If [doNotPrompt=false](#) and you provide a user name and password during the login process, the driver provides that information to the LoginModule. The driver then calls the [kinit](#) utility on your behalf.

1. On a JDBC client, call the [kinit](#) utility to acquire a ticket:

```
$ kinit kuser@EXAMPLE.COM
```

If you prefer to use a password instead of calling the [kinit](#) utility, see the next section.

2. Connect to Vertica:

```
Properties props = new Properties();
props.setProperty("user", "kuser");
props.setProperty("KerberosServiceName", "vertica");
props.setProperty("KerberosHostName", "vcluster.example.com");
props.setProperty("JAASConfigName", "verticajdbc");
Connection conn = DriverManager.getConnection
"jdbc:vertica://myserver.example.com:5433/VMart", props);
```

Have the driver acquire a ticket

Sometimes, you may want to bypass calling the [kinit](#) utility yourself but still use encrypted, mutual authentication. In such cases, you can optionally pass the driver a clear text password to acquire the ticket from the KDC. The password is encrypted when sent across the network. For example, [useTicketCache](#) and [doNotPrompt](#) are both false in the following example. Thus, the calling user's credentials are not obtained through the ticket cache or keytab.

```
$ verticajdbc {
  com.sun.security.auth.module.Krb5LoginModule
  required
  useTicketCache=false
  doNotPrompt=false;
};
```

The preceding example demonstrates the flexibility of JAAS. The driver no longer looks for a cached ticket, and you do not have to call [kinit](#). Instead, the driver takes the password and user name and calls [kinit](#) on your behalf.

Troubleshooting Kerberos authentication

These tips can help you avoid issues related to Kerberos authentication with Vertica and to troubleshoot any problems that occur.

JDBC client authentication fails

If Kerberos authentication fails on a JDBC client, check the JAAS login configuration file for syntax issues. If syntax is incorrect, authentication fails.

Working domain name service (DNS) not configured

Verify that the DNS entries and the system host file (/etc/hosts or /etc/hostnames) on the network are all properly configured for your environment. If you are using a fully qualified domain name, ensure that is properly configured as well. Refer to the Kerberos documentation for your platform for details.

System clocks out of sync

System clocks in your network must remain in sync for Kerberos authentication to work properly. If you access data in HDFS, then Vertica nodes must also be in sync with Hadoop.

All systems except red hat 7/CentOS 7

To keep system clocks in sync:

1. Install NTP on the Kerberos server (KDC).
2. Install NTP on each server in your network.
3. Synchronize system clocks on all machines that participate in the Kerberos realm within a few minutes of the KDC and each other

Clock skew can be a problem on Linux virtual machines that need to sync with the Windows Time Service. Use the following steps to keep time in sync:

1. Using any text editor, open `/etc/ntp.conf`.
2. Under the **Undisciplined Local Clock** section, add the IP address for the Vertica server. Then, remove existing server entries.
3. Log in to the server as root, and set up a cron job to sync time with the added IP address every half hour, or as often as needed. For example:

```
# 0 */2 * * * /etc/init.d/ntpd restart
```

4. Alternatively, run the following command to force clock sync immediately:

```
$ sudo /etc/init.d/ntpd restart
```

For more information, see [Enabling network time protocol \(NTP\)](#) and the [Network Time Protocol website](#).

Red hat 7/CentOS 7 systems

In Red Hat 7/CentOS 7, `ntpd` is deprecated in favor of `chrony`. To keep system clocks in your network in sync for Kerberos authentication to work properly, do the following:

1. Install `chrony` on the Kerberos server (KDC).
2. Install `chrony` on each server in your network.
3. Synchronize system clocks on all machines that participate in the Kerberos realm within a few minutes of the KDC and each other.

Clock skew on Linux virtual machines

Clock skew can be problematic on Linux virtual machines that need to sync with the Windows Time Service. Try the following to keep time in sync:

1. Using any text editor, open `/etc/chrony.conf`.
2. Under the **Undisciplined Local Clock** section, add the IP address for the Vertica server. Then, remove existing server entries.
3. Log in to the server as root, and set up a cron job to sync time with the added IP address every half hour, or as often as needed. For example:

```
# 0 */2 * * * systemctl start chronyd
```

4. Alternatively, run the following command to force clock sync immediately:

```
$ sudo systemctl start chronyd
```

For more information, see the [Red Hat chrony guide](#).

Kerberos ticket is valid, but Hadoop access fails

Vertica uses Kerberos tickets to obtain Hadoop tokens. It then uses the Hadoop tokens to access the Hadoop data. Hadoop tokens expire after a period of time, so Vertica periodically refreshes them. However, if your Hadoop cluster is set to expire tokens frequently, it is possible that tokens might not be refreshed in time. If the token expires, you cannot access data.

Setting the `HadoopFSTokenRefreshFrequency` configuration parameter allows you to specify how often Vertica should refresh the token. Specify this value, in seconds, to be smaller than the expiration period set for Hadoop. For example:

```
=> ALTER DATABASE exampledadb SET HadoopFSTokenRefreshFrequency = '86400';
```

For another cause of Hadoop access failure, see [System Clocks Out of Sync](#).

Encryption algorithm choices

Kerberos is based on symmetric encryption. Be sure that all Kerberos parties used in the Kerberos realm agree on the encryption algorithm to use. If they do not agree, authentication fails. You can review the exceptions in the [vertica.log](#).

On a Windows client, be sure the encryption types match the types set on Active Directory. See [Configure Vertica for Kerberos authentication](#).

Be aware that Kerberos is used only for securing the login process. After the login process completes, by default, information travels between client and server without encryption. If you want to encrypt traffic, use SSL. For details, see [Implementing SSL](#).

Kerberos passwords not recognized

If you change your Kerberos password, you must re-create all of your keytab files.

Using the ODBC data source configuration utility

On Windows vsql clients, you may choose to use the ODBC Data Source Configuration utility and supply a client Data Source. If so, be sure you enter a Kerberos host name in the Client Settings tab to avoid client connection failures with the Vertica Analytic Database server.

Authentication failure in backup, restore, or admin tools

This problem can arise in configurations where each Vertica node uses its own Kerberos principal. (This configuration is recommended.) When using `vbr` or `admintools` you might see an error such as the following:

```
$ vsql: GSSAPI continuation error: Miscellaenous failure
GSSAPI continuation error: Server not found in Kerberos database
```

Backup/restore and the admin tools use the value of `KerberosHostname`, if it is set, in the Kerberos principal used to authenticate. The same value is used on all nodes. If you have defined one Kerberos principal per node, as recommended, this value does not match. To correct this, unset the `KerberosHostname` parameter:

```
=> ALTER DATABASE DEFAULT CLEAR KerberosHostname;
```

Server's principal name does not match host name

This problem can arise in configurations where a single Kerberos principal is used for all nodes. Vertica recommends against using a single Kerberos principal for all nodes. Instead, use one principal per node and do not set the `KerberosHostname` parameter.

In some cases during client connection, the Vertica server's principal name might not match the host name in the connection string. (See also [Using the ODBC Data Source Configuration Utility](#) in this topic.)

On Windows vsql clients, you may choose to use the ODBC Data Source Configuration utility and supply a client Data Source. If so, be sure you enter a Kerberos host name in the Client Settings tab to avoid client connection failures with the Vertica server.

On ODBC, JDBC, and ADO.NET clients, set the host name portion of the server's principal using the `KerberosHostName` connection string.

Tip

On vsql clients, you set the host name portion of the server's principal name using the `-K KRB HOST` command-line option. The default value is specified by the `-h` switch, which is the host name of the machine on which the Vertica server is running. `-K` is equivalent to the drivers' `KerberosHostName` connection string value.

For details, see [Command Line Options](#).

Principal/host mismatch issues and resolutions

The following issues can occur if the principal and host are mismatched.

The `KerberosHostName` configuration parameter has been overridden

For example, consider the following connection string:

```
jdbc:vertica://v_vmart_node0001.example.com/vmart?user=kuser
```

Because the this connection string includes no explicit `KerberosHostName` parameter, the driver defaults to the host in the URL (`v_vmart_node0001.example.com`). If you overwrite the server-side `KerberosHostName` parameter as " abc ", the client generates an incorrect principal.

To resolve this issue, explicitly set the client's `KerberosHostName` to the connection string, as in this example:

```
jdbc:vertica://v_vmart_node0001.example.com/vmart?user=kuser&kerberoshostname=abc
```

Connection load balancing is enabled... but the node against which the client authenticates might not be the node in the connection string.

In this situation, consider changing all nodes to use the same `KerberosHostName` setting. When you use the default to the host that was originally specified in the connection string, load balancing cannot interfere with Kerberos authentication.

A DNS name does not match the Kerberos host name

For example, imagine a cluster of six servers, where you want `hr-servers` and `finance-servers` to connect to different nodes on the Vertica cluster. Kerberos authentication, however, occurs on a single (the same) KDC. In the following example, the Kerberos service host name of the servers is `server.example.com` .

Suppose you have the following list of example servers:

```
server1.example.com 192.16.10.11
server2.example.com 192.16.10.12
server3.example.com 192.16.10.13
server4.example.com 192.16.10.14
server5.example.com 192.16.10.15
server6.example.com 192.16.10.16
```

Now, assume you have the following DNS entries:

```
finance-servers.example.com 192.168.10.11, 192.168.10.12, 192.168.10.13
hr-servers.example.com 192.168.10.14, 192.168.10.15, 192.168.10.16
```

When you connect to `finance-servers.example.com` , specify:

- Kerberos `-h` host name option as `server.example.com`
- `-K` host option for `hr-servers.example.com`

For example:

```
$ vsql -h finance-servers.example.com -K server.example.com
```

No DNS is set up on the client machine... so you must connect by IP only

To resolve this issue, specify:

- Kerberos `-h` host name option for the IP address
- `-K` host option for `server.example.com`

For example:

```
$ vsql -h 192.168.1.12 -K server.example.com
```

There is a load balancer involved (Virtual IP)... but there is no DNS name for the VIP

Specify:

- Kerberos `-h` host name option for the Virtual IP address
- `-K` host option for `server.example.com`

For example:

```
$ vsql -h <virtual IP> -K server.example.com
```

You connect to Vertica using an IP address... but there is no host name to construct the Kerberos principal name.

Provide the instance or host name for the Vertica as described in [Inform Vertica about the Kerberos principal](#)

The server-side **KerberosHostName** configuration parameter is set to a name other than the Vertica node's host name... but the client cannot determine the host name based on the host name in the connection string alone.

Reset KerberosHostName to match the name of the Vertica node's host name. For more information, see the following topics:

- [ODBC DSN Parameters](#)
- [JDBC Connection Properties](#)
- [ADO.NET Connection Properties](#)

LDAP authentication

Lightweight Directory Access Protocol (LDAP) is an authentication method that works like password authentication. The main difference is that the LDAP method authenticates clients trying to access your Vertica database against an LDAP or Active Directory server. Use LDAP authentication when your database needs to authenticate a user with an LDAP or Active Directory server.

In this section

- [LDAP prerequisites and definitions](#)
- [LDAP authentication parameters](#)
- [TLS for LDAP authentication](#)
- [Authentication fallback for LDAP](#)
- [LDAP bind methods](#)

LDAP prerequisites and definitions

Prerequisites

Before you configure LDAP authentication for your Vertica database you must have:

- IP address and host name for the LDAP server. Vertica supports IPv4 and IPv6 addresses.
- Your organization's Active Directory information.
- A service account for search and bind.
- Administrative access to your Vertica database.
- [open-ldap-tools](#) package installed on at least one node. This package includes [ldapsearch](#) .

Definitions

The following definitions are important to remember for LDAP authentication:

Parameter name	Description
Host	IP address or host name of the LDAP server. Vertica supports IPv4 and IPv6 addresses. For more information, see IPv4 and IPv6 for Client Authentication .
Common name (CN)	Depending on your LDAP environment, this value can be either the username or the first and last name of the user.
Domain component (DC)	Comma-separated list that contains your organization's domain component broken up into separate values, for example: dc=vertica, dc=com
Distinguished name (DN)	<i>domain</i> .com. A DN consists of two DC components, as in "DC=example, DC= com".
Organizational unit (OU)	Unit in the organization with which the user is associated, for example, Vertica Users.
sAMAccountName	An Active Directory user account field. This value is usually the attribute to be searched when you use bind and search against the Microsoft Active Directory server.
UID	A commonly used LDAP account attribute used to store a username.
Bind	LDAP authentication method that allows basic binding using the DN.

Search and bind	LDAP authentication method that must log in to the LDAP server to search on the specified attribute.
Service account	An LDAP user account that can be used to log in to the LDAP server during bind and search. This account's password is usually shared.
Anonymous binding	Allows a client to connect and search the directory (search and bind) without needing to log in.
<code>ldapsearch</code>	A command-line utility to search the LDAP directory. It returns information that you use to configure LDAP search and bind.
<code>basedn</code>	Distinguished name where the directory search should begin.
<code>binddn</code>	Domain name to find in the directory search.
<code>search_attribute</code>	Text to search for to locate the user record. The default is UID.

LDAP authentication parameters

There are several parameters that you need to configure for LDAP authentication.

General LDAP parameters

Use the following parameters to configure for either LDAP bind or LDAP bind and search:

Parameter name	Description
<code>host</code>	<p>LDAP server URL in the following format:</p> <p><i>schema</i> <code>://host: optional_port</code></p> <p>Where <i>schema</i> is one of the following:</p> <ul style="list-style-type: none"> <code>ldap</code> : The connection between Vertica and the LDAP server uses plaintext if TLSMODE of LDAPAuth is <code>DISABLE</code> . Set TLSMODE to <code>ENABLE</code> or higher for StartTLS (LDAP over TLS). <code>ldaps</code> : If the TLSMODE of LDAPAuth is <code>ENABLE</code> or higher, the connection between Vertica and the LDAP server uses LDAPS.
<code>ldap_continue</code>	<p>When set to yes, this parameter allows a connection retry when a user not found error occurs during the previous connection attempt.</p> <p>For any other failure error, the system automatically retries the connection.</p>
<code>starttls</code>	<p>Whether to request the connection between Vertica and the LDAP server during user authentication to be upgraded to TLS. You must configure the LDAPAuth TLS Configuration before using this parameter.</p> <p><code>starttls</code> can be set to one of the following:</p> <ul style="list-style-type: none"> <code>soft</code> : If the server does not support TLS, use a plaintext connection. This value is equivalent to the <code>-Z</code> option in <code>ldapsearch</code> . If you use <code>soft</code> , Vertica ignores the certificate verification policies of the TLSMODE in the LDAPAuth TLS configuration . <code>hard</code> : If the LDAP server does not support TLS, reject the connection. This value is equivalent to the <code>-ZZ</code> in <code>ldapsearch</code> . Using <code>ldaps</code> is equivalent to <code>starttls='hard'</code> . However, if you use them together in the same connection string, authentication fails and the following error appears: FATAL 2248: Authentication failed for username "<user_name>" <p>If <code>starttls</code> is not set, whether TLS is requested and required depends on the value of the TLSMODE of the LDAPAuth TLS Configuration .</p>

LDAP bind parameters

The following parameters create a bind name string, which specifies and uniquely identifies a user to the LDAP server. For details, see [Workflow for configuring LDAP bind](#).

To create a bind name string, you must set one (and only one) of the following:

- Both `binddn_prefix` and `binddn_suffix` (must be set together)
- `domain_prefix`
- `email_suffix`

For example, if you set `binddn_prefix` and `binddn_suffix`, you cannot also set `email_suffix`. Conversely, if you set `email_suffix`, you cannot set `binddn_prefix` and `binddn_suffix`.

If you do not set a bind parameter, Vertica performs bind and search operations instead of a bind operation.

The following examples use the authentication record `v_ldap`:

```
=> CREATE AUTHENTICATION v_ldap METHOD 'ldap' HOST '10.0.0.0/23';
```

Parameter name	Description
<code>binddn_prefix</code>	<p>First half of the bind string. If you set this parameter, you must also set <code>binddn_suffix</code>.</p> <p>For example, to construct the bind name <code>cn= exampleusername,cn=Users,dc=ExampleDomain,dc=com</code>:</p> <pre>=> ALTER AUTHENTICATION v_ldap SET binddn_prefix='cn=', binddn_suffix=',cn=Users,dc=ExampleDomain,dc=com';</pre>
<code>binddn_suffix</code>	<p>Second half of bind string.</p> <p>If you set this parameter, you must also set <code>binddn_prefix</code>.</p> <p>For example, to construct the bind name <code>cn=exampleusername, ou=ExampleUsers,dc=example,dc=com</code>:</p> <pre>=> ALTER AUTHENTICATION v_ldap SET binddn_prefix='cn=', binddn_suffix=',ou=OrgUsers,dc=example,dc=com';</pre>
<code>domain_prefix</code>	<p>The domain that contains the user.</p> <p>For example, to construct the bind name <code>Example \exampleusername</code>:</p> <pre>=> ALTER AUTHENTICATION v_ldap SET domain_prefix='Example';</pre>
<code>email_suffix</code>	<p>The email domain.</p> <p>For example, to construct the bind name <code>exampleusername@ example.com</code>:</p> <pre>=> ALTER AUTHENTICATION v_ldap SET email_suffix='example.com';</pre>

LDAP search and bind parameters

Use the following parameters when authenticating with LDAP search and bind. For more information see [Workflow for configuring LDAP search and bind](#).

Parameter name	Description
<code>basedn</code>	Base DN for search.
<code>binddn</code>	Bind DN. Domain name to find in the directory search.
<code>bind_password</code>	Bind password. Required if you specify a <code>binddn</code> .
<code>search_attribute</code>	Optional attribute to search for on the LDAP server.

The following example shows how to set these three attributes. In this example, it sets

- `binddn` to `cn=Manager,dc=example,dc=com`
- `bind_password` to `secret`
- `search_attribute` to `cn`

```
=> ALTER AUTHENTICATION auth_method_name SET host='ldap://example13',
basedn='dc=example,dc=com',binddn='cn=Manager,dc=example,dc=com',
bind_password='secret',search_attribute='cn';
```

The `binddn` and `bind_password` parameters are optional. If you omit them, Vertica performs an anonymous search.

TLS for LDAP authentication

Vertica establishes a connection to an LDAP server in two contexts, and each context has a corresponding TLS Configuration that controls if each connection should use TLS:

1. **LDAPLink** : using the LDAPLink service or its dry run functions to synchronize users and groups between Vertica and the LDAP server.
2. **LDAPAuth** : when a user with an `ldap` authentication method attempts to log into Vertica, Vertica attempts to bind the user to a matching user in the LDAP server. If the bind succeeds, Vertica allows the user to log in.

Query [TLS_CONFIGURATIONS](#) to view existing TLS Configurations:

```
=> SELECT * FROM tls_configurations WHERE name IN ('LDAPLink', 'LDAPAuth');
 name | owner | certificate | ca_certificate | cipher_suites | mode
-----+-----+-----+-----+-----+-----
LDAPLink | dbadmin | client_cert | ldap_ca      |              | VERIFY_CA
LDAPAuth | dbadmin | client_cert | ldap_ca      |              | DISABLE
(2 rows)
```

This page covers the LDAPAuth context. For details on the LDAPLink context, see [TLS for LDAP link](#).

Keep in mind that configuring TLS for LDAP authentication does not encrypt the connection between Vertica and the client with TLS. To configure client-server TLS, see [Configuring client-server TLS](#).

Configuring LDAP authentication

After a client successfully establishes a connection with Vertica, they must authenticate as a user before they can interact with the database. If the user has the `ldap` authentication method, Vertica connects to the LDAP server to authenticate the user. To configure TLS for this context, use the following procedure.

Setting the LDAPAuth TLS configuration

The LDAPAuth TLS Configuration takes a client certificate and CA certificate created or imported with [CREATE CERTIFICATE](#). Vertica presents the client certificate to the LDAP server for verification by its CA. Vertica uses the CA certificate to verify the LDAP server's certificate.

For details on key and certificate generation, see [Generating TLS certificates and keys](#).

1. If you want Vertica to verify the LDAP server's certificate before establishing the connection, generate or import a CA certificate and add it to the LDAPAuth TLS CONFIGURATION.

For example, to import the existing CA certificate `LDAP_CA.crt` :

```
=> \set ldap_ca "" cat ldap_ca.crt""
=> CREATE CA CERTIFICATE ldap_ca AS :ldap_ca;
CREATE CERTIFICATE
```

Then, to add the `ldap_ca` CA certificate to LDAPAuth:

```
ALTER TLS CONFIGURATION LDAPAuth ADD CA CERTIFICATES ldap_ca;
```

2. If your LDAP server verifies client certificates, you must generate or import a client certificate and its key and add it to the LDAPAuth TLS Configuration. Vertica presents this certificate to the LDAP server for verification by its CA.

For example, to import the existing certificate `client.crt` (signed by the imported CA) and key `client.key` :

```
=> \set client_key "" cat client.key""
=> CREATE KEY client_key TYPE 'RSA' AS :client_key;
CREATE KEY

=> \set client_cert "" cat client.crt""
=> CREATE CERTIFICATE client_cert AS :client_cert SIGNED BY ldap_ca KEY client_key;
CREATE CERTIFICATE
```

Then, to add `client_cert` to LDAPAuth:

```
=> ALTER TLS CONFIGURATION LDAPAuth CERTIFICATE client_cert;
```

3. Enable TLS or LDAPS (the exact protocol used depends on the value of `host` in the AUTHENTICATION object) by setting the TLSMODE to one of the following. `TRY_VERIFY` or higher requires a CA certificate:
 - **ENABLE** : Enables TLS. Vertica does not check the LDAP server's certificate.
 - **TRY_VERIFY** : Establishes a TLS connection if one of the following is true:
 - The LDAP server presents a valid certificate.
 - The LDAP server doesn't present a certificate.If the LDAP server presents an invalid certificate, a plaintext connection is used.
 - **VERIFY_CA** : Connection succeeds if Vertica verifies that the LDAP server's certificate is from a trusted CA. Using this TLSMODE forces all connections without a certificate to use plaintext.
 - **VERIFY_FULL** : Connection succeeds if Vertica verifies that the LDAP server's certificate is from a trusted CA and the `cn` (Common Name) or `subjectAltName` attribute matches the hostname or IP address of the LDAP server.
The `cn` is used for the username, so `subjectAltName` must match the hostname or IP address of the LDAP server.

Note

The value of TLSMODE only applies to [authentication records](#) where the `starttls` LDAP authentication parameter is set to `hard` or not set at all. If `starttls` is set to `soft`, Vertica establishes a TLS connection without verifying the LDAP server's certificate and falls back to a plaintext connection if the LDAP server does not support TLS. For details, see the next section.

For example:

```
=> ALTER TLS CONFIGURATION LDAPAuth TLSMODE 'verify_ca';
ALTER TLS CONFIGURATION
```

4. Verify that the LDAPAuthConfigParameter parameter is using the TLS Configuration:

```
=> SHOW CURRENT LDAPAuthTLSConfig;
level | name | setting
-----+-----+-----
DEFAULT | LDAPAuthTLSConfig | LDAPAuth
(1 row)
```

Creating an LDAP authentication record

After a client successfully establishes a connection with Vertica, they must authenticate as a user before they can interact with the database. If the user has the `ldap` authentication method, Vertica connects to the LDAP server and attempts a bind to authenticate the user.

To view existing authentication records, query [CLIENT_AUTH](#).

For details on the parameters referenced in this procedure, see [LDAP authentication parameters](#).

1. **CREATE** an authentication record with an LDAP method.

Syntax for creating an LDAP authentication record:

```
=> CREATE AUTHENTICATION auth_record_name method 'ldap' HOST 'user_connection_source';
```

For example, to create an LDAP authentication record that applies to users that connect from any host:

```
=> CREATE AUTHENTICATION ldap_auth METHOD 'ldap' HOST '0.0.0.0/0';
```

2. **ALTER** the authentication record to set the host and port (optional) of the LDAP server and the domain name (`basedn`) and bind distinguished name (`binddn`).
 - To use a plaintext connection between Vertica and the LDAP server (disable TLS):
 - Begin the `host` URL with `ldap://`.
 - Set the TLSMODE of `LDAPAuth` to `DISABLE` and verify that `starttls` is not set.
 - To use StartTLS and reject plaintext connections:
 - Begin the `host` URL with `ldap://`.
 - Set the TLSMODE of `LDAPAuth` to `ENABLE` or higher. Vertica only verifies the LDAP server's certificate if TLSMODE is set to `TRY_VERIFY` or higher.
 - Verify that `starttls` is set to `hard` or not set.
 - To use StartTLS, but still accept a plaintext connection if the LDAP server cannot be upgrade the connection to TLS:
 - Begin the `host` URL with `ldap://`.

- Set `starttls` to `soft` and the `TLSMODE` of `LDAPAuth` to `ENABLE` or higher. Vertica does not verify the server's certificate before establishing the connection and ignores the certificate verification policy of the `LDAPAuth` `TLSMODE`.
- To use LDAPS:
 - Begin the `host` URL with `ldaps://`
 - `TLSMODE` of `LDAPAuth` to `ENABLE` or higher.

This example authentication record searches for users in the active directory `orgunit.example.com` on an LDAP server with an IP address of `192.0.2.0` on port `5389` and requires a TLS connection to the LDAP server:

```
=> ALTER AUTHENTICATION ldap_auth SET
host='ldap://192.0.2.0:5389',
basedn='ou=orgunit,dc=example,dc=com',
binddn_prefix='cn=',
binddn_suffix=',ou=orgunit,dc=example,dc=com',
starttls='hard';
```

The `binddn_prefix` and `binddn_suffix` combine to create the full DN. That is, for some Vertica user `asmith`, `'cn=asmith,ou=orgunit,dc=example,dc=com'` is the full DN when Vertica attempts the bind.

To modify the `ldap_auth` authentication record to request StartTLS, but still accept plaintext connections, set the `starttls` parameter to `soft` :

```
=> ALTER AUTHENTICATION ldap_auth SET starttls='soft';
```

3. Enable the authentication record:

```
=> ALTER AUTHENTICATION ldap_auth ENABLE;
```

4. GRANT the authentication record to a user or role.

For example:

```
=> GRANT AUTHENTICATION ldap_auth TO asmith;
```

In this case, when the user `asmith` attempts to log in, Vertica constructs the distinguished name `'cn=asmith,ou=orgunit,dc=example,dc=com'` from the search base specified in the `ldap_auth`, connects to the LDAP server, and attempts to bind it to the Vertica user. If the bind succeeds, Vertica allows `asmith` to log in.

Authentication fallback for LDAP

To use multiple search attributes for a single LDAP server or to configure multiple LDAP servers, create a separate authentication record for each search attribute or server and enable [authentication fallback](#) on each `ldap` record except the last ([in order of priority](#)).

Examples

The following example creates two authentication records, `vldap1` and `vldap2` . Together, they specify that the LDAP server should first search the entire directory (`basedn=dc=example,dc=com`) for a DN with an OU attribute `Sales` . If the first search returns no results or otherwise fails, the LDAP server should then search for a DN with the OU attribute `Marketing` :

```
=> CREATE AUTHENTICATION vldap1 method 'ldap' HOST '10.0.0.0/8' FALLTHROUGH;
=> ALTER AUTHENTICATION vldap1 PRIORITY 1;
=> ALTER AUTHENTICATION vldap1
SET host='ldap://ldap.example.com/search',
basedn='dc=example,dc=com',
search_attribute='Sales';
=> GRANT AUTHENTICATION vldap1 to public;
```

```
=> CREATE AUTHENTICATION vldap2 method 'ldap' HOST '10.0.0.0/8';
=> ALTER AUTHENTICATION vldap2 PRIORITY 0;
=> ALTER AUTHENTICATION vldap2 SET
host='ldap://ldap.example.com/search',
basedn='dc=example,dc=com',
search_attribute='Marketing';
=> GRANT AUTHENTICATION vldap2 to public;
```

LDAP bind methods

There are two LDAP methods that you use to authenticate your Vertica database against an LDAP server.

- Bind—Use LDAP bind when Vertica connects to the LDAP server and binds using the CN and password. (These values are the username and password of the user logging into the database). Use the bind method when your LDAP account's CN field matches that of the username defined in your database. For more information see [Workflow for configuring LDAP bind](#).
- Search and Bind —Use LDAP search and bind when your LDAP account's CN field is a user's full name or does not match the username defined in your database. For search and bind, the username is usually in another field such as UID or sAMAccountName in a standard Active Directory environment. Search and bind requires your organization's Active Directory information. This information allows Vertica to log into the LDAP server and search for the specified field. For more information see [Workflow for configuring LDAP search and bind](#).
If you are using search and bind, having a service account simplifies your server side configuration. In addition, you do not need to store your Active Directory password.

LDAP anonymous binding

Anonymous binding is an LDAP server function. Anonymous binding allows a client to connect and search the directory (bind and search) without logging in because binddn and bindpasswd are not needed.

You also do not need to log in when you configure LDAP authentication using Management Console.

In this section

- [Workflow for configuring LDAP bind](#)
- [Workflow for configuring LDAP search and bind](#)

Workflow for configuring LDAP bind

To configure your Vertica database to authenticate clients using LDAP bind, follow these steps:

1. Obtain a service account. For information see the [LDAP product documentation](#). You cannot use the service account in the connection parameters for LDAP bind.
2. Compare the user's LDAP account name to their Vertica username. For example, if John Smith's Active Directory (AD) sAMAccountName = jsmith, his Vertica username must also be jsmith.

However, the LDAP account does not have to match the database user name, as shown in the following example:

```
=> CREATE USER r1 IDENTIFIED BY 'password';
=> CREATE AUTHENTICATION ldap1 METHOD 'ldap' HOST '172.16.65.177';
=> ALTER AUTHENTICATION ldap1 SET HOST=
  'ldap://172.16.65.10',basedn='dc=dc,dc=com',binddn_suffix=',ou=unit2,dc=dc,dc=com',binddn_prefix='cn=use';
=> GRANT AUTHENTICATION ldap1 TO r1;
\! ${TARGET}/bin/vsqli -p $PGPORT -U r1 -w $LDAP_USER_PASSWD -h ${HOSTNAME} -c
  "select user_name, client_authentication_name from sessions;"
user_name | client_authentication_name
-----+-----
r1      | ldap
(1 row)
```

3. Run `ldapsearch` from a Vertica node against your LDAP or AD server. Verify the connection to the server and identify the values of relevant fields. Running `ldapsearch` helps you build the client authentication string needed to configure LDAP authentication. In the following example, `ldapsearch` returns the CN, DN, and sAMAccountName fields (if they exist) for any user whose CN contains the username jsmith. This search succeeds only for LDAP servers that allow anonymous binding:

```
$ ldapsearch -x -h 10.10.10.10 -b "ou=Vertica Users,dc=CompanyCorp,dc=com"
'(cn=jsmith*)' cn dn uid sAMAccountName
```

`ldapsearch` returns the following results. The relevant information for LDAP bind is in **bold** :

```
# extended LDIF
#
# LDAPv3
# base <ou=Vertica Users,dc=CompanyCorp,dc=com> with scope subtree
# filter: (cn=jsmith*)
# requesting: cn dn uid sAMAccountName
#
# jsmith, Users, CompanyCorp.com
dn:cn=jsmith,ou=Vertica Users,dc=CompanyCorp,dc=com
cn: jsmith
uid: jsmith
# search result
search: 2
result: 0 Success
# numResponses: 2
# numEntries: 1
```

4. Create a new authentication record based on the information from `ldapsearch`. In the `ldapsearch` entry, the CN is username `jsmith`, so you do not need to set it. Vertica automatically sets the CN to the username of the user who is trying to connect. Vertica uses that CN to bind against the LDAP server.

```
=> CREATE AUTHENTICATION v_ldap_bind METHOD 'ldap' HOST '0.0.0.0/0';
=> GRANT AUTHENTICATION v_ldap_bind TO public;
=> ALTER AUTHENTICATION v_ldap_bind SET
host='ldap://10.10.10.10/',
basedn='DC=CompanyCorp,DC=com',
binddn_prefix='cn=',
binddn_suffix='OU=Vertica Users,DC=CompanyCorp,DC=com';
```

For more information see [LDAP Bind Parameters](#).

Workflow for configuring LDAP search and bind

To configure your Vertica database to authenticate clients using LDAP search and bind, follow these steps:

1. Obtain a service account. For information see the [LDAP product documentation](#).
2. From a Vertica node, run `ldapsearch` against your LDAP or AD server. Verify the connection to the server, and identify the values of relevant fields. Running `ldapsearch` helps you build the client authentication string needed to configure LDAP authentication. In the following example, `ldapsearch` returns the CN, DN, and `sAMAccountName` fields (if they exist) for any user whose CN contains the username, John. This search succeeds only for LDAP servers that allow anonymous binding:

```
$ ldapsearch -x -h 10.10.10.10 -b 'OU=Vertica Users,DC=CompanyCorp,DC=com' -s sub -D
'CompanyCorpjsmith' -W '(cn=John*)' cn dn uid sAMAccountName
```

3. Review the results that `ldapsearch` returns. The relevant information for search and bind is in bold:

```
# extended LDIF
#
# LDAPv3
# base <OU=Vertica Users,DC=CompanyCorp,DC=com> with scope subtree
# filter: (cn=John*)
# requesting: cn dn sAMAccountName
#
# John Smith, Vertica Users, CompanyCorp.com
dn: CN=jsmith,OU=Vertica Users,DC=CompanyCorp,DC=com
cn: Jsmith
sAMAccountName: jsmith
# search result
search: 2
result: 0 Success
# numResponses: 2
# numEntries: 1
```

4. Create the client authentication record. The `cn` attribute contains the username you want—`jsmith`. Set your search attribute to the `CN` field so that the search finds the appropriate account.

```
=> CREATE AUTHENTICATION v_ldap_bind_search METHOD 'ldap' HOST '10.10.10.10';
=> GRANT AUTHENTICATION v_ldap_bind_search TO public;
=> ALTER AUTHENTICATION v_ldap_bind_search SET
host='ldap://10.10.10.10',
basedn='OU=Vertica,DC=CompanyCorp,DC=com',
binddn='CN=jsmith,OU=Vertica Users,DC=CompanyCorp,DC=com',
bind_password='password',
search_attribute='CN';
```

For more information see [LDAP Bind and Search Parameters](#)

OAuth 2.0 authentication

Rather than with a username and password, users can authenticate to Vertica by first verifying their identity with an identity provider, receiving an OAuth token, and then passing the token to Vertica.

OAuth in Vertica is tested with Keycloak, Okta, and OTDS but other providers should work if they support the [RFC 7662 Token Introspection](#) standard.

In this section

- [Configuring OAuth authentication](#)
- [Just-in-time user provisioning](#)
- [OAuth authentication parameters](#)

Configuring OAuth authentication

The following procedure performs the following actions:

1. Configures an identity provider for OAuth integration with Vertica (either Okta or Keycloak).
2. Creates an OAuth authentication record.
3. Retrieves an access token from the identity provider with a POST request.
4. Passes the access token to a [sample application](#), which then authenticates to Vertica.

Configure the identity provider

Vertica officially tests and supports OAuth integration with Keycloak and Okta. Other identity providers should also work as long as they implement the [RFC 7662 Token Introspection](#) standard. The following example configurations are provided for reference:

- [Configure Keycloak](#)
- [Configure Okta](#)

Create an authentication record

In Vertica, create an authentication record for OAuth. This uses the client ID, client secret, and either the discovery (Keycloak) or introspect (Okta) endpoint used by your identity provider.

The following [authentication record v_oauth](#) authenticates users from any IP address by contacting the identity provider to validate the OAuth token (rather than a username and password) and uses the following parameters:

- **validate_type** : The method used to validate the OAuth token. This should be set to **IDP** (default) to validate the OAuth token for confidential clients.
- **client_id** : The client in the identity provider.
- **client_secret** : The client secret generated by the identity provider. This is required if **validate_type** is **IDP** .
- **discovery_url** : Also known as the [OpenID Provider Configuration Document](#), Vertica uses this endpoint to retrieve information about the identity provider's configuration and other endpoints (Keycloak only).
- **introspect_url** : Used by Vertica to introspect (validate) access tokens. You must specify the **introspect_url** if you do not specify the **discovery_url** and are not using **JWT** validation.

If **discovery_url** and **introspect_url** are both set, **discovery_url** takes precedence. The following example sets both for demonstration purposes; in general, you should prefer to set the **discovery_url** :

```
=> CREATE AUTHENTICATION v_oauth METHOD 'oauth' HOST '0.0.0.0/0';
=> ALTER AUTHENTICATION v_oauth SET validate_type = 'IDP';
=> ALTER AUTHENTICATION v_oauth SET client_id = 'vertica';
=> ALTER AUTHENTICATION v_oauth SET client_secret = 'client_secret';
=> ALTER AUTHENTICATION v_oauth SET discovery_url = 'https://203.0.113.1:8443/realms/myrealm/.well-known/openid-configuration';
=> ALTER AUTHENTICATION v_oauth SET introspect_url = 'https://203.0.113.1:8443/realms/myrealm/protocol/openid-connect/token/introspect';
```

Alternatively, if your identity provider supports the OpenID Connect protocol and your client is public, Vertica can use JWT validation, where Vertica validates OAuth tokens by verifying that it was signed by the identity provider's private key.

Vertica does not contact the identity provider for JWT validation.

JWT validation requires the following parameters:

- **validate_type** : The method used to validate the OAuth token. This should be set to **JWT** to validate the OAuth token for public clients.
- **jwt_rsa_public_key** : In PEM format, the public key used to sign the client's OAuth token. Vertica uses this to validate the OAuth token. If your identity provider does not natively provide PEM-formatted public keys, you must convert them to PEM format. For example, keys retrieved from an Okta endpoint are in JWK format and must be converted.
- **jwt_issuer** : The issuer of the OAuth token. For Keycloak, this is the [token endpoint](#).
- **jwt_user_mapping** : The name of the Vertica user.

You can also specify the following parameters to define a whitelist based on fields of the OAuth token:

- **jwt_accepted_audience_list** : Optional, a comma-delimited list of values to accept from the client JWT's **aud** field. If set, tokens must include in **aud** one of the accepted audiences to authenticate.
- **jwt_accepted_scope_list** : Optional, a comma-delimited list of values to accept from the client JWT's **scope** field. If set, tokens must include in **scope** at least one of the accepted scopes to authenticate.

The following [authentication record v_oauth_jwt](#) authenticates users from any IP address by verifying that the client's OAuth token was signed by the identity provider's private key. It also requires the user to provide the proper values in the token's **aud** and **scope** fields:

```
=> CREATE AUTHENTICATION v_oauth_jwt METHOD 'oauth' HOST '0.0.0.0/0';
=> ALTER AUTHENTICATION v_oauth_jwt SET validate_type = 'JWT';
=> ALTER AUTHENTICATION v_oauth_jwt SET jwt_rsa_public_key = '-----BEGIN PUBLIC KEY-----public-key-value-----END PUBLIC KEY-----';
=> ALTER AUTHENTICATION v_oauth_jwt SET jwt_issuer = 'http://10.20.30.40:8080/realms/real_name';
=> ALTER AUTHENTICATION v_oauth_jwt SET jwt_user_mapping = 'preferred_username';
=> ALTER AUTHENTICATION v_oauth_jwt SET jwt_accepted_audience_list = 'vertica,local';
=> ALTER AUTHENTICATION v_oauth_jwt SET jwt_accepted_scope_list = 'email,profile,user';
```

Setting the required parameters automatically enables the authentication record. To manually enable the authentication record:

```
=> ALTER AUTHENTICATION v_oauth ENABLE;
```

For a full list of OAuth authentication parameters, see [OAuth authentication parameters](#).

Create a Vertica user

Vertica users map to the identity provider's users with the same username. You can either create the user manually or enable [just-in-time \(JIT\) user provisioning](#) in the authentication record to automatically create users with valid tokens.

To manually create the user:

1. To map to the user **oauth_user** in the identity provider, [create](#) a Vertica user with the same name. You do not need to specify a password because authentication is performed by the identity provider:

```
=> CREATE USER oauth_user;
```

2. Grant the OAuth authentication record to the user (or their role):

```
=> GRANT AUTHENTICATION v_oauth TO oauth_user;
=> GRANT ALL ON SCHEMA PUBLIC TO oauth_user;
```

To enable JIT user provisioning:

```
=> ALTER AUTHENTICATION v_oauth SET oauth2_jit_enabled = 'yes';
```

If the user already exists and JIT user provisioning is enabled and you use Keycloak as your IDP, Vertica automatically assigns the roles associated with the user as specified by the IDP if the roles also exist in Vertica. For details, see [Just-in-time user provisioning](#).

Retrieve an access token

To authenticate to Vertica, you must retrieve an access token from the identity provider.

Programmatic method

A simple way to get an OAuth access token and refresh token is to send a POST request to the token endpoint, providing the credentials of the user. You can then use the returned access token, refresh token, and scope with the connection properties for your client. For details, see [JDBC connection properties](#) and [ODBC DSN connection properties](#).

For example, to get an access token for `oauth_user` from Keycloak:

```
$ curl --location --request POST 'http://203.0.113.1:8080/realms/master/protocol/openid-connect/token' \
--header 'Content-Type: application/x-www-form-urlencoded' \
--data-urlencode 'username=oauth_user' \
--data-urlencode 'password=oauth_user_password' \
--data-urlencode 'client_id=vertica' \
--data-urlencode 'client_secret=client_secret' \
--data-urlencode 'grant_type=password'
```

Keycloak responds with a JSON string containing the `access_token` and `refresh_token` if you authenticated correctly:

```
{
  "access_token": "access_token",
  "expires_in": 60,
  "refresh_expires_in": 1800,
  "refresh_token": "refresh_token",
  "token_type": "Bearer",
  "not-before-policy": 0,
  "session_state": "6745892a-aa74-452f-b6b9-c45637193859",
  "scope": "profile email"
}
```

Similarly, to retrieve an access token for `oauth_user` from Okta:

```
$ curl --insecure -d "client_id=00a5c9dga1fb812rW697" -d "client_secret=aq22wRi3Z3mmtuoB13omRo6QI03Ltafet4xYi77p" \
-d "username=oauth_user" -d "password=oauth_user_password" \
-d "grant_type=password" -d "scope=offline_access%20openid" https://example.okta.com/oauth2/default/v1/introspect

{"token_type": "Bearer", "expires_in": 3600, "access_token": "access_token", "id_token": "id_token"}
```

Single-sign on (SSO)

An alternative to manually retrieving the access token is using SSO through the ODBC client driver. With this method, the ODBC driver opens the default web browser to the IDP's authentication endpoint where the user can enter their credentials. If the user successfully authenticates to the IDP, the ODBC driver automatically retrieves the token and authenticates to Vertica.

To configure and use the ODBC driver for SSO:

1. For clients that use the `confidential` access type, set the `oauthclientsecret`.
2. In the [authentication record](#), set the following [parameters](#):
 - The `discovery_url` (Keycloak only) or the following:
 - `auth_url`
 - `token_url`
 - `client_id`
3. Connect to Vertica with the ODBC driver. The default web browser opens to your IDP's sign-in page.
4. Enter your credentials to authenticate to the IDP.

Run the sample applications

The OAuth sample applications, at a minimum, take an access token as an argument to authenticate to the database until the token expires. This token is retrieved by the client application and then set as a connection property in the driver.

ODBC

1. Follow the instructions in the [README](#).
2. [Run the sample application](#), passing the OAuth parameters as arguments:
 - To authenticate until the token expires:

```
$. /a.out --access-token OAuthAccessToken
```

- To authenticate and silently refresh the access token when it expires:

```
$. /a.out --access-token OAuthAccessToken  
--refresh-token OAuthRefreshToken  
--client-secret OAuthClientSecret
```

For a list of all ODBC OAuth parameters, see [ODBC DSN connection properties](#).

JDBC

1. Follow the instructions in the [README](#).
2. [Run the sample application](#), passing the OAuth parameters as arguments:

- To authenticate until the token expires:

```
$ mvn compile exec:java -Dexec.mainClass=OAuthSampleApp -Dexec.args="vertica_host database_name --access-token oauthtoken"
```

- To authenticate and silently refresh the access token when it expires:

```
$ mvn compile exec:java -Dexec.mainClass=OAuthSampleApp -Dexec.args="vertica_host database_name --access-token oauthtoken  
--refresh_token oauthtoken  
--client-secret oauthtokensecret"
```

ADO.NET

The ADO.NET driver uses a simplified configuration scheme with a single connection property: OAuthAccessToken. Other flows like token refresh should be handled externally by the driver. The sample application in the following example demonstrates how to pass an access token to the ADO.NET driver and how to handle token refresh:

1. Follow the instructions in the [README](#).
2. [Run the sample application](#).

Troubleshooting

To get debugging information for TLS, use the `-Djavax.net.debug=ssl` flag.

Custom CA certificates

A truststore is a container for trusted certificate authority (CA) certificates. These CA certificates are used to verify the identities of other systems when establishing a TLS connection. When your JDBC client connects to the identity provider through an HTTPS endpoint, the JDBC client verifies the identity provider's certificate by making sure that it was issued by a CA in the truststore.

If you configure your identity provider with TLS (that is, if you use HTTPS endpoints for your token or refresh URLs) and its certificate is not issued by a well-known CA, you must either specify a custom truststore or import the issuer's CA certificate into the system truststore with [keytool](#).

To specify a custom truststore, set the JDBC connection properties `oauthtruststorepath` and `oauthtruststorepassword`:

```
connProps = new Properties(connProps);  
connProps.setProperty("oauthtruststorepath", "/path/to/truststore/customoauth.truststore");  
connProps.setProperty("oauthtruststorepassword", "password");
```

To add the certificate `keycloak/cert.crt` to the Java truststore:

```
$ keytool -trustcacerts -keystore /usr/lib/jvm/java-1.7.0-openjdk-1.7.0.261-2.6.22.2.el7_8.x86_64/jre/lib/security/cacerts -storepass changeit -importcert -alias keycloak -file /keycloak/cert.crt
```

In this section

- [Configure Keycloak](#)
- [Configure Okta](#)

Configure Keycloak

The following procedure configures a Keycloak 18.0.0 server on 203.0.113.1 for integration with Vertica. For details, see [Configuring OAuth authentication](#).

The goals of this procedure are to configure Keycloak and obtain the following information:

- Client ID: The ID used to identify the Vertica database. This is configured by the user and set to `vertica` in the example procedure.
- Client secret: A Keycloak-generated string used to refresh the OAuth token when it expires.
- Discovery endpoint: The endpoint that serves information for all other endpoints as a JSON string. The endpoint for a Keycloak server on 203.0.113.1 is one of the following:

- <https://203.0.113.1:8443/realms/myrealm/.well-known/openid-configuration> (if TLS is configured)
- <http://203.0.113.1:8443/realms/myrealm/.well-known/openid-configuration>

Configure TLS (optional)

If you want to use TLS, you must obtain a certificate and key for Keycloak signed by a trusted CA. This example uses a self-signed CA for convenience. The following example creates a certificate and key in Vertica:

1. [Generate](#) the CA certificate:

```
=> CREATE KEY SSCA_key TYPE 'RSA' LENGTH 2048;
CREATE KEY

=> CREATE CA CERTIFICATE SSCA_cert
SUBJECT '/C=US/ST=Massachusetts/L=Cambridge/O=Micro Focus/OU=Vertica/C N=Vertica Root CA'
VALID FOR 3650
EXTENSIONS 'nsComment' = 'Self-signed root CA cert'
KEY SSCA_key;
CREATE CERTIFICATE
```

2. Generate a server key and certificate, signed by your CA, setting the **subjectAltName** of the certificate to the DNS server and/or IP address of your Keycloak server:

```
=> CREATE KEY keycloak_key TYPE 'RSA' LENGTH 2048;
CREATE KEY

=> CREATE CERTIFICATE keycloak_cert
SUBJECT '/C=US/ST=Massachusetts/L=Cambridge/O=Micro Focus/OU=Vertica/CN=Vertica Server'
SIGNED BY SSCA_cert
EXTENSIONS 'nsComment' = 'Keycloak CA', 'extendedKeyUsage' = 'serverAuth', 'subjectAltName' = 'DNS:1:dnsserver,IP:203.0.113.1'
KEY keycloak_key;
CREATE CERTIFICATE
```

3. Create the file [keycloak_directory/conf/keyfile.pem](#) with the content from the [key](#) column for the generated key:

```
=> SELECT key FROM cryptographic_keys WHERE name = 'keycloak_key';
```

4. Create the file [keycloak_directory/conf/certfile.pem](#) with the content from the [certificate_text](#) column for the generated certificate:

```
=> SELECT certificate_text FROM certificates WHERE name = 'keycloak_cert';
```

5. Append to your system's CA bundle the content from the [certificate_text](#) column for the generated CA certificate. The default CA bundle path and format varies between distributions; for details, see [SystemCABundlePath](#):

```
=> SELECT certificate_text FROM certificates WHERE name = 'SSCA_cert';
```

6. Set the [SystemCABundlePath](#) configuration parameter:

```
=> ALTER DATABASE DEFAULT SET SystemCABundlePath = 'path/to/ca_bundle';
```

Start Keycloak

1. Enter the following commands for a minimal configuration to create the Keycloak admin and to start Keycloak in start-dev mode:

```
$ KEYCLOAK_ADMIN=kcadmin
$ export KEYCLOAK_ADMIN
$ KEYCLOAK_ADMIN_PASSWORD=password
$ export KEYCLOAK_ADMIN_PASSWORD
$ cd keycloak_directory/bin/
$ ./kc.sh start-dev --hostname 203.0.113.1 --https-certificate-file ../conf/certfile.pem --https-certificate-key-file=../conf/keyfile.pem
```

2. Open the Keycloak console with your browser (these examples use the default ports):
 - For HTTP: <http://203.0.113.1:8080>
 - For HTTPS: <http://203.0.113.1:8443>
3. Sign in as the admin.
4. Go to **Client scopes > Client scope details > Mapper details**, and toggle **Full group path** to **Off**. Vertica does not support subgroups.
5. (Optional) To make testing OAuth more convenient, go to **Realm Settings > Tokens** and increase **Access Token Lifespan** to a greater value (the default is 5 minutes).

Create the Vertica client

1. Go to **Clients** and select on **Create**. The **Add Client** page appears.
2. In **Client ID**, enter [vertica](#).

3. Select **Save** . The client configuration page appears.
4. On the **Settings** tab, use the **Access Type** dropdown to select **confidential** .
5. On the **Credentials** tab, copy the **Secret** . This is the client secret used to refresh the token when it expires.

Create a Keycloak user

Keycloak users map to Vertica users with the same name. This example creates a the Keycloak user `oauth_user` .

1. On the **Users** tab, select **Add user** . The **Add user** page appears.
2. In **Username** , enter `oauth_user` .
3. On the **Credentials** tab, enter a password.

Configure Okta

The following procedure configures Okta for integration with Vertica and requires administrator privileges. For details, see [Configuring OAuth authentication](#) .

The goals of this procedure are to configure Okta and obtain the following information:

- Client ID: The ID used to identify the Vertica database. This is generated by Okta.
- Client secret: An Okta-generated string used to refresh the OAuth token when it expires.
- Token endpoint: Used by the client to retrieve the OAuth token.
- Introspection endpoint: Used by Vertica to validate the OAuth token.

These values are used to [create the oauth authentication record in Vertica](#) and act as instructions for Vertica to communicate with Okta when a user attempts to authenticate.

Create an OIDC application

1. From the Okta dashboard, go to **Applications > Applications** and select **Create App Integration** . The **Create a new app integration** dialog box appears.
2. For the **Sign-in method** , select **OIDC - OpenID Connect** . The **Application type** section appears.
3. For the **Application type** , select **Native Application** .
4. Select **Next** . The **New Native App Integration** window opens.
5. In the **App integration name** , enter a name for your application. This example uses `Demo_Vertica` .
6. For the **Grant Type** , select **Authorization Code** , **Refresh Token** , and **Resource Owner Password** .
7. For **Controlled access** , select the option applicable to your organization. This example uses **Allow everyone in your organization to access** .
8. Select **Save** to save your application.

Retrieve the client ID and client secret

1. From the Okta dashboard, go to **Applications > Applications** and select the name of your OIDC application.
2. In the **General** tab in the **Client Credentials** section, select **Edit** .
3. For **Client authentication** , select **Client secret** and select **Save** . This generates a new client secret.
4. Copy the client ID and client secret.

Set the authentication policy

1. From the Okta dashboard, go to **Applications > Applications** and select the name of your OIDC application.
2. In the **Sign On** tab in the **User authentication** section, select **Edit** .
3. Select **Password only** .
4. Select **Save** to save the new policy.

Retrieve Okta endpoints

1. From the Okta dashboard, go to **Security > API** .
2. In the **Authorization Servers** tab, select the name of your authorization server. By default, the name of this server is **default** .
3. Select the **Metadata URI** to get a list of all endpoints for your authorization server as a `json` string.
4. Copy the values for the **token_endpoint** and **introspection_endpoint** .

Test the configuration

1. Verify that you can retrieve an OAuth token from the token endpoint. If successful, Okta respond with an `access_token` and `refresh_token` :

```
curl -insecure -d "client_id=client_id" -d "client_secret=client_secret" -d "username=okta_username" -d "password=okta_password" -d "grant_type=password" token_endpoint
```

2. Verify that the tokens are valid with the introspection endpoint. If successful, Okta responds with a `json` string containing `"active":true` :

To verify the access token:

```
curl -insecure -d "client_id=client_id" -d "client_secret=client_secret" -d "token=access_token" introspection_endpoint
```

Similarly, to verify the refresh token:

```
% curl -insecure -d "client_id=client_id" -d "client_secret=client_secret" -d "token=refresh_token" introspection_endpoint
```

The `access_token` and `refresh_token` can then be used for the `oauthaccessstoken` and `oauthrefreshstoken` parameters. For details, see [JDBC connection properties](#) and [ODBC DSN connection properties](#).

Just-in-time user provisioning

Just-in-time (JIT) user provisioning is the act of automatically configuring an authenticated user and their roles based on information provided by the identity provider (IdP).

When a client uses an OAuth [authentication record](#) that enables JIT user provisioning, Vertica automatically performs the following actions:

1. [Creates the user](#) if they do not exist in the database. The username must conform to conventions described in [Identifiers](#).
2. If you configure [automatic role assignment](#), Vertica identifies roles that exist in both the user or group identity and the database and [grants](#) each role to the Vertica database user as a [default role](#).
3. [Grants](#) to the user the authentication record that is associated with the IdP if the user or role does not already have a grant on that authentication record.

You can view all JIT-provisioned users and their authentication record with the `USERS` system table. If the user was JIT-provisioned, then the `managed_by_oauth2_auth_id` column lists the JIT-enabled authentication record:

```
-> SELECT user_name, managed_by_oauth2_auth_id FROM users;
user_name | managed_by_oauth2_auth_id
-----|-----
dbadmin   |
Bob       | 45035996273853300
Margie    |
Alice     | 45035996273866484
(4 rows)
```

Enable JIT provisioning

When Vertica authenticates a JIT-provisioned user, it loops through all existing OAuth authentication records for a record that can authenticate the OAuth token in the client request. If Vertica locates the authentication record, it assigns the record to the JIT-provisioned user.

After you [create an OAuth authentication record](#), you must [alter its authentication record](#) to enable JIT. To enable JIT, set the `oauth2_jit_enabled` OAuth authentication parameter to `yes`:

```
-> ALTER AUTHENTICATION v_oauth SET oauth2_jit_enabled = 'yes';
ALTER AUTHENTICATION
```

To confirm that JIT authentication is enabled on the authentication record, query the `CLIENT_AUTH_PARAMS` table:

```
-> SELECT * FROM CLIENT_AUTH_PARAMS WHERE auth_name = 'v_oauth' AND auth_parameter_name = 'oauth2_jit_enabled';
auth_oid | auth_name | auth_parameter_name | auth_parameter_value
-----|-----|-----|-----
45035996273859012 | v_oauth | oauth2_jit_enabled | yes
(1 row)
```

Automatic role assignment

Vertica can automatically assign a role to a JIT-provisioned user if the OAuth token contains the following:

- Client identity role that exactly matches a Vertica database role
- Group identity role that exactly matches a Vertica database role
- Group identity name that exactly matches a Vertica database role

Vertica updates the role assignment each time a JIT-provisioned user authenticates with the OAuth token. For example, if Vertica automatically assigned a role using the group identity name and then that group identity is removed from the IdP, Vertica revokes that role the next time that JIT-provisioned user authenticates to Vertica. In addition, you can add a role to a blacklist that prevents Vertica from automatically granting that role during JIT provisioning. These features ensure that Vertica reflects up-to-date role assignments so that you can manage your database user identities from a single, secure location.

Prerequisites

- [Create an OAuth authentication record](#).

- [Enable JIT provisioning.](#)
- [Create the Vertica database roles](#) that you want to automatically assign to JIT-provisioned users.

Configure role assignment

An IdP manages Vertica as a client identity. An IdP client can have zero or more roles, where each role has specific privileges in the client environment. IdPs also manage group identities, where each group identity is a collection of user identities that share attributes and roles.

During automatic role assignment, Vertica treats each IdP client role, group role, and group name the same. If the JIT-provisioned user has a client role, group role, or group name that maps to a Vertica role, Vertica automatically assigns that role to the JIT-provisioned user. A single OAuth token can contain both client and group identities.

To associate a database with an IdP client or group identity, set the corresponding [security parameter](#):

- **OAuth2JITRolesClaimName** identifies the Vertica client identity in an IdP that contains the role mappings:

```
=> ALTER DATABASE DEFAULT SET OAuth2JITRolesClaimName = 'resource_access.IdPClientName.roles';
```

- **OAuth2JITGroupsClaimName** identifies a group identity that contains Vertica client role mappings:

```
=> ALTER DATABASE DEFAULT SET OAuth2JITGroupsClaimName = 'IdPGroupClaimName';
```

Vertica automatically assigns a role only if the database security parameter setting exactly matches an IdP client or group claim name. If there is a match, then Vertica looks at the match in the IdP. If there is a client role, group name, or group role that exactly matches an existing Vertica database role, then Vertica grants the database role to the JIT-provisioned user. Vertica ignores any roles or groups that do not have exact matches in Vertica.

Restrict role assignment

Vertica can assign any role to a JIT-provisioned user, including DBADMIN and PSEUDOSUPERUSER. Because granting unrestricted privileges might raise security concerns, you can restrict Vertica role assignments with the **OAuth2JITForbiddenRoles** [security parameter](#):

```
=> ALTER DATABASE DEFAULT SET OAuth2JITForbiddenRoles = 'dbadmin,pseudosuperuser';
```

When an IdP user has a role or group mapping that matches a role in **OAuth2JITForbiddenRoles**, Vertica does not grant the JIT-provisioned user that role.

Verify role assignments

To verify which roles were automatically assigned to JIT-provisioned users, you can query the **vs_users** table. The **num_jit_roles** column lists the number of roles that were assigned with JIT provisioning, and **oauth2_jit_roles** list the names of each role:

```
=> \x
Expanded display is on.
=> SELECT num_default_roles, default_roles, num_jit_roles, oauth2_jit_roles, managed_by_oauth2_auth_id
   FROM vs_users
  WHERE name = 'username';
[ RECORD 1 ]
num_default_roles | 2
default_roles    | vertica-admin, vertica-user
num_jit_roles    | 2
oauth2_jit_roles | vertica-admin, vertica-user
managed_by_oauth2_auth_id | 45035996273851314
```

Example

In this example scenario, an organization uses the Keycloak IdP to manage user identities across their organization. The Keycloak implementation has a client identity named **vertica** and a group identity named **groups**. The following table lists the client roles, IdP groups, and group roles:

vertica client roles	groups name	groups roles
dbadmin	realm_admin	user_admin
orders_user		
view_realm		

Vertica configuration

Vertica has a database named **orders** with the following security parameter settings that define the roles claim, group claim, and restricted roles:

```

=> SELECT parameter_name, current_value FROM configuration_parameters
   WHERE parameter_name = 'OAuth2JITRolesClaimName'
   OR parameter_name = 'OAuth2JITGroupsClaimName'
   OR parameter_name = 'OAuth2JITForbiddenRoles';
 parameter_name | current_value
-----+-----
 OAuth2JITForbiddenRoles | dbadmin,pseudosuperuser
 OAuth2JITGroupsClaimName | groups
 OAuth2JITRolesClaimName | resource_access.vertica.roles
(3 rows)

```

Vertica has the following users:

```

=> SELECT USER_NAME FROM USERS;
 USER_NAME
-----
 dbadmin
(1 row)

```

Vertica has the following assigned roles:

```

=> SELECT NAME, ASSIGNED_ROLES FROM ROLES;
 NAME | ASSIGNED_ROLES
-----+-----
 public |
 dbduser |
 dbadmin | dbduser*
 pseudosuperuser | dbadmin*
 --
 orders_user |
 user_admin |

```

Role assignment process

A client authenticates to the `orders` database as a user named `Alice`, but the `Alice` user does not exist in Vertica. The authentication record associated with the `orders` database uses IDP validation and has `oauth2_jit_enabled` set to `yes`, so Vertica can JIT provision the `Alice` user and then assign roles that exist in both the IdP and Vertica.

When `Alice` authenticates to the `orders` database, Vertica performs the following steps:

1. Provisions the `Alice` user.
2. Sends a request to the IdP to retrieve roles using the `OAuth2JITRolesClaimName` and `OAuth2JITGroupsClaimName` security parameter settings. In this case, Vertica requests roles for a client identity named `vertica` and a group identity named `groups`.
3. Compares all client and group roles in the IdP response to the roles in Vertica and performs the following:
 - Grants the `orders_user` role to the JIT-provisioned `Alice` user, and sets it as a default role.
 - Grants the `user_admin` role to the JIT-provisioned `Alice` user, and sets it as a default role.
 - Does not grant the `dbadmin` role to `Alice` because it is specified by the `OAuth2JITForbiddenRoles` security parameter.
 - Ignores the `realm_admin` group name and `view_admin` group role because there is no corresponding role in Vertica.

After the automatic role assignment process completes, `Alice` has default roles that reflect the IdP configuration:

```

=> SELECT user_name, default_roles FROM users
   WHERE user_name = 'Alice';
 user_name | default_roles
-----+-----
 Alice | orders_user, user_admin
(1 row)

```

The automatic role assignment workflow occurs each time a client authenticates as the `Alice` user. This ensures that Vertica role assignments reflect the current role assignments in the IdP.

Automatic user pruning

You can enable automatic user pruning to periodically drop users created by JIT user provisioning if they do not log in after a certain period of time. This cleanup service is managed by the following [database-level configuration parameters](#):

- **EnableOAuthJITCleanup**: Whether to enable cleanup (disabled by default).

```
=> ALTER DATABASE DEFAULT SET EnableOAuthJITCleanup = 1; --enables the pruning service
=> ALTER DATABASE DEFAULT SET EnableOAuthJITCleanup = 0; --disables the pruning service
```

- **OAuth2UserExpiredInterval**: The number of days a user must be inactive before it is dropped (14 by default). This is calculated based on the current date and the **LAST_LOGIN_TIME** in the **USERS** system table.

Note

The **LAST_LOGIN_TIME** as recorded by the **USERS** system table is not persistent; if the database is restarted, the **LAST_LOGIN_TIME** for users created by just-in-time user provisioning is set to the database start time (this appears as an empty value in **LAST_LOGIN_TIME**).

You can view the database start time by querying the **DATABASES** system table:

```
=> SELECT database_name, start_time FROM databases;
database_name |      start_time
-----
VMart         | 2023-02-06 14:26:50.630054-05
(1 row)
```

```
=> ALTER DATABASE DEFAULT SET OAuth2UserExpiredInterval = 20;
```

- **GlobalHeirUsername**: The user to reassign objects to if the owner is a JIT-provisioned (or LDAP) user that got dropped by the pruning service. If set to **<auto>**, objects are reassigned to the **dbadmin**.

```
=> ALTER DATABASE DEFAULT SET GlobalHeirUsername = <auto>
```

The cleanup service runs daily and there can be a delay of up to 24 hours for dropping an expired user.

OAuth authentication parameters

Vertica OAuth [authentication records](#) uses parameters to determine how to validate client OAuth tokens and how to contact the identity provider during the validation process. These parameters should be set with [ALTER AUTHENTICATION](#).

Just-in-time provisioning parameters

The following parameters configure [just-in-time user provisioning](#) (JIT):

groups_claim_name

Sets the group claim name for the authentication record. This setting overrides the **OAuth2JITGroupsClaimName** [security parameter](#).

oauth2_jit_enabled

Whether to enable [just-in-time user provisioning](#). This parameter accepts the following values:

- **'yes'**: Vertica uses [automatic role assignment](#).
- **'no'** or unset: You must manually [create each user](#) and [grant the user](#) an **oauth** authentication record before they can authenticate to Vertica with OAuth tokens.

oauth2_jit_authorized_roles

When set, the OAuth user specifies roles that can use JIT user provisioning. When omitted, any OAuth user can use JIT provisioning.

This parameter accepts one or more roles as a comma-separated list.

role_group_suffix

OpenText Directory Service (OTDS) only.

Appends a value to the role or group name associated with the OAuth record. Vertica uses this value to identify users during authorization. Vertica recommends that you append your subscription ID in the following format: **@ subscriptionID**.

roles_claim_name

Sets the roles claim name for the authentication record. This setting overrides the **OAuth2JITRolesClaimName** [security parameter](#).

Validation modes

OAuth authentication records have two modes for validating OAuth tokens, each specified with the authentication parameter **validate_type**.

validate_type accepts one of the following values:

- **IDP** (default): Validate OAuth tokens by contacting the identity provider. This validation type requires the client to specify their client secret. This should be used with confidential clients (set for each client by the identity provider).
- **JWT** : Validate OAuth tokens by verifying that it was signed by the identity provider's private key. This does not require Vertica to contact the identity provider for validation and should be used for public clients (set for each client by the identity provider).

Each validation mode uses a different set of parameters, which are detailed in the sections below.

IDP validation parameters

The following parameters configure OAuth authentication records that use the **IDP** validation mode:

client_id

Required. The ID of the confidential client application registered in the identity provider. Vertica uses this ID to call the introspection API to retrieve user grants.

client_secret

Required. The secret of the confidential client application registered in the identity provider. This value is not shared with other clients.

discovery_url

Required for **IDP** validation if **introspect_url** is not specified.

Also known as the [OpenID Provider Configuration Document](#) or the well-known configuration endpoint, this endpoint contains information about the configuration and endpoints of the identity provider.

If you set the **discovery_url** , you do not have to set any other endpoint parameters. If you specify **discovery_url** and other endpoints, the **discovery_url** takes precedence.

introspect_url

Required if **discovery_url** is not specified. Used by Vertica to introspect (validate) access tokens. You must specify this parameter if you do not specify the **discovery_url** . For examples, see the [Keycloak](#) and [Okta](#) documentation.

auth_url

Required for [single-sign on \(SSO\)](#). The [authorization endpoint](#) for your identity provider.

token_url

Required for [single-sign on \(SSO\)](#). The [token endpoint](#) for your identity provider.

scope

Optional. The requested OAuth scopes, delimited with spaces. These scopes define the extent of access to the resource server (in this case, Vertica) granted to the client by the access token. For details, see the [OAuth documentation](#) .

validate_hostname

Optional. Boolean, whether Vertica verifies the **subjectAltName** of the identity provider host when establishing a connection. If enabled, the IP address or hostname of the identity provider must be set as the **subjectAltName** in its certificate. This parameter only applies to connections made by JDBC clients.

Hostname verification is enabled by default.

JWT validation parameters

The following parameters configure OAuth authentication records that use the **JWT** validation mode:

jwt_rsa_public_key

Required. In PEM format, the public key that corresponds to the private key used to sign the client's OAuth token. Vertica uses this to validate the OAuth token. If your identity provider does not natively provide PEM-formatted public keys, you must convert them to PEM format. For example, keys retrieved from an Okta endpoint are in JWK format and must be converted.

jwt_issuer

Required. The issuer of the OAuth token. This value is set by the identify provider.

jwt_user_mapping

Required. The name of the Vertica user.

jwt_accepted_audience_list

Optional. A comma-delimited list of values to accept from the client OAuth token's **aud** field. If set, tokens must include in **aud** one of the accepted audiences to authenticate.

jwt_accepted_scope_list

Optional. A comma-delimited list of values to accept from the client OAuth token's **scope** field. If set, tokens must include in **scope** at least one of the accepted scopes to authenticate.

TLS authentication

The `tls` authentication method authenticates users that can establish a mutual mode [client-server TLS connection](#) using a certificate that specifies a valid database username in the Common Name (CN) field.

Before you create and use a `tls` authentication method, you must configure Vertica for [client-server TLS in mutual mode](#) (disabled by default).

In this section

- [Client authentication with TLS](#)

Client authentication with TLS

Database users or roles [granted](#) a `tls` authentication record can authenticate to Vertica with a TLS certificate.

Prerequisites

You must configure Vertica for [mutual mode client-server TLS](#).

In mutual mode, the client and server must verify each other's identity before connecting. This mode allows Vertica to verify the identity of the client and allow them to authenticate the client through their certificate.

Configuring TLS authentication

The following sections [generate](#) a private key and certificate for the client. For simplicity, the example signs the client certificate with the following self-signed CA certificate (which has also, in the context of the example, signed the Vertica database's server certificate):

```
=> CREATE KEY SSSA_key TYPE 'RSA' LENGTH 2048;
=> CREATE CA CERTIFICATE ca_certificate
SUBJECT '/C=US/ST=Massachusetts/L=Cambridge/O=OpenText/OU=Vertica/CN=Vertica Root CA'
VALID FOR 3650
EXTENSIONS 'nsComment' = 'Self-signed root CA cert'
KEY SSSA_key;
```

In a production environment, you should instead use a CA certificate from a trusted certificate authority.

Create client keys

The following steps generate a client key and certificate, and then make them available to the client:

1. Generate the client key:

```
=> CREATE KEY client_private_key TYPE 'RSA' LENGTH 2048;
CREATE KEY
```

2. Generate the client certificate. Mutual TLS requires that the Common Name (`CN`) in the `SUBJECT` specifies a database username:

```
=> CREATE CERTIFICATE client_certificate
SUBJECT '/C=US/ST=Massachusetts/L=Cambridge/O=OpenText/OU=Vertica/CN=dbadmin/emailAddress=example@example.com'
SIGNED BY ca_certificate
EXTENSIONS 'nsComment' = 'Vertica client cert', 'extendedKeyUsage' = 'clientAuth'
KEY client_private_key;
CREATE CERTIFICATE
```

3. On the client machine, export the client key and client certificate to the client filesystem. The following commands use the [vsq client](#):

```
$ vsq -At -o "SELECT key FROM cryptographic_keys WHERE name = 'client_private_key';" -o client_private_key.key
$ vsq -At -o "SELECT certificate_text FROM certificates WHERE name = 'client_certificate';" -o client_cert.pem
```

In the preceding command:

- `-A` : enables unaligned output.
- `-t` : prevents the command from outputting metadata, such as column names.
- `-c` : instructs the shell to run one command and then exit.

- `-o` : writes the query output to the specified filename.

For details about all vsql command line options, see [Command-line options](#)

4. Copy or move the client key and certificate to a location that your client recognizes.

The following commands move the client key and certificate to the hidden directory `~/.client-creds` , and then grants the file owner read and write permissions with `chmod` :

```
$ mkdir ~/.client-creds
$ mv client_private_key.key ~/.client-creds/client_key.key
$ mv client_cert.pem ~/.client-creds/client_cert.pem
$ chmod 600 ~/.client-creds/client_key.key ~/.client-creds/client_cert.pem
```

Create an authentication record

Next, you must create an [authentication record](#) in the database. An authentication record defines a set of authentication and the access methods for the database. You grant this record to a user or role to control how they authenticate to the database:

1. [Create the authentication record](#) . The `tls` method requires that clients authenticate with a certificate whose Common Name (CN) specifies a database username:

```
=> CREATE AUTHENTICATION auth_record METHOD 'tls' HOST TLS '0.0.0.0/0';
CREATE AUTHENTICATION
```

2. [Grant the authentication record](#) to a user or to a role. The following example grants the authentication record to `PUBLIC` , the [default role](#) for all users:

```
=> GRANT AUTHENTICATION auth_record TO PUBLIC;
GRANT AUTHENTICATION
```

Reject plaintext connections

You can create an authentication record that rejects remote connections from a specified IP range.

For example, to reject all plaintext client connections, specify the `reject` authentication method and the `HOST NO TLS` access method as follows:

```
=> CREATE AUTHENTICATION RejectNoSSL METHOD 'reject' HOST NO TLS '0.0.0.0/0'; --IPv4
=> CREATE AUTHENTICATION RejectNoSSL METHOD 'reject' HOST NO TLS '::/0'; --IPv6
```

Internode TLS

Internode TLS secures communication between nodes within a cluster. It is important to secure communications between nodes if you do not trust the network between the nodes.

Before setting up internode TLS, check the current status of your configuration with [SECURITY_CONFIG_CHECK](#) .

```
=> SELECT SECURITY_CONFIG_CHECK('NETWORK');
```

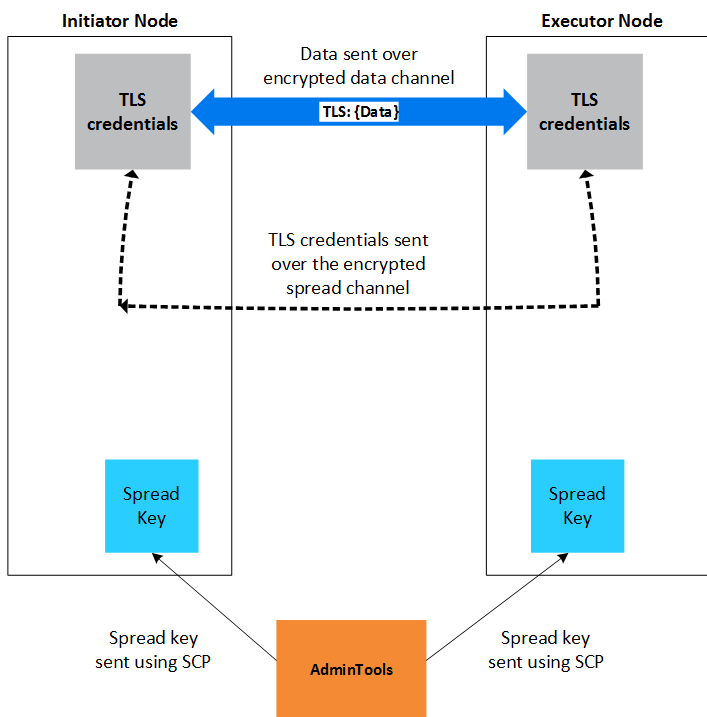

Communication between the server nodes uses two channels: the control channel and data channel. To enable internode encryption, set the [EncryptSpreadComm parameter](#) (disabled by default) to encrypt Spread communication on the control channel and configure the [data_channel TLS Configuration](#) to encrypt the data channel:

1. Encrypt Spread communication on the control channel with `EncryptSpreadComm` . See [Control channel Spread TLS](#) for details.
2. Encrypt the data channel with the `data_channel` TLS Configuration. See [Data channel TLS](#) for details.

If you enable internode encryption, some of your queries might run slower than expected. Performance depends on the data sent and network quality.

Admintools generates or retrieves the spread key to encrypt all traffic on the control channel and ships the spread key to all nodes. Vertica uses TLS to encrypt all traffic on the data channel. TLS credentials are shared between nodes over the encrypted control channel.

The following graphic illustrates the internode encryption process.

See also

- [Control channel Spread TLS](#)
- [Data channel TLS](#)
- [TLS overview](#)

In this section

- [Control channel Spread TLS](#)
- [Data channel TLS](#)

Control channel Spread TLS

The control channel allows nodes to exchange plan information with one another and to distribute calls among nodes. Enabling [Spread](#) security secures this communication with TLS. See [Internode TLS](#) for more information.

Internode TLS uses the following channels. Both must be enabled in the following order before you set other parameters:

1. Control Channel, implemented with Spread, which allows nodes to exchange plan information and distribute calls. For details, see [spread.org](#).
2. [Data Channel](#), implemented with TCP, which allows nodes to exchange table data.

Enable EncryptSpreadComm

[EncryptSpreadComm](#) controls Spread encryption and can be set to one of two values:

- **vertica** : Vertica generates the Spread encryption key for the cluster when the database starts up.
- **aws-kms|key_name** : Vertica fetches the user-specified key from the AWS Key Management Service when the database starts up, rather than generating one itself.

You can verify the current value of EncryptSpreadComm with [SECURITY_CONFIG_CHECK](#) :

```
=> SELECT SECURITY_CONFIG_CHECK('NETWORK');
```

In general, you should set the EncryptSpreadComm parameter to enable Spread encryption before setting any other security parameters.

To create a new database with EncryptSpreadComm set:

```
$ admintools -i create_db -d my_db -s 192.0.2.100, 192.0.2.101, 192.0.2.101
-c 'catalog/path' --config-param EncryptSpreadComm='aws-kms|abcde123-ab12-1234-abcd-abcde1234567'
```

To set EncryptSpreadComm on an existing database:

1. Set **EncryptSpreadComm** parameter with [ALTER DATABASE](#) :

```
=> ALTER DATABASE DEFAULT SET PARAMETER EncryptSpreadComm = 'vertica';
```

- Restart the database.
- Verify your settings with [SECURITY_CONFIG_CHECK](#).

```
=> SELECT SECURITY_CONFIG_CHECK('NETWORK');
-----
Spread security details:
* EncryptSpreadComm = [vertica]
Spread encryption is enabled
It is now safe to set/change other security knobs
```

Privileges

Superuser

Restrictions

If you set this parameter on an existing database with [ALTER DATABASE](#), you must restart the database for it to take effect.

See also

- [Internode TLS](#)
- [Data channel TLS](#)
- [TLS overview](#)

Data channel TLS

Nodes use the data channel to exchange table data during operations such as queries.

Internode communication uses the following channels. Their associated components and parameters must be enabled in the following order:

- [Control Channel](#) to exchange plan information and distribute calls. It is implemented using [Spread](#). For more information, visit [spread.org](#).
- Data Channel to exchange table data. It is implemented using TCP.

Configuring data channel TLS

This procedure configures TLS between Vertica nodes and uses the predefined TLS Configuration [data_channel](#). To use a custom TLS Configuration, see [TLS configurations](#).

- [Enable TLS on the control channel](#).
- [Generate or import](#) a CA (Certificate Authority) certificate. For example, to create a self-signed CA certificate, generate a key and sign CA certificate with the key:

```
=> CREATE KEY SSCA_key TYPE 'RSA' LENGTH 2048;
```

```
=> CREATE CA CERTIFICATE SSCA_cert
SUBJECT '/C=US/ST=Massachusetts/L=Cambridge/O=OpenText/OU=Vertica/CN=Vertica Root CA'
VALID FOR 3650
EXTENSIONS 'nsComment' = 'Self-signed root CA cert'
KEY SSCA_key;
```

- Generate or import a private key. For example, to generate the private key:

```
=> CREATE KEY internode_key TYPE 'RSA' LENGTH 2048;
```

- Generate or import a TLS certificate. The certificate must have a full chain that ends in a CA, and must be either a x509v1 certificate or use the [extendedKeyUsage](#) extensions [serverAuth](#) and [clientAuth](#). For example, to generate [internode_cert](#) and sign it with [SSCA_cert](#):

```
=> CREATE CERTIFICATE internode_cert
SUBJECT '/C=US/ST=Massachusetts/L=Cambridge/O=Micro Focus/OU=Vertica/CN=data channel'
SIGNED BY SSCA_cert
EXTENSIONS 'nsComment' = 'Vertica internode cert', 'extendedKeyUsage' = 'serverAuth, clientAuth'
KEY internode_key;
```

- [Set](#) the certificate, and optionally the TLSMODE for [data_channel](#) TLS configuration. If the TLSMODE is set to [TRY_VERIFY](#) or higher, the certificate's signing CA is added to the TLS Configuration's [list of CA certificates](#):

```
=> ALTER TLS CONFIGURATION data_channel CERTIFICATE internode_cert TLSMODE 'TRY_VERIFY'
```

If you do not specify a TLSMODE, and the TLSMODE was previously set to [DISABLE](#) (default), [TRY_VERIFY](#), [VERIFY_CA](#), or [VERIFY_FULL](#) (which behaves like [VERIFY_CA](#)), the TLSMODE automatically changes to [VERIFY_CA](#):

```
=> ALTER TLS CONFIGURATION data_channel CERTIFICATE internode_cert;
```

If the certificate is not signed by a known CA, the TLSMODE is set to **DISABLE**.

6. Verify that the InternodeTLSConfig parameter uses the TLS Configuration:

```
=> SHOW CURRENT InternodeTLSConfig;
```

level	name	setting
DEFAULT	InternodeTLSConfig	data_channel

(1 row)

7. Verify that data channel encryption is enabled with [SECURITY_CONFIG_CHECK\('NETWORK'\)](#):

```
=> SELECT SECURITY_CONFIG_CHECK('NETWORK');  
SECURITY_CONFIG_CHECK
```

Spread security details:

* EncryptSpreadComm = [vertica]

Spread encryption is enabled

It is now safe to set/change other security knobs

Data Channel security details:

TLS Configuration 'data_channel' TLSMODE is VERIFY_CA

TLS on the data channel is enabled

Privileges

Superuser

Restrictions

- In general, you should set EncryptSpreadComm before configuring data channel TLS.
- Changes to the InternodeTLSConfig parameter and its underlying TLS Configuration take effect immediately and interrupt all ongoing queries in order to update node connections.

TLS protocol

TLS (Transport Layer Security) is a cryptographic protocol used to secure communications between servers, their nodes, and clients.

When enabled, a Vertica database and the clients that connect to it use TLS 1.2.

Although TLS, SSL, and TLS/SSL are often used interchangeably, the Vertica documentation always uses TLS to reference the protocol. Some Vertica parameters and components use SSL, and in these cases the documentation uses SSL to reference them, but these too can be categorized under the TLS umbrella.

Enabling TLS is a multi-step process. First, check the status of your security configuration with [SECURITY_CONFIG_CHECK](#). Then, you can configure TLS authentication records to reject non-TLS connections.

In this section

- [TLS overview](#)

TLS overview

To secure communications and verify data integrity, you can configure Vertica and database clients to use TLS. The TLS protocol uses a key and certificate exchange system along with a trusted third party called a Certificate Authority (CA). Both the owner of a certificate and the other party that relies on the certificate must trust the CA to confirm the certificate holder's identity.

Vertica also supports the following authentication methods using the Transport Layer Security (TLS) v1.2 protocol. Both methods encrypt and verify the integrity of the data in transit:

- **Server Mode** - In server mode, the client must confirm the server's identity before connecting. The client verifies that the server's certificate and public key are valid and were issued by a certificate authority (CA) listed in the client's list of trusted CAs. This helps prevent man-in-the-middle attacks.

- **Mutual Mode** - In mutual mode, the client and server must verify each other's identity before connecting.

In addition to the requirements detailed in this section, you must create [TLS authentication records](#) to reject non-TLS client connections.

TLS handshake process

The following is a high-level/simplified overview of one possible "handshake" process for the client to verify the identity of the server in **Server Mode**. Additional actions taken in **Mutual Mode** for the server to identify the client are marked as such.

Public and Private Key Pairs - Key pairs are generated by clients and servers. The owner of a public key must be verified by a certificate authority. The key pairs are used to encrypt messages. For example, suppose Alice wants to send confidential data to Bob. Because she wants only Bob to read it, she encrypts the data with Bob's public key. Even if someone else gains access to the encrypted data, it remains protected. Because only Bob has access to his corresponding private key, he is the only person who can decrypt Alice's encrypted data back into its original form.

Certificates - Certificates contain a public key and identify the owner of the key. They are issued by the certificate authority (CA).

Certificate Authority (CA) - A certificate authority is a trusted party that verifies the identity of public key owners.

Client and Server Random - Client Random and Server Random are random strings that used to created a shared secret which encrypts communication if the handshake succeeds.

1. Before connecting, the server and client generate their own public and private key pairs. The CA then distributes identifying certificates to the server and client for their respective public keys.
2. The client sends its Client Random to the server and requests the server's certificate.
3. The server sends its certificate and its Server Random, encrypted with its private key, to the client. In **Mutual Mode**, the server also requests the client's certificate.
4. In **Mutual Mode**, the client sends its certificate.
5. The client uses the certificate to verify that the server owns its public key, then decrypts the Server Random with the server's public key to verify that the server owns its private key.
6. In **Mutual Mode**, the server uses the certificate to verify that the client owns its public key.
7. The server and client use the Client and Server Randoms to generate a new secret, called a session key, which encrypts future communication.

In this section

- [Generating TLS certificates and keys](#)
- [Configuring client-server TLS](#)
- [Managing CA bundles](#)
- [Generating certificates and keys for MC](#)
- [Importing a new certificate to MC](#)
- [Replacing the agent certificate](#)
- [Importing and exporting data with TLS](#)

TLS configurations

A TLS Configuration is a database object that encapsulates all settings and certificates needed to configure TLS. After setting up a TLS Configuration, you can use it by setting it as the value for one or more of the following database parameters, each of which controls TLS for a certain type of connection between the Vertica database and a client or server:

- ServerTLSConfig
- LDAPLinkTLSConfig
- LDAPAuthTLSConfig
- InternodeTLSConfig

These parameters are set to [predefined TLS Configurations by default](#) so if you just want to configure TLS, you should use [ALTER TLS CONFIGURATION](#) to modify a [predefined TLS Configuration](#). Otherwise, you can use [CREATE TLS CONFIGURATION](#) to [create a custom TLS Configuration](#).

Reusing an existing TLS configurations

To reuse an [existing TLS Configuration](#), use [ALTER TLS CONFIGURATION](#).

The following table lists each TLS connection type parameter with its associated connection type and predefined TLS Configuration:

Note

For OAuth, Vertica is the client and the identity provider is the server. TLS for this connection type is not controlled by a TLS Configuration. For details, see [Configure Keycloak](#).

Connection Type	Parameter	Default TLS Configuration	Example
Client-server where Vertica is the server	ServerTLSConfig	server	Configuring client-server TLS
Connections for the LDAP Link service	LDAPLinkTLSConfig	LDAPLink	TLS for LDAP link
Connections between Vertica and an LDAP server to authenticate users	LDAPAuthTLSConfig	LDAPAuth	TLS for LDAP authentication
Connections between Vertica nodes	InternodeTLSConfig	data_channel	Internode TLS

Creating custom TLS configurations

You can create TLS Configurations with [CREATE TLS CONFIGURATION](#).

The following example creates a TLS Configuration and enables it for client-server TLS by setting it in ServerTLSConfig:

1. Create the keys and certificates:

```
-- create CA certificate
=> CREATE KEY k_ca TYPE 'RSA' LENGTH 4096;
=> CREATE CA CERTIFICATE ca
  SUBJECT '/C=US/ST=Massachusetts/L=Cambridge/O=Micro Focus/OU=Vertica/CN=Vertica Root CA'
  VALID FOR 3650
  EXTENSIONS 'nsComment' = 'Vertica generated root CA cert'
  KEY k_ca;

-- create server certificate
=> CREATE KEY k_server TYPE 'RSA' LENGTH 2048;
=> CREATE CERTIFICATE server
  SUBJECT '/C=US/ST=Massachusetts/L=Cambridge/O=Micro Focus/OU=Vertica/CN=Vertica Cluster/emailAddress=example@example.com'
  SIGNED BY ca
  KEY k_server;
```

2. Create the TLS Configuration with the server's certificate:

```
=> CREATE TLS CONFIGURATION new_tls_config CERTIFICATE server TLSMODE 'ENABLE';
```

3. Set the ServerTLSConfig parameter to use the new TLS Configuration for client-server TLS:

```
=> ALTER DATABASE DEFAULT SET ServerTLSConfig = 'new_tls_config';
```

Generating TLS certificates and keys

This page includes examples and sample procedures for generating certificates and keys with [CREATE KEY](#) and [CREATE CERTIFICATE](#). To view your keys and certificates, query the [CRYPTOGRAPHIC_KEYS](#) and [CERTIFICATES](#) system tables.

For more detailed information on creating signed certificates, OpenSSL recommends the [OpenSSL Cookbook](#).

For more information on x509 extensions, see the [OpenSSL documentation](#).

Importing keys and certificates

Keys

You only need to import private keys if you intend to use its associated certificate to sign something, like a message in client-server TLS, or another certificate. That is, you only need to import keys if its associated certificate is one of the following:

- Client/server certificate
- CA certificate used to sign other certificates while in Vertica

If you only need your CA certificate to validate other certificates, you do not need to import its private key.

To import a private key:

```
=> CREATE KEY imported_key TYPE 'RSA' AS '-----BEGIN PRIVATE KEY-----...-----END PRIVATE KEY-----';
```

Certificates

To import a CA certificate that only validates other certificates (no private key):

```
=> CREATE CA CERTIFICATE imported_validating_ca AS '-----BEGIN CERTIFICATE-----...-----END CERTIFICATE-----';
```

To import a CA that can both validate and sign other certificates (private key required):

```
=> CREATE CA CERTIFICATE imported_signing_ca AS '-----BEGIN CERTIFICATE-----...-----END CERTIFICATE-----'  
KEY ca_key;
```

To import a certificate for server mode TLS:

```
=> CREATE CERTIFICATE server_mode_cert AS '-----BEGIN CERTIFICATE-----...-----END CERTIFICATE-----' KEY imported_key;
```

To import a certificate for mutual mode TLS or client authentication, you must specify its CA:

```
=> CREATE CERTIFICATE imported_cert AS '-----BEGIN CERTIFICATE-----...-----END CERTIFICATE-----'  
SIGNED BY imported_ca KEY imported_key;
```

Generating private keys and certificates

Keys

To generate an 2048-bit RSA private key:

```
=> CREATE KEY new_key TYPE 'RSA' LENGTH 2048;
```

Self-signed CA certificates

Important

A self-signed CA certificate is convenient for development purposes, but you should always use a proper certificate authority in a production environment.

A CA is a trusted entity that signs and validates other certificates with its own certificate. The following example generates a self-signed root CA certificate:

1. Generate or import a private key. The following command generates a new private key:

```
=> CREATE KEY ca_private_key TYPE 'RSA' LENGTH 4096;  
CREATE KEY
```

2. Generate the certificate with the following format. Sign the certificate the with the private key that you generated or imported in the previous step:

```
=> CREATE CA CERTIFICATE ca_certificate  
SUBJECT '/C=country_code/ST=state_or_province/L=locality/O=organization/OU=org_unit/CN=Vertica Root CA'  
VALID FOR days_valid  
EXTENSIONS 'authorityKeyIdentifier' = 'keyid:always,issuer', 'nsComment' = 'Vertica generated root CA cert'  
KEY ca_private_key;
```

Note

The CA certificate **SUBJECT** must be different from the **SUBJECT** of any certificate that it signs.

For example:

```
=> CREATE CA CERTIFICATE SCA_cert
SUBJECT '/C=US/ST=Massachusetts/L=Cambridge/O=OpenText/OU=Vertica/CN=Vertica Root CA'
VALID FOR 3650
EXTENSIONS 'nsComment' = 'Self-signed root CA cert'
KEY SCA_key;
```

Intermediate CA certificates

In addition to server certificates, CAs can also sign the certificates of other CAs. This process produces an intermediate CA and a chain of trust between the top-level CA and the intermediate CA. These intermediate CAs can then sign other certificates.

Note

Intermediate CA certificates generated with [CREATE CERTIFICATE](#) cannot sign other CA certificates.

1. Generate or import the CA that signs the intermediate CA. The example that follows generates and uses a self-signed root CA:

```
=> CREATE KEY SCA_key TYPE 'RSA' LENGTH 2048;
```

```
=> CREATE CA CERTIFICATE SCA_cert
SUBJECT '/C=US/ST=Massachusetts/L=Cambridge/O=OpenText/OU=Vertica/CN=Vertica Root CA'
VALID FOR 3650
EXTENSIONS 'nsComment' = 'Self-signed root CA cert'
KEY SCA_key;
```

2. Generate or import a private key:

```
=> CREATE KEY intermediate_key TYPE 'RSA' LENGTH 2048;
```

3. Generate the intermediate CA certificate, specifying its private key and signing CA using the following format:

```
=> CREATE CERTIFICATE intermediate_certificate_name
SUBJECT '/C=country_code/ST=state_or_province/L=locality/O=organization/OU=org_unit/CN=Vertica intermediate CA'
SIGNED BY ca_name
KEY intermediate_key;
```

For example:

```
=> CREATE CA CERTIFICATE intermediate_CA
SUBJECT '/C=US/ST=Massachusetts/L=Cambridge/O=OpenText/OU=Vertica/CN=Vertica Intermediate CA'
SIGNED BY SCA_cert
KEY intermediate_key;
```

Client/server certificates

CREATE CERTIFICATE generates x509v3 certificates, which allow you to specify extensions to restrict how the certificate can be used. The value for the [extendedKeyUsage](#) extension will differ based on your use case:

- Server certificate:

```
'extendedKeyUsage' = 'serverAuth'
```

- Client certificate:

```
'extendedKeyUsage' = 'clientAuth'
```

- Server certificate for [internode encryption](#):

```
'extendedKeyUsage' = 'serverAuth, clientAuth'
```

Because these certificates are used for client/server TLS, you must import or generate their private keys.

The following example certificates are all signed by this self-signed CA certificate:

```
=> CREATE KEY SSCA_key TYPE 'RSA' LENGTH 2048;
```

```
=> CREATE CA CERTIFICATE SSCA_cert  
SUBJECT '/C=US/ST=Massachusetts/L=Cambridge/O=OpenText/OU=Vertica/CN=Vertica Root CA'  
VALID FOR 3650  
EXTENSIONS 'nsComment' = 'Self-signed root CA cert'  
KEY SSCA_key;
```

To generate a server certificate:

```
=> CREATE KEY server_key TYPE 'RSA' LENGTH 2048;
```

```
=> CREATE CERTIFICATE server_cert  
SUBJECT '/C=US/ST=Massachusetts/L=Cambridge/O=OpenText/OU=Vertica/CN=Vertica server/emailAddress=example@example.com'  
SIGNED BY SSCA_cert  
EXTENSIONS 'nsComment' = 'Vertica server cert', 'extendedKeyUsage' = 'serverAuth'  
KEY server_key;
```

To generate a client certificate:

```
=> CREATE KEY client_key TYPE 'RSA' LENGTH 2048;
```

```
=> CREATE CERTIFICATE client_cert  
SUBJECT '/C=US/ST=Massachusetts/L=Cambridge/O=OpenText/OU=Vertica/CN=Vertica client/emailAddress=clientexample@example.com'  
SIGNED BY SSCA_cert  
EXTENSIONS 'nsComment' = 'Vertica client cert', 'extendedKeyUsage' = 'clientAuth'  
KEY client_key;
```

To generate an [internode TLS](#) certificate:

```
=> CREATE KEY internode_key TYPE 'RSA' LENGTH 2048;
```

```
=> CREATE CERTIFICATE internode_cert  
SUBJECT '/C=US/ST=Massachusetts/L=Cambridge/O=Micro Focus/OU=Vertica/CN=data channel'  
SIGNED BY SSCA_cert  
EXTENSIONS 'nsComment' = 'Vertica internode cert', 'extendedKeyUsage' = 'serverAuth, clientAuth'  
KEY internode_key;
```

Configuring client-server TLS

Vertica offers two connection modes for client-server TLS:

- In **Server Mode**, the client must verify the host's certificate. Hosts must have a server private key and certificate.
- In **Mutual Mode**, the client and host must each verify the other's certificate. Hosts must have a server private key, server certificate, and CA certificate(s).

Client-server TLS secures the connection step between Vertica and clients, not the following authentication step to authenticate these clients as users in the database. To configure authentication for TLS connections or to reject plaintext connections, see [TLS authentication](#).

Setting certificates with TLS configuration

This procedure creates keys and certificates for client-server TLS and sets them in the predefined TLS Configuration `server`, which is the default TLS configuration for ServerTLSConfig. To [create](#) a custom TLS configuration, see [TLS configurations](#).

1. [Generate](#) or import the following according to your use case:
 - **Server Mode**: server certificate private key, server certificate
 - **Mutual Mode**: server certificate private key, server certificate, CA certificate(s)
2. Run the following commands according to your desired configuration. New connections will use TLS.
 - To use **Server Mode**, set the server certificate for the server's TLS Configuration:

```
=> ALTER TLS CONFIGURATION server CERTIFICATE server_cert;
```

- To use **Mutual Mode**, set a server and CA certificate. This CA certificate is used to verify client certificates:

```
=> ALTER TLS CONFIGURATION server CERTIFICATE server_cert ADD CA CERTIFICATES ca_cert;
```

To use multiple CA certificates, separate them with commas:

```
=> ALTER TLS CONFIGURATION server CERTIFICATE server_cert
ADD CA CERTIFICATES intermediate_ca_cert, ca_cert;
```

3. Enable TLS (disabled by default). Choose one of the following TLSMODEs, listed in ascending security.

- **DISABLE** : Disables TLS. All other options for this parameter enable TLS.
- **ENABLE** : Enables TLS. Vertica does not verify client certificates.
- **TRY_VERIFY** : Establishes a TLS connection if one of the following is true:
 - The client presents a valid certificate.
 - The client doesn't present a certificateIf the client presents an invalid certificate, the connection is rejected.
- **VERIFY_CA** : Connection succeeds if Vertica verifies that the client certificate is from a trusted CA. If the client does not present a client certificate, the connection is rejected.

TLS Configurations also support the TLSMODE **VERIFY_FULL** , but this TLSMODE is unsupported for client-server TLS (the connection type handled by ServerTLSConfig) and behaves like **VERIFY_CA** .

For **Server Mode** , choose **ENABLE** :

```
=> ALTER TLS CONFIGURATION server TLSMODE 'ENABLE';
```

For **Mutual Mode** , choose **TRY_VERIFY** or higher:

```
=> ALTER TLS CONFIGURATION server TLSMODE 'VERIFY_CA';
```

4. Verify that the ServerTLSConfig parameter is set to the **server** TLS Configuration:

```
=> SHOW CURRENT ServerTLSConfig;
 level | name      | setting
-----+-----+-----
DEFAULT | ServerTLSConfig | server
(1 row)
```

If not, set the ServerTLSConfig parameter:

```
=> ALTER DATABASE DEFAULT SET ServerTLSConfig = 'server';
```

See also

- [Internode TLS](#)
- [SECURITY_CONFIG_CHECK](#)

Managing CA bundles

Certificate authority (CA) bundles allow you to group [CA certificates](#) together and use them to validate connections to your database.

You can view existing CA bundles by querying the [CA_BUNDLES](#) system table.

Creating a CA bundle

To create a CA bundle, use [CREATE CA BUNDLE](#) and specify one or more CA certificates. If you don't specify a CA certificate, the CA bundle will be empty.

This example creates a CA bundle called `ca_bundle` that contains CA certificates `root_ca` and `root_ca2`:

```
=> CREATE CA BUNDLE ca_bundle CERTIFICATES root_ca, root_ca2;
CREATE CA BUNDLE

=> SELECT * FROM ca_bundles WHERE name='ca_bundle';
  oid      | name      | owner      | certificates
-----+-----+-----+-----
45035996274026954 | ca_bundle | 45035996273704962 | [45035996274026764, 45035996274026766]
(1 row)
```

Modifying existing CA bundles

`CA_BUNDLES` only stores OIDs. Since operations on CA bundles require certificate and owner names, you can use the following query to map bundles to certificate and owner names:

```
=> SELECT user_name AS owner_name,
       owner AS owner_oid,
       b.name AS bundle_name,
       c.name AS cert_name
FROM (SELECT name,
      STRING_TO_ARRAY(certificates) :: array[INT] AS certs
FROM ca_bundles) b
LEFT JOIN certificates c
      ON CONTAINS(b.certs, c.oid)
LEFT JOIN users
      ON user_id = owner
ORDER BY 1;
```

owner_name	owner_oid	bundle_name	cert_name
dbadmin	45035996273704962	ca_bundle	root_ca
dbadmin	45035996273704962	ca_bundle	ca_cert

(2 rows)

Adding and removing CA certificates

If you have ownership of a CA bundle, you can add and remove certificates with [ALTER CA BUNDLE](#).

This example modifies ca_bundle by adding ca_cert and removing root_ca2:

```
=> ALTER CA BUNDLE ca_bundle ADD CERTIFICATES ca_cert;
ALTER CA BUNDLE
```

```
=> SELECT * FROM ca_bundles WHERE name='ca_bundle';
```

oid	name	owner	certificates
45035996274027356	ca_bundle	45035996273704962	[45035996274027342, 45035996274027348, 45035996274027396]

(1 row)

```
=> ALTER CA BUNDLE ca_bundle REMOVE CERTIFICATES root_ca2;
ALTER CA BUNDLE
```

```
=> SELECT * FROM CA_BUNDLES;
```

oid	name	owner	certificates
45035996274027356	ca_bundle	45035996273704962	[45035996274027342, 45035996274027396]

(1 row)

Managing CA bundle ownership

Superusers and CA bundle owners can see whether a bundle exists by querying the CA_BUNDLES system table, but only owners of a given bundle can see the certificates inside.

In the following example, the dbadmin user owns ca_bundle. After giving ownership of the bundle to 'Alice', the dbadmin can no longer see the certificates inside the bundle:

```
=> => SELECT * FROM ca_bundles WHERE name='ca_bundle';
  oid      | name      | owner      | certificates
-----+-----+-----+-----
45035996274027356 | ca_bundle | 45035996273704962 | [45035996274027342, 45035996274027396]
(1 row)

=> ALTER CA BUNDLE ca_bundle OWNER TO Alice;
ALTER CA BUNDLE

=> SELECT * FROM ca_bundles WHERE name='ca_bundle';
  oid      | name      | owner      | certificates
-----+-----+-----+-----
45035996274027356 | ca_bundle | 45035996274027586 | []
(1 row)
```

Dropping CA bundles

You must have ownership of a CA bundle to [drop](#) it:

```
=> DROP CA BUNDLE ca_bundle;
DROP CA BUNDLE
```

Generating certificates and keys for MC

A *certificate signing request (CSR)* is a block of encrypted text generated on the server on which the certificate is used. You send the CSR to a certificate authority (CA) to apply for a digital identity certificate. The CA uses the CSR to create your SSL certificate from information in your certificate; for example, organization name, common (domain) name, city, and country.

Management Console (MC) uses a combination of OAuth (Open Authorization), Secure Socket Layer (SSL), and locally-encrypted passwords to secure HTTPS requests between a user's browser and MC, and between MC and the [agents](#). Authentication occurs through MC and between agents within the cluster. Agents also authenticate and authorize jobs.

The MC configuration process sets up SSL automatically, but you must have the openssl package installed on your Linux environment first.

When you [connect to MC](#) through a client browser, Vertica assigns each HTTPS request a self-signed certificate, which includes a timestamp. To increase security and protect against password replay attacks, the timestamp is valid for several seconds only, after which it expires.

To avoid being blocked out of MC, synchronize time on the hosts in your Vertica cluster, and on the MC host if it resides on a dedicated server. To recover from loss or lack of synchronization, resync system time and the Network Time Protocol.

Create a certificate and submit it for signing

For production, you must use certificates signed by a certificate authority. You can create and submit a certificate and when the certificate returns from the CA, [import the certificate into MC](#).

Use the openssl command to generate a new CSR, entering the passphrase "password" when prompted:

```
$ sudo openssl req -new -key /opt/vconsole/config/keystore.key -out server.csr
Enter pass phrase for /opt/vconsole/config/keystore.key:
```

When you press **Enter**, you are prompted to enter information to be incorporated into your certificate request. Some fields contain a default value, which you should change for security reasons. Other fields you can leave blank, such as password and optional company name. To leave the field blank, type `.'.`

Important

The keystore.key value for the -key option creates private key for the keystore. If you generate a new key and import it using the Management Console interface, the MC process does restart properly. You must restore the original keystore.jks file and [restart Management Console](#).

This information is contained in the CSR and shows both the default and replacement values:

```
Country Name (2 letter code) [GB]:USState or Province Name (full name) [Berkshire]:Massachusetts
Locality Name (eg, city) [Newbury]: Cambridge
Organization Name (eg, company) [My Company Ltd]:Vertica
Organizational Unit Name (eg, section) []:Information Management
Common Name (eg, your name or your server's hostname) []:console.vertica.com
Email Address []:mcaadmin@vertica.com
```

The **Common Name** field is the fully qualified domain name of your server. Your entry must exactly match what you type in your web browser, or you receive a name mismatch error.

Self-sign a certificate for testing

To test your new SSL implementation, you can self-sign a CSR using either a temporary certificate or your own internal CA, if one is available.

Note

A self-signed certificate generates a browser-based error notifying you that the signing certificate authority is unknown and not trusted. For testing purposes, accept the risks and continue.

The following command generates a temporary certificate, which expires after 365 days:

```
$ sudo openssl x509 -req -days 365 -in server.csr -signkey /opt/vconsole/config/keystore.key -out server.crt
Enter passphrase for /opt/vconsole/config/keystore.key:
Enter same passphrase again:
```

The previous example prompts you for a passphrase. This is required for Apache to start. To implement a passphrase you must put the `SSLPassPhraseDialog` directive in the appropriate Apache configuration file. For more information see your Apache documentation.

This example shows the command's output to the terminal window:

```
Signature oksubject=/C=US/ST=Massachusetts/L=Cambridge/O=Vertica/OU=IT/
CN=console.vertica.com/emailAddress=mcadmin@vertica.com
Getting Private key
```

You can now [import the self-signed key](#), `server.crt`, into Management Console.

See also

- [Configuring TLS for JDBC clients](#)
- [Configuring TLS for ODBC Clients](#)
- [Key and Certificate Management Tool](#)

Importing a new certificate to MC

Use this procedure to import a new certificate into Management Console.

Note

To generate a new certificate for Management Console, you must use the `keystore.key` file, which is located in `/opt/vconsole/config` on the server on which you installed MC. Any other generated key/certificate pair causes MC to restart incorrectly. You will then have to restore the original `keystore.jks` file and [restart Management Console](#). See [Generating Certifications and Keys for Management Console](#).

1. [Connect to Management Console](#), and log in as an administrator.
2. On the Home page, click MC **Settings**.
3. In the button panel on the left, click **SSL certificates**.
4. To the right of "Upload a new SSL certificate," click **Browse** to import the new key.
5. Click **Apply**.
6. [Restart Management Console](#).

Replacing the agent certificate

The [Agent](#) uses a preinstalled Certificate Authority (CA) certificate. You can replace it copying the your preferred certificate and its private key to the host.

To view your current agent certificate:

```
$ openssl s_client -prexit -connect database_IP:database_port
```

Generating a certificate

If you don't already have one, you can generate a self-signed certificate. For more information, see [Generating TLS certificates and keys](#)

1. Generate the private key and certificate.

```
$ openssl req -new -newkey rsa:4096 -x509 -sha256 -days 365 -nodes -out agent.cert -keyout agent.key
```

You are about to be asked to enter information that will be incorporated into your certificate request.

What you are about to enter is what is called a Distinguished Name or a DN.

There are quite a few fields but you can leave some blank

For some fields there will be a default value,

If you enter '.', the field will be left blank.

Country Name (2 letter code) [AU]:*US*

State or Province Name (full name) [Some-State]:*MA*

Locality Name (eg, city) []:*Cambridge*

Organization Name (eg, company) [Internet Widgits Pty Ltd]:*My Company*

Organizational Unit Name (eg, section) []:*IT*

Common Name (e.g. server FQDN or YOUR name) []:**.mycompany.com*

Email Address []:*myaddress@mycompany.com*

2. Make a copy of the certificate in PEM format.

```
$ openssl x509 -in agent.cert -out agent.pem -outform PEM
```

3. Review the certificate.

```
$ openssl x509 -in agent.pem -text
```

Replacing the agent certificate on a host

The following procedure replaces the Agent's current private key and certificate on a single host. To replace this certificate and key across an entire cluster, repeat this procedure for all the hosts.

1. Stop the Agent service on the host.

```
$/etc/init.d/vertica_agent stop
```

2. Backup and rename the existing agent certificate and key.

```
$ cd /opt/vertica/config/share
$ mv agent.cert agent.cert.bck
$ mv agent.key agent.key.bck
$ mv agent.pem agent.pem.bck
```

3. Transfer the new certificate and key to the host's `/opt/vertica/config/share` directory.

```
$ scp agent.* root@123.12.12.123:/opt/vertica/config/share
```

4. Change the owner of the certificate and key to `uidbadadmin` and the group to `verticadbda`.

```
$ chown installed_Vertica_user:installed_Vertica_group agent.*
```

5. Make the certificate and key files read-only.

```
$ chmod -R 400 agent.*
```

6. Start the Agent service.

```
$/etc/init.d/vertica_agent start
starting agent
Opening PID file "/opt/vertica/log/agent.pid".
Overwriting /opt/vertica/log/agent_uidbadadmin.log
Overwriting /opt/vertica/log/agent_uidbadadmin.err
start OK for user: uidbadadmin
```

7. Verify that you can view information about your database with your API key.

```
$ curl -X GET https://10.20.80.145:5444/databases -H "VerticaApiKey:wCgXny3Wm+8OhEvGkAcLv7v9+VllXgXblpr4rf" -k
```

8. Verify that the Agent is using the new certificate.

```
$ openssl s_client -prexit -connect 10.20.80.145:5444
```

Importing and exporting data with TLS

Vertica uses TLS to secure connections and communications between clients and servers. When you import or export data between Vertica clusters, one of the clusters functions as a client, which means you can use TLS to protect that connection, too.

The `ImportExportTLSMode` parameter controls the strictness of TLS when importing or exporting data.

By default, `ImportExportTLSMode` is set to `PREFER`. With this setting, Vertica attempts to use TLS and falls back to plaintext; you can change this to always require encryption and, further, to validate the certificate on each connection. For more information about TLS during import and export operations, see [Configuring connection security between clusters](#).

LDAP link service

LDAP Link enables synchronization between the LDAP and Vertica servers. This eliminates the need for you to manage two sets of users and groups or roles, one on the LDAP server and another on the Vertica server. With LDAP synchronization, the Vertica server becomes a replication database for the LDAP server.

Note

Users created by the LDAP Link service are compatible with native Vertica roles and do not require LDAP roles for functions like [column access policies](#).

Automatic synchronization

With LDAP Link the Vertica server closely integrates with an existing directory service such as MS Active Directory or OpenLDAP. The Vertica server automatically synchronizes:

- LDAP users to Vertica users
- LDAP groups to Vertica roles

You manage all user and group properties in the LDAP server. If you are the Vertica database administrator, you need only to set up permissions for Vertica Analytic Database access on the users and groups.

Configure LDAP Link with LDAP Link connection parameters that reside in the catalog. See [General and Connection Parameters](#) for more information.

Configure LDAP link with dry runs

The LDAP Link dry run meta-functions allow you to configure the service in discrete stages before making any changes to your database. These stages are:

1. [LDAP Link Bind](#): Establishing a connection between the LDAP server and the Vertica database
2. [LDAP Link Search](#): Searching the LDAP server for users and groups
3. [LDAP Link Sync](#): Mapping LDAP users and groups to their equivalents in Vertica

Query the system table [LDAP_LINK_DRYRUN_EVENTS](#) to view the results of each dry run.

For more information on dry runs and configuring LDAP Link, see [Configuring LDAP link with dry runs](#).

Enable LDAP link

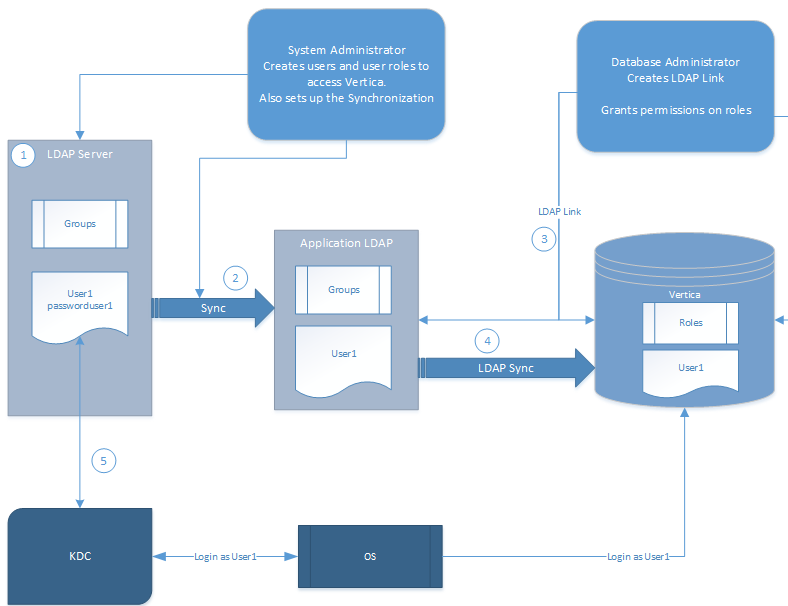

Enable LDAP Link as shown:

```
=> ALTER DATABASE dbname SET PARAMETER LDAPLinkURL='ldap://example.dc.com',
  LDAPLinkSearchBase='dc=DC,dc=com', LDAPLinkBindDN='CN=jsmith,OU=QA,DC=dc,DC=com,
  LDAPLinkBindPswd='password',LDAPLinkFilterUser='(objectClass=inetOrgPerson)', LDAPLinkFilterGroup='(objectClass=group)', LDAPLinkOn=1;
=> SELECT ldap_link_sync_start();
```

See [LDAP link parameters](#).

LDAP link workflow

After you enable LDAP Link, synchronization occurs according to this workflow:

1. The System Administrator creates users and user groups on the LDAP server.
2. The System Administrator sets up LDAP Link service parameters as required and enables the service.
3. Using the LDAP Link service, Vertica Analytic Database replicates the users and user groups from the Application LDAP to the Vertica database, creating Vertica users and roles.
4. The LDAP server uses Kerberos (KDC) to authenticate the user logging in to Vertica.
 - The LDAP user can log in to Vertica if assigned the appropriate authentication type.
 - After logging in, you can grant users privileges using GRANT statements or as part of a Group.

Note

After synchronization, the Vertica user does not have an associated authentication method. To allow the user to log in, you must assign an authentication method to the user. See [Configuring client authentication](#).

In this section

- [Configuring LDAP link with dry runs](#)
- [Using LDAP link](#)
- [LDAP link parameters](#)
- [TLS for LDAP link](#)
- [Troubleshooting LDAP link issues](#)

Configuring LDAP link with dry runs

Vertica supports several meta-functions that let you tweak LDAP Link settings before syncing with Vertica. Each meta-function takes [LDAP Link parameters](#) as arguments and tests a separate part of LDAP Link:

- [LDAP_LINK_DRYRUN_CONNECT](#) connects to the LDAP server.
- [LDAP_LINK_DRYRUN_SEARCH](#) searches for LDAP users and groups.
- [LDAP_LINK_DRYRUN_SYNC](#) maps and synchronizes LDAP users and groups to their equivalents in Vertica, creating and orphaning them accordingly.

These meta-functions should be used and tested in succession, and their arguments are cumulative. That is, the parameters you use to configure [LDAP_LINK_DRYRUN_CONNECT](#) are used for [LDAP_LINK_DRYRUN_SEARCH](#), and the arguments for those functions are used for [LDAP_LINK_DRYRUN_SYNC](#).

The dryrun and [LDAP_LINK_SYNC_START](#) functions must be run from the clerk node. To determine the clerk node, query [NODE_RESOURCES](#) :

```

-> SELECT node_name, dbclerk FROM node_resources WHERE dbclerk='T';
 node_name | dbclerk
-----+-----
 v_vmart_node0001 | t
(1 row)

```

Be sure to query the [LDAP_LINK_DRYRUN_EVENTS](#) system table to verify the results of each dry run before moving to the next meta-function.

Configuring TLS for dry runs

Like the standard LDAP Link functions, LDAP Link dry-run functions pull from the 'LDAPLink' TLS Configuration for managing TLS connections. Query the [TLS_CONFIGURATIONS](#) system table to view existing TLS Configurations.

```
=> SELECT * FROM tls_configurations WHERE name='LDAPLink';
 name | owner | certificate | ca_certificate | cipher_suites | mode
-----+-----+-----+-----+-----+-----
LDAPLink | dbadmin | client_cert | ldap_ca      |              | DISABLE
(1 row)
```

For instructions on configuring TLS for LDAP Link and its dry run functions, see [TLS for LDAP link](#).

Configuring LDAP link bind

Before configuring LDAP users and importing them to Vertica, you must first connect or "bind," with the LDAP server. Connections are managed with several parameters. For more information on each parameter, related functions, options, and default values, see [LDAP link parameters](#).

LDAP_LINK_DRYRUN_CONNECT requires a Distinguished Name (DN), a password to authenticate with the LDAP server, and the URL to the LDAP server.

To encrypt the connection, [configure the LDAPLink TLS Configuration](#).

By providing an empty string for the [LDAPLinkBindPswd](#) argument, you can also perform an [anonymous bind](#) if your LDAP server allows unauthenticated binds.

```
=> SELECT LDAP_LINK_DRYRUN_CONNECT('LDAPLinkURL','LDAPLinkBindDN','LDAPLinkBindPswd');
```

Dry run bind example

This tests the connection to an LDAP server at [ldap://example.dc.com](#) with the DN [CN=amir,OU=QA,DC=dc,DC=com](#).

```
=> SELECT LDAP_LINK_DRYRUN_CONNECT('ldap://example.dc.com','CN=amir,OU=QA,DC=dc,DC=com','password');
```

```
ldap_link_dryrun_connect
```

Dry Run Connect Completed. Query `v_monitor.ldap_link_dryrun_events` for results.

To check the results of the bind, query the system table `LDAP_LINK_DRYRUN_EVENTS`.

```
=> SELECT event_timestamp, event_type, entry_name, role_name, link_scope, search_base from LDAP_LINK_DRYRUN_EVENTS;
```

event_timestamp	event_type	entry_name	link_scope	search_base
2019-12-09 15:41:43.589398-05	BIND_STARTED			
2019-12-09 15:41:43.590504-05	BIND_FINISHED			

Configuring LDAP link search

After a successful connection between Vertica and the LDAP server, you should configure and test your user and group search space for correctness and efficiency.

To search for users and groups on the LDAP server to import to your database, pass both the connection and search parameters to the `LDAP_LINK_DRYRUN_SEARCH` meta-function. The LDAP server responds with a list of users and groups that would be imported into Vertica with the given parameters.

By providing an empty string for the [LDAPLinkBindPswd](#) argument, you can also perform an [anonymous search](#) if your LDAP server's Access Control List (ACL) is configured to allow unauthenticated searches. The settings for allowing anonymous binds are different from the ACL settings for allowing anonymous searches.

```
=> SELECT LDAP_LINK_DRYRUN_SEARCH('LDAPLinkURL','LDAPLinkBindDN','LDAPLinkBindPswd','LDAPLinkSearchBase',
'LDAPLinkScope','LDAPLinkFilterUser','LDAPLinkFilterGroup','LDAPLinkUserName','LDAPLinkGroupName',
'LDAPLinkGroupMembers',[LDAPLinkSearchTimeout],[LDAPLinkJoinAttr]);
```

Dry run search example

This searches for users and groups in the LDAP server. In this case, the [LDAPLinkSearchBase](#) parameter specifies the [dc.com](#) domain and a sub scope, which replicates the entire subtree under the DN.

To further filter results, the function checks for users and groups with the [person](#) and [group](#) objectClass attributes. It then searches the group attribute [cn](#), identifying members of that group with the [member](#) attribute, and then identifying those individual users with the attribute [uid](#).

```
=> SELECT LDAP_LINK_DRYRUN_SEARCH('ldap://example.dc.com','CN=amir,OU=QA,DC=dc,DC=com','$vertica$','dc=DC,dc=com','sub',
(objectClass=person),(objectClass=group),'uid','cn','member',10,'dn');
```

ldap_link_dryrun_search

Dry Run Search Completed. Query v_monitor.ldap_link_dryrun_events for results.

To check the results of the search, query the system table LDAP_LINK_DRYRUN_EVENTS.

```
=> SELECT event_timestamp, event_type, entry_name, ldapurihash, link_scope, search_base from LDAP_LINK_DRYRUN_EVENTS;
```

event_timestamp	event_type	entry_name	ldapurihash	link_scope	search_base
2020-01-03 21:03:26.411753+05:30	BIND_STARTED			0 sub	dc=DC,dc=com
2020-01-03 21:03:26.422188+05:30	BIND_FINISHED			0 sub	dc=DC,dc=com
2020-01-03 21:03:26.422223+05:30	SYNC_STARTED			0 sub	dc=DC,dc=com
2020-01-03 21:03:26.422229+05:30	SEARCH_STARTED	*****		0 sub	dc=DC,dc=com
2020-01-03 21:03:32.043107+05:30	LDAP_GROUP_FOUND	Account Operators		0 sub	dc=DC,dc=com
2020-01-03 21:03:32.04312+05:30	LDAP_GROUP_FOUND	Administrators		0 sub	dc=DC,dc=com
2020-01-03 21:03:32.043182+05:30	LDAP_USER_FOUND	user1		0 sub	dc=DC,dc=com
2020-01-03 21:03:32.043186+05:30	LDAP_USER_FOUND	user2		0 sub	dc=DC,dc=com
2020-01-03 21:03:32.04319+05:30	SEARCH_FINISHED	*****		0 sub	dc=DC,dc=com

Configuring LDAP link sync

After configuring the search space, you'll have a list of users and groups. LDAP sync maps LDAP users and groups to their equivalents in Vertica. The [LDAPLinkUserName](#) maps to the Vertica usernames and the [LDAPLinkGroupName](#) maps to Vertica roles.

```
=> SELECT LDAP_LINK_DRYRUN_SYNC('LDAPLinkURL','LDAPLinkBindDN','LDAPLinkBindPswd','LDAPLinkSearchBase',
'LDAPLinkScope','LDAPLinkFilterUser','LDAPLinkFilterGroup','LDAPLinkUserName','LDAPLinkGroupName',
'LDAPLinkGroupMembers',['LDAPLinkSearchTimeout'],['LDAPLinkJoinAttr']);
```

Dry run sync example

To perform a dry run to map the users and groups returned from LDAP_LINK_DRYRUN_SEARCH, pass the same parameters as arguments to LDAP_LINK_DRYRUN_SYNC.

```
=> SELECT LDAP_LINK_DRYRUN_SYNC('ldap://example.dc.com','CN=amir,OU=QA,DC=dc,DC=com','$vertica$','dc=DC,dc=com','sub',
(objectClass=person),(objectClass=group),'uid','cn','member',10,'dn');
```

LDAP_LINK_DRYRUN_SYNC

Dry Run Connect and Sync Completed. Query v_monitor.ldap_link_dryrun_events for results.

To check the results of the sync, query the system table LDAP_LINK_DRYRUN_EVENTS.

```
=> SELECT event_timestamp, event_type, entry_name, ldapurihash, link_scope, search_base from LDAP_LINK_DRYRUN_EVENTS;
```

event_timestamp	event_type	entry_name	ldapurihash	link_scope	search_base

Using LDAP link

When you use LDAP Link, the following are directly affected and help you manage and monitor the LDAP Link - Vertica Analytic Database synchronization:

- User and Group management
- LDAP Link User Flag
- Blocked Commands
- Client Authentication types

To cancel an in-progress synchronization, use [LDAP_LINK_SYNC_CANCEL](#).

User and group management

Users and groups created on the LDAP server have a specific relationship with those users and roles replicated to the Vertica server:

- The user-group relationship on the LDAP server is maintained when those users and groups (roles) are synchronized with Vertica Analytic Database.
- If a user or group name exists on the Vertica database and a user or group with the same names is synchronized from the LDAP Server using LDAP Link, the users or groups become conflicted. Vertica cannot support multiple users with the same name. To resolve this, see [User Conflicts](#).
- If the LDAP server contains a circular relationship, Vertica accepts and creates roles for the first non-circular part of the relationship returned by the LDAP server and ignores the rest.

For example, suppose the LDAP server contains groups **A** and **B**, where **A** contains **B**, and **B** contains **A**, creating a circular relationship.

If the LDAP server first returns that **A** contains **B**, Vertica creates roles **A** and **B**, and grants role **A** to role **B**. Vertica then ignores the fact that group **B** also contains **A**.

LDAP Link uses the entries in the dn: section of the LDAP configuration file as the unique user identifier when synchronizing a user to the Vertica Analytic Database:

```
dn: cn=user1,ou=dev,dc=example,dc=com
cn: user1
ou: dev
id: user1
```

The uid parameter in the LDAP configuration file indicates the LDAP user name.

```
uid: user1
```

Upon synchronization, the dn: entry gets mapped to the uid: to identify the Vertica Analytic Database user.

If you change a setting in the **dn:** and do not change the **uid:**, LDAP Link interprets the user as a new user when re-synchronizing with the Vertica Analytic Database. In this case, the existing Vertica Analytic Database user with that uid: gets deleted from Vertica and a new Vertica Analytic Database user is created.

If you change the uid: and not the dn: on LDAP, the uid on the Vertica Analytic Database gets updated to the new uid. Since you did not change the dn: LDAP Link does not interpret the user as a new user.

LDAP link user flag

As a dbadmin user, you can access the vs_users table to monitor user behavior on the Vertica Analytic Database. The users table contains an **ldap_dn** field that identifies whether or not the Vertica Analytic Database user is also an LDAP Link user. This example shows the **ldap_dn** field set to **dn** indicating the Vertica Analytic Database user is also an LDAP Link user:

```

=> SELECT * FROM vs_users;
-[ RECORD 1 ]-----+-----
user_id      | 45035996273704962
user_name    | dbadmin
is_superuser | t
profile_name | default
is_locked    | f
lock_time    |
resource_pool | general
memory_cap_kb | unlimited
temp_space_cap_kb | unlimited
run_time_cap | unlimited
max_connections | unlimited
connection_limit_mode | database
idle_session_timeout | unlimited
all_roles    | dbduser*, dbadmin*, pseudosuperuser*
default_roles | dbduser*, dbadmin*, pseudosuperuser*
search_path  |
ldap_dn      | dn
ldap_uri_hash | 0
is_orphaned_from_ldap | f

```

Blocked commands

Be aware that the following SQL statements are blocked for Vertica users with ldapdn set to dn in the vs_users table:

- [DROP USER](#) and [DROP ROLE](#)
- [ALTER ROLE RENAME](#)
- [ALTER USER](#) name IDENTIFIED BY 'password' [REPLACE 'old_password']
- [ALTER USER](#) name PASSWORD EXPIRE
- [ALTER USER](#) name PROFILE
- [ALTER USER](#) name SECURITY_ALGORITHM...
- [ALTER USER](#) name DEFAULT ROLE role-name
- [GRANT \(Role\)](#)

Client authentication types

LDAP user and groups cannot log in to Vertica if client authentication is not assigned to the user or group. You can use the following valid [authentication types](#) for LDAP users and groups:

- GSS
- Ident
- LDAP
- Reject
- Trust

LDAP link parameters

Use LDAP Link parameters to determine:

- LDAP Link operations, such as enabling or disabling LDAP Link and how often to perform replication
- Authentication parameters, including SSL authentication parameters
- Users and groups that inherit unowned objects
- How to resolve conflicts

To configure TLS for LDAP Link, see [TLS for LDAP link](#).

Set LDAP link parameters

This example shows how you can set:

- [LDAPLinkURL](#), the URL of the LDAP server.
- [LDAPLinkSearchBase](#), the base DN from which to start replication.

You also see how to set the LDAP Link Bind authentication parameters ([LDAPLinkBindDN](#) and [LDAPLinkBindPswd](#)) and enables LDAP Link ([LDAPLinkOn](#)).

```
=> ALTER DATABASE myDB1 SET PARAMETER LDAPLinkURL='ldap://10.60.55.128',
LDAPLinkSearchBase='dc=corp,dc=com',LDAPLinkBindDN='dc=corp,dc=com',LDAPLinkBindPswd='password';

=> ALTER DATABASE myDB1 SET PARAMETER LDAPLinkOn = '1';
```

General and connection parameters

Parameter	Description
LDAPLinkOn	<p>Enables or disables LDAP Link.</p> <p>Valid Values:</p> <p>0 —LDAP Link disabled</p> <p>1 —LDAP Link enabled</p> <p>Default: 0</p>
LDAPLinkURL	<p>The LDAP server URL.</p> <p>To use a plaintext connection between Vertica and the LDAP server, begin the LDAPLinkURL with ldap:// and set the TLSMODE of LDAPLink to DISABLE .</p> <p>To use StartTLS, begin the LDAPLinkURL with ldap:// and set the TLSMODE of LDAPLink to ENABLE or higher.</p> <p>To use LDAPS, begin the LDAPLinkURL with ldaps:// and set the TLSMODE of LDAPLink to ENABLE or higher.</p> <p>Example:</p> <pre>=> SET PARAMETER LDAPLinkURL='ldap://example.dc.com';</pre>
LDAPLinkCron	<p>A cron expression, the exact time at which the LDAP and Vertica servers should synchronize. Unlike LDAPLinkInterval , the runtime of the synchronization does not affect the next scheduled synchronization. Setting this parameter overrides LDAPLinkInterval .</p> <p>New synchronizations are only scheduled after the current one ends. This means that if a synchronization runs for long enough to reach the start of what would be the "next" synchronization according to the cron expression, that "next" synchronization will not run, and in fact will not be scheduled until after the current one finishes.</p> <p>Default: None (empty).</p>
LDAPLinkInterval	<p>The time interval, in seconds, by which the LDAP and Vertica servers should synchronize. The interval is calculated based on the completion time of the previous synchronization operation, not its start time. This means that with an interval of 86400 seconds (one day), if the previous synchronization started at 9:00 and ended at 9:30, then the next synchronization would start at 9:30 the next day.</p> <p>To use this scheduling method, LDAPLinkCron must not be set (default).</p> <p>Default: 86400 (one day).</p>
LDAPLinkFirstInterval	<p>The first interval, in seconds, for LDAP/Vertica synchronization after the clerk node joins the cluster.</p> <p>Default: 120</p>
LDAPLinkRetryInterval	<p>The time, in seconds, the system waits to retry a failed synchronization.</p> <p>Default: 10</p>

LDAPLinkRetryNumber	<p>The number of retry attempts if synchronization failed.</p> <p>Default: 10.</p>
LDAPLinkSearchBase	<p>The base dn from where to start replication.</p> <p>Example:</p> <p>=> SET PARAMETER LDAPLinkSearchBase='ou=vertica,dc=mycompany,dc=com';</p> <p>Vertica recommends using a separate OU for database users.</p>
LDAPLinkSearchTimeout	<p>The timeout length, in seconds, for the LDAP search operation during an LDAP Link Service run.</p> <p>Default: 10</p>
LDAPLinkScope	<p>Indicates what dn level to replicate.</p> <p>Valid Values:</p> <ul style="list-style-type: none"> • sub —Replicate entire subtree under baseDN • one —Replicate to one level under baseDN • base —Replicate only the baseDN level <p>If you decrease the scope (for example, sub to one), some users may not be recognized during the next synchronization.</p> <p>Default: sub</p>
LDAPLinkFilterUser	<p>Determines how to filter users to be replicated.</p> <p>Default: "(objectClass=inetOrgPerson)"</p>
LDAPLinkFilterGroup	<p>Determines how to filter groups to be replicated.</p> <p>Default: "(objectClass=groupofnames)"</p>
LDAPLinkGroupName	<p>[Optional] The LDAP field to use when creating a role name in Vertica.</p> <p>Default: cn</p>
LDAPLinkGroupMembers	<p>The LDAP group that identifies the members of an LDAP group. This attribute returns a Fully Qualified Domain Name (FQDN).</p> <p>Default: member</p>
LDAPLinkUserName	<p>The LDAP field to use when creating a user name in Vertica.</p> <p>Default: uid</p>

<p>LDAPLinkJoinAttr</p>	<p>Specifies the attribute on which you want to join to assign users to their roles.</p> <p>Default: <code>dn</code></p> <p>Example:</p> <p>POSIX groups associate users and groups with the <code>uid</code> attribute instead of <code>dn</code> .</p> <p>=> <code>SET PARAMETER LDAPLinkJoinAttr='uid';</code></p>
<p>LDAPLinkAddRolesAsDefault</p>	<p>Specifies whether the users synchronized through LDAP Link should have their groups set as default roles. If <code>LDAPLinkAddRolesAsDefault</code> is disabled (default), then the users are granted their groups as non- default roles, which must be manually enabled with SET ROLE .</p> <p>Default: <code>0</code> (disabled)</p> <p>Example:</p> <p>To enable:</p> <p>=> <code>ALTER DATABASE DEFAULT SET LDAPLinkAddRolesAsDefault = 1;</code></p> <p>To disable:</p> <p>=> <code>ALTER DATABASE DEFAULT SET LDAPLinkAddRolesAsDefault = 0;</code></p>

Authentication parameters

Parameter	Description
<p>LDAPLinkBindDN</p>	<p>The LDAP Bind DN used for authentication.</p> <p>Example:</p> <p>=> <code>SET PARAMETER LDAPLinkBindDN='CN=amir,OU=QA,DC=dc,DC=com';</code></p>
<p>LDAPLinkBindPswd</p>	<p>The valid password for the LDAP Bind DN to access the server. Only accessible by the dbadmin user.</p> <p>Example:</p> <p>=> <code>SET PARAMETER LDAPLinkBindPswd='password';</code></p>

Miscellaneous parameters

Parameter	Description
<p>LDAPLinkConflictPolicy</p>	<p>Determines how to resolve a user conflict.</p> <p>Valid Values:</p> <p>IGNORE—Ignores the incoming LDAP user and maintains the existing Vertica user.</p> <p>MERGE—Converts the existing user to an LDAP user.</p> <p>Default: MERGE</p>

LDAPLinkStopIfZeroUsers	<p>Enables or disables the shutdown of LDAPLink synchronization if no users are found in LDAP.</p> <p>Valid values:</p> <p>0 - Disables the LDAPLink synchronization shutdown if no users are found. This may lead to inadvertent dropping of Vertica users.</p> <p>1 - Enables the LDAPLink synchronization shutdown if no users are found. This prevents inadvertent dropping of Vertica users.</p>
LDAPLinkDryRun	<p>[Optional] Tests the connection to the LDAP server and logs the response without doing a synchronization. Also tests if parameters are correctly set.</p> <p>Note that this parameter is not the preferred dry run method. Instead, the LDAP_Link_Dryrun family of meta-functions provides more granular control over configurations and is the preferred way to perform LDAP Link dry runs.</p> <p>Valid Values:</p> <p>0 - Disables LDAPLinkDryRun</p> <p>1 - Enables LDAPLinkDryRun</p> <p>Default: 0</p>
LDAPLinkConfigFile	<p>[Optional] If this parameter is set with the path to a .LDIF file, the LDAP Link service will use the file as the source tree instead of connecting to the LDAP server.</p>

See [Configuration parameter management](#) for information on setting LDAP Link parameters.

Note

When you change any Connection or Authentication parameter, LDAP Link reconnects and re-initializes the synchronization.

TLS for LDAP link

Vertica establishes a connection to an LDAP server in two contexts, and each context has a corresponding TLS Configuration that controls if each connection should use TLS:

1. **LDAPLink** : using the LDAPLink service or its dry run functions to synchronize users and groups between Vertica and the LDAP server.
2. **LDAPAuth** : when a user with an [ldap](#) authentication method attempts to log into Vertica, Vertica attempts to bind the user to a matching user in the LDAP server. If the bind succeeds, Vertica allows the user to log in.

Query [TLS_CONFIGURATIONS](#) to view existing TLS Configurations:

```
=> SELECT * FROM tls_configurations WHERE name IN ('LDAPLink', 'LDAPAuth');
 name | owner | certificate | ca_certificate | cipher_suites | mode
-----+-----+-----+-----+-----+-----
LDAPLink | dbadmin | client_cert | ldap_ca      |              | VERIFY_CA
LDAPAuth | dbadmin | client_cert | ldap_ca      |              | DISABLE
(2 rows)
```

This page covers the LDAP Link service context. For details on the LDAP authentication context, see [TLS for LDAP authentication](#).

Configuring LDAP link TLS

Vertica uses the [LDAP Link service](#) to retrieve users and groups from the LDAP server and to create corresponding users and roles in the database. To configure TLS for LDAP Link and its [dry run functions](#), use the following procedure.

This procedure uses the predefined TLS Configuration **LDAPLink**. To [create](#) a custom TLS Configuration, see [TLS configurations](#).

For details on key and certificate generation, see [Generating TLS certificates and keys](#).

1. If you want Vertica to verify the LDAP server's certificate before establishing the connection, generate or import a CA certificate and add it to the LDAPLink TLS Configuration.

For example, to import the existing CA certificate `LDAP_CA.crt` :

```
=> \set ldap_ca "" cat ldap_ca.crt""
=> CREATE CA CERTIFICATE ldap_ca AS :ldap_ca;
CREATE CERTIFICATE
```

Then, to add the `ldap_ca` CA certificate to LDAPLink:

```
=> ALTER TLS CONFIGURATION LDAPLink ADD CA CERTIFICATES ldap_ca;
```

2. If your LDAP server verifies client certificates, you must generate or import a client certificate and its key and add it to the LDAPLink TLS Configuration. Vertica presents this certificate to the LDAP server for verification by its CA.

For example, to import the existing certificate `client.crt` (signed by the imported CA) and key `client.key` :

```
=> \set client_key "" cat client.key""
=> CREATE KEY client_key TYPE 'RSA' AS :client_key;
CREATE KEY

=> \set client_cert "" cat client.crt""
=> CREATE CERTIFICATE client_cert AS :client_cert SIGNED BY ldap_ca KEY client_key;
CREATE CERTIFICATE
```

Then, to add `client_cert` to LDAPLink:

```
=> ALTER TLS CONFIGURATION LDAPLink CERTIFICATE client_cert;
```

3. Enable TLS or LDAPS (the exact protocol used depends on the value of `host` in the AUTHENTICATION object) by setting the TLSMODE to one of the following. `TRY_VERIFY` or higher requires a CA certificate:

- **ENABLE** : Enables TLS. Vertica does not check the LDAP server's certificate.
- **TRY_VERIFY** : Establishes a TLS connection if one of the following is true:
 - The LDAP server presents a valid certificate.
 - The LDAP server doesn't present a certificate.If the LDAP server presents an invalid certificate, a plaintext connection is used.
- **VERIFY_CA** : Connection succeeds if Vertica verifies that the LDAP server's certificate is from a trusted CA. Using this TLSMODE forces all connections without a certificate to use plaintext.
- **VERIFY_FULL** : Connection succeeds if Vertica verifies that the LDAP server's certificate is from a trusted CA and the `cn` (Common Name) or `subjectAltName` attribute matches the hostname or IP address of the LDAP server.
The `cn` is used for the username, so `subjectAltName` must match the hostname or IP address of the LDAP server.

For example:

```
=> ALTER TLS CONFIGURATION LDAPLink TLSMODE 'verify_ca';
ALTER TLS CONFIGURATION
```

4. Verify that the LDAPLinkTLSConfig parameter is using the TLS Configuration:

```
=> SHOW CURRENT LDAPLinkTLSConfig;
 level | name | setting
-----+-----+-----
DEFAULT | LDAPLinkTLSConfig | LDAPLink
(1 row)
```

5. Set the [LDAP Link Parameters](#) according to your use case.

Troubleshooting LDAP link issues

Various issues can arise with LDAP Link service, including:

- Disconnected (Orphaned) users and roles
- Lost objects
- User conflicts

Disconnected (orphaned) users and roles

Vertica users and roles synchronized through LDAP Link can become disconnected, or orphaned, if an issue arises with the LDAP Link service. For example, users and roles become orphaned when you change the connection to the LDAP server as the following scenario describes:

1. Create an LDAP connection as follows:

```
=> ALTER DATABASE MyDB1 SET PARAMETER LDAPLinkURL='ldap://ebuser',
LDAPLinkSearchBase='dc=example,dc=com', LDAPLinkBindDN='mega',
LDAPLinkBindPswd='$megapassword$';
=> ALTER DATABASE MyDB1 SET PARAMETER LDAPLinkOn = '1';
```

2. Run an LDAP Link session to synchronize LDAP and Vertica users.
3. Change one or more connection parameters from Step 1. You can change the connection only if you change one of the LDAPLinkURL or LDAPLinkSearchBase parameters. Users will not be orphaned if the new and old LDAPLinkURL and LDAPLinkSearchBase contain the same set of users.
4. Run another LDAP Link session. The system attempts to re-synchronize LDAP and Vertica users. Because the connection has changed, the existing Vertica users cannot be synchronized with the LDAP users from the new connection. These Vertica users become orphaned.

As the dbadmin, you can identify orphaned users by checking the `is_orphaned_from_ldap` column in the [USERS](#) system table:

```
=> SELECT is_orphaned_from_ldap FROM users;
```

A field value of `t` indicates that the user is an orphaned user. Orphaned Vertica users cannot connect to the LDAP server and cannot login to Vertica using LDAP authentication (however, other authentication methods assigned to the user still work). In this case, you can delete the orphaned Vertica user and run the LDAP Link service to resynchronize users.

Re-parented objects

When you delete users or groups from the LDAP server, the LDAP Link service removes the same users and roles from Vertica, but does not delete objects owned by the deleted users and roles. To give these unowned objects a new owner, use the `GlobalHeirUsername` parameter, which specifies a user as the new parent for all objects originally owned by deleted users.

For example, to give ownership of unowned objects to `user1`, creating the user if it does not already exist:

```
=> ALTER DATABASE example_db SET PARAMETER GlobalHeirUsername=user1;
```

By default, this parameter is set to `<auto>` which re-parents objects to the `dbadmin` user.

If `GlobalHeirUsername` is empty, objects are not re-parented to another user.

For details, see [Security Parameters](#).

User conflicts

Vertica users and roles synchronized using LDAP Link can become conflicted. Such conflicts can occur, for example, when you create a new user or group on the LDAP server and another user or role with the same name exists on the Vertica.

As the dbadmin, use one of the following parameters to resolve user conflicts:

- `LDAPLinkConflictPolicy`
- `LDAPLinkStopIfZeroUsers`

LDAPLinkConflictPolicy

`LDAPLinkConflictPolicy` controls how Vertica behaves when it encounters a conflict. Changes to this parameter take effect during the next synchronization.

- `LDAPLinkConflictPolicy=IGNORE` ignores the incoming LDAP users and retains the existing Vertica user
- `LDAPLinkConflictPolicy=MERGE` (default) merges the incoming LDAP user with the Vertica user and converts the database user to an LDAP user, retaining the database user's objects.

For example, to set the parameter:

```
=> ALTER DATABASE example_db SET PARAMETER LDAPLinkConflictPolcy='MERGE';
```

LDAPLinkStopIfZeroUsers

`LDAPLinkStopIfZeroUsers` controls how Vertica behaves when the LDAP server has zero users during synchronization.

- `LDAPLinkStopIfZeroUsers=0` does not stop the synchronization if no users are found in the LDAP server and all Vertica users with are dropped.
- `LDAPLinkStopIfZeroUsers=1` stops the synchronization if no users are found in the LDAP server and returns an error. No Vertica users are dropped.

`LDAP_LINK_DRYRUN` and `LDAP_LINK_SYNC_START` do not populate tables

The `dryrun` and `LDAP_LINK_SYNC_START` functions must be run from the clerk node. To determine the clerk node, query [NODE_RESOURCES](#):

```
=> SELECT node_name, dbclerk FROM node_resources WHERE dbclerk='1';
 node_name | dbclerk
-----+-----
 v_vmart_node0001 | 1
(1 row)
```

Monitoring LDAP link

Use the ldap_link_events table to monitor LDAP Link synchronization:

```
=> SELECT transaction_id, event_type, entry_name, entry_oid FROM ldap_link_events;
 transaction_id | event_type | entry_name | entry_oid
-----+-----+-----+-----
45035996273705317 | SYNC_STARTED | | 0
45066962732553589 | SYNC_FINISHED | | 0
45066988112255317 | PROCESSING_STARTED | | 0
23411234566789765 | USER_CREATED | tuser | 234548899
(4 rows)
```

Connector framework service

The Connector Framework Service (CFS) allows secure indexing of documents from IDOL to the Vertica Analytic Database. Access control lists determine which users have permissions to access documents. Documents transferred from IDOL are stored in a flex table ([Flex tables](#)).

Important

Vertica 9.1.1 does not support the IdolLib function library. If you have the IdolLib function library installed and are upgrading to Vertica 9.1.1, you see an error and you cannot access the IdolLib function library.

To determine if the IdolLib library is installed, run the following script:

```
$ /opt/vertica/packages/idol/ddl/isinstalled.sql
```

To uninstall the IdolLib library, run the following script:

```
$ /opt/vertica/packages/idol/ddl/uninstall.sql
```

CFS components

Use the following CFS components to implement the service on the Vertica:

- IDOL document metadata
- CFS Configuration file

For detailed information, see [Implementing CFS](#).

IDOL document metadata

Vertica Analytic Database stores IDOL document metadata in a flex table. Set the name of the flex table with the TableName parameter in the CFS configuration file (see [Implementing CFS](#)). The metadata includes the following:

- AUTONOMYMETADATA (Mandatory): An alphanumeric designation for the ACL designated for the document.
- DREFIELD: Assigns permission levels to users and groups for accessing IDOL documents.
- DRETITLE: The document title.

CFS configuration file

You must index IDOL metadata in Vertica Analytic Database to be available for queries. See [Implementing CFS](#).

In this section

- [Implementing CFS](#)

Implementing CFS

After Vertica ingests documents from IDOL into flex tables, you can implement CFS to secure those documents. Implementing the security requires that the Vertica database administrator modify the CFS configuration file.

Modify the CFS configuration file

The database administrator must modify the following in the CFS configuration file to have CFS automatically index the metadata:

1. In the [Indexing] section, set the IndexerSections parameter to vertica:

```
[Indexing]
IndexerSections=vertica
IndexBathSize=1
IndexTimeInterval=30
```

2. Create a new section with the same name you entered in the IndexerSections parameter and enter the following parameters and keywords:

```
[vertica]
IndexerType=Library
ConnectionString=Driver=Vertica;Server=123.456.478.900;Databaswe=myDb;UID=dbadmin;PWD=password
TableName=myFlexTable
LibraryDirectory= ./shared_library_indexers
LibraryName=VerticalIndexer
```

The VerticalIndexer ([LibraryName](#) above) is part of CFS. To use this tool, you must install and configure the Vertica ODBC drivers on the same machine as CFS. CFS sends JSON-formatted data to the Flex table using ODBC.

For more information, see [Installing the ODBC client driver](#).

Query the IDOL data

To query the IDOL data in a flex table, run a simple SELECT query. In this example, idol_table is the name of the flex table:

```
=> SELECT * FROM idol_table;
```

Federal information processing standard

When running on a [FIPS-compliant operating system that Vertica supports](#), Vertica uses a certified OpenSSL FIPS 140-2 cryptographic module. This meets the security standards set by the National Institute of Standards and Technology (NIST) for Federal Agencies in the United States or other countries.

The standard specifies the security requirements that a cryptographic module needs in a system protecting sensitive information. For details on the standard see the [Computer Security Resource Center](#).

Note

Vertica itself is not FIPS compliant but it is compatible with running on a FIPS-enabled system using FIPS resources.

For a list of FIPS prerequisites, see [FIPS 140-2 supported platforms](#).

In this section

- [OpenSSL behavior](#)
- [FIPS-Enabled databases: limitations](#)
- [Implementing FIPS 140-2](#)
- [FIPS 140-2 compliance statement](#)

OpenSSL behavior

Dynamic OpenSSL linking is a requirement for a FIPS implementation on the client and server. The Vertica server uses the OpenSSL that resides on the host system (as indicated in [FIPS 140-2 supported platforms](#)). OpenSSL dynamically links with LDAP and Kerberos.

For more information see [Locate OpenSSL Libraries](#).

Libraries on CentOS systems

On a FIPS-compliant CentOS system, Vertica runs only with the OpenSSL libraries listed in [FIPS 140-2 supported platforms](#). Other versions of these libraries do not run on a FIPS system. This incompatibility occurs because the FIPS security policy checksums the library to which an application is linked and verifies that the library the application executes with the same checksum.

Library versioning on Non-FIPS systems

Be aware that on some non-FIPS systems, versioning anomalies can occur when you install a new version of OpenSSL. Sometimes, the default OpenSSL build procedure produces libraries with versions named 1.0.0. For Vertica to recognize that a library has a higher version number, you must provide the library name with a higher version number. For example, when installing OpenSSL version 1.0.1t, name the libraries libcrypto.so.1.0.1t or

libssl.1.0.1t (symbolic links with these names are sufficient).

FIPS-Enabled databases: limitations

FIPS-enabled databases have the following limitations:

- You cannot create a FIPS-enabled database on a non-FIPS machine.
- You cannot create a non-FIPS database on a FIPS-enabled machine.
- The Management Console and its daemon, [Agent](#), are not available on FIPS-enabled databases.
- Copying data generated with the MD5 hashing algorithm from a non-FIPS machine to a FIPS-enabled machine results in data corruption.
- Due to limitations in the FIPS cryptographic module, Vertica does not recommend enabling internode encryption in FIPS environments. If you use FIPS and internode encryption, you may experience occasional query failure due to socket closure in workloads that send a high volume of data across the network.

Implementing FIPS 140-2

Implementing FIPS 140-2 on your Vertica Analytic Database requires configuration on the server and client. While Vertica server uses FIPS-approved algorithms, Vertica clients may be running on non-FIPS-approved systems. Therefore, you must implement FIPS 140-2 compliance from end to end.

For more information on implementing FIPS, see:

- [FIPS compliance for the Vertica server](#)
- [Implement FIPS on the client](#)

In this section

- [FIPS compliance for the Vertica server](#)
- [Implement FIPS on the client](#)

FIPS compliance for the Vertica server

To make Vertica FIPS-compliant, you must:

- Set the RequireFIPS parameter to 1.
- Hash your passwords with SHA-512. See [Hash authentication](#) for details.
- Generate a signed TLS certificate to establish a secure connection to the client.

RequireFIPS parameter

Vertica sets the RequireFIPS configuration parameter on the server on startup to reflect the state of FIPS on the system: 1 if FIPS is enabled and 0 if FIPS is disabled.

The value of RequireFIPS matches the value of `crypto.fips_enabled` file.

Vertica sets the `RequireFIPS` parameter based on the contents of `crypto.fips_enabled` :

- If the file `/proc/sys/crypto/fips_enabled` exists and contains a 1 (FIPS-enabled), Vertica sets RequireFIPS to 1.
- If the file `/proc/sys/crypto/fips_enabled` does not exist, or exists and contains a 0 (non-FIPS), Vertica automatically sets RequireFIPS to 0.
- If the FIPS state of a node, as determined from the existence of `/proc/sys/crypto/fips_enabled`, differs from the state received from the cluster initiator, the node fails. This behavior prevents the creation of clusters of mixed FIPS and non-FIPS systems.

Important

If you attempt to restore a FIPS-enabled node to a non-FIPS cluster, the restore will fail.

Secure client-server connection

It's important to secure client-server connections with TLS. For instructions on setting up client-server TLS, see [Configuring client-server TLS](#).

FIPS-Compliant AWS endpoints

To configure AWS to use a [FIPS-compliant S3 Endpoint](#), set the following [S3 parameters](#):

```
AWSEndpoint = s3-fips.dualstack.us-east-1.amazonaws.com
S3EnableVirtualAddressing = 1
```

Implement FIPS on the client

Vertica provides a FIPS-compliant client driver, which you can install on a FIPS-enabled system. The 64-bit client includes vsqldb and ODBC drivers.

For information about installing the FIPS client, and installation, refer to the following

- [Installing the FIPS client driver for ODBC and vsqldb](#)
- [Installing the FIPS client driver for JDBC](#)

FIPS 140-2 compliance statement

Contents

[1. Summary](#)

[2. Overview](#)

[a. About Vertica](#)

[b. About FIPS 140-2](#)

[3. Vertica and FIPS 140-2](#)

1. summary

Vertica complies with Federal Information Processing Standard 140-2 (FIPS 140-2), which defines the technical requirements to be used by Federal Agencies when these organizations specify cryptographic-based security systems for protection of sensitive or valuable data. The compliance of Vertica with FIPS 140-2 is ensured by: 1) Integrating validated and NIST-certified third party cryptographic module(s), and using the module(s) as the only provider(s) of cryptographic services; 2) Using FIPS-approved cryptographic functions; 3) Using FIPS-approved and NIST-validated technologies applicable for Vertica design, implementation and operation.

2. overview

a. About Vertica

- Vertica is a high performance relational database management system used for advanced analytics applications. Its performance and scale is achieved through a columnar storage and execution architecture that offers a massively parallel processing solution. Aggressive encoding and compression allows Vertica analytics to perform by reducing CPU, memory and disk I/O Processing times.
- For more details about Vertica and its usage, see [Architecture](#).

b. About FIPS 140-2

FIPS (Federal Information Processing Standard) 140-2, *Security requirements for cryptographic modules*, is the Federal standard for proper cryptography for computer systems purchased by the government.

The Federal Information Processing Standards Publication (FIPS) 140-2, "Security Requirements for Cryptographic Modules," was issued by the National Institute of Standards and Technology (NIST) in May, 2001.

The benefits of using FIPS 140-2 validated crypto module is that the crypto algorithms are deemed appropriate and that they perform the encrypt/decrypt/hash functions correctly. The standard specifies the security requirements for cryptographic modules utilized within a security system that protects sensitive or valuable data. The requirements can be found in the following documents:

- [SECURITY REQUIREMENTS FOR CRYPTOGRAPHIC MODULES](#)
- [Annex A: Approved Security Functions for FIPS PUB 140-2, Security Requirements for Cryptographic Modules](#)

3. Vertica and FIPS 140-2

FIPS 140-2 validated third party module

Vertica conforms with FIPS 140-2 Level 1 compliance by dynamically linking to the FIPS 140-2 approved OpenSSL cryptographic module provided by the Operating System, which in our initial release is [Red Hat Enterprise Linux 6.6 OpenSSL Module](#).

Vertica can be configured to operate in FIPS-compliant mode ensuring its functions and procedures like SSL/TLS connections, which require cryptography (secure hash, encryption, digital signatures, etc.) makes use of the crypto services provided by [RedHat Enterprise Linux 6.6 OpenSSL Module v3.0](#) which is validated for FIPS 140-2. If you are not running on a [FIPS-compliant operating system that Vertica supports](#), you will not be able to run Vertica on FIPS mode. The assurance that Vertica is using the right FIPS 140-2 encryption modules is managed at the operating system level by RedHat's implementation.

Vertica checks the OS level flag setting `/proc/sys/crypto/fips_enabled` to kick off Vertica's FIPS mode installation. Further details about how to install and configure Vertica and its components to conform to FIPS 140-2 standard appear in the installation and security guides:

- [Install Vertica with the installation script](#)
- [Federal information processing standard](#)

Modes of Operation

Vertica Server operates in one of two modes determined by the OS configuration.

- FIPS-compliant mode – supports FIPS 140-2 compliant cryptographic functions. In this mode, all cryptographic functions, default algorithms and key lengths are bound to those allowed by FIPS 140-2.
- Standard mode – non-FIPS 140-2 compliant mode which utilizes all existing Vertica cryptography functions.

TLS/SSL3.x

All the Vertica client/server communications can be secured with FIPS-compliant Transport Layer Security TLS1.2/SSL3.1 or higher. It is relying on FIPS 140-2 approved hash algorithms and ciphers.

- TLS handshake, key negotiation and authentication provides data integrity and uses secure hash and FIPS 140-2 approved cryptography and digital signature.
- TLS encryption of data in transit provides confidentiality and making use of FIPS 140-2 approved cryptography.

Secure Hash

Per FIPS 140-2 standards, Vertica, in the FIPS 140-2 compliant mode, can be configured to use only the SHA-512 algorithm.

FIPS 140-2 Architecture

Vertica is a relational database system that is comprised of a client component and a server component. On the Client Side, we offer a suite of drivers for host clients to access the Vertica Server Side component. Both client and server Vertica components conform to FIPS 140-2 Level 1 compliance by dynamically linking to the FIPS 140-2 approved OpenSSL cryptographic module provided by RedHat Enterprise Linux 6.6 OpenSSL Module.

Supported Platforms

See [FIPS 140-2 supported platforms](#) for information about FIPS-compliant operating systems and client drivers that Vertica supports.

Design Assurance

Vertica uses the security provider [Red Hat Enterprise Linux 6.6 OpenSSL Module v3.0](#). This is the only supported security provider for FIPS 140-2.

Once you have configured Vertica to be compliant with FIPS 140-2, you cannot revert back to the standard configuration unless you disable FIPS 140-2 at the operating system level. Please reference the following documentation section for considerations:

- [FIPS compliance for the Vertica server](#)
- [Implement FIPS on the client](#)

Database auditing

Database auditing often involves observing a database to be aware of the actions the database users are taking. Auditing can help with security, for example, to ensure that a user does not change information to which they should not have access. Audit categories make it easier to track changes within the database. You can see system tables that will bring together logged queries, tables, and changes to configuration parameters.

For example, the authentication audit category tracks queries, system tables, and configuration parameters related to security and authentication, such as:

- DROP AUTHENTICATION statement
- GRANT/REVOKE authentication statements
- LDAP Link related configuration parameters

You can also use the authentication audit category for weekly security reports to better understand attempts to gain access to data or to view unauthorized changes.

There are three system tables that can be used to track changes for queries, parameters, and tables as follows:

- [LOG_PARAMS](#)
- [LOG_QUERIES](#)
- [LOG_TABLES](#)

There is also a system table for tracking changes to privileges for users:

- [AUDIT_MANAGING_USERS_PRIVILEGES](#)

System table restriction and access

Two functions let you restrict and open access to system tables for a given session:

- [RESTRICT_SYSTEM_TABLES_ACCESS](#) restricts access to non-superuser-only tables that are not accessible during lockdown.
- [RELEASE_SYSTEM_TABLES_ACCESS](#) allows access to non-superuser-only tables that are not accessible during lockdown.

Connecting to Vertica

This book explains several methods of connecting to Vertica, including:

- Directly connecting to Vertica using the vsql client application.
- Installing and configuring the Vertica client libraries to allow client applications to access Vertica.
- Developing your own client applications using the Vertica client libraries.

In this section

- [Using vsql](#)
- [Client libraries](#)
- [Management API](#)
- [Connect with an SSH tunnel](#)
- [SQLTools Vertica driver](#)

Using vsql

vsql is a character-based, interactive, front-end utility that lets you type SQL statements and see the results. It also provides a number of meta-commands and various shell-like features that facilitate writing scripts and automating a variety of tasks.

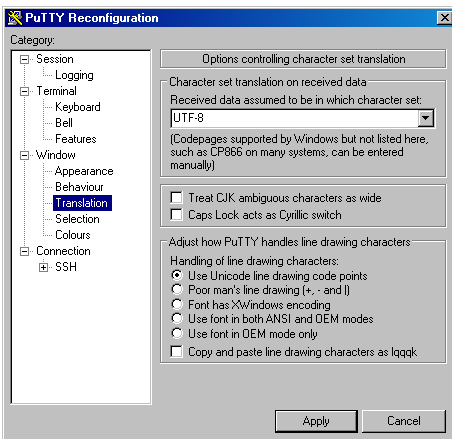

If you are using the vsql client installed on the server, then you can connect from the:

- [Administration Tools](#)
- [Linux command line](#)

You can also [install the vsql client](#) for other supported platforms.

General notes

- SQL statements can be spread over several lines for clarity.
- vsql can handle input and output in UTF-8 encoding. The terminal emulator running vsql must be set up to display the UTF-8 characters correctly. The following example shows the settings in PuTTY:

See also [Best Practices for Working with Locales](#).

- Cancel SQL statements by typing Ctrl+C.
- Traverse command history by typing Ctrl+R.
- When you disconnect a user session, any transactions in progress are automatically rolled back.
- To view wide result sets, use the Linux `less` utility to truncate long lines.
 1. Before connecting to the database, specify that you want to use `less` for query output:

```
$ export PAGER=less
```

2. Connect to the database.

3. Query a wide table:

```
=> select * from wide_table;
```

4. At the `less` prompt, type:

```
-S
```

If a shell running `vsq` fails (crashes or freezes), the `vsq` processes continue to run even if you stop the database. In that case, log in as root on the machine on which the shell was running and manually terminate the `vsq` process. For example: `$ ps -ef | grep vertica ... fred 2401 1 0 06:02 pts/1 00:00:00 /opt/vertica/bin/vsqli -p 5433 -h test01_site01 quick_start_single ... $ kill -9 2401`

Enabling autocommit

By default, you must `COMMIT` to save changes made in a transaction. To enable automatic commits, see [SET SESSION AUTOCOMMIT](#).

In this section

- [Installing the vsq client](#)
- [vsq usage on Windows](#)
- [Connecting from the administration tools](#)
- [Connecting from the command line](#)
- [Meta-commands](#)
- [Variables](#)
- [Prompting](#)
- [Command line editing](#)
- [vsq environment variables](#)
- [Locales](#)
- [Entering data with vsq](#)
- [Files](#)
- [Exporting data using vsq](#)
- [Copying data using vsq](#)
- [Output formatting examples](#)

Installing the vsq client

This page covers a non-FIPS installation. To install on a FIPS-compliant system, see [Installing the FIPS client driver for ODBC and vsq](#).

Linux and macOS

Note

For Linux: The `vsq` client is automatically installed as part of the Vertica server `.rpm`.

To install vsql manually on another system:

1. [Download](#) vsql.
2. Extract or install vsql:
 - If you downloaded the `.tar` , create the `/opt/vertica/` directory if it does not already exist, copy the `.tar` to it, navigate to it, and extract the `.tar` :

```
$ mkdir -p /opt/vertica/  
$ cp driver_name.tar.gz /opt/vertica/  
$ tar vzxvf driver_name.tar.gz
```

- If you downloaded the `.rpm` , install it with:

```
$ rpm -Uvh driver_name.rpm
```
3. Optionally add the vsql directory to your PATH. For example:

```
$ export PATH=$PATH:\opt\vertica\bin
```
4. Make the vsql client executable. For example, to allow all users to run vsql:

```
$ chmod ugo+x /path/to/vsql
```
5. Set your shell locale to a locale supported by vsql (which ones?). For example, in your `.profile` , add:

```
export LANG=end_US.UTF-8
```

Windows

To install the `vsql` client:

1. [Download](#) the Windows client driver installer. For details on the drivers included in this installer, see [Windows client driver installer](#) .
2. Run the installer and follow the prompts to install the drivers.
3. Reboot your system.

After installing the driver, you can optionally add the vsql directory to your PATH. For example, to append the vsql directory to your PATH with Windows PowerShell for the current session:

```
PS C:\> $Env:PATH += ";C:\Program Files\Vertica Systems\VSQ64\"
```

You can verify that the vsql directory is in your PATH by running `vsql -?` :

```
PS C:\> vsql -?  
This is vsql, the Vertica Analytic Database interactive terminal.  
  
Usage:  
vsql [OPTIONS]... [DBNAME [USERNAME]]
```

For usage details, see [vsql usage on Windows](#)

vsql usage on Windows

Font

The default raster font does not work well with the ANSI code page. Set the console font to "Lucida Console."

Console encoding

`vsql` is built as a "console application." The Windows console windows use a different encoding than the rest of the system, so take care when you use 8-bit characters within vsql. If vsql detects a problematic console code page, it warns you at startup.

To change the console code page, set the code page by entering `cmd.exe /c chcp 1252` .

Note

1252 is a code page that is appropriate for European languages. Replace it with your preferred locale code page.

Running under cygwin

Verify that your `cygwin.bat` file does not include the "tty" flag. If the "tty" flag is included in your `cygwin.bat` file, then banners and prompts are not displayed in vsql.

To verify, enter:

```
set CYGWIN=binmode tty ntsec
```

To remove the "tty" flag, enter:

```
set CYGWIN=binmode ntsec
```

Additionally, when running under Cygwin, vsql uses Cygwin shell conventions as opposed to Windows console conventions.

Tab completion

Tab completion is a function of the shell, not vsql. Because of this, tab completion does not work the same way in Windows vsql as it does on Linux versions of vsql.

On Windows, instead of using tab-completion, press F7 to pop-up a history window of commands. You can also press F8 after typing a few letters of a command to cycle through commands in the history buffer which begin with the same letters.

Connecting from the administration tools

You can use the [Administration tools](#) to connect to a database using vsql on any node in the cluster.

1. Log in as the database administrator user; for example, dbadmin.

Note

Vertica does not allow users with root privileges to connect to a database for security reasons.

2. Run the Administration Tools.

```
$/opt/vertica/bin/admintools
```

3. On the Main Menu, select **Connect to Database**.

4. If prompted, enter the database password:

```
Password:
```

When you create a new user with the [CREATE USER](#) command, you can configure the password or leave it empty. You cannot bypass the password if the user was created with a password configured. You can change a user's password using the [ALTER USER](#) command.

5. The Administration Tools connect to the database and transfer control to [vsql](#).

```
Welcome to vsql, the Vertica Analytic Database interactive terminal.
```

```
Type: \h or \? for help with vsql commands
```

```
\g or terminate with semicolon to execute query
```

```
\q to quit
```

```
=>
```

Note

See [Meta-commands](#) for the various commands you can run while connected to the database through the Administration Tools.

Connecting from the command line

You can connect to a database using vsql from the command line on multiple client platforms.

If the connection cannot be made for any reason—for example, you have insufficient privileges, or the server is not running on the targeted host—vsql returns an error and terminates.

Syntax

```
/opt/vertica/bin/vsql [-h host] [-p port] [ option... ] [ dbname [ username ] ]
```

Parameters

host

Optional if you connect to a local server. You can provide an IPv4 or IPv6 IP address or a host name.

For Vertica servers that have both IPv4 and IPv6 addressed and you have provided a host name instead of an IP address, you can prefer to use an IPv4 address with the `-4` option and to use the IPv6 address with the `-6` option if the DNS is configured to provide both IPv4 and IPv6 addresses. If you are using IPv6 and provide an IP address, you must append the address with an `% interface name`.

port

The database server port.

Default: 5433

option

One or more vsql [command-line options](#).

If the database is password protected, you must specify the `-w` or `--password` command line option.

dbname

The name of the target database. If unspecified, vsql automatically connects to the database on the specified *host* and *port*.

username

A database username, by default your system username.

Exit codes

vsql returns 0 to the shell when it terminates normally. Otherwise, it returns one of the following:

- 1: A fatal error occurred—for example, out of memory or file not found.
- 2: The connection to the server went bad and the session was not interactive
- 3: An error occurred in a script and the variable `ON_ERROR_STOP` was set.
- Unrecognized words in the command line might be interpreted as database or user names.

Examples

The following example shows how to capture error messages by redirecting vsql output to the output file `retail_queries.out`:

```
$ vsql --echo-all < retail_queries.sql > retail_queries.out 2>&1
```

In this section

- [Command-line options](#)
- [Connecting from a non-cluster host](#)

Command-line options

This section contains the command-line options for vsql.

General options

`--command` *command*

`-c` *command*

Runs one command and exits. This command is useful in shell scripts.

Variables set with `-v` are not processed when referenced in a `-c` command. To use variables, create a `.sql` file that references the variable and pass it to vsql with the `-f` option.

`--dbname` *dbname*

`-d` *dbname*

Specifies the name of the database to which you want to connect. Using this command is equivalent to specifying `dbname` as the first non-option argument on the command line.

`--file` *filename*

`-f` *filename*

Uses the *filename* as the source of commands instead of reading commands interactively. After the file is processed, vsql terminates.

`--help`

Displays help about vsql command line arguments and exits.

`--timing`

`-i`

Enables the [\timing](#) meta-command.

[--list](#)

[-l](#)

Returns all available databases, then exits. Other non-connection options are ignored. This command is similar to the internal command [\list](#) .

[--set assignment](#)

[--variable assignment](#)

[-v assignment](#)

Performs a variable assignment, like the vsql command [\set](#) .

[--version -V](#)

Prints the vsql version and exits.

[--no-vsqlr](#)

[-X](#)

Disables all command line editing and history functionality.

Connection options

[-4](#)

When resolving hostnames in dual stack environments, prefer IPv4 addresses.

[-6](#)

When resolving hostnames in dual stack environments, prefer IPv6 addresses.

[-B server:port \[,...\]](#)

Sets connection backup server/port. Use comma-separated multiple hosts (default: not set). If using an IPv6 address, enclose the address in brackets ([,]) and place the port outside of the brackets. For example [\B \[2620:0:a13:8a4:9d9f:e0e3:1181:7f51\]:5433](#)

[--enable-connection](#)

[-load-balance -C](#)

Enables connection load balancing (default: not enabled).

Note

You can only use load balancing with one address family in dual stack environments. For example, if you've configured load balancing for IPv6 addresses, then when an IPv4 client connects and requests load balancing the server does not allow it.

[--host hostname](#)

[-h hostname](#)

Specifies the host name of the machine on which the server is running.

[-k krb-service](#)

Provides the service name portion of the Kerberos principal (default: vertica). Using -k is equivalent to using the drivers' KerberosServiceName connection string.

[-K krb-host](#)

Provides the instance or host name portion of the Kerberos principal. -K is equivalent to the drivers' KerberosHostName connection string.

[-g client-label](#)

[--label client-label](#)

Sets the client label for the connection.

[--sslmode](#)

[-m](#)

Specifies the policy for making SSL connections to the server. Options are require, prefer, allow, and disable. You can also set the VSQL_SSLMODE variable to achieve the same effect. If the variable is set, the command-line option overrides it.

[--port port](#)

[-p port](#)

Specifies the TCP port or the local socket file extension on which the server is listening for connections. Defaults to port 5433.

[--username`*`username`*](#)

[-U`*`username`*](#)

Connects to the database as the user *username* instead of the default.

[-w password](#)

Specifies the password for a database user.

Note

Using this command-line option displays the database password in plain text. Use it with care, particularly if you are connecting as the database administrator, to avoid exposing sensitive information.

--password

-W

Forces vsql to prompt for a password before connecting to a database. The password is not displayed on the screen. This option remains set for the entire session, even if you change the database connection with the meta-command [\connect](#).

Output formatting

--no-align

-A

Switches to unaligned output mode. (The default output mode is aligned.)

-b

Beep on command completion.

--field-separator separator

-F separator

Specifies the field separator for unaligned output (default: "|") (-P fieldsep=). (See [-A --no-align](#).) Using this command is equivalent to [\pset fieldsep](#) or [\f](#).

--html

-H

Turns on HTML tabular output. Using this command is equivalent to using the [\pset format html](#) or the [\H](#) command.

--pset assignment

-P assignment

Lets you specify printing options in the style of [\pset](#) on the command line. You must separate the name and value with an equals (=) sign instead of a space. Thus, to set the output format to LaTeX, you could write [-P format=latex](#).

-Q

Turns on trailing record separator. Use [\pset trailingrecordsep](#) to toggle the trailing record separator on or off.

--record-separator separator

-R separator

Uses *separator* as the record separator. Using this command is equivalent to using the [\pset recordsep](#) command.

--tuples-only

-t

Disables printing of column names, result row count footers, and so on. This is equivalent to the [vsq meta-command \t](#).

--table-attr options

-T options

Allows you to specify options to be placed within the HTML [table](#) tag. See [\pset](#) for details.

--expanded

-x

Enables extended table formatting mode. This is equivalent to the [vsq meta-command \x](#).

Input and output options

--echo-all

-a

Prints all input lines to standard output as they are read. This approach is more useful for script processing than interactive mode. It is the same as setting the variable [ECHO](#) to [all](#).

--echo-queries

-e

Copies all SQL commands sent to the server to standard output. Using this command is equivalent to setting the variable [ECHO](#) to [queries](#).

-E

Displays queries generated by internal commands.

[-n](#)

Disables command line editing.

[--output filename](#)

[-o filename](#)

Writes all query output to *filename* . Using this command is equivalent to using the vsql meta-command `\o` .

[--quiet](#)

[-q](#)

Specifies that vsql do its work quietly (without informational output, such as welcome messages). This command is useful with the `-c` option. Within vsql you can also set the QUIET variable to achieve the same effect.

[--single-step](#)

[-s](#)

Runs in single-step mode for debugging scripts. Forces vsql to prompt before each statement is sent to the database and allows you to cancel execution.

[--single-line -S](#)

Runs in single-line mode where a newline terminates a SQL command, as if you are using a semicolon.

Note

This mode is provided only by customer request. Vertica recommends that you not use single-line mode in cases where you mix SQL and meta-commands on a line. In single-line mode, the order of execution might be unclear to the inexperienced user.

In this section

- [-A --no-align](#)
- [-a --echo-all](#)
- [-c --command](#)
- [-d --dbname](#)
- [-E](#)
- [-e --echo-queries](#)
- [-r --workload](#)
- [-F --field-separator](#)
- [-f --file](#)
- [? --help](#)
- [-H --html](#)
- [-h --host](#)
- [-i --timing](#)
- [-g --label](#)
- [-l --list](#)
- [-m --sslmode](#)
- [-n](#)
- [-o --output](#)
- [-P --pset](#)
- [-p --port](#)
- [-q --quiet](#)
- [-R --record-separator](#)
- [-S --single-line](#)
- [-s --single-step](#)
- [-T --table-attr](#)
- [-t --tuples-only](#)
- [-V --version](#)
- [-v --variable --set](#)
- [-X --no-vsqr](#)
- [-x --expanded](#)

`-A --no-align`

`-A` or `--no-align` switches to unaligned output mode. The default output mode is aligned.

`-a --echo-all`

`-a` or `--echo-all` prints all input lines to standard output as they are read. This is more useful for script processing than interactive mode. It is equivalent to setting the variable `ECHO` to `all`.

`-c --command`

`-c command` or `--command command` runs one command and exits. This is useful in shell scripts.

Use either:

- A command string that can be completely parsed by the server that does not contain features specific to vsql
- A single meta-command

You cannot mix SQL and vsql meta-commands. You can, however, pipe the string into vsql as shown:

```
echo "\timing\\select * from t" | ../Linux64/bin/vsql
      Timing is on.
      i | c | v
      ---+---+---
      (0 rows)
```

Note

If you use double quotes (") with `echo`, you must double the backslashes ().

`-d --dbname`

`-d db-name` or `--dbname db-name` specifies the name of the database to connect to. This is equivalent to specifying `db-name` as the first non-option argument on the command line.

`-E`

`-E` displays queries generated by internal commands.

`-e --echo-queries`

`-e --echo-queries` copies all SQL commands sent to the server to standard output as well. This is equivalent to setting the variable `ECHO` to `queries`.

`-r --workload`

`-r --workload` lets you specify the name of a workload. If a [routing rule](#) is associated with that workload, your connection is routed to the subcluster reserved for that workload. For details, see [Workload routing](#).

You can also specify a workload with the `VSQL_WORKLOAD` environment variable. For details, see [vsq environment variables](#).

`-F --field-separator`

`-F separator` or `--field-separator separator` specifies the field separator for unaligned output (default: "|") (-P fieldsep=). (See [-A --no-align](#).) This is equivalent to `lpset fieldsep` or `\f`.

To set the field separator value to a control character, use your shell's control character escape notation. In Bash, you specify a control character in an argument using a dollar sign (\$) followed by a string contained in single quotes. This string can contain C-string escapes (such as `\t` for tab), or a backslash () followed by an octal value for the character you want to use.

The following example demonstrates setting the separator character to tab (`\t`), vertical tab (`\v`) and the octal value of vertical tab (`\013`).

```

$ vsql -At -c "SELECT * FROM testtable;"
A|1|2|3
B|4|5|6

$ vsql -F '$\t' -At -c "SELECT * FROM testtable;"
A   1   2   3
B   4   5   6

$ vsql -F '$\v' -At -c "SELECT * FROM testtable;"
A
1
2
3
B
4
5
6

$ vsql -F '$\013' -At -c "SELECT * FROM testtable;"
A
1
2
3
B
4
5
6

```

-f --file

-f filename or **--file filename** uses *filename* as the source of commands instead of reading commands interactively. After the file is processed, vsql terminates.

If *filename* is a hyphen (-), standard input is read.

Using this option is different from writing `vsql < filename`. Using **-f** enables some additional features such as error messages with line numbers. Conversely, the variant using the shell's input redirection should always yield exactly the same output that you would have gotten had you entered everything manually.

? --help

-? --help displays help about vsql command line arguments and exits.

-H --html

-H --html turns on HTML tabular output. This is equivalent to `\pset format html` or the `\H` command.

-h --host

-h hostname or **--host hostname** specifies the host name of the machine on which the server is running. Use this flag to connect to Vertica remotely.

The following requirements and restrictions apply:

- If you use client authentication with a Kerberos connection method of either `gss` or `krb5`, you must specify **-h hostname**.
- Use the **-h** option if you want to connect to Vertica from a local connection, but want to use the an [authentication record](#) with the [access method HOST](#) (rather than `LOCAL`).

-i -- timing

Enables the `\timing` meta-command. You can only use this command with the **-c --command** and **-f --file** commands:

```
$VSQL -h host1 -U user1 -d VMart -p 15 -w ***** -i -f transactions.sql
```

You can only use **-i** with the **-c** (command) and **-f** (filename) commands. For more information see [Command-line options](#).

From the command line enter the `-i` option before running a session to turn timing on. For example:

```
$VSQL -h host1 -U user1 -d VMart -p 15 -w ***** -i -f transactions.sql
```

```
$VSQL-h host1 -U user1 -d VMart -p 15 -w ***** -i -c "SELECT user_name,  
ssl_state, authentication_method, client_authentication_name, client_type FROM sessions  
WHERE session_id=(SELECT session_id FROM current_session);"
```

`-g --label`

Assigns a client label to the connection at the start of the session. Client connections and their labels appear in the [SESSIONS](#) and some [Data collector](#) tables like `DC_REQUESTS_ISSUED`. Client labels set with this option appear in `DC_SESSION_STARTS`.

If used, this option takes precedence over the [VSQL_CLIENT_LABEL environment variable](#).

To set client labels for ongoing sessions, use [SET_CLIENT_LABEL](#).

`-l --list`

`-l` or `--list` returns all available databases, then exits. Other non-connection options are ignored. This command is similar to the internal command `\list`.

`-m --sslmode`

`-m` or `--sslmode` specifies the policy for making SSL connections to the server. Options are `verify_full`, `verify_ca require`, `prefer`, `allow`, and `disable`. You can also set the `VSQL_SSLMODE` variable to achieve the same effect. If the variable is set, the command-line option overrides it.

For information on these modes see [Configuring TLS for ODBC Clients](#).

`-n`

`-n` disables command line editing.

`-o --output`

`-o filename` or `--output filename` writes all query output into file `filename`. This is equivalent to the `vsql` meta-command `\o`.

`-P --pset`

`-P assignment` or `--pset assignment` lets you specify printing options in the style of `\pset` on the command line. Note that you have to separate name and value with an equal sign instead of a space. Thus to set the output format to LaTeX, you could write `-P format=latex`.

`-p --port`

`-p port` or `--port port` specifies the TCP port or the local socket file extension on which the server is listening for connections. Defaults to port 5433.

`-q --quiet`

`-q` or `--quiet` specifies that `vsql` do its work quietly. By default, it prints welcome messages and various informational output. If this option is used, none of this appears. This is useful with the `-c` option. Within `vsql` you can also set the [QUIET](#) variable to achieve the same effect.

`-R --record-separator`

`-R separator` or `--record-separator separator` specifies `separator` as the record separator. This is equivalent to the `\pset recordsep` command.

`-S --single-line`

`-S --single-line` runs in single-line mode where a newline terminates a SQL command, like the semicolon does.

Note

This mode is provided for those who insist on it, but you are not necessarily encouraged to use it, particularly if you mix SQL and meta-commands on a line. The order of execution might not always be clear to the inexperienced user.

-s --single-step

-s **--single-step** runs in single-step mode for debugging scripts. Forces vsql to prompt before each statement is sent to the database and allows you to cancel execution.

-T --table-attr

-T *table-options* or **--table-attr** *table-options* lets you specify options to be placed within the HTML `table` tag. See [lpset](#) for details.

-t --tuples-only

-t or **--tuples-only** disables printing of column names, result row count footers, and so on. This is equivalent to the [vsq meta-command](#) `\t`.

-V --version

-V or **--version** prints the vsql version and exits.

-v --variable --set

-v *assignment*, **--variable** *assignment*, and **--set** *assignment* perform a variable assignment, like the [vsq meta-command](#) `\set`.

Note

You must separate name and value, if any, by an equals sign (=) on the command line.

To unset a variable, omit the equal sign. To set a variable without a value, use the equals sign but omit the value. Make these assignments at a very early stage of start-up, so that variables reserved for internal purposes can get overwritten later.

-X --no-vsqr

-X **--no-vsqr** prevents the start-up file from being read: the system-wide `vsqr` file or the user's `~/.vsqr` file.

-x --expanded

-x or **--expanded** enables extended table formatting mode. This is equivalent to the [vsq meta-command](#) `\x`.

Connecting from a non-cluster host

You can use the Vertica vsql executable image on a non-cluster Linux host to connect to a Vertica database.

- On Red Hat, CentOS, and SUSE systems, you can install the client driver RPM, which includes the vsql executable. See [Installing the vsql client](#) for details.
- If the non-cluster host is running the same version of Linux as the cluster, copy the image file to the remote system. For example:

```
$ scp host01:/opt/vertica/bin/vsql .$/vsq
```

- If the non-cluster host is running a different distribution or version of Linux than your cluster hosts, you must install the Vertica server RPM in order to get vsql:
 1. Download the appropriate RPM package by browsing to [Vertica website](#). On the **Support** tab, select **Customer Downloads**.
 2. If the system you used to download the RPM is not the non-cluster host, transfer the file to the non-cluster host.
 3. Log into the non-cluster host as root and install the RPM package using the command:

```
# rpm -Uvh filename
```

Where *filename* is the package you downloaded. Note that you do not have to run the `install_vertica` script on the non-cluster host to use vsql.

Notes

- Use the same [Command-line options](#) that you would on a cluster host.
- You cannot run vsql on a Cygwin bash shell (Windows). Use ssh to connect to a cluster host, then run vsql.

Meta-commands

Anything you enter in vsql that begins with an unquoted backslash is a vsql meta-command that is processed by vsql itself. These commands help make vsql more useful for administration or scripting. Meta-commands are more commonly called slash or backslash commands.

The format of a vsql command is the backslash, followed immediately by a command verb, then any arguments. The arguments are separated from the command verb and each other by any number of whitespace characters.

To include whitespace into an argument you can quote it with a single quote. To include a single quote into such an argument, precede it by a backslash. Anything contained in single quotes is furthermore subject to C-like substitutions for `\n` (new line), `\t` (tab), `\ digits`, `\O digits`, and `\0x digits` (the character with the given decimal, octal, or hexadecimal code).

If an unquoted argument begins with a colon (:), it is taken as a vsql variable and the value of the variable is used as the argument instead.

Arguments that are enclosed in backquotes (``) are taken as a command line that is passed to the shell. The output of the command (with any trailing newline removed) is taken as the argument value. The above escape sequences also apply in backquotes.

Some commands take a SQL identifier (such as a table name) as argument. These arguments follow the syntax rules of SQL: Unquoted letters are forced to lowercase, while double quotes (") protect letters from case conversion and allow incorporation of whitespace into the identifier. Within double quotes, paired double quotes reduce to a single double quote in the resulting name. For example, `FOO"BAR"BAZ` is interpreted as `fooBARbaz`, and `"A weird"" name"` becomes `A weird" name`.

Parsing for arguments stops when another unquoted backslash occurs. This is taken as the beginning of a new meta-command. The special sequence `\\` (two backslashes) marks the end of arguments and continues parsing SQL commands, if any. That way SQL and vsql commands can be freely mixed on a line. But in any case, the arguments of a meta-command cannot continue beyond the end of the line.

Meta-commands quick reference

Syntax	Summary	Command-line Options
<code>\! [cmd]</code>	Executes a command in a Linux shell (passing arguments as entered) or starts an interactive shell.	
<code>\?</code>	Displays help information about all meta-commands, the same as <code>\h</code> .	<code>?</code>
<code>\a</code>	Toggles output format alignment. For details, see \pset format aligned .	<code>-A</code> <code>-no-align</code>
<code>\b</code>	Toggles beep on command completion.	
<code>\c[connect] [db [user-name]]</code>	Establishes a connection to database <code>db</code> , under the specified user <code>user-name</code> . For details, see \connect .	
<code>\C [' title-str ']</code>	Sets a title <code>title-str</code> that precedes query result output. For details, see \pset title title-str .	
<code>\cd [dir]</code>	Changes the current working directory to <code>dir</code> , changes to your home directory if you omit specifying a directory.	
<code>\d</code> commands	See \d meta-commands	
<code>\e[dit] [file]</code>	Edits the query buffer (or specified file) with an external editor. For details, see \edit .	

<code>\echo [str]</code>	Writes <i>str</i> to standard output. Tip Use <code>\qecho</code> to redirect query output to the query output stream, as set by <code>\o</code> .	
<code>\f [str]</code>	Sets the field separator for unaligned query output. The default is the vertical bar ().	-F --field-separator
<code>\g [file-name shell-command]</code>	Sends the query in the input buffer (see <code>\p</code>) to the server. You can send query results to <i>file-name</i> , or pipe results to <i>shell-command</i> ; otherwise, <code>\g</code> sends query results to standard output.	
<code>\H</code>	Renders output in HTML markup as a table. For details, see \pset format aligned .	-H --html
<code>\h[elp]</code>	Displays help information about the meta-commands, the same as <code>\?</code> .	--help
<code>\i file</code>	Reads and executes input from filename.	-f --file
<code>\l list</code>	Lists available databases and owners.	-l --list
<code>\locale [locale]</code>	Displays the current locale setting or sets a new locale for the session. For details, see \locale .	
<code>\o [file-name shell-command]</code>	Controls where vsql directs query output. You can send query results to <i>file-name</i> , or pipe results to <i>shell-command</i> ; otherwise, <code>\o</code> sends query results to standard output.	-o --output
<code>\p</code>	Prints the current query buffer to standard output.	
<code>\password [user-name]</code>	Starts the password change process. Superusers can specify a user name to change that user's password; otherwise, users can only change their own passwords.	
<code>\pset output-option</code>	Sets options that control how Vertica formats query result output. For details, see \pset .	-P --pset
<code>\q</code>	Quits the vsql program	
<code>\qecho [str]</code>	Writes <i>str</i> to the query output stream, as specified by <code>\o</code> .	
<code>\r</code>	Clears (resets) the query buffer	
<code>\s [file]</code>	Valid only if vsql is configured to use the GNU Readline library, prints or saves the command line history to <i>file</i> , or to standard output if no file name is supplied.	
<code>\set [var [value]...]</code>	Sets internal variable <i>var</i> to <i>value</i> . If you specify multiple values, <i>var</i> is set to their concatenated values. If no values are specified, <i>var</i> is set to no value.	--set -v --variable
<code>\t</code>	Toggles between tuples only and full display. For details, see \pset format tuples only .	-t --tuples-only
<code>\T html-attribute [...]</code>	Specifies attributes to be placed inside the HTML <code>table</code> tag—for example, <code>cellpadding</code> or <code>bgcolor</code> , the same as <code>\pset tableattr html-attribute [...]</code> . For sample usage, see Output formatting examples .	-T --table-attr

<code>\timing</code>	If set to on, returns how long (in milliseconds) each SQL statement runs. For details, see \timing .	-i -- timing
<code>\unset var</code>	Deletes internal variable <code>var</code> that was set by the meta-command <code>\set</code> .	
<code>\w file-name</code>	Outputs the current query buffer to file <code>file-name</code> .	
<code>\x</code>	Toggles between regular and expanded format. For details, see \pset format expanded .	-x --expanded
<code>\z</code>	Returns a summary of privileges on all objects in system table V_CATALOG.GRANTS : grantee, grantor, privileges, schema, and object name (equivalent to <code>\dp</code>). <code>\z</code> supports the same options as <code>\dp</code> for filtering output by schema and object name patterns, . For example:	

```
> \z *.*myseq*
Access privileges for database "dbadmin"
Grantee | Grantor | Privileges | Schema | Name
-----+-----+-----+-----+-----
dbadmin | dbadmin | SELECT*   | public | mySeq
dbadmin | dbadmin | SELECT*   | public | mySeq2
(2 rows)
```

`\connect`

Establishes a connection to database `db`, under the specified user `user-name`. The previous connection is closed. If you omit specifying a database name, Vertica connects to the current database. If you omit specifying a user name argument, Vertica assumes the current user.

Syntax

```
\c[connect] [db [user-name]]
```

Error handling

Errors that prevent execution include specifying an unknown user and denial of access to the specified database. Vertica handles errors differently, depending on whether this command is executed interactively in `vsq`, or in a script:

- VSQL handling: The current connection is maintained.
- Script: Processing immediately stops with an error. This prevents scripts from acting on the wrong database.

`\d` meta-commands

Vertica supports a number of `\d` commands, which return information on different categories of database objects. For a full list, see [\d Reference](#) below.

Syntax

Unless otherwise noted, `\d` commands generally conform to the following syntax:

```
\dCommand [ [schema.]pattern ]
```

Arguments

You can supply most `\d` commands with a string pattern argument, which filters the results that the command returns. The pattern can optionally be qualified by a schema name.

schema

Valid for most `\d` commands, restricts output to only database objects in `schema`. For example, the following `\dp` command obtains privileges information for all `V_MONITOR` tables that contain the string `resource`:

```

=> \dp V_MONITOR.*resource*
           Access privileges for database "dbadmin"
Grantee | Grantor | Privileges | Schema |      Name
-----+-----+-----+-----+-----
public | dbadmin | SELECT   | v_monitor | resource_rejections
public | dbadmin | SELECT   | v_monitor | disk_resource_rejections
public | dbadmin | SELECT   | v_monitor | resource_usage
public | dbadmin | SELECT   | v_monitor | resource_acquisitions
public | dbadmin | SELECT   | v_monitor | resource_rejection_details
public | dbadmin | SELECT   | v_monitor | resource_pool_move
public | dbadmin | SELECT   | v_monitor | host_resources
public | dbadmin | SELECT   | v_monitor | node_resources
public | dbadmin | SELECT   | v_monitor | resource_queues
public | dbadmin | SELECT   | v_monitor | resource_pool_status
(10 rows)

```

pattern

Returns only the database objects that match the specified string. Pattern strings can include the following wildcards:

- * (asterisk): zero or more characters.
- ? (question mark): any single character.

For example, the following `\dt` command returns tables that start with the string `store` :

```

=> \dt store*
           List of tables
Schema |      Name      | Kind | Owner | Comment
-----+-----+-----+-----+-----
public | store_orders   | table | dbadmin |
public | store_orders_2018 | table | dbadmin |
public | store_overseas | table | dbadmin |
store  | store_dimension | table | dbadmin |
store  | store_orders_fact | table | dbadmin |
store  | store_sales_fact | table | dbadmin |
(6 rows)

```

`\d` reference

\d

Unqualified by a pattern argument, returns all tables with their schema names, owners, and comments. If qualified by a pattern argument, `\d` returns all matching tables and all columns in each table, with details about each column, such as data type, size, and default value.

\df

Returns all function names, the function return data type, and the function argument data type. Also returns the procedure names and arguments for all procedures that are available to the user.

\dj

Returns all projections showing the schema, projection name, owner, and node. The returned rows include superprojections, live aggregate projections, Top-K projections, and projections with expressions.

\dn

Returns the schema names and schema owner.

\dp

Returns a summary of privileges on all objects in system table [V_CATALOG.GRANTS](#) : grantee, grantor, privileges, schema, and object name (equivalent to [\z](#)).

\dS

Unqualified by a pattern argument, returns all `V_CATALOG` and `V_MONITOR` system tables. To obtain system tables for just one schema, qualify the command with the schema name, as follows:

```
\dS { V_CATALOG | V_MONITOR }.*
```

\ds

Returns sequences and their parameters.

`\dT`

Returns all data types that Vertica supports.

Note

`\dT` returns no results if qualified with a pattern argument.

`\dt`

Unqualified by a pattern argument, returns the same information as an unqualified `\d` command. If qualified by a pattern argument, `\dt` returns matching tables with the same level of detail as an unqualified `\dt` command.

`\dtv`

Returns tables and views.

`\du`

Returns database users and whether they are superusers.

`\dv`

Unqualified by a pattern argument, returns all views with their schema names, owners, and comments. If qualified by a pattern argument, `\dv` returns all matching views and the columns in each view, with each column's data type and size.

`\edit`

Edits the query buffer (or specified file) with an external editor. When the editor exits, its content is copied back to the query buffer. If no argument is given, the current query buffer is copied to a temporary file which is then edited in the same fashion.

The new query buffer is then re-parsed according to the normal rules of `vsq`, where the whole buffer up to the first semicolon is treated as a single line. (Thus you cannot make scripts this way. Use `\i` for that.) If there is no semicolon, `vsq` waits for one to be entered (it does not execute the query buffer).

Tip

`vsq` searches the environment variables `VSQL_EDITOR`, `EDITOR`, and `VISUAL` (in that order) for an editor to use. If all of them are unset, `vi` is used on Linux systems, `notepad.exe` on Windows systems.

Syntax

```
e[dit] [ file ]
```

`\i`

Reads and executes input from the specified file.

Note

To see the lines on the screen as they are read, set the variable `ECHO` to all.

Syntax

```
i filename
```

Examples

The Vertica `vsq` client on Linux supports backquote (backtick) expansion. For example:

1. Set an environment variable to a path that contains scripts you want to run:

```
$ export MYSCRIPTS=/home/dbadmin/testscripts
```

2. Issue the `vsq` command.

```
$ vsq
```

3. Use backquote expansion to include the path for running an existing script—for example, `sample.sql`.

```
=> \i `echo $MYSCRIPTS/sample.sql`
```

\locale

Displays or sets the locale setting for the current session.

Note

This command does not alter the default locale for all database sessions. To change the default for all sessions, set configuration parameter [DefaultSessionLocale](#).

Syntax

```
\locale [locale-identifier]
```

Arguments

locale-identifier

Specifies the ICU locale identifier to use, by default set to:

```
en_US@collation=binary
```

If set to an empty string, Vertica sets locale to `en_US_POSIX`.

If you omit this argument, `\locale` returns the current locale setting.

For details on identifier options, see [About locale](#). For a complete list of locale identifiers, see the [ICU Project](#).

Examples

View the current locale setting:

```
=> \locale  
en_US@collation=binary
```

Change the default locale for this session:

```
=> \locale en_GBINFO:  
INFO 2567: Canonical locale: 'en_GBINFO:'  
Standard collation: 'LEN'  
English (GBINFO:)
```

Notes

The server locale settings impact only the collation behavior for server-side query processing. The client application is responsible for ensuring that the correct locale is set in order to display the characters correctly. Below are the best practices recommended by Vertica to ensure predictable results:

- The locale setting in the terminal emulator for vsql (POSIX) should be set to be equivalent to session locale setting on server side (ICU) so data is collated correctly on the server and displayed correctly on the client.
- The vsql locale should be set using the POSIX LANG environment variable in terminal emulator. Refer to the documentation of your terminal emulator for how to set locale.
- Server session locale should be set using the set as described in [Specify the default locale for the database](#).
- All input data for vsql should be in UTF-8 and all output data is encoded in UTF-8.
- Non UTF-8 encodings and associated locale values are not supported.

\pset

Sets options that control how Vertica formats query result output.

Syntax

```
\pset output-option
```

Output options

Note

Unless otherwise specified, output options are valid for all formats.

format *format-option*

Sets output format, where *format-option* is one of the following:

- `u[naligned]` writes all column data of each row on a single line, where each field is separated only by the current separator character. Use this output for use as input to other programs—for example, comma-delimited fields for CSV input.
- `a[ligned]` (default): Renders column-aligned output.
- `h[tml]` : Renders output in HTML markup as a table.
- `l[atex]` : Renders output in LaTeX markup.

border *int*

Valid only if output format is set to `html` , specifies the table border, where *int* specifies the border type.

expanded

Toggles between regular and expanded format. When expanded format is enabled, all output has two columns with the column name on the left and the data on the right. This mode is especially useful for wide tables.

fieldsep ' *arg* '

Valid only if output format is set to `unaligned` , specifies the field separator, by default | (vertical bar).

For example, to specify tab as the field separator:

```
\pset fieldsep '\t'
```

footer

Toggles display of the default footer:

(*int* rows)

null ' *string* '

Specifies to represent column null values as *string* . By default, Vertica renders null values as an empty field, which might be mistaken as an empty string.

For example:

```
\pset null '(null)'
```

pager [*always*]

Toggles use of a pager for query and vsql help output. If the environment variable `PAGER` is set, the output is piped to the specified program. Otherwise a platform-dependent default (such as `more`) is used.

When the pager is off, the pager is not used. When the pager is on, the pager is used only when appropriate; that is, the output is to a terminal and does not fit on the screen. (vsq does not do a perfect job of estimating when to use the pager.)

If qualified with the argument `always`, the pager is always used.

recordsep ' *char* '

Valid only if output format is set to `unaligned` , specifies the character used to delimit table records (tuples), by default a newline character.

tableattr *html-attribute* [...]

Specifies attributes to be placed inside the HTML `table` tag—for example, `cellpadding` or `bgcolor` .

title [' *title-str* ']

Sets a title that precedes query result output, to *title-str* . HTML output renders this as follows:

```
<caption>title-str</caption>
```

To remove the title, reissue the command omit the *title-str* argument.

trailingrecordsep

Toggles on or off the trailing record separator to use in unaligned output mode.

tuples_only

Toggles between tuples only and full display. Full display might show extra information such as column headers, titles, and various footers. In tuples only mode, only actual table data is shown.

Shortcuts

The following `\pset` commands have short-cuts:

\pset expanded

```
\x
```

\pset fieldsep ' *arg* '

`\f`

`\pset format aligned`

```
\a
```

`\pset format html`

```
\H
```

`\pset tableattr html-attribute [...]`

```
\T html-attribute[...]
```

`\pset title title-str`

```
\C [title-str]
```

`\pset tuples_only`

```
\t
```

Examples

See [Output formatting examples](#).

`\set`

Sets an internal variable to one or more values. If multiple values are specified, they are concatenated. An unqualified `\set` command lists all internal variables.

To unset a variable, use [vsq meta-command](#) `\unset`.

Syntax

```
\set [var [value]...]
```

Arguments

var

The name of an internal variable to set. Valid variable names are case sensitive and can contain characters, digits, and underscores. vsq treats several variables as special, which are described in [Variables](#).

value

A value to set in variable *var*. If no value is specified, the variable is set to no value.

If set to an empty string, the variable is set to no value. If you omit this argument, `\set` returns all internal variables.

If no arguments are supplied, `\set` returns all internal variables. For example:

```
=> \set
VERSION = 'vsq'
AUTOCOMMIT = 'off'
VERBOSITY = 'default'
PROMPT1 = '%/%R%# '
PROMPT2 = '%/%R%# '
PROMPT3 = '>> '
ROWS_AT_A_TIME = '1000'
DBNAME = 'dbadmin'
USER = 'dbadmin'
PORT = '5433'
LOCALE = 'en_US@collation=binary'
HISTSZIE = '500'
```

`\timing`

If set to on, returns how long (in milliseconds) each SQL statement runs. Results include:

- Length of time required to fetch the first block of rows
- Total time until the last block is formatted.

Unqualified, `\timing` toggles timing on and off. You can explicitly turn timing on and off by qualifying the command with options **ON** and **OFF**, respectively.

Note

You can also enable `\timing` from the command line using the `vsq -i` command.

Syntax

```
\timing [ON | OFF]
```

Examples

The following unqualified `\timing` commands toggle timing on and off:

```
=> \timing
Timing is on
=> \timing
Timing is off
```

The following example shows a SQL command with timing on:

```
=> \timing
Timing is on.
=> SELECT user_name, ssl_state, authentication_method, client_authentication_name,
       client_type FROM sessions WHERE session_id=(SELECT session_id FROM current_session);
 user_name | ssl_state | authentication_method | client_authentication_name | client_type
-----+-----+-----+-----+-----
dbadmin   | None     | ImpTrust              | default: Implicit Trust   | vsq
(1 row)

Time: First fetch (1 row): 73.684 ms. All rows formatted: 73.770 ms
```

Variables

`vsq` provides variable substitution features similar to common Linux command shells. Variables are name/value pairs, where the value can be a string of any length. To set variables, use the [vsq meta-command](#) `\set`. For example, the following statement sets the variable `fact` to the value `dim`:

```
=> \set fact dim
```

If you call `\set` on a variable and supply no value, the variable is set to an empty string.

Note

The arguments of `\set` are subject to the same substitution rules as with other commands. For example, `\set dim :fact` is a valid way to copy a variable.

Getting variables

To retrieve the content of a given variable, precede the name with a colon and use it as the argument of any slash command. For example:

```
=> \echo :fact
dim
```

An unqualified `\set` command returns all current variables and their values:

```
dbadmin=> \set
VERSION = 'vsql'
AUTOCOMMIT = 'off'
VERBOSITY = 'default'
PROMPT1 = '%/%R%# '
PROMPT2 = '%/%R%# '
PROMPT3 = '>> '
ROWS_AT_A_TIME = '1000'
DBNAME = 'dbadmin'
USER = 'dbadmin'
PORT = '5433'
LOCALE = 'en_US@collation=binary'
HISTSIZE = '500'
```

Deleting variables

To unset (or delete) a variable, use the [vsq meta-command \unset](#) .

Variable naming conventions

vsq internal variable names can contain letters, numbers, and underscores in any order and any number. Some variables are treated specially by vsq. They indicate certain option settings that can be changed at run time by altering the value of the variable or represent some state of the application. Although you can use these variables for any other purpose, this is not recommended. By convention, all specially treated variables consist of all upper-case letters (and possibly numbers and underscores). To ensure maximum compatibility in the future, avoid using such variable names for your own purposes.

SQL interpolation

You can substitute ("interpolate") vsq variables into regular SQL statements. You do so by prepending the variable name with a colon (:). For example, the following statements query the table `my_table` :

```
=> \set fact 'my_table'
=> SELECT * FROM :fact;
```

The value of the variable is copied literally, so it can even contain unbalanced quotes or backslash commands. Make sure that it makes sense where you put it. Variable interpolation is not performed into quoted SQL entities. One exception applies: the contents of backquoted strings (``) are passed to a system shell, and replaced with the shell's output. See [Using Backquotes to Read System Variables](#) below.

Using backquotes to read system variables

In vsq, the contents of backquotes are passed to the system shell to be interpreted (the same behavior as many UNIX shells). This is particularly useful in setting internal vsq variables, since you may want to access UNIX system variables (such as HOME or TMPDIR) rather than hard-code values.

For example, to set an internal variable to the full path for a file in your UNIX user directory, you can use backquotes to get the content of the system HOME variable, which is the full path to your user directory:

```
=> \set inputfile `echo $HOME`/myinput.txt=> \echo :inputfile
/home/dbadmin/myinput.txt
```

The contents of the backquotes are replaced with the results of running the contents in a system shell interpreter. In this case, the `echo $HOME` command returns the contents of the HOME system variable.

In this section

- [DBNAME](#)

DBNAME

The name of the database to which you are currently connected. DBNAME is set every time you connect to a database (including program startup), but it can be unset.

ECHO

If set to `all`, all lines entered from the keyboard or from a script are written to the standard output before they are parsed or run.

To select this behavior on program start-up, use the switch `-a`. If set to `queries`, vsql merely prints all queries as they are sent to the server. The switch for this is `-e`.

ECHO_HIDDEN

When this variable is set and a backslash command queries the database, the query is first shown. This way you can study the Vertica internals and provide similar functionality in your own programs. (To select this behavior on program start-up, use the switch `-E`.)

If you set the variable to the value `noexec`, the queries are just shown but are not actually sent to the server and run.

ENCODING

The current client character set encoding.

HISTCONTROL

If this variable is set to `ignorespace`, lines that begin with a space are not entered into the history list. If set to a value of `ignoredups`, lines matching the previous history line are not entered. A value of `ignoreboth` combines the two options. If unset, or if set to any other value than those previously mentioned, all lines read in interactive mode are saved on the history list.

Source: Bash.

HISTSIZE

Specifies how much storage space is allocated to store the history of SQL statements issued in the current vsql session. vsql uses this setting, by default 500, to calculate the size of the history buffer:

```
HISTSIZE * 50 (bytes)
```

where 50 bytes approximates the average length of a SQL statement. The actual length of SQL statements in the current session determines how many statements vsql stores.

HISTSIZE has no effect on the history that is stored in `.vsql_history`.

Source: Bash

HOST

The database server host you are currently connected to. This is set every time you connect to a database (including program startup), but can be unset.

IGNOREEOF

If unset, sending an EOF character (usually Control+D) to an interactive session of vsql terminates the application. If set to a numeric value, that many EOF characters are ignored before the application terminates. If the variable is set but has no numeric value, the default is 10.

Source: Bash.

ON_ERROR_STOP

By default, if a script command results in an error, for example, because of a malformed command or invalid data format, processing continues. If you set `ON_ERROR_STOP` to `ON` in a script and an error occurs during processing, the script terminates immediately.

For example:

```
=> \set ON_ERROR_STOP ON
```

Note

If you invoke the script on Linux with `vsq -f`, `vsq` returns with error code 3 to indicate that an error occurred in the script.

PORT

The database server port to which you are currently connected. This is set every time you connect to a database (including program start-up), but can be unset.

PROMPT1 PROMPT2 PROMPT3

These specify what the prompts `vsq` issues look like. See [Prompting](#) for details.

QUIET

This variable is equivalent to the command line option `-q`. It is probably not too useful in interactive mode.

ROWS_AT_A_TIME

`ROWS_AT_A_TIME` is set by default to 1000, and retrieves results as blocks of rows of that size. The column formatting for the first block is used for all blocks, so in later blocks some entries could overflow.

When formatting results, Vertica buffers `ROWS_AT_A_TIME` rows in memory to calculate the maximum column widths. It is possible that rows after this initial fetch are not properly aligned if any of the field values are longer than those seen in the first `ROWS_AT_A_TIME` rows. `ROWS_AT_A_TIME` can be unset with `vsq meta-command \unset` to guarantee perfect alignment. However, this requires re-buffering the entire result set in memory and might cause `vsq` to fail if the result set is too big.

SINGLELINE

This variable is equivalent to the command line option `-S`.

SINGLESTEP

This variable is equivalent to the command line option `-s`.

USER

The database user you are currently connected as. This is set every time you connect to a database (including program startup), but can be unset.

VERBOSITY

This variable can be set to the values `default`, `verbose`, or `terse` to control the verbosity of error reports.

VSQL_HOME

By default, the `vsq` program reads configuration files from the user's home directory. In cases where this is not desirable, the configuration file location can be overridden by setting the `VSQL_HOME` environment variable in a way that does not require modifying a shared resource.

In the following example, `vsq` reads configuration information out of `/tmp/jsmith` rather than out of `~`.

```
# Make an alternate configuration file in /tmp/jsmith
mkdir -p /tmp/jsmith
echo "\echo Using VSQ_LRC in tmp/jsmith" > /tmp/jsmith/.vsq_lrc
# Note that nothing is echoed when invoked normally
vsq_l
# Note that the .vsq_lrc is read and the following is
# displayed before the vsq_l prompt
#
# Using VSQ_LRC in tmp/jsmith
VSQ_L_HOME=/tmp/jsmith vsq_l
```

VSQ_L_SSLMODE

VSQ_L_SSLMODE specifies how (or whether) clients (like admintools) use SSL when connecting to servers. The default value is **prefer**, meaning to use SSL if the server offers it. Legal values are **require**, **prefer**, **allow**, and **disable**. This variable is equivalent to the command-line **-m** option (or **--sslmode**).

Prompting

The prompts vsq_l issues can be customized to your preference. The three variables **PROMPT1**, **PROMPT2**, and **PROMPT3** contain strings and special escape sequences that describe the appearance of the prompt. Prompt 1 is the normal prompt that is issued when vsq_l requests a new command. Prompt 2 is issued when more input is expected during command input because the command was not terminated with a semicolon or a quote was not closed. Prompt 3 is issued when you run a SQL **COPY** command and you are expected to type in the row values on the terminal.

The value of the selected prompt variable is printed literally, except where a percent sign (%) is encountered. Depending on the next character, certain other text is substituted instead. Defined substitutions are:

%M

The full host name (with domain name) of the database server, or [local] if the connection is over a socket, or [local:/dir/name], if the socket is not at the compiled in default location.

%m

The host name of the database server, truncated at the first dot, or [local].

%>

The port number at which the database server is listening.

%n

The database session user name.

%/

The name of the current database.

%~

Like %/, but the output is ~ (tilde) if the database is your default database.

%#

If the session user is a database superuser, then a #, otherwise a >. (The expansion of this value might change during a database session as the result of the command SET SESSION AUTHORIZATION.)

%R

In prompt 1 normally =, but ^ if in single-line mode, and ! if the session is disconnected from the database (which can happen if \connect fails). In prompt 2 the sequence is replaced by -, *, a single quote, a double quote, or a dollar sign, depending on whether vsq_l expects more input because the command wasn't terminated yet, because you are inside a /* ... */ comment, or because you are inside a quoted or dollar-escaped string. In prompt 3 the sequence doesn't produce anything.

%x

Transaction status: an empty string when not in a transaction block, or * when in a transaction block, or ! when in a failed transaction block, or ? when the transaction state is indeterminate (for example, because there is no connection).

%digits

The character with the indicated numeric code is substituted. If digits starts with 0x the rest of the characters are interpreted as hexadecimal; otherwise if the first digit is 0 the digits are interpreted as octal; otherwise the digits are read as a decimal number.

%:name:

The value of the vsq_l variable name. See the section Variables for details.

%`command`

The output of command, similar to ordinary "back- tick" substitution.

%[... %]

Prompts may contain terminal control characters which, for example, change the color, background, or style of the prompt text, or change the title of the terminal window. In order for the line editing features of Readline to work properly, these non-printing control characters must be designated as invisible by surrounding them with %[and %]. Multiple pairs of these may occur within the prompt. The following example results in a boldfaced (1;) yellow-on-black (33;40) prompt on VT100-compatible, color-capable terminals:

```
testdb=> \set PROMPT1 '%[%033[1;33;40m%]%n@%/%R%#%[%033[0m%]'
```

To insert a percent sign into your prompt, write %%. The default prompts are '%/%R%# ' for prompts 1 and 2, and '>> ' for prompt 3.

Note: See the [specification for terminal control sequences](#) (applicable to gnome-terminal and xterm).

Command line editing

`vsq` supports the [tecla](#) library for line editing and retrieval. You can define a tecla configuration with the following files:

- `~/.vsqrc` (user)
- `/opt/vertica/config/vsqrc` (global)

For details, see the [tecla documentation](#).

Command history is automatically saved in `~/.vsq_history` when `vsq` exits and is reloaded when `vsq` starts.

Disabling tab completion

To disable tab completion, add the following to `.vsqrc` :

```
\bind ^I
```

Key bindings

Key bindings are read from a global configuration at `/opt/vertica/config/vsqrc` , if present. To override key bindings, add definitions to `~/.vsqrc` .

Key bindings must be prefixed with a backslash (\). For example, the following definition binds the "backward-word" action to Ctrl+B:

```
\bind ^B backward-word
```

The following key bindings are specific to `vsq` :

- **Insert** switches between insert mode (the default) and overwrite mode.
- **Delete** deletes the character to the right of the cursor.
- **Home** moves the cursor to the front of the line.
- **End** moves the cursor to the end of the line.
- **^R** Performs a history backwards search.

Implementation differences

The `vsq` implementation of the tecla library deviates from the tecla documentation in the following ways:

- Unlike the standard tecla library, which saves all executed lines in the command history, `vsq` only saves unique non-empty lines.
- `vsq` standardizes the name and location of the history file (`~/.vsq_history`).
- `vsq` does not support 8-bit meta characters. This can affect international character sets, meta keys, and locales. You can verify that a meta character sends an escape by setting the `EightBitInput X` resource to `False` . You can do this in the following ways:
 - Add the following to `~/.Xdefaults` :

```
XTerm*EightBitInput: False
```
 - Start an `xterm` session with the `-xrm '*EightBitInput: False'` .

vsq environment variables

Set one or more of the following environment variables to be used by the defined properties automatically, each time you start `vsq`:

PAGER

If the query results do not fit on the screen, they are piped through this command. Typical values are `more` or `less` . The default is platform-dependent. Use the `\pset` command to enable/disable the pager.

VSQ_CLIENT_LABEL

The label to identify the `vsq` client in various system tables like `SESSIONS`. This is an alternative to setting the client label with the `--label` option or `SET_CLIENT_LABEL`, but if either of these is used, they take precedence over `VSQL_CLIENT_LABEL`.

VSQL_DATABASE

The database to which you are connecting. For example, `VMart`.

TMPDIR

Directory for storing temporary files. The default is platform-dependent. On Unix-like systems the default is `/tmp`.

VSQL_EDITOR

EDITOR

VISUAL

Editor used by the `\e` command. The variables are examined in the order listed; the first that is set is used.

VSQL_HOME

By default, the `vsq` program reads configuration files from the user's home directory. In cases where this is not desirable, the configuration file location can be overridden by setting the `VSQL_HOME` environment variable in a way that does not require modifying a shared resource.

VSQL_HOST

Host name or IP address of the Vertica node.

VSQL_PASSWORD

The database password. Using this environment variable increases site security by precluding the need to enter the database password on the command line.

VSQL_PORT

Port to use for the connection.

VSQL_SSLMODE

Specifies whether and how clients such as `admintools` use SSL when connecting to servers.

VSQL_USER

User name to use for the connection.

VSQL_WORKLOAD

The `workload` to use for the connection.

Locales

The default terminal emulator under Linux is `gnome-terminal`, although `xterm` can also be used.

Vertica recommends that you use `gnome-terminal` with `vsq` in UTF-8 mode, which is its default.

To change settings on Linux

1. From the tabs at the top of the `vsq` screen, select **Terminal**.
2. Click **Set Character Encoding**.
3. Select **Unicode (UTF-8)**.

Note

This works well for standard keyboards. `xterm` has a similar UTF-8 option.

To change settings on Windows using PuTTY

1. Right click the `vsq` screen title bar and select **Change Settings**.
2. Click **Window** and click **Translation**.
3. Select **UTF-8** in the drop-down menu on the right.

Notes

- `vsq` has no way of knowing how you have set your terminal emulator options.
- The `tecla` library is prepared to do POSIX-type translations from a local encoding to UTF-8 on interactive input, using the `POSIX LANG`, etc., environment variables. This could be useful to international users who have a non-UTF-8 keyboard. See the `tecla` documentation for details.

Vertica recommends the following (or whatever other .UTF-8 locale setting you find appropriate):

```
export LANG=en_US.UTF-8
```

- The vsql [\locale](#) command invokes and tracks the server [SET LOCALE TO](#) command, described. vsql itself currently does nothing with this locale setting, but rather treats its input (from files or from tecla), all its output, and all its interactions with the server as UTF-8. vsql ignores the POSIX locale variables, except for any "automatic" uses in [printf](#) , and so on.

Entering data with vsql

You often need to insert literal data when using vsql. For example:

- Adding a row of data to a table using an [INSERT](#) statement.
- Adding multiple rows of data through a [COPY FROM STDIN](#) statement.

The following table lists the data types that Vertica supports, and the format you use to enter that data in queries when using vsql.

Data Type	Inserting to vsql using	Example Use in INSERT INTO table ...	For More Information See...
Binary types, such as BINARY and VARBINARY	Helper functions such as HEX_TO_BINARY, octal strings, specified data format in COPY statements, casting string values to binary.	VALUES(HEX_TO_BINARY('0x3D'), '\\141\\337\\');	<ul style="list-style-type: none"> • Binary data types (BINARY and VARBINARY) • Binary (native) data
BOOLEAN	Literal values TRUE and FALSE or strings such as 'y' , 't' , 'true' , or 'false' .	VALUES(TRUE, 'f');	Boolean data type
Character data types such as CHAR or LONG VARCHAR	Strings enclosed in single quotes.	VALUES('my string');	Character data types (CHAR and VARCHAR)
Date and time data types, such as TIMESTAMPTZ	Formatted text string	VALUES('16:43:00', '2016-09-15 04:55:00 PDT');	<ul style="list-style-type: none"> • Date/time data types • Date/time expressions
Numeric Data Types	Literal numeric values, including scientific notation, hexadecimal, and BINARY scaling.	VALUES(3.1415, 42, 6.0221409e23);	Numeric data types
UUID	Formatted text string	VALUES('12345678-1234-1234-1234-123456789012');	UUID data type

Files

Before starting up, vsql attempts to read and execute commands from the system-wide [vsqsrc](#) file and the user's [~/.vsqsrc](#) file. The command-line history is stored in the file [~/.vsql_history](#).

Tip

If you want to save your old history file, open another terminal window and save a copy to a different file name.

Exporting data using vsql

You can use [vsql](#) for simple data-export tasks by changing its output format options so the output is suitable for importing into other systems (tab-delimited or comma-separated files, for example). These options can be set either from within an interactive vsql session, or through command-line arguments to the vsql command (making the export process suitable for automation through scripting). After you have set vsql's options so it outputs

the data in a format your target system can read, you run a query and capture the result in a text file.

The following table lists the meta-commands and command-line options that are useful for changing the format of vsql's output.

Description	Meta-command	Command-line Option
Disable padding used to align output.	<code>\a</code>	<code>-A</code> or <code>--no-align</code>
Show only tuples, disabling column headings and row counts.	<code>\t</code>	<code>-t</code> or <code>--tuples-only</code>
Set the field separator character.	<code>\pset fieldsep</code>	<code>-F</code> or <code>--field-separator</code>
Send output to a file.	<code>\o</code>	<code>-o</code> or <code>--output</code>
Specify a SQL statement to execute.	N/A	<code>-c</code> or <code>--command</code>

The following example demonstrates disabling padding and column headers in the output, and setting a field separator to dump a table to a tab-separated text file within an interactive session.

```
=> SELECT * FROM my_table;
a | b | c
---+-----+---
a | one | 1
b | two | 2
c | three | 3
d | four | 4
e | five | 5
(5 rows)
=> \a
Output format is unaligned.
=> \t
Showing only tuples.
=> \pset fieldsep '\t'
Field separator is "  ".
=> \o dumpfile.txt
=> select * from my_table;
=> \o
=> \! cat dumpfile.txt
a  one  1
b  two  2
c  three 3
d  four 4
e  five 5
```

Note

You could encounter issues with empty strings being converted to NULLs or the reverse using this technique. You can prevent any confusion by explicitly setting null values to output a unique string such as NULLNULLNULL (for example, `\pset null 'NULLNULLNULL'`). Then, on the import end, convert the unique string back to a null value. For example, if you are copying the file back into a Vertica database, you would give the argument `NULL 'NULLNULLNULL'` to the [COPY](#) statement.

When logged into one of the database nodes, you can create the same output file directly from the command line by passing the right parameters to vsql:

```
$ vsql -U username -F '$\t' -At -o dumpfile.txt -c "SELECT * FROM my_table;"
Password:
$ cat dumpfile.txt
a   one  1
b   two  2
c   three 3
d   four 4
e   five 5
```

If you want to convert null values to a unique string as mentioned earlier, you can add the argument `-P null='NULLNULLNULL'` (or whatever unique string you choose).

By adding the `-w` vsql command-line option to the example command line, you could use the command within a batch script to automate the data export. However, the script would contain the database password as plain text. If you take this approach, you should prevent unauthorized access to the batch script, and also have the script use a database user account that has limited access.

To set the field separator value to a control character, use your shell's control character escape notation. In Bash, you specify a control character in an argument using a dollar sign (\$) followed by a string contained in single quotes. This string can contain C-string escapes (such as `\t` for tab), or a backslash () followed by an octal value for the character you want to use.

The following example demonstrates setting the separator character to tab (`\t`), vertical tab (`\v`) and the octal value of vertical tab (`\013`).

```
$ vsql -At -c "SELECT * FROM testtable;"
A|1|2|3
B|4|5|6

$ vsql -F '$\t' -At -c "SELECT * FROM testtable;"
A   1   2   3
B   4   5   6

$ vsql -F '$\v' -At -c "SELECT * FROM testtable;"
A
1
2
3
B
4
5
6

$ vsql -F '$\013' -At -c "SELECT * FROM testtable;"
A
1
2
3
B
4
5
6
```

Copying data using vsql

You can use vsql to copy data between two Vertica databases. This technique is similar to the technique explained in [Exporting data using vsql](#), except instead of having vsql save data to a file for export, you pipe one vsql's output to the input of another vsql command that runs a `COPY` statement from STDIN. This technique can also work for other databases or applications that accept data from an input stream.

Note

The following technique only works for individual tables. To copy an entire database to another cluster, see [Copying the database to another cluster](#).

The easiest way to copy using vsql is to log in to a node of the target database, then issue a vsql command that connects to the source Vertica database to dump the data you want. For example, the following command copies the store.store_sales_fact table from the vmart database on node testdb01 to the vmart database on the node you are logged into:

```
vsql -U username -w passwd -h testdb01 -d vmart -At -c "SELECT * from store.store_sales_fact" \  
| vsql -U username -w passwd -d vmart -c "COPY store.store_sales_fact FROM STDIN DELIMITER '|';"
```

Note

The above example copies the data only, not the table design. The target table for the data copy must already exist in the target database. You can export the design of the table using [EXPORT_OBJECTS](#) or [EXPORT_CATALOG](#).

If you are using the Bash shell, you can escape special delimiter characters. For example, `DELIMITER E'\t'` specifies tab. Shells other than Bash may have other string-literal syntax.

Monitoring progress (optional)

You may want some way of monitoring progress when copying large amounts of data between Vertica databases. One way of monitoring the progress of the copy operation is to use a utility such as [Pipe Viewer](#) that pipes its input directly to its output while displaying the amount and speed of data it passes along. Pipe Viewer can even display a progress bar if you give it the total number of bytes or lines you expect to be processed. You can get the number of lines to be processed by running a separate vsql command that executes a [SELECT COUNT](#) query.

Note

Pipe Viewer isn't a standard Linux command, so you will need to download and install it yourself. See the [Pipe Viewer](#) page for download packages and instructions. Vertica does not support Pipe Viewer. Install and use it at your own risk.

The following command demonstrates how you can use Pipe Viewer to monitor the progress of the copy shown in the prior example. The command is complicated by the need to get the number of rows that will be copied, which is done using a separate vsql command within a Bash backquote string, which executes the string's contents and inserts the output of the command into the command line. This vsql command just counts the number of rows in the store.store_sales_fact table.

```
vsql -U username -w passwd -h testdb01 -d vmart -At -c "SELECT * from store.store_sales_fact" \  
| pv -lpetr -s `vsql -U username -w passwd -h testdb01 -d vmart -At -c "SELECT COUNT (*) FROM store.store_sales_fact;"` \  
| vsql -U username -w passwd -d vmart -c "COPY store.store_sales_fact FROM STDIN DELIMITER '|';"
```

While running, the above command displays a progress bar that looks like this:

```
0:00:39 [12.6M/s] [=====] 50% ETA 00:00:40
```

Output formatting examples

By default, Vertica formats query output as follows:

```
=> SELECT DISTINCT category_description FROM product_dimension ORDER BY category_description;  
category_description  
-----  
Food  
Medical  
Misc  
Non-food  
(4 rows)
```

You can control the format of query output in various ways with the `\pset` command—for example, change the border:

```

=> \pset border 2
Border style is 2.
=> SELECT DISTINCT category_description FROM product_dimension ORDER BY category_description;
+-----+
| category_description |
+-----+
| Food                |
| Medical              |
| Misc                 |
| Non-food             |
+-----+
(4 rows)
=> \pset border 0
Border style is 0.
=> SELECT DISTINCT category_description FROM product_dimension ORDER BY category_description;
category_description
-----
Food
Medical
Misc
Non-food
(4 rows)

```

The following sequence of `pset` commands change query output in several ways:

- Set border style to 1.
- Remove column alignment.
- Change the field separator to a comma.
- Remove column headings

```

=> \pset border 1
Border style is 1.
=> \pset format unaligned
Output format is unaligned.
=> \pset fieldsep ','
Field separator is ",".
=> \pset tuples_only
Showing only tuples.
=> SELECT product_key, product_description, category_description FROM product_dimension LIMIT 10;
1,Brand #2 bagels,Food
1,Brand #1 butter,Food
2,Brand #6 chicken noodle soup,Food
3,Brand #11 vanilla ice cream,Food
4,Brand #14 chocolate chip cookies,Food
4,Brand #12 rash ointment,Medical
6,Brand #18 bananas,Food
7,Brand #25 basketball,Misc
8,Brand #27 french bread,Food
9,Brand #32 clams,Food

```

The following example uses meta-commands to toggle output format—in this case, `\a` (alignment), `\t` (tuples only), and `-x` (extended display):

```
=> \a \t \x
Output format is aligned.
Tuples only is off.
Expanded display is off.
=> SELECT product_key, product_description, category_description FROM product_dimension LIMIT 10;
product_key | product_description | category_description
-----+-----+-----
1 | Brand #2 bagels | Food
1 | Brand #1 butter | Food
2 | Brand #6 chicken noodle soup | Food
3 | Brand #11 vanilla ice cream | Food
4 | Brand #14 chocolate chip cookies | Food
4 | Brand #12 rash ointment | Medical
6 | Brand #18 bananas | Food
7 | Brand #25 basketball | Misc
8 | Brand #27 french bread | Food
9 | Brand #32 clams | Food
(10 rows)
```

The following example sets output format to HTML, so Vertica renders query results in HTML markup as a table:

```
=> \pset format html
Output format is html.
=> \pset tableattr 'border="2" cellpadding="3"'
Table attribute is "border="2" cellpadding="3"".
=> SELECT product_key, product_description, category_description FROM product_dimension LIMIT 2;
<table border="1" border="2" cellpadding="3">
<tr>
<th align="center">product_key</th>
<th align="center">product_description</th>
<th align="center">category_description</th>
</tr>
<tr valign="top">
<td align="right">1</td>
<td align="left">Brand #2 bagels</td>
<td align="left">Food </td>
</tr>
<tr valign="top">
<td align="right">1</td>
<td align="left">Brand #1 butter</td>
<td align="left">Food </td>
</tr>
</table>
<p>(2 rows)<br />
</p>
```

Client libraries

The Vertica client driver libraries provide interfaces for connecting your client applications (or third-party applications such as Cognos and MicroStrategy) to your Vertica database. The drivers simplify exchanging data for loading, report generation, and other common database tasks.

There are three separate client drivers:

- Open Database Connectivity (ODBC)—the most commonly-used interface for third-party applications and clients written in C, Python, PHP, Perl, and most other languages.
- Java Database Connectivity (JDBC)—used by clients written in the Java programming language.
- ActiveX Data Objects for .NET (ADO.NET)—used by clients developed using Microsoft's .NET Framework and written in C#, Visual Basic .NET, and other .NET languages.

Client driver standards

The Vertica client drivers are compatible with the following driver standards:

- The ODBC driver complies with version 3.5.1 of the ODBC standard.
- The version of JDBC used depends on the version of your JVM. For details, see [JDBC feature support](#).
- ADO.NET drivers conform to .NET framework 3.0 specifications.

The drivers do not support some of the optional features in the standards. See [ODBC feature support](#) and [JDBC feature support](#) and [Using ADO.NET](#) for details.

In this section

- [Client driver and server version compatibility](#)
- [Client drivers](#)
- [Accessing Vertica](#)
- [Managing query execution between the client and Vertica](#)

Client driver and server version compatibility

Backward compatibility between Vertica server and client drivers works in both directions.

The Vertica server is compatible with all previous versions of client drivers, and all new client drivers are compatible with most versions of Vertica server. This compatibility lets you upgrade your Vertica server without having to immediately upgrade your client software, and use new client software with older versions of Vertica. Occasionally, however, individual features of a new server version might be unavailable through older drivers.

Note

While the client drivers are designed to be compatible with older versions of Vertica, hotfixes are limited to issues found in supported versions only. For details, see [Product Support Lifecycle](#).

Client	Compatible Server Versions
ODBC	9.2.x and above
JDBC	9.2.x and above
ADO.NET	9.2.x and above
FIPS-enabled ODBC	FIPS-enabled 9.2.x and above (FIPS cannot be enabled in Vertica 9.3.x and 10.0.x.)
FIPS-enabled JDBC	FIPS-enabled 9.2.x and above (FIPS cannot be enabled in Vertica 9.3.x and 10.0.x.)

Client drivers

You must install the Vertica client drivers to access Vertica from your client application. The drivers create and maintain connections to the database and provide APIs that your applications use to access your data. The client drivers support connections using JDBC, ODBC, and [ADO.NET](#).

Client driver standards

The client drivers support the following standards:

- ODBC drivers conform to ODBC 3.5.1 specifications.
- JDBC drivers conform to JDK 5 specifications.
- ADO.NET drivers conform to .NET framework 3.0 specifications.

In this section

- [Installing and configuring client drivers](#)
- [Upgrading the client drivers](#)
- [Setting a client connection label](#)
- [Using legacy drivers](#)

Installing and configuring client drivers

You can access your Vertica database with various programming languages and tools by installing the appropriate client driver. The following table lists the required client drivers for each access method:

Client Driver	Language/Tool
JDBC	Java
ODBC	<ul style="list-style-type: none"> • Python (pyodbc) • PHP • Perl
vertica-python	Python (native client)
ADO.NET	C#
vertica-nodejs	JavaScript
vertica-sql-go	Go

In this section

- [Windows client driver installer](#)
- [FIPS client drivers](#)
- [JDBC client driver](#)
- [ODBC client driver](#)
- [Python client drivers](#)
- [Node.js client driver](#)
- [Go client driver](#)
- [OLE DB client driver](#)
- [ADO.NET client driver](#)

Windows client driver installer

All available client drivers for Windows are included in the Vertica Client Drivers and Tools [installer](#). This installs the following components on systems that meet the [prerequisites](#). The individual components may require additional configuration before use, so navigate to their pages linked below for more information:

- [ODBC](#)
- [JDBC](#)
- [OLE DB](#)
- [vsq!](#)

In this section

- [System prerequisites](#)
- [Uninstalling, modifying, or repairing the client drivers and tools](#)

System prerequisites

The Vertica Client Drivers and Tools for Windows has basic system prerequisite requirements. The pack also requires that specific Microsoft components be installed for full integration.

For a list of all prerequisites, see [Client drivers support](#) in the Supported Platforms document.

Fully update your system

Before you install the Vertica driver package, verify that your system is fully up to date with all Windows updates and patches. See the documentation for your version of Windows for instructions on how to run Windows update. The Vertica client libraries and vsq! executable install updated Windows libraries that depend on Windows service packs. Be sure to resolve any issues that block the installation of Windows updates.

If your system is not fully up-to-date, you may receive error messages about missing libraries such as [api-ms-win-crt-runtime-l1-1-0.dll](#) when starting vsq!.

In this section

- [.NET framework](#)
- [Microsoft SQL server](#)

.NET framework

The Vertica Client Drivers and Tools for Windows requires and prompts you to install the Microsoft .NET Framework 4.6 if it is not installed.

To manually install the Microsoft .NET Framework 4.6, see the [Microsoft documentation](#).

Microsoft SQL server

Use SQL Server 2012, 2014 or 2016. The Vertica Client Drivers and Tools for Windows installer enables support for the following:

- **SQL Server 2012, 2014, and 2016:**
 - SQL Server Integration Services (SSIS)
 - SQL Server Reporting Services (SSRS)
 - SQL Server Analysis Services (SSAS)
- **SQL Server using 2012, 2013, and 2015** —SQL Server Data Tool - Business Intelligence (SSDT-BI)

Note

For SQL Server 2012, you can use either SQL Server 2012 or SQL Server 2012 SP1.

To use the enhanced Vertica .NET support, you must first install SQL Server. Then, you can install the Client Drivers and Tools for Windows. The following components must be installed on the SQL server:

For...	Install...
SSAS	The Analysis Services Instance Feature.
SSRS	The Reporting Services Instance Feature.
SSIS (Data Type Mappings)	The SQL Server Integration Services Shared Feature.
SSDT-BI (Visual Studio 2012, 2013, or 2015)	SQL Server Data Tool - Business Intelligence Shared Feature only <i>after</i> installing Microsoft Visual Studio 2012, 2013, or 2015.

Uninstalling, modifying, or repairing the client drivers and tools

To uninstall, modify, or repair the client drivers and tools, run the Client Drivers and Tools for Windows installer.

The installer provides three options:

Action	Description
Modify	Remove installed client drivers and tools or install missing client drivers and tools.
Repair	Reinstall already-installed client drivers and tools.
Uninstall	Uninstall all of the client drivers and tools.

Silently uninstall the client drivers and tools

1. As a Windows Administrator, open a command-line session, and change directory to the folder that contains the installer.
2. Run the command:

```
VerticaSetup.exe -q -uninstall
```

The client drivers and tools are silently uninstalled.

FIPS client drivers

Vertica offers a [FIPS-compliant](#) version of the ODBC and JDBC client drivers.

In this section

- [Installing the FIPS client driver for JDBC](#)

- [Installing the FIPS client driver for ODBC and vsq](#)

Installing the FIPS client driver for JDBC

Vertica offers a JDBC client driver that is compliant with the Federal Information Processing Standard (FIPS). Use this JDBC client driver to access systems that are FIPS-compatible. For more information on FIPS, see [Federal information processing standard](#).

Implementing FIPS on a JDBC client requires a third-party JRE extension called [BouncyCastle](#), a collection of APIs used for cryptography. Use BouncyCastle APIs with JDK 1.7 and 1.8, and a [supported FIPS-compliant operating system](#).

Important

When using the JDBC FIPS-compliant client, expect a slight delay for the client to establish a secure connection with the database. If necessary, increase your system's entropy to ensure a fast and secure connection.

The following procedure adds the FIPS BouncyCastle `.jar` as a JVM JSSE provider:

1. [Download](#) the BouncyCastle FIPS `.jar` file `bc-fips-1.0.0.jar`.

2. Add `bc-fips-1.0.0.jar` as a JRE library extension:

```
path/to/jre/lib/ext/bc-fips-1.0.0.jar
```

3. Add BouncyCastle as an SSL security provider in `<path to jre>/lib/security/java.security`:

```
security.provider.1=org.bouncycastle.jcajce.provider.BouncyCastle FipsProvider
security.provider.2=com.sun.net.ssl.internal.ssl.Provider BCFIPS
security.provider.3=sun.security.provider.Sun
```

4. Use the following JVM `java -D` system property command arguments to set the [KeyStore and TrustStore](#) files to BCFIPS:

```
export JAVA_OPTS="$JAVA_OPTS -Djavax.net.ssl.keyStoreProvider=BCFIPS
export JAVA_OPTS="$JAVA_OPTS -Djavax.net.ssl.trustStoreProvider=BCFIPS
```

5. Set the default type for the KeyStore implementation to BCFKS in `path/to/jre /lib/security/java.security`:

```
keystore type=BCFKS
ssl.keystore.type=BCFKS
```

Note

If you are using FIPS with BouncyCastle, you must create all client keys and certificates with the BCFKS store type, including the Vertica-to-Kafka keys and certificates.

6. Create the BCFKS-type keystore and truststore:

```
cd path/to/jre
-storetype BCFKS
-providername BCFIPS
-providerclass org.bouncycastle.jcajce.provider.BouncyCastleFipsProvider
-provider org.bouncycastle.jcajce.provider.BouncyCastleFipsProvider
-providerpath bc-fips-1.0.0.jar
-alias CARoot
-import -file path/to/server.crt.der
```

7. When prompted, enter the keystore password. The following message is displayed to confirm that a certificate was added to the keystore:

```
"Certificate was added to the keystore"
```

8. Run the Java program with SSL DB:

1. Copy the `vertica.kafka.keystore.bcfks` keyStore from `path/to/jre /lib/ext/` to the Java program folder.
2. Convert the Vertica server certificate to a form that Java understands:

```
$ path/to/java/bin/keytool -keystore verticastore -keypasswd -storepass password
-importkeystore -noprompt -alias verticasql -import -file server.crt.der
```

3. [Install JDBC](#).
9. Test the implementation:

```
$ java -Djavax.net.debug=ssl -Djavax.net.ssl.keyStore='vertica.kafka.keystore.bcfks'  
-Djavax.net.ssl.keyStorePassword='password'  
-Djavax.net.ssl.trustStore='path/to/verticastore'  
-Djavax.net.ssl.trustStorePassword='password'  
-cp .:vertica-jdbc-12.0.0-0.jar FIPSTest
```

Installing the FIPS client driver for ODBC and vsql

Vertica offers a FIPS client for FIPS-compatible systems. A FIPS-compatible system is FIPS-enabled and includes the OpenSSL libraries.

The FIPS client supports ODBC and vsql and is offered in 64-bit only.

Prerequisites

Verify that your host system is running a [FIPS-compliant operating system that Vertica supports](#).

The FIPS client installer checks your host system for the value of the sysctl parameter, `crypto.fips_enabled`. You must set this parameter to 1 (enabled). If your host is not enabled, the client does not install.

Installing the FIPS client

To install the FIPS client driver package:

1. Download the FIPS client package from the [Vertica driver downloads page](#).
2. Log in to the client system as root.
3. Install the RPM package that you downloaded:

```
# rpm -Uvh package_name.rpm
```

For ODBC, after you have installed the client package, create a DSN and set some additional configuration parameters. For more information, see:

- [Creating an ODBC DSN for Linux](#)
- [ODBC driver settings](#)

You can optionally add the vsql client to your PATH environment variable so that you do not need to enter its full path to run it. To do so, add the following to the `.profile` file in your home directory or the global `/etc/profile` file:

```
export PATH=$PATH:/opt/vertica/bin
```

How the client searches for OpenSSL libraries

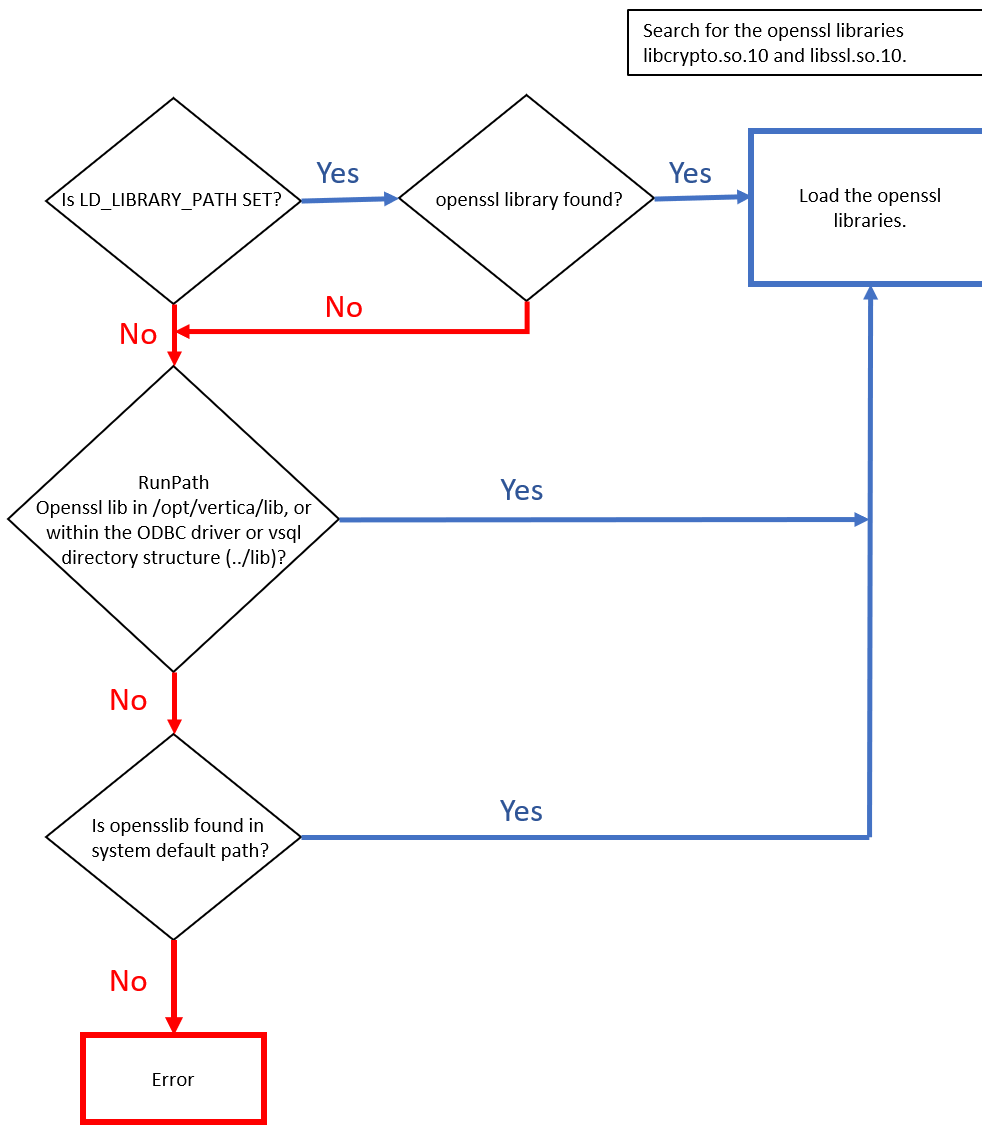

When you launch the client application to connect to the server, the client searches for and loads the OpenSSL libraries `libcrypto.so.10` and `libssl.so.10` for [supported OpenSSL versions](#):

- The client first checks to see if `LD_LIBRARY_PATH` is set.
- If the `LD_LIBRARY_PATH` location does not include the libraries, it checks `RunPath`, either `/opt/vertica/lib` or within the ODBC or vsql directory structure (`../lib`).

Important

The `LD_LIBRARY_PATH`, if set, directs the search path for the OpenSSL libraries. The client loads the libraries from any set or preset `LD_LIBRARY_PATH` location.

The following figure depicts the search process for the OpenSSL libraries:

JDBC client driver

The Vertica JDBC client driver conforms to JDK 5 specifications and provides an interface for communicating with the Vertica database with Java. For details on this and other APIs, see [API Reference](#).

To install the JDBC client driver, see [Installing the JDBC client driver](#).

In this section

- [Installing the JDBC client driver](#)
- [Modifying the Java CLASSPATH](#)

Installing the JDBC client driver

The JDBC client driver conforms to JDK 5 specifications. [Download the JDBC client driver](#) according to your environment and requirements. If you need a FIPS-compliant driver, see [Installing the FIPS client driver for JDBC](#).

Installing Vertica from the RPM automatically installs the JDBC client driver. To use the JDBC client driver, you just need to [add the Vertica JDBC .jar to your CLASSPATH](#).

To manually install the JDBC client driver:

1. [Download](#) the version of the JDBC client driver from the Client Drivers downloads page [compatible](#) with your version of Vertica.
2. Copy the `.jar` file to a directory in your Java CLASSPATH on every client system with which you want to access Vertica. You can either:
 - Copy the `.jar` file to its own directory (such as `/opt/vertica/java/lib`) and then add that directory to your CLASSPATH (recommended). See [Modifying the Java CLASSPATH](#) for details.
 - Copy the `.jar` file to directory that is already in your CLASSPATH (for example, a directory where you have placed other `.jar` files on which your application depends).

- Copy the `.jar` file to the system-wide Java Extensions directory. The exact location differs between operating systems. Some examples include:
 - Windows: `C:\Program Files\Java\jre<x.x_x>\lib\ext\`
 - Mac OS: `/Library/Java/Extensions` or `/Users/username/Library/Java/Extensions`
3. [Create a connection](#) to test your configuration.

Modifying the Java CLASSPATH

The CLASSPATH environment variable contains a list of directories where the Java runtime looks for library class files. For your Java client code to access Vertica, you must add to the CLASSPATH the directory containing the Vertica JDBC `.jar` .

Using symbolic links for the CLASSPATH

You can optionally add to the CLASSPATH a symbolic link `vertica-jdbc-x.x.x.jar` (where x.x.x is a version number) that points to the JDBC library `.jar` file, rather than the `.jar` file itself.

Using the symbolic link ensures that any updates to the JDBC library `.jar` file (which will use a different filename) will not invalidate your CLASSPATH setting, since the symbolic link's filename will remain the same. You just need to update the symbolic link to point at the new `.jar` file.

Linux and OS X

The following examples use a POSIX-compliant shell.

To set the CLASSPATH for the current session:

```
$ export CLASSPATH=$CLASSPATH:/opt/vertica/java/lib/vertica-jdbc-x.x.x.jar
```

To set the CLASSPATH for every session, add the following to your start-up file (such as `~/.profile` or `/etc/profile` :

```
$ export CLASSPATH=$CLASSPATH:/opt/vertica/java/lib/vertica-jdbc-x.x.x.jar
```

Windows

Provide the class paths to the `.jar` , `.zip` , or `.class` files.

```
C:> SET CLASSPATH=classpath1;classpath2...
```

For example:

```
C:> SET CLASSPATH=C:\java\MyClasses\vertica-jdbc-x.x.x.jar
```

As with the Linux/UNIX settings, this setting only lasts for the current session. To set the CLASSPATH permanently, set an environment variable:

1. On the Windows Control Panel, click **System** .
2. Click **Advanced** or **Advanced System Settings** .
3. Click **Environment Variables** .
4. Under User variables, click **New** .
5. In the Variable name box, type `CLASSPATH` .
6. In the Variable value box, type the path to the Vertica JDBC `.jar` file on your system (for example, `C:\Program Files (x86)\Vertica\JDBC\vertica-jdbc-x.x.x.jar`)

Specifying the library directory in the Java command

Another, OS-agnostic way to tell the Java runtime where to find the Vertica JDBC driver is to explicitly add the directory containing the `.jar` file to the Java command line using either the `-cp` or `-classpath` argument. For example, you can start your client application with:

```
java -classpath /opt/vertica/java/lib/vertica-jdbc-x.x.x.jar myapplication.class
```

Your Java IDE may also let you add directories to your CLASSPATH, or let you import the Vertica JDBC driver into your project. See your IDE documentation for details.

ODBC client driver

The Vertica ODBC client driver provides an interface for creating client applications with several languages:

- [C/C++](#)
- [Python](#)
- [Perl](#)
- [PHP](#)

To install ODBC, see [Installing the ODBC client driver](#).

In this section

- [Installing the ODBC client driver](#)
- [Upgrading and downgrading ODBC](#)
- [Uninstalling ODBC](#)
- [Creating an ODBC data source name \(DSN\)](#)
- [ODBC driver settings](#)
- [Configuring ODBC logs](#)

Installing the ODBC client driver

To install ODBC, follow the instructions according to your platform. For a list of supported platforms, see [Client drivers support](#).

This page covers a non-FIPS installation. To install ODBC on a FIPS-compliant system, see [Installing the FIPS client driver for ODBC and vsqsl](#).

Installing on Linux

Installing Vertica from the RPM automatically installs the ODBC client driver, so you do not need to install them again on the machine running Vertica. To use the ODBC client driver in this case, [create a DSN](#).

To install the ODBC client driver manually on other machines:

1. Log in to the client system as root.
2. Verify that your system has a [supported](#) ODBC driver manager.
3. Download the [ODBC client driver](#) for Linux in the format appropriate for your distribution.
4. Install or extract the driver:
 - If you downloaded the `.rpm`, install the driver:

Note

If the client driver is already installed on your system (either from a manual installation or from automatic installation from the Vertica RPM) and you attempt to reinstall them manually, you will receive error messages. To bypass these errors and overwrite the existing driver installations, use the `--force` flag.

```
$ rpm -Uvh driver_name.rpm
```

- If you downloaded the `.tar`, create the `/opt/vertica/` directory if it does not already exist, copy the `.tar` to it, navigate to it, and extract the `.tar`:

```
$ mkdir -p /opt/vertica/  
$ cp driver_name.tar.gz /opt/vertica/  
$ tar vzxvf driver_name.tar.gz
```

This creates two directories:

- `/opt/vertica/include`: Contains the header file.
- `/opt/vertica/lib64/` (64-bit) or `/opt/vertica/lib/` (32-bit): Contains library files.

5. Set the following ODBC driver settings in `vertica.ini`. For details on each, see [ODBC driver settings](#):
 - `ErrorMessagesPath`: Required, the path of the directory containing the ODBC driver's error message files.
 - `ODBCInstLib`: The path to the ODBC installer library. This is only required if the driver manager's installation library is not in the environment variables `LD_LIBRARY_PATH` or `LIB_PATH`.
 - `DriverManagerEncoding`: The UTF encoding standard used by the driver manager. This is only required if your driver manager does not use UTF-8.

The following is an example configuration in `vertica.ini`:

- Use encoding for the 64-bit UNIXODBC driver manager.
- Use the error messages defined in the standard Vertica 64-bit ODBC driver installation directory.
- [Log all warnings and more severe messages](#) to log files in `/tmp/`

```
[Driver]  
DriverManagerEncoding=UTF-16  
ODBCInstLib=/usr/lib64/libodbcinst.so  
ErrorMessagesPath=/opt/vertica  
LogLevel=4  
LogPath=/tmp
```

6. [Create a DSN](#).

Installing on macOS

Note

You can only have one installation per version of the ODBC driver on a macOS system. This is because each installation is identified by a package ID and version number, and package ID does not change between versions of the driver.

To install the ODBC client driver on macOS:

1. Verify that your system has a compatible driver manager. The driver is designed to be used with the standard [iODBC](#) Driver Manager that ships with macOS. You can also use [unixODBC](#).
2. [Download](#) the ODBC client driver.
3. If you installed a previous version of the ODBC driver, your system might already have a registered driver named "Vertica". You must remove or rename this older version of the driver before installing a new version from the `.pkg` installer. Renaming the older version allows you to retain the old version after you install the new one.
4. Run the installer.
5. [Create a DSN](#).

Installing silently

1. Log into the client macOS in one of two ways:
 - As an administrator account if you are installing the driver for system-wide use.
 - As the user who needs to use the Vertica ODBC driver.
2. Open a terminal.
3. Install the `.pkg` file containing the ODBC driver using the command:

```
sudo installer -pkg path/to/client/driver/vertica-odbc-xx.x.x-x.pkg -target /
```

Installing on Windows

To install the ODBC client driver on Windows:

1. [Download](#) the client driver installer for Windows.
2. Run the installer.
3. [Create a DSN](#).

Installing silently

1. Open a terminal as an Administrator.
2. Run the following command to silently install the drivers to `C:\Program Files\Vertica Systems` :

```
VerticaSetup.exe -q -install InstallFolder="C:\Program Files\Vertica Systems"
```

Upgrading and downgrading ODBC

Linux

To upgrade ODBC:

1. [Uninstall](#) the current version of the driver.
2. [Install](#) the new version of the driver.

macOS

To upgrade or downgrade ODBC:

- **Upgrade** : Newly installed versions of the Vertica ODBC driver for macOS automatically upgrade the relevant driver system settings. Any DSNs associated with a previous version of the driver are not affected, except that they begin using the newer version of the driver.
- **Downgrade** : Run the uninstall script to remove the current version of the Vertica ODBC driver for macOS. Complete this step before installing an older driver version.

Windows

1. [Download](#) the Windows client driver installer.
2. Run the installer and follow the prompts to upgrade the driver. The installer upgrades existing drivers in place.
3. Reboot your system.

Uninstalling ODBC

Linux

If you installed ODBC with the `.rpm` :

```
$ rpm -e package_name
```

If you installed ODBC with the `.tar` , delete the directory manually.

macOS

Uninstalling the macOS ODBC Client-Driver does not remove any existing DSNs associated with the driver.

To uninstall:

1. Open a terminal window.
2. Run the command:

```
sudo /Library/Vertica/ODBC/bin/Uninstall
```

Windows

1. Open the **Add or Remove Programs** menu.
2. Either uninstall the **Vertica Client Installer** to remove all client drivers from the system or, to only uninstall ODBC, uninstall the following applications:
 - Vertica ODBC Driver (32 Bit)
 - Vertica ODBC Driver (64 Bit)

Creating an ODBC data source name (DSN)

A Data Source Name (DSN) is the logical name that is used by Open Database Connectivity (ODBC) to refer to the driver and other information that is required to access data from a data source. Whether you are developing your own ODBC client code or you are using a third-party tool that needs to access Vertica using ODBC, you need to configure and test a DSN. The method you use depends upon the client operating system you are using.

Refer to the following sections for information specific to your client operating system.

In this section

- [Creating an ODBC DSN for Linux](#)
- [Creating an ODBC DSN for windows clients](#)
- [Creating an ODBC DSN for macOS clients](#)
- [ODBC DSN connection properties](#)
- [Setting DSN connection properties](#)

Creating an ODBC DSN for Linux

You define DSN on Linux and other UNIX-like platforms in a text file. Your client's driver manager reads this file to determine how to connect to your Vertica database. The driver manager usually looks for the DSN definitions in two places:

- `/etc/odbc.ini`
- `~/odbc.ini` (a file named `.odbc.ini` in the user's home directory)

Users must be able to read the `odbc.ini` file in order to use it to connect to the database. If you use a global `odbc.ini` file, consider creating a UNIX group with read access to the file. Then, add the users who need to use the DSN to this group.

The structure of these files is the same—only their location differs. If both files are present, the `~/odbc.ini` file usually overrides the system-wide `/etc/odbc.ini` file.

Note

See your ODBC driver manager's documentation for details on where these files should be located and any other requirements.

odbc.ini file structure

The `odbc.ini` is a text file that contains two types of lines:

- Section definitions, which are text strings enclosed in square brackets.
- Parameter definitions, which contain a parameter name, an equals sign (=), and then the parameter's value.

Caution

The unixODBC driver manager supports parameter values of up to 1000 characters in `odbc.ini`. If your parameter value is greater than 1000 characters (for example, OAuthAccessToken), you must pass it through a [connection string](#) rather than specifying it in `odbc.ini`.

The first section of the file is always named [ODBC Data Sources], and contains a list of all the DSNs that the `odbc.ini` file defines. The parameters in this section are the names of the DSNs, which appear as section definitions later in the file. The value is a text description of the DSN and has no function. For example, an `odbc.ini` file that defines a single DSN named Vertica DSN could have this ODBC Data Sources section:

```
[ODBC Data Sources]
VerticaDSN = "vmartdb"
```

Appearing after the ODBC data sources section are sections that define each DSN. The name of a DSN section must match one of the names defined in the ODBC Data Sources section.

Configuring the `odbc.ini` file:

To create or edit the DSN definition file:

1. Using the text editor of your choice, open `odbc.ini` or `~/odbc.ini`.
2. Create an ODBC Data Sources section and define a parameter:
 - Whose name is the name of the DSN you want to create
 - Whose value is a description of the DSN

For example, to create a DSN named VMart, you would enter:

```
[ODBC Data Sources]
VMart = "VMart database on Vertica"
```

3. Create a section whose name matches the DSN name you defined in step 2. In this section, you add parameters that define the DSN's settings. The most commonly-defined parameters are:
 - **Description** – Additional information about the data source.
 - **Driver** – The location and designation of the Vertica ODBC driver, or the name of a driver defined in the `odbcinst.ini` file (see below). For future compatibility, use the name of the symbolic link in the library directory, rather than the library file:
 - `/opt/vertica/lib`, on 32-bit clients
 - `/opt/vertica/lib64`, on 64-bit clients

For example, the symbolic link for the 64-bit ODBC driver library is:

```
/opt/vertica/lib64/libverticaodbc.so
```

The symbolic link always points to the most up-to-date version of the Vertica client ODBC library. Use this link so that you do not need to update all of your DSNs when you update your client drivers.

- **Database** – The name of the database running on the server. This example uses `vmartdb` for the `vmartdb`.
- **ServerName** — The name of the server where Vertica is installed. Use `localhost` if Vertica is installed on the same machine. You can provide an IPv4 address, IPv6 address, or host name. In mixed IPv4/IPv6 networks, the DNS server configuration determines which IP version address is sent first. Use the [PreferredAddressFamily](#) option to force the connection to use either IPv4 or IPv6.
- **UID** — Either the database superuser (same name as database administrator account) or a user that the superuser has created and granted privileges. This example uses the user name `dbadmin`.
- **PWD** — The password for the specified user name. This example leaves the password field blank.
- **Port** — The port number on which Vertica listens for ODBC connections. For example, `5433`.
- **ConnSettings** — Can contain SQL commands separated by a semicolon. These commands can be run immediately after connecting to the server.
- **SSLKeyFile** — The file path and name of the client's private key. This file can reside anywhere on the system.
- **SSLCertFile** — The file path and name of the client's public certificate. This file can reside anywhere on the system.
- **Locale** — The default locale used for the session. By default, the locale for the database is: `en_US@collation=binary` (English as in the United States of America). Specify the locale as an ICU Locale. See the ICU User Guide (<http://userguide.icu-project.org/locale>) for a complete list of parameters that can be used to specify a locale.
- **PreferredAddressFamily** :
The IP version to use if the client and server have both IPv4 and IPv6 addresses and you have provided a host name, one of the following:
 - `ipv4` : Connect to the server using IPv4.
 - `ipv6` : Connect to the server using IPv6.
 - `none` : Use the IP address provided by the DNS server.

For example:

```
[VMart]
Description = Vmart Database
Driver = /opt/vertica/lib64/libverticaodbc.so
Database = vmartdb
Servername = host01
UID = dbadmin
PWD =
Port = 5433
ConnSettings =
AutoCommit = 0
SSLKeyFile = /home/dbadmin/client.key
SSLCertFile = /home/dbadmin/client.crt
Locale = en_US@collation=binary
```

See [ODBC DSN connection properties](#) for a complete list of parameters including Vertica-specific ones.

Using an `odbcinst.ini` file

Instead of giving the path of the ODBC driver library in your DSN definitions, you can use the name of a driver defined in the `odbcinst.ini` file. This method is useful if you have many DSNs and often need to update them to point to new driver libraries. It also allows you to set some additional ODBC parameters, such as the threading model.

Just as in the `odbc.ini` file, `odbcinst.ini` has sections. Each section defines an ODBC driver that can be referenced in the `odbc.ini` files.

In a section, you can define the following parameters:

- **Description** — Additional information about the data source.
- **Driver** — The location and designation of the Vertica ODBC driver, such as `/opt/vertica/lib64/libverticaodbc.so`

For example:

```
[Vertica]
Description = Vertica ODBC Driver
Driver = /opt/vertica/lib64/libverticaodbc.so
```

Then, in your `odbc.ini` file, use the name of the section you created in the `odbcinst.ini` file that describes the driver you want to use. For example:

```
[VMart]
Description = Vertica Vmart database
Driver = Vertica
```

If you are using the unixODBC driver manager, you should also add an ODBC section to override its standard threading settings. By default, unixODBC serializes all SQL calls through ODBC, which prevents multiple parallel loads. To change this default behavior, add the following to your `odbcinst.ini` file:

```
[ODBC]
Threading = 1
```

Configuring additional ODBC settings

On Linux and UNIX systems, you need to configure some additional driver settings before you can use your DSN. See [ODBC driver settings](#) for details.

In this section

- [Testing an ODBC DSN using isql](#)

Testing an ODBC DSN using `isql`

The unixODBC driver manager includes a utility named `isql`, which is a simple ODBC command-line client. It lets you to connect to a DSN to send commands and receive results, similarly to `vsq`.

To use `isql` to test a DSN connection:

1. Run the following command:

```
$ isql -v DSNname
```

Where *DSNname* is the name of the DSN you created.

A connection message and a SQL prompt display. If they do not, you could have a configuration problem or you could be using the wrong user name or password.

2. Try a simple SQL statement. For example:

```
SQL> SELECT table_name FROM tables;
```

The isql tool returns the results of your SQL statement.

Note

If you have not set the `ErrorMessagesPath` in the additional driver configuration settings, any errors during testing will trigger a missing error message file ("The error message `NoSQLGetPrivateProfileString` could not be found in the en-US locale"). See [ODBC driver settings](#) for more information.

Creating an ODBC DSN for windows clients

To create a DSN for Microsoft Windows clients, you must perform the following tasks:

In this section

- [Setting up an ODBC DSN](#)
- [Encrypting passwords on ODBC DSN](#)
- [Testing an ODBC DSN using Excel](#)

Setting up an ODBC DSN

A *Data Source Name (DSN)* is the ODBC logical name for the drive and other information the database needs to access data. The name is used by Internet Information Services (IIS) for a connection to an ODBC data source.

This section describes how to use the Vertica ODBC Driver to set up an ODBC DSN. This topic assumes that the driver is already installed, as described in [Installing Client Drivers on Windows](#).

To set up a DSN

1. Open the ODBC Administrator. For example, you could navigate to **Start > Control Panel > Administrative Tools > Data Sources (ODBC)**.

Note

The method you use to open the ODBC Administrator depends on your version of Windows. Differences between Windows versions and **Start Menu** customizations could require you to take a different action to open the ODBC Administrator.

2. Decide if you want all users on your client system to be able to access to the DSN for the Vertica database.
 - If you want all users to have access, then click the **System DSN** tab.
 - Otherwise, click the **User DSN** tab to create a DSN that is only usable by your Windows user account.
3. Click **Add** to create a new DSN to connect to the Vertica database.
4. Scroll through the list of drivers in the Create a New Data Source dialog box to locate the Vertica driver. Select the driver, and then click **Finish**.

Note

If you have installed more than one version of the Vertica client drivers on your Windows client system, you may see multiple versions of the driver in this list. Choose the version that you know is compatible with your client application and Vertica Analytic Database server. If you are unsure, use the latest version of the driver.

The Vertica ODBC DSN configuration dialog box appears.

5. Click the **More >>>** button to view a description of the field you are editing and the connection string defined by the DSN.
6. Enter the information for your DSN. The following fields are required:
 - **DSN Name** — The name for the DSN. Clients use this name to identify the DSN to which they want to connect. The DSN name must satisfy the following requirements:
 - Its maximum length is 32 characters.
 - It is composed of ASCII characters except for the following: `[] ; , ? * = ! @ \`
 - It contains no spaces.
 - **Server** — The host name or IP address of the Vertica server to which you want to connect. Use localhost, if Vertica is installed on the same machine.

You can provide an IPv4 address, IPv6 address, or host name.

In mixed IPv4/IPv6 networks, the DNS server configuration determines which IP version address is sent first. Use the [PreferredAddressFamily](#)

option to force the connection to use either IPv4 or IPv6.

The **PreferredAddressFamily** option is available on the Client Settings tab.

- **Backup Servers** — A comma-separated list of host names or IP addresses used to connect to if the server specified by the Server field is down. Optional.
- **Database** —The name of the Vertica database.
- **User Name** — The name of the user account to use when connecting to the database. If the application does not supply its own user name when connecting to the DSN, this account name is used to log into the database.

The rest of the fields are optional. See [DSN Parameters](#) for detailed information about the DSN parameters you can define.

7. If you want to test your connection:

1. Enter at least a valid **DSN name** , **Server name** , **Database** , and either **User name** or select **Windows authentication** .
2. If you have not selected **Windows authentication** , you can enter a password in the **Password** box. Alternately, you can select **Password for missing password** to have the driver prompt you for a password when connecting.

Caution

Passwords entered into the **Password** box are saved, in plaintext, to the Windows registry.

3. Click **Test Connection** .

8. When you have finished editing and testing the DSN, click **OK** . The Vertica ODBC DSN configuration window closes, and your new DSN is listed in the ODBC Data Source Administrator window.

9. Click **OK** to close the ODBC Data Source Administrator.

After creating the DSN, you can test it using [Microsoft Excel 2007](#) .

Setting up a 32-Bit DSN on 64-Bit versions of Microsoft windows

On 64-bit versions of Windows, the default ODBC Data Source Administrator creates and edits DSNs that are associated with the 64-bit Vertica ODBC library.

Attempting to use these 64-bit DSNs with a 32-bit client application results in an architecture mismatch error. Instead, you must create a specific 32-bit DSN for 32-bit clients by running the 32-bit ODBC Administrator usually located at:

```
c:\Windows\SysWOW64\odbcad32.exe
```

This administrator window edits a set of DSNs that are associated with the 32-bit ODBC library. You can then use your 32-bit client applications with the DSNs you create with this version of the ODBC administrator.

Encrypting passwords on ODBC DSN

When you install an ODBC driver and create a Data Source Name (DSN) the DSN settings are stored in the registry, including the password. Encrypting passwords on ODBC DSN applies only to Windows systems.

Encrypting passwords on an ODBC data source name (DSN) provides security against unauthorized database access. The password is not encrypted by default and is stored in plain-text.

Note

ODBC DSN passwords that were created in Vertica $\leq 8.0.x$ are not encrypted when you upgrade to a higher version, regardless of encryption settings.

Enable password encryption

Use the **EncryptPassword** parameter to enable or disable password encryption for an ODBC DSN:

- **EncryptPassword = true** enables password encryption
- **EncryptPassword = false** (default) disables password encryption

Set **EncryptPassword** in the Windows registry - **HKEY_LOCAL_MACHINE > Software > Vertica > ODBC > Driver EncryptPassword=<true/false>** .

Note

For 32 bit driver running on 64 bit windows verify password encryption here:

```
HKEY_LOCAL_MACHINE > Software > Wow6432Node > Vertica > ODBC >
```

Encrypted passwords get updated in the following registry locations:

For a user DSN:

HKEY_CURRENT_USER-> Software -> ODBC -> ODBC.INI -> DSNNAME -> PWD

For a system DSN:

HKEY_LOCAL_MACHINE-> Software -> ODBC -> ODBC.INI -> DSNNAME -> PWD

Verify password encryption

Use Windows Registry editor to determine if password encryption is enabled based on the value of EncryptPassword. Depending on the type of DSN you installed, check the following:

For a user DSN: HKEY_CURRENT_USER > Software > ODBC > ODBC.INI > dsn name > isPasswordEncrypted=<1/0>

For a system DSN: HKEY_LOCAL_MACHINE > Software > ODBC > ODBC.INI > dsn name > isPasswordEncrypted=<1/0>

For each DSN, the value of the **isPasswordEncrypted** parameter indicates the status of the password encryption, where **1** indicates an encrypted password and **0** indicates an unencrypted password.

Testing an ODBC DSN using Excel

You can use Microsoft Excel to verify that an application can connect to an ODBC data source or other ODBC application.

1. Open Microsoft Excel, and select **Data > Get External Data > From Other Sources > From Microsoft Query .**
2. When the Choose Data Source dialog box opens:
 1. Select **New Data Source** , and click **OK** .
 2. Enter the name of the data source.
 3. Select the Vertica driver.
 4. Click **Connect** .
3. When the Vertica Connection Dialog box opens, enter the connection information for the DSN, and click **OK** .
4. Click **OK** on the Create New Data Source dialog box to return to the Choose Data Source dialog box.
5. Select VMart_Schema*, and verify that the Use the Query Wizard check box is deselected. Click **OK** .
6. When the Add Tables dialog box opens, click **Close** .
7. When the Microsoft Query window opens, click the **SQL** button.
8. In the SQL window, write any simple query to test your connection. For example:

```
SELECT DISTINCT calendar_year FROM date_dimension;
```

* If you see the caution, "SQL Query can't be represented graphically. Continue anyway?" click ****OK****. * The data values 2003, 2004, 2005, 2006, 2007 indicate that you successfully connected to and ran a query through ODBC.

10. Select **File > Return Data to Microsoft Office Excel** .
11. In the Import Data dialog box, click **OK** .
The data is now available for use in an Excel worksheet.

Creating an ODBC DSN for macOS clients

You can use the Vertica ODBC Driver to set up an ODBC DSN. This procedure assumes that the driver is already installed, as described in [Installing the ODBC client driver](#).

Setting up a DSN

1. Using your web browser, download and install the Apple [ODBC Administrator Tool](#).
2. Locate and open the ODBC Administrator Tool after installation:
 1. Navigate to **Finder > Applications > Utilities** .
 2. Open the ODBC Administrator Tool.

3. Click the **Drivers** tab, and verify that the Vertica driver is installed.

4. Specify if you want all users on your client system to be able to access the DSN for the Vertica database:
 - If you want all users to have access, then click the **System DSN** tab.
 - Otherwise, click the **User DSN** tab to create a DSN that is only usable by your Macintosh user account.
5. Click **Add...** to create a new DSN to connect to the Vertica database.
6. Scroll through the list of drivers in the Choose A Driver dialog box to locate the Vertica driver. Select the driver, and then click **OK** . A dialog box opens that requests DSN parameter information.
7. In the dialog box, enter the **Data Source Name (DSN)** and an optional **Description** . To do so, click **Add** to insert keywords (parameters) and values that define the settings needed to connect to your database, including database name, server host, database user name (such as dbadamin), database password, and port. Then, click **OK** .
8. In the ODBC Administrator dialog box, click **Apply** .
See [ODBC DSN connection properties](#) for a complete list of parameters including those specific to Vertica.

After configuring the ODBC Administrator Tool, you may need to configure additional driver settings before you can use your DSN, depending on your environment. See [Additional ODBC Driver Configuration Settings](#) for details.

Note

To test your connection, use the `iodbctest` utility. For details, see [Testing an ODBC DSN using iodbctest](#).

In this section

- [Testing an ODBC DSN using iodbctest](#)

Testing an ODBC DSN using iodbctest

The standard iODBC Driver Manager on OS X includes a utility named `iodbctest` that lets you test a DSN to verify that it is correctly configured. You pass this command a connection string in the same format that you would use to open an ODBC database connection. After configuring your DSN connection, you can run a query to verify that the connection works.

For example:

```
# iodbctest "DSN=VerticaDSN;UID=dbadmin;PWD=password"
iODBC Demonstration program
This program shows an interactive SQL processor
Driver Manager: 03.52.0607.1008
Driver: 07.01.0200 (verticaodbcw.so)
SQL> SELECT table_name FROM tables;
table_name
-----
customer_dimension
product_dimension
promotion_dimension
date_dimension
vendor_dimension
employee_dimension
shipping_dimension
warehouse_dimension
inventory_fact
store_dimension
store_sales_fact
store_orders_fact
online_page_dimension
call_center_dimension
online_sales_fact
numbers
result set 1 returned 16 rows.
```

ODBC DSN connection properties

The following tables list the connection properties you can set in the DSNs for use with Vertica's ODBC driver. To set these parameters, see [Setting DSN connection properties](#).

Required connection properties

These connection properties are the minimum required to create a functioning DSN.

Note

If you use a host name (Servername) whose DNS entry resolves to multiple IP addresses, the client attempts to connect to the first IP address returned by the DNS. If a connection cannot be made to the first address, the client attempts to connect to the second, then the third, continuing until it either connects successfully or runs out of addresses.

Property	Description
Driver	The file path and name of the driver used.
Database	The name of the database running on the server.
Servername	<p>The host name or IP address of any active node in a Vertica cluster.</p> <p>You can provide an IPv4 address, IPv6 address, or host name.</p> <p>In mixed IPv4/IPv6 networks, the DNS server configuration determines which IP version address is sent first. Use the PreferredAddressFamily option to force the connection to use either IPv4 or IPv6.</p> <p>You can also use the aliases "server" and "host" for this property.</p>
UID	The database username.

Optional properties

Property	Description
Port	The port number on which Vertica listens for ODBC connections. Default: 5433
PWD	The password for the specified user name. You may insert an empty string to leave this property blank. Default: None, login only succeeds if the user does not have a password set.
PreferredAddressFamily	The IP version to use if the client and server have both IPv4 and IPv6 addresses and you have provided a host name, one of the following: <ul style="list-style-type: none"> • ipv4 : Connect to the server using IPv4. • ipv6 : Connect to the server using IPv6. • none : Use the IP address provided by the DNS server. Default: none

Advanced settings

Property	Description
AutoCommit	A Boolean value that controls whether the driver automatically commits transactions after executing a DML statement. Default: true
BackupServerNode	A string containing the host name or IP address that client libraries can try to connect to if the host specified in ServerName is unreachable. Connection attempts continue until successful or until the list of server nodes is exhausted. Valid values: Comma-separated list of servers optionally followed by a colon and port number.
ConnectionLoadBalance	A Boolean value that indicates whether the connection can be redirected to a host in the database other than the ServerNode. This affects the connection only if the load balancing is set to something other than "none". When the node differs from the node the client is connected to, the client disconnects and reconnects to the targeted node. See About Native Connection Load Balancing in the Administration Guide. Default: false
ConnSettings	A string containing SQL commands that the driver should execute immediately after connecting to the server. You can use this property to configure the connection, such as setting a schema search path. Reserved symbol: In the connection string semicolon (;) is a reserved symbol. To set multiple properties as part of ConnSettings properties, use %3B as the comma delimiter, and + (plus) for spaces.
ConnectionTimeout	The number of seconds to wait for a request to complete before returning to the client application. This is equivalent to the SQL_ATTR_CONNECTION_TIMEOUT parameter in the ODBC API. Default : 0 (no timeout)

ConvertSquareBracketIdentifiers	Controls whether square-bracket query identifiers are converted to a double quote identifier for compatibility when making queries to a Vertica database. Default: false
DirectBatchInsert	Deprecated, always set to true.
DriverStringConversions	Controls whether the ODBC driver performs type conversions on strings sent between the ODBC driver and the database. Possible values are: <ul style="list-style-type: none"> • NONE: No conversion in either direction. This results in the highest performance. • INPUT: Strings sent from the client to the server are converted, but strings sent from the server to the client are not. • OUTPUT: Strings sent by the server to the client are converted, but strings sent from the client to the server are not. • BOTH: Strings are converted in both directions. Default: OUTPUT
Locale	The locale used for the session. Specify the locale as an ICU Locale. **See **the ICU User Guide for a complete list of properties that can be used to specify a locale. Default: en_US@collation=binary
PromptOnNoPassword	[Windows only] Controls whether users are prompted to enter a password, if none is supplied by the connection string or DSN used to connect to Vertica. See Prompting windows users for passwords . Default: false
ReadOnly	A true or false value that controls whether the connection can read data only from Vertica. Default: false
ResultBufferSize	Size of memory buffer for the large result sets in streaming mode. A value of 0 means ResultBufferSize is turned off. Default: 131072 (128KB)
TransactionIsolation	Sets the transaction isolation for the connection, one of the following: <ul style="list-style-type: none"> • Read Committed • Serializable • Server Default See Changing Transaction Isolation Levels for an explanation of transaction isolation. Default: Server Default
Workload	The name of the workload for the session. For details, see Workload routing . Default: None (no workload)

Identification

Property	Description	Standard/ Vertica
----------	-------------	----------------------

Description	Description for the DSN entry. Required? No Insert an empty string to leave the description empty.	Standard
Label / SessionLabel	Sets a label for the connection on the server. This value appears in the client_label column of the V_MONITOR.SESIONS system table. Label and SessionLabel are synonyms and can be used interchangeably.	Vertica

OAuth connection properties

The following connection properties pertain to [OAuth](#) in ODBC.

Caution

The unixODBC driver manager supports parameter values of up to 1000 characters in `odbc.ini`. If your parameter value is greater than 1000 characters (for example, `OAuthAccessToken`), you must pass it through a [connection string](#) rather than specifying it in `odbc.ini`.

Property	Description
OAuthAccessToken	<p>Required if OAuthRefreshToken is unspecified, an OAuth token that authorizes a user to the database.</p> <p>Either OAuthAccessToken or OAuthRefreshToken must be set (programmatically or manually) to authenticate to Vertica with OAuth authentication.</p> <p>You can omit both OAuthAccessToken and OAuthRefreshToken only if you authenticate to your identity provider directly with single sign-on through the client driver, which requires the machine running the ODBC driver to have access to a web browser.</p> <p>For details on the different methods for retrieving access tokens, see Retrieving access tokens.</p>
OAuthRefreshToken	<p>Deprecated Use OAuthAccessToken instead. Token refresh should be handled by the client application separately.</p> <p>Required if OAuthAccessToken is unspecified, a token that used to obtain a new access token when their old one expires. Either OAuthAccessToken or OAuthRefreshToken must be set (programmatically or manually) to authenticate to Vertica with OAuth authentication.</p> <p>You can omit both OAuthAccessToken and OAuthRefreshToken only if you authenticate to your identity provider directly with single sign-on through the client driver, which requires the machine running the ODBC driver to have access to a web browser.</p> <p>For details on the different methods for retrieving access tokens, see Retrieving access tokens.</p> <p>If you set this parameter, you must also set the OAuthClientSecret connection property.</p> <p>In cases where introspection fails (e.g. when the access token expires), Vertica responds to the request with an error. If introspection fails and OAuthRefreshToken is specified, the driver attempts to refresh and silently retrieve a new access token. Otherwise, the driver passes error to the client application.</p>

OAuthClientSecret	<p>Deprecated Use OAuthAccessToken instead. Token refresh should be handled by the client application separately.</p> <p>The secret provided by your identity provider for your client. This parameter is required for confidential clients.</p>
-------------------	---

Encryption

Property	Description	Standard/ Vertica
SSLMode	<p>Controls whether the connection to the database uses SSL encryption, one of the following. For information on using these parameters to configure TLS, see Configuring TLS for ODBC Clients :</p> <ul style="list-style-type: none"> require : Requires that the server use TLS. If the TLS connection attempt fails, the client rejects the connection. prefer : Prefers that the server use TLS. The client first attempts to connect using TLS. If that attempt fails, the client attempts to connect again in plaintext. allow : Makes a connection to the server whether the server uses TLS or not. The first connection attempt to the database is attempted over a clear channel. If that fails, a second connection is attempted over TLS. verify_ca : The client verifies that the server's certificate was issued by a trusted certificate authority (CA). verify_full : The client verifies that the following conditions are met: <ul style="list-style-type: none"> The server's certificate was issued by a trusted CA. One of the following: <ul style="list-style-type: none"> The server's hostname matches the common name specified in the server's certificate. The server's hostname or IP address appears in the Subject Alternative Name (SAN) field of the server's certificate. disable : Never connect to the server using TLS. This setting is typically used for troubleshooting. <p>Default: prefer</p>	Vertica
SSLCertFile	The absolute path of the client's public certificate file. This file can reside anywhere on the system.	Vertica
SSLKeyFile	The absolute path to the client's private key file. This file can reside anywhere on the system.	Vertica

Third-party compatibility

Property	Description	Default	Standard/ Vertica
ColumnsAsChar	<p>Specifies how character column types are reported when the driver is in Unicode mode. When set to false, the ODBC driver reports the data type of character columns as WCHAR. If you set ColumnsAsChar to true, the driver identifies character column as CHAR.</p> <p>You typically use this setting for compatibility with some third-party clients.</p> <p>Default: false</p>	false	Vertica

ThreePartNaming	<p>A Boolean value that controls how catalog names are interpreted by the driver. When this value is false, the driver reports that catalog names are not supported. When catalog names are not supported, they cannot be used as a filter in database metadata API calls. In this case, the driver returns NULL as the catalog name in all driver metadata results.</p> <p>When this value is true, catalog names can be used as a filter in database metadata API calls. In this case, the driver returns the database name as the catalog name in metadata results. Some third-party applications assume a certain catalog behavior and do not work properly with the default values. Enable this option if your client software expects to get the catalog name from the database metadata and use it as part of a three-part name reference.</p> <p>Default: false for UNIX, true for Windows</p>	<p>false (UNIX)</p> <p>true (Window)</p>	Vertica
EnforceBatchInsertNullConstraints	<p>Prevents NULL values from being loaded into columns with a NOT NULL constraint during batch inserts. When this value is set to true, batch inserts roll back when NULL values are inserted in to columns with NOT NULL constraints. When this value is set to false, batch insert behavior is unchanged.</p> <p>Vertica recommends only using this property with SAP Data Services as it could negatively impact database performance.</p>	false	Vertica

Kerberos connection properties

Use the following properties for client authentication using Kerberos.

Property	Description	Standard/ Vertica
KerberosServiceName	<p>Provides the service name portion of the Vertica Kerberos principal; for example: <code>vertichost@EXAMPLE.COM</code></p> <p>Default: vertica</p>	Vertica
KerberosHostname	<p>Provides the instance or host name portion of the Vertica Kerberos principal; for example: <code>verticaosEXAMPLE.COM</code></p> <p>Default: Value specified in the servername connection string property</p>	Vertica

[ODBC driver settings](#)

Setting DSN connection properties

The properties in the following tables are common for all user and system DSN entries. The examples provided are for Windows clients.

To edit DSN properties:

- On UNIX and Linux client platforms, you can edit the `odbc.ini` file. The location of this file is specific to the driver manager. See [Creating an ODBC DSN for Linux](#).
- On Windows client platforms, you can edit some DSN properties using the Vertica ODBC client driver interface. See [Creating an ODBC DSN for windows clients](#).
- You can also edit the DSN properties directly by opening the DSN entry in the Windows registry (for example, at `HKEY_LOCAL_MACHINE\SOFTWARE\ODBC\ODBC.INI\DSNname`). Directly editing the registry can be risky, so you should only use this method for properties that cannot be set through the ODBC driver's user interface, or via your client code.
- You can set properties in the connection string when opening a connection using the `SQLDriverConnect()` function:

```
sqlRet = SQLDriverConnect(sql_hDBC, 0, (SQLCHAR*)"DSN=DSNName;Locale=en_GB@collation=binary", SQL_NTS, szDNS, 1024,&nSize, SQL_DRIVER_NOPROMPT);
```

Note

In the connection string ';' is a reserved symbol. If you need to set multiple properties as part of the ConnSettings property use '%3B' in place of ';'. Also use '+' instead of spaces.

For example:

```
sqlRet = SQLDriverConnect(sql_hDBC, 0, (SQLCHAR*)"DSN=Vertica
SQL;ConnSettings=set+search_path+to+a,b,c%3Bset+locale=ch;SSLMode=prefer", SQL_NTS,
szDNS, 1024,&nSize, SQL_DRIVER_NOPROMPT);
```

- Your client code can retrieve DSN property values after a connection has been made to Vertica using the [SQLGetConnectAttr\(\)](#) and [SQLGetStmtAttr\(\)](#) API calls. Some properties can be set and using [SQLSetConnectAttr\(\)](#) and [SQLSetStmtAttr\(\)](#) . For details of the list of properties specific to Vertica see [ODBC Header Files specific to Vertica](#) .

ODBC driver settings

Note

While required settings are required for all platforms, these settings automatically set by the Windows and macOS [installers](#) , so all directives to change these settings are for Linux users.

- **DriverManagerEncoding** : The UTF encoding standard used by the driver manager. This can be one of the following:
 - UTF-8
 - UTF-16
 - UTF-32

The ODBC driver encoding must match that of your driver manager. The following table lists default encodings for various platforms that take effect if you do not set this parameter. If the defaults do not match the encoding used by your driver manager, you must set it manually. Consult your driver manager's documentation for details on its encoding.

Note

While both UTF-16 and UTF-8 are valid settings for the DataDirect driver manager, UTF-16 is recommended.

Client Platform	Default Encoding
Linux 32-bit	UTF-32
Linux 64-bit	UTF-32
Linux Itanium 64-bit	UTF-32
OS X	UTF-32
Windows 32-bit	UTF-16
Windows 64-bit	UTF-16

- **ErrorMessagesPath** : Required, the path of the directory containing the ODBC driver's error message files. These files ([ODBCMessages.xml](#) and [VerticaMessages.xml](#)) are stored in the same directory as the Vertica ODBC driver files (for example, [opt/vertica/en-US](#) in the [downloaded .tar](#)).
- **ODBCInstLib** : The path to the ODBC installer library. This setting is only required if the directory containing the library is not set in the [LD_LIBRARY_PATH](#) or [LIB_PATH](#) environment variables. The library files for the major driver managers are:
 - UnixODBC: [libodbcinst.so](#)
 - iODBC: [libodbcinst.so](#) ([libodbcinst.2.dylib](#) on macOS)
 - DataDirect: [libodbcinst.so](#)

You can also control client-server message logging for both ODBC and ADO.NET. For details, see [Configuring ODBC logs](#) .

Linux and macOS

To set these parameters on Linux or macOS:

1. Create a file `vertica.ini` anywhere on the client system. Common locations are in `/etc/` for a shared configuration, or the home directory for a per-user configuration.
2. Verify that users of the ODBC driver have read privileges on the file.
3. Set the `VERTICAINI` environment variable to the path of `vertica.ini`. For example:

```
$ export VERTICAINI=/etc/vertica.ini
```

1. Create a section called `[Driver]` in `vertica.ini`:

```
[Driver]
```

1. Under `[Driver]`, set parameters with the following format. Each parameter must have its own line:

```
[Driver]
DriverManagerEncoding=UTF-16
ODBCInstLib=/usr/lib64/libodbcinst.so
```

Windows

The Windows [client driver installer](#) automatically configures all necessary settings for the ODBC driver. Settings are stored in the registry in `HKEY_LOCAL_MACHINE\SOFTWARE\Vertica\ODBC\Driver`.

If you want to configure ODBC further, use the **ODBC Data Sources** program.

Configuring ODBC logs

The following parameters control whether and how the ODBC client driver logs messages between the client and server.

The way you set these parameters differs between operating systems:

- On Linux and macOS, edit `vertica.ini` you created during the [installation](#). For example, to log all warnings and more severe messages to log files in `/tmp/`:

```
[Driver]
LogLevel=4
LogPath=/tmp
```

- On Windows, edit the keys in the Windows Registry under `HKEY_LOCAL_MACHINE\SOFTWARE\Vertica\ODBC\Driver`.

Parameters

- **LogLevel**: The severity of messages that are logged between the client and the server. The valid values are:
 - 0: No logging
 - 1: Fatal errors
 - 2: Errors
 - 3: Warnings
 - 4: Info
 - 5: Debug
 - 6: Trace (all messages)

The value you specify for this setting sets the minimum severity for a message to be logged. For example, setting `LogLevel` to 3 means that the client driver logs all warnings, errors, and fatal errors.

- **LogPath**: The absolute path of a directory to store log files. For example: `/var/log/verticaodbc`

Diverting log entries to ETW (windows)

On Windows clients, ODBC log entries can be sent to Event Tracing for Windows (ETW) so they appear in the Windows Event Viewer:

- Register the driver as a Windows Event Log provider and enable the logs.
- Activate ETW by adding a string value `LogType` with data `ETW` to your Windows Registry.
- Understand how Vertica compresses log levels for the Windows Event Viewer.
- Know where to find the logs within Event Viewer.
- Understand the meaning of the Event IDs in your log entries.

Registering the ODBC driver as a windows event log provider

To use ETW logging, you must register the ODBC driver as a Windows Event Log provider. You can choose to register either the 32-bit or 64-bit driver. After you have registered the driver, you must enable the logs.

Important

If you do not both register the driver and enable the logs, output is directed to stdout.

1. Open a command prompt window as Administrator, or launch the command prompt with the Run as Administrator option.

Important

You must have administrator privileges to successfully complete the next step.

2. Run the command `wevtutil im` to register either the 32-bit or 64-bit version of the driver.

- o For the 64-bit ODBC driver, run:

```
wevtutil im "c:\Program Files\Vertica Systems\ODBC64\lib\VerticaODBC64.man"
/resourceFilePath:"c:\Program Files\Vertica Systems\ODBC64\lib\vertica_9.1_odbc_3.5.dll"
/messageFilePath:"c:\Program Files\Vertica Systems\ODBC64\lib\vertica_9.1_odbc_3.5.dll"
```

- o For the 32-bit ODBC driver, run:

```
wevtutil im "c:\Program Files (x86)\Vertica Systems\ODBC32\lib\VerticaODBC32.man"
/resourceFilePath:"c:\Program Files (x86)\Vertica Systems\ODBC32\lib\vertica_9.1_odbc_3.5.dll"
/messageFilePath:"c:\Program Files (x86)\Vertica Systems\ODBC32\lib\vertica_9.1_odbc_3.5.dll"
```

3. Run the command `wevtutil sl` to enable the logs.

- o For 64-bit ODBC driver logs, run:

```
wevtutil sl VerticaODBC64/e:true
```

- o For the 32-bit ODBC driver logs, run:

```
wevtutil sl VerticaODBC32/e:true
```

Note

Should you want to later disable the logs, you can use the same `wevtutil sl` command, substituting `/e:false` in place of `/e:true` when you issue the statement. Alternatively, you can enable or disable logs within the Windows Event Viewer itself.

Add the string value LogType

By default, Vertica does not send ODBC log entries to ETW. To activate ETW, add the string `LogType` to your Windows registry, and set its value to `ETW`.

1. Start the registry editor by typing `regedit.exe` in the Windows Run command box.
2. Navigate to `HKEY_LOCAL_MACHINE\SOFTWARE\Vertica\ODBC\Driver` in the registry.
3. Right-click in the right pane of the **Registry Editor** window.
4. Select **New**, then select **String Value**.
5. Change the name of the string value from `New Value #1` to `LogType`.
6. Double-click the new `LogType` entry. When prompted for a new value, enter `ETW`.
7. Exit the registry editor.

ETW is disabled by default. When ETW is enabled, you can disable it by clearing the value `ETW` from the `LogType` string.

LogLevel in the windows event viewer

While `LogLevel` ranges from 0 through 6, this range is compressed for the Windows Event Viewer to a range of 0 through 3.

Vertica LogLevel Setting	Vertica LogLevel Description	Log level sent to the Windows Event Viewer	Log level displayed by the Windows Event Viewer
0	(No logging)	0	(No logging)
1	Fatal Errors	1	Critical
2	Errors	2	Error
3	Warnings	3	Warning

4	Info	4	Information
5	Debug	4	
6	Trace (all messages)	4	

The following examples show how LogLevel is converted when displayed in the Windows Event Viewer.

- A LogLevel of 5 sends fatal errors, errors, warnings, info and debug log level entries to Event Viewer as Level 4 (Information).
- A LogLevel of 6 sends fatal errors, errors, warnings, debug and trace log level entries to Event Viewer as Level 4.

Finding logs in the event viewer

1. Launch the **Windows Event Viewer** .
2. From **Event Viewer (Local)** , expand **Applications and Services Logs** .
3. Expand the folder that contains the log you want to review (for example, [VerticaODBC64](#)).
4. Select the Vertica ODBC log under the folder. Entries appear in the right pane.
5. Note the value in the **Event ID** field. Each Event Log entry includes one of four Event IDs:
 - 0: Informational (debug, info, and trace events)
 - 1: Error
 - 2: Fatal event
 - 3: Warning

Python client drivers

Vertica supports several Python drivers for creating client applications.

Prerequisites

To create Python client applications, you must [install](#) the required drivers.

In this section

- [Installing Python client drivers](#)

Installing Python client drivers

Vertica supports several Python client drivers.

Installing vertica-python

See the [vertica-python](#) repository for installation and usage instructions.

Installing pyodbc

The [pyodbc](#) module interacts with the Vertica ODBC client driver. To install it:

1. Install the [ODBC client driver](#) .
2. Install [compatible versions](#) of [Python](#) and [pyodbc](#) .

Node.js client driver

The open-source vertica-nodejs client driver lets you interact with your database with JavaScript. For details, see the [vertica-nodejs package on npm](#) .

Go client driver

The open-source vertica-sql-go driver lets you interact with your database with Go. For details, see [vertica-sql-go](#) .

OLE DB client driver

The OLE DB client driver is an interface for [C#](#) client applications to interact with your Vertica database.

In this section

- [Installing the OLE DB client driver](#)

Installing the OLE DB client driver

To install the Vertica OLE DB client driver:

1. [Download](#) the Windows client driver installer. For details on the drivers included in this installer, see [Windows client driver installer](#).
2. Run the installer and follow the prompts to install the drivers.
3. Reboot your system.

After installing the OLE DB client driver, you can configure [ETW logging](#).

For a list of connection properties, see [OLE DB connection properties](#).

In this section

- [OLE DB connection properties](#)
- [Configuring OLE DB logs](#)

OLE DB connection properties

Use the Connection Manager to set the OLE DB connection string properties, which define your connection. You access the Connection Manager from within Visual Studio.

These connection parameters appear on the Connection page.

Parameters	Action
Provider	Select the native OLE DB provider for the connection.
OLE DB Provider	Indicates Vertica OLE DB Provider.
Server or file name	Enter the server or file name.
Location	Not supported.
Use Windows NT Integrated Security	Not supported.
Use a specific user name and password	Enter a user name and password. Connect with No Password : Select the Blank password check box. Save and Encrypt Password: Select Allow saving password .
Initial Catalog	The name of the database running on the server.

The **All** page from the **Connection Manager** dialog box includes all possible connection string properties for the provider.

The table that follows lists the connection parameters for the **All** page.

For OLE DB properties information specific to Microsoft, see the Microsoft documentation [OLE DB Properties](#).

Parameters	Action
Extended Properties	Not supported.
Locale Identifier	Indicates the Locale ID. Default: 0
Mode	Specifies access permissions. Default: 0

Connect Timeout	Not supported. Default: 0
General Timeout	Not supported.
File Name	Not supported.
OLE DB Services	Specifies which OLE DB services to enable or disable.
Password	Specifies the password for the user ID. For no password, insert an empty string.
Persist Security Info	A security measure. When False, security sensitive-information, such as the password, is not returned as part of the connection if the connection is open or has ever been in an open state. Default: true
User ID	The database username.
Data Source	The host name or IP address of any active node in a Vertica cluster. You can provide an IPv4 address, IPv6 address, or host name. In mixed IPv4/IPv6 networks, the DNS server configuration determines which IP version address is sent first. Use the PreferredAddressFamily option to force the connection to use either IPv4 or IPv6.
Initial Catalog	The name of the database running on the server.
Provider	The name of the OLE DB Provider to use when connecting to the Data Source. Default: VerticaOLEDB.1
BackupServerNode	A designated host name or IP address to use if the ServerName host is unavailable. Enter as a string. Connection attempts continue until successful or until the list of server nodes is exhausted. Valid values: Comma-separated list of servers optionally followed by a colon and port number. For example: server1:5033,server2:5034
ConnectionLoadBalance	A Boolean value that determines whether the connection can be redirected to a host in the database other than the ServerNode. This parameter affects the connection only if load balancing is set to a value other than NONE. When the node differs from the node that the client is connected to, the client disconnects and reconnects to the targeted node. See About Native Connection Load Balancing in the Administration Guide. Default: false
ConnSettings	SQL commands that the driver should execute immediately after connecting to the server. Use to configure the connection, such as setting a schema search path. Reserved symbol: ';' To set multiple parameters in this field use '%3B' for ';'. Spaces: Use '+'.

ConvertSquareBracketIdentifiers	Controls whether square-bracket query identifiers are converted to a double quote identifier for compatibility when making queries to a Vertica database. Default: false
DirectBatchInsert	Deprecated, always set to true.
KerberosHostName	Provides the instance or host name portion of the Vertica Kerberos principal; for example: <code>verticaosEXAMPLE.COM</code>
KerberosServiceName	Provides the service name portion of the Vertica Kerberos principal; for example: <code>vertichost@EXAMPLE.COM</code>
Label	Sets a label for the connection on the server. This value appears in the <code>session_id</code> column of system table SESSIONS .
LogLevel	Specifies the amount of information included in the log. Leave this field blank or set to 0 unless otherwise instructed by Vertica Customer Support.
LogPath	The path for the log file.
Port	The port number on which Vertica listens for OLE DB connections. Default: port 5433
PreferredAddressFamily	The IP version to use if the client and server have both IPv4 and IPv6 addresses and you have provided a host name, one of the following: <ul style="list-style-type: none"> • <code>ipv4</code> : Connect to the server using IPv4. • <code>ipv6</code> : Connect to the server using IPv6. • <code>none</code> : Use the IP address provided by the DNS server.
SSLCertFile	The absolute path of the client's public certificate file. This file can reside anywhere on the system.
SSLKeyFile	The absolute path to the client's private key file. This file can reside anywhere on the system.
SSLMode	Controls whether the connection to the database uses SSL encryption, one of the following: <ul style="list-style-type: none"> • <code>require</code> : Requires the server to use SSL. If the server cannot provide an encrypted channel, the connection fails. • <code>prefer</code> : Prefers that the server use SSL. If the server does not offer an encrypted channel, the client requests one. The first attempt is made with SSL. If that attempt fails, the second attempt is over a clear channel. • <code>allow</code> : Makes a connection to the server whether or not the server uses SSL. The first attempt is made over a clear channel. If that attempt fails, a second attempt is over SSL. • <code>disable</code> : Never connects to the server using SSL. Typically, you use this setting for troubleshooting. Default: <code>prefer</code>

Configuring OLE DB logs

The following parameters control how the OLE DB client driver logs messages between the client and server. To set them, edit the keys in the Windows Registry under `HKEY_LOCAL_MACHINE\SOFTWARE\Vertica\OLEDB\Driver` :

- **LogLevel** : The severity of messages that are logged between the client and the server. The valid values are:
 - 0: No logging
 - 1: Fatal errors
 - 2: Errors
 - 3: Warnings

- 4: Info
- 5: Debug
- 6: Trace (all messages)

The value you specify for this setting sets the minimum severity for a message to be logged. For example, setting `LogLevel` to 3 means that the client driver logs all warnings, errors, and fatal errors.

- **LogPath** : The absolute path of a directory to store log files. For example: `/var/log/verticaoledb`

Diverting OLE DB log entries to ETW

On Windows clients, you can direct Vertica to send OLE DB log entries to Event Tracing for Windows (ETW). Once set, OLE DB log entries appear in the Windows Event Viewer. To use ETW:

- Register the driver as a Windows Event Log provider, and enable the logs.
- Activate ETW by adding a string value to your Windows Registry.
- Understand how Vertica compresses log levels for the Windows Event Viewer.
- Know where to find the logs within Event Viewer.
- Understand the meaning of the Event IDs in your log entries.

Registering the OLE DB driver as a windows event log provider

To use ETW logging, you must register the OLE DB driver as a Windows Event Log provider. You can choose to register either the 32-bit or 64-bit driver. Once you have registered the driver, you must enable the logs.

Important

If you do not both register the driver and enable the logs, output is directed to stdout.

1. Open a command prompt window as Administrator, or launch the command prompt with the Run as Administrator option.

Important

You must have administrator privileges to successfully complete the next step.

2. Run the command `wevtutil im` to register either the 32-bit or 64-bit version of the driver.

1. For the 64-bit OLE DB driver, run:

```
wevtutil im "c:\Program Files\Vertica Systems\OLEDB64\lib\VerticaOLEDB64.man"
/resourceFilePath:"c:\Program Files\Vertica Systems\OLEDB64\lib\vertica_8.1_oledb.dll"
/messageFilePath:"c:\Program Files\Vertica Systems\OLEDB64\lib\vertica_8.1_oledb.dll"
```

2. For the 32-bit OLE DB driver, run:

```
wevtutil im "c:\Program Files (x86)\Vertica Systems\OLEDB32\lib\VerticaOLEDB32.man"
/resourceFilePath:"c:\Program Files (x86)\Vertica Systems\OLEDB32\lib\vertica_8.1_oledb.dll"
/messageFilePath:"c:\Program Files (x86)\Vertica Systems\OLEDB32\lib\vertica_8.1_oledb.dll"
```

3. Run the command `wevtutil sl` to enable the logs.

1. For 64-bit OLE DB driver logs, run:

```
wevtutil sl VerticaOLEDB64/e:true
```

2. For the 32-bit ODBC driver logs, run:

```
wevtutil sl VerticaOLEDB32/e:true
```

Note

Should you want to later disable the logs, you can use the same `wevtutil sl` command, substituting `/e:false` in place of `/e:true` when you issue the statement. Alternatively, you can enable or disable logs within the Windows Event Viewer itself.

Add the string value LogType

By default, Vertica does not send OLE DB log entries to ETW. To activate ETW, add the string `LogType` to your Windows registry, and set its value to `ETW`.

1. Start the registry editor by typing `regedit.exe` in the Windows Run command box.
2. Navigate, in the registry, to: `HKEY_LOCAL_MACHINE\SOFTWARE\Vertica\OLEDB\Driver`.
3. Right-click in the right pane of the **Registry Editor** window.
4. Select **New**, then select **String Value**.
5. Change the name of the string value from `New Value #1` to `LogType`.

6. Double-click the new **LogType** entry. When prompted for a new value, enter **ETW** .
7. Exit the registry editor.

ETW is off by default. When ETW is activated, you can subsequently turn it off by clearing the value ETW from the LogType string.

LogLevel in the windows event viewer

While LogLevel ranges from 0 through 6, this range is compressed for the Windows Event Viewer to a range of 0 through 3.

Vertica LogLevel Setting	Vertica LogLevel Description	Log level sent to the Windows Event Viewer	Log level displayed by the Windows Event Viewer
0	(No logging)	0	(No logging)
1	Fatal Errors	1	Critical
2	Errors	2	Error
3	Warnings	3	Warning
4	Info	4	Information
5	Debug	4	
6	Trace (all messages)	4	

The following examples show how LogLevel is converted when displayed in the Windows Event Viewer.

- A LogLevel of 5 sends fatal errors, errors, warnings, info and debug log level entries to Event Viewer as Level 4 (Information).
- A LogLevel of 6 sends fatal errors, errors, warnings, debug and trace log level entries to Event Viewer as Level 4.

Finding logs in the event viewer

1. Launch the **Windows Event Viewer** .
2. From **Event Viewer (Local)** , expand **Applications and Services Logs** .
3. Expand the folder that contains the log you want to review (for example, **VerticaOLEDB64**).
4. Select the Vertica ODBC log under the folder. Entries appear in the right pane.
5. Note the value in the **Event ID** field. Each Event Log entry includes one of four Event IDs:
 - 0: Informational (debug, info, and trace events)
 - 1: Error
 - 2: Fatal event
 - 3: Warning

ADO.NET client driver

The Vertica ADO.NET driver lets you [access Vertica with C#](#).

In this section

- [Installing the ADO.NET client driver](#)
- [Log properties](#)

Installing the ADO.NET client driver

Prerequisites

The ADO.NET client driver requires the following:

- [A supported operating system](#) .
- At least 512MB of memory
- A [supported version](#) of .NET Core or .NET Framework. For details, see the Microsoft documentation:
 - [Install .NET on Windows](#)
 - [Install .NET on macOS](#)
 - [Install .NET on Linux](#)

Installation

For a sample application that uses and demonstrates all of these installation methods, see the [client-application-examples](#) repository.

Package reference

The ADO.NET client driver is available on [NuGet](#) and should be installed with a package reference.

To reference the package, add the following to your `.csproj`. For an example `.csproj` file, see [SampleApp.csproj](#):

```
<ItemGroup>
  <PackageReference Include="Vertica.Data" Version="24.1.0" />
</ItemGroup>
```

Local package reference

You can also download the [Vertica.Data](#) package and reference it locally.

On Windows platforms, you can install the ADO.NET driver with the [Windows installer](#) and then reference the `.dll`. This is required for certain applications like TIBCO Spotfire to interact with the driver:

```
<ItemGroup>
  <Reference Include="Vertica.Data">
    <HintPath>path\to\Program Files\Vertica Systems\ADO.NET64\Vertica.Data.dll</HintPath>
  </Reference>
</ItemGroup>
```

Log properties

Config-level Settings

The following parameters control how messages between the client and server are logged. If they are not set, then the client library does not log any messages.

To set these parameters, create and edit the configuration file `Vertica.Data.dll.config` in one of the following locations. If the file exists in both locations, the one in the home directory takes priority:

- Home directory
- Project directory

LogLevel

The minimum severity of a message for it to be logged, one of the following:

- **0** : No logging
- **1** : Fatal errors
- **2** : Errors
- **3** : Warnings
- **4** : Info
- **5** : Debug
- **6** : Trace (all messages)

For example, a **LogLevel** of **3** means that the client driver logs messages with severities **1**, **2**, and **3**.

LogPath

The absolute path of the log file. For example: `/var/log/verticaadonet/ado.log`.

LogNamespace

Limits logging to messages generated by certain objects in the client driver.

Example configuration file

The following example configuration file uses the default values for each configuration setting:

```
<?xml version="1.0" encoding="utf-8"?>
<configuration>
  <appSettings>
    <add key="Logging.LogLevel" value="None" />
    <add key="Logging.LogPath" value="" />
    <add key="Logging.LogNamespace" value="" />
  </appSettings>
</configuration>
```

VerticaLogProperties

You can set the log properties of the ADO.NET driver with the [VerticaLogProperties](#) class, which includes the following methods:

- [SetLogPath\(String path\)](#)
- [SetLogNamespace\(String lognamespace\)](#)
- [SetLogLevel\(VerticaLogLevel loglevel\)](#)

Logs are created when the first connection is opened, so you cannot change the log path with [SetLogPath\(\)](#) after the connection starts. You can change the log level and log namespace at any time.

Changes made by these functions last for the lifetime of the application. To make permanent changes, use [Vertica.Data.dll.config](#) .

SetLogPath()

The [SetLogPath\(\)](#) method takes as an argument a [String path](#) containing the path to the log file. If the path string contains only a directory path, then the log file is created with the name vdp-driver-MM-dd_HH.mm.ss.log (where MM-dd_HH.mm.ss is the date and time the log was created). If the path ends in a filename, such as log.txt or log.log, then the log is created with that filename.

If [SetLogPath\(\)](#) is called with an empty string for the path argument, then the client executable's current directory is used as the log path.

If [SetLogPath\(\)](#) is not called and entry exists for the log path in [Vertica.Data.dll.config](#) , and you have called any of the other [VerticaLogProperties](#) methods, then the client executable's current directory is used as the log path.

Note

The path must exist on the client system prior to calling this method. The method does not create directories.

For example:

```
/set the log path
string path = "C:\log";
VerticaLogProperties.SetLogPath(path);
```

SetLogNamespace()

The [SetLogNamespace\(\)](#) method takes as an argument a [String lognamespace](#) containing the namespace to log. The namespace string to log can be one of the following:

- [Vertica](#)
- [Vertica.Data.VerticaClient](#)
- [Vertica.Data.Internal.IO](#)
- [Vertica.Data.Internal.DataEngine](#)
- [Vertica.Data.Internal.Core](#)

Namespaces can be truncated to include child namespaces. For example, you can specify [Vertica.Data.Internal](#) to log for all of the [Vertica.Data.Internal](#) namespaces.

If a log namespace is not set, and no value is stored in [Vertica.Data.dll.config](#) , then the [Vertica](#) namespace is used for logging.

For example:

```
/set namespace to log
string lognamespace = "Vertica.Data.VerticaClient";
VerticaLogProperties.SetLogNamespace(lognamespace);
```

SetLogLevel()

The [SetLogLevel\(\)](#) method takes as an argument a [VerticaLogLevel loglevel](#) , one of the following:

- [VerticaLogLevel.None](#)
- [VerticaLogLevel.Fatal](#)
- [VerticaLogLevel.Error](#)
- [VerticaLogLevel.Warning](#)
- [VerticaLogLevel.Info](#)
- [VerticaLogLevel.Debug](#)

- [VerticalLogLevel.Trace](#)

If a log level is not set, and no value is stored in [Vertica.Data.dll.config](#) , then [VerticalLogLevel.None](#) is used.

For example:

```
/set log level  
VerticalLogLevel level = VerticalLogLevel.Debug;  
VerticalLogProperties.SetLogLevel(level);
```

Getting log properties

You can retrieve the values for the following properties with the [VerticalLogProperties](#) class:

- [LogPath](#)
- [LogNamespace](#)
- [LogLevel](#)

For example:

```
/get current log settings  
string logpath = VerticalLogProperties.LogPath;  
VerticalLogLevel loglevel = VerticalLogProperties.LogLevel;  
string logns = VerticalLogProperties.LogNamespace;  
Console.WriteLine("Current Log Settings:");  
Console.WriteLine("Log Path: " + logpath);  
Console.WriteLine("Log Level: " + loglevel);  
Console.WriteLine("Log Namespace: " + logns);
```

Examples

This complete example shows how to get and set log properties:

```

using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            //configure connection properties
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";

            //get current log settings
            string logpath = VerticaLogProperties.LogPath;
            VerticaLogLevel loglevel = VerticaLogProperties.LogLevel;
            string logns = VerticaLogProperties.LogNamespace;
            Console.WriteLine("nOld Log Settings:");
            Console.WriteLine("Log Path: " + logpath);
            Console.WriteLine("Log Level: " + loglevel);
            Console.WriteLine("Log Namespace: " + logns);

            //set the log path
            string path = "C:\log";
            VerticaLogProperties.SetLogPath(path);

            // set log level
            VerticaLogLevel level = VerticaLogLevel.Debug;
            VerticaLogProperties.SetLogLevel(level);

            //set namespace to log
            string lognamespace = "Vertica";
            VerticaLogProperties.SetLogNamespace(lognamespace);

            //open the connection
            VerticaConnection _conn = new VerticaConnection(builder.ToString());
            _conn.Open();

            //get new log settings
            logpath = VerticaLogProperties.LogPath;
            loglevel = VerticaLogProperties.LogLevel;
            logns = VerticaLogProperties.LogNamespace;
            Console.WriteLine("nNew Log Settings:");
            Console.WriteLine("Log Path: " + logpath);
            Console.WriteLine("Log Level: " + loglevel);
            Console.WriteLine("Log Namespace: " + logns);

            //close the connection
            _conn.Close();
        }
    }
}

```

The example produces the following output:

```
Old Log Settings:
Log Path:
Log Level: None
Log Namespace:
New Log Settings:
Log Path: C:\log
Log Level: Debug
Log Namespace: Vertica
```

Upgrading the client drivers

The Vertica client drivers are usually updated for each new release of the Vertica server. The client driver installation packages include the version number of the corresponding Vertica server release. Usually, the drivers are forward-compatible with the next release, so your client applications are still be able to connect using the older drivers after you upgrade to the next version of Vertica Analytics Platform server. See [Client driver and server version compatibility](#) for details on which client driver versions work with each version of Vertica server.

Note

Vertica ODBC, JDBC and ADO.NET client drivers are backwards compatible to all supported Vertica server versions.

You should upgrade your clients as soon as possible after upgrading your server to take advantage of new features and to maintain maximum compatibility with the server.

To upgrade your drivers, follow the same procedure you used to install them in the first place. The new installation will overwrite the old. See the specific instructions for installing the drivers on your client platform for any special instructions regarding upgrades.

Note

Installing new ODBC drivers does not alter existing DSN settings. You may need to change the driver settings in either the DSN or in the `odbcinst.ini` file, if your client system uses one. See [Creating an ODBC Data Source Name](#) for details.

Setting a client connection label

A client connection label identifies a connection to the database with a user-defined string. You can view the label for an existing session with [GET_CLIENT_LABEL](#):

```
=> SELECT GET_CLIENT_LABEL();
   GET_CLIENT_LABEL
-----
my_client_connection_label
(1 row)
```

New connections

In JDBC, ODBC, and ADO.NET, you use each client driver's "Label" connection property to set the client label before connecting to the database. Setting the label before you connect ensures that the connection is associated with the label in all system and [Data collector](#) tables. Examples of these tables include [SESSIONS](#) and `DC_SESSION_STARTS`.

- [JDBC connection properties](#)
- [ODBC DSN connection properties](#)
- [ADO.NET connection properties](#)

You can also preemptively set the client label with `vsq` by using the `--label` option. For details, see [-g --label](#)

Existing connections

You can set a client connection label after you connect to a Vertica database with [SET_CLIENT_LABEL](#):

```

=> SELECT SET_CLIENT_LABEL('py_data_load_application');
       SET_CLIENT_LABEL
-----
client_label set to py_data_load_application
(1 row)

=> SELECT GET_CLIENT_LABEL();
       GET_CLIENT_LABEL
-----
py_data_load_application
(1 row)

```

Certain client drivers, like JDBC, have dedicated functions for setting the client connection label for existing connections. For details, see [Setting and returning a client connection label](#).

Using legacy drivers

The Vertica server supports connections from previous versions of the client drivers. For detailed information the compatibility between versions of the Vertica server and Vertica client, see [Client driver and server version compatibility](#).

Accessing Vertica

The following table shows which client drivers you have to set up to access Vertica with a supported programming language:

Client Driver	Language/Tool
JDBC	Java
ODBC	<ul style="list-style-type: none"> • C/C++ • Python (pyodbc) • PHP • Perl
vertica-python	Python (native client)
ADO.NET	C#
vertica-nodejs	JavaScript
vertica-sql-go	Go

In this section

- [C/C++](#)
- [C#](#)
- [Go](#)
- [Java](#)
- [JavaScript](#)
- [Perl](#)
- [Python](#)
- [PHP](#)

C/C++

Note

You must [install the ODBC client driver](#) before creating C/C++ client applications.

Vertica provides an Open Database Connectivity (ODBC) driver that allows applications to connect to the Vertica database. This driver can be used by custom-written client applications that use the ODBC API to interact with Vertica. ODBC is also used by many third-party applications to connect to Vertica, including business intelligence applications and extract, transform, and load (ETL) applications.

This section details the process for configuring the Vertica ODBC driver. It also explains how to use the ODBC API to connect to Vertica in your own client applications.

While client applications written in C, C++, [Perl](#), [PHP](#), etc. all use the ODBC client driver to connect to Vertica, this section only concerns C and C++ applications.

ODBC architecture

The ODBC architecture has four layers:

- **Client Application**

Is an application that opens a data source through a Data Source Name (DSN). It then sends requests to the data source, and receives the results of those requests. Requests are made in the form of calls to ODBC functions.

- **Driver Manager**

Is a library on the client system that acts as an intermediary between a client application and one or more drivers. The driver manager:

- Resolves the DSN provided by the client application.
- Loads the driver required to access the specific database defined within the DSN.
- Processes ODBC function calls from the client or passing them to the driver.
- Retrieves results from the driver.
- Unloads drivers when they are no longer needed.

On Windows and macOS client systems, the driver manager is provided by the operating system. On Linux systems, you usually need to install a driver manager. See [Client drivers support](#) for a list of driver managers that can be used with Vertica on your client platform.

- **Driver**

A library on the client system that provides access to a specific database. It translates requests into the format expected by the database, and translates results back into the format required by the client application.

- **Database**

The database processes requests initiated at the client application and returns results.

ODBC feature support

The ODBC driver for Vertica supports the most of the features defined in the Microsoft ODBC 3.5 specifications. The following features are *not* supported:

- Updatable result sets
- Backwards scrolling cursors
- Cursor attributes
- More than one open statement per connection. Simultaneously executing statements must each belong to a different connection. For example, you cannot execute a new statement while another statement has a result set open. To execute another statement with the same connection/session, wait for the current statement to finish executing and close its result set, then execute the new statement.
- Keysets
- Bookmarks

The Vertica ODBC driver accurately reports its capabilities. If you need to determine whether it complies with a specific feature, you should query the driver's capabilities directly using the [SQLGetInfo\(\)](#) function.

Vertica and ODBC data type translation

Most data types are transparently converted between Vertica and ODBC. This section explains several data types require special handling.

Vertica Data Types	C Data Type	ODBC C Typedef	C Type Identifier
BINARY , VARBINARY	char[]	SQL_BINARY	SQL_C_BINARY
LONG VARBINARY	char[]	SQL_LONGVARBINARY	SQL_C_BINARY
BOOLEAN	SQLSMALLINT	SQL_SMALLINT	SQL_C_SSHORT
CHAR , VARCHAR	char[]	SQL_CHAR	SQL_C_CHAR
LONG VARCHAR	char[]	SQL_LONGVARCHAR	SQL_C_CHAR
DATE	SQL_DATE_STRUCT	SQL_TYPE_DATE	SQL_C_TYPE_DATE
TIME	SQL_TIME_STRUCT	SQL_TYPE_TIME	SQL_C_TYPE_TIME
TIMESTAMP	SQL_TIMESTAMP_STRUCT	SQL_TYPE_TIMESTAMP	SQL_C_TYPE_TIMESTAMP
INTERVAL	SQL_INTERVAL_STRUCT	SQL_INTERVAL_DAY_TO_SECOND	SQL_C_INTERVAL_DAY_TO_SECOND
INTERVAL DAY TO SECOND	SQL_INTERVAL_STRUCT	SQL_INTERVAL_DAY_TO_SECOND	SQL_C_INTERVAL_DAY_TO_SECOND
INTERVAL YEAR TO MONTH	SQL_INTERVAL_STRUCT	SQL_INTERVAL_YEAR_TO_MONTH	SQL_C_INTERVAL_YEAR_TO_MONTH
DOUBLE PRECISION FLOAT	SQLREAL	SQL_REAL	SQL_C_FLOAT
INTEGER , BIGINT , SMALLINT	SQLBIGINT	SQL_BIGINT	SQL_C_SBIGINT
NUMERIC , DECIMAL , NUMBER , MONEY	SQL_NUMERIC_STRUCT	SQL_NUMERIC	SQL_C_NUMERIC
GEOMETRY	char[]	SQL_LONGVARBINARY	SQL_C_CHAR
GEOGRAPHY	char[]	SQL_LONGVARBINARY	SQL_C_CHAR
UUID	SQLGUID (see note below)	SQL_GUID	SQL_C_GUID

Notes

- The GEOMETRY and GEOGRAPHY data types are treated as LONG VARCHAR data by the ODBC driver.
- Vertica supports the standard interval data types supported by ODBC. See [Interval Data Types](#) in Microsoft's ODBC reference.
- Vertica version 9.0.0 introduced the UUID data type, including JDBC support for UUIDs. The Vertica ADO.NET, ODBC, and OLE DB clients added full support for UUIDs in version 9.0.1. Vertica maintains backwards compatibility with older [supported](#) client driver versions that do not support the UUID data type, as follows:

When an older client...	Vertica...
Queries tables with UUID columns	Translates the native UUID values to CHAR values.
Inserts data into a UUID column	Converts the CHAR value sent by the client into a native UUID value.
Queries a UUID column's metadata	Reports its data type as CHAR.

See also

- [Data types](#)
- [Using LONG VARCHAR and LONG VARBINARY data types with ODBC](#)
- [Using GEOMETRY and GEOGRAPHY data types in ODBC](#)
- [SQL Data Types](#) in the Microsoft ODBC reference documentation

ODBC header file

The Vertica ODBC driver provides a C header file named `verticaodbc.h` that defines several useful constants that you can use in your applications. These constants let you access and alter settings specific to Vertica.

This file's location depends on your client operating system:

- `/opt/vertica/include` on Linux and UNIX systems.
- `C:\Program Files (x86)\Vertica\ODBC\include` on Windows systems.

The constants defined in this file are listed below.

Parameter	Description
<code>SQL_ATTR_VERTICA_RESULT_BUFFER_SIZE</code>	Sets the size of the buffer used when retrieving results from the server. Associated functions : <code>SQLSetConnectAttr()</code> <code>SQLGetConnectAttr()</code>
<code>SQL_ATTR_VERTICA_DIRECT_BATCH_INSERT</code>	Deprecated, always set to 1. Associated functions: <code>SQLSetConnectAttr()</code> <code>SQLSetStmtAttr()</code> <code>SQLGetConnectAttr()</code> <code>SQLGetStmtAttr()</code>
<code>SQL_ATTR_VERTICA_LOCALE</code>	Changes the locale from <code>en_US@collation=binary</code> to the ICU locale specified. See Setting the locale and encoding for ODBC sessions for an example of using this parameter. Associated functions : <code>SQLSetConnectAttr()</code> <code>SQLGetConnectAttr()</code>

Canceling ODBC queries

You can cancel ODBC queries with the `SQLCancel()` function.

The following example:

1. Creates a table `odbccanceltest`
2. Queries `odbccanceltest` three times, canceling the third query
3. Runs another query on `dual` to show that the cancelation succeeded

```
/* Example of calling SQLCancel() during SQLFetch()
#include <stdio.h>
#include <stdlib.h>

/* Only needed for Windows clients
#include <windows.h>

/* SQL data types and ODBC API functions
```

Connecting to the database

The first step in any ODBC application is to connect to the database. When you create the connection to a data source using ODBC, you use the name of the DSN that contains the details of the driver to use, the database host, and other basic information about connecting to the data source.

There are 4 steps your application needs to take to connect to a database:

1. Call `SQLAllocHandle()` to allocate a handle for the ODBC environment. This handle is used to create connection objects and to set application-wide settings.
2. Use the environment handle to set the version of ODBC that your application wants to use. This ensures that the data source knows which API your application will use to interact with it.
3. Allocate a database connection handle by calling `SQLAllocHandle()`. This handle represents a connection to a specific data source.
4. Use the `SQLConnect()` or `SQLDriverConnect()` functions to open the connection to the database.

Note

If you specify a locale either in the connection string or in the DSN, the call to the connection function returns `SQL_SUCCESS_WITH_INFO` on a successful connection, with messages about the state of the locale.

When creating the connection to the database, use `SQLConnect()` when the only options you need to set at connection time is the username and password. Use `SQLDriverConnect()` when you want to change connection options, such as the locale.

The following example demonstrates connecting to a database using a DSN named ExampleDB. After it creates the connection successfully, this example simply closes it.

```
// Demonstrate connecting to Vertica using ODBC.
// Standard i/o library
#include <stdio.h>
#include <stdlib.h>
// Only needed for Windows clients
// #include <windows.h>
// SQL include files that define data types and ODBC API
// functions
#include <sql.h>
#include <sqlext.h>
#include <sqltypes.h>
int main()
{
    SQLRETURN ret; // Stores return value from ODBC API calls
    SQLHENV hdlEnv; // Handle for the SQL environment object
    // Allocate an a SQL environment object
    ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hdlEnv);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not allocate a handle.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Allocated an environment handle.\n");
    }

    // Set the ODBC version we are going to use to
    // 3.
    ret = SQLSetEnvAttr(hdlEnv, SQL_ATTR_ODBC_VERSION,
        (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_UIINTEGER);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not set application version to ODBC 3.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Set application version to ODBC 3.\n");
    }
}
```

```

// Allocate a database handle.
SQLHDBC hdlDbc;
ret = SQLAllocHandle(SQL_HANDLE_DBC, hdlEnv, &hdlDbc);
if(!SQL_SUCCEEDED(ret)) {
    printf("Could not allocate database handle.\n");
    exit(EXIT_FAILURE);
} else {
    printf("Allocated Database handle.\n");
}
// Connect to the database using
// SQL Connect
printf("Connecting to database.\n");
const char *dsnName = "ExampleDB";
const char *userID = "ExampleUser";
const char *passwd = "password123";
ret = SQLConnect(hdlDbc, (SQLCHAR*)dsnName,
    SQL_NTS,(SQLCHAR*)userID,SQL_NTS,
    (SQLCHAR*)passwd, SQL_NTS);
if(!SQL_SUCCEEDED(ret)) {
    printf("Could not connect to database.\n");
    exit(EXIT_FAILURE);
} else {
    printf("Connected to database.\n");
}
// We're connected. You can do real
// work here

// When done, free all of the handles to close them
// in an orderly fashion.
printf("Disconnecting and freeing handles.\n");
ret = SQLDisconnect( hdlDbc );
if(!SQL_SUCCEEDED(ret)) {
    printf("Error disconnecting from database. Transaction still open?\n");
    exit(EXIT_FAILURE);
}

SQLFreeHandle(SQL_HANDLE_DBC, hdlDbc);
SQLFreeHandle(SQL_HANDLE_ENV, hdlEnv);
exit(EXIT_SUCCESS);

```

Running the above code prints the following:

```

Allocated an environment handle.
Set application version to ODBC 3.
Allocated Database handle.
Connecting to database.
Connected to database.
Disconnecting and freeing handles.

```

See [Setting the locale and encoding for ODBC sessions](#) for an example of using `SQLDriverConnect` to connect to the database.

Notes

- If you use the DataDirect[®] driver manager, you should always use the `SQL_DRIVER_NOPROMPT` value for the `SQLDriverConnect` function's `DriverCompletion` parameter (the final parameter in the function call) when connecting to Vertica. Vertica's ODBC driver on Linux and UNIX platforms does not contain a UI, and therefore cannot prompt users for a password.
- On Windows client platforms, the ODBC driver can prompt users for connection information. See [Prompting windows users for missing connection properties](#) for more information.
- If your database does not comply with your Vertica license agreement, your application receives a warning message in the return value of the `SQLConnect()` function. Always have your application examine this return value to see if it is `SQL_SUCCESS_WITH_INFO`. If it is, have your application extract and display the message to the user.

Load balancing

Native connection load balancing

Native connection load balancing helps spread the overhead caused by client connections on the hosts in the Vertica database. Both the server and the client must enable native connection load balancing. If enabled by both, then when the client initially connects to a host in the database, the host picks a host to handle the client connection from a list of the currently up hosts in the database, and informs the client which host it has chosen.

If the initially-contacted host does not choose itself to handle the connection, the client disconnects, then opens a second connection to the host selected by the first host. The connection process to this second host proceeds as usual—if SSL is enabled, then SSL negotiations begin, otherwise the client begins the authentication process. See [About native connection load balancing](#) for details.

To enable native load balancing on your client, set the `ConnectionLoadBalance` connection parameter to true either in the DSN entry or in the connection string. The following example demonstrates connecting to the database several times with native connection load balancing enabled, and fetching the name of the node handling the connection from the `V_MONITOR.CURRENT_SESSION` system table.

```
/ Demonstrate enabling native load connection balancing.
/ Standard i/o library
#include <stdlib.h>
#include <iostream>
#include <assert.h>
/ Only needed for Windows clients
/ #include <windows.h>
/ SQL include files that define data types and ODBC API
/ functions
#include <sql.h>
#include <sqlext.h>
#include <sqltypes.h>

using namespace std;
int main()
{
    SQLRETURN ret; // Stores return value from ODBC API calls
    SQLHENV hdlEnv; // Handle for the SQL environment object
    // Allocate an a SQL environment object
    ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hdlEnv);
    assert(SQL_SUCCEEDED(ret));

    // Set the ODBC version we are going to use to
    // 3.
    ret = SQLSetEnvAttr(hdlEnv, SQL_ATTR_ODBC_VERSION,
        (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_UIINTEGER);
    assert(SQL_SUCCEEDED(ret));

    // Allocate a database handle.
    SQLHDBC hdlDbc;
    ret = SQLAllocHandle(SQL_HANDLE_DBC, hdlEnv, &hdlDbc);
    assert(SQL_SUCCEEDED(ret));

    // Connect four times. If load balancing is on, client should
    // connect to different nodes.
    for (int x=1; x <= 4; x++) {

        // Connect to the database using SQLDriverConnect. Set
        // ConnectionLoadBalance to 1 (true) to enable load
        // balancing.
        cout << endl << "Connection attempt #" << x << "... ";
        const char *connStr = "DSN=VMart;ConnectionLoadBalance=1;"
            "UID=ExampleUser;PWD=password123";

        ret = SQLDriverConnect(hdlDbc, NULL, (SQLCHAR*)connStr, SQL_NTS,
            NULL, 0, NULL, SQL_DRIVER_NOPROMPT);
```

```

if(!SQL_SUCCEEDED(ret)) {
    cout << "failed. Exiting." << endl;
    exit(EXIT_FAILURE);
} else {
    cout << "succeeded" << endl;
}
// We're connected. Query the v_monitor.current_session table to
// find the name of the node we've connected to.

// Set up a statement handle
SQLHSTMT hdlStmt;
SQLAllocHandle(SQL_HANDLE_STMT, hdlDbc, &hdlStmt);
assert(SQL_SUCCEEDED(ret));

ret = SQLExecDirect( hdlStmt, (SQLCHAR*)"SELECT node_name FROM "
    "V_MONITOR.CURRENT_SESSION;", SQL_NTS );

if(!SQL_SUCCEEDED(ret)) {
    // Bind variable to column in result set.
    SQLTCHAR node_name[256];
    ret = SQLBindCol(hdlStmt, 1, SQL_C_TCHAR, (SQLPOINTER)node_name,
        sizeof(node_name), NULL);
    while(SQL_SUCCEEDED(ret = SQLFetchScroll(hdlStmt, SQL_FETCH_NEXT,1))) {
        // Print the bound variables, which now contain the values from the
        // fetched row.
        cout << "Connected to node " << node_name << endl;
    }
}
// Free statement handle
SQLFreeHandle(SQL_HANDLE_STMT,hdlStmt);
cout << "Disconnecting." << endl;
ret = SQLDisconnect( hdlDbc );
assert(SQL_SUCCEEDED(ret));
}
// When done, free all of the handles to close them
// in an orderly fashion.
cout << endl << "Freeing handles..." << endl;
SQLFreeHandle(SQL_HANDLE_DBC, hdlDbc);
SQLFreeHandle(SQL_HANDLE_ENV, hdlEnv);
cout << "Done!" << endl;
exit(EXIT_SUCCESS);

```

Running the above example produces output similar to the following:

```
Connection attempt #1... succeeded
Connected to node v_vmart_node0001
Disconnecting.

Connection attempt #2... succeeded
Connected to node v_vmart_node0002
Disconnecting.

Connection attempt #3... succeeded
Connected to node v_vmart_node0003
Disconnecting.

Connection attempt #4... succeeded
Connected to node v_vmart_node0001
Disconnecting.

Freeing handles...
Done!
```

Hostname-based load balancing

You can also balance workloads by resolving a single hostname to multiple IP addresses. The ODBC client driver load balances by automatically resolving the hostname to one of the specified IP addresses at random.

For example, suppose the hostname `verticahost.example.com` has the following entries in `etc/hosts` :

```
192.0.2.0 verticahost.example.com
192.0.2.1 verticahost.example.com
192.0.2.2 verticahost.example.com
```

Specifying the hostname `verticahost.example.com` randomly resolves to one of the listed IP addresses.

Configuring TLS for ODBC Clients

You can configure TLS for ODBC clients by [setting the DSN connection properties](#) setting the DSN connection properties for the following. For details on these parameters, see [ODBC DSN connection properties](#) :

- `SSLMode`: Determines whether TLS is required and how the client should behave if the TLS connection attempt fails.
- `SSLCertFile` (SSL CA file in Windows): The absolute path of the client's public certificate file.
- `SSLKeyFile` (SSL cert file in Windows): The absolute path to the client's private key file.

SSLModes: `Verify_ca` and `verify_full`

You can use the `SSLMode` property values `verify_ca` and `verify_full` if you want the client to verify the server's information before establishing the connection. If any of these verifications fail, the connection fails:

- `verify_ca` : The client verifies that the server's certificate is from a trusted certificate authority (CA).
- `verify_full` : The client verifies both that the server's certificate is from a trusted CA and that the server's hostname matches the hostname on the certificate.

If `verify_ca` or `verify_full` are specified, the client requires the following to establish the connection:

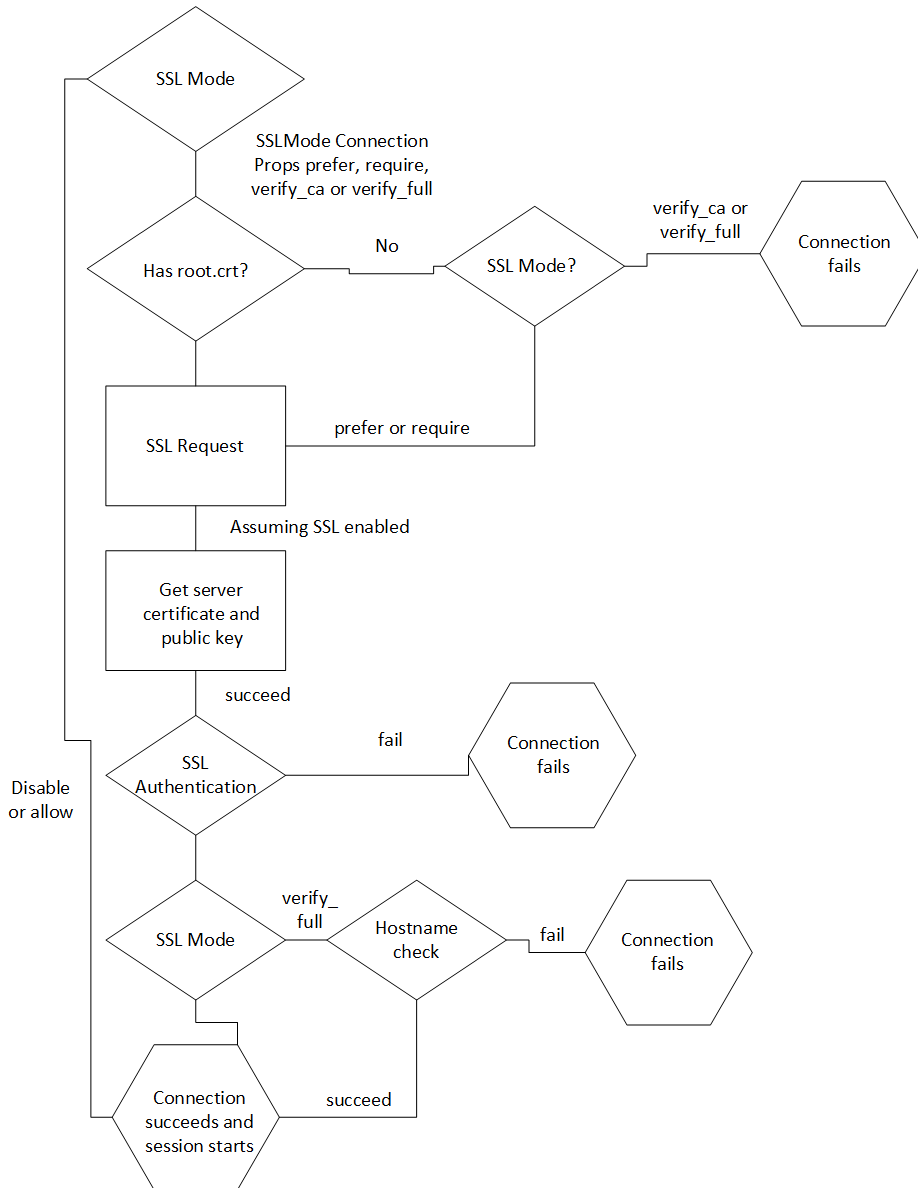

- The `root.crt` , which is the certificate of a CA trusted by both the server and the client.
- The server must have:
 - `server.crt` , a certificate signed by the trusted CA.
 - `server.key` , the server's private key.
- For `verify_full` , each server node must meet one of the following requirements:
 - Its hostname matches the common name specified in `server.crt` .
 - Its hostname or IP address appears in the Subject Alternative Name (SAN) field of `server.crt` .

TLS behavior flowchart

The following diagram shows an example flowchart for a client connecting with TLS.

In this example:

- If SSLMode is set to **none** or **allow**, the client connects without authentication.
- If SSLMode is set to **verify_ca** or **verify_full** and the client does not have **root.crt**, the connection fails.
- At the SSL authentication node, if the SSLMode connection is set to **verify_full** and the server hostname differs from the hostname specified by the client, authentication fails.

Connection failover

If a client application attempts to connect to a host in the Vertica cluster that is down, the connection attempt fails when using the default connection configuration. This failure usually returns an error to the user. The user must either wait until the host recovers and retry the connection or manually edit the connection settings to choose another host.

Due to Vertica Analytic Database's distributed architecture, you usually do not care which database host handles a client application's connection. You can use the client driver's connection failover feature to prevent the user from getting connection errors when the host specified in the connection settings is unreachable. The JDBC driver gives you several ways to let the client driver automatically attempt to connect to a different host if the one specified in the connection parameters is unreachable:

- Configure your DNS server to return multiple IP addresses for a host name. When you use this host name in the connection settings, the client attempts to connect to the first IP address from the DNS lookup. If the host at that IP address is unreachable, the client tries to connect to the second IP, and so on until it either manages to connect to a host or it runs out of IP addresses.
- Supply a list of backup hosts for the client driver to try if the primary host you specify in the connection parameters is unreachable.
- (JDBC only) Use driver-specific connection properties to manage timeouts before attempting to connect to the next node.

For all methods, the process of failover is transparent to the client application (other than specifying the list of backup hosts, if you choose to use the list method of failover). If the primary host is unreachable, the client driver automatically tries to connect to other hosts.

Failover only applies to the initial establishment of the client connection. If the connection breaks, the driver does not automatically try to reconnect to another host in the database.

Choosing a failover method

You usually choose to use one of the two failover methods. However, they do work together. If your DNS server returns multiple IP addresses and you supply a list of backup hosts, the client first tries all of the IPs returned by the DNS server, then the hosts in the backup list.

Note

If a host name in the backup host list resolves to multiple IP addresses, the client does not try all of them. It just tries the first IP address in the list.

The DNS method of failover centralizes the configuration client failover. As you add new nodes to your Vertica Analytic Database cluster, you can choose to add them to the failover list by editing the DNS server settings. All client systems that use the DNS server to connect to Vertica Analytic Database automatically use connection failover without having to change any settings. However, this method does require administrative access to the DNS server that all clients use to connect to the Vertica Analytic Database cluster. This may not be possible in your organization.

Using the backup server list is easier than editing the DNS server settings. However, it decentralizes the failover feature. You may need to update the application settings on each client system if you make changes to your Vertica Analytic Database cluster.

Using DNS failover

To use DNS failover, you need to change your DNS server's settings to map a single host name to multiple IP addresses of hosts in your Vertica Analytic Database cluster. You then have all client applications use this host name to connect to Vertica Analytic Database.

You can choose to have your DNS server return as many IP addresses for the host name as you want. In smaller clusters, you may choose to have it return the IP addresses of all of the hosts in your cluster. However, for larger clusters, you should consider choosing a subset of the hosts to return. Otherwise there can be a long delay as the client driver tries unsuccessfully to connect to each host in a database that is down.

Using the backup host list

To enable backup list-based connection failover, your client application has to specify at least one IP address or host name of a host in the **BackupServerNode** parameter. The host name or IP can optionally be followed by a colon and a port number. If not supplied, the driver defaults to the standard Vertica port number (5433). To list multiple hosts, separate them by a comma.

The following example demonstrates setting the **BackupServerNode** connection parameter to specify additional hosts for the connection attempt. The connection string intentionally has a non-existent node, so that the initial connection fails. The client driver has to resort to trying the backup hosts to establish a connection to Vertica.

```
/* Demonstrate using connection failover.
 * Standard i/o library
 */
#include <stdlib.h>
#include <iostream>
#include <assert.h>

/* Only needed for Windows clients
 */
#include <windows.h>;

/* SQL include files that define data types and ODBC API
 */
#include <sql.h>
#include <sqlext.h>
#include <sqltypes.h>

using namespace std;

int main()
{
    SQLRETURN ret; // Stores return value from ODBC API calls
    SQLHENV hdlEnv; // Handle for the SQL environment object
    // Allocate an a SQL environment object
    ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hdlEnv);
    assert(SQL_SUCCEEDED(ret));
}
```

```
// When done, free all of the handles to close them
// in an orderly fashion.
cout << endl << "Freeing handles..." << endl;
SQLFreeHandle(SQL_HANDLE_STMT, hdlStmt);
SQLFreeHandle(SQL_HANDLE_DBC, hdlDbc);
SQLFreeHandle(SQL_HANDLE_ENV, hdlEnv);
cout << "Done!" << endl;
exit(EXIT_SUCCESS);
```

When run, the example's output on the system console is similar to the following:

```
Connecting to database.
Connected to database.
Connected to node v_vmart_node0002
Disconnecting.

Freeing handles...
Done!
```

Notice that the connection was made to the first node in the backup list (node 2).

Note

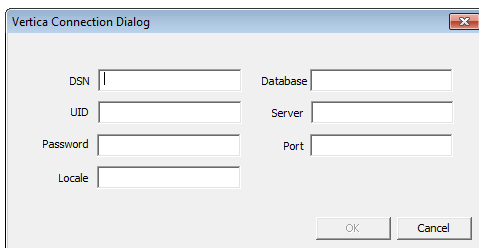

When native connection load balancing is enabled, the additional servers specified in the BackupServerNode connection parameter are only used for the initial connection to a Vertica host. If host redirects the client to another host in the database cluster to handle its connection request, the second connection does not use the backup node list. This is rarely an issue, since native connection load balancing is aware of which nodes are currently up in the database. See [Load balancing](#) for more information.

Prompting windows users for missing connection properties

The Vertica Windows ODBC driver can prompt the user for connection information if required information is missing. The driver displays the Vertica Connection Dialog if the client application calls `SQLDriverConnect` to connect to Vertica and either of the following is true:

- The DriverCompletion property is set to `SQL_DRIVER_PROMPT`.
- The DriverCompletion property is set to `SQL_DRIVER_COMPLETE` or `SQL_DRIVER_COMPLETE_REQUIRED` and the connection string or DSN being used to connect is missing the server, database, or port information.

If either of the above conditions are true, the driver displays a Vertica Connection Dialog to the user to prompt for connection information.

The dialog has all of the property values supplied in the connection string or DSN filled in.

Note

Your connection string at least needs to specify Vertica as the driver, otherwise Windows will not know to use the Vertica ODBC driver to try to open the connection.

The required fields on the connection dialog are Database, UID, Server, and Port. Once these are filled in, the form enables the **OK** button.

If the user clicks **Cancel** on the dialog, the `SQLDriverConnect` function call returns `SQL_NO_DATA` immediately, without attempting to connect to Vertica. If the user supplies incomplete or incorrect information for the connection, the connection function returns `SQL_ERROR` after the connection attempt fails.

Note

If the `DriverCompletion` property of the `SQLDriverConnect` function call is `SQL_DRIVER_NOPROMPT`, the ODBC driver immediately returns a `SQL_ERROR` indicating that it cannot connect because not enough information has been supplied and the driver is not allowed to prompt the user for the missing information.

Prompting windows users for passwords

If the connection string or DSN supplied to the `SQLDriverConnect` function that client applications call to connect to Vertica lacks any of the required connection properties needed to connect, the Vertica's Windows ODBC driver opens a dialog box to prompt the user to enter the missing information (see [Prompting windows users for missing connection properties](#)). The user's password is not normally considered a required connection property because Vertica user accounts may not have a password. If the password property is missing, the ODBC driver still tries to connect to Vertica without supplying a password.

You can use the `PromptOnNoPassword` DSN parameter to force ODBC driver to treat the password as a required connection property. This parameter is useful if you do not want to store passwords in DSN entries. Passwords saved in DSN entries are insecure, since they are stored as clear text in the Windows registry and therefore visible to other users on the same system.

There are two other factors which also decide whether the ODBC driver displays the Vertica Connection Dialog. These are (in order of priority):

- The `SQLDriverConnect` function call's `DriverCompletion` parameter.
- Whether the DSN or connection string contain a password

The following table shows how the `PromptOnNoPassword` DSN parameter, the `DriverCompletion` parameter of the `SQLDriverConnect` function, and whether the DSN or connection string contains a password interact to control whether the Vertica Connection dialog appears.

PromptOnNoPassword Setting	DriverCompletion Value	DSN or Connection String Contains Password?	Vertica Connection Dialog Displays?	Notes
any value	<code>SQL_DRIVER_PROMPT</code>	any case	Yes	This <code>DriverCompletion</code> value forces the dialog to always appear, even if all required connection properties are supplied.
any value	<code>SQL_DRIVER_NOPROMPT</code>	any case	No	This <code>DriverCompletion</code> value always prevents the dialog from appearing.
any value	<code>SQL_DRIVER_COMPLETE</code>	Yes	No	Connection dialog displays if another required connection property is missing.
true	<code>SQL_DRIVER_COMPLETE</code>	No	Yes	
false (default)	<code>SQL_DRIVER_COMPLETE</code>	No	No	Connection dialog displays if another required connection property is missing.

The following example code demonstrates using the `PromptOnNoPassword` DSN parameter along with a system DSN in C++:

```
wstring connectString = L "DSN=VerticaDSN;PromptOnNoPassword=1;";
retcode = SQLDriverConnect(
    hdbc,
    0,
    (SQLWCHAR * ) connectString.c_str(),
    connectString.length(),
    OutConnStr,
    255, &
    amp; OutConnStrLen,
    SQL_DRIVER_COMPLETE);
```

No password entry vs. empty passwords

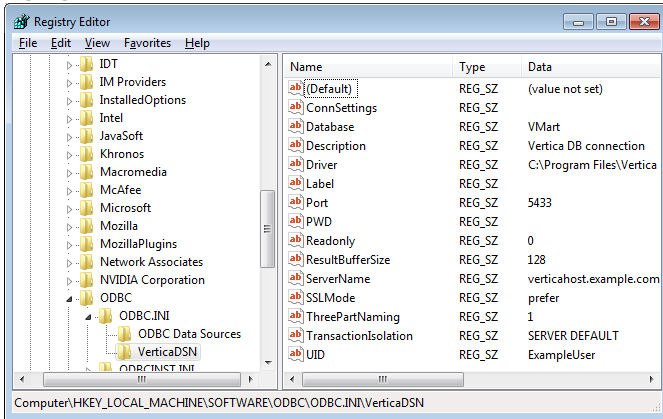

There is a difference between not having a password property in the connection string or DSN and having an empty password. The

PromptOnNoPassword DSN parameter only has an effect if the connection string or DSN does not have a PWD property (which holds the user's password). If it does, even if it is empty, PromptOnNoPassword will not prompt the Windows ODBC driver to display the Vertica Connection Dialog.

This difference can cause confusion if you are using a DSN to provide the properties for your connection. Once you enter a password for a DSN connection in the Windows ODBC Manager and save it, Windows adds a PWD property to the DSN definition in the registry. If you later delete the password, the PWD property remains in the DSN definition—value is just set to an empty string. The PWD property is created even if you just use the Test button on the ODBC Manager dialog to test the DSN and later clear it before saving the DSN.

Once the password has been set, the only way to remove the PWD property from the DSN definition is to delete it using the Windows Registry Editor:

1. On the Windows Start menu, click Run.
2. In the Run dialog, type regedit, then click OK.
3. In the Registry Editor window, click Edit > Find (or press Ctrl+F).
4. In the Find window, enter the name of the DSN whose PWD property you want to delete and click OK.
5. If find operation did not locate a folder under the ODBC.INI folder, click Edit > Find Next (or press F3) until the folder matching your DSN's name is highlighted.

6. Select the PWD entry and press Delete.
7. Click Yes to confirm deleting the value.

The DSN now does not have a PWD property and can trigger the connection dialog to appear when used along with PromptOnNoPassword=true and DriverConnect=SQL_DRIVER_COMPLETE.

Setting the locale and encoding for ODBC sessions

Vertica provides the following methods to set the locale and encoding for an ODBC session:

- Specify the locale for all connections made using the DSN:
 - On Linux and other UNIX-like platforms: [Creating an ODBC DSN for Linux](#)
 - On Windows platforms, set the locale in the ODBC DSN configuration editor's Locale field on the Server Settings tab. See [Creating an ODBC DSN for windows clients](#) for detailed information.

- Set the Locale connection parameter in the connection string in `SQLDriverConnect()` function. For example:

```
SQLDriverConnect(conn, NULL, (SQLCHAR*)"DSN=Vertica;Locale=en_GB@collation=binary", SQL_NTS, szConnOut, sizeof(szConnOut), &IAvailable, S
```

- Use `SQLSetConnectAttr()` to set the encoding and locale. In general, you should always set the encoding with this function as opposed to, for example, setting it in the DSN.

- Pass the `SQL_ATTR_VERTICA_LOCALE` constant and the ICU string as the attribute value. For example:

```
-> SQLSetConnectAttr(hdbc, SQL_ATTR_VERTICA_LOCALE, (SQLCHAR*)"newLocale", SQL_NTS);
```

- Pass the `SQL_ATTR_APP_WCHAR_TYPE` constant and the encoding as the attribute value. For example:

```
-> rc = SQLSetConnectAttr(hdbc, SQL_ATTR_APP_WCHAR_TYPE, (void*)"SQL_DD_CP_UTF16", SQL_IS_INTEGER);
```

Notes

- Having the client system use a non-Unicode locale (such as setting `LANG=C` on Linux platforms) and using a Unicode locale for the connection to Vertica can result in errors such as "(10170) String data right truncation on data from data source." If data received from Vertica isn't in UTF-8 format. The driver allocates string memory based on the system's locale setting, and non-UTF-8 data can trigger an overrun. You can avoid these errors by always using a Unicode locale on the client system.

If you specify a locale either in the connection string or in the DSN, the call to the connection function returns `SQL_SUCCESS_WITH_INFO` on a successful connection, with messages about the state of the locale.

- ODBC applications can be in either ANSI or Unicode mode:

- If Unicode, the encoding used by ODBC is UCS-2.
 - If ANSI, the data must be in single-byte ASCII, which is compatible with UTF-8 on the database server.
- The ODBC driver converts UCS-2 to UTF-8 when passing to the Vertica server and converts data sent by the Vertica server from UTF-8 to UCS-2.
- If the end-user application is not already in UCS-2, the application is responsible for converting the input data to UCS-2, or unexpected results could occur. For example:
 - On non-UCS-2 data passed to ODBC APIs, when it is interpreted as UCS-2, it could result in an invalid UCS-2 symbol being passed to the APIs, resulting in errors.
 - Or the symbol provided in the alternate encoding could be a valid UCS-2 symbol; in this case, incorrect data is inserted into the database.
- ODBC applications should set the correct server session locale using `SQLSetConnectAttr` (if different from database-wide setting) in order to set the proper collation and string functions behavior on server.

The following example code demonstrates setting the locale using both the connection string and with the `SQLSetConnectAttr()` function.

```

// Standard i/o library
#include <stdio.h>
#include <stdlib.h>
// Only needed for Windows clients
// #include <windows.h>
// SQL include files that define data types and ODBC API
// functions
#include <sql.h>
#include <sqlext.h>
#include <sqltypes.h>
// Vertica-specific definitions. This include file is located as
// /opt/vertica/include on database hosts.
#include <verticaodbc.h>
int main()
{
    SQLRETURN ret; // Stores return value from ODBC API calls
    SQLHENV hdlEnv; // Handle for the SQL environment object
    // Allocate an a SQL environment object
    ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hdlEnv);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not allocate a handle.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Allocated an environment handle.\n");
    }
    // Set the ODBC version we are going to use to 3.
    ret = SQLSetEnvAttr(hdlEnv, SQL_ATTR_ODBC_VERSION,
        (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_UIINTEGER);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not set application version to ODBC 3.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Set application version to ODBC 3.\n");
    }
    // Allocate a database handle.
    SQLHDBC hdlDbc;
    ret = SQLAllocHandle(SQL_HANDLE_DBC, hdlEnv, &hdlDbc);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not allocate database handle.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Allocated Database handle.\n");
    }
    // Connect to the database using SQLDriverConnect
    printf("Connecting to database.\n");
    // Set the locale to English in Great Britain.
    const char *connStr = "DSN=ExampleDB;locale=en_GB;"
        "UID=dbadmin;PWD=password123";
    ret = SQLDriverConnect(hdlDbc, NULL, (SQL_CHAR)connStr, SQL_NTS,

```

```

ret = SQLExecDirect(hdbc, (SQLCHAR*)"SELECT * FROM customers WHERE customer_id = 1000",
    NULL, 0, NULL, SQL_DRIVER_NOPROMPT);
if(!SQL_SUCCEEDED(ret)) {
    printf("Could not connect to database.\n");
    exit(EXIT_FAILURE);
} else {
    printf("Connected to database.\n");
}
// Get the Locale
char locale[256];
SQLGetConnectAttr(hdbc, SQL_ATTR_VERTICAL_LOCALE, locale, sizeof(locale),
    0);
printf("Locale is set to: %s\n", locale);
// Set the locale to a new value
const char* newLocale = "en_GB";
SQLSetConnectAttr(hdbc, SQL_ATTR_VERTICAL_LOCALE, (SQLCHAR*)newLocale,
    SQL_NTS);

// Get the Locale again
SQLGetConnectAttr(hdbc, SQL_ATTR_VERTICAL_LOCALE, locale, sizeof(locale),
    0);
printf("Locale is now set to: %s\n", locale);

// Set the encoding
SQLSetConnectAttr(hdbc, SQL_ATTR_APP_WCHAR_TYPE, (void*)"SQL_DD_CP_UTF16",
    SQL_IS_INTEGER);

// When done, free all of the handles to close them
// in an orderly fashion.
printf("Disconnecting and freeing handles.\n");
ret = SQLDisconnect(hdbc);
if(!SQL_SUCCEEDED(ret)) {
    printf("Error disconnecting from database. Transaction still open?\n");
    exit(EXIT_FAILURE);
}
SQLFreeHandle(SQL_HANDLE_DBC, hdbc);
SQLFreeHandle(SQL_HANDLE_ENV, henv);
exit(EXIT_SUCCESS);

```

AUTOCOMMIT and ODBC transactions

The AUTOCOMMIT connection attribute controls whether INSERT, ALTER, COPY and other data-manipulation statements are automatically committed after they complete. By default, AUTOCOMMIT is enabled—all statements are committed after they execute. This is often not the best setting to use, since it is less efficient. Also, you often want to control whether a set of statements are committed as a whole, rather than have each individual statement committed. For example, you may only want to commit a series of inserts if all of the inserts succeed. With AUTOCOMMIT disabled, you can roll back the transaction if one of the statements fail.

If AUTOCOMMIT is on, the results of statements are committed immediately after they are executed. You cannot roll back a statement executed in AUTOCOMMIT mode.

For example, when AUTOCOMMIT is on, the following single INSERT statement is automatically committed:

```

ret = SQLExecDirect(hdStmt, (SQLCHAR*)"INSERT INTO customers VALUES(500,
    \"Smith, Sam\", '123-456-789');", SQL_NTS);

```

If AUTOCOMMIT is off, you need to manually commit the transaction after executing a statement. For example:

```

ret = SQLExecDirect(hdStmt, (SQLCHAR*)"INSERT INTO customers VALUES(500,
    \"Smith, Sam\", '123-456-789');", SQL_NTS);
// Other inserts and data manipulations
// Commit the statements(s)
ret = SQLEndTran(SQL_HANDLE_DBC, hdbc, SQL_COMMIT);

```

The inserted row is only committed when you call `SQLEndTran()` . You can roll back the INSERT and other statements at any point before committing the transaction.

Note

Prepared statements cache the AUTOCOMMIT setting when you create them using `SQLPrepare()` . Later changing the connection's AUTOCOMMIT setting has no effect on the AUTOCOMMIT settings of previously created prepared statements. See [Using prepared statements](#) for details.

The following example demonstrates turning off AUTOCOMMIT, executing an insert, then manually committing the transaction.

```
// Some standard headers
#include <stdio.h>
#include <stdlib.h>
// Only needed for Windows clients
// #include <windows.h>
// Standard ODBC headers
#include <sql.h>
#include <sqltypes.h>
#include <sqlext.h>
int main()
{
    // Set up the ODBC environment
    SQLRETURN ret;
    SQLHENV hdlEnv;
    ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hdlEnv);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not allocate a handle.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Allocated an environment handle.\n");
    }
    // Tell ODBC that the application uses ODBC 3.
    ret = SQLSetEnvAttr(hdlEnv, SQL_ATTR_ODBC_VERSION,
        (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_UIINTEGER);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not set application version to ODBC3.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Set application to ODBC 3.\n");
    }
    // Allocate a database handle.
    SQLHDBC hdlDbc;
    ret = SQLAllocHandle(SQL_HANDLE_DBC, hdlEnv, &hdlDbc);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not allocate database handle.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Allocated Database handle.\n");
    }
    // Connect to the database
    printf("Connecting to database.\n");
    const char *dsnName = "ExampleDB";
    const char *userID = "dbadmin";
    const char *passwd = "password123";
    ret = SQLConnect(hdlDbc, (SQLCHAR*)dsnName,
        SQL_NTS, (SQLCHAR*)userID, SQL_NTS,
        (SQLCHAR*)passwd, SQL_NTS);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not connect to database.\n");
        exit(EXIT_FAILURE);
    }
}
```

```
SQLFreeHandle(SQL_HANDLE_STMT, hdlStmt);
SQLFreeHandle(SQL_HANDLE_DBC, hdlDbc);
SQLFreeHandle(SQL_HANDLE_ENV, hdlEnv);
exit(EXIT_SUCCESS);
```

Running the above code results in the following output:

```
Allocated an environment handle.
Set application to ODBC 3.
Allocated Database handle.
Connecting to database.
Connected to database.
Autocommit is set to: 1
Disabling autocommit.
Autocommit is set to: 0
Performed single insert.
Committing transaction.
Free handles.
```

Note

You can also disable AUTOCOMMIT in the ODBC connection string. See [Setting DSN connection properties](#) for more information.

Retrieving data

To retrieve data through ODBC, you execute a query that returns a result set ([SELECT](#), for example), then retrieve the results using one of two methods:

- Use the [SQLFetch\(\)](#) function to retrieve a row of the result set, then access column values in the row by calling [SQLGetData\(\)](#) .
- Use the [SQLBindColumn\(\)](#) function to bind a variable or array to a column in the result set, then call [SQLExtendedFetch\(\)](#) or [SQLFetchScroll\(\)](#) to read a row of the result set and insert its values into the variable or array.

In both methods you loop through the result set until you either reach the end (signaled by the SQL_NO_DATA return status) or encounter an error.

Note

Vertica supports one cursor per connection. Attempting to use more than one cursor per connection will result in an error. For example, you receive an error if you execute a statement while another statement has a result set open.

The following code example demonstrates retrieving data from Vertica by:

1. Connecting to the database.
2. Executing a SELECT statement that returns the IDs and names of all tables.
3. Binds two variables to the two columns in the result set.
4. Loops through the result set, printing the ids and name values.

```
// Demonstrate running a query and getting results by querying the tables
// system table for a list of all tables in the current schema.
// Some standard headers
#include <stdlib.h>
#include <sstream>
#include <iostream>
#include <assert.h>
// Standard ODBC headers
#include <sql.h>
#include <sqltypes.h>
#include <sqlext.h>

// Use std namespace to make output easier
using namespace std;
```

```
executeQuery(conn.hdlDbc,  
            (SQLCHAR*)"SELECT table_id, table_name FROM tables ORDER BY table_name");  
executeQuery(conn.hdlDbc,  
            (SQLCHAR*)"SELECT table_id, table_name FROM tables ORDER BY table_id");  
disconnect(&conn);  
exit(EXIT_SUCCESS);
```

Running the example code in the vmart database produces output similar to this:

```
Connecting to database.  
Connected to database.

```

Loading data

A primary task for many client applications is loading data into the Vertica database. There are several different ways to insert data using ODBC, which are covered by the topics in this section.

In this section

- [Using a single row insert](#)
- [Using prepared statements](#)
- [Using batch inserts](#)
- [Using the COPY statement](#)
- [Streaming data from the client using COPY LOCAL](#)

Using a single row insert

The easiest way to load data into Vertica is to run an INSERT SQL statement using the SQLExecuteDirect function. However this method is limited to inserting a single row of data.

```
ret = SQLExecDirect(hstmt, (SQLTCHAR*)"INSERT into Customers values"  
    "(1,'abcd','efgh',1)", SQL_NTS);
```

Using prepared statements

Vertica supports using server-side prepared statements with both ODBC and JDBC. Prepared statements let you define a statement once, and then run it many times with different parameters. The statement you want to execute contains placeholders instead of parameters. When you execute the statement, you supply values for each placeholder.

Placeholders are represented by question marks (?) as in the following example query:

```
SELECT * FROM public.inventory_fact WHERE product_key = ?
```

Server-side prepared statements are useful for:

- Optimizing queries. Vertica only needs to parse the statement once.
- Preventing SQL injection attacks. A SQL injection attack occurs when user input is either incorrectly filtered for string literal escape characters embedded in SQL statements or user input is not strongly typed and thereby unexpectedly run. Since a prepared statement is parsed separately from the input data, there is no chance the data can be accidentally executed by the database.
- Binding direct variables to return columns. By pointing to data structures, the code doesn't have to perform extra transformations.

The following example demonstrates a using a prepared statement for a single insert.

```
/* Some standard headers  
#include <stdio.h>  
#include <stdlib.h>  
/* Only needed for Windows clients  
/* #include <windows.h>  
/* Standard ODBC headers  
#include <sql.h>  
#include <sqltypes.h>  
#include <sqlext.h>  
/* Some constants for the size of the data to be inserted.  
#define CUST_NAME_LEN 50  
#define PHONE_NUM_LEN 15  
#define NUM_ENTRIES 4  
int main()  
{  
    // Set up the ODBC environment  
    SQLRETURN ret;  
    SQLHENV hdlEnv;  
    ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hdlEnv);  
    if(!SQL_SUCCEEDED(ret)) {  
        printf("Could not allocate a handle.\n");  
        exit(EXIT_FAILURE);  
    } else {  
        printf("Allocated an environment handle.\n");  
    }  
    // Tell ODBC that the application uses ODBC 3.  
    ret = SQLSetEnvAttr(hdlEnv, SQL_ATTR_ODBC_VERSION,  
        (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_UIINTEGER);  
    if(!SQL_SUCCEEDED(ret)) {  
        printf("Could not set application version to ODBC3.\n");  
        exit(EXIT_FAILURE);  
    } else {  
        printf("Set application to ODBC 3.\n");  
    }  
    // Allocate a database handle.  
    SQLHDBC hdlDbc;  
    ret = SQLAllocHandle(SQL_HANDLE_DBC, hdlEnv, &hdlDbc);  
    if(!SQL_SUCCEEDED(ret)) {  
        printf("Could not allocate a database handle.\n");  
        exit(EXIT_FAILURE);  
    } else {  
        printf("Allocated a database handle.\n");  
    }  
    // Allocate a statement handle.  
    SQLHSTMT hdlStmt;  
    ret = SQLAllocHandle(SQL_HANDLE_STMT, hdlDbc, &hdlStmt);  
    if(!SQL_SUCCEEDED(ret)) {  
        printf("Could not allocate a statement handle.\n");  
        exit(EXIT_FAILURE);  
    } else {  
        printf("Allocated a statement handle.\n");  
    }  
    // Prepare the statement.  
    ret = SQLPrepare(hdlStmt, (SQLTCHAR*)"INSERT into Customers values"  
        "(?, ?, ?, ?)", SQL_NTS);  
    if(!SQL_SUCCEEDED(ret)) {  
        printf("Could not prepare the statement.\n");  
        exit(EXIT_FAILURE);  
    } else {  
        printf("Prepared the statement.\n");  
    }  
    // Execute the statement.  
    ret = SQLExecute(hdlStmt);  
    if(!SQL_SUCCEEDED(ret)) {  
        printf("Could not execute the statement.\n");  
        exit(EXIT_FAILURE);  
    } else {  
        printf("Executed the statement.\n");  
    }  
    // Free the statement handle.  
    ret = SQLFreeHandle(SQL_HANDLE_STMT, hdlStmt);  
    if(!SQL_SUCCEEDED(ret)) {  
        printf("Could not free the statement handle.\n");  
        exit(EXIT_FAILURE);  
    } else {  
        printf("Freed the statement handle.\n");  
    }  
    // Free the database handle.  
    ret = SQLFreeHandle(SQL_HANDLE_DBC, hdlDbc);  
    if(!SQL_SUCCEEDED(ret)) {  
        printf("Could not free the database handle.\n");  
        exit(EXIT_FAILURE);  
    } else {  
        printf("Freed the database handle.\n");  
    }  
    // Free the environment handle.  
    ret = SQLFreeHandle(SQL_HANDLE_ENV, hdlEnv);  
    if(!SQL_SUCCEEDED(ret)) {  
        printf("Could not free the environment handle.\n");  
        exit(EXIT_FAILURE);  
    } else {  
        printf("Freed the environment handle.\n");  
    }  
}
```

```
exit(EXIT_SUCCESS);
```

Using batch inserts

You use batch inserts to insert chunks of data into the database. By breaking the data into batches, you can monitor the progress of the load by receiving information about any rejected rows after each batch is loaded. To perform a batch load through ODBC, you typically use a prepared statement with the parameters bound to arrays that contain the data to be loaded. For each batch, you load a new set of data into the arrays then execute the prepared statement.

When you perform a batch load, Vertica uses a [COPY](#) statement to load the data. Each additional batch you load uses the same COPY statement. The statement remains open until you end the transaction, close the cursor for the statement, or execute a non-INSERT statement.

Using a single COPY statement for multiple batches improves batch loading efficiency by:

- reducing the overhead of inserting individual batches
- combining individual batches into larger ROS containers

Note

If the database connection has AUTOCOMMIT enabled, then the transaction is automatically committed after each batch insert statement which closes the COPY statement. Leaving AUTOCOMMIT enabled makes your batch load much less efficient, and can cause added overhead in your database as all of the smaller loads are consolidated.

Even though Vertica uses a single COPY statement to insert multiple batches within a transaction, you can locate which (if any) rows were rejected due to invalid row formats or data type issues after each batch is loaded. See [Tracking load status \(ODBC\)](#) for details.

Note

While you can find rejected rows during the batch load transaction, other types of errors (such as running out of disk space or a node shutdown that makes the database unsafe) are only reported when the COPY statement ends.

Since the batch loads share a COPY statement, errors in one batch can cause earlier batches in the same transaction to be rolled back.

Batch insert steps

The steps your application needs to take in order to perform an ODBC Batch Insert are:

1. Connect to the database.
2. Disable autocommit for the connection.
3. Create a prepared statement that inserts the data you want to load.
4. Bind the parameters of the prepared statement to arrays that will contain the data you want to load.
5. Populate the arrays with the data for your batches.
6. Execute the prepared statement.
7. Optionally, check the results of the batch load to find rejected rows.
8. Repeat the previous three steps until all of the data you want to load is loaded.
9. Commit the transaction.
10. Optionally, check the results of the entire batch transaction.

The following example code demonstrates a simplified version of the above steps.

```
// Some standard headers
#include <stdio.h>
#include <stdlib.h>
// Only needed for Windows clients
// #include <windows.h>
// Standard ODBC headers
#include <sql.h>
#include <sqltypes.h>
#include <sqltext.h>
int main()

// Number of data rows to insert
```

```

ret = SQLBindParameter(hdlStmt, 4, SQL_PARAM_INPUT, SQL_C_CHAR, SQL_CHAR,
    15, 0, (SQLPOINTER)phoneNums, 15, NULL);
if(!SQL_SUCCEEDED(ret)) {
    printf("Could not bind phoneNums\n");
    exit(EXIT_FAILURE);
} else {
    printf("Bound phoneNums array to prepared statement\n");
}
// Tell the ODBC driver how many rows we have in the
// array.
ret = SQLSetStmtAttr( hdlStmt, SQL_ATTR_PARAMSET_SIZE,
    (SQLPOINTER)NUM_ENTRIES, 0 );
if(!SQL_SUCCEEDED(ret)) {
    printf("Could not bind set parameter size\n");
    exit(EXIT_FAILURE);
} else {
    printf("Bound phoneNums array to prepared statement\n");
}

// Add multiple batches to the database. This just adds the same
// batch of data four times for simplicity's sake. Each call adds
// the 4 rows into the database.
for (int batchLoop=1; batchLoop<=5; batchLoop++) {
    // Execute the prepared statement, loading all of the data
    // in the arrays.
    printf("Adding Batch #%d...", batchLoop);
    ret = SQLExecute(hdlStmt);
    if(!SQL_SUCCEEDED(ret)) {
        printf("not successful\n");
    } else {
        printf("successful.\n");
    }
}
// Done with batches, commit the transaction
printf("Committing transaction\n");
ret = SQLEndTran(SQL_HANDLE_DBC, hdlDbc, SQL_COMMIT);
if(!SQL_SUCCEEDED(ret)) {
    printf("Could not commit transaction\n");
} else {
    printf("Committed transaction\n");
}

// Clean up
printf("Free handles.\n");
ret = SQLDisconnect( hdlDbc );
if(!SQL_SUCCEEDED(ret)) {
    printf("Error disconnecting. Transaction still open?\n");
    exit(EXIT_FAILURE);
}
SQLFreeHandle(SQL_HANDLE_STMT, hdlStmt);
SQLFreeHandle(SQL_HANDLE_DBC, hdlDbc);
SQLFreeHandle(SQL_HANDLE_ENV, hdlEnv);
exit(EXIT_SUCCESS);

```

The result of running the above code is shown below.

Allocated an environment handle.
Set application to ODBC 3.
Allocated Database handle.
Connecting to database.
Connected to database.
Creating prepared statement
Created prepared statement.
Bound CustIDs array to prepared statement
Bound CustNames array to prepared statement
Bound phoneNums array to prepared statement
Adding Batch #1...successful.
Adding Batch #2...successful.
Adding Batch #3...successful.
Adding Batch #4...successful.
Adding Batch #5...successful.
Committing transaction
Committed transaction
Free handles.

The resulting table looks like this:

```
=> SELECT * FROM customers;
CustID | CustName | Phone_Number
+-----+-----+-----+
100 | Allen, Anna | 1-617-555-1234
101 | Brown, Bill | 1-781-555-1212
102 | Chu, Cindy | 1-508-555-4321
103 | Dodd, Don | 1-617-555-4444
100 | Allen, Anna | 1-617-555-1234
101 | Brown, Bill | 1-781-555-1212
102 | Chu, Cindy | 1-508-555-4321
103 | Dodd, Don | 1-617-555-4444
100 | Allen, Anna | 1-617-555-1234
101 | Brown, Bill | 1-781-555-1212
102 | Chu, Cindy | 1-508-555-4321
103 | Dodd, Don | 1-617-555-4444
100 | Allen, Anna | 1-617-555-1234
101 | Brown, Bill | 1-781-555-1212
102 | Chu, Cindy | 1-508-555-4321
103 | Dodd, Don | 1-617-555-4444
100 | Allen, Anna | 1-617-555-1234
101 | Brown, Bill | 1-781-555-1212
102 | Chu, Cindy | 1-508-555-4321
103 | Dodd, Don | 1-617-555-4444
(20 rows)
```

Note

An input parameter bound with the `SQL_C_NUMERIC` data type uses the default numeric precision (37) and the default scale (0) instead of the precision and scale set by the `SQL_NUMERIC_STRUCT` input value. This behavior adheres to the ODBC standard. If you do not want to use the default precision and scale, use `SQLSetDescField()` or `SQLSetDescRec()` to change them in the statement's attributes.

In this section

- [Tracking load status \(ODBC\)](#)
- [Error handling during batch loads](#)

Tracking load status (ODBC)

After loading a batch of data, your client application can get the number of rows that were processed and find out whether each row was accepted or rejected.

Finding the number of accepted rows

To get the number of rows processed by a batch, you add an attribute named `SQL_ATTR_PARAMS_PROCESSED_PTR` to the statement object that points to a variable to receive the number rows:

```
SQLULEN rowsProcessed;
SQLSetStmtAttr(hdlStmt, SQL_ATTR_PARAMS_PROCESSED_PTR, &rowsProcessed, 0);
```

When your application calls `SQLExecute()` to insert the batch, the Vertica ODBC driver saves the number of rows that it processed (which is not necessarily the number of rows that were successfully inserted) in the variable you specified in the `SQL_ATTR_PARAMS_PROCESSED_PTR` statement attribute.

Finding the accepted and rejected rows

Your application can also set a statement attribute named `SQL_ATTR_PARAM_STATUS_PTR` that points to an array where the ODBC driver can store the result of inserting each row:

```
SQLUSMALLINT rowResults[ NUM_ENTRIES ];
SQLSetStmtAttr(hdlStmt, SQL_ATTR_PARAM_STATUS_PTR, rowResults, 0);
```

This array must be at least as large as the number of rows being inserted in each batch.

When your application calls `SQLExecute` to insert a batch, the ODBC driver populates the array with values indicating whether each row was successfully inserted (`SQL_PARAM_SUCCESS` or `SQL_PARAM_SUCCESS_WITH_INFO`) or encountered an error (`SQL_PARAM_ERROR`).

The following example expands on the example shown in [Using batch inserts](#) to include reporting the number of rows processed and the status of each row inserted.

In this example, `SQLGetDiagRec()` is called several times to retrieve the failures for each bulk load. `SQLGetDiagRec()` returns up to 50 failures for any given operation:

```
/* Some standard headers
#include <stdio.h>
#include <stdlib.h>
// Only needed for Windows clients
// #include <windows.h>
// Standard ODBC headers
#include <sql.h>
#include <sqltypes.h>
#include <sqlext.h>
// Helper function to print SQL error messages.
template <typename HandleT>
void reportError(int handleTypeEnum, HandleT hdl)
{
    // Get the status records.
    SQLSMALLINT i, MsgLen;
    SQLRETURN ret2;
    SQLCHAR    SqlState[6], Msg[SQL_MAX_MESSAGE_LENGTH];
    SQLINTEGER NativeError;
    i = 1;
    printf("\n");
    while ((ret2 = SQLGetDiagRec(handleTypeEnum, hdl, i, SqlState, &NativeError,
        Msg, sizeof(Msg), &MsgLen)) != SQL_NO_DATA) {
        printf("error record %d\n", i);
        printf("sqlstate: %s\n", SqlState);
        printf("detailed msg: %s\n", Msg);
        printf("native error code: %d\n\n", NativeError);
        i++;
    }
}

int main()
{
    // Number of data rows to insert
    const int NUM_ENTRIES = 4;
```

```

    SQL_HANDLE_STMT, hdlStmt);
}
// Number of rows processed is in rowsProcessed
printf("Params processed: %d\n", rowsProcessed);
printf("Results of inserting each row:\n");
int i;
for (i = 0; i < NUM_ENTRIES; i++) {
    SQLUSMALLINT result = rowResults[i];
    switch(rowResults[i]) {
        case SQL_PARAM_SUCCESS:
        case SQL_PARAM_SUCCESS_WITH_INFO:
            printf(" Row %d inserted successsfully\n", i+1);
            break;
        case SQL_PARAM_ERROR:
            printf(" Row %d was not inserted due to an error.", i+1);
            break;
        default:
            printf(" Row %d had some issue with it: %d\n", i+1, result);
    }
}
}
// Done with batches, commit the transaction
printf("Commit Transaction\n");
ret = SQLEndTran(SQL_HANDLE_DBC, hdlDbc, SQL_COMMIT);
if(!SQL_SUCCEEDED(ret)) {
    reportError<SQLHDBC>(SQL_HANDLE_STMT, hdlStmt);
}

// Clean up
printf("Free handles.\n");
ret = SQLDisconnect( hdlDbc );
if(!SQL_SUCCEEDED(ret)) {
    printf("Error disconnecting. Transaction still open?\n");
    exit(EXIT_FAILURE);
}
SQLFreeHandle(SQL_HANDLE_STMT, hdlStmt);
SQLFreeHandle(SQL_HANDLE_DBC, hdlDbc);
SQLFreeHandle(SQL_HANDLE_ENV, hdlEnv);
exit(EXIT_SUCCESS);

```

Running the example code produces the following output:

Allocated an environment handle.Set application to ODBC 3.

Allocated Database handle.

Connecting to database.

Connected to database.

Creating table.

Created table.

Creating prepared statement

Created prepared statement.

Commit Transaction

Free handles.

Error handling during batch loads

When loading individual batches, you can find information on how many rows were accepted and what rows were rejected (see [Tracking load status \(ODBC\)](#) for details). Other errors, such as disk space errors, do not occur while inserting individual batches. This behavior is caused by having a single COPY statement perform the loading of multiple consecutive batches. Using the single COPY statement makes the batch load process perform much faster. It is only when the COPY statement closes that the batched data is committed and Vertica reports other types of errors.

Your bulk loading application should check for errors when the COPY statement closes. Normally, you force the COPY statement to close by calling the [SQLEndTran\(\)](#) function to end the transaction. You can also force the COPY statement to close by closing the cursor using the [SQLCloseCursor\(\)](#) function, or by setting the database connection's AutoCommit property to true before inserting the last batch in the load.

Note

The COPY statement also closes if you execute any non-insert statement. However having to deal with errors from the COPY statement in what might be an otherwise-unrelated query is not intuitive, and can lead to confusion and a harder to maintain application. You should explicitly end the COPY statement at the end of your batch load and handle any errors at that time.

Using the COPY statement

[COPY](#) lets you bulk load data from a file stored on a database node into the Vertica database. This method is the most efficient way to load data into Vertica because the file resides on the database server. You must be a superuser to use COPY to access the file system of the database node.

Important

In databases that were created in versions of Vertica ≤ 9.2 , COPY supports the DIRECT option, which specifies to load data directly into [ROS](#) rather than WOS. Use this option when loading large (>100MB) files into the database; otherwise, the load is liable to fill the WOS. When this occurs, the [Tuple Mover](#) must perform a moveout operation on the WOS data. It is more efficient to directly load into ROS and avoid forcing a moveout.

In databases created in Vertica 9.3, Vertica ignores load options and hints and always uses a load method of DIRECT. Databases created in versions ≥ 10.0 no longer support WOS and moveout operations; all data is always loaded directly into ROS.

Note

The exceptions/rejections files are created on the client machine when the exceptions and rejected data modifiers are specified on the COPY command. Specify a local path and filename for these modifiers when executing a COPY query from the driver.

The following example demonstrates using the COPY command:

```
/ Some standard headers
#include <stdio.h>
#include <stdlib.h>
// Only needed for Windows clients
// #include <windows.h>
// Standard ODBC headers
#include <sql.h>
#include <sqltypes.h>
#include <sqlext.h>
// Helper function to determine if an ODBC function call returned
// successfully.
bool notSuccess(SQLRETURN ret) {
    return (ret != SQL_SUCCESS && ret != SQL_SUCCESS_WITH_INFO);
}

int main()
{
    // Set up the ODBC environment
    SQLRETURN ret;
    SQLHENV hdlEnv;
    ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hdlEnv);
    if(notSuccess(ret)) {
        printf("Could not allocate a handle.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Allocated an environment handle.\n");
    }

    // Tell ODBC that the application uses ODBC 3.
    ret = SQLSetEnvAttr(hdlEnv, SQL_ATTR_ODBC_VERSION,
        (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_UINTEGER);
    if(notSuccess(ret)) {
        printf("Could not set application version to ODBC3.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Set application to ODBC 3.\n");
    }

    // Allocate a database handle.
    SQLHDBC hdlDbc;
    ret = SQLAllocHandle(SQL_HANDLE_DBC, hdlEnv, &hdlDbc);
    // Connect to the database
    printf("Connecting to database.\n");
```

```

SQLFreeHandle(SQL_HANDLE_STMT, hdlStmt);
SQLFreeHandle(SQL_HANDLE_DBC, hdlDbc);
SQLFreeHandle(SQL_HANDLE_ENV, hdlEnv);
exit(EXIT_SUCCESS);

```

The example prints the following when run:

```

Allocated an environment handle.
Set application to ODBC 3.
Connecting to database.
Connected to database.
Disabling autocommit.
Successfully inserted 10001 rows.
Committing transaction
Committed transaction
Free handles.

```

Streaming data from the client using COPY LOCAL

[COPY LOCAL](#) streams data from a client system file to your Vertica database. This statement works through the ODBC driver, which simplifies the task of transferring data files from the client to the server.

COPY LOCAL works transparently through the ODBC driver. When a client application executes a COPY LOCAL statement, the ODBC driver reads and streams the data file from the client to the server.

Note

COPY LOCAL must be the first statement in a query, otherwise Vertica returns an error.

This example demonstrates loading data from the client system using the COPY LOCAL statement:

```

/ Some standard headers
#include <stdio.h>
#include <stdlib.h>
/ Only needed for Windows clients
/ #include <windows.h>
/ Standard ODBC headers
#include <sql.h>
#include <sqltypes.h>
#include <sqlext.h>
int main()
{
    // Set up the ODBC environment
    SQLRETURN ret;
    SQLHENV hdlEnv;
    ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hdlEnv);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not allocate a handle.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Allocated an environment handle.\n");
    }
    // Tell ODBC that the application uses ODBC 3.
    ret = SQLSetEnvAttr(hdlEnv, SQL_ATTR_ODBC_VERSION,
        (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_UIINTEGER);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not set application version to ODBC3.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Set application to ODBC 3.\n");
    }
}

```

```

)
SQLFreeHandle(SQL_HANDLE_STMT, hdlStmt);
SQLFreeHandle(SQL_HANDLE_DBC, hdlDbc);
SQLFreeHandle(SQL_HANDLE_ENV, hdlEnv);
exit(EXIT_SUCCESS);

```

This example is essentially the same as the example shown in [Using the COPY statement](#), except it uses the COPY statement's LOCAL option to load data from the client system rather than from the file system of the database node.

Note
On Windows clients, the path you supply for the COPY LOCAL file is limited to 216 characters due to limitations in the Windows API.

C#

The Vertica driver for ADO.NET allows applications written in C# to read data from, update, and load data into Vertica databases. It provides a data adapter ([Vertica Data Adapter](#)) that facilitates reading data from a database into a data set, and then writing changed data from the data set back to the database. It also provides a data reader (`VerticaDataReader`) for reading data. The driver requires the .NET framework version 3.5+.

For more information about ADO.NET, see:

- [Overview of ADO.NET](#)
- [.NET Framework Developer Guide](#)

Prerequisites

You must [install the ADO.NET client driver](#) before creating C# client applications.

In this section

- [ADO.NET data types](#)
- [Setting the locale for ADO.NET sessions](#)
- [Connecting to the database](#)
- [Querying the database using ADO.NET](#)
- [Canceling ADO.NET queries](#)
- [Handling messages](#)
- [Getting table metadata](#)

ADO.NET data types

This table details the mapping between Vertica data types and .NET and ADO.NET data types.

.NET Framework Type	ADO.NET DbType	VerticaType	Vertica Data Type	VerticaDataReader getter
Boolean	Boolean	Bit	Boolean	GetBoolean()
byte[]	Binary	Binary VarBinary LongVarBinary	Binary VarBinary LongVarBinary	GetBytes()

Note
The limit for LongVarBinary is 32 Million bytes. If you attempt to insert more than the limit during a batch transfer for any one row, then they entire batch fails. Verify the size of the data before attempting to insert a LongVarBinary during a batch.

Datetime	DateTime	Date Time TimeStamp	Date Time TimeStamp	GetDateTime() Note The Time portion of the DateTime object for vertica dates is set to DateTime.MinValue. Previously, VerticaType.DateTime was used for all date/time types. VerticaType.DateTime still exists for backwards compatibility, but now there are more specific VerticaTypes for each type.
DateTimeOffset	DateTimeOffset	TimestampTZ TimeTZ	TimestampTZ TimeTZ	GetDateTimeOffset() Note The Date portion of the DateTime is set to DateTime.MinValue
Decimal	Decimal	Numeric	Numeric	GetDecimal()
Double	Double	Double	Double Precision	GetDouble() Note Vertica Double type uses a default precision of 53.
Int64	Int64	BigInt	Integer	GetInt64()
TimeSpan	Object	13 Interval Types	13 Interval Types	GetInterval() Note There are 13 VerticaType values for the 13 types of intervals. The specific VerticaType used determines the conversion rules that the driver applies. Year/Month intervals represented as 365/30 days
String	String	Varchar LongVarChar	Varchar LongVarChar	GetString()
String	StringFixedLengt	Char	Char	GetString()
Guid	Guid	UUID (see note below)	UUID	GetGuid()
Object	Object	N/A	N/A	GetValue()

UUID backwards compatibility

Vertica version 9.0.0 introduced the UUID data type, including JDBC support for UUIDs. The Vertica ADO.NET, ODBC, and OLE DB clients added full support for UUIDs in version 9.0.1. Vertica maintains backwards compatibility with older [supported](#) client driver versions that do not support the UUID data type, as follows:

When an older client...	Vertica...
-------------------------	------------

Queries tables with UUID columns	Translates the native UUID values to CHAR values.
Inserts data into a UUID column	Converts the CHAR value sent by the client into a native UUID value.
Queries a UUID column's metadata	Reports its data type as CHAR.

Setting the locale for ADO.NET sessions

- ADO.NET applications use a UTF-16 character set encoding and are responsible for converting any non-UTF-16 encoded data to UTF-16. The same cautions as for ODBC apply if this encoding is violated.
- The ADO.NET driver converts UTF-16 data to UTF-8 when passing to the Vertica server and converts data sent by Vertica server from UTF-8 to UTF-16.
- ADO.NET applications should set the correct server session locale by executing the [SET LOCALE TO](#) command in order to get expected collation and string functions behavior on the server.
- If there is no default session locale at the database level, ADO.NET applications need to set the correct server session locale by executing the [SET LOCALE TO](#) command in order to get expected collation and string functions behavior on the server. See the [SET LOCALE](#) command.

Connecting to the database

In this section

- [Configuring TLS for ADO.NET](#)
- [Opening and closing the database connection \(ADO.NET\)](#)
- [ADO.NET connection properties](#)
- [Load balancing in ADO.NET](#)
- [ADO.NET connection failover](#)

Configuring TLS for ADO.NET

You can optionally use TLS to secure communication between your ADO.NET application and Vertica.

Prerequisites

Before you configure ADO.NET for TLS, you must [configure client-server TLS](#), setting the TLSMODE to **ENABLE**. Mutual mode (**TRY_VERIFY** or higher) is not supported for ADO.NET.

Linux

The following procedure configures TLS on a Linux system:

Note

The paths for these certificates might vary between distributions.

1. On the client filesystem, create the file `/etc/ssl/certs/server.crt` with the certificate text of the server certificate. You can retrieve the certificate text from a certificate in Vertica by querying the [CERTIFICATES](#) system table.
2. Run the following command to verify that the certificate file is valid. If it is valid, the command outputs information about the certificate:

```

$ openssl x509 -in /etc/ssl/certs/server.crt -text -noout

```

3. On the client filesystem, create the file `/usr/local/share/ca-certificates/root.crt` with the certificate text of the CA certificate.
4. Verify that the certificate was issued by the CA certificate:

```
$ openssl verify -CAfile /usr/local/share/ca-certificates/root.crt /etc/ssl/certs/server.crt
server.crt: OK
```

5. Update the certificate store:

```
$ update-ca-certificates
```

Windows

The Vertica ADO.NET driver uses the TLS certificates in the default Windows key store.

To use TLS for ADO.NET connections to Vertica:

1. Import the server certificate into the Windows key store:
 1. Create a file `server.crt` with the certificate text of the server certificate.
 2. Double-click `server.crt` certificate file.
 3. Let Windows determine the key type and select **Install**.
2. Import the CA certificate into the Windows key store:
 1. Create a file `root.crt` with the certificate text of the CA certificate.
 2. Double-click `root.crt` certificate file.
 3. Select **Place all certificates in the following store**.
 4. Select **Browse**, **Trusted Root Certification Authorities**, and **Next**.
 5. Select **Install**.

Enable SSL in your ADO.NET applications

In your connection string, enable SSL by setting the `SSL` property in `VerticaConnectionStringBuilder` to `true`, for example:

```
//configure connection properties
VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
builder.Host = "192.168.17.10";
builder.Database = "VMart";
builder.User = "dbadmin";
builder.SSL = true;
//open the connection
VerticaConnection _conn = new VerticaConnection(builder.ToString());
_conn.Open();
```

Opening and closing the database connection (ADO.NET)

Before you can access data in Vertica through ADO.NET, you must create a connection to the database using the `VerticaConnection` class which is an implementation of `System.Data.DbConnection`. The `VerticaConnection` class takes a single argument that contains the connection properties as a string. You can manually create a string of property keywords to use as the argument, or you can use the `VerticaConnectionStringBuilder` class to build a connection string for you.

To download the ADO.NET driver, go to the [Client Drivers Downloads page](#).

This topic details the following:

- Manually building a connection string and connecting to Vertica
- Using `VerticaConnectionStringBuilder` to create the connection string and connecting to Vertica
- Closing the connection

To manually create a connection string:

See [ADO.NET connection properties](#) for a list of available properties to use in your connection string. At a minimum, you need to specify the Host, Database, and User.

1. For each property, provide a value and append the properties and values one after the other, separated by a semicolon. Assign this string to a variable. For example:

```
String connectString = "DATABASE=VMart;HOST=v_vmart_node0001;USER=dbadmin";
```

2. Build a Vertica connection object that specifies your connection string.

```
VerticaConnection _conn = new VerticaConnection(connectString)
```

3. Open the connection.

```
_conn.Open();
```

4. Create a command object and associate it with a connection. All `VerticaCommand` objects must be associated with a connection.

```
VerticaCommand command = _conn.CreateCommand();
```

To use the `VerticaConnectionStringBuilder` class to create a connection string and open a connection:

1. Create a new object of the `VerticaConnectionStringBuilder` class.

```
VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
```

2. Update your `VerticaConnectionStringBuilder` object with property values. See [ADO.NET connection properties](#) for a list of available properties to use in your connection string. At a minimum, you need to specify the Host, Database, and User.

```
builder.Host = "v_vmart_node0001";
builder.Database = "VMart";
builder.User = "dbadmin";
```

3. Build a Vertica connection object that specifies your connection `VerticaConnectionStringBuilder` object as a string.

```
VerticaConnection _conn = new VerticaConnection(builder.ToString());
```

4. Open the connection.

```
_conn.Open();
```

5. Create a command object and associate it with a connection. All `VerticaCommand` objects must be associated with a connection.

```
VerticaCommand command = _conn.CreateCommand;
```

Note

If your database is not in compliance with your Vertica license, the call to `VerticaConnection.open()` returns a warning message to the console and the log. See [Managing licenses](#) for more information.

To close the connection:

When you're finished with the database, close the connection. Failure to close the connection can deteriorate the performance and scalability of your application. It can also prevent other clients from obtaining locks.

```
_conn.Close();
```

Example usage:

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";
            VerticaConnection _conn = new VerticaConnection(builder.ToString());
            _conn.Open();
            //Perform some operations
            _conn.Close();
        }
    }
}
```

ADO.NET connection properties

To download the ADO.NET driver, go to the [Client Drivers Downloads page](#).

You use connection properties to configure the connection between your ADO.NET client application and your Vertica database. The properties provide the basic information about the connections, such as the server name and port number, needed to connect to your database.

You can set a connection property in two ways:

- Include the property name and value as part of the connection string you pass to a `VerticaConnection`.
- Set the properties in a `VerticaConnectionStringBuilder` object, and then pass the object as a string to a `VerticaConnection`.

General connection properties

Property	Description	Default Value
Database	Name of the Vertica database to which you want to connect. For example, if you installed the example VMart database, the database is "VMart".	none
User	Name of the user to log into Vertica.	none
Port	Port on which Vertica is running.	5433
Host	<p>The host name or IP address of the server on which Vertica is running.</p> <p>You can provide an IPv4 address, IPv6 address, or host name.</p> <p>In mixed IPv4/IPv6 networks, the DNS server configuration determines which IP version address is sent first. Use the PreferredAddressFamily option to force the connection to use either IPv4 or IPv6.</p>	none
PreferredAddressFamily	<p>The IP version to use if the client and server have both IPv4 and IPv6 addresses and you have provided a host name. Valid values are:</p> <ul style="list-style-type: none"> Ipv4—Connect to the server using IPv4. Ipv6—Connect to the server using IPv6. None—Use the IP address provided by the DNS server. 	Vertica.Data.VerticaClient.AddressFamilyPreference.None
Password	The password associated with the user connecting to the server.	string.Empty
BinaryTransfer	<p>Provides a Boolean value that, when set to true, uses binary transfer instead of text transfer. When set to false, the ADO.NET connection uses text transfer. Binary transfer provides faster performance in reading data from a server to an ADO.NET client. Binary transfer also requires less bandwidth than text transfer, although it sometimes uses more when transferring a large number of small values.</p> <p>Binary transfer mode is not backwards compatible to ADO.NET versions earlier than 3.8. If you are using an earlier version, set this value to false.</p> <p>The data output by both modes is identical with the following exceptions for certain data types:</p> <ul style="list-style-type: none"> FLOAT: Binary transfer has slightly better precision. TIMESTAMPZ: Binary transfer can fail to get the session time zone and default to the local time zone, while text transfer reliably uses the session time zone. NUMERIC: Binary transfer is forcibly disabled for NUMERIC data by the server for Vertica 11.0.2+. 	true
ConnSettings	SQL commands to run upon connection. Uses %3B for semicolons.	string.Empty

IsolationLevel	<p>Sets the transaction isolation level for Vertica. See Transactions for a description of the different transaction levels. This value is either Serializable, ReadCommitted, or Unspecified. See Setting the transaction isolation level for an example of setting the isolation level using this keyword.</p> <p>Note: By default, this value is set to IsolationLevel.Unspecified, which means the connection uses the server's default transaction isolation level. Vertica's default isolation level is IsolationLevel.ReadCommitted.</p>	System.Data. IsolationLevel.Unspecified
Label	A string to identify the session on the server.	string
DirectBatchInsert	Deprecated	true
ResultBufferSize	The size of the buffer to use when streaming results. A value of 0 means ResultBufferSize is turned off.	8192
ConnectionTimeout	Number seconds to wait for a connection. A value of 0 means no timeout.	0
ReadOnly	A Boolean value. If true, throw an exception on write attempts.	false
Pooling	A boolean value, whether to enable connection pooling. Connection pooling is useful for server applications because it allows the server to reuse connections. This saves resources and enhances the performance of executing commands on the database. It also reduces the amount of time a user must wait to establish a connection to the database	false
MinPoolSize	<p>An integer that defines the minimum number of connections to pool.</p> <p>Valid Values: Cannot be greater than the number of connections that the server is configured to allow. Otherwise, an exception results.</p> <p>Default: 55</p>	1
MaxPoolSize	<p>An integer that defines the maximum number of connections to pool.</p> <p>Valid Values: Cannot be greater than the number of connections that the server is configured to allow. Otherwise, an exception results.</p>	20

LoadBalanceTimeout	<p>The amount of time, expressed in seconds, to timeout or remove unused pooled connections.</p> <p>**Disable: **Set to 0 (no timeouts)</p> <p>If you are using a cluster environment to load-balance the work, then pool is restricted to the servers in the cluster when the pool was created. If additional servers are added to the cluster, and the pool is not removed, then the new servers are never added to the connection pool unless LoadBalanceTimeout is set and exceeded or VerticaConnection.ClearAllPools() is called manually from an application. If you are using load balancing, then set this property to a value that considers when new servers are added to the cluster. However, do not set it so low that pools are frequently removed and rebuilt, doing so makes pooling ineffective.</p>	0 (no timeout)
Workload	The name of the workload for the session. For details, see Workload routing .	None (no workload)
SSL	A Boolean value, indicating whether to use SSL for the connection.	false
IntegratedSecurity	Provides a Boolean value that, when set to true, uses the user's Windows credentials for authentication, instead of user/password in the connection string.	false
KerberosServiceName	Provides the service name portion of the Vertica Kerberos principal; for example: vertica/host@EXAMPLE.COM	vertica
KerberosHostname	Provides the instance or host name portion of the Vertica Kerberos principal; for example: verticaost@EXAMPLE.COM	Value specified in the servername connection string property

OAuth connection properties

For details on configuring the ADO.NET driver for OAuth authentication, see [Configuring OAuth authentication](#).

Property	Description	Default Value
OAuthAccessToken	Required, an OAuth token that authorizes a user to the database. The client retrieves this from the identity provider and then presents it to Vertica in a connection attempt. Vertica then contacts the IDP to verify that the access token is valid.	none

Load balancing in ADO.NET

Native connection load balancing

Native connection load balancing helps spread the overhead caused by client connections on the hosts in the Vertica database. Both the server and the client must enable native connection load balancing. If enabled by both, then when the client initially connects to a host in the database, the host picks a host to handle the client connection from a list of the currently up hosts in the database, and informs the client which host it has chosen.

If the initially-contacted host does not choose itself to handle the connection, the client disconnects, then opens a second connection to the host selected by the first host. The connection process to this second host proceeds as usual—if SSL is enabled, then SSL negotiations begin, otherwise the client begins the authentication process. See [About native connection load balancing](#) for details.

To enable native load balancing on your client, set the [ConnectionLoadBalance](#) connection parameter to true either in the connection string or using the [ConnectionStringBuilder\(\)](#). The following example demonstrates connecting to the database several times with native connection load balancing enabled, and fetching the name of the node handling the connection from the V_MONITOR. [CURRENT_SESSION](#) system table.

```

using System;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;

namespace ConsoleApplication1 {
    class Program {
        static void Main(string[] args) {
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "v_vmart_node0001.example.com";
            builder.Database = "VMart";
            builder.User = "dbadmin";
            // Enable native client load balancing in the client,
            // must also be enabled on the server!
            builder.ConnectionLoadBalance = true;

            // Connect 3 times to verify a new node is connected
            // for each connection.
            for (int i = 1; i <= 4; i++) {
                try {
                    VerticaConnection _conn = new VerticaConnection(builder.ToString());
                    _conn.Open();
                    if (i == 1) {
                        // On the first connection, check the server policy for load balance
                        VerticaCommand sqlcom = _conn.CreateCommand();
                        sqlcom.CommandText = "SELECT LOAD_BALANCE_POLICY FROM V_CATALOG.DATABASES";
                        var returnValue = sqlcom.ExecuteScalar();
                        Console.WriteLine("Status of load balancy policy
on server: " + returnValue.ToString() + "\n");
                    }
                    VerticaCommand command = _conn.CreateCommand();
                    command.CommandText = "SELECT node_name FROM V_MONITOR.CURRENT_SESSION";
                    VerticaDataReader dr = command.ExecuteReader();
                    while (dr.Read()) {
                        Console.Write("Connect attempt #" + i + "... ");
                        Console.WriteLine("Connected to node " + dr[0]);
                    }
                    dr.Close();
                    _conn.Close();
                    Console.WriteLine("Disconnecting.\n");
                }
                catch (Exception e) {
                    Console.WriteLine(e.Message);
                }
            }
        }
    }
}

```

Running the above example produces the following output:

Status of load balancing policy on server: roundrobin

Connect attempt #1... Connected to node v_vmart_node0001
Disconnecting.

Connect attempt #2... Connected to node v_vmart_node0002
Disconnecting.

Connect attempt #3... Connected to node v_vmart_node0003
Disconnecting.

Connect attempt #4... Connected to node v_vmart_node0001
Disconnecting.

Hostname-based load balancing

You can also balance workloads by resolving a single hostname to multiple IP addresses. The ADO.NET client driver load balances by automatically resolving the hostname to one of the specified IP addresses at random.

For example, suppose the hostname `verticahost.example.com` has the following entries in `C:\Windows\System32\drivers\etc\hosts` :

```
192.0.2.0 verticahost.example.com
192.0.2.1 verticahost.example.com
192.0.2.2 verticahost.example.com
```

Specifying the hostname `verticahost.example.com` randomly resolves to one of the listed IP addresses.

ADO.NET connection failover

If a client application attempts to connect to a host in the Vertica cluster that is down, the connection attempt fails when using the default connection configuration. This failure usually returns an error to the user. The user must either wait until the host recovers and retry the connection or manually edit the connection settings to choose another host.

Due to Vertica Analytic Database's distributed architecture, you usually do not care which database host handles a client application's connection. You can use the client driver's connection failover feature to prevent the user from getting connection errors when the host specified in the connection settings is unreachable. The JDBC driver gives you several ways to let the client driver automatically attempt to connect to a different host if the one specified in the connection parameters is unreachable:

- Configure your DNS server to return multiple IP addresses for a host name. When you use this host name in the connection settings, the client attempts to connect to the first IP address from the DNS lookup. If the host at that IP address is unreachable, the client tries to connect to the second IP, and so on until it either manages to connect to a host or it runs out of IP addresses.
- Supply a list of backup hosts for the client driver to try if the primary host you specify in the connection parameters is unreachable.
- (JDBC only) Use driver-specific connection properties to manage timeouts before attempting to connect to the next node.

For all methods, the process of failover is transparent to the client application (other than specifying the list of backup hosts, if you choose to use the list method of failover). If the primary host is unreachable, the client driver automatically tries to connect to other hosts.

Failover only applies to the initial establishment of the client connection. If the connection breaks, the driver does not automatically try to reconnect to another host in the database.

Choosing a failover method

You usually choose to use one of the two failover methods. However, they do work together. If your DNS server returns multiple IP addresses and you supply a list of backup hosts, the client first tries all of the IPs returned by the DNS server, then the hosts in the backup list.

Note

If a host name in the backup host list resolves to multiple IP addresses, the client does not try all of them. It just tries the first IP address in the list.

The DNS method of failover centralizes the configuration client failover. As you add new nodes to your Vertica Analytic Database cluster, you can choose to add them to the failover list by editing the DNS server settings. All client systems that use the DNS server to connect to Vertica Analytic Database automatically use connection failover without having to change any settings. However, this method does require administrative access to the DNS server that all clients use to connect to the Vertica Analytic Database cluster. This may not be possible in your organization.

Using the backup server list is easier than editing the DNS server settings. However, it decentralizes the failover feature. You may need to update the application settings on each client system if you make changes to your Vertica Analytic Database cluster.

Using DNS failover

To use DNS failover, you need to change your DNS server's settings to map a single host name to multiple IP addresses of hosts in your Vertica Analytic Database cluster. You then have all client applications use this host name to connect to Vertica Analytic Database.

You can choose to have your DNS server return as many IP addresses for the host name as you want. In smaller clusters, you may choose to have it return the IP addresses of all of the hosts in your cluster. However, for larger clusters, you should consider choosing a subset of the hosts to return. Otherwise there can be a long delay as the client driver tries unsuccessfully to connect to each host in a database that is down.

Using the backup host list

To enable backup list-based connection failover, your client application has to specify at least one IP address or host name of a host in the `BackupServerNode` parameter. The host name or IP can optionally be followed by a colon and a port number. If not supplied, the driver defaults to the standard Vertica port number (5433). To list multiple hosts, separate them by a comma.

The following example demonstrates setting the `BackupServerNode` connection parameter to specify additional hosts for the connection attempt. The connection string intentionally has a non-existent node, so that the initial connection fails. The client driver has to resort to trying the backup hosts to establish a connection to Vertica.

```
using System;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;

namespace ConsoleApplication1
{
    class Program
    {
        static void Main(string[] args)
        {
            VerticaConnectionStringBuilder builder =
            new VerticaConnectionStringBuilder();
            builder.Host = "not.a.real.host:5433";
            builder.Database = "VMart";
            builder.User = "dbadmin";
            builder.BackupServerNode =
            "another.broken.node:5433,v_vmart_node0002.example.com:5433";
            try
            {
                VerticaConnection _conn =
                new VerticaConnection(builder.ToString());
                _conn.Open();
                VerticaCommand sqlcom = _conn.CreateCommand();
                sqlcom.CommandText = "SELECT node_name FROM current_session";
                var returnValue = sqlcom.ExecuteScalar();
                Console.WriteLine("Connected to node: " +
                returnValue.ToString() + "\n");
                _conn.Close();
                Console.WriteLine("Disconnecting.\n");
            }
            catch (Exception e)
            {
                Console.WriteLine(e.Message);
            }
        }
    }
}
```

- When native connection load balancing is enabled, the additional servers specified in the BackupServerNode connection parameter are only used for the initial connection to a Vertica host. If host redirects the client to another host in the database cluster to handle its connection request, the second connection does not use the backup node list. This is rarely an issue, since native connection load balancing is aware of which nodes are currently up in the database. See [Load balancing in ADO.NET](#).
- Connections to a host taken from the BackupServerNode list are not pooled for ADO.NET connections.

Querying the database using ADO.NET

This section describes how to create queries to do the following:

- [Inserting data into the database](#)
- [Read data from the database](#)
- [Load data into the database](#)

Note

The ExecuteNonQuery() method used to query the database returns an int32 with the number of rows affected by the query. The maximum size of an int32 type is a constant and is defined to be 2,147,483,547. If your query returns more results than the int32 max, then ADO.NET throws an exception because of the overflow of the int32 type. However the query is still processed by Vertica even when the reporting of the return value fails. This is a limitation in .NET, as ExecuteNonQuery() is part of the standard ADO.NET interface.

In this section

- [Inserting data \(ADO.NET\)](#)
- [Reading data \(ADO.Net\)](#)
- [Loading data through ADO.Net](#)

Inserting data (ADO.NET)

Inserting data can be done using the VerticaCommand class. VerticaCommand is an implementation of DbCommand. It allows you to create and send a SQL statement to the database. Use the CommandText method to assign a SQL statement to the command and then execute the SQL by calling the ExecuteNonQuery method. The ExecuteNonQuery method is used for executing statements that do not return result sets.

To insert a single row of data:

1. [Create a connection to the database](#).

2. Create a command object using the connection.

```
VerticaCommand command = _conn.CreateCommand();
```

3. Insert data using an INSERT statement. The following is an example of a simple insert. Note that it does not contain a COMMIT statement because the Vertica ADO.NET driver operates in autocommit mode.

```
command.CommandText =  
    "INSERT into test values(2, 'username', 'email', 'password');"
```

4. Execute the query. The rowsAdded variable contains the number of rows added by the insert statement.

```
Int32 rowsAdded = command.ExecuteNonQuery();
```

The ExecuteNonQuery() method returns the number of rows affected by the command for UPDATE, INSERT, and DELETE statements. For all other types of statements it returns -1. If a rollback occurs then it is also set to -1.

Example usage:

```

using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";
            VerticaConnection _conn = new VerticaConnection(builder.ToString());
            _conn.Open();
            VerticaCommand command = _conn.CreateCommand();
            command.CommandText =
                "INSERT into test values(2, 'username', 'email', 'password')";
            Int32 rowsAdded = command.ExecuteNonQuery();
            Console.WriteLine( rowsAdded + " rows added!");
            _conn.Close();
        }
    }
}

```

In this section

- [Using parameters](#)
- [Creating and rolling back transactions](#)

Using parameters

You can use parameters to execute similar SQL statements repeatedly and efficiently.

Using parameters

VerticaParameters are an extension of the System.Data.DbParameter base class in ADO.NET and are used to set parameters in commands sent to the server. Use Parameters in all queries (SELECT/INSERT/UPDATE/DELETE) for which the values in the WHERE clause are not static; that is for all queries that have a known set of columns, but whose filter criteria is set dynamically by an application or end user. Using parameters in this way greatly decreases the chances of a SQL injection issue that can occur when simply creating a SQL query from a number of variables.

Parameters require that a valid DbType, VerticaDbType, or System type be assigned to the parameter. See [Data types](#) and [ADO.NET data types](#) for a mapping of System, Vertica, and DbTypes.

To create a parameter placeholder, place either the at sign (@) or a colon (:) character in front of the parameter name in the actual query string. Do not insert any spaces between the placeholder indicator (@ or :) and the placeholder.

Note

The @ character is the preferred way to identify parameters. The colon (:) character is supported for backward compatibility.

For example, the following typical query uses the string 'MA' as a filter.

```

SELECT customer_name, customer_address, customer_city, customer_state
FROM customer_dimension WHERE customer_state = 'MA';

```

Instead, the query can be written to use a parameter. In the following example, the string MA is replaced by the parameter placeholder @STATE.

```

SELECT customer_name, customer_address, customer_city, customer_state
FROM customer_dimension WHERE customer_state = @STATE;

```

For example, the ADO.net code for the prior example would be written as:

```
VerticaCommand command = _conn.CreateCommand();
command.CommandText = "SELECT customer_name, customer_address, customer_city, customer_state
    FROM customer_dimension WHERE customer_state = @STATE";
command.Parameters.Add(new VerticaParameter( "STATE", VerticaType.VarChar));
command.Parameters["STATE"].Value = "MA";
```

Note

Although the VerticaCommand class supports a Prepare() method, you do not need to call the Prepare() method for parameterized statements because Vertica automatically prepares the statement for you.

Creating and rolling back transactions

Creating transactions

Transactions in Vertica are atomic, consistent, isolated, and durable. When you connect to a database using the Vertica ADO.NET Driver, the connection is in autocommit mode and each individual query is committed upon execution. You can collect multiple statements into a single transaction and commit them at the same time by using a transaction. You can also choose to rollback a transaction before it is committed if your code determines that a transaction should not commit.

Transactions use the VerticaTransaction object, which is an implementation of DbTransaction. You must associate the transaction with the VerticaCommand object.

The following code uses an explicit transaction to insert one row each into to tables of the VMart schema.

To create a transaction in Vertica using the ADO.NET driver:

1. [Create a connection to the database](#).

2. Create a command object using the connection.

```
VerticaCommand command = _conn.CreateCommand();
```

3. Start an explicit transaction, and associate the command with it.

```
VerticaTransaction txn = _conn.BeginTransaction();
command.Connection = _conn;
command.Transaction = txn;
```

4. Execute the individual SQL statements to add rows.

```
command.CommandText =
    "insert into product_dimension values( ... )";
command.ExecuteNonQuery();
command.CommandText =
    "insert into store_orders_fact values( ... )";
```

5. Commit the transaction.

```
txn.Commit();
```

Rolling back transactions

If your code checks for errors, then you can catch the error and rollback the entire transaction.

```

VerticaTransaction txn = _conn.BeginTransaction();
VerticaCommand command = new
    VerticaCommand("insert into product_dimension values( 838929, 5, 'New item 5' )", _conn);
// execute the insert
command.ExecuteNonQuery();
command.CommandText = "insert into product_dimension values( 838929, 6, 'New item 6' )";
// try insert and catch any errors
bool error = false;
try
{
    command.ExecuteNonQuery();
}
catch (Exception e)
{
    Console.WriteLine(e.Message);
    error = true;
}
if (error)
{
    txn.Rollback();
    Console.WriteLine("Errors. Rolling Back.");
}
else
{
    txn.Commit();
    Console.WriteLine("Queries Successful. Committing.");
}

```

Commit and rollback example

This example details how you can commit or rollback queries during a transaction.

```

using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";
            VerticaConnection _conn = new VerticaConnection(builder.ToString());
            _conn.Open();
            bool error = false;
            VerticaCommand command = _conn.CreateCommand();
            VerticaCommand command2 = _conn.CreateCommand();
            VerticaTransaction txn = _conn.BeginTransaction();
            command.Connection = _conn;
            command.Transaction = txn;
            command.CommandText =
                "insert into test values(1, 'test', 'test', 'test' )";
            Console.WriteLine(command.CommandText);
            try
            {
                command.ExecuteNonQuery();
            }
        }
    }
}

```

```
,
catch (Exception e)
{
    Console.WriteLine(e.Message);
    error = true;
}
command.CommandText =
"insert into test values(2, 'ear', 'eye', 'nose', 'extra' )";
Console.WriteLine(command.CommandText);
try
{
    command.ExecuteNonQuery();
}
catch (Exception e)
{
    Console.WriteLine(e.Message);
    error = true;
}
if (error)
{
    txn.Rollback();
    Console.WriteLine("Errors. Rolling Back.");
}
else
{
    txn.Commit();
    Console.WriteLine("Queries Successful. Committing.");
}
_conn.Close();
}
}
```

The example displays the following output on the console:

```
insert into test values(1, 'test', 'test', 'test' )
insert into test values(2, 'ear', 'eye', 'nose', 'extra' )
[42601]ERROR: INSERT has more expressions than target columns
Errors. Rolling Back.
```

In this section

- [Setting the transaction isolation level](#)

Setting the transaction isolation level

You can set the transaction isolation level on a per-connection and per-transaction basis. See [Transaction](#) for an overview of the transaction isolation levels supported in Vertica. To set the default transaction isolation level for a connection, use the *IsolationLevel* keyword in the `VerticaConnectionStringBuilder` string (see [Connection String Keywords](#) for details). To set the isolation level for an individual transaction, pass the isolation level to the `VerticaConnection.BeginTransaction()` method call to start the transaction.

To set the isolation level on a connection-basis:

1. Use the `VerticaConnectionStringBuilder` to build the connection string.
2. Provide a value for the `IsolationLevel` builder string. It can take one of two values: `IsolationLevel.ReadCommitted` (default) or `IsolationLevel.Serializable`. For example:

```
VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
builder.Host = "192.168.1.100";
builder.Database = "VMart";
builder.User = "dbadmin";
builder.IsolationLevel = System.Data.IsolationLevel.Serializable
VerticaConnection _conn1 = new VerticaConnection(builder.ToString());
_conn1.Open();
```

To set the isolation level on a transaction basis:

1. Set the IsolationLevel on the BeginTransaction method, for example

```
VerticaTransaction txn = _conn.BeginTransaction(IsolationLevel.Serializable);
```

Example usage:

The following example demonstrates:

- getting the connection's transaction isolation level.
- setting the connection's isolation level using connection property.
- setting the transaction isolation level for a new transaction.

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";
            VerticaConnection _conn1 = new VerticaConnection(builder.ToString());
            _conn1.Open();
            VerticaTransaction txn1 = _conn1.BeginTransaction();
            Console.WriteLine("\n Transaction 1 Transaction Isolation Level: " +
                txn1.IsolationLevel.ToString());
            txn1.Rollback();
            VerticaTransaction txn2 = _conn1.BeginTransaction(IsolationLevel.Serializable);
            Console.WriteLine("\n Transaction 2 Transaction Isolation Level: " +
                txn2.IsolationLevel.ToString());
            txn2.Rollback();
            VerticaTransaction txn3 = _conn1.BeginTransaction(IsolationLevel.ReadCommitted);
            Console.WriteLine("\n Transaction 3 Transaction Isolation Level: " +
                txn3.IsolationLevel.ToString());
            _conn1.Close();
        }
    }
}
```

When run, the example code prints the following to the system console:

```
Transaction 1 Transaction Isolation Level: ReadCommitted
Transaction 2 Transaction Isolation Level: Serializable
Transaction 3 Transaction Isolation Level: ReadCommitted
```

To read data from the database use `VerticaDataReader`, an implementation of `DbDataReader`. This implementation is useful for moving large volumes of data quickly off the server where it can be run through analytic applications.

Note

A `VerticaCommand` cannot execute anything else while it has an open `VerticaDataReader` associated with it. To execute something else, close the data reader or use a different `VerticaCommand` object.

To read data from the database using `VerticaDataReader`:

1. [Create a connection to the database](#).

2. Create a command object using the connection.

```
VerticaCommand command = _conn.CreateCommand();
```

3. Create a query. This query works with the example VMart database.

```
command.CommandText =  
"SELECT fat_content, product_description " +  
"FROM (SELECT DISTINCT fat_content, product_description" +  
" FROM product_dimension " +  
" WHERE department_description " + " IN ('Dairy') " +  
" ORDER BY fat_content) AS food " +  
"LIMIT 10;";
```

4. Execute the reader to return the results from the query. The following command calls the `ExecuteReader` method of the `VerticaCommand` object to obtain the `VerticaDataReader` object.

```
VerticaDataReader dr = command.ExecuteReader();
```

5. Read the data. The data reader returns results in a sequential stream. Therefore, you must read data from tables row-by-row. The following example uses a while loop to accomplish this:

```
Console.WriteLine("\n\n Fat Content\t Product Description");  
Console.WriteLine("-----\t -----");  
int rows = 0;  
while (dr.Read())  
{  
    Console.WriteLine(" " + dr[0] + " \t " + dr[1]);  
    ++rows;  
}  
Console.WriteLine("-----\n (" + rows + " rows)\n");
```

6. When you're finished, close the data reader to free up resources.

```
dr.Close();
```

Example usage:

```

using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";
            VerticaConnection _conn = new VerticaConnection(builder.ToString());
            _conn.Open();
            VerticaCommand command = _conn.CreateCommand();
            command.CommandText =
                "SELECT fat_content, product_description " +
                "FROM (SELECT DISTINCT fat_content, product_description " +
                " FROM product_dimension " +
                " WHERE department_description " +
                " IN ('Dairy') " +
                " ORDER BY fat_content) AS food " +
                "LIMIT 10;";
            VerticaDataReader dr = command.ExecuteReader();

            Console.WriteLine("\n\n Fat Content\t Product Description");
            Console.WriteLine("-----\t -----");
            int rows = 0;
            while (dr.Read())
            {
                Console.WriteLine(" " + dr[0] + " \t " + dr[1]);
                ++rows;
            }
            Console.WriteLine("-----\n (" + rows + " rows)\n");
            dr.Close();
            _conn.Close();
        }
    }
}

```

Loading data through ADO.Net

This section details the different ways that you can load data in Vertica using the ADO.NET client driver:

- [Using the Vertica Data Adapter](#)
- [Using batch inserts and prepared statements](#)
- [Streaming data via ADO.NET](#)

In this section

- [Using the Vertica data adapter](#)
- [Using batch inserts and prepared statements](#)
- [Streaming data via ADO.NET](#)

Using the Vertica data adapter

The Vertica data adapter (VerticaDataAdapter) enables a client to exchange data between a data set and a Vertica database. It is an implementation of DbDataAdapter. You can use VerticaDataAdapter to simply read data, or, for example, read data from a database into a data set, and then write changed data from the data set back to the database.

Batching updates

When using the Update() method to update a dataset, you can optionally use the UpdateBatchSize() method prior to calling Update() to reduce the number of times the client communicates with the server to perform the update. The default value of UpdateBatchSize is 1. If you have multiple rows.Add() commands for a data set, then you can change the batch size to an optimal size to speed up the operations your client must perform to complete the update.

Reading data from Vertica using the data adapter:

The following example details how to perform a select query on the VMart schema and load the result into a DataTable, then output the contents of the DataTable to the console.

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using System.Data.SqlClient;
Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";
            VerticaConnection _conn = new VerticaConnection(builder.ToString());
            _conn.Open();

            // Try/Catch any exceptions
            try
            {
                using (_conn)
                {
                    // Create the command
                    VerticaCommand command = _conn.CreateCommand();
                    command.CommandText = "select product_key, product_description " +
                        "from product_dimension where product_key < 10";

                    // Associate the command with the connection
                    command.Connection = _conn;

                    // Create the DataAdapter
                    VerticaDataAdapter adapter = new VerticaDataAdapter();
                    adapter.SelectCommand = command;

                    // Fill the DataTable
                    DataTable table = new DataTable();
                    adapter.Fill(table);

                    // Display each row and column value.
                    int i = 1;
                    foreach (DataRow row in table.Rows)
                    {
                        foreach (DataColumn column in table.Columns)
                        {
                            Console.Write(row[column] + "\t");
                        }
                        Console.WriteLine();
                        i++;
                    }
                }
            }
        }
    }
}
```

```

        }
        Console.WriteLine(i + " rows returned.");
    }
}
catch (Exception e)
{
    Console.WriteLine(e.Message);
}
_conn.Close();
}
}
}
}

```

Reading data from Vertica into a data set and changing data:

The following example shows how to use a data adapter to read from and insert into a dimension table of the VMart schema.

```

using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using System.Data.SqlClient;
using Vertica.Data.VerticaClient
namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";
            VerticaConnection _conn = new VerticaConnection(builder.ToString());
            _conn.Open();

            // Try/Catch any exceptions
            try
            {
                using (_conn)
                {

                    //Create a data adapter object using the connection
                    VerticaDataAdapter da = new VerticaDataAdapter();

                    //Create a select statement that retrieves data from the table
                    da.SelectCommand = new
                    VerticaCommand("select * from product_dimension where product_key < 10",
                    _conn);
                    //Set up the insert command for the data adapter, and bind variables for some of the columns
                    da.InsertCommand = new
                    VerticaCommand("insert into product_dimension values( :key, :version, :desc )",
                    _conn);
                    da.InsertCommand.Parameters.Add(new VerticaParameter("key", VerticaType.BigInt));
                    da.InsertCommand.Parameters.Add(new VerticaParameter("version", VerticaType.BigInt));
                    da.InsertCommand.Parameters.Add(new VerticaParameter("desc", VerticaType.VarChar));
                    da.InsertCommand.Parameters[0].SourceColumn = "product_key";
                    da.InsertCommand.Parameters[1].SourceColumn = "product_version";
                    da.InsertCommand.Parameters[2].SourceColumn = "product_description";
                    da.TableMappings.Add("product_key", "product_key");
                    da.TableMappings.Add("product_version", "product_version");
                }
            }
        }
    }
}

```

```

da.TableMappings.Add("product_description", "product_description");

    //Create and fill a Data set for this dimension table, and get the resulting DataTable.
    DataSet ds = new DataSet();
da.Fill(ds, 0, 0, "product_dimension");
DataTable dt = ds.Tables[0];

    //Bind parameters and add two rows to the table.
    DataRow dr = dt.NewRow();
dr["product_key"] = 838929;
dr["product_version"] = 5;
dr["product_description"] = "New item 5";
dt.Rows.Add(dr);
dr = dt.NewRow();
dr["product_key"] = 838929;
dr["product_version"] = 6;
dr["product_description"] = "New item 6";
dt.Rows.Add(dr);
//Extract the changes for the added rows.
    DataSet ds2 = ds.GetChanges();

    //Send the modifications to the server.
    int updateCount = da.Update(ds2, "product_dimension");

    //Merge the changes into the original Data set, and mark it up to date.
    ds.Merge(ds2);
da.AcceptChanges();
    Console.WriteLine(updateCount + " updates made!");
}
}
catch (Exception e)
{
    Console.WriteLine(e.Message);
}
_conn.Close();
}
}
}
}

```

Using batch inserts and prepared statements

You can load data in batches using a prepared statement with parameters. You can also use transactions to rollback the batch load if any errors are encountered.

If you are loading large batches of data (more than 100MB), then consider using a direct batch insert.

The following example details using data contained in arrays, parameters, and a transaction to batch load data.

The test table used in the example is created with the command:

```
=> CREATE TABLE test (id INT, username VARCHAR(24), email VARCHAR(64), password VARCHAR(8));
```

Example batch insert using parameters and transactions

```

using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
    class Program

```

```

{
static void Main(string[] args)
{
    VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
    builder.Host = "192.168.1.10";
    builder.Database = "VMart";
    builder.User = "dbadmin";
    VerticaConnection _conn = new VerticaConnection(builder.ToString());
    _conn.Open();
    // Create arrays for column data
    int[] ids = {1, 2, 3, 4};
    string[] usernames = {"user1", "user2", "user3", "user4"};
    string[] emails = { "user1@example.com", "user2@example.com", "user3@example.com", "user4@example.com" };
    string[] passwords = { "pass1", "pass2", "pass3", "pass4" };
    // create counters for accepted and rejected rows
    int rows = 0;
    int rejRows = 0;
    bool error = false;
    // Create the transaction
    VerticaTransaction txn = _conn.BeginTransaction();
    // Create the parameterized query and assign parameter types
    VerticaCommand command = _conn.CreateCommand();
    command.CommandText = "insert into TEST values (@id, @username, @email, @password)";
    command.Parameters.Add(new VerticaParameter("id", VerticaType.BigInt));
    command.Parameters.Add(new VerticaParameter("username", VerticaType.VarChar));
    command.Parameters.Add(new VerticaParameter("email", VerticaType.VarChar));
    command.Parameters.Add(new VerticaParameter("password", VerticaType.VarChar));
    // Prepare the statement
    command.Prepare();

    // Loop through the column arrays and insert the data
    for (int i = 0; i < ids.Length; i++) {
        command.Parameters["id"].Value = ids[i];
        command.Parameters["username"].Value = usernames[i];
        command.Parameters["email"].Value = emails[i];
        command.Parameters["password"].Value = passwords[i];
        try
        {
            rows += command.ExecuteNonQuery();
        }
        catch (Exception e)
        {
            Console.WriteLine("\nInsert failed - \n " + e.Message + "\n");
            ++rejRows;
            error = true;
        }
    }
    if (error)
    {
        // Roll back if errors
        Console.WriteLine("Errors. Rolling Back Transaction.");
        Console.WriteLine(rejRows + " rows rejected.");
        txn.Rollback();
    }
    else
    {
        // Commit if no errors
        Console.WriteLine("No Errors. Committing Transaction.");
        txn.Commit();
        Console.WriteLine("Inserted " + rows + " rows. ");
    }
}
}

```

```
        _conn.Close();
    }
}
```

Streaming data via ADO.NET

There are two options to stream data from a file on the client to your Vertica database through ADO.NET:

- Use the [VerticaCopyStream](#) ADO.NET class to stream data in an object-oriented manner
- Execute a [COPY LOCAL](#) SQL statement to stream the data

The topics in this section explain how to use these options.

In this section

- [Streaming from the client via VerticaCopyStream](#)
- [Using copy with ADO.NET](#)

Streaming from the client via VerticaCopyStream

The [VerticaCopyStream](#) class lets you stream data from the client system to a Vertica database. It lets you use the SQL [COPY statement](#) directly without having to copy the data to a host in the database cluster first by substituting one or more data stream(s) for STDIN.

Notes:

- Use Transactions and disable auto commit on the copy command for better performance.
- Disable auto commit using the copy command with the 'no commit' modifier. You must explicitly disable commits. Enabling transactions does not disable autocommit when using VerticaCopyStream.
- The copy command used with VerticaCopyStream uses copy syntax.
- VerticaCopyStream.rejects is zeroed every time execute is called. If you want to capture the number of rejects, assign the value of VerticaCopyStream.rejects to another variable before calling execute again.
- You can add multiple streams using multiple AddStream() calls.

Example usage:

The following example demonstrates using VerticaCopyStream to copy a file stream into Vertica.

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using System.IO;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            // Configure connection properties
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";
            //open the connection
            VerticaConnection _conn = new VerticaConnection(builder.ToString());
            _conn.Open();
            try
            {
                using (_conn)
                {
                    // Start a transaction
                    VerticaTransaction txn = _conn.BeginTransaction();
```

```

        // Create a table for this example
        VerticaCommand command = new VerticaCommand("DROP TABLE IF EXISTS copy_table", _conn);
command.ExecuteNonQuery();
        command.CommandText = "CREATE TABLE copy_table (Last_Name char(50), "
            + "First_Name char(50),Email char(50), "
            + "Phone_Number char(15))";
        command.ExecuteNonQuery();
        // Create a new filestream from the data file
        string filename = "C:/customers.txt";
Console.WriteLine("\n\nLoading File: " + filename);
        FileStream inputfile = File.OpenRead(filename);
        // Define the copy command
        string copy = "copy copy_table from stdin record terminator E'\n' delimiter '|' + " enforcelength "
            + " no commit";
        // Create a new copy stream instance with the connection and copy statement
        VerticaCopyStream vcs = new VerticaCopyStream(_conn, copy);

        // Start the VerticaCopyStream process
        vcs.Start();
        // Add the file stream
        vcs.AddStream(inputfile, false);

        // Execute the copy
        vcs.Execute();

        // Finish stream and write out the list of inserted and rejected rows
        long rowsInserted = vcs.Finish();
        IList<long> rowsRejected = vcs.Rejects;
        // Does not work when rejected or exceptions defined
        Console.WriteLine("Number of Rows inserted: " + rowsInserted);
        Console.WriteLine("Number of Rows rejected: " + rowsRejected.Count);
        if (rowsRejected.Count > 0)
        {
            for (int i = 0; i < rowsRejected.Count; i++)
            {
                Console.WriteLine("Rejected row #{0} is row {1}", i, rowsRejected[i]);
            }
        }

        // Commit the changes
        txn.Commit();
    }
}
catch (Exception e)
{
    Console.WriteLine(e.Message);
}

        //close the connection
        _conn.Close();
    }
}
}

```

Using copy with ADO.NET

To use COPY with ADO.NET, just execute a COPY statement and the path to the source file on the client system. This method is simpler than using the VerticaCopyStream class. However, you may prefer using VerticaCopyStream if you have many files to copy to the database or if your data comes from a source other than a local file (streamed over a network connection, for example).

The following example code demonstrates using COPY to copy a file from the client to the database. It is the same as the code shown in Bulk Loading Using the COPY Statement and the path to the data file is on the client system, rather than on the server.

To load data that is stored on a database node, use a VerticaCommand object to create a [COPY](#) command:

1. [Create a connection to the database](#) through the node on which the data file is stored.
2. Create a command object using the connection.

```
VerticaCommand command = _conn.CreateCommand();
```

3. Copy data. The following is an example of using the [COPY](#) command to load data. It uses the LOCAL modifier to copy a file local to the client issuing the command.

```
command.CommandText = "copy lcopy_table from '/home/dbadmin/customers.txt'"  
+ " record terminator E'\n' delimiter '|'"  
+ " enforcelength ";  
  
Int32 insertedRows = command.ExecuteNonQuery();  
Console.WriteLine(insertedRows + " inserted.");
```

Example usage:

```

using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using System.IO;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            // Configure connection properties
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";

            // Open the connection
            VerticaConnection _conn = new VerticaConnection(builder.ToString());
            _conn.Open();
            try
            {
                using (_conn)
                {

                    // Start a transaction
                    VerticaTransaction txn = _conn.BeginTransaction();

                    // Create a table for this example
                    VerticaCommand command = new VerticaCommand("DROP TABLE IF EXISTS lcopy_table", _conn);
                    command.ExecuteNonQuery();
                    command.CommandText = "CREATE TABLE IF NOT EXISTS lcopy_table (Last_Name char(50), "
                        + "First_Name char(50),Email char(50), "
                        + "Phone_Number char(15))";
                    command.ExecuteNonQuery();
                    // Define the copy command
                    command.CommandText = "copy lcopy_table from '/home/dbadmin/customers.txt'"
                        + " record terminator E'\n' delimiter '|' "
                        + " enforcelength "
                        + " no commit";
                    // Execute the copy
                    Int32 insertedRows = command.ExecuteNonQuery();
                    Console.WriteLine(insertedRows + " inserted.");
                    // Commit the changes
                    txn.Commit();

                }
            }
            catch (Exception e)
            {
                Console.WriteLine("Exception: " + e.Message);
            }

            // Close the connection
            _conn.Close();
        }
    }
}

```

Canceling ADO.NET queries

You can cancel a running vsql query by calling the `.Cancel()` method of any Command object. The `SampleCancelTests` class demonstrates how to cancel a query after reading a specified number of rows. It implements the following methods:

- `SampleCancelTest()` executes the `Setup()` function to create a test table. Then, it calls `RunQueryAndCancel()` and `RunSecondQuery()` to demonstrate how to cancel a query after it reads a specified number of rows. Finally, it runs the `Cleanup()` function to drop the test table.
- `Setup()` creates a database for the example queries.
- `Cleanup()` drops the database.
- `RunQueryAndCancel()` reads exactly 100 rows from a query that returns more than 100 rows.
- `RunSecondQuery()` reads all rows from a query.

```
using System;
using Vertica.Data.VerticaClient;

class SampleCancelTests
{
    // Creates a database table, executes a query that cancels during a read loop,
    // executes a query that does not cancel, then drops the test database table.
    // connection: A connection to a Vertica database.

    public static void SampleCancelTest(VerticaConnection connection)
    {
        VerticaCommand command = connection.CreateCommand();

        Setup(command);

        try
        {
            Console.WriteLine("Running query that will cancel after reading 100 rows...");
            RunQueryAndCancel(command);
            Console.WriteLine("Running a second query...");
            RunSecondQuery(command);
            Console.WriteLine("Finished!");
        }
        finally
        {
            Cleanup(command);
        }
    }

    // Set up the database table for the example.
    // command: A Command object used to execute the query.
    private static void Setup(VerticaCommand command)
    {
        // Create table used for test.
        Console.WriteLine("Creating and loading table...");
        command.CommandText = "DROP TABLE IF EXISTS adocanceltest";
        command.ExecuteNonQuery();
        command.CommandText = "CREATE TABLE adocanceltest(id INTEGER, time TIMESTAMP)";
        command.ExecuteNonQuery();
        command.CommandText = @"INSERT INTO adocanceltest
SELECT row_number() OVER(), slice_time
FROM(
    SELECT slice_time FROM(
        SELECT '2021-01-01'::timestamp s UNION ALL SELECT '2022-01-01'::timestamp s
    ) sq TIMESERIES slice_time AS '1 second' OVER(ORDER BY s
    ) sq2";
        command.ExecuteNonQuery();
    }
}
```

```

// Clean up the database after running the example.
// command: A Command object used to execute the query.
private static void Cleanup(VerticaCommand command)
{
    command.CommandText = "DROP TABLE IF EXISTS adocanceltest";
    command.ExecuteNonQuery();
}

// Execute a query that returns many rows and cancels after reading 100.
// command: A Command object used to execute the query.
private static void RunQueryAndCancel(VerticaCommand command)
{
    command.CommandText = "SELECT COUNT(id) from adocanceltest";
    int fullRowCount = Convert.ToInt32(command.ExecuteScalar());

    command.CommandText = "SELECT id, time FROM adocanceltest";
    VerticaDataReader dr = command.ExecuteReader();
    int nCount = 0;
    try
    {
        while (dr.Read())
        {
            nCount++;
            if (nCount == 100)
            {
                // After reaching 100 rows, cancel the command
                // Note that it is not necessary to read the remaining rows
                command.Cancel();
                return;
            }
        }
    }
    catch (Exception e)
    {
        Console.WriteLine(e.Message);
    }
    finally
    {
        dr.Close();
        // Verify that the cancel stopped the query
        Console.WriteLine((fullRowCount - nCount) + " rows out of " + fullRowCount + " discarded by cancel");
    }
}

// Execute a simple query and read all results.
// command: A Command object used to execute the query.
private static void RunSecondQuery(VerticaCommand command)
{
    command.CommandText = "SELECT 1 FROM dual";
    VerticaDataReader dr = command.ExecuteReader();
    try
    {
        while (dr.Read())
        {
            ;
        }
    }
    catch (Exception e)
    {
        Console.WriteLine(e.Message);
        Console.WriteLine("Warning: no exception should be thrown on query after cancel");
    }
}

```

```
}  
finally  
{  
    dr.Close();  
}  
}  
}
```

Handling messages

You can capture info and warning messages that Vertica provides to the ADO.NET driver by using the `InfoMessage` event on the `VerticaConnection` delegate class. This class captures messages that are not severe enough to force an exception to be triggered, but might still provide information that can benefit your application.

To use the `VerticalInfoMessageEventHandler` class:

1. Create a method to handle the message sent from the even handler:

```
static void conn_InfoMessage(object sender, VerticalInfoMessageEventArgs e)  
{  
    Console.WriteLine(e.SqlState + ": " + e.Message);  
}
```

2. Create a [connection](#) and register a new `VerticalInfoMessageHandler` delegate for the `InfoMessage` event:

```
_conn.InfoMessage += new VerticalInfoMessageEventHandler(conn_InfoMessage);
```

3. Execute your queries. If a message is generated, then the event handle function is run.
4. You can unsubscribe from the event with the following command:

```
_conn.InfoMessage -= new VerticalInfoMessageEventHandler(conn_InfoMessage);
```

Examples

```

using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication {
class Program {
    // define message handler to deal with messages
    static void conn_InfoMessage(object sender, VerticalInfoMessageEventArgs e) {
        Console.WriteLine(e.SqlState + ": " + e.Message);
    }
    static void Main(string[] args) {
        //configure connection properties
        VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
        builder.Host = "192.168.1.10";
        builder.Database = "VMart";
        builder.User = "dbadmin";

        //open the connection
        VerticaConnection _conn = new VerticaConnection(builder.ToString());
        _conn.Open();

        //create message handler instance by subscribing it to the InfoMessage event of the connection
        _conn.InfoMessage += new VerticalInfoMessageEventHandler(conn_InfoMessage);

        //create and execute the command
        VerticaCommand cmd = _conn.CreateCommand();
        cmd.CommandText = "drop table if exists fakeTable";
        cmd.ExecuteNonQuery();

        //close the connection
        _conn.Close();
    }
}
}
}

```

This examples displays the following when run:

```
00000: Nothing was dropped
```

Getting table metadata

You can get the table metadata by using the GetSchema() method on a connection and loading the metadata into a DataTable:

- *database_name* , *schema_name* , and *table_name* can be set to **null** , a specific name, or use a LIKE pattern.
- *table_type* can be one of:
 - "SYSTEM TABLE"
 - "TABLE"
 - "GLOBAL TEMPORARY"
 - "LOCAL TEMPORARY"
 - "VIEW"
 - **null**
- If *table_type* is **null** , then the metadata for all metadata tables is returned.

For example:

```
DataTable table = _conn.GetSchema("Tables", new string[] { null, null, null, "SYSTEM TABLE" });
```

Examples

```

using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            // configure connection properties
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";

            // open the connection
            VerticaConnection _conn = new VerticaConnection(builder.ToString());
            _conn.Open();

            // create a new data table containing the schema
            // the last argument can be "SYSTEM TABLE", "TABLE", "GLOBAL TEMPORARY",
            // "LOCAL TEMPORARY", "VIEW", or null for all types
            DataTable table = _conn.GetSchema("Tables", new string[] { null, null, null, "SYSTEM TABLE" });

            // print out the schema
            foreach (DataRow row in table.Rows) {
                foreach (DataColumn col in table.Columns)
                {
                    Console.WriteLine("{0} = {1}", col.ColumnName, row[col]);
                }
                Console.WriteLine("=====");
            }

            //close the connection
            _conn.Close();
        }
    }
}

```

Go

The open-source [vertica-sql-go](#) driver lets you interact with your database with Go. For details, see [vertica-sql-go](#).

Java

The Vertica JDBC driver provides you with a standard JDBC API. If you have accessed other databases using JDBC, you should find accessing Vertica familiar. This section explains how to use the JDBC to connect your Java application to Vertica.

Prerequisites

You must [install the JDBC client driver](#) before creating Java client applications.

In this section

- [JDBC feature support](#)
- [Creating and configuring a connection](#)
- [JDBC data types](#)
- [Executing queries through JDBC](#)
- [Canceling JDBC queries](#)
- [Loading data through JDBC](#)

- [Handling errors](#)
- [Routing JDBC queries directly to a single node](#)
- [Timezones and daylight savings time](#)

JDBC feature support

The Vertica JDBC driver complies with the JDBC 4.0 standards (although it does not implement all of the optional features in them). Your application can use the [DatabaseMetaData](#) class to determine if the driver supports a particular feature it wants to use. In addition, the driver implements the [Wrapper](#) interface, which lets your client code discover Vertica-specific extensions to the JDBC standard classes, such as [VerticaConnection](#) and [VerticaStatement](#) classes.

Some important facts to keep in mind when using the Vertica JDBC driver:

- Cursors are forward only and are not scrollable. Result sets cannot be updated.
- A connection supports executing a single statement at any time. If you want to execute multiple statements simultaneously, you must open multiple connections.
- [CallableStatement](#) is supported as of the version 12.0.0 of the client driver.

Multiple SQL statement support

The Vertica JDBC driver can execute strings containing multiple statements. For example:

```
stmt.executeUpdate("CREATE TABLE t(a INT);INSERT INTO t VALUES(10);");
```

Only the [Statement](#) interface supports executing strings containing multiple SQL statements. You cannot use multiple statement strings with [PreparedStatement](#). [COPY](#) statements that copy a file from a host file system work in a multiple statement string. However, client [COPY](#) statements ([COPY FROM STDIN](#)) do not work.

Multiple batch conversion to COPY statements

The Vertica JDBC driver converts all batch inserts into Vertica [COPY](#) statements. If you turn off your JDBC connection's [AutoCommit](#) property, the JDBC driver uses a single [COPY](#) statement to load data from sequential batch inserts which can improve load performance by reducing overhead. See [Batch inserts using JDBC prepared statements](#) for details.

JDBC version

The version of JDBC is determined by the version of the JVM. A JVM version of 8 or higher uses JDBC 4.2.

Multiple active result sets (MARS)

The Vertica JDBC driver supports [Multiple active result sets \(MARS\)](#). MARS allows the execution of multiple queries on a single connection. While [ResultSetBufferSize](#) sends the results of a query directly to the client, MARS stores the results first on the server. Once query execution has finished and all of the results have been stored, you can make a retrieval request to the server to have rows returned to the client.

Creating and configuring a connection

Before your Java application can interact with Vertica, it must create a connection. Connecting to Vertica using JDBC is similar to connecting to most other databases.

Importing SQL packages

Before creating a connection, you must import the Java SQL packages. A simple way to do so is to import the entire package using a wildcard:

```
import java.sql.*;
```

You may also want to import the [Properties](#) class. You can use an instance of this class to pass connection properties when instantiating a connection, rather than encoding everything within the connection string:

```
import java.util.Properties;
```

Applications can run in a Java 6 or later JVM. If so, then the JVM automatically loads the Vertica JDBC 4.0-compatible driver without requiring the call to [Class.forName](#). However, making this call does not adversely affect the process. Thus, if you want your application to be compatible with both Java 5 and Java 6 (or later) JVMs, it can still call [Class.forName](#).

Opening the connection

With SQL packages imported, you are ready to create your connection by calling the [DriverManager.getConnection\(\)](#) method. You supply this method with at least the following information:

- The IP address or host name of a node in the database cluster.

You can provide an IPv4 address, IPv6 address, or host name.

In mixed IPv4/IPv6 networks, the DNS server configuration determines which IP version address is sent first. Use the [PreferredAddressFamily](#) option to force the connection to use either IPv4 or IPv6.

- Port number for the database
- Username of a database user account
- Password of the user (if the user has a password)

The first three parameters are always supplied as part of the *connection string*, a URL that tells the JDBC driver where to find the database. The format of the connection string is (*databaseName* is optional):

```
jdbc:vertica://VerticaHost:portNumber/databaseName
```

The first portion of the connection string selects the Vertica JDBC driver, followed by the location of the database.

You can provide the last two parameters, username and password, to the JDBC driver, in one of three ways:

- As part of the connection string. The parameters are encoded similarly to URL parameters:

```
"jdbc:vertica://VerticaHost:portNumber/databaseName?user=username&password=password"
```

- As separate parameters to [DriverManager.getConnection\(\)](#) :

```
Connection conn = DriverManager.getConnection(
    "jdbc:vertica://VerticaHost:portNumber/databaseName",
    "username", "password");
```

- In a [Properties](#) object:

```
Properties myProp = new Properties();
myProp.put("user", "username");
myProp.put("password", "password");
Connection conn = DriverManager.getConnection(
    "jdbc:vertica://VerticaHost:portNumber/databaseName", myProp);
```

Of these three methods, the [Properties](#) object is the most flexible because it makes passing additional connection properties to the [getConnection\(\)](#) method easy. See [Connection Properties](#) and [Setting and getting connection property values](#) for more information about the additional connection properties.

If there is any problem establishing a connection to the database, the [getConnection\(\)](#) method throws a [SQLException](#) on one of its subclasses. To prevent an exception, enclose the method within a try-catch block, as shown in the following complete example of establishing a connection.

```

import java.sql.*;
import java.util.Properties;

public class VerySimpleVerticaJDBCExample {
    public static void main(String[] args) {
        /*
         * If your client needs to run under a Java 5 JVM, it will use the older
         * JDBC 3.0-compliant driver, which requires you manually load the
         * driver using Class.forName
         */
        /*
         * try { Class.forName("com.vertica.jdbc.Driver"); } catch
         * (ClassNotFoundException e) { // Could not find the driver class.
         * Likely an issue // with finding the .jar file.
         * System.err.println("Could not find the JDBC driver class.");
         * e.printStackTrace(); return; // Bail out. We cannot do anything
         * further. }
         */
        Properties myProp = new Properties();
        myProp.put("user", "dbadmin");
        myProp.put("password", "vertica");
        myProp.put("loginTimeout", "35");
        myProp.put("KeystorePath", "c:/keystore/keystore.jks");
        myProp.put("KeystorePassword", "keypwd");
        myProp.put("TrustStorePath", "c:/truststore/localstore.jks");
        myProp.put("TrustStorePassword", "trustpwd");
        Connection conn;
        try {
            conn = DriverManager.getConnection(
                "jdbc:vertica://V_vmart_node0001.example.com:5433/vmart", myProp);
            System.out.println("Connected!");
            conn.close();
        } catch (SQLException connException) {
            // There was a potentially temporary network error
            // Could automatically retry a number of times here, but
            // instead just report error and exit.
            System.out.print("Network connection issue: ");
            System.out.print(connException.getMessage());
            System.out.println(" Try again later!");
            return;
        } catch (SQLInvalidAuthorizationSpecException authException) {
            // Either the username or password was wrong
            System.out.print("Could not log into database: ");
            System.out.print(authException.getMessage());
            System.out.println(" Check the login credentials and try again.");
            return;
        } catch (SQLException e) {
            // Catch-all for other exceptions
            e.printStackTrace();
        }
    }
}

```

Creating a connection with a keystore and truststore

You can create secure connections with your JDBC client driver using a keystore and a truststore. For more information on security within Vertica, refer to [Security and authentication](#).

For examples and instructions on how to generate (or import external) certificates in Vertica, see [Generating TLS certificates and keys](#).

To view your keys and certificates in Vertica, see [CERTIFICATES](#) and [CRYPTOGRAPHIC KEYS](#).

1. Generate your own self-signed certificate or use an existing CA (certificate authority) certificate as the root CA. For information on this process, refer to the [Schannel documentation](#).
2. **Optional** : Generate or import an intermediate CA certificate signed by your root CA. While not required, having an intermediate CA can be useful for testing and debugging your connection.
3. Generate and sign (or import) a server certificate for Vertica.
4. Use [ALTER TLS CONFIGURATION](#) to configure Vertica to use client/server TLS for new connections. For more information, see [Configuring client-server TLS](#).

For **Server Mode** (no client-certificate verification):

```
=> ALTER TLS CONFIGURATION server TLSMODE 'ENABLE';
=> ALTER TLS CONFIGURATION server CERTIFICATE server_cert;
```

For **Mutual Mode** (client-certificate verification of varying strictness depending on the TLSMODE):

```
=> ALTER TLS CONFIGURATION server TLSMODE 'TRY_VERIFY';
=> ALTER TLS CONFIGURATION server CERTIFICATE server_cert ADD CA CERTIFICATES ca_cert;
```

5. Optionally, you can disable all non-SSL connections with [CREATE AUTHENTICATION](#).

```
=> CREATE AUTHENTICATION no_tls METHOD reject HOST NO TLS 0.0.0.0/0;
=> CREATE AUTHENTICATION no_tls METHOD reject HOST NO TLS */*/128;
```

6. Generate and sign a certificate for your client using the same CA that signed your server certificate.
7. Convert your chain of pem certificates to a single pkcs 12 file.
8. Import the client key and chain into a keystore JKS file from your pkcs12 file. For information on using the keytool command interface, [refer to the Java documentation](#).

```
keytool -importkeystore -srckeystore alias my_alias -srcstoretype PKCS12 -srcstorepass my_password -noprompt -deststorepass my_password -destkeystore my_keystore.jks
```

9. Import the CA into a truststore JKS file.

```
keytool -import -file certs/intermediate_ca.pem -alias my_alias -trustcacerts -keystore /tmp/truststore.jks -storepass my_truststore_password -noprompt
```

Usage considerations

- When you disconnect a user session, any uncommitted transactions are automatically rolled back.
- If your database is not compliant with your Vertica license terms, Vertica issues a [SQLWarning](#) when you establish the connection to the database. You can retrieve this warning using the [Connection.getWarnings\(\)](#) method. See [Managing licenses](#) for more information about complying with your license terms.

JDBC connection properties

You use connection properties to configure the connection between your JDBC client application and your Vertica database. The properties provide the basic information about the connections, such as the server name and port number to use to connect to your database. They also let you tune the performance of your connection and enable logging.

You can set a connection property in one of the following ways:

- Include the property name and value as part of the connection string you pass to the method [DriverManager.getConnection\(\)](#) .
- Set the properties in a [Properties](#) object, and then pass it to the method [DriverManager.getConnection\(\)](#) .
- Use the method [VerticaConnection.setProperty\(\)](#) . With this approach, you can change only those connection properties that remain changeable after the connection has been established.

Also, some standard JDBC connection properties have getters and setters on the [Connection](#) interface, such as [Connection.setAutoCommit\(\)](#) .

Connection properties

The properties in the following table can only be set before you open the connection to the database. Two of them are required for every connection.

Property	Description
BinaryTransfer	<p>Boolean value that determines which mode Vertica uses when connecting to a JDBC client:</p> <ul style="list-style-type: none"> • true : binary transfer (default) • false : text transfer <p>Binary transfer is generally more efficient at reading data from a server to a JDBC client and typically requires less bandwidth than text transfer. However, when transferring a large number of small values, binary transfer may use more bandwidth.</p> <p>The data output by both modes is identical with the following exceptions for certain data types:</p> <ul style="list-style-type: none"> • FLOAT: Binary transfer has slightly better precision. • TIMESTAMPTZ: Binary transfer can fail to get the session time zone and default to the local time zone, while text transfer reliably uses the session time zone. • NUMERIC: Binary transfer is forcibly disabled for NUMERIC data by the server for Vertica 11.0.2+.
ConnSettings	<p>A string containing SQL statements that the JDBC driver automatically runs after it connects to the database. You can use this property to set the locale or schema search path, or perform other configuration that the connection requires.</p>
Label	<p>Sets a label for the connection on the server. This value appears in the client_label column of the SESSIONS system table.</p> <p>Default: <i>jdbc- driver-version - random_number</i></p>
SSL	<p>When set to true, use SSL to encrypt the connection to the server. Vertica must be configured to handle SSL connections before you can establish an SSL-encrypted connection to it. See TLS protocol. This property has been deprecated in favor of the TLSmode property.</p> <p>Default: false</p>
TLSmode	<p>TLSmode identifies the security level that Vertica applies to the JDBC connection. Vertica must be configured to handle TLS connections before you can establish an encrypted connection to it. See TLS protocol for details. Valid values are:</p> <ul style="list-style-type: none"> • disable : JDBC connects using plain text and implements no security measures. • require : JDBC connects using TLS without verifying the CA certificate. • verify-ca : JDBC connects using TLS and confirms that the server certificate has been signed by the certificate authority. This setting is equivalent to the deprecated ssl=true property. • verify-full : JDBC connects using TLS, confirms that the server certificate has been signed by the certificate authority, and verifies that the host name matches the name provided in the server certificate. <p>If this property and the SSL property are set, this property takes precedence.</p> <p>Default: disable</p>
HostnameVerifier	<p>If TLSmode is set to verify-full, this property the fully qualified domain name of the verifier that you want to confirm the host name.</p>
Password	<p>Required (for non-OAuth connections), the password to use to log into the database.</p>
User	<p>Required (for non-OAuth connections), the database user name to use to connect to the database.</p>
ConnectionLoadBalance	<p>A Boolean value indicating whether the client is willing to have its connection redirected to another host in the Vertica database. This setting has an effect only if the server has also enabled connection load balancing. See About native connection load balancing for more information about native connection load balancing.</p> <p>Default: false</p>

BackupServerNode	A string containing the host name or IP address of one or more hosts in the database. If the connection to the host specified in the connection string times out, the client attempts to connect to any host named in this string. The host name or IP address can also include a colon followed by the port number for the database. If no port number is specified, the client uses the standard port number (5433) . Separate multiple host name or IP address entries with commas.
PreferredAddressFamily	The IP version to use if the client and server have both IPv4 and IPv6 addresses and you have provided a host name, one of the following: <ul style="list-style-type: none"> • ipv4 : Connect to the server using IPv4. • ipv6 : Connect to the server using IPv6. • none : Use the IP address provided by the DNS server. Default: none
KeyStorePath	The path to a .JKS file containing your private keys and their corresponding certificate chains. For information on creating a keystore, refer to documentation for your development environment. For information on creating a keystore, refer to the Java documentation .
KeyStorePassword	The password protecting the keystore file. If individual keys are also encrypted, the keystore file password must match the password for a key within the keystore.
TrustStorePath	The path to a .JKS truststore file containing certificates from authorities you trust.
TrustStorePassword	The password protecting the truststore file.
workload	The name of the workload for the session. For details, see Workload routing .

OAuth connection properties

The following connection properties pertain to [OAuth](#) in JDBC.

Property	Description
oauthaccesstoken	Required if oauthrefresh token is unspecified, an OAuth token that authorizes a user to the database.
oauthrefresh token	<p>Deprecated Use oauthaccesstoken instead. Token refresh should be handled by the client application separately.</p> <p>Required if oauthaccesstoken is unspecified, a token used to obtain a new access token when their old one expires. Either OAuthAccessToken or OAuthRefreshToken must be set (programmatically or manually) to authenticate to Vertica with OAuth authentication.</p> <p>You can omit both OAuthAccessToken and OAuthRefreshToken only if you authenticate to your identity provider directly with single sign-on through the client driver, which requires the machine running the ODBC driver to have access to a web browser.</p> <p>For details on the different methods for retrieving access tokens, see Retrieving access tokens.</p> <p>If you set this parameter, you must also set the OAuthClientSecret connection property.</p> <p>In cases where introspection fails (e.g. when the access token expires), Vertica responds to the request with an error. If introspection fails and OAuthRefreshToken is specified, the driver attempts to refresh and silently retrieve a new access token. Otherwise, the driver passes error to the client application.</p>

oauthclientsecret	<p>Deprecated Use oauthaccesstoken instead. Token refresh should be handled by the client application separately.</p> <p>The secret provided by your identity provider for your client.</p>
oauthtruststorepath	<p>Deprecated This property is deprecated, but will still be necessary if your environment requires custom CA certificates for the driver to connect to your identity provider. Versions with this property removed will not require the driver to connect to the identity provider.</p> <p>The path to a custom truststore. If unspecified, JDBC uses the default system truststore.</p>
oauthtruststorepassword	<p>Deprecated This property is deprecated, but will still be necessary if your environment requires custom CA certificates for the driver to connect to your identity provider. Versions with this property removed will not require the driver to connect to the identity provider.</p> <p>The password to the truststore.</p>

Timeout properties

With the following parameters, you can specify various timeouts for each step and the overall connection of JDBC to your Vertica database.

Property	Description
LoginTimeout	<p>The number of seconds Vertica waits for the client to log in to the database before throwing a SQLException .</p> <p>Default: 0 (no timeout)</p>
LoginNodeTimeout	<p>The number of seconds the JDBC client waits before attempting to connect to the next node if the Vertica process is running, but does not respond. The "next" node is determined by either the BackupServerNode connection property or DNS resolution. If you only provide a single IP address, the JDBC client returns an error.</p> <p>A timeout value of 0 instructs JDBC to wait indefinitely for an error/a successful connection rather than attempt to connect to another node.</p> <p>Default: 0 (no timeout)</p>
LoginNetworkTimeout	<p>The number of seconds the JDBC client has to establish a TCP connection to a Vertica node. A typical use case for this property is to let JDBC connect to another node if the system is down for maintenance and modifying the JDBC application's connection string is infeasible.</p> <p>Default: 0 (no timeout)</p>
NetworkTimeout	<p>The number of milliseconds for the server to reply to a request after the client has established a connection with the database.</p> <p>Default: 0</p>

The relationship between these properties and the role they play when JDBC attempts to connect to a Vertica database is illustrated in the following

General properties

The following properties can be set after the connection is established. None of these properties are required.

Property	Description
AutoCommit	<p>Controls whether the connection automatically commits transactions. Set this parameter to false to prevent the connection from automatically committing its transactions. You often want to do this when you are bulk loading multiple batches of data and you want the ability to roll back all of the loads if an error occurs.</p> <p>Set After Connection: <code>Connection.setAutoCommit()</code></p> <p>Default: true</p>
DirectBatchInsert	<p>Deprecated, always set to true.</p>
DisableCopyLocal	<p>When set to true, disables file-based COPY LOCAL operations, including copying data from local files and using local files to store data and exceptions. You can use this property to prevent users from writing to and copying from files on a Vertica host, including an MC host.</p> <p>Default: false</p>
MultipleActiveResultSets	<p>Allows more than one active result set on a single connection via MultipleActiveResultSets (MARS).</p> <p>If both MultipleActiveResultSets and ResultBufferSize are turned on, MultipleActiveResultSets takes precedence. The connection does not provide an error, however ResultBufferSize is ignored.</p> <p>Set After Connection: <code>VerticaConnection.setProperty()</code></p> <p>Default: false</p>
ReadOnly	<p>When set to true, makes the data connection read-only. Any queries attempting to update the database using a read-only connection cause a <code>SQLException</code>.</p> <p>Set After Connection: <code>Connection.setReadOnly()</code></p> <p>Default: false</p>
ResultBufferSize	<p>Sets the size of the buffer the Vertica JDBC driver uses to temporarily store result sets. A value of 0 means ResultBufferSize is turned off.</p> <p>Note: This property was named maxLRSMemory in previous versions of the Vertica JDBC driver.</p> <p>Set After Connection: <code>VerticaConnection.setProperty()</code></p> <p>Default: 8912 (8KB)</p>

SearchPath	<p>Sets the schema search path for the connection. This value is a string containing a comma-separated list of schema names. See Setting Search Paths for more information on the schema search path.</p> <p>Set After Connection: <code>VerticaConnection.setProperty()</code></p> <p>Default: "\$user", public, v_catalog, v_monitor, v_internal</p>
ThreePartNaming	<p>A Boolean value that controls how DatabaseMetaData reports the catalog name. When set to true, the database name is returned as the catalog name in the database metadata. When set to false, NULL is returned as the catalog name.</p> <p>Enable this option if your client software is set up to get the catalog name from the database metadata for use in a three-part name reference.</p> <p>Set After Connection: <code>VerticaConnection.setProperty()</code></p> <p>Default: true</p>
TransactionIsolation	<p>Sets the isolation level of the transactions that use the connection. See Changing the transaction isolation level for details.</p> <p>Note: In previous versions of the Vertica JDBC driver, this property was only available using a getter and setter on the <code>PGConnection</code> object. You can now set it in the same way as other connection properties.</p> <p>Set After Connection: <code>Connection.setTransactionIsolation()</code></p> <p>Default: TRANSACTION_READ_COMMITTED</p>

Logging properties

The properties that control client logging must be set before the connection is opened. None of these properties are required, and none can be changed after the `Connection` object has been instantiated.

Property	Description
LogLevel	<p>Sets the type of information logged by the JDBC driver. The value is set to one of the following values:</p> <ul style="list-style-type: none"> "DEBUG" "ERROR" "TRACE" "WARNING" "INFO" "OFF" <p>Default: "OFF"</p>
LogNameSpace	<p>Restricts logging to just messages generated by a specific packages. Valid values are:</p> <ul style="list-style-type: none"> <code>com.vertica</code> — All messages generated by the JDBC driver <code>com.vertica.jdbc</code> — All messages generated by the top-level JDBC API <code>com.vertica.jdbc.kv</code> — All messages generated by the JDBC KV API <code>com.vertica.jdbc.core</code> — Connection and statement settings <code>com.vertica.jdbc.io</code> — Client/server protocol messages <code>com.vertica.jdbc.util</code> — Miscellaneous utilities <code>com.vertica.jdbc.dataengine</code> — Query execution and result set iteration <code>com.vertica.dataengine</code> — Query execution and result set iteration

LogPath	The path for the log file. Default: The current working directory
---------	---

Kerberos connection parameters

Use the following parameters to set the service and host name principals for client authentication using Kerberos.

Parameters	Description
JAASConfigName	Provides the name of the JAAS configuration that contains the JAAS Krb5LoginModule and its settings Default: verticajdbc
KerberosServiceName	Provides the service name portion of the Vertica Kerberos principal, for example: <code>vertichost@EXAMPLE.COM</code> Default: vertica
KerberosHostname	Provides the instance or host name portion of the Vertica Kerberos principal, for example: <code>verticaosEXAMPLE.COM</code> Default: Value specified in the servername connection string property

Routable connection API connection parameters

Use the following parameters to set properties to enable and configure the connection for Routable Connection lookups.

Parameters	Description
EnableRoutableQueries	Enables Routable Connection lookup. See Routing JDBC queries directly to a single node Default: false
FailOnMultiNodePlans	If the query plan requires more than one node, then the query fails. Only applicable when EnableRoutableQueries = true. Default: true
MetadataCacheLifetime	The time in seconds to keep projection metadata. Only applicable when EnableRoutableQueries = true. Default:
MaxPooledConnections	Cluster-wide maximum number of connections to keep in the VerticaRoutableConnection's internal pool. Only applicable when EnableRoutableQueries = true. Default: 20
MaxPooledConnectionsPerNode	Per-node maximum number of connections to keep in the VerticaRoutableConnection's internal pool. Only applicable when EnableRoutableQueries = true. Default: 5

Note

You can also use `VerticaConnection.setProperty()` method to set properties that have standard JDBC Connection setters, such as AutoCommit.

For information about manipulating these attributes, see [Setting and getting connection property values](#).

Setting and getting connection property values

You can set a connection property in one of the following ways:

- Include the property name and value as part of the connection string you pass to the method `DriverManager.getConnection()` .
- Set the properties in a `Properties` object, and then pass it to the method `DriverManager.getConnection()` .
- Use the method `VerticaConnection.setProperty()` . With this approach, you can change only those connection properties that remain changeable after the connection has been established.

Also, some standard JDBC connection properties have getters and setters on the `Connection` interface, such as `Connection.setAutoCommit()` .

Setting properties when connecting

When creating a connection to Vertica, you can set connection properties by:

- Specifying them in the connection string.
- Modifying the `Properties` object passed to `getConnection()` .

Connection string properties

You can specify connection properties in the connection string with the same URL parameter format used for usernames and passwords. For example, the following string enables a TLS connection:

```
"jdbc:vertica://VerticaHost:5433/db?user=UserName&password=Password&TLSmode=require"
```

Setting a host name using the `setProperty()` method overrides the host name set in a connection string. If this occurs, Vertica might not be able to connect to a host. For example, using the connection string above, the following overrides the `VerticaHost` name:

```
Properties props = new Properties();
props.setProperty("dataSource", dataSourceURL);
props.setProperty("database", database);
props.setProperty("user", user);
props.setProperty("password", password);
props.setProperty("jdbcDriver", jdbcDriver);
props.setProperty("hostName", "NonVertica_host");
```

However, if a new connection or override connection is needed, you can enter a valid host name in the hostname properties object.

The `NonVertica_host` hostname overrides `VerticaHost` name in the connection string. To avoid this issue, comment out the `props.setProperty("hostName", "NonVertica_host");` line:

```
//props.setProperty("hostName", "NonVertica_host");
```

Properties object

To set connection properties with the `Properties` object passed to the `getConnection()` call:

1. Import the `java.util.Properties` class to instantiate a `Properties` object.
2. Use the `put()` method to add name-value pairs to the object.

```
Properties myProp = new Properties();
myProp.put("user", "ExampleUser");
myProp.put("password", "password123");
myProp.put("LoginTimeout", "35");
Connection conn;
try {
    conn = DriverManager.getConnection(
        "jdbc:vertica://VerticaHost:ExampleDB", myProp);
} catch (SQLException e) {
    e.printStackTrace();
}
```

Note

The data type of all of the values you set in the `Properties` object are strings, regardless of the property value's data type.

Getting and setting properties after connecting

After you establish a connection with Vertica, you can use the `VerticaConnection` methods `getProperty()` and `setProperty()` to set the values of some connection properties, respectively.

The `VerticaConnection.getProperty()` method lets you get the value of some connection properties. Use this method to change the value for properties that can be set after you establish a connection with Vertica.

Because these methods are Vertica-specific, you must cast your `Connection` object to the `VerticaConnection` interface with one of the following methods:

- Import the `Connection` object into your client application.
- Use a fully-qualified reference: `com.vertica.jdbc.VerticaConnection` .

The following example demonstrates getting and setting the value of the [ReadOnly property](#).

```
import java.sql.*;
import java.util.Properties;
import com.vertica.jdbc.*;

public class SetConnectionProperties {
    public static void main(String[] args) {
        // Note: If your application needs to run under Java 5, you need to
        // load the JDBC driver using Class.forName() here.
        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser");
        myProp.put("password", "password123");
        // Set ReadOnly to true initially
        myProp.put("ReadOnly", "true");
        Connection conn;
        try {
            conn = DriverManager.getConnection(
                "jdbc:vertica://VerticaHost:5433/ExampleDB",
                myProp);

            // Show state of the ReadOnly property. This was set at the
            // time the connection was created.
            System.out.println("ReadOnly state: "
                + ((VerticaConnection) conn).getProperty(
                    "ReadOnly"));

            // Change it and show it again
            ((VerticaConnection) conn).setProperty("ReadOnly", false);
            System.out.println("ReadOnly state is now: " +
                ((VerticaConnection) conn).getProperty(
                    "ReadOnly"));

            conn.close();
        } catch (SQLException e) {
            e.printStackTrace();
        }
    }
}
```

When run, the example prints the following on the standard output:

```
ReadOnly state: true
ReadOnly state is now: false
```

Configuring TLS for JDBC clients

To configure TLS for JDBC clients:

- [Configure Vertica for client-server TLS](#) .
- Set the keystore and truststore properties.
- Set the `TLSmode` parameter.

- (Optional) Run the SSL debug utility to test your configuration.

Setting keystore/truststore properties

You can set the keystore and truststore properties in the following ways, each with their own pros and cons:

- At the driver level.
- At the JVM level.

Driver-level configuration

If you use tools like DbVizualizer with many connections, configure the keystore and truststore with the [JDBC connection properties](#). This does, however, expose these values in the connection string:

- `KeyStorePath`
- `KeyStorePassword`
- `TrustStorePath`
- `TrustStorePassword`

For example:

```
Properties props = new Properties();
props.setProperty("KeyStorePath", keystorepath);
props.setProperty("KeyStorePassword", keystorepassword);
props.setProperty("TrustStorePath", truststorepath);
props.setProperty("TrustStorePassword", truststorepassword);
```

JVM-level configuration

Setting keystore and truststore parameters at the JVM level excludes them from the connection string, which may be more accommodating for environments with more stringent security requirements:

- `javax.net.ssl.keyStore`
- `javax.net.ssl.trustStore`
- `javax.net.ssl.keyStorePassword`
- `javax.net.ssl.trustStorePassword`

For example:

```
System.setProperty("javax.net.ssl.keyStore", "clientKeyStore.key");
System.setProperty("javax.net.ssl.trustStore", "clientTrustStore.key");
System.setProperty("javax.net.ssl.keyStorePassword", "new_keystore_password");
System.setProperty("javax.net.ssl.trustStorePassword", "new_truststore_password");
```

Set the TLSmode connection property

You can set the TLSmode [connection property](#) to determine how certificates are handled. TLSmode is disabled by default.

TLSmode identifies the security level that Vertica applies to the JDBC connection. Vertica must be configured to handle TLS connections before you can establish an encrypted connection to it. See [TLS protocol](#) for details. Valid values are:

- `disable` : JDBC connects using plain text and implements no security measures.
- `require` : JDBC connects using TLS without verifying the CA certificate.
- `verify-ca` : JDBC connects using TLS and confirms that the server certificate has been signed by the certificate authority. This setting is equivalent to the deprecated `ssl=true` property.
- `verify-full` : JDBC connects using TLS, confirms that the server certificate has been signed by the certificate authority, and verifies that the host name matches the name provided in the server certificate.

If this property and the SSL property are set, this property takes precedence.

For example, to configure JDBC to connect to the server with TLS without verifying the CA certificate, you can [set the TLSmode property](#) to 'require' with the method `VerticaConnection.setProperty()` :

```
Properties props = new Properties();
props.setProperty("TLSmode", "verify-full");
```

Run the SSL debug utility

After configuring TLS, you can run the following for a debugging utility:

```
$ java -Djavax.net.debug=ssl
```

You can use several debug specifiers (options) with the debug utility. The specifiers help narrow the scope of the debugging information that is returned. For example, you could specify one of the options that prints handshake messages or session activity.

For information on the debug utility and its options, see Debugging Utilities in the Oracle document, [JSSE Reference Guide](#).

For information on interpreting debug information, refer to the Oracle document, [Debugging SSL/TLS Connections](#).

Setting and returning a client connection label

The JDBC Client has a method to set and return the client connection label: `getClientInfo()` and `setClientInfo()`. You can use these methods with the SQL Functions [GET_CLIENT_LABEL](#) and [SET_CLIENT_LABEL](#).

When you use these two methods, make sure you pass the string value `APPLICATIONNAME` to both the setter and getter methods.

Use `setClientInfo()` to create a client label, and use `getClientInfo()` to return the client label:

```
import java.sql.*;
import java.util.Properties;

public class ClientLabelJDBC {

    public static void main(String[] args) {
        Properties myProp = new Properties();
        myProp.put("user", "dbadmin");
        myProp.put("password", "");
        myProp.put("loginTimeout", "35");
        Connection conn;
        try {
            conn = DriverManager.getConnection(
                "jdbc:vertica://example.com:5433/mydb", myProp);
            System.out.println("Connected!");
            conn.setClientInfo("APPLICATIONNAME", "JDBC Client - Data Load");
            System.out.println("New Conn label: " + conn.getClientInfo("APPLICATIONNAME"));
            conn.close();
        } catch (SQLException connException) {
            // There was a potentially temporary network error
            // Could automatically retry a number of times here, but
            // instead just report error and exit.
            System.out.print("Network connection issue: ");
            System.out.print(connException.getMessage());
            System.out.println(" Try again later!");
            return;
        } catch (SQLInvalidAuthorizationSpecException authException) {
            // Either the username or password was wrong
            System.out.print("Could not log into database: ");
            System.out.print(authException.getMessage());
            System.out.println(" Check the login credentials and try again.");
            return;
        } catch (SQLException e) {
            // Catch-all for other exceptions
            e.printStackTrace();
        }
    }
}
```

When you run this method, it prints the following result to the standard output:

```
Connected!
New Conn Label: JDBC Client - Data Load
```

Setting the locale for JDBC sessions

You set the locale for a connection while opening it by including a `SET LOCALE` statement in the `ConnSettings` property, or by executing a [SET LOCALE](#) statement at any time after opening the connection. Changing the locale of a `Connection` object affects all of the `Statement` objects you instantiated using it.

You can get the locale by executing a [SHOW LOCALE](#) query. The following example demonstrates setting the locale using `ConnSettings` and executing a statement, as well as getting the locale:

```
import java.sql.*;
import java.util.Properties;

public class GetAndSetLocale {
    public static void main(String[] args) {

        // If running under a Java 5 JVM, you need to load the JDBC driver
        // using Class.forName here

        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser");
        myProp.put("password", "password123");

        // Set Locale to true en_GB on connection. After the connection
        // is established, the JDBC driver runs the statements in the
        // ConnSettings property.
        myProp.put("ConnSettings", "SET LOCALE TO en_GB");
        Connection conn;
        try {
            conn = DriverManager.getConnection(
                "jdbc:vertica://VerticaHost:5433/ExampleDB",
                myProp);

            // Execute a query to get the locale. The results should
            // show "en_GB" as the locale, since it was set by the
            // conn settings property.
            Statement stmt = conn.createStatement();
            ResultSet rs = null;
            rs = stmt.executeQuery("SHOW LOCALE");
            System.out.print("Query reports that Locale is set to: ");
            while (rs.next()) {
                System.out.println(rs.getString(2).trim());
            }

            // Now execute a query to set locale.
            stmt.execute("SET LOCALE TO en_US");

            // Run query again to get locale.
            rs = stmt.executeQuery("SHOW LOCALE");
            System.out.print("Query now reports that Locale is set to: ");
            while (rs.next()) {
                System.out.println(rs.getString(2).trim());
            }
            // Clean up
            conn.close();
        } catch (SQLException e) {
            e.printStackTrace();
        }
    }
}
```

Running the above example displays the following on the system console:

```
Query reports that Locale is set to: en_GB (LEN)
Query now reports that Locale is set to: en_US (LEN)
```

Notes:

- JDBC applications use a UTF-16 character set encoding and are responsible for converting any non-UTF-16 encoded data to UTF-16. Failing to convert the data can result in errors or the data being stored incorrectly.
- The JDBC driver converts UTF-16 data to UTF-8 when passing to the Vertica server and converts data sent by Vertica server from UTF-8 to UTF-16 .

Changing the transaction isolation level

Changing the transaction isolation level lets you choose how transactions prevent interference from other transactions. By default, the JDBC driver matches the transaction isolation level of the Vertica server. The Vertica default transaction isolation level is **READ_COMMITTED** , which means any changes made by a transaction cannot be read by any other transaction until after they are committed. This prevents a transaction from reading data inserted by another transaction that is later rolled back.

Vertica also supports the **SERIALIZABLE** transaction isolation level. This level locks tables to prevent queries from having the results of their **WHERE** clauses changed by other transactions. Locking tables can have a performance impact, since only one transaction is able to access the table at a time.

A transaction retains its isolation level until it completes, even if the session's isolation level changes during the transaction. Vertica internal processes (such as the [Tuple Mover](#) and [refresh](#) operations) and DDL operations always run at the **SERIALIZABLE** isolation level to ensure consistency.

You can change the transaction isolation level connection property after the connection has been established using the **Connection** object's setter (`setTransactionIsolation()`) and getter (`getTransactionIsolation()`). The value for transaction isolation property is an integer. The **Connection** interface defines constants to help you set the value in a more intuitive manner:

Constant	Value
<code>Connection.TRANSACTION_READ_COMMITTED</code>	2
<code>Connection.TRANSACTION_SERIALIZABLE</code>	8

Note

The **Connection** interface also defines several other transaction isolation constants (`READ_UNCOMMITTED` and `REPEATABLE_READ`). Since Vertica does not support these isolation levels, they are converted to `READ_COMMITTED` and `SERIALIZABLE` , respectively.

The following example demonstrates setting the transaction isolation level to **SERIALIZABLE**.

```

import java.sql.*;
import java.util.Properties;

public class SetTransactionIsolation {
    public static void main(String[] args) {
        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser");
        myProp.put("password", "password123");
        Connection conn;
        try {
            conn = DriverManager.getConnection(
                "jdbc:vertica://VerticaHost:5433/ExampleDB",
                myProp);

            // Get default transaction isolation
            System.out.println("Transaction Isolation Level: "
                + conn.getTransactionIsolation());

            // Set transaction isolation to SERIALIZABLE
            conn.setTransactionIsolation(Connection.TRANSACTION_SERIALIZABLE);

            // Get the transaction isolation again
            System.out.println("Transaction Isolation Level: "
                + conn.getTransactionIsolation());

            conn.close();
        } catch (SQLException e) {
            e.printStackTrace();
        }
    }
}

```

Running the example results in the following being printed out to the console:

```
Transaction Isolation Level: 2Transaction Isolation Level: 8
```

JDBC connection pools

A pooling data source uses a collection of persistent connections in order to reduce the overhead of repeatedly opening network connections between the client and server. Opening a new connection for each request is more costly for both the server and the client than keeping a small pool of connections open constantly, ready to be used by new requests. When a request comes in, one of the pre-existing connections in the pool is assigned to it. Only if there are no free connections in the pool is a new connection created. Once the request is complete, the connection returns to the pool and waits to service another request.

The Vertica JDBC driver supports connection pooling as defined in the JDBC 4.0 standard. If you are using a J2EE-based application server in conjunction with Vertica, it should already have a built-in data pooling feature. All that is required is that the application server work with the [PooledConnection](#) interface implemented by Vertica's JDBC driver. An application server's pooling feature is usually well-tuned for the works loads that the server is designed to handle. See your application server's documentation for details on how to work with pooled connections. Normally, using pooled connections should be transparent in your code—you will just open connections and the application server will worry about the details of pooling them.

If you are not using an application server, or your application server does not offer connection pooling that is compatible with Vertica, you can use a third-party pooling library, such as the open-source c3p0 or DBCP libraries, to implement connection pooling.

Note

The Vertica Analytic Database client driver's native connection load balancing feature works with third-party connection pooling supplied by application servers and third-party pooling libraries. See [Load balancing in JDBC](#) for more information.

Load balancing in JDBC

Native connection load balancing

Native connection load balancing helps spread the overhead caused by client connections on the hosts in the Vertica database. Both the server and the client must enable native connection load balancing. If enabled by both, then when the client initially connects to a host in the database, the host picks a host to handle the client connection from a list of the currently up hosts in the database, and informs the client which host it has chosen.

If the initially-contacted host does not choose itself to handle the connection, the client disconnects, then opens a second connection to the host selected by the first host. The connection process to this second host proceeds as usual—if SSL is enabled, then SSL negotiations begin, otherwise the client begins the authentication process. See [About native connection load balancing](#) for details.

To enable native load balancing on your client, set the `ConnectionLoadBalance` connection parameter to `true`. The following example demonstrates:

- Connecting to the database several times with native connection load balancing enabled.
- Fetching the name of the node handling the connection from the `V_MONITOR.CURRENT_SESSION` system table.

```
import java.sql.*;
import java.util.Properties;
import java.sql.*;
import java.util.Properties;

public class JDBCLoadingBalanceExample {
    public static void main(String[] args) {
        Properties myProp = new Properties();
        myProp.put("user", "dbadmin");
        myProp.put("password", "example_password123");
        myProp.put("loginTimeout", "35");
        myProp.put("ConnectionLoadBalance", "1");
        Connection conn;

        for (int x = 1; x <= 4; x++) {
            try {
                System.out.print("Connect attempt #" + x + "...");
                conn = DriverManager.getConnection(
                    "jdbc:vertica://node01.example.com:5433/vmart", myProp);
                Statement stmt = conn.createStatement();
                // Set the load balance policy to round robin before testing the database's load balancing.
                stmt.execute("SELECT SET_LOAD_BALANCE_POLICY('ROUNDROBIN');");
                // Query system table to see what node we are connected to. Assume a single row
                // in response set.
                ResultSet rs = stmt.executeQuery("SELECT node_name FROM v_monitor.current_session;");
                rs.next();
                System.out.println("Connected to node " + rs.getString(1).trim());
                conn.close();
            } catch (SQLException connException) {
                // There was a potentially temporary network error
                // Could automatically retry a number of times here, but
                // instead just report error and exit.
                System.out.print("Network connection issue: ");
                System.out.print(connException.getMessage());
                System.out.println(" Try again later!");
                return;
            } catch (SQLInvalidAuthorizationSpecException authException) {
                // Either the username or password was wrong
                System.out.print("Could not log into database: ");
                System.out.print(authException.getMessage());
                System.out.println(" Check the login credentials and try again.");
                return;
            } catch (SQLException e) {
                // Catch-all for other exceptions
                e.printStackTrace();
            }
        }
    }
}
```

Running the previous example produces the following output:

```
Connect attempt #1...Connected to node v_vmart_node0002
Connect attempt #2...Connected to node v_vmart_node0003
Connect attempt #3...Connected to node v_vmart_node0001
Connect attempt #4...Connected to node v_vmart_node0002
```

Hostname-based load balancing

You can load balance workloads by resolving a single hostname to multiple IP addresses. When you specify the hostname for the `DriverManager.getConnection()` method, the hostname resolves to a random listed IP address from the each connection.

For example, the hostname `verticahost.example.com` has the following entries in `etc/hosts` :

```
192.0.2.0 verticahost.example.com
192.0.2.1 verticahost.example.com
192.0.2.2 verticahost.example.com
```

Specifying `verticahost.example.com` as the connection for `DriverManager.getConnection()` randomly resolves to one of the listed IP address.

JDBC connection failover

If a client application attempts to connect to a host in the Vertica cluster that is down, the connection attempt fails when using the default connection configuration. This failure usually returns an error to the user. The user must either wait until the host recovers and retry the connection or manually edit the connection settings to choose another host.

Due to Vertica Analytic Database's distributed architecture, you usually do not care which database host handles a client application's connection. You can use the client driver's connection failover feature to prevent the user from getting connection errors when the host specified in the connection settings is unreachable. The JDBC driver gives you several ways to let the client driver automatically attempt to connect to a different host if the one specified in the connection parameters is unreachable:

- Configure your DNS server to return multiple IP addresses for a host name. When you use this host name in the connection settings, the client attempts to connect to the first IP address from the DNS lookup. If the host at that IP address is unreachable, the client tries to connect to the second IP, and so on until it either manages to connect to a host or it runs out of IP addresses.
- Supply a list of backup hosts for the client driver to try if the primary host you specify in the connection parameters is unreachable.
- (JDBC only) Use driver-specific connection properties to manage timeouts before attempting to connect to the next node.

For all methods, the process of failover is transparent to the client application (other than specifying the list of backup hosts, if you choose to use the list method of failover). If the primary host is unreachable, the client driver automatically tries to connect to other hosts.

Failover only applies to the initial establishment of the client connection. If the connection breaks, the driver does not automatically try to reconnect to another host in the database.

Choosing a failover method

You usually choose to use one of the two failover methods. However, they do work together. If your DNS server returns multiple IP addresses and you supply a list of backup hosts, the client first tries all of the IPs returned by the DNS server, then the hosts in the backup list.

Note

If a host name in the backup host list resolves to multiple IP addresses, the client does not try all of them. It just tries the first IP address in the list.

The DNS method of failover centralizes the configuration client failover. As you add new nodes to your Vertica Analytic Database cluster, you can choose to add them to the failover list by editing the DNS server settings. All client systems that use the DNS server to connect to Vertica Analytic Database automatically use connection failover without having to change any settings. However, this method does require administrative access to the DNS server that all clients use to connect to the Vertica Analytic Database cluster. This may not be possible in your organization.

Using the backup server list is easier than editing the DNS server settings. However, it decentralizes the failover feature. You may need to update the application settings on each client system if you make changes to your Vertica Analytic Database cluster.

Using DNS failover

To use DNS failover, you need to change your DNS server's settings to map a single host name to multiple IP addresses of hosts in your Vertica Analytic Database cluster. You then have all client applications use this host name to connect to Vertica Analytic Database.

You can choose to have your DNS server return as many IP addresses for the host name as you want. In smaller clusters, you may choose to have it return the IP addresses of all of the hosts in your cluster. However, for larger clusters, you should consider choosing a subset of the hosts to return. Otherwise there can be a long delay as the client driver tries unsuccessfully to connect to each host in a database that is down.

Using the backup host list

To enable backup list-based connection failover, your client application has to specify at least one IP address or host name of a host in the `BackupServerNode` parameter. The host name or IP can optionally be followed by a colon and a port number. If not supplied, the driver defaults to the standard Vertica port number (5433). To list multiple hosts, separate them by a comma.

The following example demonstrates setting the `BackupServerNode` connection parameter to specify additional hosts for the connection attempt. The connection string intentionally has a non-existent node, so that the initial connection fails. The client driver has to resort to trying the backup hosts to establish a connection to Vertica.

```
import java.sql.*;
import java.util.Properties;

public class ConnectionFailoverExample {
    public static void main(String[] args) {
        // Assume using JDBC 4.0 driver on JVM 6+. No driver loading needed.
        Properties myProp = new Properties();
        myProp.put("user", "dbadmin");
        myProp.put("password", "vertica");

        // Set two backup hosts to be used if connecting to the first host
        // fails. All of these hosts will be tried in order until the connection
        // succeeds or all of the connections fail.
        myProp.put("BackupServerNode", "VerticaHost02,VerticaHost03");
        Connection conn;
        try {
            // The connection string is set to try to connect to a known
            // bad host (in this case, a host that never existed).
            // The database name is optional.
            conn = DriverManager.getConnection(
                "jdbc:vertica://BadVerticaHost:5433/vmart", myProp);
            System.out.println("Connected!");
            // Query system table to see what node we are connected to.
            // Assume a single row in response set.
            Statement stmt = conn.createStatement();
            ResultSet rs = stmt.executeQuery(
                "SELECT node_name FROM v_monitor.current_session;");
            rs.next();
            System.out.println("Connected to node " + rs.getString(1).trim());
            // Done with connection.
            conn.close();
        } catch (SQLException e) {
            // Catch-all for other exceptions
            e.printStackTrace();
        }
    }
}
```

When run, the example outputs output similar to the following on the system console:

```
Connected!
Connected to node v_vmart_node0002
```

Notice that the connection was made to the first node in the backup list (node 2).

Specifying connection timeouts

`LoginTimeout` controls the timeout for JDBC to establish establish a TCP connection with a node and log in to Vertica.

`LoginNodeTimeout` controls the timeout for JDBC to log in to the Vertica database. After the specified timeout, JDBC attempts to connect to the "next" node, which is determined by either the connection property `BackupServerNode` or DNS resolution. This is useful if the node is up, but something is wrong with the Vertica process.

[LoginNetworkTimeout](#) controls the timeout for JDBC to establish a TCP connection to a Vertica node. If you do not set this connection property, if the node to which the JDBC client attempts to connect is down, the JDBC client will wait "indefinitely," but practically, the system default timeout of 70 seconds is used. A typical use case for LoginNetworkTimeout is to let JDBC connect to another node if the current Vertica node is down for maintenance and modifying the JDBC application's connection string is infeasible.

[NetworkTimeout](#) controls the timeout for Vertica to respond to a request from a client after it has established a connection and logged in to the database.

To set these parameters in a connection string:

```
# LoginTimeout is 30 seconds, LoginNodeTimeout is 10 seconds, LoginNetworkTimeout is 2 seconds, NetworkTimeout is 0.5 seconds
Connection conn = DriverManager.getConnection("jdbc:vertica://VerticaHost:5433/verticadb?user=dbadmin&loginTimeout=30&loginNodeTimeout=10&loginNetworkTimeout=2&networkTimeout=0.5");
```

To set these parameters as a connection property:

```
Properties myProp = new Properties();
myProp.put("user", "dbadmin");
myProp.put("loginTimeout", "30"); // overall connection timeout is 30 seconds to make sure it is not too small for failover
myProp.put("loginNodeTimeout", "10"); // JDBC waits 10 seconds before attempting to connect to the next node if the Vertica process is running but does not
myProp.put("loginNetworkTimeout", "2"); // node connection timeout is 2 seconds
myProp.put("networkTimeout", "500"); // after the client has logged in, Vertica has 0.5 seconds to respond to each request
Connection conn = DriverManager.getConnection("jdbc:vertica://VerticaHost:5433/verticadb", myProp);
```

Interaction with load balancing

When native connection load balancing is enabled, the additional servers specified in the BackupServerNode connection parameter are only used for the initial connection to a Vertica host. If host redirects the client to another host in the database cluster to handle its connection request, the second connection does not use the backup node list. This is rarely an issue, since native connection load balancing is aware of which nodes are currently up in the database.

See [Load balancing in JDBC](#) for more information.

JDBC data types

The JDBC driver transparently converts most Vertica data types to the appropriate Java data type. In a few cases, a Vertica data type cannot be directly translated to a Java data type; these exceptions are explained in this section.

In this section

- [The VerticaTypes class](#)
- [Numeric data alias conversion](#)
- [Using intervals with JDBC](#)
- [UUID values](#)
- [Complex types in JDBC](#)
- [Date types in JDBC](#)

The VerticaTypes class

JDBC does not support all of the data types that Vertica supports. The Vertica JDBC client driver contains an additional class named [VerticaTypes](#) that helps you handle identifying these Vertica-specific data types. It contains constants that you can use in your code to specify Vertica data types. This class defines two different categories of data types:

- Vertica's 13 types of interval values. This class contains constant properties for each of these types. You can use these constants to select a specific interval type when instantiating members of the [VerticaDayTimeInterval](#) and [VerticaYearMonthInterval](#) classes:

```
// Create a day to second interval
VerticaDayTimeInterval dayInt = new VerticaDayTimeInterval(
    VerticaTypes.INTERVAL_DAY_TO_SECOND, 10, 0, 5, 40, 0, 0, false);
// Create a year to month interval
VerticaYearMonthInterval monthInt = new VerticaYearMonthInterval(
    VerticaTypes.INTERVAL_YEAR_TO_MONTH, 10, 6, false);
```

- Vertica UUID data type. One way you can use the [VerticaTypes.UUID](#) is to query a table's metadata to see if a column is a UUID. See [UUID values](#) for an example.

See the [JDBC documentation](#) for more information on this class.

Numeric data alias conversion

The Vertica server supports data type aliases for integer, float and numeric types. The JDBC driver reports these as its basic data types (BIGINT, DOUBLE PRECISION, and NUMERIC), as follows:

Vertica Server Types and Aliases	Vertica JDBC Type
INTEGER INT INT8 BIGINT SMALLINT TINYINT	BIGINT
DOUBLE PRECISION FLOAT5 FLOAT8 REAL	DOUBLE PRECISION
DECIMAL NUMERIC NUMBER MONEY	NUMERIC

If a client application retrieves the values into smaller data types, Vertica JDBC driver does not check for overflows. The following example demonstrates the results of this overflow.

```
import java.sql.*;
import java.util.Properties;

public class JDBCDataTypes {
    public static void main(String[] args) {
        // If running under a Java 5 JVM, use you need to load the JDBC driver
        // using Class.forName here

        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser");
        myProp.put("password", "password123");
        Connection conn;
        try {
            conn = DriverManager.getConnection(
                "jdbc:vertica://VerticaHost:5433/VMart",
                myProp);
            Statement statement = conn.createStatement();
            // Create a table that will hold a row of different types of
            // numeric data.
            statement.executeUpdate(
                "DROP TABLE IF EXISTS test_all_types cascade");
            statement.executeUpdate("CREATE TABLE test_all_types ("
                + "c0 INTEGER, c1 TINYINT, c2 DECIMAL, "
                + "c3 MONEY, c4 DOUBLE PRECISION, c5 REAL");
            // Add a row of values to it
```

```

// Insert a row of values into
statement.executeUpdate("INSERT INTO test_all_types VALUES("
    + "11111111111111, 444, 555555555555.5555, "
    + "77777777.77, 888888888888888888.88, "
    + "10101010.10101010101010)");
// Query the new table to get the row back as a result set.
ResultSet rs = statement
    .executeQuery("SELECT * FROM test_all_types");
// Get the metadata about the row, including its data type.
ResultSetMetaData md = rs.getMetaData();
// Loop should only run once...
while (rs.next()) {
    // Print out the data type used to defined the column, followed
    // by the values retrieved using several different retrieval
    // methods.

    String[] vertTypes = new String[] {"INTEGER", "TINYINT",
        "DECIMAL", "MONEY", "DOUBLE PRECISION", "REAL"};

    for (int x=1; x<7; x++) {
        System.out.println("\n\nColumn " + x + " (" + vertTypes[x-1]
            + ")");
        System.out.println("\tgetColumnType()\t\t"
            + md.getColumnType(x));
        System.out.println("\tgetColumnTypeName()\t\t"
            + md.getColumnTypeName(x));
        System.out.println("\tgetShort()\t\t"
            + rs.getShort(x));
        System.out.println("\tgetLong()\t\t" + rs.getLong(x));
        System.out.println("\tgetInt()\t\t" + rs.getInt(x));
        System.out.println("\tgetBytes()\t\t" + rs.getBytes(x));
    }
}
rs.close();
statement.executeUpdate("drop table test_all_types cascade");
statement.close();
} catch (SQLException e) {
    e.printStackTrace();
}
}
}

```

The above example prints the following on the console when run:

```

Column 1 (INTEGER)
  getColumnType()      -5
  getColumnTypeName()  BIGINT
  getShort()           455
  getLong()            111111111111
  getInt()             -558038585
  getByte()            -57
Column 2 (TINYINT)
  getColumnType()      -5
  getColumnTypeName()  BIGINT
  getShort()           444
  getLong()            444
  getInt()             444
  getByte()            -68
Column 3 (DECIMAL)
  getColumnType()      2
  getColumnTypeName()  NUMERIC
  getShort()           -1
  getLong()            55555555555
  getInt()             2147483647
  getByte()            -1
Column 4 (MONEY)
  getColumnType()      2
  getColumnTypeName()  NUMERIC
  getShort()           -13455
  getLong()            77777777
  getInt()             77777777
  getByte()            113
Column 5 (DOUBLE PRECISION)
  getColumnType()      8
  getColumnTypeName()  DOUBLE PRECISION
  getShort()           -1
  getLong()            8888888888888900
  getInt()             2147483647
  getByte()            -1
Column 6 (REAL)
  getColumnType()      8
  getColumnTypeName()  DOUBLE PRECISION
  getShort()           8466
  getLong()            10101010
  getInt()             10101010
  getByte()            18

```

Using intervals with JDBC

The JDBC standard does not contain a data type for intervals (the duration between two points in time). To handle Vertica's [INTERVAL](#) data type, you must use JDBC's database-specific object type.

When reading an interval value from a result set, use the [ResultSet.getObject\(\)](#) method to retrieve the value, and then cast it to one of the Vertica interval classes: [VerticaDayTimeInterval](#) (which represents all ten types of day/time intervals) or [VerticaYearMonthInterval](#) (which represents all three types of year/month intervals).

Note

The units interval style is not supported. Do not use the [SET INTERVALSTYLE](#) statement to change the interval style in your client applications.

Using intervals in batch inserts

When inserting batches into tables that contain interval data, you must create instances of the [VerticaDayTimeInterval](#) or [VerticaYearMonthInterval](#) classes to hold the data you want to insert. You set values either when calling the class's constructor, or afterwards using setters. You then insert your interval values using the [PreparedStatement.setObject\(\)](#) method. You can also use the [.setString\(\)](#) method, passing it a string in " *DD* ** *HH* : *MM* : *SS* "

or "YY-MM" format.

The following example demonstrates inserting data into a table containing a day/time interval and a year/month interval:

```
import java.sql.*;
import java.util.Properties;
// You need to import the Vertica JDBC classes to be able to instantiate
// the interval classes.
import com.vertica.jdbc.*;

public class IntervalDemo {
    public static void main(String[] args) {
        // If running under a Java 5 JVM, use you need to load the JDBC driver
        // using Class.forName here
        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser");
        myProp.put("password", "password123");
        Connection conn;
        try {
            conn = DriverManager.getConnection(
                "jdbc:vertica://VerticaHost:5433/VMart", myProp);
            // Create table for interval values
            Statement stmt = conn.createStatement();
            stmt.execute("DROP TABLE IF EXISTS interval_demo");
            stmt.executeUpdate("CREATE TABLE interval_demo("
                + "DayInt INTERVAL DAY TO SECOND, "
                + "MonthInt INTERVAL YEAR TO MONTH)");
            // Insert data into interval columns using
            // VerticaDayTimeInterval and VerticaYearMonthInterval
            // classes.
            PreparedStatement pstmt = conn.prepareStatement(
                "INSERT INTO interval_demo VALUES(?,?)");
            // Create instances of the Vertica classes that represent
            // intervals.
            VerticaDayTimeInterval dayInt = new VerticaDayTimeInterval(10, 0,
                5, 40, 0, 0, false);
            VerticaYearMonthInterval monthInt = new VerticaYearMonthInterval(
                10, 6, false);
            // These objects can also be manipulated using setters.
            dayInt.setHour(7);
            // Add the interval values to the batch
            ((VerticaPreparedStatement) pstmt).setObject(1, dayInt);
            ((VerticaPreparedStatement) pstmt).setObject(2, monthInt);
            pstmt.addBatch();
            // Set another row from strings.
            // Set day interval in "days HH:MM:SS" format
            pstmt.setString(1, "10 10:10:10");
            // Set year to month value in "MM-YY" format
            pstmt.setString(2, "12-09");
            pstmt.addBatch();
            // Execute the batch to insert the values.
            try {
                pstmt.executeBatch();
            } catch (SQLException e) {
                System.out.println("Error message: " + e.getMessage());
            }
        }
    }
}
```

Reading interval values

You read an interval value from a result set using the [ResultSet.getObject\(\)](#) method, and cast the object to the appropriate Vertica object class: [VerticaDayTimeInterval](#) for day/time intervals or [VerticaYearMonthInterval](#) for year/month intervals. This is easy to do if you know that the column contains an interval, and you know what type of interval it is. If your application cannot assume the structure of the data in the result set it reads in,

you can test whether a column contains a database-specific object type, and if so, determine whether the object belongs to either the `VerticaDayTimeInterval` or `VerticaYearMonthInterval` classes.

```
// Retrieve the interval values inserted by previous demo.
// Query the table to get the row back as a result set.
ResultSet rs = stmt.executeQuery("SELECT * FROM interval_demo");
// If you do not know the types of data contained in the result set,
// you can read its metadata to determine the type, and use
// additional information to determine the interval type.
ResultSetMetaData md = rs.getMetaData();
while (rs.next()) {
    for (int x = 1; x <= md.getColumnCount(); x++) {
        // Get data type from metadata
        int colDataType = md.getColumnType(x);
        // You can get the type in a string:
        System.out.println("Column " + x + " is a "
            + md.getColumnTypeName(x));
        // Normally, you'd have a switch statement here to
        // handle all sorts of column types, but this example is
        // simplified to just handle database-specific types
        if (colDataType == Types.OTHER) {
            // Column contains a database-specific type. Determine
            // what type of interval it is. Assuming it is an
            // interval...
            Object columnVal = rs.getObject(x);
            if (columnVal instanceof VerticaDayTimeInterval) {
                // We know it is a date time interval
                VerticaDayTimeInterval interval =
                    (VerticaDayTimeInterval) columnVal;
                // You can use the getters to access the interval's
                // data
                System.out.print("Column " + x + "'s value is ");
                System.out.print(interval.getDay() + " Days ");
                System.out.print(interval.getHour() + " Hours ");
                System.out.println(interval.getMinute()
                    + " Minutes");
            } else if (columnVal instanceof VerticaYearMonthInterval) {
                VerticaYearMonthInterval interval =
                    (VerticaYearMonthInterval) columnVal;
                System.out.print("Column " + x + "'s value is ");
                System.out.print(interval.getYear() + " Years ");
                System.out.println(interval.getMonth() + " Months");
            } else {
                System.out.println("Not an interval.");
            }
        }
    }
}
} catch (SQLException e) {
    e.printStackTrace();
}
}
```

The example prints the following to the console:

Column 1 is a INTERVAL DAY TO SECOND
Column 1's value is 10 Days 7 Hours 5 Minutes
Column 2 is a INTERVAL YEAR TO MONTH
Column 2's value is 10 Years 6 Months
Column 1 is a INTERVAL DAY TO SECOND
Column 1's value is 10 Days 10 Hours 10 Minutes
Column 2 is a INTERVAL YEAR TO MONTH
Column 2's value is 12 Years 9 Months

Another option is to use database metadata to find columns that contain intervals.

```
// Determine the interval data types by examining the database
// metadata.
DatabaseMetaData dbmd = conn.getMetaData();
ResultSet dbMeta = dbmd.getColumns(null, null, "interval_demo", null);
int colcount = 0;
while (dbMeta.next()) {

    // Get the metadata type for a column.
    int javaType = dbMeta.getInt("DATA_TYPE");

    System.out.println("Column " + ++colcount + " Type name is " +
        dbMeta.getString("TYPE_NAME"));

    if(javaType == Types.OTHER) {
        // The SQL_DATETIME_SUB column in the metadata tells you
        // Specifically which subtype of interval you have.
        // The VerticaDayTimeInterval.isDayTimeInterval()
        // methods tells you if that value is a day time.
        //
        int intervalType = dbMeta.getInt("SQL_DATETIME_SUB");
        if(VerticaDayTimeInterval.isDayTimeInterval(intervalType)) {
            // Now you know it is one of the 10 day/time interval types.
            // When you select this column you can cast to
            // VerticaDayTimeInterval.
            // You can get more specific by checking intervalType
            // against each of the 10 constants directly, but
            // they all are represented by the same object.
            System.out.println("column " + colcount + " is a " +
                "VerticaDayTimeInterval intervalType = "
                + intervalType);
        } else if(VerticaYearMonthInterval.isYearMonthInterval(
            intervalType)) {
            //now you know it is one of the 3 year/month intervals,
            //and you can select the column and cast to
            // VerticaYearMonthInterval
            System.out.println("column " + colcount + " is a " +
                "VerticaDayTimeInterval intervalType = "
                + intervalType);
        } else {
            System.out.println("Not an interval type.");
        }
    }
}
```

UUID values

[UUID](#) is a core data type in Vertica. However, it is not a core Java data type. You must use the [java.util.UUID](#) class to represent UUID values in your Java code. The JDBC driver does not translate values from Vertica to non-core Java data types. Therefore, you must send UUID values to Vertica using generic object methods such as [PreparedStatement.setObject\(\)](#) . You also use generic object methods (such as [ResultSet.getObject\(\)](#)) to retrieve UUID values from Vertica. You then cast the retrieved objects as a member of the [java.util.UUID](#) class.

The following example code demonstrates inserting UUID values into and retrieving UUID values from Vertica.

```
package jdbc_uuid_example;

import java.sql.*;
import java.util.Properties;

public class VerticaUUIDExample {

    public static void main(String[] args) {

        Properties myProp = new Properties();
        myProp.put("user", "dbadmin");
        myProp.put("password", "");
        Connection conn;

        try {
            conn = DriverManager.getConnection("jdbc:vertica://doch01:5433/VMart",
                                             myProp);
            Statement stmt = conn.createStatement();

            // Create a table with a UUID column and a VARCHAR column.
            stmt.execute("DROP TABLE IF EXISTS UUID_TEST CASCADE;");
            stmt.execute("CREATE TABLE UUID_TEST (id UUID, description VARCHAR(25));");

            // Prepare a statement to insert a UUID and a string into the table.
            PreparedStatement ps = conn.prepareStatement("INSERT INTO UUID_TEST VALUES(?,?)");

            java.util.UUID uuid; // Holds the UUID value.

            for (Integer x = 0; x < 10; x++) {
                // Generate a random uuid
                uuid = java.util.UUID.randomUUID();
                // Set the UUID value by calling setObject.
                ps.setObject(1, uuid);
                // Set the String value to indicate which UUID this is.
                ps.setString(2, "UUID #" + x);
                ps.execute();
            }

            // Query the uuid
            ResultSet rs = stmt.executeQuery("SELECT * FROM UUID_TEST ORDER BY description ASC");
            while (rs.next()) {
                // Cast the object from the result set as a UUID.
                uuid = (java.util.UUID) rs.getObject(1);
                System.out.println(rs.getString(2) + " : " + uuid.toString());
            }
        } catch (SQLException e) {
            e.printStackTrace();
        }
    }
}
```

The previous example prints output similar to the following:

```
UUID #0 : 67b6dcb6-c28c-4965-b9f7-5c830a04664d
UUID #1 : 485d3835-2887-4233-b003-392254fa97e0
UUID #2 : 81421f51-c803-473d-8cfc-2c184582a117
UUID #3 : bec8b86a-b650-47b0-852c-8229155332d9
UUID #4 : 8ae5e3ec-d143-4ef7-8901-24f6d0483abf
UUID #5 : 669696ce-5e86-4e87-b8d0-a937f5fc18d7
UUID #6 : 19609ec9-ec56-4444-9cfe-ad2b8de537dd
UUID #7 : 97182e1d-5c7e-4da1-9922-67e804fde173
UUID #8 : c76c3a2b-a9ef-4d65-b2fb-7c637f872b3c
UUID #9 : 3cbbcd26-c177-4277-b3df-bf4d9389f69d
```

Determining whether a column has a UUID data type

JDBC does not support the UUID data type. This limitation means you cannot use the usual `ResultSetMetaData.getColumnType()` method to determine column's data type is UUID. Calling this method on a UUID column returns `Types.OTHER`. This value is also to identify interval columns. You can use two ways to determine if a column contains UUIDs:

- Use `ResultSetMetaData.getColumnTypeName()` to get the name of the column's data type. For UUID columns, this method returns the value "Uuid" as a `String`.
- Query the table's metadata to get the SQL data type of the column. If this value is equal to `VerticaTypes.UUID`, the column's data type is UUID.

The following example demonstrates both of these techniques:

```
// This example assumes you already have a database connection
// and result set from a query on a table that may contain a UUID.

// Get the metadata of the result set to get the column definitions
ResultSetMetaData meta = rs.getMetaData();
int colcount;
int maxcol = meta.getColumnCount();

System.out.println("Using column metadata:");
for (colcount = 1; colcount < maxcol; colcount++) {
    // .getColumnType() always returns "OTHER" for UUID columns.
    if (meta.getColumnType(colcount) == Types.OTHER) {
        // To determine that it is a UUID column, test the name of the column type.
        if (meta.getColumnTypeName(colcount).equalsIgnoreCase("uuid")) {
            // It's a UUID column
            System.out.println("Column " + colcount + " is UUID");
        }
    }
}

// You can also query the table's metadata to find its column types and compare
// it to the VerticaType.UUID constant to see if it is a UUID column.
System.out.println("Using table metadata:");
DatabaseMetaData dbmd = conn.getMetaData();
// Get the metadata for the previously-created test table.
ResultSet tableMeta = dbmd.getColumns(null, null, "UUID_TEST", null);
colcount = 0;
// Each row in the result set has metadata that describes a single column.
while (tableMeta.next()) {
    colcount++;
    // The SQL_DATA_TYPE column holds the Vertica database data type. You compare
    // this value to the VerticaTypes.UUID constant to see if it is a UUID.
    if (tableMeta.getInt("SQL_DATA_TYPE") == VerticaTypes.UUID) {
        // Column is a UUID data type...
        System.out.println("Column " + colcount + " is a UUID column.");
    }
}
}
```

This example prints the following to the console if it is run after running the prior example:

Using column metadata:
 Column 1 is UUID
 Using table metadata:
 Column 1 is a UUID column.

Complex types in JDBC

The results of a `java.sql` query are stored in a `ResultSet`. If the `ResultSet` contains a column of [complex type](#), you can retrieve it with one of the following:

- For columns of type [ARRAY](#), [SET](#), or [MAP](#), use `getArray()`, which returns a `java.sql.Array`.
- For columns of type [ROW](#), use `getObject()`, which returns a `java.sql.Struct`.

Type conversion table

The objects `java.sql.Array` and `java.sql.Struct` each have their own API for accessing complex type data. In each case, the data is returned as `java.lang.Object` and will need to be type cast to a Java type. The exact Java type to expect depends on the Vertica type used in the complex type definition, as shown in this type conversion table:

java.sql Type	Vertica Type	Java Type
BIT	BOOL	<code>java.lang.Boolean</code>
BIGINT	INT	<code>java.lang.Long</code>
DOUBLE	FLOAT	<code>java.lang.Double</code>
CHAR	CHAR	<code>java.lang.String</code>
VARCHAR	VARCHAR	<code>java.lang.String</code>
LONGVARCHAR	LONGVARCHAR	<code>java.lang.String</code>
DATE	DATE	<code>java.sql.Date</code>
TIME	TIME	<code>java.sql.Time</code>
TIME	TIMETZ	<code>java.sql.Time</code>
TIMESTAMP	TIMESTAMP	<code>java.sql.Timestamp</code>
TIMESTAMP	TIMESTAMPTZ	<code>com.vertica.dsi.dataengine.utilities.TimestampTz</code>
<code>getIntervalRange(oid, typmod)</code>	INTERVAL	<code>com.vertica.jdbc.VerticaDayTimeInterval</code>
<code>getIntervalRange(oid, typmod)</code>	INTERVALYM	<code>com.vertica.jdbc.VerticaYearMonthInterval</code>
BINARY	BINARY	<code>byte[]</code>
VARBINARY	VARBINARY	<code>byte[]</code>
LONGVARBINARY	LONGVARBINARY	<code>byte[]</code>
NUMERIC	NUMERIC	<code>java.math.BigDecimal</code>
TYPE_SQL_GUID	UUID	<code>java.util.UUID</code>
ARRAY	ARRAY	<code>java.lang.Object[]</code>

ARRAY	SET	java.lang.Object[]
STRUCT	ROW	java.sql.Struct
ARRAY	MAP	java.lang.Object[]

ARRAY, SET, and MAP columns

For example, the following methods run queries that return an [ARRAY](#) of some Vertica type, which is then type cast to an array of its corresponding Java type by the JDBC driver when retrieved with `getArray()`. This particular example starts with ARRAY[INT] and ARRAY[FLOAT], so they are type cast to `Long[]` and `Double[]`, respectively, as determined by the type conversion table.

- `getArrayResultSetExample()` shows how the ARRAY can be processed as a `java.sql.ResultSet`. This example uses `getResultSet()` which returns the underlying array as another `ResultSet`. You can use this underlying `ResultSet` to:
 - Retrieve the parent `ResultSet`.
 - Treat it as an `Object` array or `ResultSet`.
- `getArrayObjectExample()` shows how the ARRAY can be processed as a native Java array. This example uses `getArray()` which returns the underlying array as an `Object` array rather than a `ResultSet`. This has the following implications:
 - You cannot use an underlying `Object` array to retrieve its parent array.
 - All underlying arrays are treated as `Object` arrays (rather than `ResultSet` s).

```
package com.vertica.jdbc.test.samples;

import java.sql.Connection;
import java.sql.SQLException;
import java.sql.Statement;
import java.sql.ResultSet;
import java.sql.Array;
import java.sql.Struct;

public class ComplexTypesArraySamples
{
    /**
     * Executes a query and gets a java.sql.Array from the ResultSet. It then uses the Array#getResultSet
     * method to get a ResultSet containing the contents of the array.
     * @param conn A Connection to a Vertica database
     * @throws SQLException
     */
    public static void getArrayResultSetExample (Connection conn) throws SQLException {
        Statement stmt = conn.createStatement();

        final String queryText = "SELECT ARRAY[ARRAY[1,2,3],ARRAY[4,5,6],ARRAY[7,8,9]]::ARRAY[ARRAY[INT]] as array";
        final String targetColumnName = "array";

        System.out.println ("queryText: " + queryText);
        ResultSet rs = stmt.executeQuery(queryText);
        int targetColumnId = rs.findColumn (targetColumnName);

        while (rs.next ()) {
            Array currentSqlArray = rs.getArray (targetColumnId);
            ResultSet level1ResultSet = currentSqlArray.getResultSet();
            if (level1ResultSet != null) {
                while (level1ResultSet.next ()) {
                    // The first column of the result set holds the row index
                    int i = level1ResultSet.getInt(1) - 1;
                    Array level2SqlArray = level1ResultSet.getArray (2);
                    Object level2Object = level2SqlArray.getArray ();
                    // For this ARRAY[INT], the driver returns a Long[]
                    assert (level2Object instanceof Long[]);
                    Long [] lev2Array = (Long [])level2Object;
                }
            }
        }
    }
}
```

```

        System.out.println (" level1Object [" + i + "]: " + level2SqlArray.toString () + " (" + level2SqlArray.getClass () + ")");

        for (int j = 0; j < level2Array.length; j++) {
            System.out.println (" Value [" + i + ", " + j + "]: " + level2Array[j] + " (" + level2Array[j].getClass () + ")");
        }
    }
}

/**
 * Executes a query and gets a java.sql.Array from the ResultSet. It then uses the Array#getArray
 * method to get the contents of the array as a Java Object [].
 * @param conn A Connection to a Vertica database
 * @throws SQLException
 */
public static void getArrayObjectExample (Connection conn) throws SQLException {
    Statement stmt = conn.createStatement();

    final String queryText = "SELECT ARRAY[ARRAY[0,0,0,1,0,2],ARRAY[1,0,1,1,1,2],ARRAY[2,0,2,1,2,2]]:ARRAY[ARRAY[FLOAT]] as array";
    final String targetColumnName = "array";

    System.out.println ("queryText: " + queryText);
    ResultSet rs = stmt.executeQuery(queryText);
    int targetColumnId = rs.findColumn (targetColumnName);

    while (rs.next ()) {
        // Get the java.sql.Array from the result set
        Array currentSqlArray = rs.getArray (targetColumnId);
        // Get the internal Java Object implementing the array
        Object level1ArrayObject = currentSqlArray.getArray ();
        if (level1ArrayObject != null) {
            // All returned instances are Object[]
            assert (level1ArrayObject instanceof Object[]);
            Object [] level1Array = (Object [])level1ArrayObject;
            System.out.println ("Vertica driver returned a: " + level1Array.getClass());

            for (int i = 0; i < level1Array.length; i++) {
                Object level2Object = level1Array[i];
                // For this ARRAY[FLOAT], the driver returns a Double[]
                assert (level2Object instanceof Double[]);
                Double [] level2Array = (Double [])level2Object;
                for (int j = 0; j < level2Array.length; j++) {
                    System.out.println (" Value [" + i + ", " + j + "]: " + level2Array[j] + " (" + level2Array[j].getClass () + ")");
                }
            }
        }
    }
}

```

The output of `getArrayResultSetExample()` shows that the Vertica column type `ARRAY[INT]` is type cast to `Long[]` :

```

queryText: SELECT ARRAY[ARRAY[1,2,3],ARRAY[4,5,6],ARRAY[7,8,9]]::ARRAY[ARRAY[INT]] as array
level1Object [0]: [1,2,3] (class com.vertica.jdbc.jdbc42.S42Array)
Value [0, 0]: 1 (class java.lang.Long)
Value [0, 1]: 2 (class java.lang.Long)
Value [0, 2]: 3 (class java.lang.Long)
level1Object [1]: [4,5,6] (class com.vertica.jdbc.jdbc42.S42Array)
Value [1, 0]: 4 (class java.lang.Long)
Value [1, 1]: 5 (class java.lang.Long)
Value [1, 2]: 6 (class java.lang.Long)
level1Object [2]: [7,8,9] (class com.vertica.jdbc.jdbc42.S42Array)
Value [2, 0]: 7 (class java.lang.Long)
Value [2, 1]: 8 (class java.lang.Long)
Value [2, 2]: 9 (class java.lang.Long)

```

The output of `getArrayObjectExample()` shows that the Vertica column type `ARRAY[FLOAT]` is type cast to `Double[]` :

```

queryText: SELECT ARRAY[ARRAY[0.0,0.1,0.2],ARRAY[1.0,1.1,1.2],ARRAY[2.0,2.1,2.2]]::ARRAY[ARRAY[FLOAT]] as array
Vertica driver returned a: class [Ljava.lang.Object;
Value [0, 0]: 0.0 (class java.lang.Double)
Value [0, 1]: 0.1 (class java.lang.Double)
Value [0, 2]: 0.2 (class java.lang.Double)
Value [1, 0]: 1.0 (class java.lang.Double)
Value [1, 1]: 1.1 (class java.lang.Double)
Value [1, 2]: 1.2 (class java.lang.Double)
Value [2, 0]: 2.0 (class java.lang.Double)
Value [2, 1]: 2.1 (class java.lang.Double)
Value [2, 2]: 2.2 (class java.lang.Double)

```

ROW columns

Calling `getObject()` on a `java.sql.ResultSet` that contains a column of type `ROW` retrieves the column as a `java.sql.Struct` which contains an `Object[]` (itself retrievable with `getAttributes()`).

Each element of the `Object[]` represents an attribute from the struct, and each attribute has a corresponding Java type shown in the type conversion table above.

This example defines a ROW with the following attributes:

Name	Value	Vertica Type	Java Type
name	Amy	VARCHAR	String
date	'07/10/2021'	DATE	java.sql.Date
id	5	INT	java.lang.Long
current	false	BOOLEAN	java.lang.Boolean

```

package com.vertica.jdbc.test.samples;

import java.sql.Connection;
import java.sql.SQLException;
import java.sql.Statement;
import java.sql.ResultSet;
import java.sql.Array;
import java.sql.Struct;

public class ComplexTypesSamples
{
    /**
     * Executes a query and gets a java.sql.Struct from the ResultSet. It then uses the Struct#getAttributes
     * method to get the contents of the struct as a Java Object [].
     * @param conn A Connection to a Vertica database
     * @throws SQLException
     */
    public static void getRowExample (Connection conn) throws SQLException {
        Statement stmt = conn.createStatement();

        final String queryText = "SELECT ROW('Amy', '07/10/2021'::Date, 5, false) as rowExample(name, date, id, current)";
        final String targetColumnName = "rowExample";

        System.out.println ("queryText: " + queryText);
        ResultSet rs = stmt.executeQuery(queryText);
        int targetColumnId = rs.findColumn (targetColumnName);

        while (rs.next ()) {
            // Get the java.sql.Array from the result set
            Object currentObject = rs.getObject (targetColumnId);
            assert (currentObject instanceof Struct);
            Struct rowStruct = (Struct)currentObject;

            Object[] attributes = rowStruct.getAttributes();

            // attributes.length should be 4 based on the queryText
            assert (attributes.length == 4);
            assert (attributes[0] instanceof String);
            assert (attributes[1] instanceof java.sql.Date);
            assert (attributes[2] instanceof java.lang.Long);
            assert (attributes[3] instanceof java.lang.Boolean);

            System.out.println ("attributes[0]: " + attributes[0] + " (" + attributes[0].getClass().getName() + ")");
            System.out.println ("attributes[1]: " + attributes[1] + " (" + attributes[1].getClass().getName() + ")");
            System.out.println ("attributes[2]: " + attributes[2] + " (" + attributes[2].getClass().getName() + ")");
            System.out.println ("attributes[3]: " + attributes[3] + " (" + attributes[3].getClass().getName() + ")");
        }
    }
}

```

The output of `getRowExample()` shows the attribute of each element and its corresponding Java type:

```

queryText: SELECT ROW('Amy', '07/10/2021'::Date, 5, false) as rowExample(name, date, id, current)
attributes[0]: Amy (java.lang.String)
attributes[1]: 2021-07-10 (java.sql.Date)
attributes[2]: 5 (java.lang.Long)
attributes[3]: false (java.lang.Boolean)

```

Converting a date to a string

For the purposes of this page, a large date is defined as a date with a year that exceeds 9999.

If your database doesn't contain any large [dates](#), then you can reliably call `toString()` to convert the dates to strings.

Otherwise, if your database contains large dates, you should use `java.text.SimpleDateFormat` and its `format()` method:

1. Define a String format with `java.text.SimpleDateFormat`. The number of characters in `yyyy` in the format defines the minimum number of characters to use in the date.
2. Call `SimpleDateFormat.format()` to convert the `java.sql.Date` object to a String.

Examples

For example, the following method returns a string when passed a `java.sql.Date` object as an argument. Here, the year part of the format, `YYYY` indicates that this format is compatible with all dates with at least four characters in its year.

```
import java.sql.Date;

private String convertDate (Date date) {
    SimpleDateFormat dateFormat = new SimpleDateFormat ("yyyy-MM-dd");
    return dateFormat.format (date);
}
```

Executing queries through JDBC

To run a query through JDBC:

1. Connect with the Vertica database. See [Creating and configuring a connection](#).
2. Run the query.

The method you use to run the query depends on the type of query you want to run:

- a DDL query that does not return a result set.
- a DDL query that returns a result set.
- a DML query

Executing DDL (data definition language) queries

To run DDL queries, such as [CREATE TABLE](#) and [COPY](#), use the `Statement.execute()` method. You get an instance of this class by calling the `createStatement` method of your connection object.

The following example creates an instance of the `Statement` class and uses it to execute a [CREATE TABLE](#) and a [COPY](#) query:

```
Statement stmt = conn.createStatement();
stmt.execute("CREATE TABLE address_book (Last_Name char(50) default '', " +
    "First_Name char(50),Email char(50),Phone_Number char(50))");
stmt.execute("COPY address_book FROM 'address.dat' DELIMITER ';' NULL 'null');
```

Executing queries that return result sets

Use the `Statement` class's `executeQuery` method to execute queries that return a result set, such as [SELECT](#). To get the data from the result set, use methods such as `getInt`, `getString`, and `getDouble` to access column values depending upon the data types of columns in the result set. Use `ResultSet.next` to advance to the next row of the data set.

```
ResultSet rs = null;
rs = stmt.executeQuery("SELECT First_Name, Last_Name FROM address_book");
int x = 1;
while(rs.next()){
    System.out.println(x + ". " + rs.getString(1).trim() + " "
        + rs.getString(2).trim());
    x++;
}
```

Note

The Vertica JDBC driver does not support scrollable cursors. You can only read forwards through the result set.

Executing DML (data manipulation language) queries using `executeUpdate`

Use the `executeUpdate` method for DML SQL queries that change data in the database, such as [INSERT](#), [UPDATE](#) and [DELETE](#) which do not return a result set.

```
stmt.executeUpdate("INSERT INTO address_book " +
    "VALUES ('Ben-Shachar', 'Tamar', 'tamar@example.com', " +
    "'555-380-6466')");
stmt.executeUpdate("INSERT INTO address_book (First_Name, Email) " +
    "VALUES ('Pete', 'pete@example.com')");
```

Note

The Vertica JDBC driver's `Statement` class supports executing multiple statements in the SQL string you pass to the `execute` method. The `PreparedStatement` class does not support using multiple statements in a single execution.

Executing stored procedures

You can create and execute [stored procedures](#) with [CallableStatement](#)s.

To [create](#) a [stored procedure](#):

```
Statement st = conn.createStatement();
String createSimpleSp = "CREATE OR REPLACE PROCEDURE raiseInt(IN x INT) LANGUAGE PLvSQL AS $$ " +
    "BEGIN " +
    "    RAISE INFO 'x = %', x;" +
    "END;" +
    "$$";
st.execute(createSimpleSp);
```

To [call](#) a stored procedure:

```
String spCall = "CALL raiseInt (?)";
CallableStatement stmt = conn.prepareCall(spCall);
stmt.setInt(1, 42);
```

Stored procedures do not yet support [OUT parameters](#). Instead, you can return and retrieve execution information with [RAISE](#) and [getWarnings\(\)](#) respectively:

```
System.out.println(stmt.getWarnings().toString());
```

Canceling JDBC queries

You can cancel JDBC queries with the `Statement.cancel()` method.

The following example creates a table `jdbccanceltest` and runs two queries, canceling the first:

```
import java.sql.Connection;
import java.sql.SQLException;
import java.sql.Statement;
import java.sql.ResultSet;
import java.sql.Array;
import java.sql.Struct;

public class CancelSamples
{
    /**
     * Sets up a large test table, queries its contents and cancels the query.
     * @param conn A connection to a Vertica database
     * @throws SQLException
     */
}
```

```

 * @param conn A connection to a Vertica database
 * @throws SQLException
 */
private static void runSecondQuery(Connection conn) throws SQLException
{
    String queryText = "select 1 from dual";
    Statement stmt = conn.createStatement();
    try
    {
        ResultSet rs = stmt.executeQuery(queryText);
        while (rs.next()) ;
    }
    catch (SQLException e)
    {
        System.out.println(e.getMessage());
        System.out.println("warning: no exception should have been thrown on query after cancel");
    }
}

/**
 * Clean up table used in test.
 * @param conn A connection to a Vertica database
 * @throws SQLException
 */
private static void cleanup(Connection conn) throws SQLException
{
    String queryText = "drop table if exists jdbcanceltest";
    Statement stmt = conn.createStatement();
    stmt.execute(queryText);
}

```

Loading data through JDBC

You can use any of the following methods to load data via the JDBC interface:

- Executing a SQL INSERT statement to insert a single row directly.
- Batch loading data using a prepared statement.
- Bulk loading data from files or streams using [COPY](#).

The following sections explain in detail how you load data using JDBC.

In this section

- [Using a single row insert](#)
- [Batch inserts using JDBC prepared statements](#)
- [Bulk loading using the COPY statement](#)
- [Streaming data via JDBC](#)

Using a single row insert

The simplest way to insert data into a table is to use the SQL [INSERT](#) statement. You can use this statement by instantiating a member of the [Statement](#) class, and use its [executeUpdate\(\)](#) method to run your SQL statement.

The following code fragment demonstrates how you can create a [Statement](#) object and use it to insert data into a table named `address_book`:

```

Statement stmt = conn.createStatement();
stmt.executeUpdate("INSERT INTO address_book " +
    "VALUES ('Smith', 'John', 'jsmith@example.com', " +
    "'555-123-4567')");

```

This method has a few drawbacks: you need convert your data to string and escape any special characters in your data. A better way to insert data is to use prepared statements. See [Batch inserts using JDBC prepared statements](#).

Batch inserts using JDBC prepared statements

You can load batches of data into Vertica using prepared [INSERT](#) statements—server-side statements that you set up once, and then call repeatedly. You instantiate a member of the [PreparedStatement](#) class with a SQL statement that contains question mark placeholders for data. For example:

```
PreparedStatement pstmt = conn.prepareStatement(
    "INSERT INTO customers(last, first, id) VALUES(?, ?, ?);");
```

You then set the parameters using data-type-specific methods on the [PreparedStatement](#) object, such as [setString\(\)](#) and [setInt\(\)](#). Once your parameters are set, call the [addBatch\(\)](#) method to add the row to the batch. When you have a complete batch of data ready, call the [executeBatch\(\)](#) method to execute the insert batch.

Behind the scenes, the batch insert is converted into a [COPY](#) statement. When the connection's `AutoCommit` parameter is disabled, Vertica keeps the `COPY` statement open and uses it to load subsequent batches until the transaction is committed, the cursor is closed, or your application executes anything else (or executes any statement using another [Statement](#) or [PreparedStatement](#) object). Using a single `COPY` statement for multiple batch inserts makes loading data more efficient. If you are loading multiple batches, you should disable the `AutoCommit` property of the database to take advantage of this increased efficiency.

When performing batch inserts, experiment with various batch and row sizes to determine the settings that provide the best performance.

The following example demonstrates using a prepared statement to batch insert data.

```
import java.sql.*;
import java.util.Properties;

public class BatchInsertExample {
    public static void main(String[] args) {
        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser");
        myProp.put("password", "password123");

        //Set streamingBatchInsert to True to enable streaming mode for batch inserts.
        //myProp.put("streamingBatchInsert", "True");

        Connection conn;
        try {
            conn = DriverManager.getConnection(
                "jdbc:vertica://VerticaHost:5433/ExampleDB",
                myProp);

            // establish connection and make a table for the data.
            Statement stmt = conn.createStatement();

            // Set AutoCommit to false to allow Vertica to reuse the same
            // COPY statement
            conn.setAutoCommit(false);

            // Drop table and recreate.
            stmt.execute("DROP TABLE IF EXISTS customers CASCADE");
            stmt.execute("CREATE TABLE customers (CustID int, Last_Name"
                + " char(50), First_Name char(50), Email char(50), "
                + "Phone_Number char(12))");

            // Some dummy data to insert.
            String[] firstNames = new String[] { "Anna", "Bill", "Cindy",
                "Don", "Eric" };
            String[] lastNames = new String[] { "Allen", "Brown", "Chu",
                "Dodd", "Estavez" };
            String[] emails = new String[] { "aang@example.com",
                "b.brown@example.com", "cindy@example.com",
                "d.d@example.com", "e.estavez@example.com" };
            String[] phoneNumbers = new String[] { "123-456-7890",
                "555-51-2222", "555-867-5309"
            };
        } catch (SQLException e) {
            e.printStackTrace();
        }
    }
}
```

```

        "555-555-1212", "781-555-0000" };
// Create the prepared statement
PreparedStatement pstmt = conn.prepareStatement(
    "INSERT INTO customers (CustID, Last_Name, " +
    "First_Name, Email, Phone_Number) " +
    "VALUES(?, ?, ?, ?, ?)");
// Add rows to a batch in a loop. Each iteration adds a
// new row.
for (int i = 0; i < firstNames.length; i++) {
    // Add each parameter to the row.
    pstmt.setInt(1, i + 1);
    pstmt.setString(2, lastNames[i]);
    pstmt.setString(3, firstNames[i]);
    pstmt.setString(4, emails[i]);
    pstmt.setString(5, phoneNumbers[i]);
    // Add row to the batch.
    pstmt.addBatch();
}

try {
    // Batch is ready, execute it to insert the data
    pstmt.executeBatch();
} catch (SQLException e) {
    System.out.println("Error message: " + e.getMessage());
    return; // Exit if there was an error
}

// Commit the transaction to close the COPY command
conn.commit();

// Print the resulting table.
ResultSet rs = null;
rs = stmt.executeQuery("SELECT CustID, First_Name, "
    + "Last_Name FROM customers ORDER BY CustID");
while (rs.next()) {
    System.out.println(rs.getInt(1) + " - "
        + rs.getString(2).trim() + " "
        + rs.getString(3).trim());
}
// Cleanup
conn.close();
} catch (SQLException e) {
    e.printStackTrace();
}
}

```

The result of running the example code is:

```

1 - Anna Allen
2 - Bill Brown
3 - Cindy Chu
4 - Don Dodd
5 - Eric Estavez

```

Streaming batch inserts

By default, Vertica performs batch inserts by caching each row and inserting the cache when the user calls the `executeBatch()` method. Vertica also supports streaming batch inserts. A streaming batch insert adds a row to the database each time the user calls `addBatch()`. Streaming batch inserts improve database performance by allowing parallel processing and reducing memory demands.

Note

Once you begin a streaming batch insert, you cannot make other JDBC calls that require client-server communication until you have executed the batch or closed or rolled back the connection.

To enable streaming batch inserts, set the `streamingBatchInsert` property to True. The preceding code sample includes a line enabling `streamingBatchInsert` mode. Remove the `//` comment marks to enable this line and activate streaming batch inserts.

The following table explains the various batch insert methods and how their behavior differs between default batch insert mode and streaming batch insert mode.

Method	Default Batch Insert Behavior	Streaming Batch Insert Behavior
<code>addBatch()</code>	Adds a row to the row cache.	Inserts a row into the database.
<code>executeBatch()</code>	Adds the contents of the row cache to the database in a single action.	Sends an end-of-batch message to the server and returns an array of integers indicating the success or failure of each <code>addBatch()</code> attempt.
<code>clearBatch()</code>	Clears the row cache without inserting any rows.	Not supported. Triggers an exception if used when streaming batch inserts are enabled.

Notes

- Using the `PreparedStatement.setFloat()` method can cause rounding errors. If precision is important, use the `.setDouble()` method instead.
- The `PreparedStatement` object caches the connection's `AutoCommit` property when the statement is prepared. Later changes to the `AutoCommit` property have no effect on the prepared statement.

In this section

- [Error handling during batch loads](#)
- [Identifying accepted and rejected rows \(JDBC\)](#)
- [Rolling back batch loads on the server](#)

Error handling during batch loads

When loading individual batches, you can find how many rows were accepted and what rows were rejected (see [Identifying Accepted and Rejected Rows](#) for details). If you have disabled the `AutoCommit` connection setting, other errors (such as disk space errors, for example) do not occur while inserting individual batches. This behavior is caused by having a single SQL `COPY` statement perform the loading of multiple consecutive batches (which makes the load process more efficient). It is only when the `COPY` statement closes that the batched data is committed and Vertica reports other types of errors.

Therefore, your bulk loading application should be prepared to check for errors when the `COPY` statement closes. You can trigger the `COPY` statement to close by:

- ending the batch load transaction by calling `Connection.commit()`
- closing the statement using `Statement.close()`
- setting the connection's `AutoCommit` property to true before inserting the last batch in the load

Note

The `COPY` statement also closes if you execute any non-insert statement or execute any statement using a different `Statement` or `PreparedStatement` object. Ending the `COPY` statement using either of these methods can lead to confusion and a harder-to-maintain application, since you would need to handle batch load errors in a non-batch load statement. You should explicitly end the `COPY` statement at the end of your batch load and handle any errors at that time.

Identifying accepted and rejected rows (JDBC)

The return value of `PreparedStatement.executeBatch` is an integer array containing the success or failure status of inserting each row. A value 1 means the row was accepted and a value of -3 means that the row was rejected. In the case where an exception occurred during the batch execution, you can also get the array using `BatchUpdateException.getUpdateCounts()`.

The following example extends the example shown in [Batch inserts using JDBC prepared statements](#) to retrieve this array and display the results the batch load.

```
import java.sql.*;
import java.util.Arrays;
import java.util.Properties;

public class BatchInsertErrorHandlingExample {
    public static void main(String[] args) {
        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser");
        myProp.put("password", "password123");
        Connection conn;

        // establish connection and make a table for the data.
        try {
            conn = DriverManager.getConnection(
                "jdbc:vertica://VerticaHost:5433/ExampleDB",
                myProp);

            // Disable auto commit
            conn.setAutoCommit(false);

            // Create a statement
            Statement stmt = conn.createStatement();
            // Drop table and recreate.
            stmt.execute("DROP TABLE IF EXISTS customers CASCADE");
            stmt.execute("CREATE TABLE customers (CustID int, Last_Name"
                + " char(50), First_Name char(50), Email char(50),"
                + "Phone_Number char(12))");

            // Some dummy data to insert. The one row won't insert because
            // the phone number is too long for the phone column.
            String[] firstNames = new String[] { "Anna", "Bill", "Cindy",
                "Don", "Eric" };
            String[] lastNames = new String[] { "Allen", "Brown", "Chu",
                "Dodd", "Estavez" };
            String[] emails = new String[] { "aang@example.com",
                "b.brown@example.com", "cindy@example.com",
                "d.d@example.com", "e.estavez@example.com" };
            String[] phoneNumbers = new String[] { "123-456-789",
                "555-444-3333", "555-867-53093453453",
                "555-555-1212", "781-555-0000" };

            // Create the prepared statement
            PreparedStatement pstmt = conn.prepareStatement(
                "INSERT INTO customers (CustID, Last_Name, " +
                "First_Name, Email, Phone_Number) +
                " VALUES(?, ?, ?, ?, ?)");

            // Add rows to a batch in a loop. Each iteration adds a
            // new row.
            for (int i = 0; i < firstNames.length; i++) {
                // Add each parameter to the row.
                pstmt.setInt(1, i + 1);
                pstmt.setString(2, lastNames[i]);
                pstmt.setString(3, firstNames[i]);
                pstmt.setString(4, emails[i]);
                pstmt.setString(5, phoneNumbers[i]);
                // Add row to the batch.
                pstmt.addBatch();
            }
        } catch (SQLException e) {
            e.printStackTrace();
        }
    }
}
```

```

        pstmt.addBatch(),
    }

    // Integer array to hold the results of inserting
    // the batch. Will contain an entry for each row,
    // indicating success or failure.
    int[] batchResults = null;

    try {
        // Batch is ready, execute it to insert the data
        batchResults = pstmt.executeBatch();
    } catch (BatchUpdateException e) {
        // We expect an exception here, since one of the
        // inserted phone numbers is too wide for its column. All of the
        // rest of the rows will be inserted.
        System.out.println("Error message: " + e.getMessage());

        // Batch results isn't set due to exception, but you
        // can get it from the exception object.
        //
        // In your own code, you shouldn't assume the a batch
        // exception occurred, since exceptions can be thrown
        // by the server for a variety of reasons.
        batchResults = e.getUpdateCounts();
    }
    // You should also be prepared to catch SQLExceptions in your own
    // application code, to handle dropped connections and other general
    // problems.

    // Commit the transaction
    conn.commit();

    // Print the array holding the results of the batch insertions.
    System.out.println("Return value from inserting batch: "
        + Arrays.toString(batchResults));
    // Print the resulting table.
    ResultSet rs = null;
    rs = stmt.executeQuery("SELECT CustID, First_Name, "
        + "Last_Name FROM customers ORDER BY CustID");
    while (rs.next()) {
        System.out.println(rs.getInt(1) + " - "
            + rs.getString(2).trim() + " "
            + rs.getString(3).trim());
    }

    // Cleanup
    conn.close();
} catch (SQLException e) {
    e.printStackTrace();
}
}
}

```

Running the above example produces the following output on the console:

```

Error message: [Vertica][VJDBC](100172) One or more rows were rejected by the server.
Return value from inserting batch: [1, 1, -3, 1, 1]
1 - Anna Allen
2 - Bill Brown
4 - Don Dodd
5 - Eric Estavez

```

Notice that the third row failed to insert because its phone number is too long for the `Phone_Number` column. All of the rest of the rows in the batch (including those after the error) were correctly inserted.

Note

It is more efficient for you to ensure that the data you are inserting is the correct data type and width for the table column you are inserting it into than to handle exceptions after the fact.

Rolling back batch loads on the server

Batch loads always insert all of their data, even if one or more rows is rejected. Only the rows that caused errors in a batch are not loaded. When the database connection's `AutoCommit` property is true, batches automatically commit their transactions when they complete, so once the batch finishes loading, the data is committed.

In some cases, you may want all of the data in a batch to be successfully inserted—none of the data should be committed if an error occurs. The best way to accomplish this is to turn off the database connection's `AutoCommit` property to prevent batches from automatically committing themselves. Then, if a batch encounters an error, you can roll back the transaction after catching the `BatchUpdateException` caused by the insertion error.

The following example demonstrates performing a rollback if any error occurs when loading a batch.

```
import java.sql.*;
import java.util.Arrays;
import java.util.Properties;

public class RollbackBatchOnError {
    public static void main(String[] args) {
        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser");
        myProp.put("password", "password123");
        Connection conn;
        try {
            conn = DriverManager.getConnection(
                "jdbc:vertica://VerticaHost:5433/ExampleDB",
                myProp);

            // Disable auto-commit. This will allow you to roll back a
            // a batch load if there is an error.
            conn.setAutoCommit(false);

            // establish connection and make a table for the data.
            Statement stmt = conn.createStatement();
            // Drop table and recreate.
            stmt.execute("DROP TABLE IF EXISTS customers CASCADE");
            stmt.execute("CREATE TABLE customers (CustID int, Last_Name"
                + " char(50), First_Name char(50),Email char(50),"
                + "Phone_Number char(12))");

            // Some dummy data to insert. The one row won't insert because
            // the phone number is too long for the phone column.
            String[] firstNames = new String[] { "Anna", "Bill", "Cindy",
                "Don", "Eric" };
            String[] lastNames = new String[] { "Allen", "Brown", "Chu",
                "Dodd", "Estavez" };
            String[] emails = new String[] { "aang@example.com",
                "b.brown@example.com", "cindy@example.com",
                "d.d@example.com", "e.estavez@example.com" };
            String[] phoneNumbers = new String[] { "123-456-789",
                "555-444-3333", "555-867-53094535", "555-555-1212",
                "781-555-0000" };

            // Create the prepared statement
            PreparedStatement pstmt = conn.prepareStatement(
                "INSERT INTO customers (CustID, Last_Name, " +
                "First_Name, Email, Phone_Number) "+
```

Running the above example prints the following on the system console:

```
Error message: [Vertica][VJDBC](100172) One or more rows were rejected by the server.Rolling back batch insertion
Return value from inserting batch: [1, 1, -3, 1, 1]
Customers table contains:
```

The return values indicate whether each row was successfully inserted. The value 1 means the row inserted without any issues, and a -3 indicates the row failed to insert.

The customers table is empty since the batch insert was rolled back due to the error caused by the third column.

Bulk loading using the COPY statement

One of the fastest ways to load large amounts of data into Vertica at once (bulk loading) is to use the [COPY statement](#). This statement loads data from a file stored on a Vertica host (or in a data stream) into a table in the database. You can pass the COPY statement parameters that define the format of the data in the file, how the data is to be transformed as it is loaded, how to handle errors, and how the data should be loaded. See the [COPY](#) documentation for details.

Important

In databases that were created in versions of Vertica ≤ 9.2 , COPY supports the DIRECT option, which specifies to load data directly into [ROS](#) rather than WOS. Use this option when loading large (>100MB) files into the database; otherwise, the load is liable to fill the WOS. When this occurs, the [Tuple Mover](#) must perform a moveout operation on the WOS data. It is more efficient to directly load into ROS and avoid forcing a moveout.

In databases created in Vertica 9.3, Vertica ignores load options and hints and always uses a load method of DIRECT. Databases created in versions ≥ 10.0 no longer support WOS and moveout operations; all data is always loaded directly into ROS.

Only a [superuser](#) can use COPY to copy a file stored on a host, so you must connect to the database with a superuser account. If you want to have a non-superuser user bulk-load data, you can use COPY to load from a stream on the host (such as STDIN) rather than a file or stream data from the client (see [Streaming data via JDBC](#)). You can also perform a standard [batch insert using a prepared statement](#), which uses the COPY statement in the background to load the data.

Note

When using COPY parameter [ON ANY NODE](#), confirm that the source file is identical on all nodes. Using different files can produce inconsistent results.

The following example demonstrates using the COPY statement through the JDBC to load a file named `customers.txt` into a new database table. This file must be stored on the database host to which your application connects—in this example, a host named VerticaHost.

```

import java.sql.*;
import java.util.Properties;
import com.vertica.jdbc.*;

public class COPYFromFile {
    public static void main(String[] args) {
        Properties myProp = new Properties();
        myProp.put("user", "ExampleAdmin"); // Must be superuser
        myProp.put("password", "password123");
        Connection conn;
        try {
            conn = DriverManager.getConnection(
                "jdbc:vertica://VerticaHost:5433/ExampleDB",myProp);
            // Disable AutoCommit
            conn.setAutoCommit(false);
            Statement stmt = conn.createStatement();
            // Create a table to hold data.
            stmt.execute("DROP TABLE IF EXISTS customers;");
            stmt.execute("CREATE TABLE IF NOT EXISTS customers (Last_Name char(50) "
                + "NOT NULL, First_Name char(50),Email char(50), "
                + "Phone_Number char(15))");

            // Use the COPY command to load data. Use ENFORCELENGTH to reject
            // strings too wide for their columns.
            boolean result = stmt.execute("COPY customers FROM "
                + "'/data/customers.txt' ENFORCELENGTH");

            // Determine if execution returned a count value, or a full result
            // set.
            if (result) {
                System.out.println("Got result set");
            } else {
                // Count will usually return the count of rows inserted.
                System.out.println("Got count");
                int rowCount = stmt.getUpdateCount();
                System.out.println("Number of accepted rows = " + rowCount);
            }

            // Commit the data load
            conn.commit();
        } catch (SQLException e) {
            System.out.print("Error: ");
            System.out.println(e.toString());
        }
    }
}

```

The example prints the following out to the system console when run (assuming that the `customers.txt` file contained two million valid rows):

```
Number of accepted rows = 2000000
```

Streaming data via JDBC

There are two options to stream data from a file on the client to your Vertica database:

- Use the `VerticaCopyStream` class to stream data in an object-oriented manner - details on the class are available in the [JDBC documentation](#).
- Execute a `COPY LOCAL` SQL statement to stream the data

The topics in this section explain how to use these options.

In this section

- [Using VerticaCopyStream](#)
- [Using COPY LOCAL with JDBC](#)

Using VerticaCopyStream

The [VerticaCopyStream](#) class lets you stream data from the client system to a Vertica database. It lets you use [COPY](#) directly without first copying the data to a host in the database cluster. Using COPY to load data from the host requires superuser privileges to access the host's file system. The COPY statement used to load data from a stream does not require superuser privileges, so your client can connect with any user account that has INSERT privileges on the target table.

To copy streams into the database:

1. Disable the database connections AutoCommit connection parameter.
2. Instantiate a [VerticaCopyStreamObject](#) , passing it at least the database connection objects and a string containing a COPY statement to load the data. This statement must copy data from the STDIN into your table. You can use any parameters that are appropriate for your data load.

Note

The [VerticaCopyStreamObject](#) constructor optionally takes a single [InputStream](#) object, or a [List](#) of [InputStream](#) objects. This option lets you pre-populate the list of streams to be copied into the database.

3. Call [VerticaCopyStreamObject.start\(\)](#) to start the COPY statement and begin streaming the data in any streams you have already added to the [VerticaCopyStreamObject](#) .
4. Call [VerticaCopyStreamObject.addStream\(\)](#) to add additional streams to the list of streams to send to the database. You can then call [VerticaCopyStreamObject.execute\(\)](#) to stream them to the server.
5. Optionally, call [VerticaCopyStreamObject.getRejects\(\)](#) to get a list of rejected rows from the last [.execute\(\)](#) call. The list of rejects is reset by each call to [.execute\(\)](#) or [.finish\(\)](#) .

Note

If you used either the REJECTED DATA or EXCEPTIONS options in the COPY statement you passed to [VerticaCopyStreamObject](#) the object in step 2, [.getRejects\(\)](#) returns an empty list. You can only use one method of tracking the rejected rows at a time.

6. When you are finished adding streams, call [VerticaCopyStreamObject.finish\(\)](#) to send any remaining streams to the database and close the COPY statement.
7. Call [Connection.commit\(\)](#) to commit the loaded data.

Getting rejected rows

The [VerticaCopyStreamObject.getRejects\(\)](#) method returns a List containing the row numbers of rows that were rejected after the previous [.execute\(\)](#) method call. Each call to [.execute\(\)](#) clears the list of rejected rows, so you need to call [.getRejects\(\)](#) after each call to [.execute\(\)](#) . Since [.start\(\)](#) and [.finish\(\)](#) also call [.execute\(\)](#) to send any pending streams to the server, you should also call [.getRejects\(\)](#) after these methods as well.

The following example demonstrates loading the content of five text files stored on the client system into a table.

```
import java.io.File;
import java.io.FileInputStream;
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.Statement;
import java.util.Iterator;
import java.util.List;
import java.util.Properties;
import com.vertica.jdbc.VerticaConnection;
import com.vertica.jdbc.VerticaCopyStream;

public class CopyMultipleStreamsExample {
    public static void main(String[] args) {
        // Note: If running on Java 5, you need to call Class.forName
        // to manually load the JDBC driver.
        // Set up the properties of the connection
```

```

// high. Also, high numbers of InputStreams could create a
// resource issue on your client system.
stream.execute();

// Show any rejects from this execution of the stream load
// getRejects() returns a List containing the
// row numbers of rejected rows.
List<Long> rejects = stream.getRejects();

// The size of the list gives you the number of rejected rows.
int numRejects = rejects.size();
totalRejects += numRejects;
System.out.println("Number of rows rejected in load #"
    + loadNum + ": " + numRejects);

// List all of the rows that were rejected.
Iterator<Long> rejIt = rejects.iterator();
long linecount = 0;
while (rejIt.hasNext()) {
    System.out.print("Rejected row #" + ++linecount);
    System.out.println(" is row " + rejIt.next());
}
}
// Finish closes the COPY command. It returns the number of
// rows inserted.
long results = stream.finish();
System.out.println("Finish returned " + results);

// If you added any streams that hadn't been executed(),
// you should also check for rejects here, since finish()
// calls execute() to

// You can also get the number of rows inserted using
// getRowCount().
System.out.println("Number of rows accepted: "
    + stream.getRowCount());
System.out.println("Total number of rows rejected: " + totalRejects);

// Commit the loaded data
conn.commit();

} catch (Exception e) {
    e.printStackTrace();
}
}
}

```

Running the above example on some sample data results in the following output:

```
Loading file: C:\Data\customers-1.txtNumber of rows rejected in load #1: 3
Rejected row #1 is row 3
Rejected row #2 is row 7
Rejected row #3 is row 51
Loading file: C:\Data\customers-2.txt
Number of rows rejected in load #2: 5Rejected row #1 is row 4143
Rejected row #2 is row 6132
Rejected row #3 is row 9998
Rejected row #4 is row 10000
Rejected row #5 is row 10050
Loading file: C:\Data\customers-3.txt
Number of rows rejected in load #3: 9
Rejected row #1 is row 14142
Rejected row #2 is row 16131
Rejected row #3 is row 19999
Rejected row #4 is row 20001
Rejected row #5 is row 20005
Rejected row #6 is row 20049
Rejected row #7 is row 20056
Rejected row #8 is row 20144
Rejected row #9 is row 20236
Loading file: C:\Data\customers-4.txt
Number of rows rejected in load #4: 8
Rejected row #1 is row 23774
Rejected row #2 is row 24141
Rejected row #3 is row 25906
Rejected row #4 is row 26130
Rejected row #5 is row 27317
Rejected row #6 is row 28121
Rejected row #7 is row 29321
Rejected row #8 is row 29998
Loading file: C:\Data\customers-5.txt
Number of rows rejected in load #5: 1
Rejected row #1 is row 39997
Finish returned 39995
Number of rows accepted: 39995
Total number of rows rejected: 26
```

Note

The above example shows a simple load process that targets one node in the Vertica cluster. It is more efficient to simultaneously load multiple streams to multiple database nodes. Doing so greatly improves performance because it spreads the processing for the load across the cluster.

Using COPY LOCAL with JDBC

To use COPY LOCAL with JDBC, just execute a [COPY LOCAL](#) statement with the path to the source file on the client system. This method is simpler than using the [VerticaCopyStream](#) class (details on the class are available in the [JDBC documentation](#)). However, you may prefer using [VerticaCopyStream](#) if you have many files to copy to the database or if your data comes from a source other than a file (streamed over a network connection, for example).

You can use COPY LOCAL in a multiple-statement query. However, you should always make it the first statement in the query. You should not use it multiple times in the same query.

The following example code demonstrates using COPY LOCAL to copy a file from the client to the database. It is the same as the code shown in [Bulk loading using the COPY statement](#), except for the use of the LOCAL option in the COPY statement, and the path to the data file is on the client system, rather than on the server.

Note

The exceptions/rejections files are created on the client machine when the exceptions and rejected data modifiers are specified on the copy local command. Specify a local path and filename for these modifiers when executing a COPY LOCAL query from the driver.

```

import java.sql.*;
import java.util.Properties;

public class COPYLocal {
    public static void main(String[] args) {
        // Note: If using Java 5, you must call Class.forName to load the
        // JDBC driver.
        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser"); // Do not need to superuser
        myProp.put("password", "password123");
        Connection conn;
        try {
            conn = DriverManager.getConnection(
                "jdbc:vertica://VerticaHost:5433/ExampleDB",myProp);
            // Disable AutoCommit
            conn.setAutoCommit(false);
            Statement stmt = conn.createStatement();
            // Create a table to hold data.
            stmt.execute("DROP TABLE IF EXISTS customers;");
            stmt.execute("CREATE TABLE IF NOT EXISTS customers (Last_Name char(50) "
                + "NOT NULL, First_Name char(50),Email char(50), "
                + "Phone_Number char(15))");

            // Use the COPY command to load data. Load directly into ROS, since
            // this load could be over 100MB. Use ENFORCELENGTH to reject
            // strings too wide for their columns.
            boolean result = stmt.execute("COPY customers FROM LOCAL "
                + "'C:\\Data\\customers.txt' DIRECT ENFORCELENGTH");

            // Determine if execution returned a count value, or a full result
            // set.
            if (result) {
                System.out.println("Got result set");
            } else {
                // Count will usually return the count of rows inserted.
                System.out.println("Got count");
                int rowCount = stmt.getUpdateCount();
                System.out.println("Number of accepted rows = " + rowCount);
            }

            conn.close();
        } catch (SQLException e) {
            System.out.print("Error: ");
            System.out.println(e.toString());
        }
    }
}

```

The result of running this code appears below. In this case, the customers.txt file contains 10000 rows, seven of which get rejected because they contain data too wide to fit into their database columns.

```
Got countNumber of accepted rows = 9993
```

Handling errors

When the Vertica JDBC driver encounters an error, it throws a [SQLException](#) or one of its subclasses. The specific subclass it throws depends on the type of error that has occurred. Most of the JDBC method calls can result in several different types of errors, in response to which the JDBC driver throws a specific [SQLException](#) subclass. Your client application can choose how to react to the error based on the specific exception that the JDBC driver threw.

Note

The specific `SQLException` subclasses were introduced in the JDBC 4.0 standard.

The hierarchy of `SQLException` subclasses is arranged to help your client application determine what actions it can take in response to an error condition. For example:

- The JDBC driver throws `SQLTransientException` subclasses when the cause of the error may be a temporary condition, such as a timeout error (`SQLTimeoutException`) or a connection issue (`SQLTransientConnectionIssue`). Your client application can choose to retry the operation without making any sort of attempt to remedy the error, since it may not reoccur.
- The JDBC driver throws `SQLNonTransientException` subclasses when the client needs to take some action before it could retry the operation. For example, executing a statement with a SQL syntax error results in the JDBC driver throwing the a `SQLSyntaxErrorException` (a subclass of `SQLNonTransientException`). Often, your client application just has to report these errors back to the user and have him or her resolve them. For example, if the user supplied your application with a SQL statement that triggered a `SQLSyntaxErrorException` , it could prompt the user to fix the SQL error.

See [SQLState mapping to Java exception classes](#) for a list Java exceptions thrown by the JDBC driver.

SQLState mapping to java exception classes

SQLSTATE Class or Value	Description	Java Exception Class
Class 00	Successful Completion	<code>SQLException</code>
Class 01	Warning	<code>SQLException</code>
Class 02	No Data	<code>SQLException</code>
Class 03	SQL Statement Not Yet Complete	<code>SQLException</code>
Class 08	Client Connection Exception	<code>SQLNonTransientConnectionException</code>
Class 09	Triggered Action Exception	<code>SQLException</code>
Class 0A	Feature Not Supported	<code>SQLFeatureNotSupportedException</code>
Class 0B	Invalid Transaction Initiation	<code>SQLException</code>
Class 0F	Locator Exception	<code>SQLException</code>
Class 0L	Invalid Grantor	<code>SQLException</code>
Class 0P	Invalid Role Specification	<code>SQLException</code>
Class 20	Case Not Found	<code>SQLException</code>
Class 21	Cardinality Violation	<code>SQLException</code>
Class 22	Data Exception	<code>SQLDataException</code>
22V21	INVALID_EPOCH	<code>SQLNonTransientException</code>
Class 23	Integrity Constraint Violation	<code>SQLIntegrityConstraintViolationException</code>

Class 24	Invalid Cursor State	SQLException
Class 25	Invalid Transaction State	SQLTransactionRollbackException
Class 26	Invalid SQL Statement Name	SQLException
Class 27	Triggered Data Change Violation	SQLException
Class 28	Invalid Authorization Specification	SQLInvalidAuthorizationException
Class 2B	Dependent Privilege Descriptors Still Exist	SQLDataException
Class 2D	Invalid Transaction Termination	SQLException
Class 2F	SQL Routine Exception	SQLException
Class 34	Invalid Cursor Name	SQLException
Class 38	External Routine Exception	SQLException
Class 39	External Routine Invocation Exception	SQLException
Class 3B	Savepoint Exception	SQLException
Class 3D	Invalid Catalog Name	SQLException
Class 3F	Invalid Schema Name	SQLException
Class 40	Transaction Rollback	SQLTransactionRollbackException
Class 42	Syntax Error or Access Rule Violation	SQLClientSyntaxErrorException
Class 44	WITH CHECK OPTION Violation	SQLException
Class 53	Insufficient Resources	SQLTransientException
53300	TOO_MANY_CONNECTIONS	SQLTransientConnectionException
Class 54	Program Limit Exceeded	SQLNonTransientException
Class 55	Object Not In Prerequisite State	SQLNonTransientException
55V03	LOCK_NOT_AVAILABLE	SQLTransactionRollbackException
Class 57	Operator Intervention	SQLTransientException
57V01	ADMIN_SHUTDOWN	SQLNonTransientConnectionException
57V02	CRASH_SHUTDOWN	SQLNonTransientConnectionException
57V03	CANNOT_CONNECT_NOW	SQLNonTransientConnectionException
Class 58	System Error	SQLException
Class V0	PL/vSQL errors	SQLException
Class V1	Vertica-specific multi-node errors class	SQLException

Class V2	Vertica-specific miscellaneous errors class	SQLException
V2000	AUTH_FAILED	SQLInvalidAuthorizationException
Class VC	Configuration File Error	SQLNonTransientException
Class VD	DB Designer errors	SQLNonTransientException
Class VP	User procedure errors	SQLNonTransientException
Class VX	Internal Error	SQLException

Routing JDBC queries directly to a single node

The JDBC driver has the ability to route queries directly to a single node using a special connection called a Routable Connection. This feature is ideal for high-volume "short" requests that return a small number of results that all exist on a single node. The common scenario for using this feature is to do high-volume lookups on data that is identified with a unique key. Routable queries typically provide lower latency and use less system resources than distributed queries. However, the data being queried must be segmented in such a way that the JDBC client can determine on which node the data resides.

Vertica Typical Analytic Query

Typical analytic queries require dense computation on data across all nodes in the cluster and benefit from having all nodes involved in the planning and execution of the queries.

Vertica Routable Query API Query

For high-volume queries that return a single or a few rows of data, it is more efficient to execute the query on the single node that contains the data.

To effectively route a request to a single node, the client must determine the specific node on which the data resides. For the client to be able to determine the correct node, the table must be [segmented](#) by one or more columns. For example, if you segment a table on a Primary Key (PK) column, then the client can determine on which node the data resides based on the Primary Key and directly connect to that node to quickly fulfill the request.

The Routable Query API provides two classes for performing routable queries: `VerticaRoutableExecutor` and `VGet`. `VerticaRoutableExecutor` provides a more expressive SQL-based API while `VGet` provides a more structured API for programmatic access.

- The **VerticaRoutableExecutor** class allows you to use traditional SQL with a reduced feature set to query data on a single node. For joins, the table must be joined on a key column that exists in each table you are joining, and the tables must be segmented on that key. However, this is not true for unsegmented tables, which can always be joined (since all the data in an unsegmented table is available on all nodes).

- The **VGet** class does not use traditional SQL syntax. Instead, it uses a data structure that you build by defining predicates and predicate expressions and outputs and output expressions. This class is ideal for doing Key/Value type lookups on single tables. The data structure used for querying the table must provide a predicate for each segmented column defined in the projection for the table. You must provide, at a minimum, a predicate with a constant value for each segmented column. For example, an **id** with a value of 12234 if the table is segmented only on the **id** column. You can also specify additional predicates for the other, non-segmented, columns in the table. Predicates act like a SQL *WHERE* clause and multiple predicates/predicate expressions apply together with a SQL AND modifier. Predicates must be defined with a constant value. Predicate expressions can be used to refine the query and can contain any arbitrary SQL expressions (such as less than, greater than, and so on) for any of the non-segmented columns in the table.

Java documentation for all classes and methods in the JDBC Driver is available in the Vertica [JDBC documentation](#).

Note

The JDBC Routable Query API is read-only and requires JDK 1.6 or greater.

In this section

- [Creating tables and projections for use with the routable query API](#)
- [Creating a connection for routable queries](#)
- [Defining the query for routable queries using the VerticaRoutableExecutor class](#)
- [Defining the query for routable queries using the VGet class](#)
- [Routable query performance and troubleshooting](#)
- [Pre-segmenting data using VHash](#)

Creating tables and projections for use with the routable query API

For routable queries, the client must determine the appropriate node to get the data. The client does this by comparing all projections available for the table, and determining the best projection to use to find the single node that contains data. You must create a projection segmented by the key column(s) on at least one table to take full advantage of the routable query API. Other tables that join to this table must either have an unsegmented projection, or a projection segmented as described below.

Note

Tables must be segmented by hash for routable queries. See [Hash segmentation clause](#). Other segmentation types are not supported.

Creating tables for use with routable queries

To create a table that can be used with the routable query API, segment (by hash) the table on a uniformly distributed column. Typically, you segment on a primary key. For faster lookups, sort the projection on the same columns on which you segmented. For example, to create a table that is well suited to routable queries:

```
CREATE TABLE users (  
id INT NOT NULL PRIMARY KEY,  
username VARCHAR(32),  
email VARCHAR(64),  
business_unit VARCHAR(16))  
ORDER BY id  
SEGMENTED BY HASH(id)  
ALL NODES;
```

This table is segmented based on the **id** column (and ordered by **id** to make lookups faster). To build a query for this table using the routable query API, you only need to provide a single predicate for the **id** column which returns a single row when queried.

However, you might add multiple columns to the segmentation clause. For example:

```
CREATE TABLE users2 (
  id INT NOT NULL PRIMARY KEY,
  username VARCHAR(32),
  email VARCHAR(64),
  business_unit VARCHAR(16))
ORDER BY id, business_unit
SEGMENTED BY HASH(id, business_unit)
ALL NODES;
```

In this case, you need to provide two predicates when querying the `users2` table, as it is segmented on two columns, `id` and `business_unit`. However, if you know both `id` and `business_unit` when you perform the queries, then it is beneficial to segment on both columns, as it makes it easier for the client to determine that this projection is the best projection to use to determine the correct node.

Designing tables for single-node JOINS

If you plan to use the `VerticaRoutableExecutor` class and join tables during routable queries, then you must segment all tables being joined by the same segmentation key. Typically this key is a primary/foreign key on all the tables being joined. For example, the `customer_key` may be the primary key in a customers dimension table, and the same key is a foreign key in a sales fact table. Projections for a `VerticaRoutableExecutor` query using these tables must be segmented by hash on the customer key in each table.

If you want to join with small dimension tables, such as date dimensions, then it may be appropriate to make those tables unsegmented so that the `date_dimension` data exists on all nodes. It is important to note that when joining unsegmented tables, you still must specify a segmented table in the `createRoutableExecutor()` call.

Verifying existing projections for tables

If tables are already segmented by hash (for example, on an ID column), then you can determine what predicates are needed to query the table by using the Vertica function [GET_PROJECTIONS](#) to view that table's projections. For example:

```
=> SELECT GET_PROJECTIONS ('users');
...
Projection Name: [Segmented] [Seg Cols] [# of Buddies] [Buddy Projections] [Safe] [UptoDate] [Stats]
-----
public.users_b1 [Segmented: Yes] [Seg Cols: "public.users.id"] [K: 1] [public.users_b0] [Safe: Yes] [UptoDate: Yes] [Stats: RowCounts]
public.users_b0 [Segmented: Yes] [Seg Cols: "public.users.id"] [K: 1] [public.users_b1] [Safe: Yes] [UptoDate: Yes] [Stats: RowCounts]
```

For each projection, only the `public.users.id` column is specified, indicating your query predicate should include this column.

If the table is segmented on multiple columns, for example `id` and `business_unit`, then you need to provide both columns as predicates to the routable query.

Creating a connection for routable queries

The JDBC Routable Query API provides the `VerticaRoutableConnection` (details are available in the [JDBC documentation](#) interface to connect to a cluster and allow for Routable Queries. This interface provides advanced routing capabilities beyond those of a normal `VerticaConnection`. The `VerticaRoutableConnection` provides access to the `VerticaRoutableExecutor` and `VGet` classes. See [Defining the query for routable queries using the VerticaRoutableExecutor class](#) and [Defining the query for routable queries using the VGet class](#) respectively.

You enable access to this class by setting the `EnableRoutableQueries` JDBC connection property to true.

The `VerticaRoutableConnection` maintains an internal pool of connections and a cache of table metadata that is shared by all `VerticaRoutableExecutor/VGet` objects that are produced by the connection's `createRoutableExecutor()/prepareGet()` method. It is also a fully-fledged JDBC connection on its own and supports all the functionality that a `VerticaConnection` supports. When this connection is closed, all pooled connections managed by this `VerticaRoutableConnection` and all child objects are closed too. The connection pool and metadata is only used by child Routable Query operations.

Example:

You can create the connection using a JDBC `DataSource`:

```
com.vertica.jdbc.DataSource jdbcSettings = new com.vertica.jdbc.DataSource();
jdbcSettings.setDatabase("exampleDB");
jdbcSettings.setHost("v_vmart_node0001.example.com");
jdbcSettings.setUserID("dbadmin");
jdbcSettings.setPassword("password");
jdbcSettings.setEnableRoutableQueries(true);
jdbcSettings.setPort((short) 5433);

VerticaRoutableConnection conn;
conn = (VerticaRoutableConnection)jdbcSettings.getConnection();
```

You can also create the connection using a connection string and the `DriverManager.getConnection()` method:

```
String connectionString = "jdbc:vertica://v_vmart_node0001.example.com:5433/exampleDB?user=dbadmin&password=&EnableRoutableQueries=true";
VerticaRoutableConnection conn = (VerticaRoutableConnection) DriverManager.getConnection(connectionString);
```

Both methods result in a `conn` connection object that is identical.

Note

Avoid opening many `VerticaRoutableConnection` connections because this connection maintains its own private pool of connections which are not shared with other connections. Instead, your application should use a single connection and issue multiple queries through that connection.

In addition to the `setEnableRoutableQueries` property that the Routable Query API adds to the Vertica JDBC connection class, the API also adds additional properties. The complete list is below.

- `EnableRoutableQueries` : Enables Routable Query lookup capability. Default is false.
- `FailOnMultiNodePlans` : If the plan requires more than one node, and `FailOnMultiNodePlans` is true, then the query fails. If it is set to false then a warning is generated and the query continues. However, latency is greatly increased as the Routable Query must first determine the data is on multiple nodes, then a normal query is run using traditional (all node) execution and execution. Defaults to true. Note that this failure cannot occur on simple calls using only predicates and constant values.
- `MetadataCacheLifetime` : The time in seconds to keep projection metadata. The API caches metadata about the projection used for the query (such as projections). The cache is used on subsequent queries to reduce response time. The default is 300 seconds.
- `MaxPooledConnections` : Cluster-wide maximum number of connections to keep in the `VerticaRoutableConnection`'s internal pool. Default 20.
- `MaxPooledConnectionsPerNode` : Per-node maximum number of connections to keep in the `VerticaRoutableConnection`'s internal pool. Default 5.

Defining the query for routable queries using the `VerticaRoutableExecutor` class

Use the `VerticaRoutableExecutor` class to access table data directly from a single node. `VerticaRoutableExecutor` directly queries Vertica only on the node that has all the data needed for the query, avoiding the distributed planning and execution costs associated with Vertica query execution. You can use `VerticaRoutableExecutor` to join tables or use a GROUP BY clause, as these operations are not possible using `VGet`.

When using the `VerticaRoutableExecutor` class, the following rules apply:

- If joining tables, all tables being joined must be segmented (by hash) on the same set of columns referenced in the join predicate, unless the table to join is unsegmented.
- Multiple conditions in a join WHERE clause must be AND'd together. Using OR in the WHERE clause causes the query to degenerate to a multi-node plan. You can specify OR, IN list, or range conditions on columns *outside* the join condition if the data exists on the same node.
- You can only execute a single statement per request. Chained SQL statements are not permitted.
- Your query can be used in a driver-generated subquery to help determine whether the query can execute on a single node. Therefore, you cannot include the semi-colon at the end of the statement and you cannot include SQL comments using double-dashes (`--`), as these cause the driver-generated query to fail.

You create a `VerticaRoutableExecutor` by calling the `createRoutableExecutor` method on a connection object:

```
createRoutableExecutor( schema-name, table-name )
```

For example:

```

VerticaRoutableConnection conn;
    Map<String, Object> map = new HashMap<String, Object>();
    map.put("customer_key", 1);
try {
    conn = (VerticaRoutableConnection)
        jdbcSettings.getConnection();
    String table = "customers";
    VerticaRoutableExecutor q = conn.createRoutableExecutor(null, table);
    ...
}

```

If *schema-name* is set to null, then the search path is used to find the table.

VerticaRoutableExecutor methods

VerticaRoutableExecutor has the following methods:

- [execute](#)
- [close](#)
- [getWarnings](#)

For details on this class, see the [JDBC documentation](#).

Execute

```
execute( query-string, { column, value | map } )
```

Runs the query.

<i>query-string</i>	The query to execute
<i>column, value</i>	The column and value when the lookup is done on a single value. For example: <pre>String column = "customer_key"; Integer value = 1; ResultSet rs = q.execute(query, column, value)</pre>
<i>map</i>	A Java map of the column names and corresponding values if the lookup is done on one or more columns. For example: <code>ResultSet rs = q.execute(query, map);</code> . The table must have at least one projection segmented by a set of columns that exactly match the columns in the map. Each column defined in the map can have only one value. For example: <pre>Map<String, Object> map = new HashMap<String, Object>(); map.put("customer_key", 1); map.put("another_key", 42); ResultSet rs = q.execute(query, map);</pre>

The following requirements apply:

- The query to execute must use regular SQL that complies with the rules of the **VerticaRoutableExecutor** class. For example, you can add limits and sorts, or use aggregate functions, provided the data exists on a single node.
- The JDBC client uses the *column / value* or *map* arguments to determine on which node to execute the query. The content of the query must use the same values that you provide in the column/value or map arguments.
- The following data types cannot be used as column values: * [INTERVAL](#) * [TIMETZ](#) * [TIMESTAMPZ](#)
Also, if a table is segmented on any columns with the following data types then the table cannot be queried with the routable query API:

The driver does not verify the syntax of the query before it sends the query to the server. If your expression is incorrect, then the query fails.

Close

```
close()
```

Closes this **VerticaRoutableExecutor** by releasing resources used by this **VerticaRoutableExecutor** . It does not close the parent JDBC connection to Vertica.

getWarnings

```
getWarnings()
```

Retrieves the first warning reported by calls on this [VerticaRoutableExecutor](#) . Additional warnings are chained and can be accessed with the JDBC method [getNextWarning\(\)](#) .

Example

The following example shows how to use [VerticaRoutableExecutor](#) to execute a query using both a JOIN clause and an aggregate function with a GROUP BY clause. The example also shows how to create a customer and sales table, and segment the tables so they can be joined using the [VerticaRoutableExecutor](#) class. This example uses the [date_dimension](#) table in the VMart schema to show how to join data on unsegmented tables.

1. Create the [customers](#) table to store customer details, and then create projections that are segmented on the table's [customer_key](#) column:

```
=> CREATE TABLE customers (customer_key INT, customer_name VARCHAR(128), customer_email VARCHAR(128));
=> CREATE PROJECTION cust_proj_b0 AS SELECT * FROM customers SEGMENTED BY HASH (customer_key) ALL NODES;
=> CREATE PROJECTION cust_proj_b1 AS SELECT * FROM customers SEGMENTED BY HASH (customer_key) ALL NODES OFFSET 1;
=> CREATE PROJECTION cust_proj_b2 AS SELECT * FROM customers SEGMENTED BY HASH (customer_key) ALL NODES OFFSET 2;
=> SELECT start_refresh();
```

2. Create the [sales](#) table, then create projections that are segmented on its [customer_key](#) column. Because the [customer](#) and [sales](#) tables are segmented on the same key, you can join them later with the [VerticaRoutableExecutor](#) routable query lookup.

```
=> CREATE TABLE sales (sale_key INT, customer_key INT, date_key INT, sales_amount FLOAT);
=> CREATE PROJECTION sales_proj_b0 AS SELECT * FROM sales SEGMENTED BY HASH (customer_key) ALL NODES;
=> CREATE PROJECTION sales_proj_b1 AS SELECT * FROM sales SEGMENTED BY HASH (customer_key) ALL NODES OFFSET 1;
=> CREATE PROJECTION sales_proj_b2 AS SELECT * FROM sales SEGMENTED BY HASH (customer_key) ALL NODES OFFSET 2;
=> SELECT start_refresh();
```

3. Add some sample data:

```
=> INSERT INTO customers VALUES (1, 'Fred', 'fred@example.com');
=> INSERT INTO customers VALUES (2, 'Sue', 'Sue@example.com');
=> INSERT INTO customers VALUES (3, 'Dave', 'Dave@example.com');
=> INSERT INTO customers VALUES (4, 'Ann', 'Ann@example.com');
=> INSERT INTO customers VALUES (5, 'Jamie', 'Jamie@example.com');
=> COMMIT;

=> INSERT INTO sales VALUES(1, 1, 1, '100.00');
=> INSERT INTO sales VALUES(2, 2, 2, '200.00');
=> INSERT INTO sales VALUES(3, 3, 3, '300.00');
=> INSERT INTO sales VALUES(4, 4, 4, '400.00');
=> INSERT INTO sales VALUES(5, 5, 5, '400.00');
=> INSERT INTO sales VALUES(6, 1, 15, '500.00');
=> INSERT INTO sales VALUES(7, 1, 15, '400.00');
=> INSERT INTO sales VALUES(8, 1, 35, '300.00');
=> INSERT INTO sales VALUES(9, 1, 35, '200.00');
=> COMMIT;
```

4. Create an unsegmented projection of the VMart [date_dimension](#) table for use in this example. Call the meta-function [START_REFRESH](#) to unsegment the existing data:

```
=> CREATE PROJECTION date_dim AS SELECT * FROM date_dimension UNSEGMENTED ALL NODES;
=> SELECT start_refresh();
```

Using the [customer](#) , [sales](#) , and [date_dimension](#) data, you can now create a routable query lookup that uses joins and a group by to query the customers table and return the total number of purchases per day for a given customer:

```

import java.sql.*;
import java.util.HashMap;
import java.util.Map;
import com.vertica.jdbc.kv.*;

public class verticaKV_doc {
    public static void main(String[] args) {
        com.vertica.jdbc.DataSource jdbcSettings
            = new com.vertica.jdbc.DataSource();
        jdbcSettings.setDatabase("VMart");
        jdbcSettings.setHost("vertica.example.com");
        jdbcSettings.setUserID("dbadmin");
        jdbcSettings.setPassword("password");
        jdbcSettings.setEnableRoutableQueries(true);
        jdbcSettings.setFailOnMultiNodePlans(true);
        jdbcSettings.setPort((short) 5433);
        VerticaRoutableConnection conn;
        Map<String, Object> map = new HashMap<String, Object>();
        map.put("customer_key", 1);
        try {
            conn = (VerticaRoutableConnection)
                jdbcSettings.getConnection();
            String table = "customers";
            VerticaRoutableExecutor q = conn.createRoutableExecutor(null, table);
            String query = "select d.date, SUM(s.sales_amount) as Total ";
            query += " from customers as c";
            query += " join sales as s ";
            query += " on s.customer_key = c.customer_key ";
            query += " join date_dimension as d ";
            query += " on d.date_key = s.date_key ";
            query += " where c.customer_key = " + map.get("customer_key");
            query += " group by (d.date) order by Total DESC";
            ResultSet rs = q.execute(query, map);
            while(rs.next()) {
                System.out.print("Date: " + rs.getString("date") + ": ");
                System.out.println("Amount: " + rs.getString("Total"));
            }
            conn.close();
        } catch (SQLException e) {
            e.printStackTrace();
        }
    }
}

```

The example code produces output like this:

```

Date: 2012-01-15: Amount: 900.0
Date: 2012-02-04: Amount: 500.0
Date: 2012-01-01: Amount: 100.0

```

Note

Your output might be different, because the VMart schema randomly generates dates in the `date_dimension` table.

Defining the query for routable queries using the VGet class

The [VGet class](#) is used to access table data directly from a single node when you do not need to join the data or use a group by clause. Like `VerticaRoutableExecutor`, `VGet` directly queries Vertica nodes that have the data needed for the query, avoiding the distributed planning and execution costs associated with a normal Vertica execution. However, `VGet` does not use SQL. Instead, you define predicates and values to perform key/value

type lookups on a single table. VGet is especially suited to key/value-type lookups on single tables.

You create a VGet by calling the prepareGet method on a connection object:

```
prepareGet( schema-name, { table-name | projection-name } )
```

For example:

```
VerticaRoutableConnection conn;  
try {  
    conn = (VerticaRoutableConnection)  
        jdbcSettings.getConnection();  
    System.out.println("Connected.");  
    VGet get = conn.prepareGet("public", "users");  
    ...  
}
```

VGet operations span multiple JDBC connections (and multiple Vertica sessions) and do not honor the parent connection's transaction semantics. If consistency is required across multiple executions, the parent VerticaRoutableConnection's consistent read API can be used to guarantee all operations occur at the same epoch.

VGet is thread safe, but all methods are synchronized, so threads that share a VGet instance are never run in parallel. For better parallelism, each thread should have its own VGet instance. Different VGet instances that operate on the same table share pooled connections and metadata in a manner that enables a high degree of parallelism.

VGet methods

VGet has the following methods:

- [VGet methods](#)
 - [addPredicate](#)
 - [addPredicateExpression](#)
 - [addOutputColumn](#)
 - [addOutputExpression](#)
 - [addSortColumn](#)
 - [setLimit](#)
 - [clearPredicates](#)
 - [clearOutputs](#)
 - [clearSortColumns](#)
 - [Execute](#)
 - [Close](#)
 - [getWarnings](#)
- [Example](#)

By default, VGet fetches all columns of all rows that satisfy the logical AND of predicates passed via the [addPredicate](#) method. You can further customize the get operation with the following methods: [addOutputColumn](#), [addOutputExpression](#), [addPredicateExpression](#), [addSortColumn](#), and [setLimit](#).

addPredicate

```
addPredicate(string, object)
```

Adds a predicate column and a constant value to the query. You must include a predicate for each column on which the table is segmented. The predicate acts as the query WHERE clause. Multiple addPredicate method calls are joined by AND modifiers. The VGet retains this value after each call to execute. To remove it, use [clearPredicates](#).

The following data types cannot be used as column values. Also, if a table is segmented on any columns with these data types then the table cannot be queried with the Routable Query API:

- [INTERVAL](#)
- [TIMETZ](#)
- [TIMESTAMPTZ](#)

addPredicateExpression

```
addPredicateExpression( string )
```

Accepts arbitrary SQL expressions that operate on the table's columns as input to the query. Predicate expressions and predicates are joined by AND modifiers. You can use segmented columns in predicate expressions, but they must also be specified as a regular predicate with [addPredicate](#). The VGet retains this value after each call to execute. To remove it, use [clearPredicates](#).

The driver does not verify the syntax of the expression before it sends it to the server. If your expression is incorrect then the query fails.

addOutputColumn

```
addOutputColumn(string)
```

Adds a column to be included in the output. By default the query runs as `SELECT *` and you do not need to define any output columns to return the data. If you add output columns then you must add all the columns to be returned. The VGet retains this value after each call to execute. To remove it, use [clearOutputs](#).

addOutputExpression

```
addOutputExpression(string)
```

Accepts arbitrary SQL expressions that operate on the table's columns as output. The VGet retains this value after each call to execute. To remove it, use `ClearOutputs`.

The following restrictions apply:

- The driver does not verify the syntax of the expression before it sends it to the server. If your expression is incorrect then the query fails.
- `addOutputExpression` is not supported when querying [flex tables](#). If you use `addOutputExpression` on a flex table query, then a `SQLFeatureNotSupportedException` is thrown.

addSortColumn

```
addSortColumn(string, SortOrder)
```

Adds a sort order to an output column. The output column can be either the one returned by the default query (`SELECT *`) or one of the columns defined in [addSortColumn](#) or `addOutputExpress`. You can defined multiple sort columns.

setLimit

```
setLimit(int)
```

Sets a limit on the number of results returned. A limit of 0 is unlimited.

clearPredicates

```
clearPredicates()
```

Removes predicates that were added by [addPredicate](#) and [addPredicateExpression](#).

clearOutputs

```
clearOutputs()
```

Removes outputs added by [addOutputColumn](#) and [addOutputExpression](#).

clearSortColumns

```
clearSortColumns()
```

Removes sort columns previously added by [addSortColumn](#).

Execute

```
execute()
```

Runs the query. Care must be taken to ensure that the predicate columns exist on the table and projection used by VGet, and that the expressions do not require multiple nodes to execute. If an expression is sufficiently complex as to require more than one node to execute, `execute` throws a `SQLException` if the `FailOnMultiNodePlans` connection property is true.

Close

```
close()
```

Closes this VGet by releasing resources used by this VGet. It does not close the parent JDBC connection to Vertica.

getWarnings

```
getWarnings()
```

Retrieves the first warning reported by calls on this VGet. Additional warnings are chained and can be accessed with the JDBC method `getNextWarning`.

Example

The following code queries the `users` table that is defined in [Creating tables and projections for use with the routable query API](#). The table defines an `id` column that is segmented by hash.

```
import java.sql.*;
import com.vertica.jdbc.kv.*;

public class verticaKV2 {
    public static void main(String[] args) {
        com.vertica.jdbc.DataSource jdbcSettings
            = new com.vertica.jdbc.DataSource();
        jdbcSettings.setDatabase("exampleDB");
        jdbcSettings.setHost("v_vmart_node0001.example.com");
        jdbcSettings.setUserID("dbadmin");
        jdbcSettings.setPassword("password");
        jdbcSettings.setEnableRoutableQueries(true);
        jdbcSettings.setPort((short) 5433);

        VerticaRoutableConnection conn;
        try {
            conn = (VerticaRoutableConnection)
                jdbcSettings.getConnection();
            System.out.println("Connected.");
            VGet get = conn.prepareGet("public", "users");
            get.addPredicate("id", 5);
            ResultSet rs = get.execute();
            rs.next();
            System.out.println("ID: " +
                rs.getString("id"));
            System.out.println("Username: "
                + rs.getString("username"));
            System.out.println("Email: "
                + rs.getString("email"));
            System.out.println("Closing Connection.");
            conn.close();
        } catch (SQLException e) {
            System.out.println("Error! Stacktrace:");
            e.printStackTrace();
        }
    }
}
```

This code produces the following output:

```
Connected.
ID: 5
Username: userE
Email: usere@example.com
Closing Connection.
```

Routable query performance and troubleshooting

This topic details performance considerations and common issues you might encounter when using the routable query API.

Using resource pools with routable queries

Individual routable queries are serviced quickly since they directly access a single node and return only one or a few rows of data. However, by default, Vertica resource pools use an AUTO setting for the `execution parallelism` parameter. When set to AUTO, the setting is determined by the number of CPU cores available and generally results in multi-threaded execution of queries in the resource pool. It is not efficient to create parallel threads on

the server because routable query operations return data so quickly and routable query operations only use a single thread to find a row. To prevent the server from opening unneeded processing threads, you should create a specific resource pool for routable query clients. Consider the following settings for the resource pool you use for routable queries:

- Set execution parallelism to 1 to force single-threaded queries. This setting improves routable query performance.
- Use CPU affinity to limit the resource pool to a specific CPU or CPU set. The setting ensures that the routable queries have resources available to them, but it also prevents routable queries from significantly impacting performance on the system for other general queries.
- If you do not set a CPU affinity for the resource pool, consider setting the maximum concurrency value of the resource pool to a setting that ensures good performance for routable queries, but does not negatively impact the performance of general queries.

Performance considerations for routable query connections

Because a `VerticaRoutableConnection` opens an internal pool of connections, it is important to configure `MaxPooledConnections` and `MaxPooledConnectionsPerNode` appropriately for your cluster size and the amount of simultaneous client connections. It is possible to impact normal database connections if you are overloading the cluster with `VerticaRoutableConnection`s.

The initial connection to the initiator node discovers all other nodes in the cluster. The internal-pool connections are not opened until a `VerticaRoutableExecutor` or `VGet` query is sent. All `VerticaRoutableExecutors/VGets` in a connection object use connections from the internal pool and are limited by the `MaxPooledConnections` settings. Connections remain open until they are closed so a new connection can be opened elsewhere if the connection limit has been reached.

Troubleshooting routable queries

Routable query issues generally fall into two categories:

- Not providing enough predicates.
- Queries having to span multiple nodes.

Predicate Requirements

You must provide the same number of predicates that correspond to the columns of the table segmented by hash. To determine the segmented columns, call the Vertica function `GET_PROJECTIONS`. You must provide a predicate for each column displayed in the `Seg Cols` field.

For `VGet`, this means you must use `addPredicate()` to add each of the columns. For `VerticaRoutableExecutor`, this means you must provide all of the predicates and values in the map sent to `execute()`.

Multi-node Failures

It is possible to define the correct number of predicates, but still have a failure because multiple nodes contain the data. This failure occurs because the projection's data is not segmented in such a way that the data being queried is contained on a single node. Enable logging for the connection and view the logs to verify the projection being used. If the client is not picking the correct projection, then try to query the projection directly by specifying the projection instead of the table in the create/prepare statement, for example:

- Using `VerticaRoutableExecutor`:

```
conn.createRoutableExecutor(schema, table/projection);
```

- Using `VGet`:

```
conn.prepareGet('schema', table/projection)
```

Additionally, you can use the `EXPLAIN` command in `vsq` to help determine if your query can run in single node. `EXPLAIN` can help you understand why the query is being run as single or multi-node.

Pre-segmenting data using `VHash`

The `VHash` class is an implementation of the Vertica hash function for use with JDBC client applications.

Hash segmentation in Vertica allows you to segment a projection based on a built-in hash function. The built-in hash function provides even data distribution across some or all nodes in a cluster, resulting in optimal query execution.

Suppose you have several million rows of values spread across thousands of CSV files. Assume that you already have a table segmented by hash. Before you load the values into your database, you probably want to know to which node a particular value loads. For this reason, using `VHash` can be particularly helpful, by allowing you to pre-segment your data before loading.

The following example shows the `VHash` class hashing the first column of a file named "testFile.csv". The name of the first column in this file is `meterId`.

Segment the data using `VHash`

This example demonstrates how you can read the testFile.csv file from the local file system and run a hash function on the meterId column. Using the database metadata from a projection, you can then pre-segment the individual rows in the file based on the hash value of meterId.

```
import java.io.BufferedReader;
import java.io.FileNotFoundException;
import java.io.FileOutputStream;
import java.io.FileReader;
import java.io.UnsupportedEncodingException;
import java.util.*;
import java.io.IOException;
import java.sql.*;

import com.vertica.jdbc.kv.VHash;

public class VerticaKVDoc {

    final Map<String, FileOutputStream> files;
    final Map<String, List<Long>> nodeToHashList;
    String segmentationMetadata;
    List<String> lines;

    public static void main(String[] args) throws Exception {
        try {
            Class.forName("com.vertica.jdbc.Driver");
        } catch (ClassNotFoundException e) {
            System.err.println("Could not find the JDBC driver class.");
            e.printStackTrace();
            return;
        }

        Properties myProp = new Properties();
        myProp.put("user", "username");
        myProp.put("password", "password");

        VerticaKVDoc ex = new VerticaKVDoc();

        // Read in the data from a CSV file.
        ex.readLinesFromFile("C:\\testFile.csv");

        try (Connection conn = DriverManager.getConnection(
            "jdbc:vertica://VerticaHost:portNumber/databaseName", myProp)) {

            // Compute the hashes and create FileOutputStreams.
            ex.prepareForHashing(conn);

        }

        // Write to files.
        ex.writeLinesToFiles();
    }

    public VerticaKVDoc() {
        files = new HashMap<String, FileOutputStream>();
        nodeToHashList = new HashMap<String, List<Long>>();
    }

    public void prepareForHashing(Connection conn) throws SQLException,
        FileNotFoundException {

        // Send a query to Vertica to return the projection segments.
        try (ResultSet rs = conn.createStatement().executeQuery(
            "SELECT * FROM projection_name FROM public.projectionName")) {
```

```

        SELECT get_projection_segments(public.projectionname) )) {
    rs.next();
    segmentationMetadata = rs.getString(1);
}

// Initialize the data files.
try (ResultSet rs = conn.createStatement().executeQuery(
    "SELECT node_name FROM nodes") {
    while (rs.next()) {
        String node = rs.getString(1);
        files.put(node, new FileOutputStream(node + ".csv"));
    }
}

public void writeLinesToFiles() throws UnsupportedEncodingException,
    IOException {
    for (String line : lines) {

        long hashedValue = VHash.hashLong(getMeterIdFromLine(line));

        // Write the row data to that node's data file.
        String node = VHash.getNodeFor(segmentationMetadata, hashedValue);

        FileOutputStream fos = files.get(node);
        fos.write(line.getBytes("UTF-8"));
    }
}

private long getMeterIdFromLine(String line) {

    // In our file, "meterid" is the name of the first column in the file.
    return Long.parseLong(line.split(",")[0]);
}

public void readLinesFromFile(String filename) throws IOException {
    lines = new ArrayList<String>();
    String line;
    try (BufferedReader reader = new BufferedReader(
        new FileReader(filename))) {
        while ((line = reader.readLine()) != null) {
            lines.add(line);
        }
    }
}
}

```

Timezones and daylight savings time

When building Java applications that query `TimeTZ` and `TimestampTZ` values, the JVM and session must use the same timezone to get accurate results. In particular, the [CURRENT_TIME](#) and [CURRENT_TIMESTAMP](#) functions can return different values if the following conditions are met:

- The JVM and session timezones are different
- One of the timezones is one where daylight savings time is in effect

The following example demonstrates how to query for the current timestamp:

1. The `run()` method sets the JVM timezone to `US/Eastern`.
2. `US/Eastern` is then passed to the `getConnection()` method, which sets the session timezone.
3. The `printCurrentTimeAndTimeStamp()` method executes the [CURRENT_TIME](#) and [CURRENT_TIMESTAMP](#) functions, which return `TimeTZ` and `TimestampTZ`, respectively. These values should match because the JVM and session use the same timezone.

```

private Connection getConnection(String timezone) throws SQLException {
    final String host = "host";
    final String port = "5433";
    final String dbName = "database";
    Properties jdbcOptions = new Properties();
    jdbcOptions.put("User", "Your Username");
    jdbcOptions.put("Password", "Your Password");

    // Use the ConnSettings connection property to ensure the session's timezone
    // matches the JVM's timezone
    jdbcOptions.put("ConnSettings", "SET TIMEZONE TO '" + timezone + "'");

    return DriverManager.getConnection(
        "jdbc:vertica://" + host + ":" + port + "/" + dbName, jdbcOptions);
}

private void printCurrentTimeAndTimeStamp(Connection conn) throws SQLException
{
    Statement st = conn.createStatement();
    String queryString = "SELECT CURRENT_TIME(0) AS time , CURRENT_TIMESTAMP(0) AS timestamp";
    ResultSet rs = st.executeQuery(queryString);
    rs.next();
    String timeValue = rs.getString("time");
    String timeStampValue = rs.getString("timestamp");
    System.out.println("CURRENT_TIME(): " + timeValue);
    System.out.println("CURRENT_TIMESTAMP(): " + timeStampValue);
}

public void run() throws SQLException
{
    final String timezone = "US/Eastern";
    // set JVM timezone
    TimeZone.setDefault(TimeZone.getTimeZone(timezone));
    Connection conn = getConnection(timezone);
    try {
        printCurrentTimeAndTimeStamp(conn);
    } finally {
        conn.close();
    }
}

```

JavaScript

The open-source [vertica-nodejs](#) client driver lets you interact with your database with JavaScript. For details, see the [vertica-nodejs package on npm](#).

Perl

Perl scripts can interact with Vertica using the Perl DBI module along with the DBD::ODBC database driver to interface to the Vertica ODBC driver.

Prerequisites

You must [configure a Perl development environment](#) before creating Perl client applications.

In this section

- [Configuring a Perl development environment](#)
- [Connecting to Vertica using Perl](#)
- [Executing statements using Perl](#)
- [Batch loading data using Perl](#)
- [Using COPY LOCAL to load data in Perl](#)
- [Querying using Perl](#)
- [Conversions between Perl and Vertica data types](#)
- [Perl unicode support](#)

Configuring a Perl development environment

Perl has a Database Interface module (DBI) that creates a standard interface for Perl scripts to interact with databases. The interface module relies on Database Driver modules (DBDs) to handle all of the database-specific communication tasks. The result is an interface that provides a consistent way for Perl scripts to interact with many different types of databases.

Note

With Perl ODBC clients, Vertica allows a forked process (a child process) to drop the parent connection to the Vertica server when the child process completes and exits. Vertica allows this behavior regardless of the setting of the Perl DBI `AutoInactiveDestroy` attribute.

To change the default setting so that Vertica honors the setting of the Perl DBI `AutoInactiveDestroy` attribute, add the parameter `CleanupInForkChild` to your `vertica.ini` file, and set its value to 1. When the Perl DBI `AutoInactiveDestroy` attribute is set to 1, and the Vertica parameter `CleanupInForkChild` is set to 1, Vertica does not drop the parent connection upon child process completion.

Perl scripts can interact with Vertica using the Perl DBI module along with the `DBD::ODBC` database driver to interface to the Vertica ODBC driver. See the CPAN pages for Perl's [DBI](#) and [DBD::ODBC](#) modules for detailed documentation.

A Perl development environment depends on the Vertica ODBC driver and the DBI and `DBD::ODBC` modules.

1. [Install and configure ODBC](#).
2. Verify that Perl is installed with the following command. If this command does not return version information, you must [install Perl](#). For version support, see [Perl driver requirements](#).

```
$ perl -v
```

3. Install [compatible versions](#) of the Perl modules [DBI](#) and [DBD::ODBC](#). Installation methods vary between environments. For details on installing Perl modules, see the [cpan documentation](#).
4. Run the following commands to verify that DBI and `DBD::ODBC` are installed. If installed, these commands should return nothing. Otherwise, they return an error:

```
$ perl -e "use DBI;"
$ perl -e "use DBD::ODBC;"
```

Listing DSNs and verifying the installation

Another way to verify your installation is with the following Perl script. This script verifies if DBI and `DBD::ODBC` are installed and prints your ODBC DSN, if any:

```
#!/usr/bin/perl
use strict;
# Attempt to load the DBI module in an eval using require. Prevents
# script from erroring out if DBI is not installed.
eval
{
    require DBI;
    DBI->import();
};
if ($?) {
    # The eval failed, so DBI must not be installed
    print "DBI module is not installed\n";
} else {
    # Eval was successful, so DBI is installed
    print "DBI Module is installed\n";
    # List the drivers that DBI knows about.
    my @drivers = DBI->available_drivers;
    print "Available Drivers: \n";
    foreach my $driver (@drivers) {
        print "\t$driver\n";
    }
    # See if DBD::ODBC is installed by searching driver array.
    if (grep {/ODBC/i} @drivers) {
        print "\nDBD::ODBC is installed.\n";
        # List the ODBC data sources (DSNs) defined on the system
        print "Defined ODBC Data Sources:\n";
        my @dsns = DBI->data_sources('ODBC');
        foreach my $dsn (@dsns) {
            print "\t$dsn\n";
        }
    } else {
        print "DBD::ODBC is not installed\n";
    }
}
}
```

If your system is properly configured, the output should resemble the following:

```
DBI Module is installed
Available Drivers:
    ADO
    DBM
    ExampleP
    File
    Gofer
    ODBC
    Pg
    Proxy
    SQLite
    Sponge
    mysql
DBD::ODBC is installed.
Defined ODBC Data Sources:
    dbi:ODBC:dBASE Files
    dbi:ODBC:Excel Files
    dbi:ODBC:MS Access Database
    dbi:ODBC:VerticaDSN
```

Connecting to Vertica using Perl

You use the Perl DBI module's [connect](#) function to connect to Vertica. This function takes a required data source string argument and optional arguments for the username, password, and connection attributes.

The data source string must start with "dbi:ODBC:", which tells the DBI module to use the DBD::ODBC driver to connect to Vertica. The remainder of the string is interpreted by the DBD::ODBC driver. It usually contains the name of a DSN that contains the connection information needed to connect to your Vertica database. For example, to tell the DBD::ODBC driver to use the DSN named VerticaDSN, you use the data source string:

```
"dbi:ODBC:VerticaDSN"
```

The username and password parameters are optional. However, if you do not supply them (or just the username for a passwordless account) and they are not set in the DSN, attempting to connect always fails.

The `connect` function returns a database handle if it connects to Vertica. If it does not, it returns `undef`. In that case, you can access the DBI module's error string property (`$DBI::errstr`) to get the error message.

Note

By default, the DBI module prints an error message to STDERR whenever it encounters an error. If you prefer to display your own error messages or handle errors in some other manner, you may want to disable these automatic messages by setting DBI's `PrintError` connection attribute to false. See [Setting Perl DBI connection attributes](#) for details. Otherwise, users may see two error messages: the one that DBI prints automatically, and the one that your script prints on its own.

The following example connects to Vertica with a DSN named VerticaDSN. The call to `connect` supplies a username and password. After connecting, it calls the database handle's `disconnect` function, which closes the connection:

```
#!/usr/bin/perl -w
use strict;
use DBI;
# Open a connection using a DSN. Supply the username and password.
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN","ExampleUser","password123");
unless (defined $dbh) {
    # Connection failed.
    die "Failed to connect: $DBI::errstr";
}
print "Connected!\n";
$dbh->disconnect();
```

In this section

- [Setting ODBC connection parameters in Perl](#)
- [Setting Perl DBI connection attributes](#)
- [Connecting from Perl without a DSN](#)

Setting ODBC connection parameters in Perl

To set ODBC connection parameters, replace the DSN name with a semicolon delimited list of parameter name and value pairs in the source data string. Use the DSN parameter to tell DBD::ODBC which DSN to use, then add in other the other ODBC parameters you want to set. For example, the following code connects using a DSN named VerticaDSN and sets the connection's locale to en_GB.

```
#!/usr/bin/perl -w
use strict;
use DBI;
# Instead of just using the DSN name, use name and value pairs.
my $dbh = DBI->connect("dbi:ODBC:DSN=VerticaDSN;Locale=en_GB@collation=binary","ExampleUser","password123");
unless (defined $dbh) {
    # Connection failed.
    die "Failed to connect: $DBI::errstr";
}
print "Connected!\n";
$dbh->disconnect();
```

See [ODBC DSN connection properties](#) for a list of the connection parameters you can set in the source data string.

Setting Perl DBI connection attributes

The Perl DBI module has attributes that you can use to control the behavior of its database connection. These attributes are similar to the ODBC connection parameters (in several cases, they duplicate each other's functionality). The DBI connection attributes are a cross-platform way of controlling the behavior of the database connection.

You can set the DBI connection attributes when establishing a connection by passing the DBI `connect` function a hash containing attribute and value pairs. For example, to set the DBI connection attribute `AutoCommit` to false, you would use:

```
# Create a hash that holds attributes for the connection
my $attr = {AutoCommit => 0};
# Open a connection using a DSN. Supply the username and password.
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN","ExampleUser","password123",
    $attr);
```

See the DBI documentation's [Database Handle Attributes](#) section for a full description of the attributes you can set on the database connection.

After your script has connected, it can access and modify the connection attributes through the database handle by using it as a hash reference. For example:

```
print "The AutoCommit attribute is: " . $dbh->{AutoCommit} . "\n";
```

The following example demonstrates setting two connection attributes:

- `RaiseError` controls whether the DBI driver generates a Perl error if it encounters a database error. Usually, you set this to true (1) if you want your Perl script to exit if there is a database error.
- `AutoCommit` controls whether statements automatically commit their transactions when they complete. DBI defaults to Vertica's default `AutoCommit` value of true. Always set `AutoCommit` to false (0) when bulk loading data to increase database efficiency.

```
#!/usr/bin/perl
use strict;
use DBI;
# Create a hash that holds attributes for the connection
my $attr = {
    RaiseError => 1, # Make database errors fatal to script
    AutoCommit => 0, # Prevent statements from committing
                  # their transactions.
};
# Open a connection using a DSN. Supply the username and password.
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN","ExampleUser","password123",
    $attr);

if (defined $dbh->err) {
    # Connection failed.
    die "Failed to connect: $DBI::errstr";
}
print "Connected!\n";
# The database handle lets you access the connection attributes directly:
print "The AutoCommit attribute is: " . $dbh->{AutoCommit} . "\n";
print "The RaiseError attribute is: " . $dbh->{RaiseError} . "\n";
# And you can change values, too...
$dbh->{AutoCommit} = 1;
print "The AutoCommit attribute is now: " . $dbh->{AutoCommit} . "\n";
$dbh->disconnect();
```

The example outputs the following when run:

```
Connected!The AutoCommit attribute is: 0
The RaiseError attribute is: 1
The AutoCommit attribute is now: 1
```

Connecting from Perl without a DSN

If you do not want to set up a Data Source Name (DSN) for your database, you can supply all of the information Perl's `DBD::ODBC` driver requires to connect to your Vertica database in the data source string. This source string must the `DRIVER=` parameter that tells `DBD::ODBC` which driver library to use in order to connect. The value for this parameter is the name assigned to the driver by the client system's driver manager:

- On Windows, the name assigned to the Vertica ODBC driver by the driver manager is Vertica.
- On Linux and other UNIX-like operating systems, the Vertica ODBC driver's name is assigned in the system's `odbcinst.ini` file. For example, if your `/etc/odbcint.ini` contains the following:

```
[Vertica]
Description = Vertica ODBC Driver
Driver = /opt/vertica/lib64/libverticaodbc.so
```

you would use the name Vertica. See [Creating an ODBC DSN for Linux](#) for more information about the `odbcinst.ini` file.

You can take advantage of Perl's variable expansion within strings to use variables for most of the connection properties as the following example demonstrates.

```
#!/usr/bin/perl
use strict;
use DBI;
my $server='VerticaHost';
my $port = '5433';
my $database = 'VMart';
my $user = 'ExampleUser';
my $password = 'password123';
# Connect without a DSN by supplying all of the information for the connection.
# The DRIVER value on UNIX platforms depends on the entry in the odbcinst.ini
# file.
my $dbh = DBI->connect("dbi:ODBC:DRIVER={Vertica};Server=$server;" .
    "Port=$port;Database=$database;UID=$user;PWD=$password")
    or die "Could not connect to database: " . DBI::errstr;
print "Connected!\n";
$dbh->disconnect();
```

Note

Surrounding the driver name with braces (`{` and `}`) in the source string is optional.

Executing statements using Perl

Once your Perl script has connected to Vertica (see [Connecting to Vertica Using Perl](#)), it can execute simple statements that return a value rather than a result set by using the Perl DBI module's `do` function. You usually use this function to execute DDL statements or data loading statements such as `COPY` (see [Using `COPY LOCAL` to load data in Perl](#)).

```
#!/usr/bin/perl
use strict;
use DBI;
# Disable autocommit
my $attr = {AutoCommit => 0};
# Open a connection using a DSN.
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN","ExampleUser","password123",
    $attr);
unless (defined $dbh) {
    # Connection failed.
    die "Failed to connect: $DBI::errstr";
}
# You can use the do function to perform DDL commands.
# Drop any existing table.
$dbh->do("DROP TABLE IF EXISTS TEST CASCADE;");
# Create a table to hold data.
$dbh->do("CREATE TABLE TEST( \
    C_ID INT, \
    C_FP FLOAT, \
    C_VARCHAR VARCHAR(100), \
    C_DATE DATE, C_TIME TIME, \
    C_TS TIMESTAMP, \
    C_BOOL BOOL)");
# Commit changes and exit.
$dbh->commit();
$dbh->disconnect();
```

Note

The `do` function returns the number of rows that were affected by the statement (or -1 if the count of rows doesn't apply or is unavailable). Usually, the only time you need to consult this value is after you deleted a number of rows or if you used a bulk load command such as [COPY](#). You use other DBI functions instead of `do` to perform batch inserts and selects (see [Batch loading data using Perl](#) and [Querying using Perl](#) for details).

Batch loading data using Perl

To load large batches of data into Vertica using Perl:

1. Set DBI's `AutoCommit` connection attribute to false to improve the batch load speed. See [Setting Perl DBI connection attributes](#) for an example of disabling `AutoCommit`.
2. Call the database handle's `prepare` function to prepare a SQL [INSERT](#) statement that contains placeholders for the data values you want to insert.

For example:

```
# Prepare an INSERT statement for the test table
$stmt = $dbh->prepare("INSERT into test values(?,?,?,?);");
```

The `prepare` function returns a statement handle that you will use to insert the data.

3. Assign data to the placeholders. There are several ways to do this. The easiest is to populate an array with a value for each placeholder in your `INSERT` statement.
4. Call the statement handle's `execute` function to insert a row of data into Vertica. The return value of this function call lets you know whether Vertica accepted or rejected the row.
5. Repeat steps 3 and 4 until you have loaded all of the data you need to load.
6. Call the database handle's `commit` function to commit the data you inserted.

The following example demonstrates inserting a small batch of data by populating an array of arrays with data, then looping through it and inserting each row.

```
#!/usr/bin/perl
use strict;
use DBI;
# Create a hash reference that holds a hash of parameters for the
# connection.
```

```

my $attr = {AutoCommit => 0, # Turn off autocommit
            PrintError => 0 # Turn off automatic error printing.
            # This is handled manually.
};

# Open a connection using a DSN. Supply the username and password.
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN","ExampleUser","password123",
    $attr);
if (defined DBI::err) {
    # Connection failed.
    die "Failed to connect: $DBI::errstr";
}
print "Connection AutoCommit state is: " . $dbh->{AutoCommit} . "\n";
# Create table to hold inserted data
$dbh->do("DROP TABLE IF EXISTS TEST CASCADE;") or die "Could not drop table";
$dbh->do("CREATE TABLE TEST( \
    C_ID INT, \
    C_FP FLOAT, \
    C_VARCHAR VARCHAR(100), \
    C_DATE DATE, C_TIME TIME, \
    C_TS TIMESTAMP, \
    C_BOOL BOOL)") or die "Could not create table";
# Populate an array of arrays with values. One of these rows contains
# data that will not be successfully inserted. Another contains an
# undef value, which gets inserted into the database as a NULL.
my @data = (
    [1,1.111,'Hello World!','2001-01-01','01:01:01'
     , '2001-01-01 01:01:01','t'],
    [2,2.22222,'How are you?','2002-02-02','02:02:02'
     , '2002-02-02 02:02:02','f'],
    ['bad value',2.22222,'How are you?','2002-02-02','02:02:02'
     , '2002-02-02 02:02:02','f'],
    [4,4.22222,undef,'2002-02-02','02:02:02'
     , '2002-02-02 02:02:02','f'],
);
# Create a prepared statement to use parameters for inserting values.
my $sth = $dbh->prepare_cached("INSERT into test values(?,?,?,?,?,?,?)");
my $rowcount = 0; # Count # of rows
# Loop through the arrays to insert values
foreach my $tuple (@data) {
    $rowcount++;
    # Insert the row
    my $retval = $sth->execute(@$tuple);

    # See if the row was successfully inserted.
    if ($retval == 1) {
        # Value of 1 means the row was inserted (1 row was affected by insert)
        print "Row $rowcount successfully inserted\n";
    } else {
        print "Inserting row $rowcount failed";
        # Error message is not set on some platforms/versions of DBUI. Check to
        # ensure a message exists to avoid getting an uninitialized var warning.
        if ($sth->err()) {
            print ": " . $sth->errstr();
        }
        print "\n";
    }
}
# Commit changes. With AutoCommit off, you need to use commit for batched
# data to actually be committed into the database. If your Perl script exits
# without committing its data, Vertica rolls back the transaction and the
# data is not committed.

```

```
$dbh->commit();  
$dbh->disconnect();
```

The previous example displays the following when successfully run:

```
Connection AutoCommit state is: 0  
Row 1 successfully inserted  
Row 2 successfully inserted  
Inserting row 3 failed with error 01000 [Vertica][VerticaDSII] (20) An  
error occurred during query execution: Row rejected by server; see  
server log for details (SQL-01000)  
Row 4 successfully inserted
```

Note that one of the rows was not inserted because it contained a string value that could not be stored in an integer column. See [Conversions between Perl and Vertica Data Types](#) for details of data type handling in Perl scripts that communicate with Vertica.

Using COPY LOCAL to load data in Perl

You can use [COPY LOCAL](#) to load delimited files on your client system—for example, a file with comma-separated values—into Vertica. Rather than use Perl to read, parse, and then batch insert the file data, COPY LOCAL directly loads the file data from the local file system into Vertica. When execution completes, COPY LOCAL returns the number of rows that it successfully inserted.

Note

COPY LOCAL must be the first statement in a query, otherwise Vertica returns an error.

The following example uses COPY LOCAL to load into Vertica local file `data.txt`, which is located in the same directory as the Perl file.

```

#!/usr/bin/perl
use strict;
use DBI;
# Filesystem path handling module
use File::Spec;
# Create a hash reference that holds a hash of parameters for the
# connection.
my $attr = {AutoCommit => 0}; # Turn off AutoCommit
# Open a connection using a DSN. Supply the username and password.
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN","ExampleUser","password123",
    $attr) or die "Failed to connect: $DBI::errstr";
print "Connected!\n";
# Drop any existing table.
$dbh->do("DROP TABLE IF EXISTS Customers CASCADE;");
# Create a table to hold data.
$dbh->do("CREATE TABLE Customers( \
    ID INT, \
    FirstName VARCHAR(100),\
    LastName VARCHAR(100),\
    Email VARCHAR(100),\
    Birthday DATE)");
# Find the absolute path to the data file located in the current working
# directory and named data.txt
my $currDir = File::Spec->rel2abs(File::Spec->curdir());
my $dataFile = File::Spec->catfile($currDir, 'data.txt');
print "Loading file $dataFile\n";
# Load local file using copy local. Return value is the # of rows affected
# which equates to the number of rows inserted.
my $rows = $dbh->do("COPY Customers FROM LOCAL '$dataFile' DIRECT")
    or die $dbh->errstr;
print "Copied $rows rows into database.\n";
$dbh->commit();
# Prepare a query to get the first 15 rows of the results
my $sth = $dbh->prepare("SELECT * FROM Customers WHERE ID < 15 \
    ORDER BY ID");

$sth->execute() or die "Error querying table: " . $dbh->errstr;
my @row; # Pre-declare variable to hold result row used in format statement.
# Use Perl formats to pretty print the output. Declare the heading for the
# form.
format STDOUT_TOP =
ID First      Last      EMail      Birthday
== =====
.
# The Perl write statement will output a formatted line with values from the
# @row array. See http://perldoc.perl.org/perlform.html for details.
format STDOUT =
@> @<<<<<<<<<<<<< @<<<<<<<<<< @<<<<<<<<<<<<<<<<<<<<<<<<<<<< @<<<<<<<<
@row
.
# Loop through result rows while we have them
while (@row = $sth->fetchrow_array()) {
    write; # Format command does the work of extracting the columns from
        # the @row array and writing them out to STDOUT.
}
# Call commit to prevent Perl from complaining about uncommitted transactions
# when disconnecting
$dbh->commit();
$dbh->disconnect();

```

`data.txt` is a text file with a row of data on each line. The columns are delimited by pipe (|) characters. This is the default COPY [delimiter](#) for command accepts, which simplifies the COPY LOCAL statement.

Here is an example of the file content:

```
1|Georgia|Gomez|Rhiannon@magna.us|1937-10-03
2|Abdul|Alexander|Kathleen@ipsum.gov|1941-03-10
3|Nigel|Contreras|Tanner@et.com|1955-06-01
4|Gray|Holt|Thomas@Integer.us|1945-12-06
5|Candace|Bullock|Scott@vitae.gov|1932-05-27
6|Matthew|Dotson|Keith@Cras.com|1956-09-30
7|Haviva|Hopper|Morgan@porttitor.edu|1975-05-10
8|Stewart|Sweeney|Rhonda@lectus.us|2003-06-20
9|Allen|Rogers|Alexander@enim.gov|2006-06-17
10|Trevor|Dillon|Eagan@id.org|1988-11-27
11|Leroy|Ashley|Carter@turpis.edu|1958-07-25
12|Elmo|Malone|Carla@enim.edu|1978-08-29
13|Laurel|Ball|Zelenia@Integer.us|1989-09-20
14|Zeus|Phillips|Branden@blandit.gov|1996-08-08
15|Alexis|Mclean|Flavia@Suspendisse.org|2008-01-07
```

The example code produces the following output when run on a large sample file:

```
Connected!
Loading file /home/dbadmin/Perl/data.txt
Copied 1000000 rows into database.
ID First      Last      EMail          Birthday
==  =====  =====  =====
 1 Georgia    Gomez    Rhiannon@magna.us    1937-10-03
 2 Abdul     Alexander Kathleen@ipsum.gov    1941-03-10
 3 Nigel     Contreras Tanner@et.com         1955-06-01
 4 Gray      Holt      Thomas@Integer.us    1945-12-06
 5 Candace   Bullock   Scott@vitae.gov       1932-05-27

10 Trevor    Dillon    Eagan@id.org          1988-11-27
11 Leroy     Ashley    Carter@turpis.edu     1958-07-25
12 Elmo      Malone    Carla@enim.edu        1978-08-29
13 Laurel    Ball      Zelenia@Integer.us   1989-09-20
14 Zeus      Phillips  Branden@blandit.gov   1996-08-08
```

Note

Loading a single, large data file into Vertica through a single data connection is less efficient than loading a number of smaller files onto multiple nodes in parallel. Loading onto multiple nodes prevents any one node from becoming a bottleneck.

Querying using Perl

To query Vertica using Perl:

1. Prepare a query statement using the Perl DBI module's `prepare` function. This function returns a statement handle that you use to execute the query and get the result set.
2. Execute the prepared statement by calling the `execute` function on the statement handle.
3. Retrieve the results of the query from the statement handle using one of several methods, such as calling the statement handle's `fetchrow_array` function to retrieve a row of data, or `fetchall_array` to get an array of arrays containing the entire result set (not a good idea if your result set may be very large!).

The following example demonstrates querying the table created by the example shown in [Batch loading data using Perl](#). It executes a query to retrieve all of the content of the table, then repeatedly calls the statement handle's `fetchrow_array` function to get rows of data in an array. It repeats this process until `fetchrow_array` returns undef, which means that there are no more rows to be read.

```
#!/usr/bin/perl
use strict;
use DBI;
my $attr = {RaiseError => 1 }; # Make errors fatal to the Perl script.
# Open a connection using a DSN. Supply the username and password.
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN","ExampleUser","password123",
    $attr);
# Prepare a query to get the content of the table
my $sth = $dbh->prepare("SELECT * FROM TEST ORDER BY C_ID ASC");
# Execute the query by calling execute on the statement handle
$sth->execute();
# Loop through result rows while we have them, getting each row as an array
while (my @row = $sth->fetchrow_array()) {
    # The @row array contains the column values for this row of data
    # Loop through the column values
    foreach my $column (@row) {
        if (!defined $column) {
            # NULLs are signaled by undefs. Set to NULL for clarity
            $column = "NULL";
        }
        print "$column\t"; # Output the column separated by a tab
    }
    print "\n";
}
$dbh->disconnect();
```

The example prints the following when run:

```
1 1.111 Hello World! 2001-01-01 01:01:01 2001-01-01 01:01:01 1
2 2.22222 How are you? 2002-02-02 02:02:02 2002-02-02 02:02:02 0
4 4.22222 NULL 2002-02-02 02:02:02 2002-02-02 02:02:02 0
```

Binding variables to column values

Another method of retrieving the query results is to bind variables to columns in the result set using the statement handle's `bind_columns` function. You may find this method convenient if you need to perform extensive processing on the returned data, since your code can use variables rather than array references to access the data. The following example demonstrates binding variables to the result set, rather than looping through the row and column values.

```
#!/usr/bin/perl
use strict;
use DBI;
my $attr = {RaiseError => 1 }; # Make SQL errors fatal to the Perl script.
# Open a connection using a DSN. Supply the username and password.
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN32","ExampleUser","password123",
    $attr);
# Prepare a query to get the content of the table
my $sth = $dbh->prepare("SELECT * FROM TEST ORDER BY C_ID ASC");
$sth->execute();
# Create a set of variables to bind to the column values.
my ($C_ID, $C_FP, $C_VARCHAR, $C_DATE, $C_TIME, $C_TS, $C_BOOL);
# Bind the variable references to the columns in the result set.
$sth->bind_columns(\$C_ID, \$C_FP, \$C_VARCHAR, \$C_DATE, \$C_TIME,
    \$C_TS, \$C_BOOL);
# Now, calling fetch() to get a row of data updates the values of the bound
# variables. Continue calling fetch until it returns undefined.
while ($sth->fetch()) {
    # Note, you should always check that values are defined before using them,
    # since NULL values are translated into Perl as undefined. For this
    # example, just check the VARCHAR column for undefined values.
    if (!defined $C_VARCHAR) {
        $C_VARCHAR = "NULL";
    }
    # Just print values separated by tabs.
    print "$C_ID\t$C_FP\t$C_VARCHAR\t$C_DATE\t$C_TIME\t$C_TS\t$C_BOOL\n";
}
$dbh->disconnect();
```

The output of this example is identical to the output of the previous example.

Preparing, querying, and returning a single row

If you expect a single row as the result of a query (for example, when you execute a [COUNT\(*\)](#) query), you can use the DBI module's [selectrow_array](#) function to combine executing a statement and retrieving an array as a result.

The following example shows using [selectrow_array](#) to execute and get the results of the [SHOW LOCALE](#) statement. It also demonstrates changing the locale using the [do](#) function.

```
#!/usr/bin/perl
use strict;
use DBI;
my $attr = {RaiseError => 1 }; # Make SQL errors fatal to the Perl script.
# Open a connection using a DSN. Supply the username and password.
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN","ExampleUser","password123",
    $attr);
# Demonstrate setting/getting locale.
# Use selectrow_array to combine preparing a statement, executing it, and
# getting an array as a result.
my @localerv = $dbh->selectrow_array("SHOW LOCALE;");
# The locale name is the 2nd column (array index 1) in the result set.
print "Locale: $localerv[1]\n";
# Use do() to execute a SQL statement to set the locale.
$dbh->do("SET LOCALE TO en_GB");
# Get the locale again.
@localerv = $dbh->selectrow_array("SHOW LOCALE;");
print "Locale is now: $localerv[1]\n";
$dbh->disconnect();
```

The result of running the example is:

Locale: en_US@collation=binary (LEN_KBINARY)

Locale is now: en_GB (LEN)

Executing queries and ResultBufferSize settings

When you call the `execute()` function on a prepared statement, the client library retrieves results up to the size of the result buffer. The result buffer size is set using ODBC's [ResultBufferSize](#) setting.

Vertica does not allow multiple active queries per connection. However, you can simulate multiple active queries by setting the result buffer to be large enough to accommodate the entire results from the first query. To ensure that the ODBC client driver's buffer is large enough to store result set for first query you can set `ResultBufferSize` to 0. Setting this parameter to 0 makes the result buffer size unlimited. The ODBC driver allocates enough memory to read the entire result set. With the entire result set from the first query stored in the result set buffer, the database connection is free to perform another query. Your client can execute this second query even though it has not processed the entire result set from the first query.

However, if you set the `ResultBufferSize` to 0, you may find that your calls to `execute()` result in the operating system killing your Perl client script. The operating system may terminate your script if the ODBC driver allocates too much memory to store a large result set.

A workaround for this behavior is limit the number of rows returned by your query. Then you can set the `ResultBufferSize` to a value that accommodates this limited result set. For example, you can estimate the amount of memory needed to store a single row of your query result. Then use the [LIMIT](#) and [OFFSET](#) clauses to get a specific number of rows that will fit into the space you allocated using `ResultBufferSize`. If the results of your query is able to fit within the limited result set buffer, you can then perform additional queries with the same database connection. This solution makes your code more complex as you will need to perform multiple queries to get the entire result set. Also, it is not appropriate in cases where you need to operate on an entire result set at once, rather than just a portion of it at a time.

A better solution is to use separate database connections for each query you want to perform. The overhead of the additional database connection is small compared to the resources needed to process large data sets.

Conversions between Perl and Vertica data types

Perl is a loosely-typed programming language that does not assign specific data types to values. It converts between string and numeric values based on the operations being performed on the values. For this reason, Perl has little problem extracting most string and numeric data types from Vertica. All interval data types (DATE, TIMESTAMP, etc.) are converted to strings. You can use several different date and time handling Perl modules to manipulate these values in your scripts.

Vertica NULL values translate to Perl's undefined (`undef`) value. When reading data from columns that can contain NULL values, you should always test whether a value is defined before using it.

When inserting data into Vertica, Perl's DBI module attempts to coerce the data into the correct format. By default, it assumes column values are VARCHAR unless it can determine that they are some other data type. If given a string value to insert into a column that has an integer or numeric data type, DBI attempts to convert the string's contents to the correct data type. If the entire string can be converted to a value of the appropriate data type, it inserts the value into the column. If not, inserting the row of data fails.

DBI transparently converts integer values into numeric or float values when inserting into column of FLOAT, NUMERIC, or similar data types. It converts numeric or floating values to integers only when there would be no loss of precision (the value to the right of the decimal point is 0). For example, it can insert the value 3.0 into an INTEGER column since there is no loss of precision when converting the value to an integer. It cannot insert 3.1 into an INTEGER column, since that would result in a loss of precision. It returns an error instead of truncating the value to 3.

The following example demonstrates some of the conversions that the DBI module performs when inserting data into Vertica.

```
#!/usr/bin/perl
use strict;
use DBI;
# Create a hash reference that holds a hash of parameters for the
# connection.
my $attr = {AutoCommit => 0, # Turn off autocommit
            PrintError => 0 # Turn off print error. Manually handled
            };
# Open a connection using a DSN. Supply the username and password.
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN","ExampleUser","password123",
    $attr);
if (defined DBI::err) {
    # Connection failed.
    die "Failed to connect: $DBI::errstr";
}
print "Connection AutoCommit state is: " . $dbh->{AutoCommit} . "\n";
```

```

# Create table to hold inserted data
$dbh->do("DROP TABLE IF EXISTS TEST CASCADE;");
$dbh->do("CREATE TABLE TEST( \
    C_ID INT, \
    C_FP FLOAT, \
    C_VARCHAR VARCHAR(100), \
    C_DATE DATE, C_TIME TIME, \
    C_TS TIMESTAMP, \
    C_BOOL BOOL)");
# Populate an array of arrays with values.
my @data = (
    # Start with matching data types
    [1,1.111,'Matching datatypes','2001-01-01','01:01:01'
    , '2001-01-01 01:01:01','t'],
    # Force floats -> int and int -> float.
    [2.0,2,"Ints <-> floats",'2002-02-02','02:02:02'
    , '2002-02-02 02:02:02',1],
    # Float -> int *only* works when there is no loss of precision.
    # this row will fail to insert:
    [3.1,3,"float -> int with trunc?",'2003-03-03','03:03:03'
    , '2003-03-03 03:03:03',1],
    # String values are converted into numbers
    ["4","4.4","Strings -> numbers", '2004-04-04','04:04:04',
    , '2004-04-04 04:04:04',0],
    # String -> numbers only works if the entire string can be
    # converted into a number
    ["5 and a half","5.5","Strings -> numbers", '2005-05-05',
    , '05:05:05', '2005-05-05 05:05:05',0],
    # Number are converted into string values automatically,
    # assuming they fit into the column width.
    [6,6.6,3.14159, '2006-06-06','06:06:06',
    , '2006-06-06 06:06:06',0],
    # There are some variations in the accepted date strings
    [7,7.7,'Date/time formats', '07/07/2007','07:07:07',
    , '07-07-2007 07:07:07',1],
);
# Create a prepared statement to use parameters for inserting values.
my $sth = $dbh->prepare_cached("INSERT into test values(?,?,?,?,?,?)");
my $rowcount = 0; # Count # of rows
# Loop through the arrays to insert values
foreach my $tuple (@data) {
    $rowcount++;
    # Insert the row
    my $retval = $sth->execute(@$tuple);

    # See if the row was successfully inserted.
    if ($retval == 1) {
        # Value of 1 means the row was inserted (1 row was affected by insert)
        print "Row $rowcount successfully inserted\n";
    } else {
        print "Inserting row $rowcount failed with error " .
            $sth->state . " " . $sth->errstr . "\n";
    }
}
# Commit the data
$dbh->commit();
# Prepare a query to get the content of the table
my $sth = $dbh->prepare("SELECT * FROM TEST ORDER BY C_ID ASC");
my @row; # Need to pre-declare to use in the format statement.
# Use Perl formats to pretty print the output.

```

```

#!/usr/bin/perl
use strict;
use DBI;
# Open a connection using a DSN.
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN","ExampleUser","password123");
unless (defined $dbh) {
    # Connection failed.
    die "Failed to connect: $DBI::errstr";
}
# Output to a file. Displaying Unicode characters to a console or terminal
# window has many problems. This outputs a UTF-8 text file that can
# be handled by many Unicode-aware text editors:
open OUTFILE, '>:utf8', "unicodeout.txt";
# See if the DBD::ODBC driver was compiled with Unicode support. If this returns
# 1, your Perl script will get strings from the driver with the UTF-8
# flag set on them, ensuring that Perl handles them correctly.
print OUTFILE "Was DBD::ODBC compiled with Unicode support? " .
    $dbh->{odbc_has_unicode} . "\n";
# Create a table to hold VARCHARs
$dbh->do("DROP TABLE IF EXISTS TEST CASCADE;");
# Create a table to hold data. Remember that the width of the VARCHAR column
# is the number of bytes set aside to store strings, which often does not equal
# the number of characters it can hold when it comes to Unicode!
$dbh->do("CREATE TABLE test( C_VARCHAR VARCHAR(100) );");
print OUTFILE "Inserting data...\n";
# Use Do to perform simple inserts
$dbh->do("INSERT INTO test VALUES('Hello')");
# This string contains several non-latin accented characters and symbols, encoded
# with Unicode escape notation. They are converted by Perl into UTF-8 characters
$dbh->do("INSERT INTO test VALUES('My favorite band is " .
    "\N{U+00DC}m\N{U+00E4}\N{U+00FC}t \N{U+00D6}v\N{U+00EB}rk\N{U+00EF}ll" .
    " \N{U+263A}')");
# Some Chinese (Simplified) characters. This again uses escape sequence
# that Perl translates into UTF-8 characters.
$dbh->do("INSERT INTO test VALUES('\x{4F60}\x{597D}')");
print OUTFILE "Getting data...\n";
# Prepare a query to get the content of the table
my $sth = $dbh->prepare_cached("SELECT * FROM test");
# Execute the query by calling execute on the statement handle
$sth->execute();
# Loop through result rows while we have them
while (my @row = $sth->fetchrow_array()) {
    # Loop through the column values
    foreach my $column (@row) {
        print OUTFILE "$column\t";
    }
    print OUTFILE "\n";
}
close OUTFILE;
$dbh->disconnect();

```

Viewing the unicodeout.txt file in a UTF-8-capable text editor or viewer displays:

```

Was DBD::ODBC compiled with Unicode support? 1
Inserting data...
Getting data...
My favorite band is Ümläüt Övärkill ☺
你好
Hello

```

Note

Terminal windows and consoles often have problems properly displaying Unicode characters. That is why the example writes the output to a text file. With some text editors, you may need to manually set the encoding of the text file to UTF-8 in order for the characters to properly appear (and the font used to display text must have a full Unicode character set). If the character still do not show up, it may be that your version of DBD::ODBC was not compiled with UTF-8 support.

Python

The Vertica Python drivers provide an interface for Python client applications to interact with the database.

Prerequisites

You must [configure a Python development environment](#) before creating Python client applications.

Note

Both the Vertica Python client and Vertica ODBC driver (that pyodbc interacts with) do not support the native Vertica UUID data type. Values retrieved using these drivers from a UUID column are converted to strings. When your client queries the metadata for a UUID column, the drivers report its data type as a string. Convert any UUID values that you want to insert into a UUID column to strings. Vertica automatically converts these values into the native UUID data type before inserting them into a table.

In this section

- [Configuring the ODBC run-time environment on Linux](#)
- [Querying the database with pyodbc](#)

Configuring the ODBC run-time environment on Linux

To configure the ODBC run-time environment on Linux:

1. Create the `odbc.ini` file if it does not already exist.
2. Add the ODBC driver directory to the `LD_LIBRARY_PATH` system environment variable:

```
export LD_LIBRARY_PATH=/path-to-vertica-odbc-driver:$LD_LIBRARY_PATH
```

Important

If you skip Step 2, the ODBC manager cannot find the driver in order to load it.

These steps are relevant only for unixODBC and iODBC. See their respective documentation for details on [odbc.ini](#).

See also

- [unixODBC Web site](#)
- [iODBC Web site](#)

Querying the database with pyodbc

The example session below uses pyodbc with the Vertica ODBC driver to connect Python to the Vertica database.

Note

`SQLFetchScroll` and `SQLFetch` functions cannot be mixed together in iODBC code. When using pyodbc with the iODBC driver manager, `skip` cannot be used with the `fetchall`, `fetchone`, and `fetchmany` functions.

Example script

The following example script shows how to query Vertica using Python 3, pyodbc, and an ODBC DSN.

```

import pyodbc
cnxn = pyodbc.connect("DSN=VerticaDSN", ansi=True)
cursor = cnxn.cursor()
# create table
cursor.execute("CREATE TABLE TEST("
    "C_ID INT,"
    "C_FP FLOAT,"
    "C_VARCHAR VARCHAR(100),"
    "C_DATE DATE, C_TIME TIME,"
    "C_TS TIMESTAMP,"
    "C_BOOL BOOL)")
cursor.execute("INSERT INTO test VALUES(1,1.1,'abcdefg1234567890','1901-01-01','23:12:34','1901-01-01 09:00:09','t')")
cursor.execute("INSERT INTO test VALUES(2,3.4,'zxcasdqwe09876543','1991-11-11','00:00:01','1981-12-31 19:19:19','f')")
cursor.execute("SELECT * FROM TEST")
rows = cursor.fetchall()
for row in rows:
    print(row, end='\n')
cursor.execute("DROP TABLE TEST CASCADE")
cursor.close()
cnxn.close()

```

The resulting output displays:

```

(2, 3.4, 'zxcasdqwe09876543', datetime.date(1991, 11, 11), datetime.time(0, 0, 1), datetime.datetime(1981, 12, 31, 19, 19, 19), False)
(1, 1.1, 'abcdefg1234567890', datetime.date(1901, 1, 1), datetime.time(23, 12, 34), datetime.datetime(1901, 1, 1, 9, 0, 9), True)

```

Notes

SQLPrimaryKeys returns the table name in the primary (`pk_name`) column for unnamed primary constraints. For example:

- Unnamed primary key:

```
CREATE TABLE schema.test(c INT PRIMARY KEY);
```

SQLPrimaryKeys

```
"TABLE_CAT", "TABLE_SCHEM", "TABLE_NAME", "COLUMN_NAME", "KEY_SEQ", "PK_NAME" <Null>, "SCHEMA", "TEST", "C", 1, "TEST"
```

- Named primary key:

```
CREATE TABLE schema.test(c INT CONSTRAINT pk_1 PRIMARY KEY);
```

SQLPrimaryKeys

```
"TABLE_CAT", "TABLE_SCHEM", "TABLE_NAME", "COLUMN_NAME", "KEY_SEQ", "PK_NAME" <Null>, "SCHEMA", "TEST", "C", 1, "PK_1"
```

OpenText recommends that you name your constraints.

- [Loading data](#)

PHP

Note

You must [configure a PHP development environment](#) before creating PHP client applications.

Setup

You must read [C/C++](#) before connecting to Vertica through PHP. The following example ODBC configuration entries detail the typical settings required for PHP ODBC connections. The driver location assumes you have copied the Vertica drivers to `/usr/lib64`.

Example odbc.ini

```
[ODBC Data Sources]
VerticaDSNunixodbc = exampleldb
VerticaDNSiodbc = exampledb2
[VerticaDSNunixodbc]
Description = VerticaDSN Unix ODBC driver
Driver = /usr/lib64/libverticaodbc.so
Database = Telecom
Servername = localhost
Username = dbadmin
Password =
Port = 5433
[VerticaDNSiodbc]
Description = VerticaDSN iODBC driver
Driver = /usr/lib64/libverticaodbc.so
Database = Telecom
Servername = localhost
Username = dbadmin
Password =
Port = 5433
```

Example odbcinst.ini

```
# Vertica
[VerticaDSNunixodbc]
Description = VerticaDSN Unix ODBC driver
Driver = /usr/lib64/libverticaodbc.so
[VerticaDNSiodbc]
Description = VerticaDSN iODBC driver
Driver = /usr/lib64/libverticaodbc.so
[ODBC]
Threading = 1
```

Verify the Vertica UnixODBC or iODBC library

Verify the Vertica UnixODBC library can load all dependant libraries with the following command (assuming you have copies the libraries to /usr/lib64):

For example:

```
ldd /usr/lib64/libverticaodbc.so
```

You must resolve any "not found" libraries before continuing.

Test your ODBC connection

Test your ODBC connection with the following.

```
isql -v VerticaDSN
```

In this section

- [Configuring a PHP development environment](#)
- [PHP unicode support](#)
- [Querying the database using PHP](#)

Configuring a PHP development environment

To configure a PHP development environment:

1. [Install and configure ODBC](#).
2. Install PHP.
3. Install the PDO and ODBC PHP extensions. On Linux, these are available as the following packages:
 - php-odbc
 - php-pdo

PHP unicode support

PHP does not offer native Unicode support. PHP only supports a 256-character set. However, PHP provides the UTF-8 functions [utf8_encode\(\)](#) and [utf8_decode\(\)](#) to provide some basic Unicode functionality.

See the PHP manual for [strings](#) for more details about PHP and Unicode.

Querying the database using PHP

The example script below details the use of PHP ODBC functions to connect to the Vertica Analytics Platform.

```

<?php
# Turn on error reporting
error_reporting(E_ERROR | E_WARNING | E_PARSE | E_NOTICE);
# A simple function to trap errors from queries
function odbc_exec_echo($conn, $sql) {
    if(!$rs = odbc_exec($conn,$sql)) {
        echo "<br/>Failed to execute SQL: $sql<br/>" . odbc_errormsg($conn);
    } else {
        echo "<br/>Success: " . $sql;
    }
    return $rs;
}
# Connect to the Database
$dsn = "VerticaDSNunixodbc";
$conn = odbc_connect($dsn, "", "") or die ("<br/>CONNECTION ERROR");
echo "<p>Connected with DSN: $dsn</p>";
# Create a table
$sql = "CREATE TABLE TEST(
    C_ID INT,
    C_FP FLOAT,
    C_VARCHAR VARCHAR(100),
    C_DATE DATE, C_TIME TIME,
    C_TS TIMESTAMP,
    C_BOOL BOOL)";
$result = odbc_exec_echo($conn, $sql);
# Insert data into the table with a standard SQL statement
$sql = "INSERT into test values(1,1.1,'abcdefg1234567890','1901-01-01','23:12:34',
'1901-01-01 09:00:09','t')";
$result = odbc_exec_echo($conn, $sql);
# Insert data into the table with odbc_prepare and odbc_execute
$values = array(2,2.28,'abcdefg1234567890','1901-01-01','23:12:34','1901-01-01 0
9:00:09','t');
$statement = odbc_prepare($conn,"INSERT into test values(?,?,?, ?, ?, ?)");
if(!$result = odbc_execute($statement, $values)) {
    echo "<br/>odbc_execute Failed!";
} else {
    echo "<br/>Success: odbc_execute.";
}
# Get the data from the table and display it
$sql = "SELECT * FROM TEST";
if($result = odbc_exec_echo($conn, $sql)) {
    echo "<pre>";
    while($row = odbc_fetch_array($result) ) {
        print_r($row);
    }
    echo "</pre>";
}
# Drop the table and projection
$sql = "DROP TABLE TEST CASCADE";
$result = odbc_exec_echo($conn, $sql);
# Close the ODBC connection
odbc_close($conn);
?>

```

Example output

The following is the example output from the script.

```
Success: CREATE TABLE TEST( C_ID INT, C_FP FLOAT, C_VARCHAR VARCHAR(100), C_DATE DATE, C_TIME TIME, C_TS TIMESTAMP, C_BOOL
BOOL)
Success: INSERT into test values(1,1.1,'abcdefg1234567890','1901-01-01','23:12:34 ','1901-01-01 09:00:09','t')
Success: odbc_execute.
Success: SELECT * FROM TEST
Array
(
  [C_ID] => 1
  [C_FP] => 1.1
  [C_VARCHAR] => abcdefg1234567890
  [C_DATE] => 1901-01-01
  [C_TIME] => 23:12:34
  [C_TS] => 1901-01-01 09:00:09
  [C_BOOL] => 1
)
Array
(
  [C_ID] => 2
  [C_FP] => 2.28
  [C_VARCHAR] => abcdefg1234567890
  [C_DATE] => 1901-01-01
  [C_TIME] => 23:12:34
  [C_TS] => 1901-01-01 23:12:34
  [C_BOOL] => 1
)
Success: DROP TABLE TEST CASCADE
```

Managing query execution between the client and Vertica

The following topics describe techniques that help you manage query execution between your client and your Vertica database.

In this section

- [ResultBufferSize](#)
- [Multiple active result sets \(MARS\)](#)

ResultBufferSize

By default, Vertica uses the ResultBufferSize parameter to determine the maximum size (in bytes) of a result set that a client can retrieve from a server. When ResultBufferSize is enabled, Vertica sends rows of data directly to the client making the query. The number of rows returned to the client at each fetch of data depends on the size (in bytes) of the ResultBufferSize parameter.

Sometimes, the size of the result set requested by the client is greater than what the ResultBufferSize parameter allows. In such cases, Vertica retrieves only a portion of the result set at a time. Each fetch of data returns the amount of data equal to the size set by the ResultBufferSize parameter. Ultimately, as the client iterates over the individual fetches of data, the entire result set is returned.

Benefits of ResultBufferSize

If you are concerned with the effect of your queries on network latency, ResultBufferSize may provide an advantage over MARS. MARS requires that the client wait until all rows of data are written to the server before the client can retrieve the data. This delay may cause latency issues for your network while waiting for the results to be stored.

In addition, MARS requires that you send two separate requests to return rows of data. The first request performs the query execution which stores the result set on the server. The second request retrieves the data rows that are stored on the server. With ResultBufferSize, you only need to send one request. This request both executes and retrieves the data rows of interest.

Query execution with ResultBufferSize

The following graphic shows how Vertica returns rows of data from a database to the client with ResultBufferSize enabled:

The query execution performs the following steps:

1. The client sends a query, such as a [SELECT](#) statement, to the server. In the preceding graphic, the first query is named Query 1.
2. The server receives the client's request and begins to send both a description of the result set and the requested rows of data back to the client.
3. After all possible rows are returned to the client, the execution is complete. The size of the data set returned equals either that of the data that was requested or the maximum amount of data that ResultBufferSize parameter can retrieve. If the ResultBufferSize maximum size is not yet reached, Vertica can execute Query 2.

The server can accept Query 2 and perform the same steps that it did for Query 1. If the results for Query 1 had reached the maximum ResultBufferSize allowable, Vertica could not execute Query 2 until the client freed the results from Query 1.

After Query 2 runs, you cannot view the results you retrieved for Query 1, unless you execute Query 1 again.

Setting an unlimited buffer size

Setting ResultBufferSize to 0 tells the client driver to use an unlimited result set buffer. With this setting, the client library allocates as much memory as it needs to read the entire result set of a query. You may choose to set ResultBufferSize to 0 if you want to simulate having multiple active queries over a single database connection at the same time. With an unlimited buffer size, your client can run a query and have its entire result set stored in memory. This ends the first query, so your client can execute a second query before it fully processes the results of the first query.

A drawback of this method is that your query may consume too much memory if your queries return large result sets. This over-allocation of memory can result in the operating system terminating your client. Due to this risk, consider using multiple database connections instead of trying to reuse a single connection for multiple queries. The overhead of multiple database connections is small compared to the overall amount of resources required to process a large data set.

Multiple active result sets (MARS)

You can only enable MARS when you connect to Vertica using a JDBC client connection. MARS allows the execution of multiple queries on a single connection. While ResultBufferSize sends the results of a query directly to the client, MARS stores the results first on the server. Once query execution has finished and all of the results have been stored, you can make a retrieval request to the server to have rows returned to the client.

MARS is set at the session level and must be enabled for every new session. When MARS is enabled, ResultBufferSize is disabled. No error is returned, however the ResultBufferSize parameter is ignored.

Benefits of MARS

In comparison with ResultBufferSize, MARS enables you to store multiple result sets from different queries at the same time. You can also send new queries before all of the results of a previous result set have been returned to the client. This allows applications to decouple query execution from result retrieval so that, on a single connection, you can process different results at the same time.

When you enable ResultBufferSize, you must wait until all result sets have been returned to the client before a new query can be executed.

Another benefit of MARS is that it allows you to free up query resources faster than ResultBufferSize allows. While a query is running, resources are held by that query session. When ResultBufferSize is enabled, a client that is performing slowly might read a single row of a result set and then have to stop to retrieve the next row. This prevents the query from finishing quickly and, therefore, prevents the resources used from being freed up for other applications. With MARS, the speed of the client is irrelevant to the reading of rows. As soon as the results are written to the MARS storage, the resources are freed and the speed at which the client retrieves rows no longer matters.

Query execution with MARS

The following graphic demonstrates how multiple queries to the server are handled when MARS is enabled:

Query 1:

- Query 1 is sent to the server.
- Query 1's row description and the status of its result set are returned to the client. However, no results are returned to the client at this time.
- Query 1 completes and its results are saved on the server.
 - You can now send commands to retrieve the rows of Query 1's result set. These rows are stored on the server. Retrieved rows are sent to the client along with the status of the result set. By keeping track of the status of the result set, Vertica is able to keep track of which rows have been retrieved from the server.

4. Now that Query 1 has successfully completed, and its result sets are being stored on the server, Query 2 can be executed.

Query 2:

1. Query 2 is sent to the server.
2. Query 2's row description and the status of its result set are returned to the client. However, no results are returned to the client at this time.
3. Query 2 completes and its results are stored on the server. Both Query 1 and Query 2 now have result sets stored on the server.
4. You can now send retrieval requests to both Query 1 and Query 2's result sets that are stored on the server. Whenever a retrieval request is made for rows from Query 1, the request is sent and rows and the result set status are sent to the client. The same occurs for Query 2.

Once all rows have been read by the client, the MARS storage on the server closes the active results session. The MARS storage on the server is then freed to store more data. The MARS storage also closes and frees once your session is finished.

Enabling and disabling MARS

You can enable and disable MARS in two different ways:

1. To enable MARS using the JDBC client connection properties, see [JDBC connection properties](#).
2. To enable MARS using the SET SESSION command, see [SET SESSION MULTIPLEACTIVERESULTSETS](#).

- [CLOSE_ALL_RESULTSETS](#)

Management API

The Management API is a REST API that you can use to view and manage Vertica databases with scripts or applications that accept REST and JSON. The response format for all requests is JSON.

In this section

- [cURL](#)
- [General API information](#)
- [Rest APIs for the agent](#)
- [Rest APIs for the Management Console](#)

cURL

cURL is a command-line tool and application library used to transfer data to or from a server. All API requests sent to a Vertica server must be made with [HTTPS](#).

There are four HTTP requests that can be passed using cURL to call API methods:

- GET: Retrieves data.
- PUT: Updates data.
- POST: Creates new data.
- DELETE: Deletes data.

Syntax

```
curl https://<NODE>:5444/
```

Options

The following is a truncated list of options. For a complete list, see the [cURL documentation](#).

<code>-h --help</code>	Lists all available options.
<code>-H --header</code>	Specifies custom headers. This is useful for sending a request that requires a Vertica API key. Example: <pre>\$ curl -H "VerticaApiKey: ValidAPIKey" https://<NODE>:5444/</pre>

<p>-k --insecure</p>	<p>Connects with TLS without validating the database's server certificate.</p> <p>Example:</p> <pre>\$ curl -k https://<NODE>:5444/</pre>
<p>-X --request</p>	<p>Specifies a request type, one of the following:</p> <ul style="list-style-type: none"> • GET (default) • PUT • POST • DELETE <p>Example:</p> <pre>\$ curl -X REQUEST https://<NODE>:5444/</pre>

General API information

These API calls can interact with either standard Vertica nodes or Management Console nodes.

<p>GET /</p>	<p>Returns the agent-specific information useful for version checking and service discovery.</p>
<p>GET api</p>	<p>Returns a list of api objects and properties.</p>

In this section

- [GET /](#)
- [GET api](#)

GET /

Returns API version information and a list of links to child resources for the Management API.

Resource URL

```
https://<NODE>:5444/
```

Authentication

Not required.

Parameters

None.

Rest APIs for the agent

These API calls interact with standard Vertica nodes.

Backup and restore

GET backups	Returns all the backups that have been created for all vbr configuration files (*.ini) that are located in the <code>/opt/vertica/config</code> directory.
POST backups/:config_script_base	Creates a new backup as defined by the given vbr configuration script base (filename without the .ini extension).
GET backups/:config_script_base/:archive_id	Returns details for a specific backup archive.
POST restore/:archive_id	Restores a backup.

Databases

GET databases	Returns a list of databases, their properties, and current status.
POST databases	Creates a new database by supplying a valid set of parameters.
GET databases/:database_name	Returns details about a specific database.
PUT databases/:database_name	Starts, stops, rebalances, or runs Workload Analyzer on a database.
DELETE databases/:database_name	Deletes an existing database.
GET databases/:database_name/configuration	Returns the current configuration parameters from the database.
PUT databases/:database_name/configuration	Sets one or more configuration parameters in the database.
GET databases/:database_name/hosts	Returns hosts details for a specific database.
POST databases/:database_name/hosts	Adds a new host to the database.
DELETE databases/:database_name/hosts/:host_id	Removes a host from the database.
POST databases/:database_name/hosts/:host_id/process	Starts the database process on a specific host.
DELETE databases/:database_name/hosts/:host_id/process	Stops the database on a specific host.
POST databases/:database_name/hosts/:host_id/replace_with/:host_id_new	Replaces a host with a standby host in the database.
GET databases/:database_name/license	Returns the Vertica license that the specified database is using.
GET databases/:database_name/licenses	Returns all the feature licenses that the specified database is using.
GET databases/:database_name/nodes	Returns a list of nodes for the specified database.
GET databases/:database_name/nodes/:node_id	Returns details on a specific node for the specified database.
POST databases/:database_name/process	Starts the specified database.

GET databases/:database_name/process	Returns the state of the database as either UP or DOWN.
DELETE databases/:database_name/process	Stops the specified database on all hosts.
POST databases/:database_name/rebalance/process	Rebalances the specified database. This option can have a long run time.
GET databases/:database_name/status [broken]	Retrieves the database properties structure.
POST databases/:database_name/Workload Analyzer/process	Runs the analyze workload action against the specified database. This option can have a long run time.

Hosts

GET hosts	Returns a list of hosts in this cluster.
GET hosts/:hostid	Returns details for a specific host in this cluster.

Jobs

GET jobs	Returns a list of jobs the agent is tracking, along with their current status and exit codes.
GET jobs/:id	Returns the details (the saved output) for a specific job.

Licenses

POST licenses	Uploads and applies a new license to this cluster.
GET licenses	Returns the license field that databases created on this cluster use.

Nodes

GET nodes	Returns a list of nodes in this cluster.
GET nodes/:nodeid	Returns details for a specific node in this cluster.

Webhooks

GET webhooks	Returns a list of active webhooks.
POST webhooks/subscribe	Creates a new webhook.
DELETE webhooks/:subscriber_id	Deletes an existing webhook.

VerticaAPIKey

The Management API requires an authentication key, named VerticaAPIKEY, to access some API resources. You can manage API keys by using the **apikeymgr** command-line tool.

```
usage: apikemgr [-h] [--user REQUESTOR] [--app APPLICATION] [--delete]
               [--create] [--update] [--migrate]
               [--secure {restricted,normal,admin}] [--list]
```

API key management tool

optional arguments:

```
-h, --help            show this help message and exit
--user REQUESTOR      The name of the person requesting the key
--app APPLICATION      The name of the application that will use the key
--delete              Delete the key for the given R & A
--create              Create a key for the given R & A
--update              Update a key for the given R & A
--migrate             migrate the keyset to the latest format
--secure {restricted,normal,admin}
                    Set the keys security level
--list               List all the keys known
```

Example request

To create a new VerticaAPIKEY for the `dbadmin` user with `admin` access, enter the following:

```
$ apikemgr --user dbadmin --app vertica --create --secure admin
```

Response:

```
Requestor : dbadmin
Application: vertica
API Key   : ValidAPIKey
Synchronizing cluster...
```

Backup and restore

You can use these API calls to perform backup and restore tasks for your database.

GET backups	Returns all the backups that have been created for all vbr configuration files (*.ini) that are located in the <code>/opt/vertica/config</code> directory.
POST backups/:config_script_base	Creates a new backup as defined by the given vbr configuration script base (filename without the .ini extension).
GET backups/:config_script_base/:archive_id	Returns details for a specific backup archive.
POST restore/:archive_id	Restores a backup.

In this section

- [POST backups/:config_script_base](#)
- [GET backups/:config_script_base/:archive_id](#)
- [POST restore/:archive_id](#)

GET backups

Returns a list of all backups created for vbr configuration (*.ini) files that reside in `/opt/vertica/config` and provides details about each backup.

Resource URL

```
https://<NODE>:5444/backups
```

Authentication

Requires a [VerticaAPIKey](#) in the request header.

The API key must have **restricted** level security or higher.

Parameters

None.

Example request

GET	<a href="https://<NODE>:5444/backups">https://<NODE>:5444/backups
------------	---

Response:

```
{
  "data": [
    {
      "backups": [
        {
          "archive_id": "v_vdb_bk_snapshot_20190305_174428",
          "version": "v9.2.1-20190305",
          "href": "/backups/fullbk/v_vdb_bk_snapshot_20190305_174428",
          "exclude_patterns": "",
          "backup_type": "full",
          "include_patterns": "",
          "epoch": "16",
          "objects": "",
          "hosts": "v_vdb_bk_node0001(10.20.91.240), v_vdb_bk_node0002(10.20.91.241), v_vdb_bk_node0003(10.20.91.242), v_vdb_bk_node0004(10.20.91.243), v_vdb_bk_node0005(10.20.91.244)"
        },
        {
          "archive_id": "v_vdb_bk_snapshot_20190305_174025",

          "exclude_patterns": "",
          "backup_type": "full",
          "include_patterns": "",
          "epoch": "16",
          "objects": "",
          "hosts": "v_vdb_bk_node0001(10.20.91.240), v_vdb_bk_node0002(10.20.91.241), v_vdb_bk_node0003(10.20.91.242), v_vdb_bk_node0004(10.20.91.243), v_vdb_bk_node0005(10.20.91.244)"
        }
      ],
      "config_file": "/opt/vertica/config/fullbk.ini",
      "config_script_base": "fullbk",
      "num_backups": 2
    }
  ],
  "href": "/backups",
  "mime-type": "application/vertica.databases.json-v2"
}
```

POST backups/:config_script_base

Creates a new backup job for the backup defined in the vbr configuration script `:config_script_base`. The vbr configuration script must reside in `/opt/vertica/configuration`. The `:config_script_base` value does not include the `.ini` filename extension.

To determine valid `:config_script_base` values, see [GET backups](#).

Returns a job ID that you can use to determine the status of the job.

Resource URL

<a href="https://<NODE>:5444/backups/:config_script_base">https://<NODE>:5444/backups/:config_script_base

Authentication

Requires a [VerticaAPIKey](#) in the request header.

The API key must have **restricted** level security or higher.

Parameters

None.

Example request

POST	<a href="https://<NODE>:5444/backups/backup3">https://<NODE>:5444/backups/backup3
-------------	---

Response:

```
{
  "id": "CreateBackup-VMart-1404750602.03",
  "url": "/jobs/CreateBackup-VMart-1404750602.03"
}
```

GET backups/:config_script_base/:archive_id

Returns details on a specific backup. You must provide the `:config_script_base`. This value is the name of a vbr config file (without the .ini filename extension) that resides in `/opt/vertica/config`. The `:archive_id` is the value of the `backup` field that the [GET backups](#) command returns.

Resource URL

https://<NODE>:5444/backups/:config_script_base/:archive_id

Authentication

Requires a [VerticaAPIKey](#) in the request header.

The API key must have **restricted** level security or higher.

Parameters

None.

Example request

GET	<a href="https://<NODE>:5444/backups/fullbk/v_vdb_bk_snapshot_20190304_204814">https://<NODE>:5444/backups/fullbk/v_vdb_bk_snapshot_20190304_204814
------------	---

Response:

```
{
  "archive_id": "v_vdb_bk_snapshot_20190304_204814",
  "config_file": "/opt/vertica/config/fullbk.ini",
  "objects": "",
  "href": "/backups/fullbk/v_vdb_bk_snapshot_20190304_204814",
  "exclude_patterns": "",
  "epoch": "16",
  "include_patterns": "",
  "backup_type": "full",
  "version": "v9.2.1-20190304",
  "hosts": "v_vdb_bk_node0001(10.20.91.240),
  v_vdb_bk_node0002(10.20.91.241),
  v_vdb_bk_node0003(10.20.91.242),
  v_vdb_bk_node0004(10.20.91.243),
  v_vdb_bk_node0005(10.20.91.244)"
}
```

POST restore/:archive_id

Creates a new restore job to restore the database from the backup archive identified by `:archive_id`. The `:archive_id` is the value of a `backup` field that the [GET backups](#) command returns.

Returns a job ID that you can use to determine the status of the job. See [GET jobs](#).

Resource URL

https://<NODE>:5444/restore/:archive_id

Authentication

Requires a [VerticaAPIKey](#) in the request header.

The API key must have **restricted** level security or higher.

Parameters

None.

Example request

POST	<a href="https://<NODE>:5444/restore/backup3_20140707_132904">https://<NODE>:5444/restore/backup3_20140707_132904
-------------	---

Response:

```
{
  "id": "RestoreBackup-VMart-1404760113.71",
  "url": "/jobs/RestoreBackup-VMart-1404760113.71"
}
```

Databases

You can use these API calls to interact with your database.

GET databases	Returns a list of databases, their properties, and current status.
POST databases	Creates a new database by supplying a valid set of parameters.
GET databases/:database_name	Returns details about a specific database.
PUT databases/:database_name	Starts, stops, rebalances, or runs Workload Analyzer on a database.
DELETE databases/:database_name	Deletes an existing database.
GET databases/:database_name/configuration	Returns the current configuration parameters from the database.
PUT databases/:database_name/configuration	Sets one or more configuration parameters in the database.
GET databases/:database_name/hosts	Returns hosts details for a specific database.
POST databases/:database_name/hosts	Adds a new host to the database.
DELETE databases/:database_name/hosts/:host_id	Removes a host from the database.
POST databases/:database_name/hosts/:host_id/process	Starts the database process on a specific host.
DELETE databases/:database_name/hosts/:host_id/process	Stops the database on a specific host.
POST databases/:database_name/hosts/:host_id/replace_with/:host_id_new	Replaces a host with a standby host in the database.
GET databases/:database_name/license	Returns the Vertica license that the specified database is using.
GET databases/:database_name/licenses	Returns all the feature licenses that the specified database is using.
GET databases/:database_name/nodes	Returns a list of nodes for the specified database.
GET databases/:database_name/nodes/:node_id	Returns details on a specific node for the specified database.
POST databases/:database_name/process	Starts the specified database.
GET databases/:database_name/process	Returns the state of the database as either UP or DOWN.

DELETE databases/:database_name/process	Stops the specified database on all hosts.
POST databases/:database_name/rebalance/process	Rebalances the specified database. This option can have a long run time.
GET databases/:database_name/status [broken]	Retrieves the database properties structure.
POST databases/:database_name/Workload Analyzer/process	Runs the analyze workload action against the specified database. This option can have a long run time.

GET databases

Returns a list of databases, their current status, and database properties.

Resource URL

```
https://<NODE>:5444/databases
```

Authentication

Requires a [VerticaAPIKey](#) in the request header.

The API key must have **restricted** level security or higher.

Parameters

None.

Example request

GET	<a href="https://<NODE>:5444/databases">https://<NODE>:5444/databases
------------	---

An example of the full request using cURL:

```
curl -H "VerticaApiKey: ValidAPIKey" https://<NODE>:5444/databases
```

Response:

```
{
  "body": [
    {
      "href": "/databases/VMart",
      "mime-type": [
        "application/vertica.database.json-v2"
      ],
      "name": "VMart",
      "port": "5433",
      "status": "UP"
    },
    {
      "href": "/databases/testDB",
      "mime-type": [
        "application/vertica.database.json-v2"
      ],
      "name": "testDB",
      "port": "5433",
      "status": "DOWN"
    }
  ],
  "href": "/databases",
  "links": [
    "/:database_name"
  ],
  "mime-type": "application/vertica.databases.json-v2"
}
```

POST databases

Creates a job to create a new database with the provided parameters.

Important

You must stop any running databases on the nodes on which you want to create the new database. If you do not, database creation fails.

Returns a job ID that can be used to determine the status of the job. See [GET jobs](#).

Resource URL

`https://<NODE>:5444/databases`

Authentication

Requires a [VerticaAPIKey](#) in the request header.

The API key must have **admin** level security.

Parameters

name	Name of the database to create.
passwd	Password for the new database.
only	Optional list of hostnames to include in the database. By default, all nodes in the cluster are added to the database.
exclude	Optional list of hostnames to exclude from the database.
catalog	Path of the catalog directory.
data	Path of the data directory.
port	Port where the database listens for client connections. Default is 5433.

Example request

POST

```
https://:5444/databases?passwd=db_password&name=db_name&catalog=%2Fpath%2Fto%2Fcatalog&data=%2Fpath%2Fto%2Fdata_directory
```

Response:

```
{
  "jobid": "CreateDatabase-testDB-2014-07-07 15:49:53.219445",
  "resource": "/jobs/CreateDatabase-testDB-2014-07-07 15:49:53.219445",
  "userid": "dbadmin"
}
```

GET databases/:database_name

Returns details about a specific database. The `:database_name` is the value of the `name` field that the [GET databases](#) command returns.

Resource URL

```
https://<NODE>:5444/databases/:database_name
```

Authentication

Requires a [VerticaAPIKey](#) in the request header.

The API key must have **restricted** level security or higher.

Parameters

None.

Example request

GET

```
https://<NODE>:5444/databases/VMart
```

Response:

```

{
  "body": {
    "database_id": "VMart",
    "id": "VMart",
    "nodes": "v_vmart_node0001,v_vmart_node0002,v_vmart_node0003",
    "nodes_new": [
      {
        "catalog_base": "/home/dbadmin",
        "data_base": "/home/dbadmin",
        "host": "10.20.100.247",
        "id": "v_vmart_node0001"
      },
      {
        "catalog_base": "/home/dbadmin",
        "data_base": "/home/dbadmin",
        "host": "10.20.100.248",
        "id": "v_vmart_node0002"
      },
      {
        "catalog_base": "/home/dbadmin",
        "data_base": "/home/dbadmin",
        "host": "10.20.100.249",
        "id": "v_vmart_node0003"
      }
    ],
    "path": "/home/dbadmin/VMart",
    "port": "5433",
    "restartpolicy": "ksafe",
    "status": "UP"
  },
  "href": "/databases/VMart",
  "links": [
    "/configuration",
    "/hosts",
    "/license",
    "/nodes",
    "/process",
    "/rebalance/process",
    "/status",
    "/Workload Analyzer/process"
  ],
  "mime-type": "application/vertica.database.json-v2"
}

```

PUT databases/:database_name

Creates a job to run the action specified by the *action* parameter against the database identified by *:database_name*. The *:database_name* is the value of the *name* field that the [GET databases](#) command returns.

Returns a job ID that you can use to determine the status of the job. See [GET jobs](#).

Resource URL

`https://<NODE>:5444/databases/:database_name`

Authentication

Requires a [VerticaAPIKey](#) in the request header.

The API key must have **normal** level security or higher.

Parameters

<code>user_id</code>	A database username.
----------------------	----------------------

passwd	A password for the username.
action	Can be one of the following values: <ul style="list-style-type: none"> • start — Start the database. • stop — Stop the database. • rebalance — Rebalance the database. • Workload Analyzer — Run Work Load Analyzer against the database.

Example request

PUT	<code>https://:5444/databases/testDB?user_id= username &passwd= username_password &action=stop</code>
------------	---

Response:

```
{
  "id": "StopDatabase-testDB-2014-07-20 13:28:49.321744",
  "url": "/jobs/StopDatabase-testDB-2014-07-20 13:28:49.321744"
}
```

DELETE databases/:database_name

Creates a job to delete (drop) an existing database on the cluster. To perform this operation, you must first stop the database. The :database_name is the value of the name field that the [GET databases](#) command returns.

Returns a job ID that you can use to determine the status of the job. See [GET jobs](#).

Resource URL

```
https://<NODE>:5444/databases/:database_name
```

Authentication

Requires a [VerticaAPIKey](#) in the request header.

The API key must have **admin** level security.

Parameters

None.

Example request

DELETE	<code>https://<NODE>:5444/databases/TestDB</code>
---------------	---

Response:

```
{
  "id": "DropDatabase-TestDB-2014-07-18 12:50:33.332383",
  "url": "/jobs/DropDatabase-TestDB-2014-07-18 12:50:33.332383"
}
```

GET databases/:database_name/configuration

Returns a list of configuration parameters for the database identified by :database_name . The :database_name is the value of the name field that the [GET databases](#) command returns.

Resource URL

```
https://<NODE>:5444/databases/:database_name/configuration
```

Authentication

Requires a [VerticaAPIKey](#) in the request header.

The API key must have **restricted** level security or higher.

Parameters

user_id	A database username.
passwd	The password for the username.

Example request

GET	https://:5444/databases/testDB/configuration?user_id= username &passwd= username_password
------------	---

Response:

This API call returns over 100 configuration parameters.. The following response is a small subset of the total amount returned.

```
[
  {
    "node_name": "ALL",

```

PUT databases/:database_name/configuration

Sets one or more configuration parameters for the database identified by :database_name . The :database_name is the value of the name field that the [GET databases](#) command returns.

Returns the parameter name, the requested value, and the result of the attempted change (Success or Failed).

Resource URL

`https://<NODE>:5444/databases/:database_name/configuration`

Authentication

Requires a [VerticaAPIKey](#) in the request header.

The API key must have **admin** level security.

Parameters

<code>user_id</code>	A database username.
<code>passwd</code>	The password for the username.
<code>parameter_name</code>	A parameter name and value combination for the parameter to be changed. Values must be URL encoded. You can include multiple name/value pairs to set multiple parameters with a single API call.

Example request

PUT	<code>https://:5444/databases/testDB/configuration?user_id=username&passwd=username_password &JavaBinaryForUDx=%2Fusr%2Fbin%2Fjava&TransactionIsolationLevel=SERIALIZABLE</code>
------------	--

Response:

```
[
  {
    "key": "JavaBinaryForUDx",
    "result": "Success",
    "value": "/usr/bin/java"
  },
  {
    "key": "TransactionIsolationLevel",
    "result": "Success",
    "value": "SERIALIZABLE"
  }
]
```

GET databases/:database_name/hosts

Returns the hostname/IP address, node name, and UP/DOWN status of each host associated with the database identified by `:database_name`. The `:database_name` is the value of the `name` field that the [GET databases](#) command returns.

Resource URL

`https://<NODE>:5444/databases/:database_name/hosts`

Authentication

Requires a [VerticaAPIKey](#) in the request header.

The API key must have **restricted** level security or higher.

Parameters

None.

Example request

GET	<code>https://<NODE>:5444/databases/VMart/hosts</code>
------------	--

Response:

```
{
  "body": [
    {
      "hostname": "10.20.100.247",
      "nodename": "v_vmart_node0001",
      "status": "UP",
      "ts": "2014-07-18T13:12:31.904191"
    },
    {
      "hostname": "10.20.100.248",
      "nodename": "v_vmart_node0002",
      "status": "UP",
      "ts": "2014-07-18T13:12:31.904209"
    },
    {
      "hostname": "10.20.100.249",
      "nodename": "v_vmart_node0003",
      "status": "UP",
      "ts": "2014-07-18T13:12:31.904215"
    }
  ],
  "href": "/databases/VMart/hosts",
  "links": [],
  "mime-type": "application/vertica.hosts.json-v2"
}
```

POST databases/:database_name/hosts

Creates a job to add a host to the database identified by `:database_name` . This host must already be part of the cluster. The `:database_name` is the value of the `name` field that the [GET databases](#) command returns.

Returns a job ID that you can use to determine the status of the job. See [GET jobs](#).

Resource URL

`https://<NODE>:5444/databases/:database_name/hosts`

Authentication

Requires a [VerticaAPIKey](#) in the request header.

The API key must have **admin** level security.

Parameters

<code>user_id</code>	A database username.
<code>passwd</code>	The password for the username.
<code>hostname</code>	The hostname to add to the database. This host must already be part of the cluster.

Example request

```
POST https://:5444/databases/testDB/hosts?hostname=192.168.232.181&user_id= username &passwd= username_password
```

Response:

```
{
  "id": "AddHostToDatabase-testDB-2014-07-20 12:24:04.088812",
  "url": "/jobs/AddHostToDatabase-testDB-2014-07-20 12:24:04.088812"
}
```

DELETE databases/:database_name/hosts/:host_id

Creates a job to remove the host identified by `:host_id` from the database identified by `:database_name` . The `:database_name` is the value of the `name`

field that the [GET databases](#) command returns. The `:host_id` is the value of the `host` field returned by [GET databases/:database_name](#).

Returns a job ID that you can use to determine the status of the job. See [GET jobs](#).

Resource URL

```
https://<NODE>:5444/databases/:database_name/hosts/:host_id
```

Authentication

Requires a [VerticaAPIKey](#) in the request header.

The API key must have **admin** level security.

Parameters

<code>user_id</code>	A database username.
<code>passwd</code>	A password for the username.

Example request

DELETE	<code>https://:5444/databases/testDB/hosts/192.168.232.181?user_id= username &passwd= username_password</code>
---------------	--

Response:

```
{
  "id": "RemoveHostFromDatabase-testDB-2014-07-20 13:41:15.646235",
  "url": "/jobs/RemoveHostFromDatabase-testDB-2014-07-20 13:41:15.646235"
}
```

POST `databases/:database_name/hosts/:host_id/process`

Creates a job to start the vertica process for the database identified by `:database_name` on the host identified by `:host_id`. The `:database_name` is the value of the `name` field that the [GET databases](#) command returns. The `:host_id` is the value of the `host` field returned by [GET databases/:database_name](#).

Returns a job ID that you can use to determine the status of the job. See [GET jobs](#).

Resource URL

```
https://<NODE>:5444/databases/:database_name/hosts/:host_id/process
```

Authentication

Requires a [VerticaAPIKey](#) in the request header.

The API key must have **restricted** level security or higher.

Parameters

None.

Example request

POST	<code>https://<NODE>:5444/databases/testDB/hosts/192.168.232.181/process</code>
-------------	---

Response:

```
{
  "id": "StartDatabase-testDB-2014-07-20 13:14:03.968340",
  "url": "/jobs/StartDatabase-testDB-2014-07-20 13:14:03.968340"
}
```

GET `databases/:database_name/license`

Returns details about the database license being used by the database identified by `:database_name`. The `:database_name` is the value of the `name` field that the [GET databases](#) command returns.

Resource URL

https://<NODE>:5444/:database_name/license

Authentication

Requires a [VerticaAPIKey](#) in the request header.

The API key must have **restricted** level security or higher.

Parameters

user_id	A database username.
passwd	The password for the username.

Example request

GET	<code>https://:5444/VMart/license?user_id= username &passwd= username_password</code>
------------	---

Response:

```
{
  "body": {
    "details": {
      "assigned_to": "Vertica Systems, Inc.",
      "grace_period": 0,
      "is_ce": false,
      "is_unlimited": false,
      "name": "vertica",
      "not_after": "Perpetual",
      "not_before": "2007-08-03"
    },
    "last_audit": {
      "audit_date": "2014-07-18 13:49:22.530105-04",
      "database_size_bytes": "814060522",
      "license_size_bytes": "536870912000",
      "usage_percent": "0.00151630588248372"
    }
  },
  "href": "/databases/VMart/license",
  "links": [],
  "mime-type": "application/vertica.license.json-v2"
}
```

GET databases/:database_name/licenses

Returns details about all license being used by the database identified by :database_name . The :database_name is the value of the name field that the [GET databases](#) command returns.

Resource URL

https://<NODE>:5444/:database_name/licenses

Authentication

Requires a [VerticaAPIKey](#) in the request header.

The API key must have **restricted** level security or higher.

Parameters

user_id	A database username.
passwd	The password for the username.

Example request

GET https://:5444/VMart/licenses?user_id= username &passwd= username_password

Response:

```
{
  "body": [
    {
      "details": {
        "assigned_to": "Vertica Systems, Inc.",

        "usage_percent": 0
      }
    }
  ],
  "href": "/databases/VMart/licenses",
  "links": [],
  "mime-type": "application/vertica.features.json-v2"
}
```

DELETE databases/:database_name/hosts/:host_id/process

Creates a job to stop the vertica process for the database identified by :database_name on the host identified by :host_id . The :database_name is the value of the name field that the [GET databases](#) command returns. The :host_id is the value of the host field returned by [GET databases/:database_name](#).

Returns a job ID that can be used to determine the status of the job. See [GET jobs](#).

Note

If stopping the database on the hosts causes the database to no longer be k-safe, then the all database nodes may shut down.

Resource URL

https://<NODE>:5444/databases/:database_name/hosts/:host_id/process

Authentication

Requires a [VerticaAPIKey](#) in the request header.

The API key must have **restricted** level security or higher.

Parameters

None.

Example request

DELETE	https://<NODE>:5444/databases/testDB/hosts/192.168.232.181/process
---------------	--

Response:

```
{
  "id": "StopDatabase-testDB-2014-07-20 13:02:08.453547",
  "url": "/jobs/StopDatabase-testDB-2014-07-20 13:02:08.453547"
}
```

POST databases/:database_name/hosts/:host_id/replace_with/:host_id_new

Creates a job to replace the host identified by `hosts/:host_id` with the host identified by `replace_with/:host_id`. Vertica performs these operations for the database identified by `:database_name`. The `:database_name` is the value of the `name` field that the [GET databases](#) command returns. The `:host_id` is the value of the `host` field as returned by [GET databases/:database_name](#). You can find valid replacement hosts using [GET hosts](#). The replacement host cannot already be part of the database. You must stop the vertica process on the host being replaced.

Returns a job ID that you can use to determine the status of the job. See [GET jobs](#).

Resource URL

https://<NODE>:5444/databases/:database_name/hosts/:host_id/replace_with/:host_id_new

Authentication

Requires a [VerticaAPIKey](#) in the request header.

The API key must have **admin** level security.

Parameters

<code>user_id</code>	A database username.
<code>passwd</code>	A password for the username.

Example request

POST	https:// :5444/databases/testDB/hosts/192.168.232.180/replace_with/192.168.232.181?user_id= <i>username</i> &passwd= <i>username_password</i>
-------------	---

Response:

```
{
  "id": "ReplaceNode-testDB-2014-07-20 13:50:28.423509",
  "url": "/jobs/ReplaceNode-testDB-2014-07-20 13:50:28.423509"
}
```

GET databases/:database_name/nodes

Returns a comma-separated list of node IDs for the database identified by `:database_name`. The `:database_name` is the value of the `name` field that the [GET databases](#) command returns.

Resource URL

https://<NODE>:5444/:database_name/nodes

Authentication

Requires a [VerticaAPIKey](#) in the request header.

The API key must have **restricted** level security or higher.

Parameters

None.

Example request

GET	<a href="https://<NODE>:5444/VMart/nodes">https://<NODE>:5444/VMart/nodes
------------	---

Response:

<pre>[{ "database_id": "VMart", "node_id": "v_vmart_node0001,v_vmart_node0002,v_vmart_node0003", "status": "Unknown" }]</pre>

GET databases/:database_name/nodes/:node_id

Returns details about the node identified by :node_id . The :node_id is one of the node IDs returned by [GET databases/:database_name/nodes](#) .

Resource URL

<a href="https://<NODE>:5444/:database_name/nodes/:node_id">https://<NODE>:5444/:database_name/nodes/:node_id

Authentication

Requires a [VerticaAPIKey](#) in the request header.

The API key must have **restricted** level security or higher.

Parameters

None.

Example request

GET	<a href="https://<NODE>:5444/databases/VMart/nodes/v_vmart_node0001">https://<NODE>:5444/databases/VMart/nodes/v_vmart_node0001
------------	---

Response:

<pre>{ "db": "VMart", "host": "10.20.100.247", "name": "v_vmart_node0001", "state": "UP" }</pre>
--

POST databases/:database_name/process

Creates a job to start the database identified by :database_name . The :database_name is the value of the name field that the [GET databases](#) command returns.

Returns a job ID that can be used to determine the status of the job. See [GET jobs](#) .

Resource URL

<a href="https://<NODE>:5444/databases/:database_name/process">https://<NODE>:5444/databases/:database_name/process

Authentication

Requires a [VerticaAPIKey](#) in the request header.

The API key must have **restricted** level security or higher.

Parameters

epoch	Start the database from this epoch.
include	Include only these hosts when starting the database. Use a comma-separated list of hostnames.

Example request

POST	<code>https://<NODE>:5444/databases/:testDB/process</code>
-------------	--

An example of the full request using cURL:

```
curl -d "epoch=epoch_number&include=host1,host2" -X POST -H "VerticaApiKey: ValidAPIKey" https://<NODE>:5444/:testDB/process
```

Response:

```
{
  "id": "StartDatabase-testDB-2014-07-20 12:41:46.061408",
  "url": "/jobs/StartDatabase-testDB-2014-07-20 12:41:46.061408"
}
```

GET databases/:database_name/process

Returns a state of UP or DOWN for the database identified by `:database_name`. The `:database_name` is the value of the `name` field that the [GET databases](#) command returns.

Resource URL

```
https://<NODE>:5444/databases/:database_name/process
```

Authentication

Requires a [VerticaAPIKey](#) in the request header.

The API key must have **restricted** level security or higher.

Parameters

None.

Example request

GET	<code>https://<NODE>:5444/databases/VMart/process</code>
------------	--

Response:

```
{
  "state": "UP"
}
```

DELETE databases/:database_name/process

Creates a job to stop the database identified by `:database_name`. The `:database_name` is the value of the `name` field that the [GET databases](#) command returns.

Returns a job ID that you can use to determine the status of the job. See [GET jobs](#).

Resource URL

```
https://<NODE>:5444/databases/:database_name/process
```

Authentication

Requires a [VerticaAPIKey](#) in the request header.

The API key must have **restricted** level security or higher.

Parameters

user_id	A database username.
passwd	The password for the username.

Example request

DELETE	<code>https://:5444/databases/testDB/process?user_id= username &passwd= username_password</code>
---------------	--

An example of the full request using cURL:

```
curl -X DELETE -H "VerticaApiKey: ValidAPIKey" https://<NODE>:5444/:testDB/process?user_id=dbadmin"&"passwd=vertica
```

Response:

```
{
  "id": "StopDatabase-testDB-2014-07-20 12:46:04.406637",
  "url": "/jobs/StopDatabase-testDB-2014-07-20 12:46:04.406637"
}
```

POST databases/:database_name/rebalance/process

Creates a job to run a rebalance on the database identified by host identified by :database_name . The :database_name is the value of the name field that the [GET databases](#) command returns.

Returns a job ID that you can use to determine the status of the job. See [GET jobs](#).

Resource URL

```
https://<NODE>:5444/databases/:database_name/rebalance/process
```

Authentication

Requires a [VerticaAPIKey](#) in the request header.

The API key must have **restricted** level security or higher.

Parameters

user_id	A database username.
passwd	A password for the username.

Example request

POST	<code>https://:5444/databases/testDB/rebalance/process?user_id= username &passwd= username_password</code>
-------------	--

Response:

```
{
  "id": "RebalanceData-testDB-2014-07-20 21:42:45.731038",
  "url": "/jobs/RebalanceData-testDB-2014-07-20 21:42:45.731038"
}
```

POST databases/:database_name/Workload analyzer/process

Creates a job to run Workload Analyzer on the database identified by host identified by :database_name . The :database_name is the value of the name field that the [GET databases](#) command returns.

Returns a job ID that you can use to determine the status of the job. See [GET jobs](#).

Resource URL

```
https://<NODE>:5444/databases/:database_name/Workload Analyzer/process
```

Authentication

Requires a [VerticaAPIKey](#) in the request header.

The API key must have **restricted** level security or higher.

Parameters

<code>user_id</code>	A database username.
<code>passwd</code>	A password for the username.

Example request

POST	<code>https://:5444/databases/testDB/Workload Analyzer/process?user_id= username &passwd= username_password</code>
-------------	--

Response:

<pre>{ "id": "AnalyzeWorkLoad-testDB-2014-07-20 21:48:27.972989", "url": "/jobs/AnalyzeWorkLoad-testDB-2014-07-20 21:48:27.972989" }</pre>
--

Hosts

You can use these API calls to get information on the hosts in your cluster.

GET hosts	Returns a list of hosts in this cluster.
GET hosts/:hostid	Returns details for a specific host in this cluster.

In this section

- [GET hosts](#)
- [GET hosts/:hostid](#)

GET hosts

Returns a list of the hosts in the cluster and the hardware, software, and network details about each host.

Resource URL

<code>https://<NODE>:5444/hosts</code>
--

Authentication

Requires a [VerticaAPIKey](#) in the request header.

The API key must have **restricted** level security or higher.

Parameters

None.

Example request

GET	<code>https://<NODE>:5444/hosts</code>
------------	--

Response:

<pre>{ "body": [{ "cpu_info": { "cpu_type": " Intel(R) Xeon(R) CPU E5-2695 v2 @ 2.40GHz", "number_of_cpus": 2 }, "host_id": "10.20.100.247", "hostname": "v_vmart_node0001.example.com", "max_user_proc": "3833", "nics": [</pre>

},
"href": "/hosts",
"links": [
  "/:hostid"
],
"mime-type": "application/vertica.hosts.json-v2"
}
```

GET hosts/:hostid

Returns hardware, software, and network details about the host identified by `:host_id`. You can find `:host_id` for each host using [GET hosts](#).

Resource URL

```
https://<NODE>:5444/hosts/:hostid
```

Authentication

Requires a [VerticaAPIKey](#) in the request header.

The API key must have **restricted** level security or higher.

Parameters

None.

Example request

GET	<code>https://<NODE>:5444/hosts/:10.20.100.247</code>
------------	---

Response:

```
{
  "body": {
    "cpu_info": {
      "cpu_type": " Intel(R) Xeon(R) CPU E5-2695 v2 @ 2.40GHz",

    }
  },
  "href": "/hosts/10.20.100.247",
  "links": [],
  "mime-type": "application/vertica.host.json-v2"
}
```

Jobs

You can use these API calls to get information on your database's jobs.

GET jobs	Returns a list of jobs the agent is tracking, along with their current status and exit codes.
GET jobs/:id	Returns the details (the saved output) for a specific job.

In this section

- [GET jobs](#)
- [GET jobs/:id](#)

GET jobs

Returns a list of jobs being tracked by the agent and job details.

Jobs always start immediately. The `is_running` field is a Boolean value. If `is_running` is false, then the job is complete.

The `exit_code` details the status of the job. The `exit_code` is different for certain types of jobs:

- For Backup jobs:
 - 0 indicates success.
 - Any other number indicates a failure.
- For all other jobs:

- -9 indicates success.
- Any other number indicates a failure.

You can see details about failures in </opt/vertica/log/agentStdMsg.log> .

Resource URL

<https://<NODE>:5444/jobs>

Authentication

Requires a [VerticaAPIKey](#) in the request header.

The API key must have **restricted** level security or higher.

Parameters

None.

Example request

GET	<a href="https://<NODE>:5444/jobs">https://<NODE>:5444/jobs
------------	---

Response:

```
{
  "body": [
    {
      "exit_code": 0,
      "id": "CreateBackup-VMart-1405012447.75",
      "is_running": false,
      "status": "unused",
      "ts": "1405012461.18"
    },
    {
      "exit_code": 1,
      "id": "CreateBackup-VMart-1405012454.88",
      "is_running": false,
      "status": "unused",
      "ts": "1405012455.18"
    }
  ],
  "href": "/jobs",
  "links": [
    "/:jobid"
  ],
  "mime-type": "application/vertica.jobs.json-v2"
}
```

GET jobs/:id

Gets the details for a specific job with the provided `:id` . You can determine the list of job `:ids` using [GET jobs](#) .

Details for a specific job are the same as the details provided for all jobs by [GET jobs](#) .

Note

You must URL encode the `:id` as some IDs may contain spaces or other special characters.

Resource URL

<https://<NODE>:5444/jobs/:id>

Authentication

Requires a [VerticaAPIKey](#) in the request header.

The API key must have **restricted** level security or higher.

Parameters

None.

Example request

GET	<a href="https://<NODE>:5444/jobs/CreateBackup-VMart-1405012454.88">https://<NODE>:5444/jobs/CreateBackup-VMart-1405012454.88
------------	---

Licenses

You can use these API calls to manage licenses for your database.

POST licenses	Uploads and applies a new license to this cluster.
GET licenses	Returns the license field that databases created on this cluster use.

In this section

- [POST licenses](#)
- [GET licenses](#)

POST licenses

Uploads and applies a license file to this cluster.

You must provide the license file as an HTTP POST form upload, identified by the name *license* . For example, you can use cURL:

```
curl -k --request POST -H "VerticaApiKey:ValidAPIKey" \  
https://v_vmart_node0001:5444/licenses --form "license=@vlicense.dat"
```

Resource URL

```
https://<NODE>:5444/licenses
```

Authentication

Requires a [VerticaAPIKey](#) in the request header.

The API key must have **admin** level security.

Parameters

None.

Example request

POST	<a href="https://<NODE>:5444/licenses">https://<NODE>:5444/licenses
-------------	---

Response:

There is no HTTP body response for successful uploads. A successful upload returns an HTTP 200/OK header.

GET licenses

Returns any license files that are used by this cluster when creating databases. License files must reside in [/opt/vertica/config/share](#) .

Resource URL

```
https://<NODE>:5444/licenses
```

Authentication

Requires a [VerticaAPIKey](#) in the request header.

The API key must have **restricted** level security or higher.

Parameters

None.

Example request

GET	https://<NODE>:5444/licenses
-----	------------------------------

Response:

```
{
  "body": [
    {
      "comment": "Vertica license is valid",
      "end": "Perpetual",
      "grace": "0",
      "size": "1TB CE Nodes 3",
      "start": "2011-11-22",
      "status": true,
      "vendor": "Vertica Community Edition"
    }
  ],
  "href": "/license",
  "links": [],
  "mime-type": "application/vertica.license.json-v2"
}
```

Nodes

You can use these API calls to retrieve information on the nodes in your cluster.

GET nodes	Returns a list of nodes in this cluster.
GET nodes/:nodeid	Returns details for a specific node in this cluster.

In this section

- [GET nodes](#)
- [GET nodes/:nodeid](#)

GET nodes

Returns a list of nodes associated with this cluster.

Resource URL

```
https://<NODE>:5444/nodes
```

Authentication

Requires a [VerticaAPIKey](#) in the request header.

The API key must have **restricted** level security or higher.

Parameters

None.

Example request

GET	https://<NODE>:5444/nodes
-----	---------------------------

Response:

```
{
  "body": [
    "node0001",
    "node0002",
    "node0003",
    "v_testdb_node0001",
    "v_testdb_node0002",
    "v_testdb_node0003",
    "v_vmart_node0001",
    "v_vmart_node0002",
    "v_vmart_node0003"
  ],
  "href": "/nodes",
  "links": [
    "/:nodeid"
  ],
  "mime-type": "application/vertica.nodes.json-v2"
}
```

GET nodes/:nodeid

Returns details about the node identified by `:node_id`. You can find the `:node_id` for each node using [GET nodes](#).

In the body field, the following information is detailed in comma-separated format:

- Node Name
- Host Address
- Catalog Directory
- Data Directory

Resource URL

`https://<NODE>:5444/nodes/:node_id`

Authentication

Requires a [VerticaAPIKey](#) in the request header.

The API key must have **restricted** level security or higher.

Parameters

None.

Example request

GET	<code>https://<NODE>:5444/nodes/v_vmart_node0001</code>
------------	---

Response:

```
{
  "body": [
    "v_vmart_node0001",
    "10.20.100.247,/home/dbadmin,/home/dbadmin"
  ],
  "href": "/nodes/v_vmart_node0001",
  "links": [],
  "mime-type": "application/vertica.node.json-v2"
}
```

Webhooks

You can use these API calls to obtain information on, create, or delete webhooks.

GET webhooks	Returns a list of active webhooks.
------------------------------	------------------------------------

POST webhooks/subscribe	Creates a new webhook.
DELETE webhooks/:subscriber_id	Deletes an existing webhook.

In this section

- [GET webhooks](#)
- [POST webhooks/subscribe](#)
- [DELETE webhooks/:subscriber_id](#)

GET webhooks

Returns a list of active webhooks for this cluster.

Resource URL

`https://<NODE>:5444/webhooks`

Authentication

Requires a [VerticaAPIKey](#) in the request header.

The API key must have **restricted** level security or higher.

Parameters

None.

Example request

GET	<code>https://<NODE>:5444/webhooks</code>
------------	---

Response:

```
{
  "body": [
    {
      "host": "192.168.232.1",
      "id": "79c1c8a18be02804b3d2f48ea6462909",
      "port": 80,
      "timestamp": "2014-07-20 22:54:09.829642",
      "url": "/gettest.htm"
    },
    {
      "host": "192.168.232.1",
      "id": "9c32cb0f3d2f9a7cb10835f1732fd4a7",
      "port": 80,
      "timestamp": "2014-07-20 22:54:09.829707",
      "url": "/getwebhook.php"
    }
  ],
  "href": "/webhooks",
  "links": [
    "/subscribe",
    "/:subscriber_id"
  ],
  "mime-type": "application/vertica.webhooks.json-v2"
}
```

POST webhooks/subscribe

Creates a subscription for a webhook.

Resource URL

`https://<NODE>:5444/webhooks/subscribe`

Authentication

Requires a [VerticaAPIKey](#) in the request header.

The API key must have **restricted** level security or higher.

Parameters

url	A URL to an application that accepts JSON messages from this cluster.
------------	---

Example request

POST	<code>https://:5444/webhooks/subscribe?url=http%3A%2F%2F example.com %2F getwebhook.php</code>
-------------	--

Response:

The response is not JSON encoded. The only text response is the ID of the webhook subscription. Additionally, an HTTP 200/OK header indicates success.

```
79c1c8a18be02804b3d2f48ea6462909
```

DELETE webhooks/:subscriber_id

Deletes the webhook identified by `:subscriber_id`. The `:subscriber_id` is the value of the `id` field that the [GET webhooks](#) command returns.

Resource URL

```
https://<NODE>:5444/webhooks/:subscriber_id
```

Authentication

Requires a [VerticaAPIKey](#) in the request header.

The API key must have **restricted** level security or higher.

Parameters

None.

Example request

DELETE	<code>https://<NODE>:5444/webhooks/79c1c8a18be02804b3d2f48ea6462909</code>
---------------	--

Response:

There is no HTTP body response for successful deletes. A successful delete returns an HTTP 200/OK header.

Rest APIs for the Management Console

These API calls interact with Management Console nodes.

Alerts

GET alerts	Returns alerts for the current user.
----------------------------	--------------------------------------

Time information

GET mcTimeInfo	Returns the current time for the MC server and the timezone of the location where the MC server is located.
--------------------------------	---

In this section

- [MC-User-ApiKey](#)
- [GET alerts](#)
- [GET mcTimeInfo](#)
- [Thresholds category filter](#)
- [Database name category filter](#)
- [Combining sub-category filters with category filters](#)

The MC-User-ApiKey is a user-specific key used with Management Console. Users must have an MC-User-ApiKey to interact with MC using the Rest API. All users with roles other than None automatically receive an MC-User-ApiKey.

This key grants users the same rights through the API that they have available through their MC roles. To interact with the MC, users pass the key in the request header for the API.

View the MC-User-ApiKey

If you are the database administrator, you can view the MC-User-ApiKey for all users. Individual users can view their own keys.

1. Connect to MC and go to MC Settings > User Management.
2. Select the user to view and click Edit. The user's key appears in the User API Key field.

GET alerts

Returns a list of MC alerts, their current status, and database properties.

Resource URL

```
https://<MC_NODE>:5450/webui/api/alerts
```

Authentication

Requires an [MC-User-Apikey](#) in the request header.

Filter parameters

types	The type of alert to retrieve. Valid values are: <ul style="list-style-type: none">• info• notice• warning• error• critical• alert• emergency
category	For information, see Thresholds category filter .
db_name	For information, see Database name category filter .
limit	The maximum number of alerts to retrieve. If the limit is lower than the number of existing alerts, Vertica retrieves the most recent alerts. Used with the type parameter, Vertica retrieves up to the limit for each type. For example, for a limit of five and types of critical and emergency, you could receive up to ten total alerts.
time_from	The timestamp start point from which to retrieve alerts. You can use this parameter in combination with the time_to parameter to retrieve alerts for a specific time range. Values must be passed in the following format: yyyy-MM-ddTHH:mm . If you provide only the time_from parameter, and omit the time_to parameter, the response contains all alerts generated from the time_from parameter to the current time.
time_to	The timestamp end point from which to retrieve alerts. You can use this parameter in combination with the time_from parameter to retrieve alerts for a specific time range. Values must be passed in the following format: yyyy-MM-ddTHH:mm . If you provide only the time_to parameter, and omit the time_from parameter , the response contains all alerts generated from the earliest possible time to the time passed in time_to .

Example request

GET	<code>https://<MC_NODE>:5450/webui/api/alerts?types=critical</code>
------------	---

Request alerts using cURL

This example shows how you can request alerts using cURL. In this example, the **limit** parameter is set to '2' and the **types** parameters is set to **info** and **notice** :

```
curl -H "MC-User-APIKey: ValidUserKey" https://<MC_NODE>:5450/webui/api/alerts?limit=2&types=info,notice
```

Response:

```
[
  {
    "alerts":[
      {
        "id":5502,
        "markedRead":false,
        "eventTypeCode":0,
        "create_time":"2016-02-02 05:12:10.0",
        "updated_time":"2016-02-02 15:50:20.511",
        "severity":"warning",
        "status":1,
        "nodeName":"v_vmart_node0001",
        "databaseName":"VMart",
        "databaseId":1,
        "clusterName":"1449695416208_cluster",
        "description":"Warning: Low disk space detected (73% in use)",
        "summary":"Low Disk Space",
        "internal":false,
        "count":3830
      },
      {
        "id":5501,
        "markedRead":false,
        "eventTypeCode":2,
        "create_time":"2016-02-02 05:12:02.31",
        "updated_time":"2016-02-02 05:12:02.31",
        "severity":"notice",
        "status":1,
        "databaseName":"VMart",
        "databaseId":1,
        "clusterName":"1449695416208_cluster",
        "description":"Analyze Workload operation started on Database",
        "summary":"Analyze Workload operation started on Database",
        "internal":false,
        "count":1
      }
    ],
    "total_alerts":190,
    "request_query":"limit=2",
    "request_time":"2016-02-02 15:50:26 -0500"
  }
]
```

Request alerts within a time range

These examples show various ways in which you can request the same alert as in the preceding example, but within specified time ranges.

Request the alert within a specific time range, using the `time_from` and `time_to` parameters:

```
curl -H "MC-User-APIKey: ValidUserKey" https://<MC_NODE>:5450/webui/api/alerts?types=info,notice&time_from=2016-01-01T12:12&time_to=2016-02-01T12:12
```

Request the alert from a specific start time to the present using the `time_from` parameter:

```
curl -H "MC-User-APIKey: ValidUserKey" https://<MC_NODE>:5450/webui/api/alerts?types=info,notice&time_from=2016-01-01T12:12
```

Request the alert to a specific end point using the `time_to` parameter. When you use the `time_to` parameter without the `time_from` parameter, the `time_from` parameter defaults to the oldest alerts your MC contains:

```
curl -H "MC-User-ApiKey: ValidUserKey" https://<MC_NODE>:5450/webui/api/alerts?types=info,notice&time_to=2016-01-01T12:12
```

GET mcTimeInfo

Returns the current time for the MC server and the timezone where the MC server is located.

Resource URL

```
https://<MC_NODE>:5450/webui/api/mcTimeInfo
```

Authentication

Requires an [MC-User-Apikey](#) in the request header.

Parameters

None.

Example request

```
GET https://<MC_NODE>:5450/webui/api/mcTimeInfo
```

This example shows how you can request MC time information using cURL:

```
curl -H "MC-User-ApiKey: ValidUserKey" https://<MC_NODE>:5450/webui/api/mcTimeInfo
```

Response:

```
{"mc_current_time":"Tue, 2000-01-01 01:02:03 -0500","mc_timezone":"US/Eastern"}
```

Thresholds category filter

Returns a list of alerts related to threshold settings in MC.

Resource URL

```
https://<MC_NODE>:5450/webui/api/alerts?category=thresholds
```

Authentication

Requires an [MC-User-Apikey](#) in the request header.

Example request

```
GET https://<MC_NODE>:5450/webui/api/alerts?category=thresholds
```

This example shows how you can request alerts on thresholds using cURL:

```
curl -H "MC-User-ApiKey: ValidUserKey" https://<MC_NODE>:5450/webui/api/alerts?category=thresholds
```

Response:

```
[
  {
    "alerts":[
      {
        "id":33,
        "markedRead":false,
        "eventTypeCode":2,

Database name category filter

Returns a list of MC alerts for a specific database.

Resource URL

```
https://<MC_NODE>:5450/webui/api/alerts?db_name=
```

Authentication

Requires an [MC-User-Apikey](#) in the request header.

Example request

```
GET https://<MC_NODE>:5450/webui/api/alerts?db_name= database_name
```

This example shows how you can view alerts on a specific database using cURL:

```
curl -H "MC-User-ApiKey: ValidUserKey" https://<MC_NODE>:5450/webui/api/alerts?db_name="mydb"
```

Response:

```
[
  {
    "alerts":[
      {
        "id":9,

```

You can combine category filters with sub-category filters, to obtain alert messages for specific thresholds you set in MC. You can also use sub-category filters to obtain information about alerts on specific resource pools in your database.

Sub-category filters

You can use the following sub-category filters with the category filters. Sub-category filters are case sensitive and must be lowercase.

Sub-Category Filter	Alerts Related to Threshold Value Set For:
THRESHOLD_NODE_CPU	Node CPU
THRESHOLD_NODE_MEMORY	Node Memory
THRESHOLD_NODE_DISK_USAGE	Node Disk Usage
THRESHOLD_NODE_DISKIO	Node Disk I/O
THRESHOLD_NODE_CPUIO	Node CPU I/O Wait
THRESHOLD_NODE_REBOOTRATE	Node Reboot Rate
THRESHOLD_NETIO	Network I/O Error
THRESHOLD_QUERY_QUEUED	Queued Query Number
THRESHOLD_QUERY_FAILED	Failed Query Number
THRESHOLD_QUERY_SPILLED	Spilled Query Number
THRESHOLD_QUERY_RETRIED	Retried Query Number
THRESHOLD_QUERY_RUNTIME	Query Running Time

Resource pool-specific sub-category filters

To retrieve alerts for a specific resource pool, you can use sub-category filters in combination with the following category filters:

- `thresholds`
- `rp_name`

If you use these sub-category filters without the `RP_NAME` filter, the query retrieves alerts for all resource pools in your database.

Sub-Category Filter	Alerts Related to Threshold Value Set For:
THRESHOLD_RP_QUERY_MAX_TIME	Queries reaching the maximum allowed execution time.
THRESHOLD_RP_QUERY_RESOURCE_REJECT	The number of queries with resource rejections.
THRESHOLD_RP_QUERY_QUEUE_TIME	The number of queries that ended because of queue time exceeding a limit.
THRESHOLD_RP_QUERY_RUN_TIME	The number of queries that ended because of run time exceeding a limit.
THRESHOLD_RP_MEMORY	The minimum allowed resource pool size.
THRESHOLD_RP_MAX_MEMORY	The maximum allowed resource pool size.

Authentication

Requires an [MC-User-Apikey](#) in the request header.

Example request

```
GET https://<MC_NODE>:5450/webui/api/alerts?category=thresholds&subcategory= <subcategory_filter>
```

Combine the thresholds category filter with a sub-category filter

This example shows how you can request alerts using cURL with the thresholds category filter and a sub-category filter. You apply the following filters:

- THRESHOLDS
- THRESHOLD_NODE_CPU

```
curl -H "MC-User-ApiKey: ValidUserKey" https://<MC_NODE>:5450/webui/api/alerts?category=thresholds&subcategory=threshold_node_cpu
```

Response:

```

```

Connect with an SSH tunnel

You can set up an [SSH](#) tunnel to connect to Vertica through a proxy server. This can be useful in cases where the client or Vertica server is on a private network.

Server on private network

If the Vertica server is on a private network, run `ssh -R` to configure remote port forwarding on the Vertica server host. For example, to let the client connect to Vertica through a proxy hosted on `proxy.example.com:9595` :

1. On the proxy server, add `GatewayPorts yes` to `/etc/ssh/sshd_config` .

2. On the proxy server, restart the SSH service:

```
sudo systemctl restart ssh
```

3. On the Vertica server host, run:

```
ssh -N -R 9595:localhost:5433 user@proxy.example.com
```

4. On the client host, run the following to connect to Vertica through the proxy server:

```
vsqll -h proxy.example.com -p 9595
```

Client on private network

If the client machine is on a private network, run `ssh -L` on the client to configure local port forwarding. For example, to let the client use `localhost:9595` to connect to Vertica hosted on `vertica.example.com:5433` through a proxy on `proxy.example.com` :

```
ssh -N -L 9595:vertica.example.com:5433 user@proxy.example.com
```

You can then connect to Vertica from the client:

```
vsqll -p 9595
```

Extending Vertica

You can extend Vertica to perform new operations or handle new types of data. There are several types of extensions:

- **External procedures:** external scripts or programs that are installed on a host in your database cluster.
- **User-defined SQL functions:** Frequently-used SQL expressions, which help you simplify and standardize your SQL scripts.
- **Stored Procedures:** SQL procedures that are stored in the database (as opposed to external procedures). Stored procedures can communicate and interact with your database directly to perform maintenance, execute queries, and update tables.
- **User-defined extensions (UDxs):** functions or data-load steps written in the C++, Python, Java, and R programming languages. They are useful when the type of data processing you want to perform is difficult or slow using SQL. [User-defined extensions](#) explains how to use them and [Developing user-defined extensions \(UDxs\)](#) explains how to create them.

In this section

- [External procedures](#)
- [User-defined SQL functions](#)
- [Stored procedures](#)
- [User-defined extensions](#)
- [Developing user-defined extensions \(UDxs\)](#)

External procedures

Enterprise Mode only

An external procedure is a script or executable program on a host in your database cluster that you can call from within Vertica. External procedures cannot communicate back to Vertica.

To implement an external procedure:

1. Create an external procedure executable file. See [Requirements for external procedures](#).
2. Enable the `set-user-ID(SUID)`, `user execute`, and `group execute` attributes for the file. Either the file must be readable by the `dbadmin` or the file owner's password must be given with the [Administration tools](#) `install_procedure` command.
3. [Install the external procedure executable file](#).
4. [Create the external procedure in Vertica](#).

After a procedure is created in Vertica, you can [execute](#) or [drop](#) it, but you cannot alter it.

In this section

- [Requirements for external procedures](#)
- [Installing external procedure executable files](#)
- [Creating external procedures](#)
- [Executing external procedures](#)
- [Dropping external procedures](#)

Requirements for external procedures

Enterprise Mode only

External procedures have requirements regarding their attributes, where you store them, and how you handle their output. You should also be cognizant of their resource usage.

Procedure file attributes

The procedure file cannot be owned by root. It must have the set-user-ID (SUID), user execute, and group execute attributes set. If it is not readable by the Linux database administrator user, then the owner's password will have to be specified when installing the procedure.

Handling procedure output

Vertica does not provide a facility for handling procedure output. Therefore, you must make your own arrangements for handling procedure output, which should include writing error, logging, and program information directly to files that you manage.

Handling resource usage

The Vertica resource manager is unaware of resources used by external procedures. Additionally, Vertica is intended to be the only major process running on your system. If your external procedure is resource intensive, it could affect the performance and stability of Vertica. Consider the types of external procedures you create and when you run them. For example, you might run a resource-intensive procedure during off hours.

Sample procedure file

```
#!/bin/bash
echo "hello planet argument: $1" >> /tmp/myprocedure.log
```

Installing external procedure executable files

Enterprise Mode only

To install an external procedure, use the Administration Tools through either the menu or the command line.

Menu

1. Run the [Administration tools](#).

```
$ /opt/vertica/bin/adminTools
```

2. On the AdminTools **Main Menu**, click **Configuration Menu**, and then click **OK**.
3. On the **Configuration Menu**, click **Install External Procedure** and then click **OK**.
4. Select the database on which you want to install the external procedure.
5. Either select the file to install or manually type the complete file path, and then click **OK**.
6. If you are not the superuser, you are prompted to enter your password and click **OK**.
The Administration Tools automatically create the *database-name /procedures* directory on each node in the database and installs the external procedure in these directories for you.
7. Click **OK** in the dialog that indicates that the installation was successful.

Command line

If you use the command line, be sure to specify the full path to the procedure file and the password of the Linux user who owns the procedure file. For example:

```
$ admintools -t install_procedure -d vmartdb -f /scratch/helloworld.sh -p ownerpassword
Installing external procedure...
External procedure installed
```

After you have installed an external procedure, you need to make Vertica aware of it. To do so, use the [CREATE PROCEDURE](#) statement, but review [Creating external procedures](#) first.

Creating external procedures

Enterprise Mode only

After you install an external procedure, you must make Vertica aware of it with [CREATE PROCEDURE \(external\)](#).

Only superusers can create an external procedure, and by default, only they have execute privileges. However, superusers can [grant](#) users and roles EXECUTE privilege on the stored procedure.

After you create a procedure, its metadata is stored in system table [USER_PROCEDURES](#). Users can see only those procedures that they have been granted the privilege to execute.

Example

The following example creates a procedure named `helloplanet` for external procedure file `helloplanet.sh`. This file accepts one `VARCHAR` argument. The sample code is provided in [Requirements for external procedures](#).

```
=> CREATE PROCEDURE helloplanet(arg1 VARCHAR) AS 'helloplanet.sh' LANGUAGE 'external'
  USER 'dbadmin';
```

The next example creates a procedure named `proctest` for the script `copy_vertica_database.sh`. This script copies a database from one cluster to another; it is included in the server RPM located in directory `/opt/vertica/scripts`.

```
=> CREATE PROCEDURE proctest(shosts VARCHAR, thosts VARCHAR, dbdir VARCHAR)
  AS 'copy_vertica_database.sh' LANGUAGE 'external' USER 'dbadmin';
```

Overloading external procedures

You can create multiple external procedures with the same name if they have different signatures—that is, accept a different set of arguments. For example, you can overload the `helloplanet` external procedure to also accept an integer value:

```
=> CREATE PROCEDURE helloplanet(arg1 INT) AS 'helloplanet.sh' LANGUAGE 'external'
  USER 'dbadmin';
```

After executing this statement, the database catalog stores two external procedures named `helloplanet`—one that accepts a `VARCHAR` argument and one that accepts an integer. When you call the external procedure, Vertica evaluates the arguments in the procedure call to determine which procedure to call.

See also

- [CREATE PROCEDURE \(external\)](#)
- [GRANT \(procedure\)](#)

Executing external procedures

Enterprise Mode only

After you define a procedure using the [CREATE PROCEDURE \(external\)](#) statement, you can use it as a meta command in a `SELECT` statement. Vertica does not support using procedures in more complex statements or in expressions.

The following example runs a procedure named `helloplanet`:

```
=> SELECT helloplanet('earthlings');
helloplanet
-----
         0
(1 row)
```

The following example runs a procedure named `proctest`. This procedure references the `copy_vertica_database.sh` script that copies a database from one cluster to another. It is installed by the server RPM in the `/opt/vertica/scripts` directory.

```
=> SELECT proctest(
  '-s qa01',
  '-t rbench1',
  '-D /scratch_b/qa/PROC_TEST');
```

Note

External procedures have no direct access to database data. Use ODBC or JDBC for this purpose.

Procedures are executed on the initiating node. Vertica runs the procedure by forking and executing the program. Each procedure argument is passed to the executable file as a string. The parent fork process waits until the child process ends.

If the child process exits with status 0, Vertica reports the operation took place by returning one row as shown in the `helloplanet` example. If the child process exits with any other status, Vertica reports an error like the following:

```
ERROR 7112: Procedure reported: Procedure execution error: exit status = code
```

To stop execution, cancel the process by sending a cancel command (for example, `CTRL+C`) through the client. If the procedure program exits with an error, an error message with the exit status is returned.

Permissions

To execute an external procedure, the user needs:

- EXECUTE privilege on procedure
- USAGE privilege on schema that contains the procedure

Dropping external procedures

Enterprise Mode only

Only a superuser can drop an external procedure. To drop the definition for an external procedure from Vertica, use the [DROP PROCEDURE \(external\)](#) statement. Only the reference to the procedure is removed. The external file remains in the `<database>/procedures` directory on each node in the database.

Note

The definition Vertica uses for a procedure cannot be altered; it can only be dropped.

Example

```
=> DROP PROCEDURE helloplanet(arg1 varchar);
```

See also

- [DROP PROCEDURE \(external\)](#)

User-defined SQL functions

User-defined SQL functions let you define and store commonly-used SQL expressions as a function. User-defined SQL functions are useful for executing complex queries and combining Vertica built-in functions. You simply call the function name you assigned in your query.

A user-defined SQL function can be used anywhere in a query where an ordinary SQL expression can be used, except in a table partition clause or the projection segmentation clause.

For syntax and parameters for the commands and system table discussed in this section, see the following topics:

- [CREATE FUNCTION](#)
- [ALTER FUNCTION \(scalar\)](#)
- [DROP FUNCTION](#)
- [GRANT \(user defined extension\)](#)
- [REVOKE \(user defined extension\)](#)
- [V_CATALOG.USER_FUNCTIONS](#)

In this section

- [Creating user-defined SQL functions](#)
- [Altering and dropping user-defined SQL functions](#)
- [Managing access to SQL functions](#)
- [Viewing information about user-defined SQL functions](#)
- [Migrating built-in SQL functions](#)

Creating user-defined SQL functions

A user-defined SQL function can be used anywhere in a query where an ordinary SQL expression can be used, except in the table partition clause or the projection segmentation clause.

To create a SQL function, the user must have CREATE privileges on the schema. To use a SQL function, the user must have USAGE privileges on the schema and EXECUTE privileges on the defined function.

This following statement creates a SQL function called `myzeroifnull` that accepts an `INTEGER` argument and returns an `INTEGER` result.

```
=> CREATE FUNCTION myzeroifnull(x INT) RETURN INT
AS BEGIN
  RETURN (CASE WHEN (x IS NOT NULL) THEN x ELSE 0 END);
END;
```

You can use the new SQL function (`myzeroifnull`) anywhere you use an ordinary SQL expression. For example, create a simple table:

```
=> CREATE TABLE tabwnulls(col1 INT);
=> INSERT INTO tabwnulls VALUES(1);
=> INSERT INTO tabwnulls VALUES(NULL);
=> INSERT INTO tabwnulls VALUES(0);
=> SELECT * FROM tabwnulls;
a
---
1
0
(3 rows)
```

Use the `myzeroifnull` function in a `SELECT` statement, where the function calls `col1` from table `tabwnulls`:

```
=> SELECT myzeroifnull(col1) FROM tabwnulls;
myzeroifnull
-----
1
0
0
(3 rows)
```

Use the `myzeroifnull` function in the `GROUP BY` clause:

```
=> SELECT COUNT(*) FROM tabwnulls GROUP BY myzeroifnull(col1);
count
-----
2
1
(2 rows)
```

If you want to change a user-defined SQL function's body, use the `CREATE OR REPLACE` syntax. The following command modifies the CASE expression:

```
=> CREATE OR REPLACE FUNCTION myzeroifnull(x INT) RETURN INT
AS BEGIN
RETURN (CASE WHEN (x IS NULL) THEN 0 ELSE x END);
END;
```

To see how this information is stored in the Vertica catalog, see [Viewing Information About SQL Functions](#) .

See also

- [CREATE FUNCTION \(SQL\)](#)
- [USER FUNCTIONS](#)

Altering and dropping user-defined SQL functions

Vertica allows multiple functions to share the same name with different argument types. Therefore, if you try to alter or drop a SQL function without specifying the argument data type, the system returns an error message to prevent you from dropping the wrong function:

```
=> DROP FUNCTION myzeroifnull();
ROLLBACK: Function with specified name and parameters does not exist: myzeroifnull
```

Note

Only a superuser or owner can alter or drop a SQL Function.

Altering a user-defined SQL function

The `ALTER FUNCTION (scalar)` command lets you assign a new name to a user-defined function, as well as move it to a different schema.

In the previous topic, you created a SQL function called `myzeroifnull` . The following command renames the `myzeroifnull` function to `zerowhennull` :

```
=> ALTER FUNCTION myzeroifnull(x INT) RENAME TO zerowhennull;  
ALTER FUNCTION
```

This next command moves the renamed function into a new schema called **macros** :

```
=> ALTER FUNCTION zerowhennull(x INT) SET SCHEMA macros;  
ALTER FUNCTION
```

Dropping a SQL function

The [DROP FUNCTION](#) command drops a SQL function from the Vertica catalog.

Like with ALTER FUNCTION, you must specify the argument data type or the system returns the following error message:

```
=> DROP FUNCTION zerowhennull();  
ROLLBACK: Function with specified name and parameters does not exist: zerowhennull
```

Specify the argument type:

```
=> DROP FUNCTION macros.zerowhennull(x INT);  
DROP FUNCTION
```

Vertica does not check for dependencies, so if you drop a SQL function where other objects reference it (such as views or other SQL Functions), Vertica returns an error when those objects are used, not when the function is dropped.

Tip

To view a list of all user-defined SQL functions on which you have EXECUTE privileges, (which also returns their argument types), query the [V_CATALOG.USER_FUNCTIONS](#) system table.

See also

- [ALTER FUNCTION \(scalar\)](#)
- [DROP FUNCTION](#)

Managing access to SQL functions

Before a user can execute a user-defined SQL function, he or she must have USAGE privileges on the schema and EXECUTE privileges on the defined function. Only the superuser or owner can grant/revoke EXECUTE usage on a function.

To grant EXECUTE privileges to user Fred on the **myzeroifnull** function:

```
=> GRANT EXECUTE ON FUNCTION myzeroifnull (x INT) TO Fred;
```

To revoke EXECUTE privileges from user Fred on the **myzeroifnull** function:

```
=> REVOKE EXECUTE ON FUNCTION myzeroifnull (x INT) FROM Fred;
```

See also

- [GRANT \(user defined extension\)](#)
- [REVOKE \(user defined extension\)](#)

Viewing information about user-defined SQL functions

You can access information about user-defined SQL functions on which you have EXECUTE privileges. This information is available in system table [USER_FUNCTIONS](#) and from the vsql meta-command `\df` .

To view all user-defined SQL functions on which you have EXECUTE privileges, query USER_FUNCTIONS:

```
=> SELECT * FROM USER_FUNCTIONS;
-[ RECORD 1 ]-----+-----
schema_name      | public
function_name    | myzeroifnull
function_return_type | Integer
function_argument_type | x Integer
function_definition | RETURN CASE WHEN (x IS NOT NULL) THEN x ELSE 0 END
volatility       | immutable
is_strict        | f
```

If you want to change the body of a user-defined SQL function, use the CREATE OR REPLACE syntax. The following command modifies the CASE expression:

```
=> CREATE OR REPLACE FUNCTION myzeroifnull(x INT) RETURN INT
AS BEGIN
RETURN (CASE WHEN (x IS NULL) THEN 0 ELSE x END);
END;
```

Now when you query USER_FUNCTIONS, you can see the changes in the `function_definition` column:

```
=> SELECT * FROM USER_FUNCTIONS;
-[ RECORD 1 ]-----+-----
schema_name      | public
function_name    | myzeroifnull
function_return_type | Integer
function_argument_type | x Integer
function_definition | RETURN CASE WHEN (x IS NULL) THEN 0 ELSE x END
volatility       | immutable
is_strict        | f
```

If you use CREATE OR REPLACE syntax to change only the argument name or argument type (or both), the system maintains both versions of the function. For example, the following command tells the function to accept and return a numeric data type instead of an integer for the `myzeroifnull` function:

```
=> CREATE OR REPLACE FUNCTION myzeroifnull(z NUMERIC) RETURN NUMERIC
AS BEGIN
RETURN (CASE WHEN (z IS NULL) THEN 0 ELSE z END);
END;
```

Now query the USER_FUNCTIONS table, and you can see the second instance of `myzeroifnull` in Record 2, as well as the changes in the `function_return_type`, `function_argument_type`, and `function_definition` columns.

Note

Record 1 still holds the original definition for the `myzeroifnull` function:

```

=> SELECT * FROM USER_FUNCTIONS;
-[ RECORD 1 ]-----+-----
schema_name      | public
function_name    | myzeroifnull
function_return_type | Integer
function_argument_type | x Integer
function_definition | RETURN CASE WHEN (x IS NULL) THEN 0 ELSE x END
volatility       | immutable
is_strict        | f
-[ RECORD 2 ]-----+-----
schema_name      | public
function_name    | myzeroifnull
function_return_type | Numeric
function_argument_type | z Numeric
function_definition | RETURN (CASE WHEN (z IS NULL) THEN (0) ELSE z END)::numeric
volatility       | immutable
is_strict        | f

```

Because Vertica allows functions to share the same name with different argument types, you must specify the argument type when you [alter](#) or [drop](#) a function. If you do not, the system returns an error message:

```

=> DROP FUNCTION myzeroifnull();
ROLLBACK: Function with specified name and parameters does not exist: myzeroifnull

```

Migrating built-in SQL functions

If you have built-in SQL functions from another RDBMS that do not map to a Vertica-supported function, you can migrate them into your Vertica database by using a user-defined SQL function.

The example scripts below show how to create user-defined functions for the following DB2 built-in functions:

- [UCASE\(\)](#)
- [LCASE\(\)](#)
- [LOCATE\(\)](#)
- [POSSTR\(\)](#)

UCASE()

This script creates a user-defined SQL function for the [UCASE\(\)](#) function:

```

=> CREATE OR REPLACE FUNCTION UCASE (x VARCHAR)
RETURN VARCHAR
AS BEGIN
RETURN UPPER(x);
END;

```

LCASE()

This script creates a user-defined SQL function for the [LCASE\(\)](#) function:

```

=> CREATE OR REPLACE FUNCTION LCASE (x VARCHAR)
RETURN VARCHAR
AS BEGIN
RETURN LOWER(x);
END;

```

LOCATE()

This script creates a user-defined SQL function for the [LOCATE\(\)](#) function:

```

=> CREATE OR REPLACE FUNCTION LOCATE(a VARCHAR, b VARCHAR)
RETURN INT
AS BEGIN
RETURN POSITION(a IN b);
END;

```

POSSTR()

This script creates a user-defined SQL function for the `POSSTR()` function:

```
=> CREATE OR REPLACE FUNCTION POSSTR(a VARCHAR, b VARCHAR)
  RETURN INT
  AS BEGIN
  RETURN POSITION(b IN a);
  END;
```

Stored procedures

You can condense complex database tasks and routines into stored procedures. Unlike [external procedures](#), stored procedures live and can be executed from inside your database; this lets them communicate and interact with your database directly to perform maintenance, execute queries, and update tables.

Best practices

Many other databases are optimized for online transaction processing (OLTP), which focuses on frequent transactions. In contrast, Vertica is optimized for online analytical processing (OLAP), which instead focuses on storing and analyzing large amounts of data and delivering the fastest responses to the most complex queries on that data.

This architecture difference means that the recommended use cases and best practices for stored procedures in Vertica differ slightly from stored procedures in other databases.

While stored procedures in OLTP-oriented databases are often used to perform small transactions, stored procedures in OLAP-oriented databases like Vertica should instead be used to enhance analytical workloads. Vertica can handle isolated transactions, but frequent small transactions can potentially hinder performance.

[Some recommended use cases](#) for stored procedures in Vertica include information lifecycle management (ILM) activities such as extract, transform, and load (ETL), and data preparation for tasks like machine learning. For example:

- Swapping partitions according to age
- Exporting data at end-of-life and dropping the partitions
- Saving inputs, outputs, and metadata from a machine learning model—who ran the model, the version of the model, how many times the model was run, and who received the results

Stored procedures in Vertica can also operate on objects that require higher privileges than that of the caller. [An optional parameter](#) allows procedures to run using the privileges of the definer, allowing callers to perform sensitive operations in a controlled way.

Viewing stored procedures

To view existing stored procedures, see [USER_PROCEDURES](#).

```
=> SELECT * FROM USER_PROCEDURES;
 procedure_name | owner | language | security | procedure_arguments | schema_name
-----+-----+-----+-----+-----+-----
 simple_procedure | dbadmin | PL/vSQL | INVOKER | INOUT x int, INOUT y varchar | public
 raiseXY          | dbadmin | PL/vSQL | INVOKER | INOUT x int, INOUT y int | public
(2 rows)
```

To view the the source code for stored procedures, export them with [EXPORT_OBJECTS](#).

To export a particular implementation of a stored procedure, specify either the types or both the names and types of the procedure's formal parameters. The following example specifies the types:

```

=> SELECT EXPORT_OBJECTS('raiseXY(int, int)');
   EXPORT_OBJECTS
-----
CREATE PROCEDURE public.raiseXY(x int, y int)
LANGUAGE 'PLvSQL'
SECURITY INVOKER
AS '
BEGIN
RAISE NOTICE "x = %", x;
RAISE NOTICE "y = %", y;
-- some processing statements
END
';

SELECT MARK_DESIGN_KSAFE(0);

(1 row)

```

To export all implementations of an overloaded stored procedure, export its parent schema:

```

=> SELECT EXPORT_OBJECTS('public');
   EXPORT_OBJECTS
-----
--

CREATE PROCEDURE public.raiseXY(x int, y varchar)
LANGUAGE 'PLvSQL'
SECURITY INVOKER
AS '
BEGIN
RAISE NOTICE "x = %", x;
RAISE NOTICE "y = %", y;
-- some processing statements
END
';

CREATE PROCEDURE public.raiseXY(x int, y int)
LANGUAGE 'PLvSQL'
SECURITY INVOKER
AS '
BEGIN
RAISE NOTICE "x = %", x;
RAISE NOTICE "y = %", y;
-- some processing statements
END
';

SELECT MARK_DESIGN_KSAFE(0);

(1 row)

```

Known issues and workarounds

- You cannot use [PERFORM CREATE FUNCTION](#) to create a SQL macro.

Workaround

Use EXECUTE to make [SQL macros](#) inside a stored procedure:

```
CREATE PROCEDURE procedure_name()
LANGUAGE PLvSQL AS $$
BEGIN
    EXECUTE 'macro';
end;
$$;
```

where *macro* is the creation statement for a SQL macro. For example, this procedure creates the argmax macro:

```
=> CREATE PROCEDURE make_argmax() LANGUAGE PLvSQL AS $$
BEGIN
    EXECUTE
        'CREATE FUNCTION
         argmax(x int) RETURN int AS
         BEGIN
             RETURN (CASE WHEN (x IS NOT NULL) THEN x ELSE 0 END);
         END';
END;
$$;
```

- Non-error exceptions in [embedded SQL statements](#) are not reported.
- DECIMAL, NUMERIC, NUMBER, MONEY, and UUID data types cannot yet be used for arguments.
- [Cursors](#) should capture the variable context at declaration time, but they currently capture the variable context at open time.
- DML queries on tables with key constraints cannot yet return a value.

Workaround

Rather than:

```
DO $$
DECLARE
    y int;
BEGIN
    y := UPDATE tbl WHERE col1 = 3 SET col2 = 4;
END;
$$
```

Check the result of the DML query with SELECT:

```
DO $$
DECLARE
    y int;
BEGIN
    y := SELECT COUNT(*) FROM tbl WHERE col1 = 3;
    PERFORM UPDATE tbl SET col2 = 4 WHERE col1 = 3;
END;
$$;
```

PL/vSQL

PL/vSQL is a powerful and expressive procedural language for creating reusable procedures, manipulating data, and simplifying otherwise complex database routines.

Vertica PL/vSQL is largely compatible with PostgreSQL PL/pgSQL, with minor semantic differences. For details on migrating your [PostgreSQL PL/pgSQL](#) stored procedures to Vertica, see the [PL/pgSQL to PL/vSQL migration guide](#).

For real-world, practical examples of PL/vSQL usage, see [Stored procedures: use cases and examples](#).

In this section

- [Supported types](#)
- [Scope and structure](#)

- [Embedded SQL](#)
- [Control flow](#)
- [Errors and diagnostics](#)
- [Cursors](#)
- [PL/pgSQL to PL/vSQL migration guide](#)

Supported types

Vertica PL/vSQL supports non-complex [data types](#). The following types are supported as [variables](#) only and not as arguments:

- DECIMAL
- NUMERIC
- NUMBER
- MONEY
- UUID

Scope and structure

PL/vSQL uses block scope, where a block has the following structure:

```
[ <<label>> ]
[ DECLARE
  declarations ]
BEGIN
  statements
  ...
END [ label ];
```

Declarations

Variable *declarations* in the DECLARE block are structured as:

```
variable_name [ CONSTANT ] data_type [ NOT NULL ] [ := { expression | statement } ];
```

<i>variable_name</i>	Variable names must meet the following requirements: <ul style="list-style-type: none"> • Must be SQL identifiers • Cannot be reserved keywords • Cannot duplicate those in previous declarations inside the same block.
CONSTANT	Defines the variable as a constant (immutable). You can only set a constant variable's value during initialization.
<i>data_type</i>	The variable data type. PL/vSQL supports non-complex data types , with the following exceptions: <ul style="list-style-type: none"> • GEOMETRY • GEOGRAPHY You can optionally reference a particular column's data type: <i>variable_name table_name.column_name%TYPE ;</i>
NOT NULL	Specifies that the variable cannot hold a NULL value. If declared with NOT NULL, the variable must be initialized (otherwise, throws ERRCODE_SYNTAX_ERROR) and cannot be assigned NULL (otherwise, throws ERRCODE_WRONG_OBJECT_TYPE).

`:= expression`

Initializes a variable with *expression* or statement.

If the variable is declared with **NOT NULL**, *expression* is required.

Variable declarations in a given block execute sequentially, so old declarations can be referenced by newer ones. For example:

```
DECLARE
```

```
  x int := 3;
```

```
  y int := x;
```

Default (uninitialized): NULL

Aliases

Aliases are alternate names for the same variable. An alias of a variable is not a copy, and changes made to either reference affect the same underlying variable.

```
new_name ALIAS FOR variable;
```

Here, the identifier *y* is now an alias for variable *x*, and changes to *y* are reflected in *x*.

```
DO $$
DECLARE
  x int := 3;
  y ALIAS FOR x;
BEGIN
  y := 5; -- since y refers to x, x = 5
  RAISE INFO 'x = %, y = %', x, y;
END;
$$;

INFO 2005: x = 5, y = 5
```

BEGIN and nested blocks

BEGIN contains *statements*. A *statement* is defined as a line or block of PL/SQL.

Variables declared in inner blocks [shadow](#) those declared in outer blocks. To unambiguously specify a variable in a particular block, you can name the block with a *label* (case-insensitive), and then reference the variable declared in that block with:

```
label.variable_name
```

For example, specifying the variable *x* from inside the inner block implicitly refers to *inner_block.x* rather than *outer_block.x* because of shadowing:

```
<<outer_block>>
DECLARE
  x int;
BEGIN
  <<inner_block>>
  DECLARE
    x int;
  BEGIN
    x := 1000; -- implicitly specifies x in inner_block because of shadowing
    OUTER_BLOCK.x := 0; -- specifies x in outer_block; labels are case-insensitive
  END inner_block;
END outer_block;
```

NULL statement

The NULL statement does nothing. This can be useful as a placeholder statement or a way to show that a code block is intentionally empty. For example:

```
DO $$
BEGIN
  NULL;
END;
$$
```

Comments

Comments have the following syntax. You cannot nest comments.

```
-- single-line comment

/* multi-line
comment
*/
```

Nested stored procedures

Stored procedures that call other stored procedures, also called nested stored procedures, can be useful for simplifying complex functions and reusing code.

You can enable nested stored procedures by setting the `EnableNestedStoredProcedures` configuration parameter (disabled by default):

```
--Enable nested calls
=> ALTER DATABASE DEFAULT SET EnableNestedStoredProcedures = 1;

--Disable nested calls
=> ALTER DATABASE DEFAULT SET EnableNestedStoredProcedures = 0;
```

In the following example, `proc2()` calls `proc1()` to insert values into a table:

```
CREATE PROCEDURE proc1() AS
$$
  BEGIN PERFORM INSERT INTO t_int VALUES(2023);
  END;
$$;

CREATE PROCEDURE proc2() AS $$
BEGIN
  PERFORM CREATE TABLE IF NOT EXISTS t_int(x int);
  PERFORM CALL proc1();
END;
$$;
```

You can also use this feature to call meta-functions:

```
CREATE PROCEDURE RUN_ANALYZE_STATS() AS
$$
  BEGIN PERFORM SELECT analyze_statistics("");
  END;
$$;

CALL run_analyze_stats();
```

Depth limits

Stored procedures can only be nested up to a depth of 50. If a stored procedure exceeds the call depth, the entire operation is terminated and [rolled back](#).

The stored procedure `recursive_proc()` calls itself to insert sequential values into a table, but it has no condition to stop before the depth limit. Calling the procedure causes a rollback and no changes are made to the table:

```

=> CREATE TABLE numbers (n INT);

=> SELECT * FROM numbers;
n
--
(0 rows)

=> CREATE OR REPLACE PROCEDURE recursive_proc(x int) AS
$$
BEGIN
    PERFORM INSERT INTO numbers VALUES(x + 1);
    PERFORM CALL recursive_proc(x + 1);
END;
$$;

=> CALL recursive_proc(0);

ERROR 0: Nested stored procedure call exceeds call depth limit
CONTEXT: PL/vSQL procedure recursive_proc line 4 at static SQL
PL/vSQL procedure recursive_proc line 4 at static SQL
PL/vSQL procedure recursive_proc line 4 at static SQL
--
=> SELECT * FROM numbers;
n
--
(0 rows)

```

Embedded SQL

You can embed and execute SQL [statements](#) and [expressions](#) from within stored procedures.

Assignment

To save the value of an expression or returned value, you can assign it to a variable:

```

variable_name := expression;
variable_name := statement;

```

For example, this procedure assigns 3 into **i** and 'message' into **v**.

```

=> CREATE PROCEDURE performless_assignment() LANGUAGE PLvSQL AS $$
DECLARE
    i int;
    v varchar;
BEGIN
    i := SELECT 3;
    v := 'message';
END;
$$;

```

This type of assignment will fail if the query returns no rows or more than one row. For returns of multiple rows, use [LIMIT](#) or [truncating assignment](#):

```

=> SELECT * FROM t1;
b
---
t
f
f
(3 rows)

=> CREATE PROCEDURE more_than_one_row() LANGUAGE PLvSQL as $$
DECLARE
  x boolean;
BEGIN
  x := SELECT * FROM t1;
END;
$$;
CREATE PROCEDURE

=> CALL more_than_one_row();
ERROR 10332: Query returned multiple rows where 1 was expected

```

Truncating assignment

Truncating assignment stores in a variable the first row returned by a query. Row order is nondeterministic unless you specify an [ORDER BY clause](#) :

```

variable_name <- expression;
variable_name <- statement;

```

The following procedure takes the first row of the results returned by the specified query and assigns it to `x` :

```

=> CREATE PROCEDURE truncating_assignment() LANGUAGE PLvSQL AS $$
DECLARE
  x boolean;
BEGIN
  x <- SELECT * FROM t1 ORDER BY b DESC; -- x is now assigned the first row returned by the SELECT query
END;
$$;

```

PERFORM

The PERFORM keyword runs a SQL [statement](#) or [expression](#) and discards the returned result.

```

PERFORM statement;
PERFORM expression;

```

For example, this procedure inserts a value into a table. INSERT returns the number of rows inserted, so you must pair it with PERFORM.

```

=> DO $$
BEGIN
  PERFORM INSERT INTO coordinates VALUES(1,2,3);
END;
$$;

```

Note

If a SQL statement has no return value or you don't assign the return value to a variable, you must use PERFORM.

EXECUTE

EXECUTE allows you to dynamically construct a SQL query during execution:

```

EXECUTE command_expression [ USING expression [, ... ] ];

```

`command_expression` is a SQL expression that can reference PL/vSQL variables and evaluates to a string literal. The string literal is executed as a SQL statement, and \$1, \$2, ... are substituted with the corresponding * `expression` *s.

Constructing your query with PL/SQL variables can be dangerous and expose your system to SQL injection, so wrap them with [QUOTE_IDENT](#), [QUOTE_LITERAL](#), and [QUOTE_NULLABLE](#).

The following procedure constructs a query with a WHERE clause:

```
DO $$
BEGIN
  EXECUTE 'SELECT * FROM t1 WHERE x = $1' USING 10; -- becomes WHERE x = 10
END;
$$;
```

The following procedure creates a user with a password from the `username` and `password` arguments. Because the constructed CREATE USER statement uses variables, use the functions QUOTE_IDENT and QUOTE_LITERAL, [concatenating](#) them with `||`.

```
=> CREATE PROCEDURE create_user(username varchar, password varchar) LANGUAGE PLvSQL AS $$
BEGIN
  EXECUTE 'CREATE USER ' || QUOTE_IDENT(username) || ' IDENTIFIED BY ' || QUOTE_LITERAL(password);
END;
$$;
```

EXECUTE is a SQL statement, so you can assign it to a variable or pair it with PERFORM:

```
variable_name:= EXECUTE command_expression;
PERFORM EXECUTE command_expression;
```

FOUND (special variable)

The special boolean variable FOUND is initialized as false and assigned true or false based on whether:

- A statement (but not expression) returns results with non-zero number of rows, or
- A [FOR](#) loop iterates at least once

You can use FOUND to distinguish between a NULL and 0-row return.

Special variables exist between the [scope](#) of a procedure's argument and the outermost block of its definition. This means that:

- Special variables shadow procedure arguments
- Variables declared in the body of the stored procedure will shadow the special variable

The following procedure demonstrates how FOUND changes. Before the SELECT statement, FOUND is false; after the SELECT statement, FOUND is true.

```
=> DO $$
BEGIN
  RAISE NOTICE 'Before SELECT, FOUND = %', FOUND;
  PERFORM SELECT 1; -- SELECT returns 1
  RAISE NOTICE 'After SELECT, FOUND = %', FOUND;
END;
$$;

NOTICE 2005: Before SELECT, FOUND = f
NOTICE 2005: After SELECT, FOUND = t
```

Similarly, UPDATE, DELETE, and INSERT return the number of rows affected. In the next example, UPDATE doesn't change any rows, but returns the value 0 to indicate that no rows were affected, so FOUND is set to true:

```

=> SELECT * t1;
  a | b
-----+-----
100 | abc
(1 row)

DO $$
BEGIN
  PERFORM UPDATE t1 SET a=200 WHERE b='efg'; -- no rows affected since b doesn't contain 'efg'
  RAISE INFO 'FOUND = %', FOUND;
END;
$$;

INFO 2005: FOUND = t

```

FOUND starts as false and is set to true if the loop iterates at least once:

```

=> DO $$
BEGIN
  RAISE NOTICE 'FOUND = %', FOUND;
  FOR i IN RANGE 1..1 LOOP -- RANGE is inclusive, so iterates once
    RAISE NOTICE 'i = %', i;
  END LOOP;
  RAISE NOTICE 'FOUND = %', FOUND;
END;
$$;

NOTICE 2005: FOUND = f
NOTICE 2005: FOUND = t

DO $$
BEGIN
  RAISE NOTICE 'FOUND = %', FOUND;
  FOR i IN RANGE 1..0 LOOP
    RAISE NOTICE 'i = %', i;
  END LOOP;
  RAISE NOTICE 'FOUND = %', FOUND;
END;
$$;

NOTICE 2005: FOUND = f
NOTICE 2005: FOUND = f

```

Control flow

Control flow constructs give you control over how many times and under what conditions a block of statements should run.

Conditionals

IF/ELSIF/ELSE

IF/ELSIF/ELSE statements let you perform different actions based on a specified condition.

```

IF condition_1 THEN
  statement_1;
[ ELSIF condition_2 THEN
  statement_2 ]
...
[ ELSE
  statement_n; ]
END IF;

```

Vertica successively evaluates each condition as a boolean until it finds one that's true, then executes the block of statements and exits the IF statement. If no conditions are true, it executes the ELSE block, if one exists.

```
IF i = 3 THEN...
ELSIF 0 THEN...
ELSIF true THEN...
ELSIF x <= 4 OR x >= 10 THEN...
ELSIF y = 'this' AND z = 'THAT' THEN...
```

For example, this procedure demonstrates a simple IF...ELSE branch. Because `b` is declared to be true, Vertica executes the first branch.

```
=> DO LANGUAGE PLvSQL $$
DECLARE
  b bool := true;
BEGIN
  IF b THEN
    RAISE NOTICE 'true branch';
  ELSE
    RAISE NOTICE 'false branch';
  END IF;
END;
$$;
```

```
NOTICE 2005: true branch
```

CASE

CASE expressions are often more readable than IF...ELSE chains. After executing a CASE expression's branch, control jumps to the statement after the enclosing END CASE.

PL/vSQL CASE expressions are more flexible and powerful than [SQL case expressions](#), but the latter are more efficient; you should favor SQL case expressions when possible.

```
CASE [ search_expression ]
  WHEN expression_1 [, expression_2, ...] THEN
    when_statements
[ ... ]
[ ELSE
  else_statements ]
END CASE;
```

search_expression is evaluated once and then compared with *expression_n* in each branch from top to bottom. If *search_expression* and a given *expression_n* are equal, then Vertica executes the WHEN block for *expression_n* and exits the CASE block. If no matching expression is found, the ELSE branch is executed, if one exists.

Case expressions must have either a matching case or an ELSE branch, otherwise Vertica throws a CASE_NOT_FOUND error.

If you omit *search_expression*, its value defaults to `true`.

For example, this procedure plays the game FizzBuzz, printing Fizz if the argument is divisible by 3, Buzz if the argument is divisible by 5, FizzBuzz if the if the argument is divisible by 3 and 5.

```

=> CREATE PROCEDURE fizzbuzz(IN x int) LANGUAGE PLvSQL AS $$
DECLARE
  fizz int := x % 3;
  buzz int := x % 5;
BEGIN
  CASE fizz
    WHEN 0 THEN -- if fizz = 0, execute WHEN block
      CASE buzz
        WHEN 0 THEN -- if buzz = 0, execute WHEN block
          RAISE INFO 'FizzBuzz';
        ELSE -- if buzz != 0, execute WHEN block
          RAISE INFO 'Fizz';
        END CASE;
    ELSE -- if fizz != 0, execute ELSE block
      CASE buzz
        WHEN 0 THEN
          RAISE INFO 'Buzz';
        ELSE
          RAISE INFO "";
        END CASE;
    END CASE;
END;
$$;

```

```

=> CALL fizzbuzz(3);
INFO 2005: Fizz

```

```

=> CALL fizzbuzz(5);
INFO 2005: Buzz

```

```

=> CALL fizzbuzz(15);
INFO 2005: FizzBuzz

```

Loops

Loops repeatedly execute a block of code until a given condition is satisfied.

WHILE

A WHILE loop checks a given condition and, if the condition is true, it executes the loop body, after which the condition is checked again: if true, the loop body executes again; if false, control jumps to the end of the loop body.

```

[ <<label>> ]
WHILE condition LOOP
  statements;
END LOOP;

```

For example, this procedure computes the factorial of the argument:

```

=> CREATE PROCEDURE factorialSP(input int) LANGUAGE PLvSQL AS $$
DECLARE
  i int := 1;
  output int := 1;
BEGIN
  WHILE i <= input loop
    output := output * i;
    i := i + 1;
  END LOOP;
  RAISE INFO '%! = %', input, output;
END;
$$;

```

```

=> CALL factorialSP(5);
INFO 2005: 5! = 120

```

LOOP

This type of loop is equivalent to **WHILE true** and only terminates if it encounters a RETURN or EXIT statement, or if an exception is thrown.

```
[ <<label>> ]  
LOOP  
  statements;  
END LOOP;
```

For example, this procedure prints the integers from **counter** up to **upper_bound** , inclusive:

```
DO $$  
DECLARE  
  counter int := 1;  
  upper_bound int := 3;  
BEGIN  
  LOOP  
    RAISE INFO '%', counter;  
    IF counter >= upper_bound THEN  
      RETURN;  
    END IF;  
    counter := counter + 1;  
  END LOOP;  
END;  
$$;  
  
INFO 2005: 1  
INFO 2005: 2  
INFO 2005: 3
```

FOR

FOR loops iterate over a collection, which can be an integral range, query, or cursor.

If a FOR loop iterates at least once, the special **FOUND variable** is set to true after the loop ends. Otherwise, FOUND is set to false.

The FOUND variable can be useful for distinguishing between a NULL and 0-row return, or creating an IF branch if a LOOP didn't run.

FOR (RANGE)

A FOR (RANGE) loop iterates over a range of integers specified by the expressions **left** and **right** .

```
[ <<label>> ]  
FOR loop_counter IN RANGE [ REVERSE ] left..right [ BY step ] LOOP  
  statements  
END LOOP [ label];
```

loop_counter :

- does not have to be declared and is initialized with the value of **left**
- is only available within the scope of the FOR loop

loop_counter iterates from **left** to **right** (inclusive), incrementing by **step** at the end of each iteration.

The **REVERSE** option instead iterates from **right** to **left** (inclusive), decrementing by **step** .

For example, here is a standard ascending FOR loop with **step** = 1:

```

=> DO $$
BEGIN
  FOR i IN RANGE 1..4 LOOP -- loop_counter i does not have to be declared
    RAISE NOTICE 'i = %', i;
  END LOOP;
  RAISE NOTICE 'after loop: i = %', i; -- fails
END;
$$;

NOTICE 2005: i = 1
NOTICE 2005: i = 2
NOTICE 2005: i = 3
NOTICE 2005: i = 4
ERROR 2624: Column "i" does not exist -- loop_counter i is only available inside the FOR loop

```

Here, the *loop_counter* *i* starts at 4 and decrements by 2 at the end of each iteration:

```

=> DO $$
BEGIN
  FOR i IN RANGE REVERSE 4..0 BY 2 LOOP
    RAISE NOTICE 'i = %', i;
  END LOOP;
END;
$$;

NOTICE 2005: i = 4
NOTICE 2005: i = 2
NOTICE 2005: i = 0

```

FOR (query)

A FOR (QUERY) loop iterates over the results of a query.

```

[ <<label>> ]
FOR target IN QUERY statement LOOP
  statements
END LOOP [ label ];

```

You can include an [ORDER BY clause](#) in the query to make the ordering deterministic.

Unlike FOR (RANGE) loops, you must declare the *target* variables. The values of these variables persist after the loop ends.

For example, suppose given the table *tuple* :

```

=> SELECT * FROM tuples ORDER BY x ASC;
 x | y | z
---+---+---
 1 | 2 | 3
 4 | 5 | 6
 7 | 8 | 9
(3 rows)

```

This procedure retrieves the tuples in each row and stores them in the variables *a* , *b* , and *c* , and prints them after each iteration:

```
=>
=> DO $$
DECLARE
  a int; -- target variables must be declared
  b int;
  c int;
  i int := 1;
BEGIN
  FOR a,b,c IN QUERY SELECT * FROM tuples ORDER BY x ASC LOOP
    RAISE NOTICE 'iteration %: a = %, b = %, c = %', i,a,b,c;
    i := i + 1;
  END LOOP;
  RAISE NOTICE 'after loop: a = %, b = %, c = %', a,b,c;
END;
$$;

NOTICE 2005: iteration 1: a = 1, b = 2, c = 3
NOTICE 2005: iteration 2: a = 4, b = 5, c = 6
NOTICE 2005: iteration 3: a = 7, b = 8, c = 9
NOTICE 2005: after loop: a = 7, b = 8, c = 9
```

You can also use a query constructed dynamically with [EXECUTE](#):

```
[ <<label>> ]
FOR target IN EXECUTE 'statement' [ USING expression [, ... ] ] LOOP
  statements
END LOOP [ label];
```

The following procedure uses EXECUTE to construct a FOR (QUERY) loop and stores the results of that SELECT statement in the variables **x** and **y**. The result set of a statement like this has only one row, so it only iterates once.

```
=> SELECT 'first string', 'second string';
?column? | ?column?
-----+-----
first string | second string
(1 row)

=> DO $$
DECLARE
  x varchar; -- target variables must be declared
  y varchar;
BEGIN
  -- substitute the placeholders $1 and $2 with the strings
  FOR x, y IN EXECUTE 'SELECT $1, $2' USING 'first string', 'second string' LOOP
    RAISE NOTICE '%', x;
    RAISE NOTICE '%', y;
  END LOOP;
END;
$$;

NOTICE 2005: first string
NOTICE 2005: second string
```

FOR (cursor)

A FOR (CURSOR) loop iterates over a [bound, unopened cursor](#), executing some set of *statements* for each iteration.

```
[ <<label>> ]
FOR loop_variable [, ...] IN CURSOR bound_unopened_cursor [ ( [ arg_name := ] arg_value [, ...] ) ] LOOP
  statements
END LOOP [ label];
```

This type of FOR loop opens the cursor at start of the loop and closes at the end.

For example, this procedure creates a cursor `c`. The procedure passes `6` as an argument to the cursor, so the cursor only retrieves rows where the `y`-coordinate is `6`, storing the coordinates in the variables `x_`, `y_`, and `z_` and printing them at the end of each iteration:

```
=> SELECT * FROM coordinates;
x | y | z
-----+-----
14 | 6 | 19
 1 | 6 |  2
10 | 6 | 39
10 | 2 |  1
 7 | 1 | 10
67 | 1 | 77
(6 rows)

DO $$
DECLARE
  c CURSOR (key int) FOR SELECT * FROM coordinates WHERE y=key;
  x_ int;
  y_ int;
  z_ int;
BEGIN
  FOR x_,y_,z_ IN CURSOR c(6) LOOP
    RAISE NOTICE 'cursor returned %,%,% FOUND=%', x_,y_,z_,FOUND;
  END LOOP;
  RAISE NOTICE 'after loop: %,%,% FOUND=%', x_,y_,z_,FOUND;
END;
$$;

NOTICE 2005: cursor returned 14,6,19 FOUND=f -- FOUND is only set after the loop ends
NOTICE 2005: cursor returned 1,6,2 FOUND=f
NOTICE 2005: after loop: 10,6,39 FOUND=t -- x_, y_, and z_ retain their values, FOUND is now true because the FOR loop iterated at least once
```

Manipulating loops

RETURN

You can exit the entire procedure (and therefore the loop) with `RETURN`. `RETURN` is an optional statement and can be added to signal to readers the end of a procedure.

```
RETURN;
```

EXIT

Similar to a `break` or labeled `break` in other programming languages, `EXIT` statements let you exit a loop early, optionally specifying:

- `loop_label`: the name of the loop to exit from
- `condition`: if the `condition` is `true`, execute the `EXIT` statement

```
EXIT [ loop_label ] [ WHEN condition ];
```

CONTINUE

`CONTINUE` skips to the next iteration of the loop without executing statements that follow the `CONTINUE` itself. You can specify a particular loop with `loop_label`:

```
CONTINUE [ loop_label ] [ WHEN condition ];
```

For example, this procedure doesn't print during its first two iterations because the `CONTINUE` statement executes and moves on to the next iteration of the loop before control reaches the `RAISE NOTICE` statement:

```

=> DO $$
BEGIN
  FOR i IN RANGE 1..5 LOOP
    IF i < 3 THEN
      CONTINUE;
    END IF;
    RAISE NOTICE 'i = %', i;
  END LOOP;
END;
$$;

```

```

NOTICE 2005: i = 3
NOTICE 2005: i = 4
NOTICE 2005: i = 5

```

Errors and diagnostics

ASSERT

ASSERT is a debugging feature that checks whether a condition is `true`. If the condition is `false`, ASSERT raises an `ASSERT_FAILURE` exception with an optional error message.

To escape a `'` (single quote) character, use `"`. Similarly, to escape a `"` (double quote) character, use `""`.

```
ASSERT condition [ , message ];
```

For example, this procedure checks the number of rows in the `products` table and uses ASSERT to check that the table is populated. If the table is empty, Vertica raises an error:

```

=> CREATE TABLE products(id UUID, name VARCHAR, price MONEY);
CREATE TABLE

=> SELECT * FROM products;
 id | name | price
----+-----+-----
(0 rows)

DO $$
DECLARE
  prod_count INT;
BEGIN
  prod_count := SELECT count(*) FROM products;
  ASSERT prod_count > 0, 'products table is empty';
END;
$$;

ERROR 2005: products table is empty

```

To stop Vertica from checking ASSERT statements, [you can set the boolean session-level parameter `PLpgSQLCheckAsserts`](#).

RAISE

RAISE can throw errors or print a user-specified error message, one of the following:

```

RAISE [ level ] 'format' [ , arg_expression [ , ... ] ] [ USING option = expression [ , ... ] ];
RAISE [ level ] condition_name [ USING option = expression [ , ... ] ];
RAISE [ level ] SQLSTATE 'sql-state' [ USING option = expression [ , ... ] ];
RAISE [ level ] USING option = expression [ , ... ] ;

```

<i>level</i>	<p>VARCHAR, one of the following:</p> <ul style="list-style-type: none"> • LOG: Sends the <i>format</i> to vertica.log • INFO: Prints an INFO message in VSQL • NOTICE: Prints a NOTICE in VSQL • WARNING: Prints a WARNING in VSQL • EXCEPTION: Throws catchable exception <p>Default: EXCEPTION</p>																				
<i>format</i>	<p>VARCHAR, a string literal error message where the percent character % is substituted with the * <i>arg_expression</i> *s. %% escapes the substitution and results in a single % in plaintext.</p> <p>If the number of % characters doesn't equal the number of arguments, Vertica throws an error.</p> <p>To escape a ' (single quote) character, use ". Similarly, to escape a " (double quote) character, use "" .</p>																				
<i>arg_expression</i>	<p>An expression that substitutes for the percent character (%) in the <i>format</i> string.</p>																				
<i>option = expression</i>	<p><i>option</i> must be one of the following and paired with an <i>expression</i> that elaborates on the <i>option</i> :</p> <table border="1"> <thead> <tr> <th><i>option</i></th> <th><i>expression content</i></th> </tr> </thead> <tbody> <tr> <td>MESSAGE</td> <td> <p>An error message.</p> <p>Default: the ERRCODE associated with the exception</p> </td> </tr> <tr> <td>DETAIL</td> <td> <p>Details about the error.</p> </td> </tr> <tr> <td>HINT</td> <td> <p>A hint message.</p> </td> </tr> <tr> <td>ERRCODE</td> <td> <p>The error code to report, one of the following:</p> <ul style="list-style-type: none"> • A condition name specified in the <i>description</i> column of the SQL state list (with optional ERRCODE_ prefix) • A code that satisfies the SQLSTATE formatting: 5-character sequence of numbers and capital letters (not necessarily on the SQL State List) <p>Default: ERRCODE_RAISE_EXCEPTION (V0002)</p> </td> </tr> <tr> <td>COLUMN</td> <td> <p>A column name relevant to the error</p> </td> </tr> <tr> <td>CONSTRAINT</td> <td> <p>A constraint relevant to the error</p> </td> </tr> <tr> <td>DATATYPE</td> <td> <p>A data type relevant to the error</p> </td> </tr> <tr> <td>TABLE</td> <td> <p>A table name relevant to the error</p> </td> </tr> <tr> <td>SCHEMA</td> <td> <p>A schema name relevant to the error</p> </td> </tr> </tbody> </table>	<i>option</i>	<i>expression content</i>	MESSAGE	<p>An error message.</p> <p>Default: the ERRCODE associated with the exception</p>	DETAIL	<p>Details about the error.</p>	HINT	<p>A hint message.</p>	ERRCODE	<p>The error code to report, one of the following:</p> <ul style="list-style-type: none"> • A condition name specified in the <i>description</i> column of the SQL state list (with optional ERRCODE_ prefix) • A code that satisfies the SQLSTATE formatting: 5-character sequence of numbers and capital letters (not necessarily on the SQL State List) <p>Default: ERRCODE_RAISE_EXCEPTION (V0002)</p>	COLUMN	<p>A column name relevant to the error</p>	CONSTRAINT	<p>A constraint relevant to the error</p>	DATATYPE	<p>A data type relevant to the error</p>	TABLE	<p>A table name relevant to the error</p>	SCHEMA	<p>A schema name relevant to the error</p>
<i>option</i>	<i>expression content</i>																				
MESSAGE	<p>An error message.</p> <p>Default: the ERRCODE associated with the exception</p>																				
DETAIL	<p>Details about the error.</p>																				
HINT	<p>A hint message.</p>																				
ERRCODE	<p>The error code to report, one of the following:</p> <ul style="list-style-type: none"> • A condition name specified in the <i>description</i> column of the SQL state list (with optional ERRCODE_ prefix) • A code that satisfies the SQLSTATE formatting: 5-character sequence of numbers and capital letters (not necessarily on the SQL State List) <p>Default: ERRCODE_RAISE_EXCEPTION (V0002)</p>																				
COLUMN	<p>A column name relevant to the error</p>																				
CONSTRAINT	<p>A constraint relevant to the error</p>																				
DATATYPE	<p>A data type relevant to the error</p>																				
TABLE	<p>A table name relevant to the error</p>																				
SCHEMA	<p>A schema name relevant to the error</p>																				

This procedure demonstrates various RAISE levels:

```

=> DO $$
DECLARE
  logfile varchar := 'vertica.log';
BEGIN
  RAISE LOG 'this message was sent to %', logfile;
  RAISE INFO 'info';
  RAISE NOTICE 'notice';
  RAISE WARNING 'warning';
  RAISE EXCEPTION 'exception';

  RAISE NOTICE 'exception changes control flow; this is not printed';
END;
$$;

INFO 2005: info
NOTICE 2005: notice
WARNING 2005: warning
ERROR 2005: exception

$ grep 'this message was sent to vertica.log' v_vmart_node0001_catalog/vertica.log
<LOG> @v_vmart_node0001: V0002/2005: this message is sent to vertica.log

```

Exceptions

EXCEPTION blocks let you catch and handle [exceptions](#) that might get thrown from *statements* :

```

[ <<label>> ]
[ DECLARE
  declarations ]
BEGIN
  statements
EXCEPTION
  WHEN exception_condition [ OR exception_condition ... ] THEN
    handler_statements
  [ WHEN exception_condition [ OR exception_condition ... ] THEN
    handler_statements
    ... ]
END [ label ];

```

exception_condition has one of the following forms:

```

WHEN errcode_division_by_zero THEN ...
WHEN division_by_zero THEN ...
WHEN SQLSTATE '22012' THEN ...
WHEN OTHERS THEN ...

```

OTHERS is a special condition that catches all exceptions except **QUERY_CANCELLED** , **ASSERT_FAILURE** , and **FEATURE_NOT_SUPPORTED** .

When an exception is thrown, Vertica checks the list of exceptions for a matching *exception_condition* from top to bottom. If it finds a match, it executes the *handler_statements* and then leaves the exception block's scope.

If Vertica can't find a match, it propagates the exception up to the next enclosing block. You can do this manually within an exception handler with RAISE:

```

RAISE;

```

For example, the following procedure divides 3 by 0 in the *inner_block* , which is an illegal operation that throws the exception *division_by_zero* with SQL state 22012. Vertica checks the inner EXCEPTION block for a matching condition:

1. The first condition checks for SQL state 42501, so Vertica, so Vertica moves to the next condition.
2. WHEN OTHERS THEN catches all exceptions, so it executes that block.
3. The bare RAISE then propagates the exception to the *outer_block* .
4. The outer EXCEPTION block successfully catches the exception and prints a message.

```

=> DO $$
<<outer_block>>
BEGIN
  <<inner_block>>
  DECLARE
    x int;
  BEGIN
    x := 3 / 0; -- throws exception division_by_zero, SQLSTATE 22012
  EXCEPTION -- this block is checked first for matching exceptions
    WHEN SQLSTATE '42501' THEN
      RAISE NOTICE 'caught insufficient_privilege exception';
    WHEN OTHERS THEN -- catches all exceptions
      RAISE; -- manually propagate the exception to the next enclosing block
  END inner_block;
EXCEPTION -- exception is propagated to this block
  WHEN division_by_zero THEN
    RAISE NOTICE 'caught division_by_zero exception';
END outer_block;
$$;

NOTICE 2005: caught division_by_zero exception

```

SQLSTATE and SQLERRM variables

When handling an exception, you can use the following variables to retrieve error information:

- **SQLSTATE** contains the SQL state
- **SQLERRM** contains the error message

For details, see [SQL state list](#).

This procedure catches the exception thrown by attempting to assign NULL to a NOT NULL variable and prints the SQL state and error message:

```

DO $$
DECLARE
  i int NOT NULL := 1;
BEGIN
  i := NULL; -- illegal, i was declared with NOT NULL
EXCEPTION
  WHEN OTHERS THEN
    RAISE WARNING 'SQL State: %', SQLSTATE;
    RAISE WARNING 'Error message: %', SQLERRM;
END;
$$;

WARNING 2005: SQLSTATE: 42809
WARNING 2005: SQLERRM: Cannot assign null into NOT NULL variable

```

Retrieving exception information

You can retrieve information about exceptions inside exception handlers with GET STACKED DIAGNOSTICS:

```
GET STACKED DIAGNOSTICS variable_name { = | := } item [, ... ];
```

Where *item* can be any of the following:

<i>item</i>	Description
RETRUNED_SQLSTATE	SQLSTATE error code of the exception
COLUMN_NAME	Name of the column related to exception
CONSTRAINT_NAME	Name of the constraint related to exception

DATATYPE_NAME	Name of the data type related to exception
MESSAGE_TEXT	Text of the exception's primary message
TABLE_NAME	Name of the table related to exception
SCHEMA_NAME	Name of the schema related to exception
DETAIL_TEXT	Text of the exception's detail message, if any
HINT_TEXT	Text of the exception's hint message, if any
EXCEPTION_CONTEXT	Description of the call stack at the time of the exception

For example, this procedure has an EXCEPTION block that catches the [division_by_zero](#) error and prints SQL state, error message, and the exception context:

```
=> DO $$
DECLARE
  message_1 varchar;
  message_2 varchar;
  message_3 varchar;
  x int;
BEGIN
  x := 5 / 0;
EXCEPTION
  WHEN OTHERS THEN -- OTHERS catches all exceptions
    GET STACKED DIAGNOSTICS message_1 = RETURNED_SQLSTATE,
                          message_2 = MESSAGE_TEXT,
                          message_3 = EXCEPTION_CONTEXT;

  RAISE INFO 'SQLSTATE: %', message_1;
  RAISE INFO 'MESSAGE: %', message_2;
  RAISE INFO 'EXCEPTION_CONTEXT: %', message_3;
END;
$$;

INFO 2005: SQLSTATE: 22012
INFO 2005: MESSAGE: Division by zero
INFO 2005: EXCEPTION_CONTEXT: PL/vSQL procedure inline_code_block line 8 at static SQL
```

Cursors

A cursor is a reference to the result set of a query and allows you to view the results one row at a time. Cursors remember their positions in result sets, which can be one of the following:

- a result row
- before the first row
- after the last row

You can also iterate over unopened, bound cursors with a FOR loop. See [Control Flow](#) for more information.

Declaring cursors

Bound cursors

To bind a cursor to a *statement* on declaration, use the FOR keyword:

```
cursor_name CURSOR [ ( arg_name arg_type [, ...] ) ] FOR statement;
```

The arguments to a cursor give you more control over which rows to process. For example, suppose you have the following table:

```
=> SELECT * FROM coordinates_xy;
x | y
---+----
1 | 2
9 | 5
7 | 13
...
(100000 rows)
```

If you're only interested in the rows where **y** is 6, you might declare the following cursor and then provide the argument **6** when you [OPEN](#) the cursor:

```
c CURSOR (key int) FOR SELECT * FROM coordinates_xy WHERE y=key;
```

Unbound cursors

To declare a cursor without binding it to a particular query, use the **refcursor** type:

```
cursor_name refcursor;
```

You can bind an unbound cursor at any time with [OPEN](#).

For example, to declare the cursor **my_unbound_cursor** :

```
my_unbound_cursor refcursor;
```

Opening and closing cursors

OPEN

Opening a cursor executes the query with the given arguments, and puts the cursor before the first row of the result set. The ordering of query results (and therefore, the start of the result set) is non-deterministic, unless you specify an [ORDER BY clause](#).

OPEN a bound cursor

To open a cursor that was bound during declaration:

```
OPEN bound_cursor [ ( [ arg_name := ] arg_value [, ...] ) ];
```

For example, given the following declaration:

```
c CURSOR (key int) FOR SELECT * FROM t1 WHERE y=key;
```

You can open the cursor with one of the following:

```
OPEN c(5);
OPEN c(key := 5);
```

CLOSE

Open cursors are automatically closed when the cursor leaves scope, but you can close the cursor preemptively with **CLOSE**. Closed cursors can be reopened later, which re-executes the query and prepares a new result set.

```
CLOSE cursor;
```

OPEN an unbound cursor

To bind an unbound cursor and then open it:

```
OPEN unbound_cursor FOR statement;
```

You can also use [EXECUTE](#) because it's a statement:

```
OPEN unbound_cursor FOR EXECUTE statement_string [ USING expression [, ...] ];
```

For example, to bind the cursor **c** to a query to a table **product_data** :

```
OPEN c for SELECT * FROM product_data;
```

FETCH rows

FETCH statements:

1. Retrieve the row that the specified cursor currently points to and stores it in some variable.
2. Advance the cursor to the next position.

```
variable [, ...] := FETCH opened_cursor;
```

The retrieved value is stored in *variable* . Rows typically have more than one value, so you can use one variable for each.

If FETCH successfully retrieves a value, the special variable `FOUND` is set to `true` . Otherwise, if you call FETCH when the cursor is past the final row of the result set, it returns NULL and the special variable `FOUND` is set to `false` .

The following procedure creates a cursor `c` , binding it to a SELECT query on the `coordinates` table. The procedure passes the argument 1 to the cursor, so the cursor only retrieves rows where the y-coordinate is 1, storing the coordinates in the variables `x_` , `y_` , and `z_` .

Only two rows have a y-coordinate of 1, so after using FETCH twice, the third FETCH starts to return NULL values and `FOUND` is set to `false` :

```
=> SELECT * FROM coordinates;
x | y | z
----+-----
14 | 6 | 19
 1 | 6 |  2
10 | 6 | 39
10 | 2 |  1
 7 | 1 | 10
67 | 1 | 77
(6 rows)

DO $$
DECLARE
  c CURSOR (key int) FOR SELECT * FROM coordinates WHERE y=key;
  x_ int;
  y_ int;
  z_ int;
BEGIN
  OPEN c(1); -- only retrieve rows where y=1
  x_,y_,z_ := FETCH c;
  RAISE NOTICE 'cursor returned %, %, %, FOUND=%',x_, y_, z_, FOUND;
  x_,y_,z_ := FETCH c; -- fetches the last set of results and moves to the end of the result set
  RAISE NOTICE 'cursor returned %, %, %, FOUND=%',x_, y_, z_, FOUND;
  x_,y_,z_ := FETCH c; -- cursor has advanced past the final row
  RAISE NOTICE 'cursor returned %, %, %, FOUND=%',x_, y_, z_, FOUND;
END;
$$;

NOTICE 2005: cursor returned 7, 1, 10, FOUND=t
NOTICE 2005: cursor returned 67, 1, 77, FOUND=t
NOTICE 2005: cursor returned <NULL>, <NULL>, <NULL>, FOUND=f
```

MOVE cursors

MOVE advances an [open cursor](#) to the next position without retrieving the row. The special `FOUND` variable is set to `true` if the cursor's position (before MOVE) was not past the final row—that is, if calling FETCH instead of MOVE would have retrieved the row.

```
MOVE bound_cursor;
```

For example, this cursor only retrieves rows where the y-coordinate is 2. The result set is only one row, so using MOVE twice advances past the first (and last) row, setting `FOUND` to `false`:

```
=> SELECT * FROM coordinates WHERE y=2;
```

```
x | y | z
```

```
-----
```

```
10 | 2 | 1
```

```
(1 row)
```

```
DO $$
DECLARE
  c CURSOR (key int) FOR SELECT * FROM coordinates WHERE y=key;
BEGIN
  OPEN c(2); -- only retrieve rows where y=2, cursor starts before the first row
  MOVE c; -- cursor advances to the first (and last) row
  RAISE NOTICE 'FOUND=%', FOUND; -- FOUND is true because the cursor points to a row in the result set
  MOVE c; -- cursor advances past the final row
  RAISE NOTICE 'FOUND=%', FOUND; -- FOUND is false because the cursor is past the final row
END;
$$;
```

```
NOTICE 2005: FOUND=t
```

```
NOTICE 2005: FOUND=f
```

PL/pgSQL to PL/vSQL migration guide

While Vertica PL/vSQL is largely compatible with PostgreSQL PL/pgSQL, there are some easily-resolved semantic and SQL-level differences when migrating from PostgreSQL PL/pgSQL.

Language-level differences

PL/vSQL differs from PL/pgSQL in the following ways:

- You must use the [PERFORM](#) statement for SQL statements that return no value.
- [UPDATE/DELETE WHERE CURRENT OF](#) is not currently supported.
- [FOR](#) loops have additional keywords:
 - FOR (RANGE) loops: RANGE keyword
 - FOR (QUERY) loops: QUERY keyword
 - FOR (CURSOR) loops: CURSOR keyword
- By default, NULL cannot be coerced to FALSE.

Coercing NULL to FALSE

NULL is not coercible to FALSE by default, and expressions that expect a BOOLEAN value throw an exception when given a NULL:

```
=> DO $$
BEGIN
  IF NULL THEN -- BOOLEAN value expected for IF
  END IF;
END;
$$;

ERROR 10268: Query returned null where a value was expected
```

To enable NULL-to-FALSE coercion, set the configuration parameter `PLvSQLCoerceNull`:

```
=> ALTER DATABASE DEFAULT SET PLvSQLCoerceNull = 1;
```

Planned features

Support for the following features is planned for a future release:

- Full transaction semantics: Currently, stored procedures only [COMMIT](#) changes after successful execution. This means that you cannot manually [ROLLBACK](#). However, changes made by [nested stored procedures](#) are automatically rolled back if they reach the depth limit. You can also use `PERFORM COMMIT` to commit changes during execution.
- `FOREACH (ARRAY) loops`
- Using the following types as arguments:
 - DECIMAL
 - NUMERIC

- NUMBER
- MONEY
- UUID
- Non-forward moving [cursors](#)
- CONTEXT/EXCEPTION_CONTEXT for [diagnostics](#)
- The special variable ROW_COUNT: To work around this, you can rely on INSERT, UPDATE, and DELETE to return the number of rows affected:

```

-> CREATE TABLE t1(i int);
CREATE TABLE
-> DO $$
DECLARE
  x int;
BEGIN
  x := INSERT INTO t1 VALUES (200);
  RAISE INFO 'rows inserted: %', x;
END;
$$;
INFO 2005: rows inserted: 1

```

SQL-level differences

Vertica differs from PostgreSQL in the following ways:

- Some [data types](#) are different sizes—for example, the standard INTEGER type in Vertica is 8 bytes, but 4 bytes in PostgreSQL.
- In Vertica, INSERT, UPDATE, and DELETE return the number of rows affected.
- Certain SQLSTATE codes are different, which affects [exception handling](#).

Parameter modes

Each formal parameter of a stored procedure can be set to one of the following parameter modes. If unspecified, the parameter is set to IN:

- IN: An input parameter. The caller uses this to pass arguments to the stored procedure.
- OUT: An output parameter. The stored procedure returns values as a result set, the columns of which are identified by the name of the output parameter.
- INOUT: An input and output parameter. The caller can both pass an argument to the stored procedure and retrieve it from the result set.

Function signatures and overloading

A function's signature is defined by the function's name and input parameter (IN and INOUT) types. You cannot [create](#) two stored procedures with the same function signature.

An overloaded function is a set of functions that share the same name but have different input parameters. This can be useful in cases where a function needs to operate on multiple types. For example, the two functions `find_average(int, int, int)` and `find_average(float, float, float)` describe the overloaded function `find_average()` that operates on integers and floats.

When an overloaded procedure is [called](#), Vertica runs the procedure whose signature matches the types of the arguments passed in the invocation.

The example procedures below use RAISE NOTICE for informational messages. For details, see [Errors and diagnostics](#).

IN

IN parameters specify the name and type of an argument. For example, the caller of this procedure must pass in an INT and a VARCHAR value:

```

-> CREATE PROCEDURE raiseXY(IN x INT, y VARCHAR) LANGUAGE PLVSQL AS $$
BEGIN
  RAISE NOTICE 'x = %', x;
  RAISE NOTICE 'y = %', y;
END;
$$;
CALL raiseXY(3, 'some string');
NOTICE 2005: x = 3
NOTICE 2005: y = some string

```

OUT

OUT parameters specify the name and type of a return value. When the procedure runs, the OUT parameter is added to the scope of the stored procedure as a variable. This variable's value is initialized as NULL and is returned in a result set after execution:

```
CREATE PROCEDURE sum_procedure(IN x INT, IN y INT, OUT z INT) LANGUAGE PLvSQL AS $$
BEGIN
    RAISE NOTICE 'This procedure returns the sum of x and y as z:';
    z := x + y;
END
$$;

=> CALL sum_procedure(38,19);
NOTICE 2005: This procedure returns the sum of x and y as z:
 z
--
 57
(1 row)
```

INOUT

INOUT parameters specify the name and type of both an input value and return value. When the procedure runs, the IN/OUT parameter is initialized to the value passed in by the caller and is returned in a result set after execution:

```
=> CREATE PROCEDURE echo(INOUT x INT) LANGUAGE PLvSQL AS $$
BEGIN
    RAISE NOTICE 'This procedure returns its input:';
END
$$;

=> CALL echo(19);
NOTICE 2005: This procedure returns its input:
 x
--
 19
(1 row)
```

Executing stored procedures

If you have EXECUTE privileges on a stored procedure, you can execute it with a CALL statement that specifies the procedure and its [IN](#) arguments.

Syntax

```
CALL stored_procedure_name();
```

For example, the stored procedure `raiseXY()` is defined as:

The following procedure echoes its inputs as a result set:

```
=> CREATE PROCEDURE echo_int_varchar(INOUT x INT, INOUT y VARCHAR) LANGUAGE PLvSQL AS $$
BEGIN
    RAISE NOTICE 'This procedure outputs a result set of its inputs:~';
END
$$;

=> CALL echo_int_varchar(3, 'a string');
NOTICE 2005: This procedure outputs a result set of its inputs:
 x | y
--+-----
 3 | a string
(1 row)
```

You can execute an anonymous (unnamed) procedure with [DO](#). This requires no privileges:

```
=> DO $$  
BEGIN  
  RAISE NOTICE '% ran an anonymous procedure', current_user();  
END;  
$$;
```

NOTICE 2005: Bob ran an anonymous procedure

Transaction semantics

A procedure takes on one of two types depending on how it's called:

- **Nested**: A procedure that is called in the body of some other procedure.
- **Top-level**: A non-nested stored procedure. A procedure called directly by a user (with either [CALL](#) or [DO](#)) or [trigger](#) is top-level.

For example, if **A()** calls **B()**, then **A()** would be a top-level procedure and **B()** would be a nested procedure in the context of **A()**'s execution. If **B()** is called directly by the user or a trigger, it would be a top-level procedure.

Similarly, if some procedure **C()** calls **A()**, then **C()** would be the top-level procedure and **A()** and **B()** would both be nested procedures in the context of **C()**'s execution.

Automatic commits

Executing a top-level procedure opens a new transaction, which is committed if its execution (including those of any nested procedures) succeeds and [rolled back](#) otherwise. If an ongoing transaction exists in the current session before execution, Vertica commits that transaction before calling the procedure. Nested procedures do not start their own transactions.

Note

While triggers also execute top-level stored procedures and therefore also perform a pre-execution commit, triggers execute in their own session, so the commit does not affect the ongoing transactions of other sessions.

For example, when **A()** is called, the following occurs:

1. Before executing **A()**, commit any ongoing transaction.
2. Start a new transaction for the execution of **A()**.
3. Execute **A()**.
4. **A()** calls **B()**.
5. If **A()** and **B()** both successfully execute without errors, commit the transaction. Otherwise, any changes performed by **A()** and **B()** are rolled back.

Manual commits

You can also manually commit changes in the middle of a stored procedure. If execution fails after the commit, the committed changes persist even after the automatic rollback.

In this example, `manual_commit()` inserts two values into a table and then commits. The third insert attempts to insert a CHAR into an INT column, which causes the stored procedure to fail and triggers an automatic rollback. This rollback does not affect the first two inserts because they were manually committed:

```

=> CREATE TABLE numbers (n INT);

=> CREATE PROCEDURE manualcommit() AS
$$
BEGIN
  PERFORM INSERT INTO numbers VALUES(1);
  PERFORM INSERT INTO numbers VALUES(2);
  PERFORM COMMIT;
  PERFORM INSERT INTO numbers VALUES('a');
END;
$$;

=> CALL manualcommit();

ERROR 3681: Invalid input syntax for integer: "a"
CONTEXT: PL/vSQL procedure manualcommit line 6 at static SQL

=> SELECT * FROM numbers;
 n
--
 1
 2
(2 rows)

```

Session semantics

Operations that modify the session persist after execution of the stored procedure, including [ALTER SESSION](#) and [SET statements](#).

[Triggers](#) execute in their own, isolated session.

Limiting runtime

You can set the maximum runtime of a procedure with session parameter `RUNTIMECAP`.

This example sets the runtime of all stored procedures to one second for duration of session and runs an anonymous procedure with an [infinite loop](#). Vertica terminates the procedure after it runs for more than one second:

```

=> SET SESSION RUNTIMECAP '1 SECOND';

=> DO $$
BEGIN
  LOOP
  END LOOP;
END;
$$;

ERROR 0: Query exceeded maximum runtime
HINT: Change the maximum runtime using SET SESSION RUNTIMECAP

```

Execution security and privileges

By default, stored procedures execute with the privileges of the caller (invoker), so callers must have the necessary privileges on the catalog objects accessed by the stored procedure. You can allow callers to execute the procedure with the privileges, [default roles](#), [user parameters](#), and [user attributes](#) (`RESOURCE_POOL`, `MEMORY_CAP_KB`, `TEMP_SPACE_CAP_KB`, `RUNTIMECAP`) of the definer by specifying [DEFINER for the SECURITY option](#).

For example, the following procedure inserts a value into table `s1.t1`. If the DEFINER has the required privileges (`USAGE` on the schema and `INSERT` on table), this requirement is waived for callers.

```

=> CREATE PROCEDURE insert_into_s1_t1(IN x int, IN y int)
LANGUAGE PLvSQL
SECURITY DEFINER AS $$
BEGIN
  PERFORM INSERT INTO s1.t1 VALUES(x,y);
END;
$$;

```

A procedure with SECURITY DEFINER effectively executes the procedure as that user, so changes to the database appear to be performed by the procedure's definer rather than its caller.

Caution

Improper use of SECURITY DEFINER can lead to the [confused deputy problem](#) and introduce vulnerabilities into your system like SQL injection.

Execution privileges for nested stored procedures

A stored procedure cannot call stored procedures that require additional privileges. For example, if a stored procedure executes with privileges A, B, and C, it cannot call a stored procedure that requires privileges C, D, and E.

For details on nested stored procedures, see [Scope and structure](#).

Examples

In this example, this table:

```
records(i INT, updated_date TIMESTAMP DEFAULT sysdate, updated_by VARCHAR(128) DEFAULT current_user())
```

Contains the following content:

```
=> SELECT * FROM records;
i | updated_date | updated_by
-----+-----
1 | 2021-08-27 15:54:05.709044 | Bob
2 | 2021-08-27 15:54:07.051154 | Bob
3 | 2021-08-27 15:54:08.301704 | Bob
(3 rows)
```

Bob creates a procedure to update the table and uses the SECURITY DEFINER option and grants EXECUTE on the procedure to Alice. Alice can now use the procedure to update the table without any additional privileges:

```
=> GRANT EXECUTE ON PROCEDURE update_records(int,int) to Alice;
GRANT PRIVILEGE

=> \c - Alice
You are now connected as user "Alice".

=> CALL update_records(99,1);
update_records
-----
0
(1 row)
```

Because calls to `update_records()` effectively run the procedure as Bob, Bob is listed as the updater of the table rather than Alice:

```
=> SELECT * FROM records;
i | updated_date | updated_by
-----+-----
99 | 2021-08-27 15:55:42.936404 | Bob
2 | 2021-08-27 15:54:07.051154 | Bob
3 | 2021-08-27 15:54:08.301704 | Bob
(3 rows)
```

In this section

- [Triggers](#)

Triggers

You can automate the execution of stored procedures with triggers. A [trigger](#) listens to database events and executes its associated [stored procedure](#) when the events occur. You can use triggers with [CREATE SCHEDULE](#) to implement [Scheduled execution](#).

Individual triggers can be enabled and disabled with [ENABLE TRIGGER](#), and can be manually executed with [EXECUTE TRIGGER](#).

In this section

- [Scheduled execution](#)

Scheduled execution

Stored procedures can be scheduled to execute automatically with the privileges of the trigger definer. You can use this to automate various tasks, like logging database activity, revoking privileges, creating roles, or [loading data](#).

Enabling and disabling scheduling

Scheduling can be toggled at the database level with the [EnableStoredProcedureScheduler](#) configuration parameter:

```
- Enable scheduler
-> SELECT SET_CONFIG_PARAMETER('EnableStoredProcedureScheduler', 1);

- Disable scheduler
-> SELECT SET_CONFIG_PARAMETER('EnableStoredProcedureScheduler', 0);
```

You can toggle an individual schedule [ENABLE_TRIGGER](#), or disable it by [dropping](#) the schedule's associated trigger.

Scheduling a stored procedure

The general workflow for implementing scheduled execution for a single stored procedure is as follows:

1. [Create](#) a stored procedure.
2. [Create](#) a schedule. A schedule can either use a list of timestamps for one-off triggers or a [cron](#) expression for recurring events.
3. [Create](#) a trigger, associating it with the stored procedure and trigger.
4. (Optional) [Manually execute the trigger](#) to test it.

One-off triggers

One-off triggers run a finite number of times.

The following example creates a trigger that revokes privileges on the customer_dimension table from the user Bob after 24 hours:

1. Create a stored procedure to [revoke](#) privileges from Bob:

```
-> CREATE OR REPLACE PROCEDURE revoke_all_on_table(table_name VARCHAR, user_name VARCHAR)
LANGUAGE PLvSQL
AS $$
BEGIN
    EXECUTE 'REVOKE ALL ON ' || QUOTE_IDENT(table_name) || ' FROM ' || QUOTE_IDENT(user_name);
END;
$$;
```

2. Create a schedule with a timestamp for 24 hours later:

```
-> CREATE SCHEDULE 24_hours_later USING DATETIMES('2022-12-16 12:00:00');
```

3. Create a trigger with the stored procedure and schedule:

```
-> CREATE TRIGGER revoke_trigger ON SCHEDULE 24_hours_later EXECUTE PROCEDURE revoke_all_on_table('customer_dimension', 'Bob') AS D
```

Recurring triggers

Recurring triggers run at a recurring date or time specified by a [cron](#) expression:

```
-> CREATE SCHEDULE every_saturday_12am USING cron '0 0 * * 6';
-> CREATE SCHEDULE every_5_minutes USING CRON '* * * * * /5';
-> CREATE SCHEDULE every_hour_from_12pm_to_6pm USING CRON '0 12-17 * * *';
```

The following example creates a weekly trigger that logs to the USER_COUNT table the number of users in the database:

```
-> SELECT * FROM USER_COUNT;
total |      timestamp
-----+-----
 293 | 2022-12-04 00:00:00.346664-00
 302 | 2022-12-11 00:00:00.782242-00
 301 | 2022-12-18 00:00:00.144633-00
 301 | 2022-12-25 00:00:00.548832-00
(4 rows)
```

1. Create the table to log the user counts:

```
=> CREATE TABLE USER_COUNT(total INT, timestamp TIMESTAMPTZ)
```

2. Create the stored procedure to log to the table:

```
=> CREATE OR REPLACE PROCEDURE log_user_count()
LANGUAGE PLvSQL
AS $$
DECLARE
    num_users int := SELECT count (user_id) FROM users;
    timestamp datetime := SELECT NOW();
BEGIN
    PERFORM INSERT INTO USER_COUNT VALUES(num_users, timestamp);
END;
$$;
```

3. Create the schedule for 12:00 AM on Sunday:

```
=> CREATE SCHEDULE weekly_sunday USING CRON '0 0 * * 0';
```

4. Create the trigger with the stored procedure and schedule:

```
=> CREATE TRIGGER user_log_trigger ON SCHEDULE weekly_sunday EXECUTE PROCEDURE log_user_count() AS DEFINER;
```

Viewing upcoming schedules

Schedules are managed and coordinated by the Active Scheduler Node (ASN). If the ASN goes down, a different node is automatically designated as the new ASN. To view scheduled tasks, query [SCHEDULER_TIME_TABLE](#) on the ASN.

1. Determine the ASN with [ACTIVE_SCHEDULER_NODE](#) :

```
=> SELECT active_scheduler_node();
active_scheduler_node
-----
initiator
(1 row)
```

2. On the ASN, query [SCHEDULER_TIME_TABLE](#) :

```
=> SELECT * FROM scheduler_time_table;

schedule_name | attached_trigger | scheduled_execution_time
-----+-----+-----
daily_1am_gmt | log_user_actions | 2022-12-15 01:00:00-00
24_hours_later | revoke_trigger   | 2022-12-16 12:00:00-00
```

Altering stored procedures

You can alter a stored procedure and retain its grants with [ALTER PROCEDURE](#).

Examples

The examples below use the following procedure:

```
=> CREATE PROCEDURE echo_integer(IN x int) LANGUAGE PLvSQL AS $$
BEGIN
    RAISE INFO 'x is %', x;
END;
$$;
```

By default, stored procedures execute with the privileges of the caller (invoker), so callers must have the necessary privileges on the catalog objects accessed by the stored procedure. You can allow callers to execute the procedure with the privileges, [default roles](#), [user parameters](#), and [user attributes](#) (RESOURCE_POOL, MEMORY_CAP_KB, TEMP_SPACE_CAP_KB, RUNTIMECAP) of the definer by specifying [DEFINER for the SECURITY option](#).

To [execute](#) the procedure with privileges of the...

- Definer (owner):

```
=> ALTER PROCEDURE echo_integer(int) SECURITY DEFINER;
```

- Invoker:

```
=> ALTER PROCEDURE echo_integer(int) SECURITY INVOKER;
```

To change a procedure's source code:

```
=> ALTER PROCEDURE echo_integer(int) SOURCE TO $$  
BEGIN  
    RAISE INFO 'the integer is: %', x;  
END;  
$$;
```

To change a procedure's owner (definer):

```
=> ALTER PROCEDURE echo_integer(int) OWNER TO u1;
```

To change a procedure's schema:

```
=> ALTER PROCEDURE echo_integer(int) SET SCHEMA s1;
```

To rename a procedure:

```
=> ALTER PROCEDURE echo_integer(int) RENAME TO echo_int;
```

Stored procedures: use cases and examples

Stored procedures in Vertica are best suited for [complex, analytical workflows](#) rather than small, transaction-heavy ones. Some recommended use cases include information lifecycle management (ILM) activities like extract, transform, and load (ETL), and data preparation for more complex analytical tasks like machine learning. For example:

- Swapping partitions according to age
- Exporting data at end-of-life and dropping the partitions
- Saving inputs, outputs, and metadata from a machine learning model (e.g. who ran the model, the version of the model, how many times the model was run, who received the results, etc.) for auditing purposes

Searching for a value

The `find_my_value()` procedure searches for a user-specified value in any table column in a given schema and stores the locations of instances of the value in a user-specified table:

```

=> CREATE PROCEDURE find_my_value(p_table_schema VARCHAR(128), p_search_value VARCHAR(1000), p_results_schema VARCHAR(128),
p_results_table VARCHAR(128)) AS $$
DECLARE
    sql_cmd VARCHAR(65000);
    sql_cmd_result VARCHAR(65000);
    results VARCHAR(65000);
BEGIN
    IF p_table_schema IS NULL OR p_table_schema = " OR
    p_search_value IS NULL OR p_search_value = " OR
    p_results_schema IS NULL OR p_results_schema = " OR
    p_results_table IS NULL OR p_results_table = " THEN
        RAISE EXCEPTION 'Please provide a schema to search, a search value, a results table schema, and a results table name.';
    RETURN;
    END IF;

    sql_cmd := 'CREATE TABLE IF NOT EXISTS ' || QUOTE_IDENT(p_results_schema) || '.' || QUOTE_IDENT(p_results_table) ||
        '(found_timestamp TIMESTAMP, found_value VARCHAR(1000), table_name VARCHAR(128), column_name VARCHAR(128));';

    sql_cmd_result := EXECUTE 'SELECT LISTAGG(c USING PARAMETERS max_length=1000000, separator=" ")
    FROM (SELECT "
    (SELECT "" || NOW() || ""::TIMESTAMP , "" || QUOTE_IDENT(p_search_value) || "" , "" || table_name || "" , "" || column_name || ""
    FROM " || table_schema || "." || table_name || "
    WHERE " || column_name || "::" ||
    CASE
        WHEN data_type_id IN (17, 115, 116, 117) THEN data_type
        ELSE "VARCHAR(" || LENGTH(" || QUOTE_IDENT(p_search_value) || ") || ")" END || " = "" || QUOTE_IDENT(p_search_value) || ""
    DECODE(LEAD(column_name) OVER(ORDER BY table_schema, table_name, ordinal_position), NULL, " LIMIT 1);", " LIMIT 1)

    UNION ALL " ) c
    FROM (SELECT table_schema, table_name, column_name, ordinal_position, data_type_id, data_type
    FROM columns WHERE NOT is_system_table AND table_schema !LIKE "" || QUOTE_IDENT(p_table_schema) || "" AND data_type_id < 1000
    ORDER BY table_schema, table_name, ordinal_position) foo) foo;';

    results := EXECUTE 'INSERT INTO ' || QUOTE_IDENT(p_results_schema) || '.' || QUOTE_IDENT(p_results_table) || ' ' || sql_cmd_result;

    RAISE INFO 'Matches Found: %', results;
END;
$$;

```

For example, to search the `public` schema for instances of the string `'dog'` and then store the results in `public.table_list` :

```

=> CALL find_my_value('public', 'dog', 'public', 'table_list');
find_my_value
-----
      0
(1 row)

=> SELECT * FROM public.table_list;
 found_timestamp | found_value | table_name | column_name
-----+-----+-----+-----
2021-08-25 22:13:20.147889 | dog | another_table | b
2021-08-25 22:13:20.147889 | dog | some_table | c
(2 rows)

```

Optimizing tables

You can automate loading data from Parquet files and optimizing your queries with the `create_optimized_table()` procedure. This procedure:

1. Creates an external table whose structure is built from Parquet files using the Vertica [INFER_TABLE_DDL](#) function.
2. Creates a native Vertica table, like the external table, resizing all VARCHAR columns to the MAX length of the data to be loaded.
3. Creates a super projection using the optional segmentation/order by columns passed in as a parameter.
4. Adds an optional primary key to the native table passed in as a parameter.
5. Loads a sample data set (1 million rows) from the external table into the native table.

6. Drops the external table.
7. Runs the [ANALYZE_STATISTICS](#) function on the native table.
8. Runs the [DESIGNER_DESIGN_PROJECTION_ENCODINGS](#) function to get a properly encoded super projection for the native table.
9. Truncates the now-optimized native table (we will load the entire data set in a separate script/stored procedure).

```
=> CREATE OR REPLACE PROCEDURE create_optimized_table(p_file_path VARCHAR(1000), p_table_schema VARCHAR(128), p_table_name
VARCHAR(128), p_seg_columns VARCHAR(1000), p_pk_columns VARCHAR(1000)) LANGUAGE PLvSQL AS $$
DECLARE
    command_sql VARCHAR(1000);
    seg_columns VARCHAR(1000);
BEGIN
-- First 3 parms are required.
-- Segmented and PK columns names, if present, must be Unquoted Identifiers
IF p_file_path IS NULL OR p_file_path = '' THEN
    RAISE EXCEPTION 'Please provide a file path.';
ELSEIF p_table_schema IS NULL OR p_table_schema = '' THEN
    RAISE EXCEPTION 'Please provide a table schema.';
ELSEIF p_table_name IS NULL OR p_table_name = '' THEN
    RAISE EXCEPTION 'Please provide a table name.';
END IF;

-- Pass optional segmented columns parameter as null or empty string if not used
IF p_seg_columns IS NULL OR p_seg_columns = '' THEN
    seg_columns := '';
ELSE
    seg_columns := 'ORDER BY ' || p_seg_columns || ' SEGMENTED BY HASH(' || p_seg_columns || ') ALL NODES';
END IF;

-- Add '_external' to end of p_table_name for the external table and drop it if it already exists
EXECUTE 'DROP TABLE IF EXISTS ' || QUOTE_IDENT(p_table_schema) || '.' || QUOTE_IDENT(p_table_name) || '_external CASCADE';

-- Execute INFER_TABLE_DDL to generate CREATE EXTERNAL TABLE from the Parquet files
command_sql := EXECUTE 'SELECT infer_table_ddl(' || QUOTE_LITERAL(p_file_path) || ' USING PARAMETERS format = "parquet", table_schema = ' ||
QUOTE_IDENT(p_table_schema) || ', table_name = ' || QUOTE_IDENT(p_table_name) || '_external', table_type = "external");';

-- Run the CREATE EXTERNAL TABLE DDL
EXECUTE command_sql;

-- Generate the Internal/ROS Table DDL and generate column lengths based on maximum column lengths found in external table
command_sql := EXECUTE 'SELECT LISTAGG(y USING PARAMETERS separator=" ")
FROM ((SELECT 0 x, "SELECT ""CREATE TABLE ' || QUOTE_IDENT(p_table_schema) || '.' || QUOTE_IDENT(p_table_name) || ' (" y
UNION ALL SELECT ordinal_position, column_name || " " ||
CASE WHEN data_type LIKE "varchar%"
THEN "varchar(" || (SELECT MAX(LENGTH(" || column_name || "))
FROM " || table_schema || "." || table_name || ") || """) ELSE data_type END || NVL2(LEAD(" || column_name || ", 1) OVER (ORDER BY
ordinal_position), ",", ""))
FROM columns WHERE table_schema = ' || QUOTE_IDENT(p_table_schema) || ' AND table_name = ' || QUOTE_IDENT(p_table_name) ||
'_external'
UNION ALL SELECT 10000, ' || seg_columns || ' UNION ALL SELECT 10001, ";" || "" ORDER BY x) foo WHERE y <> ""';
command_sql := EXECUTE command_sql;
EXECUTE command_sql;

-- Alter the Internal/ROS Table if primary key columns were passed as a parameter
IF p_pk_columns IS NOT NULL AND p_pk_columns <> '' THEN
    EXECUTE 'ALTER TABLE ' || QUOTE_IDENT(p_table_schema) || '.' || QUOTE_IDENT(p_table_name) || ' ADD CONSTRAINT ' ||
QUOTE_IDENT(p_table_name) || '_pk PRIMARY KEY (' || p_pk_columns || ') ENABLED';
END IF;

-- Insert 1M rows into the Internal/ROS Table, analyze stats, and generate encodings
EXECUTE 'INSERT INTO ' || QUOTE_IDENT(p_table_schema) || '.' || QUOTE_IDENT(p_table_name) || ' SELECT * FROM ' ||
```

```

EXECUTE INSERT INTO || QUOTE_IDENT(p_table_schema) || . || QUOTE_IDENT(p_table_name) || SELECT FROM ||
QUOTE_IDENT(p_table_schema) || '.' || QUOTE_IDENT(p_table_name) || '_external LIMIT 1000000;';

EXECUTE 'SELECT analyze_statistics("'" || QUOTE_IDENT(p_table_schema) || '.' || QUOTE_IDENT(p_table_name) || "');";

EXECUTE 'SELECT designer_design_projection_encodings("'" || QUOTE_IDENT(p_table_schema) || '.' || QUOTE_IDENT(p_table_name) || "',
"/tmp/toss.sql", TRUE, TRUE);';

-- Truncate the Internal/ROS Table and you are now ready to load all rows
-- Drop the external table

EXECUTE 'TRUNCATE TABLE ' || QUOTE_IDENT(p_table_schema) || '.' || QUOTE_IDENT(p_table_name) || ';';

EXECUTE 'DROP TABLE IF EXISTS ' || QUOTE_IDENT(p_table_schema) || '.' || QUOTE_IDENT(p_table_name) || '_external CASCADE;';

END;

$$;

```

```

Pivoting tables dynamically

The stored procedure `unpivot()` takes as input a source table and target table. It unpivots the source table and outputs it into a target table.

This example uses the following table:

```
=> SELECT * FROM make_the_columns_into_rows;
c1 | c2 | c3 | c4 | c5 | c6
-----+-----+-----+-----+-----+-----
123 | ABC | cf470c5b-50e3-492a-8483-b9e4f20d195a | 2021-08-24 18:49:40.835802 | 1.72964 | t
567 | EFG | 25ea7636-d924-4b4f-81b5-1e1c884b06e3 | 2021-08-04 18:49:40.835802 | 41.46100 | f
890 | XYZ | f588935a-35a4-4275-9e7f-ebb3986390e3 | 2021-08-29 19:53:39.465778 | 8.58207 | t
(3 rows)
```

This table contains the following columns:

```
=> \d make_the_columns_into_rows
List of Fields by Tables
Schema | Table | Column | Type | Size | Default | Not Null | Primary Key | Foreign Key
-----+-----+-----+-----+-----+-----+-----+-----+-----
public | make_the_columns_into_rows | c1 | int | 8 | | f | f | |
public | make_the_columns_into_rows | c2 | varchar(80) | 80 | | f | f | |
public | make_the_columns_into_rows | c3 | uuid | 16 | | f | f | |
public | make_the_columns_into_rows | c4 | timestamp | 8 | | f | f | |
public | make_the_columns_into_rows | c5 | numeric(10,5) | 8 | | f | f | |
public | make_the_columns_into_rows | c6 | boolean | 1 | | f | f | |
(6 rows)
```

The target table has columns from the source table pivoted into rows as key/value pairs. It also has a **ROWID** column to tie the key/value pairs back to their original row from the source table:

```
=> CREATE PROCEDURE unpivot(p_source_table_schema VARCHAR(128), p_source_table_name VARCHAR(128), p_target_table_schema
VARCHAR(128), p_target_table_name VARCHAR(128)) AS $$
DECLARE
    explode_command VARCHAR(10000);
BEGIN
    explode_command := EXECUTE 'SELECT "explode(string_to_array("""["" || " || LISTAGG("NVL(" || column_name || "::VARCHAR, ""))" USING
PARAMETERS separator=" || "" || "" || " || " || "" || "")) OVER (PARTITION BY rn)" explode_command FROM (SELECT table_schema, table_name,
column_name, ordinal_position FROM columns ORDER BY table_schema, table_name, ordinal_position LIMIT 1000000) foo WHERE table_schema = ' ||
QUOTE_IDENT(p_source_table_schema) || "' AND table_name = ' || QUOTE_IDENT(p_source_table_name) || "'";

    EXECUTE 'CREATE TABLE ' || QUOTE_IDENT(p_target_table_schema) || '.' || QUOTE_IDENT(p_target_table_name) || '
AS SELECT rn rowid, column_name key, value FROM (SELECT (ordinal_position - 1) op, column_name
FROM columns WHERE table_schema = ' || QUOTE_IDENT(p_source_table_schema) || "'
AND table_name = ' || QUOTE_IDENT(p_source_table_name) || "' ) a
JOIN (SELECT rn, ' || explode_command || '
FROM (SELECT ROW_NUMBER() OVER() rn, *
FROM ' || QUOTE_IDENT(p_source_table_schema) || '.' || QUOTE_IDENT(p_source_table_name) || ') foo) b ON b.position = a.op';
END;
$$;
```

Call the procedure:

```
=> CALL unpivot('public', 'make_the_columns_into_rows', 'public', 'columns_into_rows');
```

```
unpivot
```

```
-----  
0  
(1 row)
```

```
=> SELECT * FROM columns_into_rows ORDER BY rowid, key;
```

```
rowid | key | value
```

```
-----+-----  
1 | c1 | 123  
1 | c2 | ABC  
1 | c3 | cf470c5b-50e3-492a-8483-b9e4f20d195a  
1 | c4 | 2021-08-24 18:49:40.835802  
1 | c5 | 1.72964  
1 | c6 | t  
2 | c1 | 890  
2 | c2 | XYZ  
2 | c3 | f588935a-35a4-4275-9e7f-ebb3986390e3  
2 | c4 | 2021-08-29 19:53:39.465778  
2 | c5 | 8.58207  
2 | c6 | t  
3 | c1 | 567  
3 | c2 | EFG  
3 | c3 | 25ea7636-d924-4b4f-81b5-1e1c884b06e3  
3 | c4 | 2021-08-04 18:49:40.835802  
3 | c5 | 41.46100  
3 | c6 | f
```

```
(18 rows)
```

The `unpivot()` procedure can handle new columns in the source table as well.

Add a new column `z` to the source table, and then unpivot the table with the same procedure:

```

=> ALTER TABLE make_the_columns_into_rows ADD COLUMN z VARCHAR;
ALTER TABLE

=> UPDATE make_the_columns_into_rows SET z = 'ZZZ' WHERE c1 IN (123, 890);
OUTPUT
-----
      2
(1 row)

=> CALL unpivot('public', 'make_the_columns_into_rows', 'public', 'columns_into_rows');
unpivot
-----
      0
(1 row)

=> SELECT * FROM columns_into_rows;
rowid | key |          value
-----+-----+-----
  1 | c1 | 567
  1 | c2 | EFG
  1 | c3 | 25ea7636-d924-4b4f-81b5-1e1c884b06e3
  1 | c4 | 2021-08-04 18:49:40.835802
  1 | c5 | 41.46100
  1 | c6 | f
  1 | z | -- new column
  2 | c1 | 123

  2 | c3 | cf470c5b-50e3-492a-8483-b9e4f20d195a
  2 | c4 | 2021-08-24 18:49:40.835802
  2 | c5 | 1.72964
  2 | c6 | t
  2 | z | ZZZ -- new column
  3 | c1 | 890
  3 | c2 | XYZ
  3 | c3 | f588935a-35a4-4275-9e7f-ebb3986390e3
  3 | c4 | 2021-08-29 19:53:39.465778
  3 | c5 | 8.58207
  3 | c6 | t
  3 | z | ZZZ -- new column
(21 rows)

```

Machine learning: optimizing AUC estimation

The [ROC](#) function can approximate the AUC (area under the curve), the accuracy of which depends on the `num_bins` parameter; greater values of `num_bins` give you more precise approximations, but may impact performance.

You can use the stored procedure `accurate_auc()` to approximate the AUC, which automatically determines the optimal `num_bins` value for a given epsilon (error term):

```

=> CREATE PROCEDURE accurate_auc(relation VARCHAR, observation_col VARCHAR, probability_col VARCHAR, epsilon FLOAT) AS $$
DECLARE
  auc_value FLOAT;
  previous_auc FLOAT;
  nbins INT;
BEGIN
  IF epsilon > 0.25 THEN
    RAISE EXCEPTION 'epsilon must not be bigger than 0.25';
  END IF;
  IF epsilon < 1e-12 THEN
    RAISE EXCEPTION 'epsilon must be bigger than 1e-12';
  END IF;
  auc_value := 0.5;
  previous_auc := 0; -- epsilon and auc should be always less than 1
  nbins := 100;
  WHILE abs(auc_value - previous_auc) > epsilon and nbins < 1000000 LOOP
    RAISE INFO 'auc_value: %', auc_value;
    RAISE INFO 'previous_auc: %', previous_auc;
    RAISE INFO 'nbins: %', nbins;
    previous_auc := auc_value;
    auc_value := EXECUTE 'SELECT auc FROM (select roc(' || QUOTE_IDENT(observation_col) || ',' || QUOTE_IDENT(probability_col) || ' USING
parameters num_bins=$1, auc=true) over() FROM ' || QUOTE_IDENT(relation) || ') subq WHERE auc IS NOT NULL' USING nbins;
    nbins := nbins * 2;
  END LOOP;
  RAISE INFO 'Result_auc_value: %', auc_value;
END;
$$;

```

For example, given the following data in [test_data.csv](#) :

```

1,0,0.186
1,1,0.993
1,1,0.9
1,1,0.839
1,0,0.367
1,0,0.362
0,1,0.6
1,1,0.726
...

```

(see [test_data.csv](#) for the complete set of data)

You can load the data into table [categorical_test_data](#) as follows:

```

=> \set datafile "\data/test_data.csv"
=> CREATE TABLE categorical_test_data(obs INT, pred INT, prob FLOAT);
CREATE TABLE

=> COPY categorical_test_data FROM :datafile DELIMITER ',';

```

Call [accurate_auc\(\)](#) . For this example, the approximated AUC will be within the an epsilon of 0.01:

```

=> CALL accurate_auc('categorical_test_data', 'obs', 'prob', 0.01);
INFO 2005: auc_value: 0.5
INFO 2005: previous_auc: 0
INFO 2005: nbins: 100
INFO 2005: auc_value: 0.749597423510467
INFO 2005: previous_auc: 0.5
INFO 2005: nbins: 200
INFO 2005: Result_auc_value: 0.750402576489533

```

test_data.csv

```

User-defined extensions

A user-defined extension (UDx) is a component that expands Vertica functionality—for example, new types of data analysis and the ability to parse and load new types of data.

This section provides an overview of how to install and use a UDx. If you are using a UDx developed by a third party, consult its documentation for detailed installation and usage instructions.

In this section

- [Loading UDxs](#)
- [Installing Java on Vertica hosts](#)
- [UDx restrictions](#)
- [Fenced and unfenced modes](#)
- [Updating UDx libraries](#)
- [Listing the UDxs contained in a library](#)
- [Using wildcards in your UDx](#)

Loading UDxs

User-defined extensions (UDxs) are contained in libraries. A library can contain multiple UDxs. To add UDxs to Vertica, you must:

1. Deploy the library (once per library).
2. Create each UDx (once per UDx).

If you are using UDxs written in Java, you must also set up a Java runtime environment. See [Installing Java on Vertica hosts](#).

Deploying libraries

To deploy a library to your Vertica database:

1. Copy the UDx shared library file (`.so`), Python file, Java JAR file, or R functions file that contains your function to a node on your Vertica cluster. You do not need to copy it to every node.
2. Connect to the node where you copied the library (for example, using `vsq`).
3. Add your library to the database catalog using the [CREATE LIBRARY](#) statement.

```
=> CREATE LIBRARY libname AS 'path_to_lib/filename'  
LANGUAGE 'language';
```

libname is the name you want to use to reference the library. *path_to_lib/filename* is the fully-qualified path to the library or JAR file you copied to the host. *language* is the implementation language.

For example, if you created a JAR file named `TokenizeStringLib.jar` and copied it to the dbadmin account's home directory, you would use this command to load the library:

```
=> CREATE LIBRARY tokenizelib AS '/home/dbadmin/TokenizeStringLib.jar'  
LANGUAGE 'Java';
```

You can load any number of libraries into Vertica.

Privileges

Superusers can create, modify, and drop any library. Users with the [UDXDEVELOPER](#) role or explicit grants can also act on libraries, as shown in the following table:

Operation	Requires
CREATE LIBRARY	UDXDEVELOPER
Replace a library (CREATE OR REPLACE LIBRARY)	UDXDEVELOPER and one of: <ul style="list-style-type: none">• owner of library being replaced• DROP privilege on the target library
DROP LIBRARY	UDXDEVELOPER and one of: <ul style="list-style-type: none">• owner of library being dropped• DROP privilege on the target library
ALTER LIBRARY	UDXDEVELOPER and owner

Creating UDx functions

After the library is loaded, define individual UDxs using SQL statements such as [CREATE FUNCTION](#) and [CREATE SOURCE](#). These statements assign SQL function names to the extension classes in the library. They add the UDx to the database catalog and remain available after a database restart.

The statement you use depends on the type of UDx you are declaring, as shown in the following table:

UDx Type	SQL Statement
Aggregate Function (UDAF)	CREATE AGGREGATE FUNCTION
Analytic Function (UDAnF)	CREATE ANALYTIC FUNCTION
Scalar Function (UDSF)	CREATE FUNCTION (scalar)
Transform Function (UDTF)	CREATE TRANSFORM FUNCTION
Load (UDL): Source	CREATE SOURCE
Load (UDL): Filter	CREATE FILTER

If a UDX of the given name already exists, you can replace it or instruct Vertica to not replace it. To replace it, use the OR REPLACE syntax, as in the following example:

```
=> CREATE OR REPLACE TRANSFORM FUNCTION tokenize
  AS LANGUAGE 'C++' NAME 'TokenFactory' LIBRARY TransformFunctions;
CREATE TRANSFORM FUNCTION
```

You might want to replace an existing function to change between fenced and unfenced modes.

Alternatively, you can use IF NOT EXISTS to prevent the function from being created again if it already exists. You might want to use this in upgrade or test scripts that require, and therefore load, UDXs. By using IF NOT EXISTS, you preserve the original definition including fenced status. The following example shows this syntax:

```
--- original creation:
=> CREATE TRANSFORM FUNCTION tokenize
  AS LANGUAGE 'C++' NAME 'TokenFactory' LIBRARY TransformFunctions NOT FENCED;
CREATE TRANSFORM FUNCTION

--- function is not replaced (and is still unfenced):
=> CREATE TRANSFORM FUNCTION IF NOT EXISTS tokenize
  AS LANGUAGE 'C++' NAME 'TokenFactory' LIBRARY TransformFunctions FENCED;
CREATE TRANSFORM FUNCTION
```

After you add the UDX to the database, you can use your extension within SQL statements. The database superuser can grant access privileges to the UDX for users. See [GRANT \(user defined extension\)](#) for details.

When you call a UDX, Vertica creates an instance of the UDX class on each node in the cluster and provides it with the data it needs to process.

Installing Java on Vertica hosts

If you are using UDXs written in Java, follow the instructions in this section.

You must install a Java Virtual Machine (JVM) on every host in your cluster in order for Vertica to be able to execute your Java UDXs.

Installing Java on your Vertica cluster is a two-step process:

1. Install a Java runtime on all of the hosts in your cluster.
2. Set the `JavaBinaryForUDx` configuration parameter to tell Vertica the location of the Java executable.

Installing a Java runtime

For Java-based features, Vertica requires a 64-bit Java 6 (Java version 1.6) or later Java runtime. Vertica supports runtimes from either Oracle or [OpenJDK](#). You can choose to install either the Java Runtime Environment (JRE) or Java Development Kit (JDK), since the JDK also includes the JRE.

Many Linux distributions include a package for the OpenJDK runtime. See your Linux distribution's documentation for information about installing and configuring OpenJDK.

To install the Oracle Java runtime, see the [Java Standard Edition \(SE\) Download Page](#). You usually run the installation package as root in order to install it. See the download page for instructions.

Once you have installed a JVM on each host, ensure that the `java` command is in the search path and calls the correct JVM by running the command:

```
$ java -version
```

This command should print something similar to:

```
java version "1.8.0_102"
Java(TM) SE Runtime Environment (build 1.8.0_102-b14)
Java HotSpot(TM) 64-Bit Server VM (build 25.102-b14, mixed mode)
```

Note

Any previously installed Java VM on your hosts may interfere with a newly installed Java runtime. See your Linux distribution's documentation for instructions on configuring which JVM is the default. Unless absolutely required, you should uninstall any incompatible version of Java before

installing the Java 6 or Java 7 runtime.

Setting the JavaBinaryForUDx configuration parameter

The JavaBinaryForUDx configuration parameter tells Vertica where to look for the JRE to execute Java UDxs. After you have installed the JRE on all of the nodes in your cluster, set this parameter to the absolute path of the Java executable. You can use the symbolic link that some Java installers create (for example `/usr/bin/java`). If the Java executable is in your shell search path, you can get the path of the Java executable by running the following command from the Linux command line shell:

```
$ which java
/usr/bin/java
```

If the `java` command is not in the shell search path, use the path to the Java executable in the directory where you installed the JRE. Suppose you installed the JRE in `/usr/java/default` (which is where the installation package supplied by Oracle installs the Java 1.6 JRE). In this case the Java executable is `/usr/java/default/bin/java`.

You set the configuration parameter by executing the following statement as a [database superuser](#):

```
=> ALTER DATABASE DEFAULT SET PARAMETER JavaBinaryForUDx = '/usr/bin/java';
```

See [ALTER DATABASE](#) for more information on setting configuration parameters.

To view the current setting of the configuration parameter, query the [CONFIGURATION_PARAMETERS](#) system table:

```
=> \x
Expanded display is on.
=> SELECT * FROM CONFIGURATION_PARAMETERS WHERE parameter_name = 'JavaBinaryForUDx';
-[ RECORD 1 ]-----+-----
node_name          | ALL
parameter_name     | JavaBinaryForUDx
current_value      | /usr/bin/java
default_value      |
change_under_support_guidance | f
change_requires_restart | f
description        | Path to the java binary for executing UDx written in Java
```

Once you have set the configuration parameter, Vertica can find the Java executable on each node in your cluster.

Note

Since the location of the Java executable is set by a single configuration parameter for the entire cluster, you must ensure that the Java executable is installed in the same path on all of the hosts in the cluster.

UDx restrictions

Some UDx types have special considerations or restrictions.

UDxs written in Java and R do not support complex types.

Aggregate functions

You cannot use the `DISTINCT` clause in queries with more than one aggregate function or provide inputs or return values containing complex types.

Analytic functions

UDAnFs do not support [framing windows using ROWS](#).

Only UDAnFs written in C++ can use complex types.

As with Vertica's built-in analytic functions, UDAnFs cannot be used with [MATCH clause functions](#).

Scalar functions

If the result of applying a UDSF is an invalid record, `COPY` aborts the load even if `CopyFaultTolerantExpressions` is set to true.

A ROW returned from a UDSF cannot be used as an argument to `COUNT`.

Transform functions

A query that includes a UDTF cannot:

- Include statements other than the [SELECT](#) statement that calls the UDTF and a PARTITION BY expression unless the UDTF is marked as a [one-to-many UDTF](#)
- Call an [analytic function](#)
- Call another UDTF
- Include one of the following clauses:
 - [TIMESERIES](#)
 - [Pattern matching](#)
 - [Gap filling and interpolation](#)

Load functions

Installing an untrusted UDL function can compromise the security of the server. UDxs can contain arbitrary code. In particular, user-defined parser functions can read data from any arbitrary location. It is up to the developer of the function to enforce proper security limitations. Superusers must not grant access to UDxs to untrusted users.

You cannot ALTER UDL functions.

UDFilter and UDSrc functions do not support complex types.

Fenced and unfenced modes

User-defined extensions (UDxs) written in the C++ programming language have the option of running in fenced or unfenced mode. Fenced mode runs the UDx code outside of the main Vertica process in a separate zygote process. UDxs that use unfenced mode run directly within the Vertica process.

Fenced mode

You can run most C++ UDxs in fenced mode. Fenced mode uses a separate zygote process, so fenced UDx crashes do not impact the core Vertica process. There is a small performance impact when running UDx code in fenced mode. On average, using fenced mode adds about 10% more time to execution compared to unfenced mode.

Fenced mode is currently available for all C++ UDxs with the exception of user-defined aggregates. All UDxs developed in the Python, R, and Java programming languages must run in fenced mode, since the Python, R, and Java runtimes cannot run directly within the Vertica process.

Using fenced mode does not affect the development of your UDx. Fenced mode is enabled by default for UDxs that support fenced mode. Optionally, you can issue the [CREATE FUNCTION](#) command with the **NOT FENCED** modifier to disable fenced mode for the function. Additionally, you can enable or disable fenced mode on any fenced mode-supported C++ UDx by using the [ALTER FUNCTION](#) command.

Unfenced mode

Unfenced UDxs run within Vertica, so they have little overhead, and can perform almost as fast as Vertica's own built-in functions. However, because they run within Vertica directly, any bugs in their code (memory leaks, for example) can destabilize the main Vertica process and bring one or more database nodes down.

Important

Always carefully review code downloaded from third-party sources and test UDxs in a test or staging environment before deciding to run them in unfenced mode in production.

About the zygote process

The Vertica zygote process starts when Vertica starts. Each node has a single zygote process. Side processes are created "on demand". The zygote listens for requests and spawns a UDx side session that runs the UDx in fenced mode when a UDx is called by the user.

About fenced mode logging:

UDx code that runs in fenced mode is logged in the [UDxZygote.log](#) and is stored in the [UDxLogs](#) directory in the catalog directory of Vertica. Log entries for the side process are denoted by the UDx language (for example, C++), node, zygote process ID, and the UDxSideProcess ID.

For example, for the following query returns the current fenced processes:

```
=> SELECT * FROM UDX_FENCED_PROCESSES;
 node_name | process_type | session_id | pid | port | status
-----+-----+-----+-----+-----+-----
 v_vmart_node0001 | UDxZygoteProcess |          | 27468 | 51900 | UP
 v_vmart_node0001 | UDxSideProcess | localhost.localdoma-27465:0x800b | 5677 | 44123 | UP
```

Below is the corresponding log file for the fenced processes returned in the previous query:

```
2016-05-16 11:24:43.990 [C++-localhost.localdoma-27465:0x800b-5677] 0x2b3ff17e7fd0 UDX side process started
11:24:43.996 [C++-localhost.localdoma-27465:0x800b-5677] 0x2b3ff17e7fd0 Finished setting up signal handlers.
11:24:43.996 [C++-localhost.localdoma-27465:0x800b-5677] 0x2b3ff17e7fd0 My port: 44123
11:24:43.996 [C++-localhost.localdoma-27465:0x800b-5677] 0x2b3ff17e7fd0 My address: 0.0.0.0
11:24:43.996 [C++-localhost.localdoma-27465:0x800b-5677] 0x2b3ff17e7fd0 Vertica port: 51900
11:24:43.996 [C++-localhost.localdoma-27465:0x800b-5677] 0x2b3ff17e7fd0 Vertica address: 127.0.0.1
11:25:19.749 [C++-localhost.localdoma-27465:0x800b-5677] 0x41837940 Setting memory resource limit to -1
11:30:11.523 [C++-localhost.localdoma-27465:0x800b-5677] 0x41837940 Exiting UDX side process
```

The last line indicates that the side process was killed. In this case it was killed when the user session (vsq) closed.

About fenced mode configuration parameters

Fenced mode supports the following [configuration parameters](#):

- **FencedUDxMemoryLimitMB**: The maximum memory size, in MB, to use for fenced mode processes. The default is **-1** (no limit). The side process is killed if this limit is exceeded.
- **ForceUDxFencedMode**: When set to **1**, force all UDXs that support fenced mode to run in fenced mode even if their definitions specify NOT FENCED. The default is **0** (disabled).
- **UDxFencedBlockTimeout**: The maximum time, in seconds, that the Vertica server waits for a UDX to return before aborting with ERROR 3399. The default is **60**.

Updating UDX libraries

There are two cases where you need to update libraries that you have already deployed:

- When you have upgraded Vertica to a new version that contains changes to the SDK API. For your libraries to work with the new server version, you need to recompile them with new version of the SDK. See [UDx library compatibility with new server versions](#) for more information.
- When you have made changes to your UDXs and you want to deploy these changes. Before updating your UDX library, you need to determine if you have changed the signature of any of the functions contained in the library. If you have, you need to drop the functions from the Vertica catalog before you update the library.

In this section

- [UDx library compatibility with new server versions](#)
- [Determining if a UDX signature has changed](#)
- [Deploying a new version of your UDX library](#)

UDx library compatibility with new server versions

The Vertica SDK defines an application programming interface (API) that UDXs use to interact with the database. When developers compile their UDX code, it is linked to the SDK code to form a library. This library is only compatible with Vertica servers that support the version of the SDK API used to compile the code. The library and servers that share the same API version are compatible on a binary level (referred to as "binary compatible").

The Vertica server returns an error message if you attempt to load a library that is not binary compatible with it. Similarly, if you upgrade your Vertica server to a version that supports a new SDK API, any existing UDX that relies on newly-incompatible libraries returns an error messages when you call it:

```
ERROR 2858: Could not find function definition
HINT:
This usually happens due to missing or corrupt libraries, libraries built
with the wrong SDK version, or due to a concurrent session dropping the library
or function. Try recreating the library and function
```

To resolve this issue, you must install UDX libraries that have been recompiled with the correct version of the SDK.

New versions of the Vertica server do not always change the SDK API version. The SDK API version changes whenever OpenText changes the components that make up the SDK. If the SDK API does not change in a new version of the server, then the old libraries remain compatible with the new server.

The SDK API almost always changes in Vertica releases (major, minor, service pack) as OpenText expands the SDK's features. Vertica will never change the API in a hotfix patch.

These policies mean that you must update UDX libraries when you upgrade between major versions. For example, if you upgrade from version 10.0 to 10.1, you must update your UDX libraries.

Note

A UDX written in a scripting language has no compiled binary, and so does not need to maintain binary compatibility from one version to another. UDXs written in scripting languages only become incompatible if the APIs used in the SDK actually change. For example, if the number of arguments to an API call changes, a UDX has to be changed to use the new number of arguments.

Pre-upgrade steps

Before upgrading your Vertica server, consider whether you have any UDX libraries that may be incompatible with the new version. Consult the release notes of the new server version to determine whether the SDK API has changed between the version of Vertica server you currently have installed and the new version. As mentioned previously, only upgrades from a previous major version or from the initial release of a major version to a service pack release can cause your currently-loaded UDX libraries to become incompatible with the server.

Any UDX libraries that are incompatible with the new version of the Vertica server must be recompiled. If you got the UDX library from a third party, you need to see if a new version has been released. If so, deploy the new version after you have upgraded the server (see [Deploying a new version of your UDX library](#)).

If you developed the UDX yourself (or if you have the source code) you must:

1. Recompile your UDX library using the new version of the Vertica SDK. See [Compiling your C++ library](#) or [Compiling and packaging a Java library](#) for more information.
2. Deploy the new version of your library. See [Deploying a new version of your UDX library](#).

Determining if a UDX signature has changed

You need to be careful when making changes to UDX libraries that contain functions you have already deployed in your Vertica database. When you deploy a new version of your UDX library, Vertica does not ensure that the signatures of the functions that are defined in the library match the signature of the function that is already defined in the Vertica catalog. If you have changed the signature of a UDX in the library then update the library in the Vertica database, calls to the altered UDX will produce errors.

Making any of the following changes to a UDX alters its signature:

- Changing the number of arguments accepted or the data type of any argument accepted by your function (not including polymorphic functions).
- Changing the number or data types of any return values or output columns.
- Changing the name of the factory class that Vertica uses to create an instance of your function code.
- Changing the null handling or volatility behavior of your function.
- Removed the function's factory class from the library completely.

The following changes do not alter the signature of your function, and do not require you to drop the function before updating the library:

- Changing the number or type of arguments handled by a polymorphic function. Vertica does not process the arguments the user passes to a polymorphic function.
- Changing the name, data type, or number of parameters accepted by your function. The parameters your function accepts are not determined by the function signature. Instead, Vertica passes all of the parameters the user included in the function call, and your function processes them at runtime. See [UDX parameters](#) for more information about parameters.
- Changing any of the internal processing performed by your function.
- Adding new UDXs to the library.

After you drop any functions whose signatures have changed, you load the new library file, then re-create your altered functions. If you have not made any changes to the signature of your UDXs, you can just update the library file in your Vertica database without having to drop or alter your function definitions. As long as the UDX definitions in the Vertica catalog match the signatures of the functions in your library, function calls will work transparently after you have updated the library. See [Deploying a new version of your UDX library](#).

Deploying a new version of your UDX library

You need to deploy a new version of your UDx library if:

- You have made changes to the library that you now want to roll out to your Vertica database.
- You have upgraded Vertica to a new version whose SDK is incompatible with the previous version.

The process of deploying a new version of your library is similar to deploying it initially.

1. If you are deploying a UDx library developed in C++ or Java, you must compile it with the current version of the Vertica SDK.
2. Copy your UDx's library file (a `.so` file for libraries developed in C++, a `.py` file for libraries developed in Python, or a `.jar` file for libraries developed in Java) or R source file to a host in your Vertica database.
3. Connect to the host using [vsq](#).
4. If you have changed the signature of any of the UDxs in the shared library, you must drop them using DROP statements such as [DROP FUNCTION](#) or [DROP SOURCE](#). If you are unsure whether any of the signatures of your functions have changed, see [Determining if a UDx signature has changed](#).

Note

If all of the UDx signatures in your library have changed, you may find it more convenient to drop the library using the [DROP LIBRARY](#) statement with the CASCADE option to drop the library and all of the functions and loaders that reference it. Dropping the library can save you the time it would take to drop each UDx individually. You can then reload the library and recreate all of the extensions using the same process you used to deploy the library in the first place. See [CREATE LIBRARY](#).

5. Use the [ALTER LIBRARY](#) statement to update the UDx library definition with the file you copied in step 1. For example, if you want to update the library named `ScalarFunctions` with a file named `ScalarFunctions-2.0.so` in the `dbadmin` user's home directory, you could use the command:

```
=> ALTER LIBRARY ScalarFunctions AS '/home/dbadmin/ScalarFunctions-2.0.so';
```

After you have updated the UDx library definition to use the new version of your shared library, the UDxs that are defined using classes in your UDx library begin using the new shared library file without any further changes.

6. If you had to drop any functions in step 4, recreate them using the new signature defined by the factory classes in your library. See [CREATE FUNCTION statements](#).

Listing the UDxs contained in a library

Once a library has been loaded using the [CREATE LIBRARY](#) statement, you can find the UDxs and UDLs it contains by querying the [USER_LIBRARY_MANIFEST](#) system table:

```

=> CREATE LIBRARY ScalarFunctions AS '/home/dbadmin/ScalarFunctions.so';
CREATE LIBRARY
=> \x
Expanded display is on.
=> SELECT * FROM USER_LIBRARY_MANIFEST WHERE lib_name = 'ScalarFunctions';
-[ RECORD 1 ]-----
schema_name | public
lib_name    | ScalarFunctions
lib_oid     | 45035996273792402
obj_name    | RemoveSpaceFactory
obj_type    | Scalar Function
arg_types   | Varchar
return_type | Varchar
-[ RECORD 2 ]-----
schema_name | public
lib_name    | ScalarFunctions
lib_oid     | 45035996273792402
obj_name    | Div2intsInfo
obj_type    | Scalar Function
arg_types   | Integer, Integer
return_type | Integer
-[ RECORD 3 ]-----
schema_name | public
lib_name    | ScalarFunctions
lib_oid     | 45035996273792402
obj_name    | Add2intsInfo
obj_type    | Scalar Function
arg_types   | Integer, Integer
return_type | Integer

```

The **obj_name** column lists the factory classes contained in the library. These are the names you use to define UDXs and UDLs in the database catalog using statements such as [CREATE FUNCTION](#) and [CREATE SOURCE](#).

Using wildcards in your UDX

Vertica supports wildcard * characters in the place of column names in user-defined functions.

You can use wildcards when:

- Your query contains a table in the FROM clause
- You are using a Vertica-supported development language
- Your UDX is running in fenced or unfenced mode

Supported SQL statements

The following SQL statements can accept wildcards:

- DELETE
- INSERT
- SELECT
- UPDATE

Unsupported configurations

The following situations do not support wildcards:

- You cannot pass a wildcard in the OVER clause of a query
- You cannot use a wildcard with a DROP statement
- You cannot use wildcards with any other arguments

Examples

These examples show wildcards and user-defined functions in a range of data manipulation operations.

DELETE statements:

```

=> DELETE FROM tablename WHERE udf(tablename.*) = 5;

```

INSERT statements:

```
=> INSERT INTO table1 SELECT udf(*) FROM table2;
```

SELECT statements:

```
=> SELECT udf(*) FROM tablename;
=> SELECT udf(tablename.*) FROM tablename;
=> SELECT udf(f.*) FROM table f;
=> SELECT udf(*) FROM table1,table2;
=> SELECT udf1( udf2(*) ) FROM table1,table2;
=> SELECT udf( db.schema.table.*) FROM tablename;
=> SELECT udf(sub.*) FROM (select col1, col2 FROM table) sub;
=> SELECT x FROM tablename WHERE udf(*) = y;
=> WITH sub as (SELECT * FROM tablename) select x, udf(*) FROM sub;
=> SELECT udf( * using parameters x=1) FROM tablename;
=> SELECT udf(table1.*, table2.col2) FROM table1,table2;
```

UPDATE statements:

```
=> UPDATE tablename set col1 = 4 FROM tablename WHERE udf(*) = 3;
```

Developing user-defined extensions (UDxs)

User-defined extensions (UDxs) are functions contained in external libraries that are developed in C++, Python, Java, or R using the Vertica SDK. The external libraries are defined in the Vertica catalog using the [CREATE LIBRARY](#) statement. They are best suited for analytic operations that are difficult to perform in SQL, or that need to be performed frequently enough that their speed is a major concern.

The primary strengths of UDxs are:

- They can be used anywhere an internal function can be used.
- They take full advantage of Vertica's distributed computing features. The extensions usually execute in parallel on each node in the cluster.
- They are distributed to all nodes by Vertica. You only need to copy the library to the initiator node.
- All of the complicated aspects of developing a distributed piece of analytic code are handled for you by Vertica. Your main programming task is to read in data, process it, and then write it out using the Vertica SDK APIs.

There are a few things to keep in mind about developing UDxs:

- UDxs can be developed in the programming languages C++, Python, Java, and R. (Not all UDx types support all languages.)
- UDxs written in Java always run in [fenced mode](#), because the Java Virtual Machine that executes Java programs cannot run directly within the Vertica process.
- UDxs written in Python and R always run in [fenced mode](#).
- UDxs developed in C++ have the option of running in [unfenced mode](#), which means they load and run directly in the Vertica database process. This option provides the lowest overhead and highest speed. However, any bugs in the UDx's code can cause database instability. You must thoroughly test any UDxs you intend to run in unfenced mode before deploying them in a live environment. Consider whether the performance boost of running a C++ UDx unfenced is worth the potential database instability that a buggy UDx can cause.
- Because a UDx runs on the Vertica cluster, it can take processor time and memory away from the database processes. A UDx that consumes large amounts of computing resources can negatively impact database performance.

Types of UDxs

Vertica supports five types of user-defined extensions:

- [User-defined scalar functions](#) (UDSFs) take in a single row of data and return a single value. These functions can be used anywhere a native function can be used, except CREATE TABLE BY PARTITION and SEGMENTED BY expressions. UDSFs can be developed in C++, Python, Java, and R.
- [User-defined aggregate functions](#) (UDAF) allow you to create custom [Aggregate functions](#) specific to your needs. They read one column of data, and return one output column. UDAFs can be developed in C++.
- [User-defined analytic functions](#) (UDAnF) are similar to UDSFs, in that they read a row of data and return a single row. However, the function can read input rows independently of outputting rows, so that the output values can be calculated over several input rows. The function can be used with the query's [OVER\(\)](#) clause to partition rows. UDAnFs can be developed in C++ and Java.
- [User-defined transform functions](#) (UDTFs) operate on table partitions (as specified by the query's [OVER\(\)](#) clause) and return zero or more rows of data. The data they return can be an entirely new table, unrelated to the schema of the input table, with its own ordering and segmentation expressions. They can only be used in the SELECT list of a query. UDTFs can be developed in C++, Python, Java, and R. To optimize query performance, you can use live aggregate projections to pre-aggregate the data that a UDTF returns. For more information, see [Pre-aggregating UDTF results](#).

- [User-defined load](#) allows you to create custom [sources](#), [filters](#), and [parsers](#) to load data. These extensions can be used in [COPY](#) statements. UDLs can be developed C++, Java and Python.

While each UDx type has a unique base class, developing them is similar in many ways. Different UDx types can also share the same library.

Structure

Each UDx type consists of two primary classes. The main class does the actual work (a transformation, an aggregation, and so on). The class usually has at least three methods: one to set up, one to tear down (release reserved resources), and one to do the work. Sometimes additional methods are defined.

The main processing method receives an instance of the [ServerInterface](#) class as an argument. This object is used by the underlying Vertica SDK code to make calls back into the Vertica process, for example to allocate memory. You can use this class to write to the server log during UDx execution.

The second class is a singleton factory. It defines one method that produces instances of the first class, and might define other methods to manage parameters.

When implementing a UDx you must subclass both classes.

Conventions

The C++, Python, and Java APIs are nearly identical. Where possible, this documentation describes these interfaces without respect to language. Documentation specific to C++, Python, or Java is covered in language-specific sections.

Because some documentation is language-independent, it is not always possible to use ideal, language-based terminology. This documentation uses the term "method" to refer to a Java method or a C++ member function.

Developing with the Vertica SDK

Before you can write a user-defined extension you must set up a development environment. After you do so, a good test is to download, build, and run the published examples.

In addition to covering how to set up your environment, this section covers general information about working with the Vertica SDK, including language-specific considerations.

In this section

- [Setting up a development environment](#)
- [Downloading and running UDx example code](#)
- [C++ SDK](#)
- [Java SDK](#)
- [Python SDK](#)
- [R SDK](#)
- [Debugging tips](#)

Setting up a development environment

Before you start developing your UDx, you need to configure your development and test environments. Development and test environments must use the same operating system and Vertica version as the production environment.

For additional language-specific requirements, see the following topics:

- [Setting up the C++ SDK](#)

- [Setting up the Java SDK](#)
- [Python SDK](#)
- [Installing/upgrading the R language pack for Vertica](#)

Development environment options

The language that you use to develop your UDX determines the setup options and requirements for your development environment. C++ developers can use the [C++ UDX container](#), and all developers can use a [non-production Vertica environment](#).

C++ UDX container

C++ developers can develop with the C++ UDX container. The [UDx-container GitHub repository](#) provides the tools to build a container that packages the binaries, libraries, and compilers required to develop C++ Vertica extensions. The C++ UDX container has the following build options:

- CentOS or Ubuntu base image
- Vertica 12.x and 11.x versions

For requirement, build, and test details, see the repository [README](#).

Non-production Vertica environments

You can use a node in a non-production Vertica database or another machine that runs the same operating system and Vertica version as your production environment. For specific requirements and dependencies, refer to [Operating System Requirements](#) and [Language Requirements](#).

Test environment options

To test your UDX, you need access to a non-production Vertica database. You have the following options:

- Install a single-node Vertica database on your development machine.
- Download and build a containerized test environment.

Containerized test environments

Vertica provides the following containerized options to simplify your test environment setup:

- [Vertica Community Edition \(CE\) container image](#) from the [OpenText DockerHub registry](#). See the Overview for base image and Vertica version details.
For details about Vertica CE, see [Vertica community edition \(CE\)](#).
- Custom CE image with the [one-node-ce GitHub repository](#). You can build CentOS- and Debian-based containers that are compatible with Vertica 10.x and 11.x versions.

Downloading and running UDX example code

You can download all of the examples shown in this documentation, and many more, from the Vertica [GitHub repository](#). This repository includes examples of all types of UDXs.

You can download the examples in either of two ways:

- Download the ZIP file. Extract the contents of the file into a directory.
- Clone the repository. Using a terminal window, run the following command:

```
$ git clone https://github.com/vertica/UDx-Examples.git
```

The repository includes a makefile that you can use to compile the C++ and Java examples. It also includes .sql files that load and use the examples. See the README file for instructions on compiling and running the examples. To compile the examples you will need g++ or a JDK and make. See [Setting up a development environment](#) for related information.

Running the examples not only helps you understand how a UDX works, but also helps you ensure your development environment is properly set up to compile UDX libraries.

- [User-defined load \(UDL\)](#)

C++ SDK

The Vertica SDK supports writing both fenced and unfenced UDXs in C++ 11. You can download, compile, and run the examples; see [Downloading and running UDX example code](#). Running the examples is a good way to verify that your development environment has all needed libraries.

If you do not have access to a Vertica test environment, you can install Vertica on your development machine and run a single node. Each time you rebuild your UDx library, you need to re-install it into Vertica. The following diagram illustrates the typical development cycle.

This section covers C++-specific topics that apply to all UDx types. For information that applies to all languages, see [Arguments and return values](#), [UDx parameters](#), [Errors, warnings, and logging](#), [Handling cancel requests](#) and the sections for specific UDx types. For full API documentation, see the [C++ SDK Documentation](#).

In this section

- [Setting up the C++ SDK](#)
- [Compiling your C++ library](#)
- [Adding metadata to C++ libraries](#)
- [C++ SDK data types](#)
- [Resource use for C++ UDxs](#)

Setting up the C++ SDK

The Vertica C++ Software Development Kit (SDK) is distributed as part of the server installation. It contains the source and header files you need to create your UDx library. For examples that you can compile and run, see [Downloading and running UDx example code](#).

Requirements

At a minimum, install the following on your development machine:

- `gcc` version 8 or higher. Vertica has not tested UDx builds with versions higher than 9.
- `g++` and its associated toolchain, such as `ld`. Some Linux distributions package `g++` separately from `gcc`.
- A copy of the Vertica SDK.

Note

The Vertica binaries are compiled using the default version of `g++` installed on the supported Linux platforms.

You must compile with a `std` flag value of `c++11` or later.

The following optional software packages can simplify development:

- `make`, or some other build-management tool.
- `gdb`, or some other debugger.
- Valgrind, or similar tools that detect memory leaks.

If you want to use any third-party libraries, such as statistical analysis libraries, you need to install them on your development machine. If you do not statically link these libraries into your UDx library, you must install them on every node in the cluster. See [Compiling your C++ library](#) for details.

SDK files

The SDK files are located in the `sdk` subdirectory under the root Vertica server directory (usually, `/opt/vertica/sdk`). This directory contains a subdirectory, `include`, which contains the headers and source files needed to compile UDx libraries.

There are two files in the `include` directory you need when compiling your UDx:

- `Vertica.h` is the main header file for the SDK. Your UDx code needs to include this file in order to find the SDK's definitions.
- `Vertica.cpp` contains support code that needs to be compiled into the UDx library.

Much of the Vertica SDK API is defined in the `VerticaUDx.h` header file (which is included by the `Vertica.h` file). If you're curious, you might want to review the contents of this file in addition to reading the API documentation.

Finding the current SDK version

You must develop your UDx using the same SDK version as the database in which you plan to use it. To display the SDK version currently installed on your system, run the following command in `vsq`:

```
=> SELECT sdk_version();
```

Running the examples

You can download the examples from the GitHub repository (see [Downloading and running UDx example code](#)). Compiling and running the examples helps you to ensure that your development environment is properly set up.

To compile all of the examples, including the Java examples, issue the following command in the `Java-and-C++` directory under the examples directory:

```
$ make
```

Note

To compile the examples, you must have a g++ development environment installed. To install a g++ development environment on Red Hat systems, run `yum install gcc gcc-c++ make`.

Compiling your C++ library

GNU g++ is the only supported compiler for compiling UDx libraries. Always compile your UDx code on the same version of Linux that you use on your Vertica cluster.

When compiling your library, you must always:

- Compile with a `-std` flag value of `c++11` or later.
- Pass the `-shared` and `-fPIC` flags to the linker. The simplest method is to just pass these flags to g++ when you compile and link your library.
- Use the `-Wno-unused-value` flag to suppress warnings when macro arguments are not used. If you do not use this flag, you may get "left-hand operand of comma has no effect" warnings.
- Compile `sdk/include/Vertica.cpp` and link it into your library. This file contains support routines that help your UDx communicate with Vertica. The easiest way to do this is to include it in the g++ command to compile your library. Vertica supplies this file as C++ source rather than a library to limit library compatibility issues.
- Add the Vertica SDK include directory in the include search path using the g++ `-I` flag.

The SDK examples include a working makefile. See [Downloading and running UDx example code](#).

Example of compiling a UDx

The following command compiles a UDx contained in a single source file named `MyUDx.cpp` into a shared library named `MyUDx.so` :

```
g++ -I /opt/vertica/sdk/include -Wall -shared -Wno-unused-value \  
-fPIC -o MyUDx.so MyUDx.cpp /opt/vertica/sdk/include/Vertica.cpp
```

Important

Vertica only supports UDx development on 64-bit architectures.

After you debug your UDx, you are ready to deploy it. Recompile your UDx using the `-O3` flag to enable compiler optimization.

You can add additional source files to your library by adding them to the command line. You can also compile them separately and then link them together.

Tip

The examples subdirectory in the Vertica SDK directory contains a make file that you can use as starting point for your own UDx project.

Handling external libraries

You must link your UDx library to any supporting libraries that your UDx code relies on. These libraries might be either ones you developed or others provided by third parties. You have two options for linking:

- Statically link the support libraries into your UDx. The benefit of this method is that your UDx library does not rely on external files. Having a single UDx library file simplifies deployment because you just transfer a single file to your Vertica cluster. This method's main drawback is that it increases the size of your UDx library file.
- Dynamically link the library to your UDx. You must sometimes use dynamic linking if a third-party library does not allow static linking. In this case, you must copy the libraries to your Vertica cluster in addition to your UDx library file.

Adding metadata to C++ libraries

You can add metadata, such as author name, the version of the library, a description of your library, and so on to your library. This metadata lets you track the version of your function that is deployed on a Vertica Analytic Database cluster and lets third-party users of your function know who created the function. Your library's metadata appears in the [USER_LIBRARIES](#) system table after your library has been loaded into the Vertica Analytic Database catalog.

You declare the metadata for your library by calling the `RegisterLibrary()` function in one of the source files for your UDX. If there is more than one function call in the source files for your UDX, whichever gets interpreted last as Vertica Analytic Database loads the library is used to determine the library's metadata.

The `RegisterLibrary()` function takes eight string parameters:

```
RegisterLibrary(author,  
               library_build_tag,  
               library_version,  
               library_sdk_version,  
               source_url,  
               description,  
               licenses_required,  
               signature);
```

- `author` contains whatever name you want associated with the creation of the library (your own name or your company's name for example).
- `library_build_tag` is a string you want to use to represent the specific build of the library (for example, the SVN revision number or a timestamp of when the library was compiled). This is useful for tracking instances of your library as you are developing them.
- `library_version` is the version of your library. You can use whatever numbering or naming scheme you want.
- `library_sdk_version` is the version of the Vertica Analytic Database SDK Library for which you've compiled the library.

Note

This field isn't used to determine whether a library is compatible with a version of the Vertica Analytic Database server. The version of the Vertica Analytic Database SDK you use to compile your library is embedded in the library when you compile it. It is this information that Vertica Analytic Database server uses to determine if your library is compatible with it.

- `source_url` is a URL where users of your function can find more information about it. This can be your company's website, the GitHub page hosting your library's source code, or whatever site you like.
- `description` is a concise description of your library.
- `licenses_required` is a placeholder for licensing information. You must pass an empty string for this value.
- `signature` is a placeholder for a signature that will authenticate your library. You must pass an empty string for this value.

For example, the following code demonstrates adding metadata to the Add2Ints example (see [C++ example: Add2Ints](#)).

```
/ Register the factory with Vertica  
RegisterFactory(Add2IntsFactory);  
  
/ Register the library's metadata  
RegisterLibrary("Whizzo Analytics Ltd.",  
               "1234",  
               "2.0",  
               "7.0.0",  
               "http://www.example.com/add2ints",  
               "Add 2 Integer Library",  
               "",  
               "");
```

Loading the library and querying the [USER_LIBRARIES](#) system table shows the metadata supplied in the call to `RegisterLibrary()` :

```

=> CREATE LIBRARY add2intslib AS '/home/dbadmin/add2ints.so';
CREATE LIBRARY
=> \x
Expanded display is on.
=> SELECT * FROM USER_LIBRARIES WHERE lib_name = 'add2intslib';
-[ RECORD 1 ]-----+-----

```

C++ SDK data types

The Vertica SDK has typedefs and classes for representing Vertica data types within your UDX code. Using these typedefs ensures data type compatibility between the data your UDX processes and generates and the Vertica database. The following table describes some of the typedefs available. Consult the [C++ SDK Documentation](#) for a complete list, as well as lists of helper functions to convert and manipulate these data types.

For information about SDK support for complex data types, see [Complex Types as Arguments and Return Values](#).

Type Definition	Description
Interval	A Vertica interval
IntervalYM	A Vertica year-to-month interval.
Timestamp	A Vertica timestamp
vint	A standard Vertica 64-bit integer
vbool	A Boolean value in Vertica
vbool_null	A null value for a Boolean data types
vfloat	A Vertica floating point value
VString	String data types (such as varchar and char) Note: Do not use a VString object to hold an intermediate result. Use a std::string or char[] instead.
VNumeric	Fixed-point data types from Vertica
VUuid	A Vertica universally unique identifier

Notes

- When making some Vertica SDK API calls (such as `VerticaType::getNumericLength()`) on objects, make sure they have the correct data type. To minimize overhead and improve performance, most of the APIs do not check the data types of the objects on which they are called. Calling a function on an incorrect data type can result in an error.

- You cannot create instances of `VString` or `VNumeric` yourself. You can manipulate the values of existing objects of these classes that Vertica passes to your UDX, and extract values from them. However, only Vertica can instantiate these classes.

Resource use for C++ UDXs

Your UDXs consume at least a small amount of memory by instantiating classes and creating local variables. This basic memory usage by UDXs is small enough that you do not need to be concerned about it.

If your UDX needs to allocate more than one or two megabytes of memory for data structures, or requires access to additional resources such as files, you must inform Vertica about its resource use. Vertica can then ensure that the resources your UDX requires are available before running a query that uses it. Even moderate memory use (10MB per invocation of a UDX, for example) can become an issue if there are many simultaneous queries that call it.

Note

If your UDX allocates its own memory, you must make **absolutely sure** it properly frees it. Failing to free even a single byte of allocated memory can have significant consequences at scale. Instead of having your code allocate its own memory, you should use the C++ `vt_alloc` macro, which uses Vertica's own memory manager to allocate and track memory. This memory is guaranteed to be properly disposed of when your UDX completes execution. See [Allocating resources for UDXs](#) for more information.

In this section

- [Allocating resources for UDXs](#)
- [Allocating resources with the SDK macros](#)
- [Informing Vertica of resource requirements](#)
- [Setting memory limits for fenced-mode UDXs](#)
- [How resource limits are enforced](#)

Allocating resources for UDXs

You have two options for allocating memory and file handles for your user-defined extensions (UDXs):

- Use Vertica SDK macros to allocate resources. This is the best method, since it uses Vertica's own resource manager, and guarantees that resources used by your UDX are reclaimed. See [Allocating resources with the SDK macros](#).
- While not the recommended option, you can allocate resources in your UDXs yourself using standard C++ methods (instantiating objects using `new`, allocating memory blocks using `malloc()`, etc.). You must manually free these resources before your UDX exits.

Note

You must be extremely careful if you choose to allocate your own resources in your UDX. Failing to free resources properly will have significant negative impact, especially if your UDX is running in unfenced mode.

Whichever method you choose, you usually allocate resources in a function named `setup()` in your UDX class. This function is called after your UDX function object is instantiated, but before Vertica calls it to process data.

If you allocate memory on your own in the `setup()` function, you must free it in a corresponding function named `destroy()`. This function is called after your UDX has performed all of its processing. This function is also called if your UDX returns an error (see [Handling errors](#)).

Note

Always use the `setup()` and `destroy()` functions to allocate and free resources instead of your own constructors and destructors. The memory for your UDX object is allocated from one of Vertica's own memory pools. Vertica always calls your UDX's `destroy()` function before it deallocates the object's memory. There is no guarantee that your UDX's destructor will be called before the object is deallocated. Using the `destroy()` function ensures that your UDX has a chance to free its allocated resources before it is destroyed.

The following code fragment demonstrates allocating and freeing memory using a `setup()` and `destroy()` function.

```

class MemoryAllocationExample : public ScalarFunction
{
public:
    uint64* myarray;
    // Called before running the UDF to allocate memory used throughout
    // the entire UDF processing.
    virtual void setup(ServerInterface &srvInterface, const SizedColumnTypes
        &argTypes)
    {
        try
        {
            // Allocate an array. This memory is directly allocated, rather than
            // letting Vertica do it. Remember to properly calculate the amount
            // of memory you need based on the data type you are allocating.
            // This example divides 500MB by 8, since that's the number of
            // bytes in a 64-bit unsigned integer.
            myarray = new uint64[1024 * 1024 * 500 / 8];
        }
        catch (std::bad_alloc &ba)
        {
            // Always check for exceptions caused by failed memory
            // allocations.
            vt_report_error(1, "Couldn't allocate memory :[%s]", ba.what());
        }
    }

    // Called after the UDF has processed all of its information. Use to free
    // any allocated resources.
    virtual void destroy(ServerInterface &srvInterface, const SizedColumnTypes
        &argTypes)
    {
        // srvInterface.log("RowNumber processed %d records", *count_ptr);
        try
        {
            // Properly dispose of the allocated memory.
            delete[] myarray;
        }
        catch (std::bad_alloc &ba)
        {
            // Always check for exceptions caused by failed memory
            // allocations.
            vt_report_error(1, "Couldn't free memory :[%s]", ba.what());
        }
    }
}

```

Allocating resources with the SDK macros

The Vertica SDK provides three macros to allocate memory:

- **vt_alloc** allocates a block of memory to fit a specific data type (vint, struct, etc.).
- **vt_allocArray** allocates a block of memory to hold an array of a specific data type.
- **vt_allocSize** allocates an arbitrarily-sized block of memory.

All of these macros allocate their memory from memory pools managed by Vertica. The main benefit of allowing Vertica to manage your UDF's memory is that the memory is automatically reclaimed after your UDF has finished. This ensures there is no memory leaks in your UDF.

Because Vertica frees this memory automatically, do not attempt to free any of the memory you allocate through any of these macros. Attempting to free this memory results in run-time errors.

Informing Vertica of resource requirements

When you run your UDX in fenced mode, Vertica monitors its use of memory and file handles. If your UDX uses more than a few megabytes of memory or any file handles, it should tell Vertica about its resource requirements. Knowing the resource requirements of your UDX allows Vertica to determine whether it can run the UDX immediately or needs to queue the request until enough resources become available to run it.

Determining how much memory your UDX requires can be difficult in some cases. For example, if your UDX extracts unique data elements from a data set, there is potentially no bound on the number of data items. In this case, a useful technique is to run your UDX in a test environment and monitor its memory use on a node as it handles several differently-sized queries, then extrapolate its memory use based on the worst-case scenario it may face in your production environment. In all cases, it's usually a good idea to add a safety margin to the amount of memory you tell Vertica your UDX uses.

Note

The information on your UDX's resource needs that you pass to Vertica is used when planning the query execution. There is no way to change the amount of resources your UDX requests from Vertica while the UDX is actually running.

Your UDX informs Vertica of its resource needs by implementing the `getPerInstanceResources()` function in its factory class (see [Vertica::UDXFactory::getPerInstanceResources\(\)](#) in the SDK documentation). If your UDX's factory class implements this function, Vertica calls it to determine the resources your UDX requires.

The `getPerInstanceResources()` function receives an instance of the `Vertica::VResources` struct. This struct contains fields that set the amount of memory and the number of file handles your UDX needs. By default, the Vertica server allocates zero bytes of memory and 100 file handles for each instance of your UDX.

Your implementation of the `getPerInstanceResources()` function sets the fields in the `VResources` struct based on the maximum resources your UDX may consume for each instance of the UDX function. So, if your UDX's `processBlock()` function creates a data structure that uses at most 100MB of memory, your UDX must set the `VResources.scratchMemory` field to at least 104857600 (the number of bytes in 100MB). Leave yourself a safety margin by increasing the number beyond what your UDX should normally consume. In this example, allocating 115000000 bytes (just under 110MB) is a good idea.

The following `ScalarFunctionFactory` class demonstrates calling `getPerInstanceResources()` to inform Vertica about the memory requirements of the `MemoryAllocationExample` class shown in [Allocating resources for UDXs](#). It tells Vertica that the UDSF requires 510MB of memory (which is a bit more than the UDSF actually allocates, to be on the safe size).

```
class MemoryAllocationExampleFactory : public ScalarFunctionFactory
{
    virtual Vertica::ScalarFunction *createScalarFunction(Vertica::ServerInterface
        &srvInterface)
    {
        return vt_createFuncObj(srvInterface.allocator, MemoryAllocationExample);
    }
    virtual void getPrototype(Vertica::ServerInterface &srvInterface,
        Vertica::ColumnTypes &argTypes,
        Vertica::ColumnTypes &returnType)
    {
        argTypes.addInt();
        argTypes.addInt();
        returnType.addInt();
    }
    // Tells Vertica the amount of resources that this UDF uses.
    virtual void getPerInstanceResources(ServerInterface &srvInterface,
        VResources &res)
    {
        res.scratchMemory += 1024LL * 1024 * 510; // request 510MB of memory
    }
};
```

Setting memory limits for fenced-mode UDXs

Vertica calls a fenced-mode UDX's implementation of `Vertica::UDXFactory::getPerInstanceResources()` to determine if there are enough free resources to run the query containing the UDX (see [Informing Vertica of resource requirements](#)). Since these reports are not generated by actual memory use, they can be inaccurate. Once started by Vertica, a UDX could allocate far more memory or file handles than it reported it needs.

The `FencedUDXMemoryLimitMB` configuration parameter lets you create an absolute memory limit for UDXs. Any attempt by a UDX to allocate more memory than this limit results in a `bad_alloc` exception. For an example of setting `FencedUDXMemoryLimitMB`, see [How resource limits are enforced](#).

How resource limits are enforced

Before running a query, Vertica determines how much memory it requires to run. If the query contains a fenced-mode UDX which implements the `getPerInstanceResources()` function in its factory class, Vertica calls it to determine the amount of memory the UDX needs and adds this to the total required for the query. Based on these requirements, Vertica decides how to handle the query:

- If the total amount of memory required (including the amount that the UDXs report that they need) is larger than the session's `MEMORYCAP` or `resource pool's MAXMEMORYSIZE` setting, Vertica rejects the query. For more information about resource pools, see [Resource pool architecture](#).
- If the amount of memory is below the limit set by the session and resource pool limits, but there is currently not enough free memory to run the query, Vertica queues it until enough resources become available.
- If there are enough free resources to run the query, Vertica executes it.

Note

Vertica has no other way to determine the amount of resources a UDX requires other than the values it reports using the `getPerInstanceResources()` function. A UDX could use more resources than it claims, which could cause performance issues for other queries that are denied resources. You can set an absolute limit on the amount of memory UDXs can allocate. See [Setting memory limits for fenced-mode UDXs](#) for more information.

If the process executing your UDX attempts to allocate more memory than the limit set by the `FencedUDXMemoryLimitMB` configuration parameter, it receives a `bad_alloc` exception. For more information about `FencedUDXMemoryLimitMB`, see [Setting memory limits for fenced-mode UDXs](#).

Below is the output of loading a UDSF that consumes 500MB of memory, then changing the memory settings to cause out-of-memory errors. The `MemoryAllocationExample` UDSF in the following example is just the `Add2Ints` UDSF example altered as shown in [Allocating resources for UDXs](#) and [Informing Vertica of resource requirements](#) to allocate 500MB of RAM.

```
=> CREATE LIBRARY mylib AS '/home/dbadmin/MemoryAllocationExample.so';
CREATE LIBRARY
=> CREATE FUNCTION usemem AS NAME 'MemoryAllocationExampleFactory' LIBRARY mylib
-> FENCED;
CREATE FUNCTION
=> SELECT usemem(1,2);
usemem
-----
   3
(1 row)
```

The following statements demonstrate setting the session's `MEMORYCAP` to lower than the amount of memory that the UDSF reports it uses. This causes Vertica to return an error before it executes the UDSF.

```
=> SET SESSION MEMORYCAP '100M';
SET
=> SELECT usemem(1,2);
ERROR 3596: Insufficient resources to execute plan on pool sysquery
[Request exceeds session memory cap: 520328KB > 102400KB]
=> SET SESSION MEMORYCAP = default;
SET
```

The [resource pool](#) can also prevent a UDX from running if it requires more memory than is available in the pool. The following statements demonstrate the effect of creating and using a resource pool that has too little memory for the UDSF to run. Similar to the session's `MAXMEMORYCAP` limit, the pool's `MAXMEMORYSIZE` setting prevents Vertica from executing the query containing the UDSF.

```

=> CREATE RESOURCE POOL small MEMORYSIZE '100M' MAXMEMORYSIZE '100M';
CREATE RESOURCE POOL
=> SET SESSION RESOURCE POOL small;
SET
=> CREATE TABLE ExampleTable(a int, b int);
CREATE TABLE
=> INSERT /*+direct*/ INTO ExampleTable VALUES (1,2);
OUTPUT
-----
 1
(1 row)
=> SELECT usemem(a, b) FROM ExampleTable;
ERROR 3596: Insufficient resources to execute plan on pool small
[Request Too Large:Memory(KB) Exceeded: Requested = 523136, Free = 102400 (Limit = 102400, Used = 0)]
=> DROP RESOURCE POOL small; --Dropping the pool resets the session's pool
DROP RESOURCE POOL

```

Finally, setting the `FencedUDxMemoryLimitMB` configuration parameter to lower than the UDx actually allocates results in the UDx throwing an exception. This is a different case than either of the previous two examples, since the query actually executes. The UDx's code needs to catch and handle the exception. In this example, it uses the `vt_report_error` macro to report the error back to Vertica and exit.

```

=> ALTER DATABASE DEFAULT SET FencedUDxMemoryLimitMB = 300;

=> SELECT usemem(1,2);
ERROR 3412: Failure in UDx RPC call InvokeSetup(): Error calling setup() in
User Defined Object [usemem] at [MemoryAllocationExample.cpp:32], error code:
 1, message: Couldn't allocate memory :[std::bad_alloc]

=> ALTER DATABASE DEFAULT SET FencedUDxMemoryLimitMB = -1;

=> SELECT usemem(1,2);
usemem
-----
 3
(1 row)

```

Java SDK

The Vertica SDK supports writing Java UDxs of all types except aggregate functions. All Java UDxs are fenced.

You can download, compile, and run the examples; see [Downloading and running UDx example code](#). Running the examples is a good way to verify that your development environment has all needed libraries.

If you do not have access to a Vertica test environment, you can install Vertica on your development machine and run a single node. Each time you rebuild your UDx library, you need to re-install it into Vertica. The following diagram illustrates the typical development cycle.

This section covers Java-specific topics that apply to all UDx types. For information that applies to all languages, see [Arguments and return values](#), [UDx parameters](#), [Errors, warnings, and logging](#), [Handling cancel requests](#) and the sections for specific UDx types. For full API documentation, see the [Java SDK Documentation](#).

In this section

- [Setting up the Java SDK](#)
- [Compiling and packaging a Java library](#)
- [Handling Java UDx dependencies](#)

- [Java and Vertica data types](#)
- [Handling NULL values](#)
- [Adding metadata to Java UDX libraries](#)
- [Java UDX resource management](#)

Setting up the Java SDK

The Vertica Java Software Development Kit (SDK) is distributed as part of the server installation. It contains the source and JAR files you need to create your UDX library. For examples that you can compile and run, see [Downloading and running UDX example code](#).

Requirements

At a minimum, install the following on your development machine:

- The Java Development Kit (JDK) version that matches the Java version you have installed on your database hosts (see [Installing Java on Vertica Hosts](#)).
- A copy of the Vertica SDK.

Optionally, you can simplify development with a build-management tool, such as `make`.

SDK files

To use the SDK you need two files from the Java support package:

- `/opt/vertica/bin/VerticaSDK.jar` contains the Vertica Java SDK and other supporting files.
- `/opt/vertica/sdk/BuildInfo.java` contains version information about the SDK. You must compile this file and include it within your Java UDX JAR files.

If you are not doing your development on a database node, you can copy these two files from one of the database nodes to your development system.

The `BuildInfo.java` and `VerticaSDK.jar` files that you use to compile your UDX must be from the same SDK version. Both files must also match the version of the SDK files on your Vertica hosts. Versioning is only an issue if you are not compiling your UDXs on a Vertica host. If you are compiling on a separate development system, always refresh your copies of these two files and recompile your UDXs just before deploying them.

Finding the current SDK version

You must develop your UDX using the same SDK version as the database in which you plan to use it. To display the SDK version currently installed on your system, run the following command in vsq:

```
=> SELECT sdk_version();
```

Compiling BuildInfo.java

You need to compile the `BuildInfo.java` file into a class file, so you can include it in your Java UDX JAR library. If you are using a Vertica node as a development system, you can either:

- Copy the `BuildInfo.java` file to another location on your host.
- If you have root privileges, compile the `BuildInfo.java` file in place. (Only the root user has privileges to write files to the `/opt/vertica/sdk` directory.)

Compile the file using the following command. Replace `path` with the path to the file and `output-directory` with the directory where you will compile your UDXs.

```
$ javac -classpath /opt/vertica/bin/VerticaSDK.jar \  
/path/BuildInfo.java -d output-directory
```

If you use an IDE such as Eclipse, you can include the `BuildInfo.java` file in your project instead of compiling it separately. You must also add the `VerticaSDK.jar` file to the project's build path. See your IDE's documentation for details on how to include files and libraries in your projects.

Running the examples

You can download the examples from the GitHub repository (see [Downloading and running UDX example code](#)). Compiling and running the examples helps you to ensure that your development environment is properly set up.

If you have not already done so, set the `JAVA_HOME` environment variable to your JDK (not JRE) directory.

To compile all of the examples, including the Java examples, issue the following command in the `Java-and-C++` directory under the examples directory:

```
$ make
```

To compile only the Java examples, issue the following command in the [Java-and-C++](#) directory under the examples directory:

```
$ make JavaFunctions
```

Compiling and packaging a Java library

Before you can use your Java UDX, you need to compile it and package it into a JAR file.

The SDK examples include a working makefile. See [Downloading and running UDX example code](#).

Compile your Java UDX

You must include the SDK JAR file in the CLASSPATH when you compile your Java UDX source files so the Java compiler can resolve the Vertica API calls. If you are using the command-line Java compiler on a host in your database cluster, enter this command:

```
$ javac -classpath /opt/vertica/bin/VerticaSDK.jar factorySource.java \  
[functionSource.java...] -d output-directory
```

If all of your source files are in the same directory, you can use `*.java` on the command line instead of listing the files individually.

If you are using an IDE, verify that a copy of the [VerticaSDK.jar](#) file is in the build path.

UDX class file organization

After you compile your UDX, you must package its class files and the [BuildInfo.class](#) file into a JAR file.

Note

You can package as many UDXs as you want into the same JAR file. Bundling your UDXs together saves you from having to load multiple libraries.

To use the jar command packaged as part of the JDK, you must organize your UDX class files into a directory structure matching your class package structure. For example, suppose your UDX's factory class has a fully-qualified name of `com.mycompany.udfs.Add2ints`. In this case, your class files must be in the directory hierarchy `com/mycompany/udfs` relative to your project's base directory. In addition, you must have a copy of the [BuildInfo.class](#) file in the path `com/vertica/sdk` so that it can be included in the JAR file. This class must appear in your JAR file to indicate the SDK version that was used to compile your Java UDX.

The JAR file for the Add2ints UDSF example has the following directory structure after compilation:

```
com/vertica/sdk/BuildInfo.class  
com/mycompany/example/Add2intsFactory.class  
com/mycompany/example/Add2intsFactory$Add2ints.class
```

Package your UDX into a JAR file

To create a JAR file from the command line:

1. Change to the root directory of your project.
2. Use the jar command to package the [BuildInfo.class](#) file and all of the classes in your UDX:

```
# jar -cvf libname.jar com/vertica/sdk/BuildInfo.class \  
packagePath/*.class
```

When you type this command, `libname` is the filename you have chosen for your JAR file (choose whatever name you like), and `packagePath` is the path to the directory containing your UDX's class files.

- For example, to package the files from the Add2ints example, you use the command:

```
# jar -cvf Add2intsLib.jar com/vertica/sdk/BuildInfo.class \  
com/mycompany/example/*.class
```

- More simply, if you compiled [BuildInfo.class](#) and your class files into the same root directory, you can use the following command:

```
# jar -cvf Add2intsLib.jar .
```

You must include all of the class files that make up your UDX in your JAR file. Your UDX always consists of at least two classes (the factory class and the function class). Even if you defined your function class as an inner class of your factory class, Java generates a separate class file for the inner class.

After you package your UDX into a JAR file, you are ready to deploy it to your Vertica database.

Handling Java UDX dependencies

If your Java UDX relies on one or more external libraries, you can handle the dependencies in one of three ways:

- Bundle the JAR files into your UDX JAR file using a tool such as [One-JAR](#) or Eclipse Runnable JAR Export Wizard.
- Unpack the JAR file and then repack its contents in your UDX's JAR file.
- Copy the libraries to your Vertica cluster in addition to your UDX library. Then, use the `DEPENDS` keyword of the [CREATE LIBRARY](#) statement to tell Vertica that the UDX library depends on the external libraries. This keyword acts as a library-specific `CLASSPATH` setting. Vertica distributes the support libraries to all of the nodes in the cluster and sets the class path for the UDX so it can find them.

If your UDX depends on native libraries (SO files), use the `DEPENDS` keyword to specify their path. When you call `System.loadLibrary` in your UDX (which you must do before using a native library), this function uses the `DEPENDS` path to find them. You do not need to also set the `LD_LIBRARY_PATH` environment variable.

External library example

The following example demonstrates using an external library with a Java UDX.

The following sample code defines a simple class, named `VowelRemover`. It contains a single method, named `removevowels`, that removes all of the vowels (the letters *a*, *e*, *i*, *o*, *u*, and *y*) from a string.

```
package com.mycompany.libs;

public class VowelRemover {
    public String removevowels(String input) {
        return input.replaceAll("[aeiouy]", "");
    }
}
```

You can compile this class and package it into a JAR file with the following commands:

```
$ javac -g com/mycompany/libs/VowelRemover.java
$ jar cf mycompanylibs.jar com/mycompany/libs/VowelRemover.class
```

The following code defines a Java UDSF, named `DeleteVowels`, that uses the library defined in the preceding example code. `DeleteVowels` accepts a single `VARCHAR` as input, and returns a `VARCHAR`.

```

package com.mycompany.udx;
// Import the support class created earlier
import com.mycompany.libs.VowelRemover;
// Import the Vertica SDK
import com.vertica.sdk.*;

public class DeleteVowelsFactory extends ScalarFunctionFactory {

    @Override
    public ScalarFunction createScalarFunction(ServerInterface arg0) {
        return new DeleteVowels();
    }

    @Override
    public void getPrototype(ServerInterface arg0, ColumnTypes argTypes,
        ColumnTypes returnTypes) {
        // Accept a single string and return a single string.
        argTypes.addVarchar();
        returnTypes.addVarchar();
    }

    @Override
    public void getReturnType(ServerInterface srvInterface,
        SizedColumnTypes argTypes,
        SizedColumnTypes returnType){
        returnType.addVarchar(
            // Output will be no larger than the input.
            argTypes.getColumnType(0).getStringLength(), "RemovedVowels");
    }

    public class DeleteVowels extends ScalarFunction
    {
        @Override
        public void processBlock(ServerInterface arg0, BlockReader argReader,
            BlockWriter resWriter) throws UdfException, DestroyInvocation {

            // Create an instance of the VowelRemover object defined in
            // the library.
            VowelRemover remover = new VowelRemover();

            do {
                String instr = argReader.getString(0);
                // Call the removevowels method defined in the library.
                resWriter.setString(remover.removevowels(instr));
                resWriter.next();
            } while (argReader.next());
        }
    }
}

```

Use the following commands to build the example UDSF and package it into a JAR:

- The first `javac` command compiles the SDK's `BuildInfo` class. Vertica requires all UDX libraries to contain this class. The `javac` command's `-d` option outputs the class file in the directory structure of your UDSF's source.
- The second `javac` command compiles the UDSF class. It adds the previously-created `mycompanylibs.jar` file to the class path so compiler can find the the `VowelRemover` class.
- The `jar` command packages the `BuildInfo` and the classes for the UDX library together.

```

$ javac -g -cp /opt/vertica/bin/VerticaSDK.jar \
  /opt/vertica/sdk/com/vertica/sdk/BuildInfo.java -d \
  /opt/vertica/sdk/com/vertica/sdk \
$ javac -g -cp mycompanylibs.jar:/opt/vertica/bin/VerticaSDK.jar \
  com/mycompany/udx/DeleteVowelsFactory.java \
  com/mycompany/udx/DeleteVowelsLib.jar \
$ jar cf DeleteVowelsLib.jar com/mycompany/udx/*.class \
  com/vertica/sdk/*.class

```

To install the UDX library, you must copy both of the JAR files to a node in the Vertica cluster. Then, connect to the node to execute the CREATE LIBRARY statement.

The following example demonstrates how to load the UDX library after you copy the JAR files to the home directory of the dbadmin user. The DEPENDS keyword tells Vertica that the UDX library depends on the [mycompanylibs.jar](#) file.

```

-> CREATE LIBRARY DeleteVowelsLib AS
  '/home/dbadmin/DeleteVowelsLib.jar' DEPENDS '/home/dbadmin/mycompanylibs.jar'
  LANGUAGE 'JAVA';
CREATE LIBRARY
-> CREATE FUNCTION deleteVowels AS language 'java' NAME
  'com.mycompany.udx.DeleteVowelsFactory' LIBRARY DeleteVowelsLib;
CREATE FUNCTION
-> SELECT deleteVowels('I hate vowels');
deleteVowels
-----
ht vwls!
(1 row)

```

Java and Vertica data types

The Vertica Java SDK converts Vertica's native data types into the appropriate Java data type. The following table lists the Vertica data types and their corresponding Java data types.

Vertica Data Type	Java Data Type
INTEGER	long
FLOAT	double
NUMERIC	com.vertica.sdk.VNumeric
DATE	java.sql.Date
CHAR, VARCHAR, LONG VARCHAR	com.vertica.sdk.VString
BINARY, VARBINARY, LONG VARBINARY	com.vertica.sdk.VString
TIMESTAMP	java.sql.Timestamp

Note

Some Vertica data types are not supported.

Setting BINARY, VARBINARY, and LONG VARBINARY values

The Vertica BINARY, VARBINARY, and LONG VARBINARY data types are converted as the Java UDX SDK's VString class. You can also set the value of a column with one of these data types with a [ByteBuffer](#) object (or a byte array wrapped in a [ByteBuffer](#)) using the [PartitionWriter.setStringBytes\(\)](#) method. See the Java API UDX entry for [PartitionWriter.setStringBytes\(\)](#) for more information.

Timestamps and time zones

When the SDK converts a Vertica timestamp into a Java timestamp, it uses the time zone of the JVM. If the JVM is running in a different time zone than the one used by Vertica, the results can be confusing.

Vertica stores timestamps in the database in UTC. (If a database time zone is set, the conversion is done at query time.) To prevent errors from the JVM time zone, add the following code to the processing method of your UDX:

```
TimeZone.setDefault(TimeZone.getTimeZone("UTC"));
```

Strings

The Java SDK contains a class named `StringUtils` that assists you when manipulating string data. One of its more useful features is its `getStringBytes()` method. This method extracts bytes from a `String` in a way that prevents the creation of invalid strings. If you attempt to extract a substring that would split part of a multi-byte UTF-8 character, `getStringBytes()` truncates it to the nearest whole character.

Handling NULL values

Your UDXs must be prepared to handle NULL values. These values usually must be handled separately from regular values.

Reading NULL values

Your UDX reads data from instances of the `BlockReader` or `PartitionReader` classes. If the value of a column is NULL, the methods you use to get data (such as `getLong()`) return a Java `null` reference. If you attempt to use the value without checking for NULL, the Java runtime will throw a null pointer exception.

You can test for null values before reading columns by using the data-type-specific methods (such as `isLongNull()`, `isDoubleNull()`, and `isBooleanNull()`). For example, to test whether the INTEGER first column of your UDX's input is a NULL, you would use the statement:

```
// See if the Long value in column 0 is a NULL
if (inputReader.isLongNull(0)) {
    // value is null
}
```

Writing NULL values

You output NULL values using type-specific methods on the `BlockWriter` and `PartitionWriter` classes (such as `setLongNull()` and `setStringNull()`). These methods take the column number to receive the NULL value. In addition, the `PartitionWriter` class has data-type specific set value methods (such as `setLongValue()` and `setStringValue()`). If you pass these methods a value, they set the output column to that value. If you pass them a Java `null` reference, they set the output column to NULL.

Adding metadata to Java UDX libraries

You can add metadata, such as author name, the version of the library, a description of your library, and so on to your library. This metadata lets you track the version of your function that is deployed on a Vertica Analytic Database cluster and lets third-party users of your function know who created the function. Your library's metadata appears in the [USER_LIBRARIES](#) system table after your library has been loaded into the Vertica Analytic Database catalog.

To add metadata to your Java UDX library, you create a subclass of the `UDXLibrary` class that contains your library's metadata. You then include this class within your JAR file. When you load your class into the Vertica Analytic Database catalog using the [CREATE LIBRARY](#) statement, looks for a subclass of `UDXLibrary` for the library's metadata.

In your subclass of `UDXLibrary`, you need to implement eight getters that return String values containing the library's metadata. The getters in this class are:

- `getAuthor()` returns the name you want associated with the creation of the library (your own name or your company's name for example).
- `getLibraryBuildTag()` returns whatever String you want to use to represent the specific build of the library (for example, the SVN revision number or a timestamp of when the library was compiled). This is useful for tracking instances of your library as you are developing them.
- `getLibraryVersion()` returns the version of your library. You can use whatever numbering or naming scheme you want.
- `getLibrarySDKVersion()` returns the version of the Vertica Analytic Database SDK Library for which you've compiled the library.

Note

This field isn't used to determine whether a library is compatible with a version of the Vertica Analytic Database server. The version of the Vertica Analytic Database SDK you use to compile your library is embedded in the library when you compile it. It is this information that Vertica Analytic Database server uses to determine if your library is compatible with it.

- `getSourceUrl()` returns a URL where users of your function can find more information about it. This can be your company's website, the GitHub page hosting your library's source code, or whatever site you like.

- `getDescription()` returns a concise description of your library.
- `getLicensesRequired()` returns a placeholder for licensing information. You must pass an empty string for this value.
- `getSignature()` returns a placeholder for a signature that will authenticate your library. You must pass an empty string for this value.

For example, the following code demonstrates creating a UDXLibrary subclass to be included in the Add2Ints UDSF example JAR file (see [/opt/vertica/sdk/examples/JavaUDx/ScalarFunctions](#) on any Vertica node).

```

import com.vertica.sdk.UDXLibrary;

public class Add2IntsLibrary extends UDXLibrary
{
    // Return values for the metadata about this library.

    @Override public String getAuthor() {return "Whizzo Analytics Ltd.";}
    @Override public String getLibraryBuildTag() {return "1234";}
    @Override public String getLibraryVersion() {return "1.0";}
    @Override public String getLibrarySDKVersion() {return "7.0.0";}
    @Override public String getSourceUrl() {
        return "http://example.com/add2ints";
    }
    @Override public String getDescription() {
        return "My Awesome Add 2 Ints Library";
    }
    @Override public String getLicensesRequired() {return "";}
    @Override public String getSignature() {return "";}
}

```

When the library containing the Add2IntsLibrary class loaded, the metadata appears in the USER_LIBRARIES system table:

```

=> CREATE LIBRARY JavaAdd2IntsLib AS :libfile LANGUAGE 'JAVA';
CREATE LIBRARY
=> CREATE FUNCTION JavaAdd2Ints as LANGUAGE 'JAVA' name 'com.mycompany.example.Add2IntsFactory' library JavaAdd2IntsLib;
CREATE FUNCTION
=> \x
Expanded display is on.
=> SELECT * FROM USER_LIBRARIES WHERE lib_name = 'JavaAdd2IntsLib';

```

Java UDX resource management

Java Virtual Machines (JVMs) allocate a set amount of memory when they start. This set memory allocation complicates memory management for Java UDXs, because memory cannot be dynamically allocated and freed by the UDX as it is processing data. This differs from C++ UDXs which can dynamically allocate resources.

To control the amount of memory consumed by Java UDxs, Vertica has a memory pool named `jvm` that it uses to allocate memory for JVMs. If this memory pool is exhausted, queries that call Java UDxs block until enough memory in the pool becomes free to start a new JVM.

By default, the `jvm` pool has:

- no memory of its own assigned to it, so it borrows memory from the `GENERAL` pool.
- its `MAXMEMORYSIZE` set to either 10% of system memory or 2GB, whichever is smaller.
- its `PLANNEDCONCURRENCY` set to `AUTO`, so that it inherits the `GENERAL` pool's `PLANNEDCONCURRENCY` setting.

You can view the current settings for the `jvm` pool by querying the `RESOURCE_POOLS` table:

```
=> SELECT MAXMEMORYSIZE,PLANNEDCONCURRENCY FROM V_CATALOG.RESOURCE_POOLS WHERE NAME = 'jvm';
MAXMEMORYSIZE | PLANNEDCONCURRENCY
-----+-----
10%           | AUTO
```

When a SQL statement calls a Java UDX, Vertica checks if the `jvm` memory pool has enough memory to start a new JVM instance to execute the function call. Vertica starts each new JVM with its heap memory size set to approximately the `jvm` pool's `MAXMEMORYSIZE` parameter divided by its `PLANNEDCONCURRENCY` parameter. If the memory pool does not contain enough memory, the query blocks until another JVM exits and return their memory to the pool.

If your Java UDX attempts to consume more memory than has been allocated to the JVM's heap size, it exits with a memory error. You can attempt to resolve this issue by:

- increasing the `jvm` pool's `MAXMEMORYSIZE` parameter.
- decreasing the `jvm` pool's `PLANNEDCONCURRENCY` parameter.
- changing your Java UDX's code to consume less memory.

Adjusting the `jvm` pool

When adjusting the `jvm` pool to your needs, you must consider two factors:

- the amount of RAM your Java UDX requires to run
- how many concurrent Java UDX functions you expect your database to run

You can learn the amount of memory your Java UDX needs using several methods. For example, your code can use Java's `Runtime` class to get an estimate of the total memory it has allocated and then log the value using `ServerInterface.log()`. (An instance of this class is passed to your UDX.) If you have multiple Java UDxs in your database, set the `jvm` pool memory size based on the UDX that uses the most memory.

The number of concurrent sessions that need to run Java UDxs may not be the same as the global `PLANNEDCONCURRENCY` setting. For example, you may have just a single user who runs a Java UDX, which means you can lower the `jvm` pool's `PLANNEDCONCURRENCY` setting to 1.

When you have an estimate for the amount of RAM and the number of concurrent user sessions that need to run Java UDxs, you can adjust the `jvm` pool to an appropriate size. Set the pool's `MAXMEMORYSIZE` to the maximum amount of RAM needed by the most demanding Java UDX multiplied by the number of concurrent user sessions that need to run Java UDxs. Set the pool's `PLANNEDCONCURRENCY` to the number of simultaneous user sessions that need to run Java UDxs.

For example, suppose your Java UDX requires up to 4GB of memory to run and you expect up to two user sessions use Java UDX's. You would use the following command to adjust the `jvm` pool:

```
=> ALTER RESOURCE POOL jvm MAXMEMORYSIZE '8G' PLANNEDCONCURRENCY 2;
```

The `MEMORYSIZE` is set to 8GB, which is the 4GB maximum memory use by the Java UDX multiplied by the 2 concurrent user sessions.

Note

The `PLANNEDCONCURRENCY` value is **not** the number of calls to Java UDX that you expect to happen simultaneously. Instead, it is the number of concurrently open user sessions that call Java UDxs at any time during the session. See below for more information.

See [Managing workloads](#) for more information on tuning the `jvm` and other resource pools.

Freeing JVM memory

The first time users call a Java UDX during their session, Vertica allocates memory from the `jvm` pool and starts a new JVM. This JVM remains running for as long as the user's session is open so it can process other Java UDX calls. Keeping the JVM running lowers the overhead of executing multiple Java UDxs by the same session. If the JVM did not remain open, each call to a Java UDX would require additional time for Vertica to allocate resources and

start a new JVM. However, having the JVM remain open means that the JVM's memory remains allocated for the life of the session whether or not it will be used again.

If the jvm memory pool is depleted, queries containing Java UDxs either block until memory becomes available or eventually fail due a lack of resources. If you find queries blocking or failing for this reason, you can allocate more memory to the jvm pool and increase its PLANNEDCONCURRENCY. Another option is to ask users to call the [RELEASE_JVM_MEMORY](#) function when they no longer need to run Java UDxs. This function closes any JVM belonging to the user's session and returns its allocated memory to the jvm memory pool.

The following example demonstrates querying V_MONITOR.SESSIONS to find the memory allocated to JVMs by all sessions. It also demonstrates how the memory is allocated by a call to a Java UDx, and then freed by calling RELEASE_JVM_MEMORY.

```
=> SELECT USER_NAME,EXTERNAL_MEMORY_KB FROM V_MONITOR.SESSIONS;
user_name | external_memory_kb
-----+-----
dbadmin   |          0
(1 row)

=> -- Call a Java UDx
=> SELECT add2ints(123,456);
add2ints
-----
      579
(1 row)

=> -- JVM is now running and memory is allocated to it.
=> SELECT USER_NAME,EXTERNAL_MEMORY_KB FROM V_MONITOR.SESSIONS;
USER_NAME | EXTERNAL_MEMORY_KB
-----+-----
dbadmin   |       79705
(1 row)

=> -- Shut down the JVM and deallocate memory
=> SELECT RELEASE_JVM_MEMORY();
      RELEASE_JVM_MEMORY
-----
Java process killed and memory released
(1 row)

=> SELECT USER_NAME,EXTERNAL_MEMORY_KB FROM V_MONITOR.SESSIONS;
USER_NAME | EXTERNAL_MEMORY_KB
-----+-----
dbadmin   |          0
(1 row)
```

In rare cases, you may need to close all JVMs. For example, you may need to free memory for an important query, or several instances of a Java UDx may be taking too long to complete. You can use the [RELEASE_ALL_JVM_MEMORY](#) to close all of the JVMs in all user sessions:

```

=> SELECT USER_NAME,EXTERNAL_MEMORY_KB FROM V_MONITOR.SESIONS;
  USER_NAME | EXTERNAL_MEMORY_KB
-----+-----
ExampleUser |      79705
dbadmin    |      79705
(2 rows)

=> SELECT RELEASE_ALL_JVM_MEMORY();
      RELEASE_ALL_JVM_MEMORY
-----
Close all JVM sessions command sent. Check v_monitor.sessions for progress.
(1 row)

=> SELECT USER_NAME,EXTERNAL_MEMORY_KB FROM V_MONITOR.SESIONS;
  USER_NAME | EXTERNAL_MEMORY_KB
-----+-----
dbadmin    |          0
(1 row)

```

Caution

This function terminates all JVMs, including ones that are currently executing Java UDXs. This will cause any query that is currently executing a Java UDX to return an error.

Notes

- The jvm resource pool is used only to allocate memory for the Java UDX function calls in a statement. The rest of the resources required by the SQL statement come from other memory pools.
- The first time a Java UDX is called, Vertica starts a JVM to execute some Java methods to get metadata about the UDX during the query planning phase. The memory for this JVM is also taken from the jvm memory pool.

Python SDK

The Vertica SDK supports writing UDXs of some types in Python 3.

The Python SDK does not require any additional system configuration or header files. This low overhead allows you to develop and deploy new capabilities to your Vertica cluster in a short amount of time.

The following workflow is typical for the Python SDK:

Because Python has an interpreter, you do not have to compile your program before loading the UDX in Vertica. However, you should expect to do some debugging of your code after you create your function and begin testing it in Vertica.

When Vertica calls your UDX, it starts a side process that manages the interaction between the server and the Python interpreter.

This section covers Python-specific topics that apply to all UDX types. For information that applies to all languages, see [Arguments and return values](#), [UDX parameters](#), [Errors, warnings, and logging](#), [Handling cancel requests](#) and the sections for specific UDX types. For full API documentation, see the [Python SDK](#).

Important

Your UDX must be able to run with the version of Python bundled with Vertica. You can find this with `/opt/vertica/sbin/python3 --version`. You cannot change the version used by the Vertica Python interpreter.

In this section

- [Setting up a Python development environment](#)
- [Python and Vertica data types](#)

Setting up a Python development environment

To avoid problems when loading and executing your UDxs, develop your UDxs using the same version of Python that Vertica uses. To do this without changing your environment for projects that might require other Python versions, you can use a [Python virtual environment \(venv\)](#). You can install libraries that your UDX depends on into your `venv` and use that path when you create your UDX library with [CREATE LIBRARY](#).

Setting up venv

Set up `venv` using the Python version bundled with Vertica. If you have direct access to a database node, you can use that Python binary directly to create your `venv`:

```
$ /opt/vertica/sbin/python3 -m venv /path/to/new/environment
```

The result is a directory with a default environment, including a `site-packages` directory:

```
$ ls venv/lib/  
python3.9  
$ ls venv/lib/python3.9/  
site-packages
```

If your UDX depends on libraries that are not packaged with Vertica, install them into this directory:

```
$ source venv/bin/activate  
(venv) $ pip install numpy  
...
```

The `lib/python3.9/site-packages` directory now contains the installed library. The change affects only your virtual environment.

UDx imports

Your UDX code must import, in addition to any libraries you add, the `vertica_sdk` library:

```
# always required:  
import vertica_sdk  
# other libs:  
import numpy as np  
# ...
```

The `vertica_sdk` library is included as a part of the Vertica server. You do not need to add it to `site-packages` or declare it as a dependency.

Deployment

For libraries you add, you must declare dependencies when using [CREATE LIBRARY](#). This declaration allows Vertica to find the libraries and distribute them to all database nodes. You can supply a path instead of enumerating the libraries:

```
=> CREATE OR REPLACE LIBRARY pylib AS  
  '/path/to/udx/add2ints.py'  
  DEPENDS '/path/to/new/environment/lib/python3.9/site-packages/'  
  LANGUAGE 'Python';  
  
=> CREATE OR REPLACE FUNCTION add2ints AS LANGUAGE 'Python'  
  NAME 'add2ints_factory' LIBRARY pylib;
```

`CREATE LIBRARY` copies the UDX and the contents of the `DEPENDS` path and stores them with the database. Vertica then distributes copies to all database nodes.

Python and Vertica data types

The Vertica Python SDK converts native Vertica data types into the appropriate Python data types. The following table describes some of the data type conversions. Consult the [Python SDK](#) for a complete list, as well as lists of helper functions to convert and manipulate these data types.

For information about SDK support for complex data types, see [Complex Types as Arguments and Return Values](#).

Vertica Data Type	Python Data Type
INTEGER	int

FLOAT	float
NUMERIC	decimal.Decimal
DATE	datetime.date
CHAR, VARCHAR, LONG VARCHAR	string (UTF-8 encoded)
BINARY, VARBINARY, LONG VARBINARY	binary
TIMESTAMP	datetime.datetime
TIME	datetime.time
ARRAY	list Note: Nested ARRAY types are also converted into lists.
ROW	collections.OrderedDict Note: Nested ROW types are also converted into collections.OrderedDicts.

Note

Some Vertica data types are not supported in Python. For a list of all Vertica data types, see [Data types](#).

R SDK

The Vertica R SDK extends the capabilities of the Vertica Analytic Database so you can leverage additional R libraries. Before you can begin developing User Defined Extensions (UDxs) in R, you must install the R Language Pack for Vertica on each of the nodes in your cluster. The R SDK supports scalar and transform functions in fenced mode. Other UDx types are not supported.

The following workflow is typical for the R SDK:

You can find detailed documentation of all of the classes in the Vertica [R SDK](#).

In this section

- [Installing/upgrading the R language pack for Vertica](#)
- [R packages](#)
- [R and Vertica data types](#)
- [Adding metadata to R libraries](#)
- [Setting null input and volatility behavior for R functions](#)

Installing/upgrading the R language pack for Vertica

To create R UDxs in Vertica, install the R Language Pack package that matches your server version. The R Language Pack includes the R runtime and associated libraries for interfacing with Vertica. You must use this version of the R runtime; you cannot upgrade it.

You must install the R Language Pack on each node in the cluster. The Vertica R Language Pack must be the only R Language Pack installed on the node.

Vertica R language pack prerequisites

The R Language Pack package requires a number of packages for installation and execution. The names of these dependencies vary among Linux distributions. For Vertica-supported Linux platforms the packages are:

- RHEL/CentOS: [libgfortran](#) , [xz-libs](#) , [libgomp](#)

- SUSE Linux Enterprise Server: [libgfortran](#) , [liblzma5](#) , [libgomp1](#)
- Debian/Ubuntu: [libgfortran](#) , [liblzma5](#) , [libgomp1](#)
- Amazon Linux 2023: [libgfortran](#) , [xz-libs](#) , [libgomp](#)

Vertica requires version 5 of the [libgfortran](#) library later than 8.3.0 to create R extensions. The [libgfortran](#) library is included by default with the [devtool](#) and [gcc](#) packages.

Installing the Vertica R language pack

If you use your operating systems package manager, rather than the rpm or dpkg command, for installation, you do not need to manually install the R Language Pack. The native package managers for each supported Linux version are:

- RHEL/CentOS: yum
- SUSE Linux Enterprise Server: zypper
- Debian/Ubuntu: apt-get
- Amazon Linux 2023: yum

1. Download the R language package by browsing to the [Vertica website](#) .
2. On the **Support** tab, select **Customer Downloads** .
3. When prompted, log in using your Micro Focus credentials.
4. Located and select the [vertica-R-lang_ version .rpm](#) or [vertica-R-lang_ version .deb](#) file for your server version. The R language package version must match your server version to three decimal points.
5. Install the package as root or using sudo:

- RHEL/CentOS

```
$ yum install vertica-R-lang-<version>.rpm
```

- SUSE Linux Enterprise Server

```
$ zypper install vertica-R-lang-<version>.rpm
```

- Debian

```
$ apt-get install ./vertica-R-lang_<version>.deb
```

- Amazon Linux 2023

```
$ yum install vertica-R-lang-<version>.AMZN.rpm
```

The installer puts the R binary in [/opt/vertica/R](#) .

Upgrading the Vertica R language pack

When upgrading, some R packages you have manually installed may not work and may have to be reinstalled. If you do not update your package(s), then R returns an error if the package cannot be used. Instructions for upgrading these packages are below.

Note

The R packages provided in the R Language Pack are automatically upgraded and do not need to be reinstalled.

1. You must uninstall the R Language package before upgrading Vertica. Any additional R packages you manually installed remain in [/opt/vertica/R](#) and are not removed when you uninstall the package.
2. Upgrade your server package as detailed in [Upgrading Vertica to a New Version](#) .
3. After the server package has been updated, install the new R Language package on each host.

If you have installed additional R packages, on each node:

1. As root run [/opt/vertica/R/bin/R](#) and issue the command:

```
> update.packages(checkBuilt=TRUE)
```

2. Select a CRAN mirror from the list displayed.
3. You are prompted to update each package that has an update available for it. You must update any packages that you manually installed and are not compatible with the current version of R in the R Language Pack.

Do **NOT** update:

- Rcpp
- Rinside

The packages you selected to be updated are installed. Quit R with the command:

```
> quit()
```

Vertica UDx functions written in R do not need to be compiled and you do not need to reload your Vertica-R libraries and functions after an upgrade.

R packages

The Vertica R Language Pack includes the following R packages in addition to the default packages bundled with R:

- Rcpp
- RInside
- IpSolve
- IpSolveAPI

You can install additional R packages not included in the Vertica R Language Pack by using one of two methods. You must install the same packages on all nodes.

Installing R packages

You can install additional R packages by using one of the two following methods.

Using the `install.packages()` R command:

```
$ sudo /opt/vertica/R/bin/R  
> install.packages("Zelig");
```

Using CMD INSTALL:

```
/opt/vertica/R/bin/R CMD INSTALL <path-to-package-tgz>
```

The installed packages are located in: `/opt/vertica/R/library` .

R and Vertica data types

The following data types are supported when passing data to/from an R UDx:

Vertica Data Type	R Data Type
BOOLEAN	logical
DATE, DATETIME, SMALLDATETIME, TIME, TIMESTAMP, TIMESTAMPTZ, TIMETZ	numeric
DOUBLE PRECISION, FLOAT, REAL	numeric
BIGINT, DECIMAL, INT, NUMERIC, NUMBER, MONEY	numeric
BINARY, VARBINARY	character
CHAR, VARCHAR	character

NULL values in Vertica are translated to R NA values when sent to the R function. R NA values are translated into Vertica null values when returned from the R function to Vertica.

Important
When specifying LONG VARCHAR or LONG VARBINARY data types, include the space between the two words. For example, `datatype = c("long varchar")`

Adding metadata to R libraries

You can add metadata, such as author name, the version of the library, a description of your library, and so on to your library. This metadata lets you track the version of your function that is deployed on a Vertica Analytic Database cluster and lets third-party users of your function know who created the function. Your library's metadata appears in the [USER_LIBRARIES](#) system table after your library has been loaded into the Vertica Analytic Database catalog.

You declare the metadata for your library by calling the `RegisterLibrary()` function in one of the source files for your UDx. If there is more than one function call in the source files for your UDx, whichever gets interpreted last as Vertica Analytic Database loads the library is used to determine the library's metadata.

The `RegisterLibrary()` function takes eight string parameters:

```
RegisterLibrary(author,  
               library_build_tag,  
               library_version,  
               library_sdk_version,  
               source_url,  
               description,  
               licenses_required,  
               signature);
```

- `author` contains whatever name you want associated with the creation of the library (your own name or your company's name for example).
- `library_build_tag` is a string you want to use to represent the specific build of the library (for example, the SVN revision number or a timestamp of when the library was compiled). This is useful for tracking instances of your library as you are developing them.
- `library_version` is the version of your library. You can use whatever numbering or naming scheme you want.
- `library_sdk_version` is the version of the Vertica Analytic Database SDK Library for which you've compiled the library.

Note

This field isn't used to determine whether a library is compatible with a version of the Vertica Analytic Database server. The version of the Vertica Analytic Database SDK you use to compile your library is embedded in the library when you compile it. It is this information that Vertica Analytic Database server uses to determine if your library is compatible with it.

- `source_url` is a URL where users of your function can find more information about it. This can be your company's website, the GitHub page hosting your library's source code, or whatever site you like.
- `description` is a concise description of your library.
- `licenses_required` is a placeholder for licensing information. You must pass an empty string for this value.
- `signature` is a placeholder for a signature that will authenticate your library. You must pass an empty string for this value.

The following example shows how to add metadata to an R UDx.

```
RegisterLibrary("Speedy Analytics Ltd.",  
               "1234",  
               "1.0",  
               "8.1.0",  
               "http://www.example.com/sales_tax_calculator.R",  
               "Sales Tax R Library",  
               "",  
               "")
```

Loading the library and querying the `USER_LIBRARIES` system table shows the metadata supplied in the call to `RegisterLibrary` :

```

=> CREATE LIBRARY rLib AS '/home/dbadmin/sales_tax_calculator.R' LANGUAGE 'R';
CREATE LIBRARY
=> SELECT * FROM USER_LIBRARIES WHERE lib_name = 'rLib';
-[ RECORD 1 ]-----+-----

```

Setting null input and volatility behavior for R functions

Vertica supports defining volatility and null-input settings for UDxs written in R. Both settings aid in the performance of your R function.

Volatility settings

Volatility settings describe the behavior of the function to the Vertica optimizer. For example, if you have identical rows of input data and you know the UDX is immutable, then you can define the UDX as IMMUTABLE. This tells the Vertica optimizer that it can return a cached value for subsequent identical rows on which the function is called rather than having the function run on each identical row.

To indicate your UDX's volatility, set the volatility parameter of your R factory function to one of the following values:

Value	Description
VOLATILE	Repeated calls to the function with the same arguments always result in different values. Vertica always calls volatile functions for each invocation.
IMMUTABLE	Calls to the function with the same arguments always results in the same return value.
STABLE	Repeated calls to the function with the same arguments <i>within the same statement</i> returns the same output. For example, a function that returns the current user name is stable because the user cannot change within a statement. The user name could change between statements.
DEFAULT_VOLATILITY	The default volatility. This is the same as VOLATILE.

If you do not define a volatility, then the function is considered to be VOLATILE.

The following example sets the volatility to STABLE in the multiplyTwoIntsFactory function:

```

multiplyTwoIntsFactory <- function() {
  list(name       = multiplyTwoInts,
       udxtype    = c("scalar"),
       in_type    = c("float", "float"),
       out_type   = c("float"),
       volatility  = c("stable"),
       parameter_type_callback = multiplyTwoIntsParameters)
}

```

Null input behavior

Null input setting determine how to respond to rows that have null input. For example, you can choose to return null if any inputs are null rather than calling the function and having the function deal with a NULL input.

To indicate how your UDx reacts to NULL input, set the strictness parameter of your R factory function to one of the following values:

Value	Description
CALLED_ON_NULL_INPUT	The function must be called, even if one or more arguments are NULL.
RETURN_NULL_ON_NULL_INPUT	The function always returns a NULL value if any of its arguments are NULL.
STRICT	A synonym for RETURN_NULL_ON_NULL_INPUT
DEFAULT_STRICTNESS	The default strictness setting. This is the same as CALLED_ON_NULL_INPUT.

If you do not define a null input behavior, then the function is called on every row of data regardless of the presence of NULL values.

The following example sets the NULL input behavior to STRICT in the multiplyTwoIntsFactory function:

```
multiplyTwoIntsFactory <- function() {
  list(name       = multiplyTwoInts,
       udxtype    = c("scalar"),
       intype     = c("float","float"),
       outtype    = c("float"),
       strictness = c("strict"),
       parametertypecallback = multiplyTwoIntsParameters)
```

Debugging tips

The following tips can help you debug your UDx before deploying it in a production environment.

Use a single node for initial debugging

You can attach to the Vertica process using a debugger such as gdb to debug your UDx code. Doing this in a multi-node environment, however, is very difficult. Therefore, consider setting up a single-node Vertica test environment to initially debug your UDx.

Use logging

Each UDx has an associated [ServerInterface](#) instance. The [ServerInterface](#) provides functions to write to the Vertica log and, in the C++ API only, a system table. See [Logging](#) for more information.

Arguments and return values

For all UDx types except load (UDL), the factory class declares the arguments and return type of the associated function. Factories have two methods for this purpose:

- [getPrototype\(\)](#) (required): declares input and output types
- [getReturnType\(\)](#) (sometimes required): declares the return types, including length and precision, when applicable

The [getPrototype\(\)](#) method receives two [ColumnTypes](#) parameters, one for input and one for output. The factory in [C++ example: string tokenizer](#) takes a single input string and returns a string:

```
virtual void getPrototype(ServerInterface &svInterface,
                        ColumnTypes &argTypes, ColumnTypes &returnType)
{
  argTypes.addVarchar();
  returnType.addVarchar();
}
```

The [ColumnTypes](#) class provides "add" methods for each supported type, like [addVarchar\(\)](#). This class supports complex types with the [addArrayType\(\)](#) and [addRowType\(\)](#) methods; see [Complex Types as Arguments](#). If your function is polymorphic, you can instead call [addAny\(\)](#). You are then responsible for validating your inputs and outputs. For more information about implementing polymorphic UDxs, see [Creating a polymorphic UDx](#).

The `getReturnType()` method computes a maximum length for the returned value. If your UDX returns a sized column (a return data type whose length can vary, such as a VARCHAR), a value that requires precision, or more than one value, implement this factory method. (Some UDX types require you to implement it.)

The input is a `SizedColumnTypes` containing the input argument types along with their lengths. Depending on the input types, add one of the following to the output types:

- CHAR, (LONG) VARCHAR, BINARY, and (LONG) VARBINARY: return the maximum length.
- NUMERIC types: specify the precision and scale.
- TIME and TIMESTAMP values (with or without timezone): specify precision.
- INTERVAL YEAR TO MONTH: specify range.
- INTERVAL DAY TO SECOND: specify precision and range.
- ARRAY: specify the maximum number of array elements.

In the case of the string tokenizer, the output is a VARCHAR and the function determines its maximum length:

```
// Tell Vertica what our return string length will be, given the input
// string length
virtual void getReturnType(ServerInterface &srvInterface,
                           const SizedColumnTypes &inputTypes,
                           SizedColumnTypes &outputTypes)
{
    // Error out if we're called with anything but 1 argument
    if (inputTypes.getColumnCount() != 1)
        vt_report_error(0, "Function only accepts 1 argument, but %zu provided", inputTypes.getColumnCount());

    int input_len = inputTypes.getColumnType(0).getStringLength();

    // Our output size will never be more than the input size
    outputTypes.addVarchar(input_len, "words");
}
```

Complex types as arguments and return values

The `ColumnTypes` class supports [ARRAY](#) and [ROW](#) types. Arrays have elements and rows have fields, both of which have types that you need to describe. To work with complex types, you build `ColumnTypes` objects for the array or row and then add them to the `ColumnTypes` objects representing the function inputs and outputs.

In the following example, the input to a transform function is an array of orders, which are rows, and the output is the individual rows with their positions in the array. An order consists of a shipping address (VARCHAR) and an array of product IDs (INT).

[C++](#)

[Python](#)

The factory's `getPrototype()` method first creates `ColumnTypes` for the array and row elements and then calls `addArrayType()` and `addRowType()` using them:

```

void getPrototype(ServerInterface &srv,
    ColumnTypes &argTypes,
    ColumnTypes &retTypes)
{
    // item ID (int), to be used in an array
    ColumnTypes itemidProto;
    itemidProto.addInt();

    // row: order = address (varchar) + array of previously-created item IDs
    ColumnTypes orderProto;
    orderProto.addVarchar();          /* address */
    orderProto.addArrayType(itemidProto); /* array of item ID */

    /* argument (input) is array of orders */
    argTypes.addArrayType(orderProto);

    /* return values: index in the array, order */
    retTypes.addInt();                /* index of element */
    retTypes.addRowType(orderProto);  /* element return type */
}

```

The arguments include a sized type (the VARCHAR). The `getReturnType()` method uses a similar approach, using the `Fields` class to build the two fields in the order.

```

void getReturnType(ServerInterface &srv,
    const SizedColumnTypes &argTypes,
    SizedColumnTypes &retTypes)
{
    Fields itemidElementFields;
    itemidElementFields.addInt("item_id");

    Fields orderFields;
    orderFields.addVarchar(32, "address");
    orderFields.addArrayType(itemidElementFields[0], "item_id");
    // optional third arg: max length, default unbounded

    /* declare return type */
    retTypes.addInt("index");
    static_cast<Fields &>(retTypes).addRowType(orderFields, "element");

    /* NOTE: presumably we have verified that the arguments match the prototype, so really we could just do this: */
    retTypes.addInt("index");
    retTypes.addArg(argTypes.getColumnType(0).getElementType(), "element");
}

```

To access complex types in the UDX processing method, use the `ArrayReader`, `ArrayWriter`, `StructReader`, and `StructWriter` classes.

See [C++ example: using complex types](#) for a polymorphic function that uses arrays.

Handling different numbers and types of arguments

You can create UDXs that handle multiple signatures, or even accept all arguments supplied to them by the user, using either overloading or polymorphism.

You can overload your UDX by assigning the same SQL function name to multiple factory classes, each of which defines a unique function signature. When a user uses the function name in a query, Vertica tries to match the signature of the function call to the signatures declared by the factory's `getPrototype()` method. This is the best technique to use if your UDX needs to accept a few different signatures (for example, accepting two required and one optional argument).

Alternatively, you can write a polymorphic function, writing one factory method instead of several and declaring that it accepts any number and type of arguments. When a user uses the function name in a query, Vertica calls your function regardless of the signature. In exchange for this flexibility, your UDX's main "process" method has to determine whether it can accept the arguments and emit errors if not.

All UDX types can use polymorphic inputs. Transform functions and analytic functions can also use polymorphic outputs. This means that `getPrototype()` can declare a return type of "any" and set the actual return type at runtime. For example, a function that returns the largest value in an input would return the same type as the input type.

In this section

- [Overloading your UDX](#)
- [Creating a polymorphic UDX](#)

Overloading your UDX

You may want your UDX to accept several different signatures (sets of arguments). For example, you might want your UDX to accept:

- One or more optional arguments.
- One or more arguments that can be one of several data types.
- Completely distinct signatures (either all INTEGER or all VARCHAR, for example).

You can create a function with this behavior by creating several factory classes, each of which accepts a different signature (the number and data types of arguments). You can then associate a single SQL function name with all of them. You can use the same SQL function name to refer to multiple factory classes as long as the signature defined by each factory is unique. When a user calls your UDX, Vertica matches the number and types of arguments supplied by the user to the arguments accepted by each of your function's factory classes. If one matches, Vertica uses it to instantiate a function class to process the data.

Multiple factory classes can instantiate the same function class, so you can re-use one function class that is able to process multiple sets of arguments and then create factory classes for each of the function signatures. You can also create multiple function classes if you want.

See the [C++ example: overloading your UDX](#) and [Java example: overloading your UDX](#) examples.

In this section

- [C++ example: overloading your UDX](#)
- [Java example: overloading your UDX](#)

C++ example: overloading your UDX

The following example code demonstrates creating a user-defined scalar function (UDSF) that adds two or three integers together. The `Add2or3ints` class is prepared to handle two or three arguments. The `processBlock()` function checks the number of arguments that have been passed to it, and adds all two or three of them together. It also exits with an error message if it has been called with less than 2 or more than 3 arguments. In theory, this should never happen, since Vertica only calls the UDSF if the user's function call matches a signature on one of the factory classes you create for your function. In practice, it is a good idea to perform this sanity checking, in case your (or someone else's) factory class inaccurately reports a set of arguments your function class cannot handle.

```
#include "Vertica.h"
using namespace Vertica;
using namespace std;
// a ScalarFunction that accepts two or three
// integers and adds them together.
class Add2or3ints : public Vertica::ScalarFunction
{
public:
    virtual void processBlock(Vertica::ServerInterface &srvInterface,
                             Vertica::BlockReader &arg_reader,
                             Vertica::BlockWriter &res_writer)
    {
        const size_t numCols = arg_reader.getNumCols();

        // Ensure that only two or three parameters are passed in
        if ( numCols < 2 || numCols > 3)
            vt_report_error(0, "Function only accept 2 or 3 arguments, "
                           "but %zu provided", arg_reader.getNumCols());

        // Add two integers together
        do {
```

```

--
    const vint a = arg_reader.getIntRef(0);
    const vint b = arg_reader.getIntRef(1);
    vint c = 0;
    // Check for third argument, add it in if it exists.
    if (numCols == 3)
        c = arg_reader.getIntRef(2);
    res_writer.setInt(a+b+c);
    res_writer.next();
} while (arg_reader.next());
}
}

// This factory accepts function calls with two integer arguments.
class Add2intsFactory : public Vertica::ScalarFunctionFactory
{
    virtual Vertica::ScalarFunction *createScalarFunction(Vertica::ServerInterface
        &srvInterface)
    { return vt_createFuncObj(srvInterface.allocator, Add2or3ints); }
    virtual void getPrototype(Vertica::ServerInterface &srvInterface,
        Vertica::ColumnTypes &argTypes,
        Vertica::ColumnTypes &returnType)
    { // Accept 2 integer values
        argTypes.addInt();
        argTypes.addInt();
        returnType.addInt();
    }
};
RegisterFactory(Add2intsFactory);

// This factory defines a function that accepts 3 ints.
class Add3intsFactory : public Vertica::ScalarFunctionFactory
{
    virtual Vertica::ScalarFunction *createScalarFunction(Vertica::ServerInterface
        &srvInterface)
    { return vt_createFuncObj(srvInterface.allocator, Add2or3ints); }
    virtual void getPrototype(Vertica::ServerInterface &srvInterface,
        Vertica::ColumnTypes &argTypes,
        Vertica::ColumnTypes &returnType)
    { // accept 3 integer values
        argTypes.addInt();
        argTypes.addInt();
        argTypes.addInt();
        returnType.addInt();
    }
};
RegisterFactory(Add3intsFactory);

```

The example has two **ScalarFunctionFactory** classes, one for each signature that the function accepts (two integers and three integers). There is nothing unusual about these factory classes, except that their implementation of **ScalarFunctionFactory::createScalarFunction()** both create **Add2or3ints** objects.

The final step is to bind the same SQL function name to both factory classes. You can assign multiple factories to the same SQL function, as long as the signatures defined by each factory's **getPrototype()** implementation are different.

```

=> CREATE LIBRARY add2or3IntsLib AS '/home/dbadmin/Add2or3Ints.so';
CREATE LIBRARY
=> CREATE FUNCTION add2or3Ints as NAME 'Add2intsFactory' LIBRARY add2or3IntsLib FENCED;
CREATE FUNCTION
=> CREATE FUNCTION add2or3Ints as NAME 'Add3intsFactory' LIBRARY add2or3IntsLib FENCED;
CREATE FUNCTION
=> SELECT add2or3Ints(1,2);
add2or3Ints
-----
      3
(1 row)
=> SELECT add2or3Ints(1,2,4);
add2or3Ints
-----
      7
(1 row)
=> SELECT add2or3Ints(1,2,3,4); -- Will generate an error
ERROR 3467: Function add2or3Ints(int, int, int, int) does not exist, or
permission is denied for add2or3Ints(int, int, int, int)
HINT: No function matches the given name and argument types. You may
need to add explicit type casts

```

The error message in response to the final call to the `add2or3Ints` function was generated by Vertica, since it could not find a factory class associated with `add2or3Ints` that accepted four integer arguments. To expand `add2or3Ints` further, you could create another factory class that accepted this signature, and either change the `Add2or3ints ScalarFunction` class or create a totally different class to handle adding more integers together. However, adding more classes to accept each variation in the arguments quickly becomes overwhelming. In that case, you should consider creating a polymorphic UDX.

Java example: overloading your UDX

The following example code demonstrates creating a user-defined scalar function (UDSF) that adds two or three integers together. The `Add2or3ints` class is prepared to handle two or three arguments. It checks the number of arguments that have been passed to it, and adds all two or three of them together. The `processBlock()` method checks whether it has been called with less than 2 or more than 3 arguments. In theory, this should never happen, since Vertica only calls the UDSF if the user's function call matches a signature on one of the factory classes you create for your function. In practice, it is a good idea to perform this sanity checking, in case your (or someone else's) factory class reports that your function class accepts a set of arguments that it actually does not.

```

// You need to specify the full package when creating functions based on
// the classes in your library.
package com.mycompany.multiparamexample;
// Import the entire Vertica SDK
import com.vertica.sdk.*;
// This ScalarFunction accepts two or three integer arguments. It tests
// the number of input columns to determine whether to read two or three
// arguments as input.
public class Add2or3ints extends ScalarFunction
{
    @Override
    public void processBlock(ServerInterface srvInterface,
        BlockReader argReader,
        BlockWriter resWriter)
        throws UdfException, DestroyInvocation
    {
        // See how many arguments were passed in
        int numCols = argReader.getNumCols();

        // Return an error if less than two or more than 3 arguments
        // were given. This error only occurs if a Factory class that
        // accepts the wrong number of arguments instantiates this
        // class.
        if (numCols < 2 || numCols > 3) {
            throw new UdfException(0,
                "Must supply 2 or 3 integer arguments");
        }

        // Process all of the rows of input.
        do {
            // Get the first two integer arguments from the BlockReader
            long a = argReader.getLong(0);
            long b = argReader.getLong(1);

            // Assume no third argument.
            long c = 0;

            // Get third argument value if it exists
            if (numCols == 3) {
                c = argReader.getLong(2);
            }

            // Process the arguments and come up with a result. For this
            // example, just add the three arguments together.
            long result = a+b+c;

            // Write the integer output value.
            resWriter.setLong(result);

            // Advance the output BlockWriter to the next row.
            resWriter.next();

            // Continue processing input rows until there are no more.
        } while (argReader.next());
    }
}

```

The main difference between the [Add2ints](#) class and the [Add2or3ints](#) class is the inclusion of a section that gets the number of arguments by calling `BlockReader.getNumCols()` . This class also tests the number of columns it received from Vertica to ensure it is in the range it is prepared to handle. This test will only fail if you create a [ScalarFunctionFactory](#) whose `getPrototype()` method defines a signature that accepts less than two or more than

three arguments. This is not really necessary in this simple example, but for a more complicated class it is a good idea to test the number of columns and data types that Vertica passed your function class.

Within the `do` loop, `Add2or3ints` uses a default value of zero if Vertica sent it two input columns. Otherwise, it retrieves the third value and adds that to the other two. Your own class needs to use default values for missing input columns or alter its processing in some other way to handle the variable columns.

You must define your function class in its own source file, rather than as an inner class of one of your factory classes since Java does not allow the instantiation of an inner class from outside its containing class. Your factory class has to be available for instantiation by multiple factory classes.

Once you have created a function class or classes, you create a factory class for each signature you want your function class to handle. These factory classes can call individual function classes, or they can all call the same class that is prepared to accept multiple sets of arguments.

The following example's `createScalarFunction()` method instantiates a member of the `Add2or3ints` class.

```
// You will need to specify the full package when creating functions based on
// the classes in your library.
package com.mycompany.multiparamexample;
// Import the entire Vertica SDK
import com.vertica.sdk.*;
public class Add2intsFactory extends ScalarFunctionFactory
{
    @Override
    public void getPrototype(ServerInterface srvInterface,
                            ColumnTypes argTypes,
                            ColumnTypes returnType)
    {
        // Accept two integers as input
        argTypes.addInt();
        argTypes.addInt();
        // writes one integer as output
        returnType.addInt();
    }
    @Override
    public ScalarFunction createScalarFunction(ServerInterface srvInterface)
    {
        // Instantiate the class that can handle either 2 or 3 integers.
        return new Add2or3ints();
    }
}
```

The following `ScalarFunctionFactory` subclass accepts three integers as input. It, too, instantiates a member of the `Add2or3ints` class to process the function call:

```

// You will need to specify the full package when creating functions based on
// the classes in your library.
package com.mycompany.multiparamexample;
// Import the entire Vertica SDK
import com.vertica.sdk.*;
public class Add3intsFactory extends ScalarFunctionFactory
{
    @Override
    public void getPrototype(ServerInterface srvInterface,
                            ColumnTypes argTypes,
                            ColumnTypes returnType)
    {
        // Accepts three integers as input
        argTypes.addInt();
        argTypes.addInt();
        argTypes.addInt();
        // Returns a single integer
        returnType.addInt();
    }
    @Override
    public ScalarFunction createScalarFunction(ServerInterface srvInterface)
    {
        // Instantiates the Add2or3ints ScalarFunction class, which is able to
        // handle either 2 or 3 integers as arguments.
        return new Add2or3ints();
    }
}

```

The factory classes and the function class or classes they call must be packaged into the same JAR file (see [Compiling and packaging a Java library](#) for details). If a host in the database cluster has the JDK installed on it, you could use the following commands to compile and package the example:

```

$ cd pathToJavaProject$ javac -classpath /opt/vertica/bin/VerticaSDK.jar \
> com/mycompany/multiparamexample/*.java
$ jar -cvf Add2or3intslib.jar com/vertica/sdk/BuildInfo.class \
> com/mycompany/multiparamexample/*.class
added manifest
adding: com/vertica/sdk/BuildInfo.class(in = 1202) (out= 689)(deflated 42%)
adding: com/mycompany/multiparamexample/Add2intsFactory.class(in = 677) (out= 366)(deflated 45%)
adding: com/mycompany/multiparamexample/Add2or3ints.class(in = 919) (out= 601)(deflated 34%)
adding: com/mycompany/multiparamexample/Add3intsFactory.class(in = 685) (out= 369)(deflated 46%)

```

Once you have packaged your overloaded UDX, you deploy it the same way as you do a regular UDX, except you use multiple [CREATE FUNCTION](#) statements to define the function, once for each factory class.

```

=> CREATE LIBRARY add2or3intslib as '/home/dbadmin/Add2or3intslib.jar'
-> language 'Java';
CREATE LIBRARY
=> CREATE FUNCTION add2or3ints as LANGUAGE 'Java' NAME 'com.mycompany.multiparamexample.Add2intsFactory' LIBRARY add2or3intslib;
CREATE FUNCTION
=> CREATE FUNCTION add2or3ints as LANGUAGE 'Java' NAME 'com.mycompany.multiparamexample.Add3intsFactory' LIBRARY add2or3intslib;
CREATE FUNCTION

```

You call the overloaded function the same way you call any other function.

```
=> SELECT add2or3ints(2,3);
add2or3ints
-----
      5
(1 row)
=> SELECT add2or3ints(2,3,4);
add2or3ints
-----
      9
(1 row)
=> SELECT add2or3ints(2,3,4,5);
ERROR 3457: Function add2or3ints(int, int, int, int) does not exist, or permission is denied for add2or3ints(int, int, int, int)
HINT: No function matches the given name and argument types. You may need to add explicit type casts
```

The last error was generated by Vertica, not the UDX code. It returns an error if it cannot find a factory class whose signature matches the function call's signature.

Creating an overloaded UDX is useful if you want your function to accept a limited set of potential arguments. If you want to create a more flexible function, you can create a polymorphic function.

Creating a polymorphic UDX

Polymorphic UDXs accept any number and type of argument that the user supplies. Transform functions (UDTFs), analytic functions (UDAFs), and aggregate functions (UDAFs) can define their output return types at runtime, usually based on the input arguments. For example, a UDTF that adds two numbers could return an integer or a float, depending on the input types.

Vertica does not check the number or types of argument that the user passes to the UDX—it just passes the UDX all of the arguments supplied by the user. It is up to your polymorphic UDX's main processing function (for example, `processBlock()` in user-defined scalar functions) to examine the number and types of arguments it received and determine if it can handle them. UDXs support up to 9800 arguments.

Polymorphic UDXs are more flexible than using multiple factory classes for your function (see [Overloading your UDX](#)). They also allow you to write more concise code, instead of writing versions for each data type. The tradeoff is that your polymorphic function needs to perform more work to determine whether it can process its arguments.

Your polymorphic UDX declares that it accepts any number of arguments in its factory's `getPrototype()` function by calling the `addAny()` function on the `ColumnTypes` object that defines its arguments, as follows:

```
// C++ example
void getPrototype(ServerInterface &svInterface,
                 ColumnTypes &argTypes,
                 ColumnTypes &returnType)
{
    argTypes.addAny(); // Must be only argument type.
    returnType.addInt(); // or whatever the function returns
}
```

This "any parameter" argument type is the only one that your function can declare. You cannot define required arguments and then call `addAny()` to declare the rest of the signature as optional. If your function has requirements for the arguments it accepts, your `process()` function must enforce them.

The `getPrototype()` example shown previously accepts any type and declares that it returns an integer. The following example shows a version of the method that defers resolving the return type until runtime. You can only use the "any" return type for transform and analytic functions.

```
void getPrototype(ServerInterface &svInterface,
                 ColumnTypes &argTypes,
                 ColumnTypes &returnType)
{
    argTypes.addAny();
    returnType.addAny(); // type determined at runtime
}
```

If you use polymorphic return types, you must also define `getReturnType()` in your factory. This function is called at runtime to determine the actual return type. See [C++ example: PolyNthValue](#) for an example.

Polymorphic UDxs and schema search paths

If a user does not supply a schema name as part of a UDX call, Vertica searches each schema in the schema search path for a function whose name and signature match the function call. See [Setting search paths](#) for more information about schema search paths.

Because polymorphic UDxs do not have specific signatures associated with them, Vertica initially skips them when searching for a function to handle the function call. If none of the schemas in the search path contain a UDX whose name and signature match the function call, Vertica searches the schema search path again for a polymorphic UDX whose name matches the function name in the function call.

This behavior gives precedence to a UDX whose signature exactly matches the function call. It allows you to create a "catch-all" polymorphic UDX that Vertica calls only when none of the non-polymorphic UDxs with the same name have matching signatures.

This behavior may cause confusion if your users expect the first polymorphic function in the schema search path to handle a function call. To avoid confusion, you should:

- Avoid using the same name for different UDxs. You should always uniquely name UDxs unless you intend to create an overloaded UDX with multiple signatures.
- When you cannot avoid having UDxs with the same name in different schemas, always supply the schema name as part of the function call. Using the schema name prevents ambiguity and ensures that Vertica uses the correct UDX to process your function calls.

In this section

- [Java example: AddAnyInts](#)
- [R example: kmeansPoly](#)

C++ example: PolyNthValue

The PolyNthValue example is an analytic function that returns the value in the Nth row in each partition in its input. This function is a generalization of [FIRST_VALUE \[analytic\]](#) and [LAST_VALUE \[analytic\]](#).

The values can be of any primitive data type.

For the complete source code, see [PolymorphicNthValue.cpp](#) in the examples (in `/opt/vertica/sdk/examples/AnalyticFunctions/`).

Loading and using the example

Load the library and create the function as follows:

```
=> CREATE LIBRARY AnalyticFunctions AS '/home/dbadmin/AnalyticFns.so';
CREATE LIBRARY
=> CREATE ANALYTIC FUNCTION poly_nth_value AS LANGUAGE 'C++'
  NAME 'PolyNthValueFactory' LIBRARY AnalyticFunctions;
CREATE ANALYTIC FUNCTION
```

Consider a table of scores for different test groups:

```
=> SELECT cohort, score FROM trials;
cohort | score
-----+-----
 1 | 9
 1 | 8
 1 | 7
 3 | 3
 3 | 2
 3 | 1
 2 | 4
 2 | 5
 2 | 6
(9 rows)
```

Call the function in a query that uses an OVER clause to partition the data. This example returns the second-highest score in each cohort:

```
=> SELECT cohort, score, poly_nth_value(score USING PARAMETERS n=2) OVER (PARTITION BY cohort) AS nth_value
FROM trials;
cohort | score | nth_value
-----+-----+-----
 1 | 9 | 8
 1 | 8 | 8
 1 | 7 | 8
 3 | 3 | 2
 3 | 2 | 2
 3 | 1 | 2
 2 | 4 | 5
 2 | 5 | 5
 2 | 6 | 5
(9 rows)
```

Factory implementation

The factory declares that the class is polymorphic, and then sets the return type based on the input type. Two factory methods specify the argument and return types.

Use the `getPrototype()` method to declare that the analytic function takes and returns any type:

```
void getPrototype(ServerInterface &srvInterface, ColumnTypes &argTypes, ColumnTypes &returnType)
{
    // This function supports any argument data type
    argTypes.addAny();

    // Output data type will be the same as the argument data type
    // We will specify that in getReturnType()
    returnType.addAny();
}
```

The `getReturnType()` method is called at runtime. This is where you set the return type based on the input type:

```
void getReturnType(ServerInterface &srvInterface, const SizedColumnTypes &inputTypes,
                  SizedColumnTypes &outputTypes)
{
    // This function accepts only one argument
    // Complain if we find a different number
    std::vector<size_t> argCols;
    inputTypes.getArgumentColumns(argCols); // get argument column indices

    if (argCols.size() != 1)
    {
        vt_report_error(0, "Only one argument is expected but %s provided",
                       argCols.size() ? std::to_string(argCols.size()).c_str() : "none");
    }

    // Define output type the same as argument type
    outputTypes.addArg(inputTypes.getColumnType(argCols[0]), inputTypes.getColumnName(argCols[0]));
}
```

Function implementation

The analytic function itself is type-agnostic:

```

void processPartition(ServerInterface &srvInterface, AnalyticPartitionReader &inputReader,
                    AnalyticPartitionWriter &outputWriter)
{
    try {
        const SizedColumnTypes &inTypes = inputReader.getTypeMetaData();
        std::vector<size_t> argCols; // Argument column indexes.
        inTypes.getArgumentColumns(argCols);

        vint currentRow = 1;
        bool nthRowExists = false;

        // Find the value of the n-th row
        do {
            if (currentRow == this->n) {
                nthRowExists = true;
                break;
            } else {
                currentRow++;
            }
        } while (inputReader.next());

        if (nthRowExists) {
            do {
                // Return n-th value
                outputWriter.copyFromInput(0 /*dest column*/, inputReader,
                                           argCols[0] /*source column*/);
            } while (outputWriter.next());
        } else {
            // The partition has less than n rows
            // Return NULL value
            do {
                outputWriter.setNull(0);
            } while (outputWriter.next());
        }
    } catch(std::exception& e) {
        // Standard exception. Quit.
        vt_report_error(0, "Exception while processing partition: [%s]", e.what());
    }
}

```

Java example: AddAnyInts

The following example shows an implementation of a Java **ScalarFunction** that adds together two or more integers.

For the complete source code, see [AddAnyIntsInfo.java](#) in the examples (in `/opt/vertica/sdk/examples/JavaUDx/ScalarFunctions`).

Loading and using the example

Load the library and create the function as follows:

```

=> CREATE LIBRARY JavaScalarFunctions AS '/home/dbadmin/JavaScalarLib.jar' LANGUAGE 'JAVA';
CREATE LIBRARY

=> CREATE FUNCTION addAnyInts AS LANGUAGE 'Java' NAME 'com.vertica.JavaLibs.AddAnyIntsInfo'
    LIBRARY JavaScalarFunctions;
CREATE FUNCTION

```

Call the function with two or more integer arguments:

```
=> SELECT addAnyInts(1,2);
```

```
addAnyInts
```

```
-----
```

```
3
```

```
(1 row)
```

```
=> SELECT addAnyInts(1,2,3,40,50,60,70,80,900);
```

```
addAnyInts
```

```
-----
```

```
1206
```

```
(1 row)
```

Calling the function with too few arguments, or with non-integer arguments, produces errors that are generated from the `processBlock()` method. It is up to your UDX to ensure that the user supplies the correct number and types of arguments to your function and exit with an error if it cannot process them.

Function implementation

Most of the work in the example is done by the `processBlock()` method. It performs two checks on the arguments that have been passed in through the `BlockReader` object:

- There are at least two arguments.
- The data types of all arguments are integers.

It is up to your polymorphic UDX to determine that all of the input passed to it is valid.

Once the `processBlock()` method validates its arguments, it loops over them, adding them together.

```
@Override
public void processBlock(ServerInterface srvinterface,
                        BlockReader arg_reader,
                        BlockWriter res_writer)
    throws UdfException, DestroyInvocation
{
    SizedColumnTypes inTypes = arg_reader.getTypeMetaData();
    ArrayList<Integer> argCols = new ArrayList<Integer>(); // Argument column indexes.
    inTypes.getArgumentColumns(argCols);
    // While we have inputs to process
    do {
        long sum = 0;
        for (int i = 0; i < argCols.size(); ++i){
            long a = arg_reader.getLong(i);
            sum += a;
        }
        res_writer.setLong(sum);
        res_writer.next();
    } while (arg_reader.next());
}
```

Factory implementation

The factory declares the number and type of arguments in the `getPrototype()` function.

```
@Override
public void getPrototype(ServerInterface srvinterface,
                        ColumnTypes argTypes,
                        ColumnTypes returnType)
{
    argTypes.addAny();
    returnType.addInt();
}
```

The following example shows an implementation of a Transform Function (UDTF) that performs kmeans clustering on one or more input columns.

```
kmeansPoly <- function(v.data.frame,v.param.list) {
  # Computes clusters using the kmeans algorithm.
  #
  # Input: A dataframe and a list of parameters.
  # Output: A dataframe with one column that tells the cluster to which each data
  #        point belongs.
  # Args:
  # v.data.frame: The data from Vertica cast as an R data frame.
  # v.param.list: List of function parameters.
  #
  # Returns:
  # The cluster associated with each data point.
  # Ensure k is not null.
  if(!is.null(v.param.list[["k"]])) {
    number_of_clusters <- as.numeric(v.param.list[["k"]])
  } else {
    stop("k cannot be NULL! Please use a valid value.")
  }
  # Run the kmeans algorithm.
  kmeans_clusters <- kmeans(v.data.frame, number_of_clusters)
  final.output <- data.frame(kmeans_clusters$cluster)
  return(final.output)
}

kmeansFactoryPoly <- function() {
  # This function tells Vertica the name of the R function,
  # and the polymorphic parameters.
  list(name=kmeansPoly, udstype=c("transform"), intype=c("any"),
        outtype=c("int"), parametercallback=kmeansParameters)
}

kmeansParameters <- function() {
  # Callback function for the parameter types.
  function.parameters <- data.frame(datatype=rep(NA, 1), length=rep(NA,1),
                                    scale=rep(NA,1), name=rep(NA,1))
  function.parameters[1,1] = "int"
  function.parameters[1,4] = "k"
  return(function.parameters)
}
```

The polymorphic R function declares it accepts any number of arguments in its factory function by specifying "any" as the argument to the **intype** parameter and optionally the **outtype** parameter. If you define "any" argument for **intype** or **outtype**, then it is the only type that your function can declare for the respective parameter. You cannot define required arguments and then call "any" to declare the rest of the signature as optional. If your function has requirements for the arguments it accepts, your process function must enforce them.

The **outtypecallback** method is used to indicate the argument types and sizes it has been called with, and is expected to indicate the types and sizes that the function returns. The **outtypecallback** method can also be used to check for unsupported types and/or number of arguments. For example, the function may require only integers, with no more than 10 of them.

You assign a SQL name to your polymorphic UDF using the same statement you use to assign one to a non-polymorphic UDF. The following statements show how you load and call the polymorphic function from the example.

```

=> CREATE LIBRARY rlib2 AS '/home/dbadmin/R_UDx/poly_kmeans.R' LANGUAGE 'R';
CREATE LIBRARY
=> CREATE TRANSFORM FUNCTION kmeansPoly AS LANGUAGE 'R' name 'kmeansFactoryPoly' LIBRARY rlib2;
CREATE FUNCTION
=> SELECT spec, kmeansPoly(sl,sw,pl,pw USING PARAMETERS k = 3)
   OVER(PARTITION BY spec) AS Clusters
   FROM iris;
spec    | Clusters
-----+-----
Iris-setosa | 1
Iris-setosa | 1
Iris-setosa | 1
Iris-setosa | 1
.
.
.
(150 rows)

```

UDx parameters

Parameters let you define arguments for your UDxs that remain constant across all of the rows processed by the SQL statement that calls your UDx. Typically, your UDxs accept arguments that come from columns in a SQL statement. For example, in the following SQL statement, the arguments a and b to the `add2ints` UDSF change value for each row processed by the SELECT statement:

```

=> SELECT a, b, add2ints(a,b) AS 'sum' FROM example;
a | b | sum
---+---+---
1 | 2 | 3
3 | 4 | 7
5 | 6 | 11
7 | 8 | 15
9 | 10 | 19
(5 rows)

```

Parameters remain constant for all the rows your UDx processes. You can also make parameters optional so that if the user does not supply it, your UDx uses a default value. For example, the following example demonstrates calling a UDSF named `add2intsWithConstant` that has a single parameter value named constant whose value is added to each the arguments supplied in each row of input:

```

=> SELECT a, b, add2intsWithConstant(a, b USING PARAMETERS constant=42)
   AS 'a+b+42' from example;
a | b | a+b+42
---+---+---
1 | 2 | 45
3 | 4 | 49
5 | 6 | 53
7 | 8 | 57
9 | 10 | 61
(5 rows)

```

Note

When calling a UDx with parameters, there is no comma between the last argument and the USING PARAMETERS clause.

The topics in this section explain how to develop UDxs that accept parameters.

- [C++ example: defining parameters](#)
- [C++ example: using session parameters](#)
- [Java example: defining parameters](#)
- [Java example: using session parameters](#)

Defining UDx parameters

You define the parameters that your UDx accepts in its factory class ([ScalarFunctionFactory](#) , [AggregateFunctionFactory](#) , and so on) by implementing [getParameterType\(\)](#) . This method is similar to [getReturnType\(\)](#) : you call data-type-specific methods on a [SizedColumnTypes](#) object that is passed in as a parameter. Each function call sets the name, data type, and width or precision (if the data type requires it) of the parameter.

Note

Parameter names in the `__param-name__` format are reserved for internal use.

Setting parameter properties (C++ only)

When you add parameters to the [getParameterType\(\)](#) function using the C++ API, you can also set properties for each parameter. For example, you can define a parameter as being required by the UDx. Doing so lets the Vertica server know that every UDx invocation must provide the specified parameter, or the query fails.

By passing an object to the [SizedColumnTypes::Properties](#) class, you can define the following four parameter properties:

Parameter	Type	Description
visible	BOOLEAN	If set to TRUE, the parameter appears in the USER_FUNCTION_PARAMETERS table. You may want to set this to FALSE to declare a parameter for internal use only.
required	BOOLEAN	If set to TRUE: <ul style="list-style-type: none"> • The parameter is required when invoking the UDx. • Invoking the UDx without supplying the parameter results in an error, and the UDx does not run.
canBeNull	BOOLEAN	If set to TRUE, the parameter can have a NULL value. If set to FALSE, make sure that the supplied parameter does not contain a NULL value when invoking the UDx. Otherwise, an error results, and the UDx does not run.
comment	VARCHAR(128)	A comment to describe the parameter. If you exceed the 128 character limit, Vertica generates an error when you run the CREATE_FUNCTION command. Additionally, if you replace the existing function definition in the comment parameter, make sure that the new definition does not exceed 128 characters. Otherwise, you delete all existing entries in the USER_FUNCTION_PARAMETERS table related to the UDx.

Setting parameter properties (R only)

When using parameters in your R UDx, you must specify a field in the factory function called [parametertypecallback](#) . This field points to the callback function that defines the parameters expected by the function. The callback function defines a four-column data frame with the following properties:

Parameter	Type	Description
datatype	VARCHAR(128)	The data type of the parameter.
length	INTEGER	The dimension of the parameter.
scale	INTEGER	The proportional dimensions of the parameter.
name	VARCHAR(128)	The name of the parameter.

If any of the columns are left blank (or the [parametertypecallback](#) function is omitted), then Vertica uses default values.

For more information, see [Parametertypecallback function](#).

Redacting UDX parameters

If a parameter name meets any of the following criteria, its value is automatically redacted from logs and system tables like [QUERY_REQUESTS](#):

- Named "secret" or "password"
- Ends with "_secret" or "_password"

Getting parameter values in UDXs

Your UDX uses the parameter values it declared in its factory class (see [Defining UDX parameters](#)) in its function class's processing method (for example, [processBlock\(\)](#) or [processPartition\(\)](#)). It gets its parameter values from a [ParamReader](#) object, which is available from the [ServerInterface](#) object that is passed to your processing method. Reading parameters from this object is similar to reading argument values from [BlockReader](#) or [PartitionReader](#) objects: you call a data-type-specific function with the name of the parameter to retrieve its value. For example, in C++:

```
// Get the parameter reader from the ServerInterface to see if there are supplied parameters.  
ParamReader paramReader = svinterface.getParamReader();  
  
// Get the value of an int parameter named constant.  
const vint constant = paramReader.getIntRef("constant");
```

Note

String data values do not have any of their escape characters processed before they are passed to your function. Therefore, your function may need to process the escape sequences itself if it needs to operate on unescaped character values.

Using parameters in the factory class

In addition to using parameters in your UDX function class, you can also access the parameters in the factory class. You may want to access the parameters to let the user control the input or output values of your function in some way. For example, your UDX can have a parameter that lets the user choose to have your UDX return a single- or double-precision value. The process of accessing parameters in the factory class is the same as accessing it in the function class: get a [ParamReader](#) object from the [ServerInterface](#)'s [getParamReader\(\)](#) method, then read the parameter values.

Testing whether the user supplied parameter values

Unlike its handling of arguments, Vertica does not immediately return an error if a user's function call does not include a value for a parameter defined by your UDX's factory class. This means that your function can attempt to read a parameter value that the user did not supply. If it does so, by default Vertica returns a non-existent parameter warning to the user, and the query containing the function call continues.

If you want your parameter to be optional, you can test whether the user supplied a value for the parameter before attempting to access its value. Your function determines if a value exists for a particular parameter by calling the [ParamReader](#)'s [containsParameter\(\)](#) method with the parameter's name. If this call returns true, your function can safely retrieve the value. If this call returns false, your UDX can use a default value or change its processing in some other way to compensate for not having the parameter value. As long as your UDX does not try to access the non-existent parameter value, Vertica does not generate an error or warning about missing parameters.

Note

If the user passes your UDX a parameter that it has not defined, by default Vertica issues a warning that the parameter is not used. It still executes the SQL statement, ignoring the parameter. You can change this behavior by altering the [StrictUDXParameterChecking](#) configuration parameter.

See [C++ example: defining parameters](#) for an example.

Calling UDXs with parameters

You pass parameters to a UDX by adding a USING PARAMETERS clause in the function call after the last argument.

- Do *not* insert a comma between the last argument and the USING PARAMETERS clause.
- After the USING PARAMETERS clause, add one or more parameter definitions, in the following form:

```
<parameter name> = <parameter value>
```

- Separate parameter definitions by commas.

Parameter values can be a constant expression (for example `1234 + SQRT(5678)`). You cannot use volatile functions (such as `RANDOM()`) in the expression, because they do not return a constant value. If you do supply a volatile expression as a parameter value, by default, Vertica returns an incorrect parameter type warning. Vertica then tries to run the UDX without the parameter value. If the UDX requires the parameter, it returns its own error, which cancels the query.

Calling a UDX with a single parameter

The following example demonstrates how you can call the `Add2intsWithConstant` UDSF example shown in [C++ example: defining parameters](#):

```
=> SELECT a, b, Add2intsWithConstant(a, b USING PARAMETERS constant=42) AS 'a+b+42' from example;
a | b | a+b+42
-----+-----
1 | 2 | 45
3 | 4 | 49
5 | 6 | 53
7 | 8 | 57
9 | 10 | 61
(5 rows)
```

To remove the first instance of the number 3, you can call the `RemoveSymbol` UDSF example:

```
=> SELECT '3re3mo3ve3sy3mb3ol' original_string, RemoveSymbol('3re3mo3ve3sy3mb3ol' USING PARAMETERS symbol='3');
original_string | RemoveSymbol
-----+-----
3re3mo3ve3sy3mb3ol | re3mo3ve3sy3mb3ol
(1 row)
```

Calling a UDX with multiple parameters

The following example shows how you can call a version of the `tokenize` UDTF. This UDTF includes parameters to limit the shortest allowed word and force the words to be output in uppercase. Separate multiple parameters with commas.

```
=> SELECT url, tokenize(description USING PARAMETERS minLength=4, uppercase=true) OVER (partition by url) FROM T;
url | words
-----+-----
www.amazon.com | ONLINE
www.amazon.com | RETAIL
www.amazon.com | MERCHANT
www.amazon.com | PROVIDER

www.amazon.com | SERVICES
www.dell.com | LEADING
www.dell.com | PROVIDER
www.dell.com | COMPUTER
www.dell.com | HARDWARE
www.vertica.com | WORLD'S
www.vertica.com | FASTEST
www.vertica.com | ANALYTIC
www.vertica.com | DATABASE
(16 rows)
```

The following example calls the `RemoveSymbol` UDSF. By changing the value of the optional parameter, `n`, you can remove all instances of the number 3:

```
=> SELECT '3re3mo3ve3sy3mb3ol' original_string, RemoveSymbol('3re3mo3ve3sy3mb3ol' USING PARAMETERS symbol='3', n=6);
original_string | RemoveSymbol
-----+-----
3re3mo3ve3sy3mb3ol | removesymbol
(1 row)
```

Calling a UDX with optional or incorrect parameters

You can optionally add the `Add2intsWithConstant` UDSF's constant parameter. Calling this constraint without the parameter does not return an error or warning:

```
=> SELECT a,b,Add2intsWithConstant(a, b) AS 'sum' FROM example;
```

```
a | b | sum
---+-----
1 | 2 | 3
3 | 4 | 7
5 | 6 | 11
7 | 8 | 15
9 | 10 | 19
(5 rows)
```

Although calling a UDX with incorrect parameters generates a warning, by default, the query still runs. For further information on setting the behavior of your UDX when you supply incorrect parameters, see [Specifying the behavior of passing unregistered parameters](#).

```
=> SELECT a, b, add2intsWithConstant(a, b USING PARAMETERS wrongparam=42) AS 'result' from example;
```

```
WARNING 4332: Parameter wrongparam was not registered by the function and cannot be coerced to a definite data type
```

```
a | b | result
---+-----
1 | 2 | 3
3 | 4 | 7
5 | 6 | 11
7 | 8 | 15
9 | 10 | 19
(5 rows)
```

Specifying the behavior of passing unregistered parameters

By default, Vertica issues a warning message when you pass a UDX an unregistered parameter. An *unregistered parameter* is one that you did not declare in the `getParameterType()` method.

You can control the behavior of your UDX when you pass it an unregistered parameter by altering the `StrictUDXParameterChecking` configuration parameter.

Unregistered parameter behavior settings

You can specify the behavior of your UDX in response to one or more unregistered parameters. To do so, set the `StrictUDXParameterChecking` configuration parameter to one of the following values:

- 0: Allows unregistered parameters to be accessible to the UDX. The `ParamReader` class's `getType()` method determines the data type of the unregistered parameter. Vertica does not display any warning or error message.
- 1 (default): Ignores the unregistered parameter and allows the function to run. Vertica displays a warning message.
- 2: Returns an error and does not allow the function to run.

Examples

The following examples demonstrate the behavior you can specify using different values with the `StrictUDXParameterChecking` parameter.

View the current value of `StrictUDXParameterChecking`

To view the current value of the `StrictUDXParameterChecking` configuration parameter, run the following query:

```
=> \x
Expanded display is on.
=> SELECT * FROM configuration_parameters WHERE parameter_name = 'StrictUDxParameterChecking';
-[ RECORD 1 ]-----+-----
node_name          | ALL
parameter_name     | StrictUDxParameterChecking
current_value      | 1
restart_value      | 1
database_value     | 1
default_value      | 1
current_level      | DATABASE
restart_level      | DATABASE
is_mismatch        | f
groups             |
allowed_levels     | DATABASE
superuser_only     | f
change_under_support_guidance | f
change_requires_restart | f
description        | Sets the behavior to deal with undeclared UDx function parameters
```

Change the value of StrictUDxParameterChecking

You can change the value of the [StrictUDxParameterChecking](#) configuration parameter at the database, node, or session level. For example, you can change the value to '0' to specify that unregistered parameters can pass to the UDx without displaying a warning or error message:

```
=> ALTER DATABASE DEFAULT SET StrictUDxParameterChecking = 0;
ALTER DATABASE
```

Invalid parameter behavior with RemoveSymbol

The following example demonstrates how to call the RemoveSymbol UDSF example. The RemoveSymbol UDSF has a required parameter, [symbol](#), and an optional parameter, [n](#). In this case, you do not use the optional parameter.

If you pass both [symbol](#) and an additional parameter called [wrongParam](#), which is not declared in the UDx, the behavior of the UDx changes corresponding to the value of [StrictUDxParameterChecking](#).

When you set [StrictUDxParameterChecking](#) to '0', the UDx runs normally without a warning. Additionally, [wrongParam](#) becomes accessible to the UDx through the [ParamReader](#) object of the [ServerInterface](#) object:

```
=> ALTER DATABASE DEFAULT SET StrictUDxParameterChecking = 0;
ALTER DATABASE

=> SELECT '3re3mo3ve3sy3mb3ol' original_string, RemoveSymbol('3re3mo3ve3sy3mb3ol' USING PARAMETERS symbol='3', wrongParam='x');
original_string | RemoveSymbol
-----+-----
3re3mo3ve3sy3mb3ol | re3mo3ve3sy3mb3ol
(1 row)
```

When you set [StrictUDxParameterChecking](#) to '1', the UDx ignores [wrongParam](#) and runs normally. However, it also issues a warning message:

```
=> ALTER DATABASE DEFAULT SET StrictUDxParameterChecking = 1;
ALTER DATABASE

=> SELECT '3re3mo3ve3sy3mb3ol' original_string, RemoveSymbol('3re3mo3ve3sy3mb3ol' USING PARAMETERS symbol='3', wrongParam='x');
WARNING 4320: Parameter wrongParam was not registered by the function and cannot be coerced to a definite data type
original_string | RemoveSymbol
-----+-----
3re3mo3ve3sy3mb3ol | re3mo3ve3sy3mb3ol
(1 row)
```

When you set `StrictUDxParameterChecking` to '2', the UDx encounters an error when it tries to call `wrongParam` and does not run. Instead, it generates an error message:

```
=> ALTER DATABASE DEFAULT SET StrictUDxParameterChecking = 2;
ALTER DATABASE

=> SELECT '3re3mo3ve3sy3mb3ol' original_string, RemoveSymbol('3re3mo3ve3sy3mb3ol' USING PARAMETERS symbol='3', wrongParam='x');
ERROR 0: Parameter wrongParam was not registered by the function
```

User-defined session parameters

User-defined session parameters allow you to write more generalized parameters than what Vertica provides. You can configure user-defined session parameters in these ways:

- From the client—for example, with [ALTER SESSION](#)
- Through the UDx itself

A user-defined session parameter can be passed into any type of UDx supported by Vertica. You can also set parameters for your UDx at the session level. By specifying a user-defined session parameter, you can have the state of a parameter saved continuously. Vertica saves the state of the parameter even when the UDx is invoked multiple times during a single session.

The RowCount example uses a user-defined session parameter. This parameter counts the total number of rows processed by the UDx each time it runs. RowCount then displays the aggregate number of rows processed for all executions. See [C++ example: using session parameters](#) and [Java example: using session parameters](#) for implementations.

Viewing the user-defined session parameter

Enter the following command to see the value of all session parameters:

```
=> SHOW SESSION UDPARAMETER all;
schema | library | key | value
-----+-----+-----+-----
(0 rows)
```

No value has been set, so the table is empty. Now, execute the UDx:

```
=> SELECT RowCount(5,5);
RowCount
-----
10
(1 row)
```

Again, enter the command to see the value of the session parameter:

```
=> SHOW SESSION UDPARAMETER all;
schema | library | key | value
-----+-----+-----+-----
public | UDSession | rowcount | 1
(1 row)
```

The library column shows the name of the library containing the UDx. This is the name set with [CREATE LIBRARY](#). Because the UDx has processed one row, the value of the rowcount session parameter is now 1. Running the UDx two more times should increment the value twice.

```
=> SELECT RowCount(10,10);
RowCount
-----
20
(1 row)
=> SELECT RowCount(15,15);
RowCount
-----
30
(1 row)
```

You have now executed the UDx three times, obtaining the sum of 5 + 5, 10 + 10, and 15 + 15. Now, check the value of rowcount.

```
=> SHOW SESSION UDPARAMETER all;
schema | library | key | value
-----+-----+-----+-----
public | UDSession | rowcount | 3
(1 row)
```

Altering the user-defined session parameter

You can also manually alter the value of rowcount. To do so, enter the following command:

```
=> ALTER SESSION SET UDPARAMETER FOR UDSession rowcount = 25;
ALTER SESSION
```

Check the value of RowCount:

```
=> SHOW SESSION UDPARAMETER all;
schema | library | key | value
-----+-----+-----+-----
public | UDSession | rowcount | 25
(1 row)
```

Clearing the user-defined session parameter

From the client :

To clear the current value of rowcount, enter the following command:

```
=> ALTER SESSION CLEAR UDPARAMETER FOR UDSession rowcount;
ALTER SESSION
```

Verify that rowcount has been cleared:

```
=> SHOW SESSION UDPARAMETER all;
schema | library | key | value
-----+-----+-----+-----
(0 rows)
```

Through the UDx in C++ :

You can set the session parameter to clear through the UDx itself. For example, to clear rowcount when its value reaches 10 or greater, do the following:

1. Remove the following line from the `destroy()` method in the RowCount class:

```
udParams.getUDSessionParamWriter("library").getStringRef("rowCount").copy(i_as_string);
```

2. Replace the removed line from the `destroy()` method with the following code:

```
if (rowCount < 10)
{
    udParams.getUDSessionParamWriter("library").getStringRef("rowCount").copy(i_as_string);
}
else
{
    udParams.getUDSessionParamWriter("library").clearParameter("rowCount");
}
```

3. To see the UDx clear the session parameter, set rowcount to a value of 9:

```
=> ALTER SESSION SET UDPARAMETER FOR UDSession rowcount = 9;
ALTER SESSION
```

4. Check the value of rowcount:

```
=> SHOW SESSION UDPARAMETER all;
schema | library | key | value
-----+-----+-----+-----
public | UDSession | rowcount | 9
(1 row)
```

5. Invoke RowCount so that its value becomes 10:

```
=> SELECT RowCount(15,15);
RowCount
-----
      30
(1 row)
```

6. Check the value of rowcount again. Because the value has reached 10, the threshold specified in the UDx, expect that rowcount is cleared:

```
=> SHOW SESSION UDPARAMETER all;
schema | library | key | value
-----+-----+-----+-----
(0 rows)
```

As expected, RowCount is cleared.

Through the UDx in Java :

1. Remove the following lines from the `destroy()` method in the RowCount class:

```
udParams.getUDSessionParamWriter("library").setString("rowCount", Integer.toString(rowCount));
srvInterface.log("RowNumber processed %d records", count);
```

2. Replace the removed lines from the `destroy()` method with the following code:

```
if (rowCount < 10)
{
    udParams.getUDSessionParamWriter("library").setString("rowCount", Integer.toString(rowCount));
    srvInterface.log("RowNumber processed %d records", count);
}
else
{
    udParams.getUDSessionParamWriter("library").clearParameter("rowCount");
}
```

3. To see the UDx clear the session parameter, set rowcount to a value of 9:

```
=> ALTER SESSION SET UDPARAMETER FOR UDSession rowcount = 9;
ALTER SESSION
```

4. Check the value of rowcount:

```
=> SHOW SESSION UDPARAMETER all;
schema | library | key | value
-----+-----+-----+-----
public | UDSession | rowcount | 9
(1 row)
```

5. Invoke RowCount so that its value becomes 10:

```
=> SELECT RowCount(15,15);
RowCount
-----
      30
(1 row)
```

6. Check the value of rowcount. Since the value has reached 10, the threshold specified in the UDx, expect that rowcount is cleared:

```
=> SHOW SESSION UDPARAMETER all;
schema | library | key | value
-----+-----+-----+-----
(0 rows)
```

As expected, rowcount is cleared.

Read-only and hidden session parameters

If you don't want a parameter to be set anywhere except in the UDx, you can make it read-only. If, additionally, you don't want a parameter to be visible in the client, you can make it hidden.

To make a parameter read-only, meaning that it cannot be set in the client, but can be viewed, add a single underscore before the parameter's name. For example, to make `rowCount` read-only, change all instances in the UDX of "rowCount" to "`_rowCount`".

To make a parameter hidden, meaning that it cannot be viewed in the client nor set, add two underscores before the parameter's name. For example, to make `rowCount` hidden, change all instances in the UDX of "rowCount" to "`__rowCount`".

Redacted parameters

If a parameter name meets any of the following criteria, its value is automatically redacted from logs and system tables like [QUERY_REQUESTS](#):

- Named "secret" or "password"
- Ends with "`_secret`" or "`_password`"

See also

[Kafka user-defined session parameters](#)

C++ example: defining parameters

The following code fragment demonstrates adding a single parameter to the C++ `add2ints` UDSF example. The `getParameterType()` function defines a single integer parameter that is named `constant`.

```
class Add2intsWithConstantFactory : public ScalarFunctionFactory
{
    // Return an instance of Add2ints to perform the actual addition.
    virtual ScalarFunction *createScalarFunction(ServerInterface &interface)
    {
        // Calls the vt_createFuncObj to create the new Add2ints class instance.
        return vt_createFuncObj(interface.allocator, Add2intsWithConstant);
    }
    // Report the argument and return types to Vertica.
    virtual void getPrototype(ServerInterface &interface,
                             ColumnTypes &argTypes,
                             ColumnTypes &returnType)
    {
        // Takes two ints as inputs, so add ints to the argTypes object.
        argTypes.addInt();
        argTypes.addInt();
        // Returns a single int.
        returnType.addInt();
    }
    // Defines the parameters for this UDSF. Works similarly to defining arguments and return types.
    virtual void getParameterType(ServerInterface &srvInterface,
                                  SizedColumnTypes &parameterTypes)
    {
        // One int parameter named constant.
        parameterTypes.addInt("constant");
    }
};
RegisterFactory(Add2intsWithConstantFactory);
```

See the Vertica SDK entry for [SizedColumnTypes](#) for a full list of the data-type-specific functions you can call to define parameters.

The following code fragment demonstrates using the parameter value. The `Add2intsWithConstant` class defines a function that adds two integer values. If the user supplies it, the function also adds the value of the optional integer parameter named `constant`.

```

/**
 * A UDSF that adds two numbers together with a constant value.
 */
class Add2intsWithConstant : public ScalarFunction
{
public:
    // Processes a block of data sent by Vertica.
    virtual void processBlock(ServerInterface &srvInterface,
                             BlockReader &arg_reader,
                             BlockWriter &res_writer)
    {
        try
        {
            // The default value for the constant parameter is 0.
            vint constant = 0;

            // Get the parameter reader from the ServerInterface to see if there are supplied parameters.
            ParamReader paramReader = srvInterface.getParamReader();
            // See if the user supplied the constant parameter.
            if (paramReader.containsParameter("constant"))
                // There is a parameter, so get its value.
                constant = paramReader.getIntRef("constant");
            // While we have input to process:
            do
            {
                // Read the two integer input parameters by calling the BlockReader.getIntRef class function.
                const vint a = arg_reader.getIntRef(0);
                const vint b = arg_reader.getIntRef(1);
                // Add arguments plus constant.
                res_writer.setInt(a+b+constant);
                // Finish writing the row, and advance to the next output row.
                res_writer.next();
                // Continue looping until there are no more input rows.
            }
            while (arg_reader.next());
        }
        catch (exception& e)
        {
            // Standard exception. Quit.
            vt_report_error(0, "Exception while processing partition: %s",
                           e.what());
        }
    }
};

```

C++ example: using session parameters

The RowCount example uses a user-defined session parameter, also called RowCount. This parameter counts the total number of rows processed by the UDx each time it runs. RowCount then displays the aggregate number of rows processed for all executions.

```

#include <string>
#include <sstream>
#include <iostream>
#include "Vertica.h"
#include "VerticaUDx.h"

using namespace Vertica;

class RowCount : public Vertica::ScalarFunction
{
private:

```

```

private:
    int rowCount;
    int count;

public:

    virtual void setup(Vertica::ServerInterface &srvInterface, const Vertica::SizedColumnTypes &argTypes) {
        ParamReader pSessionParams = srvInterface.getUDSessionParamReader("library");
        std::string rCount = pSessionParams.containsParameter("rowCount")?
            pSessionParams.getStringRef("rowCount").str(): "0";
        rowCount=atoi(rCount.c_str());
    }

    virtual void processBlock(Vertica::ServerInterface &srvInterface, Vertica::BlockReader &arg_reader, Vertica::BlockWriter &res_writer) {

        count = 0;
        if(arg_reader.getNumCols() != 2)
            vt_report_error(0, "Function only accepts two arguments, but %zu provided", arg_reader.getNumCols());

        do {
            const Vertica::vint a = arg_reader.getIntRef(0);
            const Vertica::vint b = arg_reader.getIntRef(1);
            res_writer.setInt(a+b);
            count++;
            res_writer.next();
        } while (arg_reader.next());

        srvInterface.log("count %d", count);

    }

    virtual void destroy(ServerInterface &srvInterface, const SizedColumnTypes &argTypes, SessionParamWriterMap &udParams) {
        rowCount = rowCount + count;

        std::ostringstream s;
        s << rowCount;
        const std::string i_as_string(s.str());

        udParams.getUDSessionParamWriter("library").getStringRef("rowCount").copy(i_as_string);
    }
};

class RowCountsInfo : public Vertica::ScalarFunctionFactory {
    virtual Vertica::ScalarFunction *createScalarFunction(Vertica::ServerInterface &srvInterface)
    { return Vertica::vt_createFuncObject<RowCount>(srvInterface.allocator);
    }

    virtual void getPrototype(Vertica::ServerInterface &srvInterface, Vertica::ColumnTypes &argTypes, Vertica::ColumnTypes &returnType)
    {
        argTypes.addInt();
        argTypes.addInt();
        returnType.addInt();
    }
};

RegisterFactory(RowCountsInfo);

```

Java example: defining parameters

The following code fragment demonstrates adding a single parameter to the Java add2ints UDSF example. The `getParameterType()` method defines a single integer parameter that is named constant.

```
package com.mycompany.example;
import com.verica.sdk.*;
public class Add2intsWithConstantFactory extends ScalarFunctionFactory
{
    @Override
    public void getPrototype(ServerInterface srvInterface,
        ColumnTypes argTypes,
        ColumnTypes returnType)
    {
        argTypes.addInt();
        argTypes.addInt();
        returnType.addInt();
    }

    @Override
    public void getReturnType(ServerInterface srvInterface,
        SizedColumnTypes argTypes,
        SizedColumnTypes returnType)
    {
        returnType.addInt("sum");
    }

    // Defines the parameters for this UDSF. Works similarly to defining
    // arguments and return types.
    public void getParameterType(ServerInterface srvInterface,
        SizedColumnTypes parameterTypes)
    {
        // One INTEGER parameter named constant
        parameterTypes.addInt("constant");
    }

    @Override
    public ScalarFunction createScalarFunction(ServerInterface srvInterface)
    {
        return new Add2intsWithConstant();
    }
}
```

See the Vertica Java SDK entry for [SizedColumnTypes](#) for a full list of the data-type-specific methods you can call to define parameters.

Java example: using session parameters

The RowCount example uses a user-defined session parameter, also called RowCount. This parameter counts the total number of rows processed by the UDX each time it runs. RowCount then displays the aggregate number of rows processed for all executions.

```

package com.mycompany.example;

import com.vertica.sdk.*;

public class RowCountFactory extends ScalarFunctionFactory {

    @Override
    public void getPrototype(ServerInterface srvInterface, ColumnTypes argTypes, ColumnTypes returnType)
    {
        argTypes.addInt();
        argTypes.addInt();
        returnType.addInt();
    }

public class RowCount extends ScalarFunction {

    private Integer count;
    private Integer rowCount;

    // In the setup method, you look for the rowCount parameter. If it doesn't exist, it is created.
    // Look in the default namespace which is "library," but it could be anything else, most likely "public" if not "library".
    @Override
    public void setup(ServerInterface srvInterface, SizedColumnTypes argTypes) {
        count = new Integer(0);
        ParamReader pSessionParams = srvInterface.getUDSessionParamReader("library");
        String rCount = pSessionParams.containsParameter("rowCount")?
        pSessionParams.getString("rowCount"): "0";
        rowCount = Integer.parseInt(rCount);

    }

    @Override
    public void processBlock(ServerInterface srvInterface, BlockReader arg_reader, BlockWriter res_writer)
        throws UdfException, DestroyInvocation {
        do {
            ++count;
            long a = arg_reader.getLong(0);
            long b = arg_reader.getLong(1);

            res_writer.setLong(a+b);
            res_writer.next();
        } while (arg_reader.next());
    }

    @Override
    public void destroy(ServerInterface srvInterface, SizedColumnTypes argTypes, SessionParamWriterMap udParams){
        rowCount = rowCount+count;
        udParams.getUDSessionParamWriter("library").setString("rowCount", Integer.toString(rowCount));
        srvInterface.log("RowNumber processed %d records", count);
    }
}

    @Override
    public ScalarFunction createScalarFunction(ServerInterface srvInterface){
        return new RowCount();
    }
}

```

The SDK provides several ways for a UDX to report errors, warnings, and other messages. For a UDX written in C++ or Python, use the messaging APIs described in [Sending messages](#). UDXs in all languages can halt execution with an error, as explained in [Handling errors](#).

UDXs can also [write messages to the Vertica log](#), and UDXs written in C++ can write messages to a system table.

In this section

- [Sending messages](#)
- [Handling errors](#)
- [Logging](#)

Sending messages

A UDX can handle a problem by reporting an error and terminating execution, but in some cases you might want to send a warning and proceed. For example, a UDX might ignore or use a default for an unexpected input and report that it did so. The C++ and Python messaging APIs support reporting messages at different severity levels.

A UDX has access to a [ServerInterface](#) instance. This class has the following methods for reporting messages, in order of severity:

- [reportError](#) (also terminates execution)
- [reportWarning](#)
- [reportNotice](#)
- [reportInfo](#)

Each method produces messages with the following components:

- ID code: an identification code, any integer. This code does not interact with Vertica error codes.
- Message string: a succinct description of the issue.
- Optional details string: provides more contextual information.
- Optional hint string: provides other guidance.

Duplicate messages are condensed into a single report if they have the same code and message string, even if the details and hint strings differ.

Constructing messages

The UDX should report errors immediately, usually during a process call. For all other message types, record information during processing and call the reporting methods from the UDX's [destroy](#) method. The other reporting methods do not produce output if called during processing.

The process of constructing messages is language-specific.

C++

Each [ServerInterface](#) reporting method takes a [ClientMessage](#) argument. The [ClientMessage](#) class has the following methods to set the code and message, detail, and hint:

- [makeMessage](#): sets the ID code and message string.
- [setDetail](#): sets the optional detail string.
- [setHint](#): sets the optional hint string.

These method calls can be chained to simplify creating and passing the message.

All strings support [printf](#)-style arguments and formatting.

In the following example, a function records issues in [processBlock](#) and reports them in [destroy](#) :

```

class PositiveIdentity : public Vertica::ScalarFunction
{
public:
    using ScalarFunction::destroy;
    bool hitNotice = false;

    virtual void processBlock(Vertica::ServerInterface &srvInterface,
                              Vertica::BlockReader &arg_reader,
                              Vertica::BlockWriter &res_writer)
    {
        do {
            const Vertica::vint a = arg_reader.getIntRef(0);
            if (a < 0 && a != vint_null) {
                hitNotice = true;
                res_writer.setInt(null);
            } else {
                res_writer.setInt(a);
            }
            res_writer.next();
        } while (arg_reader.next());
    }

    virtual void destroy(ServerInterface &srvInterface,
                        const SizedColumnTypes &argTypes) override
    {
        if (hitNotice) {
            ClientMessage msg = ClientMessage::makeMessage(100, "Passed negative argument")
                .setDetail("Value set to null");
            srvInterface.reportNotice(msg);
        }
    }
}

```

Python

Each `ServerInterface` reporting method has the following positional and keyword arguments:

- `idCode`: integer ID code, positional argument.
- `message`: message text, positional argument.
- `hint`: optional hint text, keyword argument.
- `detail`: optional detail text, keyword argument.

All arguments support `str.format()` and `f-string` formatting.

In the following example, a function records issues in `processBlock` and reports them in `destroy`:

```

class PositiveIdentity(vertica_sdk.ScalarFunction):
    def __init__(self):
        self.hitNotice = False

    def processBlock(self, server_interface, arg_reader, res_writer):
        while True:
            arg = arg_reader.getInt(0)
            if arg < 0 and arg is not None:
                self.hitNotice = True
                res_writer.setNull()
            else:
                res_writer.setInt(arg)
                res_writer.next()
            if not arg_reader.next():
                break

    def destroy(self, srv, argType):
        if self.hitNotice:
            srv.reportNotice(100, "Passed negative arguement", detail="Value set to null")
        return

```

API

[C++](#)

[Python](#)

Before calling a ServerInterface reporting method, construct and populate a message with the ClientMessage class.

The ServerInterface API provides the following methods for reporting messages:

```

// ClientMessage methods
template<typename... Argtypes>
static ClientMessage makeMessage(int errorcode, const char *fmt, Argtypes&&... args);

template <typename... Argtypes>
ClientMessage & setDetail(const char *fmt, Argtypes&&... args);

template <typename... Argtypes>
ClientMessage & setHint(const char *fmt, Argtypes&&... args);

// ServerInterface reporting methods
virtual void reportError(ClientMessage msg);

virtual void reportInfo(ClientMessage msg);

virtual void reportNotice(ClientMessage msg);

virtual void reportWarning(ClientMessage msg);

```

Handling errors

If your UDX encounters an unrecoverable error, it should report the error and terminate. How you do this depends on the language:

- C++: Consider using the API described in [Sending messages](#), which is more expressive than the error-handling described in this topic. Alternatively, you can use the `vt_report_error` macro to report an error and exit. The macro takes two parameters: an error number and an error message string. Both the error number and message appear in the error that Vertica reports to the user. The error number is not defined by Vertica. You can use whatever value that you wish.

- Java: Instantiate and throw a `UdfException`, which takes a numeric code and a message string to report to the user.
- Python: Consider using the API described in [Sending messages](#), which is more expressive than the error-handling described in this topic. Alternatively, raise an exception built into the Python language; the SDK does not include a UDX-specific exception.
- R: Use `stop` to halt execution with a message.

An exception or halt causes the transaction containing the function call to be rolled back.

The following examples demonstrate error-handling:

[C++](#)

[Java](#)

[Python](#)

[R](#)

The following function divides two integers. To prevent division by zero, it tests the second parameter and fails if it is zero:

```
class Div2ints : public ScalarFunction
{
public:
    virtual void processBlock(ServerInterface &srvinterface,
                             BlockReader &arg_reader,
                             BlockWriter &res_writer)
    {
        // While we have inputs to process
        do
        {
            const vint a = arg_reader.getIntRef(0);
            const vint b = arg_reader.getIntRef(1);
            if (b == 0)
            {
                vt_report_error(1, "Attempted divide by zero");
            }
            res_writer.setInt(a/b);
            res_writer.next();
        }
        while (arg_reader.next());
    }
};
```

Loading and invoking the function demonstrates how the error appears to the user. Fenced and unfenced modes use different error numbers.

```

=> CREATE LIBRARY Div2IntsLib AS '/home/dbadmin/Div2ints.so';
CREATE LIBRARY
=> CREATE FUNCTION div2ints AS LANGUAGE 'C++' NAME 'Div2intsInfo' LIBRARY Div2IntsLib;
CREATE FUNCTION
=> SELECT div2ints(25, 5);
div2ints
-----
      5
(1 row)
=> SELECT * FROM MyTable;
a | b
---+---
12 | 6
 7 | 0
12 | 2
18 | 9
(4 rows)
=> SELECT * FROM MyTable WHERE div2ints(a, b) > 2;
ERROR 3399: Error in calling processBlock() for User Defined Scalar Function
div2ints at Div2ints.cpp:21, error code: 1, message: Attempted divide by zero

```

To report additional diagnostic information about the error, you can write messages to a log file before throwing the exception (see [Logging](#)).

Your UDX must not consume exceptions that it did not throw. Intercepting server exceptions can lead to database instability.

Logging

Each UDX written in C++, Java, or Python has an associated instance of [ServerInterface](#). The [ServerInterface](#) class provides a function to write to the Vertica log, and the C++ implementation also provides a function to log events in a system table.

Writing messages to the Vertica log

You can write to log files using the [ServerInterface.log\(\)](#) function. The function acts similarly to [printf\(\)](#), taking a formatted string and an optional set of values and writing the string to the log file. Where the message is written depends on whether your function runs in fenced mode or unfenced mode:

- Functions running in unfenced mode write their messages into the [vertica.log](#) file in the catalog directory.
- Functions running in fenced mode write their messages into a log file named [UDxLogs/UDxFencedProcesses.log](#) in the catalog directory.

To help identify your function's output, Vertica adds the SQL function name bound to your UDX to the log message.

The following example logs a UDX's input values:

[C++](#)

[Java](#)

[Python](#)

```

virtual void processBlock(ServerInterface &srvInterface,
                          BlockReader &argReader,
                          BlockWriter &resWriter)
{
    try {
        // While we have inputs to process
        do {
            if (argReader.isNull(0) || argReader.isNull(1)) {
                resWriter.setNull();
            } else {
                const vint a = argReader.getIntRef(0);
                const vint b = argReader.getIntRef(1);
                srvInterface.log("got a: %d and b: %d", (int) a, (int) b);
                resWriter.setInt(a+b);
            }
            resWriter.next();
        } while (argReader.next());
    } catch (std::exception& e) {
        // Standard exception. Quit.
        vt_report_error(0, "Exception while processing block: [%s]", e.what());
    }
}

```

The `log()` function generates entries in the log file like the following:

```

$ tail /home/dbadmin/py_db/v_py_db_node0001_catalog/UDxLogs/UDxFencedProcesses.log
07:52:12.862 [Python-v_py_db_node0001-7524:0x206c-40575] 0x7f70eee2f780 PythonExecutionContext::processBlock
07:52:12.862 [Python-v_py_db_node0001-7524:0x206c-40575] 0x7f70eee2f780 [UserMessage] add2ints - Python UDx - Adding 2 ints!
07:52:12.862 [Python-v_py_db_node0001-7524:0x206c-40575] 0x7f70eee2f780 [UserMessage] add2ints - Values: first_int is 100 second_int is 100

```

For details on viewing the Vertica log files, see [Monitoring log files](#).

Writing messages to the UDX_EVENTS table (C++ only)

In the C++ API, you can write messages to the [UDX_EVENTS](#) system table instead of or in addition to writing to the log. Writing to a system table allows you to collect events from all nodes in one place.

You can write to this table using the [ServerInterface.logEvent\(\)](#) function. The function takes one argument, a map. The map is written into the `__RAW__` column of the table as a Flex VMap. The following example shows how the Parquet exporter creates and logs this map.

```

/ Log exported parquet file details to v_monitor.udx_events
std::map<std::string, std::string> details;
details["file"] = escapedPath;
details["created"] = create_timestamp_;
details["closed"] = close_timestamp_;
details["rows"] = std::to_string(num_rows_in_file);
details["row_groups"] = std::to_string(num_row_groups_in_file);
details["size_mb"] = std::to_string((double)outputStream->Tell()/(1024*1024));
srvInterface.logEvent(details);

```

You can select individual fields from the VMap as in the following example.

```

=> SELECT __RAW__[file] FROM UDX_EVENTS;
      __RAW__
-----
/tmp/export_tmpzLkrKq3a/450c4213-v_vmart_node0001-139770732459776-0.parquet
/tmp/export_tmpzLkrKq3a/9df1c797-v_vmart_node0001-139770860660480-0.parquet
(2 rows)

```

Alternatively, you can define a view to make it easier to query fields directly, as columns. See [Monitoring exports](#) for an example.

Handling cancel requests

Users of your UDX might cancel the operation while it is running. How Vertica handles the cancellation of the query and your UDX depends on whether your UDX is running in fenced or unfenced mode:

- If your UDX is running in unfenced mode, Vertica either stops the function when it requests a new block of input or output, or waits until your function completes running and discards the results.
- If your UDX is running in [Fenced and unfenced modes](#), Vertica kills the zygote process that is running your function if it continues processing past a timeout.

In addition, you can implement the `cancel()` method in any UDX to perform any necessary additional work. Vertica calls your function when a query is canceled. This cancellation can occur at any time during your UDX's lifetime, from `setup()` through `destroy()`.

You can check for cancellation before starting an expensive operation by calling `isCanceled()`.

In this section

- [Implementing the cancel callback](#)
- [Checking for cancellation during execution](#)
- [C++ example: cancelable UDSOURCE](#)

Implementing the cancel callback

Your UDX can implement a `cancel()` callback function. Vertica calls this function if the query that invoked the UDX has been canceled.

You usually implement this function to perform an orderly shutdown of any additional processing that your UDX spawned. For example, you can have your `cancel()` function shut down threads that your UDX has spawned or signal a third-party library that it needs to stop processing and exit. Your `cancel()` function should leave your UDX's function class ready to be destroyed, because Vertica calls the UDX's `destroy()` function after the `cancel()` function has exited.

A UDX's default `cancel()` behavior is to do nothing.

The contract for `cancel()` is:

- Vertica will call `cancel()` at most once per UDX instance.
- Vertica can call `cancel()` concurrently with any other method of the UDX object except the constructor and destructor.
- Vertica can call `cancel()` from another thread, so implementations should be thread-safe.
- Vertica will call `cancel()` for either an explicit user cancellation or an error in the query.
- Vertica does not guarantee that `cancel()` will run to completion. Long-running cancellations might be aborted.

The call to `cancel()` is not synchronized in any way with your UDX's other functions. If you need your processing function to exit before your `cancel()` function performs some action (killing threads, for example), you must have the two function synchronize their actions.

Vertica always calls `destroy()` if it called `setup()`. Cancellation does not prevent destruction.

See [C++ example: cancelable UDSOURCE](#) for an example that implements `cancel()`.

Checking for cancellation during execution

You can call the `isCanceled()` method to check for user cancellation. Typically you check for cancellation from the method that does the main processing in your UDX before beginning expensive operations. If `isCanceled()` returns true, the query has been canceled and your method should exit immediately to prevent it from wasting CPU time. If your UDX is not running fenced mode, Vertica cannot halt your function and has to wait for it to finish. If it is running in fenced mode, Vertica eventually kills the side process running it.

See [C++ example: cancelable UDSOURCE](#) for an example that uses `isCanceled()`.

C++ example: cancelable UDSOURCE

The `FifoSource` example, found in `filelib.cpp` in the SDK examples, demonstrates use of `cancel()` and `isCanceled()`. This source reads from a named pipe. Unlike reads from files, reads from pipes can block. Therefore, we need to be able to cancel a load from this source.

To manage cancellation, the UDX uses a `pipe`, a data channel used for inter-process communication. A process can write data to the write end of the pipe, and it remains available until another process reads it from the read end of the pipe. This example doesn't pass data through this pipe; rather, it uses the pipe to manage cancellation, as explained further below. In addition to the pipe's two file descriptors (one for each end), the UDX creates a file descriptor for the file to read from. The `setup()` function creates the pipe and then opens the file.

```

virtual void setup(ServerInterface &srvInterface) {
    // cancelPipe is a pipe used only for checking cancellation
    if (pipe(cancelPipe)) {
        vt_report_error(0, "Error opening control structure");
    }

    // handle to the named pipe from which we read data
    namedPipeFd = open(filename.c_str(), O_RDONLY | O_NONBLOCK);
    if (namedPipeFd < 0) {
        vt_report_error(0, "Error opening fifo [%s]", filename.c_str());
    }
}

```

We now have three file descriptors: `namedPipeFd` , `cancelPipe[PIPE_READ]` , and `cancelPipe[PIPE_WRITE]` . Each of these must eventually be closed.

This UDx uses the `poll()` system call to wait either for data to arrive from the named pipe (`namedPipeFd`) or for a cancellation (`cancelPipe[PIPE_READ]`). The `process()` function polls, checks for results, checks for cancellation, writes output if needed, and returns.

```

virtual StreamState process(ServerInterface &srvInterface, DataBuffer &output) {
    struct pollfd pollfds[2] = {
        { namedPipeFd, POLLIN, 0 },
        { cancelPipe[PIPE_READ], POLLIN, 0 }
    };

    if (poll(pollfds, 2, -1) < 0) {
        vt_report_error(1, "Error reading [%s]", filename.c_str());
    }

    if (pollfds[1].revents & (POLLIN | POLLHUP)) {
        /* This can only happen after cancel() has been called */
        VIAssert(isCanceled());
        return DONE;
    }

    VIAssert(pollfds[PIPE_READ].revents & (POLLIN | POLLHUP));

    const ssize_t amount = read(namedPipeFd, output.buf + output.offset, output.size - output.offset);
    if (amount < 0) {
        vt_report_error(1, "Error reading from fifo [%s]", filename.c_str());
    }

    if (amount == 0 || isCanceled()) {
        return DONE;
    } else {
        output.offset += amount;
        return OUTPUT_NEEDED;
    }
}

```

If the query is canceled, the `cancel()` function closes the write end of the pipe. The next time `process()` polls for input, it finds no input on the read end of the pipe and exits. Otherwise, it continues. The function also calls `isCanceled()` to check for cancellation before returning `OUTPUT_NEEDED` , the signal that it has filled its buffer and is waiting for it to be processed downstream.

The `cancel()` function does only the work needed to interrupt a call to `process()` . Cleanup that is always needed, not just for cancellation, is instead done in `destroy()` or the destructor. The `cancel()` function closes the write end of the pipe. (The helper function will be shown later.)

```

virtual void cancel(ServerInterface &srvInterface) {
    closeIfNeeded(cancelPipe[PIPE_WRITE]);
}

```

It is not safe to close the named pipe in `cancel()`, because closing it could create a race condition if another process (like another query) were to reuse the file descriptor number for a new descriptor before the UDx finishes. Instead we close it, and the read end of the pipe, in `destroy()`.

```
virtual void destroy(ServerInterface &svInterface) {
    closeIfNeeded(namedPipeFd);
    closeIfNeeded(cancelPipe[PIPE_READ]);
}
```

It is not safe to close the write end of the pipe in `destroy()`, because `cancel()` closes it and can be called concurrently with `destroy()`. Therefore, we close it in the destructor.

```
FifoSource() {
    closeIfNeeded(cancelPipe[PIPE_WRITE]);
}
```

The UDx uses a helper function, `closeIfNeeded()`, to make sure each file descriptor is closed exactly once.

```
void closeIfNeeded(int &fd) {
    if (fd >= 0) {
        close(fd);
        fd = -1;
    }
}
```

Aggregate functions (UDAFs)

Aggregate functions perform an operation on a set of values and return one value. Vertica provides standard built-in aggregate functions such as [AVG](#), [MAX](#), and [MIN](#). User-defined aggregate functions (UDAFs) provide similar functionality:

- Support a single input column (or set) of values and provide a single output column.
- Support [RLE](#) decompression. RLE input is decompressed before it is sent to a UDAF.
- Support use with [GROUP BY](#) and [HAVING](#) clauses. Only columns appearing in the GROUP BY clause can be selected.

Restrictions

The following restrictions apply to UDAFs:

- Available for C++ only.
- Cannot be run in fenced mode.
- Cannot be used with correlated subqueries.

In this section

- [AggregateFunction class](#)
- [AggregateFunctionFactory class](#)
- [UDAF performance in statements containing a GROUP BY clause](#)
- [C++ example: average](#)

AggregateFunction class

The `AggregateFunction` class performs the aggregation. It computes values on each database node where relevant data is stored and then combines the results from the nodes. You must implement the following methods:

- `initAggregate()` - Initializes the class, defines variables, and sets the starting value for the variables. This function must be idempotent.
- `aggregate()` - The main aggregation operation, executed on each node.
- `combine()` - If multiple invocations of `aggregate()` are needed, Vertica calls `combine()` to combine all the sub-aggregations into a final aggregation. Although this method might not be called, you must define it.
- `terminate()` - Terminates the function and returns the result as a column.

Important

The `aggregate()` function might not operate on the complete input set all at once. For this reason, `initAggregate()` must be idempotent.

The `AggregateFunction` class also provides optional methods that you can implement to allocate and free resources: `setup()` and `destroy()`. You should use these methods to allocate and deallocate resources that you do not allocate through the UDAF API (see [Allocating resources for UDxs](#) for details).

API

Aggregate functions are supported for C++ only.

The [AggregateFunction](#) API provides the following methods for extension by subclasses:

```
virtual void setup(ServerInterface &srvInterface,
                  const SizedColumnTypes &argTypes);

virtual void initAggregate(ServerInterface &srvInterface, IntermediateAggs &aggs)=0;

void aggregate(ServerInterface &srvInterface, BlockReader &arg_reader,
              IntermediateAggs &aggs);

virtual void combine(ServerInterface &srvInterface, IntermediateAggs &aggs_output,
                   MultipleIntermediateAggs &aggs_other)=0;

virtual void terminate(ServerInterface &srvInterface, BlockWriter &res_writer,
                     IntermediateAggs &aggs);

virtual void cancel(ServerInterface &srvInterface);

virtual void destroy(ServerInterface &srvInterface, const SizedColumnTypes &argTypes);
```

AggregateFunctionFactory class

The [AggregateFunctionFactory](#) class specifies metadata information such as the argument and return types of your aggregate function. It also instantiates your [AggregateFunction](#) subclass. Your subclass must implement the following methods:

- [getPrototype\(\)](#) - Defines the number of parameters and data types accepted by the function. There is a single parameter for aggregate functions.
- [getIntermediateTypes\(\)](#) - Defines the intermediate variable(s) used by the function. These variables are used when combining the results of [aggregate\(\)](#) calls.
- [getReturnType\(\)](#) - Defines the type of the output column.

Your function may also implement [getParameterType\(\)](#) , which defines the names and types of parameters that this function uses.

Vertica uses this data when you call the [CREATE AGGREGATE FUNCTION](#) SQL statement to add the function to the database catalog.

API

Aggregate functions are supported for C++ only.

The [AggregateFunctionFactory](#) API provides the following methods for extension by subclasses:

```
virtual AggregateFunction *
    createAggregateFunction(ServerInterface &srvInterface)=0;

virtual void getPrototype(ServerInterface &srvInterface,
                        ColumnTypes &argTypes, ColumnTypes &returnType)=0;

virtual void getIntermediateTypes(ServerInterface &srvInterface,
                                const SizedColumnTypes &inputTypes, SizedColumnTypes &intermediateTypeMetaData)=0;

virtual void getReturnType(ServerInterface &srvInterface,
                          const SizedColumnTypes &argTypes, SizedColumnTypes &returnType)=0;

virtual void getParameterType(ServerInterface &srvInterface,
                             SizedColumnTypes &parameterTypes);
```

UDAF performance in statements containing a GROUP BY clause

You may see slower-than-expected performance from your UDAF if the SQL statement calling it also contains a [GROUP BY clause](#) . For example:

```
=> SELECT a, MYUDAF(b) FROM samplatable GROUP BY a;
```

In statements like this one, Vertica does not consolidate row data together before calling your UDAF's `aggregate()` method. Instead, it calls `aggregate()` once for each row of data. Usually, the overhead of having Vertica consolidate the row data is greater than the overhead of calling `aggregate()` for each row of data. However, if your UDAF's `aggregate()` method has significant overhead, then you might notice an impact on your UDAF's performance.

For example, suppose `aggregate()` allocates memory. When called in a statement with a GROUP BY clause, it performs this memory allocation for each row of data. Because memory allocation is a relatively expensive process, this allocation can impact the overall performance of your UDAF and the query.

There are two ways you can address UDAF performance in a statement containing a GROUP BY clause:

- Reduce the overhead of each call to `aggregate()` . If possible, move any allocation or other setup operations to the UDAF's `setup()` function.
- Declare a special parameter that tells Vertica to group row data together when calling a UDAF. This technique is explained below.

Using the `_minimizeCallCount` parameter

Your UDAF can tell Vertica to always batch row data together to reduce the number of calls to its `aggregate()` method. To trigger this behavior, your UDAF must declare an integer parameter named `_minimizeCallCount` . You do not need to set a value for this parameter in your SQL statement. The fact that your UDAF declares this parameter triggers Vertica to group row data together when calling `aggregate()` .

You declare the `_minimizeCallCount` parameter the same way you declare other UDF parameters. See [UDx parameters](#) for more information.

Important
Always test the performance of your UDAF before and after implementing the `_minimizeCallCount` parameter to ensure that it improves performance. You might find that the overhead of having Vertica group row data for your UDAF is greater than the cost of the repeated calls to `aggregate()` .

C++ example: average

The `Average` aggregate function created in this example computes the average of values in a column.

You can find the source code used in this example on the [Vertica GitHub page](#).

Loading the example

Use CREATE LIBRARY and CREATE AGGREGATE FUNCTION to declare the function:

```
=> CREATE LIBRARY AggregateFunctions AS
/opt/vertica/sdk/examples/build/AggregateFunctions.so';
CREATE LIBRARY
=> CREATE aggregate function ag_avg AS LANGUAGE 'C++'
name 'AverageFactory' library AggregateFunctions;
CREATE AGGREGATE FUNCTION
```

Using the example

Use the function as part of a SELECT statement:

```
=> SELECT * FROM average;
id | count
----+-----
A | 8
B | 3
C | 6
D | 2
E | 9
F | 7
G | 5
H | 4
I | 1
(9 rows)
=> SELECT ag_avg(count) FROM average;
ag_avg
-----
5
(1 row)
```

AggregateFunction implementation

This example adds the input argument values in the `aggregate()` method and keeps a counter of the number of values added. The server runs `aggregate()` on every node and different data chunks, and combines all the individually added values and counters in the `combine()` method. Finally, the average value is computed in the `terminate()` method by dividing the total sum by the total number of values processed.

For this discussion, assume the following environment:

- A three-node Vertica cluster
- A table column that contains nine values that are evenly distributed across the nodes. Schematically, the nodes look like the following figure:

The function uses `sum` and `count` variables. `sum` contains the sum of the values, and `count` contains the count of values.

First, `initAggregate()` initializes the variables and sets their values to zero.

```
virtual void initAggregate(ServerInterface &srvInterface,
                          IntermediateAggs &aggs)
{
    try {
        VNumeric &sum = aggs.getNumericRef(0);
        sum.setZero();

        vint &count = aggs.getIntRef(1);
        count = 0;
    }
    catch(std::exception &e) {
        vt_report_error(0, "Exception while initializing intermediate aggregates: [%s]", e.what());
    }
}
```

The `aggregate()` function reads the block of data on each node and calculates partial aggregates.

```
void aggregate(ServerInterface &srvInterface,
              BlockReader &argReader,
              IntermediateAggs &aggs)
{
    try {
        VNumeric &sum = aggs.getNumericRef(0);
        vint &count = aggs.getIntRef(1);
        do {
            const VNumeric &input = argReader.getNumericRef(0);
            if (!input.isNull()) {
                sum.accumulate(&input);
                count++;
            }
        } while (argReader.next());
    } catch (std::exception &e) {
        vt_report_error(0, "Exception while processing aggregate: [%s]", e.what());
    }
}
```

Each completed instance of the `aggregate()` function returns multiple partial aggregates for sum and count. The following figure illustrates this process using the `aggregate()` function:

The `combine()` function puts together the partial aggregates calculated by each instance of the average function.

```

virtual void combine(ServerInterface &svInterface,
                    IntermediateAggs &aggs,
                    MultipleIntermediateAggs &aggsOther)
{
    try {
        VNumeric &mySum = aggs.getNumericRef(0);
        vint &myCount = aggs.getIntRef(1);

        // Combine all the other intermediate aggregates
        do {
            const VNumeric &otherSum = aggsOther.getNumericRef(0);
            const vint &otherCount = aggsOther.getIntRef(1);

            // Do the actual accumulation
            mySum.accumulate(&otherSum);
            myCount += otherCount;

        } while (aggsOther.next());
    } catch(std::exception &e) {
        // Standard exception. Quit.
        vt_report_error(0, "Exception while combining intermediate aggregates: [%s]", e.what());
    }
}

```

The following figure shows how each partial aggregate is combined:

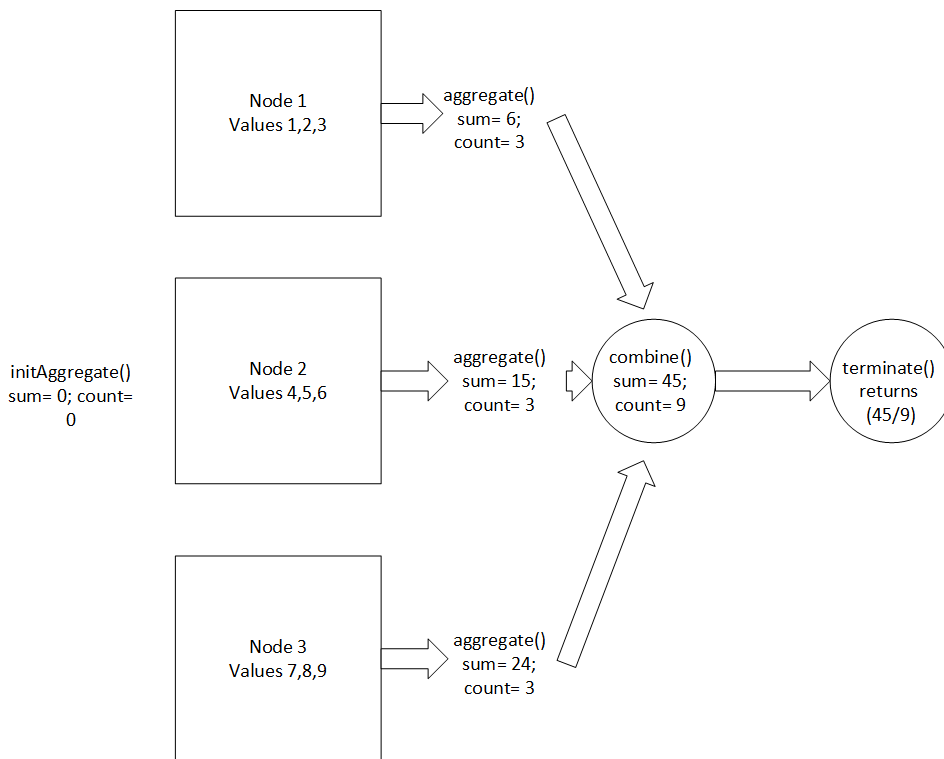

After all input has been evaluated by the `aggregate()` function Vertica calls the `terminate()` function. It returns the average to the caller.

```

virtual void terminate(ServerInterface &srvInterface,
                      BlockWriter &resWriter,
                      IntermediateAggs &aggs)
{
    try {
        const int32 MAX_INT_PRECISION = 20;
        const int32 prec = Basics::getNumericWordCount(MAX_INT_PRECISION);
        uint64 words[prec];
        VNumeric count(words,prec,0/"scale*");
        count.copy(aggs.getIntRef(1));
        VNumeric &out = resWriter.getNumericRef();
        if (count.isZero()) {
            out.setNull();
        } else
            const VNumeric &sum = aggs.getNumericRef(0);
            out.div(&sum, &count);
    }
}

```

The following figure shows the implementation of the `terminate()` function:

AggregateFunctionFactory implementation

The `getPrototype()` function allows you to define the variables that are sent to your aggregate function and returned to Vertica after your aggregate function runs. The following example accepts and returns a numeric value:

```

virtual void getPrototype(ServerInterface &srvInterface,
                          ColumnTypes &argTypes,
                          ColumnTypes &returnType)
{
    argTypes.addNumeric();
    returnType.addNumeric();
}

```

The `getIntermediateTypes()` function defines any intermediate variables that you use in your aggregate function. *Intermediate variables* are values used to pass data among multiple invocations of an aggregate function. They are used to combine results until a final result can be computed. In this example, there are two results - total (numeric) and count (int).

```

virtual void getIntermediateTypes(ServerInterface &srvInterface,
                                const SizedColumnTypes &inputTypes,
                                SizedColumnTypes &intermediateTypeMetaData)
{
    const VerticaType &inType = inputTypes.getColumnType(0);
    intermediateTypeMetaData.addNumeric(interPrec, inType.getNumericScale());
    intermediateTypeMetaData.addInt();
}

```

The `getReturnType()` function defines the output data type:

```

virtual void getReturnType(ServerInterface &srvInterface,
                           const SizedColumnTypes &inputTypes,
                           SizedColumnTypes &outputTypes)
{
    const VerticaType &inType = inputTypes.getColumnType(0);
    outputTypes.addNumeric(inType.getNumericPrecision(),
                          inType.getNumericScale());
}

```

Analytic functions (UDAnFs)

User-defined analytic functions (UDAnFs) are used for analytics. See [SQL analytics](#) for an overview of Vertica's built-in analytics. Like user-defined scalar functions (UDSFs), UDAnFs must output a single value for each row of data read and can have no more than 9800 arguments.

Unlike UDSFs, the UDAnF's input reader and output reader can be advanced independently. This feature lets you create analytic functions where the output value is calculated over multiple rows of data. By advancing the reader and writer independently, you can create functions similar to the built-in analytic functions such as [LAG](#), which uses data from prior rows to output a value for the current row.

In this section

- [AnalyticFunction class](#)
- [AnalyticFunctionFactory class](#)
- [C++ example: rank](#)

AnalyticFunction class

The `AnalyticFunction` class performs the analytic processing. Your subclass must define the `processPartition()` method to perform the operation. It may define methods to set up and tear down the function.

Performing the operation

The `processPartition()` method reads a partition of data, performs some sort of processing, and outputs a single value for each input row.

Vertica calls `processPartition()` once for each partition of data. It supplies the partition using an `AnalyticPartitionReader` object from which you read its input data. In addition, there is a unique method on this object named `isNewOrderByKey()`, which returns a Boolean value indicating whether your function has seen a row with the same ORDER BY key (or keys). This method is very useful for analytic functions (such as the example RANK function) which need to handle rows with identical ORDER BY keys differently than rows with different ORDER BY keys.

Note

You can specify multiple ORDER BY columns in the SQL query you use to call your UDAnF. The `isNewOrderByKey` method returns true if any of the ORDER BY keys are different than the previous row.

Once your method has finished processing the row of data, you advance it to the next row of input by calling `next()` on `AnalyticPartitionReader`.

Your method writes its output value using an `AnalyticPartitionWriter` object that Vertica supplies as a parameter to `processPartition()`. This object has data-type-specific methods to write the output value (such as `setInt()`). After setting the output value, call `next()` on `AnalyticPartitionWriter` to advance to the next row in the output.

Note

You must be sure that your function produces a row of output for each row of input in the partition. You must also not output more rows than are in the partition, otherwise the zygote size process (if running in [Fenced and unfenced modes](#)) or Vertica itself could generate an out of

bounds error.

Setting up and tearing down

The `AnalyticFunction` class defines two additional methods that you can optionally implement to allocate and free resources: `setup()` and `destroy()`. You should use these methods to allocate and deallocate resources that you do not allocate through the UDx API (see [Allocating resources for UDxs](#) for details).

API

[C++](#)

[Java](#)

The [AnalyticFunction](#) API provides the following methods for extension by subclasses:

```
virtual void setup(ServerInterface &srvInterface,
                  const SizedColumnTypes &argTypes);

virtual void processPartition (ServerInterface &srvInterface,
                              AnalyticPartitionReader &input_reader,
                              AnalyticPartitionWriter &output_writer)=0;

virtual void cancel(ServerInterface &srvInterface);

virtual void destroy(ServerInterface &srvInterface, const SizedColumnTypes &argTypes);
```

AnalyticFunctionFactory class

The `AnalyticFunctionFactory` class tells Vertica metadata about your UDAnF: its number of parameters and their data types, as well as the data type of its return value. It also instantiates a subclass of `AnalyticFunction`.

Your `AnalyticFunctionFactory` subclass must implement the following methods:

- `getPrototype()` describes the input parameters and output value of your function. You set these values by calling functions on two `ColumnTypes` objects that are passed to your method.
- `createAnalyticFunction()` supplies an instance of your `AnalyticFunction` that Vertica can call to process a UDAnF function call.
- `getReturnType()` provides details about your function's output. This method is where you set the width of the output value if your function returns a variable-width value (such as VARCHAR) or the precision of the output value if it has a settable precision (such as TIMESTAMP).

API

[C++](#)

[Java](#)

The [AnalyticFunctionFactory](#) API provides the following methods for extension by subclasses:

```
virtual AnalyticFunction * createAnalyticFunction (ServerInterface &srvInterface)=0;

virtual void getPrototype(ServerInterface &srvInterface,
                          ColumnTypes &argTypes, ColumnTypes &returnType)=0;

virtual void getReturnType(ServerInterface &srvInterface,
                           const SizedColumnTypes &argTypes, SizedColumnTypes &returnType)=0;

virtual void getParameterType(ServerInterface &srvInterface,
                              SizedColumnTypes &parameterTypes);
```

C++ example: rank

The **Rank** analytic function ranks rows based on how they are ordered. A Java version of this UDX is included in `/opt/vertica/sdk/examples` .

Loading and using the example

The following example shows how to load the function into Vertica. It assumes that the `AnalyticFunctions.so` library that contains the function has been copied to the dbadmin user's home directory on the initiator node.

```
=> CREATE LIBRARY AnalyticFunctions AS '/home/dbadmin/AnalyticFunctions.so';
CREATE LIBRARY
=> CREATE ANALYTIC FUNCTION an_rank AS LANGUAGE 'C++'
  NAME 'RankFactory' LIBRARY AnalyticFunctions;
CREATE ANALYTIC FUNCTION
```

An example of running this rank function, named `an_rank` , is:

```
=> SELECT * FROM hits;
  site   |  date   | num_hits
-----+-----+-----
www.example.com | 2012-01-02 |    97
www.vertica.com | 2012-01-01 | 343435
www.example.com | 2012-01-01 |   123
www.example.com | 2012-01-04 |   112
www.vertica.com | 2012-01-02 | 503695
www.vertica.com | 2012-01-03 | 490387
www.example.com | 2012-01-03 |   123
(7 rows)
=> SELECT site,date,num_hits,an_rank()
  OVER (PARTITION BY site ORDER BY num_hits DESC)
  AS an_rank FROM hits;
  site   |  date   | num_hits | an_rank
-----+-----+-----+-----
www.example.com | 2012-01-03 |   123 |    1
www.example.com | 2012-01-01 |   123 |    1
www.example.com | 2012-01-04 |   112 |    3
www.example.com | 2012-01-02 |    97 |    4
www.vertica.com | 2012-01-02 | 503695 |    1
www.vertica.com | 2012-01-03 | 490387 |    2
www.vertica.com | 2012-01-01 | 343435 |    3
(7 rows)
```

As with the built-in `RANK` analytic function, rows that have the same value for the ORDER BY column (`num_hits` in this example) have the same rank, but the rank continues to increase, so that the next row that has a different ORDER BY key gets a rank value based on the number of rows that preceded it.

AnalyticFunction implementation

The following code defines an `AnalyticFunction` subclass named `Rank` . It is based on example code distributed in the examples directory of the SDK.

```

/**
 * User-defined analytic function: Rank - works mostly the same as SQL-99 rank
 * with the ability to define as many order by columns as desired
 */
class Rank : public AnalyticFunction
{
    virtual void processPartition(ServerInterface &srvInterface,
                                AnalyticPartitionReader &inputReader,
                                AnalyticPartitionWriter &outputWriter)
    {
        // Always use a top-level try-catch block to prevent exceptions from
        // leaking back to Vertica or the fenced-mode side process.
        try {
            rank = 1; // The rank to assign a row
            rowCount = 0; // Number of rows processed so far
            do {
                rowCount++;
                // Do we have a new order by row?
                if (inputReader.isNewOrderByKey()) {
                    // Yes, so set rank to the total number of rows that have been
                    // processed. Otherwise, the rank remains the same value as
                    // the previous iteration.
                    rank = rowCount;
                }
                // Write the rank
                outputWriter.setInt(0, rank);
                // Move to the next row of the output
                outputWriter.next();
            } while (inputReader.next()); // Loop until no more input
        } catch(exception& e) {
            // Standard exception. Quit.
            vt_report_error(0, "Exception while processing partition: %s", e.what());
        }
    }
private:
    vint rank, rowCount;
};

```

In this example, the `processPartition()` method does not actually read any of the data from the input row; it just advances through the rows. It does not need to read data; it just counts the rows that have been read and determine whether those rows have the same ORDER BY key as the previous row. If the current row is a new ORDER BY key, then the rank is set to the total number of rows that have been processed. If the current row has the same ORDER BY value as the previous row, then the rank remains the same.

Note that the function has a top-level try-catch block. All of your UDX functions should always have one to prevent stray exceptions from being passed back to Vertica (if you run the function unfenced) or the side process.

AnalyticFunctionFactory implementation

The following code defines the `AnalyticFunctionFactory` that corresponds with the `Rank` analytic function.

```

class RankFactory : public AnalyticFunctionFactory
{
    virtual void getPrototype(ServerInterface &svInterface,
                             ColumnTypes &argTypes, ColumnTypes &returnType)
    {
        returnType.addInt();
    }
    virtual void getReturnType(ServerInterface &svInterface,
                              const SizedColumnTypes &inputTypes,
                              SizedColumnTypes &outputTypes)
    {
        outputTypes.addInt();
    }
    virtual AnalyticFunction *createAnalyticFunction(ServerInterface
                                                    &svInterface)
    { return vt_createFuncObj(svInterface.allocator, Rank); }
};

```

The first method defined by the `RankFactory` subclass, `getPrototype()`, sets the data type of the return value. Because the Rank UDAF does not read input, it does not define any arguments by calling methods on the `ColumnTypes` object passed in the `argTypes` parameter.

The next method is `getReturnType()`. If your function returns a data type that needs to define a width or precision, your implementation of the `getReturnType()` method calls a method on the `SizedColumnType` object passed in as a parameter to tell Vertica the width or precision. `Rank` returns a fixed-width data type (an INTEGER) so it does not need to set the precision or width of its output; it just calls `addInt()` to report its output data type.

Finally, `RankFactory` defines the `createAnalyticFunction()` method that returns an instance of the `AnalyticFunction` class that Vertica can call. This code is mostly boilerplate. All you need to do is add the name of your analytic function class in the call to `vt_createFuncObj()`, which takes care of allocating the object for you.

Scalar functions (UDSFs)

A user-defined scalar function (UDSF) returns a single value for each row of data it reads. You can use a UDSF anywhere you can use a built-in Vertica function. You usually develop a UDSF to perform data manipulations that are too complex or too slow to perform using SQL statements and functions. UDSFs also let you use analytic functions provided by third-party libraries within Vertica while still maintaining high performance.

A UDSF returns a single column. You can automatically return multiple values in a [ROW](#). A ROW is a group of property-value pairs. In the following example, `div_with_rem` is a UDSF that performs a division operation, returning the quotient and remainder as integers:

```

=> SELECT div_with_rem(18,5);
       div_with_rem
-----
{"quotient":3,"remainder":3}
(1 row)

```

A ROW returned from a UDSF cannot be used as an argument to COUNT.

Alternatively, you can construct a complex return value yourself, as described in [Complex Types as Arguments](#).

Your UDSF must return a value for every input row (unless it generates an error; see [Handling errors](#) for details). Failure to return a value for an input row results in incorrect results and potentially destabilizes the Vertica server if not run in [Fenced and unfenced modes](#).

A UDSF can have up to 9800 arguments.

ScalarFunction class

The `ScalarFunction` class is the heart of a UDSF. Your subclass must define the `processBlock()` method to perform the scalar operation. It may define methods to set up and tear down the function.

For scalar functions written in C++, you can provide information that can help with query optimization. See [Improving query performance \(C++ only\)](#).

Performing the operation

The `processBlock()` method carries out all of the processing that you want your UDSF to perform. When a user calls your function in a SQL statement, Vertica bundles together the data from the function parameters and passes it to `processBlock()`.

The input and output of the `processBlock()` method are supplied by objects of the `BlockReader` and `BlockWriter` classes. They define methods that you use to read the input data and write the output data for your UDSF.

The majority of the work in developing a UDSF is writing `processBlock()`. This is where all of the processing in your function occurs. Your UDSF should follow this basic pattern:

- Read in a set of arguments from the `BlockReader` object using data-type-specific methods.
- Process the data in some manner.
- Output the resulting value using one of the `BlockWriter` class's data-type-specific methods.
- Advance to the next row of output and input by calling `BlockWriter.next()` and `BlockReader.next()`.

This process continues until there are no more rows of data to be read (`BlockReader.next()` returns false).

You must make sure that `processBlock()` reads all of the rows in its input and outputs a single value for each row. Failure to do so can corrupt the data structures that Vertica reads to get the output of your UDSF. The only exception to this rule is if your `processBlock()` function reports an error back to Vertica (see [Handling errors](#)). In that case, Vertica does not attempt to read the incomplete result set generated by the UDSF.

Setting up and tearing down

The `ScalarFunction` class defines two additional methods that you can optionally implement to allocate and free resources: `setup()` and `destroy()`. You should use these methods to allocate and deallocate resources that you do not allocate through the UDx API (see [Allocating resources for UDxs](#) for details).

Notes

- While the name you choose for your `ScalarFunction` subclass does not have to match the name of the SQL function you will later assign to it, Vertica considers making the names the same a best practice.
- Do not assume that your function will be called from the same thread that instantiated it.
- The same instance of your `ScalarFunction` subclass can be called on to process multiple blocks of data.
- The rows of input sent to `processBlock()` are not guaranteed to be any particular order.
- Writing too many output rows can cause Vertica to emit an out-of-bounds error.

API

[C++](#)

[Java](#)

[Python](#)

[R](#)

The `ScalarFunction` API provides the following methods for extension by subclasses:

```
virtual void setup(ServerInterface &srvInterface,
                  const SizedColumnTypes &argTypes);

virtual void processBlock(ServerInterface &srvInterface,
                          BlockReader &arg_reader, BlockWriter &res_writer)=0;

virtual void getOutputRange (ServerInterface &srvInterface,
                              ValueRangeReader &inRange, ValueRangeWriter &outRange)

virtual void cancel(ServerInterface &srvInterface);

virtual void destroy(ServerInterface &srvInterface, const SizedColumnTypes &argTypes);
```

ScalarFunctionFactory class

The [ScalarFunctionFactory](#) class tells Vertica metadata about your UDSF: its number of parameters and their data types, as well as the data type of its return value. It also instantiates a subclass of [ScalarFunction](#) .

Methods

You must implement the following methods in your [ScalarFunctionFactory](#) subclass:

- [createScalarFunction\(\)](#) instantiates a [ScalarFunction](#) subclass. If writing in C++, you can call the `vt_createFuncObj` macro with the name of the [ScalarFunction](#) subclass. This macro takes care of allocating and instantiating the class for you.
- [getPrototype\(\)](#) tells Vertica about the parameters and return type(s) for your UDSF. In addition to a [ServerInterface](#) object, this method gets two [ColumnTypes](#) objects. All you need to do in this function is to call class functions on these two objects to build the list of parameters and the return value type(s). If you return more than one value, the results are packaged into a [ROW](#) type.

After defining your factory class, you need to call the [RegisterFactory](#) macro. This macro instantiates a member of your factory class, so Vertica can interact with it and extract the metadata it contains about your UDSF.

Declaring return values

If your function returns a sized column (a return data type whose length can vary, such as a VARCHAR), a value that requires precision, or more than one value, you must implement [getReturnType\(\)](#) . This method is called by Vertica to find the length or precision of the data being returned in each row of the results. The return value of this method depends on the data type your [processBlock\(\)](#) method returns:

- CHAR, (LONG) VARCHAR, BINARY, and (LONG) VARBINARY return the maximum length.
- NUMERIC types specify the precision and scale.
- TIME and TIMESTAMP values (with or without timezone) specify precision.
- INTERVAL YEAR TO MONTH specifies range.
- INTERVAL DAY TO SECOND specifies precision and range.
- ARRAY types specify the maximum number of elements.

If your UDSF does not return one of these data types and returns a single value, it does not need a [getReturnType\(\)](#) method.

The input to the [getReturnType\(\)](#) method is a [SizedColumnTypes](#) object that contains the input argument types along with their lengths. This object will be passed to an instance of your [processBlock\(\)](#) function. Your implementation of [getReturnType\(\)](#) must extract the data types and lengths from this input and determine the length or precision of the output rows. It then saves this information in another instance of the [SizedColumnTypes](#) class.

API

[C++](#)

[Java](#)

[Python](#)

[R](#)

The [ScalarFunctionFactory](#) API provides the following methods for extension by subclasses:

```
virtual ScalarFunction * createScalarFunction(ServerInterface &svInterface);

virtual void getPrototype(ServerInterface &svInterface,
    ColumnTypes &argTypes, ColumnTypes &returnType)=0;

virtual void getReturnType(ServerInterface &svInterface,
    const SizedColumnTypes &argTypes, SizedColumnTypes &returnType);

virtual void getParameterType(ServerInterface &svInterface,
    SizedColumnTypes &parameterTypes);
```

Setting null input and volatility behavior

Normally, Vertica calls your UDSF for every row of data in the query. There are some cases where Vertica can avoid executing your UDSF. You can tell Vertica when it can skip calling your function and just supply a return value itself by changing your function's volatility and strictness settings.

- Your function's **volatility** indicates whether it always returns the same output value when passed the same arguments. Depending on its behavior, Vertica can cache the arguments and the return value. If the user calls the UDSF with the same set of arguments, Vertica returns the cached value instead of calling your UDSF.
- Your function's **strictness** indicates how it reacts to NULL arguments. If it always returns NULL when *any* argument is NULL, Vertica can just return NULL without having to call the function. This optimization also saves you work, because you do not need to test for and handle null arguments in your UDSF code.

You indicate the volatility and null handling of your function by setting the **vol** and **strict** fields in your **ScalarFunctionFactory** class's constructor.

Volatility settings

To indicate your function's volatility, set the **vol** field to one of the following values:

Value	Description
VOLATILE	Repeated calls to the function with the same arguments always result in different values. Vertica always calls volatile functions for each invocation.
IMMUTABLE	Calls to the function with the same arguments always results in the same return value.
STABLE	Repeated calls to the function with the same arguments <i>within the same statement</i> returns the same output. For example, a function that returns the current user name is stable because the user cannot change within a statement. The user name could change between statements.
DEFAULT_VOLATILITY	The default volatility. This is the same as VOLATILE.

Example

[C++](#)

[Java](#)

The following example shows a version of the **Add2ints** example factory class that makes the function immutable.

```

class Add2intsImmutableFactory : public Vertica::ScalarFunctionFactory
{
    virtual Vertica::ScalarFunction *createScalarFunction(Vertica::ServerInterface &srvInterface)
    { return vt_createFuncObj(srvInterface allocator, Add2ints); }
    virtual void getPrototype(Vertica::ServerInterface &srvInterface,
        Vertica::ColumnTypes &argTypes,
        Vertica::ColumnTypes &returnType)
    {
        argTypes.addInt();
        argTypes.addInt();
        returnType.addInt();
    }
public:
    Add2intsImmutableFactory() (vol = IMMUTABLE);
};
RegisterFactory(Add2intsImmutableFactory);

```

Null input behavior

To indicate how your function reacts to NULL input, set the **strictness** field to one of the following values.

Value	Description
CALLED_ON_NULL_INPUT	The function must be called, even if one or more arguments are NULL.
RETURN_NULL_ON_NULL_INPUT	The function always returns a NULL value if any of its arguments are NULL.
STRICT	A synonym for RETURN_NULL_ON_NULL_INPUT
DEFAULT_STRICTNESS	The default strictness setting. This is the same as CALLED_ON_NULL_INPUT.

Example

The following C++ example demonstrates setting the null behavior of Add2ints so Vertica does not call the function with NULL values.

```

class Add2intsNullOnNullInputFactory : public Vertica::ScalarFunctionFactory
{
    virtual Vertica::ScalarFunction *createScalarFunction(Vertica::ServerInterface &srvInterface)
    { return vt_createFuncObj(srvInterface allocator, Add2ints); }
    virtual void getPrototype(Vertica::ServerInterface &srvInterface,
        Vertica::ColumnTypes &argTypes,
        Vertica::ColumnTypes &returnType)
    {
        argTypes.addInt();
        argTypes.addInt();
        returnType.addInt();
    }
public:
    Add2intsNullOnNullInputFactory() (strict = RETURN_NULL_ON_NULL_INPUT);
};
RegisterFactory(Add2intsNullOnNullInputFactory);

```

Improving query performance (C++ only)

When evaluating a query, Vertica can take advantage of available information about the ranges of values. For example, if data is partitioned and a query restricts output by the partitioned value, Vertica can ignore partitions that cannot possibly contain data that would satisfy the query. Similarly, for a scalar function, Vertica can skip processing rows in the data where the value returned from the function cannot possibly affect the results.

Consider a table with millions of rows of data on customer orders and a scalar function that computes the total price paid for everything in an order. A query uses a WHERE clause to restrict results to orders above a given value. A scalar function is called on a block of data; if no rows within that block could produce the target value, skipping the processing of the block could improve query performance.

A scalar function written in C++ can implement the `getOutputRange` method. Before calling `processBlock`, Vertica calls `getOutputRange` to determine the minimum and maximum return values from this block given the input ranges. It then decides whether to call `processBlock` to perform the computations.

The [Add2Ints example](#) implements this function. The minimum output value is the sum of the smallest values of each of the two inputs, and the maximum output is the sum of the largest values of each of the inputs. This function does not consider individual rows. Consider the following inputs:

a	b
21	92
500	19
111	11

The smallest values of the two inputs are 21 and 11, so the function reports 32 as the low end of the output range. The largest input values are 500 and 92, so it reports 592 as the high end of the output range. 592 is larger than the value returned for any of the input rows and 32 is smaller than any row's return value.

The purpose of `getOutputRange` is to quickly eliminate calls where outputs would definitely be out of range. For example, if the query included "WHERE Add2Ints(a,b) > 600", this block of data could be skipped. There can still be cases where, after calling `getOutputRange`, `processBlock` returns no results. If the query included "WHERE Add2Ints(a,b) > 500", `getOutputRange` would not eliminate this block of data.

Add2Ints implements `getOutputRange` as follows:

```

/*
 * This method computes the output range for this scalar function from
 * the ranges of its inputs in a single invocation.
 *
 * The input ranges are retrieved via inRange
 * The output range is returned via outRange
 */
virtual void getOutputRange(Vertica::ServerInterface &srvInterface,
                           Vertica::ValueRangeReader &inRange,
                           Vertica::ValueRangeWriter &outRange)
{
    if (inRange.hasBounds(0) && inRange.hasBounds(1)) {
        // Input ranges have bounds defined
        if (inRange.isNull(0) || inRange.isNull(1)) {
            // At least one range has only NULL values.
            // Output range can only have NULL values.
            outRange.setNull();
            outRange.setHasBounds();
            return;
        } else {
            // Compute output range
            const vint& a1LoBound = inRange.getIntRefLo(0);
            const vint& a2LoBound = inRange.getIntRefLo(1);
            outRange.setIntLo(a1LoBound + a2LoBound);

            const vint& a1UpBound = inRange.getIntRefUp(0);
            const vint& a2UpBound = inRange.getIntRefUp(1);
            outRange.setIntUp(a1UpBound + a2UpBound);
        }
    } else {
        // Input ranges are unbounded. No output range can be defined
        return;
    }

    if (!inRange.canHaveNulls(0) && !inRange.canHaveNulls(1)) {
        // There cannot be NULL values in the output range
        outRange.setCanHaveNulls(false);
    }

    // Let Vertica know that the output range is bounded
    outRange.setHasBounds();
}

```

If `getOutputRange` produces an error, Vertica issues a warning and does not call the method again for the current query.

C++ example: Add2Ints

The following example shows a basic subclass of `ScalarFunction` called `Add2ints`. As the name implies, it adds two integers together, returning a single integer result.

For the complete source code, see `/opt/vertica/sdk/examples/ScalarFunctions/Add2Ints.cpp`. Java and Python versions of this UDX are included in `/opt/vertica/sdk/examples`.

Loading and using the example

Use [CREATE LIBRARY](#) to load the library containing the function, and then use [CREATE FUNCTION \(scalar\)](#) to declare the function as in the following example:

```

=> CREATE LIBRARY ScalarFunctions AS '/home/dbadmin/examples/ScalarFunctions.so';

=> CREATE FUNCTION add2ints AS LANGUAGE 'C++' NAME 'Add2IntsFactory' LIBRARY ScalarFunctions;

```

The following example shows how to use this function:

```
=> SELECT Add2Ints(27,15);
```

```
Add2ints
```

```
-----  
    42
```

```
(1 row)
```

```
=> SELECT * FROM MyTable;
```

```
a | b
```

```
-----+-----
```

```
 7 | 0
```

```
12 | 2
```

```
12 | 6
```

```
18 | 9
```

```
 1 | 1
```

```
58 | 4
```

```
450 | 15
```

```
(7 rows)
```

```
=> SELECT * FROM MyTable WHERE Add2ints(a, b) > 20;
```

```
a | b
```

```
-----+-----
```

```
18 | 9
```

```
58 | 4
```

```
450 | 15
```

```
(3 rows)
```

Function implementation

A scalar function does its computation in the `processBlock` method:

```

class Add2Ints : public ScalarFunction
{
public:
/*
 * This method processes a block of rows in a single invocation.
 *
 * The inputs are retrieved via argReader
 * The outputs are returned via resWriter
 */
virtual void processBlock(ServerInterface &srvInterface,
                          BlockReader &argReader,
                          BlockWriter &resWriter)
{
    try {
        // While we have inputs to process
        do {
            if (argReader.isNull(0) || argReader.isNull(1)) {
                resWriter.setNull();
            } else {
                const vint a = argReader.getIntRef(0);
                const vint b = argReader.getIntRef(1);
                resWriter.setInt(a+b);
            }
            resWriter.next();
        } while (argReader.next());
    } catch(std::exception& e) {
        // Standard exception. Quit.
        vt_report_error(0, "Exception while processing block: [%s]", e.what());
    }
}
// ...
}

```

Implementing `getOutputRange`, which is optional, allows your function to skip rows where the result would not be within a target range. For example, if a WHERE clause restricts the query results to those in a certain range, calling the function for cases that could not possibly be in that range is unnecessary.

```

/*
 * This method computes the output range for this scalar function from
 * the ranges of its inputs in a single invocation.
 *
 * The input ranges are retrieved via inRange
 * The output range is returned via outRange
 */
virtual void getOutputRange(Vertica::ServerInterface &srvInterface,
                           Vertica::ValueRangeReader &inRange,
                           Vertica::ValueRangeWriter &outRange)
{
    if (inRange.hasBounds(0) && inRange.hasBounds(1)) {
        // Input ranges have bounds defined
        if (inRange.isNull(0) || inRange.isNull(1)) {
            // At least one range has only NULL values.
            // Output range can only have NULL values.
            outRange.setNull();
            outRange.setHasBounds();
            return;
        } else {
            // Compute output range
            const vint& a1LoBound = inRange.getIntRefLo(0);
            const vint& a2LoBound = inRange.getIntRefLo(1);
            outRange.setIntLo(a1LoBound + a2LoBound);

            const vint& a1UpBound = inRange.getIntRefUp(0);
            const vint& a2UpBound = inRange.getIntRefUp(1);
            outRange.setIntUp(a1UpBound + a2UpBound);
        }
    } else {
        // Input ranges are unbounded. No output range can be defined
        return;
    }

    if (!inRange.canHaveNulls(0) && !inRange.canHaveNulls(1)) {
        // There cannot be NULL values in the output range
        outRange.setCanHaveNulls(false);
    }

    // Let Vertica know that the output range is bounded
    outRange.setHasBounds();
}

```

Factory implementation

The factory instantiates a member of the class ([createScalarFunction](#)), and also describes the function's inputs and outputs ([getPrototype](#)):

```

class Add2IntsFactory : public ScalarFunctionFactory
{
    // return an instance of Add2Ints to perform the actual addition.
    virtual ScalarFunction *createScalarFunction(ServerInterface &interface)
    { return vt_createFuncObject<Add2Ints>(interface allocator); }

    // This function returns the description of the input and outputs of the
    // Add2Ints class's processBlock function. It stores this information in
    // two ColumnTypes objects, one for the input parameters, and one for
    // the return value.
    virtual void getPrototype(ServerInterface &interface,
                              ColumnTypes &argTypes,
                              ColumnTypes &returnType)
    {
        argTypes.addInt();
        argTypes.addInt();

        // Note that ScalarFunctions *always* return a single value.
        returnType.addInt();
    }
};

```

The RegisterFactory macro

Use the **RegisterFactory** macro to register a UDX. This macro instantiates the factory class and makes the metadata it contains available for Vertica to access. To call this macro, pass it the name of your factory class:

```
RegisterFactory(Add2IntsFactory);
```

Python example: currency_convert

The **currency_convert** scalar function reads two values from a table, a currency and a value. It then converts the item's value to USD, returning a single float result.

You can find more UDX examples in the Vertica Github repository, <https://github.com/vertica/UDx-Examples>.

UDSF Python code

Load the function and library

Create the library and the function.

```
=> CREATE LIBRARY pylib AS '/home/dbadmin/python_udx/currency_convert/currency_convert.py' LANGUAGE 'Python';  
CREATE LIBRARY  
=> CREATE FUNCTION currency_convert AS LANGUAGE 'Python' NAME 'currency_convert_factory' LIBRARY pylib fenced;  
CREATE FUNCTION
```

Querying data with the function

The following query shows how you can run a query with the UDSF.

```
=> SELECT product, currency_convert(currency, value) AS cost_in_usd  
FROM items;  
product | cost_in_usd  
-----+-----  
Shoes   | 133.4008  
Soccer Ball | 110.2817  
Coffee  | 13.5190  
Surfboard | 176.2593  
Hockey Stick | 76.7177  
Car     | 17000.0000  
Software | 10.4424  
Hamburger | 7.5000  
Fish    | 130.4272  
Cattle  | 269.2367  
(10 rows)
```

Python example: validate_url

The `validate_url` scalar function reads a string from a table, a URL. It then validates if the URL is responsive, returning a status code or a string indicating the attempt failed.

You can find more UDX examples in the Vertica Github repository, <https://github.com/vertica/UDx-Examples>.

UDSF Python code

```

import vertica_sdk
import urllib.request
import time

class validate_url(vertica_sdk.ScalarFunction):
    """Validates HTTP requests.

    Returns the status code of a webpage. Pages that cannot be accessed return
    "Failed to load page."

    """

    def __init__(self):
        pass

    def setup(self, server_interface, col_types):
        pass

    def processBlock(self, server_interface, arg_reader, res_writer):
        # Writes a string to the UDX log file.
        server_interface.log("Validating webpage accessibility - UDX")

        while(True):
            url = arg_reader.getString(0)
            try:
                status = urllib.request.urlopen(url).getcode()
                # Avoid overwhelming web servers -- be nice.
                time.sleep(2)
            except (ValueError, urllib.error.HTTPError, urllib.error.URLError):
                status = 'Failed to load page'
            res_writer.setString(str(status))
            res_writer.next()
            if not arg_reader.next():
                # Stop processing when there are no more input rows.
                break

    def destroy(self, server_interface, col_types):
        pass

class validate_url_factory(vertica_sdk.ScalarFunctionFactory):

    def createScalarFunction(self, srv):
        return validate_url()

    def getPrototype(self, srv_interface, arg_types, return_type):
        arg_types.addVarchar()
        return_type.addChar()

    def getReturnType(self, srv_interface, arg_types, return_type):
        return_type.addChar(20)

```

Load the function and library

Create the library and the function.

```

=> CREATE OR REPLACE LIBRARY pylib AS 'webpage_tester/validate_url.py' LANGUAGE 'Python';
=> CREATE OR REPLACE FUNCTION validate_url AS LANGUAGE 'Python' NAME 'validate_url_factory' LIBRARY pylib fenced;

```

Querying data with the function

The following query shows how you can run a query with the UDSF.

```
=> SELECT url, validate_url(url) AS url_status FROM webpages;
      url          | url_status
-----+-----
http://www.vertica.com/documentation/vertica/ | 200
http://www.google.com/                       | 200
http://www.mass.gov.com/                     | Failed to load page
http://www.espn.com                          | 200
http://blah.blah.blah.blah                   | Failed to load page
http://www.vertica.com/                      | 200
(6 rows)
```

Python example: matrix multiplication

Python UDxs can accept and return complex types. The `MatrixMultiply` class multiplies input matrices and returns the resulting matrix product. These matrices are represented as two-dimensional arrays. In order to perform the matrix multiplication operation, the number of columns in the first input matrix must equal the number of rows in the second input matrix.

The complete source code is in `/opt/vertica/sdk/examples/python/ScalarFunctions.py`.

Loading and using the example

Load the library and create the function as follows:

```
=> CREATE OR REPLACE LIBRARY ScalarFunctions AS '/home/dbadmin/examples/python/ScalarFunctions.py' LANGUAGE 'Python';
=> CREATE FUNCTION MatrixMultiply AS LANGUAGE 'Python' NAME 'matrix_multiply_factory' LIBRARY ScalarFunctions;
```

You can create input matrices and then call the function, for example:

```
=> CREATE TABLE mn (id INTEGER, data ARRAY[ARRAY[INTEGER, 3], 2]);
CREATE TABLE

=> CREATE TABLE np (id INTEGER, data ARRAY[ARRAY[INTEGER, 2], 3]);
CREATE TABLE

=> COPY mn FROM STDIN PARSER fjsonparser();
{"id": 1, "data": [[1, 2, 3], [4, 5, 6]] }
{"id": 2, "data": [[7, 8, 9], [10, 11, 12]] }
\

=> COPY np FROM STDIN PARSER fjsonparser();
{"id": 1, "data": [[0, 0], [0, 0], [0, 0]] }
{"id": 2, "data": [[1, 1], [1, 1], [1, 1]] }
{"id": 3, "data": [[2, 0], [0, 2], [2, 0]] }
\

=> SELECT mn.id, np.id, MatrixMultiply(mn.data, np.data) FROM mn CROSS JOIN np ORDER BY 1, 2;
id | id | MatrixMultiply
---+---+-----
1 | 1 | [[0,0],[0,0]]
1 | 2 | [[6,6],[15,15]]
1 | 3 | [[8,4],[20,10]]
2 | 1 | [[0,0],[0,0]]
2 | 2 | [[24,24],[33,33]]
2 | 3 | [[32,16],[44,22]]
(6 rows)
```

Setup

All Python UDxs must import the Vertica SDK library:

```
import vertica_sdk
```

Factory implementation

The `getPrototype()` method declares that the function arguments and return type must all be two-dimensional arrays, represented as arrays of integer arrays:

```
def getPrototype(self, srv_interface, arg_types, return_type):
    array1dtype = vertica_sdk.ColumnTypes.makeArrayType(vertica_sdk.ColumnTypes.makeInt())
    arg_types.addArrayType(array1dtype)
    arg_types.addArrayType(array1dtype)
    return_type.addArrayType(array1dtype)
```

`getReturnType()` validates that the product matrix has the same number of rows as the first input matrix and the same number of columns as the second input matrix:

```
def getReturnType(self, srv_interface, arg_types, return_type):
    (_, a1type) = arg_types[0]
    (_, a2type) = arg_types[1]
    m = a1type.getArrayBound()
    p = a2type.getElementType().getArrayBound()
    return_type.addArrayType(vertica_sdk.SizedColumnTypes.makeArrayType(vertica_sdk.SizedColumnTypes.makeInt(), p), m)
```

Function implementation

The `processBlock()` method is called with a `BlockReader` and a `BlockWriter`, named `arg_reader` and `res_writer` respectively. To access elements of the input arrays, the method uses `ArrayReader` instances. The arrays are nested, so an `ArrayReader` must be instantiated for both the outer and inner arrays. List comprehension simplifies the process of reading the input arrays into lists. The method performs the computation and then uses an `ArrayWriter` instance to construct the product matrix.

```
def processBlock(self, server_interface, arg_reader, res_writer):
    while True:
        lmat = [[cell.getInt(0) for cell in row.getArrayReader(0)] for row in arg_reader.getArrayReader(0)]
        rmat = [[cell.getInt(0) for cell in row.getArrayReader(0)] for row in arg_reader.getArrayReader(1)]
        omat = [[0 for c in range(len(rmat[0]))] for r in range(len(lmat))]

        for i in range(len(lmat)):
            for j in range(len(rmat[0])):
                for k in range(len(rmat)):
                    omat[i][j] += lmat[i][k] * rmat[k][j]

        res_writer.setArray(omat)
        res_writer.next()

        if not arg_reader.next():
            break
```

R example: SalesTaxCalculator

The `SalesTaxCalculator` scalar function reads a float and a varchar from a table, an item's price and the state abbreviation. It then uses the state abbreviation to find the sales tax rate from a list and calculates the item's price including the state's sales tax, returning the total cost of the item.

You can find more UDX examples in the Vertica Github repository, <https://github.com/vertica/UDx-Examples>.

Load the function and library

Create the library and the function.

```
=> CREATE OR REPLACE LIBRARY rLib AS 'sales_tax_calculator.R' LANGUAGE 'R';
CREATE LIBRARY
=> CREATE OR REPLACE FUNCTION SalesTaxCalculator AS LANGUAGE 'R' NAME 'SalesTaxCalculatorFactory' LIBRARY rLib FENCED;
CREATE FUNCTION
```

Querying data with the function

The following query shows how you can run a query with the UDSF.

```
=> SELECT item, state_abbreviation,
         price, SalesTaxCalculator(price, state_abbreviation) AS Price_With_Sales_Tax
FROM inventory;
item | state_abbreviation | price | Price_With_Sales_Tax
-----+-----+-----+-----
Scarf | AZ | 6.88 | 7.53016
Software | MA | 88.31 | 96.655295
Soccer Ball | MS | 12.55 | 13.735975
Beads | LA | 0.99 | 1.083555
Baseball | TN | 42.42 | 46.42869
Cheese | WI | 20.77 | 22.732765
Coffee Mug | MA | 8.99 | 9.839555
Shoes | TN | 23.99 | 26.257055
(8 rows)
```

UDSF R code

```
SalesTaxCalculator <- function(input.data.frame) {
  # Not a complete list of states in the USA, but enough to get the idea.
  state.sales.tax <- list(ma = 0.0625,
                          az = 0.087,
                          la = 0.0891,
                          tn = 0.0945,
                          wi = 0.0543,
                          ms = 0.0707)
  for ( state_abbreviation in input.data.frame[, 2] ) {
    # Ensure state abbreviations are lowercase.
    lower_state <- tolower(state_abbreviation)
    # Check if the state is in our state.sales.tax list.
    if (is.null(state.sales.tax[[lower_state]])) {
      stop("State is not in our small sample!")
    } else {
      sales.tax.rate <- state.sales.tax[[lower_state]]
      item.price <- input.data.frame[, 1]
      # Calculate the price including sales tax.
      price.with.sales.tax <- (item.price) + (item.price * sales.tax.rate)
    }
  }
  return(price.with.sales.tax)
}

SalesTaxCalculatorFactory <- function() {
  list(name = SalesTaxCalculator,
       udxtype = c("scalar"),
       intype = c("float", "varchar"),
       outtype = c("float"))
}
```

R example: kmeans

The `KMeans_User` scalar function reads any number of columns from a table, the observations. It then uses the observations and the two parameters when applying the kmeans clustering algorithm to the data, returning an integer value associated with the cluster of the row.

You can find more UDX examples in the Vertica Github repository, <https://github.com/vertica/UDx-Examples>.

Load the function and library

Create the library and the function:

```
=> CREATE OR REPLACE LIBRARY rLib AS 'kmeans.R' LANGUAGE 'R';
CREATE LIBRARY
=> CREATE OR REPLACE FUNCTION KMeans_User AS LANGUAGE 'R' NAME 'KMeans_UserFactory' LIBRARY rLib FENCED;
CREATE FUNCTION
```

Querying data with the function

The following query shows how you can run a query with the UDSF:

```
=> SELECT spec,  
       KMeans_User(sl, sw, pl, pw USING PARAMETERS clusters = 3, nstart = 20)  
FROM iris;  
spec | KMeans_User  
-----+-----  
Iris-setosa | 2  
Iris-setosa | 2  
Iris-setosa | 2  
Iris-setosa | 2  
Iris-setosa | 2  
Iris-setosa | 2  
Iris-setosa | 2  
Iris-setosa | 2  
Iris-setosa | 2  
Iris-setosa | 2  
Iris-setosa | 2  
.  
.  
.  
(150 rows)
```

UDSF R code

```

KMeans_User <- function(input.data.frame, parameters.data.frame) {
  # Take the clusters and nstart parameters passed by the user and assign them
  # to variables in the function.
  if ( is.null(parameters.data.frame[['clusters']]) ) {
    stop("NULL value for clusters! clusters cannot be NULL.")
  } else {
    clusters.value <- parameters.data.frame[['clusters']]
  }
  if ( is.null(parameters.data.frame[['nstart']]) ) {
    stop("NULL value for nstart! nstart cannot be NULL.")
  } else {
    nstart.value <- parameters.data.frame[['nstart']]
  }
  # Apply the algorithm to the data.
  kmeans.clusters <- kmeans(input.data.frame[, 1:length(input.data.frame)],
                             clusters.value, nstart = nstart.value)
  final.output <- data.frame(kmeans.clusters$cluster)
  return(final.output)
}

KMeans_UserFactory <- function() {
  list(name = KMeans_User,
       udxtype = c("scalar"),
       # Since this is a polymorphic function the intype must be any
       intype = c("any"),
       outtype = c("int"),
       parameterstypecallback=KMeansParameters)
}

KMeansParameters <- function() {
  parameters <- list(datatype = c("int", "int"),
                    length = c("NA", "NA"),
                    scale = c("NA", "NA"),
                    name = c("clusters", "nstart"))
  return(parameters)
}

```

C++ example: using complex types

UDxs can accept and return complex types. The [ArraySlice](#) example takes an array and two indices as inputs and returns an array containing only the values in that range. Because array elements can be of any type, the function is polymorphic.

The complete source code is in </opt/vertica/sdk/examples/ScalarFunctions/ArraySlice.cpp> .

Loading and using the example

Load the library and create the function as follows:

```

=> CREATE OR REPLACE LIBRARY ScalarFunctions AS '/home/dbadmin/examplesUDSF.so';

=> CREATE FUNCTION ArraySlice AS
LANGUAGE 'C++' NAME 'ArraySliceFactory' LIBRARY ScalarFunctions;

```

Create some data and call the function on it as follows:

```

=> CREATE TABLE arrays (id INTEGER, aa ARRAY[INTEGER]);
COPY arrays FROM STDIN;
1|[]
2|[1,2,3]
3|[5,4,3,2,1]
\.

=> CREATE TABLE slices (b INTEGER, e INTEGER);
COPY slices FROM STDIN;
0|2
1|3
2|4
\.

=> SELECT id, b, e, ArraySlice(aa, b, e) AS slice FROM arrays, slices;
id | b | e | slice
-----+-----
1 | 0 | 2 | []
1 | 1 | 3 | []
1 | 2 | 4 | []
2 | 0 | 2 | [1,2]
2 | 1 | 3 | [2,3]
2 | 2 | 4 | [3]
3 | 0 | 2 | [5,4]
3 | 1 | 3 | [4,3]
3 | 2 | 4 | [3,2]
(9 rows)

```

Factory implementation

Because the function is polymorphic, `getPrototype()` declares that the inputs and outputs can be of any type, and type enforcement must be done elsewhere:

```

void getPrototype(ServerInterface &srvinterface,
                 ColumnTypes &argTypes,
                 ColumnTypes &returnType) override
{
    /*
     * This is a polymorphic function that accepts any array
     * and returns an array of the same type
     */
    argTypes.addAny();
    returnType.addAny();
}

```

The factory validates input types and determines the return type in `getReturnType()` :

```

void getReturnType(ServerInterface &srvInterface,
                  const SizedColumnTypes &argTypes,
                  SizedColumnTypes &returnType) override
{
    /*
     * Three arguments: (array, slicebegin, sliceend)
     * Validate manually since the prototype accepts any arguments.
     */
    if (argTypes.size() != 3) {
        vt_report_error(0, "Three arguments (array, slicebegin, sliceend) expected");
    } else if (!argTypes[0].getType().isArrayType()) {
        vt_report_error(1, "Argument 1 is not an array");
    } else if (!argTypes[1].getType().isInt()) {
        vt_report_error(2, "Argument 2 (slicebegin) is not an integer");
    } else if (!argTypes[2].getType().isInt()) {
        vt_report_error(3, "Argument 3 (sliceend) is not an integer");
    }

    /* return type is the same as the array arg type, copy it over */
    returnType.push_back(argTypes[0]);
}

```

Function implementation

The `processBlock()` method is called with a `BlockReader` and a `BlockWriter`. The first argument is an array. To access elements of the array, the method uses an `ArrayReader`. Similarly, it uses an `ArrayWriter` to construct the output.

```

void processBlock(ServerInterface &srvInterface,
                 BlockReader &argReader,
                 BlockWriter &resWriter) override
{
    do {
        if (argReader.isNull(0) || argReader.isNull(1) || argReader.isNull(2)) {
            resWriter.setNull();
        } else {
            Array::ArrayReader argArray = argReader.getArrayRef(0);
            const vint slicebegin = argReader.getIntRef(1);
            const vint sliceend = argReader.getIntRef(2);

            Array::ArrayWriter outArray = resWriter.getArrayRef(0);
            if (slicebegin < sliceend) {
                for (int i = 0; i < slicebegin && argArray->hasData(); i++) {
                    argArray->next();
                }
                for (int i = slicebegin; i < sliceend && argArray->hasData(); i++) {
                    outArray->copyFromInput(*argArray);
                    outArray->next();
                    argArray->next();
                }
            }
            outArray.commit(); /* finalize the written array elements */
        }
        resWriter.next();
    } while (argReader.next());
}

```

C++ example: returning multiple values

When writing a UDSF, you can specify more than one return value. If you specify multiple values, Vertica packages them into a single [ROW](#) as a return value. You can query fields in the ROW or the entire ROW.

The following example implements a function named `div` (division) that returns two integers, the quotient and the remainder.

This example shows one way to return a ROW from a UDSF. Returning multiple values and letting Vertica build the ROW is convenient when inputs and outputs are all of primitive types. You can also work directly with the complex types, as described in [Complex Types as Arguments](#) and illustrated in [C++ example: using complex types](#).

Loading and using the example

Load the library and create the function as follows:

```
=> CREATE OR REPLACE LIBRARY ScalarFunctions AS '/home/dbadmin/examplesUDSF.so';  
  
=> CREATE FUNCTION div AS  
LANGUAGE 'C++' NAME 'DivFactory' LIBRARY ScalarFunctions;
```

Create some data and call the function on it as follows:

```
=> CREATE TABLE D (a INTEGER, b INTEGER);  
COPY D FROM STDIN DELIMITER ',';  
10,0  
10,1  
10,2  
10,3  
10,4  
10,5  
\.  
  
=> SELECT a, b, Div(a, b), (Div(a, b)).quotient, (Div(a, b)).remainder FROM D;
```

a	b	Div	quotient	remainder
10	0	{"quotient":null,"remainder":null}		
10	1	{"quotient":10,"remainder":0}	10	0
10	2	{"quotient":5,"remainder":0}	5	0
10	3	{"quotient":3,"remainder":1}	3	1
10	4	{"quotient":2,"remainder":2}	2	2
10	5	{"quotient":2,"remainder":0}	2	0

(6 rows)

Factory implementation

The factory declares the two return values in `getPrototype()` and in `getReturnType()`. The factory is otherwise unremarkable.

```
void getPrototype(ServerInterface &interface,  
                  ColumnTypes &argTypes,  
                  ColumnTypes &returnType) override  
{  
    argTypes.addInt();  
    argTypes.addInt();  
    returnType.addInt(); /* quotient */  
    returnType.addInt(); /* remainder */  
}  
  
void getReturnType(ServerInterface &srvInterface,  
                   const SizedColumnTypes &argTypes,  
                   SizedColumnTypes &returnType) override  
{  
    returnType.addInt("quotient");  
    returnType.addInt("remainder");  
}
```

Function implementation

The function writes two output values in `processBlock()`. The number of values here must match the factory declarations.

```

class Div : public ScalarFunction {
    void processBlock(Vertica::ServerInterface &srvInterface,
                     Vertica::BlockReader &argReader,
                     Vertica::BlockWriter &resWriter) override
    {
        do {
            if (argReader.isNull(0) || argReader.isNull(1) || (argReader.getIntRef(1) == 0)) {
                resWriter.setNull(0);
                resWriter.setNull(1);
            } else {
                const vint dividend = argReader.getIntRef(0);
                const vint divisor = argReader.getIntRef(1);
                resWriter.setInt(0, dividend / divisor);
                resWriter.setInt(1, dividend % divisor);
            }
            resWriter.next();
        } while (argReader.next());
    }
};

```

C++ example: calling a UDSF from a check constraint

This example shows you the C++ code needed to create a UDSF that can be called by a check constraint. The name of the sample function is [LargestSquareBelow](#). The sample function determines the largest number whose square is less than the number in the subject column. For example, if the number in the column is 1000, the largest number whose square is less than 1000 is 31 (961).

Important

A UDSF used within a check constraint must be immutable, and the constraint must handle null values properly. Otherwise, the check constraint might not work as you intended. In addition, Vertica evaluates the predicate of an enabled check constraint on every row that is loaded or updated, so consider performance in writing your function.

For information on check constraints, see [Check constraints](#).

Loading and using the example

The following example shows how you can create and load a library named MySQLib, using [CREATE LIBRARY](#). Adjust the library path in this example to the absolute path and file name for the location where you saved the shared object [LargestSquareBelow](#).

Create the library:

```
=> CREATE OR REPLACE LIBRARY MySQLib AS '/home/dbadmin/LargestSquareBelow.so';
```

After you create and load the library, add the function to the catalog using the [CREATE FUNCTION \(scalar\)](#) statement:

```
=> CREATE OR REPLACE FUNCTION largestSqBelow AS LANGUAGE 'C++' NAME 'LargestSquareBelowInfo' LIBRARY MySQLib;
```

Next, include the UDSF in a check constraint:

```
=> CREATE TABLE squaretest(
    ceiling INTEGER UNIQUE,
    CONSTRAINT chk_sq CHECK (largestSqBelow(ceiling) < ceiling*ceiling)
);
```

Add data to the table, [squaretest](#) :

```
=> COPY squaretest FROM stdin DELIMITER ','NULL>null';
```

```
-1  
null  
0  
1  
1000  
1000000  
1000001  
\.
```

Your output should be similar to the following sample, based upon the data you use:

```
=> SELECT ceiling, largestSqBelow(ceiling)  
FROM squaretest ORDER BY ceiling;
```

```
ceiling | largestSqBelow
```

```
-----+-----  
      |  
-1 |  
0 |  
1 |      0  
1000 |      31  
1000000 |      999  
1000001 |      1000
```

```
(7 rows)
```

ScalarFunction implementation

This [ScalarFunction](#) implementation does the processing work for a UDSF that determines the largest number whose square is less than the number input.

```

#include "Vertica.h"
/*
 * ScalarFunction implementation for a UDSF that
 * determines the largest number whose square is less than
 * the number input.
 */
class LargestSquareBelow : public Vertica::ScalarFunction
{
public:
/*
 * This function does all of the actual processing for the UDSF.
 * The inputs are retrieved via arg_reader
 * The outputs are returned via arg_writer
 */
virtual void processBlock(Vertica::ServerInterface &srvInterface,
                          Vertica::BlockReader &arg_reader,
                          Vertica::BlockWriter &res_writer)
{
    if (arg_reader.getNumCols() != 1)
        vt_report_error(0, "Function only accept 1 argument, but %zu provided", arg_reader.getNumCols());
// While we have input to process
    do {
        // Read the input parameter by calling the
        // BlockReader.getIntRef class function
        const Vertica::vint a = arg_reader.getIntRef(0);
        Vertica::vint res;
        //Determine the largest square below the number
        if ((a != Vertica::vint_null) && (a > 0))
        {
            res = (Vertica::vint)sqrt(a - 1);
        }
        else
            res = Vertica::vint_null;
        //Call BlockWriter.setInt to store the output value,
        //which is the largest square
        res_writer.setInt(res);
        //Write the row and advance to the next output row
        res_writer.next();
        //Continue looping until there are no more input rows
    } while (arg_reader.next());
}
}

```

ScalarFunctionFactory implementation

This **ScalarFunctionFactory** implementation does the work of handling input and output, and marks the function as immutable (a requirement if you plan to use the UDSF within a check constraint).

```

class LargestSquareBelowInfo : public Vertica::ScalarFunctionFactory
{
    //return an instance of LargestSquareBelow to perform the computation.
    virtual Vertica::ScalarFunction *createScalarFunction(Vertica::ServerInterface &srvInterface)
    //Call the vt_createFuncObj to create the new LargestSquareBelow class instance.
    { return Vertica::vt_createFuncObject<LargestSquareBelow>(srvInterface,allocator); }

    /*
    * This function returns the description of the input and outputs of the
    * LargestSquareBelow class's processBlock function. It stores this information in
    * two ColumnTypes objects, one for the input parameter, and one for
    * the return value.
    */
    virtual void getPrototype(Vertica::ServerInterface &srvInterface,
                             Vertica::ColumnTypes &argTypes,
                             Vertica::ColumnTypes &returnType)
    {
        // Takes one int as input, so adds int to the argTypes object
        argTypes.addInt();
        // Returns a single int, so add a single int to the returnType object.
        // ScalarFunctions always return a single value.
        returnType.addInt();
    }
public:
    // the function cannot be called within a check constraint unless the UDX author
    // certifies that the function is immutable:
    LargestSquareBelowInfo() { vol = Vertica::IMMUTABLE; }
};

```

The RegisterFactory macro

Use the [RegisterFactory](#) macro to register a [ScalarFunctionFactory](#) subclass. This macro instantiates the factory class and makes the metadata it contains available for Vertica to access. To call this macro, pass it the name of your factory class.

```
RegisterFactory(LargestSquareBelowInfo);
```

Transform functions (UDTFs)

A user-defined transform function (UDTF) lets you transform a table of data into another table. It reads one or more arguments (treated as a row of data), and returns zero or more rows of data consisting of one or more columns. A UDTF can produce any number of rows as output. However, each row it outputs must be complete. Advancing to the next row without having added a value for each column produces incorrect results.

The schema of the output table does not need to correspond to the schema of the input table—they can be totally different. The UDTF can return any number of output rows for each row of input.

Unless a UDTF is marked as [one-to-many](#) in its factory function, it can only be used in a [SELECT](#) list that contains the UDTF call and a required [OVER](#) clause. A multi-phase UDTF can make use of partition columns (PARTITION BY), but other UDTFs cannot.

UDTFs are run after [GROUP BY](#), but before the final [ORDER BY](#), when used in conjunction with [GROUP BY](#) and [ORDER BY](#) in a statement. The [ORDER BY](#) clause may contain only columns or expressions that are in a window partition clause (see [Window partitioning](#)).

UDTFs can take up to 9800 parameters (input columns). Attempts to pass more parameters to a UDTF return an error.

TransformFunction class

The `TransformFunction` class is where you perform the data-processing, transforming input rows into output rows. Your subclass must define the `processPartition()` method. It may define methods to set up and tear down the function.

Performing the transformation

The `processPartition()` method carries out all of the processing that you want your UDTF to perform. When a user calls your function in a SQL statement, Vertica bundles together the data from the function parameters and passes it to `processPartition()`.

The input and output of the `processPartition()` method are supplied by objects of the `PartitionReader` and `PartitionWriter` classes. They define methods that you use to read the input data and write the output data for your UDTF.

A UDTF does not necessarily operate on a single row the way a UDSF does. A UDTF can read any number of rows and write output at any time.

Consider the following guidelines when implementing `processPartition()`:

- Extract the input parameters by calling data-type-specific functions in the `PartitionReader` object to extract each input parameter. Each of these functions takes a single parameter: the column number in the input row that you want to read. Your function might need to handle NULL values.
- When writing output, your UDTF must supply values for all of the output columns you defined in your factory. Similarly to reading input columns, the `PartitionWriter` object has functions for writing each type of data to the output row.
- Use `PartitionReader.next()` to determine if there is more input to process, and exit when the input is exhausted.
- In some cases, you might want to determine the number and types of parameters using `PartitionReader`'s `getNumCols()` and `getTypeMetaData()` functions, instead of just hard-coding the data types of the columns in the input row. This is useful if you want your `TransformFunction` to be able to process input tables with different schemas. You can then use different `TransformFunctionFactory` classes to define multiple function signatures that call the same `TransformFunction` class. See [Overloading your UDx](#) for more information.

Setting up and tearing down

The `TransformFunction` class defines two additional methods that you can optionally implement to allocate and free resources: `setup()` and `destroy()`. You should use these methods to allocate and deallocate resources that you do not allocate through the UDx API (see [Allocating resources for UDxs](#) for details).

API

[C++](#)

[Java](#)

[Python](#)

[R](#)

The `TransformFunction` API provides the following methods for extension by subclasses:

```
virtual void setup(ServerInterface &srvInterface,
                  const SizedColumnTypes &argTypes);

virtual void processPartition(ServerInterface &srvInterface,
                             PartitionReader &input_reader, PartitionWriter &output_writer)=0;

virtual void cancel(ServerInterface &srvInterface);

virtual void destroy(ServerInterface &srvInterface,
                    const SizedColumnTypes &argTypes);
```

The `PartitionReader` and `PartitionWriter` classes provide getters and setters for column values, along with `next()` to iterate through partitions. See the API reference documentation for details.

TransformFunctionFactory class

The `TransformFunctionFactory` class tells Vertica metadata about your UDTF: its number of parameters and their data types, as well as function properties and the data type of the return value. It also instantiates a subclass of `TransformFunction`.

You must implement the following methods in your `TransformFunctionFactory`:

- `getPrototype()` returns two `ColumnTypes` objects that describe the columns your UDTF takes as input and returns as output.
- `getReturnType()` tells Vertica details about the output values: the width of variable-sized data types (such as VARCHAR) and the precision of data types that have settable precision (such as TIMESTAMP). You can also set the names of the output columns using this function. While this method is optional for UDTFs that return single values, you must implement it for UDTFs.
- `createTransformFunction()` instantiates your `TransformFunction` subclass.

For UDTFs written in C++ and Python, you can implement the `getTransformFunctionProperties()` method to set transform function class properties, including:

- `isExploder`: By default False, indicates whether a single-phase UDTF performs a transform from one input row to a result set of N rows, often called a one-to-many transform. If set to True, each partition to the UDTF must consist of exactly one input row. When a UDTF is labeled as one-to-many, Vertica is able to optimize query plans and users can write SELECT queries that include any expression and do not require an OVER clause. For more information about UDTF partitioning options and instructions on how to set this class property, see [Partitioning options for UDTFs](#). See [Python example: exploder](#) for an in-depth example detailing a one-to-many UDTF.

For transform functions written in C++, you can provide information that can help with query optimization. See [Improving query performance \(C++ only\)](#).

API

[C++](#)

[Java](#)

[Python](#)

[R](#)

The [TransformFunctionFactory](#) API provides the following methods for extension by subclasses:

```
virtual TransformFunction*
    createTransformFunction (ServerInterface &srvInterface)=0;

virtual void getPrototype(ServerInterface &srvInterface,
    ColumnTypes &argTypes, ColumnTypes &returnType)=0;

virtual void getReturnType(ServerInterface &srvInterface,
    const SizedColumnTypes &argTypes,
    SizedColumnTypes &returnType)=0;

virtual void getParameterType(ServerInterface &srvInterface,
    SizedColumnTypes &parameterTypes);

virtual void getTransformFunctionProperties(ServerInterface &srvInterface,
    const SizedColumnTypes &argTypes,
    Properties &properties);
```

MultiPhaseTransformFunctionFactory class

Multi-phase UDTFs let you break your data processing into multiple steps. Using this feature, your UDTFs can perform processing in a way similar to Hadoop or other MapReduce frameworks. You can use the first phase to break down and gather data, and then use subsequent phases to process the data. For example, the first phase of your UDTF could extract specific types of user interactions from a web server log stored in the column of a table, and subsequent phases could perform analysis on those interactions.

Multi-phase UDTFs also let you decide where processing should occur: locally on each node, or throughout the cluster. If your multi-phase UDTF is like a MapReduce process, you want the first phase of your multi-phase UDTF to process data that is stored locally on the node where the instance of the UDTF is running. This prevents large segments of data from being copied around the Vertica cluster. Depending on the type of processing being

performed in later phases, you may choose to have the data segmented and distributed across the Vertica cluster.

Each phase of the UDTF is the same as a traditional (single-phase) UDTF: it receives a table as input, and generates a table as output. The schema for each phase's output does not have to match its input, and each phase can output as many or as few rows as it wants.

You create a subclass of `TransformFunction` to define the processing performed by each stage. If you already have a `TransformFunction` from a single-phase UDTF that performs the processing you want a phase of your multi-phase UDTF to perform, you can easily adapt it to work within the multi-phase UDTF.

What makes a multi-phase UDTF different from a traditional UDTF is the factory class you use. You define a multi-phase UDTF using a subclass of `MultiPhaseTransformFunctionFactory`, rather than the `TransformFunctionFactory`. This special factory class acts as a container for all of the phases in your multi-step UDTF. It provides Vertica with the input and output requirements of the entire multi-phase UDTF (through the `getPrototype()` function), and a list of all the phases in the UDTF.

Within your subclass of the `MultiPhaseTransformFunctionFactory` class, you define one or more subclasses of `TransformFunctionPhase`. These classes fill the same role as the `TransformFunctionFactory` class for each phase in your multi-phase UDTF. They define the input and output of each phase and create instances of their associated `TransformFunction` classes to perform the processing for each phase of the UDTF. In addition to these subclasses, your `MultiPhaseTransformFunctionFactory` includes fields that provide a handle to an instance of each of the `TransformFunctionPhase` subclasses.

Note

The `MultiPhaseTransformFunctionFactory` and `TransformFunctionPhase` classes do not support the `isExploder` class property.

API

[C++](#)

[Java](#)

[Python](#)

The `MultiPhaseTransformFunctionFactory` class extends `TransformFunctionFactory`. The API provides the following additional methods for extension by subclasses:

```
virtual void getPhases(ServerInterface &srvInterface,  
                      std::vector< TransformFunctionPhase * > &phases)=0;
```

If using this factory you must also extend `TransformFunctionPhase`. See the SDK reference documentation.

Improving query performance (C++ only)

When evaluating a query, the Vertica optimizer might sort its input to improve performance. If a function already returns sorted data, this means the optimizer is doing extra work. A transform function written in C++ can declare how the data it returns is sorted, and the optimizer can take advantage of that information.

A transform function does the actual sorting in the function's `processPartition()` method. To take advantage of this optimization, sorts must be ascending. You need not sort all columns, but you must return the sorted column or columns first.

You can declare how the function sorts its output in the factory's `getReturnType()` method.

Caution

If the sorting declared in the factory does not match the sorting provided by the function, query results can be incorrect.

The `PolyTopKPerPartition` example sorts input columns and returns a given number of rows:

```
=> SELECT polykSort(14, a, b, c) OVER (ORDER BY a, b, c)
      AS (sort1,sort2,sort3) FROM observations ORDER BY 1,2,3;
sort1 | sort2 | sort3
-----+-----+-----
 1 | 1 | 1
 1 | 1 | 2
 1 | 1 | 3
 1 | 2 | 1
 1 | 2 | 2
 1 | 3 | 1
 1 | 3 | 2
 1 | 3 | 3
 1 | 3 | 4
 2 | 1 | 1
 2 | 1 | 2
 2 | 2 | 3
 2 | 2 | 34
 2 | 3 | 5
(14 rows)
```

The factory declares this sorting in `getReturnType()` by setting the `isSortedBy` property on each column. Each `SizedColumnType` has an associated `Properties` object where this value can be set:

```
virtual void getReturnType(ServerInterface &srvInterface, const SizedColumnTypes &inputTypes, SizedColumnTypes &outputTypes)
{
    vector<size_t> argCols; // Argument column indexes.
    inputTypes.getArgumentColumns(argCols);
    size_t colIdx = 0;

    for (vector<size_t>::iterator i = argCols.begin() + 1; i < argCols.end(); i++)
    {
        SizedColumnTypes::Properties props;
        props.isSortedBy = true;
        std::stringstream cname;
        cname << "col" << colIdx++;
        outputTypes.addArg(inputTypes.getColumnType(*i), cname.str(), props);
    }
}
```

You can see the effects of this optimization by reviewing the EXPLAIN plans for queries with and without this setting. The following output shows the query plan for `polyk`, the unsorted version. Note the cost for sorting:

```
=> EXPLAIN SELECT polyk(14, a, b, c) OVER (ORDER BY a, b, c)
      FROM observations ORDER BY 1,2,3;

Access Path:
+-SORT [Cost: 2K, Rows: 10K] (PATH ID: 1)
| Order: col0 ASC, col1 ASC, col2 ASC
| +----> ANALYTICAL [Cost: 2K, Rows: 10K] (PATH ID: 2)
| | Analytic Group
| | Functions: polyk()
| | Group Sort: observations.a ASC NULLS LAST, observations.b ASC NULLS LAST, observations.c ASC NULLS LAST
| +----> STORAGE ACCESS for observations [Cost: 2K, Rows: 10K]
(PATH ID: 3)
| | Projection: public.observations_super
| | Materialize: observations.a, observations.b, observations.c
```

The query plan for the sorted version omits this step (and cost) and starts with the analytical step (the second step in the previous plan):

```
=> EXPLAIN SELECT polykSort(14, a, b, c) OVER (ORDER BY a, b, c)
FROM observations ORDER BY 1,2,3;
```

Access Path:

```
+ANALYTICAL [Cost: 2K, Rows: 10K] (PATH ID: 2)
| Analytic Group
| Functions: polykSort()
| Group Sort: observations.a ASC NULLS LAST, observations.b ASC NULLS LAST, observations.c ASC NULLS LAST
|----> STORAGE ACCESS for observations [Cost: 2K, Rows: 10K] (PATH ID: 3)
| Projection: public.observations_super
| Materialize: observations.a, observations.b, observations.c
```

Partitioning options for UDTFs

Depending on the application, a UDTF might require the input data to be partitioned in a specific way. For example, a UDTF that processes a web server log file to count the number of hits referred by each partner web site needs to have its input partitioned by a referrer column. However, in other cases—such as a string tokenizer—the sort order of the data does not matter. Vertica provides partition options for both of these types of UDTFs.

Data sort required

In cases where a specific sort order is required, the [window partitioning clause](#) in the query that calls the UDTF should use a **PARTITION BY** clause. Each node in the cluster partitions the data it stores, sends some of these partitions off to other nodes, and then consolidates the partitions it receives from other nodes and runs an instance of the UDTF to process them.

For example, the following UDTF partitions the input data by store ID and then computes the count of each distinct array element in each partition:

```
=> SELECT * FROM orders;
storeID | productIDs
-----+-----
 1 | [101,102,103]
 1 | [102,104]
 1 | [101,102,102,201,203]
 2 | [101,202,203,202,203]
 2 | [203]
 2 | []
(6 rows)

=> SELECT storeID, CountElements(productIDs) OVER (PARTITION BY storeID) FROM orders;
storeID | element_count
-----+-----
 1 | {"element":101,"count":2}
 1 | {"element":102,"count":4}
 1 | {"element":103,"count":1}
 1 | {"element":104,"count":1}
 1 | {"element":201,"count":1}
 1 | {"element":202,"count":1}
 2 | {"element":101,"count":1}
 2 | {"element":202,"count":2}
 2 | {"element":203,"count":3}
(9 rows)
```

No sort needed

Some UDTFs, such as [Explode](#), do not need to partition input data in a particular way. In these cases, you can specify that each UDTF instance process only the data that is stored locally by the node on which it is running. By eliminating the overhead of partitioning data and the cost of sort and merge operations, processing can be much more efficient.

You can use the following window partition options for UDTFs that do not require a specific data partitioning:

- **PARTITION ROW** : For single-phase UDTFs where each partition is one input row, allows users to write SELECT queries that include any expression. The UDTF calls the `processPartition()` method once per input row. UDTFs of this type, often called one-to-many transforms, can be explicitly marked as such with the `exploder` class property in the [TransformFunctionFactory class](#). This class property helps Vertica optimize query

plans and removes the need for an OVER clause. See [One to Many UDTFs](#) for details on how to set this class property for UDTFs written in C++ and Python.

- **PARTITION BEST** : For thread-safe UDTFs only, optimizes performance through multi-threaded queries across multiple nodes. The UDTF calls the `processPartition()` method once per thread per node.
- **PARTITION NODES** : Optimizes performance of single-threaded queries across multiple nodes. The UDTF calls the `processPartition()` method once per node.

For more information about these partition options, see [Window partitioning](#).

One-to-many UDTFs

C++

[Python](#)

To mark a UDTF as one-to-many, you must set the `isExploder` class property to True within the `getTransformFunctionProperties()` method. Whether a UDTF is marked as one-to-many can be determined by the transform function's arguments and parameters, for example:

```
void getFunctionProperties(ServerInterface &srvInterface,
    const SizedColumnTypes &argTypes,
    Properties &properties) override
{
    if (argTypes.getColumnCount() > 1) {
        properties.isExploder = false;
    }
    else {
        properties.isExploder = true;
    }
}
```

If the exploder class property is set to True, the OVER clause is by default OVER(PARTITION ROW). This allows users to call the UDTF without specifying an OVER clause:

```
=> SELECT * FROM reviews;
```

```
id | sentence
```

```
-----+-----
 1 | Customer service was slow
 2 | Product is exactly what I needed
 3 | Price is a bit high
 4 | Highly recommended
(4 rows)
```

```
=> SELECT tokenize(sentence) FROM reviews;
```

```
tokens
```

```
-----
Customer
service
was
slow
Product
...
bit
high
Highly
recommended
(17 rows)
```

Note

If a user writes an OVER clause with PARTITION BY for a function marked as one-to-many, the function replaces the OVER clause with OVER(PARTITION ROW) and emits a notice to the user.

One-to-many UDTFs also support any expression in the SELECT clause, unlike UDTFs that use either the PARTITION BEST or the PARTITION NODES clause:

```
=> SELECT id, tokenize(sentence) FROM reviews;
id | tokens
-----+-----
 1 | Customer
 1 | service
 1 | was
 1 | respond
 2 | Product
...
 3 | high
 4 | Highly
 4 | recommended
(17 rows)
```

For an in-depth example detailing a one-to-many UDTF, see [Python example: explode](#).

C++ example: string tokenizer

The following example shows a subclass of `TransformFunction` named `StringTokenizer`. It defines a UDTF that reads a table containing an INTEGER ID column and a VARCHAR column. It breaks the text in the VARCHAR column into tokens (individual words). It returns a table containing each token, the row it occurred in, and its position within the string.

Loading and using the example

The following example shows how to load the function into Vertica. It assumes that the `TransformFunctions.so` library that contains the function has been copied to the dbadmin user's home directory on the initiator node.

```
=> CREATE LIBRARY TransformFunctions AS
  '/home/dbadmin/TransformFunctions.so';
CREATE LIBRARY
=> CREATE TRANSFORM FUNCTION tokenize
  AS LANGUAGE 'C++' NAME 'TokenFactory' LIBRARY TransformFunctions;
CREATE TRANSFORM FUNCTION
```

You can then use it from SQL statements, for example:

```

=> CREATE TABLE T (url varchar(30), description varchar(2000));
CREATE TABLE
=> INSERT INTO T VALUES ('www.amazon.com','Online retail merchant and provider of cloud services');
OUTPUT
-----
 1
(1 row)
=> INSERT INTO T VALUES ('www.vertica.com','World"s fastest analytic database');
OUTPUT
-----
 1
(1 row)
=> COMMIT;
COMMIT

=> -- Invoke the UDTF
=> SELECT url, tokenize(description) OVER (partition by url) FROM T;
  url | words
-----+-----
www.amazon.com | Online
www.amazon.com | retail
www.amazon.com | merchant
www.amazon.com | and
www.amazon.com | provider
www.amazon.com | of
www.amazon.com | cloud
www.amazon.com | services
www.vertica.com | World's
www.vertica.com | fastest
www.vertica.com | analytic
www.vertica.com | database
(12 rows)

```

Notice that the number of rows and columns in the result table are different than the input table. This is one of the strengths of a UDTF.

TransformFunction implementation

The following code shows the [StringTokenizer](#) class.

```

class StringTokenizer : public TransformFunction
{
    virtual void processPartition(ServerInterface &srvInterface,
                                PartitionReader &inputReader,
                                PartitionWriter &outputWriter)
    {
        try {
            if (inputReader.getNumCols() != 1)
                vt_report_error(0, "Function only accepts 1 argument, but %zu provided", inputReader.getNumCols());

            do {
                const VString &sentence = inputReader.getStringRef(0);

                // If input string is NULL, then output is NULL as well
                if (sentence.isNull())
                {
                    VString &word = outputWriter.getStringRef(0);
                    word.setNull();
                    outputWriter.next();
                }
                else
                {
                    // Otherwise, let's tokenize the string and output the words
                    std::string tmp = sentence.str();
                    std::istringstream ss(tmp);

                    do
                    {
                        std::string buffer;
                        ss >> buffer;

                        // Copy to output
                        if (!buffer.empty()) {
                            VString &word = outputWriter.getStringRef(0);
                            word.copy(buffer);
                            outputWriter.next();
                        }
                    } while (ss);
                }
            } while (inputReader.next() && !isCanceled());
        } catch(std::exception& e) {
            // Standard exception. Quit.
            vt_report_error(0, "Exception while processing partition: [%s]", e.what());
        }
    }
};

```

The `processPartition()` function in this example follows a pattern that you will follow in your own UDTF: it loops over all rows in the table partition that Vertica sends it, processing each row and checking for cancellation before advancing. For UDTFs you do not have to actually process every row. You can exit your function without having read all of the input without any issues. You may choose to do this if your UDTF is performing some sort search or some other operation where it can determine that the rest of the input is unneeded.

In this example, `processPartition()` first extracts the `VString` containing the text from the `PartitionReader` object. The `VString` class represents a Vertica string value (VARCHAR or CHAR). If there is input, it then tokenizes it and adds it to the output using the `PartitionWriter` object.

Similarly to reading input columns, the `PartitionWriter` class has functions for writing each type of data to the output row. In this case, the example calls the `PartitionWriter` object's `getStringRef()` function to allocate a new `VString` object to hold the token to output for the first column, and then copies the token's value into the `VString`.

TransformFunctionFactory implementation

The following code shows the factory class.

```

class TokenFactory : public TransformFunctionFactory
{
    // Tell Vertica that we take in a row with 1 string, and return a row with 1 string
    virtual void getPrototype(ServerInterface &srvInterface, ColumnTypes &argTypes, ColumnTypes &returnType)
    {
        argTypes.addVarchar();
        returnType.addVarchar();
    }

    // Tell Vertica what our return string length will be, given the input
    // string length
    virtual void getReturnType(ServerInterface &srvInterface,
                               const SizedColumnTypes &inputTypes,
                               SizedColumnTypes &outputTypes)
    {
        // Error out if we're called with anything but 1 argument
        if (inputTypes.getColumnCount() != 1)
            vt_report_error(0, "Function only accepts 1 argument, but %zu provided", inputTypes.getColumnCount());

        int input_len = inputTypes.getColumnType(0).getStringLength();

        // Our output size will never be more than the input size
        outputTypes.addVarchar(input_len, "words");
    }

    virtual TransformFunction *createTransformFunction(ServerInterface &srvInterface)
    { return vt_createFuncObject<StringTokenizer>(srvInterface.allocator); }
};

```

In this example:

- The UDTF takes a VARCHAR column as input. To define the input column, `getPrototype()` calls `addVarchar()` on the `ColumnTypes` object that represents the input table.
- The UDTF returns a VARCHAR as output. The `getPrototype()` function calls `addVarchar()` to define the output table.

This example must return the maximum length of the VARCHAR output column. It sets the length to the length of the input string. This is a safe value, because the output will never be longer than the input string. It also sets the name of the VARCHAR output column to "words".

Note

You are not required to supply a name for an output column in this function. However, it is a best practice to do so. If you do not name an output column, `getReturnType()` sets the column name to "". The SQL statements that call your UDTF must provide aliases for any unnamed columns to access them or else they return an error. From a usability standpoint, it is easier for you to supply the column names here once. The alternative is to force all of the users of your function to supply their own column names for each call to the UDTF.

The implementation of the `createTransformFunction()` function in the example is boilerplate code. It just calls the `vt_returnFuncObj` macro with the name of the `TransformFunction` class associated with this factory class. This macro takes care of instantiating a copy of the `TransformFunction` class that Vertica can use to process data.

The RegisterFactory macro

The final step in creating your UDTF is to call the `RegisterFactory` macro. This macro ensures that your factory class is instantiated when Vertica loads the shared library containing your UDTF. Having your factory class instantiated is the only way that Vertica can find your UDTF and determine what its inputs and outputs are.

The `RegisterFactory` macro just takes the name of your factory class:

```
RegisterFactory(TokenFactory);
```

Python example: string tokenizer

The following example shows a transform function that breaks an input string into tokens (based on whitespace). It is similar to the tokenizer examples for C++ and Java.

Loading and using the example

Create the library and function:

```
=> CREATE LIBRARY pyudtf AS '/home/dbadmin/udx/tokenize.py' LANGUAGE 'Python';
CREATE LIBRARY
=> CREATE TRANSFORM FUNCTION tokenize AS NAME 'StringTokenizerFactory' LIBRARY pyudtf;
CREATE TRANSFORM FUNCTION
```

You can then use the function in SQL statements, for example:

```
=> CREATE TABLE words (w VARCHAR);
CREATE TABLE
=> COPY words FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> this is a test of the python udtf
>> \.

=> SELECT tokenize(w) OVER () FROM words;
 token
-----
this
is
a
test
of
the
python
udtf
(8 rows)
```

Setup

All Python UDXs must import the Vertica SDK.

```
import vertica_sdk
```

UDTF Python code

The following code defines the tokenizer and its factory.

```

class StringTokenizer(vertica_sdk.TransformFunction):
    """
    Transform function which tokenizes its inputs.
    For each input string, each of the whitespace-separated tokens of that
    string is produced as output.
    """
    def processPartition(self, server_interface, input, output):
        while True:
            for token in input.getString(0).split():
                output.setString(0, token)
                output.next()
            if not input.next():
                break

class StringTokenizerFactory(vertica_sdk.TransformFunctionFactory):
    def getPrototype(self, server_interface, arg_types, return_type):
        arg_types.addVarchar()
        return_type.addVarchar()
    def getReturnType(self, server_interface, arg_types, return_type):
        return_type.addColumn(arg_types.getColumnType(0), "tokens")
    def createTransformFunction(cls, server_interface):
        return StringTokenizer()

```

R example: log tokenizer

The **LogTokenizer** transform function reads a varchar from a table, a log message. It then tokenizes each of the log messages, returning each of the tokens.

You can find more UDX examples in the Vertica Github repository, <https://github.com/vertica/UDx-Examples>.

Load the function and library

Create the library and the function.

```

=> CREATE OR REPLACE LIBRARY rLib AS 'log_tokenizer.R' LANGUAGE 'R';
CREATE LIBRARY
=> CREATE OR REPLACE TRANSFORM FUNCTION LogTokenizer AS LANGUAGE 'R' NAME 'LogTokenizerFactory' LIBRARY rLib FENCED;
CREATE FUNCTION

```

Querying data with the function

The following query shows how you can run a query with the UDTF.

```
=> SELECT machine,
      LogTokenizer(error_log USING PARAMETERS spliton = ' ') OVER(PARTITION BY machine)
FROM error_logs;
machine | Token
-----+-----
node001 | ERROR
node001 | 345
node001 | -
node001 | Broken
node001 | pipe
node001 | WARN
node001 | -
node001 | Nearly
node001 | filled
node001 | disk
node002 | ERROR
node002 | 111
node002 | -
node002 | Flooded
node002 | roads
node003 | ERROR
node003 | 222
node003 | -
node003 | Plain
node003 | old
node003 | broken
(21 rows)
```

UDTF R code

```

LogTokenizer <- function(input.data.frame, parameters.data.frame) {
  # Take the spliton parameter passed by the user and assign it to a variable
  # in the function so we can use that as our tokenizer.
  if ( is.null(parameters.data.frame[["spliton"]]) ) {
    stop("NULL value for spliton! Token cannot be NULL.")
  } else {
    split.on <- as.character(parameters.data.frame[["spliton"]])
  }
  # Tokenize the string.
  tokens <- vector(length=0)
  for ( string in input.data.frame[, 1] ) {
    tokenized.string <- strsplit(string, split.on)
    for ( token in tokenized.string ) {
      tokens <- append(tokens, token)
    }
  }
  final.output <- data.frame(tokens)
  return(final.output)
}

```

```

LogTokenizerFactory <- function() {
  list(name = LogTokenizer,
       udxtype = c("transform"),
       intype = c("varchar"),
       outtype = c("varchar"),
       outtypecallback=LogTokenizerReturn,
       parameterstypecallback=LogTokenizerParameters)
}

```

```

LogTokenizerParameters <- function() {
  parameters <- list(datatype = c("varchar"),
                    length = c("NA"),
                    scale = c("NA"),
                    name = c("spliton"))
  return(parameters)
}

```

```

LogTokenizerReturn <- function(arg.data.frame, parm.data.frame) {
  output.return.type <- data.frame(datatype = rep(NA,1),
                                  length = rep(NA,1),
                                  scale = rep(NA,1),
                                  name = rep(NA,1))
  output.return.type$datatype <- c("varchar")
  output.return.type$name <- c("Token")
  return(output.return.type)
}

```

C++ example: multi-phase indexer

The following code fragment is from the InvertedIndex UDTF example distributed with the Vertica SDK. It demonstrates subclassing the `MultiPhaseTransformFunctionFactory` including two `TransformFunctionPhase` subclasses that define the two phases in this UDTF.

```

class InvertedIndexFactory : public MultiPhaseTransformFunctionFactory
{
public:
  /**
   * Extracts terms from documents.
   */
  class ForwardIndexPhase : public TransformFunctionPhase
  {

```

```

    outputTypes.addInt("corp_freq");
}

virtual TransformFunction *createTransformFunction(ServerInterface
    &srvInterface)
{ return vt_createFuncObj(srvInterface allocator, InvertedIndexBuilder); }
};
ForwardIndexPhase fwardIdxPh;
InvertedIndexPhase invIdxPh;
virtual void getPhases(ServerInterface &srvInterface,
    std::vector<TransformFunctionPhase *> &phases)
{
    fwardIdxPh.setPrepass(); // Process documents wherever they're originally stored.
    phases.push_back(&fwardIdxPh);
    phases.push_back(&invIdxPh);
}
virtual void getPrototype(ServerInterface &srvInterface,
    ColumnTypes &argTypes,
    ColumnTypes &returnType)
{
    // Expected input: (doc_id INTEGER, text VARCHAR).
    argTypes.addInt();
    argTypes.addVarchar();
    // Output is: (term VARCHAR, doc_id INTEGER, term_freq INTEGER, corp_freq INTEGER)
    returnType.addVarchar();
    returnType.addInt();
    returnType.addInt();
    returnType.addInt();
}
};
RegisterFactory(InvertedIndexFactory);

```

Most of the code in this example is similar to the code in a [TransformFunctionFactory](#) class:

- Both [TransformFunctionPhase](#) subclasses implement the [getReturnType\(\)](#) function, which describes the output of each stage. This is similar to the [getReturnType\(\)](#) function from the [TransformFunctionFactory](#) class. However, this function also lets you control how the data is partitioned and ordered between each phase of your multi-phase UDTF. The first phase calls [SizedColumnTypes::addVarcharPartitionColumn\(\)](#) (rather than just [addVarcharColumn\(\)](#)) to set the phase's output table to be partitioned by the column containing the extracted words. It also calls [SizedColumnTypes::addOrderColumn\(\)](#) to order the output table by the document ID column. It calls this function instead of one of the data-type-specific functions (such as [addIntOrderColumn\(\)](#)) so it can pass the data type of the original column through to the output column.

Note

Any order by column or partition by column set by the final phase of the UDTF in its [getReturnType\(\)](#) function is ignored. Its output is returned to the initiator node rather than partitioned and reordered then sent to another phase.

- The [MultiPhaseTransformFunctionFactory](#) class implements the [getPrototype\(\)](#) function, that defines the schemas for the input and output of the multi-phase UDTF. This function is the same as the [TransformFunctionFactory::getPrototype\(\)](#) function.

The unique function implemented by the [MultiPhaseTransformFunctionFactory](#) class is [getPhases\(\)](#) . This function defines the order in which the phases are executed. The fields that represent the phases are pushed into this vector in the order they should execute.

The [MultiPhaseTransformFunctionFactory.getPhases\(\)](#) function is also where you flag the first phase of the UDTF as operating on data stored locally on the node (called a "pre-pass" phase) rather than on data partitioned across all nodes. Using this option increases the efficiency of your multi-phase UDTF by avoiding having to move significant amounts of data around the Vertica cluster.

Note

Only the first phase of your UDTF can be a pre-pass phase. You cannot have multiple pre-pass phases, and no later phase can be a pre-pass phase.

To mark the first phase as pre-pass, you call the `TransformFunctionPhase::setPrepass()` function of the first phase's `TransformFunctionPhase` instance from within the `getPhase()` function.

Notes

- You need to ensure that the output schema of each phase matches the input schema expected by the next phase. In the example code, each `TransformFunctionPhase::getReturnType()` implementation performs a sanity check on its input and output schemas. Your `TransformFunction` subclasses can also perform these checks in their `processPartition()` function.
- There is no built-in limit on the number of phases that your multi-phase UDTF can have. However, more phases use more resources. When running in fenced mode, Vertica may terminate UDTFs that use too much memory. See [Resource use for C++ UDxs](#).

Python example: multi-phase calculation

The following example shows a multi-phase transform function that computes the average value on a column of numbers in an input table. It first defines two transform functions, and then defines a factory that creates the phases using them.

See [AvgMultiPhaseUDT.py](#) in the examples distribution for the complete code.

Loading and using the example

Create the library and function:

```
=> CREATE LIBRARY pylib_avg AS '/home/dbadmin/udx/AvgMultiPhaseUDT.py' LANGUAGE 'Python';
CREATE LIBRARY
=> CREATE TRANSFORM FUNCTION myAvg AS NAME 'MyAvgFactory' LIBRARY pylib_avg;
CREATE TRANSFORM FUNCTION
```

You can then use the function in SELECT statements:

```
=> CREATE TABLE IF NOT EXISTS numbers(num FLOAT);
CREATE TABLE

=> COPY numbers FROM STDIN delimiter ',';
1
2
3
4
\

=> SELECT myAvg(num) OVER() FROM numbers;
average | ignored_rows | total_rows
-----+-----+-----
 2.5 |      0 |      4
(1 row)
```

Setup

All Python UDxs must import the Vertica SDK. This example also imports another library.

```
import vertica_sdk
import math
```

Component transform functions

A multi-phase transform function must define two or more `TransformFunction` subclasses to be used in the phases. This example uses two classes: `LocalCalculation`, which does calculations on local partitions, and `GlobalCalculation`, which aggregates the results of all `LocalCalculation` instances to calculate a final result.

In both functions, the calculation is done in the `processPartition()` function:

```

class LocalCalculation(vertica_sdk.TransformFunction):
    """
    This class is the first phase and calculates the local values for sum, ignored_rows and total_rows.
    """

    def setup(self, server_interface, col_types):
        server_interface.log("Setup: Phase0")
        self.local_sum = 0.0
        self.ignored_rows = 0
        self.total_rows = 0

    def processPartition(self, server_interface, input, output):
        server_interface.log("Process Partition: Phase0")

        while True:
            self.total_rows += 1

            if input.isNull(0) or math.isinf(input.getFloat(0)) or math.isnan(input.getFloat(0)):
                # Null, Inf, or Nan is ignored
                self.ignored_rows += 1
            else:
                self.local_sum += input.getFloat(0)

            if not input.next():
                break

        output.setFloat(0, self.local_sum)
        output.setInt(1, self.ignored_rows)
        output.setInt(2, self.total_rows)
        output.next()

```

```

class GlobalCalculation(vertica_sdk.TransformFunction):
    """
    This class is the second phase and aggregates the values for sum, ignored_rows and total_rows.
    """

    def setup(self, server_interface, col_types):
        server_interface.log("Setup: Phase1")
        self.global_sum = 0.0
        self.ignored_rows = 0
        self.total_rows = 0

    def processPartition(self, server_interface, input, output):
        server_interface.log("Process Partition: Phase1")

        while True:
            self.global_sum += input.getFloat(0)
            self.ignored_rows += input.getInt(1)
            self.total_rows += input.getInt(2)

            if not input.next():
                break

        average = self.global_sum / (self.total_rows - self.ignored_rows)

        output.setFloat(0, average)
        output.setInt(1, self.ignored_rows)
        output.setInt(2, self.total_rows)
        output.next()

```

A `MultiPhaseTransformFunctionFactory` ties together the individual functions as phases. The factory defines a `TransformFunctionPhase` for each function. Each phase defines `createTransformFunction()`, which calls the constructor for the corresponding `TransformFunction`, and `getReturnType()`.

The first phase, `LocalPhase`, follows.

```
class MyAvgFactory(vertica_sdk.MultiPhaseTransformFunctionFactory):
    """ Factory class """

    class LocalPhase(vertica_sdk.TransformFunctionPhase):
        """ Phase 1 """
        def getReturnType(self, server_interface, input_types, output_types):
            # sanity check
            number_of_cols = input_types.getColumnCount()
            if (number_of_cols != 1 or not input_types.getColumnType(0).isFloat()):
                raise ValueError("Function only accepts one argument (FLOAT)")

            output_types.addFloat("local_sum");
            output_types.addInt("ignored_rows");
            output_types.addInt("total_rows");

        def createTransformFunction(cls, server_interface):
            return LocalCalculation()
```

The second phase, `GlobalPhase`, does not check its inputs because the first phase already did. As with the first phase, `createTransformFunction` merely constructs and returns the corresponding `TransformFunction`.

```
class GlobalPhase(vertica_sdk.TransformFunctionPhase):
    """ Phase 2 """
    def getReturnType(self, server_interface, input_types, output_types):
        output_types.addFloat("average");
        output_types.addInt("ignored_rows");
        output_types.addInt("total_rows");

    def createTransformFunction(cls, server_interface):
        return GlobalCalculation()
```

After defining the `TransformFunctionPhase` subclasses, the factory instantiates them and chains them together in `getPhases()`.

```
ph0Instance = LocalPhase()
ph1Instance = GlobalPhase()

def getPhases(cls, server_interface):
    cls.ph0Instance.setPrepass()
    phases = [cls.ph0Instance, cls.ph1Instance]
    return phases
```

Python example: count elements

The following example details a UDTF that takes a partition of arrays, computes the count of each distinct array element in the partition, and outputs each element and its count as a row value. You can call the function on tables that contain multiple partitions of arrays.

The complete source code is in `/opt/vertica/sdk/examples/python/TransformFunctions.py`.

Loading and using the example

Load the library and create the transform function as follows:

```
=> CREATE OR REPLACE LIBRARY TransformFunctions AS '/home/dbadmin/examples/python/TransformFunctions.py' LANGUAGE 'Python';
=> CREATE TRANSFORM FUNCTION CountElements AS LANGUAGE 'Python' NAME 'countElementsUDTF' LIBRARY TransformFunctions;
```

You can create some data and then call the function on it, for example:

```

=> CREATE TABLE orders (storeID int, productIDs array[int]);
CREATE TABLE

=> INSERT INTO orders VALUES
  (1, array[101, 102, 103]),
  (1, array[102, 104]),
  (1, array[101, 102, 102, 201, 203]),
  (2, array[101, 202, 203, 202, 203]),
  (2, array[203]),
  (2, array[]);
OUTPUT
-----
6
(1 row)

=> COMMIT;
COMMIT

=> SELECT storeID, CountElements(productIDs) OVER (PARTITION BY storeID) FROM orders;
storeID | element_count
-----+-----
 1 | {"element":101,"count":2}
 1 | {"element":102,"count":4}
 1 | {"element":103,"count":1}
 1 | {"element":104,"count":1}
 1 | {"element":201,"count":1}
 1 | {"element":202,"count":1}
 2 | {"element":101,"count":1}
 2 | {"element":202,"count":2}
 2 | {"element":203,"count":3}
(9 rows)

```

Setup

All Python UDxs must import the Vertica SDK library:

```
import vertica_sdk
```

Factory implementation

The `getPrototype()` method declares that the inputs and outputs can be of any type, which means that type enforcement must be done elsewhere:

```
def getPrototype(self, srv_interface, arg_types, return_type):
    arg_types.addAny()
    return_type.addAny()
```

`getReturnType()` validates that the only argument to the function is an array and that the return type is a row with 'element' and 'count' fields:

```
def getReturnType(self, srv_interface, arg_types, return_type):

    if arg_types.getColumnCount() != 1:
        srv_interface.reportError(1, 'countElements UDT should take exactly one argument')

    if not arg_types.getColumnType(0).isArrayType():
        srv_interface.reportError(2, 'Argument to countElements UDT should be an ARRAY')

    retRowFields = vertica_sdk.SizedColumnTypes.makeEmpty()
    retRowFields.addColumn(arg_types.getColumnType(0).getElementType(), 'element')
    retRowFields.addInt('count')
    return_type.addRowType(retRowFields, 'element_count')
```

The `countElementsUDTFFactory` class also contains a `createTransformFunction()` method that instantiates and returns the transform function.

Function implementation

The `processBlock()` method is called with a `BlockReader` and a `BlockWriter`, named `arg_reader` and `res_writer` respectively. The function loops through all the input arrays in a partition and uses a dictionary to collect the frequency of each element. To access elements of each input array, the method instantiates an `ArrayReader`. After collecting the element counts, the function writes each element and its count to a row. This process is repeated for each partition.

```
def processPartition(self, srv_interface, arg_reader, res_writer):

    elemCounts = dict()
    # Collect element counts for entire partition
    while (True):
        if not arg_reader.isNull(0):
            arr = arg_reader.getArray(0)
            for elem in arr:
                elemCounts[elem] = elemCounts.setdefault(elem, 0) + 1

        if not arg_reader.next():
            break

    # Write at least one value for each partition
    if len(elemCounts) == 0:
        elemCounts[None] = 0

    # Write out element counts as (element, count) pairs
    for pair in elemCounts.items():
        res_writer.setRow(0, pair)
        res_writer.next()
```

Python example: explode

The following example details a UDTF that accepts a one-dimensional array as input and outputs each element of the array as a separate row, similar to functions commonly known as [EXPLODE](#). Because this UDTF always accepts one array as input, you can explicitly mark it as a [one-to-many UDTF](#) in the factory function, which helps Vertica optimize query plans and allows users to write SELECT queries that include any expression and do not require an OVER clause.

The complete source code is in [/opt/vertica/sdk/examples/python/TransformFunctions.py](#).

Loading and using the example

Load the library and create the transform function as follows:

```
=> CREATE OR REPLACE LIBRARY PyTransformFunctions AS '/opt/vertica/sdk/examples/python/TransformFunctions.py' LANGUAGE 'Python';
CREATE LIBRARY

=> CREATE TRANSFORM FUNCTION py_explode AS LANGUAGE 'Python' NAME 'ExplodeFactory' LIBRARY TransformFunctions;
CREATE TRANSFORM FUNCTION
```

You can then use the function in SQL statements, for example:

```

=> CREATE TABLE reviews (id INTEGER PRIMARY KEY, sentiment VARCHAR(16), review ARRAY[VARCHAR(16), 32]);
CREATE TABLE

=> INSERT INTO reviews VALUES(1, 'Very Negative', string_to_array('This was the worst restaurant I have ever had the misfortune of eating at' USING
PARAMETERS collection_delimiter = ' ')),
  (2, 'Neutral', string_to_array('This restaurant is pretty decent' USING PARAMETERS collection_delimiter = ' ')),
  (3, 'Very Positive', string_to_array('Best restaurant in the Western Hemisphere' USING PARAMETERS collection_delimiter = ' ')),
  (4, 'Positive', string_to_array('Prices low for the area' USING PARAMETERS collection_delimiter = ' '));
OUTPUT
-----
4
(1 row)

=> COMMIT;
COMMIT

=> SELECT id, sentiment, py_explode(review) FROM reviews; --no OVER clause because "is_exploder = True", see below
id | sentiment | element
-----+-----+-----
1 | Very Negative | This
1 | Very Negative | was
1 | Very Negative | the
1 | Very Negative | worst
1 | Very Negative | restaurant
1 | Very Negative | I
1 | Very Negative | have
...
3 | Very Positive | Western
3 | Very Positive | Hemisphere
4 | Positive | Prices
4 | Positive | low
4 | Positive | for
4 | Positive | the
4 | Positive | area
(30 rows)

```

Setup

All Python UDxs must import the Vertica SDK library:

```
import vertica_sdk
```

Factory implementation

The following code shows the `ExplodeFactory` class.

```

class ExplodeFactory(vertica_sdk.TransformFunctionFactory):
    def getPrototype(self, srv_interface, arg_types, return_type):
        arg_types.addAny()
        return_type.addAny()

    def getTransformFunctionProperties(cls, server_interface, arg_types):
        props = vertica_sdk.TransformFunctionFactory.Properties()
        props.is_exploder = True
        return props

    def getReturnType(self, srv_interface, arg_types, return_type):
        if arg_types.getColumnCount() != 1:
            srv_interface.reportError(1, 'explode UDT should take exactly one argument')
        if not arg_types.getColumnType(0).isArrayType():
            srv_interface.reportError(2, 'Argument to explode UDT should be an ARRAY')

        return_type.addColumn(arg_types.getColumnType(0).getElementType(), 'element')

    def createTransformFunction(cls, server_interface):
        return Explode()

```

In this example:

- The `getTransformFunctionProperties` method sets the `is_exploder` class property to True, explicitly marking the UDTF as one-to-many. This indicates that the function uses an OVER(PARTITION ROW) clause by default and thereby removes the need to specify an OVER clause when calling the UDTF. With `is_exploder` set to True, users can write SELECT queries that include any expression, unlike queries that use PARTITION BEST or PARTITION NODES.
- The `getReturnType` method verifies that the input contains only one argument and is of type ARRAY. The method also sets the return type to that of the elements in the input array.

Function implementation

The following code shows the `Explode` class:

```

class Explode(vertica_sdk.TransformFunction):
    """
    Transform function that turns an array into one row
    for each array element.
    """

    def processPartition(self, srv_interface, arg_reader, res_writer):
        while True:
            arr = arg_reader.getArrayReader(0)
            for elt in arr:
                res_writer.copyRow(elt)
                res_writer.next()
            if not arg_reader.next():
                break;

```

The `processPartition()` method accepts a single row of the input data, processes each element of the array, and then breaks the loop. The method accesses the elements of the array with an `ArrayReader` object and then uses an `ArrayWriter` object to write each element of the array to a separate output row. The UDTF calls `processPartition()` for each row of the input data.

User-defined load (UDL)

[COPY](#) offers extensive options and settings to control how to load data. However, you may find that these options do not suit the type of data load that you want to perform. The user-defined load (UDL) feature lets you develop one or more functions that change how the COPY statement operates. You can create custom libraries using the Vertica SDK to handle various steps in the loading process. .

You use three types of UDL functions during development, one for each stage of the data-load process:

- [User-defined source](#) (UDSource): Controls how COPY obtains the data it loads into the database. For example, COPY might obtain data by fetching it through HTTP or cURL. Up to one UDSource reads data from a file or input stream. Your UDSource can read from more than one source, but COPY invokes only one UDSource.
API support: C++, Java.
- [User-defined filter](#) (UDFilter): Preprocesses the data. For example, a filter might unzip a file or convert UTF-16 to UTF-8. You can chain multiple user-defined filters together, for example unzipping and then converting.
API support: C++, Java, Python.
- [User-defined parser](#) (UDParser): Up to one parser parses the data into tuples that are ready to be inserted into a table. For example, a parser could extract data from an XML-like format. You can optionally define a user-defined chunker (UDChunker, C++ only), to have the parser perform parallel parsing.
API support: C++, Java, Python.

After the final step, COPY inserts the data into a table, or rejects it if the format is incorrect.

In this section

- [User-defined source](#)
- [User-defined filter](#)
- [User-defined parser](#)
- [Load parallelism](#)
- [Continuous load](#)
- [Buffer classes](#)

User-defined source

A user-defined source allows you to process a source of data using a method that is not built into Vertica. For example, you can write a user-defined source to access the data from an HTTP source using cURL. While a given [COPY](#) statement can use specify only one user-defined source statement, the source function itself can pull data from multiple sources.

The [UDSource](#) class acquires data from an external source. It reads data from an input stream and produces an output stream to be filtered and parsed. If you implement a [UDSource](#), you must also implement a corresponding [SourceFactory](#).

In this section

- [UDSource class](#)
- [SourceFactory class](#)
- [C++ example: CurlSource](#)
- [C++ example: concurrent load](#)
- [Java example: FileSource](#)

UDSource class

You can subclass the [UDSource](#) class when you need to load data from a source type that COPY does not already support.

Each instance of your [UDSource](#) subclass reads from a single data source. Examples of a single data source are a single file or the results of a single function call to a RESTful web application.

UDSource methods

Your [UDSource](#) subclass must override [process\(\)](#) or [processWithMetadata\(\)](#) :

Note

[processWithMetadata\(\)](#) is available only for user-defined extensions (UDxs) written in the C++ programming language.

- [process\(\)](#) reads the raw input stream as one large file. If there are any errors or failures, the entire load fails.
- [processWithMetadata\(\)](#) is useful when the data source has metadata about record boundaries available in some structured format that's separate from the data payload. With this interface, the source emits a record length for each record in addition to the data. By implementing [processWithMetadata\(\)](#) instead of [process\(\)](#) in each phase, you can retain this record length metadata throughout the load stack, which enables a more efficient parse that can recover from errors on a per-message basis, rather than a per-file or per-source basis. [KafkaSource](#) and the Kafka parsers ([KafkaAvroParser](#), [KafkaJSONParser](#), and [KafkaParser](#)) use this mechanism to support per-Kafka-message rejections when individual Kafka messages are cannot be parsed.

Note

To implement `processWithMetadata()`, you must override `useSideChannel()` to return `true`.

Additionally, you can override the other `UDSource` class methods.

Source execution

The following sections detail the execution sequence each time a user-defined source is called. The following example overrides the `process()` method.

Setting Up

COPY calls `setup()` before the first time it calls `process()`. Use `setup()` to perform any necessary setup steps to access the data source. This method establishes network connections, opens files, and similar tasks that need to be performed before the `UDSource` can read data from the data source. Your object might be destroyed and re-created during use, so make sure that your object is restartable.

Processing a Source

COPY calls `process()` repeatedly during query execution to read data and write it to the `DataBuffer` passed as a parameter. This buffer is then passed to the first filter.

If the source runs out of input, or fills the output buffer, it must return the value `StreamState.OUTPUT_NEEDED`. When Vertica gets this return value, it will call the method again. This second call occurs after the output buffer has been processed by the next stage in the data-load process. Returning `StreamState.DONE` indicates that all of the data from the source has been read.

The user can cancel the load operation, which aborts reading.

Tearing Down

COPY calls `destroy()` after the last time that `process()` is called. This method frees any resources reserved by the `setup()` or `process()` methods, such as file handles or network connections that the `setup()` method allocated.

Accessors

A source can define two accessors, `getSize()` and `getUri()`.

COPY might call `getSize()` to estimate the number of bytes of data to be read before calling `process()`. This value is an estimate only and is used to indicate the file size in the `LOAD_STREAMS` table. Because Vertica can call this method before calling `setup()`, `getSize()` must not rely on any resources allocated by `setup()`.

This method should not leave any resources open. For example, do not save any file handles opened by `getSize()` for use by the `process()` method. Doing so can exhaust the available resources, because Vertica calls `getSize()` on all instances of your `UDSource` subclass before any data is loaded. If many data sources are being opened, these open file handles could use up the system's supply of file handles. Thus, none would remain available to perform the actual data load.

Vertica calls `getUri()` during execution to update status information about which resources are currently being loaded. It returns the URI of the data source being read by this `UDSource`.

API

[C++](#)

[Java](#)

The [UDSource](#) API provides the following methods for extension by subclasses:

```

virtual void setup(ServerInterface &srvInterface);

virtual bool useSideChannel();

virtual StreamState process(ServerInterface &srvInterface, DataBuffer &output)=0;

virtual StreamState processWithMetadata(ServerInterface &srvInterface, DataBuffer &output, LengthBuffer &output_len);

virtual void cancel(ServerInterface &srvInterface);

virtual void destroy(ServerInterface &srvInterface);

virtual vint getSize();

virtual std::string getUri();

```

SourceFactory class

If you write a source, you must also write a source factory. Your subclass of the `SourceFactory` class is responsible for:

- Performing the initial validation of the parameters passed to your `UDSource` .
- Setting up any data structures your `UDSource` instances need to perform their work. This information can include recording which nodes will read which data source.
- Creating one instance of your `UDSource` subclass for each data source (or portion thereof) that your function reads on each host.

The simplest source factory creates one `UDSource` instance per data source per executor node. You can also use multiple concurrent `UDSource` instances on each node. This behavior is called *concurrent load* . To support both options, `SourceFactory` has two versions of the method that creates the sources. You must implement exactly one of them.

Source factories are singletons. Your subclass must be stateless, with no fields containing data. The subclass also must not modify any global variables.

SourceFactory methods

The `SourceFactory` class defines several methods. Your class must override `prepareUDSources()` ; it may override the other methods.

Setting up

Vertica calls `plan()` once on the initiator node to perform the following tasks:

- Check the parameters the user supplied to the function call in the COPY statement and provide error messages if there are any issues. You can read the parameters by getting a `ParamReader` object from the instance of `ServerInterface` passed into the `plan()` method.
- Decide which hosts in the cluster will read the data source. How you divide up the work depends on the source your function is reading. Some sources can be split across many hosts, such as a source that reads data from many URLs. Others, such as an individual local file on a host's file system, can be read only by a single specified host. You store the list of hosts to read the data source by calling the `setTargetNodes()` method on the `NodeSpecifyingPlanContext` object. This object is passed into your `plan()` method.
- Store any information that the individual hosts need to process the data sources in the `NodeSpecifyingPlanContext` instance passed to the `plan()` method. For example, you could store assignments that tell each host which data sources to process. The `plan()` method runs only on the initiator node, and the `prepareUDSources()` method runs on each host reading from a data source. Therefore, this object is the only means of communication between them. You store data in the `NodeSpecifyingPlanContext` by getting a `ParamWriter` object from the `getWriter()` method. You then write parameters by calling methods on the `ParamWriter` such as `setString()` .

Note

`ParamWriter` offers the ability to store only simple data types. For complex types, you must serialize the data in some manner and store it as a string or long string.

Creating sources

Vertica calls `prepareUDSources()` on all hosts that the `plan()` method selected to load data. This call instantiates and returns a list of `UDSource` subclass

instances. If you are not using concurrent load, return one [UDSource](#) for each of the sources that the host is assigned to process. If you are using concurrent load, use the version of the method that takes an [ExecutorPlanContext](#) as a parameter, and return as many sources as you can use. Your factory must implement exactly one of these methods.

Note

In the C++ API, the function that supports concurrent load is named [prepareUDSourcesExecutor\(\)](#) . In the Java API the class provides two overloads of [prepareUDSources\(\)](#) .

For concurrent load, you can find out how many threads are available on the node to run [UDSource](#) instances by calling [getLoadConcurrency\(\)](#) on the [ExecutorPlanContext](#) that is passed in.

Defining parameters

Implement [getParameterTypes\(\)](#) to define the names and types of parameters that your source uses. Vertica uses this information to warn callers about unknown or missing parameters. Vertica ignores unknown parameters and uses default values for missing parameters. While you should define the types and parameters for your function, you are not required to override this method.

Requesting threads for concurrent load

When a source factory creates sources on an executor node, by default, it creates one thread per source. If your sources can use multiple threads, implement [getDesiredThreads\(\)](#) . Vertica calls this method before it calls [prepareUDSources\(\)](#) , so you can also use it to decide how many sources to create. Return the number of threads your factory can use for sources. The maximum number of available threads is passed in, so you can take that into account. The value your method returns is a hint, not a guarantee; each executor node determines the number of threads to allocate. The [FilePortionSourceFactory](#) example implements this method; see [C++ example: concurrent load](#) .

You can allow your source to have control over parallelism, meaning that it can divide a single input into multiple load streams, by implementing [isSourceApportionable\(\)](#) . Returning [true](#) from this method does not guarantee that the source *will* apportion the load. However, returning [false](#) indicates that it will not try to do so. See [Apportioned load](#) for more information.

Often, a [SourceFactory](#) that implements [getDesiredThreads\(\)](#) also uses apportioned load. However, using apportioned load is not a requirement. A source reading from Kafka streams, for example, could use multiple threads without ssapportioning.

API

[C++](#)

[Java](#)

The [SourceFactory](#) API provides the following methods for extension by subclasses:

```
virtual void plan(ServerInterface &svInterface, NodeSpecifyingPlanContext &planCtx);

// must implement exactly one of prepareUDSources() or prepareUDSourcesExecutor()
virtual std::vector< UDSource * > prepareUDSources(ServerInterface &svInterface,
    NodeSpecifyingPlanContext &planCtx);

virtual std::vector< UDSource * > prepareUDSourcesExecutor(ServerInterface &svInterface,
    ExecutorPlanContext &planCtx);

virtual void getParameterType(ServerInterface &svInterface,
    SizedColumnTypes &parameterTypes);

virtual bool isSourceApportionable();

ssize_t getDesiredThreads(ServerInterface &svInterface,
    ExecutorPlanContext &planContext);
```

After creating your [SourceFactory](#) , you must register it with the [RegisterFactory](#) macro.

C++ example: CurlSource

The [CurlSource](#) example allows you to use cURL to open and read in a file over HTTP. The example provided is part of:

[/opt/vertica/sdk/examples/SourceFunctions/cURL.cpp](#) .

Source implementation

This example uses the helper library available in [/opt/vertica/sdk/examples/HelperLibraries/](#) .

CurlSource loads the data in chunks. If the parser encounters an EndOfFile marker, then the `process()` method returns DONE. Otherwise, the method returns OUTPUT_NEEDED and processes another chunk of data. The functions included in the helper library (such as `url_fread()` and `url_fopen()`) are based on examples that come with the libcurl library. For an example, see <http://curl.haxx.se/libcurl/c/fopen.html>.

The `setup()` function opens a file handle and the `destroy()` function closes it. Both use functions from the helper library.

```
class CurlSource : public UDSource {private:
    URL_FILE *handle;
    std::string url;
    virtual StreamState process(ServerInterface &srvInterface, DataBuffer &output) {
        output.offset = url_fread(output.buf, 1, output.size, handle);
        return url_feof(handle) ? DONE : OUTPUT_NEEDED;
    }
public:
    CurlSource(std::string url) : url(url) {}
    void setup(ServerInterface &srvInterface) {
        handle = url_fopen(url.c_str(), "r");
    }
    void destroy(ServerInterface &srvInterface) {
        url_fclose(handle);
    }
};
```

Factory implementation

`CurlSourceFactory` produces `CurlSource` instances.

```
class CurlSourceFactory : public SourceFactory {public:
    virtual void plan(ServerInterface &srvInterface,
        NodeSpecifyingPlanContext &planCtx) {
        std::vector<std::string> args = srvInterface.getParamReader().getParamNames();
        /* Check parameters */
        if (args.size() != 1 || find(args.begin(), args.end(), "url") == args.end()) {
            vt_report_error(0, "You must provide a single URL.");
        }
        /* Populate planData */
        planCtx.getWriter().getStringRef("url").copy(
            srvInterface.getParamReader().getStringRef("url"));

        /* Assign Nodes */
        std::vector<std::string> executionNodes = planCtx.getClusterNodes();
        while (executionNodes.size() > 1) executionNodes.pop_back();
        // Only run on the first node in the list.
        planCtx.setTargetNodes(executionNodes);
    }
    virtual std::vector<UDSource*> prepareUDSources(ServerInterface &srvInterface,
        NodeSpecifyingPlanContext &planCtx) {
        std::vector<UDSource*> retVal;
        retVal.push_back(vt_createFuncObj(srvInterface.allocator, CurlSource,
            planCtx.getReader().getStringRef("url").str()));
        return retVal;
    }
    virtual void getParameterType(ServerInterface &srvInterface,
        SizedColumnTypes &parameterTypes) {
        parameterTypes.addVarchar(65000, "url");
    }
};
RegisterFactory(CurlSourceFactory);
```

C++ example: concurrent load

The `FilePortionSource` example demonstrates the use of concurrent load. This example is a refinement of the `FileSource` example. Each input file is divided into portions and distributed to `FilePortionSource` instances. The source accepts a list of offsets at which to break the input into portions; if offsets are not provided, the source divides the input dynamically.

Concurrent load is handled in the factory, so this discussion focuses on `FilePortionSourceFactory`. The full code for the example is located in `/opt/vertica/sdk/examples/ApportionLoadFunctions`. The distribution also includes a Java version of this example.

Loading and using the example

Load and use the `FilePortionSource` example as follows.

```
=> CREATE LIBRARY FilePortionLib AS '/home/dbadmin/FP.so';

=> CREATE SOURCE FilePortionSource AS LANGUAGE 'C++'
-> NAME 'FilePortionSourceFactory' LIBRARY FilePortionLib;

=> COPY t WITH SOURCE FilePortionSource(file='g1/*.dat', nodes='initiator,e0,e1', offsets = '0,380000,820000');

=> COPY t WITH SOURCE FilePortionSource(file='g2/*.dat', nodes='e0,e1,e2', local_min_portion_size = 2097152);
```

Implementation

Concurrent load affects the source factory in two places, `getDesiredThreads()` and `prepareUDSourcesExecutor()`.

`getDesiredThreads()`

The `getDesiredThreads()` member function determines the number of threads to request. Vertica calls this member function on each executor node before calling `prepareUDSourcesExecutor()`.

The function begins by breaking an input file path, which might be a glob, into individual paths. This discussion omits those details. If apportioned load is not being used, then the function allocates one source per file.

```
virtual ssize_t getDesiredThreads(ServerInterface &srvInterface,
    ExecutorPlanContext &planCtx) {
    const std::string filename = srvInterface.getParamReader().getStringRef("file").str();

    std::vector<std::string> paths;
    // expand the glob - at least one thread per source.
    ...

    // figure out how to assign files to sources
    const std::string nodeName = srvInterface.getCurrentNodeName();
    const size_t nodeId = planCtx.getWriter().getIntRef(nodeName);
    const size_t numNodes = planCtx.getTargetNodes().size();

    if (!planCtx.canApportionSource()) {
        /* no apportioning, so the number of files is the final number of sources */
        std::vector<std::string> *expanded =
            vt_createFuncObject<std::vector<std::string> >(srvInterface.allocator, paths);
        /* save expanded paths so we don't have to compute expansion again */
        planCtx.getWriter().setPointer("expanded", expanded);
        return expanded->size();
    }
    // ...
}
```

If the source can be apportioned, then `getDesiredThreads()` uses the offsets that were passed as arguments to the factory to divide the file into portions. It then allocates portions to available nodes. This function does not actually assign sources directly; this work is done to determine how many threads to request.

```

else if (srvInterface.getParamReader().containsParameter("offsets")) {

    // if the offsets are specified, then we will have a fixed number of portions per file.
    // Round-robin assign offsets to nodes.
    // ...

    /* Construct the portions that this node will actually handle.
     * This isn't changing (since the offset assignments are fixed),
     * so we'll build the Portion objects now and make them available
     * to prepareUDSourcesExecutor() by putting them in the ExecutionContext.
     */
    /* We don't know the size of the last portion, since it depends on the file
     * size. Rather than figure it out here we will indicate it with -1 and
     * defer that to prepareUDSourcesExecutor().
     */
    std::vector<Portion> *portions =
        vt_createFuncObject<std::vector<Portion>>(srvInterface.allocator);

    for (std::vector<size_t>::const_iterator offset = offsets.begin();
         offset != offsets.end(); ++offset) {
        Portion p(*offset);
        p.is_first_portion = (offset == offsets.begin());
        p.size = (offset + 1 == offsets.end() ? -1 : (*(offset + 1) - *offset));

        if ((offset - offsets.begin()) % numNodes == nodeId) {
            portions->push_back(p);
            srvInterface.log("FilePortionSource: assigning portion %ld: [offset = %ld, size = %ld]",
                            offset - offsets.begin(), p.offset, p.size);
        }
    }
}

```

The function now has all the portions and thus the number of portions:

```

planCtxt.getWriter().setPointer("portions", portions);

/* total number of threads we want is the number of portions per file, which is fixed */
return portions->size() * expanded->size();
} // end of "offsets" parameter

```

If offsets were not provided, the function divides the file into portions dynamically, one portion per thread. This discussion omits the details of this computation. There is no point in requesting more threads than are available, so the function calls [getMaxAllowedThreads\(\)](#) on the [PlanContext](#) (an argument to the function) to set an upper bound:

```

if (portions->size() >= planCtxt.getMaxAllowedThreads()) {
    return paths.size();
}

```

See the full example for the details of how this function divides the file into portions.

This function uses the [vt_createFuncObject](#) template to create objects. Vertica calls the destructors of returned objects created using this macro, but it does not call destructors for other objects like vectors. You must call these destructors yourself to avoid memory leaks. In this example, these calls are made in [prepareUDSourcesExecutor\(\)](#).

[prepareUDSourcesExecutor\(\)](#)

The [prepareUDSourcesExecutor\(\)](#) member function, like [getDesiredThreads\(\)](#), has separate blocks of code depending on whether offsets are provided. In both cases, the function breaks input into portions and creates [UDSource](#) instances for them.

If the function is called with offsets, [prepareUDSourcesExecutor\(\)](#) calls [prepareCustomizedPortions\(\)](#). This function follows.

```

/* prepare portions as determined via the "offsets" parameter */
void prepareCustomizedPortions(ServerInterface &srvInterface,
                               ExecutorPlanContext &planCtx,
                               std::vector<UDSource *> &sources,
                               const std::vector<std::string> &expandedPaths,
                               std::vector<Portion> &portions) {
    for (std::vector<std::string>::const_iterator filename = expandedPaths.begin();
         filename != expandedPaths.end(); ++filename) {
        /*
         * the "portions" vector contains the portions which were generated in
         * "getDesiredThreads"
         */
        const size_t fileSize = getFileSize(*filename);
        for (std::vector<Portion>::const_iterator portion = portions.begin();
             portion != portions.end(); ++portion) {
            Portion fportion(*portion);
            if (fportion.size == -1) {
                /* as described above, this means from the offset to the end */
                fportion.size = fileSize - portion->offset;
                sources.push_back(vt_createFuncObject<FilePortionSource>(srvInterface.allocator,
                                                                           *filename, fportion));
            } else if (fportion.size > 0) {
                sources.push_back(vt_createFuncObject<FilePortionSource>(srvInterface.allocator,
                                                                           *filename, fportion));
            }
        }
    }
}

```

If `prepareUDSourcesExecutor()` is called without offsets, then it must decide how many portions to create.

The base case is to use one portion per source. However, if extra threads are available, the function divides the input into more portions so that a source can process them concurrently. Then `prepareUDSourcesExecutor()` calls `prepareGeneratedPortions()` to create the portions. This function begins by calling `getLoadConcurrency()` on the plan context to find out how many threads are available.

```

void prepareGeneratedPortions(ServerInterface &srvInterface,
                               ExecutorPlanContext &planCtx,
                               std::vector<UDSource *> &sources,
                               std::map<std::string, Portion> initialPortions) {

    if ((ssize_t) initialPortions.size() >= planCtx.getLoadConcurrency()) {
        /* all threads will be used, don't bother splitting into portions */

        for (std::map<std::string, Portion>::const_iterator file = initialPortions.begin();
             file != initialPortions.end(); ++file) {
            sources.push_back(vt_createFuncObject<FilePortionSource>(srvInterface.allocator,
                                                                           file->first, file->second));
        } // for
        return;
    } // if

    // Now we can split files to take advantage of potentially-unused threads.
    // First sort by size (descending), then we will split the largest first.

    // details elided...
}

```

For more information

See the source code for the full implementation of this example.

Java example: FileSource

The example shown in this section is a simple UDL Source function named `FileSource`. This function loads data from files stored on the host's file system (similar to the standard `COPY` statement). To call `FileSource`, you must supply a parameter named `file` that contains the absolute path to one or more files on the host file system. You can specify multiple files as a comma-separated list.

The `FileSource` function also accepts an optional parameter, named `nodes`, that indicates which nodes should load the files. If you do not supply this parameter, the function defaults to loading data on the initiator node only. Because this example is simple, the nodes load only the files from their own file systems. Any files in the `file` parameter must exist on all of the hosts in the `nodes` parameter. The `FileSource` UDSOURCE attempts to load all of the files in the `file` parameter on all of the hosts in the `nodes` parameter.

Generating files

You can use the following Python script to generate files and distribute them to hosts in your Vertica cluster. With these files, you can experiment with the example `UDSource` function. Running the function requires passwordless-SSH logins to copy the files to the other hosts. Therefore, you must run the script using the database administrator account on one of your database hosts.

```

#!/usr/bin/python
# Save this file as UDLDataGen.py
import string
import random
import sys
import os

# Read in the dictionary file to provide random words. Assumes the words
# file is located in /usr/share/dict/words
wordFile = open("/usr/share/dict/words")
wordDict = []
for line in wordFile:
    if len(line) > 6:
        wordDict.append(line.strip())

MAXSTR = 4 # Maximum number of words to concatenate
NUMROWS = 1000 # Number of rows of data to generate
#FILEPATH = '/tmp/UDLdata.txt' # Final filename to use for UDL source
TMPFILE = '/tmp/UDLtemp.txt' # Temporary filename.

# Generate a random string by concatenating several words together. Max
# number of words set by MAXSTR
def randomWords():
    words = [random.choice(wordDict) for n in xrange(random.randint(1, MAXSTR))]
    sentence = " ".join(words)
    return sentence

# Create a temporary data file that will be moved to a node. Number of
# rows for the file is set by NUMROWS. Adds the name of the node which will
# get the file, to show which node loaded the data.
def generateFile(node):
    outFile = open(TMPFILE, 'w')
    for line in xrange(NUMROWS):
        outFile.write('{0}|{1}|{2}\n'.format(line,randomWords(),node))
    outFile.close()

# Copy the temporary file to a node. Only works if passwordless SSH login
# is enabled, which it is for the database administrator account on
# Vertica hosts.
def copyFile(fileName,node):
    os.system('scp "%s" "%s:%s"' % (TMPFILE, node, fileName) )

# Loop through the comma-separated list of nodes given in the first
# parameter, creating and copying data files whose full comma-separated
# paths are passed in the second parameter
for node in [x.strip() for x in sys.argv[1].split(',')]:
    for fileName in [y.strip() for y in sys.argv[2].split(',')]:
        print "generating file", fileName, "for", node
        generateFile(node)
        print "Copying file to",node
        copyFile(fileName,node)

```

You call this script by giving it a comma-separated list of hosts to receive the files and a comma-separated list of absolute paths of files to generate. For example:

```
$ python UDLDataGen.py v_vmart_node0001,v_vmart_node0002,v_vmart_node0003 /tmp/UDLdata01.txt,/tmp/UDLdata02.txt,UDLdata03.txt
```

This script generates files that contain a thousand rows of columns delimited with the pipe character (|). These columns contain an index value, a set of random words, and the node for which the file was generated, as shown in the following output sample:

```
0|megabits embanks|v_vmart_node0001
1|unneatly|v_vmart_node0001
2|self-precipitation|v_vmart_node0001
3|antihistamine scalados Vatter|v_vmart_node0001
```

Loading and using the example

Load and use the [FileSource](#) UDSOURCE as follows:

```
=> --Load library and create the source function
=> CREATE LIBRARY JavaLib AS '/home/dbadmin/JavaUDLib.jar'
-> LANGUAGE 'JAVA';
CREATE LIBRARY
=> CREATE SOURCE File as LANGUAGE 'JAVA' NAME
-> 'com.mycompany.UDL.FileSourceFactory' LIBRARY JavaLib;
CREATE SOURCE FUNCTION
=> --Create a table to hold the data loaded from files
=> CREATE TABLE t (i integer, text VARCHAR, node VARCHAR);
CREATE TABLE
=> -- Copy a single file from the currently host using the FileSource
=> COPY t SOURCE File(file='/tmp/UDLdata01.txt');
Rows Loaded
-----
      1000
(1 row)

=> --See some of what got loaded.
=> SELECT * FROM t WHERE i < 5 ORDER BY i;
i|          text          | node
-----+-----+-----
0 | megabits embanks      | v_vmart_node0001

```

Parser implementation

The following code shows the source of the `FileSource` class that reads a file from the host file system. The constructor, which is called by `FileSourceFactory.prepareUDSources()`, gets the absolute path for the file containing the data to be read. The `setup()` method opens the file and the `destroy()` method closes it. The `process()` method reads from the file into a buffer provided by the instance of the `DataBuffer` class passed to it as a parameter. If the read operation filled the output buffer, it returns `OUTPUT_NEEDED`. This value tells Vertica to call the method again after the next stage of the load has processed the output buffer. If the read did not fill the output buffer, then `process()` returns `DONE` to indicate it has finished processing the data source.

public class FileSource extends UDSource {

    private String filename; // The file for this UDSource to read
    private RandomAccessFile reader; // handle to read from file

    // The constructor just stores the absolute filename of the file it will

```

```
return StreamState.OUTPUT_NEEDED;
```

Factory implementation

The following code is a modified version of the example Java UDSOURCE function provided in the Java UDX support package. You can find the full example in `/opt/vertica/sdk/examples/JavaUDx/UDLFuctions/com/vertica/JavaLibs/FileSourceFactory.java`. Its override of the `plan()` method verifies that the user supplied the required `file` parameter. If the user also supplied the optional `nodes` parameter, this method verifies that the nodes exist in the Vertica cluster. If there is a problem with either parameter, the method throws an exception to return an error to the user. If there are no issues with the parameters, the `plan()` method stores their values in the plan context object.

```

import com.vertica.sdk.ParamReader;
import com.vertica.sdk.ParamWriter;
import com.vertica.sdk.ServerInterface;
import com.vertica.sdk.SizedColumnTypes;
import com.vertica.sdk.SourceFactory;
import com.vertica.sdk.UDSource;
import com.vertica.sdk.UdfException;

public class FileSourceFactory extends SourceFactory {

    // Called once on the initiator host to do initial setup. Checks
    // parameters and chooses which nodes will do the work.
    @Override
    public void plan(ServerInterface srvInterface,
        NodeSpecifyingPlanContext planCtx) throws UdfException {

        String nodes; // stores the list of nodes that will load data

        // Get copy of the parameters the user supplied to the UDSOURCE
        // function call.
        ParamReader args = srvInterface.getParamReader();

        // A list of nodes that will perform work. This gets saved as part
        // of the plan context.
        ArrayList<String> executionNodes = new ArrayList<String>();

        // First, ensure the user supplied the file parameter
        if (!args.containsParameter("file")) {
            // Without a file parameter, we cannot continue. Throw an
            // exception that will be caught by the Java UDX framework.
            throw new UdfException(0, "You must supply a file parameter");
        }

        // If the user specified nodes to read the file, parse the
        // comma-separated list and save. Otherwise, assume just the
        // Initiator node has the file to read.
        if (args.containsParameter("nodes")) {
            nodes = args.getString("nodes");

            // Get list of nodes in cluster, to ensure that the node the
            // user specified actually exists. The list of nodes is available
            // from the planCtx (plan context) object.
            ArrayList<String> clusterNodes = planCtx.getClusterNodes();
```

```

String fileNames = params.getString("filesFor" + myName);

// Note that you can also be lazy and directly grab the parameters
// the user passed to the UDSource function in the COPY statement directly
// by getting parameters from the ServerInterface object. I.e.:

//String fileNames = srvInterface.getParamReader().getString("file");

// Split comma-separated list into a single list.
String[] fileList = fileNames.split(",");
for (int i = 0; i < fileList.length; i++){
    // Instantiate a FileSource object (which is a subclass of UDSource)
    // to read each file. The constructor for FileSource takes the
    // file name of the
    retVal.add(new FileSource(fileList[i]));
}

// Return the collection of FileSource objects. They will be called,
// in turn, to read each of the files.
return retVal;
}

// Declares which parameters that this factory accepts.
@Override
public void getParameterTypes(ServerInterface srvInterface,
                             SizedColumnTypes parameterTypes) {
    parameterTypes.addVarchar(65000, "file");
    parameterTypes.addVarchar(65000, "nodes");
}

```

User-defined filter

User-defined filter functions allow you to manipulate data obtained from a source in various ways. For example, a filter can:

- Process a compressed file in a compression format not natively supported by Vertica.
- Take UTF-16-encoded data and transcode it to UTF-8 encoding.
- Perform search-and-replace operations on data before it is loaded into Vertica.

You can also process data through multiple filters before it is loaded into Vertica. For instance, you could unzip a file compressed with GZip, convert the content from UTF-16 to UTF-8, and finally search and replace certain text strings.

If you implement a [UDFilter](#) , you must also implement a corresponding [FilterFactory](#) .

See [UDFilter class](#) and [FilterFactory class](#) for API details.

In this section

- [UDFilter class](#)
- [FilterFactory class](#)
- [Java example: ReplaceCharFilter](#)
- [C++ example: converting encoding](#)

UDFilter class

The [UDFilter](#) class is responsible for reading raw input data from a source and preparing it to be loaded into Vertica or processed by a parser. This preparation may involve decompression, re-encoding, or any other sort of binary manipulation.

A [UDFilter](#) is instantiated by a corresponding [FilterFactory](#) on each host in the Vertica cluster that is performing filtering for the data source.

UDFilter methods

Your [UDFilter](#) subclass must override [process\(\)](#) or [processWithMetadata\(\)](#) :

Note

`processWithMetadata()` is available only for user-defined extensions (UDxs) written in the C++ programming language.

- `process()` reads the raw input stream as one large file. If there are any errors or failures, the entire load fails. You can implement `process()` when the upstream source implements `processWithMetadata()`, but it might result in parsing errors.
- `processWithMetadata()` is useful when the data source has metadata about record boundaries available in some structured format that's separate from the data payload. With this interface, the source emits a record length for each record in addition to the data. By implementing `processWithMetadata()` instead of `process()` in each phase, you can retain this record length metadata throughout the load stack, which enables a more efficient parse that can recover from errors on a per-message basis, rather than a per-file or per-source basis. [KafkaSource](#) and the Kafka parsers ([KafkaAvroParser](#), [KafkaJSONParser](#), and [KafkaParser](#)) use this mechanism to support per-Kafka-message rejections when individual Kafka messages are corrupted. Using `processWithMetadata()` with your `UDFilter` subclass enables you to write an internal filter that integrates the record length metadata from the source into the data stream, producing a single byte stream with boundary information to help parsers extract and process individual messages. [KafkaInsertDelimiters](#) and [KafkaInsertLengths](#) use this mechanism to insert message boundary information into Kafka data streams.

Note

To implement `processWithMetadata()`, you must override `useSideChannel()` to return `true`.

Optionally, you can override other `UDFilter` class methods.

Filter execution

The following sections detail the execution sequence each time a user-defined filter is called. The following example overrides the `process()` method.

Setting Up

COPY calls `setup()` before the first time it calls `process()`. Use `setup()` to perform any necessary setup steps that your filter needs to operate, such as initializing data structures to be used during filtering. Your object might be destroyed and re-created during use, so make sure that your object is restartable.

Filtering Data

COPY calls `process()` repeatedly during query execution to filter data. The method receives two instances of the `DataBuffer` class among its parameters, an input and an output buffer. Your implementation should read from the input buffer, manipulate it in some manner (such as decompressing it), and write the result to the output. A one-to-one correlation between the number of bytes your implementation reads and the number it writes might not exist. The `process()` method should process data until it either runs out of data to read or runs out of space in the output buffer. When one of these conditions occurs, your method should return one of the following values defined by `StreamState`:

- `OUTPUT_NEEDED` if the filter needs more room in its output buffer.
- `INPUT_NEEDED` if the filter has run out of input data (but the data source has not yet been fully processed).
- `DONE` if the filter has processed all of the data in the data source.
- `KEEP_GOING` if the filter cannot proceed for an extended period of time. The method will be called again, so do not block indefinitely. If you do, then you prevent your user from canceling the query.

Before returning, your `process()` method must set the `offset` property in each `DataBuffer`. In the input buffer, set it to the number of bytes that the method successfully read. In the output buffer, set it to the number of bytes the method wrote. Setting these properties allows the next call to `process()` to resume reading and writing data at the correct points in the buffers.

Your `process()` method also needs to check the `InputState` object passed to it to determine if there is more data in the data source. When this object is equal to `END_OF_FILE`, then the data remaining in the input data is the last data in the data source. Once it has processed all of the remaining data, `process()` must return `DONE`.

Tearing Down

COPY calls `destroy()` after the last time it calls `process()`. This method frees any resources reserved by the `setup()` or `process()` methods. Vertica calls this method after the `process()` method indicates it has finished filtering all of the data in the data stream.

If there are still data sources that have not yet been processed, Vertica may later call `setup()` on the object again. On subsequent calls Vertica directs the method to filter the data in a new data stream. Therefore, your `destroy()` method should leave an object of your `UDFilter` subclass in a state where the `setup()` method can prepare it to be reused.

[C++](#)

[Java](#)

[Python](#)

The [UDFilter](#) API provides the following methods for extension by subclasses:

```
virtual void setup(ServerInterface &srvInterface);  
  
virtual bool useSideChannel();  
  
virtual StreamState process(ServerInterface &srvInterface, DataBuffer &input, InputState input_state, DataBuffer &output, LengthBuffer &output_lengths);  
  
virtual StreamState processWithMetadata(ServerInterface &srvInterface, DataBuffer &input, LengthBuffer &input_lengths, InputState input_state, DataBuffer &output, LengthBuffer &output_lengths)=0;  
  
virtual void cancel(ServerInterface &srvInterface);  
  
virtual void destroy(ServerInterface &srvInterface);
```

FilterFactory class

If you write a filter, you must also write a filter factory to produce filter instances. To do so, subclass the [FilterFactory](#) class.

Your subclass performs the initial validation and planning of the function execution and instantiates [UDFilter](#) objects on each host that will be filtering data.

Filter factories are singletons. Your subclass must be stateless, with no fields containing data. The subclass also must not modify any global variables.

FilterFactory methods

The [FilterFactory](#) class defines the following methods. Your subclass must override the [prepare\(\)](#) method. It may override the other methods.

Setting up

Vertica calls [plan\(\)](#) once on the initiator node, to perform the following tasks:

- Check any parameters that have been passed from the function call in the COPY statement and error messages if there are any issues. You read the parameters by getting a [ParamReader](#) object from the instance of [ServerInterface](#) passed into your [plan\(\)](#) method.
- Store any information that the individual hosts need in order to filter data in the [PlanContext](#) instance passed as a parameter. For example, you could store details of the input format that the filter will read and output the format that the filter should produce. The [plan\(\)](#) method runs only on the initiator node, and the [prepare\(\)](#) method runs on each host reading from a data source. Therefore, this object is the only means of communication between them.

You store data in the [PlanContext](#) by getting a [ParamWriter](#) object from the [getWriter\(\)](#) method. You then write parameters by calling methods on the [ParamWriter](#) such as [setString](#) .

Note

[ParamWriter](#) offers only the ability to store simple data types. For complex types, you need to serialize the data in some manner and store it as a string or long string.

Creating filters

Vertica calls [prepare\(\)](#) to create and initialize your filter. It calls this method once on each node that will perform filtering. Vertica automatically selects the best nodes to complete the work based on available resources. You cannot specify the nodes on which the work is done.

Defining parameters

Implement [getParameterTypes\(\)](#) to define the names and types of parameters that your filter uses. Vertica uses this information to warn callers about unknown or missing parameters. Vertica ignores unknown parameters and uses default values for missing parameters. While you should define the types and parameters for your function, you are not required to override this method.

[C++](#)

[Java](#)

[Python](#)

The [FilterFactory](#) API provides the following methods for extension by subclasses:

```
virtual void plan(ServerInterface &srvInterface, PlanContext &planCtx);  
  
virtual UDFilter * prepare(ServerInterface &srvInterface, PlanContext &planCtx)=0;  
  
virtual void getParameterType(ServerInterface &srvInterface, SizedColumnTypes &parameterTypes);
```

After creating your [FilterFactory](#) , you must register it with the [RegisterFactory](#) macro.

Java example: [ReplaceCharFilter](#)

The example in this section demonstrates creating a [UDFilter](#) that replaces any occurrences of a character in the input stream with another character in the output stream. This example is highly simplified and assumes the input stream is ASCII data.

Always remember that the input and output streams in a [UDFilter](#) are actually binary data. If you are performing character transformations using a [UDFilter](#) , convert the data stream from a string of bytes into a properly encoded string. For example, your input stream might consist of UTF-8 encoded text. If so, be sure to transform the raw binary being read from the buffer into a UTF string before manipulating it.

Loading and using the example

The example [UDFilter](#) has two required parameters. The [from_char](#) parameter specifies the character to be replaced, and the [to_char](#) parameter specifies the replacement character. Load and use the [ReplaceCharFilter](#) UDFilter as follows:

```

=> CREATE LIBRARY JavaLib AS '/home/dbadmin/JavaUDLib.jar'
->LANGUAGE 'JAVA';
CREATE LIBRARY
=> CREATE FILTER ReplaceCharFilter as LANGUAGE 'JAVA'
->name 'com.mycompany.UDL.ReplaceCharFilterFactory' library JavaLib;
CREATE FILTER FUNCTION
=> CREATE TABLE t (text VARCHAR);
CREATE TABLE
=> COPY t FROM STDIN WITH FILTER ReplaceCharFilter(from_char='a', to_char='z');
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> Mary had a little lamb
>> a man, a plan, a canal, Panama
>> \.

=> SELECT * FROM t;
      text
-----
Mzry hzd z little lzmb
z mzn, z plzn, z cznzl, Pznmz
(2 rows)

=> --Calling the filter with incorrect parameters returns errors
=> COPY t from stdin with filter ReplaceCharFilter();
ERROR 3399: Failure in UDx RPC call InvokePlanUDL(): Error in User Defined Object [
ReplaceCharFilter], error code: 0

```

Parser implementation

The [ReplaceCharFilter](#) class reads the data stream, replacing each occurrence of a user-specified character with another character.

Factory implementation

ReplaceCharFilterFactory requires two parameters (**from_char** and **to_char**). The **plan()** method verifies that these parameters exist and are single-character strings. The method then stores them in the plan context. The **prepare()** method gets the parameter values and passes them to the **ReplaceCharFilter** objects, which it instantiates, to perform the filtering.

```
package com.vertica.JavaLibs;

import java.util.ArrayList;
import java.util.Vector;

import com.vertica.sdk.FilterFactory;
import com.vertica.sdk.PlanContext;
import com.vertica.sdk.ServerInterface;
import com.vertica.sdk.SizedColumnTypes;
import com.vertica.sdk.UDFilter;
import com.vertica.sdk.UdfException;

public class ReplaceCharFilterFactory extends FilterFactory {

    // Run on the initiator node to perform verification and basic setup.
    @Override
    public void plan(ServerInterface srvInterface, PlanContext planCtx)
        throws UdfException {
        ArrayList<String> args =
            srvInterface.getParamReader().getParamNames();

        // Ensure user supplied two arguments
        if (!(args.contains("from_char") && args.contains("to_char"))) {
            throw new UdfException(0, "You must supply two parameters" +
                " to ReplaceChar: 'from_char' and 'to_char'");
        }

        // Verify that the from_char is a single character.
        String fromChar = srvInterface.getParamReader().getString("from_char");
        if (fromChar.length() != 1) {
            String message = String.format("Replacechar expects a single " +
                "character in the 'from_char' parameter. Got length %d",
                fromChar.length());
            throw new UdfException(0, message);
        }

        // Save the from character in the plan context, to be read by
        // prepare() method.
        planCtx.getWriter().setString("fromChar", fromChar);

        // Ensure to character parameter is a single character
        String toChar = srvInterface.getParamReader().getString("to_char");
        if (toChar.length() != 1) {
            String message = String.format("Replacechar expects a single " +
                "character in the 'to_char' parameter. Got length %d",
                toChar.length());
            throw new UdfException(0, message);
        }

        // Save the to character in the plan data
        planCtx.getWriter().setString("toChar", toChar);
    }

    // Called on every host that will filter data. Must instantiate the
    // UDFilter subclass.
    @Override
    public UDFilter prepare(ServerInterface srvInterface, PlanContext planCtx)
```

```

        throws UdiException {
// Get data stored in the context by the plan() method.
String fromChar = planCtxt.getWriter().getString("fromChar");
String toChar = planCtxt.getWriter().getString("toChar");

// Instantiate a filter object to perform filtering.
return new ReplaceCharFilter(fromChar, toChar);
}

// Describe the parameters accepted by this filter.
@Override
public void getParameterType(ServerInterface srvInterface,
        SizedColumnTypes parameterTypes) {
    parameterTypes.addVarchar(1, "from_char");
    parameterTypes.addVarchar(1, "to_char");
}
}

```

C++ example: converting encoding

The following example shows how you can convert encoding for a file from one type to another by converting UTF-16 encoded data to UTF-8. You can find this example in the SDK at </opt/vertica/sdk/examples/FilterFunctions/IConverter.cpp> .

Filter implementation

```

class Iconverter : public UDFilter{
private:
    std::string fromEncoding, toEncoding;
    iconv_t cd; // the conversion descriptor opened
    uint converted; // how many characters have been converted
protected:
    virtual StreamState process(ServerInterface &srvInterface, DataBuffer &input,
        InputState input_state, DataBuffer &output)
    {
        char *input_buf = (char *)input.buf + input.offset;
        char *output_buf = (char *)output.buf + output.offset;
        size_t inBytesLeft = input.size - input.offset, outBytesLeft = output.size - output.offset;
        // end of input
        if (input_state == END_OF_FILE && inBytesLeft == 0)
        {
            // Gnu libc iconv doc says, it is good practice to finalize the
            // outbuffer for stateful encodings (by calling with null inbuffer).
            //
            // http://www.gnu.org/software/libc/manual/html_node/Generic-Conversion-Interface.html
            iconv(cd, NULL, NULL, &output_buf, &outBytesLeft);
            // output buffer can be updated by this operation
            output.offset = output.size - outBytesLeft;
            return DONE;
        }
        size_t ret = iconv(cd, &input_buf, &inBytesLeft, &output_buf, &outBytesLeft);
        // if conversion is successful, we ask for more input, as input has not reached EOF.
        StreamState retStatus = INPUT_NEEDED;
        if (ret == (size_t)(-1))
        {
            // seen an error
            switch (errno)
            {
                {
            case E2BIG:
                // input size too big, not a problem, ask for more output.
                retStatus = OUTPUT_NEEDED;
                break;
            case EINVAL:

```

```

    // input stops in the middle of a byte sequence, not a problem, ask for more input
    retStatus = input_state == END_OF_FILE ? DONE : INPUT_NEEDED;
    break;
case EILSEQ:
    // invalid sequence seen, throw
    // TODO: reporting the wrong byte position
    vt_report_error(1, "Invalid byte sequence when doing %u-th conversion", converted);
case EBADF:
    // something wrong with descriptor, throw
    vt_report_error(0, "Invalid descriptor");
default:
    vt_report_error(0, "Uncommon Error");
    break;
}
}
else converted += ret;
// move position pointer
input.offset = input.size - inBytesLeft;
output.offset = output.size - outBytesLeft;
return retStatus;
}
public:
    lconverter(const std::string &from, const std::string &to)
        : fromEncoding(from), toEncoding(to), converted(0)
    {
        // note "to encoding" is first argument to iconv...
        cd = iconv_open(to.c_str(), from.c_str());
        if (cd == (iconv_t)(-1))
        {
            // error when creating converters.
            vt_report_error(0, "Error initializing iconv: %m");
        }
    }
    ~lconverter()
    {
        // free iconv resources;
        iconv_close(cd);
    }
};

```

Factory implementation

```

class IconverterFactory : public FilterFactory{
public:
    virtual void plan(ServerInterface &srvInterface,
        PlanContext &planCtxt) {
        std::vector<std::string> args = srvInterface.getParamReader().getParamNames();
        /* Check parameters */
        if (!(args.size() == 0 ||
            (args.size() == 1 && find(args.begin(), args.end(), "from_encoding")
                != args.end()) || (args.size() == 2
                && find(args.begin(), args.end(), "from_encoding") != args.end()
                && find(args.begin(), args.end(), "to_encoding") != args.end())) {
            vt_report_error(0, "Invalid arguments. Must specify either no arguments, or "
                "'from_encoding' alone, or 'from_encoding' and 'to_encoding'.");
        }
        /* Populate planData */
        // By default, we do UTF16->UTF8, and x->UTF8
        VString from_encoding = planCtxt.getWriter().getStringRef("from_encoding");
        VString to_encoding = planCtxt.getWriter().getStringRef("to_encoding");
        from_encoding.copy("UTF-16");
        to_encoding.copy("UTF-8");
        if (args.size() == 2)
        {
            from_encoding.copy(srvInterface.getParamReader().getStringRef("from_encoding"));
            to_encoding.copy(srvInterface.getParamReader().getStringRef("to_encoding"));
        }
        else if (args.size() == 1)
        {
            from_encoding.copy(srvInterface.getParamReader().getStringRef("from_encoding"));
        }
        if (!from_encoding.length()) {
            vt_report_error(0, "The empty string is not a valid from_encoding value");
        }
        if (!to_encoding.length()) {
            vt_report_error(0, "The empty string is not a valid to_encoding value");
        }
    }
    virtual UDFilter* prepare(ServerInterface &srvInterface,
        PlanContext &planCtxt) {
        return vt_createFuncObj(srvInterface.allocator, Iconverter,
            planCtxt.getReader().getStringRef("from_encoding").str(),
            planCtxt.getReader().getStringRef("to_encoding").str());
    }
    virtual void getParameterType(ServerInterface &srvInterface,

        parameterTypes.addVarchar(32, "to_encoding");
    }
};
RegisterFactory(IconverterFactory);

```

User-defined parser

A parser takes a stream of bytes and passes a corresponding sequence of tuples to the Vertica load process. You can use user-defined parser functions to parse:

- Data in formats not understood by the Vertica built-in parser.
- Data that requires more specific control than the built-in parser supplies.

For example, you can load a CSV file using a specific CSV library. See the Vertica SDK for two CSV examples.

[COPY](#) supports a single user-defined parser that you can use with a [user-defined source](#) and zero or more instances of a [user-defined filter](#). If you implement a [UDParser class](#), you must also implement a corresponding [ParserFactory](#).

Sometimes, you can improve the performance of your parser by adding a *chunker*. A chunker divides up the input and uses multiple threads to parse it. Chunkers are available only in the C++ API. For details, see [Cooperative parse](#) and [UDChunker class](#). Under special circumstances you can further improve performance by using [apportioned load](#), an approach where multiple Vertica nodes parse the input.

In this section

- [UDParser class](#)
- [UDChunker class](#)
- [ParserFactory class](#)

UDParser class

You can subclass the `UDParser` class when you need to parse data that is in a format that the COPY statement's native parser cannot handle.

During parser execution, Vertica always calls three methods: `setup()`, `process()`, and `destroy()`. It might also call `getRejectedRecord()`.

UDParser constructor

The `UDParser` class performs important initialization required by all subclasses, including initializing the `StreamWriter` object used by the parser. Therefore, your constructor must call `super()`.

UDParser methods

Your `UDParser` subclass must override `process()` or `processWithMetadata()`:

Note

`processWithMetadata()` is available only for user-defined extensions (UDxs) written in the C++ programming language.

- `process()` reads the raw input stream as one large file. If there are any errors or failures, the entire load fails. You can implement `process()` with a source or filter that implements `processWithMetadata()`, but it might result in parsing errors. You can implement `process()` when the upstream source or filter implements `processWithMetadata()`, but it might result in parsing errors.
- `processWithMetadata()` is useful when the data source has metadata about record boundaries available in some structured format that's separate from the data payload. With this interface, the source emits a record length for each record in addition to the data. By implementing `processWithMetadata()` instead of `process()` in each phase, you can retain this record length metadata throughout the load stack, which enables a more efficient parse that can recover from errors on a per-message basis, rather than a per-file or per-source basis. [KafkaSource](#) and Kafka parsers ([KafkaAvroParser](#), [KafkaJSONParser](#), and [KafkaParser](#)) use this mechanism to support per-Kafka-message rejections when individual Kafka messages are corrupted.

Note

To implement `processWithMetadata()`, you must override `useSideChannel()` to return `true`.

Additionally, you must override `getRejectedRecord()` to return information about rejected records.

Optionally, you can override the other `UDParser` class methods.

Parser execution

The following sections detail the execution sequence each time a user-defined parser is called. The following example overrides the `process()` method.

Setting up

COPY calls `setup()` before the first time it calls `process()`. Use `setup()` to perform any initial setup tasks that your parser needs to parse data. This setup includes retrieving parameters from the class context structure or initializing data structures for use during filtering. Vertica calls this method before calling the `process()` method for the first time. Your object might be destroyed and re-created during use, so make sure that your object is restartable.

Parsing

COPY calls `process()` repeatedly during query execution. Vertica passes this method a buffer of data to parse into columns and rows and one of the following input states defined by `InputState` :

- **OK** : currently at the start of or in the middle of a stream
- **END_OF_FILE** : no further data is available.
- **END_OF_CHUNK** : the current data ends on a record boundary and the parser should consume all of it before returning. This input state only occurs when using a chunker.
- **START_OF_PORTION** : the input does not start at the beginning of a source. The parser should find the first end-of-record mark. This input state only occurs when using apportioned load. You can use the `getPortion()` method to access the offset and size of the portion.
- **END_OF_PORTION** : the source has reached the end of its portion. The parser should finish processing the last record it started and advance no further. This input state only occurs when using apportioned load.

The parser must reject any data that it cannot parse, so that Vertica can report the rejection and write the rejected data to files.

The `process()` method must parse as much data as it can from the input buffer. The buffer might not end on a row boundary. Therefore, it might have to stop parsing in the middle of a row of input and ask for more data. The input can contain null bytes, if the source file contains them, and is *not* automatically null-terminated.

A parser has an associated `StreamWriter` object, which performs the actual writing of the data. When your parser extracts a column value, it uses one of the type-specific methods on `StreamWriter` to write that value to the output stream. See [Writing Data](#) for more information about these methods.

A single call to `process()` might write several rows of data. When your parser finishes processing a row of data, it must call `next()` on its `StreamWriter` to advance the output stream to a new row. (Usually a parser finishes processing a row because it encounters an end-of-row marker.)

When your `process()` method reaches the end of the buffer, it tells Vertica its current state by returning one of the following values defined by `StreamState` :

- **INPUT_NEEDED** : the parser has reached the end of the buffer and needs more data to parse.
- **DONE** : the parser has reached the end of the input data stream.
- **REJECT** : the parser has rejected the last row of data it read (see [Rejecting Rows](#)).

Tearing down

COPY calls `destroy()` after the last time that `process()` is called. It frees any resources reserved by the `setup()` or `process()` method.

Vertica calls this method after the `process()` method indicates it has completed parsing the data source. However, sometimes data sources that have not yet been processed might remain. In such cases, Vertica might later call `setup()` on the object again and have it parse the data in a new data stream. Therefore, write your `destroy()` method so that it leaves an instance of your `UDParser` subclass in a state where `setup()` can be safely called again.

Reporting rejections

If `process()` rejects a row, Vertica calls `getRejectedRecord()` to report it. Usually, this method returns an instance of the `RejectedRecord` class with details of the rejected row.

Writing data

A parser has an associated `StreamWriter` object, which you access by calling `getStreamWriter()` . In your `process()` implementation, use the `set Type ()` methods on the `StreamWriter` object to write values in a row to specific column indexes. Verify that the data types you write match the data types expected by the schema.

The following example shows how you can write a value of type `long` to the fourth column (index 3) in the current row:

```
StreamWriter writer = getStreamWriter();
...
writer.setLongValue(3, 98.6);
```

`StreamWriter` provides methods for all the basic types, such as `setBooleanValue()` , `setStringValue()` , and so on. See the API documentation for a complete list of `StreamWriter` methods, including options that take primitive types or explicitly set entries to null.

Rejecting rows

If your parser finds data it cannot parse, it should reject the row by:

1. Saving details about the rejected row data and the reason for the rejection. These pieces of information can be directly stored in a `RejectedRecord` object, or in fields on your `UDParser` subclass, until they are needed.
2. Updating the row's position in the input buffer by updating `input.offset` so it can resume parsing with the next row.

3. Signaling that it has rejected a row by returning with the value `StreamState.REJECT`.
4. Returning an instance of the `RejectedRecord` class with the details about the rejected row.

Breaking up large loads

Vertica provides two ways to break up large loads. [Apportioned load](#) allows you to distribute a load among several database nodes. [Cooperative parse](#) (C++ only) allows you to distribute a load among several threads on one node.

API

[C++](#)

[Java](#)

[Python](#)

The `UDParser` API provides the following methods for extension by subclasses:

```
virtual void setup(ServerInterface &srvInterface, SizedColumnTypes &returnType);

virtual bool useSideChannel();

virtual StreamState process(ServerInterface &srvInterface, DataBuffer &input, InputState input_state)=0;

virtual StreamState processWithMetadata(ServerInterface &srvInterface, DataBuffer &input,
                                         LengthBuffer &input_lengths, InputState input_state)=0;

virtual void cancel(ServerInterface &srvInterface);

virtual void destroy(ServerInterface &srvInterface, SizedColumnTypes &returnType);

virtual RejectedRecord getRejectedRecord();
```

UDChunker class

You can subclass the `UDChunker` class to allow your parser to support [Cooperative parse](#). This class is available only in the C++ API.

Fundamentally, a `UDChunker` is a very simplistic parser. Like `UDParser`, it has the following three methods: `setup()`, `process()`, and `destroy()`. You must override `process()`; you may override the others. This class has one additional method, `alignPortion()`, which you must implement if you want to enable [Apportioned load](#) for your `UDChunker`.

Setting up and tearing down

As with `UDParser`, you can define initialization and cleanup code for your chunker. Vertica calls `setup()` before the first call to `process()` and `destroy()` after the last call to `process()`. Your object might be reused among multiple load sources, so make sure that `setup()` completely initializes all fields.

Chunking

Vertica calls `process()` to divide an input into chunks that can be parsed independently. The method takes an input buffer and an indicator of the input state:

- `OK`: the input buffer begins at the start of or in the middle of a stream.
- `END_OF_FILE`: no further data is available.
- `END_OF_PORTION`: the source has reached the end of its portion. This state occurs only when using apportioned load.

If the input state is `END_OF_FILE`, the chunker should set the `input.offset` marker to `input.size` and return `DONE`. Returning `INPUT_NEEDED` is an error.

If the input state is `OK`, the chunker should read data from the input buffer and find record boundaries. If it finds the end of at least one record, it should align the `input.offset` marker with the byte after the end of the last record in the buffer and return `CHUNK_ALIGNED`. For example, if the input is "abc~def" and "~" is a record terminator, this method should set `input.offset` to 4, the position of "d". If `process()` reaches the end of the input without finding a record boundary, it should return `INPUT_NEEDED`.

You can divide the input into smaller chunks, but consuming all available records in the input can have better performance. For example, a chunker could scan backwards from the end of the input to find a record terminator, which might be the last of many records in the input, and return it all as one chunk without scanning through the rest of the input.

If the input state is `END_OF_PORTION`, the chunker should behave as it does for an input state of `OK`, except that it should also set a flag. When called again, it should find the first record in the next portion and align the chunk to that record.

The input data can contain null bytes, if the source file contains them. The input argument is not automatically null-terminated.

The `process()` method must not block indefinitely. If this method cannot proceed for an extended period of time, it should return `KEEP_GOING`. Failing to return `KEEP_GOING` has several consequences, such as preventing your user from being able to cancel the query.

See [C++ example: delimited parser and chunker](#) for an example of the `process()` method using chunking.

Aligning portions

If your chunker supports apportioned load, implement the `alignPortion()` method. Vertica calls this method one or more times, before calling `process()`, to align the input offset with the beginning of the first complete chunk in the portion. The method takes an input buffer and an indicator of the input state:

- `START_OF_PORTION`: the beginning of the buffer corresponds to the start of the portion. You can use the `getPortion()` method to access the offset and size of the portion.
- `OK`: the input buffer is in the middle of a portion.
- `END_OF_PORTION`: the end of the buffer corresponds to the end of the portion or beyond the end of a portion.
- `END_OF_FILE`: no further data is available.

The method should scan from the beginning of the buffer to the start of the first complete record. It should set `input.offset` to this position and return one of the following values:

- `DONE`, if it found a chunk. `input.offset` is the first byte of the chunk.
- `INPUT_NEEDED`, if the input buffer does not contain the start of any chunk. It is an error to return this from an input state of `END_OF_FILE`.
- `REJECT`, if the portion (not buffer) does not contain the start of any chunk.

API

The [UDChunker](#) API provides the following methods for extension by subclasses:

```
virtual void setup(ServerInterface &svInterface,
                  SizedColumnTypes &returnType);

virtual StreamState alignPortion(ServerInterface &svInterface,
                                DataBuffer &input, InputState state);

virtual StreamState process(ServerInterface &svInterface,
                            DataBuffer &input, InputState input_state)=0;

virtual void cancel(ServerInterface &svInterface);

virtual void destroy(ServerInterface &svInterface,
                    SizedColumnTypes &returnType);
```

ParserFactory class

If you write a parser, you must also write a factory to produce parser instances. To do so, subclass the `ParserFactory` class.

Parser factories are singletons. Your subclass must be stateless, with no fields containing data. Your subclass also must not modify any global variables.

The `ParserFactory` class defines the following methods. Your subclass must override the `prepare()` method. It may override the other methods.

Setting up

Vertica calls `plan()` once on the initiator node to perform the following tasks:

- Check any parameters that have been passed from the function call in the COPY statement and error messages if there are any issues. You read the parameters by getting a `ParamReader` object from the instance of `ServerInterface` passed into your `plan()` method.
- Store any information that the individual hosts need in order to parse the data. For example, you could store parameters in the `PlanContext`

instance passed in through the `planCtxt` parameter. The `plan()` method runs only on the initiator node, and the `prepareUDSources()` method runs on each host reading from a data source. Therefore, this object is the only means of communication between them. You store data in the `PlanContext` by getting a `ParamWriter` object from the `getWriter()` method. You then write parameters by calling methods on the `ParamWriter` such as `setString`.

Note

`ParamWriter` offers only the ability to store simple data types. For complex types, you need to serialize the data in some manner and store it as a string or long string.

Creating parsers

Vertica calls `prepare()` on each node to create and initialize your parser, using data stored by the `plan()` method.

Defining parameters

Implement `getParameterTypes()` to define the names and types of parameters that your parser uses. Vertica uses this information to warn callers about unknown or missing parameters. Vertica ignores unknown parameters and uses default values for missing parameters. While you should define the types and parameters for your function, you are not required to override this method.

Defining parser outputs

Implement `getParserReturnType()` to define the data types of the table columns that the parser outputs. If applicable, `getParserReturnType()` also defines the size, precision, or scale of the data types. Usually, this method reads data types of the output table from the `argType` and `perColumnParamReader` arguments and verifies that it can output the appropriate data types. If `getParserReturnType()` is prepared to output the data types, it calls methods on the `SizedColumnTypes` object passed in the `returnType` argument. In addition to the data type of the output column, your method should also specify any additional information about the column's data type:

- For binary and string data types (such as CHAR, VARCHAR, and LONG VARBINARY), specify its maximum length.
- For NUMERIC types, specify its precision and scale.
- For Time/Timestamp types (with or without time zone), specify its precision (-1 means unspecified).
- For ARRAY types, specify the maximum number of elements.
- For all other types, no length or precision specification is required.

Supporting cooperative parse

To support [Cooperative parse](#), implement `prepareChunker()` and return an instance of your `UDChunker` subclass. If `isChunkerApportionable()` returns `true`, then it is an error for this method to return null.

Cooperative parse is currently supported only in the C++ API.

Supporting apportioned load

To support [Apportioned load](#), your parser, chunker, or both must support apportioning. To indicate that the parser can apportion a load, implement `isParserApportionable()` and return `true`. To indicate that the chunker can apportion a load, implement `isChunkerApportionable()` and return `true`.

The `isChunkerApportionable()` method takes a `ServerInterface` as an argument, so you have access to the parameters supplied in the COPY statement. You might need this information if the user can specify a record delimiter, for example. Return `true` from this method if and only if the factory can create a chunker for this input.

API

[C++](#)

[Java](#)

[Python](#)

The [ParserFactory](#) API provides the following methods for extension by subclasses:

```
virtual void plan(ServerInterface &srvInterface, PerColumnParamReader &perColumnParamReader, PlanContext &planContext, const SizedColumnTypes &returnTypes)=0;

virtual UDFParser * prepare(ServerInterface &srvInterface, PerColumnParamReader &perColumnParamReader, PlanContext &planCtx, const SizedColumnTypes &returnTypes)=0;

virtual void getParameterType(ServerInterface &srvInterface, SizedColumnTypes &parameterTypes);

virtual void getParserReturnType(ServerInterface &srvInterface, PerColumnParamReader &perColumnParamReader, PlanContext &planCtx, const SizedColumnTypes &argTypes, SizedColumnTypes &returnTypes);

virtual bool isParserApportionable();

// C++ API only:
virtual bool isChunkerApportionable(ServerInterface &srvInterface);

virtual UDChunker * prepareChunker(ServerInterface &srvInterface, PerColumnParamReader &perColumnParamReader, PlanContext &planCtx, const SizedColumnTypes &returnTypes);
```

If you are using [Apportioned load](#) to divide a single input into multiple load streams, implement [isParserApportionable\(\)](#) and/or [isChunkerApportionable\(\)](#) and return **true** . Returning **true** from these methods does not guarantee that Vertica *will* apportion the load. However, returning **false** from both indicates that it will not try to do so.

If you are using [Cooperative parse](#) , implement [prepareChunker\(\)](#) and return an instance of your [UDChunker](#) subclass. Cooperative parse is supported only for the C++ API.

Vertica calls the [prepareChunker\(\)](#) method *only* for unfenced functions. This method is not available when you use the function in fenced mode.

If you want your chunker to be available for apportioned load, implement [isChunkerApportionable\(\)](#) and return **true** .

After creating your [ParserFactory](#) , you must register it with the [RegisterFactory](#) macro.

C++ example: BasicIntegerParser

The [BasicIntegerParser](#) example parses a string of integers separated by non-numeric characters. For a version of this parser that uses continuous load, see [C++ example: ContinuousIntegerParser](#) .

Loading and using the example

Load and use the [BasicIntegerParser](#) example as follows.

```
=> CREATE LIBRARY BasicIntegerParserLib AS '/home/dbadmin/BIP.so';

=> CREATE PARSE BasicIntegerParser AS
LANGUAGE 'C++' NAME 'BasicIntegerParserFactory' LIBRARY BasicIntegerParserLib;

=> CREATE TABLE t (i integer);

=> COPY t FROM stdin WITH PARSE BasicIntegerParser();
0
1
2
3
4
5
\.
```

Implementation

The `BasicIntegerParser` class implements only the `process()` method from the API. (It also implements a helper method for type conversion.) This method processes each line of input, looking for numbers on each line. When it advances to a new line it moves the `input.offset` marker and checks the input state. It then writes the output.

```
virtual StreamState process(ServerInterface &srvInterface, DataBuffer &input,
    InputState input_state) {
    // WARNING: This implementation is not trying for efficiency.
    // It is trying for simplicity, for demonstration purposes.

    size_t start = input.offset;
    const size_t end = input.size;

    do {
        bool found_newline = false;
        size_t numEnd = start;
        for (; numEnd < end; numEnd++) {
            if (input.buf[numEnd] < '0' || input.buf[numEnd] > '9') {
                found_newline = true;
                break;
            }
        }

        if (!found_newline) {
            input.offset = start;
            if (input_state == END_OF_FILE) {
                // If we're at end-of-file,
                // emit the last integer (if any) and return DONE.
                if (start != end) {
                    writer->setInt(0, strToInt(input.buf + start, input.buf + numEnd));
                    writer->next();
                }
                return DONE;
            } else {
                // Otherwise, we need more data.
                return INPUT_NEEDED;
            }
        }

        writer->setInt(0, strToInt(input.buf + start, input.buf + numEnd));
        writer->next();

        start = numEnd + 1;
    } while (true);
}
```

In the factory, the `plan()` method is a no-op; there are no parameters to check. The `prepare()` method instantiates the parser using the macro provided by the SDK:

```
virtual UDParser* prepare(ServerInterface &srvInterface,
    PerColumnParamReader &perColumnParamReader,
    PlanContext &planCtx,
    const SizedColumnTypes &returnType) {

    return vt_createFuncObject<BasicIntegerParser>(srvInterface.allocator);
}
```

The `getParserReturnType()` method declares the single output:

```

virtual void getParserReturnType(ServerInterface &srvInterface,
    PerColumnParamReader &perColumnParamReader,
    PlanContext &planCtx,
    const SizedColumnTypes &argTypes,
    SizedColumnTypes &returnType) {
    // We only and always have a single integer column
    returnType.addInt(argTypes.getColumn(0));
}

```

As for all UDxs written in C++, the example ends by registering its factory:

```
registerFactory(BasicIntegerParserFactory);
```

C++ example: ContinuousIntegerParser

The [ContinuousIntegerParser](#) example is a variation of [BasicIntegerParser](#) . Both examples parse integers from input strings. [ContinuousIntegerParser](#) uses [Continuous load](#) to read data.

Loading and using the example

Load the [ContinuousIntegerParser](#) example as follows.

```

=> CREATE LIBRARY ContinuousIntegerParserLib AS '/home/dbadmin/CIP.so';

=> CREATE PARSE ContinuousIntegerParser AS
LANGUAGE 'C++' NAME 'ContinuousIntegerParserFactory'
LIBRARY ContinuousIntegerParserLib;

```

Use it in the same way that you use [BasicIntegerParser](#) . See [C++ example: BasicIntegerParser](#) .

Implementation

[ContinuousIntegerParser](#) is a subclass of [ContinuousUDParser](#) . Subclasses of [ContinuousUDParser](#) place the processing logic in the `run()` method.

```

virtual void run() {

    // This parser assumes a single-column input, and
    // a stream of ASCII integers split by non-numeric characters.
    size_t pos = 0;
    size_t reserved = cr.reserve(pos+1);
    while (!cr.isEof() || reserved == pos + 1) {
        while (reserved == pos + 1 && isdigit(*ptr(pos))) {
            pos++;
            reserved = cr.reserve(pos + 1);
        }

        std::string st(ptr(), pos);
        writer->setInt(0, strToInt(st));
        writer->next();

        while (reserved == pos + 1 && !isdigit(*ptr(pos))) {
            pos++;
            reserved = cr.reserve(pos + 1);
        }
        cr.seek(pos);
        pos = 0;
        reserved = cr.reserve(pos + 1);
    }
}

```

For a more complex example of a [ContinuousUDParser](#) , see [ExampleDelimitedParser](#) in the examples. (See [Downloading and running Udx example code](#).) [ExampleDelimitedParser](#) uses a chunker; see [C++ example: delimited parser and chunker](#) .

Java example: numeric text

This `NumericTextParser` example parses integer values spelled out in words rather than digits (for example "one two three" for one-hundred twenty three). The parser:

- Accepts a single parameter to set the character that separates columns in a row of data. The separator defaults to the pipe (|) character.
- Ignores extra spaces and the capitalization of the words used to spell out the digits.
- Recognizes the digits using the following words: zero, one, two, three, four, five, six, seven, eight, nine.
- Assumes that the words spelling out an integer are separated by at least one space.
- Rejects any row of data that cannot be completely parsed into integers.
- Generates an error, if the output table has a non-integer column.

Loading and using the example

Load and use the parser as follows:

```
=> CREATE LIBRARY JavaLib AS '/home/dbadmin/JavaLib.jar' LANGUAGE 'JAVA';
CREATE LIBRARY

=> CREATE PARSEr NumericTextParser AS LANGUAGE 'java'
->   NAME 'com.myCompany.UDParser.NumericTextParserFactory'
->   LIBRARY JavaLib;
CREATE PARSEr FUNCTION
=> CREATE TABLE t (i INTEGER);
CREATE TABLE
=> COPY t FROM STDIN WITH PARSEr NumericTextParser();
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.

```

Parser implementation

The following code implements the parser.

```

    }
    return value;
}

// Vertica calls this method if the parser rejected a row of data
// to find out what went wrong and add to the proper logs. Just gathers
// information stored in fields and returns it in an object.
@Override
public RejectedRecord getRejectedRecord() throws UdfException {
    return new RejectedRecord(rejectedReason,rejectedRow.toCharArray(),
        rejectedRow.length(), "\n");
}

```

ParserFactory implementation

The following code implements the parser factory.

NumericTextParser accepts a single optional parameter named **separator** . This parameter is defined in the **getParameterType()** method, and the **plan()** method stores its value. **NumericTextParser** outputs only integer values. Therefore, if the output table contains a column whose data type is not integer, the **getParserReturnType()** method throws an exception.

```

public UDXParser prepare(ServerInterface srvInterface,
    PerColumnParamReader perColumnParamReader, PlanContext planCtxt,
    SizedColumnTypes returnType) throws UdfException {
    // Get the separator character from the context
    String separator = planCtxt.getReader().getString("separator");
    return new NumericTextParser(separator);
}

// Describe the parameters accepted by this parser.
@Override
public void getParameterType(ServerInterface srvInterface,
    SizedColumnTypes parameterTypes) {
    parameterTypes.addVarchar(1, "separator");
}
}

```

Java example: JSON parser

The JSON Parser consumes a stream of JSON objects. Each object must be well formed and on a single line in the input. Use line breaks to delimit the objects. The parser uses the field names as keys in a map, which become column names in the table. You can find the code for this example in `/opt/vertica/packages/flexible/examples`. This directory also contains an example data file.

This example uses the `setRowFromMap()` method to write data.

Loading and using the example

Load the library and define the JSON parser, using the third-party library ([gson-2.2.4.jar](#)) as follows. See the comments in `JsonParser.java` for a download URL:

```
-> CREATE LIBRARY json
-> AS '/opt/vertica/packages/flexible/examples/java/output/json.jar'
-> DEPENDS '/opt/vertica/bin/gson-2.2.4.jar' language 'java';
CREATE LIBRARY

-> CREATE PARSEr JsonParser AS LANGUAGE 'java'
-> NAME 'com.vertica.flex.JsonParserFactory' LIBRARY json;
CREATE PARSEr FUNCTION
```

You can now define a table and then use the JSON parser to load data into it, as follows:

```
-> CREATE TABLE mountains(name varchar(64), type varchar(32), height integer);
CREATE TABLE

-> COPY mountains FROM '/opt/vertica/packages/flexible/examples/mountains.json'
-> WITH PARSEr JsonParser();
{ RECORD 1 }--
Rows Loaded | 2

-> SELECT * from mountains;
{ RECORD 1 }-----
name | Everest
type | mountain
height | 29029
{ RECORD 2 }-----
name | Mt St Helens
type | volcano
height |
```

The data file contains a value (`hike_safety`) that was not loaded because the table definition did not include that column. The data file follows:

```
{ "name": "Everest", "type": "mountain", "height": 29029, "hike_safety": 34.1 }
{ "name": "Mt St Helens", "type": "volcano", "hike_safety": 15.4 }
```

Implementation

The following code shows the `process()` method from `JsonParser.java`. The parser attempts to read the input into a `Map`. If the read is successful, the JSON Parser calls `setRowFromMap()` :

```

@Override
public StreamState process(ServerInterface srvInterface, DataBuffer input,
    InputState inputState) throws UdfException, DestroyInvocation {
    clearReject();
    StreamWriter output = getStreamWriter();

    while (input.offset < input.buf.length) {
        ByteBuffer lineBytes = consumeNextLine(input, inputState);

        if ((lineBytes == null) {
            return StreamState.INPUT_NEEDED;
        }

        String lineString = StringUtils.newString(lineBytes);

        try {
            Map<String, Object> map = gson.fromJson(lineString, parseType);

            if (map == null) {
                continue;
            }

            output.setRowFromMap(map);
            // No overrides needed, so just call next() here.
            output.next();
        } catch (Exception ex) {
            setReject(lineString, ex);
            return StreamState.REJECT;
        }
    }
}

```

The factory, `JsonParserFactory.java`, instantiates and returns a parser in the `prepare()` method. No additional setup is required.

C++ example: delimited parser and chunker

The `ExampleDelimitedUDChunker` class divides an input at delimiter characters. You can use this chunker with any parser that understands delimited input. `ExampleDelimitedParser` is a `ContinuousUDParser` subclass that uses this chunker.

Loading and using the example

Load and use the example as follows.

```

=> CREATE LIBRARY ExampleDelimitedParserLib AS '/home/dbadmin/EDP.so';

=> CREATE PARSE ExampleDelimitedParser AS
LANGUAGE 'C++' NAME 'DelimitedParserFrameworkExampleFactory'
LIBRARY ExampleDelimitedParserLib;

=> COPY t FROM stdin WITH PARSE ExampleDelimitedParser();
0
1
2
3
4
5
6
7
8
9
\.
```

Chunker implementation

This chunker supports apportioned load. The `alignPortion()` method finds the beginning of the first complete record in the current portion and aligns the input buffer with it. The record terminator is passed as an argument and set in the constructor.

```
StreamState ExampleDelimitedUDChunker::alignPortion(
    ServerInterface &srvinterface,
    DataBuffer &input, InputState state)
{
    /* find the first record terminator. Its record belongs to the previous portion */
    void *buf = reinterpret_cast<void*>(input.buf + input.offset);
    void *term = memchr(buf, recordTerminator, input.size - input.offset);

    if (term) {
        /* record boundary found. Align to the start of the next record */
        const size_t chunkSize = reinterpret_cast<size_t>(term) - reinterpret_cast<size_t>(buf);
        input.offset += chunkSize
            + sizeof(char) /* length of record terminator */;

        /* input.offset points at the start of the first complete record in the portion */
        return DONE;
    } else if (state == END_OF_FILE || state == END_OF_PORTION) {
        return REJECT;
    } else {
        VIAssert(state == START_OF_PORTION || state == OK);
        return INPUT_NEEDED;
    }
}
```

The `process()` method has to account for chunks that span portion boundaries. If the previous call was at the end of a portion, the method set a flag. The code begins by checking for and handling that condition. The logic is similar to that of `alignPortion()`, so the example calls it to do part of the division.

```

StreamState ExampleDelimitedUDChunker::process(
    ServerInterface &srvInterface,
    DataBuffer &input,
    InputState input_state)
{
    const size_t termLen = 1;
    const char *terminator = &recordTerminator;

    if (pastPortion) {
        /*
         * Previous state was END_OF_PORTION, and the last chunk we will produce
         * extends beyond the portion we started with, into the next portion.
         * To be consistent with alignPortion(), that means finding the first
         * record boundary, and setting the chunk to be at that boundary.
         * Fortunately, this logic is identical to aligning the portion (with
         * some slight accounting for END_OF_FILE!)
         */
        const StreamState findLastTerminator = alignPortion(srvInterface, input);

        switch (findLastTerminator) {
            case DONE:
                return DONE;
            case INPUT_NEEDED:
                if (input_state == END_OF_FILE) {
                    /* there is no more input where we might find a record terminator */
                    input.offset = input.size;
                    return DONE;
                }
                return INPUT_NEEDED;
            default:
                VIAssert("Invalid return state from alignPortion()");
        }
        return findLastTerminator;
    }
}

```

Now the method looks for the delimiter. If the input began at the end of a portion, it sets the flag.

```

    size_t ret = input.offset, term_index = 0;
    for (size_t index = input.offset; index < input.size; ++index) {
        const char c = input.buf[index];
        if (c == terminator[term_index]) {
            ++term_index;
            if (term_index == termLen) {
                ret = index + 1;
                term_index = 0;
            }
            continue;
        } else if (term_index > 0) {
            index -= term_index;
        }

        term_index = 0;
    }

    if (input_state == END_OF_PORTION) {
        /*
         * Regardless of whether or not a record was found, the next chunk will extend
         * into the next portion.
         */
        pastPortion = true;
    }
}

```

Finally, `process()` moves the input offset and returns.

```
// if we were able to find some rows, move the offset to point at the start of the next (potential) row, or end of block
if (ret > input.offset) {
    input.offset = ret;
    return CHUNK_ALIGNED;
}

if (input_state == END_OF_FILE) {
    input.offset = input.size;
    return DONE;
}

return INPUT_NEEDED;
```

Factory implementation

The file `ExampleDelimitedParser.cpp` defines a factory that uses this `UDChunker`. The chunker supports apportioned load, so the factory implements `isChunkerApportionable()`:

```
virtual bool isChunkerApportionable(ServerInterface &srvInterface) {
    ParamReader params = srvInterface.getParamReader();
    if (params.containsParameter("disable_chunker") && params.getBoolRef("disable_chunker")) {
        return false;
    } else {
        return true;
    }
}
```

The `prepareChunker()` method creates the chunker:

```
virtual UDChunker* prepareChunker(ServerInterface &srvInterface,
    PerColumnParamReader &perColumnParamReader,
    PlanContext &planCtx,
    const SizedColumnTypes &returnType)
{
    ParamReader params = srvInterface.getParamReader();
    if (params.containsParameter("disable_chunker") && params.getBoolRef("disable_chunker")) {
        return NULL;
    }

    std::string recordTerminator("\n");

    ParamReader args(srvInterface.getParamReader());
    if (args.containsParameter("record_terminator")) {
        recordTerminator = args.getStringRef("record_terminator").str();
    }

    return vt_createFuncObject<ExampleDelimitedUDChunker>(srvInterface, allo\
cator,
        recordTerminator[0]);
}
```

Python example: complex types JSON parser

The following example details a `UDParser` that takes a JSON object and parses it into complex types. For this example, the parser assumes the input data are arrays of rows with two integer fields. The input records should be separated by newline characters. If any row fields aren't specified by the JSON input, the function parses those fields as `NULL`.

The source code for this UDParser also contains a factory method for parsing rows that have an integer and an array of integer fields. The implementation of the parser is independent of the return type in the factory, so you can create factories with different return types that all point to the `ComplexJsonParser()` class in the `prepare()` method. The complete source code is in </opt/vertica/sdk/examples/python/UDParsers.py>.

Loading and using the example

Load the library and create the parser as follows:

```
=> CREATE OR REPLACE LIBRARY UDParsers AS '/home/dbadmin/examples/python/UDParsers.py' LANGUAGE 'Python';
=> CREATE PARSER ComplexJsonParser AS LANGUAGE 'Python' NAME 'ArrayJsonParserFactory' LIBRARY UDParsers;
```

You can now define a table and then use the JSON parser to load data into it, for example:

```
=> CREATE TABLE orders (a bool, arr array[row(a int, b int)]);
CREATE TABLE

=> COPY orders (arr) FROM STDIN WITH PARSER ComplexJsonParser();
[]
[{"a":1, "b":10}]
[{"a":1, "b":10}, {"a":null, "b":10}]
[{"a":1, "b":10}, {"a":10, "b":20}]
[{"a":1, "b":10}, {"a":null, "b":null}]
[{"a":1, "b":2}, {"a":3, "b":4}, {"a":5, "b":6}, {"a":7, "b":8}, {"a":9, "b":10}, {"a":11, "b":12}, {"a":13, "b":14}]
\

=> SELECT * FROM orders;
a |          arr
-----+-----
| []
| [{"a":1,"b":10}]
| [{"a":1,"b":10},{"a":null,"b":10}]
| [{"a":1,"b":10},{"a":10,"b":20}]
| [{"a":1,"b":10},{"a":null,"b":null}]
| [{"a":1,"b":2}, {"a":3,"b":4}, {"a":5,"b":6}, {"a":7,"b":8}, {"a":9,"b":10}, {"a":11,"b":12}, {"a":13,"b":14}]
(6 rows)
```

Setup

All Python UDxs must import the Vertica SDK library. `ComplexJsonParser()` also requires the json library.

```
import vertica_sdk
import json
```

Factory implementation

The `prepare()` method instantiates and returns a parser:

```
def prepare(self, srvInterface, perColumnParamReader, planCtx, returnType):
    return ComplexJsonParser()
```

`getParserReturnType()` declares that the return type must be an array of rows that each have two integer fields:

```
def getParserReturnType(self, rvInterface, perColumnParamReader, planCtx, argTypes, returnType):
    fieldTypes = vertica_sdk.SizedColumnTypes.makeEmpty()
    fieldTypes.addInt('a')
    fieldTypes.addInt('b')
    returnType.addArrayType(vertica_sdk.SizedColumnTypes.makeRowType(fieldTypes, 'elements'), 64, 'arr')
```

Parser implementation

The `process()` method reads in data with an `InputBuffer` and then splits that input data on the newline character. The method then passes the processed data to the `writeRows()` method. `writeRows()` turns each data row into a JSON object, checks the type of that JSON object, and then writes the appropriate value or object to the output.

```
class ComplexJsonParser(vertica_sdk.UDParser):

    leftover = ""

    def process(self, srvInterface, input_buffer, input_state, writer):
        input_buffer.setEncoding("utf-8")

        self.count = 0
        rec = self.leftover + input_buffer.read()
        row_lst = rec.split('\n')
        self.leftover = row_lst[-1]
        self.writeRows(row_lst[:-1], writer)
        if input_state == InputState.END_OF_FILE:
            self.writeRows([self.leftover], writer)
            return StreamState.DONE
        else:
            return StreamState.INPUT_NEEDED

    def writeRows(self, str_lst, writer):
        for s in str_lst:
            stripped = s.strip()
            if len(stripped) == 0:
                return
            elif len(stripped) > 1 and stripped[0:2] == "//":
                continue
            jsonValue = json.loads(stripped)
            if type(jsonValue) is list:
                writer.setArray(0, jsonValue)
            elif jsonValue is None:
                writer.setNull(0)
            else:
                writer.setRow(0, jsonValue)
        writer.next()
```

Load parallelism

Vertica can divide the work of loading data, taking advantage of parallelism to speed up the operation. Vertica supports several types of parallelism:

- **Distributed load:** Vertica distributes files in a multi-file load to several nodes to load in parallel, instead of loading all of them on a single node. Vertica manages distributed load; you do not need to do anything special in your UDL.
- **Cooperative parse:** A source being loaded on a single node uses multi-threading to parallelize the parse. Cooperative parse divides a load at execution time, based on how threads are scheduled. You must enable cooperative parse in your parser. See [Cooperative parse](#).
- **Apportioned load:** Vertica divides a single large file or other single source into segments, which it assigns to several nodes to load in parallel. Apportioned load divides the load at planning time, based on available nodes and cores on each node. You must enable apportioned load in your source and parser. See [Apportioned load](#).

You can support both cooperative parse and apportioned load in the same UDL. Vertica decides which to use for each load operation and might use both. See [Combining cooperative parse and apportioned load](#).

In this section

- [Cooperative parse](#)
- [Apportioned load](#)
- [Combining cooperative parse and apportioned load](#)

Cooperative parse

By default, Vertica parses a data source in a single thread on one database node. You can optionally use *cooperative parse* to parse a source using multiple threads on a node. More specifically, data from a source passes through a *chunker* that groups blocks from the source stream into logical units. These chunks can be parsed in parallel. The chunker divides the input into pieces that can be individually parsed, and the parser then parses them concurrently. Cooperative parse is available only for unfenced UDxs. (See [Fenced and unfenced modes.](#))

To use cooperative parse, a chunker must be able to locate end-of-record markers in the input. Locating these markers might not be possible in all input formats.

Chunkers are created by parser factories. At load time, Vertica first calls the `UDChunker` to divide the input into chunks and then calls the `UDParser` to parse each chunk.

You can use cooperative parse and apportioned load independently or together. See [Combining cooperative parse and apportioned load.](#)

How Vertica divides a load

When Vertica receives data from a source, it calls the chunker's `process()` method repeatedly. A chunker is, essentially, a lightweight parser; instead of parsing, the `process()` method divides the input into chunks.

After the chunker has finished dividing the input into chunks, Vertica sends those chunks to as many parsers as are available, calling the `process()` method on the parser.

Implementing cooperative parse

To implement cooperative parse, perform the following actions:

- Subclass `UDChunker` and implement `process()` .
- In your `ParserFactory` , implement `prepareChunker()` to return a `UDChunker` .

See [C++ example: delimited parser and chunker](#) for a `UDChunker` that also supports apportioned load.

Apportioned load

A parser can use more than one database node to load a single input source in parallel. This approach is referred to as *apportioned load* . Among the parsers built into Vertica, the default (delimited) parser supports apportioned load.

Apportioned load, like cooperative parse, requires an input that can be divided at record boundaries. The difference is that cooperative parse does a sequential scan to find record boundaries, while apportioned load first jumps (seeks) to a given position and then scans. Some formats, like generic XML, do not support seeking.

To use apportioned load, you must ensure that the source is reachable by all participating database nodes. You typically use apportioned load with distributed file systems.

It is possible for a parser to not support apportioned load directly but to have a chunker that supports apportioning.

You can use apportioned load and cooperative parse independently or together. See [Combining cooperative parse and apportioned load.](#)

How Vertica apports a load

If both the parser and its source support apportioning, then you can specify that a single input is to be distributed to multiple database nodes for loading. The `SourceFactory` breaks the input into portions and assigns them to execution nodes. Each `Portion` consists of an offset into the input and a size. Vertica distributes the portions and their parameters to the execution nodes. A source factory running on each node produces a `UDSource` for the given portion.

The `UDParser` first determines where to start parsing:

- If the portion is the first one in the input, the parser advances to the offset and begins parsing.
- If the portion is not the first, the parser advances to the offset and then scans until it finds the end of a record. Because records can break across portions, parsing begins after the first record-end encountered.

The parser must complete a record, which might require it to read past the end of the portion. The parser is responsible for parsing all records that *begin* in the assigned portion, regardless of where they end. Most of this work occurs within the `process()` method of the parser.

Sometimes, a portion contains nothing to be parsed by its assigned node. For example, suppose you have a record that begins in portion 1, runs through all of portion 2, and ends in portion 3. The parser assigned to portion 1 parses the record, and the parser assigned to portion 3 starts after that record. The parser assigned to portion 2, however, has no record starting within its portion.

If the load also uses [Cooperative parse](#) , then after apportioning the load and before parsing, Vertica divides portions into chunks for parallel loading.

Implementing apportioned load

To implement apportioned load, perform the following actions in the source, the parser, and their factories.

In your `SourceFactory` subclass:

- Implement `isSourceApportionable()` and return `true` .
- Implement `plan()` to determine portion size, designate portions, and assign portions to execution nodes. To assign portions to particular executors, pass the information using the parameter writer on the plan context (`PlanContext::getWriter()`).
- Implement `prepareUDSources()` . Vertica calls this method on each execution node with the plan context created by the factory. This method returns the `UDSource` instances to be used for this node's assigned portions.
- If sources can take advantage of parallelism, you can implement `getDesiredThreads()` to request a number of threads for each source. See [SourceFactory class](#) for more information about this method.

In your `UDSource` subclass, implement `process()` as you would for any other source, using the assigned portion. You can retrieve this portion with `getPortion()` .

In your `ParserFactory` subclass:

- Implement `isParserApportionable()` and return `true` .
- If your parser uses a `UDChunker` that supports apportioned load, implement `isChunkerApportionable()` .

In your `UDParser` subclass:

- Write your `UDParser` subclass to operate on portions rather than whole sources. You can do so by handling the stream states `PORTION_START` and `PORTION_END` , or by using the `ContinuousUDParser` API. Your parser must scan for the beginning of the portion, find the first record boundary after that position, and parse to the end of the last record beginning in that portion. Be aware that this behavior might require that the parser read beyond the end of the portion.
- Handle the special case of a portion containing no record start by returning without writing any output.

In your `UDChunker` subclass, implement `alignPortion()` . See [Aligning Portions](#) .

Example

The SDK provides a C++ example of apportioned load in the `ApportionLoadFunctions` directory:

- `FilePortionSource` is a subclass of `UDSource` .
- `DelimFilePortionParser` is a subclass of `ContinuousUDParser` .

Use these classes together. You could also use `FilePortionSource` with the built-in delimited parser.

The following example shows how you can load the libraries and create the functions in the database:

```
=> CREATE LIBRARY FilePortionSourceLib as '/home/dbadmin/FP.so';
=> CREATE LIBRARY DelimFilePortionParserLib as '/home/dbadmin/Delim.so';
=> CREATE SOURCE FilePortionSource AS
LANGUAGE 'C++' NAME 'FilePortionSourceFactory' LIBRARY FilePortionSourceLib;
=> CREATE PARSER DelimFilePortionParser AS
LANGUAGE 'C++' NAME 'DelimFilePortionParserFactory' LIBRARY DelimFilePortionParserLib;
```

The following example shows how you can use the source and parser to load data:

```
=> COPY t WITH SOURCE FilePortionSource(file='g1/*.dat') PARSER DelimFilePortionParser(delimiter = '|',
record_terminator = '~');
```

Combining cooperative parse and apportioned load

You can enable both [Cooperative parse](#) and [Apportioned load](#) in the same parser, allowing Vertica to decide how to load data.

Deciding how to divide a load

Vertica uses apportioned load, where possible, at query-planning time. It decides whether to also use cooperative parse at execution time.

Apportioned load requires [SourceFactory](#) support. Given a suitable [UDSource](#) , at planning time Vertica calls the [isParserApportionable\(\)](#) method on the [ParserFactory](#) . If this method returns [true](#) , Vertica apportioned the load.

If [isParserApportionable\(\)](#) returns [false](#) but [isChunkerApportionable\(\)](#) returns [true](#) , then a chunker is available for cooperative parse and that chunker supports apportioned load. Vertica apportioned the load.

If neither of these methods returns [true](#) , then Vertica does not apportion the load.

At execution time, Vertica first checks whether the load is running in unfenced mode and proceeds only if it is. Cooperative parse is not supported in fenced mode.

If the load is not apportioned, and more than one thread is available, Vertica uses cooperative parse.

If the load is apportioned, and exactly one thread is available, Vertica uses cooperative parse if and only if the parser is not apportionable. In this case, the chunker is apportionable but the parser is not.

If the load is apportioned, and more than one thread is available, and the chunker is apportionable, Vertica uses cooperative parse.

If Vertica uses cooperative parse but [prepareChunker\(\)](#) does not return a [UDChunker](#) instance, Vertica reports an error.

Executing apportioned, cooperative loads

If a load uses both apportioned load and cooperative parse, Vertica uses the [SourceFactory](#) to break the input into portions. It then assigns the portions to execution nodes. See [How Vertica Apportions a Load](#) .

On the execution node, Vertica calls the chunker's [alignPortion\(\)](#) method to align the input with portion boundaries. (This step is skipped for the first portion, which by definition is already aligned at the beginning.) This step is necessary because a parser using apportioned load sometimes has to read beyond the end of the portion, so a chunker needs to find the end point.

After aligning the portion, Vertica calls the chunker's [process\(\)](#) method repeatedly. See [How Vertica Divides a Load](#) .

The chunks found by the chunker are then sent to the parser's [process\(\)](#) method for processing in the usual way.

Continuous load

The [ContinuousUDSource](#) , [ContinuousUDFilter](#) , and [ContinuousUDParser](#) classes allow you to write and process data as needed instead of having to iterate through the data. The Python API does not support continuous load.

Each class includes the following functions:

- [initialize\(\)](#) - Invoked before [run\(\)](#) . You can optionally override this function to perform setup and initialization.
- [run\(\)](#) - Processes the data.
- [deinitialize\(\)](#) - Invoked after [run\(\)](#) has returned. You can optionally override this function to perform tear-down and destruction.

Do not override the [setup\(\)](#) , [process\(\)](#) , and [destroy\(\)](#) functions that are inherited from parent classes.

You can use the [yield\(\)](#) function to yield control back to the server during idle or busy loops so the server can check for status changes or query cancellations.

These three classes use associated [ContinuousReader](#) and [ContinuousWriter](#) classes to read input data and write output data.

ContinuousUDSource API (C++)

The [ContinuousUDSource](#) class extends [UDSource](#) and adds the following methods for extension by subclasses:

```
virtual void initialize(ServerInterface &srvInterface);  
  
virtual void run();  
  
virtual void deinitialize(ServerInterface &srvInterface);
```

ContinuousUDFilter API (C++)

The [ContinuousUDFilter](#) class extends [UDFilter](#) and adds the following methods for extension by subclasses:

```
virtual void initialize(ServerInterface &srvInterface);

virtual void run();

virtual void deinitialize(ServerInterface &srvInterface);
```

ContinuousUDParser API

[C++](#)

[Java](#)

The [ContinuousUDParser](#) class extends [UDParser](#) and adds the following methods for extension by subclasses:

```
virtual void initialize(ServerInterface &srvInterface);

virtual void run();

virtual void deinitialize(ServerInterface &srvInterface);
```

See the API documentation for additional utility methods.

Buffer classes

Buffer classes are used as handles to the raw data stream for all UDL functions. The C++ and Java APIs use a single [DataBuffer](#) class for both input and output. The Python API has two classes, [InputBuffer](#) and [OutputBuffer](#) .

DataBuffer API (C++, java)

[C++](#)

[Java](#)

The [DataBuffer](#) class has a pointer to a buffer and size, and an offset indicating how much of the stream has been consumed.

```
/**
 * A contiguous in-memory buffer of char *
 */
struct DataBuffer {
    // Pointer to the start of the buffer
    char * buf;

    // Size of the buffer in bytes
    size_t size;

    // Number of bytes that have been processed by the UDL
    size_t offset;
};
```

InputBuffer and OutputBuffer APIs (python)

The Python [InputBuffer](#) and [OutputBuffer](#) classes replace the [DataBuffer](#) class in the C++ and Java APIs.

InputBuffer class

The [InputBuffer](#) class decodes and translates raw data streams depending on the specified encoding. Python natively supports a [wide range of languages and codecs](#) . The [InputBuffer](#) is an argument to the [process\(\)](#) method for both [UDFilters](#) and [UDParsers](#). A user interacts with the UDL's data stream by calling methods of the [InputBuffer](#)

If you do not specify a value for [setEncoding\(\)](#) , Vertica assumes a value of [NONE](#).

```

class InputBuffer:
    def getSize(self):
        ...

    def getOffset(self):
        ...

    def setEncoding(self, encoding):
        """
        Set the encoding of the data contained in the underlying buffer
        """
        pass

    def peek(self, length = None):
        """
        Copy data from the input buffer into Python.
        If no encoding has been specified, returns a Bytes object containing raw data.
        Otherwise, returns data decoded into an object corresponding to the specified encoding
        (for example, 'utf-8' would return a string).
        If length is None, returns all available data.
        If length is not None then the length of the returned object is at most what is requested.
        This method does not advance the buffer offset.
        """
        pass

    def read(self, length = None):
        """
        See peek().
        This method does the same thing as peek(), but it also advances the
        buffer offset by the number of bytes consumed.
        """
        pass

        # Advances the DataBuffer offset by a number of bytes equal to the result
        # of calling "read" with the same arguments.
    def advance(self, length = None):
        """
        Advance the buffer offset by the number of bytes indicated by
        the length and encoding arguments. See peek().
        Returns the new offset.
        """
        pass

```

OutputBuffer class

The OutputBuffer class encodes and outputs data from Python to Vertica. The OutputBuffer is an argument to the `process()` method for both UDFilters and UDParsers. A user interacts with the UDL's data stream by calling methods of the OutputBuffer to manipulate and encode data.

The `write()` method transfers all data from the Python client to Vertica. The output buffer can accept any size object. If a user writes an object to the OutputBuffer larger than Vertica can immediately process, Vertica stores the overflow. During the next call to `process()`, Vertica checks for leftover data. If there is any, Vertica copies it to the DataBuffer before determining whether it needs to call `process()` from the Python UDL.

If you do not specify a value for `setEncoding()`, Vertica assumes a value of NONE.

```
class OutputBuffer:
def setEncoding(self, encoding):
    """
Specify the encoding of the data which will be written to the underlying buffer
    """
class
def write(self, data):
    """
Transfer bytes from the data object into Vertica.
If an encoding was specified via setEncoding(), the data object will be converted to bytes using the specified encoding.
Otherwise, the data argument is expected to be a Bytes object and is copied to the underlying buffer.
    """
class
```

Apache Hadoop integration

Apache™ Hadoop™, like Vertica, uses a cluster of nodes for distributed processing. The primary component of interest is HDFS, the Hadoop Distributed File System.

You can use Vertica with HDFS in several ways:

- You can import HDFS data into locally-stored ROS files.
- You can access HDFS data in place using external tables. You can define the tables yourself or get schema information from Hive, a Hadoop component.
- You can use HDFS as a storage location for ROS files.
- You can export data from Vertica to share with other Hadoop components using a Hadoop columnar format. See [File export](#) for more information.

Hadoop file paths are expressed as URLs in the [webhdfs](#) or [hdfs](#) URL scheme. For more about using these schemes, see [HDFS file system](#).

Hadoop distributions

Vertica can be used with Hadoop distributions from Hortonworks, Cloudera, and MapR. See [Hadoop integrations](#) for the specific versions that are supported.

If you are using Cloudera, you can manage your Vertica cluster using Cloudera Manager. See [Integrating with Cloudera Manager](#).

If you are using MapR, see [Integrating Vertica with the MapR distribution of Hadoop](#).

WebHDFS requirement

By default, if you use a URL in the [hdfs](#) scheme, Vertica treats it as [webhdfs](#). If you instead use the (deprecated) LibHDFS++ library, you must still have a WebHDFS service available. LibHDFS++ does not support some WebHDFS features, such as encryption zones, wire encryption, or writes, and falls back to WebHDFS when needed.

For some uses, such as Eon Mode communal storage, you must use WebHDFS directly with the [webhdfs](#) scheme.

Deprecated

Support for LibHDFS++ is deprecated. You can set the [HDFSUseWebHDFS](#) configuration parameter to 0 (disabled) to use LibHDFS++ until it is removed.

In this section

- [Integrating Vertica with the MapR distribution of Hadoop](#)
- [Hive primer for Vertica integration](#)

Cluster layout

Vertica supports two cluster architectures for Hadoop integration. Which architecture you use affects the decisions you make about integration with HDFS. These options might also be limited by license terms.

- You can co-locate Vertica on some or all of your Hadoop nodes. Vertica can then take advantage of data locality.
- You can build a Vertica cluster that is separate from your Hadoop cluster. In this configuration, Vertica can fully use each of its nodes; it does not share resources with Hadoop.

With either architecture, if you are using the `hdfs` scheme to read ORC or Parquet files, you must do some additional configuration. See [Configuring HDFS access](#).

In this section

- [Co-located clusters](#)
- [Configuring Hadoop for co-located clusters](#)
- [Configuring rack locality](#)
- [Separate clusters](#)

Co-located clusters

With co-located clusters, Vertica is installed on some or all of your Hadoop nodes. The Vertica nodes use a private network in addition to the public network used by all Hadoop nodes, as the following figure shows:

You might choose to place Vertica on all of your Hadoop nodes or only on some of them. If you are using HDFS Storage Locations you should use at least three Vertica nodes, the minimum number for [K-safety in an Enterprise Mode database](#).

Using more Vertica nodes can improve performance because the HDFS data needed by a query is more likely to be local to the node.

You can place Hadoop and Vertica clusters within a single rack, or you can span across many racks and nodes. If you do not co-locate Vertica on every node, you can improve performance by co-locating it on at least one node in each rack. See [Configuring rack locality](#).

Normally, both Hadoop and Vertica use the entire node. Because this configuration uses shared nodes, you must address potential resource contention in your configuration on those nodes. See [Configuring Hadoop for co-located clusters](#) for more information. No changes are needed on Hadoop-only nodes.

Hardware recommendations

Hadoop clusters frequently do not have identical provisioning requirements or hardware configurations. However, Vertica nodes should be equivalent in size and capability, per the best-practice standards recommended in [Platform and hardware requirements and recommendations](#).

Because Hadoop cluster specifications do not always meet these standards, Vertica recommends the following specifications for Vertica nodes in your Hadoop cluster.

Specifications for...	Recommendation
Processor	For best performance, run: <ul style="list-style-type: none">• Two-socket servers with 8–14 core CPUs, clocked at or above 2.6 GHz for clusters over 10 TB• Single-socket servers with 8–12 cores clocked at or above 2.6 GHz for clusters under 10 TB

Memory	<p>Distribute the memory appropriately across all memory channels in the server:</p> <ul style="list-style-type: none"> • Minimum —8 GB of memory per physical CPU core in the server • High-performance applications —12–16 GB of memory per physical core • Type —at least DDR3-1600, preferably DDR3-1866
Storage	<p>Read/write:</p> <ul style="list-style-type: none"> • Minimum —40 MB/s per physical core of the CPU • For best performance —60–80 MB/s per physical core <p>Storage post RAID: Each node should have 1–9 TB. For a production setting, Vertica recommends RAID 10. In some cases, RAID 50 is acceptable.</p> <p>Because Vertica performs heavy compression and encoding, SSDs are not required. In most cases, a RAID of more, less-expensive HDDs performs just as well as a RAID of fewer SSDs.</p> <p>If you intend to use RAID 50 for your data partition, you should keep a spare node in every rack, allowing for manual failover of a Vertica node in the case of a drive failure. A Vertica node recovery is faster than a RAID 50 rebuild. Also, be sure to never put more than 10 TB compressed on any node, to keep node recovery times at an acceptable rate.</p>
Network	10 GB networking in almost every case. With the introduction of 10 GB over cat6a (Ethernet), the cost difference is minimal.

Configuring Hadoop for co-located clusters

If you are co-locating Vertica on any HDFS nodes, there are some additional configuration requirements.

Hadoop configuration parameters

For best performance, set the following parameters with the specified minimum values:

Parameter	Minimum Value
HDFS block size	512MB
Namenode Java Heap	1GB
Datanode Java Heap	2GB

WebHDFS

Hadoop has two services that can provide web access to HDFS:

- WebHDFS
- httpFS

For Vertica, you must use the WebHDFS service.

YARN

The YARN service is available in newer releases of Hadoop. It performs resource management for Hadoop clusters. When co-locating Vertica on YARN-managed Hadoop nodes you must make some changes in YARN.

Vertica recommends reserving at least 16GB of memory for Vertica on shared nodes. Reserving more will improve performance. How you do this depends on your Hadoop distribution:

- If you are using Hortonworks, create a "Vertica" node label and assign this to the nodes that are running Vertica.
- If you are using Cloudera, enable and configure static service pools.

Consult the documentation for your Hadoop distribution for details. Alternatively, you can disable YARN on the shared nodes.

Hadoop balancer

The Hadoop Balancer can redistribute data blocks across HDFS. For many Hadoop services, this feature is useful. However, for Vertica this can reduce performance under some conditions.

If you are using HDFS storage locations, the Hadoop load balancer can move data away from the Vertica nodes that are operating on it, degrading performance. This behavior can also occur when reading ORC or Parquet files if Vertica is not running on all Hadoop nodes. (If you are using separate Vertica and Hadoop clusters, all Hadoop access is over the network, and the performance cost is less noticeable.)

To prevent the undesired movement of data blocks across the HDFS cluster, consider excluding Vertica nodes from rebalancing. See the Hadoop documentation to learn how to do this.

Replication factor

By default, HDFS stores three copies of each data block. Vertica is generally set up to store two copies of each data item through K-Safety. Thus, lowering the replication factor to 2 can save space and still provide data protection.

To lower the number of copies HDFS stores, set `HadoopFSReplication`, as explained in [Troubleshooting HDFS storage locations](#).

Disk space for Non-HDFS use

You also need to reserve some disk space for non-HDFS use. To reserve disk space using Ambari, set `dfs.datanode.du.reserved` to a value in the `hdfs-site.xml` configuration file.

Setting this parameter preserves space for non-HDFS files that Vertica requires.

Configuring rack locality

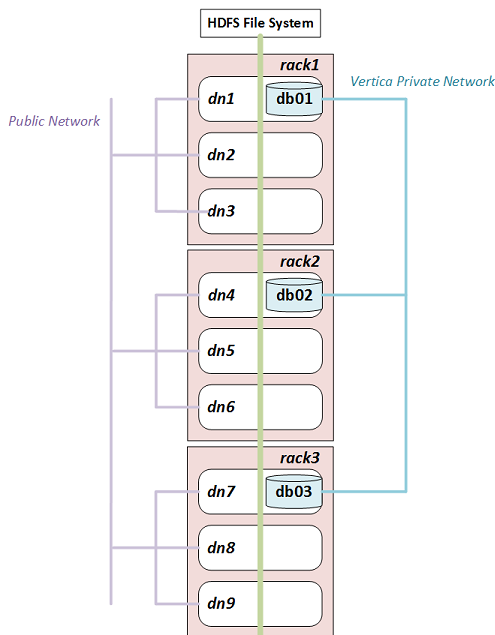

Note

This feature is supported only for reading ORC and Parquet data on co-located clusters. It is only meaningful on Hadoop clusters that span multiple racks.

When possible, when planning a query Vertica automatically uses database nodes that are co-located with the HDFS nodes that contain the data. Moving query execution closer to the data reduces network latency and can improve performance. This behavior, called node locality, requires no additional configuration.

When Vertica is co-located on only a subset of HDFS nodes, sometimes there is no database node that is co-located with the data. However, performance is usually better if a query uses a database node in the same rack. If configured with information about Hadoop rack structure, Vertica attempts to use a database node in the same rack as the data to be queried.

For example, the following diagram illustrates a Hadoop cluster with three racks each containing three data nodes. (Typical production systems have more data nodes per rack.) In each rack, Vertica is co-located on one node.

If you configure rack locality, Vertica uses db01 to query data on dn1, dn2, or dn3, and uses db02 and db03 for data on rack2 and rack3 respectively. Because HDFS replicates data, any given data block can exist in more than one rack. If a data block is replicated on dn2, dn3, and dn6, for example, Vertica uses either db01 or db02 to query it.

Hadoop components are rack-aware, so configuration files describing rack structure already exist in the Hadoop cluster. To use this information in Vertica, configure fault groups that describe this rack structure. Vertica uses fault groups in query planning.

Configuring fault groups

Vertica uses [Fault groups](#) to describe physical cluster layout. Because your database nodes are co-located on HDFS nodes, Vertica can use the information about the physical layout of the HDFS cluster.

Tip

For best results, ensure that each Hadoop rack contains at least one co-located Vertica node.

Hadoop stores its cluster-layout data in a topology mapping file in HADOOP_CONF_DIR. On HortonWorks the file is typically named topology_mappings.data. On Cloudera it is typically named topology.map. Use the data in this file to create an input file for the fault-group script. For more information about the format of this file, see [Creating a fault group input file](#).

Following is an example topology mapping file for the cluster illustrated previously:

```
[network_topology]
dn1.example.com=/rack1
10.20.41.51=/rack1
dn2.example.com=/rack1
10.20.41.52=/rack1
dn3.example.com=/rack1
10.20.41.53=/rack1
dn4.example.com=/rack2
10.20.41.71=/rack2
dn5.example.com=/rack2
10.20.41.72=/rack2
dn6.example.com=/rack2
10.20.41.73=/rack2
dn7.example.com=/rack3
10.20.41.91=/rack3
dn8.example.com=/rack3
10.20.41.92=/rack3
dn9.example.com=/rack3
10.20.41.93=/rack3
```

From this data, you can create the following input file describing the Vertica subset of this cluster:

```
/rack1 /rack2 /rack3
/rack1 = db01
/rack2 = db02
/rack3 = db03
```

This input file tells Vertica that the database node "db01" is on rack1, "db02" is on rack2, and "db03" is on rack3. In creating this file, ignore Hadoop data nodes that are not also Vertica nodes.

After you create the input file, run the fault-group tool:

```
$ python /opt/vertica/scripts/fault_group_ddl_generator.py dbName input_file > fault_group_ddl.sql
```

The output of this script is a SQL file that creates the fault groups. Execute it following the instructions in [Creating fault groups](#).

You can review the new fault groups with the following statement:

```
=> SELECT member_name,node_address,parent_name FROM fault_groups
INNER JOIN nodes ON member_name=node_name ORDER BY parent_name;
```

member_name	node_address	parent_name
db01	10.20.41.51	/rack1
db02	10.20.41.71	/rack2
db03	10.20.41.91	/rack3

(3 rows)

Working with multi-level racks

A Hadoop cluster can use multi-level racks. For example, /west/rack-w1, /west/rack-2, and /west/rack-w3 might be served from one data center, while /east/rack-e1, /east/rack-e2, and /east/rack-e3 are served from another. Use the following format for entries in the input file for the fault-group script:

```
/west /east
/west = /rack-w1 /rack-w2 /rack-w3
/east = /rack-e1 /rack-e2 /rack-e3
/rack-w1 = db01
/rack-w2 = db02
/rack-w3 = db03
/rack-e1 = db04
/rack-e2 = db05
/rack-e3 = db06
```

Do not create entries using the full rack path, such as /west/rack-w1.

Auditing results

To see how much data can be loaded with rack locality, use [EXPLAIN](#) with the query and look for statements like the following in the output:

```
100% of ORC data including co-located data can be loaded with rack locality.
```

Separate clusters

With separate clusters, a Vertica cluster and a Hadoop cluster share no nodes. You should use a high-bandwidth network connection between the two clusters.

The following figure illustrates the configuration for separate clusters::

Network

The network is a key performance component of any well-configured cluster. When Vertica stores data to HDFS it writes and reads data across the network.

The layout shown in the figure calls for two networks, and there are benefits to adding a third:

- Database Private Network: Vertica uses a private network for command and control and moving data between nodes in support of its database functions. In some networks, the command and control and passing of data are split across two networks.
- Database/Hadoop Shared Network: Each Vertica node must be able to connect to each Hadoop data node and the NameNode. Hadoop best practices generally require a dedicated network for the Hadoop cluster. This is not a technical requirement, but a dedicated network improves Hadoop performance. Vertica and Hadoop should share the dedicated Hadoop network.
- Optional Client Network: Outside clients may access the clustered networks through a client network. This is not an absolute requirement, but the use of a third network that supports client connections to either Vertica or Hadoop can improve performance. If the configuration does not support a client network, than client connections should use the shared network.

Hadoop configuration parameters

For best performance, set the following parameters with the specified minimum values:

Parameter	Minimum Value
HDFS block size	512MB
Namenode Java Heap	1GB
Datanode Java Heap	2GB

Configuring HDFS access

Vertica uses information from the Hadoop cluster configuration to support reading data (COPY or external tables). In Eon Mode, it also uses this information to access communal storage on HDFS. Vertica nodes therefore must have access to certain Hadoop configuration files.

For both co-located and separate clusters that use Kerberos authentication, configure Vertica for Kerberos as explained in [Configure Vertica for Kerberos Authentication](#).

Vertica requires access to the WebHDFS service and ports on all name nodes and data nodes. For more information about WebHDFS ports, see [HDFS Ports in the Cloudera documentation](#).

Accessing Hadoop configuration files

Your Vertica nodes need access to certain Hadoop configuration files:

- If Vertica is co-located on HDFS nodes, then those configuration files are already present.
- If Vertica is running on a separate cluster, you must copy the required files to all database nodes. A simple way to do so is to configure your Vertica nodes as Hadoop edge nodes. Client applications run on *edge nodes*; from Hadoop's perspective, Vertica is a client application. You can use Ambari or Cloudera Manager to configure edge nodes. For more information, see the documentation from your Hadoop vendor.

Verify that the value of the HadoopConfDir configuration parameter (see [Hadoop parameters](#)) includes a directory containing the `core-site.xml` and `hdfs-site.xml` files. If you do not set a value, Vertica looks for the files in `/etc/hadoop/conf`. For all Vertica users, the directory is accessed by the Linux user under which the Vertica server process runs.

Vertica uses several properties defined in these configuration files. These properties are listed in [HDFS file system](#).

Using a cluster with high availability NameNodes

If your Hadoop cluster uses High Availability (HA) Name Nodes, verify that the `dfs.nameservices` parameter and the individual name nodes are defined in `hdfs-site.xml`.

Using more than one Hadoop cluster

In some cases, a Vertica cluster requires access to more than one HDFS cluster. For example, your business might use separate HDFS clusters for separate regions, or you might need data from both test and deployment clusters.

To support multiple clusters, perform the following steps:

1. Copy the configuration files from all HDFS clusters to your database nodes. You can place the copied files in any location readable by Vertica. However, as a best practice, you should place them all in the same directory tree, with one subdirectory per HDFS cluster. The locations must be the same on all database nodes.
2. Set the HadoopConfDir configuration parameter. The value is a colon-separated path containing the directories for all of your HDFS clusters.
3. Use an explicit name node or name service in the URL when creating an external table or copying data. Do not use `hdfs://` because it could be ambiguous. For more information about URLs, see [HDFS file system](#).

Vertica connects directly to a name node or name service; it does not otherwise distinguish among HDFS clusters. Therefore, names of HDFS name nodes and name services must be globally unique.

Verifying the configuration

Use the [VERIFY_HADOOP_CONF_DIR](#) function to verify that Vertica can find configuration files in HadoopConfDir.

Use the [HDFS_CLUSTER_CONFIG_CHECK](#) function to test access through the `hdfs` scheme.

For more information about testing your configuration, see [Verifying HDFS configuration](#).

Updating configuration files

If you update the configuration files after starting Vertica, use the following statement to refresh them:

```
=> SELECT CLEAR_HDFS_CACHES();
```

The [CLEAR_HDFS_CACHES](#) function also flushes information about which name node is active in a High Availability (HA) Hadoop cluster. Therefore, the first request after calling this function is slow, because the initial connection to the name node can take more than 15 seconds.

In this section

- [Verifying HDFS configuration](#)
- [Troubleshooting reads from HDFS](#)

Verifying HDFS configuration

Use the [EXTERNAL_CONFIG_CHECK](#) function to test access to HDFS. This function calls several others. If you prefer to test individual components, or if some tests do not apply to your configuration, you can instead call the functions individually. For example, if you are not using the HCatalog Connector then you do not need to call that function. The functions are:

- [KERBEROS_CONFIG_CHECK](#): tests the Vertica keytab and the user's Kerberos credential.
- [HADOOP_IMPERSONATION_CONFIG_CHECK](#): shows the delegation tokens that are in use. This function does not test them.
- [HDFS_CLUSTER_CONFIG_CHECK](#): tests access to the HDFS clusters found in HadoopConfDir, including using Kerberos and impersonation (delegation tokens).
- [HCATALOGCONNECTOR_CONFIG_CHECK](#): tests HCatalog Connector access to HiveServer2.

To run all tests, call [EXTERNAL_CONFIG_CHECK](#) with no arguments:

```
=> SELECT EXTERNAL_CONFIG_CHECK();
```

To test only some authorities, nameservices, or Hive schemas, pass a single string argument. The format is a comma-separated list of "key=value" pairs, where keys are "authority", "nameservice", and "schema". The value is passed to all of the sub-functions; see those reference pages for details on how values are interpreted.

The following example tests the configuration of only the nameservice named "ns1":

```
=> SELECT EXTERNAL_CONFIG_CHECK('nameservice=ns1');
```

Troubleshooting reads from HDFS

You might encounter the following issues when accessing data in HDFS.

Queries using `[web]hdfs://` show unexpected results

If you are using the `///` shorthand to query external tables and see unexpected results, such as production data in your test cluster, verify that [HadoopConfDir](#) is set to the value you expect. The `HadoopConfDir` configuration parameter defines a path to search for the Hadoop configuration files that Vertica needs to resolve file locations. The `HadoopConfDir` parameter can be set at the session level, overriding the permanent value set in the database.

To debug problems with `///` URLs, try replacing the URLs with ones that use an explicit nameservice or name node. If the explicit URL works, then the problem is with the resolution of the shorthand. If the explicit URL also does not work as expected, then the problem is elsewhere (such as your nameservice).

Queries take a long time to run when using HA

The High Availability Name Node feature in HDFS allows a name node to fail over to a standby name node. The `dfs.client.failover.max.attempts` configuration parameter (in `hdfs-site.xml`) specifies how many attempts to make when failing over. Vertica uses a default value of 4 if this parameter is not set. After reaching the maximum number of failover attempts, Vertica concludes that the HDFS cluster is unavailable and aborts the operation.

Vertica uses the `dfs.client.failover.sleep.base.millis` and `dfs.client.failover.sleep.max.millis` parameters to decide how long to wait between retries. Typical ranges are 500 milliseconds to 15 seconds, with longer waits for successive retries.

A second parameter, `ipc.client.connect.retry.interval`, specifies the time to wait between attempts, with typical values being 10 to 20 seconds.

Cloudera and Hortonworks both provide tools to automatically generate configuration files. These tools can set the maximum number of failover attempts to a much higher number (50 or 100). If the HDFS cluster is unavailable (all name nodes are unreachable), Vertica can appear to hang for an extended period (minutes to hours) while trying to connect.

Failover attempts are logged in the [QUERY_EVENTS](#) system table. The following example shows how to query this table to find these events:

```
=> SELECT event_category, event_type, event_description, operator_name,
  event_details, count(event_type) AS count
  FROM query_events
  WHERE event_type ilike 'WEBHDFS FAILOVER RETRY'
  GROUP BY event_category, event_type, event_description, operator_name, event_details;
-[ RECORD 1 ]-----+-----
event_category | EXECUTION
event_type     | WEBHDFS FAILOVER RETRY
event_description | WebHDFS Namenode failover and retry.
operator_name  | WebHDFS FileSystem
event_details  | WebHDFS request failed on ns
count         | 4
```

You can either wait for Vertica to complete or abort the connection, or set the `dfs.client.failover.max.attempts` parameter to a lower value.

WebHDFS error when using LibHDFS++

When creating an external table or loading data and using the `hdfs` scheme, you might see errors from WebHDFS failures. Such errors indicate that Vertica was not able to use the `hdfs` scheme and fell back to `webhdfs`, but that the WebHDFS configuration is incorrect.

First verify the value of the [HadoopConfDir](#) configuration parameter, which can be set at the session level. Then verify that the HDFS configuration files found there have the correct WebHDFS configuration for your Hadoop cluster. See [Configuring HDFS access](#) for information about use of these files. See your Hadoop documentation for information about WebHDFS configuration.

Vertica places too much load on the name node (LibHDFS++)

Large HDFS clusters can sometimes experience heavy load on the name node when clients, including Vertica, need to locate data. If your name node is sensitive to this load and if you are using LibHDFS++, you can instruct Vertica to distribute metadata about block locations to its nodes so that they do not have to contact the name node as often. Distributing this metadata can degrade database performance somewhat in deployments where the name node isn't contended. This performance effect is because the data must be serialized and distributed.

If protecting your name node from load is more important than query performance, set the [EnableHDFSBlockInfoCache](#) configuration parameter to 1 (true). Usually this applies to large HDFS clusters where name node contention is already an issue.

This setting applies to access through LibHDFS++ (`hdfs` scheme). Sometimes LibHDFS++ falls back to WebHDFS, which does not use this setting. If you have enabled this setting and you are still seeing high traffic on your name node from Vertica, check the [QUERY_EVENTS](#) system table for `LibHDFS++ UNSUPPORTED OPERATION` events.

Kerberos authentication errors

Kerberos authentication can fail even though a ticket is valid if Hadoop expires tickets frequently. It can also fail due to clock skew between Hadoop and Vertica nodes. For details, see [Troubleshooting Kerberos authentication](#).

Accessing kerberized HDFS data

If your Hortonworks or Cloudera Hadoop cluster uses Kerberos authentication to restrict access to HDFS, Vertica must be granted access. If you use Kerberos authentication for your Vertica database, and database users have HDFS access, then you can configure Vertica to use the same principals to authenticate. However, not all Hadoop administrators want to grant access to all database users, preferring to manage access in other ways. In addition, not all Vertica databases use Kerberos.

Vertica provides the following options for accessing Kerberized Hadoop clusters:

- Using Vertica Kerberos principals.
- Using Hadoop proxy users combined with Vertica users.
- Using a user-specified delegation token which grants access to HDFS. Delegation tokens are issued by the Hadoop cluster.

Proxy users and delegation tokens both use a session parameter to manage identities. Vertica need not be Kerberized when using either of these methods.

Vertica does not support Kerberos for MapR.

To test your Kerberos configuration, see [Verifying HDFS configuration](#).

In this section

- [Using Kerberos with Vertica](#)
- [Proxy users and delegation tokens](#)
- [Token expiration](#)

Using Kerberos with Vertica

If you use Kerberos for your Vertica cluster and your principals have access to HDFS, then you can configure Vertica to use the same credentials for HDFS.

Vertica authenticates with Hadoop in two ways that require different configurations:

- **User Authentication** —On behalf of the user, by passing along the user's existing Kerberos credentials. This method is also called user impersonation. Actions performed on behalf of particular users, like executing queries, generally use user authentication.
- **Vertica Authentication** —On behalf of system processes that access ROS data or the catalog, by using a special Kerberos credential stored in a keytab file.

Note

Vertica and Hadoop must use the same Kerberos server or servers (KDCs).

Vertica can interact with more than one Kerberos realm. To configure multiple realms, see [Multi-realm Support](#).

Vertica attempts to automatically refresh Hadoop tokens before they expire. See [Token expiration](#).

User authentication

To use Vertica with Kerberos and Hadoop, the client user first authenticates with one of the Kerberos servers (Key Distribution Center, or KDC) being used by the Hadoop cluster. A user might run `kinit` or sign in to Active Directory, for example.

A user who authenticates to a Kerberos server receives a Kerberos ticket. At the beginning of a client session, Vertica automatically retrieves this ticket. Vertica then uses this ticket to get a Hadoop token, which Hadoop uses to grant access. Vertica uses this token to access HDFS, such as when executing a query on behalf of the user. When the token expires, Vertica automatically renews it, also renewing the Kerberos ticket if necessary.

The user must have been granted permission to access the relevant files in HDFS. This permission is checked the first time Vertica reads HDFS data.

Vertica can use multiple KDCs serving multiple Kerberos realms, if proper cross-realm trust has been set up between realms.

Vertica authentication

Automatic processes, such as the Tuple Mover or the processes that access Eon Mode communal storage, do not log in the way users do. Instead, Vertica uses a special identity (principal) stored in a keytab file on every database node. (This approach is also used for Vertica clusters that use Kerberos but do not use Hadoop.) After you configure the keytab file, Vertica uses the principal residing there to automatically obtain and maintain a Kerberos ticket, much as in the client scenario. In this case, the client does not interact with Kerberos.

Each Vertica node uses its own principal; it is common to incorporate the name of the node into the principal name. You can either create one keytab per node, containing only that node's principal, or you can create a single keytab containing all the principals and distribute the file to all nodes. Either way, the node uses its principal to get a Kerberos ticket and then uses that ticket to get a Hadoop token.

When creating HDFS storage locations Vertica uses the principal in the keytab file, not the principal of the user issuing the CREATE LOCATION statement. The HCatalog Connector sometimes uses the principal in the keytab file, depending on how Hive authenticates users.

Configuring users and the keytab file

If you have not already configured Kerberos authentication for Vertica, follow the instructions in [Configure Vertica for Kerberos authentication](#). Of particular importance for Hadoop integration:

1. Create one Kerberos principal per node.
2. Place the keytab files in the same location on each database node and set configuration parameter `KerberosKeytabFile` to that location.
3. Set `KerberosServiceName` to the name of the principal. (See [Inform Vertica about the Kerberos principal](#).)

If you are using the HCatalog Connector, follow the additional steps in [Configuring security](#) in the HCatalog Connector documentation.

If you are using HDFS storage locations, give all node principals read and write permission to the HDFS directory you will use as a storage location.

Proxy users and delegation tokens

An alternative to granting HDFS access to individual Vertica users is to use delegation tokens, either directly or with a proxy user. In this configuration, Vertica accesses HDFS on behalf of some other (Hadoop) user. The Hadoop users need not be Vertica users at all.

In Vertica, you can either specify the name of the Hadoop user to act on behalf of (doAs), or you can directly use a Kerberos delegation token that you obtain from HDFS (Bring Your Own Delegation Token). In the doAs case, Vertica obtains a delegation token for that user, so both approaches ultimately use delegation tokens to access files in HDFS.

Use the [HadoopImpersonationConfig](#) session parameter to specify a user or delegation token to use for HDFS access. Each session can use a different user and can use either doAs or a delegation token. The value of HadoopImpersonationConfig is a set of JSON objects.

To use delegation tokens of either type (more specifically, when HadoopImpersonationConfig is set), you must access HDFS through WebHDFS.

In this section

- [User impersonation \(doAs\)](#)
- [Bring your own delegation token](#)
- [Getting a HiveServer2 delegation token](#)
- [HadoopImpersonationConfig format](#)

User impersonation (doAs)

You can use user impersonation to access data in an HDFS cluster from Vertica. This approach is called "doAs" (for "do as") because Vertica uses a single proxy user on behalf of another (Hadoop) user. The impersonated Hadoop user does not need to also be a Vertica user.

In the following illustration, Alice is a Hadoop user but not a Vertica user. She connects to Vertica as the proxy user, vertica-etl. In her session, Vertica obtains a delegation token (DT) on behalf of the doAs user (Alice), and uses that delegation token to access HDFS.

You can use doAs with or without Kerberos, so long as HDFS and Vertica match. If HDFS uses Kerberos then Vertica must too.

User configuration

The Hadoop administrator must create a [proxy user](#) and allow it to access HDFS on behalf of other users. Set values in core-site.xml as in the following example:

```
<name>hadoop.proxyuser.vertica-etl.users</name>
<value>*</value>
<name>hadoop.proxyuser.vertica-etl.hosts</name>
<value>*</value>
```

In Vertica, create a corresponding user.

Session configuration

To make requests on behalf of a Hadoop user, first set the [HadoopImpersonationConfig](#) session parameter to specify the user and HDFS cluster. Vertica will access HDFS as that user until the session ends or you change the parameter.

The value of this session parameter is a collection of JSON objects. Each object specifies an HDFS cluster and a Hadoop user. For the cluster, you can specify either a name service or an individual name node. If you are using HA name node, then you must either use a name service or specify all name nodes. [HadoopImpersonationConfig format](#) describes the full JSON syntax.

The following example shows access on behalf of two different users. The users "stephanie" and "bob" are Hadoop users, not Vertica users. "vertica-etl" is a Vertica user.

```
$ vsql -U vertica-etl

=> ALTER SESSION SET
  HadoopImpersonationConfig = '[{"nameservice":"hadoopNS", "doAs":"stephanie"}]';
=> COPY nation FROM 'webhdfs:///user/stephanie/nation.dat';

=> ALTER SESSION SET
  HadoopImpersonationConfig = '[{"nameservice":"hadoopNS", "doAs":"bob"}, {"authority":"hadoop2:50070", "doAs":"rob"}]';
=> COPY nation FROM 'webhdfs:///user/bob/nation.dat';
```

Vertica uses Hadoop delegation tokens, obtained from the name node, to impersonate Hadoop users. In a long-running session, a token could expire. Vertica attempts to renew tokens automatically; see [Token expiration](#).

Testing the configuration

You can use the [HADOOP_IMPERSONATION_CONFIG_CHECK](#) function to test your HDFS delegation tokens and [HCATALOGCONNECTOR_CONFIG_CHECK](#) to test your HCatalog Connector delegation token.

Bring your own delegation token

Instead of creating a proxy user and giving it access to HDFS for use with doAs, you can give Vertica a Hadoop delegation token to use. You must obtain this delegation token from the Hadoop name node. In this model, security is handled entirely on the Hadoop side, with Vertica just passing along a token. Vertica may or may not be Kerberized.

A typical workflow is:

- In an ETL front end, a user submits a query.
- The ETL system uses authentication and authorization services to verify that the user has sufficient permission to run the query.
- The ETL system requests a delegation token for the user from the name node.
- The ETL system makes a client connection to Vertica, sets the delegation token for the session, and runs the query.

When using a delegation token, clients can connect as any Vertica user. No proxy user is required.

In the following illustration, Bob has a Hadoop-issued delegation token. He connects to Vertica and Vertica uses that delegation token to access files in HDFS.

Session configuration

Set the [HadoopImpersonationConfig](#) session parameter to specify the delegation token and HDFS cluster. Vertica will access HDFS using that delegation token until the session ends, the token expires, or you change the parameter.

The value of this session parameter is a collection of JSON objects. Each object specifies a delegation token ("token") in WebHDFS format and an HDFS name service or name node. [HadoopImpersonationConfig format](#) describes the full JSON syntax.

The following example shows access on behalf of two different users. The users "stephanie" and "bob" are Hadoop users, not Vertica users. "dbuser1" is a Vertica user with no special privileges.

```
$ vsql -U dbuser1
```

```
=> ALTER SESSION SET
```

```
  HadoopImpersonationConfig = [{"authority":"hadoop1:50070","token":"JAAGZGJldGwxBmRiZXRsMQCKAWDX.JgB9igFg-  
zKEfY4gao4BmhSJYtXiWqrhBHbbUn4VScNg58HWQxJXRUIREZTIGRlBGVnYXRpb24RMTAuMjAuMTAwLjU0OjgwMjA"}];
```

```
=> COPY nation FROM 'webhdfs:///user/stephanie/nation.dat';
```

```
=> ALTER SESSION SET
```

```
  HadoopImpersonationConfig = [{"authority":"hadoop1:50070","token":"HgADdG9tA3RvbQCKAWDX.JgAoigFg-  
zKEKl4gal4BmhRoOUpq_jPxrVhZ1NSMnodAQnhUthJXRUIREZTIGRlBGVnYXRpb24RMTAuMjAuMTAwLjU0OjgwMjA"}];
```

```
=> COPY nation FROM 'webhdfs:///user/bob/nation.dat';
```

You can use the [WebHDFS REST API](#) to get delegation tokens:

```
$ curl -s --noproxy "*" --negotiate -u: -X GET "http://hadoop1:50070/webhdfs/v1/?op=GETDELEGATIONTOKEN"
```

Vertica does not, and cannot, renew delegation tokens when they expire. You must either keep sessions shorter than token lifetime or implement a renewal scheme.

Delegation tokens and the HCatalog Connector

HiveServer2 uses a different format for delegation tokens. To use the HCatalog Connector, therefore, you must set two delegation tokens, one as usual (authority) and one for HiveServer2 (schema). The HCatalog Connector uses the schema token to access metadata and the authority token to access data. The schema name is the same Hive schema you specified in CREATE HCATALOG SCHEMA. The following example shows how to use these two delegation tokens.

```
$ vsql -U dbuser1
```

```
-- set delegation token for user and HiveServer2
```

```
=> ALTER SESSION SET
```

```
  HadoopImpersonationConfig=[  
    {"nameservice":"hadoopNS","token":"JQAHCmVsZWFzZQdyZWxIYXNlAloBYVJKrYsKAWF2VzGEjgmzj_IUCIrI9b8Dqu6awFTHk5nC-  
fHB8xsSV0VCSERGUyBkZWxlZ2F0aW9uETEwLjU0OjgwMjA"},
```

```
    {"schema":"access","token":"UwAHcmVsZWFzZQdyZWxIYXNlL2hpdmUvZW5nLWc5LTEwMC52ZXJ0aWNhY29ycC5jb21AVkVSVEIDQUNPUIAuQ09NigFhU  
kmyT0oBYXZWNk4BjgETFKN2xPURn19Yq9tf-0nekoD51TZvFUhJVkVfREVMRUdBVEIPTI9UT0tFThZoaXZlc2VydMvYmMkNsaWVudFRva2Vu"}];
```

```
-- uses HiveServer2 token to get metadata
```

```
=> CREATE HCATALOG SCHEMA access WITH hcatalog_schema 'access';
```

```
-- uses both tokens
```

```
=> SELECT * FROM access.t1;
```

```
--uses only HiveServer2 token
```

```
=> SELECT * FROM hcatalog_tables;
```

HiveServer2 does not provide a REST API for delegation tokens like WebHDFS does. See [Getting a HiveServer2 delegation token](#) for some tips.

Testing the configuration

You can use the [HADOOP_IMPERSONATION_CONFIG_CHECK](#) function to test your HDFS delegation tokens and [HCATALOGCONNECTOR_CONFIG_CHECK](#) to test your HCatalog Connector delegation token.

Getting a HiveServer2 delegation token

To access Hive metadata using HiveServer2, you need a special delegation token. (See [Bring your own delegation token](#).) HiveServer2 does not provide an easy way to get this token, unlike the REST API that grants HDFS (data) delegation tokens.

The following utility code shows a way to get this token. You will need to modify this code for your own cluster; in particular, change the value of the `connectURL` static.

```
import java.io.FileWriter;  
import java.io.PrintStream;  
import java.io.PrintWriter;  
import java.io.StringWriter;  
.....
```

```

import java.io.Writer;
import java.security.PrivilegedExceptionAction;
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.ResultSet;
import java.sql.Statement;
import org.apache.hadoop.conf.Configuration;
import org.apache.hadoop.hive.shims.Utils;
import org.apache.hadoop.security.UserGroupInformation;
import org.apache.hive.jdbc.HiveConnection;
import org.json.simple.JSONArray;
import org.json.simple.JSONObject;

public class JDBCtest {
    public static final String driverName = "org.apache.hive.jdbc.HiveDriver";
    public static String connectURL =
"jdbc:hive2://node2.cluster0.example.com:2181,node1.cluster0.example.com:2181,node3.cluster0.example.com:2181;/serviceDiscoveryMode=zooKeeper;zooKeeperNamespace=hiveserver2";

HadoopImpersonationConfig format

The value of the [HadoopImpersonationConfig](#) session parameter is a set of one or more JSON objects. Each object describes one doAs user or delegation token for one Hadoop destination. You must use WebHDFS, not LibHDFS++, to use impersonation.

Syntax

```
[ { ("doAs" | "token"): value,
  ("nameservice" | "authority" | "schema"): value } [...]
```

Properties

doAs	The name of a Hadoop user to impersonate.
token	A delegation token to use for HDFS access.
nameservice	A Hadoop name service. All access to this name service uses the doAs user or delegation token.
authority	A name node authority. All access to this authority uses the doAs user or delegation token. If the name node fails over to another name node, the doAs user or delegation token does <i>not</i> automatically apply to the failover name node. If you are using HA name node, use nameservice instead of authority or include objects for every name node.
schema	A Hive schema, for use with the HCatalog Connector. Vertica uses this object's doAs user or token to access Hive metadata only. For data access you must also specify a name service or authority object, just like for all other data access.

Examples

In the following example of doAs, Bob is a Hadoop user and vertica-etl is a Kerberized proxy user.

```
$ kinit vertica-etl -kt /home/dbadmin/vertica-etl.keytab
$ vsql -U vertica-etl

=> ALTER SESSION SET
  HadoopImpersonationConfig = '[{"nameservice":"hadoopNS", "doAs":"Bob"}]';
=> COPY nation FROM 'webhdfs:///user/bob/nation.dat';
```

In the following example, the current Vertica user (it doesn't matter who that is) uses a Hadoop delegation token. This token belongs to Alice, but you never specify the user name here. Instead, you use it to get the delegation token from Hadoop.

```
$ vsql -U dbuser1
=> ALTER SESSION SET
  HadoopImpersonationConfig = [{"nameservice":"hadoopNS","token":"JAAGZGJldGwxBmRiZXRMsMQCKAWDXJgB9igFg-
zKEfY4gao4BmhSJYtXiWqrhBHbbUn4VScNg58HWQxJXRUIJIREZTIGRlBGVnYXRpb24RMTAuMjAuMTAwLjU0OjgwMjA"}];
=> COPY nation FROM 'webhdfs://user/alice/nation.dat';
```

In the following example, "authority" specifies the (single) name node on a Hadoop cluster that does not use high availability.

```
$ vsql -U dbuser1
=> ALTER SESSION SET
  HadoopImpersonationConfig = [{"authority":"hadoop1:50070", "doAs":"Stephanie"}];
=> COPY nation FROM 'webhdfs://hadoop1:50070/user/stephanie/nation.dat';
```

To access data in Hive you need to specify two delegation tokens. The first, for a name service or authority, is for data access as usual. The second is for the HiveServer2 metadata for the schema. HiveServer2 requires a delegation token in WebHDFS format. The schema name is the Hive schema you specify with CREATE HCATALOG SCHEMA.

```
$ vsql -U dbuser1
-- set delegation token for user and HiveServer2
=> ALTER SESSION SET
  HadoopImpersonationConfig=[
  {"nameservice":"hadoopNS","token":"JQAHcmVsZWFzZQdyZWxIYXNlIoBYVJKrYsKAWF2VzGEjgmzj_IUCIrI9b8Dqu6awFTHk5nC-
fHB8xsSV0VCSERGUyBkZWxlZ2F0aW9uETEwLjIwLjU0OjgwMjA"},
{"schema":"access","token":"UwAHcmVsZWFzZQdyZWxIYXNlL2hpdmUvZW5nLWc5LTEwMC52ZXJ0aWNhY29ycC5jb21AVkVSVEIDQUNPUIAuQ09NigFhU
kmyTooBYXZWNk4BjgETFKN2xPURn19Yq9tf-0nekoD51TZvFUhJVkVfREVMRUdBEIPTI9UT0tFTThZoaXZlc2VydmdyMkNsaWVudFRva2Vu"}];
-- uses HiveServer2 token to get metadata
=> CREATE HCATALOG SCHEMA access WITH hcatalog_schema 'access';
-- uses both tokens
=> SELECT * FROM access.t1;
--uses only HiveServer2 token
=> SELECT * FROM hcatalog_tables;
```

Each object in the HadoopImpersonationConfig collection specifies one connection to one Hadoop cluster. You can add as many connections as you like, including to more than one Hadoop cluster. The following example shows delegation tokens for two different Hadoop clusters. Vertica uses the correct token for each cluster when connecting.

```
$ vsql -U dbuser1
=> ALTER SESSION SET
  HadoopImpersonationConfig = [
  {"nameservice":"productionNS","token":"JAAGZGJldGwxBmRiZXRMsMQCKAWDXJgB9igFg-
zKEfY4gao4BmhSJYtXiWqrhBHbbUn4VScNg58HWQxJXRUIJIREZTIGRlBGVnYXRpb24RMTAuMjAuMTAwLjU0OjgwMjA"},
  {"nameservice":"testNS", "token":"HQAHCmVsZWFzZQdyZWxIYXNlIoBYVJKrYsKAWF2VzGEjgmzj_IUCIrI9b8Dqu6awFTHk5nC-
fHB8xsSV0VCSERGUyBkZWxlZ2F0aW9uETEwLjIwLjU0OjgwMjA"}];
=> COPY clicks FROM 'webhdfs://productionNS/data/clickstream.dat';
=> COPY testclicks FROM 'webhdfs://testNS/data/clickstream.dat';
```

Token expiration

Vertica uses Hadoop tokens when using Kerberos tickets ([Using Kerberos with Vertica](#)) or doAs ([User impersonation \(doAs\)](#)). Vertica attempts to automatically refresh Hadoop tokens before they expire, but you can also set a minimum refresh frequency if you prefer. Use the `HadoopFSTokenRefreshFrequency` configuration parameter to specify the frequency in seconds:

```
=> ALTER DATABASE exampledb SET HadoopFSTokenRefreshFrequency = '86400';
```

If the current age of the token is greater than the value specified in this parameter, Vertica refreshes the token before accessing data stored in HDFS.

Vertica does not refresh delegation tokens ([Bring your own delegation token](#)).

Using HDFS storage locations

Vertica stores data in its native format, ROS, in storage locations. You can place storage locations on the local Linux file system or in HDFS. If you place storage locations on HDFS, you must perform additional configuration in HDFS to be able to manage them. These are in addition to the requirements in Vertica for [managing storage locations](#) and [backup/restore](#) .

If you use HDFS storage locations, the HDFS data must be available when you start Vertica. Your HDFS cluster must be operational, and the ROS files must be present. If you moved data files, or they are corrupted, or your HDFS cluster is not responsive, Vertica cannot start.

In this section

- [Hadoop configuration for backup and restore](#)
- [Removing HDFS storage locations](#)

Hadoop configuration for backup and restore

If your Vertica cluster uses storage locations on HDFS, and you want to be able to back up and restore those storage locations using `vbr` , you must enable snapshotting in HDFS.

The Vertica backup script uses HDFS's snapshotting feature to create a backup of HDFS storage locations. A directory must allow snapshotting before HDFS can take a snapshot. Only a Hadoop superuser can enable snapshotting on a directory. Vertica can enable snapshotting automatically if the database administrator is also a Hadoop superuser.

If HDFS is unsecured, the following instructions apply to the database administrator account, usually `dbadmin`. If HDFS uses Kerberos security, the following instructions apply to the principal stored in the Vertica keytab file, usually `vertica`. The instructions below use the term "database account" to refer to this user.

We recommend that you make the database administrator or principal a Hadoop superuser. If you are not able to do so, you must enable snapshotting on the directory before configuring it for use by Vertica.

The steps you need to take to make the Vertica database administrator account a superuser depend on the distribution of Hadoop you are using. Consult your Hadoop distribution's documentation for details.

Manually enabling snapshotting for a directory

If you cannot grant superuser status to the database account, you can instead enable snapshotting of each directory manually. Use the following command:

```
$ hdfs dfsadmin -allowSnapshot path
```

Issue this command for each directory on each node. Remember to do this each time you add a new node to your HDFS cluster.

Nested snapshottable directories are not allowed, so you cannot enable snapshotting for a parent directory to automatically enable it for child directories. You must enable it for each individual directory.

Additional requirements for Kerberos

If HDFS uses Kerberos, then in addition to granting the keytab principal access, you must give Vertica access to certain Hadoop configuration files. See [Configuring Kerberos](#) .

Testing the database account's ability to make HDFS directories snapshottable

After making the database account a Hadoop superuser, verify that the account can set directories snapshottable:

1. Log into the Hadoop cluster as the database account (`dbadmin` by default).
2. Determine a location in HDFS where the database administrator can create a directory. The `/tmp` directory is usually available. Create a test HDFS directory using the command:

```
$ hdfs dfs -mkdir /path/testdir
```

3. Make the test directory snapshottable using the command:

```
$ hdfs dfsadmin -allowSnapshot /path/testdir
```

The following example demonstrates creating an HDFS directory and making it snapshottable:

```
$ hdfs dfs -mkdir /tmp/snaptest
$ hdfs dfsadmin -allowSnapshot /tmp/snaptest
Allowing snapshot on /tmp/snaptest succeeded
```

Removing HDFS storage locations

The steps to remove an HDFS storage location are similar to standard storage locations:

1. Remove any existing data from the HDFS storage location by using [SET_OBJECT_STORAGE_POLICY](#) to change each object's storage location. Alternatively, you can use [CLEAR_OBJECT_STORAGE_POLICY](#). Because the Tuple Mover runs infrequently, set the `enforce-storage-move` parameter to `true` to make the change immediately.
2. Retire the location on each host that has the storage location defined using [RETIRE_LOCATION](#). Set `enforce-storage-move` to `true`.
3. Drop the location on each node using [DROP_LOCATION](#).
4. Optionally remove the snapshots and files from the HDFS directory for the storage location.
5. Perform a full database backup.

For more information about changing storage policies, changing usage, retiring locations, and dropping locations, see [Managing storage locations](#).

Important

If you have backed up the data in the HDFS storage location you are removing, you must perform a full database backup after you remove the location. If you do not and restore the database to a backup made before you removed the location, the location's data is restored.

Removing storage location files from HDFS

Dropping an HDFS storage location does not automatically clean the HDFS directory that stored the location's files. Any snapshots of the data files created when backing up the location are also not deleted. These files consume disk space on HDFS and also prevent the directory from being reused as an HDFS storage location. Vertica cannot create a storage location in a directory that contains existing files or subdirectories.

You must log into the Hadoop cluster to delete the files from HDFS. An alternative is to use some other HDFS file management tool.

Removing backup snapshots

HDFS returns an error if you attempt to remove a directory that has snapshots:

```
$ hdfs dfs -rm -r -f -skipTrash /user/dbadmin/v_vmart_node0001
rm: The directory /user/dbadmin/v_vmart_node0001 cannot be deleted since
/user/dbadmin/v_vmart_node0001 is snapshottable and already has snapshots
```

The Vertica backup script creates snapshots of HDFS storage locations as part of the backup process. If you made backups of your HDFS storage location, you must delete the snapshots before removing the directories.

HDFS stores snapshots in a subdirectory named `.snapshot`. You can list the snapshots in the directory using the standard HDFS `ls` command:

```
$ hdfs dfs -ls /user/dbadmin/v_vmart_node0001/.snapshot
Found 1 items
drwxrwx--- - dbadmin supergroup    0 2014-09-02 10:13 /user/dbadmin/v_vmart_node0001/.snapshot/s20140902-101358.629
```

To remove snapshots, use the command:

```
$ hdfs dfs -removeSnapshot directory snapshotname
```

The following example demonstrates the command to delete the snapshot shown in the previous example:

```
$ hdfs dfs -deleteSnapshot /user/dbadmin/v_vmart_node0001 s20140902-101358.629
```

You must delete each snapshot from the directory for each host in the cluster. After you have deleted the snapshots, you can delete the directories in the storage location.

Important

Each snapshot's name is based on a timestamp down to the millisecond. Nodes independently create their own snapshots. They do not synchronize snapshot creation, so their snapshot names differ. You must list each node's snapshot directory to learn the names of the snapshots it contains.

See Apache's [HDFS Snapshot documentation](#) for more information about managing and removing snapshots.

Removing the storage location directories

You can remove the directories that held the storage location's data by either of the following methods:

- Use an HDFS file manager to delete directories. See your Hadoop distribution's documentation to determine if it provides a file manager.
- Log into the Hadoop Name Node using the database administrator's account and use HDFS's `rmr` command to delete the directories. See Apache's [File System Shell Guide](#) for more information.

The following example uses the HDFS `rmr` command from the Linux command line to delete the directories left behind in the HDFS storage location directory `/user/dbadmin`. It uses the `-skipTrash` flag to force the immediate deletion of the files:

```
$ hdfs dfs -ls /user/dbadmin
Found 3 items
drwxrwx--- - dbadmin supergroup    0 2014-08-29 15:11 /user/dbadmin/v_vmart_node0001
drwxrwx--- - dbadmin supergroup    0 2014-08-29 15:11 /user/dbadmin/v_vmart_node0002
drwxrwx--- - dbadmin supergroup    0 2014-08-29 15:11 /user/dbadmin/v_vmart_node0003

$ hdfs dfs -rmr -skipTrash /user/dbadmin/*
Deleted /user/dbadmin/v_vmart_node0001
Deleted /user/dbadmin/v_vmart_node0002
Deleted /user/dbadmin/v_vmart_node0003
```

Using the HCatalog Connector

The Vertica HCatalog Connector lets you access data stored in Apache's Hive data warehouse software the same way you access it within a native Vertica table.

If your files are in the Optimized Columnar Row (ORC) or Parquet format and do not use complex types, the HCatalog Connector creates an external table and uses the ORC or Parquet reader instead of using the Java SerDe. See [ORC](#) and [PARQUET](#) for more information about these readers.

The HCatalog Connector performs predicate pushdown to improve query performance. Instead of reading all data across the network to evaluate a query, the HCatalog Connector moves the evaluation of predicates closer to the data. Predicate pushdown applies to Hive partition pruning, ORC stripe pruning, and Parquet row-group pruning. The HCatalog Connector supports predicate pushdown for the following predicates: `>`, `>=`, `=`, `<>`, `<=`, `<`.

In this section

- [Using nonstandard SerDes](#)
- [Troubleshooting HCatalog Connector problems](#)

Overview

There are several Hadoop components that you need to understand to use the HCatalog connector:

- Apache Hive lets you query data stored in a Hadoop Distributed File System (HDFS) the same way you query data stored in a relational database. Behind the scenes, Hive uses a set of serializer and deserializer (SerDe) classes to extract data from files stored in HDFS and break it into columns and rows. Each SerDe handles data files in a specific format. For example, one SerDe extracts data from comma-separated data files while another interprets data stored in JSON format.
- Apache HCatalog is a component of the Hadoop ecosystem that makes Hive's metadata available to other Hadoop components (such as Pig).
- HiveServer2 makes HCatalog and Hive data available via JDBC. Through it, a client can make requests to retrieve data stored in Hive, as well as information about the Hive schema. HiveServer2 can use authorization services (Sentry or Ranger). HiveServer2 can use Hive LLAP (Live Long And Process).

The Vertica HCatalog Connector lets you transparently access data that is available through HiveServer2. You use the connector to define a schema in Vertica that corresponds to a Hive database or schema. When you query data within this schema, the HCatalog Connector transparently extracts and formats the data from Hadoop into tabular data. Vertica supports authorization services and Hive LLAP.

Note

You can use the WebHCat service instead of HiveServer2, but performance is usually better with HiveServer2. Support for WebHCat is deprecated. To use WebHCat, set the `HCatalogConnectorUseHiveServer2` configuration parameter to 0. See [Hadoop parameters](#). WebHCat does not support authorization services.

HCatalog connection features

The HCatalog Connector lets you query data stored in Hive using the Vertica native SQL syntax. Some of its main features are:

- The HCatalog Connector always reflects the current state of data stored in Hive.
- The HCatalog Connector uses the parallel nature of both Vertica and Hadoop to process Hive data. The result is that querying data through the HCatalog Connector is often faster than querying the data directly through Hive.
- Because Vertica performs the extraction and parsing of data, the HCatalog Connector does not significantly increase the load on your Hadoop cluster.
- The data you query through the HCatalog Connector can be used as if it were native Vertica data. For example, you can execute a query that joins data from a table in an HCatalog schema with a native table.

HCatalog Connector considerations

There are a few things to keep in mind when using the HCatalog Connector:

- Hive's data is stored in flat files in a distributed file system, requiring it to be read and deserialized each time it is queried. This deserialization causes Hive performance to be much slower than that of Vertica. The HCatalog Connector has to perform the same process as Hive to read the data. Therefore, querying data stored in Hive using the HCatalog Connector is much slower than querying a native Vertica table. If you need to perform extensive analysis on data stored in Hive, you should consider loading it into Vertica. Vertica optimization often makes querying data through the HCatalog Connector faster than directly querying it through Hive.
- If Hive uses Kerberos security, the HCatalog Connector uses the querying user's credentials in queries by default. If Hive uses Sentry or Ranger to enforce security, then you must either disable this behavior in Vertica by setting `EnableHCatImpersonation` to 0 or grant users access to the underlying data in HDFS. (Sentry supports ACL synchronization to automatically grant access.) Alternatively, you can specify delegation tokens for data and metadata access. See [Configuring security](#).
- Hive supports complex data types such as lists, maps, and structs that Vertica does not support. Columns containing these data types are converted to a JSON representation of the data type and stored as a VARCHAR. See [Data type conversions from Hive to Vertica](#).

Note

The HCatalog Connector is read-only. It cannot insert data into Hive.

How the HCatalog Connector works

When planning a query that accesses data from a Hive table, the Vertica HCatalog Connector on the initiator node contacts HiveServer2 (or WebHCat) in your Hadoop cluster to determine if the table exists. If it does, the connector retrieves the table's metadata from the metastore database so the query planning can continue. When the query executes, all nodes in the Vertica cluster directly retrieve the data necessary for completing the query from HDFS. They then use the Hive SerDe classes to extract the data so the query can execute. When accessing data in ORC or Parquet format, the HCatalog Connector uses Vertica's internal readers for these formats instead of the Hive SerDe classes.

This approach takes advantage of the parallel nature of both Vertica and Hadoop. In addition, by performing the retrieval and extraction of data directly, the HCatalog Connector reduces the impact of the query on the Hadoop cluster.

For files in the Optimized Columnar Row (ORC) or Parquet format that do not use complex types, the HCatalog Connector creates an external table and uses the ORC or Parquet reader instead of using the Java SerDe. You can direct these readers to access custom Hive partition locations if Hive used them when writing the data. By default these extra checks are turned off to improve performance.

HCatalog Connector requirements

Before you can use the HCatalog Connector, both your Vertica and Hadoop installations must meet the following requirements.

Vertica requirements

All of the nodes in your cluster must have a Java Virtual Machine (JVM) installed. You must use the same Java version that the Hadoop cluster uses. See [Installing the Java Runtime on Your Vertica Cluster](#).

You must also add certain libraries distributed with Hadoop and Hive to your Vertica installation directory. See [Configuring Vertica for HCatalog](#).

Hadoop requirements

Your Hadoop cluster must meet several requirements to operate correctly with the Vertica Connector for HCatalog:

- It must have Hive, HiveServer2, and HCatalog installed and running. See Apache's [HCatalog](#) page for more information.
- The HiveServer2 server and all of the HDFS nodes that store HCatalog data must be directly accessible from all of the hosts in your Vertica database. Verify that any firewall separating the Hadoop cluster and the Vertica cluster will pass HiveServer2, metastore database, and HDFS traffic.
- The data that you want to query must be in an internal or external Hive table.
- If a table you want to query uses a non-standard SerDe, you must install the SerDe's classes on your Vertica cluster before you can query the data. See [Using nonstandard SerDes](#).

Installing the Java runtime on your Vertica cluster

The HCatalog Connector requires a 64-bit Java Virtual Machine (JVM). The JVM must support Java 6 or later, and must be the same version as the one installed on your Hadoop nodes.

Note

If your Vertica cluster is configured to execute User Defined Extensions (UDxs) written in Java, it already has a correctly-configured JVM installed. See [Developing user-defined extensions \(UDxs\)](#) for more information.

Installing Java on your Vertica cluster is a two-step process:

1. Install a Java runtime on all of the hosts in your cluster.
2. Set the `JavaBinaryForUDx` configuration parameter to tell Vertica the location of the Java executable.

Installing a Java runtime

For Java-based features, Vertica requires a 64-bit Java 6 (Java version 1.6) or later Java runtime. Vertica supports runtimes from either Oracle or [OpenJDK](#). You can choose to install either the Java Runtime Environment (JRE) or Java Development Kit (JDK), since the JDK also includes the JRE.

Many Linux distributions include a package for the OpenJDK runtime. See your Linux distribution's documentation for information about installing and configuring OpenJDK.

To install the Oracle Java runtime, see the [Java Standard Edition \(SE\) Download Page](#). You usually run the installation package as root in order to install it. See the download page for instructions.

Once you have installed a JVM on each host, ensure that the `java` command is in the search path and calls the correct JVM by running the command:

```
$ java -version
```

This command should print something similar to:

```
java version "1.8.0_102"  
Java(TM) SE Runtime Environment (build 1.8.0_102-b14)  
Java HotSpot(TM) 64-Bit Server VM (build 25.102-b14, mixed mode)
```

Note

Any previously installed Java VM on your hosts may interfere with a newly installed Java runtime. See your Linux distribution's documentation for instructions on configuring which JVM is the default. Unless absolutely required, you should uninstall any incompatible version of Java before installing the Java 6 or Java 7 runtime.

Setting the `JavaBinaryForUDx` configuration parameter

The `JavaBinaryForUDx` configuration parameter tells Vertica where to look for the JRE to execute Java UDxs. After you have installed the JRE on all of the nodes in your cluster, set this parameter to the absolute path of the Java executable. You can use the symbolic link that some Java installers create (for example `/usr/bin/java`). If the Java executable is in your shell search path, you can get the path of the Java executable by running the following command from the Linux command line shell:

```
$ which java  
/usr/bin/java
```

If the `java` command is not in the shell search path, use the path to the Java executable in the directory where you installed the JRE. Suppose you installed the JRE in `/usr/java/default` (which is where the installation package supplied by Oracle installs the Java 1.6 JRE). In this case the Java executable is `/usr/java/default/bin/java`.

You set the configuration parameter by executing the following statement as a [database superuser](#):

```
=> ALTER DATABASE DEFAULT SET PARAMETER JavaBinaryForUDx = '/usr/bin/java';
```

See [ALTER DATABASE](#) for more information on setting configuration parameters.

To view the current setting of the configuration parameter, query the [CONFIGURATION_PARAMETERS](#) system table:

```
=> \x  
Expanded display is on.  
=> SELECT * FROM CONFIGURATION_PARAMETERS WHERE parameter_name = 'JavaBinaryForUDx';  
-[ RECORD 1 ]-----+-----  
node_name          | ALL  
parameter_name     | JavaBinaryForUDx  
current_value      | /usr/bin/java  
default_value      |  
change_under_support_guidance | f  
change_requires_restart | f  
description        | Path to the java binary for executing UDx written in Java
```

Once you have set the configuration parameter, Vertica can find the Java executable on each node in your cluster.

Note

Since the location of the Java executable is set by a single configuration parameter for the entire cluster, you must ensure that the Java executable is installed in the same path on all of the hosts in the cluster.

Configuring Vertica for HCatalog

Before you can use the HCatalog Connector, you must add certain Hadoop and Hive libraries to your Vertica installation. You must also copy the Hadoop configuration files that specify various connection properties. Vertica uses the values in those configuration files to make its own connections to Hadoop.

You need only make these changes on one node in your cluster. After you do this you can install the HCatalog connector.

Copy Hadoop libraries and configuration files

Vertica provides a tool, `hcatUtil`, to collect the required files from Hadoop. This tool copies selected libraries and XML configuration files from your Hadoop cluster to your Vertica cluster. This tool might also need access to additional libraries:

- If you plan to use Hive to query files that use Snappy compression, you need access to the Snappy native libraries, `libhadoop*.so` and `libsnapappy*.so`.
- If you plan to use Hive to query files that use LZO compression, you need access to the `hadoop-lzo-*.jar` and `libgplcompression.so*` libraries. In `core-site.xml` you must also edit the `io.compression.codecs` property to include `com.hadoop.compression.lzo.LzopCodec`.
- If you plan to use a JSON SerDe with a Hive table, you need access to its library. This is the same library that you used to configure Hive; for example:

```
hive> add jar /home/release/json-serde-1.3-jar-with-dependencies.jar;

hive> create external table nationjson (id int,name string,rank int,text string)
  ROW FORMAT SERDE 'org.openx.data.jsonserde.JsonSerDe'
  LOCATION '/user/release/vt/nationjson';
```

- If you are using any other libraries that are not standard across all supported Hadoop versions, you need access to those libraries.

If any of these cases applies to you, do one of the following:

- Include the path(s) in the path you specify as the value of `--hcatLibPath`, or
- Copy the file(s) to a directory already on that path.

If Vertica is not co-located on a Hadoop node, you should do the following:

1. Copy `/opt/vertica/packages/hcat/tools/hcatUtil` to a Hadoop node and run it there, specifying a temporary output directory. Your Hadoop, HIVE, and HCatalog lib paths might be different. In newer versions of Hadoop the HCatalog directory is usually a subdirectory under the HIVE directory, and Cloudera creates a new directory for each revision of the configuration files. Use the values from your environment in the following command:

```
hcatUtil --copyJars
  --hadoopHiveHome="$HADOOP_HOME/lib;$HIVE_HOME/lib;/hcatalog/dist/share"
  --hadoopHiveConfPath="$HADOOP_CONF_DIR;$HIVE_CONF_DIR;$WEBHCAT_CONF_DIR"
  --hcatLibPath="/tmp/hadoop-files"
```

If you are using Hive LLAP, specify the `hive2` directories.

2. Verify that all necessary files were copied:

```
hcatUtil --verifyJars --hcatLibPath=/tmp/hadoop-files
```

3. Copy that output directory (`/tmp/hadoop-files`, in this example) to `/opt/vertica/packages/hcat/lib` on the Vertica node you will connect to when installing the HCatalog connector. If you are updating a Vertica cluster to use a new Hadoop cluster (or a new version of Hadoop), first remove all JAR files in `/opt/vertica/packages/hcat/lib` except `vertica-hcatalogudl.jar`.
4. Verify that all necessary files were copied:

```
hcatUtil --verifyJars --hcatLibPath=/opt/vertica/packages/hcat
```

If Vertica is co-located on some or all Hadoop nodes, you can do this in one step on a shared node. Your Hadoop, HIVE, and HCatalog lib paths might be different; use the values from your environment in the following command:

```
hcatUtil --copyJars
  --hadoopHiveHome="$HADOOP_HOME/lib;$HIVE_HOME/lib;/hcatalog/dist/share"
  --hadoopHiveConfPath="$HADOOP_CONF_DIR;$HIVE_CONF_DIR;$WEBHCAT_CONF_DIR"
  --hcatLibPath="/opt/vertica/packages/hcat/lib"
```

The `hcatUtil` script has the following arguments:

<code>-c, --copyJars</code>	Copy the required JAR files from <code>hadoopHiveHome</code> and configuration files from <code>hadoopHiveConfPath</code> .
<code>-v, --verifyJars</code>	Verify that the required files are present in <code>hcatLibPath</code> . Check the output of <code>hcatUtil</code> for error and warning messages.
<code>--hadoopHiveHome= "value1;value2;..."</code>	<p>Paths to the Hadoop, Hive, and HCatalog home directories. Separate directories by semicolons (;). Enclose paths in double quotes.</p> <div style="background-color: #e6f2ff; padding: 10px;"> <p>Note</p> <p>Always place <code>\$HADOOP_HOME</code> on the path before <code>\$HIVE_HOME</code>. In some Hadoop distributions, these two directories contain different versions of the same library.</p> </div>
<code>--hadoopHiveConfPath= "value1;value2;..."</code>	<p>Paths of the following configuration files:</p> <ul style="list-style-type: none"> • <code>hive-site.xml</code> • <code>core-site.xml</code> • <code>yarn-site.xml</code> • <code>webhcat-site.xml</code> (optional with the default configuration; required if you use WebHCat instead of HiveServer2) • <code>hdfs-site.xml</code> <p>Separate directories by semicolons (;). Enclose paths in double quotes.</p> <p>In previous releases of Vertica this parameter was optional under some conditions. It is now required.</p>
<code>--hcatLibPath= "value"</code>	Output path for the libraries and configuration files. On a Vertica node, use <code>/opt/vertica/packages/hcat/lib</code> . If you have previously run <code>hcatUtil</code> with a different version of Hadoop, first remove the old JAR files from the output directory (all except <code>vertica-hcatalogudl.jar</code>).

After you have copied the files and verified them, install the HCatalog connector.

Install the HCatalog Connector

On the same node where you copied the files from `hcatUtil`, install the HCatalog connector by running the `install.sql` script. This script resides in the `ddl/` folder under your HCatalog connector installation path. This script creates the library and `VHCatalogSource` and `VHCatalogParser`.

Note

The data that was copied using `hcatUtil` is now stored in the database. If you change any of those values in Hadoop, you need to rerun `hcatUtil` and `install.sql`. The following statement returns the names of the libraries and configuration files currently being used:

```
=> SELECT dependencies FROM user_libraries WHERE lib_name='VHCatalogLib';
```

Now you can create HCatalog schema parameters, which point to your existing Hadoop services, as described in [Defining a schema using the HCatalog Connector](#).

Upgrading to a new version of Vertica

After upgrading to a new version of Vertica, perform the following steps:

1. Uninstall the HCatalog Connector using the `uninstall.sql` script. This script resides in the `ddl/` folder under your HCatalog connector installation path.
2. Delete the contents of the `hcatLibPath` directory except for `vertica-hcatalogudl.jar`.
3. Rerun `hcatUtil`.
4. Reinstall the HCatalog Connector using the `install.sql` script.

For more information about upgrading Vertica, see [Upgrade Vertica](#).

Additional options for Hadoop columnar file formats

When reading Hadoop columnar file formats (ORC or Parquet), the HCatalog Connector attempts to use the built-in readers. When doing so, it uses WebHDFS by default. You can use the deprecated LibHDFS++ library by using the `hdfs` URI scheme and using [ALTER DATABASE](#) to set `HDFSUseWebHDFS` to 0. This setting applies to all HDFS access, not just the HCatalog Connector.

In either case, you must perform the configuration described in [Configuring HDFS access](#).

Configuring security

You can use any of the security options described in [Accessing kerberized HDFS data](#) to access Hive data. This topic describes additional steps needed specifically for using the HCatalog Connector.

If you use Kerberos from Vertica, the HCatalog Connector can use an authorization service (Sentry or Ranger). If you use delegation tokens, you must manage authorization yourself.

Kerberos

You can use Kerberos from Vertica as described in [Using Kerberos with Vertica](#).

How you configure the HCatalog Connector depends on how Hive manages authorization.

- If Hive uses Sentry to manage authorization, and if Sentry uses ACL synchronization, then the HCatalog Connector must access HDFS as the current user. Verify that the `EnableHCatImpersonation` configuration parameter is set to 1 (the default). ACL synchronization automatically provides authorized users with read access to the underlying HDFS files.
- If Hive uses Sentry without ACL synchronization, then the HCatalog Connector must access HDFS data as the Vertica principal. (The user still authenticates and accesses metadata normally.) Set the `EnableHCatImpersonation` configuration parameter to 0. The Vertica principal must have read access to the underlying HDFS files.
- If Hive uses Ranger to manage authorization, and the Vertica users have read access to the underlying HDFS files, then you can use user impersonation. Verify that the `EnableHCatImpersonation` configuration parameter is set to 1 (the default). You can, instead, disable user impersonation and give the Vertica principal read access to the HDFS files.
- If Hive uses either Sentry or Ranger, the HCatalog Connector must use `HiveServer2` (the default). WebHCat does not support authorization services.
- If Hive does not use an authorization service, or if you are connecting to Hive using WebHCat instead of `HiveServer2`, then the HCatalog Connector accesses Hive as the current user. Verify that `EnableHCatImpersonation` is set to 1. All users must have read access to the underlying HDFS files.

In addition, in your Hadoop configuration files (`core-site.xml` in most distributions), make sure that you enable all Hadoop components to impersonate the Vertica user. The easiest way to do so is to set the `proxyuser` property using wildcards for all users on all hosts and in all groups. Consult your Hadoop documentation for instructions. Make sure you set this property before running `hcatUtil` (see [Configuring Vertica for HCatalog](#)).

Delegation tokens

You can use delegation tokens for a session as described in [Bring your own delegation token](#). When using the HCatalog Connector you specify two delegation tokens, one for the data and one for the metadata. The metadata token is tied to a Hive schema. See [HadoopImpersonationConfig format](#) for information about how to specify these two delegation tokens.

Verifying security configuration

To verify that the HCatalog Connector can access Hive data, use the `HCATALOGCONNECTOR_CONFIG_CHECK` function.

For more information about testing your configuration, see [Verifying HDFS configuration](#).

Defining a schema using the HCatalog Connector

After you set up the HCatalog Connector, you can use it to define a schema in your Vertica database to access the tables in a Hive database. You define the schema using the `CREATE HCATALOG SCHEMA` statement.

When creating the schema, you must supply the name of the schema to define in Vertica. Other parameters are optional. If you do not supply a value, Vertica uses default values. Vertica reads some default values from the HDFS configuration files; see [Configuration Parameters](#).

To create the schema, you must have read access to all Hive data. Verify that the user creating the schema has been granted access, either directly or through an authorization service such as Sentry or Ranger. The `dbadmin` user has no automatic special privileges.

After you create the schema, you can change many parameters using the `ALTER HCATALOG SCHEMA` statement.

After you define the schema, you can query the data in the Hive data warehouse in the same way you query a native Vertica table. The following example demonstrates creating an HCatalog schema and then querying several system tables to examine the contents of the new schema. See [Viewing Hive schema and table metadata](#) for more information about these tables.

```
=> CREATE HCATALOG SCHEMA hcat WITH HOSTNAME='hcathost' PORT=9083
  HCATALOG_SCHEMA='default' HIVESERVER2_HOSTNAME='hs.example.com'
  SSL_CONFIG='/etc/hadoop/conf/ssl-client.xml' HCATALOG_USER='admin';
CREATE SCHEMA
=> \x
Expanded display is on.
```

```

```

Configuration parameters

The HCatalog Connector uses the following values from the Hadoop configuration files if you do not override them when creating the schema.

File	Properties
hive-site.xml	hive.server2.thrift.bind.host (used for HIVESERVER2_HOSTNAME)

	hive.server2.thrift.port
	hive.server2.transport.mode
	hive.server2.authentication
	hive.server2.authentication.kerberos.principal
	hive.server2.support.dynamic.service.discovery
	hive.zookeeper.quorum (used as HIVESERVER2_HOSTNAME if dynamic service discovery is enabled)
	hive.zookeeper.client.port
	hive.server2.zookeeper.namespace
	hive.metastore.uris (used for HOSTNAME and PORT)
ssl-client.xml	ssl.client.truststore.location
	ssl.client.truststore.password

Using partitioned data

Hive supports partitioning data, as in the following example:

```
hive> create table users (name varchar(64), address string, city varchar(64))
partitioned by (state varchar(64)) stored as orc;
```

Vertica takes advantage of partitioning information for formats that provide it in metadata (ORC and Parquet). Queries can skip irrelevant partitions entirely (partition pruning), and Vertica does not need to materialize partition columns. For more about how to use partitions in Vertica, see [Partitioned data](#). For more information about how to create compatible partitions in Hive, see [Hive primer for Vertica integration](#).

By default Hive stores partition information under the path for the table definition, which might be local to Hive. However, a Hive user can choose to store partition information elsewhere, such as in a shared location like S3, as in the following example:

```
hive> alter table users add partition (state='MA')
location 's3a://DataLake/partitions/users/state=MA';
```

During query execution, therefore, Vertica must query Hive for the location of a table's partition information.

Because the additional Hive queries can be expensive, Vertica defaults to looking for partition information only in Hive's default location. If your Hive table specified a custom location, use the CUSTOM_PARTITIONS parameter:

```
=> CREATE HCATALOG SCHEMA hcat WITH HOSTNAME='hcat' PORT=9083
HCATALOG_SCHEMA='default' HIVESERVER2_HOSTNAME='hs.example.com'
SSL_CONFIG='/etc/hadoop/conf/ssl-client.xml' HCATALOG_USER='admin'
CUSTOM_PARTITIONS='yes';
```

Vertica can access partition locations in the S3 and S3a schemes, and does not support the S3n scheme.

The [HIVE_CUSTOM_PARTITIONS_ACCESSED](#) system table records all custom partition locations that have been used in queries.

Using the HCatalog Connector with WebHCat

By default the HCatalog Connector uses HiveServer2 to access Hive data. If you are instead using WebHCat, set the HCatalogConnectorUseHiveServer2 configuration parameter to 0 before creating the schema as in the following example.

```
=> ALTER DATABASE DEFAULT SET PARAMETER HCatalogConnectorUseHiveServer2 = 0;
=> CREATE HCATALOG SCHEMA hcat WITH WEBSERVICE_HOSTNAME='webhcat.example.com';
```

If you have previously used WebHCat, you can switch to using HiveServer2 by setting the configuration parameter to 1 and using [ALTER HCATALOG SCHEMA](#) to set HIVESERVER2_HOSTNAME. You do not need to remove the WebHCat values; the HCatalog Connector uses the value of HCatalogConnectorUseHiveServer2 to determine which parameters to use.

Querying Hive tables using HCatalog Connector

Once you have defined the HCatalog schema, you can query data from the Hive database by using the schema name in your query.

```
=> SELECT * from hcat.messages limit 10;
messageid | userid | time | message
-----+-----+-----+-----
1 | nPfQ1ayhi | 2013-10-29 00:10:43 | hymenaeos cursus lorem Suspendis
2 | N7svORloZ | 2013-10-29 00:21:27 | Fusce ad sem vehicula morbi
3 | 4VvzN3d | 2013-10-29 00:32:11 | porta Vivamus condimentum
4 | heojkmTmc | 2013-10-29 00:42:55 | lectus quis imperdiet
5 | coROws3OF | 2013-10-29 00:53:39 | sit eleifend tempus a aliquam mauri
6 | oDRP1i | 2013-10-29 01:04:23 | risus facilisis sollicitudin sceler
7 | AU7a9Kp | 2013-10-29 01:15:07 | turpis vehicula tortor
8 | ZJWg185DkZ | 2013-10-29 01:25:51 | sapien adipiscing eget Aliquam tor
9 | E7ipAsYC3 | 2013-10-29 01:36:35 | varius Cum iaculis metus
10 | kStCv | 2013-10-29 01:47:19 | aliquam libero nascetur Cum mal
(10 rows)
```

Since the tables you access through the HCatalog Connector act like Vertica tables, you can perform operations that use both Hive data and native Vertica data, such as a join:

```
=> SELECT u.FirstName, u.LastName, d.time, d.Message from UserData u
-> JOIN hcat.messages d ON u.UserID = d.UserID LIMIT 10;
FirstName | LastName | time | Message
-----+-----+-----+-----
Whitney | Kerr | 2013-10-29 00:10:43 | hymenaeos cursus lorem Suspendis
Troy | Oneal | 2013-10-29 00:32:11 | porta Vivamus condimentum
Renee | Coleman | 2013-10-29 00:42:55 | lectus quis imperdiet
Fay | Moss | 2013-10-29 00:53:39 | sit eleifend tempus a aliquam mauri
Dominique | Cabrera | 2013-10-29 01:15:07 | turpis vehicula tortor

Oprah | Mcmillan | 2013-10-29 01:36:35 | varius Cum iaculis metus
Astra | Sherman | 2013-10-29 01:58:03 | dignissim odio Pellentesque primis
Chelsea | Malone | 2013-10-29 02:08:47 | pede tempor dignissim Sed luctus
(10 rows)
```

Viewing Hive schema and table metadata

When using Hive, you access metadata about schemas and tables by executing statements written in HiveQL (Hive's version of SQL) such as **SHOW TABLES**. When using the HCatalog Connector, you can get metadata about the tables in the Hive database through several Vertica system tables.

There are four system tables that contain metadata about the tables accessible through the HCatalog Connector:

- [HCATALOG_SCHEMATA](#) lists all of the schemas that have been defined using the HCatalog Connector.
- [HCATALOG_TABLE_LIST](#) contains an overview of all of the tables available from all schemas defined using the HCatalog Connector. This table only shows the tables that the user querying the table can access. The information in this table is retrieved using a single call to HiveServer2 for each schema defined using the HCatalog Connector, which means there is a little overhead when querying this table.
- [HCATALOG_TABLES](#) contains more in-depth information than HCATALOG_TABLE_LIST.
- [HCATALOG_COLUMNS](#) lists metadata about all of the columns in all of the tables available through the HCatalog Connector. As for HCATALOG_TABLES, querying this table results in one call to HiveServer2 per table, and therefore can take a while to complete.

The following example demonstrates querying the system tables containing metadata for the tables available through the HCatalog Connector.

```
=> CREATE HCATALOG SCHEMA hcat WITH hostname='hcatost'
-> HCATALOG_SCHEMA='default' HCATALOG_DB='default' HCATALOG_USER='hcatuser';
CREATE SCHEMA
=> SELECT * FROM HCATALOG_SCHEMATA;
-[ RECORD 1 ]-----+-----

Synchronizing an HCatalog schema or table with a local schema or table

Querying data from an HCatalog schema can be slow due to Hive performance issues. This slow performance can be especially annoying when you want to examine the structure of the tables in the Hive database. Getting this information from Hive requires you to query the HCatalog schema's metadata using the HCatalog Connector.

To avoid this performance problem you can use the [SYNC_WITH_HCATALOG_SCHEMA](#) function to create a snapshot of the HCatalog schema's metadata within a Vertica schema. You supply this function with the name of a pre-existing Vertica schema, typically the one created through CREATE HCATALOG SCHEMA, and a Hive schema available through the HCatalog Connector. You must have permission both in Vertica to write the data and in Hive and HDFS to read it.

Note

To synchronize a schema, you must have read permission for the underlying files in HDFS. If Hive uses Sentry to manage authorization, then you can use ACL synchronization to manage HDFS access. Otherwise, the user of this function must have read access in HDFS.

The function creates a set of external tables within the Vertica schema that you can then use to examine the structure of the tables in the Hive database. Because the metadata in the Vertica schema is local, query planning is much faster. You can also use standard Vertica statements and system-table queries to examine the structure of Hive tables in the HCatalog schema.

Caution

The SYNC_WITH_HCATALOG_SCHEMA function overwrites tables in the Vertica schema whose names match a table in the HCatalog schema. Do not use the Vertica schema to store other data.

When SYNC_WITH_HCATALOG_SCHEMA creates tables in Vertica, it matches Hive's STRING and BINARY types to Vertica's VARCHAR(65000) and VARBINARY(65000) types. You might want to change these lengths, using [ALTER TABLE SET DATA TYPE](#), in two cases:

- If the value in Hive is larger than 65000 bytes, increase the size and use LONG VARCHAR or LONG VARBINARY to avoid data truncation. If a Hive string uses multi-byte encodings, you must increase the size in Vertica to avoid data truncation. This step is needed because Hive counts string length in characters while Vertica counts it in bytes.
- If the value in Hive is much smaller than 65000 bytes, reduce the size to conserve memory in Vertica.

The Vertica schema is just a snapshot of the HCatalog schema's metadata. Vertica does not synchronize later changes to the HCatalog schema with the local schema after you call SYNC_WITH_HCATALOG_SCHEMA. You can call the function again to re-synchronize the local schema to the HCatalog schema. If you altered column data types, you will need to repeat those changes because the function creates new external tables.

By default, SYNC_WITH_HCATALOG_SCHEMA does not drop tables that appear in the local schema that do not appear in the HCatalog schema. Thus, after the function call the local schema does not reflect tables that have been dropped in the Hive database since the previous call. You can change this behavior by supplying the optional third Boolean argument that tells the function to drop any table in the local schema that does not correspond to a table in the HCatalog schema.

Instead of synchronizing the entire schema, you can synchronize individual tables by using [SYNC_WITH_HCATALOG_SCHEMA_TABLE](#). If the table already exists in Vertica the function overwrites it. If the table is not found in the HCatalog schema, this function returns an error. In all other respects this function behaves in the same way as SYNC_WITH_HCATALOG_SCHEMA.

If you change the settings of any HCatalog Connector configuration parameters ([Hadoop parameters](#)), you must call this function again.

Examples

The following example demonstrates calling SYNC_WITH_HCATALOG_SCHEMA to synchronize the HCatalog schema in Vertica with the metadata in Hive. Because it synchronizes the HCatalog schema directly, instead of synchronizing another schema with the HCatalog schema, both arguments are the same.

```
=> CREATE HCATALOG SCHEMA hcat WITH hostname='hcatost' HCATALOG_SCHEMA='default'
  HCATALOG_USER='hcatuser';
CREATE SCHEMA
=> SELECT sync_with_hcatalog_schema('hcat', 'hcat');
sync_with_hcatalog_schema
-----
Schema hcat synchronized with hcat
tables in hcat = 56
tables altered in hcat = 0
tables created in hcat = 56
stale tables in hcat = 0
table changes erred in hcat = 0
(1 row)

=> -- Use vsq!s \d command to describe a table in the synced schema

=> \d hcat.messages
List of Fields by Tables
 Schema | Table | Column | Type   | Size | Default | Not Null | Primary Key | Foreign Key
-----+-----+-----+-----+-----+-----+-----+-----+-----
 hcat   | messages | id      | int    | 8    |         | f        | f          |
 hcat   | messages | userid  | varchar(65000) | 65000 |         | f        | f          |
 hcat   | messages | "time"  | varchar(65000) | 65000 |         | f        | f          |
 hcat   | messages | message | varchar(65000) | 65000 |         | f        | f          |
(4 rows)
```

This example shows synchronizing with a schema created using CREATE HCATALOG SCHEMA. Synchronizing with a schema created using CREATE SCHEMA is also supported.

You can query tables in the local schema that you synchronized with an HCatalog schema. However, querying tables in a synchronized schema isn't much faster than directly querying the HCatalog schema, because SYNC_WITH_HCATALOG_SCHEMA only duplicates the HCatalog schema's metadata. The data in the table is still retrieved using the HCatalog Connector.

Data type conversions from Hive to Vertica

The data types recognized by Hive differ from the data types recognized by Vertica. The following table lists how the HCatalog Connector converts Hive data types into data types compatible with Vertica.

Hive Data Type	Vertica Data Type
TINYINT (1-byte)	TINYINT (8-bytes)
SMALLINT (2-bytes)	SMALLINT (8-bytes)
INT (4-bytes)	INT (8-bytes)

BIGINT (8-bytes)	BIGINT (8-bytes)
BOOLEAN	BOOLEAN
FLOAT (4-bytes)	FLOAT (8-bytes)
DECIMAL (precision, scale)	DECIMAL (precision, scale)
DOUBLE (8-bytes)	DOUBLE PRECISION (8-bytes)
CHAR (length in characters)	CHAR (length in bytes)
VARCHAR (length in characters)	VARCHAR (length in bytes), if length <= 65000 LONG VARCHAR (length in bytes), if length > 65000
STRING (2 GB max)	VARCHAR (65000)
BINARY (2 GB max)	VARBINARY (65000)
DATE	DATE
TIMESTAMP	TIMESTAMP
LIST/ARRAY	VARCHAR (65000) containing a JSON-format representation of the list.
MAP	VARCHAR (65000) containing a JSON-format representation of the map.
STRUCT	VARCHAR (65000) containing a JSON-format representation of the struct.

Data-width handling differences between Hive and Vertica

The HCatalog Connector relies on Hive SerDe classes to extract data from files on HDFS. Therefore, the data read from these files are subject to Hive's data width restrictions. For example, suppose the SerDe parses a value for an INT column into a value that is greater than $2^{32} - 1$ (the maximum value for a 32-bit integer). In this case, the value is rejected even if it would fit into a Vertica's 64-bit INTEGER column because it cannot fit into Hive's 32-bit INT.

Hive measures CHAR and VARCHAR length in characters and Vertica measures them in bytes. Therefore, if multi-byte encodings are being used (like Unicode), text might be truncated in Vertica.

Once the value has been parsed and converted to a Vertica data type, it is treated as native data. This treatment can result in some confusion when comparing the results of an identical query run in Hive and in Vertica. For example, if your query adds two INT values that result in a value that is larger than $2^{32} - 1$, the value overflows its 32-bit INT data type, causing Hive to return an error. When running the same query with the same data in Vertica using the HCatalog Connector, the value will probably still fit within Vertica's 64-bit integer value. Thus the addition is successful and returns a value.

Using nonstandard SerDes

Hive stores its data in unstructured flat files located in the Hadoop Distributed File System (HDFS). When you execute a Hive query, it uses a set of serializer and deserializer (SerDe) classes to extract data from these flat files and organize it into a relational database table. For Hive to be able to extract data from a file, it must have a SerDe that can parse the data the file contains. When you create a table in Hive, you can select the SerDe to be used for the table's data.

Hive has a set of standard SerDes that handle data in several formats such as delimited data and data extracted using regular expressions. You can also use third-party or custom-defined SerDes that allow Hive to process data stored in other file formats. For example, some commonly-used third-party SerDes handle data stored in JSON format.

The HCatalog Connector directly fetches file segments from HDFS and uses Hive's SerDes classes to extract data from them. The Connector includes all Hive's standard SerDes classes, so it can process data stored in any file that Hive natively supports. If you want to query data from a Hive table that uses a custom SerDe, you must first install the SerDe classes on the Vertica cluster.

Determining which SerDe you need

If you have access to the Hive command line, you can determine which SerDe a table uses by using Hive's SHOW CREATE TABLE statement. This statement shows the HiveQL statement needed to recreate the table. For example:

```
hive> SHOW CREATE TABLE msgjson;
OK
CREATE EXTERNAL TABLE msgjson(
messageid int COMMENT 'from deserializer',
userid string COMMENT 'from deserializer',
time string COMMENT 'from deserializer',
message string COMMENT 'from deserializer')
ROW FORMAT SERDE
'org.apache.hadoop.hive.contrib.serde2.JsonSerde'
STORED AS INPUTFORMAT
'org.apache.hadoop.mapred.TextInputFormat'
OUTPUTFORMAT
'org.apache.hadoop.hive.ql.io.HiveIgnoreKeyTextOutputFormat'
LOCATION
'hdfs://hivehost.example.com:8020/user/exampleuser/msgjson'
TBLPROPERTIES (
'transient_lastDdlTime'='1384194521')
Time taken: 0.167 seconds
```

In the example, **ROW FORMAT SERDE** indicates that a special SerDe is used to parse the data files. The next row shows that the class for the SerDe is named `org.apache.hadoop.hive.contrib.serde2.JsonSerde`. You must provide the HCatalog Connector with a copy of this SerDe class so that it can read the data from this table.

You can also find out which SerDe class you need by querying the table that uses the custom SerDe. The query will fail with an error message that contains the class name of the SerDe needed to parse the data in the table. In the following example, the portion of the error message that names the missing SerDe class is in bold.

```
=> SELECT * FROM hcat.jsontable;
ERROR 3399: Failure in UDX RPC call InvokePlanUDL(): Error in User Defined
Object [VHCatSource], error code: 0
com.vertica.sdk.UdfException: Error message is [

at com.vertica.udxfence.UDXExecContext.planUDSource(UDXExecContext.java:898)
. . .
```

Installing the SerDe on the Vertica cluster

You usually have two options to getting the SerDe class file the HCatalog Connector needs:

- Find the installation files for the SerDe, then copy those over to your Vertica cluster. For example, there are several third-party JSON SerDes available from sites like Google Code and GitHub. You may find the one that matches the file installed on your Hive cluster. If so, then download the package and copy it to your Vertica cluster.
- Directly copy the JAR files from a Hive server onto your Vertica cluster. The location for the SerDe JAR files depends on your Hive installation. On some systems, they may be located in `/usr/lib/hive/lib`.

Wherever you get the files, copy them into the `/opt/vertica/packages/hcat/lib` directory on every node in your Vertica cluster.

Important

If you add a new host to your Vertica cluster, remember to copy every custom SerDer JAR file to it.

Troubleshooting HCatalog Connector problems

You may encounter the following issues when using the HCatalog Connector.

Connection errors

The HCatalog Connector can encounter errors both when you define a schema and when you query it. The types of errors you get depend on which CREATE HCATALOG SCHEMA parameters are incorrect. Suppose you have incorrect parameters for the metastore database, but correct parameters for HiveServer2. In this case, HCatalog-related system table queries succeed, while queries on the HCatalog schema fail. The following example demonstrates creating an HCatalog schema with the correct default HiveServer2 information. However, the port number for the metastore database is incorrect.

```
=> CREATE HCATALOG SCHEMA hcat2 WITH hostname='hcahost'
-> HCATALOG_SCHEMA='default' HCATALOG_USER='hive' PORT=1234;
CREATE SCHEMA
=> SELECT * FROM HCATALOG_TABLE_LIST;
-[ RECORD 1 ]-----+-----
table_schema_id | 45035996273864536
table_schema    | hcat2
hcatalog_schema | default
table_name      | test
hcatalog_user_name | hive

=> SELECT * FROM hcat2.test;
ERROR 3399: Failure in UDX RPC call InvokePlanUDL(): Error in User Defined
Object [VHCatSource], error code: 0
com.vertica.sdk.UdfException: Error message is [
org.apache.hcatalog.common.HCatException : 2004 : HCatOutputFormat not
initialized, setOutput has to be called. Cause : java.io.IOException:
MetaException(message:Could not connect to meta store using any of the URIs
provided. Most recent failure: org.apache.thrift.transport.TTTransportException:
java.net.ConnectException:
Connection refused
at org.apache.thrift.transport.TSocket.open(TSocket.java:185)
at org.apache.hadoop.hive.metastore.HiveMetaStoreClient.open(
HiveMetaStoreClient.java:277)
. . .
```

To resolve these issues, you must drop and recreate the schema or alter the schema to correct the parameters. If you still have issues, determine whether there are connectivity issues between your Vertica cluster and your Hadoop cluster. Such issues can include a firewall that prevents one or more Vertica hosts from contacting the HiveServer2, metastore, or HDFS hosts.

UDx failure when querying data: error 3399

You might see an error message when querying data (as opposed to metadata like schema information). This might be accompanied by a `ClassNotFoundException` in the log. This can happen for the following reasons:

- You are not using the same version of Java on your Hadoop and Vertica nodes. In this case you need to change one of them to match the other.
- You have not used `hcatUtil` to copy all Hadoop and Hive libraries and configuration files to Vertica, or you ran `hcatutil` and then changed your version of Hadoop or Hive.
- You upgraded Vertica to a new version and did not rerun `hcatutil` and reinstall the HCatalog Connector.
- The version of Hadoop you are using relies on a third-party library that you must copy manually.
- You are reading files with LZO compression and have not copied the libraries or set the `io.compression.codecs` property in `core-site.xml`.
- You are reading Parquet data from Hive, and columns were added to the table after some data was already present in the table. Adding columns does not update existing data, and the `ParquetSerDe` provided by Hive and used by the HCatalog Connector does not handle this case. This error is due to a limitation in Hive and there is no workaround.
- The query is taking too long and is timing out. If this is a frequent problem, you can increase the value of the `UDxFencedBlockTimeout` configuration parameter. See [General parameters](#).

If you did not copy the libraries or configure LZO compression, follow the instructions in [Configuring Vertica for HCatalog](#).

If the Hive jars that you copied from Hadoop are out of date, you might see an error message like the following:

```
ERROR 3399: Failure in UDX RPC call InvokePlanUDL(): Error in User Defined Object [VHCatSource],
error code: 0 Error message is [ Found interface org.apache.hadoop.mapreduce.JobContext, but
class was expected ]
HINT hive metastore service is thrift://localhost:13433 (check UDXLogs/UDxFencedProcessesJava.log
in the catalog directory for more information)
```

This error usually signals a problem with [hive-hcatalog-core jar](#) . Make sure you have an up-to-date copy of this file. Remember that if you rerun hcatUtil you also need to re-create the HCatalog schema.

You might also see a different form of this error:

```
ERROR 3399: Failure in UDX RPC call InvokePlanUDL(): Error in User Defined Object [VHCatSource],
error code: 0 Error message is [ javax/servlet/Filter ]
```

This error can be reported even if hcatUtil reports that your libraries are up to date. The [javax.servlet.Filter](#) class is in a library that some versions of Hadoop use but that is not usually part of the Hadoop installation directly. If you see an error mentioning this class, locate [servlet-api-*.jar](#) on a Hadoop node and copy it to the [hcat/lib](#) directory on all database nodes. If you cannot locate it on a Hadoop node, locate and download it from the Internet. (This case is rare.) The library version must be 2.3 or higher.

After you have copied the jar to the [hcat/lib](#) directory, reinstall the HCatalog connector as explained in [Configuring Vertica for HCatalog](#) .

Authentication error when querying data

You might have successfully created a schema using CREATE HCATALOG SCHEMA but get errors at query time such as the following:

```
=> SELECT * FROM hcat.clickdata;
ERROR 6776: Failed to glob [hdfs:///user/hive/warehouse/click-*.parquet]
because of error: hdfs:///user/hive/warehouse/click-12214.parquet: statAll failed;
error: AuthenticationFailed
```

You might see this error if Hive uses an authorization service. If the permissions on the underlying files in HDFS match those in the authorization service, then Vertica must use user impersonation when accessing that data. To enable user impersonation, set the EnableHCatImpersonation configuration parameter to 1.

Vertica uses the database principal to access HDFS. Therefore, if EnableHCatImpersonation is 0, the Vertica database principal must have access to the data inside the hive warehouse on HDFS. If it does not, you might see the following error:

```
=> SELECT * FROM hcat.salesdata;
ERROR 6776: Failed to glob [vertica-hdfs:///hive/warehouse/sales/*/*]
because of error: vertica-hdfs:///hive/warehouse/sales/: listStat failed;
error: Permission denied: user=vertica, access=EXECUTE, inode="/hive/warehouse/sales":hdfs:hdfs:d-----
```

The URL scheme in this error message has been changed from [hdfs](#) to [vertica-hdfs](#) . This is an internal scheme and is not valid in URLs outside of Vertica. You cannot use this scheme when specifying paths in HDFS.

Differing results between Hive and Vertica queries

Sometimes, running the same query on Hive and on Vertica through the HCatalog Connector can return different results. There are a few common causes of this problem.

This discrepancy is often caused by the differences between the data types supported by Hive and Vertica. See [Data type conversions from Hive to Vertica](#) for more information about supported data types.

If Hive string values are being truncated in Vertica, this might be caused by multi-byte character encodings in Hive. Hive reports string length in characters, while Vertica records it in bytes. For a two-byte encoding such as Unicode, you need to double the column size in Vertica to avoid truncation.

Discrepancies can also occur if the Hive table uses partition columns of types other than string.

If the Hive table stores partition data in custom locations instead of the default, you will see different query results if you do not specify the CUSTOM_PARTITIONS parameter when creating the Vertica schema. See [Using Partitioned Data](#) . Further, even when using custom partitions, there are differences between Vertica and Hive:

- If a custom partition is unavailable at query time, Hive ignores it and returns the rest of the results. Vertica reports an error.
- If a partition is altered in Hive to use a custom location after table creation, Hive reads data from only the new location while Vertica reads data from both the default and the new locations.
- If a partition value and its corresponding directory name disagree, Hive uses the value in its metadata while Vertica uses the value in the directory name.

The following example illustrates these differences. A table in Hive, partitioned on the state column, starts with the following data:

```
hive> select * from inventory;
+-----+-----+-----+
| inventory.ID | inventory.quant | inventory.state |
+-----+-----+-----+
| 2          | 300            | CA              |
| 4          | 400            | CA              |
| 5          | 500            | DC              |
| 1          | 100            | PA              |
| 2          | 200            | PA              |
+-----+-----+-----+
```

The partition for one state, CA, is then moved. This directory contains some data already. Note that the query now returns different results for the CA partitions.

```
hive> ALTER TABLE inventory PARTITION (state='CA') SET LOCATION 'hdfs:///partitions/inventory/state=MD';
hive> select * from inventory;
+-----+-----+-----+
| inventory.ID | inventory.quant | inventory.state |
+-----+-----+-----+
| 20          | 30000           | CA              |
| 40          | 40000           | CA              |
| 5          | 500            | DC              |
| 1          | 100            | PA              |
| 2          | 200            | PA              |
+-----+-----+-----+
5 rows selected (0.399 seconds)
```

The CA partitions were moved to a directory named state=MD. Vertica reports the state for the first two rows, the ones in the new partition location, as MD because of the directory name. It also reports the CA values from the original location in addition to the new one:

```
=> SELECT * FROM hcat.inventory;
ID | quant | state
-----+-----+-----
20 | 30000 | MD
40 | 40000 | MD
 2 | 300   | CA
 4 | 400   | CA
 1 | 100   | PA
 2 | 200   | PA
 5 | 500   | DC
(7 rows)
```

HCatalog Connector installation fails on MapR

If you mount a MapR file system as an NFS mount point and then install the HCatalog Connector, it could fail with a message like the following:

```
ROLLBACK 2929: Couldn't create new UDX side process,
failed to get UDX side process info from zygoter: Broken pipe
```

This might be accompanied by an error like the following in [dbLog](#) :

```
java.io.IOException: Couldn't get lock for /home/dbadmin/node02_catalog/UDxLogs/UDxFencedProcessesJava.log
    at java.util.logging.FileHandler.openFiles(FileHandler.java:389)
    at java.util.logging.FileHandler.<init>(FileHandler.java:287)
    at com.vertica.udxfence.UDxLogger.setup(UDxLogger.java:78)
    at com.vertica.udxfence.UDxSideProcess.go(UDxSideProcess.java:75)
    ...
```

This error occurs if you locked your NFS mount point when creating it. Locking is the default. If you use the HCatalog Connector with MapR mounted as an NFS mount point, you must create the mount point with the `-o nolock` option. For example:

```
sudo mount -o nolock -t nfs MaprCLDBserviceHostname:/mapr/ClusterName/vertica/${hostname -f}/ vertica
```

You can use the HCatalog Connector with MapR without mounting the MapR file system. If you mount the MapR file system, you must do so without a lock.

Excessive query delays

Network issues or high system loads on the HiveServer2 server can cause long delays while querying a Hive database using the HCatalog Connector. While Vertica cannot resolve these issues, you can set parameters that limit how long Vertica waits before canceling a query on an HCatalog schema. You can set these parameters globally using Vertica configuration parameters. You can also set them for specific HCatalog schemas in the [CREATE HCATALOG SCHEMA](#) statement. These specific settings override the settings in the configuration parameters.

The HCatConnectionTimeout configuration parameter and the CREATE HCATALOG SCHEMA statement's HCATALOG_CONNECTION_TIMEOUT parameter control how many seconds the HCatalog Connector waits for a connection to the HiveServer2 server. A value of 0 (the default setting for the configuration parameter) means to wait indefinitely. If the server does not respond by the time this timeout elapses, the HCatalog Connector breaks the connection and cancels the query. If you find that some queries on an HCatalog schema pause excessively, try setting this parameter to a timeout value, so the query does not hang indefinitely.

The HCatSlowTransferTime configuration parameter and the CREATE HCATALOG SCHEMA statement's HCATALOG_SLOW_TRANSFER_TIME parameter specify how long the HCatalog Connector waits for data after making a successful connection to the server. After the specified time has elapsed, the HCatalog Connector determines whether the data transfer rate from the server is at least the value set in the HCatSlowTransferLimit configuration parameter (or by the CREATE HCATALOG SCHEMA statement's HCATALOG_SLOW_TRANSFER_LIMIT parameter). If it is not, then the HCatalog Connector terminates the connection and cancels the query.

You can set these parameters to cancel queries that run very slowly but do eventually complete. However, query delays are usually caused by a slow connection rather than a problem establishing the connection. Therefore, try adjusting the slow transfer rate settings first. If you find the cause of the issue is connections that never complete, you can alternately adjust the Linux TCP socket timeouts to a suitable value instead of relying solely on the HCatConnectionTimeout parameter.

Serde errors

Errors can occur if you attempt to query a Hive table that uses a nonstandard SerDe. If you have not installed the SerDe JAR files on your Vertica cluster, you receive an error similar to the one in the following example:

```
=> SELECT * FROM hcat.jsontable;
ERROR 3399: Failure in UDX RPC call InvokePlanUDL(): Error in User Defined
Object [VHCatSource], error code: 0
com.vertica.sdk.UdfException: Error message is [
org.apache.hcatalog.common.HCatException : 2004 : HCatOutputFormat not
initialized, setOutput has to be called. Cause : java.io.IOException:
java.lang.RuntimeException:
MetaException(message:org.apache.hadoop.hive.serde2.SerdeException
Serde com.cloudera.hive.serde.JSONSerDe does not exist) ] HINT If error
message is not descriptive or local, may be we cannot read metadata from hive
metastore service thrift://hcathost:9083 or HDFS namenode (check
UDXLogs/UDXFencedProcessesJava.log in the catalog directory for more information)
at com.vertica.hcatalogudl.HCatalogSplitsNoOpSourceFactory
.plan(HCatalogSplitsNoOpSourceFactory.java:98)
at com.vertica.udxfence.UDXExecContext.planUDSource(UDXExecContext.java:898)
. . .
```

In the error message, you can see that the root cause is a missing SerDe class (shown in bold). To resolve this issue, install the SerDe class on your Vertica cluster. See [Using nonstandard SerDes](#) for more information.

This error may occur intermittently if just one or a few hosts in your cluster do not have the SerDe class.

Integrating with Cloudera Manager

The Cloudera distribution of Hadoop includes Cloudera Manager, a web-based tool for managing a Hadoop cluster. Cloudera Manager can manage any service for which a service description is available, including Vertica.

You can use Cloudera Manager to start, stop, and monitor individual database nodes or the entire database. You can manage both co-located and separate Vertica clusters—Cloudera can manage services on nodes that are not part of the Hadoop cluster.

You must install and configure your Vertica database before proceeding; you cannot use Cloudera Manager to create the database.

Installing the service

Note

Because the service has to send the database password over the network, you should enable encryption on your Hadoop cluster before

A Cloudera Service Description (CSD) file describes a service that Cloudera can manage. The Vertica CSD is in `/opt/vertica/share/CSD` on a database node.

To install the Vertica CSD, follow these steps:

1. On a Vertica node, follow the instructions in [VerticaAPIKey](#) to generate an API key. You need this key to finish the installation of the CSD.
2. On the Hadoop node that hosts Cloudera Manager, copy the CSD file into `/opt/cloudera/csd`.
3. Restart Cloudera Manager:

```
$ service cloudera-scm-server restart
```

4. In a web browser, go to Cloudera Manager and restart the Cloudera Management Service.
5. If your Vertica cluster is separate from your Hadoop cluster (not co-located on it): Use Cloudera Manager to add the hosts for your database nodes. If your cluster is co-located, skip this step.
6. Use Cloudera Manager to add the Vertica service.
7. On the "Role Assignment" page, select the hosts that are database nodes.
8. On the "Configuration" page, specify values for the following fields:
 - database name
 - agent port (accept the default if you're not sure)
 - API key
 - database user to run as (usually dbadmin) and password

About the agent

When you manage Vertica through Cloudera Manager, you are actually interacting with the Vertica Agent, not the database directly. The [Agent](#) runs on all database nodes and interacts with the database on your behalf. Management Console uses the same agent. Most of the time this extra indirection is transparent to you.

A Cloudera-managed service contains one or more roles. In this case the service is "Vertica" and the single role is "Vertica Node".

Available operations

Cloudera Manager shows two groups of operations. Service-level operations apply to the service on all nodes, while role-level operations apply only to a single node.

You can perform the following service-level operations on all nodes:

- Start: Starts the agent and, if it is not already running, the database.
- Stop: Stops the database and agent.
- Restart: Calls Stop and then Start.
- Add Role Instances: Adds new database nodes to Cloudera Manager. The nodes must already be part of the Vertica cluster, and the hosts must already be known to Cloudera Manager.
- Enter Maintenance Mode: Suppresses health alerts generated by Cloudera Manager.
- Exit Maintenance Mode: Resumes normal reporting.
- Update Memory Pool Size: Applies memory-pool settings from the Static Service Pools configuration page.

You can perform all of these operations except Add Role Instances on individual nodes as role-level operations.

Managing memory pools

Cloudera Manager allows you to change resource allocations, such as memory and CPU, for the nodes it manages. If you are using co-located clusters, centrally managing resources can simplify your cluster management. If you are using separate Hadoop and Vertica clusters, you might prefer to manage Vertica separately as described in [Managing the database](#).

Use the Cloudera Manager "Static Service Pools" configuration page to configure resource allocations. The "Vertica Memory Pool" value, specified in GB, is the maximum amount of memory to allocate to the database on each node. If the configuration page includes "Cgroup Memory Hard Limit", set it to the same value as "Vertica Memory Pool".

After you have set these values, you can use the "Update Memory Pool Size" operation to apply the value to the managed nodes. This operation is equivalent to `ALTER RESOURCE POOL GENERAL MAXMEMORYSIZE`. Configuration changes in "Static Service Pools" do not take effect in Vertica until you perform this operation.

Uninstalling the service

To uninstall the Vertica CSD, follow these steps:

1. Stop the Vertica service and then remove it from Cloudera Manager.
2. Remove the CSD file from `/opt/cloudera/csd`.
3. From the command line, restart the Cloudera Manager server.
4. In Cloudera Manager, restart the Cloudera Management Service.

Integrating Vertica with the MapR distribution of Hadoop

MapR is a distribution of Apache Hadoop produced by MapR Technologies that extends the standard Hadoop components with its own features. Vertica can integrate with MapR in the following ways:

- You can read data from MapR through an NFS mount point. After you mount the MapR file system as an NFS mount point, you can use [CREATE EXTERNAL TABLE AS COPY](#) or [COPY](#) to access the data as if it were on the local file system. This option provides the best performance for reading data.
- You can use the HCatalog Connector to read Hive data. Do not use the HCatalog Connector with ORC or Parquet data in MapR for performance reasons. Instead, mount the MapR file system as an NFS mount point and create external tables without using the Hive schema. For more about reading Hive data, see [Using the HCatalog Connector](#).
- You can create a storage location to store data in MapR using the native Vertica format (ROS). Mount the MapR file system as an NFS mount point and then use [CREATE LOCATION](#)...ALL NODES SHARED to create a storage location. (CREATE LOCATION does not support NFS mount points in general, but does support them for MapR.)

Note

If you create a Vertica database and place its initial storage location on MapR, Vertica designates the storage location for both DATA and TEMP usage. Vertica does not support TEMP storage locations on MapR, so after you create the location, you must alter it to store only DATA files. See [Altering location use](#). Ensure that you have a TEMP location on the Linux file system.

Other Vertica integrations for Hadoop are not available for MapR.

For information on mounting the MapR file system as an NFS mount point, see [Accessing Data with NFS](#) and [Configuring Vertica Analytics Platform with MapR](#) on the MapR website. In particular, you must configure MapR to add Vertica as a MapR service.

Examples

In the following examples, the MapR file system has been mounted as `/mapr`.

The following statement creates an external table from ORC data:

```
=> CREATE EXTERNAL TABLE t (a1 INT, a2 VARCHAR(20))
AS COPY FROM '/mapr/data/file.orc' ORC;
```

The following statement creates an external table from Parquet data and takes advantage of partition pruning (see [Partitioned data](#)):

```
=> CREATE EXTERNAL TABLE t2 (id int, name varchar(50), created date, region varchar(50))
AS COPY FROM '/mapr/*/*/*' PARTITION COLUMNS created, region PARQUET();
```

The following statement loads ORC data from MapR into Vertica:

```
=> COPY t FROM '/mapr/data/*.orc' ON ANY NODE ORC;
```

The following statements create a storage location to hold ROS data in the MapR file system:

```
=> CREATE LOCATION '/mapr/my.cluster.com/data' SHARED USAGE 'DATA' LABEL 'maprfs';

=> SELECT ALTER_LOCATION_USE('/mapr/my.cluster.com/data', '', 'DATA');
```

Hive primer for Vertica integration

You can use Hive to export data for use by Vertica. Decisions you make when doing the Hive export affect performance in Vertica.

Tuning ORC stripes and Parquet rowgroups

Vertica can read ORC and Parquet files generated by any Hive version. However, newer Hive versions store more metadata in these files. This metadata is used by both Hive and Vertica to prune values and to read only the required data. Use the latest Hive version to store data in these formats. ORC and Parquet are fully forward- and backward-compatible. To get the best performance, use Hive 0.14 or later.

The ORC format splits a table into groups of rows called stripes and stores column-level metadata in each stripe. The Parquet format splits a table into groups of rows called rowgroups and stores column-level metadata in each rowgroup. Each stripe/rowgroup's metadata is used during predicate evaluation to determine whether the values from this stripe need to be read. Large stripes usually yield better performance, so set the stripe size to at least 256M.

Hive writes ORC stripes and Parquet rowgroups to HDFS, which stores data in HDFS blocks distributed among multiple physical data nodes. Accessing an HDFS block requires opening a separate connection to the corresponding data node. It is advantageous to ensure that an ORC stripe or Parquet rowgroup does not span more than one HDFS block. To do so, set the HDFS block size to be larger than the stripe/rowgroup size. Setting HDFS block size to 512M is usually sufficient.

Hive provides three compression options: None, Snappy, and Zlib. Use Snappy or Zlib compression to reduce storage and I/O consumption. Usually, Snappy is less CPU-intensive but can yield lower compression ratios compared to Zlib.

Storing data in sorted order can improve data access and predicate evaluation performance. Sort table columns based on the likelihood of their occurrence in query predicates; columns that most frequently occur in comparison or range predicates should be sorted first.

Partitioning tables is a very useful technique for data organization. Similarly to sorting tables by columns, partitioning can improve data access and predicate evaluation performance. Vertica supports Hive-style partitions and partition pruning.

The following Hive statement creates an ORC table with stripe size 256M and Zlib compression:

```
hive> CREATE TABLE customer_visits (  
    customer_id bigint,  
    visit_num int,  
    page_view_dt date)  
    STORED AS ORC tblproperties("orc.compress"="ZLIB",  
    "orc.stripe.size"="268435456");
```

The following statement creates a Parquet table with stripe size 256M and Zlib compression:

```
hive> CREATE TABLE customer_visits (  
    customer_id bigint,  
    visit_num int,  
    page_view_dt date)  
    STORED AS PARQUET tblproperties("parquet.compression"="ZLIB",  
    "parquet.stripe.size"="268435456");
```

Creating sorted files in Hive

Unlike Vertica, Hive does not store table columns in separate files and does not create multiple projections per table with different sort orders. For efficient data access and predicate pushdown, sort Hive table columns based on the likelihood of their occurrence in query predicates. Columns that most frequently occur in comparison or range predicates should be sorted first.

Data can be inserted into Hive tables in a sorted order by using the ORDER BY or SORT BY keywords. For example, to insert data into the ORC table "customer_visit" from another table "visits" with the same columns, use these keywords with the INSERT INTO command:

```
hive> INSERT INTO TABLE customer_visits  
    SELECT * from visits  
    ORDER BY page_view_dt;
```

```
hive> INSERT INTO TABLE customer_visits  
    SELECT * from visits  
    SORT BY page_view_dt;
```

The difference between the two keywords is that ORDER BY guarantees global ordering on the entire table by using a single MapReduce reducer to populate the table. SORT BY uses multiple reducers, which can cause ORC or Parquet files to be sorted by the specified column(s) but not be globally sorted. Using the latter keyword can increase the time taken to load the file.

You can combine clustering and sorting to sort a table globally. The following table definition adds a hint that data is inserted into this table bucketed by customer_id and sorted by page_view_dt:

```
hive> CREATE TABLE customer_visits_bucketed (  
    customer_id bigint,  
    visit_num int,  
    page_view_dt date)  
CLUSTERED BY (page_view_dt)  
SORTED BY (page_view_dt) INTO 10 BUCKETS  
STORED AS ORC;
```

When inserting data into the table, you must explicitly specify the clustering and sort columns, as in the following example:

```
hive> INSERT INTO TABLE customer_visits_bucketed  
SELECT * from visits  
DISTRIBUTE BY page_view_dt  
SORT BY page_view_dt;
```

The following statement is equivalent:

```
hive> INSERT INTO TABLE customer_visits_bucketed  
SELECT * from visits  
CLUSTER BY page_view_dt;
```

Both of the above commands insert data into the customer_visits_bucketed table, globally sorted on the page_view_dt column.

Partitioning Hive tables

Table partitioning in Hive is an effective technique for data separation and organization, as well as for reducing storage requirements. To partition a table in Hive, include it in the PARTITIONED BY clause:

```
hive> CREATE TABLE customer_visits (  
    customer_id bigint,  
    visit_num int)  
PARTITIONED BY (page_view_dt date)  
STORED AS ORC;
```

Hive does not materialize partition column(s). Instead, it creates subdirectories of the following form:

```
path_to_table/partition_column_name=value/
```

When the table is queried, Hive parses the subdirectories' names to materialize the values in the partition columns. The value materialization in Hive is a plain conversion from a string to the appropriate data type.

Inserting data into a partitioned table requires specifying the value(s) of the partition column(s). The following example creates two partition subdirectories, "customer_visits/page_view_dt=2016-02-01" and "customer_visits/page_view_dt=2016-02-02":

```
hive> INSERT INTO TABLE customer_visits  
PARTITION (page_view_dt='2016-02-01')  
SELECT customer_id, visit_num from visits  
WHERE page_view_dt='2016-02-01'  
ORDER BY page_view_dt;  
  
hive> INSERT INTO TABLE customer_visits  
PARTITION (page_view_dt='2016-02-02')  
SELECT customer_id, visit_num from visits  
WHERE page_view_dt='2016-02-02'  
ORDER BY page_view_dt;
```

Each directory contains ORC files with two columns, customer_id and visit_num.

Example: a partitioned, sorted ORC table

Suppose you have data stored in CSV files containing three columns: customer_id, visit_num, page_view_dtm:

```
1,123,2016-01-01  
33,1,2016-02-01  
2,57,2016-01-03  
...
```

The goal is to create the following Hive table:

```
hive> CREATE TABLE customer_visits (  
    customer_id bigint,  
    visit_num int)  
PARTITIONED BY (page_view_dt date)  
STORED AS ORC;
```

To achieve this, perform the following steps:

1. Copy or move the CSV files to HDFS.
2. Define a textfile Hive table and copy the CSV files into it:

```
hive> CREATE TABLE visits (  
    customer_id bigint,  
    visit_num int,  
    page_view_dt date)  
ROW FORMAT DELIMITED FIELDS TERMINATED BY ','  
STORED AS TEXTFILE;  
  
hive> LOAD DATA INPATH path_to_csv_files INTO TABLE visits;
```

3. For each unique value in `page_view_dt`, insert the data into the target table while materializing `page_view_dt` as `page_view_dtm`:

```
hive> INSERT INTO TABLE customer_visits  
PARTITION (page_view_dt='2016-01-01')  
SELECT customer_id, visit_num FROM visits  
WHERE page_view_dt='2016-01-01'  
ORDER BY page_view_dt;  
...
```

This operation inserts data from `visits.customer_id` into `customer_visits.customer_id`, and from `visits.visit_num` into `customer_visits.visit_num`. These two columns are stored in generated ORC files. Simultaneously, values from `visits.page_view_dt` are used to create partitions for the partition column `customer_visits.page_view_dt`, which is not stored in the ORC files.

Data modification in Hive

Hive is well-suited for reading large amounts of write-once data. Its optimal usage is loading data in bulk into tables and never modifying the data. In particular, for data stored in the ORC and Parquet formats, this usage pattern produces large, globally (or nearly globally) sorted files.

Periodic addition of data to tables (known as “trickle load”) is likely to produce many small files. The disadvantage of this is that Vertica has to access many more files during query planning and execution. These extra access can result in longer query-processing time. The major performance degradation comes from the increase in the number of file seeks on HDFS.

Hive can also modify underlying ORC or Parquet files without user involvement. If enough records in a Hive table are modified or deleted, for example, Hive deletes existing files and replaces them with newly-created ones. Hive can also be configured to automatically merge many small files into a few larger files.

When new tables are created, or existing tables are modified in Hive, you must manually synchronize Vertica to keep it up to date. The following statement synchronizes the Vertica schema “hcat” after a change in Hive:

```
=> SELECT sync_with_hcatalog_schema('hcat_local', 'hcat');
```

Schema evolution in Hive

Hive supports two kinds of schema evolution:

1. New columns can be added to existing tables in Hive. Vertica automatically handles this kind of schema evolution. The old records display NULLs for the newer columns.
2. The type of a column for a table can be modified in Hive. Vertica does not support this kind of schema evolution.

The following example demonstrates schema evolution through new columns. In this example, `hcat.parquet.txt` is a file with the following values:

```
-1|0.65|0.65|6|'b'
```

```

hive> create table hcat.parquet_tmp (a int, b float, c double, d int, e varchar(4))
row format delimited fields terminated by '|' lines terminated by '\n';

hive> load data local inpath 'hcat.parquet.txt' overwrite into table
hcat.parquet_tmp;

hive> create table hcat.parquet_evolve (a int) partitioned by (f int) stored as
parquet;
hive> insert into table hcat.parquet_evolve partition (f=1) select a from
hcat.parquet_tmp;
hive> alter table hcat.parquet_evolve add columns (b float);
hive> insert into table hcat.parquet_evolve partition (f=2) select a, b from
hcat.parquet_tmp;
hive> alter table hcat.parquet_evolve add columns (c double);
hive> insert into table hcat.parquet_evolve partition (f=3) select a, b, c from
hcat.parquet_tmp;
hive> alter table hcat.parquet_evolve add columns (d int);
hive> insert into table hcat.parquet_evolve partition (f=4) select a, b, c, d from
hcat.parquet_tmp;
hive> alter table hcat.parquet_evolve add columns (e varchar(4));
hive> insert into table hcat.parquet_evolve partition (f=5) select a, b, c, d, e
from hcat.parquet_tmp;
hive> insert into table hcat.parquet_evolve partition (f=6) select a, b, c, d, e
from hcat.parquet_tmp;

=> SELECT * from hcat_local.parquet_evolve;

```

```

a | b | c | d | e | f
-----+-----+-----+-----+-----+-----
-1 | | | | | 1
-1 | 0.649999976158142 | | | | 2
-1 | 0.649999976158142 | 0.65 | | | 3
-1 | 0.649999976158142 | 0.65 | 6 | | 4
-1 | 0.649999976158142 | 0.65 | 6 | b | 5
-1 | 0.649999976158142 | 0.65 | 6 | b | 6
(6 rows)

```

Apache Kafka integration

Vertica provides a high-performance mechanism for integrating with [Apache Kafka](#), an open-source distributed real-time streaming platform. Because Vertica can both consume data from and produce data for Kafka, you can use Vertica as part of an automated analytics workflow: Vertica can retrieve data from Kafka, perform analytics on the data, and then send the results back to Kafka for consumption by other applications.

Prerequisites

- [Install Vertica](#).
- [Configure the database](#).
- Install and configure [Apache Kafka](#).

Architecture overview

The Vertica and Kafka integration provides the following features:

- A UDX library containing functions that load and parse data from Kafka topics into Vertica
- A job scheduler that uses the UDL library to continuously consume data from Kafka with exactly-once semantics
- Push-based [notifiers](#) that send data collector messages from Vertica to Kafka
- A [KafkaExport](#) function that sends Vertica data to Kafka

Vertica as a Kafka consumer

A Kafka consumer reads messages written to Kafka by other data streams. Because Vertica can read messages from Kafka, you can store and analyze data from any application that sends data to Kafka without configuring each individual application to connect to Vertica. Vertica provides tools to automatically or manually consume data loads from Kafka.

Manual loads

Manually load a finite amount of data from Kafka by directly executing a COPY statement. This is useful if you want to analyze, test, or perform additional processing on a set of messages.

For more information, see [Consuming data from Kafka](#).

Automatic loads

Automatically load data from Kafka with a job scheduler. A scheduler constantly loads data and ensures that each Kafka message is loaded exactly once.

You must install Java 8 on each Vertica node that runs the scheduler. For more information, see [Automatically consume data from Kafka with a scheduler](#).

Vertica as a Kafka producer

A Kafka producer sends data to Kafka, which is then available to Kafka consumers for processing. You can send the following types of data to Kafka:

- Vertica analytics results. Use [KafkaExport](#) to export Vertica tables and queries.
- Health and performance data from [Data Collector](#) tables. Create push-based [notifiers](#) to send this data for consumption for third-party monitoring tools.
- Ad hoc messages. Use [NOTIFY](#) to signal that tasks such as stored procedures are complete.

For more information, see [Producing data for Kafka](#).

Data streaming integration terms

Vertica uses the following terms to describe its streaming feature. These are general terms, which may differ from each specific streaming platform's terminology.

Terminology

Host

A data streaming server.

Source

A feed of messages in a common category which streams into the same Vertica target tables. In Apache Kafka, a source is known as a topic.

Partition

Unit of parallelism within data streaming. Data streaming splits a source into multiple partitions, which can each be served in parallel to consumers such as a Vertica database. Within a partition, messages are usually ordered chronologically.

Offset

An index into a partition. This index is the position within an ordered queue of messages, not an index into an opaque byte stream.

Message

A unit of data within data streaming. The data is typically in JSON or Avro format. Messages are loaded as rows into Vertica tables, and are uniquely identified by their source, partition, and offset.

Data loader terminology

Scheduler

An external tool that schedules data loads from a streaming data source into Vertica.

Microbatch

A microbatch represents a single segment of a data load from a streaming data source. It encompasses all of the information the scheduler needs to perform a load from a streaming data source into Vertica.

Frame

The window of time during which a Scheduler executes microbatches to load data. This window controls the duration of each COPY statement the scheduler runs as a part of the microbatch. During the frame, the scheduler gives an active microbatch from each source an opportunity to load data. It gives priority to microbatches that need more time to load data based on the history of previous microbatches.

Stream

A feed of messages that is identified by a source and partition.

The offset uniquely identifies the position within a particular source-partition stream.

Lane

A thread within a job scheduler instance that issues microbatches to perform the load.

The number of lanes available is based on the PlannedConcurrency of the job scheduler's resource pool. Multiple lanes allow the scheduler to run microbatches for different sources in parallel during a frame.

Configuring Vertica and Kafka

Both Vertica and Kafka have settings you can use to optimize your streaming data loads. The topics in this section explain these settings.

In this section

- [Kafka and Vertica configuration settings](#)
- [Directly setting Kafka library options](#)
- [Configuring Vertica for Apache Kafka version 0.9 and earlier](#)

Kafka and Vertica configuration settings

You can fine-tune configuration settings for Vertica and Kafka that optimize performance.

The Vertica and Kafka integration uses rdkafka version 0.11.6. Unless otherwise noted, the following configuration settings use the default librdkafka configuration properties values. For instructions on how to override the default values, see [Directly setting Kafka library options](#).

Vertica producer settings

These settings change how Vertica produces data for Kafka with the [KafkaExport](#) function and [notifiers](#).

queue.buffering.max.messages

Size of the Vertica producer queue. If Vertica generates too many messages too quickly, the queue can fill, resulting in dropped messages. Increasing this value consumes more memory, but reduces the chance of lost messages.

Defaults :

- KafkaExport: 1000
- Notifiers: 10000

queue.buffering.max.ms

Frequency with which Vertica flushes the producer message queue. Lower values decrease latency at the cost of throughput. Higher values increase throughput, but can cause the producer queue (set by `queue.buffering.max.messages`) to fill more frequently, resulting in dropped messages.

Default: 100 ms

message.max.bytes

Maximum size of a Kafka protocol request message batch. This value should be the same on your sources, brokers, and producers.

message.send.max.retries

Number of attempts the producer makes to deliver the message to a broker. Higher values increase the chance of success.

retry.backoff.ms

Interval Vertica waits before resending a failed message.

request.required.acks

Number of broker replica acknowledgments Kafka requires before it considers message delivery successful. Requiring acknowledgments increases latency. Removing acknowledgments increases the risk of message loss.

request.timeout.ms

Interval that the producer waits for a response from the broker. Broker response time is affected by server load and the number of message acknowledgments you require.

Higher values increase latency.

compression.type

Compression algorithm used to encode data before sending it to a broker. Compression helps to reduce the network footprint of your Vertica producers and increase disk utilization. Vertica supports `gzip` and `snappy`.

Kafka broker settings

Kafka brokers receive messages from producers and distribute them among Kafka consumers. Configure these settings on the brokers themselves. These settings function independently of your producer and consumer settings. For detailed information on Apache Kafka broker settings, refer to the [Apache Kafka documentation](#).

message.max.bytes

Maximum size of a Kafka protocol request message batch. This value should be the same on your sources, brokers, and producers.

num.io.threads

Number of network threads the broker uses to receive and process requests. More threads can increase your concurrency.

num.network.threads

Number of network threads the broker uses to accept network requests. More threads can increase your concurrency.

Vertica consumer settings

The following settings changes how Vertica acts when it consumes data from Kafka. You can set this value using the `kafka_conf` parameter on the KafkaSource UDL when directly executing a COPY statement. For schedulers, use the `--message_max_bytes` settings in the [scheduler tool](#).

message.max.bytes

Maximum size of a Kafka protocol request message batch. Set this value to a high enough value to prevent the overhead of fetching batches of messages interfering with loading data. Defaults to 24MB for newly-created load specs.

Directly setting Kafka library options

Vertica relies on the open source rdkafka library to communicate with Apache Kafka. This library contains many configuration properties that control how Vertica and Kafka interact. You set the most common rdkafka library properties through the settings in the [vkconfig utility](#) and the [Kafka integration functions](#).

There are some rdkafka properties that you cannot directly set from within the Vertica. Under normal circumstances, you do not need to change them. However, if you find that you need to set a specific rdkafka property that is not directly available from Vertica, you can set the property directly through one of the following options or parameters:

- `kafka_conf` : sets global configuration options. This is available as a vkconfig option and a function parameter.
- `kafka_topic_conf` : sets topic-level configuration options. This is available as a parameter in the [KafkaExport](#) and [KafkaSource](#) functions.
- `kafka_conf_secret` : sets options that accept sensitive information, such as passwords. This is available as a vkconfig option and a function parameter. Values passed to `kafka_conf_secret` are not logged or stored in system tables.

For a list of global and topic rdkafka configuration properties, see the [rdkafka repository on GitHub](#).

Important

Arbitrarily setting configuration properties might result in errors or unpredictable behavior. If you encounter a problem loading messages after setting an rdkafka property using the configuration options that Vertica provides, roll back your change to see if that was the source of the problem.

To prevent confusion, never use one of the `kafka_*` options or parameters to set an rdkafka library property if you can set the property with an existing scheduler option. For example, do not use the `kafka_conf` option to set the Kafka `message.max.bytes` setting. Instead, use the [load-spec tool --message-max-bytes](#) option.

Setting vkconfig properties

The `kafka_conf` option sets rdkafka properties when you [automatically consume data from Kafka](#) with the vkconfig scheduler. You can set its values in the following ways, listed in descending order of precedence:

1. The `--kafka_conf` option of the vkconfig utility. This option can be set in the [cluster](#), [source](#), [launch](#), and `sync` tools. Note that the setting only applies to each vkconfig utility call—it does not persist between calls and does not carry over to other vkconfig utility calls. For example, if you need to supply an option to the cluster and source tool, you must supply the `kafka_conf` option to both of them.
2. The Linux environment variable `VERTICA_RDKAFKA_CONF_KAFKA_CLUSTER` set on the host where you run the vkconfig utility. The `KAFKA_CLUSTER` portion of the variable name is the name of a Kafka cluster you have defined using vkconfig's [cluster utility](#). The settings in this environment variable only affect the specific Kafka cluster you name in `KAFKA_CLUSTER`.
3. The Linux environment variable `VERTICA_RDKAFKA_CONF` set on the host where you run the vkconfig utility.

Note

Setting an rdkafka property with an environment variable helps to keep your settings consistent. It is easy to forget to set the `--kafka_conf` option for each call to the vkconfig script.

All of these options cascade, so setting an option using the `--kafka_conf` argument to the cluster tool overrides the same option that was set in the environment variables.

Option and parameter formats

All `kafka_*` options and parameters accept a JSON string. You can pass configuration property settings in one of the following formats:

- One or more property/value pairs:

```
# vkconfig scheduler option
--kafka_conf '{"option1":value1,{"option2":value2...}]'

# function parameter
kafka_conf='{"option1":value1,"option2":value2...}]'
```

- A single property with multiple values:

```
# vkconfig scheduler option
--kafka_conf '{"option1":["value1","value2...}]'

# function parameter
kafka_conf='{"option1":["value1","value2...}]'
```

Examples

The following example demonstrates disabling rdkafka's `api.version.request` property when manually loading messages using KafkaSource. You should always disable this property when accessing Kafka cluster running version 0.9 or earlier. See [Configuring Vertica for Apache Kafka version 0.9 and earlier](#) for more information.

```

-> CREATE FLEX TABLE iot_data();
CREATE TABLE
-> COPY public.iot_data SOURCE KafkaSource(stream='iot_json|0|-2',
      brokers='kafka-01.example.com:9092',
      stop_on_eof=True,
      kafka_conf='{"api.version.request":false}')
      PARSER KafkaJSONParser();
Rows Loaded
-----
      5000
(1 row)

```

This example demonstrates setting two properties with a JSON string when calling the cluster tool. It disables the `api.version.request` property and enables CRC checks of messages from Kafka using the `check.crcs` property:

```

$ vkconfig cluster --create --cluster StreamCluster1 \
  --hosts kafka01.example.com:9092,kafka02.example.com:9092 \
  --conf myscheduler.config \
  --kafka_conf '{"api.version.request":false, "check.crcs":true}'

```

The following example demonstrates setting the same properties using an environment variable:

```

$ export VERTICA_RDKAFKA_CONF='{"api.version.request":false, "check.crcs":true}'
$ vkconfig cluster --create --cluster StreamCluster1 \
  --hosts kafka01.example.com:9092,kafka02.example.com:9092 \
  --conf myscheduler.config

```

Important
 Setting the `check.crc` property is just an example. Vertica does not suggest you enable the CRC check in your schedulers under normal circumstances. It adds additional overhead and can result in slower performance.

Configuring Vertica for Apache Kafka version 0.9 and earlier

Apache Kafka version 0.10 introduced a new feature that allows consumers to determine which version of the Kafka API the Kafka brokers support. Consumers that support this feature send an initial API version query to the Kafka broker to determine the API version to use when communicating with them. Kafka brokers running version 0.9.0 or earlier cannot respond to the API query. If the consumer does not receive a reply from the Kafka broker within a timeout period (set to 10 seconds by default) the consumer can assume the Kafka broker is running Kafka version 0.9.0 or earlier.

The Vertica integration with Kafka supports this API query feature starting in version 9.1.1. This API check can cause problems if you are connecting Vertica to a Kafka cluster running 0.9.0 or earlier. You may notice poorer performance loading messages from Kafka and may experience errors as the 10 second API request timeout can cause parts of the Kafka integration feature to time out and report errors.

For example, if you run the `vkconfig` source utility to configure a source on a Kafka 0.9 cluster, you may get the following error:

```

$ vkconfig source --create --conf weblog.conf --cluster kafka_weblog --source web_hits
Exception in thread "main" com.vertica.solutions.kafka.exception.ConfigurationException:

```

Disabling the API version request when using the streaming job scheduler

To avoid these problems, you must disable the API version request feature in the rdkafka library that Vertica uses to communicate with Kafka. The easiest way to disable this setting when using the scheduler is to set a Linux environment variable on the host on which you run the vkconfig script. Using the environment variable ensures that each call to vkconfig includes the setting to disable the API version request. The vkconfig script checks two variables:

- `VERTICA_RDKAFKA_CONF` applies to all Kafka clusters that the scheduler running on the host communicates with.
- `VERTICA_RDKAFKA_CONF_CLUSTER_NAME` applies to just the Kafka cluster named `CLUSTER_NAME`. Use this variable if your scheduler communicates with several Kafka clusters, some of which are not running version 0.9 or earlier.

If you set both variables, the cluster-specific one takes precedence. This feature is useful if most of the clusters your scheduler connects to are running Kafka 0.9 or earlier, but a few run 0.10 or later. This case, you can disable the API version check for most clusters using the `VERTICA_RDKAFKA_CONF` variable and re-enable the check for specific clusters using `VERTICA_RDKAFKA_CONF_CLUSTER_NAME`.

If just a few of your Kafka clusters run version 0.9 or earlier, you can just set the cluster-specific variables for them, and leave the default values in place for the majority of your clusters.

The contents of the environment variable is a JSON object that tells the rdkafka library whether to query the Kafka cluster for the API version it supports:

```

{"api.version.request":false}

```

To set the environment variable in BASH, use the export command:

```

$ export VERTICA_RDKAFKA_CONF='{"api.version.request":false}'

```

If you wanted the setting to just affect a cluster named `kafka_weblog`, the command is:

```

$ export VERTICA_RDKAFKA_CONF_kafka_weblog='{"api.version.request":false}'

```

You can add the command to any of the common user environment configuration files such as `~/.bash_profile` or the system-wide files such as `/etc/profile`. You must ensure that the same setting is used for all users who may run the vkconfig script, including any calls made by daemon processes such as `init`. You can also directly include this command in any script you use to set configure or start your scheduler.

Disabling the API version request when directly loading messages

You can disable the API request when you directly call `KafkaSource` to load messages by using the `kafka_conf` parameter:

```
-> CREATE FLEX TABLE iot_data();
CREATE TABLE
-> COPY public.iot_data SOURCE KafkaSource(stream='iot_json101-2',
      brokers='kafka-01.example.com:9092',

Vertica Eon Mode and Kafka

You can use the Vertica integration with Apache Kafka when Vertica is running in [Eon Mode](#). For Eon Mode running in a cloud environment, consider using a larger frame duration for schedulers in clusters. Cloud infrastructures lead to larger latencies overall, especially when storage layers are separated from compute layers. If you do not account for the added latency, you can experience a lower data throughput, as more of the frame's time is lost to overhead caused by the cloud environment. Using a longer frame length can also help prevent Vertica from creating many small ROS containers when loading data from Kafka. The trade off when you use a larger frame length is that your data load experiences more latency. See [Choosing a frame duration](#) for more information.

Consuming data from Kafka

A Kafka consumer subscribes to one or more topics managed by a Kafka cluster. Each topic is a data stream, an unbounded dataset that is represented as an ordered sequence of messages. Vertica can manually or automatically consume Kafka topics to perform analytics on your streaming data.

Manually consume data

Manually consume data from Kafka with a COPY statement that calls a KafkaSource function and parser. Manual loads are helpful when you want to:

- Populate a table one time with the messages currently in Kafka.
- Analyze a specific set of messages. You can choose the subset of data to load from the Kafka stream.
- Explore the data in a Kafka stream before you set up a scheduler to continuously stream the data into Vertica.
- Control the data load in ways not possible with the scheduler. For example, you cannot perform business logic or custom rejection handling during the data load from Kafka because the scheduler does not support additional processing during its transactions. Instead, you can periodically run a transaction that executes a COPY statement to load data from Kafka, and then perform additional processing.

For a detailed example, see [Manually consume data from Kafka](#).

Automatically consume data

Automatically consume streaming data from Kafka into Vertica with a [scheduler](#), a command-line tool that loads data as it arrives. The scheduler loads data in segments defined by a microbatch, a unit of work that processes the partitions of a single Kafka topic for a specified duration of time. You can manage scheduler configuration and options using the [vkconfig tool](#).

For details, see [Automatically consume data from Kafka with a scheduler](#).

Monitoring consumption

You must monitor message consumption to ensure that Kafka and Vertica are communicating effectively. You can use native Kafka tools to monitor consumer groups, or you can use [vkconfig tool](#) to view consumption details.

For additional information, see [Monitoring message consumption](#).

Parsing data with Kafka filters

Your data stream might encode data that the Kafka parser functions cannot parse by default. Use Kafka filters to delimit messages in your stream to improve data consumption.

For details, see [Parsing custom formats](#).

In this section

- [Manually consume data from Kafka](#)
- [Automatically consume data from Kafka with a scheduler](#)
- [Monitoring message consumption](#)
- [Parsing custom formats](#)

Manually consume data from Kafka

You can manually load streaming data from Kafka into Vertica using a [COPY](#) statement, just as you can load a finite set of data from a file or other source. Unlike a standard data source, Kafka data arrives continuously as a stream of messages that you must parse before loading into Vertica. Use [Kafka functions](#) in the COPY statement to prepare the data stream.

This example incrementally builds a COPY statement that manually loads JSON-encoded data from a Kafka topic named `web_hits`. The `web_hits` topic streams server logs of web site requests.

For information about loading data into Vertica, see [Data load](#).

Creating the target table

To determine the target table schema, you must identify the message structure. The following is a sample of the `web_hits` stream:

```
{ "url": "list.jsp", "ip": "144.177.38.106", "date": "2017/05/02 20:56:00",  
  "user-agent": "Mozilla/5.0 (compatible; MSIE 6.0; Windows NT 6.0; Trident/5.1)" }  
{ "url": "search/wp-content.html", "ip": "215.141.172.28", "date": "2017/05/02 20:56:01",  
  "user-agent": "Opera/9.53.(Windows NT 5.2; sl-SI) Presto/2.9.161 Version/10.00" }
```

This topic streams JSON-encoded data. Because JSON data is inconsistent and might contain unpredictable added values, store this data stream in a flex table. Flex tables dynamically accept additional fields that appear in the data.

The following statement creates a flex table named `web_table` to store the data stream:

```
=> CREATE FLEX TABLE web_table();
```

To begin the COPY statement, add the `web_table` as the target table:

```
COPY web_table
```

For more information about flex tables, see [Flex tables](#).

Note

If you are copying data containing default values into a flex table, you must identify the default value column as `__raw__`. For more information, see [Bulk Loading Data into Flex Tables](#).

Defining KafkaSource

The source of your COPY statement is always [KafkaSource](#). `KafkaSource` accepts details about the data stream, Kafka brokers, and additional processing options to continuously load data until an [end condition](#) is met.

Stream details

The stream parameter defines the data segment that you want to load from one or more topic partitions. Each Kafka topic splits its messages into different partitions to get scalable throughput. Kafka keeps a backlog of messages for each topic according to rules set by the Kafka administrator. You can choose to load some or all of the messages in the backlog, or just load the currently streamed messages.

For each partition, the stream parameter requires the topic name, topic partition, and the partition offset as a list delimited by a pipe character (`|`). Optionally, you can provide an end offset as an end condition to stop loading from the data stream:

```
'stream=' topic_name | partition | start_offset [| end_offset ]
```

To load the entire backlog from a single partition of the `web_hits` topic, use the `SOURCE` keyword to append `KafkaSource` with the following `stream` parameter values:

```
COPY ...  
SOURCE KafkaSource(stream='web_hits|0|-2', ...
```

In the previous example:

- `web_hits` is the name of the topic to load data from.
- `0` is the topic partition to load data from. Topic partitions are 0-indexed, and `web_hits` contains only one partition.
- `-2` loads the entire backlog. This is a special offset value that tells `KafkaSource` to start loading at the earliest available message offset.

Loading multiple partitions

This example loads from only one partition, but it is important to understand how to load from multiple partitions in a single `COPY` statement.

To load from additional partitions in the same topic, or even additional topics, supply a comma-separated list of topic name, partition number, and offset values delimited by pipe characters. For example, the following `stream` argument loads the entire message backlog from partitions 0 through 2 of the `web_hits` topic:

```
KafkaSource(stream='web_hits|0|-2,web_hits|1|-2,web_hits|2|-2'...
```

Note

While you can load messages from different Kafka topics in the same `COPY` statement, you must ensure the data from the different topics is compatible with the target table's schema. The schema is less of a concern if you are loading data into a flex table, which can accommodate almost any data you want to load.

When you load multiple partitions in the same `COPY` statement, you can set the `executionparallelism` parameter to define the number of threads created for the `COPY` statement. Ideally, you want to use one thread per partition. You can choose to not specify a value and let Vertica determine the number of threads based on the number of partitions and the resources available in the resource pool. In this example, there is only one partition, so there's no need for additional threads to load data.

Note

The `EXECUTIONPARALLELISM` setting on the resource pool assigned is the upper limit on the number of threads your `COPY` statement can use. Setting `executionparallelism` on the `KafkaSource` function call to a value that is higher than that of the resource pool's `EXECUTIONPARALLELISM` setting does not increase the number of threads Vertica uses beyond the limits of the resource pool.

Adding the Kafka brokers

`KafkaSource` requires the host names (or IP addresses) and port numbers of the brokers in your Kafka cluster. The Kafka brokers are the service Vertica accesses in order to retrieve the Kafka data. In this example, the Kafka cluster has one broker named `kafka01.example.com`, running on port 9092. Append the `brokers` parameter and value to the `COPY` statement:

```
COPY ...
SOURCE KafkaSource(stream='web_hits|0|-2',
                    brokers='kafka01.example.com:9092', ...
```

Choosing the end condition

Because data continuously arrives from Kafka, manual loads from Kafka require that you define an end condition that indicates when to stop loading data. In addition to the end offset described in [Stream Details](#), you can choose to:

- Copy as much data as possible for a set duration of time.
- Load data until no new data arrives within a timeout period.
- Load all available data, and not wait for any further data to arrive.

This example runs `COPY` for 10000 milliseconds (10 seconds) to get a sample of the data. If the `COPY` statement is able to load the entire backlog of data in under 10 seconds, it spends the remaining time loading streaming data as it arrives. This value is set in the `duration` parameter. Append the `duration` value to complete the `KafkaSource` definition:

```
COPY ...
SOURCE KafkaSource(stream='web_hits|0|-2',
                    brokers='kafka01.example.com:9092',
                    duration=interval '10000 milliseconds')
```

If you start a long-duration `COPY` statement from Kafka and need to stop it, you can call one of the functions that closes its session, such as [CLOSE_ALL_SESSIONS](#).

Important

The duration that you set for your data load is not exact. The duration controls how long the `KafkaSource` process runs.

Selecting a parser

Kafka does not enforce message formatting on its data streams. Messages are often in Avro or JSON format, but they could be in any format. Your COPY statement usually uses one of three Kafka-specific parsers:

- [KafkaParser](#)
- [KafkaJSONParser](#)
- [KafkaAvroParser](#)

Because the Kafka parsers can recognize record boundaries in streaming data, the other parsers (such as the [Flex parsers](#)) are not directly compatible with the output of KafkaSource. You must alter the KafkaSource output using filters before other parsers can process the data. See [Parsing custom formats](#) for more information.

In this example, the data in the web_hits is encoded in JSON format, so it uses the KafkaJSONParser. This value is set in the COPY statement's PARSER clause:

```
COPY ...
SOURCE ...
PARSER KafkaJSONParser()
```

Storing rejected data

Vertica saves raw Kafka messages that the parser cannot parse to a rejects table, along with information on why it was rejected. This table is created by the COPY statement. This example saves rejects to the table named web_hits_rejections. This value is set in the COPY statement's REJECTED DATA AS TABLE clause:

```
COPY ...
SOURCE ...
PARSER ...
REJECTED DATA AS TABLE public.web_hits_rejections;
```

Loading the data stream into Vertica

The following steps load JSON data from the web_hits topic for 10 seconds using the COPY statement that was incrementally built in the previous sections:

1. Execute the COPY statement:

```
=> COPY web_table
  SOURCE KafkaSource(stream='web_hits|0|-2',
    brokers='kafka01.example.com:9092',
    duration=interval '10000 milliseconds')
  PARSER KafkaJSONParser()
  REJECTED DATA AS TABLE public.web_hits_rejections;
Rows Loaded
-----
      800
(1 row)
```

2. Compute the flex table keys:

```
=> SELECT compute_flextable_keys('web_table');
      compute_flextable_keys
-----
Please see public.web_table_keys for updated keys
(1 row)
```

For additional details, see [Computing flex table keys](#).

3. Query web_table_keys to return the keys:

```
=> SELECT * FROM web_table_keys;
key_name | frequency | data_type_guess
-----+-----+-----
date     |      800 | Timestamp
user_agent |      800 | Varchar(294)
ip       |      800 | Varchar(30)
url      |      800 | Varchar(88)
(4 rows)
```

4. Query web_table to return the data loaded from the web_hits Kafka topic:

```
=> SELECT date, url, ip FROM web_table LIMIT 10;
```

Automatically consume data from Kafka with a scheduler

Vertica offers a scheduler that loads streamed messages from one or more Kafka topics. Automatically loading streaming data has a number of advantages over manually using COPY:

- The streamed data automatically appears in your database. The frequency with which new data appears in your database is governed by the scheduler's frame duration.
- The scheduler provides an exactly-once consumption process. The schedulers manage offsets for you so that each message sent by Kafka is consumed once.
- You can configure backup schedulers to provide high-availability. Should the primary scheduler fail for some reason, the backup scheduler automatically takes over loading data.
- The scheduler manages resources for the data load. You control its resource usage through the settings on the resource pool you assign to it. When loading manually, you must take into account the resources your load consumes.

There are a few drawbacks to using a scheduler which may make it unsuitable for your needs. You may find that schedulers do not offer the flexibility you need for your load process. For example, schedulers cannot perform business logic during the load transaction. If you need to perform this sort of processing, you are better off creating your own load process. This process would periodically run COPY statements to load data from Kafka. Then it would perform the business logic processing you need before committing the transaction.

For information on job scheduler requirements, refer to [Apache Kafka integrations](#).

What the job scheduler does

The scheduler is responsible for scheduling loads of data from Kafka. The scheduler's basic unit of processing is a frame, which is a period of time. Within each frame, the scheduler assigns a slice of time for each active microbatch to run. Each microbatch is responsible for loading data from a single source. Once the frame ends, the scheduler starts the next frame. The scheduler continues this process until you stop it.

The anatomy of a scheduler

Each scheduler has several groups of settings, each of which control an aspect of the data load. These groups are:

- The scheduler itself, which defines the configuration schema, frame duration, and resource pool.
- Clusters, which define the hosts in the Kafka cluster that the scheduler contacts to load data. Each scheduler can contain multiple clusters, allowing you to load data from multiple Kafka clusters with a single scheduler.
- Sources, which define the Kafka topics and partitions in those topics to read data from.
- Targets, which define the tables in Vertica that will receive the data. These tables can be traditional Vertica database tables, or they can be flex tables.
- Load specs, which define setting Vertica uses while loading the data. These settings include the parsers and filters Vertica needs to use to load the data. For example, if you are reading a Kafka topic that is in Avro format, your load spec needs to specify the Avro parser and schema.
- Microbatches, which represent an individual segment of a data load from a Kafka stream. They combine the definitions for your cluster, source, target, and load spec that you create using the other vkconfig tools. The scheduler uses all of the information in the microbatch to execute [COPY](#) statements using the [KafkaSource](#) UDL function to transfer data from Kafka to Vertica. The statistics on each microbatch's load is stored in the [stream_microbatch_history](#) table.

The vkconfig script

You use a Linux command-line script named vkconfig to create, configure, and run schedulers. This script is installed on your Vertica hosts along with the Vertica server in the following path:

```
/opt/vertica/packages/kafka/bin/vkconfig
```

Note

You can install and use the vkconfig utility on a non-Vertica host. You may want to do this if:

- You do not want the scheduler to use Vertica host resources.
- You want users who do not have shell accounts on the Vertica hosts to be able to set up and alter schedulers.

The easiest way to install vkconfig on a host is to install the Vertica server RPM. You must use the RPM that matches the version of Vertica installed on your database cluster. Do not create a database after installing the RPM. The vkconfig utility and its associated files will be in the `/opt/vertica/packages/kafka/bin` directory on the host.

The vkconfig script contains multiple tools. The first argument to the vkconfig script is always the tool you want to use. Each tool performs one function, such as changing one group of settings (such as clusters or sources) or starting and stopping the scheduler. For example, to create or configure a scheduler, you use the command:

```
$ /opt/vertica/packages/kafka/bin/vkconfig scheduler other options...
```

What happens when you create a scheduler

When you create a new scheduler, the vkconfig script takes the following steps:

- Creates a new Vertica schema using the name you specified for the scheduler. You use this name to identify the scheduler during configuration.
- Creates the tables needed to manage the Kafka data load in the newly-created schema. See [Data streaming schema tables](#) for more information.

Validating schedulers

When you create or configure a scheduler, it validates the following settings:

- Confirms that all brokers in the specified cluster exist.
- Connects to the specified host or hosts and retrieves the list of all brokers in the Kafka cluster. Getting this list always ensures that the scheduler has an up-to-date list of all the brokers. If the host is part of a cluster that has already been defined, the scheduler cancels the configuration.
- Confirms that the specified source exists. If the source no longer exists, the source is disabled.
- Retrieves the number of partitions in the source. If the number of partitions retrieved from the source is different than the partitions value saved by the scheduler, Vertica updates the scheduler with the number of partitions retrieved from the source in the cluster.

You can disable validation using the `--validation-type` option in the vkconfig script's scheduler tool. See [Scheduler tool options](#) for more information.

Synchronizing schedulers

By default, the scheduler automatically synchronizes its configuration and source information with Kafka host clusters. You can configure the synchronization interval using the `--config-refresh` scheduler utility option. Each interval, the scheduler:

- Checks for updates to the scheduler's configuration by querying its settings in its Vertica configuration schema.
- Performs all of the checks listed in [Validating Schedulers](#).

You can configure synchronization settings using the `--auto-sync` option using the vkconfig script's scheduler tool. [Scheduler tool options](#) for details.

Launching a scheduler

You use the vkconfig script's launch tool to launch a scheduler.

When you launch a scheduler, it collects data from your sources, starting at the specified offset. You can view the [stream_microbatch_history](#) table to see what the scheduler is doing at any given time.

To learn how to create, configure, and launch a scheduler, see [Setting up a scheduler](#) in this guide.

You can also choose to bypass the scheduler. For example, you might want to do a single load with a specific range of offsets. For more information, see [Manually consume data from Kafka](#) in this guide.

If the Vertica cluster goes down, the scheduler attempts to reconnect and fails. You must relaunch the scheduler when the cluster is restarted.

Managing a running scheduler

When you launch a scheduler from the command line, it runs in the foreground. It will run until you kill it (or the host shuts down). Usually, you want to start the scheduler as a daemon process that starts it when the host operating system starts, or after the Vertica database has started.

You shut down a running scheduler using the vkconfig script's shutdown tool. See [Shutdown tool options](#) for details.

You can change most of a scheduler's settings (adding or altering clusters, sources, targets, and microbatches for example) while it is running. The scheduler automatically acts on the configuration updates.

Launching multiple job schedulers for high availability

For high availability, you can launch two or more identical schedulers that target the same configuration schema. You differentiate the schedulers using the launch tool's `--instance-name` option (see [Launch tool options](#)).

The active scheduler loads data and maintains an [S lock](#) on the [stream_lock](#) table. The scheduler not in use remains in stand-by mode until the active scheduler fails or is disabled. If the active scheduler fails, the backup scheduler immediately obtains the lock on the `stream_lock` table, and takes over loading data from Kafka where the failed scheduler left off.

Managing messages rejected during automatic loads

Vertica rejects messages during automatic loads using the parser definition, which is required in the [microbatch load spec](#).

The scheduler creates a rejection table to store rejected messages for each microbatch automatically. To manually specify a rejection table, use the `--rejection-schema` and `--rejection-table` [microbatch utility options](#) when creating the microbatch. Query the [stream_microbatches](#) table to return the rejection schema and table for a microbatch.

For additional details about how Vertica handles rejected data, see [Handling messy data](#).

Passing options to the scheduler's JVM

The scheduler uses a Java Virtual Machine to connect to Vertica via JDBC. You can pass command-line options to the JVM through a Linux environment variable named `VKCONFIG_JVM_OPTS`. This option is useful when configuring a scheduler to use TLS/SSL encryption when connecting to Vertica. See [Configuring your scheduler for TLS connections](#) for more information.

Viewing schedulers from the MC

You can view the status of Kafka jobs from the MC. For more information, refer to [Viewing load history](#).

In this section

- [Setting up a scheduler](#)
- [Choosing a frame duration](#)
- [Managing scheduler resources and performance](#)

- [Updating schedulers after Vertica upgrades](#)

Setting up a scheduler

Note

This document describes how to create and launch a scheduler in a Linux environment. For details about creating a containerized scheduler, see [Containerized Kafka Scheduler](#).

You set up a scheduler using the Linux command line. Usually you perform the configuration on the host where you want your scheduler to run. It can be one of your Vertica hosts, or a separate host where you have installed the `vkconfig` utility (see [The vkconfig Script](#) for more information).

The steps to launch a scheduler are explained in the following sections. These sections will use the example of loading web log data (hits on a web site) from Kafka into a Vertica table.

Create a config file (optional)

Many of the arguments you supply to the `vkconfig` script while creating a scheduler do not change. For example, you often need to pass a username and password to Vertica to authorize the changes to be made in the database. Adding the username and password to each call to `vkconfig` is tedious and error-prone.

Instead, you can pass the `vkconfig` utility a configuration file using the `--conf` option that specifies these arguments for you. It can save you a lot of typing and frustration.

The config file is a text file with a `keyword = value` pair on each line. Each keyword is a `vkconfig` command-line option, such as the ones listed in [Common vkconfig script options](#).

The following example shows a config file named `weblog.conf` that will be used to define a scheduler named `weblog_sched`. This config file is used throughout the rest of this example.

```
# The configuraton options for the weblog_sched scheduler.
username=dbadmin
password=myspassword
dbhost=vertica01.example.com
dbport=5433
config-schema=weblog_sched
```

Add the vkconfig directory to your path (optional)

The vkconfig script is located in the `/opt/vertica/packages/kafka/bin` directory. Typing this path for each call to vkconfig is tedious. You can add vkconfig to your search path for your current Linux session using the following command:

```
$ export PATH=/opt/vertica/packages/kafka/bin:$PATH
```

For the rest of your session, you are able to call vkconfig without specifying its entire path:

```
$ vkconfig
Invalid tool
Valid options are scheduler, cluster, source, target, load-spec, microbatch, sync, launch,
shutdown, help
```

If you want to make this setting permanent, add the export statement to your `~/.profile` file. The rest of this example assumes that you have added this directory to your shell's search path.

Create a resource pool for your scheduler

Vertica recommends that you always create a [resource pool](#) specifically for each scheduler. Schedulers assume that they have exclusive use of their assigned resource pool. Using a separate pool for a scheduler lets you fine-tune its impact on your Vertica cluster's performance. You create resource pools with [CREATE RESOURCE POOL](#).

The following [resource pool settings](#) play an important role when creating your scheduler's resource pool:

- `PLANNEDCONCURRENCY` determines the number of microbatches (COPY statements) that the scheduler sends to Vertica simultaneously.
- `EXECUTIONPARALLELISM` determines the maximum number of threads that each node creates to process a microbatch's partitions.
- `QUEUETIMEOUT` provides manual control over resource timings. Set this to 0 to allow the scheduler to manage timings.

See [Managing scheduler resources and performance](#) for detailed information about these settings and how to fine-tune a resource pool for your scheduler.

The following CREATE RESOURCE POOL statement creates a resource pool that loads 1 microbatch and processes 1 partition:

```
=> CREATE RESOURCE POOL weblog_pool
  MEMORYSIZE '10%'
  PLANNEDCONCURRENCY 1
  EXECUTIONPARALLELISM 1
  QUEUETIMEOUT 0;
```

If you do not create and assign a resource pool for your scheduler, it uses a portion of the GENERAL resource pool. Vertica recommends that you do not use the GENERAL pool for schedulers in production environments. This fallback to the GENERAL pool is intended as a convenience when you test your scheduler configuration. When you are ready to deploy your scheduler, create a resource pool that you tuned to its specific needs. Each time that you start a scheduler that is using the GENERAL pool, the vkconfig utility displays a warning message.

Not allocating enough resources to your schedulers can result in errors. For example, you might get `OVERSHOT DEADLINE FOR FRAME` errors if the scheduler is unable to load data from all topics in a data frame.

See [Resource pool architecture](#) for more information about resource pools.

Create the scheduler

Vertica includes a default scheduler named `stream_config`. You can use this scheduler or create a new scheduler using the vkconfig script's [scheduler tool](#) with the `--create` and `--config-schema` options:

```
$ vkconfig scheduler --create --config-schema scheduler_name --conf conf_file
```

The `--create` and `--config-schema` options are the only ones required to add a scheduler with default options. This command creates a new schema in Vertica that holds the scheduler's configuration. See [What Happens When You Create a Scheduler](#) for details on the creation of the scheduler's schema.

You can use additional configuration parameters to further customize your scheduler. See [Scheduler tool options](#) for more information.

The following example:

- Creates a scheduler named `weblog_sched` using the `--config-schema` option.
- Grants privileges to configure and run the scheduler to the Vertica user named `kafka_user` with the `--operator` option. The `dbadmin` user must specify additional privileges separately.
- Specifies a frame duration of seven minutes with the `--frame-duration` option. For more information about picking a frame duration, see [Choosing a frame duration](#).
- Sets the resource pool that the scheduler uses to the `weblog_pool` created earlier:

```
$ vkconfig scheduler --create --config-schema weblog_sched --operator kafka_user \  
--frame-duration '00:07:00' --resource-pool weblog_pool --conf weblog.conf
```

Note

Technically, the previous example doesn't need to supply the `--config-schema` argument because it is set in the `weblog.conf` file. It appears in this example for clarity. There's no harm in supplying it on the command line as well as in the configuration file, as long as the values match. If they do not match, the value given on the command line takes priority.

Create a cluster

You must associate at least one Kafka cluster with your scheduler. Schedulers can access more than one Kafka cluster. To create a cluster, you supply a name for the cluster and host names and ports the Kafka cluster's brokers.

When you create a cluster, the scheduler attempts to validate it by connecting to the Kafka cluster. If it successfully connects, the scheduler automatically retrieves the list of all brokers in the cluster. Therefore, you do not have to list every single broker in the `--hosts` parameter.

The following example creates a cluster named `kafka_weblog`, with two Kafka broker hosts: `kafka01` and `kafka03` in the `example.com` domain. The Kafka brokers are running on port 9092.

```
$ vkconfig cluster --create --cluster kafka_weblog \  
--hosts kafka01.example.com:9092,kafka03.example.com:9092 --conf weblog.conf
```

See [Cluster tool options](#) for more information.

Create a source

Next, create at least one source for your scheduler to read. The source defines the Kafka topic the scheduler loads data from as well as the number of partitions the topic contains.

To create and associate a source with a configured scheduler, use the `source` tool. When you create a source, Vertica connects to the Kafka cluster to verify that the topic exists. So, before you create the source, make sure that the topic already exists in your Kafka cluster. Because Vertica verifies the existence of the topic, you must supply the previously-defined cluster name using the `--cluster` option.

The following example creates a source for the Kafka topic named `web_hits` on the cluster created in the previous step. This topic has a single partition.

```
$ vkconfig source --create --cluster kafka_weblog --source web_hits --partitions 1 --conf weblog.conf
```

Note

The `--partitions` parameter is the number of partitions to load, not a list of individual partitions. For example, if you set this parameter to 3, the scheduler will load data from partitions 0, 1, and 2.

See [Source tool options](#) for more information.

Create a data table

Before you can create a target for your scheduler, you must create a target table in your Vertica database. This is the table Vertica uses to store the data the scheduler loads from Kafka. You must decide which type of table to create for your target:

- A standard Vertica database table, which you create using the `CREATE TABLE` statement. This type of table stores data efficiently. However, you must ensure that its columns match the data format of the messages in Kafka topic you are loading. You cannot load complex types of data into a standard Vertica table.

- A flex table, which you create using [CREATE FLEXIBLE TABLE](#). A flex table is less efficient than a standard Vertica database table. However, it is flexible enough to deal with data whose schema varies and changes. It also can load most complex data types that (such as maps and lists) that standard Vertica tables cannot.

Important
Avoid having columns with primary key restrictions in your target table. The scheduler stops loading data if it encounters a row that has a value which violates this restriction. If you must have a primary key restricted column, try to filter out any redundant values for that column in the streamed data before it is loaded by the scheduler.

The data in this example is in a set format, so the best table to use is a standard Vertica table. The following example creates a table named `web_hits` to hold four columns of data. This table is located in the public schema.

```
=> CREATE TABLE web_hits (ip VARCHAR(16), url VARCHAR(256), date DATETIME, user_agent VARCHAR(1024));
```

Note
You do not need to create a rejection table to store rejected messages. The scheduler creates the rejection table automatically.

Create a target

Once you have created your target table, you can create your scheduler's target. The target tells your scheduler where to store the data it retrieves from Kafka. This table must exist when you create your target. You use the `vkconfig` script's target tool with the `--target-schema` and `--target_table` options to specify the Vertica target table's schema and name. The following example adds a target for the table created in the previous step.

```
$ vkconfig target --create --target-schema public --target-table web_hits --conf weblog.conf
```

See [Target tool options](#) for more information.

Create a load spec

The scheduler's load spec provides parameters that Vertica uses when parsing the data loaded from Kafka. The most important option is `--parser` which sets the parser that Vertica uses to parse the data. You have three parser options:

- [KafkaAvroParser](#) for data in Avro format.
- [KafkaJSONParser](#) for data in JSON format.
- [KafkaParser](#) to load each message into a single VARCHAR field. See [Parsing custom formats](#) for more information.

In this example, the data being loaded from Kafka is in JSON format. The following command creates a load spec named `weblog_load` and sets the parser to `KafkaJSONParser`.

```
$ vkconfig load-spec --create --parser KafkaJSONParser --load-spec weblog_load --conf weblog.conf
```

See [Load spec tool options](#) for more information.

Create a microbatch

The microbatch combines all of the settings added to the scheduler so far to define the individual COPY statements that the scheduler uses to load data from Kafka.

The following example uses all of the settings created in the previous examples to create a microbatch called `weblog`.

```
$ vkconfig microbatch --create --microbatch weblog --target-schema public --target-table web_hits \  
  --add-source web_hits --add-source-cluster kafka_weblog --load-spec weblog_load \  
  --conf weblog.conf
```

For microbatches that might benefit from a reduced transaction size, consider using the `--max-parallelism` option when creating the microbatch. This option splits a single microbatch with multiple partitions into the specified number of simultaneous COPY statements consisting of fewer partitions.

See [Microbatch tool options](#) for more information about `--max-parallelism` and other options.

Launch the scheduler

Once you've created at least one microbatch, you can run your scheduler. You start your scheduler using the launch tool, passing it the name of the scheduler's schema. The scheduler begins scheduling microbatch loads for every enabled microbatch defined in its schema.

The following example launches the `weblog` scheduler defined in the previous steps. It uses the `nohup` command to prevent the scheduler being killed when the user logs out, and redirects `stdout` and `stderr` to prevent a `nohup.out` file from being created.

```
$ nohup vkconfig launch --conf weblog.conf >/dev/null 2>&1 &
```

Important
Vertica does not recommend specifying a password on the command line. Passwords on the command line can be exposed by the system's list of processes, which shows the command line for each process. Instead, put the password in a configuration file. Make sure the configuration file's permissions only allow it to be read by the user.

See [Launch tool options](#) for more information.

Checking that the scheduler is running

Once you have launched your scheduler, you can verify that it is running by querying the [stream_microbatch_history](#) table in the scheduler's schema. This table lists the results of each microbatch the scheduler has run.

For example, this query lists the microbatch name, the start and end times of the microbatch, the start and end offset of the batch, and why the batch ended. The results are ordered to start from when the scheduler was launched:

```
=> SELECT microbatch, batch_start, batch_end, start_offset,
        end_offset, end_reason
        FROM weblog_sched.stream_microbatch_history
        ORDER BY batch_start DESC LIMIT 10;
```

microbatch	batch_start	batch_end	start_offset	end_offset	end_reason

Choosing a frame duration

One key setting for your scheduler is its frame duration. The duration sets the amount of time the scheduler has to run all of the microbatches you have defined for it. This setting has significant impact on how data is loaded from Apache Kafka.

What happens during each frame

To understand the right frame duration, you first need to understand what happens during each frame.

The frame duration is split among the microbatches you add to your scheduler. In addition, there is some overhead in each frame that takes some time away from processing the microbatches. Within each microbatch, there is also some overhead which reduces the time the microbatch spends loading data from Kafka. The following diagram shows roughly how each frame is divided:

As you can see, only a portion of the time in the frame is spent actually loading the streaming data.

How the scheduler prioritizes microbatches

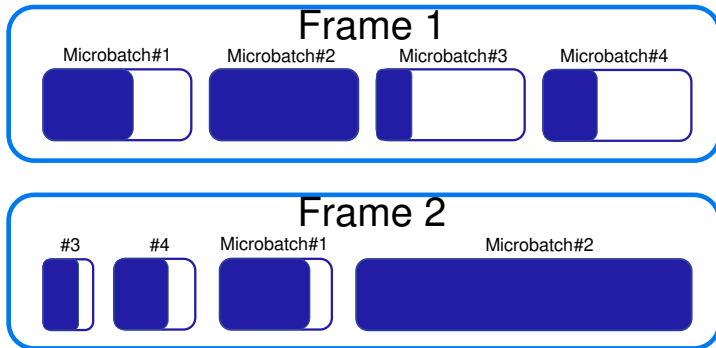

To start with, the scheduler evenly divides the time in the frame among the microbatches. It then runs each microbatch in turn.

In each microbatch, the bulk of the time is dedicated to loading data using a [COPY](#) statement. This statement loads data using the [KafkaSource](#) UDL. It runs until one of two conditions occurs:

- It reaches the ends of the data streams for the topics and partitions you defined for the microbatch. In this case, the microbatch completes processing early.
- It reaches a timeout set by the scheduler.

As the scheduler processes frames, it notes which microbatches finish early. It then schedules them to run first in the next frame. Arranging the microbatches in this manner lets the scheduler allocate more of the time in the frame to the microbatches that are spending the most time loading data (and perhaps have not had enough time to reach the end of their data streams).

For example, consider the following diagram. During the first frame, the scheduler evenly divides the time between the microbatches. Microbatch #2 uses all of the time allocated to it (as indicated by the filled-in area), while the other microbatches do not. In the next frame, the scheduler rearranges the microbatches so that microbatches that finished early go first. It also allocates less time to the microbatches that ran for a shorter period. Assuming these microbatches finish early again, the scheduler is able to give the rest of the time in the frame to microbatch #2. This shifting of priorities continues while the scheduler runs. If one topic sees a spike in traffic, the scheduler compensates by giving the microbatch reading from that topic more time.

What happens if the frame duration is too short

If you make the scheduler's frame duration too short, microbatches may not have enough time to load all of the data in the data streams they are responsible for reading. In the worst case, a microbatch could fall further behind when reading a high-volume topic during each frame. If left unaddressed, this issue could result in messages never being loaded, as they age out of the data stream before the microbatch has a chance to read them.

In extreme cases, the scheduler may not be able to run each microbatch during each frame. This problem can occur if the frame duration is so short that much of it is spent in overhead tasks such as committing data and preparing to run microbatches. The COPY statement that each microbatch runs to load data from Kafka has a minimum duration of 1 second. Add to this the overhead of processing data loads. In general, if the frame duration is shorter than 2 seconds times the number of microbatches in the scheduler, then some microbatches may not get a chance to run in each frame.

If the scheduler runs out of time during a frame to run each microbatch, it compensates during the next frame by giving priority to the microbatches that didn't run in the prior frame. This strategy makes sure each microbatch gets a chance to load data. However, it cannot address the root cause of the problem. Your best solution is to increase the frame duration to give each microbatch enough time to load data during each frame.

What happens if the frame duration is too long

One downside of a long frame duration is increased data latency. This latency is the time between when Kafka sends data out and when that data becomes available for queries in your database. A longer frame duration means that there is more time between each execution of a microbatch. That translates into more time between the data in your database being updated.

Depending on your application, this latency may not be important. When determining your frame duration, consider whether having the data potentially delayed up to the entire length of the frame duration will cause an issue.

Another issue to consider when using a long frame duration is the time it takes to shut down the scheduler. The scheduler does not shut down until the current COPY statement completes. Depending on the length of your frame duration, this process might take a few minutes.

The minimum frame duration

At a minimum, allocate two seconds for each microbatch you add to your scheduler. The vkconfig utility warns you if your frame duration is shorter than this lower limit. In most cases, you want your frame duration to be longer. Two seconds per microbatch leaves little time for data to actually load.

Balancing frame duration requirements

To determine the best frame duration for your deployment, consider how sensitive you are to data latency. If you are not performing time-sensitive queries against the data streaming in from Kafka, you can afford to have the default 5 minute or even longer frame duration. If you need a shorter data latency, then consider the volume of data being read from Kafka. High volumes of data, or data that has significant spikes in traffic can cause problems if you have a short frame duration.

Using different schedulers for different needs

Suppose you are loading streaming data from a few Kafka topics that you want to query with low latency and other topics that have a high volume but which you can afford more latency. Choosing a "middle of the road" frame duration in this situation may not meet either need. A better solution is to use multiple schedulers: create one scheduler with a shorter frame duration that reads just the topics that you need to query with low latency. Then create another scheduler that has a longer frame duration to load data from the high-volume topics.

For example, suppose you are loading streaming data from an Internet of Things (IOT) sensor network via Kafka into Vertica. You use the most of this data to periodically generate reports and update dashboard displays. Neither of these use cases are particularly time sensitive. However, three of the topics you are loading from do contain time-sensitive data (system failures, intrusion detection, and loss of connectivity) that must trigger immediate alerts.

In this case, you can create one scheduler with a frame duration of 5 minutes or more to read most of the topics that contain the non-critical data. Then create a second scheduler with a frame duration of at least 6 seconds (but preferably longer) that loads just the data from the three time-sensitive topics. The volume of data in these topics is hopefully low enough that having a short frame duration will not cause problems.

Managing scheduler resources and performance

Your scheduler's performance is impacted by the number of [microbatches](#) in your scheduler, partitions in each microbatch, and nodes in your Vertica cluster. Use resource pools to allocate a subset of system resources for your scheduler, and fine-tune those resources to optimize automatic loads into Vertica.

The following sections provide details about scheduler resource pool configurations and processing scenarios.

Schedulers and resource pools

Vertica recommends that you always create a [resource pool](#) specifically for each scheduler. Schedulers assume that they have exclusive use of their assigned resource pool. Using a separate pool for a scheduler lets you fine-tune its impact on your Vertica cluster's performance. You create resource pools with [CREATE RESOURCE POOL](#).

If you do not create and assign a resource pool for your scheduler, it uses a portion of the GENERAL resource pool. Vertica recommends that you do not use the GENERAL pool for schedulers in production environments. This fallback to the GENERAL pool is intended as a convenience when you test your scheduler configuration. When you are ready to deploy your scheduler, create a resource pool that you tuned to its specific needs. Each time that you start a scheduler that is using the GENERAL pool, the vkconfig utility displays a warning message.

Not allocating enough resources to your schedulers can result in errors. For example, you might get OVERSHOT DEADLINE FOR FRAME errors if the scheduler is unable to load data from all topics in a data frame.

See [Resource pool architecture](#) for more information about resource pools.

Key resource pool settings

A microbatch is a unit of work that processes the partitions of a single Kafka topic within the [duration of a frame](#). The following [resource pool settings](#) play an important role in how Vertica loads microbatches and processes partitions:

- **PLANNEDCONCURRENCY** determines the number of microbatches (COPY statements) the scheduler sends to Vertica simultaneously. At the start of each frame, the scheduler creates the number of scheduler threads specified by PLANNEDCONCURRENCY. Each scheduler thread connects to Vertica and loads one microbatch at a time. If there are more microbatches than scheduler threads, the scheduler queues the extra microbatches and loads them as threads become available.
- **EXECUTIONPARALLELISM** determines the maximum number of threads each node creates to process a microbatch's partitions. When a microbatch is loaded into Vertica, its partitions are distributed evenly among the nodes in the cluster. During each frame, a node creates a maximum of one thread for each partition. Each thread reads from one partition at a time until processing completes, or the frame ends. If there are more partitions than threads across all nodes, remaining partitions are processed as threads become available.
- **QUEUETIMEOUT** provides manual control over resource timings. Set the resource pool parameter QUEUETIMEOUT to 0 to allow the scheduler to manage timings. After all of the microbatches are processed, the scheduler waits for the remainder of the frame to process the next microbatch. A properly sized configuration includes rest time to plan for traffic surges. See [Choosing a frame duration](#) for information about the impacts of frame duration size.

For example, the following CREATE RESOURCE POOL statement creates a resource pool named weblogs_pool that loads 2 microbatches simultaneously. Each node in the Vertica cluster creates 10 threads per microbatch to process partitions:

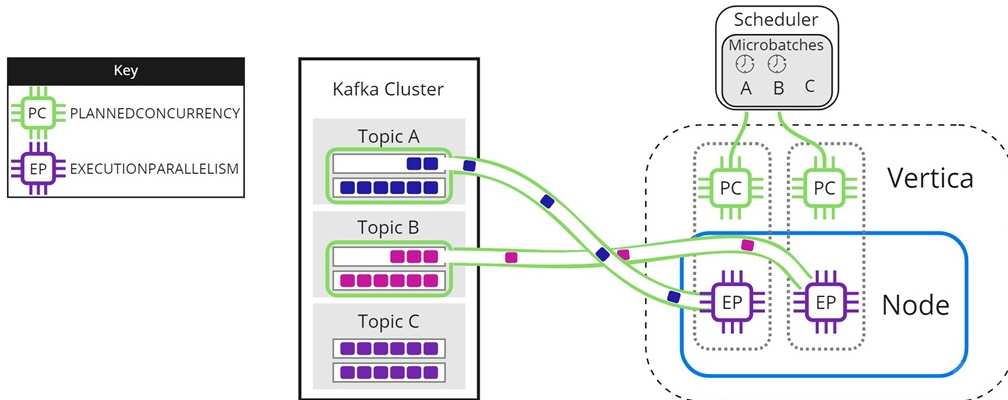

```
=> CREATE RESOURCE POOL weblogs_pool
    MEMORYSIZE '10%'
    PLANNEDCONCURRENCY 2
    EXECUTIONPARALLELISM 10
    QUEUETIMEOUT 0;
```

For a three-node Vertica cluster, weblogs_pool provides resources for each node to create up to 10 threads to process partitions, or 30 total threads per microbatch.

Loading multiple microbatches concurrently

In some circumstances, you might have more microbatches in your scheduler than available [PLANNEDCONCURRENCY](#). The following images illustrate how the scheduler loads microbatches into a single Vertica node when there are not enough scheduler threads to load each microbatch simultaneously. The resource pool's `PLANNEDCONCURRENCY` (PC) is set to 2, but the scheduler must load three microbatches: A, B, and C. For simplicity, `EXECUTIONPARALLELISM` (EP) is set to 1.

To begin, the scheduler loads microbatch A and microbatch B while microbatch C waits:

When either microbatch finishes loading, the scheduler loads any remaining microbatches. In the following image, microbatch A is completely loaded into Vertica. The scheduler continues to load microbatch B, and uses the newly available scheduler thread to load microbatch C:

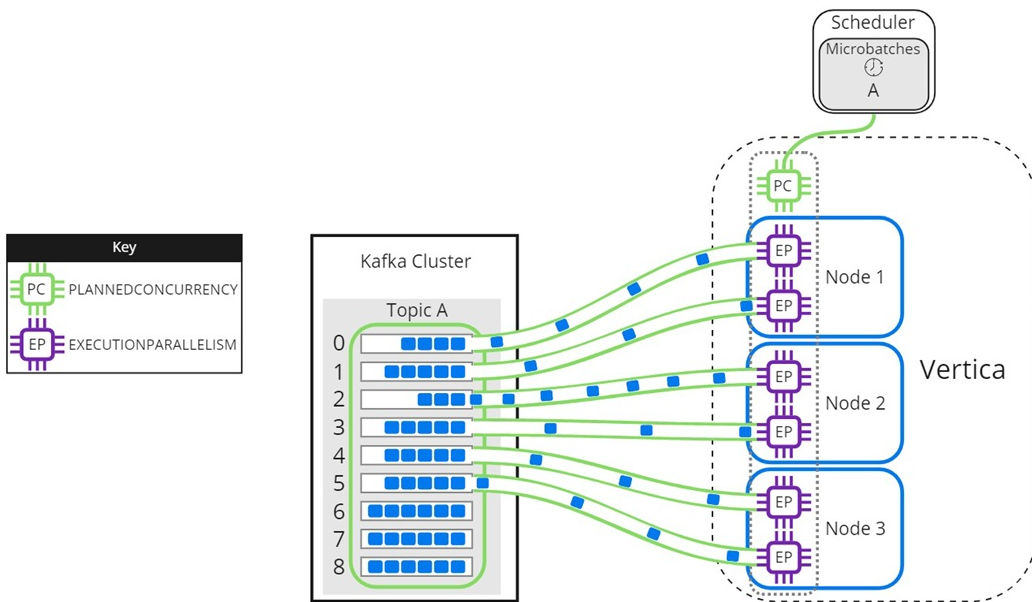

The scheduler continues sending data until all microbatches are loaded into Vertica, or the frame ends.

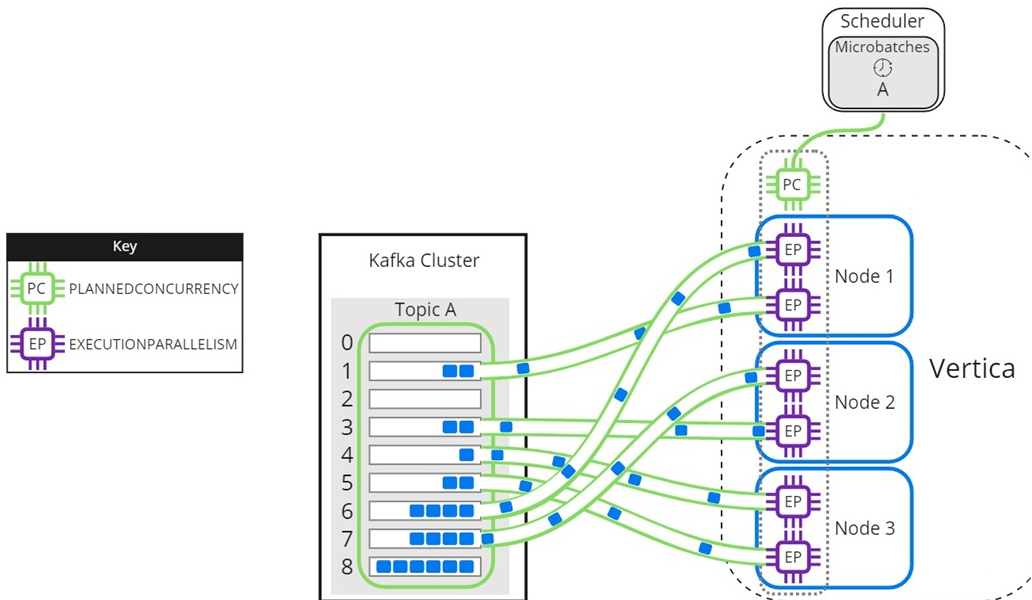

Experiment with `PLANNEDCONCURRENCY` to optimize performance. Note that setting it too high might create too many connections at the beginning of each frame, resulting in scalability stress on Vertica or Kafka. Setting `PLANNEDCONCURRENCY` too low does not take full advantage of the multiprocessing power of Vertica.

Parallel processing within Vertica

The resource pool setting [EXECUTIONPARALLELISM](#) limits the number of threads each Vertica node creates to process partitions. The following image illustrates how a three-node Vertica cluster processes a topic with nine partitions, when there is not enough `EXECUTIONPARALLELISM` to create one thread per partition. The partitions are distributed evenly among Node 1, Node 2, and Node 3 in the Vertica cluster. The scheduler's resource pool has `PLANNEDCONCURRENCY` (PC) set to 1 and `EXECUTIONPARALLELISM` (EP) set to 2, so each node creates a maximum of 2 threads when the scheduler loads microbatch A. Each thread reads from one partition at a time. Partitions that are not assigned a thread must wait for processing:

As threads finish processing their assigned partitions, the remaining partitions are distributed to threads as they become available:

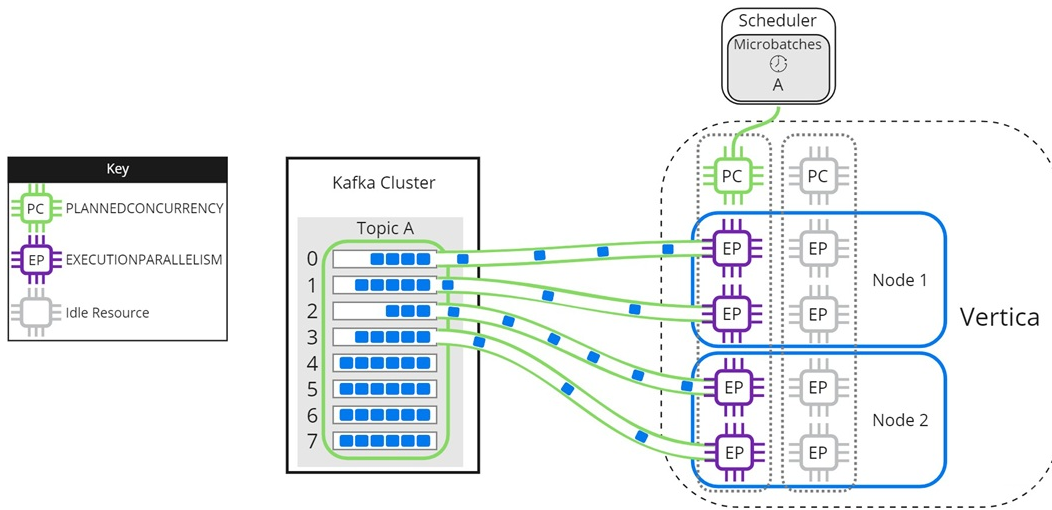

When setting the EXECUTIONPARALLELISM on your scheduler's resource pool, consider the number of partitions across all microbatches in the scheduler.

Loading partitioned topics concurrently

Single topics with multiple partitions might benefit from increased parallel loading or a reduced transaction size. The `--max-parallelism` [microbatch utility option](#) enables you to dynamically split a topic with multiple partitions into multiple, load-balanced microbatches that each consist of a subset of the original microbatch's partitions. The scheduler loads the dynamically split microbatches simultaneously using the [PLANNEDCONCURRENCY](#) available in its resource pool.

The [EXECUTIONPARALLELISM](#) setting in the scheduler's resource pool determines the maximum number of threads each node creates to process its portion of a single microbatch's partitions. Splitting a microbatch enables each node to create more threads for the same unit of work. When there is enough [PLANNEDCONCURRENCY](#) and the number of partitions assigned per node is greater than the [EXECUTIONPARALLELISM](#) setting in the scheduler's resource pool, use `--max-parallelism` to split the microbatch and create more threads per node to process more partitions in parallel.

The following image illustrates how a two-node Vertica cluster loads and processes microbatch A using a resource pool with [PLANNEDCONCURRENCY](#) (PC) set to 2, and [EXECUTIONPARALLELISM](#) (EP) set to 2. Because the scheduler is loading only one microbatch, there is 1 scheduler thread left unused. Each node creates 2 threads per scheduler thread to process its assigned partitions:

Setting microbatch A's `--max-parallelism` option to 2 enables the scheduler to dynamically split microbatch A into 2 smaller microbatches, A1 and A2. Because there are 2 available scheduler threads, the subset microbatches are loaded into Vertica simultaneously. Each node creates 2 threads per scheduler thread to process partitions for microbatches A1 and A2:

Use `--max-parallelism` to prevent bottlenecks in microbatches consisting of high-volume Kafka topics. It also provides faster loads for microbatches that require additional processing, such as text indexing.

Using connection load balancing with the Kafka scheduler

You supply the scheduler with the name of a Vertica node in the `--dbhost` option or the `dbhost` entry in your configuration file. The scheduler connects to this node to initiate all of the statements it executes to load data from Kafka. For example, each time it executes a microbatch, the scheduler connects to the same node to run the COPY statement. Having a single node act as the initiator node for all of the scheduler's actions can affect the performance of the node, and in turn the database as a whole.

To avoid a single node becoming a bottleneck, you can use connection load balancing to spread the load of running the scheduler's statements across multiple nodes in your database. Connection load balancing distributes client connections among the nodes in a load balancing group. See [About native connection load balancing](#) for an overview of this feature.

Enabling connection load balancing for a scheduler is a two-step process:

1. Choose or create a load balancing policy for your scheduler.
2. Enable load balancing in the scheduler.

Choosing or creating a load balancing policy for the scheduler

A connecting load balancing policy redirects incoming connections in from a specific set of network addresses to a group of nodes. If your database already defines a suitable load balancing policy, you can use it instead of creating one specifically for your scheduler.

If your database does not have a suitable policy, create one. Have your policy redirect connections coming from the IP addresses of hosts running Kafka schedulers to a group of nodes in your database. The group of nodes that you select will act as the initiators for the statements that the scheduler executes.

Important

In an [Eon Mode](#) database, only include nodes that are part of a [primary subcluster](#) in the scheduler's load balancing group. These nodes are the most efficient for loading data.

The following example demonstrates setting up a load balancing policy for all three nodes in a three-node database. The scheduler runs on node 1 in the database, so the source address range (192.168.110.0/24) of the routing rule covers the IP addresses of the nodes in the database. The last step of the example verifies that connections from the first node (IP address 10.20.110.21) are load balanced.

```
=> SELECT node_name,node_address,node_address_family FROM v_catalog.nodes;
node_name | node_address | node_address_family
```

```
-----+-----+-----
v_vmart_node0001 | 10.20.110.21 | ipv4
v_vmart_node0002 | 10.20.110.22 | ipv4
v_vmart_node0003 | 10.20.110.23 | ipv4
(4 rows)
```

```
=> CREATE NETWORK ADDRESS node01 ON v_vmart_node0001 WITH '10.20.110.21';
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS node02 ON v_vmart_node0002 WITH '10.20.110.22';
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS node03 on v_vmart_node0003 WITH '10.20.110.23';
CREATE NETWORK ADDRESS
```

```
=> CREATE LOAD BALANCE GROUP kafka_scheduler_group WITH ADDRESS node01,node02,node03;
CREATE LOAD BALANCE GROUP
=> CREATE ROUTING RULE kafka_scheduler_rule ROUTE
'10.20.110.0/24' TO kafka_scheduler_group;
CREATE ROUTING RULE
=> SELECT describe_load_balance_decision('10.20.110.21');
describe_load_balance_decision
```

```
-----
Describing load balance decision for address [10.20.110.21]
Load balance cache internal version id (node-local): [2]

input address matches this rule
Matched to load balance group [kafka_scheduler_group] the group has policy [ROUNDROBIN]
number of addresses [3]
(0) LB Address: [10.20.110.21]:5433
(1) LB Address: [10.20.110.22]:5433
(2) LB Address: [10.20.110.23]:5433
Chose address at position [1]
Routing table decision: Success. Load balance redirect to: [10.20.110.23] port [5433]
```

(1 row)

Important

Be careful if you run your scheduler on a Vertica node and have either set its dbhost name to localhost or are not specifying a value (which means dbhost defaults to localhost). Connections to localhost use the loopback IP address 127.0.0.1 instead of the node's primary network address. If you create a load balancing routing rule that redirects incoming connections from the node's IP address range, it will not apply to connections made using localhost. The best solution is to use the node's IP address or FQDN as the dbhost setting.

If your scheduler connects to Vertica from an IP address that no routing rule applies to, you will see messages similar to the following in the vertica.log:

```
[Session] <INFO> Load balance request from client address ::1 had decision:
Classic load balancing considered, but either the policy was NONE or no target was
available. Details: [NONE or invalid]
<LOG> @v_vmart_node0001: 00000/5789: Connection load balance request
refused by server
```

Enabling load balancing in the scheduler

Clients must opt-in to load balancing for Vertica to apply the connection load balancing policies to the connection. For example, you must pass the `-C` flag to the `vsq` command for your interactive session to be load balanced.

The scheduler uses the Java JDBC library to connect to Vertica. To have the scheduler opt-in to load balancing, you must set the JDBC library's `ConnectionLoadBalance` option to 1. See [Load balancing in JDBC](#) for details.

Use the `vkconfig` script's `--jdbc-opt` option, or add the `jdbc-opt` option to your configuration file to set the `ConnectionLoadBalance` option. For example, to start the scheduler from the command line using a configuration file named `weblog.conf`, use the command:

```
$ nohup vkconfig launch --conf weblog.conf --jdbc-opt ConnectionLoadBalance=1 >/dev/null 2>&1 &
```

To permanently enable load balancing, you can add the load balancing option to your configuration file. The following example shows the `weblog.conf` file from the example in [Setting up a scheduler](#) configured to use connection load balancing.

```
username=dbadmin
password=mypassword
dbhost=10.20.110.21
dbport=5433
config-schema=weblog_sched
jdbc-opt=ConnectionLoadBalance=1
```

You can check whether the scheduler's connections are being load balanced by querying the [SESSIONS](#) table:

```
=> SELECT node_name, user_name, client_label FROM V_MONITOR.SESSIONS;
 node_name | user_name | client_label
-----+-----+-----
v_vmart_node0001 | dbadmin | vkstream_weblog_sched_leader_persistent_4
v_vmart_node0001 | dbadmin |
v_vmart_node0002 | dbadmin | vkstream_weblog_sched_lane-worker-0_0_8
v_vmart_node0003 | dbadmin | vkstream_weblog_sched_VDBLogger_0_9
(4 rows)
```

In the `client_labels` column, the scheduler's connections have labels starting with `vkstream` (the row without a client label is an interactive session). You can see that the three connections the scheduler has opened all go to different nodes.

Limiting loads using offsets

Kafka maintains a user-configurable backlog of messages. By default, a newly-created scheduler reads all of the messages in a Kafka topic, including all of the messages in the backlog, not just the messages that are streamed out after the scheduler starts. Often, this is what you want.

In some cases, however, you may want to stream just a section of a source into a table. For example, suppose you want to analyze the web traffic of your e-commerce site starting at specific date and time. However, your Kafka topic contains web access records from much further back in time than you want to analyze. In this case, you can use an offset to stream just the data you want into Vertica for analysis.

Another common use case is when you have already loaded data some from Kafka manually (see [Manually consume data from Kafka](#)). Now you want to stream all of the newly-arriving data. By default, your scheduler will reload all of the previously loaded data (assuming it is still available from Kafka). You can use an offset to tell your scheduler to start automatically loading data at the point where your manual data load left off.

Configuring a scheduler to start streaming from an offset

The `vkconfig` script's `microbatch` tool has an `--offset` option that lets you specify the index of the message in the source where you want the scheduler to begin loading. This option accepts a comma-separated list of index values. You must supply one index value for each partition in the source unless you use the `--partition` option. This option lets you choose the partitions the offsets apply to. The scheduler cannot be running when you set an offset in the `microbatch`.

If your `microbatch` defines more than one cluster, use the `--cluster` option to select which one the offset option applies to. Similarly, if your `microbatch` has more than one source, you must select one using the `--source` option.

For example, suppose you want to load just the last 1000 messages from a source named `web_hits`. To make things easy, suppose the source contains just a single partition, and the `microbatch` defines just a single cluster and single topic.

Your first task is to determine the current offset of the end of the stream. You can do this on one of the Kafka nodes by calling the `GetOffsetShell` class with the `time` parameter set to `-1` (the end of the topic):

```
$ path to kafka/bin/kafka-run-class.sh kafka.tools.GetOffsetShell \  
    --broker-list kafka01:9092,kafka03:9092 --time -1 \  
    --topic web_hits  
  
{metadata.broker.list=kafka01:9092,kafka03:9092, request.timeout.ms=1000,  
client.id=GetOffsetShell, security.protocol=PLAINTEXT}  
web_hits:0:8932
```

You can also use `GetOffsetShell` to find the offset in the stream that occurs before a timestamp.

In the above example, the `web_hits` topic's single partition has an ending offset of 8932. If we want to load the last 1000 messages from the source, we need to set the microbatch's offset to `8932 - 1001` or `7931`.

Note

The start of an offset is inclusive in the Vertica `COPY` statement. Kafka's native starting offset is exclusive. Therefore, you must add one to the offset to get the correct number of messages.

With the offset calculated, you are ready to set it in the microbatch's configuration. The following example:

- Shuts down the scheduler whose configuration information stored in the `weblog.conf` file.
- Sets the starting offset using the microbatch utility.
- Restarts the scheduler.

```
$ vkconfig shutdown --conf weblog.conf  
$ vkconfig microbatch --microbatch weblog --update --conf weblog.conf --offset 7931  
$ nohup vkconfig launch --conf weblog.conf >/dev/null 2>&1 &
```

If the target table was empty or truncated before the scheduler started, it will have 1000 rows in the table in it (until more messages are streamed through the source):

```
=> select count(*) from web_hits;  
count  
-----  
1000  
(1 row)
```

Note

The last example assumes that the offset values for the last 1000 messages in the Kafka topic were assigned consecutively. This assumption is not always be true. A Kafka topic can have gaps in its offset numbering for a variety of reasons. Offsets refer to the key value assigned to a message by Kafka, not its position in the topic.

Updating schedulers after Vertica upgrades

A scheduler is only compatible with the version of Vertica that created it. Between Vertica versions, the scheduler's configuration schema or the UDX function the scheduler calls may change. After you upgrade Vertica, you must update your schedulers to account for these changes.

When you upgrade Vertica to a new major version or service pack, use the `vkconfig` scheduler tool's `--upgrade` option to update your scheduler. If you do not update a scheduler, you receive an error message if you try to launch it. For example:

```
$ nohup vkconfig launch --conf weblog.conf >/dev/null 2>&1 &
com.vertica.solutions.kafka.exception.FatalException: Configured scheduler schema and current
scheduler configuration schema version do not match. Upgrade configuration by running:
vkconfig scheduler --upgrade
  at com.vertica.solutions.kafka.scheduler.StreamCoordinator.assertVersion(StreamCoordinator.java:64)
  at com.vertica.solutions.kafka.scheduler.StreamCoordinator.run(StreamCoordinator.java:125)
  at com.vertica.solutions.kafka.Launcher.run(Launcher.java:205)
  at com.vertica.solutions.kafka.Launcher.main(Launcher.java:258)
Scheduler instance failed. Check log file. Check log file.
$ vkconfig scheduler --upgrade --conf weblog.conf
Checking if UPGRADE necessary...
UPGRADE required, running UPGRADE...
UPGRADE completed successfully, now the scheduler configuration schema version is v8.1.1
$ nohup vkconfig launch --conf weblog.conf >/dev/null 2>&1 &
. . .
```

Monitoring message consumption

You can monitor the progress of your data streaming from Kafka several ways:

- Monitoring the consumer groups to which Vertica reports its progress. This technique is best if the tools you want to use to monitor your data load work with Kafka.
- Use the monitoring APIs built into the vkconfig tool. These APIs report the configuration and consumption of your streaming scheduler in JSON format. These APIs are useful if you are developing your own monitoring scripts, or your monitoring tools can consume status information in JSON format.

In this section

- [Monitoring Vertica message consumption with consumer groups](#)
- [Getting configuration and statistics information from vkconfig](#)

Monitoring Vertica message consumption with consumer groups

Apache Kafka has a feature named consumer groups that helps distribute message consumption loads across sets of consumers. When using consumer groups, Kafka evenly divides up messages based on the number of consumers in the group. Consumers report back to the Kafka broker which messages it read successfully. This reporting helps Kafka to manage message offsets in the topic's partitions, so that no consumer in the group is sent the same message twice.

Vertica does not rely on Kafka's consumer groups to manage load distribution or preventing duplicate loads of messages. The streaming job scheduler manages topic partition offsets on its own.

Even though Vertica does not need consumer groups to manage offsets, it does report back to the Kafka brokers which messages it consumed. This feature lets you use third-party tools to monitor the Vertica cluster's progress as it loads messages. By default, Vertica reports its progress to a consumer group named `vertica- databaseName`, where `databaseName` is the name of the Vertica database. You can change the name of the consumer group that Vertica reports its progress to when defining a scheduler or during manual loads of data. Third party tools can query the Kafka brokers to monitor the Vertica cluster's progress when loading data.

For example, you can use Kafka's `kafka-consumer-groups.sh` script (located in the `bin` directory of your Kafka installation) to view the status of the Vertica consumer group. The following example demonstrates listing the consumer groups available defined in the Kafka cluster and showing the details of the Vertica consumer group:

```
$ cd /path/to/kafka/bin
$ ./kafka-consumer-groups.sh --list --bootstrap-server localhost:9092
Note: This will not show information about old Zookeeper-based consumers.
```

```
vertica-vmart
$ ./kafka-consumer-groups.sh --describe --group vertica-vmart \
  --bootstrap-server localhost:9092
Note: This will not show information about old Zookeeper-based consumers.
```

Consumer group 'vertica-vmart' has no active members.

TOPIC	PARTITION	CURRENT-OFFSET	LOG-END-OFFSET	LAG	CONSUMER-ID	HOST
CLIENT-ID						
web_hits	0	24500	30000	5500	-	-

From the output, you can see that Vertica reports its consumption of messages back to the vertica-vmart consumer group. This group is the default consumer group when Vertica has the example VMart database loaded. The second command lists the topics being consumed by the vertica-vmart consumer group. You can see that the Vertica cluster has read 24500 of the 30000 messages in the topic's only partition. Later, running the same command will show the Vertica cluster's progress:

```
$ cd /path/to/kafka/bin
$ ./kafka-consumer-groups.sh --describe --group vertica-vmart \
  --bootstrap-server localhost:9092
Note: This will not show information about old Zookeeper-based consumers.
```

Consumer group 'vertica-vmart' has no active members.

TOPIC	PARTITION	CURRENT-OFFSET	LOG-END-OFFSET	LAG	CONSUMER-ID	HOST
CLIENT-ID						
web_hits	0	30000	30000	0	-	-

Changing the consumer group where Vertica reports its progress

You can change the consumer group that Vertica reports its progress to when consuming messages.

Changing for automatic loads with the scheduler

When using a scheduler, you set the consumer group by setting the `--consumer-group-id` argument to the vkconfig script's [scheduler](#) or [microbatch](#) utilities. For example, suppose you want the example scheduler shown in [Setting up a scheduler](#) to report its consumption to the consumer group name vertica-database. Then you could use the command:

```
$ /opt/vertica/packages/kafka/bin/vkconfig microbatch --update \
  --conf weblog.conf --microbatch weblog --consumer-group-id vertica-database
```

When the scheduler begins loading data, it will start updating the new consumer group. You can see this on a Kafka node using `kafka-consumer-groups.sh`.

Use the `--list` option to return the consumer groups:

```
$ /path/to/kafka/bin/kafka-consumer-groups.sh --list --bootstrap-server localhost:9092
Note: This will not show information about old Zookeeper-based consumers.
```

```
vertica-database
vertica-vmart
```

Use the `--describe` and `--group` options to return details about a specific consumer group:

```
$ /path/to/kafka/bin/kafka-consumer-groups.sh --describe --group vertica-database \  
--bootstrap-server localhost:9092
```

Note: This will not show information about old Zookeeper-based consumers.

Consumer group 'vertica-database' has no active members.

TOPIC	PARTITION	CURRENT-OFFSET	LOG-END-OFFSET	LAG	CONSUMER-ID	HOST
CLIENT-ID						
web_hits	0	30300	30300	0	-	-

Changing for manual loads

To change the consumer group when manually loading data, use the `group_id` parameter of `KafkaSource` function:

```
=> COPY web_hits SOURCE KafkaSource(stream='web_hits|0|-2',  
    brokers='kafka01.example.com:9092',  
    stop_on_eof=True,  
    group_id='vertica_database')  
    PARSER KafkaJSONParser();
```

Rows Loaded

```
-----  
50000  
(1 row)
```

Using consumer group offsets when loading messages

You can choose to have your scheduler, manual load, or custom loading script start loading messages from the consumer group's offset. To load messages from the last offset stored in the consumer group, use the special `-3` offset.

Automatic load with the scheduler example

To instruct your scheduler to load messages from the consumer group's saved offset, use the `vkconfig` script [microbatch tool's --offset](#) argument.

1. Stop the scheduler using the shutdown command and the configuration file that you used to create the scheduler:

```
$ /opt/vertica/packages/kafka/bin/vkconfig microbatch shutdown --conf weblog.conf
```

2. Set the `microbatch --offset` option to `-3`:

```
$ /opt/vertica/packages/kafka/bin/vkconfig microbatch --update --conf weblog.conf --microbatch weblog --offset -3
```

This sets the offset to `-3` for all topic partitions that your scheduler reads from. The scheduler begins the next load with the consumer group's saved offset, and all subsequent loads use the offset saved in [stream_microbatch_history](#).

Manual load example

This example loads messages from the `web_hits` topic that has one partition consisting of 51,000 messages. For details about manual loads with `KafkaSource`, see [Manually consume data from Kafka](#).

1. The first `COPY` statement creates a consumer group named `vertica_manual`, and loads the first 50,000 messages from the first partition in the `web_hits` topic:

```
=> COPY web_hits  
SOURCE KafkaSource(stream='web_hits|0|50000',  
    brokers='kafka01.example.com:9092',  
    stop_on_eof=True,  
    group_id='vertica_manual')  
PARSER KafkaJSONParser()  
REJECTED DATA AS TABLE public.web_hits_rejections;
```

Rows Loaded

```
-----  
50000  
(1 row)
```

2. The next `COPY` statement passes `-3` as the `start_offset` stream parameter to load from the consumer group's saved offset:

```

=> COPY web_hits
SOURCE KafkaSource(stream='web_hits|0|-3',
                    brokers='kafka01.example.com:9092',
                    stop_on_eof=True,
                    group_id='vertica_manual')
PARSER KafkaJSONParser()
REJECTED DATA AS TABLE public.web_hits_rejections;
Rows Loaded
-----
      1000
(1 row)

```

Disabling consumer group reporting

Vertica reports the offsets of the messages it consumes to Kafka by default. If you do not specifically configure a consumer group for Vertica, it still reports its offsets to a consumer group named `vertica_<database-name>` (where `database-name` is the name of the database Vertica is currently running).

If you want to completely disable having Vertica report its consumption back to Kafka, you can set the consumer group to an empty string or NULL. For example:

```

=> COPY web_hits SOURCE KafkaSource(stream='web_hits|0|-2',
                                   brokers='kafka01.example.com:9092',
                                   stop_on_eof=True,
                                   group_id=NULL)
PARSER KafkaJsonParser();
Rows Loaded
-----
      60000
(1 row)

```

Getting configuration and statistics information from vkconfig

The `vkconfig` tool has two features that help you examine your scheduler's configuration and monitor your data load:

- The `vkconfig` tools that configure your scheduler (scheduler, cluster, source, target, load-spec, and microbatch) have a `--read` argument that has them output their current settings in the scheduler.
- The `vkconfig` statistics tool lets you get statistics on your microbatches. You can filter the microbatch records based on a date and time range, cluster, partition, and other criteria.

Both of these features output their data in JSON format. You can use third-party tools that can consume JSON data or write your own scripts to process the configuration and statics data.

You can also access the data provided by these `vkconfig` options by querying the configuration tables in the scheduler's schema. However, you may find these options easier to use as they do not require you to connect to the Vertica database.

Getting configuration information

You pass the `--read` option to `vkconfig`'s configuration tools to get the current settings for the options that the tool can set. This output is in JSON format. This example demonstrates getting the configuration information from the scheduler and cluster tools for the scheduler defined in the `weblog.conf` configuration file:

```

$ vkconfig scheduler --read --conf weblog.conf
{"version":"v9.2.0", "frame_duration":"00:00:10", "resource_pool":"weblog_pool",
 "config_refresh":"00:05:00", "new_source_policy":"FAIR",
 "pushback_policy":"LINEAR", "pushback_max_count":5, "auto_sync":true,
 "consumer_group_id":null}

$ vkconfig cluster --read --conf weblog.conf
{"cluster":"kafka_weblog", "hosts":"kafak01.example.com:9092,kafka02.example.com:9092"}

```

The `--read` option lists all of values created by the tool in the scheduler schema. For example, if you have defined multiple targets in your scheduler, the `--read` option lists all of them.

```
$ vkconfig target --list --conf weblog.conf
{"target_schema":"public", "target_table":"health_data"}
{"target_schema":"public", "target_table":"iot_data"}
{"target_schema":"public", "target_table":"web_hits"}
```

You can filter the `--read` option output using the other arguments that the vkconfig tools accept. For example, in the cluster tool, you can use the `--host` argument to limit the output to just show clusters that contain a specific host. These arguments support LIKE-predicate wildcards, so you can match partial values. See [LIKE](#) for more information about using wildcards.

The following example demonstrates how you can filter the output of the `--read` option of the cluster tool using the `--host` argument. The first call shows the unfiltered output. The second call filters the output to show only those clusters that start with "kafka":

```
$ vkconfig cluster --read --conf weblog.conf
{"cluster":"some_cluster", "hosts":"host01.example.com"}
{"cluster":"iot_cluster",
 "hosts":"kafka-iot01.example.com:9092,kafka-iot02.example.com:9092"}
{"cluster":"weblog",
 "hosts":"web01.example.com.com:9092,web02.example.com:9092"}
{"cluster":"streamcluster1",
 "hosts":"kafka-a-01.example.com:9092,kafka-a-02.example.com:9092"}
{"cluster":"test_cluster",
 "hosts":"test01.example.com:9092,test02.example.com:9092"}

$ vkconfig cluster --read --conf weblog.conf --hosts kafka%
{"cluster":"iot_cluster",
 "hosts":"kafka-iot01.example.com:9092,kafka-iot02.example.com:9092"}
{"cluster":"streamcluster1",
 "hosts":"kafka-a-01.example.com:9092,kafka-a-02.example.com:9092"}
```

See the [Cluster tool options](#), [Load spec tool options](#), [Microbatch tool options](#), [Scheduler tool options](#), [Target tool options](#), and [Source tool options](#) for more information.

Getting streaming data load statistics

The vkconfig script's statistics tool lets you view the history of your scheduler's microbatches. You can filter the results using any combination of the following criteria:

- The name of the microbatch
- The Kafka cluster that was the source of the data load
- The name of the topic
- The partition within the topic
- The Vertica schema and table targeted by the data load
- A date and time range
- The latest microbatches

See [Statistics tool options](#) for all of the options available in this tool.

This example gets the last two microbatches that the scheduler ran:

```
$ vkconfig statistics --last 2 --conf weblog.conf
{"microbatch":"weblog", "target_schema":"public", "target_table":"web_hits",
"source_name":"web_hits", "source_cluster":"kafka_weblog", "source_partition":0,
"start_offset":73300, "end_offset":73399, "end_reason":"END_OF_STREAM",
"end_reason_message":null, "partition_bytes":19588, "partition_messages":100,
"timeslice":"00:00:09.807000", "batch_start":"2018-11-02 13:22:07.825295",
"batch_end":"2018-11-02 13:22:08.135299", "source_duration":"00:00:00.219619",
"consecutive_error_count":null, "transaction_id":45035996273976123,
"frame_start":"2018-11-02 13:22:07.601", "frame_end":null}
{"microbatch":"weblog", "target_schema":"public", "target_table":"web_hits",
"source_name":"web_hits", "source_cluster":"kafka_weblog", "source_partition":0,
"start_offset":73200, "end_offset":73299, "end_reason":"END_OF_STREAM",
"end_reason_message":null, "partition_bytes":19781, "partition_messages":100,
"timeslice":"00:00:09.561000", "batch_start":"2018-11-02 13:21:58.044698",
"batch_end":"2018-11-02 13:21:58.335431", "source_duration":"00:00:00.214868",
"consecutive_error_count":null, "transaction_id":45035996273976095,
"frame_start":"2018-11-02 13:21:57.561", "frame_end":null}
```

This example gets the microbatches from the source named `web_hits` between 13:21:00 and 13:21:20 on November 2nd 2018:

```
$ vkconfig statistics --source "web_hits" --from-timestamp \
    "2018-11-02 13:21:00" --to-timestamp "2018-11-02 13:21:20" \
    --conf weblog.conf
{"microbatch":"weblog", "target_schema":"public", "target_table":"web_hits",
"source_name":"web_hits", "source_cluster":"kafka_weblog", "source_partition":0,
"start_offset":72800, "end_offset":72899, "end_reason":"END_OF_STREAM",
"end_reason_message":null, "partition_bytes":19989, "partition_messages":100,
"timeslice":"00:00:09.778000", "batch_start":"2018-11-02 13:21:17.581606",
"batch_end":"2018-11-02 13:21:18.850705", "source_duration":"00:00:01.215751",
"consecutive_error_count":null, "transaction_id":45035996273975997,
"frame_start":"2018-11-02 13:21:17.34", "frame_end":null}
{"microbatch":"weblog", "target_schema":"public", "target_table":"web_hits",
"source_name":"web_hits", "source_cluster":"kafka_weblog", "source_partition":0,
"start_offset":72700, "end_offset":72799, "end_reason":"END_OF_STREAM",
"end_reason_message":null, "partition_bytes":19640, "partition_messages":100,
"timeslice":"00:00:09.857000", "batch_start":"2018-11-02 13:21:07.470834",
"batch_end":"2018-11-02 13:21:08.737255", "source_duration":"00:00:01.218932",
"consecutive_error_count":null, "transaction_id":45035996273975978,
"frame_start":"2018-11-02 13:21:07.309", "frame_end":null}
```

See [Statistics tool options](#) for more examples of using this tool.

Parsing custom formats

To process a Kafka data stream, the parser must identify the boundary between each message. Vertica provides Kafka parsers that can identify boundaries for [Avro](#), [JSON](#), and [raw data](#) formats, but your data stream might use a custom format. To parse custom formats, Vertica provides filters that insert boundary information in the data stream before it reaches the parser.

Kafka filters

Vertica provides the following filters:

- `KafkaInsertDelimiters`: Inserts a user-specified delimiter between each message in the data stream. The delimiter can contain any characters and be of any length. This parser uses the following syntax:
`KafkaInsertDelimiters(delimiter = ' delimiter')`
- `KafkaInsertLengths`: Inserts the message length in bytes at the beginning of the message. Vertica writes the length as a 4-byte uint32 value in big-endian network byte order. For example, a 100-byte message is preceded by 0x00000064. This parser uses the following syntax:
`KafkaInsertLengths()`

Note

Because each Kafka filter requires input from a stream source and outputs a non-stream source, you cannot use both Kafka filters in the same COPY statement to process a Kafka data stream.

In addition to one of the Kafka filters, you can include one or more user-defined filters in a single COPY statement. Specify multiple filters as a comma-separated list, and list the Vertica filter first. If you use a non-Kafka parser, you must use at least one filter to prepare the data stream for the parser, or the parser fails and returns an error.

Examples

The following COPY statement loads comma-separated values from two partitions in a topic named `iot-data`. The load exits after it processes all messages in both partitions. The `KafkaInsertDelimiters` filter inserts newlines between the Kafka messages to convert them into traditional rows of data. The statement uses the standard COPY parser to delimit CSV values with a comma:

```
=> COPY kafka_iot SOURCE KafkaSource(stream='iot-data|0|-2,iot-data|1|-2',
    brokers='kafka01:9092',
    stop_on_eof=True)
    FILTER KafkaInsertDelimiters(delimiter = E'\n')
    DELIMITER ',';

Rows Loaded
-----
      3430
(1 row)
```

Avro Schema Registry

Vertica supports the use of a Confluent schema registry for Avro schemas with the [KafkaAvroParser](#). By using a schema registry, you enable the Avro parser to parse and decode messages written by the registry and to retrieve schemas stored in the registry. In addition, a schema registry enables Vertica to process streamed data without sending a copy of the schema with each record. Vertica can access a schema registry in the following ways:

- schema ID
- subject and version

Note

If you use the compatibility config resource in your schema registry, you should specify a value of at least BACKWARD. You may also choose to use a stricter compatibility setting. For more information on installing and configuring a schema registry, refer to the [Confluent documentation](#).

Schema ID Loading

In schema ID based loading, the Avro parser checks the schema ID associated with each message to identify the correct schema to use. A single COPY statement can reference multiple schemas. Because each message is not validated, Vertica recommends that you use a flex table as the target table for schema ID based loading.

The following example shows a COPY statement that refers to a schema registry located on the same host:

```
=> COPY logs source kafkasource(stream='simple|0|0', stop_on_eof=true,
duration=interval '10 seconds') parser
KafkaAvroParser(schema_registry_url='http://localhost:8081/');
```

Subject and Version Loading

In subject and version loading, you specify a subject and version in addition to the schema registry URL. The addition of the subject and version identifies a single schema to use for all messages in the COPY. If any message in the statement is incompatible with the schema, the COPY fails. Because all messages are validated prior to loading, Vertica recommends that you use a standard Vertica table as the target for subject and version loading.

The following example shows a COPY statement that identifies a schema subject and schema version as well as a schema registry.

```
=> COPY t source kafkasource(stream='simpleEvolution|0|0',
stop_on_eof=true, duration=interval '10 seconds') parser
KafkaAvroParser(schema_registry_url='http://repository:8081/schema-repo',
schema_registry_subject='simpleEvolution-value', schema_registry_version='1')
REJECTED DATA AS TABLE 't_rejects';
```

Producing data for Kafka

In addition to consuming data from Kafka, Vertica can produce data for Kafka. Stream the following data from Vertica for consumption by other Kafka consumers:

- Vertica analytics results. Use [KafkaExport](#) to export Vertica tables and queries.
- Health and performance data from [Data Collector](#) tables. Create push-based [notifiers](#) to send this data for consumption for third-party monitoring tools.
- Ad hoc messages. Use [NOTIFY](#) to signal that tasks such as stored procedures are complete.

In this section

- [Producing data using KafkaExport](#)
- [Producing Kafka messages using notifiers](#)

Producing data using KafkaExport

The `KafkaExport` function lets you stream data from Vertica to Kafka. You pass this function three arguments and two or three parameters:

```
SELECT KafkaExport(partitionColumn, keyColumn, valueColumn
  USING PARAMETERS brokers='host[:port][.host...]',
  topic='topicname'
  [,kafka_conf='kafka_configuration_setting']
  [,kafka_topic_conf='kafka_configuration_setting']
  [,kafka_conf_secret='kafka_configuration_setting']
  [,fail_on_conf_parse_error=Boolean])
OVER (partition_clause) FROM table;
```

The *partitionColumn* and *keyColumn* arguments set the Kafka topic's partition and key value, respectively. You can set either or both of these values to NULL. If you set the partition to NULL, Kafka uses its default partitioning scheme (either randomly assigning partitions if the key value is NULL, or based on the key value if it is not).

The *valueColumn* argument is a LONG VARCHAR containing message data that you want to send to Kafka. Kafka does not impose structure on the message content. Your only restriction on the message format is what the consumers of the data are able to parse.

You are free to convert your data into a string in any way you like. For simple messages (such as a comma-separated list), you can use functions such as [CONCAT](#) to assemble your values into a message. If you need a more complex data format, such as JSON, consider writing a UDX function that accepts columns of data and outputs a LONG VARCHAR containing the data in the format you require. See [Developing user-defined extensions \(UDxs\)](#) for more information.

See [KafkaExport](#) for detailed information about `KafkaExport`'s syntax.

Export example

This example shows you how to perform a simple export of several columns of a table. Suppose you have the following table containing a simple set of Internet of things (IOT) data:

```
=> SELECT * FROM iot_report LIMIT 10;
server | date | location | id
-----+-----+-----+-----

```

List of Fields by Tables

Schema	Table	Column	Type	Size	Default	Not Null	Primary Key	Foreign Key
public	iot_report	server	int	8		f	f	
public	iot_report	date	timestamp	8		f	f	
public	iot_report	location	varchar(40)	40		f	f	
public	iot_report	id	int	8		f	f	

(4 rows)

You want to send the data in this table to a Kafka topic named `iot_results` for consumption by other applications. Looking at the data and the structure of the `iot_report`, you may decide the following:

- The `server` column is a good match for the partitions in `iot_report`. There are three partitions in the Kafka topic, and the values in `server` column are between 1 and 3. Suppose the partition column had a larger range of values (for example, between 1 and 100). Then you could use the modulo operator (%) to coerce the values into the same range as the number of partitions (`server % 3`). A complication with these values is that the values in the `server` are 1-based (the lowest value in the column is 1). Kafka's partition numbering scheme is zero-based. So, you must adjust the values in the `server` column by subtracting 1 from them.
- The `id` column can act as the key. This column has a data type of `INTEGER`. The `KafkaExport` function expects the key value to be a `VARCHAR`. Vertica does not automatically cast `INTEGER` values to `VARCHAR`, so you must explicitly cast the value in your function call.
- The consumers of the `iot_report` topic expect values in comma-separated format. You can combine the values from the `date` and `location` columns into a single `VARCHAR` using nested calls to the `CONCAT` function.

The final piece of information you need to know is the host names and port numbers of the brokers in your Kafka cluster. In this example, there are two brokers named `kafka01` and `kafka03`, running on port 6667 (the port that Hortonworks clusters use). Once you have all of this information, you are ready to export your data.

The following example shows how you might export the contents of `iot_report`:

```
=> SELECT KafkaExport(server - 1, id::VARCHAR,
CONCAT(CONCAT(date, ', '), location)
USING PARAMETERS brokers='kafka01:6667,kafka03:6667',
topic='iot_results') OVER (PARTITION BEST) FROM iot_report;
partition | key | message | failure_reason
```

(0 rows)

`KafkaExport` returned 0 rows which means Vertica was able to send all of your data to Kafka without any errors.

Other things to note about the example:

- The `CONCAT` function automatically converts the `date` column's `DATETIME` value to a `VARCHAR` for you, so you do not need to explicitly cast it.
- Two nested `CONCAT` functions are necessary to concatenate the `date` field with a comma, and the resulting string with the `location` field.
- Adding a third column to the `message` field would require *two* additional `CONCAT` function calls (one to concatenate a comma after the `location` column, and one to concatenate the additional column's value). Using `CONCAT` becomes messy after just a few column's worth of data.

On the Kafka side, you will see whatever you sent as the `valueColumn` (third) argument of the `KafkaExport` function. In the above example, this is a CSV list. If you started a console consumer for `iot_results` topic before running the example query, you would see the following output when the query runs:

```
$ /opt/kafka/bin/kafka-console-consumer.sh --topic iot_results --zookeeper localhost
```

```

2017-01-20 03:05:24, 37.17372, 136.14026
2017-07-29 11:38:37, -38.99517, 171.72671
2018-04-19 13:06:58, 69.28989, 133.98275
2018-08-28 01:09:51, -59.71784, -144.97142
2018-09-14 23:16:15, 58.07275, 111.07354
```

KafkaExport's return value

KafkaExport outputs any rows that Kafka rejected. For example, suppose you forgot to adjust the partition column to be zero-based in the previous example. Then some of the rows exported to Kafka would specify a partition that does not exist. In this case, Kafka rejects these rows, and KafkaExport reports them in table format:

```
=> SELECT KafkaExport(server, id::VARCHAR,
  CONCAT(CONCAT(date, ' '), location)
  USING PARAMETERS brokers='kafka01:6667,kafka03:6667',
  topic='iot_results') OVER (PARTITION BEST) FROM iot_report;
partition | key | message | failure_reason
-----+-----+-----+-----
3 | 40492866 | 2017-10-10 12:08:33, 78.84883, -137.56584, | Local: Unknown partition
3 | 73846006 | 2017-12-06 16:50:57, -25.33024, -157.91389, | Local: Unknown partition
3 | 45020829 | 2018-01-12 21:27:39, 82.34027, 116.66703, | Local: Unknown partition
3 | 27462612 | 2018-08-19 00:02:18, 13.00436, 85.44815, | Local: Unknown partition
(4 rows)
```

Note

Another common reason for Kafka rejecting a row is that its message value is longer than Kafka's `message.max.bytes` setting.

You can capture this output by creating a table to hold the rejects. Then use an INSERT statement to insert KafkaExport's results:

```
=> CREATE TABLE export_rejects (partition INTEGER, key VARCHAR, message LONG VARCHAR, failure_reason VARCHAR);
CREATE TABLE
=> INSERT INTO export_rejects SELECT KafkaExport(server, id::VARCHAR,
  CONCAT(CONCAT(date, ' '), location)
  USING PARAMETERS brokers='kafka01:6667,kafka03:6667',
  topic='iot_results') OVER (PARTITION BEST) FROM iot_report;
OUTPUT
-----
4
(1 row)
=> SELECT * FROM export_rejects;
partition | key | message | failure_reason
-----+-----+-----+-----
3 | 27462612 | 2018-08-19 00:02:18, 13.00436, 85.44815 | Local: Unknown partition
3 | 40492866 | 2017-10-10 12:08:33, 78.84883, -137.56584 | Local: Unknown partition
3 | 73846006 | 2017-12-06 16:50:57, -25.33024, -157.91389 | Local: Unknown partition
3 | 45020829 | 2018-01-12 21:27:39, 82.34027, 116.66703 | Local: Unknown partition
(4 rows)
```

Producing Kafka messages using notifiers

You can use notifiers to help you monitor your Vertica database using third-party Kafka-aware tools by producing messages to a Kafka topic. You can directly publish messages (for example, from a SQL script to indicate a long-running query has finished). Notifiers can also automatically send messages when a component in the data collector tables is updated.

In this section

- [Creating a Kafka notifier](#)
- [Sending individual messages via a Kafka notifier](#)
- [Monitoring DC tables with Kafka notifiers](#)

Creating a Kafka notifier

The following procedure creates a Kafka notifier. At a minimum, a notifier defines:

- A unique name.
- A message protocol. This is `kafka://` when sending messages to Kafka.
- The server to communicate with. For Kafka, this is the address and port number of a Kafka broker.
- The maximum message buffer size. If the queue of messages to be sent via the notifier exceed this limit, messages are dropped.

You create the notifier with [CREATE NOTIFIER](#). This example creates a notifier named `load_progress_notifier` that sends messages via the Kafka broker running on `kafka01.example.com` on port 9092:

```
=> CREATE NOTIFIER load_progress_notifier
ACTION 'kafka://kafka01.example.com:9092'
MAXMEMORYSIZE '10M';
```

While not required, it is best practice to create notifiers that use an encrypted connection. The following example creates a notifier that uses an encrypted connection and verifies the Kafka server's certificate with the provided [TLS configurations](#):

```
=> CREATE NOTIFIER encrypted_notifier
ACTION 'kafka://127.0.0.1:9092'
MAXMEMORYSIZE '10M'
TLS CONFIGURATION 'notifier_tls_config'
```

Follow this procedure to create or alter notifiers for Kafka endpoints that use SASL_SSL. Note that you must repeat this procedure whenever you change the TLSMODE, certificates, or CA bundle for a given notifier.

1. [Create a TLS Configuration](#) with the desired TLS mode, certificate, and CA certificates.
2. Use CREATE or ALTER to disable the notifier and set the TLS Configuration:

```
=> ALTER NOTIFIER encrypted_notifier
DISABLE
TLS CONFIGURATION kafka_tls_config;
```

3. ALTER the notifier and set the proper rdkafka adapter parameters for SASL_SSL:

```
=> ALTER NOTIFIER encrypted_notifier PARAMETERS
'sasl.username=user;sasl.password=password;sasl.mechanism=PLAIN;security.protocol=SASL_SSL';
```

4. Enable the notifier:

```
=> ALTER NOTIFIER encrypted_notifier ENABLE;
```

Sending individual messages via a Kafka notifier

You can send an individual message via a Kafka notifier using the [NOTIFY](#) function. This feature is useful for reporting the progress of SQL scripts such as ETL tasks to third-party reporting tools.

You pass this function three string values:

- The message to send.
- The name of the notifier to send the message.
- The Kafka topic to receive the message.

For example, suppose you want to send the message "Daily load finished" to the `vertica_notifications` topic of the Kafka cluster defined in the `load_progress_notifier` notifier created earlier. Then you could execute the following statement:

```
=> SELECT NOTIFY('Daily load finished.',
                'load_progress_notifier',
                'vertica_notifications');
NOTIFY
-----
OK
(1 row)
```

The message the notifier sends to Kafka is in JSON format. You can see the resulting message by using the console consumer on a Kafka node. For example:

```
$ /opt/kafka/bin/kafka-console-consumer.sh --bootstrap-server localhost:9092 \
      --from-beginning \
      --topic vertica_notifications \
      --max-messages 1
```

```
{"_db":"vmart","_schema":"v_internal","_table":"dc_notifications",
"channel":"vertica_notifications","message":"Daily load finished.",
"node_name":"v_vmart_node0001","notifier":"load_progress_notifier",
"request_id":2,"session_id":"v_vmart_node0001-463079:0x4ba6f",
"statement_id":-1,"time":"2018-06-19 09:48:42.314181-04",
"transaction_id":45035996275565458,"user_id":45035996273704962,
"user_name":"dbadmin"}
```

Processed a total of 1 messages

Monitoring DC tables with Kafka notifiers

The Vertica [Data collector](#) (DC) tables monitor many different database functions. You can have a [notifier](#) automatically send a message to a Kafka endpoint when a DC component updates. You can query the [DATA_COLLECTOR](#) table to get a list of the DC components.

You configure the notifier to send DC component updates to Kafka using the function [SET_DATA_COLLECTOR_NOTIFY_POLICY](#).

To be notified of failed login attempts, you can create a notifier that sends a notification when the DC component [LoginFailures](#) updates. The [TLSMODE](#) 'verify-ca' verifies that the server's certificate is signed by a trusted CA.

```
=> CREATE NOTIFIER vertica_stats ACTION 'kafka://kafka01.example.com:9092' MAXMEMORYSIZE '10M' TLSMODE 'verify-ca';
CREATE NOTIFIER
=> SELECT SET_DATA_COLLECTOR_NOTIFY_POLICY('LoginFailures','vertica_stats', 'vertica_notifications', true);
SET_DATA_COLLECTOR_NOTIFY_POLICY
-----
SET
(1 row)
```

Like the messages sent via the NOTIFY function, the data sent to Kafka from the DC components is in JSON format. The previous example results in messages like the following being sent to the vertica_notifications Kafka topic:

```
{"_db":"vmart","_schema":"v_internal","_table":"dc_login_failures",
"authentication_method":"Reject","client_authentication_name":"","
"client_hostname":"","client_label":"","client_os_user_name":"dbadmin",
"client_pid":481535,"client_version":"","database_name":"alice",
"effective_protocol":"3.8","node_name":"v_vmart_node0001",
"reason":"INVALID USER","requested_protocol":"3.8","ssl_client_fingerprint":"","
"time":"2018-06-19 14:51:22.437035-04","user_name":"alice"}
```

Viewing notification policies for a DC component

Use the [GET_DATA_COLLECTOR_NOTIFY_POLICY](#) function to list the policies set for a DC component.

```
=> SELECT GET_DATA_COLLECTOR_NOTIFY_POLICY('LoginFailures');
GET_DATA_COLLECTOR_NOTIFY_POLICY
-----
Notifiable; Notifier: vertica_stats; Channel: vertica_notifications
(1 row)
```

Disabling a notification policy

You can call [SET_DATA_COLLECTOR_NOTIFY_POLICY](#) function with its fourth argument set to FALSE to disable a notification policy. The following example disables the notify policy for the LoginFailures component:

```
=> SELECT SET_DATA_COLLECTOR_NOTIFY_POLICY('LoginFailures','vertica_stats', 'vertica_notifications', false);  
SET_DATA_COLLECTOR_NOTIFY_POLICY
```

```
-----  
SET  
(1 row)
```

```
=> SELECT GET_DATA_COLLECTOR_NOTIFY_POLICY('LoginFailures');  
GET_DATA_COLLECTOR_NOTIFY_POLICY
```

```
-----  
Not notifiable;  
(1 row)
```

TLS/SSL encryption with Kafka

You can use TLS/SSL encryption between Vertica, your scheduler, and Kafka. This encryption prevents others from accessing the data that is sent between Kafka and Vertica. It can also verify the identity of all parties involved in data streaming, so no impostor can pose as your Vertica cluster or a Kafka broker.

Note

Many people often confuse the terms TLS and SSL. SSL is an older encryption protocol that has been largely replaced with the newer and more secure TLS standard. However, many people still use the term SSL to refer to encryption between servers and applications, even when that encryption is actually TLS. For example, Java and Kafka use the term SSL exclusively, even when dealing with TLS. This document uses SSL/TLS and SSL interchangeably.

Some common cases where you want to use SSL encryption between Vertica and Kafka are:

- Your Vertica database and Kafka communicate over an insecure network. For example, suppose your Kafka cluster is located in a cloud service and your Vertica cluster is within your internal network. In this case, any data you read from Kafka travels over an insecure connection across the Internet.
- You are required by security policies, laws, or other requirements to encrypt all of your network traffic.

For more information about TLS/SSL encryption in Vertica, see [TLS protocol](#).

Using TLS/SSL between the scheduler and Vertica

The scheduler connects to Vertica the same way other client applications do. There are two ways you can configure Vertica to use SSL/TLS authentication and encryption with clients:

- If Vertica is configured to use SSL/TLS server authentication, you can choose to have your scheduler confirm the identity of the Vertica server.
- If Vertica is configured to use mutual SSL/TLS authentication, you can configure your scheduler to identify itself to Vertica as well as have it verify the identity of the Vertica server. Depending on your database's configuration, the Vertica server may require your scheduler to use TLS when connecting. See [Client authentication with TLS](#) for more information.

For information on encrypted client connections with Vertica, refer to [TLS protocol](#).

The scheduler runs on a Java Virtual Machine (JVM) and uses JDBC to connect to Vertica. It acts like any other JDBC client when connecting to Vertica. To use TLS/SSL encryption for the scheduler's connection to Vertica, use the Java keystore and truststore mechanism to hold the keys and certificates the scheduler uses to identify itself and Vertica.

- The keystore contains your scheduler's private encryption key and its certificate (public key).
- The truststore contains CAs that you trust. If you enable authentication, the scheduler uses these CAs to verify the identity of the Vertica cluster it connects to. If one of the CAs in the trust store was used to sign the server's certificate, then the Scheduler knows it can trust the identity of the Vertica server.

You can pass options to the JVM that executes the scheduler through the Linux environment variable named VKCONFIG_JVM_OPTS. You add the parameters to this variable that alter the scheduler's JDBC settings (such as the truststore and keystore for the scheduler's JDBC connection). See [Step 2: Set the VKCONFIG_JVM_OPTS Environment Variable](#) for an example.

You can also use the `--jdbc-url` scheduler option to alter the JDBC configuration. See [Common vkconfig script options](#) for more information about the scheduler options and [JDBC connection properties](#) for more information about the properties they can alter.

Using TLS/SSL between Vertica and Kafka

You can stream data from Kafka into Vertica two ways: manually using a [COPY](#) statement and the [KafkaSource](#) UD source function, or automatically using the scheduler.

To directly copy data from Kafka via an SSL connection, you set session variables containing an SSL key and certificate. When KafkaSource finds that you have set these variables, it uses the key and certificate to create a secure connection to Kafka. See [Kafka TLS/SSL Example Part 4: Loading Data Directly From Kafka](#) for details.

When automatically streaming data from Kafka to Vertica, you configure the scheduler the same way you do to use an SSL connection to Vertica. When the scheduler executes COPY statements to load data from Kafka, it uses its own keystore and truststore to create an SSL connection to Kafka.

To use an SSL connection when producing data from Vertica to Kafka, you set the same session variables you use when directly streaming data from Kafka via an SSL connection. The [KafkaExport](#) function uses these variables to establish a secure connection to Kafka.

Note

[Notifiers](#) do not currently support using TLS/SSL connections.

See the [Apache Kafka documentation](#) for more information about [using SSL/TLS authentication with Kafka](#).

In this section

- [Planning TLS/SSL encryption between Vertica and Kafka](#)
- [Configuring your scheduler for TLS connections](#)
- [Using TLS/SSL when directly loading data from Kafka](#)
- [Configure Kafka for TLS/SSL](#)
- [Troubleshooting Kafka TLS/SSL connection issues](#)

Planning TLS/SSL encryption between Vertica and Kafka

Some things to consider before you begin configuring TLS/SSL:

- Which connections between the scheduler, Vertica, and Kafka needs to be encrypted? In some cases, you may only need to enable encryption between Vertica and Kafka. This scenario is common when Vertica and the Kafka cluster are on different networks. For example, suppose Kafka is hosted in a cloud provider and Vertica is hosted in your internal network. Then the data must travel across the unsecured Internet between the two. However, if Vertica and the scheduler are both in your local network, you may decide that configuring them to use SSL/TLS is unnecessary. In other cases, you will want all parts of the system to be encrypted. For example, you want to encrypt all traffic when Kafka, Vertica, and the scheduler are all hosted in a cloud provider whose network may not be secure.
- Which connections between the scheduler, Vertica, and Kafka require trust? You can opt to have any of these connections fail if one system cannot verify the identity of another. See [Verifying Identities](#) below.
- Which CAs will you be using to sign each certificate? The simplest way to configure the scheduler, Kafka, and Vertica is to use the same CA to sign all of the certificates you will use when setting up TLS/SSL. Using the same root CA to sign the certificates requires you to be able to edit the configuration of Kafka, Vertica, and the scheduler. If you cannot use the same CA to sign all certificates, all truststores must contain the entire chain of CAs used to sign the certificates, all the way up to the root CA. Including the entire chain of trust ensures each system can verify each other's identities.

Verifying identities

Your primary challenge when configuring TLS/SSL encryption between Vertica, the scheduler, and Kafka is making sure the scheduler, Kafka, and Vertica can all verify each other's identity. The most common problem people have encountered when setting up TLS/SSL encryption is ensuring the remote system can verify the authenticity of a system's certificate. The best way to prevent this problem is to ensure that the all systems have their certificates signed by a CA that all of the systems explicitly trust.

When a system attempts to start an encrypted connection with another system, it sends its certificate to the remote system. This certificate can be signed by one or more Certificate Authorities (CA) that help identify the system making the connection. These signatures form a "chain of trust." A certificate is signed by a CA. That CA, in turn, could have been signed by another CA, and so forth. Often, the chain ends with a CA (referred to as the root CA) from a well-known commercial provider of certificates, such as Comodo SSL or DigiCert, that are trusted by default on many platforms such as operating systems and web browsers.

If the remote system finds a CA in the chain that it trusts, it verifies the identity of the system making the connection, and the connection can continue. If the remote system cannot find the signature of a CA it trusts, it may block the connection, depending on its configuration. Systems can be configured to only allow connections from systems whose identity has been verified.

Note

Verifying the identity of another system making a TLS/SSL connection is often referred to as "authentication." Do not confuse this use of authentication with other forms of authentication used with Vertica. For example, TLS/SSL's authentication of a client connection has nothing to do with Vertica user authentication. Even if you successfully establish a TLS/SSL connection to Vertica using a client, Vertica still requires you to provide a user name and password before you can interact with it.

Configuring your scheduler for TLS connections

The scheduler can use TLS for two different connections: the one it makes to Vertica, and the connection it creates when running COPY statements to retrieve data from Kafka. Because the scheduler is a Java application, you supply the TLS key and the certificate used to sign it in a keystore. You also supply a truststore that contains in the certificates that the scheduler should trust. Both the connection to Vertica and to Kafka can use the same keystore and truststore. You can also choose to use separate keystores and truststores for these two connections by setting different JDBC settings for the scheduler. See [JDBC connection properties](#) for a list of these settings.

See [Kafka TLS-SSL Example Part 5: Configure the Scheduler](#) for detailed steps on configuring your scheduler to use SSL.

Important

If you choose to use a file format other than the standard Java Keystore (JKS) format for your keystore or truststore files, you must use the correct file extension in the filename. For example, suppose you choose to use a keystore and truststore saved in PKCS#12 format. Then your keystore and truststore files must end with the `.pfx` or `.p12` extension.

If the scheduler does not recognize the file's extension (or there is no extension in the file name), it assumes that the file is in JKS format. If the file is not in JKS format, you will see an error message when starting the scheduler, similar to "Failed to create an SSLSocketFactory when setting up TLS: keystore not found."

Note that if the Kafka server's parameter `client.ssl.auth` is set to `none` or `requested`, you do not need to create a keystore.

Using TLS/SSL when directly loading data from Kafka

You can manually load data from Kafka using the `COPY` statement and the `KafkaSource` user-defined load function (see [Manually consume data from Kafka](#)). To have `KafkaSource` open a secure connection to Kafka, you must supply it with an SSL key and other information.

When starting, the `KafkaSource` function checks if several user session variables are defined. These variables contain the SSL key, the certificate used to sign the key, and other information that the function needs to create the SSL connection. See [Kafka user-defined session parameters](#) for a list of these variables. If `KafkaSource` finds these variables are defined, it uses them to create an SSL connection to Kafka.

See [Kafka TLS/SSL Example Part 4: Loading Data Directly From Kafka](#) for a step-by-step guide on configuring and using an SSL connection when directly copying data from Kafka.

These variables are also used by the `KafkaExport` function to establish a secure connection to Kafka when exporting data.

Configure Kafka for TLS/SSL

This page covers procedures for configuring TLS connections Vertica, Kafka, and the scheduler.

Note that the following example configures TLS for a Kafka server where `ssl.client.auth=required`, which requires the following:

- `kafka_SSL_Certificate`
- `kafka_SSL_PrivateKey_secret`
- `kafka_SSL_PrivateKeyPassword_secret`
- A keystore for the Scheduler

If your configuration uses `ssl.client.auth=none` or `ssl.client.auth=requested`, these parameters and the scheduler keystore are optional.

Creating certificates for Vertica and clients

The CA certificate in this example is self-signed. In a production environment, you should instead use a trusted CA.

This example uses the same self-signed root CA to sign all of the certificates used by the scheduler, Kafka brokers, and Vertica. If you cannot use the same CA to sign the keys for all of these systems, make sure you include the entire chain of trust in your keystores.

For more information, see [Generating TLS certificates and keys](#).

1. Generate a private key, `root.key` .

```
$ openssl genrsa -out root.key
Generating RSA private key, 2048 bit long modulus
.....
.....+++
.....+++
e is 65537 (0x10001)
```

2. Generate a self-signed CA certificate.

```
$ openssl req -new -x509 -key root.key -out root.crt
You are about to be asked to enter information that will be incorporated
into your certificate request.
What you are about to enter is what is called a Distinguished Name or a DN.
There are quite a few fields but you can leave some blank
For some fields there will be a default value,
If you enter '.', the field will be left blank.

Email Address []:myemail@mycompany.com
```

3. Restrict to the owner read/write permissions for `root.key` and `root.crt` . Grant read permissions to other groups for `root.crt` .

```
$ ls
root.crt root.key
$ chmod 600 root.key
$ chmod 644 root.crt
```

4. Generate the server private key, `server.key` .

```
$ openssl genrsa -out server.key
Generating RSA private key, 2048 bit long modulus
.....+++
.....+++
e is 65537 (0x10001)
```

5. Create a certificate signing request (CSR) for your CA. Be sure to set the "Common Name" field to a wildcard (asterisk) so the certificate is accepted for all Vertica nodes in the cluster:

```
$ openssl req -new -key server.key -out server_reqout.txt
You are about to be asked to enter information that will be incorporated
into your certificate request.
What you are about to enter is what is called a Distinguished Name or a DN.
There are quite a few fields but you can leave some blank
For some fields there will be a default value,
If you enter '.', the field will be left blank.
-----
Country Name (2 letter code) [AU]:US
State or Province Name (full name) [Some-State]:MA
Locality Name (eg, city) []:Cambridge
Organization Name (eg, company) [Internet Widgits Pty Ltd]:My Company
Organizational Unit Name (eg, section) []:
Common Name (e.g. server FQDN or YOUR name) []:*.mycompany.com
Email Address []:myemail@mycompany.com

Please enter the following 'extra' attributes
to be sent with your certificate request
A challenge password []: server_key_password
An optional company name []:
```

6. Sign the server certificate with your CA. This creates the server certificate `server.crt`.

```
$ openssl x509 -req -in server_reqout.txt -days 3650 -sha1 -CAcreateserial -CA root.crt \
-CAkey root.key -out server.crt
Signature ok
subject=/C=US/ST=MA/L=Cambridge/O=My Company/CN=*.mycompany.com/emailAddress=myemail@mycompany.com
Getting CA Private Key
```

7. Set the appropriate permissions for the key and certificate.

```
$ chmod 600 server.key
$ chmod 644 server.crt
```

Create a client key and certificate (mutual mode only)

In **Mutual Mode**, clients and servers verify each other's certificates before establishing a connection. The following procedure creates a client key and certificate to present to Vertica. The certificate must be signed by a CA that Vertica trusts.

The steps for this are identical to those above for creating a server key and certificate for Vertica.

```
$ openssl genrsa -out client.key
Generating RSA private key, 2048 bit long modulus
.....+++
.....+++
e is 65537 (0x10001)

$ openssl req -new -key client.key -out client_reqout.txt
You are about to be asked to enter information that will be incorporated
into your certificate request.
What you are about to enter is what is called a Distinguished Name or a DN.
There are quite a few fields but you can leave some blank
For some fields there will be a default value,
If you enter '.', the field will be left blank.
-----
Country Name (2 letter code) [AU]:US
State or Province Name (full name) [Some-State]:MA
Locality Name (eg, city) []:Cambridge
Organization Name (eg, company) [Internet Widgits Pty Ltd]:My Company
Organizational Unit Name (eg, section) []:
Common Name (e.g. server FQDN or YOUR name) []:*.mycompany.com
Email Address []:myemail@mycompany.com

Please enter the following 'extra' attributes
to be sent with your certificate request
A challenge password []: server_key_password
An optional company name []:

$ openssl x509 -req -in client_reqout.txt -days 3650 -sha1 -CAcreateserial -CA root.crt \
-CAkey root.key -out client.crt
Signature ok
subject=/C=US/ST=MA/L=Cambridge/O=My Company/CN=*.mycompany.com/emailAddress=myemail@mycompany.com
Getting CA Private Key

$ chmod 600 client.key
$ chmod 644 client.crt
```

Set up mutual mode client-server TLS

Configure Vertica for mutual mode

The following keys and certificates must be imported and then distributed to the nodes on your Vertica cluster with TLS Configuration for **Mutual Mode**:

- `root.key`
- `root.crt`
- `server.key`
- `server.crt`

You can view existing keys and certificates by querying [CRYPTOGRAPHIC_KEYS](#) and [CERTIFICATES](#).

1. Import the server and root keys and certificates into Vertica with [CREATE KEY](#) and [CREATE CERTIFICATE](#). See [Generating TLS certificates and keys](#) for details.

```
=> CREATE KEY imported_key TYPE 'RSA' AS '-----BEGIN PRIVATE KEY-----.....END PRIVATE KEY-----';
=> CREATE CA CERTIFICATE imported_ca AS '-----BEGIN CERTIFICATE-----.....END CERTIFICATE-----';
=> CREATE CERTIFICATE imported_cert AS '-----BEGIN CERTIFICATE-----.....END CERTIFICATE-----';
```

In this example, `\set` is used to retrieve the contents of `root.key`, `root.crt`, `server.key`, and `server.crt`.

```
=> \set ca_cert ""`cat root.crt`""
=> \set serv_key ""`cat server.key`""
=> \set serv_cert ""`cat server.crt`""

=> CREATE CA CERTIFICATE root_ca AS :ca_cert;
CREATE CERTIFICATE
=> CREATE KEY server_key TYPE 'RSA' AS :serv_key;
CREATE KEY
=> CREATE CERTIFICATE server_cert AS :serv_cert;
CREATE CERTIFICATE
```

2. Follow the steps for **Mutual Mode** in [Configuring client-server TLS](#) to set the proper TLSMODE and TLS Configuration parameters.

Configure a client for mutual mode

Clients must have their private key, certificate, and CA certificate. The certificate will be presented to Vertica when establishing a connection, and the CA certificate will be used to verify the server certificate from Vertica.

This example configures the `vsq` client for mutual mode.

1. Create a `.vsq` directory in the user's home directory.

```
$ mkdir ~/.vsq
```

2. Copy `client.key`, `client.crt`, and `root.crt` to the `vsq` directory.

```
$ cp client.key client.crt root.crt ~/.vsq
```

3. Log into Vertica with `vsq` and query the `SESSIONS` system table to verify that the connection is using mutual mode:

```
$ vsq
Password: user-password
Welcome to vsq, the Vertica Analytic Database interactive terminal.

Type: \h or \? for help with vsq commands
      \g or terminate with semicolon to execute query
      \q to quit

SSL connection (cipher: DHE-RSA-AES256-GCM-SHA384, bits: 256, protocol: TLSv1.2)

=> select user_name,ssl_state from sessions;
 user_name | ssl_state
-----+-----
 dbadmin  | Mutual
(1 row)
```

Configure Kafka for TLS

Configure the Kafka brokers

This procedure configures Kafka to use TLS with client connections. You can also configure Kafka to use TLS to communicate between brokers. However, inter-broker TLS has no impact on establishing an encrypted connection between Vertica and Kafka.

1. Create a truststore file for all of your Kafka brokers, importing your CA certificate. This example uses the self-signed `root.crt` created above.

```

=> $ keytool -keystore kafka.truststore.jks -alias CARoot -import \
      -file root.crt
Enter keystore password: some_password
Re-enter new password: some_password
Owner: EMAILADDRESS=myemail@mycompany.com, CN=*.mycompany.com, O=MyCompany, L=Cambridge, ST=MA, C=US
Issuer: EMAILADDRESS=myemail@mycompany.com, CN=*.mycompany.com, O=MyCompany, L=Cambridge, ST=MA, C=US
Serial number: c3f02e87707d01aa
Valid from: Fri Mar 22 13:37:37 EDT 2019 until: Sun Apr 21 13:37:37 EDT 2019
Certificate fingerprints:
    MD5: 73:B1:87:87:7B:FE:F1:6E:94:55:FD:AF:5D:D0:C3:0C

Trust this certificate? [no]: yes
Certificate was added to keystore

```

2. Create a keystore file for the Kafka broker named `kafka01` . Each broker's keystore should be unique. The `keytool` command adds the a Subject Alternative Name (SAN) used as a fallback when establishing a TLS connection. Use your Kafka' broker's fully-qualified domain name (FQDN) as the value for the SAN and "What is your first and last name?" prompt. In this example, the FQDN is `kafka01.example.com` . The alias for `keytool` is set to `localhost` , so local connections to the broker use TLS.

```
$ keytool -keystore kafka01.keystore.jks -alias localhost -validity 365 -genkey -keyalg RSA \
-ext SAN=DNS:kafka01.mycompany.com
Enter keystore password: some_password
Re-enter new password: some_password
What is your first and last name?
[Unknown]: kafka01.mycompany.com
What is the name of your organizational unit?
[Unknown]:
What is the name of your organization?
[Unknown]: MyCompany
What is the name of your City or Locality?
[Unknown]: Cambridge
What is the name of your State or Province?
[Unknown]: MA
What is the two-letter country code for this unit?
[Unknown]: US
Is CN=Database Admin, OU=MyCompany, O=Unknown, L=Cambridge, ST=MA, C=US correct?
[no]: yes

Enter key password for <localhost>
(RETURN if same as keystore password):
```

3. Export the Kafka broker's certificate. In this example, the certificate is exported as **kafka01.unsigned.crt** .

```
$ keytool -keystore kafka01.keystore.jks -alias localhost \
-certreq -file kafka01.unsigned.crt
Enter keystore password: some_password
```

4. Sign the broker's certificate with the CA certificate.

```
$ openssl x509 -req -CA root.crt -CAkey root.key -in kafka01.unsigned.crt \
-out kafka01.signed.crt -days 365 -CAcreateserial
Signature ok
subject=/C=US/ST=MA/L=Cambridge/O=Unknown/OU=MyCompany/CN=Database Admin
Getting CA Private Key
```

5. Import the CA certificate into the broker's keystore.

Note

If you use different CAs to sign the certificates in your environment, you must add the entire chain of CAs you used to sign your certificate to the keystore, all the way up to the root CA. Including the entire chain of trust helps other systems verify the identity of your Kafka broker.

```
$ keytool -keystore kafka01.keystore.jks -alias CARoot -import -file root.crt
```

```
Enter keystore password: some_password
```

```
Owner: EMAILADDRESS=myemail@mycompany.com, CN=*.mycompany.com, O=MyCompany, L=Cambridge, ST=MA, C=US

Certificate was added to keystore
```

- If you are not logged into the Kafka broker for which you prepared the keystore, copy the truststore and keystore to it using `scp`. If you have already decided where to store the keystore and truststore files in the broker's filesystem, you can directly copy them to their final destination. This example just copies them to the root user's home directory temporarily. The next step moves them into their final location.

```
$ scp kafka.truststore.jks kafka01.keystore.jks root@kafka01.mycompany.com:
```

```
root@kafka01.mycompany.com's password: root_password
kafka.truststore.jks      100% 1048  1.0KB/s  00:00
kafka01.keystore.jks     100% 3277  3.2KB/s  00:00
```

- Repeat steps 2 through 7 for the remaining Kafka brokers.

Allow Kafka to read the keystore and truststore

If you did not copy the truststore and keystore to directory where Kafka can read them in the previous step, you must copy them to a final location on the broker. You must also allow the user account you use to run Kafka to read these files. The easiest way to ensure the user's access is to give this user ownership of these files.

In this example, Kafka is run by a Linux user `kafka`. If you use another user to run Kafka, be sure to set the permissions on the truststore and keystore files appropriately.

- Log into the Kafka broker as root.
- Copy the truststore and keystore to a directory where Kafka can access them. There is no set location for these files: you can choose a directory under `/etc`, or some other location where configuration files are usually stored. This example copies them from root's home directory to Kafka's configuration directory named `/opt/kafka/config/`. In your own system, this configuration directory may be in a different location depending on how you installed Kafka.
- Copy the truststore and keystore to a directory where Kafka can access them. There is no set location for these files: you can choose a directory under `/etc`, or some other location where configuration files are usually stored. This example copies them from root's home directory to Kafka's configuration directory named `/opt/kafka/config/`. In your own system, this configuration directory may be in a different location depending on how you installed Kafka.

```
~# cd /opt/kafka/config/
/opt/kafka/config# cp /root/kafka01.keystore.jks /root/kafka.truststore.jks .
```

- If you aren't logged in as a user account that runs Kafka, change the ownership of the truststore and keystore files. This example changes the ownership from root (which is the user currently logged in) to the kafka user:

```
/opt/kafka/config# ls -l
total 80
...
-rw-r--r-- 1 kafka nogroup 1221 Feb 21 2018 consumer.properties
-rw----- 1 root root 3277 Mar 27 08:03 kafka01.keystore.jks
-rw-r--r-- 1 root root 1048 Mar 27 08:03 kafka.truststore.jks
-rw-r--r-- 1 kafka nogroup 4727 Feb 21 2018 log4j.properties
...
/opt/kafka/config# chown kafka kafka01.keystore.jks kafka.truststore.jks
/opt/kafka/config# ls -l
total 80
...
-rw-r--r-- 1 kafka nogroup 1221 Feb 21 2018 consumer.properties
-rw----- 1 kafka root 3277 Mar 27 08:03 kafka01.keystore.jks
-rw-r--r-- 1 kafka root 1048 Mar 27 08:03 kafka.truststore.jks
-rw-r--r-- 1 kafka nogroup 4727 Feb 21 2018 log4j.properties
...
```

- Repeat steps 1 through 3 for the remaining Kafka brokers.

Configure Kafka to use TLS

With the truststore and keystore in place, your next step is to edit the Kafka's `server.properties` configuration file to tell Kafka to use TLS/SSL encryption. This file is usually stored in the Kafka config directory. The location of this directory depends on how you installed Kafka. In this example, the file is located in `/opt/kafka/config`.

When editing the files, be sure you do not change their ownership. The best way to ensure Linux does not change the file's ownership is to use `su` to become the user account that runs Kafka, assuming you are not already logged in as that user:

```
$/opt/kafka/config# su -s /bin/bash kafka
```

Note

The previous command lets you start a shell as the kafka system user even if that user cannot log in.

The `server.properties` file contains Kafka broker settings in a `property = value` format. To configure the Kafka broker to use SSL, alter or add the following property settings:

listeners

Host names and ports on which the Kafka broker listens. If you are not using SSL for connections between brokers, you must supply both a PLAINTEXT and SSL option. For example:

```
listeners=PLAINTEXT:// hostname :9092,SSL:// hostname :9093
```

ssl.keystore.location

Absolute path to the keystore file.

ssl.keystore.password

Password for the keystore file.

ssl.key.password

Password for the Kafka broker's key in the keystore. You can make this password different than the keystore password if you choose.

ssl.truststore.location

Location of the truststore file.

ssl.truststore.password

Password to access the truststore.

ssl.enabled.protocols

TLS/SSL protocols that Kafka allows clients to use.

ssl.client.auth

Specifies whether SSL authentication is required or optional. The most secure setting for this setting is required to verify the client's identity.

Important
These settings vary depending on your version of Kafka. Always consult the [Apache Kafka documentation](#) for your version of Kafka before making changes to `server.properties`. In particular, be aware that Kafka version 2.0 and later enables host name verification for clients and inter-broker communications by default.

This example configures Kafka to verify client identities via SSL authentication. It does not use SSL to communicate with other brokers, so the `server.properties` file defines both SSL and PLAINTEXT listener ports. It does not supply a host name for listener ports which tells Kafka to listen on the default network interface.

The lines added to the kafka01 broker's copy of `server.properties` for this configuration are:

```
listeners=PLAINTEXT://:9092,SSL://:9093
ssl.keystore.location=/opt/kafka/config/kafka01.keystore.jks
ssl.keystore.password=vertica
ssl.key.password=vertica
ssl.truststore.location=/opt/kafka/config/kafka.truststore.jks
ssl.truststore.password=vertica
ssl.enabled.protocols=TLSv1.2,TLSv1.1,TLSv1
ssl.client.auth=required
```

You must make these changes to the `server.properties` file on all of your brokers.

After making your changes to your broker's `server.properties` files, restart Kafka. How you restart Kafka depends on your installation:

- If Kafka is running as part of a Hadoop cluster, you can usually restart it from within whatever interface you use to control Hadoop (such as Ambari).
- If you installed Kafka directly, you can restart it either by directly running the `kafka-server-stop.sh` and `kafka-server-start.sh` scripts or via the Linux system's service control commands (such as `systemctl`). You must run this command on each broker.

Test the configuration

If you have not configured client authentication, you can quickly test whether Kafka can access its keystore by running the command:

```
$ openssl s_client -debug -connect broker_host_name:9093 -tls1
```

If Kafka is able to access its keystore, this command will output a dump of the broker's certificate (exit with CTRL+C):

```
=> # openssl s_client -debug -connect kafka01.mycompany.com:9093 -tls1
CONNECTED(00000003)
write to 0xa4e4f0 [0xa58023] (197 bytes => 197 (0xC5))

read from 0xa4e4f0 [0xa53ad3] (5 bytes => 5 (0x5))
0000 - 16 03 01 08 fc .....
...
```

The above method is not conclusive, however; it only tells you if Kafka is able to find its keystore.

The best test of whether Kafka is able to accept TLS connections is to configure the command-line Kafka producer and consumer. In order to configure these tools, you must first create a client keystore. These steps are identical to creating a broker keystore.

Note

This example assumes that Kafka has a topic named test that you can send test messages to.

1. Create the client keystore:

```
keytool -keystore client.keystore.jks -alias localhost -validity 365 -genkey -keyalg RSA -ext SAN=DNS:fqdn_of_client_system
```

2. Respond to the "What is your first and last name?" with the FQDN of the system you will use to run the producer and/or consumer. Answer the rest of the prompts with the details of your organization.
3. Export the client certificate so it can be signed:

```
keytool -keystore client.keystore.jks -alias localhost -certreq -file client.unsigned.cert
```

4. Sign the client certificate with the root CA:

```
openssl x509 -req -CA root.crt -CAkey root.key -in client.unsigned.cert -out client.signed.cert \
-days 365 -CAcreateserial
```

5. Add the root CA to keystore:

```
keytool -keystore client.keystore.jks -alias CARoot -import -file root.crt
```

6. Add the signed client certificate to the keystore:

```
keytool -keystore client.keystore.jks -alias localhost -import -file client.signed.cert
```

7. Copy the keystore to a location where you will use it. For example, you could choose to copy it to the same directory where you copied the keystore for the Kafka broker. If you choose to copy it to some other location, or intend to use some other user to run the command-line clients, be sure to add a copy of the truststore file you created for the brokers. Clients can reuse this truststore file for authenticating the Kafka brokers because the same CA is used to sign all of the certificates. Also set the file's ownership and permissions accordingly.

Next, you must create a properties file (similar to the broker's `server.properties` file) that configures the command-line clients to use TLS. For a client running on the Kafka broker named kafka01, your configuration file could look like this:

```
security.protocol=SSL
ssl.truststore.location=/opt/kafka/config/kafka.truststore.jks
ssl.truststore.password=trustore_password
ssl.keystore.location=/opt/kafka/config/client.keystore.jks
ssl.keystore.password=keystore_password
ssl.key.password=key_password
ssl.enabled.protocols=TLSv1.2,TLSv1.1,TLSv1
ssl.client.auth=required
```

This property file assumes the keystore file is located in the Kafka configuration directory.

Finally, you can run the command line producer or consumer to ensure they can connect and process data. You supply these clients the properties file you just created. The following example assumes you stored the properties file in the Kafka configuration directory, and that Kafka is installed in `/opt/kafka` :

```
~# cd /opt/kafka

/opt/kafka# bin/kafka-console-producer.sh --broker-list kafka01.mycompany.com:9093 \
--topic test --producer.config config/client.properties
>test
>test again
>More testing. These messages seem to be getting through!
^D
/opt/kafka# bin/kafka-console-consumer.sh --bootstrap-server kafaka01.mycompany.com:9093 --topic test \
--consumer.config config/client.properties --from-beginning
test
test again
More testing. These messages seem to be getting through!
^C
Processed a total of 3 messages
```

Loading data from Kafka

After you configure Kafka to accept TLS connections, verify that you can directly load data from it into Vertica. You should perform this step even if you plan to create a scheduler to automatically stream data.

You can choose to create a separate key and certificate for directly loading data from Kafka. This example re-uses the key and certificate created for the Vertica server in part 2 of this example.

You directly load data from Kafka by using the [KafkaSource](#) data source function with the `COPY` statement (see [Manually consume data from Kafka](#)). The `KafkaSource` function creates the connection to Kafka, so it needs a key, certificate, and related passwords to create an encrypted connection. You pass this information via session parameters. See [Kafka user-defined session parameters](#) for a list of these parameters.

The easiest way to get the key and certificate into the parameters is by first reading them into [vsq variables](#). You get their contents by using back quotes to read the file contents via the Linux shell. Then you set the session parameters from the variables. Before setting the session parameters, increase the `MaxSessionUDParameterSize` session parameter to add enough storage space in the session variables for the key and the certificates. They can be larger than the default size limit for session variables (1000 bytes).

The following example reads the server key and certificate and the root CA from the a directory named `/home/dbadmin/SSL` . Because the server's key password is not saved in a file, the example sets it in a Linux environment variable named `KVERTICA_PASS` before running `vsq`. The example sets `MaxSessionUDParameterSize` to 100000 before setting the session variables. Finally, it enables TLS for the Kafka connection and streams data from the topic named `test`.

```

$ export KVERTICA_PASS=server_key_password
$ vsql
Password:
Welcome to vsql, the Vertica Analytic Database interactive terminal.

Type: \h or \? for help with vsql commands
      \g or terminate with semicolon to execute query
      \q to quit

Configure the scheduler

The final piece of the configuration is to set up the scheduler to use SSL when communicating with Kafka (and optionally with Vertica). When the scheduler runs a COPY command to get data from Kafka, it uses its own key and certificate to authenticate with Kafka. If you choose to have the scheduler use TLS/SSL to connect to Vertica, it can reuse the same keystore and truststore to make this connection.

Create a truststore and keystore for the scheduler

Because the scheduler is a separate component, it must have its own key and certificate. The scheduler runs in Java and uses the JDBC interface to connect to Vertica. Therefore, you must create a keystore (when `ssl.client.auth=required`) and truststore for it to use when making a TLS-encrypted connection to Vertica.

Keep in mind that creating a keystore is optional if your Kafka server sets `ssl.client.auth` to `none` or `requested`.

This process is similar to creating the truststores and keystores for Kafka brokers. The main difference is using the the `-dname` option for `keytool` to set the Common Name (CN) for the key to a domain wildcard. Using this setting allows the key and certificate to match any host in the network. This option is especially useful if you run multiple schedulers on different servers to provide redundancy. The schedulers can use the same key and certificate, no matter which server they are running on in your domain.

1. Create a truststore file for the scheduler. Add the CA certificate that you used to sign the keystore of the Kafka cluster and Vertica cluster. If you are using more than one CA to sign your certificates, add all of the CAs you used.

```
$ keytool -keystore scheduler.truststore.jks -alias CARoot -import \  
-file root.crt  
Enter keystore password: some_password  
Re-enter new password: some_password  
Owner: EMAILADDRESS=myemail@mycompany.com, CN=*.mycompany.com, O=MyCompany, L=Cambridge, ST=MA, C=US

0010: E5 3D 78 16 .=x.  
]  
]  
  
Trust this certificate? [no]: yes  
Certificate was added to keystore
```

2. Initialize the keystore, passing it a wildcard host name as the Common Name. The alias parameter in this command is important, as you use it later to identify the key the scheduler must use when creating SSL connections:

```
keytool -keystore scheduler.keystore.jks -alias vsched -validity 365 -genkey \  
-keyalg RSA -dname CN=*.mycompany.com
```

Important

If you choose to use a file format other than the standard Java Keystore (JKS) format for your keystore or truststore files, you must use the correct file extension in the filename. For example, suppose you choose to use a keystore and truststore saved in PKCS#12 format. Then your keystore and truststore files must end with the `.pfx` or `.p12` extension.

If the scheduler does not recognize the file's extension (or there is no extension in the file name), it assumes that the file is in JKS format. If the file is not in JKS format, you will see an error message when starting the scheduler, similar to "Failed to create an SSLSocketFactory when setting up TLS: keystore not found."

3. Export the scheduler's key so you can sign it with the root CA:

```
$ keytool -keystore scheduler.keystore.jks -alias vsched -certreq \  
-file scheduler.unsigned.cert
```

4. Sign the scheduler key with the root CA:

```
$ openssl x509 -req -CA root.crt -CAkey root.key -in scheduler.unsigned.cert \  
-out scheduler.signed.cert -days 365 -CAcreateserial
```

5. Re-import the scheduler key into the keystore:

```
$ keytool -keystore scheduler.keystore.jks -alias localhost -import -file scheduler.signed.cert
```

Set environment variable VKCONFIG_JVM_OPTS

You must pass several settings to the JDBC interface of the Java Virtual Machine (JVM) that runs the scheduler. These settings tell the JDBC driver where to find the keystore and truststore, as well as the key's password. The easiest way to pass in these settings is to set a Linux environment variable named VKCONFIG_JVM_OPTS. As it starts, the scheduler checks this environment variable and passes any properties defined in it to the JVM.

The properties that you need to set are:

- `javax.net.ssl.keystore`: the absolute path to the keystore file to use.
- `javax.net.ssl.keyStorePassword`: the password for the scheduler's key.
- `javax.net.ssl.trustStore`: The absolute path to the truststore file.

The Linux command line to set the environment variable is:

```
export VKCONFIG_JVM_OPTS="$VKCONFIG_JVM_OPTS -Djavax.net.ssl.trustStore=/path/to/truststore \  
-Djavax.net.ssl.keyStore=/path/to/keystore \  
-Djavax.net.ssl.keyStorePassword=keystore_password"
```

Note

The previous command preserves any existing contents of the VKCONFIG_JVM_OPTS variable. If you find the variable has duplicate settings, remove the `$VKCONFIG_JVM_OPTS` from your statement so you override the existing values in the variable.

For example, suppose the scheduler's truststore and keystore are located in the directory `/home/dbadmin/SSL`. Then you could use the following command to set the VKCONFIG_JVM_OPTS variable:

```
$ export VKCONFIG_JVM_OPTS="$VKCONFIG_JVM_OPTS \  
-Djavax.net.ssl.trustStore=/home/dbadmin/SSL/scheduler.truststore.jks \  
-Djavax.net.ssl.keyStore=/home/dbadmin/SSL/scheduler.keystore.jks \  
-Djavax.net.ssl.keyStorePassword=key_password"
```

Important

The Java property names are case sensitive.

To ensure that this variable is always set, add the command to the `~/.bashrc` or other startup file of the user account that runs the scheduler.

If you require TLS on the JDBC connection to Vertica, add `TLSmode=require` to the JDBC URL that the scheduler uses. The easiest way to add this is to use the scheduler's `--jdbc-url` option. Assuming that you use a configuration file for your scheduler, you can add this line to it:

```
--jdbc-url=jdbc:vertica://VerticaHost:portNumber/databaseName?user=username&password=password&TLSmode=require
```

For more information about using the JDBC with Vertica, see [Java](#).

Enable TLS in the scheduler configuration

Lastly, enable TLS. Every time you run `vkconfig`, you must pass it the following options:

--enable-ssl

`true`, to enable the scheduler to use SSL when connecting to Kafka.

--ssl-ca-alias

Alias for the CA you used to sign your Kafka broker's keys. This must match the value you supplied to the `-alias` argument of the `keytool` command to import the CA into the truststore.

Note

If you used more than one CA to sign keys, omit this option to import all of the CAs into the truststore.

--ssl-key-alias

Alias assigned to the scheduler key. This value must match the value you supplied to the `-alias` you supplied to the `keytool` command when creating the scheduler's keystore.

--ssl-key-password

Password for the scheduler key.

See [Common vkconfig script options](#) for details of these options. For convenience and security, add these options to a configuration file that you pass to `vkconfig`. Otherwise, you run the risk of exposing the key password via the process list which can be viewed by other users on the same system. See [Configuration File Format](#) for more information on setting up a configuration file.

Add the following to the scheduler configuration file to allow it to use the keystore and truststore and enable TLS when connecting to Vertica:

```
enable-ssl=true
ssl-ca-alias=CAroot
ssl-key-alias=vsched
ssl-key-password=vertica
jdbc-url=jdbc:vertica://VerticaHost:portNumber/databaseName?user=username&password=password&TLSmode=require
```

Start the scheduler

Once you have configured the scheduler to use SSL, start it and verify that it can load data. For example, to start the scheduler with a configuration file named `weblog.conf`, use the command:

```
$ nohup vkconfig launch --conf weblog.conf >/dev/null 2>&1 &
```

Troubleshooting Kafka TLS/SSL connection issues

After configuring Vertica, Kafka, and your scheduler to use TLS/SSL authentication and encryption, you may encounter issues with data streaming. This section explains some of the more common errors you may encounter, and how to trouble shoot them.

Errors when launching the scheduler

You may see errors like this when launching the scheduler:

```
$ vkconfig launch --conf weblog.conf
java.sql.SQLException: com.vertica.solutions.kafka.exception.ConfigurationException:
  No keystore system property found: null
  at com.vertica.solutions.kafka.util.SQLUtilities.getConnection(SQLUtilities.java:181)
  at com.vertica.solutions.kafka.cli.CLIUtil.assertDBCConnectionWorks(CLIUtil.java:40)
  at com.vertica.solutions.kafka.Launcher.run(Launcher.java:135)
  at com.vertica.solutions.kafka.Launcher.main(Launcher.java:263)
Caused by: com.vertica.solutions.kafka.exception.ConfigurationException: No keystore system property found: null
  at com.vertica.solutions.kafka.security.KeyStoreUtil.loadStore(KeyStoreUtil.java:77)
  at com.vertica.solutions.kafka.security.KeyStoreUtil.<init>(KeyStoreUtil.java:42)
  at com.vertica.solutions.kafka.util.SQLUtilities.getConnection(SQLUtilities.java:179)
  ... 3 more
```

The scheduler throws these errors when it cannot locate or read the keystore or truststore files. To resolve this issue:

- Verify you have set the `VKCONFIG_JVM_OPTS` Linux environment variable. Without this variable, the scheduler will not know where to find the truststore and keystore to use when creating TLS/SSL connections. See [Step 2: Set the VKCONFIG_JVM_OPTS Environment Variable](#) for more information.
- Verify that the keystore and truststore files are located in the path you set in the `VKCONFIG_JVM_OPTS` environment variable.
- Verify that the user account that runs the scheduler has read access to the truststore and keystore files.
- Verify that the key password you provide in the scheduler configuration is correct. Note that you must supply the password for the key, not the keystore.

Another possible error message is a failure to set up a TLS Keystore:

```
Exception in thread "main" java.sql.SQLRecoverableException: [Vertica][VJDBC](100024) IOException while communicating with server: java.io.IOException:
Failed to create an SSLSocketFactory when setting up TLS: keystore not found.
    at com.vertica.io.ProtocolStream.logAndConvertToNetworkException(Unknown Source)
    at com.vertica.io.ProtocolStream.enableSSL(Unknown Source)
    at com.vertica.io.ProtocolStream.initSession(Unknown Source)
    at com.vertica.core.VConnection.tryConnect(Unknown Source)
    at com.vertica.core.VConnection.connect(Unknown Source)
    . . .
```

This error can be caused by using a keystore or truststore file in a format other than JKS and not supplying the correct file extension. If the scheduler does not recognize the file extension of your keystore or truststore file name, it assumes the file is in JKS format. If the file isn't in this format, the scheduler will exit with the error message shown above. To correct this error, rename the keystore and truststore files to use the correct file extension. For example, if your files are in PKCS 12 filemat, change their file extension to `.p12` or `.pks`.

Data does not load

If you find that scheduler is not loading data into your database, you should first query the [stream_microbatch_history](#) table to determine whether the scheduler is executing microbatches, and if so, what their results are. A faulty TLS/SSL configuration usually results in a status of NETWORK_ISSUE:

```
=> SELECT frame_start, end_reason, end_reason_message FROM weblog_sched.stream_microbatch_history;
   frame_start   | end_reason   | end_reason_message
-----+-----+-----
2019-04-05 11:35:18.365 | NETWORK_ISSUE |
2019-04-05 11:35:38.462 | NETWORK_ISSUE |
```

If you suspect an SSL issue, you can verify that Vertica is establishing a connection to Kafka by looking at Kafka's `server.log` file. Failed SSL connection attempts can appear in this log like this example:

```
java.io.IOException: Unexpected status returned by SSLEngine.wrap, expected
CLOSED, received OK. Will not send close message to peer.
    at org.apache.kafka.common.network.SslTransportLayer.close(SslTransportLayer.java:172)
    at org.apache.kafka.common.utils.Utils.closeAll(Utils.java:703)
    at org.apache.kafka.common.network.KafkaChannel.close(KafkaChannel.java:61)
    at org.apache.kafka.common.network.Selector.doClose(Selector.java:739)
    at org.apache.kafka.common.network.Selector.close(Selector.java:727)
    at org.apache.kafka.common.network.Selector.pollSelectionKeys(Selector.java:520)
    at org.apache.kafka.common.network.Selector.poll(Selector.java:412)
    at kafka.network.Processor.poll(SocketServer.scala:551)
    at kafka.network.Processor.run(SocketServer.scala:468)
    at java.lang.Thread.run(Thread.java:748)
```

If you do not see errors of this sort, you likely have a network problem between Kafka and Vertica. If you do see these errors, consider the following debugging steps:

- Verify that the configuration of your Kafka cluster is uniform. For example, you may see connection errors if some Kafka nodes are set to require client authentication and others aren't.
- Verify that the Common Names (CN) in the certificates and keys match the host name of the system.
- Verify that the Kafka cluster is accepting connections on the ports and host names you specify in the `server.properties` file's listeners property. For example, suppose you use IP addresses in this setting, but use host names when defining the cluster in the scheduler's configuration. Then Kafka may reject the connection attempt by Vertica or Vertica may reject the Kafka node's identity.
- If you are using client authentication in Kafka, try turning it off to see if the scheduler can connect. If disabling authentication allows the scheduler to stream data, then you can isolate the problem to client authentication. In this case, review the certificates and CAs of both the Kafka cluster and the scheduler. Ensure that the truststores include all of the CAs used to sign the key, up to and including the root CA.

Avro schema registry and KafkaAvroParser

At minimum, the [KafkaAvroParser](#) requires the following parameters to create a TLS connection between the Avro Schema Registry and Vertica:

- `schema_registry_url` with the https scheme
- `schema_registry_ssl_ca_path`

If and only if TLS access fails, determine what TLS schema registry information Vertica requires from the following:

- Certificate Authority (CA)

- TLS server certificate
- TLS key

Provide only the necessary TLS schema registry information with KafkaAvroParser parameters. The TLS information must be accessible in the filesystem of each Vertica node that processes Avro data.

The following example shows how to pass these parameters to KafkaAvroParser:

```
KafkaAvroParser(
  schema_registry_url='https://localhost:8081'
  schema_registry_ssl_ca_path='path/to/certificate-authority',
  schema_registry_ssl_cert_path='path/to/tls-server-certificate',
  schema_registry_ssl_key_path='path/to/private-tls-key',
  schema_registry_ssl_key_password_path='path/to/private-tls-key-password'
)
```

Authenticating with Kafka using SASL

Kafka supports using Simple Authentication and Security Layer (SASL) to authenticate producers and consumers. You can use SASL to authenticate Vertica with Kafka when using most of the Kafka-related functions such as [KafkaSource](#).

Vertica supports using the SASL_PLAINTEXT and SASL_SSL protocols with the following authentication mechanisms:

- PLAIN
- SCRAM-SHA-256
- SCRAM-SHA-512

You must configure your Kafka cluster to enable SASL authentication. See the [Kafka documentation](#) for your Kafka version to learn how to configure SASL authentication.

Note

[KafkaExport](#) does not support using TLS/SSL with SASL authentication at this time.

To use SASL authentication between Vertica and Kafka, directly set SASL-related configuration options in the rdkafka library using the `kafka_conf` parameter. Vertica uses this library to connect to Kafka. See [Directly setting Kafka library options](#) for more information on directly setting configuration options in the rdkafka library.

Among the relevant configuration options are:

- `security.protocol` sets the security protocol to use to authenticate with Kafka.
- `sasl.mechanism` sets the security mechanism.
- `sasl.username` sets the SASL user to use for authentication.
- `sasl.password` sets the password to use for SASL authentication.

See the [rdkafka configuration documentation](#) for a list of all the SASL-related settings.

The following example demonstrates calling [KafkaCheckBrokers](#) using the `SASL_PLAINTEXT` security protocol:

```
=> SELECT KafkaCheckBrokers(USING PARAMETERS
  brokers='kafka01.example.com:9092',
  kafka_conf='{"sasl.username":"dbadmin", "sasl.mechanism":"PLAIN", "security.protocol":"SASL_PLAINTEXT"}',
  kafka_conf_secret='{"sasl.password":"password"}'
) OVER ();
```

This example demonstrates using SASL authentication when copying data from Kafka via an SSL connection. This example assumes that Vertica and Kafka have been configured to use TLS/SSL encryption as described in [TLS/SSL encryption with Kafka](#):

```
=> COPY mytopic_table
SOURCE KafkaSource(
  stream='mytopic|0|-2',
  brokers='kafka01.example.com:9092',
  stop_on_eof=true,
  kafka_conf={'sas.username':"dbadmin", "sas.password":"pword", "sas.mechanism":"PLAIN", "security.protocol":"SASL_SSL"}
)
FILTER KafkaInsertDelimiters(delimiter = E'\n')
DELIMITER ','
ENCLOSED BY '';
```

For more information about using SASL with the rdkafka library, see [Using SASL with librdkafka](#) on the rdkafka github site.

Troubleshooting Kafka integration issues

The following topics can help you troubleshoot issues integrating Vertica with Apache Kafka.

In this section

- [Using kafkacat to troubleshoot Kafka integration issues](#)
- [Troubleshooting slow load speeds](#)
- [Troubleshooting missing messages](#)

Using kafkacat to troubleshoot Kafka integration issues

Kafkacat is a third-party open-source utility that lets you connect to Kafka from the Linux command line. It uses the same underlying library that the Vertica integration for Apache Kafka uses to connect to Kafka. This shared library makes kafkacat a useful tool for testing and debugging your Vertica integration with Kafka.

You may find kafkacat useful for:

- Testing connectivity between your Vertica and Kafka clusters.
- Examining Kafka data for anomalies that may prevent some of it from loading into Vertica.
- Producing data for test loads into Vertica.
- Listing details about a Kafka topic.

For more information about kafkacat, see its [project page at Github](#).

Running kafkacat on Vertica nodes

The kafkacat utility is bundled in the Vertica install package, so it is available on all nodes of your Vertica cluster in the `/opt/vertica/packages/kafka/bin` directory. This is the same directory containing the vkconfig utility, so if you have added it to your path, you can use the kafkacat utility without specifying its full path. Otherwise, you can add this path to your shell's environment variable using the command:

```
set PATH=/opt/vertica/packages/kafka/bin:$PATH
```

Note

On Debian and Ubuntu systems, you must tell kafkacat to use Vertica's own copy of the SSL libraries by setting the LD_LIBRARY_PATH environment variable:

```
$ export LD_LIBRARY_PATH=/opt/vertica/lib
```

If you do not set this environment variable, the kafkacat utility exits with the error:

```
kafkacat: error while loading shared libraries: libcrypto.so.10:
cannot open shared object file: No such file or directory
```

Executing kafkacat without any arguments gives you a basic help message:

```
$ kafkacat
Error: -b <broker,...> missing

Usage: kafkacat <options> [file1 file2 .. | topic1 topic2 ..]
kafkacat - Apache Kafka producer and consumer tool
```

General options:

- C | -P | -L Mode: Consume, Produce or metadata List
- G <group-id> Mode: High-level KafkaConsumer (Kafka 0.9 balanced consumer groups)
Expects a list of topics to subscribe to
- t <topic> Topic to consume from, produce to, or list
- p <partition> Partition
- b <brokers,..> Bootstrap broker(s) (host[:port])
- D <delim> Message delimiter character:
a-z.. | \r | \n | \t | \xNN
Default: \n
- K <delim> Key delimiter (same format as -D)
- c <cnt> Limit message count
- X list List available librdkafka configuration properties
- X prop=val Set librdkafka configuration property.
Properties prefixed with "topic." are applied as topic properties.
- X dump Dump configuration and exit.
- d <dbg1,..> Enable librdkafka debugging:
all,generic,broker,topic,metadata,queue,msg,protocol,cgrp,security,fetch,feature
- q Be quiet (verbosity set to 0)
- v Increase verbosity
- V Print version

Producer options:

- z snappy|gzip Message compression. Default: none
- p -1 Use random partitioner
- D <delim> Delimiter to split input into messages
- K <delim> Delimiter to split input key and message
- l Send messages from a file separated by
delimiter, as with stdin.
(only one file allowed)
- T Output sent messages to stdout, acting like tee.
- c <cnt> Exit after producing this number of messages
- Z Send empty messages as NULL messages
- file1 file2.. Read messages from files.
With -l, only one file permitted.
Otherwise, the entire file contents will
be sent as one single message.

Consumer options:

- o <offset> Offset to start consuming from:
beginning | end | stored |
<value> (absolute offset) |
-<value> (relative offset from end)
- e Exit successfully when last message received
- f <fmt..> Output formatting string, see below.
Takes precedence over -D and -K.
- D <delim> Delimiter to separate messages on output
- K <delim> Print message keys prefixing the message
with specified delimiter.
- O Print message offset using -K delimiter
- c <cnt> Exit after consuming this number of messages
- Z Print NULL messages and keys as "NULL"(instead of empty)
- u Unbuffered output

Metadata options:

-t <topic> Topic to query (optional)

Format string tokens:

%s Message payload
%S Message payload length (or -1 for NULL)
%R Message payload length (or -1 for NULL) serialized
as a binary big endian 32-bit signed integer
%k Message key
%K Message key length (or -1 for NULL)
%t Topic
%p Partition
%o Message offset
\n \r \t Newlines, tab
\xXX \xNNN Any ASCII character

Example:

```
-f 'Topic %t [%p] at offset %o: key %k: %s\n'
```

Consumer mode (writes messages to stdout):

```
kafkacat -b <broker> -t <topic> -p <partition>
```

or:

```
kafkacat -C -b ...
```

High-level KafkaConsumer mode:

```
kafkacat -b <broker> -G <group-id> topic1 top2 ^aregex\d+
```

Producer mode (reads messages from stdin):

```
... | kafkacat -b <broker> -t <topic> -p <partition>
```

or:

```
kafkacat -P -b ...
```

Metadata listing:

```
kafkacat -L -b <broker> [-t <topic>]
```

Testing connectivity to a Kafka cluster and getting metadata

One basic troubleshooting step you often need to perform is verifying that Vertica nodes can connect to the Kafka cluster. Successfully executing just about any kafkacat command will prove the Vertica node you are logged into is able to reach the Kafka cluster. One simple command you can execute to verify connectivity is to get the metadata for all of the topics the Kafka cluster has defined. The following example demonstrates using kafkacat's metadata listing command to connect to the broker named kafka01 running on port 6667 (the Kafka broker port used by Hortonworks Hadoop clusters).

```
$ kafkacat -L -b kafka01:6667
```

Metadata for all topics (from broker -1: kafka01:6667/bootstrap):

2 brokers:

```
broker 1001 at kafka03.example.com:6667
```

```
broker 1002 at kafka01.example.com:6667
```

4 topics:

topic "iot-data" with 3 partitions:

```
partition 2, leader 1002, replicas: 1002, isrs: 1002
```

```
partition 1, leader 1001, replicas: 1001, isrs: 1001
```

```
partition 0, leader 1002, replicas: 1002, isrs: 1002
```

topic "__consumer_offsets" with 50 partitions:

```
partition 23, leader 1001, replicas: 1002,1001, isrs: 1001,1002
```

```
partition 41, leader 1001, replicas: 1002,1001, isrs: 1001,1002
```

```
partition 32, leader 1002, replicas: 1002,1001, isrs: 1001,1002
```

```
partition 8, leader 1002, replicas: 1002,1001, isrs: 1001,1002
```

```
partition 17, leader 1001, replicas: 1002,1001, isrs: 1001,1002
```

```
partition 44, leader 1002, replicas: 1002,1001, isrs: 1001,1002
```

```
partition 35, leader 1001, replicas: 1002,1001, isrs: 1001,1002
```

```
partition 26, leader 1002, replicas: 1002,1001, isrs: 1001,1002
```

```
partition 11, leader 1001, replicas: 1002,1001, isrs: 1001,1002
partition 29, leader 1001, replicas: 1002,1001, isrs: 1001,1002
partition 38, leader 1002, replicas: 1002,1001, isrs: 1001,1002
partition 47, leader 1001, replicas: 1002,1001, isrs: 1001,1002
partition 20, leader 1002, replicas: 1002,1001, isrs: 1001,1002
partition 2, leader 1002, replicas: 1002,1001, isrs: 1001,1002
partition 5, leader 1001, replicas: 1002,1001, isrs: 1001,1002
partition 14, leader 1002, replicas: 1002,1001, isrs: 1001,1002
partition 46, leader 1002, replicas: 1002,1001, isrs: 1001,1002
partition 49, leader 1001, replicas: 1002,1001, isrs: 1001,1002
partition 40, leader 1002, replicas: 1002,1001, isrs: 1001,1002
partition 4, leader 1002, replicas: 1002,1001, isrs: 1001,1002
partition 13, leader 1001, replicas: 1002,1001, isrs: 1001,1002
partition 22, leader 1002, replicas: 1002,1001, isrs: 1001,1002
partition 31, leader 1001, replicas: 1002,1001, isrs: 1001,1002
partition 16, leader 1002, replicas: 1002,1001, isrs: 1001,1002
partition 7, leader 1001, replicas: 1002,1001, isrs: 1001,1002
partition 43, leader 1001, replicas: 1002,1001, isrs: 1001,1002
partition 25, leader 1001, replicas: 1002,1001, isrs: 1001,1002
partition 34, leader 1002, replicas: 1002,1001, isrs: 1001,1002
partition 10, leader 1002, replicas: 1002,1001, isrs: 1001,1002
partition 37, leader 1001, replicas: 1002,1001, isrs: 1001,1002
partition 1, leader 1001, replicas: 1002,1001, isrs: 1001,1002
partition 19, leader 1001, replicas: 1002,1001, isrs: 1001,1002
partition 28, leader 1002, replicas: 1002,1001, isrs: 1001,1002
partition 45, leader 1001, replicas: 1002,1001, isrs: 1001,1002
partition 36, leader 1002, replicas: 1002,1001, isrs: 1001,1002
partition 27, leader 1001, replicas: 1002,1001, isrs: 1001,1002
partition 9, leader 1001, replicas: 1002,1001, isrs: 1001,1002
partition 18, leader 1002, replicas: 1002,1001, isrs: 1001,1002
partition 21, leader 1001, replicas: 1002,1001, isrs: 1001,1002
partition 48, leader 1002, replicas: 1002,1001, isrs: 1001,1002
partition 12, leader 1002, replicas: 1002,1001, isrs: 1001,1002
partition 3, leader 1001, replicas: 1002,1001, isrs: 1001,1002
partition 30, leader 1002, replicas: 1002,1001, isrs: 1001,1002
partition 39, leader 1001, replicas: 1002,1001, isrs: 1001,1002
partition 15, leader 1001, replicas: 1002,1001, isrs: 1001,1002
partition 42, leader 1002, replicas: 1002,1001, isrs: 1001,1002
partition 24, leader 1002, replicas: 1002,1001, isrs: 1001,1002
partition 33, leader 1001, replicas: 1002,1001, isrs: 1001,1002
partition 6, leader 1002, replicas: 1002,1001, isrs: 1001,1002
partition 0, leader 1002, replicas: 1002,1001, isrs: 1001,1002
topic "web_hits" with 1 partitions:
  partition 0, leader 1001, replicas: 1001, isrs: 1001
topic "ambari_kafka_service_check" with 1 partitions:
  partition 0, leader 1002, replicas: 1002, isrs: 1002
```

You can also use this output to verify the topics defined by your Kafka cluster, as well as the number of partitions each topic defines. You need this information when copying data between Kafka and Vertica.

Retrieving messages from a Kafka topic

When you are troubleshooting issues with streaming messages from Kafka in Vertica, you often want to look at the raw data that Kafka sent. For example, you may want to verify that the messages are in the format that you expect. Or, you may want to review specific messages to see if some of them weren't in the right format for Vertica to parse. You can use `kafkacat` to read messages from a topic using its consume command (`-C`). At the very least, you must pass `kafkacat` the brokers (`-b` argument) and the topic you want to read from (`-t`). You can also choose to read messages from a specific offset (`-o`) and partition (`-p`). You will usually also want `kafkacat` to exit after completing the data read (`-e`) instead continuing to wait for more messages.

This example gets the last message in the topic named `web_hits`. The offset argument uses a negative value, which tells `kafkacat` to read from the end of the topic.

```
$ kafkacat -C -b kafka01:6667 -t web_hits -o -1 -e
{"url": "wp-content/list/search.php", "ip": "132.74.240.52",
"date": "2018/03/28 14:12:34",
"user_agent": "Mozilla/5.0 (iPod; U; CPU iPhone OS 4_2 like
Mac OS X; sl-SI) AppleWebKit/532.22.4 (KHTML, like Gecko) Version/3.0.5
Mobile/8B117 Safari/6532.22.4"}
% Reached end of topic web_hits [0] at offset 54932: exiting
```

You can also read a specific range of messages by specifying an offset and a limit (`-c` argument). For example, you may want to look at a specific range of data to determine why Vertica could not load it. The following example reads 10 messages from the topic `iot-data` starting at offset 3280:

```
$ kafkacat -C -b kafka01:6667 -t iot-data -o 3280 -c 10 -e
63680, 19, 24.439323, 26.0128725
43510, 71, 162.319805, -37.4924025
91113, 53, 139.764857, -74.735731
88508, 14, -85.821967, -7.236280
20419, 31, -129.583988, 13.995481
79365, 79, 153.184594, 51.1583485
26283, 25, -168.911020, 35.331027
32111, 56, -157.930451, 82.2676385
56808, 17, 19.603286, -0.7698495
91118, 73, 97.365445, -74.8593245
```

Generating data for a Kafka topic

If you are preparing to stream data from a Kafka topic that is not yet active, you may want a way to stream test messages. You can then verify that the topic's messages load into Vertica without worrying that you will miss actual data.

To send data to Kafka, use `kafkacat`'s `produce` command (`-P`). The easiest way to supply it with messages is to pipe them in via STDIN, one message per line. You can choose a specific partition for the data, or have `kafkacat` randomly assign each message to a random partition by setting the partition number to `-1`. For example, suppose you have a file named `iot-data.csv` that you wanted to produce to random partitions of a Kafka topic named `iot-data`. Then you could use the following command:

```
$ cat iot_data.csv | kafkacat -P -p -1 -b kafka01:6667 -t iot-data
```

Troubleshooting slow load speeds

Here are some potential issues that could cause messages to load slowly from Kafka.

Verify you have disabled the API version check when communicating with Kafka 0.9 or earlier

If your Kafka cluster is running 0.9 or earlier, be sure you have disabled the `rdkafka` library's `api.version.request` option. If you do not, every Vertica connection to Kafka will pause for 10 seconds until the API version request times out. Depending on the frame size of your load or other timeout settings, this delay can either reduce the throughput of your data loads. It can even totally prevent messages from being loaded. See [Configuring Vertica for Apache Kafka version 0.9 and earlier](#) for more information.

Eon Mode and cloud latency

Eon Mode separates compute from storage in a Vertica cluster, which can cause a small amount of latency when Vertica loads and saves data. Cloud computing infrastructure can also cause latency. This latency can eat into the frame duration for your schedulers, causing them to load less data in each frame. For this reason, you should consider increasing frame durations when loading data from Kafka in an Eon Mode database. See [Vertica Eon Mode and Kafka](#) for more information.

Troubleshooting missing messages

Kafka producers that emit a high data volume might overwhelm Vertica, possibly resulting in messages expiring in Kafka before the [scheduler](#) loads them into Vertica. This is more common when Vertica performs additional processing on the loaded messages, such as text indexing.

If you see that you are missing messages from a topic with multiple partitions, consider configuring the `--max-parallelism` [microbatch utility option](#). The `--max-parallelism` option splits a microbatch into multiple subset microbatches. This enables you to use `PLANNEDCONCURRENCY` available in the scheduler's resource pool to create more scheduler threads for simultaneous loads of a single microbatch. Each node uses the resource pool `EXECUTIONPARALLELISM` setting to determine the number of threads created to process partitions. Because `EXECUTIONPARALLELISM` threads are created per scheduler thread, using more `PLANNEDCONCURRENCY` per microbatch enables you to process more partitions in parallel for a single unit of work.

For details, see [Managing scheduler resources and performance](#).

vkconfig script options

Vertica includes the vkconfig script that lets you configure your schedulers. This script contains multiple tools that set groups of options in the scheduler, as well as starting and shutting it down. You supply the tool you want to use as the first argument in your call to the vkconfig script.

The topics in this section explain each of the tools available in the vkconfig script as well as their options. You can use the options in the [Common vkconfig script options](#) topic with any of the utilities. Utility-specific options appear in their respective tables.

In this section

- [Common vkconfig script options](#)
- [Scheduler tool options](#)
- [Cluster tool options](#)
- [Source tool options](#)
- [Target tool options](#)
- [Load spec tool options](#)
- [Microbatch tool options](#)
- [Launch tool options](#)
- [Shutdown tool options](#)
- [Statistics tool options](#)
- [Sync tool options](#)

Common vkconfig script options

These options are available across the different tools available in the vkconfig script.

--conf *filename*

A text file containing configuration options for the vkconfig script. See [Configuration File Format](#) below.

--config-schema *schema_name*

The name of the scheduler's Vertica schema. This value is the same as the name of the scheduler. You use this name to identify the scheduler during configuration.

Default:

stream_config

--dbhost *host name*

The host name or IP address of the Vertica node acting as the initiator node for the scheduler.

Default:

localhost

--dbport *port_number*

The port to use to connect to a Vertica database.

Default:

5433

--enable-ssl

Enables the vkconfig script to use SSL to connect to Vertica or between Vertica and Kafka. See [Configuring your scheduler for TLS connections](#) for more information.

--help

Prints out a help menu listing available options with a description.

--jdbc-opt *option = value* [& *option2 = value2* ...]

One or more options to add to the standard JDBC URL that vkconfig uses to connect to Vertica. Cannot be combined with `--jdbc-url`.

--jdbc-url *url*

A complete JDBC URL that vkconfig uses instead of standard JDBC URL string to connect to Vertica.

--password *password*

Password for the database user.

--ssl-ca-alias *alias_name*

The alias of the root certificate authority in the truststore. When set, the scheduler loads only the certificate associated with the specified alias. When omitted, the scheduler loads all certificates into the truststore.

--ssl-key-alias *alias_name*

The alias of the key and certificate pairs within the keystore. Must be set when Vertica uses SSL to connect to Kafka.

--ssl-key-password *password*

The password for the SSL key. Must be set when Vertica uses SSL to connect to Kafka.

Caution

Specifying this option on the command line can expose it to other users logged into the host. Always use a configuration file to set this option.

--username *username*

The Vertica database user used to alter the configuration of the scheduler. This user must have create privileges on the scheduler's schema.

Default:

Current user

--version

Displays the version number of the scheduler.

Configuration file format

You can use a configuration file to store common parameters you use in your calls to the vkconfig utility. The configuration file is a text file containing one option setting per line in the format:

```
option=value
```

You can also include comments in the option file by prefixing them with a hash mark (#).

```
#config.properties:
username=myuser
password=mypassword
dbhost=localhost
dbport=5433
```

You tell vkconfig to use the configuration file using the --conf option:

```
$ /opt/vertica/packages/kafka/bin/vkconfig source --update --conf config.properties
```

You can override any stored parameter from the command line:

```
$ /opt/vertica/packages/kafka/bin/vkconfig source --update --conf config.properties --dbhost otherVerticaHost
```

Examples

These examples show how you can use the shared utility options.

Display help for the scheduler utility:

```
$ vkconfig scheduler --help
This command configures a Scheduler, which can run and load data from configured sources and clusters into Vertica tables. It provides options for changing the 'frame duration' (time given per set of batches to resolve), as well as the dedicated Vertica resource pool the Scheduler will use while running.
```

Available Options:

PARAMETER	#ARGS	DESCRIPTION
conf	1	Allow the use of a properties file to associate parameter keys and values. This file enables command string reuse and cleaner command strings.
help	0	Outputs a help context for the given subutility.
version	0	Outputs the current Version of the scheduler.
skip-validation	0	[Deprecated] Use --validation-type.
validation-type	1	Determine what happens when there are configuration errors. Accepts: ERROR - errors out, WARN - prints out a message and continues, SKIP - skip running validations

ORN - snp running validations

dbhost	1	The Vertica database hostname that contains metadata and configuration information. The default value is 'localhost'.
dbport	1	The port at the hostname to connect to the Vertica database. The default value is '5433'.
username	1	The user to connect to Vertica. The default value is the current system user.
password	1	The password for the user connecting to Vertica. The default value is empty.
jdbc-url	1	A JDBC URL that can override Vertica connection parameters and provide additional JDBC options.
jdbc-opt	1	Options to add to the JDBC URL used to connect to Vertica ('&'-separated key=value list). Used with generated URL (i.e. not with '--jdbc-url' set).
enable-ssl	1	Enable SSL between JDBC and Vertica and/or Vertica and Kafka.
ssl-ca-alias	1	The alias of the root CA within the provided truststore used when connecting between Vertica and Kafka.
ssl-key-alias	1	The alias of the key and certificate pair within the provided keystore used when connecting between Vertica and Kafka.
ssl-key-password	1	The password for the key used when connecting between Vertica and Kafka. Should be hidden with file access (see --conf).
config-schema	1	The schema containing the configuration details to be used, created or edited. This parameter defines the scheduler. The default value is 'stream_config'.
create	0	Create a new instance of the supplied type.
read	0	Read an instance of the supplied type.
update	0	Update an instance of the supplied type.
delete	0	Delete an instance of the supplied type.
drop	0	Drops the specified configuration schema. CAUTION: this command will completely delete and remove all configuration and monitoring data for the specified scheduler.
dump	0	Dump the config schema query string used to answer this command in the output.
operator	1	Specifies a user designated as an operator for the created configuration. Used with --create.
add-operator	1	Add a user designated as an operator for the specified configuration. Used with --update.
remove-operator	1	Removes a user designated as an operator for the specified configuration. Used with --update.
upgrade	0	Upgrade the current scheduler configuration schema to the current version of this scheduler. WARNING: if upgrading between EXCAVATOR and FRONTLOADER be aware that the Scheduler is not backwards compatible. The upgrade procedure will translate your kafka model into the new stream model.
upgrade-to-schema	1	Used with upgrade: will upgrade the configuration to a new given schema instead of upgrading within the same schema.
fix-config	0	Attempts to fix the configuration (ex: dropped tables) before doing any other updates. Used with --update.
frame-duration	1	The duration of the Scheduler's frame. in

name	1	The name of the Scheduler's frame, in which every configured Microbatch runs. Default is 300 seconds: '00:05:00'
resource-pool	1	The Vertica resource pool to run the Scheduler on. Default is 'general'.
config-refresh	1	The interval of time between Scheduler configuration refreshes. Default is 5 minutes: '00:05'
new-source-policy	1	The policy for new Sources to be scheduled during a frame. Options are: START, END, and FAIR. Default is 'FAIR'.
pushback-policy	1	
pushback-max-count	1	
auto-sync	1	Automatically update configuration based on metadata from the Kafka cluster
consumer-group-id	1	The Kafka consumer group id to report offsets to.
eof-timeout-ms	1	[DEPRECATED] This option has no effect.

Scheduler tool options

The vkconfig script's scheduler tool lets you configure schedulers that continuously loads data from Kafka into Vertica. Use the scheduler tool to create, update, or delete a scheduler, defined by [config-schema](#) . If you do not specify a scheduler, commands apply to the default stream_config scheduler.

Syntax

```
vkconfig scheduler {--create | --read | --update | --drop} other_options...
```

--create

Creates a new scheduler. Cannot be used with [--delete](#) , [--read](#) , or [--update](#) .

--read

Outputs the current setting of the scheduler in JSON format. Cannot be used with [--create](#) , [--delete](#) , or [--update](#) .

--update

Updates the settings of the scheduler. Cannot be used with [--create](#) , [--delete](#) , or [--read](#) .

--drop

Drops the scheduler's schema. Dropping its schema deletes the scheduler. After you drop the scheduler's schema, you cannot recover it.

--add-operator *user_name*

Grants a Vertica user account or role access to use and alter the scheduler. Requires the [--update](#) shared utility option.

--auto-sync {TRUE|FALSE}

When TRUE, Vertica automatically synchronizes scheduler source information at the interval specified in [--config-refresh](#) .

For details about what the scheduler synchronizes at each interval, see the "Validating Schedulers" and "Synchronizing Schedulers" sections in [Automatically consume data from Kafka with a scheduler](#) .

Default: TRUE

--config-refresh *HH:MM:SS*

The interval of time that the scheduler runs before synchronizing its settings and updating its cached metadata (such as changes made by using the [--update](#) option).

Default: 00:05:00

--consumer-group-id *id_name*

The name of the Kafka consumer group to which Vertica reports its progress consuming messages. Set this value to disable progress reports to a Kafka consumer group. For details, see [Monitoring Vertica message consumption with consumer groups](#) .

Default: *vertica_database-name*

--dump

When you use this option along with the `--read` option, `vkconfig` outputs the Vertica query it would use to retrieve the data, rather than outputting the data itself. This option is useful if you want to access the data from within Vertica without having to go through `vkconfig`. This option has no effect if not used with `--read`.

--eof-timeout-ms *number of milliseconds*

If a COPY command does not receive any messages within the `eof-timeout-ms` interval, Vertica responds by ending that COPY statement.
