Management Console security

The Management Console (MC) manages multiple Vertica clusters, all of which might have different levels and types of security, such as user names and passwords and LDAP authentication. You can also manage MC users who have varying levels of access across these components.

Open authorization and SSL

Management Console (MC) uses a combination of OAuth (Open Authorization), Secure Socket Layer (SSL), and locally-encrypted passwords to secure HTTPS requests between a user's browser and MC, and between MC and the [agents](#). Authentication occurs through MC and between agents within the cluster. Agents also authenticate and authorize jobs.

The MC configuration process sets up SSL automatically, but you must have the openssl package installed on your Linux environment first.

See the following topics for more information:

- [TLS protocol](#)
- [Generating certificates and keys for MC](#)
- [Importing a new certificate to MC](#)

User authentication and access

MC provides two user authentication methods, LDAP or MC. You can use only one method at a time. For example, if you chose LDAP, all MC users will be authenticated against your organization's LDAP server.

You set up LDAP authentication up through MC Settings > Authentication on the MC interface.

Note

MC uses LDAP data for authentication purposes only. It does not modify user information in the LDAP repository.

The MC authentication method stores MC user information internally and encrypts passwords. These MC users are not system (Linux) users. They are accounts that have access to MC and, optionally, to one or more MC-managed Vertica databases through the MC interface.

Management Console also has rules for what users can see when they sign in to MC from a client browser. These rules are governed by access levels, each of which is made up of a set of roles.

- [Users, roles, and privileges in MC](#)
- [User administration in MC](#)
- [User administration in MC](#)

Determining the TLS mode of a Vertica database

When you configure Vertica for TLS through the Management Console, you must configure the security mode to match what the Vertica database is configured to require: server mode or mutual mode.

To determine the TLS mode for existing sessions, query the [SESSIONS](#) system table:

```
=> SELECT session_id, user_name, ssl_state FROM sessions;
  session_id      | user_name | ssl_state
-----+-----+-----
v_vmart_node0001-333611:0x1ab | dbadmin  | mutual
```

To determine the Vertica database's client-server TLS configuration, query the [TLS_CONFIGURATIONS](#) system table for the "server":

```
=> SELECT name, certificate, ca_certificates, mode FROM tls_configurations WHERE name = 'server';
 name | certificate | ca_certificates | mode
-----+-----+-----
server | server_cert | ca_cert,ica_cert | VERIFY_CA
(1 row)
```

The "mode" can be one of the following, in ascending security:

- **DISABLE** : Disables TLS. All other options for this parameter enable TLS.
- **ENABLE** : Enables TLS. Vertica does not check client certificates.
- **TRY_VERIFY** : Establishes a TLS connection if one of the following is true:
 - the other host presents a valid certificate
 - the other host doesn't present a certificate

If the other host presents an invalid certificate, the connection will use plaintext.

- **VERIFY_CA** : Connection succeeds if Vertica verifies that the other host's certificate is from a trusted CA. If the other host does not present a certificate, the connection uses plaintext.

- **VERIFY_FULL** : Connection succeeds if Vertica verifies that the other host's certificate is from a trusted CA and the certificate's **cn** (Common Name) or **subjectAltName** attribute matches the hostname or IP address of the other host.

Note that for client certificates, **cn** is used for the username, so **subjectAltName** must match the hostname or IP address of the other host.

Mutual mode corresponds to **TRY_VERIFY** or higher, which indicates that Vertica is in mutual mode. In mutual mode, Vertica sends its server certificate to the client for verification, and uses the CA certificates (in this case, "ca_cert" and "ica_cert") to verify client certificates.

In contrast, a server mode configuration (which doesn't verify client certificates) might have the following TLS configuration instead:

```
=> SELECT name, certificate, ca_certificates, mode FROM tls_configurations WHERE name = 'server';
 name | certificate | ca_certificates | mode
-----+-----+-----+-----
server | server_cert |                 | ENABLE
(1 row)
```

Configuring TLS while importing a database on MC

To configure TLS as you are importing an existing Vertica database on MC:

1. Follow the steps in [Importing an existing database into MC](#).
2. In the **Import Vertica** window, select the database and click the **Use TLS** checkbox.
3. Click **Configure TLS and Import DB** to launch and complete the Certificates wizard.

MC certificates wizard

The MC Certificates wizard lets you configure a CA certificate for the Vertica database server and client certificates for MC to allow secure TLS communication over the JDBC connections between MC and the Vertica database server. Each screen presents options. When you select an option, the wizard displays additional options and details.

1. The first wizard screen provides helpful overview information. Read it, and click **Configure TLS Certificates** to continue.
2. On the **Configure CA Certificates** screen, configure a CA certificate (public key) to add to MC. MC uses this trusted certificate to verify the server's identity during TLS communications over JDBC connections between MC and the Vertica database server.

Complete one of these options:

- **Upload a new CA certificate** Browse and select the certificate file and enter an alias for this certificate
 - To add another CA certificate, click **Add More CA Certificates**.
 - Continue adding additional CA certificates until you are finished.
 - **Choose a certificate alias from previously uploaded certificates** Select the alias for the previously uploaded CA certificate you wish to configure for the current database.
3. When you are done adding CA certificates, click **Next**.
 4. The **Configure Client Certificate** screen displays the check box **Add Client Certificate and Private Key for Mutual Mode TLS Connection**.
 5. If the database is configured for [server mode](#), you do not need a client certificate or key.
 - Leave the **Add Client Certificate** check box *un* checked and click **Review**.
 - Skip to step 10.
 6. If the database is configured for [mutual mode](#):
 - Click the **Add Client Certificate** check box.
 - Select one of the options below.
 - **Upload Client Certificate and Private Key files on MC** (shown above.) MC uses its https connection from the browser to MC's host to upload the files.
 - To add an additional client certificate and create a certificate chain, click **Add Certificate to Chain**. MC reinitializes the Client Certificate file field so you can add another certificate. After you add the last certificate path, click **Next**.
 - To upload an existing certificate chain file, click **Browse** next to the Upload Client Certificate/Certificate chain file field, select the file, and click **Open**.
 - **Manually upload client Certificate and Private Key on MC host and provide paths** Avoids sending the encrypted certificate and private key files over an https connection. To add an additional path for a client certificate and create a certificate chain, click **Add More Certificate Paths**. MC reinitializes the path field so you can add another path. After you add the last certificate path, click **Next**.
 - **Choose Client Certificate and Private Key alias of previously uploaded keypair to use for this database.** (To use existing certificate and key files.)
 7. Complete the detail fields for the client certificate and private key option you have chosen above, then click **Next**.
 8. The Apply TLS configuration to MC users mapped to database window allows you to configure the client certificate-key pair you have just entered, for use by multiple MC users.

Note

All the MC users you select must be mapped to the same user id on the Vertica database server.

9. Click **Review**. The wizard displays a review window with the TLS options you have configured.
10. Select one of these options:
 - To modify your TLS choices, click **Back**.
 - To confirm your choices:
 - If you are importing a database, click **Configure TLS and Import DB**.
 - If you are configuring TLS for a database already imported to MC, click **Configure TLS for DB**.
 - Click **Close** to complete the wizard.
 - To close the wizard without importing the database and without setting up TLS configuration, click **Cancel**.

MC certificates wizard

The MC Certificates wizard lets you configure a CA certificate for the Vertica database server and client certificates for MC to allow secure TLS communication over the JDBC connections between MC and the Vertica database server. Each screen presents options. When you select an option, the wizard displays additional options and details.

1. The first wizard screen provides helpful overview information. Read it, and click **Configure TLS Certificates** to continue.
2. On the **Configure CA Certificates** screen, configure a CA certificate (public key) to add to MC. MC uses this trusted certificate to verify the server's identity during TLS communications over JDBC connections between MC and the Vertica database server.

Complete one of these options:

- **Upload a new CA certificate** Browse and select the certificate file and enter an alias for this certificate
 - To add another CA certificate, click **Add More CA Certificates**.
 - Continue adding additional CA certificates until you are finished.
 - **Choose a certificate alias from previously uploaded certificates** Select the alias for the previously uploaded CA certificate you wish to configure for the current database.
3. When you are done adding CA certificates, click **Next**.
 4. The **Configure Client Certificate** screen displays the check box **Add Client Certificate and Private Key for Mutual Mode TLS Connection**.
 5. If the database is configured for [server mode](#), you do not need a client certificate or key.
 - Leave the **Add Client Certificate** check box *un* checked and click **Review**.
 - Skip to step 10.
 6. If the database is configured for [mutual mode](#):
 - Click the **Add Client Certificate** check box.
 - Select one of the options below.
 - **Upload Client Certificate and Private Key files on MC** (shown above.) MC uses its https connection from the browser to MC's host to upload the files.)
 - To add an additional client certificate and create a certificate chain, click **Add Certificate to Chain**. MC reinitializes the Client Certificate file field so you can add another certificate. After you add the last certificate path, click **Next**.
 - To upload an existing certificate chain file, click **Browse** next to the Upload Client Certificate/Certificate chain file field, select the file, and click **Open**.
 - **Manually upload client Certificate and Private Key on MC host and provide paths** Avoids sending the encrypted certificate and private key files over an https connection. To add an additional path for a client certificate and create a certificate chain, click **Add More Certificate Paths**. MC reinitializes the path field so you can add another path. After you add the last certificate path, click **Next**.
 - **Choose Client Certificate and Private Key alias of previously uploaded keypair to use for this database.** (To use existing certificate and key files.)
 7. Complete the detail fields for the client certificate and private key option you have chosen above, then click **Next**.
 8. The Apply TLS configuration to MC users mapped to database window allows you to configure the client certificate-key pair you have just entered, for use by multiple MC users.

Note

All the MC users you select must be mapped to the same user id on the Vertica database server.

9. Click **Review**. The wizard displays a review window with the TLS options you have configured.
10. Select one of these options:
 - To modify your TLS choices, click **Back**.
 - To confirm your choices:
 - If you are importing a database, click **Configure TLS and Import DB**.
 - If you are configuring TLS for a database already imported to MC, click **Configure TLS for DB**.
 - Click **Close** to complete the wizard.

- To close the wizard without importing the database and without setting up TLS configuration, click **Cancel**.

Configuring TLS for a monitored database in MC

This procedure describes how to configure TLS for all JDBC connections to a database that is already being monitored in MC. Note that the Vertica database should already be configured with the TLS certificates required for TLS connections.

1. In MC, navigate to **Databases and Clusters > DB-name > Settings** and click the **Security** tab in the left navigation bar.
2. In the **Configure TLS Connection for Database** section, click **Enabled** in the drop-down beside **Use TLS Connection to database**.
3. Click **Configure TLS Connection** to launch and complete the Certificates wizard.

MC certificates wizard

The MC Certificates wizard lets you configure a CA certificate for the Vertica database server and client certificates for MC to allow secure TLS communication over the JDBC connections between MC and the Vertica database server. Each screen presents options. When you select an option, the wizard displays additional options and details.

1. The first wizard screen provides helpful overview information. Read it, and click **Configure TLS Certificates** to continue.
2. On the **Configure CA Certificates** screen, configure a CA certificate (public key) to add to MC. MC uses this trusted certificate to verify the server's identity during TLS communications over JDBC connections between MC and the Vertica database server.

Complete one of these options:

- **Upload a new CA certificate** Browse and select the certificate file and enter an alias for this certificate
 - To add another CA certificate, click **Add More CA Certificates**.
 - Continue adding additional CA certificates until you are finished.
 - **Choose a certificate alias from previously uploaded certificates** Select the alias for the previously uploaded CA certificate you wish to configure for the current database.
3. When you are done adding CA certificates, click **Next**.
 4. The **Configure Client Certificate** screen displays the check box **Add Client Certificate and Private Key for Mutual Mode TLS Connection**.
 5. If the database is configured for [server mode](#), you do not need a client certificate or key.
 - Leave the **Add Client Certificate** check box *un* checked and click **Review**.
 - Skip to step 10.
 6. If the database is configured for [mutual mode](#):
 - Click the **Add Client Certificate** check box.
 - Select one of the options below.
 - **Upload Client Certificate and Private Key files on MC** (shown above.) MC uses its https connection from the browser to MC's host to upload the files.)
 - To add an additional client certificate and create a certificate chain, click **Add Certificate to Chain**. MC reinitializes the Client Certificate file field so you can add another certificate. After you add the last certificate path, click **Next**.
 - To upload an existing certificate chain file, click **Browse** next to the Upload Client Certificate/Certificate chain file field, select the file, and click **Open**.
 - **Manually upload client Certificate and Private Key on MC host and provide paths** Avoids sending the encrypted certificate and private key files over an https connection. To add an additional path for a client certificate and create a certificate chain, click **Add More Certificate Paths**. MC reinitializes the path field so you can add another path. After you add the last certificate path, click **Next**.
 - **Choose Client Certificate and Private Key alias of previously uploaded keypair to use for this database.** (To use existing certificate and key files.)
 7. Complete the detail fields for the client certificate and private key option you have chosen above, then click **Next**.
 8. The Apply TLS configuration to MC users mapped to database window allows you to configure the client certificate-key pair you have just entered, for use by multiple MC users.

Note

All the MC users you select must be mapped to the same user id on the Vertica database server.

9. Click **Review**. The wizard displays a review window with the TLS options you have configured.
10. Select one of these options:
 - To modify your TLS choices, click **Back**.
 - To confirm your choices:
 - If you are importing a database, click **Configure TLS and Import DB**.
 - If you are configuring TLS for a database already imported to MC, click **Configure TLS for DB**.
 - Click **Close** to complete the wizard.
 - To close the wizard without importing the database and without setting up TLS configuration, click **Cancel**.

Configuring mutual TLS for MC users

You can configure TLS for existing MC users who are already mapped to Vertica database user ids. You would do so if you had just configured TLS in mutual mode on a previously unsecured Vertica database, and needed to configure a client certificate and private key for each MC user who accesses that database.

1. In MC, navigate to **MC Settings** and click the **User Management** tab.
2. Select a user from the list and click **Edit**.
3. In the **Add permissions** window:
 - Choose the database for which you want to edit this MC user's security permissions.
 - MC displays the database username to which this MC user is currently mapped.
 - In the **Restrict Access** drop-down, choose **Admin, Associate, IT,** or **User** to specify the privilege level for this user.
 - In the **Use TLS Connection** drop-down, choose **Yes**.
 - Click **Configure TLS for user** to launch and complete the Certificates wizard.

MC certificates wizard

The MC Certificates wizard lets you configure a CA certificate for the Vertica database server and client certificates for MC to allow secure TLS communication over the JDBC connections between MC and the Vertica database server. Each screen presents options. When you select an option, the wizard displays additional options and details.

1. The first wizard screen provides helpful overview information. Read it, and click **Configure TLS Certificates** to continue.
2. On the **Configure CA Certificates** screen, configure a CA certificate (public key) to add to MC. MC uses this trusted certificate to verify the server's identity during TLS communications over JDBC connections between MC and the Vertica database server.

Complete one of these options:

- **Upload a new CA certificate** Browse and select the certificate file and enter an alias for this certificate
 - To add another CA certificate, click **Add More CA Certificates**.
 - Continue adding additional CA certificates until you are finished.
 - **Choose a certificate alias from previously uploaded certificates** Select the alias for the previously uploaded CA certificate you wish to configure for the current database.
3. When you are done adding CA certificates, click **Next**.
 4. The **Configure Client Certificate** screen displays the check box **Add Client Certificate and Private Key for Mutual Mode TLS Connection**.
 5. If the database is configured for [server mode](#), you do not need a client certificate or key.
 - Leave the **Add Client Certificate** check box *un* checked and click **Review**.
 - Skip to step 10.
 6. If the database is configured for [mutual mode](#):
 - Click the **Add Client Certificate** check box.
 - Select one of the options below.
 - **Upload Client Certificate and Private Key files on MC** (shown above.) MC uses its https connection from the browser to MC's host to upload the files.)
 - To add an additional client certificate and create a certificate chain, click **Add Certificate to Chain**. MC reinitializes the Client Certificate file field so you can add another certificate. After you add the last certificate path, click **Next**.
 - To upload an existing certificate chain file, click **Browse** next to the Upload Client Certificate/Certificate chain file field, select the file, and click **Open**.
 - **Manually upload client Certificate and Private Key on MC host and provide paths** Avoids sending the encrypted certificate and private key files over an https connection. To add an additional path for a client certificate and create a certificate chain, click **Add More Certificate Paths**. MC reinitializes the path field so you can add another path. After you add the last certificate path, click **Next**.
 - **Choose Client Certificate and Private Key alias of previously uploaded keypair to use for this database.** (To use existing certificate and key files.)
 7. Complete the detail fields for the client certificate and private key option you have chosen above, then click **Next**.
 8. The Apply TLS configuration to MC users mapped to database window allows you to configure the client certificate-key pair you have just entered, for use by multiple MC users.

Note

All the MC users you select must be mapped to the same user id on the Vertica database server.

9. Click **Review**. The wizard displays a review window with the TLS options you have configured.
10. Select one of these options:
 - To modify your TLS choices, click **Back**.
 - To confirm your choices:
 - If you are importing a database, click **Configure TLS and Import DB**.

- If you are configuring TLS for a database already imported to MC, click **Configure TLS for DB**.
- Click **Close** to complete the wizard.
- To close the wizard without importing the database and without setting up TLS configuration, click **Cancel**.

Updating TLS security for MC connections

Maintaining TLS security for MC JDBC connections to a Vertica database is an ongoing process. Initially, you as the MC administrator must configure the appropriate certificates and keys. As time passes, certificates expire or otherwise become invalid. To maintain TLS security in MC, you must configure new certificates to replace any that are about to expire.

If any of the certificates that secure an MC connection to a Vertica database changes or expires, the MC administrator must update the TLS configuration for that database on MC to ensure that unexpired certificates are available so that connections can succeed.

- To update the certificates, simply configure new certificates for the connection between MC and that Vertica database.
- To configure new certificates for a database monitored in MC, see [Configuring TLS for a monitored database in MC](#).
- To configure new client certificates for an MCC user, see [Configuring mutual TLS for MC users](#).
- To replace an expiring or invalid certificate for a database or client, see [Updating a TLS certificate in MC](#).

MC flags the current certificate for a given connection with a "use me" bit. This bit is set only for the current certificate. When you configure a new certificate for a given connection, the new certificate is marked current, and the previous certificate (although still present in the trust store or keystore) is no longer marked as the current certificate.

Enabling or disabling TLS for a database in MC

To enable TLS for all JDBC connections from MC to a Vertica database, configure the certificate and key appropriate for that connection. See:

- [Configuring TLS while importing a database on MC](#)
- [Configuring TLS for a monitored database in MC](#)
- [Configuring mutual TLS for MC users](#)

Disabling a TLS connection

Under some conditions, you as the system administrator might need to disable TLS for JDBC connections from MC to a Vertica database. Here are some examples:

- The TLS certificates are expired and you have not yet obtained new certificates.
- The TLS certificates and keys are revoked and the user does not have new certificates and keys, but you still want to allow that user to connect from MC to the database to show monitoring information and run queries.

To disable TLS for connecting to a Vertica database:

1. In MC, navigate to **Home > Databases and Clusters > DatabaseName > Settings**.
2. Click the **Security** tab in the left navigation bar.
3. In the **Use TLS Connection to database** drop-down, choose **Disabled**.

Note

To reenable TLS for a database connection after you disable it, you must reconfigure the necessary certificates.

Disabling TLS for a database removes the configuration that tells MC to use the current certificates and keys for a given database, for all users. If it is a mutual mode TLS connection and each user had a separate client certificate and private key configured for that database, to re-enable TLS you must reconfigure the certificate and key for each user individually, for that database.

Re-enabling a disabled TLS connection

1. In MC, navigate to **Home > Databases and Clusters > DatabaseName > Settings**.
2. Click the **Security** tab in the left navigation bar.
3. In the **Use TLS Connection to database** drop-down, choose **Enabled**.
4. MC displays **Configure MC to use secured connection to query Vertica database or modify existing configuration**.
5. To finish re-enabling TLS, click **Configure TLS Connection** to launch the Certificates Wizard.
6. Complete the [MC certificates wizard](#).

Adding TLS certificates in MC

You can add one or more certificates to MC for later use, without immediately associating the certificates with a database. Adding certificates ahead of time makes it easier to configure security for a database or for one or more MC users, because you can just choose a CA or client certificate from a list rather than having to add it to MC during the configuration steps.

Adding CA certificates in MC

To add one or more CA certificates in MC:

1. From the MC home page, navigate to **MC Settings > SSL/TLS Certificates** .
2. Under Manage TLS Certificates for Database Connection, click **Add New CA Certificate** .
3. In the Add new CA certificates for TLS connection window, enter an alias for the certificate, to make it easier to refer to later.
4. Click **Browse** to locate the certificate file you want to add. MC opens an Explorer window.
5. Select the file you want to upload, and click **Open** .

Note

Make sure the certificate file is unexpired, and is not protected by a password.

6. To add just this one certificate, click **Add New CA** . MC adds the certificate to its list.
7. To add additional CA certificates, click **Add More CA Certificates** . MC adds the certificate to a list, and clears the fields so you can enter the next CA certificate.
8. Repeat the process until you have entered the last certificate you want to add.
9. Click **Add New CA** to add all the CA certificates in the list to the MC:

Adding client certificates and keys in MC

You can add one or more client certificate and private key pairs to MC. In each pair, you can add either a single certificate, a preexisting certificate chain, or a series of client certificates that MC uses to create a new certificate chain.

To add one or more client certificates with their private key files to MC for later use:

1. Navigate to **Home > MC Settings > SSL/TLS Certificates**.
2. Under Manage TLS Certificates for Database Connection, click **Add New Client Certificate** . MC displays the Add new Client Certificate and Private Key for TLS Connection screen.

Note

When you add a client certificate to MC, you always add it with its private key file. The client certificate and its key are a *key pair* .

3. Click one of these file upload options:
 - **Upload Client Certificate and Private Key for TLS Connection** . With this option, you paste a certificate and key into browser fields. MC posts the certificate and key from your browser to the MC server via an https connection over the network, secured with TLS/SSL.
 - **Manually upload Client Certificate and Private Key on MC host and provide paths** . Sending the certificates from your browser to the MC server across an https network connection may not be your preference. If so, you can use this option to specify the paths on the MC server host where you have manually uploaded the client certificate and private key files, instead. The URL of your MC browser shows the IP address of the MC host. Using this option, you must manually handle the transfer of the certificate and the key files to the server.
4. To provide a single client certificate and private key with either input option:
 - Enter a recognizable alias for the key pair.
 - Browse and select the private key file or provide the path.
 - Browse and select the client certificate file or provide the path.
 - Click **Add New Client Certificate**.
 - MC adds the key pair to its list.
5. To upload several certificates and private keys and create a certificate chain:
 - Enter an alias for the key pair.
 - Browse and select the private key file or provide the path.
 - Browse and select the client certificate file or provide the path.
 - Click **Add Certificate to Chain** (or **Add More Certificate Paths**).
 - Repeat the process until you have added the last certificate and key for this certificate chain.
 - Click **Add New Client Certificate**.
 - MC adds the resulting certificate chain to its list.

Adding a new certificate for the browser connection

You can view the existing TLS certificate for the browser connection to the MC server, or add a new certificate to replace it.

To view or replace the current SSL/TLS certificate that MC uses for the user's browser's HTTPS connection to the MC server:

1. From the MC home page, navigate to **MC Settings > SSL/TLS Certificates**.

The top pane displays the current certificate for the browser connection to the MC server, including the certificate's expiration date:

Current SSL certificate information for Browser connection to MC Server

Issued To		Issued By		Validity Period	
Common Name (CN)	Vertica	Common Name (CN)	Vertica	Issued On	2018-02-12
Organization (O)	Vertica	Organization (O)	Vertica	Expires On	2028-02-10
Organizational Unit (OU)	Vertica	Organizational Unit (OU)	Vertica		

Upload a new SSL certificate

2. To replace the current certificate, click **Browse** next to the **Upload a new SSL certificate** field.

MC opens an explorer window.

3. Select the certificate file you wish to upload and click **Open**. The certificate file must be in PEM (Privacy-enhanced Email Message) format. MC replaces the prior certificate with the new certificate.

Managing TLS certificates in MC

MC maintains a secure list containing all the CA certificates, and the client certificates or certificate chains and their corresponding key files, that you have uploaded into MC.

To manage the certificates already uploaded to MC, navigate to **Home > MC Settings > SSL/TLS Certificates**. This screen controls the TLS security settings for all of MC.

The top pane displays information about the current TLS certificate used to secure the user's browser connection to the MC server. You can add a new certificate to replace it. See .

Current SSL certificate information for Browser connection to MC Server

Issued To		Issued By		Validity Period	
Common Name (CN)	Vertica	Common Name (CN)	Vertica	Issued On	2018-02-12
Organization (O)	Vertica	Organization (O)	Vertica	Expires On	2028-02-10
Organizational Unit (OU)	Vertica	Organizational Unit (OU)	Vertica		

Upload a new SSL certificate

The middle and lower panes allow you to add and remove CA and client certificates in MC.

Manage TLS Certificates for Database Connection

NOTE: Only certificates that are not associated with a database can be removed

CA Certificates

Select (All)	Certificate Alias ^	Database associated	MC User (Mapped DB User)
<input type="checkbox"/>	ca-cert-1		
<input type="checkbox"/>	ca-cert-2		
<input type="checkbox"/>	db_ca_921	secureDB	bob (uidbadadmin) , bhavik (uidbadadmin) , uidbadadmin

Client Certificates

Select (All)	Certificate Alias ^	Database associated	MC User (Mapped DB User)
<input type="checkbox"/>	cert_pair_alice		
<input type="checkbox"/>	client-cert-chain	secureDB	bob (uidbadadmin) , bhavik (uidbadadmin) , uidbadadmin (uidbadadmin) , elizabeth (uidbadadmin)

You can perform the following tasks to manage your TLS certificates and keys in MC.

- [Adding TLS certificates in MC](#)
- [Removing TLS certificates from MC](#)

For the security settings for a specific database, open the database in MC and navigate to **Home > Databases and Clusters > DatabaseName > Settings** and click the **Security** tab in the left navigation bar.

Updating a TLS certificate in MC

When a TLS certificate is about to expire, has already expired, or otherwise becomes unusable, it needs to be updated.

This is the method for updating a certificate:

1. In MC, add the new certificate that will replace the expiring or invalid certificate. See [Adding TLS certificates in MC](#).

Note

You can add and configure the new certificate for the database or user whose existing certificate is or will soon be invalid, as a single step, or two steps. Configuring the new certificate for the database dissociates the previously configured certificate from that database. See [Connecting securely from MC to a Vertica database](#).

2. After the old certificate has been disassociated from all databases and users, you can remove it from the MC. See [Removing TLS certificates from MC](#).

Removing TLS certificates from MC

In some cases, it may be appropriate to disable TLS for a database in MC. Disabling TLS for the database disassociates all the certificates configured for that database. For more information, see [Enabling or disabling TLS for a database in MC](#).

Disassociating a certificate from a database in MC

Before you can remove a certificate from MC, you must be sure the certificate is not associated with (being used by) any databases. The MC administrator can disassociate a certificate from a database in MC using either of these methods:

Configuring a new certificate on the database in MC

When you configure a new certificate to serve a specific purpose on a database in MC, the new certificate replaces the old certificate. The newly configured certificate is now associated with the database, and the old certificate is no longer associated and can be removed.

Navigate to **Databases and Clusters > dbName > Database Settings > Configure TLS**.

For details, see [Configuring TLS for a monitored database in MC](#)

Removing the TLS configuration on the database

You can remove one or more TLS certificates from the MC, provided the certificates are not associated with a database. To remove a certificate:

1. From the MC home page, navigate to **MC Settings > SSL/TLS Certificates**.
2. In the **Manage TLS Certificates for Database Connection** section, locate the row or rows for one or more CA or client certificates you want to remove. This example shows only the **CA Certificates** pane:

Manage TLS Certificates for Database Connection

NOTE: Only certificates that are not associated with a database can be removed.

CA Certificates

Select (All)	Certificate Alias	Database associated	MC User
<input type="checkbox"/>	ca-cert-db	Vdb_secure	uidbadmi (vertica_)
<input checked="" type="checkbox"/>	CA_cert_02		
<input checked="" type="checkbox"/>	CA_cert_01		

Remove Selected

3. If the **Database associated** field is empty for that certificate, you can click to select the certificate for removal, and click **Remove Selected**. In the illustration above, CA_cert_02 and CA_cert_01 are selected for removal.

Note

If you remove one client certificate that is part of a certificate chain, MC removes the entire certificate chain.

MC icons display database TLS status

MC displays an icon at top left of the database in the Database and Cluster/Infrastructure view, that shows the current TLS status of the database. These same icons appear in the breadcrumbs to the left of the database name, to show the current TLS security status of the database:

Icon	Description
 DB_145 10.20.80.145 Type:Database Status:Up	No icon. The database is not configured to use TLS, and MC is not configured to connect to the database using TLS, either. When neither side has TLS configured, all connections are open and unsecured.
 DB_143 10.20.80.143 Type:Database Status:Up	Gray lock icon. TLS is configured on this database and also in MC.
 MCStorage.. 10.20.80.148 Type:Database Status:Up	Gray lock icon with orange alert. Database is configured to use TLS but MC is not configured to use a TLS connection. An internal MC job checks the status of MC's connection.
 DB_147 10.20.80.147 Type:Database Status:Up	Red lock with red X. Both the database and MC are configured for TLS, but MC is not able to connect using TLS.

Bulk-configure a group of MC users for TLS

You as the MC administrator can create multiple MC users and map them all to the same database user id on the Vertica database server side. You map the users in MC when you create them. For details, see [User administration in MC](#).

You can then configure all the MC users that are mapped to a single Vertica database user id, to use the same client certificate or certificate chain and private key in MC, in a single bulk configuration process:

1. Navigate to **MC Home > Databases and Clusters > dbName> Settings > Security**.
2. Click **Configure TLS Connection** to launch the MC certificates wizard.
3. Complete steps 1 through 3 in the wizard to configure a CA certificate and the client certificate or certificate chain and key that you want to use for multiple MC users. For details, see [MC certificates wizard](#).
4. After you complete these steps, the wizard displays the **Apply TLS configuration to MC users mapped to database** page as step 4 in the left wizard pane.
5. To apply the same CA certificate, client certificate and key you just configured to one or more additional users, click the check boxes for those users.

Note

All the users you select must be mapped to the same Vertica database user id.

6. To complete the configuration, click Review. MC displays a confirmation screen:
7. To complete the configuration of this CA certificate for the database and this client certificate/key pair for the selected MC users, click **Configure TLS for DB**.
8. MC confirms that the action was a success. Click **Close** to close the Certificate wizard.

Upgrading Management Console manually

If you installed MC manually, follow the procedure below to upgrade MC.

If you installed MC automatically on AWS resources, see [Upgrading MC automatically on AWS](#).

Backing up MC before you upgrade

1. Log in as root or a user with sudo privileges on the server where MC is already installed.
2. Open a terminal window and shut down the MC process:

```
# /etc/init.d/vertica-console stop
```

For versions of Red Hat 7/CentOS 7 and above, use:

```
# systemctl stop vertica-console
```

3. Back up MC to preserve configuration metadata.

Important

A full backup is required in order to restore MC to its previous state. Restoring MC is essential if the upgrade fails, or you decide to revert to the previous version of Vertica. For details, see [Backing up MC](#).

4. Stop the database if MC was installed on an Ubuntu or Debian platform.

Extended monitoring upgrade recommendations

If you use [Extended monitoring](#) to monitor a database with MC, Vertica recommends the following upgrade procedure to avoid data loss.

1. Log in to MC as an administrator.
2. To stop the monitored database, navigate to the Existing Infrastructure > Databases and Clusters page, select the monitored database and click **Stop**.
3. On MC Settings > MC Storage DB Setup, click **Disable Streaming** to stop the storage database's collection of monitoring data.
4. To stop the storage database, navigate to the Existing Infrastructure > Databases and Clusters page, select the monitored database and click **Stop**.
5. Upgrade MC and Vertica according to Upgrade MC and [Upgrading Vertica](#) instructions.
6. To start the storage database, navigate to the Existing Infrastructure > Databases and Clusters page, select the monitored database and click **Start**.
7. Start the monitored database.
8. On MC Settings > MC Storage DB Setup, click **Enable Streaming** to enable collection of monitoring data.

Important

To avoid data loss, enable streaming soon after starting your monitored database. While your storage database is down and streaming is disabled, the Kafka server can retain data from your running monitored database for a limited amount of time. Data loss occurs when the data exceeds the Kafka retention policy's log size or retention time limits.

Upgrading MC

Note

After you upgrade, you can authenticate users to the MC with a federated server or your corporate identity provider. In addition, you are prompted to provide the following information:

- A new password.
- If your user profile does not have an email address, you must enter one immediately after accepting the end-user license agreement (EULA).

1. Download the MC package from the [Vertica website](#) :

```
vertica-console-current-version.Linux-distro)
```

Save the package to a location on the target server, such as `/tmp`.

2. On the target server, log in as root or a user with sudo privileges.
3. Change to the directory where you saved the MC package.
4. Install MC using your local Linux distribution package management system—rpm, yum, zypper, apt, dpkg. For example:

Red Hat 8

```
# rpm -Uvh vertica-console-current-version.x86_64.rpm
```

Debian and Ubuntu

```
# dpkg -i vertica-console-current-version.deb
```

5. If you stopped the database before upgrading MC, restart the database.
As the root user, use the following command:

```
/etc/init.d/verticad start
```

For versions of Red Hat 8/CentOS 8 and above, run:

```
# systemctl start verticad
```

6. Open a browser and enter the URL of the MC installation, one of the following:

◦ IP address:

```
https://ip-address:mc-port/
```

◦ Server host name:

```
https://hostname:mc-port/
```

By default, *mc-port* is 5450.

If MC was not previously configured, the Configuration Wizard dialog box appears. Configuration steps are described in [Configuring MC](#).

If MC was previously configured, Vertica prompts you to accept the end-user license agreement (EULA) when you first log in to MC after the upgrade.

Additionally, you can choose to provide Vertica with analytic information about your MC usage. For details, see [Management Console settings](#).

Upgrading MC automatically on AWS

If you automatically installed Management Console (MC) version 9.1.1 or later on AWS resources, you can automatically upgrade it from the MC interface using the Upgrade wizard.

This process provisions a new Management Console instance and copies any current MC configuration data to the new MC. All MC settings, users, and monitored clusters will be transferred.

After upgrading, you can terminate the previous Management Console instance.

In addition, when you revive an Eon Mode database through the upgraded Management Console, that database will also be automatically upgraded to the same Vertica version as MC.

Upgrade MC automatically

Automatic upgrade is only available if the existing MC has been installed automatically through the AWS Marketplace.

1. From the MC home page, select **MC Settings**.
2. From the menu on the left side of the page, select **Upgrade MC**. The Upgrade MC page displays current Management Console information and indicates whether you are using the latest version of MC, or if a newer version is available.
3. Click **Start MC Upgrade** at the bottom of the page (this button is only displayed if a newer version of MC is available). The Upgrade wizard appears.
4. Go through the wizard and enter the following information when prompted:
 - AWS access key ID and AWS secret key (only required if existing MC was not installed using an IAM role)
 - AWS key pair
 - MC version to upgrade to
 - EC2 instance type for new MC host
 - EC2 instance tags (optional)
5. When upgrade is successful, the wizard displays the URL for the upgraded Management Console. Save this URL; this how to access your new MC. It is important to save this URL for future use; after you terminate your previous MC, the new MC URL will *not* be available elsewhere. (The MC URL referenced from the original stack when you created MC will continue to reference the previous MC, not the new MC.)
6. Follow the URL and log into your new MC.
7. To terminate the previous version of MC:
 1. If necessary, disable termination protection for the previous MC instance. You can do so from the AWS console. [See the AWS guide for enabling and disabling instance termination protection](#).
 2. From the AWS console, terminate the instance on which the previous MC resides. [See the AWS guide for how to terminate instances](#).

Note

Do not delete other associated resources for the previous MC. Some of these resources may still be in use by the new MC, or by any clusters that were created using the previous MC.

Next steps

If you plan to upgrade an Eon Mode database from Vertica version 9.1.0 or above to a later version, you can do so automatically by reviving it through a newer version of Management Console. As MC revives the database, it will also upgrade the Eon Mode database to the same Vertica version as the upgraded MC. See [Reviving an Eon Mode database on AWS in MC](#).

Localizing user interface text

You can translate Management Console (MC) user interface (UI) text with language files in the Vertica server. After you translate the UI text, users can select the language from the language selector, a dropdown located to the right of the **Message Center** bell icon in the MC toolbar.

The required language files include the `locales.json` file and the resource bundle, a directory of JSON-formatted files that contain the text strings translated into the target language.

Language files are located in the `/opt/vconsole/temp/webapp/resources/i18n/lang` directory.

locales.json

The `locales.json` file contains an array of JSON objects with a name key and properties, where each object represents a language that the MC supports. For example, the following object represents Mexican Spanish:

```
"es_MX": {
  "code": "es_MX",
  "name": "Spanish - Mexico",
  "country_code": "MX"
}
```

The preceding object provides the following information that you use to translate UI text:

- The object name key is a two- or four-letter country code. In the preceding example, the name key is `es_MX`. The resource bundle name must match this country code, or the MC cannot detect the translation files.
- The MC lists the `name` value in the language selector. If you translated the UI text into Mexican Spanish, the language selector would list **Spanish - Mexico**.

Resource bundle

The resource bundle is a directory in `/opt/vconsole/temp/webapp/resources/i18n/lang` that stores a collection of JSON-formatted files that contain the UI text strings that you can translate. By default, Vertica provides the following resource bundles:

- `en_US` (American English)
- `zh_CN` (Simplified Chinese)

Creating a custom resource bundle

Important
Custom resource bundles are not preserved when you upgrade Management Console versions. Before you upgrade, you must back up your resource files when you back up your Management Console configuration.

For details, see [Upgrading Management Console manually](#).

To create a resource bundle, you must manually create a new directory and copy files from one of the default resource bundles. For example, to create a resource bundle for Mexican Spanish:

1. Navigate to the directory that contains the language files:

```
$ cd /opt/vconsole/temp/webapp/resources/i18n/lang
```

2. Create a new directory named `es_MX`:

```
$ mkdir es_MX
```

Note

If the name of a resource bundle does not exactly match a name key in `locales.json`, the MC cannot detect the translation, and the translated language is not available in the language selector.

3. Copy all files from the default `en_US` resource bundle into the new `es_MX` resource bundle:

```
$ cp en_US/* es_MX
```

Text string file structure

Each JSON file in the resource bundle contains text strings for a specific section of the MC interface. For example, the `homepage.json` file stores text strings for the [Management Console home page](#). Each JSON file represents MC pages and any child UI components that contain text—including subsections, tabs, and buttons—as individual objects. The file nests these pages and child components hierarchically to convey the page structure. For example, the `homepage.json` file uses the following structure:

```
{
  "homepage": {
    ...
  },
  "recentDatabase": {
    ...
  },
  "copyright": {
    ...
  },
  ...
}
```

The object properties represent the UI text as key/value pairs, where the key is the component with UI text, and the value is the text string that the MC displays in the UI.

Translating text

To translate a text string, edit the text string value. For example, to translate the title of the **Recent Databases** section into Spanish, open the `homepage.json` file in a text editor and update `homepage.recentDatabase.title` value:

```
{
  "homepage": {
    ...
  },
  "recentDatabase": {
    "title": "Bases de Datos Recientes",
    ...
  }
}
```

Getting started with MC

Use Management Console to monitor the performance of your Vertica clusters. This tool provides a graphical view of your Vertica database cluster, nodes, network status, and detailed monitoring charts and graphs.

MC allows you to:

- Create, import, and connect to Vertica databases.
- Manage your Vertica database and clusters.
- Receive and view messages regarding the health and performance of your Vertica database and clusters.
- View diagnostics and support information for Management Console.
- Manage application and user settings for Management Console.

MC installation process

To install MC, complete these tasks:

1. Follow the steps listed in [Installing Management Console](#).
2. After you have installed MC, configure it according to the instructions in [Configuring Management Console](#).

In this section

- [Connecting to MC](#)
- [Management Console toolbar and navigation](#)
- [Management Console home page](#)
- [Creating a cluster using MC](#)
- [Monitoring existing infrastructure using MC](#)

Connecting to MC

To connect to Management Console:

1. Open a [supported web browser](#).
2. Enter the IP address or host name of the host on which you installed MC (or any cluster node if you installed Vertica first), followed by the MC port you assigned when you [configured MC](#). For example:

Enter the IP address and port:

https://10.20.30.40:5450/

Enter the host name and port:

https://hostname:5450/

3. When the MC logon dialog appears, enter your MC username and password and click **Log in**.

Note

When MC users log in to the MC interface, MC checks their privileges on Vertica [Data collector](#) (DC) tables on MC-monitored databases. Based on DC table privileges, along with the role assigned the MC user, each user's access to the MC's Overview, Activity and Node details pages could be limited. See [Users, roles, and privileges in MC](#) for more information.

If you do not have an MC username/password, contact your MC administrator.

Managing client connections

Each client session to MC uses a connection from [MaxClientSessions](#), a database configuration parameter. This parameter determines the maximum number of sessions that can run on a single database cluster node. Sometimes multiple MC users, mapped to the same database account, are concurrently monitoring the Overview and Activity pages.

Tip

You can increase the value for [MaxClientSessions](#) on an MC-monitored database to account for extra sessions. See [Managing sessions](#) for details.

Management Console toolbar and navigation

The toolbar and left navigation pane are available in all areas of the Management Console (MC).

Toolbar

The toolbar provides icons for quick access to important MC features:

You can view Message Center notifications, change the MC user interface (UI) text language, access Vertica resources, and access user account options.

Message Center quick view

The Message Center quick view is the bell icon on the left. The number in the red circle slightly above the bell icon indicates the current number of alerts. To view these alerts, select the bell icon to open the following quick view window:

! MCDemoDB	Sep 12 06:59:08	Agent status is DOWN on IP 10.20.41.11
! MCDemoDB	Sep 11 02:49:08	Agent status is DOWN on IP 10.20.41.11
! MCDemoDB	Sep 08 22:24:08	Agent status is DOWN on IP 10.20.41.11
! MCDemoDB	Sep 08 18:49:08	Agent status is DOWN on IP 10.20.41.11
! MCDemoDB	Sep 08 13:24:08	Agent status is DOWN on IP 10.20.41.11

[viewAll](#)

Select **viewAll** to go to the **Message Center**. For additional details, see [Monitoring database messages and alerts with MC](#).

Language selector

The language selector is the globe icon and language description located to the right of the Message Center bell icon. It lets you select the current language that the MC uses for UI text.

To change languages, select the globe icon or language description, and select a language from the dropdown:

By default, the MC displays UI text in **English - United States** . To add new languages, you must configure the MC with a set of language files. For details, see [Localizing user interface text](#) .

User account menu

The user account menu provides quick links to Vertica resources, password management for local users, and a **Log out** option:

For details about managing passwords, see [User authentication in MC](#) .

Navigation pane

The Management Console (MC) left navigation pane provides access to system-level MC options and section-specific options in a single, multi-level component. Each system-level option has section-specific options that display to the right of the selected system-level option.

System-level options

The system-level navigation pane provides access to MC options from any area within the MC:

This pane provides the following options:

- **Databases** : View all databases managed by the MC.
- **MC Settings** : Settings that apply to the MC installation. For details, see [Configuring Management Console](#) .
- **MC Diagnostics** : Access diagnostic information to resolve issues. For details, see [Troubleshooting with MC diagnostics](#) .
- **View infrastructure** : Go to the **Database and Cluster View** page. For details, see [Viewing cluster infrastructure](#) .

To expand or collapse the system-level navigation, select the double arrows located above the options.

Section-specific options

When you select a system-level option, the navigation displays a menu that lists options for the system-level option. For example, the following image shows the options available for the system-level **MC Settings** :

☰	Configuration
⚙️	Monitoring
📜	SSL/TLS Certificates
👤	User Federation
	Identity Providers
	User Management
	Change Password
	Theme
	Data Source
	Email Gateway
	MC Storage DB Setup
	Extended Monitoring

When section-specific options are displayed, the system-level pane collapses. To view the expanded system-level options, hover the cursor over the collapsed pane.

Management Console home page

After you log in to the MC, the [Databases](#) page displays. Your assigned [roles and privileges](#) determine what information you can view and which areas you can access.

The following image is an example of what the [MC SUPER administrator](#) views after login:

The screenshot displays the 'Databases' page in the Vertica Management Console. The page title is 'Databases' and the current database is 'MCDemoDB'. The dashboard includes several key metrics:

- Node State:** 6/6 nodes are running, with a note 'Running since Sep 12, 7:30'.
- Queries:** 97% of queries are completed in the past hour.
- CPU & Memory (Hourly):** A line graph showing resource usage over time.
- Projections:**
 - Total Projections: 60
 - Safe Projections: 60 (indicated by a green checkmark)
 - Uptodate Projections: 60 (indicated by a green checkmark)
 - Unused Projections: 0 (indicated by a red X)

The page also features a 'Create new database' button and a 'Feedback' button. The footer indicates the version is 'Vertica Management Console, v23.4.0 - Build: 23.4.0 - 20230828' and includes a copyright notice for 2007-2023 Open Text.

Databases overview

The **Databases** page displays a dynamic dashboard that describes the health and important statistics for all databases that the MC manages. If you have not yet created or imported a database with the MC, this page lists no databases.

Dashboard refresh

The MC provides dashboard refresh options so you can view the most recent information about your databases:

The image shows a refresh button with the text '19 Sep 2023 10:07:57' and a refresh icon (a circular arrow) followed by a dropdown arrow.

The refresh section consists of the following:

- Timestamp that displays the date and time of the most recent dashboard refresh.
- Manual refresh icon that refreshes the dashboard as needed.
- **Auto Refresh** feature, which is available from the down arrow to the right of the manual refresh icon. You can select the down arrow, then select the **Auto Refresh** box so that the MC refreshes the dashboard every two minutes.

Database actions

You can perform database actions with the dropdown directly below the refresh options. The following image shows the expanded dropdown:

The [Create new database](#) option is always displayed. The dropdown lists the following database actions:

- **Revive Eon Mode database** . For details, see the revive documentation for your [cloud provider](#) .
- [Import database](#) .

Note

Your environment determines the options available in the dropdown. For example, if you deploy only an Enterprise database, the **Revive Eon Mode database** option is not in the list.

Database views

The MC provides information about your databases in detailed or condensed views. To select the view, use the icons to the right of the database actions dropdown:

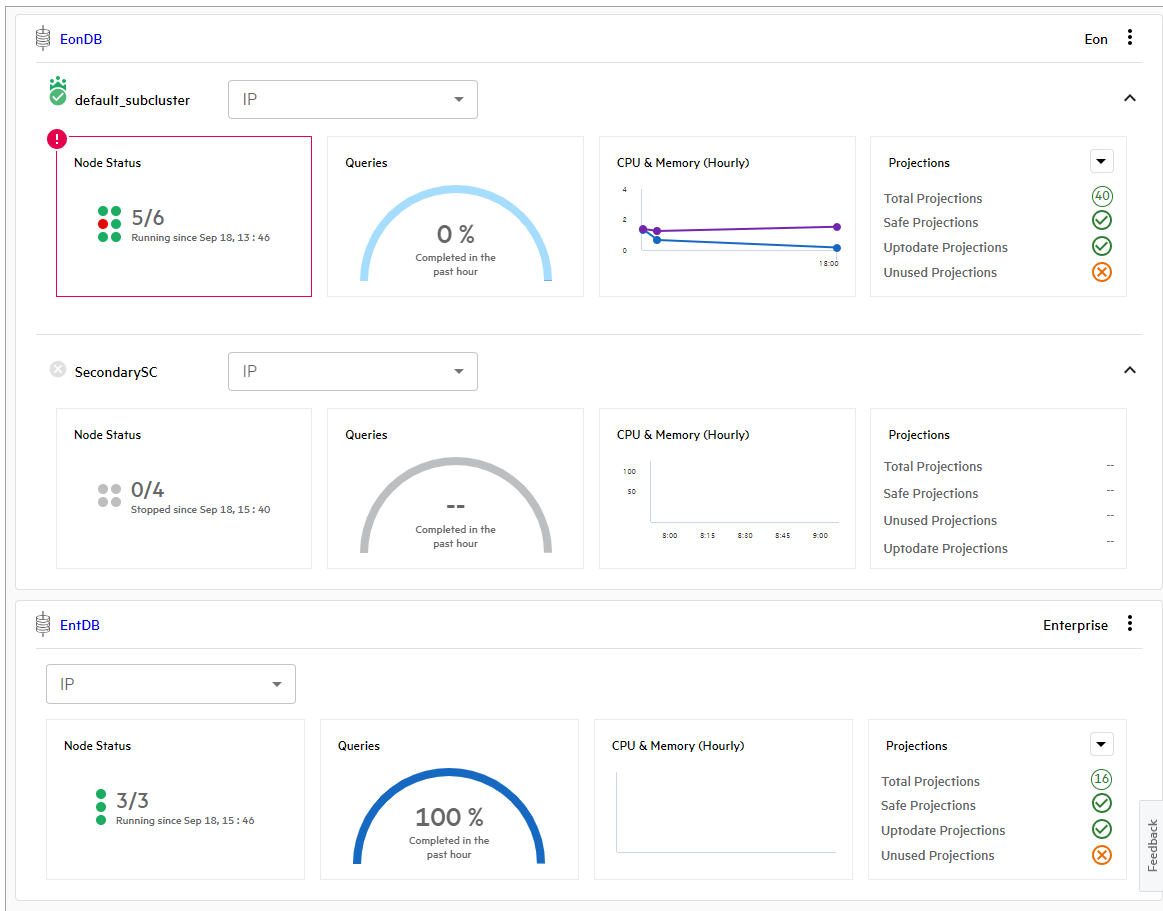

The left button displays the [Condensed view](#) , and the right button displays the [Detailed view](#) . Both views provide the following features:

- If the database contains multiple subclusters, the subclusters are grouped together in a single tile. Within that database tile, there is a row that displays information for each subcluster. The default subcluster is displayed in the top row of each database tile.
- You can select the database name in the top-left of the database tile and go to its Overview page.
- The **IP** dropdown lists the IP addresses of each node in the database. Select an IP address from the list to [monitor the node activity](#) .
- The vertical ellipses in the top-right of each database tile provides the following options:
 - **Manage Database** to go to the [Manage page](#) to view your subcluster layout.
 - **Execute Query** to go the [Query Execution](#) page.

Detailed view

By default, the MC displays database information in the detailed view. The following image shows two databases, and the first database has two subclusters:

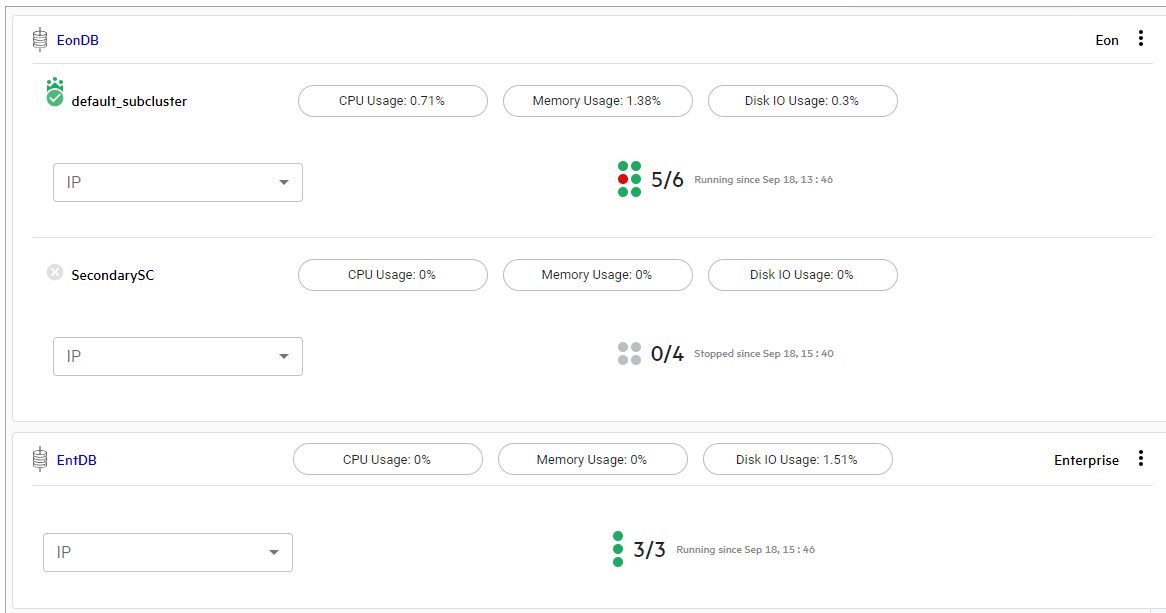

Each subcluster row contains four tiles that display the following information:

- **Node State** : Graphic representation of the node state for the cluster. This tile displays how many nodes are in the UP state and when the database was last started or stopped. Select this tile to go to the database's [Manage page](#) to view the subcluster layout. Each circle represents a database node, and its color represents its state:
 - Green: Node is healthy and UP.
 - Yellow: Critical state and needs attention.
 - Red: Node is DOWN.
 - Gray: Cluster is stopped, and the node is DOWN.
- **Queries** : Query success rate for the past hour. Select this tile to go to the [Query Monitoring](#) page.
- **CPU & Memory (Hourly)** : Database CPU and memory usage for the past hour. Select this tile to go to the [Overview](#) page.
- **Projections** : Details about the database projections. Select the down arrow to view the projections for a specific schema. Select this tile to go to the [Table Utilization](#) page in the **Activity** section.

If there are multiple subclusters in a database, you can toggle the arrow in the top-right of the subcluster row to collapse or expand the subcluster row.

Condensed view

The condensed view displays minimal information about each database and its subclusters. If you have multiple databases, this view lets you view more information on the screen simultaneously. The following image shows two databases, and the first database has two subclusters:

To view a description of the current status of your database, hover your cursor over the subcluster name.

Each subcluster row contains buttons that display important cluster information. You can select one for the following buttons to go to the [Overview](#) page and view detailed information about the cluster:

- **CPU Usage**
- **Memory Usage**
- **Disk IO Usage**

Below the buttons, there is a graphic representation of the node state for the subcluster and a timestamp that describes when the subcluster last started or stopped.

Creating a cluster using MC

Enterprise Mode only

After you install and configure MC, you can use Management Console to install a Vertica cluster on hosts where Vertica software has not been installed. The Cluster Installation assistant lets you specify the hosts you want to include in your Vertica cluster, loads the Vertica software onto the hosts, validates the hosts, and assembles the nodes into a cluster.

Complete the following tasks:

1. [Prepare the hosts](#) - Prepare each host that will become a node in the cluster.
2. [Create a private key file](#) - MC needs password-less SSH to connect to hosts and install Vertica software. Create a private key to enable MC access to the hosts.
3. [Use the MC cluster installation wizard](#) - Use the wizard to install a Vertica cluster on hosts that do not have Vertica software already installed on them.
4. [Validate hosts and create the cluster](#) - Host validation is the process where the MC runs tests against each host in a [proposed cluster](#). You must validate hosts before the MC can install Vertica on each host.

After you successfully create a cluster using MC, see [Create a database on a cluster](#).

In this section

- [Prepare the hosts](#)
- [Create a private key file](#)
- [Use the MC cluster installation wizard](#)
- [Validate hosts and create the cluster](#)
- [Create a database on a cluster](#)

Prepare the hosts

This topic applies only to on-premises installations.

Before you can install a Vertica cluster using the MC, you must prepare each host that will become a node in the cluster. The cluster creation process runs validation tests against each host before it attempts to install the Vertica software. These tests ensure that the host is correctly configured to run Vertica.

Validate the hosts

The validation tests provide:

- Warnings and error messages when they detect a configuration setting that conflicts with the Vertica requirements or any performance issue
- Suggestions for configuration changes when they detect an issue

Note

The validation tests do not automatically fix all problems they encounter.

All hosts must pass validation before the cluster can be created.

If you accepted the default configuration options when installing the OS on your host, then the validation tests will likely return errors, since some of the default options used on Linux systems conflict with Vertica requirements. See [Operating system configuration overview](#) for details on OS settings. To speed up the validation process you can perform the following steps on the prospective hosts before you attempt to validate the hosts. These steps are based on Red Hat Enterprise Linux and CentOS systems, but other supported platforms have similar settings.

Create a private key file

Before you can install a cluster, Management Console must be able to access the hosts on which you plan to install Vertica. MC uses password-less SSH to connect to the hosts and install Vertica software using a private key file.

If you already have a private key file that allows access to all hosts in the potential cluster, you can use it in the cluster creation wizard.

Note

The private key file is required to complete the MC cluster installation wizard.

Create a private key file

1. Log into the server as root or as a user with sudo privileges.
2. Change to your home directory.

```
$ cd ~
```

3. Create an `.ssh` directory if one does not already exist.

```
$ mkdir .ssh
```

4. Generate a passwordless private key/public key pair.

```
$ ssh-keygen -q -t rsa -f ~/.ssh/vid_rsa -N "
```

This command creates two files: `vid_rsa` and `vid_rsa.pub`. The `vid_rsa` file is the private key file that you upload to the MC so that it can access nodes on the cluster and install Vertica. The `vid_rsa.pub` file is copied to all other hosts so that they can be accessed by clients using the `vid_rsa` file.

5. Make your `.ssh` directory readable and writable only by yourself.

```
$ chmod 700 /root/.ssh
```

6. Change to the `.ssh` directory.

```
$ cd ~/.ssh
```

7. Edit `sshd.config` as follows to disable password authentication for root:

```
PermitRootLogin without-password
```

8. Concatenate the public key into to the file `vauthorized_keys2`.

```
$ cat vid_rsa.pub >> vauthorized_keys2
```

9. If the host from which you are creating the public key will also be in the cluster, copy the public key into the local-hosts authorized key file:

```
cat vid_rsa.pub >> authorized_keys
```

10. Make the files in your `.ssh` directory readable and writable only by yourself.

```
$ chmod 600 ~/.ssh/*
```

11. Create the .ssh directory on the other nodes.

```
$ ssh <host> "mkdir /root/.ssh"
```

12. Copy the vauthorized key file to the other nodes.

```
$ scp -r /root/.ssh/vauthorized_keys2 <host>:/root/.ssh/.
```

13. On each node, concatenate the vauthorized_keys2 public key to the authorized_keys file and make the file readable and writable only by the owner.

```
$ ssh <host> "cd /root/.ssh/;cat vauthorized_keys2 >> authorized_keys; chmod 600 /root/.ssh/authorized_keys"
```

14. On each node, remove the vauthorized_keys2 file.

```
$ ssh -i /root/.ssh/vid_rsa <host> "rm /root/.ssh/vauthorized_keys2"
```

15. Copy the vid_rsa file to the workstation from which you will access the MC cluster installation wizard. This file is required to install a cluster from the MC.

A complete example of the commands for creating the public key and allowing access to three hosts from the key is below. The commands are being initiated from the docg01 host, and all hosts will be included in the cluster (docg01 - docg03):

```
ssh docg01
cd ~/.ssh
ssh-keygen -q -t rsa -f ~/.ssh/vid_rsa -N ""
cat vid_rsa.pub > vauthorized_keys2
cat vid_rsa.pub >> authorized_keys
chmod 600 ~/.ssh/*
scp -r /root/.ssh/vauthorized_keys2 docg02:/root/.ssh/
scp -r /root/.ssh/vauthorized_keys2 docg03:/root/.ssh/
ssh docg02 "cd /root/.ssh/;cat vauthorized_keys2 >> authorized_keys; chmod 600 /root/.ssh/authorized_keys"
ssh docg03 "cd /root/.ssh/;cat vauthorized_keys2 >> authorized_keys; chmod 600 /root/.ssh/authorized_keys"
ssh -i /root/.ssh/vid_rsa docg02 "rm /root/.ssh/vauthorized_keys2"
ssh -i /root/.ssh/vid_rsa docg03 "rm /root/.ssh/vauthorized_keys2"
rm ~/.ssh/vauthorized_keys2
```

Use the MC cluster installation wizard

The Cluster Installation Wizard guides you through the steps required to install a Vertica cluster on hosts that do not already have Vertica software installed.

Note

If you are using MC with the Vertica AMI on Amazon Web Services, note that the Create Cluster and Import Cluster options are not supported.

Prerequisites

Before you proceed, make sure you:

- [Installed and configured Management Console](#).
- [Prepared the hosts](#) that you will include in the Vertica database cluster.
- [Created the private key \(pem\) file](#) and copied it to your local machine.
- Obtained a copy of your Vertica license if you are installing the Premium Edition. If you are using the Community Edition, a license key is not required.
- Downloaded the Vertica server RPM (or DEB file).
- Have read/copy permissions on files stored on the local browser host that you will transfer to the host on which MC is installed.

Permissions on files to transfer to MC

On your local workstation, you must have at least read/write privileges on files you'll upload to MC through the Cluster Installation Wizard. These files include the Vertica server package, the license key (if needed), the private key file, and an optional CSV file of IP addresses.

Create a Vertica cluster using MC

1. [Connect](#) to Management Console and log in as an MC administrator.
2. On MC's Home page, click the **Provisioning** task. The Provisioning dialog appears.
3. Click **Create new database**.
4. The Create Cluster wizard opens. Provide the following information:

1. Cluster name—A label for the cluster. Choose a name that is unique within MC. If you do not enter a name here, MC assigns a random unique cluster name. You can edit the name later when you view the cluster on the Infrastructure page. Note that this name is an alias that exists only in MC. If you reimport the cluster, you would need to edit the cluster name again to reestablish this name.
2. Vertica Admin User—The user that is created on each of the nodes when they are installed, typically 'dbadmin'. This user has access to Vertica and is also an OS user on the host.
3. Password for the Vertica Admin User—The password you enter (required) is set for each node when MC installs Vertica.

Note

MC does not support an empty password for the administrative user.

4. Vertica Admin Path—Storage location for catalog files, which defaults to /home/dbadmin unless you specified a different path during MC configuration (or later on MC's Settings page).

Important

The Vertica Admin Path must be the same as the Linux database administrator's home directory. If you specify a path that is not the Linux dbadmin's home directory, MC returns an error.

5. Click **Next** and specify the private key file and host information:
 1. Click **Browse** and navigate to the private key file (vid_rsa) that you created earlier.

Note

You can change the private key file at the beginning of the validation stage by clicking the name of the private key file in the bottom-left corner of the page. However, you cannot change the private key file after validation has begun unless the first host fails validation due to an SSH login error.

2. Include the host IP addresses. You have three options:
 - Specify later* (but include number of nodes). This option allows you to specify the number of nodes, but not the specific IPs. You can specify the specific IPs before you validate hosts.
 - Import IP addresses from local file* . You can specify the hosts in a CSV file using either IP addresses or host names.
 - Enter a range of IP addresses* . You can specify a range of IPs to use for new nodes. For example 192.168.1.10 to 192.168.1.30. The range of IPs must be on the same or contiguous subnets.
6. Click **Next** and select the software and license:
 1. Vertica Software. If one or more Vertica packages have been uploaded, you can select one from the list. Otherwise, select **Upload a new local vertica binary file** and browse to a Vertica server file on your local system.
 2. Vertica License. Click **Browse** and navigate to a local copy of your Vertica license if you are installing the Premium Edition. Community Edition versions require no license key.
7. Click **Next** . The Create cluster page opens. If you did not specify the IP addresses, select each host icon and provide an IP address by entering the IP in the box and clicking **Apply** for each host you add.

You are now ready to [Validate hosts and create the cluster](#).

Validate hosts and create the cluster

Host validation is the process where the MC runs tests against each host in a [proposed cluster](#).

You can validate hosts only after you have completed the cluster installation wizard. You must validate hosts before the MC can install Vertica on each host.

At any time during the validation process, but before you create the cluster, you can add and remove hosts by clicking the appropriate button in the upper left corner of the page on MC. A Create Cluster button appears when all hosts that appear in the node list are validated.

How to validate hosts

To validate one or more hosts:

1. [Connect](#) to Management Console and log in as an MC administrator.
2. On the MC Home page, click the **Databases and Clusters** task.
3. In the list of databases and clusters, select the cluster on which you have recently run the cluster installation wizard (**Creating...** appears under the cluster) and click **View** .
4. Validate one or several hosts:
 - To validate a single host, click the host icon, then click **Validate Host** .

- To validate all hosts at the same time, click **All** in the Node List, then click **Validate Host** .
 - To validate more than one host, but not all of them, Ctrl+click the host numbers in the node list, then click **Validate Host** .
5. Wait while validation proceeds.
- The validation step takes several minutes to complete. The tests run in parallel for each host, so the number of hosts does not necessarily increase the amount of time it takes to validate all the hosts if you validate them at the same time. Hosts validation results in one of three possible states:
- Green check mark—The host is valid and can be included in the cluster.
 - Orange triangle—The host can be added to the cluster, but warnings were generated. Click the tests in the host validation window to see details about the warnings.
 - Red X—The host is not valid. Click the tests in the host validation window that have red X's to see details about the errors. You must correct the errors re-validate or remove the host before MC can create the cluster.
- To remove an invalid host:** Highlight the host icon or the IP address in the Node List and click **Remove Host** .

All hosts must be valid before you can create the cluster. Once all hosts are valid, a **Create Cluster** button appears near the top right corner of the page.

How to create the cluster

1. Click **Create Cluster** to install Vertica on each host and assemble the nodes into a cluster.
The process, done in parallel, takes a few minutes as the software is copied to each host and installed.
2. Wait for the process to complete. When the **Success** dialog opens, you can do one of the following:
 - Optionally create a database on the new cluster at this time by clicking **Create Database**
 - Click **Done** to create the database at a later time

See [Creating a Database on a Cluster](#) for details on creating a database on the new cluster.

Create a database on a cluster

After you use the [MC Cluster Installation Wizard](#) to create a Vertica cluster, you can create a database on that cluster through the MC interface. You can create the database on all cluster nodes or on a subset of nodes.

If a database had been created using the Administration Tools on any of the nodes, MC detects (autodiscovers) that database and displays it on the Manage (Cluster Administration) page so you can import it into the MC interface and begin monitoring it.

MC allows only one database running on a cluster at a time, so you might need to stop a running database before you can create a new one.

The following procedure describes how to create a database on a cluster that you created using the MC [Cluster Installation Wizard](#). To create a database on a cluster that you created by running the `install_vertica` script, see [Creating an Empty Database](#).

Create a database on a cluster

To create a new empty database on a new cluster:

1. If you are already on the **Databases and Clusters** page, skip to the next step. Otherwise:
 1. [Connect](#) to MC and sign in as an MC administrator.
 2. On the Home page, select **View Infrastructure** .
2. If no databases exist on the cluster, continue to the next step. Otherwise:
 1. If a database is running on the cluster on which you want to add a new database, select the database and click **Stop** .
 2. Wait for the running database to have a status of *Stopped* .
3. Click the cluster on which you want to create the new database and click **Create Database** .
4. The Create Database wizard opens. Provide the following information:
 - Database name and password. See [Creating a database name and password](#) for rules.
 - Optionally click **Advanced** to open the advanced settings and change the port, and catalog path, and data path. By default the MC application/web server port is 5450 and paths are `/home/dbadmin` , or whatever you defined for the paths when you ran the cluster creation wizard. Do not use the default agent port 5444 as a new setting for the MC application/web server port. See **MC Settings > Configuration** for port values.
5. Click **Continue** .
6. Select nodes to include in the database.
The Database Configuration window opens with the options you provided and a graphical representation of the nodes appears on the page. By default, all nodes are selected to be part of this database (denoted by a green check mark). You can optionally click each node and clear **Include host in new database** to exclude that node from the database. Excluded nodes are gray. If you change your mind, click the node and select the **Include** check box.
7. Click **Create** in the Database Configuration window to create the database on the nodes.
The creation process takes a few moments and then the database is started and a **Success** message appears.
8. Click **OK** to close the success message.

The Database Manager page opens and displays the database nodes. Nodes not included in the database are gray.

Monitoring existing infrastructure using MC

Use Management Console to monitor the health of your Vertica databases and clusters. Click the **Infrastructure** button on the Home page to see the Databases and Clusters page. Then click the cluster of interest to view the health of the nodes in that cluster and the key information associated with the cluster such as:

- Vertica version
- Number of hosts
- CPU type
- Last updated date
- Node list.

You can also zoom in and out for better view of this page.

On the Databases and Clusters page or the Home page, click the database which you want to monitor, to go to its **Overview** page:

You can perform the following tasks from the Overview page:

- View **Quick Stats** to get instant alerts and information about your cluster's status.
- View **Status Summary** that provides a general overview of the status of your cluster (as shown in preceding figure).
- Analyze **System Health** using a comprehensive summary of your system resource usage and node information, with configurable statistics that allow you to specify acceptable ranges of resource usage.
- Use **Query Synopsis** to monitor system query activity and resource pool usage.

For Eon mode databases, the **Status Summary** and **Query Synopsis** pages allow you to display information for the entire database. If subclusters are defined, you can also display information for a specific subcluster or node, or the nodes not assigned to a subcluster.

Additionally, you can perform the following tasks from the Overview page:

- [Monitoring cluster nodes with MC](#)
- [Monitoring cluster CPU and Memory with MC](#)
- [Monitoring cluster performance with MC](#)

Monitoring system resources

On the main window, you can click the database, and navigate to the **MC Activity** tab to monitor system resources such as:

- [Queries](#)
- [Internal Sessions](#)
- [User Sessions](#)
- [Memory Usage](#)
- [System Bottlenecks](#)
- [User Query Phases](#)
- [Table Treemap](#)
- [Query Monitoring](#)
- [Resource Pool Monitoring](#)

Monitoring node and MC user activity

You can use the **MC Manage** page to monitor node activity. When you click the node you want to investigate, the Node Detail page opens and provides:

- Summary information for the node
- Resources consumed by the node for last three hours

You can also browse and export log-level data from AgentTools and Vertica log files. MC retains a maximum of 2000 log records. See [Monitoring node activity with MC](#) for further details.

Use **MC Diagnostics** tab and navigate to **Audit Log** page to manage MC User activity. See [Monitoring MC user activity using audit log](#).

Monitoring messages in databases managed by MC

You can view critical database related messages from **MC Message Center**. The **MC Message Center** reports on several critical database-related conditions using a color code to indicate the message severity. For further details, see [Monitoring database messages and alerts with MC](#).

You can also search and sort database messages, mark messages read or unread and delete them. You can filter messages by message type, and export messages. For additional information, refer to [Message center](#) and [Exporting MC-managed database messages and logs](#).

Monitoring and configuring resource pools

Use the **MC Activity** page to monitor resource pools. Select the resource pool you want to monitor. MC displays the following charts for the selected pool:

- Resource Usages in Pool
- Memory Usage in Node and Subclusters
- Average Query Execution and Query Time in Pool
- Resource Rejections in Pool

If you are a database administrator, you can click the database you want on the main window. You can then use the **MC Settings** tab to view and edit the resource pool parameters. Only the database administrator can monitor and configure the resource pools in Management Console.

See [Monitoring resource pools with MC](#) for further information.

Users, roles, and privileges in MC

A Management Console (MC) user is separate from a Linux system user or a Vertica server database user. An MC user account exists only within the MC. Each MC user account requires two sets of privileges:

- MC configuration roles that grant access to MC functionality and user administration.
- Database privileges that grant access to a database that is managed by the MC.

Default user

The [MC SUPER administrator](#) account is the only default user, and it is created when you [configure the MC](#). The MC SUPER administrator is the only user that can set up federated servers or identity provider (IDP) user authentication. For additional details about MC SUPER administrator privileges, see [Configuration roles in MC](#).

Authorization

You can control what a user is authorized to access in the MC and what actions a user can perform with their associated databases.

Configuration roles

Each MC configuration role is predefined with a set of privileges that control what Management Console features the user can access. Configuration privileges include the following:

- Modify MC settings
- Create and import Vertica databases
- Restart the MC
- Create a Vertica cluster with MC
- Create and administer user profiles

For details about each role, see [Configuration roles in MC](#).

Database privileges

Database privileges are granted with predefined roles that determine what a user can access and the available actions on a Vertica database that is created by or imported to the MC. Database privileges include the following:

- View the database cluster state
- Access query and session activity
- Monitor database messages
- Read log files
- Replace cluster nodes
- Stop databases

For details about each role, see [Database privileges](#).

Authentication

The Management Console supports multiple ways to authenticate users to the Management Console. The MC supports the following authentication methods:

- **Local** : Users are authenticated internally in the MC.
- **Federated** : Authenticate MC users with a Federation server.
- **Identity Provider (IDP)** : Authenticate MC users with your corporate identity provider.

For details about implementing each authentication method, see [User authentication in MC](#).

In this section

- [Configuration roles in MC](#)
- [Database privileges](#)
- [User authentication in MC](#)
- [User administration in MC](#)

Configuration roles in MC

A configuration role is a predefined role with a set of privileges that determine what users can configure on the Management Console. You grant configuration privileges on **MC Settings > User Management** when you [add or edit](#) a user account.

The following table provides a brief overview of each role:

Role	Description
SUPER	A Linux user account, the MC SUPER administrator is the default superuser that gets created when you configure the MC .
Admin	Full access to all MC functionality and databases managed by MC.
Manager	Access to MC user settings, monitors all databases managed by MC, and non-database MC alerts.
IT	Limited access to MC user settings, monitors all databases managed by MC, MC logs, and non-database MC alerts.
None	No configuration privileges. This user can access one or more databases managed by MC.

Super

The MC SUPER administrator is a Linux user account that is created when you [configure the MC](#). This user account is unique: it cannot be altered or dropped, and you cannot grant the SUPER role to other MC users. The only property you can change for the MC SUPER administrator is the password.

The MC SUPER administrator is a [Local user account](#), so the MC stores its login credentials and profile information internally. This account is different from the [dbadmin account](#) that is created when you install Vertica. The dbadmin account is a Linux account that owns the database catalog and storage locations, and can bypass database authorization rules, such as creating or dropping schemas, roles, and users. The MC SUPER administrator does not have the same privileges as dbadmin.

The MC SUPER administrator has the following privileges:

- Oversee the entire Management Console, including all database clusters managed by the MC.

Note

The MC SUPER administrator inherits the privileges and roles of the user name provided when importing a Vertica database into MC. Vertica recommends that you use the database administrator's credentials when you import a database.

- Create the first MC user account.
- Assign MC configuration roles.
- Grant [database privileges](#) to one or more databases managed by MC.
- Configure federated server and identify provider authentication methods. For details, see [User authentication in MC](#).

On MC-managed Vertica databases, MC SUPER administrator has the same privileges as the [Admin database role](#).

Admin

A user with **Admin** configuration privileges can perform all administrative operations on the Management Console, including configuring and restarting the MC, and adding, editing, and deleting user accounts. An **Admin** has access to all databases that the MC manages and inherits the [database privileges](#) of the user account that sets up a database on the MC.

The **Admin** role grants a user the same configuration privileges as the MC SUPER administrator account, but you can alter and delete user accounts with **Admin** privileges.

Important

There is also an [Admin database role](#) that grants MC database privileges. The two Admin roles are not the same. Because the Admin configuration role inherits all database privileges from the user account that created or imported the database into the MC, you do not need to grant the Admin database role to users with the Admin configuration role.

Manager

Users assigned the **Manager** role can add, edit, and delete users in the MC. The **Manager** role grants full access to the **MC Settings > User Management** tab. Additionally, a **Manager** can view the following:

- On the MC Home page, all databases monitored by MC.
- MC log.
- Non-database MC alerts.

The **Manager** role has similar database privileges to the [IT database privileges role](#).

IT

Users assigned the **IT** role have the following privileges:

- Monitor all MC-managed databases.
- View non-database MC messages, logs, and alerts.
- Disable or enable user access to MC.
- Reset local user passwords.

You can assign **IT** users specific database privileges by mapping them to a user on a server database. The **IT** user inherits the privileges assigned to the mapped server user.

None

The default role for all users on MC is **None**, which does not grant any MC configuration privileges. A common strategy is to assign the **None** role to grant no MC configuration privileges, and then [map the MC user](#) to a Vertica server database user so that they can inherit database privileges from the mapped server user.

Role comparison

You grant the following configuration privileges by MC role:

Privileges	Admin	Manager	IT	None
Configure MC settings: <ul style="list-style-type: none"> • Configure storage locations and ports • Upload new SSL certificates • Manage LDAP authentication • Update Vertica installation • Change MC theme • Map to an external data source 	Yes			
Configure user settings: <ul style="list-style-type: none"> • Add, edit, delete users • Add, change, delete user permissions • Map users to one or more databases 	Yes	Yes		
Configure user settings: <ul style="list-style-type: none"> • Enable or disable user access to MC • Reset user passwords 	Yes	Yes	Yes	
Monitor user activity on MC using audit log	Yes			
Create and manage databases and clusters: <ul style="list-style-type: none"> • Create a new database or import an existing one • Create a new cluster or import an existing one • Remove databases and clusters from MC 	Yes			
Reset MC to its original, preconfigured state	Yes			
Restart Management Console	Yes			
View full list of databases monitored by MC	Yes	Yes	Yes	
View MC log	Yes		Yes	
View non-database MC alerts	Yes	Yes	Yes	Yes

- [Users, roles, and privileges in MC](#)
- [Database privileges](#)
- [User administration in MC](#)
- [Database privileges](#)

Database privileges

You can assign database privileges with a predefined database role. Each role is associated with a set of privileges that determines what a user can access on a database that the MC manages.

You grant database privileges on **MC Settings > User Management** when you [add or edit](#) a user account. You can also map an MC user to a Vertica server database user, which allows the MC user to inherit database privileges from the server user.

The following table provides a brief overview of each role:

Role	Description
------	-------------

Admin	Full access to all databases managed by MC. Actual privileges ADMINs inherit depend on the database user account used to create or import the Vertica database into the MC interface.
Associate	Full access to all databases managed by MC. Cannot start, stop, or drop a database. Actual privileges that Associates receive depend on those defined for the database user account to which the Associate user is mapped.
IT	Can start and stop a database but cannot remove it from the MC interface or drop it.
User	Can view database information through the database Overview and Activities pages but is restricted from viewing more detailed data.

Admin

Admin is the most permissive role. It is a [superuser](#) with full privileges to monitor activity and messages on databases that the MC manages. Other database privileges (such as stop or drop the database) are inherited from its [mapped server user account](#).

There is also an [Admin configuration role](#) that grants configuration privileges for the MC. The two Admin roles are not the same. The Admin MC configuration role can manage all MC users and all databases imported into the UI, but the MC database Admin role has privileges only on the databases you map this user to.

Associate

The Associate role has the same monitoring privileges as an [Admin](#) user—full privileges to monitor MC-managed database activity and messages. Unlike the Admin user, the Associate cannot start, stop, or drop a database. The Associate user inherits database privileges its [mapped server user account](#), including the following:

- Install or audit a license
- Manage database settings
- View Database Designer
- View the database Activity page

IT

The IT role can view most details about a database that the MC manages, including the following:

- Messages (and mark them read/unread)
- Overall database health, activity, and resources
- Cluster and node state
- MC settings

There is also an IT role at the MC configuration access level. The two IT roles are not the same. For additional details, see [Configuration roles in MC](#).

User

The User role has limited database privileges, such as viewing database cluster health, activity, resources, and messages. MC users with the User database role might have higher MC privileges, granted with [configuration roles](#).

Role comparison

The following table summarizes default MC database privileges by role:

Note

Inherited indicates that MC user database privileges depend on the privileges of the [mapped server user account](#).

Privileges	Admin	Associate	IT	User
View database Overview page	Yes	Yes	Yes	Yes
View database messages	Yes	Yes	Yes	Yes
Delete messages and mark read/unread	Yes	Yes	Yes	
Audit and install Vertica licenses	Inherited	Inherited		

View database Activity page: <ul style="list-style-type: none"> • Queries chart • Internal Sessions chart • User Sessions chart • System Bottlenecks chart • User Query Phases chart 	Yes	Inherited	Inherited	Inherited
View database Activity page: <ul style="list-style-type: none"> • Queries chart > Detail page • Table Treemap chart • Query Monitoring chart • Resource Pools Monitoring chart 	Inherited	Inherited		
Start a database	Yes			
Rebalance, stop, or drop databases	Inherited			
View Manage page	Yes	Yes	Yes	Yes
View node details	Yes	Yes	Yes	
Replace, add, or remove nodes	Inherited			
Start/stop a node	Yes			
View database Settings page	Yes	Yes	Yes	
Modify database Settings page	Inherited	Inherited		
View Database Designer	Inherited	Inherited		

Granting database privileges

You can grant database privileges to new and existing users on **MC Settings > User Management** .

Prerequisites

- Determine the [database privileges](#) that you want to grant the new MC user.
- Optional: [Create](#) or [import](#) a database to associate with the new user.
- Optional: [Create a database user account](#) if you want to map a server database user to an MC user account.

Mapping to server users

When you assign MC database privileges, map the MC user account to a Vertica server database user account for the following benefits:

- The MC user inherits database privileges from the database user, so you need to maintain privileges for one user.
- Restrict the MC user from accessing functionality not permitted by the Vertica server database user account privileges.

If there is a conflict between server and MC database privileges, server privileges supersede MC privileges. When the MC user logs in, Vertica compares the MC user database privileges to the privileges assigned to its mapped server user account. Vertica permits the user to perform an operation in MC only when the MC user has both MC and server database privileges for that operation.

Grant a database role

When you grant an MC user a database role, that user inherits the privileges assigned to its mapped server user account.

Note

For maximum access, use the dbadmin username and password.

1. Log in to Management Console as an administrator, and go to **MC Settings > User management** .
2. In the grid, select an MC user and select **Edit** .

3. Verify that **MC configuration permissions** lists the correct [configuration role](#). **None** is the default setting.
4. In **DB access levels**, select **Add** and provide the following information:
 1. **Choose a database**. Select a database from the list databases that you imported or created with the MC.
 2. **Database username**. Enter an existing database username or select the ellipsis [...] button to browse running databases for a list of database users.
 3. **Database password**. Enter the password to the server database user account.
 4. **Restricted access**. Choose a database level. For details, see [Admin](#), [IT](#), or [User](#).
 5. Select **OK**.
 6. If the Vertica database requires TLS, select **Yes** in the **Use TLS Connection**, then select **Configure TLS for user**. MC launches the Certificates wizard to let you configure TLS. For details, see [MC certificates wizard](#).

Note

If TLS/SSL is configured in mutual mode on the Vertica database, each MC user must be configured with an individual client certificate and private key, to log into the database from MC. See [Configuring mutual TLS for MC users](#). If the individual certificate has not been configured, you see an error message. contact your Management Console administrator.

5. Select **Save**.

User authentication in MC

The MC provides authentication options that integrate the MC with your existing corporate authentication workflows. By default, the MC provides [local authentication](#), which stores all user information in the MC. The MC integrates with [Keycloak](#) so you can configure [federated](#) or [identity provider](#) (IDP) authentication with the [MC SUPER administrator](#) account.

Local authentication

Local user authentication is the default authentication method and does not require additional steps after you install and configure the MC. Local user information is stored on an internal database on the MC web server.

You can edit or reset local user passwords in the following locations:

- [Email Gateway](#).
- **MC Settings > Change Password**.
- In the user account menu in the toolbar, select **Change Password**.

Federated server authentication

Federated servers store your organization's user credentials in a single location so you can authenticate user identities across one or more applications. The MC integrates with Keycloak to support LDAP and LDAPS federated server configurations.

The MC can access only usernames in federated servers for authentication purposes—it cannot modify any other federated user information. To edit or reset a user password, contact your organization's federated server administrator.

For additional details about how LDAP and LDAPS federated services work with Vertica and the MC, see [LDAP authentication](#).

Add SSL/TLS certificate

If you authenticate users with LDAPS or StartTLS, you must upload a certificate to the MC to encrypt communications between the MC and the server. If you do not upload a valid certificate, the MC cannot verify the connection:

1. Log in to the Management Console, then go to **MC Settings > SSL/TLS Certificates**.
2. In the **Manage Authentication Certificates** section, select **Add New Certificate**.
3. Browse your filesystem and upload your certificate.
4. Restart the MC.

After the MC restarts, the new certificate takes effect.

Set up a federated server

This section provides guidance about how to connect the MC to a federated server for MC user authentication. Only the [MC SUPER administrator](#) can configure an MC and federated server integration.

The steps to configure a federated server for MC user authentication vary by organization. Refer to the following sources for comprehensive documentation about integrating federated servers:

- [LDAP documentation](#) for protocol details.

- [Keycloak documentation](#) for details about configuring Keycloak.

Note

The steps in this section serve as a guide only—your organization might require different settings and values. The MC provides tooltips for each field, and you can refer to the [Keycloak documentation](#) for details about specific values.

The following steps connect the MC and an [OpenLDAP](#) federated server:

1. Log in to the Management Console, then go to **MC Settings > User Federation** . You are prompted to [add an SSL/TLS certificate](#) . OpenLDAP does not require a certificate, so ignore the prompt and continue.
The **User Federation** screen opens in a new tab.
2. On the **User Federation** screen, select **Idap** from the **Add provider...** dropdown list.
The **Add user federation provider** screen displays.
3. In **Required Settings** , enter or select information for the following fields:
 - **Console Display Name** : Enter a name for the federated server. This value is listed in the grid on the **User Federation** screen.
 - **Priority** : Enter **0** to indicate the highest priority.
 - **Edit Mode** : Select **READ_ONLY** .
 - **Vendor : Active Directory** is populated in this field.
 - **Username LDAP attribute** : Enter **cn=inetOrgPerson** .
 - **RDN LDAP attribute** : Enter **cn=inetOrgPerson** .
 - **UUID LDAP attribute** : Enter **cn=inetOrgPerson** .
 - **User Object Classes** : Enter **inetOrgPerson** .
 - **Connection URL** : For LDAP, use port 389. For example, **ldap://10.20.30.40:389** .

Note

Like LDAP, StartTLS uses port 389. For LDAPS, use port 636. For example, **ldaps://10.20.30.40:636** .

- **Users DN** : A distinguished name (DN) consists of two DC components. For example, **dc=example,dc=com** .
 - **Bind Type** : If the LDAP server supports anonymous binding, select **none** .
Otherwise, select **simple** . This setting makes the **Bind DN** field available. In **Bind DN** , enter the administrator's DN and password.
4. Select **Save** .

The federated server is listed in the grid on the **User Federation** screen. When you add a new user in MC, the new user is authenticated to each MC session with credentials stored in the federated server.

For details on adding a federated user, see [User administration in MC](#).

Identity provider (IDP) authentication

You can authenticate users with an IDP service. The MC integrates with Keycloak to configure IDP services and supports the following identity protocols and social IDPs:

- SAML v2.0
- OpenID Connect v1.0
- Keycloak OpenID Connect
- Various social providers, including GitHub, Facebook, and Google.

The MC can access only usernames from IDP servers for authentication purposes—it cannot modify any IDP user information. To edit or reset a user password, you must log into your IDP server and edit the information.

The steps to configure an IDP for MC user authentication vary depending on the IDP service. Refer to the [Keycloak IDP documentation](#) for comprehensive details about integrating identity providers.

Integrate MC and Azure AD IDP

The following sections explain how to configure IDP authentication with [Microsoft Azure AD OpenID Connect \(OIDC\)](#). This requires that you register an application in Azure, and then add that application as an IDP in the MC. For comprehensive documentation about creating an app in Azure, see the [Microsoft Azure documentation](#).

Register the app

First, you must create your application in Microsoft Azure:

1. Log in to the [Azure portal](#).
2. In the search bar, enter [Azure Active Directory](#) and open it.
3. In the **+ Add** menu at the top, select **App registration** from the dropdown list.
4. Complete the fields on **Register an application** . For details about each field, see the [Microsoft Azure documentation](#) .
5. Select **Register** .
Your new application's **Overview** page displays.

Next, create the client secret. This secret authenticates your Azure app to the MC:

1. In the menu on the left, select **Certificates & secrets** .
2. On the **Client secrets** tab, select **+ New client secret** .
3. In **Add a client secret** , enter a description, and choose an expiration date.
4. Select **Add** .
The new secret is listed in the **Client secrets** tab.
5. Copy the secret listed in the **Value** column, and store it in a secure location for later use.
Important
This secret is available to copy when you generate it. If you lose this value or need to copy it during a later session, you must delete the existing secret and generate a new one.

Next, add [optional claims](#) to your token configuration:

1. In the left-hand menu, select **Token configuration** .
2. Select **+ Add optional claim** to open the **Add optional claim** pane to the right.
3. In the **Add optional claim** pane, select **ID** as the **Token type** , and then select the following boxes:
 - **email**
 - **given_name**
 - **family_name**
 - **upn**
4. Select **Add** .
A pop-up displays and asks you about API permissions.
5. In the pop-up, select the checkbox and select **Add** . The claims are listed on the **Token configuration** page.

Next, retrieve the client ID and application endpoint:

1. Select **Overview** from the left-hand menu.
2. In the **Essentials** section, copy the **Application (client) ID** .
Save the **Application (client) ID** in a secure location for later use.
3. At the top of the screen, select the **Endpoints** tab to display the application's available endpoints.
4. Copy the value in **OpenID Connect metadata document** .
Save this endpoint in a secure location.

Add Azure AD IDP to the MC

This section requires the following information from the [Azure AD app](#) :

- Client secret Value
- Application (client) ID
- OpenID Connect metadata document endpoint

Only the [MC SUPER administrator](#) can add Azure AD as an IDP in the MC:

1. Log in to the Management Console, then go to **MC Settings > Identity Providers** .
The **Identity Providers** screen opens in a new tab.
2. Select **OpenID Connect v1.0** from the **Add provider...** list.
The **Add identity provider** screen displays.
3. In the top section, add or select the following:
 - **Alias** : (Optional) Edit this field to distinguish this IDP from others that you might integrate with the MC.
 - **Display Name** : Enter **Azure AD** . This is the name that displays on the IDP login button after you complete configuration.
 - **Trust Email** : Toggle to **On** .
 - **First Login Flow** : Select **auto_detect** so that the MC can detect the new user in the IDP during the first user login.
4. In the **OpenID Connect Config** section, select or add the following:
 - **Client Authentication** : Select **Client secret sent as post** .
 - **Client ID** : Add the **Azure AD Application (client) ID** that you saved from the previous section.
 - **Client Secret** : Add the **Azure AD Client secret Value** that you saved from the previous section.

- In **Default Scopes** , enter [openid profile email](#) .
- 5. Go to the **Import External IDP Config** section. In **Import from URL** , add the **OpenID Connect metadata document endpoint** that you saved from the previous section.
- 6. Select **Import** .
MC imports the Azure application configuration and populates the URL fields.
- 7. Select **Save** .
- 8. Copy the value in **Redirect URI** and store it in a secure location for later use. You must add this URI in Azure.

Complete configuration

This section requires the **Redirect URI** value from [Add the IDP to MC](#) . Return to Azure, and complete the MC registration:

1. Log in to the [Azure portal](#) .
2. In the search bar, enter [App registrations](#) and go to your application's overview page.
3. Select **Authentication** in the left menu.
4. In **Platform configurations** , select **Add a platform** .
5. Select **Web** , then add the **Redirect URI** value from the MC.
For details about additional Redirect URI options and your Azure AD application, see the [Microsoft Azure documentation](#) .
6. Select **Configure** .

After you complete the configuration, the MC SUPER administrator can [add MC user accounts](#) with user identities from Azure AD. Before each user can log in to the MC, they must accept the [Microsoft Azure app permissions request](#) .

Accept permissions request

After the MC SUPER administrator [adds an Azure AD IDP user](#) to the MC, the user must accept the Microsoft Azure permissions request to view the MC and access its data before they can log in to the MC:

1. On the MC login screen, select the **Azure AD** option at the bottom of the **Sign in to your account** section.

Note

The **Azure AD** option displays the **Display Name** value that you entered in [Add Azure AD IDP to the MC](#) .

2. Enter your Azure credentials for your organization's Azure AD.
3. When Microsoft requests permissions, select **Accept** to grant Azure AD access to the MC.

After you accept the permissions request, the user is authenticated to each MC session with Azure AD credentials.

User administration in MC

Management Console (MC) users are separate from Vertica server database users. MC user accounts exist in the MC only, and you cannot alter MC users with SQL statements. You add, edit, and delete MC users entirely within the MC.

Add a user

After you install and configure the MC, only the [MC SUPER administrator \(superuser\)](#) user exists. The MC SUPER administrator can create the other users and assign them [MC configuration roles](#) that grant privileges to perform user actions.

Prerequisites

- Determine the [MC configuration role](#) that you want to grant the new MC user.
- Determine the [database privileges](#) that you want to grant the new MC user.
- Optional: [Create](#) or [import](#) a database to associate with the new user.
- Optional: [Create a database user account](#) if you want to map a server database user to an MC user profile.

Note

If you are mapping an existing user to a new MC user profile, the user must have [SYSMONITOR](#) or [DBADMIN](#) privileges to do the following:

- View data in MC monitoring tables
- Load Kafka streaming data

Add a local user

To add a local user, you must have the required [MC configuration privileges](#) :

1. Log in to the Management Console, then go to **MC Settings > User Management** .
2. Select **Add** . The **Add a new user** screen displays.
3. Select or enter the following information:
 - **Authentication** : How the user authenticates to the MC. Select **Local** .
 - **MC username** : The username of the new user. After you create and save a user, you cannot edit the username, but you can [delete the user account](#) and create a new user account with a new username.
 - **MC password** : The new user's password. The MC has the following default password requirements:
 - Cannot be the same as **MC username**
 - Between 3 and 30 characters in length
 - One number
 - One uppercase letter
 - One lowercase letter
 As the user enters the new password, the MC verifies that the password meets the preceding requirements. If the password does not meet the requirements, then an error message is displayed. If you have the required [MC configuration privileges](#) , you can edit password requirements in **MC Settings > Configuration > MC Password configuration settings** .
When a new user logs in, they are prompted to create a new password.
 - **Email address** : Required. The new user's email address.
 - **MC configuration privileges** : The user's configuration role privileges. For details, see [Configuration roles in MC](#) .
 - **DB access levels** : The user's database privileges. For details, see [Database privileges](#) .
 - **Status** : Select **Enabled** .
4. Select **Add user** .

After you add the user, the **User Management** screen displays, and the user is listed in the grid.

Add a federated or IDP user

After you [set up a federated server](#) or [set up an IDP](#) , you can create MC user accounts with the user identities that the federated server or IDP manages. To add a user, you must have the required [MC configuration privileges](#) :

1. Log in to the Management Console, then select **MC Settings > User Management** .
2. Select **Add** . The **Add a new user** screen displays.
3. Select or enter the following information:
 - **Authentication** : How the user authenticates to the MC. This list displays only the names of the federated servers or IDPs that you have set up to authenticate users:
 - For federated users, select **Federated** .
 - For IDP users, select **IDP** .
 - **MC username** : Add the username.
For IDP users, the username is their email address.
For federated users, enter the username stored in the federated server. As you enter the username, the MC searches the federated server for the username and displays the results in a list. Select the username from the list. You can use the wildcard character (*) to filter names. For example, if you enter **mcuser*** , the MC will list all users in the federation server whose usernames begin with **mcuser** .
 - **MC configuration privileges** : The user's configuration role privileges. For details, see [Configuration roles in MC](#) .
 - **DB access levels** : The user's database privileges. For details, see [Database privileges](#) .
 - **Status** : Select **Enabled** .

Note

You cannot edit the user's **Email address** because it is managed by the federation server.

4. Select **Add user** .

After you add the user, the **User Management** screen displays, and the user is listed in the grid.

Edit a user

Edit a user to update their MC configuration or database privileges. The only user account that you cannot edit is the MC SUPER administrator. You must have the required [MC configuration roles](#) to edit a user account:

1. Log in to the Management Console, then select **MC Settings > User Management** .
2. In the grid, select the row that lists the user that you want to edit.
3. Select **Edit** .
4. Update the fields. You cannot edit the **MC password** or **Email address** for [federated](#) or [IDP](#) users.

For [local users](#), you can edit the password from the **Change Password** screen. To access this screen, log in to the Management Console, then select **MC Settings > Change Password**.

5. Select **Save**.

Delete a user

Delete a user that you no longer authorize to access the MC. When you delete an MC user, you delete the user's audit activity and their MC profile, which includes configuration roles and database access privileges. If you do not want to delete a user but you do want to revoke a user's MC authorization, consider setting the user's **Status** to **Disabled**. For details, see [Edit a user](#).

The only user account you cannot delete is the MC SUPER administrator. If you delete a [federated](#) or [IDP user](#), you delete their MC profile only. The MC cannot change user identity information stored in federated servers or IDPs.

You must have the required [MC configuration roles](#) to delete a user account:

1. Log in to the Management Console, then select **MC Settings > User Management**.
2. In the grid, select the row that lists the user that you want to delete.
3. Select **Delete**.
The **Confirm** window is displayed and asks you if you are sure that you want to delete this user.
4. Select **OK**.
The user is no longer listed in the **User Management** grid.

Note

If you delete a user that is currently logged in, that user receives a message that explains that they were removed as a user and must contact the system administrator.

Database management

The Management Console provides tools to manage Eon Mode and Enterprise Mode databases, including creating a database, provisioning resources, subcluster management, and query optimization.

In this section

- [Creating a database using MC](#)
- [Provisioning databases using MC](#)
- [Managing database clusters](#)
- [Subclusters in MC](#)
- [Eon Mode on-premises](#)
- [Managing queries using MC](#)
- [Working with query plans in MC](#)
- [Creating a database design in Management Console](#)
- [Running queries in Management Console](#)
- [Working with workload analyzer recommendations in MC](#)
- [Running Database Designer using MC](#)
- [Using the Management Console to replace nodes](#)
- [Import and monitor a database in a Hadoop environment](#)

Creating a database using MC

If you installed the Management Console using an RPM, there is a wizard to help you create a new database on an existing Vertica cluster.

Note

If you did not install MC with an RPM, see one of the following:

- For Management Console on Amazon Web Services (AWS) [using a CloudFormation Template](#), see [Creating an Eon Mode database in AWS with MC](#) or [Creating an Enterprise Mode database in AWS with MC](#).

- For Google Cloud Platform (GCP), see [Provision an Eon Mode cluster and database on GCP in MC](#).
- To provision a new database and cluster on-premises, see [Creating a cluster using MC](#).

1. Connect to Management Console, and log in.
2. On the home page, click **View Infrastructure** to go to the **Database and Cluster View**. This tab provides a summary of your environment, clusters, and databases.
3. If the **Database** row displays a database running on the cluster that you want to add a new database to, select the database and click **Stop**. Wait until the database status is **Stopped**.
4. In the **Clusters** row, click the existing cluster that you want to create a database on. If a database is already running on it, you must stop the database.
5. Click **Create Database** in the window to start the database creation wizard.
6. Follow the steps in the wizard to successfully create a database.

You can close the web browser during the process and sign back in to MC later. The creation process continues unless an unexpected error occurs.

See also

- [Creating a cluster using MC](#)
- [Troubleshooting with MC diagnostics](#)
- [Restarting MC](#)

Provisioning databases using MC

Management Console allows all users to create, import, and connect to Vertica databases using the **MC Provision Databases** tab.

- Import cluster or database using IP discovery
- Create a new cluster
- [Import and monitor a database in a Hadoop environment](#)

Managing database clusters

Management Console allows you to monitor multiple databases on one or more clusters at the same time. MC administrators can see and manage all databases and clusters monitored by MC, while non-administrative MC users see only databases on which they have been assigned the appropriate [access levels](#).

Depending on your access level, you can use the MC to perform the following database and cluster-related management operations:

- Create an [Eon Mode](#) and [Enterprise Mode](#) database.
- Install an Eon Mode and Enterprise Mode database in a cloud or [on-premises](#) environment.
- [Create an empty database in an existing cluster](#).
- [Import an existing database or cluster](#) into the MC interface.
- Start the database, unless it is already running.
- Stop the database, if no users are connected.
- Remove the database from the MC interface.

Note

Remove does not drop the database. A Remove operation leaves it in the cluster, hidden from the UI. To add the database back to the MC interface, import it using the IP address of any cluster node. A Remove operation also stops metrics gathering on that database, but statistics gathering automatically resumes after you re-import.

- Drop the database when you are certain that no users are connected. Drop is a permanent action that drops the database from the cluster.

Database clusters in the cloud

When you use the Management Console to create a database or cluster on a [supported cloud provider](#), you can perform the following operations on individual machines or the entire cluster:

- Start
- Stop
- Revive
- Reboot

- Terminate

For details, see [Viewing and managing your cluster](#).

In this section

- [Viewing cluster infrastructure](#)
- [Viewing and managing your cluster](#)
- [Importing an existing database into MC](#)

Viewing cluster infrastructure

For a summary of all databases and clusters currently monitored by MC, click **View Infrastructure** on the MC Home page.

Note

Some of the features on this page are currently available in MC only on AWS and GCP.

The first tab on the Infrastructure page, **Database and Cluster View**, is overview of the infrastructure of all the clusters and databases currently monitored by MC.

Three rows are displayed: Infrastructure, Clusters, and Databases.

- **Infrastructure.** Specifies the type of environment on which your clusters reside:
 - Cloud: Displays the name of the cloud platform, such as AWS or GCP
 - On premises: Displays "Data Center"
 - Apache Hadoop: Displays "Hadoop Environment"
- **Clusters.** You can click a cluster to see its full details. From the dialog that opens, you can:
 - Add the cluster's master API key
 - [View or Manage the cluster page](#)
 - Remove the cluster from MC monitoring
 - [Create a new database](#) on the cluster (if all other databases on the cluster are stopped)
- **Databases.** A numbered badge on the top right displays the number of highest-priority messages from that database that are in your inbox. If a handshake icon () displays next to "Type," that indicates the database is running in Eon Mode. If the handshake is absent, the database is running in Enterprise Mode. Click any database for more details. From the dialog that opens, you can:
 - [View the database's Overview page](#)
 - Stop or start the database
 - Drop the database (if the database is stopped)
 - Remove the database from MC monitoring

In the illustration below, MC is monitoring two different clusters that both reside on an AWS environment. One database is running on each cluster. The DemoDB database, displayed on the left, has a handshake icon next to its "Type" label that indicates it is running in Eon Mode. The VMart database on the 3-node cluster, displayed on the right, is running in Enterprise Mode.

The screenshot displays the 'Infrastructure' view in the Vertica Management Console. It is organized into three main categories:

- Infrastructure:** Shows an 'AWS Environment' with 'Vertica Clusters:2' and 'Vertica Databases:2'.
- Clusters:** Displays two cluster cards. The first is labeled 'Type:Cluster' with 'Size (# nodes):4'. The second is labeled 'Type:Cluster' with 'Size (# nodes):3'.
- Databases:** Displays two database cards. The first is 'DemoDB' with 'Type:Database' and 'Status:UP', showing '17 (H)' nodes. The second is 'VMart' with 'Type:Database' and 'Status:UP', showing '6 (H)' nodes.

Viewing and managing your cluster

The **Cluster** page in Management Console shows a node-based visualization of your cluster. This page shows the cluster's host addresses, the installed version of Vertica running, and a list of the databases on the cluster that MC is currently monitoring.

Note

Some of the features on this page are currently available in MC only on AWS and GCP.

From the **Cluster** page, you can also [create a new empty database](#) on the cluster, or [import any existing databases](#) MC discovers on the cluster. (These features are currently available only on AWS and GCP.)

MC displays different options depending on whether you imported the cluster to MC, or created the cluster using MC:

- Imported cluster: MC displays monitoring information about the cluster.
- Cluster created using MC: MC displays both monitoring information and management options for third-party cloud platforms such as AWS. For clusters you created using the current MC, the **Cluster** page provides cluster and instance management options.

Cluster and instance management option availability

For Eon Mode databases, MC supports actions for subcluster and node management for the following public and private cloud providers:

- [Amazon Web Services](#) (AWS)
- [Google Cloud Platform](#) (GCP)
- [Microsoft Azure](#)
- [Pure Storage FlashBlade](#)

Note

Enterprise Mode does not support subclusters.

For Enterprise Mode databases, MC supports these actions:

- In the cloud on AWS: Add Node action, Add Instance action.

- On-premises: Add Node action.

Note

In the cloud on GCP, Enterprise Mode databases are not supported.

Go to the cluster page

To view the **Cluster** page:

1. On the MC Home page, click **View Infrastructure** to go to the [Infrastructure page](#). This page lists all the clusters the MC is monitoring.
2. Click any cluster shown on the Infrastructure page.
3. Select **View** or **Manage** from the dialog that displays, to view its Cluster page. (In a cloud environment, if MC was deployed from a cloud template the button says "Manage". Otherwise, the button says "View".)

Note

You can click the pencil icon beside the cluster name to rename the cluster. Enter a name that is unique within MC.

Monitor imported clusters

Whether you have imported or created a cluster using MC, you can view information about it through the Cluster page.

This page includes the following information:

- **Node visualization** : A visualization of all nodes within the cluster. Icons at the top right of each node indicate if the nodes are up. Click any node to see details about its host name, CPU information and total memory. If there are many nodes in the cluster, use the **Zoom Level** slider at the bottom right of the page to zoom the visualization in or out.
- **Instance List** : A list of all the instance IPs within the cluster. Click any instance in the list to see details about it.
- **Cluster Summary** : A summary of details about the cluster, including the version of Vertica running on the cluster and the number of hosts. If the cluster is running on cloud-platform resources such as AWS, you can also see region and instance type information.
- **Databases** : Lists all databases monitored by MC and their current state.
 - At the bottom of the **Databases** section, click **Create New** to [create a new empty database](#).
 - This section also lists any Vertica databases on this cluster, if existing, that are not yet monitored by Management Console. See [Importing an existing database into MC](#) for the process of importing a discovered database.

The following image shows an overview of a 7-node cluster, which was created in MC using a Cloud Formation Template. This cluster has a running Eon Mode database on it.

Vertica Management Console

Cluster:1589594481421_cluster | Start Cluster | Stop Cluster | Advanced | Show Cluster Summary | Show Instance List

Cluster Summary:
 Vertica Version: 10.0.0.0 (x86_64)
 Hosts: 7
 Region: us-east-1
 Availability Zone: us-east-1e
 Instance Type: m4.4xlarge
 Last Updated: 15 May 2020 22:01:25

Instance List:
 10.11.12.10
 10.11.12.120
 10.11.12.177
 10.11.12.20
 10.11.12.30
 10.11.12.71
 10.11.12.8

Databases:
 Monitored: + verticadb (7)

Node Visualization:
 7 nodes in a diamond topology. Each node is represented by a server icon with a green checkmark indicating it is up. The nodes are connected by dashed lines. The nodes are labeled with their private and public IP addresses:

- Top Node: Private: 10.11.12.30, Public: 34.204.249.86
- Top-Left Node: Private: 10.11.12.20, Public: 54.208.1.163
- Top-Right Node: Private: 10.11.12.177, Public: 34.232.133.127
- Center Node: Private: 10.11.12.8, Public: 34.231.170.177
- Bottom-Left Node: Private: 10.11.12.71, Public: 3.210.206.28
- Bottom-Right Node: Private: 10.11.12.120, Public: 80.16.63.169

Zoom Level: 7

Manage a cluster created on AWS with the cluster creation wizard

If you installed Vertica from the AWS Marketplace [using AWS resources](#), MC offers cluster management operations that are specific to the cloud. Using MC, you can manage a cluster running on AWS without going to the AWS console.

Note

Note: The AWS management operations to add or terminate instances are only available for clusters on AWS resources that were created using the *current* MC. Add and terminate capabilities are disabled for any cluster imported to MC, even if the imported cluster is on an AWS environment.

If you upgrade the cluster's Vertica version manually through the command line, AWS management operations in MC become disabled for the cluster, even if you created that cluster using MC. Make sure to upgrade the cluster's Vertica version through MC in order to preserve AWS management capabilities for that cluster in MC.

In the screen capture below, the Cluster page shows a 7-node cluster, which was provisioned using the Cluster Creation wizard. Use the wizard to create an [Eon Mode](#) or [Enterprise Mode](#).

The screenshot displays the Vertica Management Console interface. At the top, the user 'uidbadmin' is logged in. The main navigation bar shows 'Databases and Clusters' and the current cluster 'Cluster:1589594481421_cluster'. Action buttons include 'Start Cluster', 'Stop Cluster', 'Advanced', 'Show Cluster Summary', and 'Show Instance List'. A left sidebar provides cluster details: Vertica Version 10.0.0 O (x86_64), 7 hosts, Region us-east-1, Availability Zone us-east-1e, Instance Type m4.4xlarge, and last updated on May 15, 2020. A 'Databases' section shows 'verticadb (7)' is monitored. The central area features a network diagram of 7 nodes with their private and public IP addresses. A right sidebar lists the instance IDs. A 'Zoom Level: 7' slider is at the bottom right.

Cluster management actions (Eon Mode and Enterprise Mode)

You can perform the following operations on your cluster through the **Cluster** page. These options are available at the top of the **Cluster** page or in the **Advanced** menu at the top of the page:

You can perform the following operations on your cluster through the cluster page:

- **Start Cluster** : Start all the instances in the cluster. Available at the top of the Cluster page.
- **Stop Cluster** : Stop all the instances in the cluster. You must first stop any running database on the cluster. Available at the top of the cluster page.
- **Reboot Cluster** : Restart all instances in the cluster. Available under the **Advanced** menu at the top of the page. **Note: Reboot Cluster** is currently available only on AWS.
- **Terminate Cluster** : Terminate all instances in the cluster, the databases on it, and all AWS resources from the cluster. The **Terminate Cluster** operation is available under the **Advanced** menu at the top of the page.
 - For Enterprise Mode databases, this operation *permanently deletes* any data you had on the cluster or its databases.
 - For [Eon Mode](#) databases, the data is preserved in communal storage and you can later [revive the database in a new cluster](#). When you choose to terminate the cluster, MC gives you the option to also stop the database before termination, which is recommended in order to safely revive later.

View cluster instance details

You can view the details for any instance in your cluster. Select the IP address of an instance in the **Instance List**. MC displays a popup beside that instance showing information about its private and public IP addresses, host name, total memory, and other details.

Manage individual instances/nodes in Eon Mode

If your database is Eon Mode, you use actions available on the **Database > Manage > Subclusters** tab in MC to manage individual nodes.

To change the state of individual nodes in your Eon Mode database, you can:

- Start, stop, or terminate a node in a subcluster.

See [Node action rules in MC](#).

To change the number of nodes in your Eon Mode database, you can:

- Add or subtract individual nodes from a subcluster by [scaling the subcluster up or down](#).
- [Add](#) or [terminate](#) an entire subcluster.

See [Subcluster action rules in MC](#).

Manage individual instances in Enterprise Mode

If your database is Enterprise Mode, the **Cluster** page **Instance List** includes action icons you use to manage individual instances in your cluster.

In the **Instance List** panel of the **Cluster** page, select the IP address of any instance in your cluster that you want to perform the action on. Then click an icon from the icon menu at the top of the panel. Hover over an icon to read the action it performs.

- **Start Instance** : Start an individual instance in the cluster.
- **Stop Instance** : Stop an individual instance in the cluster.
- **Add Instance** : Add another instance to your cluster. When you select this action, Management Console opens the Add AWS Instance wizard, where you specify volume and storage information for the instance. You must supply your AWS key pair (and a Vertica Premium Edition license if you are adding more nodes to the cluster than a Community Edition license allows). You can add up to 10 instances at a time using the Add Instance action.
- **Restart Instance** : Restart an individual instance in the cluster.
- **Terminate Instance** : Permanently remove the instance from your cluster.

Importing an existing database into MC

If you have already created a Vertica database, you can import it into MC to monitor its health and activity.

When you install MC on the same cluster as the existing database you intend to monitor, MC automatically discovers the cluster and any databases installed on it, whether those databases are currently running or are down.

Note

If you haven't created a database and want to create one through the MC, see [Creating a database using MC](#).

Import a database existing on a monitored cluster

The following procedure describes how to import an existing database that is on a cluster MC is already monitoring.

1. [Connect](#) to Management Console and sign in as an MC administrator.
2. On the MC Home page, click **View Your Infrastructure**.
3. On the Databases and Clusters page, click the cluster and click **View** in the dialog box that opens.
4. On the left side of the page under the Databases heading, click **Import Discovered**.

Tip

A running database appears as Monitored; any non-running databases appear as Discovered. MC supports only one running database on a single cluster at a time. You must shut down a running database on a cluster in order to monitor another database on that cluster.

5. In the **Import Database** dialog box:
 - Select the database you want to import.
 - Optionally clear auto-discovered databases you don't want to import.
 - Supply the database administrator username and password and click **Import** . (Supplying a non-administrator username prevents MC from displaying some charts after import.)
 - If the Vertica database is configured for TLS security, you need to configure TLS for all Management Console connections to this database over JDBC. Click **Use TLS**. Management Console launches the Certificates wizard. See [MC certificates wizard](#) .

After Management Console connects to the database it opens the **Manage** page, which provides a view of the cluster nodes. See [Monitoring Cluster Status](#) for more information.

You perform the import process once per existing database. Next time you connect to Management Console, your database appears under the Recent Databases section on the Home page, as well as on the Databases and Clusters page.

Note

The system clocks in your cluster must be synchronized with the system that is running Management Console to allow automatic discovery of local clusters.

Import a database existing on a new cluster

If the database you intend to monitor is on a cluster MC is not currently monitoring, MC cannot automatically discover it. You can import it with the following procedure.

1. [Connect](#) to Management Console and sign in as an MC administrator.
2. On the MC Home page, click **Import a Vertica Database Cluster** .
3. Enter the IP address of one of the database's cluster nodes.
4. Enter the master API key for the cluster. Find the key here: `/opt/vertica/config/apikeys.dat`
5. In the **Import Database** dialog box:
 - Select the database you want to import.
 - Optionally clear auto-discovered databases you don't want to import.
 - Supply the database administrator username and password and click **Import** . (Supplying a non-administrator username prevents MC from displaying some charts after import.)
 - To configure TLS security for all Management Console connections to this database over JDBC, click **Use TLS**. Management Console launches the Certificates wizard. For instructions on completing the wizard, see [Configuring TLS while importing a database on MC](#) .

Subclusters in MC

In Eon Mode databases, you can use subclusters (groups of nodes) to separate different workloads, to control how those workloads use resources, and to facilitate scaling your database up and down as workloads fluctuate. This allows you to better manage your cloud resource expenses or data center resources. For an overview of subcluster concepts and how subclusters work, see [Subclusters](#) .

MC makes it easy to view and manage your subclusters. You can track how queries are performing and how well your subcluster resources are balanced. Using MC, you can use the information to adjust the number and size of your subclusters to improve your query throughput and system performance.

Visualizing your subclusters

The charts on the **Database Overview** page allow you to view and drill down into the resource usage of your database at any level. You can look at the resource usage of all nodes, or all subclusters, or individual subclusters. For details, see [Charting subcluster resource usage in MC](#) .

You can view statistics for the individual nodes in each subcluster in table format on the **Database Manage** page, in the **Subclusters** tab.

For a tour of the monitoring features of the **Manage > Subclusters** tab, see [Viewing subcluster layout in MC](#) .

Managing your subclusters

For Eon Mode databases, MC supports actions for subcluster and node management for the following public and private cloud providers:

- [Amazon Web Services](#) (AWS)
- [Google Cloud Platform](#) (GCP)
- [Microsoft Azure](#)
- [Pure Storage FlashBlade](#)

Note

Enterprise Mode does not support subclusters.

For Enterprise Mode databases, MC supports these actions:

- In the cloud on AWS: Add Node action, Add Instance action.
- On-premises: Add Node action.

Note

In the cloud on GCP, Enterprise Mode databases are not supported.

To view and manage your subclusters, select your database from the **MC Home** page or the **Databases and Clusters** page. MC displays your database's **Overview** page. Select **Manage** at the bottom of the **Overview** page.

To view the Subclusters page, click the **Manage > Subclusters** tab:

Vertica Management Console

Overview Activity **Manage** Design Load Query Execution Query Plan License Settings

Eon Mode in the cloud

In Eon Mode on cloud platforms, you can use the **Manage > Subclusters** tab to add subclusters, rebalance your subclusters, stop and start subclusters, scale subclusters up or down, or terminate a subcluster. You can also stop or start a node, or restart a database node and its underlying instance.

Eon Mode on-premises

In Eon Mode on-premises, available subcluster and node actions behave a little differently than in the cloud, because your Vertica nodes reside on actual machines in your data center rather than on cloud instances.

Subcluster Actions in Eon Mode on Premises

- In Eon Mode on-premises, you can use the **Manage > Subclusters** tab to add subclusters, rebalance your subclusters, or delete a subcluster.
- You can add (create) a subcluster only if additional Vertica host machines are available.
- When you delete a subcluster, MC deletes the subcluster from the database but does not delete the actual machines. MC stops the nodes in the subcluster, removes them from the subcluster, and deletes the subcluster. The Vertica host machines are then available to be added to other subclusters.
- When you start or stop a subcluster in an Eon Mode database on-premises, MC starts or stops the subcluster nodes on the Vertica host machines, but not the machines themselves.
- When you scale up a subcluster on-premises, the MC wizard displays a list of the available Vertica host machines that are not currently part of a database. You select the ones you want to add to the subcluster as nodes, then confirm that you want to scale up the subcluster. When you scale down a subcluster on-premises, MC removes the nodes from the subcluster in the database, but does not terminate the Vertica host machines. The hosts are now available for scaling up other subclusters.
- **Scale Up** displays the IP addresses of all available Vertica hosts that are not part of the database. The **Scale Up** button is grayed out if there are no Vertica hosts in the cluster that are not part of the database.

Node actions in Eon Mode on premises

When you start or stop a node on-premises, MC starts or stops the node in the database, but does not start or stop the Vertica host machine. The Restart Node action is not available for on-premises Eon Mode databases.

In this section

- [Charting subcluster resource usage in MC](#)

Charting subcluster resource usage in MC

On the **Database Overview** page, in the **CPU/Memory/Disk I/O** chart and the **Database General Pool Usage** chart, you can use the dropdown in the title bar to focus the chart on:

- All nodes in the database
- All subclusters in the database
- An individual subcluster, by name

For example, the CPU/Memory/Disk I/O chart dropdown allows you to choose the database nodes, one named subcluster, or all subclusters.

If you choose **Database - Subclusters**, the line in a given color represents the trend of all subclusters averaged together for that statistic, and each dot of the same color represents an individual subcluster at a certain time, for that same statistic.

For more in-depth information on how expand detail areas of charts and drill into the details, see [Viewing the overview page](#).

Viewing subcluster layout in MC

The MC **Database Manage** page displays two tabs, the **Subclusters** tab and the **Database** tab.

This topic describes the monitoring functions of the **Subclusters** tab. To monitor your subclusters, on the **Subclusters** tab you can view, sort, and search for subclusters and view their layout and statistics.

For information about using the **Subclusters** tab to make changes — adding, rebalancing, stopping and starting, scaling up or down, or terminating subclusters — see [Subclusters in MC](#) and its subtopics.

The **Subclusters** tab includes the following statistics in table form for the nodes in each subcluster:

- Node name
- Private IP address
- Status (UP or DOWN)
- CPU Usage %
- Memory Usage %
- Disk Usage %

The screenshot shows the Vertica Management Console interface. At the top, there are navigation tabs for 'Start Database', 'Stop Database', and 'Manage Cluster'. Below this, there are two subcluster sections. The first section, 'Subcluster: default_subcluster', is marked as 'Primary' and shows 3 nodes. The second section, 'Subcluster: secondary_subcluster_em', shows 5 nodes. Each node row includes columns for Node Name, Private IP, Status, CPU Usage %, Memory Usage %, Disk Usage %, and Node Actions. The 'Node Actions' column contains icons for starting, stopping, and removing nodes. At the bottom of the console, there is a navigation bar with tabs for Overview, Activity, Manage, Design, Load, Query Execution, Query Plan, License, and Settings.

Node Name	Private IP	Status	CPU Usage %	Memory Usage %	Disk Usage %	Node Actions
v_verticadb_node0001	10.11.12.10	UP	0.07	1.61	13	[Start] [Stop] [Remove]
v_verticadb_node0002	10.11.12.20	UP	0.08	1.31	12	[Start] [Stop] [Remove]
v_verticadb_node0003	10.11.12.30	UP	0.03	1.3	12	[Start] [Stop] [Remove]
Node Name	Private IP	Status	CPU Usage %	Memory Usage %	Disk Usage %	Node Actions
v_verticadb_node0004	10.11.12.71	UP	0.06	1.02	6	[Start] [Stop] [Remove]
v_verticadb_node0005	10.11.12.98	UP	0.04	1.01	6	[Start] [Stop] [Remove]
v_verticadb_node0006	10.11.12.8	UP	0.02	1.01	6	[Start] [Stop] [Remove]
v_verticadb_node0007	10.11.12.177	UP	0.02	1.01	6	[Start] [Stop] [Remove]
v_verticadb_node0008	10.11.12.137	UP	0.02	1.01	6	[Start] [Stop] [Remove]

Searching for nodes

To find a particular node, enter its node name or IP address in the "node name or IP" search field at the top right of the **Subclusters** tab. Searching for nodes is especially helpful if your cluster is very large. To find a specific node, enter its complete node name or IP address. You can enter a partial node name or IP address to find all nodes whose name or IP address contains that string. For example, if you enter "240" in the search field, MC would find both of the following nodes:

- Node name: MyNode24018
- Node IP address: 1.160.10.240

Note

Wildcard characters are not supported in the search field.

Starting, stopping, or removing nodes

The right column provides icons for executing node actions. You can start, stop, or remove a node in the subcluster. Removing a node also removes it from the database. Only the Start, Stop, and Remove actions are available on this page. For details, see [Starting, stopping, and restarting nodes in MC](#)

Note

If you change the layout of your subcluster, for example by removing nodes, you must rebalance shards. See [REBALANCE_SHARDS](#).

Sorting nodes within a subcluster

You can sort the nodes within each subcluster by the values in any column, by clicking on the column heading.

Collapsing or expanding a subcluster, or the entire table

To collapse a subcluster section to one summary row, click the minus icon or the subcluster heading. To collapse the entire table to summary rows, click the minus icon or "Collapse All".

To expand a collapsed subcluster section, click the plus icon or the subcluster heading. To expand the entire table, click the plus icon or **Expand All**.

Adding subclusters in MC

You can add a subcluster to an Eon Mode database on-premises or in the cloud, to provide your database with more compute power, and to separate workloads.

For more information about the rules governing subclusters, see [Subclusters](#).

Adding a subcluster on a cloud platform

When you use MC to add an Eon Mode subcluster on a cloud platform, MC provisions the requested instances, configures them as nodes in your database cluster, and forms those nodes into a new subcluster.

You can add a second primary subcluster in order to stop the original primary. Be sure to make the replacement primary subcluster at least one node larger than the original. (If you make them the same size, they both count equally toward the quorum, and stopping either would violate the quorum, so you cannot stop either one. For more information, see [Data integrity and high availability in an Eon Mode database.](#))

Amazon Web Services (AWS)

The following steps add a subcluster on AWS:

1. On the **Manage > Subclusters** tab, click **Add Subcluster** to open the Add Subcluster window.
2. On **Enter AWS Credentials and preferences**, some values might populate based on your current configuration. Accept the defaults or enter the following values:
 - **AWS Region**: Enter the same region as your cluster.
 - **AWS Subnet**: The subnet for your cluster. By default, Vertica creates your cluster in the same subnet as your MC instance. Important
Use security groups and network access control lists (ACLs) to secure your subnet. For details, see the [Amazon documentation](#).
 - **AWS Key Pair**: Your Amazon key pair for SSH access to EC2 instances.
3. Select **Next**. On the **Specify Subcluster Information** screen, supply the following information:
 - **Subcluster Name**: Enter a name for your subcluster.
 - Subcluster type from the dropdown list. Select **Primary** or **Secondary**.
 - **Number of instances in this subcluster**: Select the number of nodes that you want in the subcluster. If you are using the free [Community Edition](#) license, you are limited to 3 nodes. If you enter a value greater than 3, you are prompted to enter an upgraded license to continue.
 - **Vertica License**: Click **Browse** to locate and upload your Vertica license key file.
If you do not supply a license key file here, the MC uses the Vertica Community Edition license. This license has a three node limit, so the value in **Number of instances in this subcluster** cannot be larger than 3 if you do not supply a license. See [Managing licenses](#) for more information.
 - **Node IP setting**: Choose a node IP setting. If you choose **Public IP**, the address is not persistent across instance stop and start.
4. Select **Next**. On the **Specify cloud instance and data storage info** screen, **Database Depot Path** is populated to match the original cluster configuration. Choose or enter a value in the following:
 - **EC2 Instance Type**: For recommended instance types, see [Choosing AWS Eon Mode Instance Types](#). For a comprehensive list of Vertica supported instance types, see [Supported AWS instance types](#).
 - **Database Depot Path**: This field is populated with the existing subcluster's depot path.
 - **EBS Volume Type**: This field is populated with the [volume configuration defaults](#) for the associated instance type. Select a new value to change the default.
 - **EBS Volume Size (GB) per Volume per Available Node**: This field is populated with the [volume configuration defaults](#) for the associated instance type. Enter a new value to change the default.
5. Select **Next**. On the **Specify additional storage and tag info** screen, the following fields are populated:
 - **Database Catalog Path**: The path to a persistent storage location.
 - **Database Temp Path**: The path to an ephemeral storage location if the node instance type includes the ephemeral storage option. Under each path, there are **EBS Volume Type** and **EBS Volume Size (GB) per Volume per Available Node** fields that are populated with [volume configuration defaults](#) for the associated instance type. Select or enter a new value to change the default path.
 - Optionally, select **Tag EC2 Instances** to assign distinctive, searchable metadata tags to the instances in your new subcluster. Existing tags are displayed.
6. Select **Next**. On **Review 'Add Subcluster' information**, confirm the configuration details for your new subcluster.
7. Select **Add Subcluster** to create the subcluster.

After the subcluster is created, The Subcluster page displays. The MC automatically subscribes the nodes in your new subcluster to shards so that the nodes are ready to use.

Google Cloud Platform (GCP)

The following steps add a subcluster on GCP:

1. On the **Manage > Subclusters** tab, click **Add Subcluster** to open the Add Subcluster window.
2. On **Specify Subcluster Information**, supply the following information:
 - **Subcluster Name**: Enter a name for your subcluster.
 - Subcluster type from the dropdown list. Select **Primary** or **Secondary**.
 - **Number of instances in this subcluster**: Select the number of nodes that you want in the subcluster. If you are using the free [Community Edition](#) license, you are limited to 3 nodes. If you enter a value greater than 3, you are prompted to enter an upgraded license to continue.
 - **Vertica License**: Click **Browse** to locate and upload your Vertica license key file.
If you do not supply a license key file here, the MC uses the Vertica Community Edition license. This license has a three node limit, so the value in **Number of instances in this subcluster** cannot be larger than 3 if you do not supply a license. See [Managing licenses](#) for more information.
 - **Node IP setting**: Choose a node IP setting. If you choose **Public IP**, the address is not persistent across instance stop and start.

3. Select **Next** . Cluster configuration might take a few minutes.
4. On **Specify cloud instance and depot storage info** , supply the following information:
 - **Instance Type** : Select the instance type. For recommended instance types, see [GCP Eon Mode instance recommendations](#) . For a comprehensive list of Vertica supported instance types, see [Supported GCP machine types](#) .
 - **Database Depot Path** : This value is populated to match the original cluster configuration.
 - **Disk Type** : Volume type for each node. This value is populated with the [volume configuration defaults](#) for the associated instance type.
 - **Volume Size (GB) per Volume per Available Node** : Volume size for each node. This value is populated with the [volume configuration defaults](#) for the associated instance type.
5. Select **Next** . On Specify additional storage and label info, supply the following:
 - **Database Catalog Path** : The path to a persistent storage location.
 - **Disk Type** : Volume type for the database catalog.
 - **Size (GB) per Available Node** : Volume size for the database catalog.
 - **Database Temp Path** : The path to an ephemeral storage location if the node instance type includes the ephemeral storage option.
 - **Disk Type** : Volume type for the database temp storage location.
 - **Size (GB) per Available Node** : Volume size for the database temp storage location.
 - **Label Instances** : Optional. Assign distinctive, searchable metadata tags to the instances in your new subcluster. Existing tags are displayed.
6. Select **Next** . On **Review Information** , confirm the configuration details for your new subcluster, and accept the terms and conditions.
7. Select **Add Subcluster** to create the subcluster.

After the subcluster is created, The **Subcluster** page displays. The MC automatically subscribes the nodes in your new subcluster to shards so that the nodes are ready to use.

Microsoft Azure

The following steps add a subcluster on Azure:

1. On the **Manage > Subclusters** tab, click **Add Subcluster** to open the Add Subcluster window.
2. On **Specify Subcluster Information** , supply the following information:
 - **Subcluster Name** : Enter a name for your subcluster.
 - Subcluster type from the dropdown list. Select **Primary** or **Secondary** .
 - **Number of instances in this subcluster** : Select the number of nodes that you want in the subcluster. If you are using the free [Community Edition](#) license, you are limited to 3 nodes. If you enter a value greater than 3, you are prompted to enter an upgraded license to continue.
 - **Vertica License** : Click **Browse** to locate and upload your Vertica license key file.
If you do not supply a license key file here, the MC uses the Vertica Community Edition license. This license has a three node limit, so the value in **Number of instances in this subcluster** cannot be larger than 3 if you do not supply a license. See [Managing licenses](#) for more information.
 - **Node IP setting** : Choose a node IP setting. If you choose **Public IP** , the address is not persistent across instance stop and start.
3. Select **Next** . Cluster configuration might take a few minutes.
4. On **Specify cloud instance and depot storage info** , supply the following information:
 - **Virtual Machine (VM) Size** : Select the instance type. For a comprehensive list of Vertica supported instance types, see [Recommended Azure VM types and operating systems](#) .
 - **Database Depot Path** : This value is populated to match the original cluster configuration.
 - **Managed Disk Volume Type** : Volume type for each node. This value is populated with the [volume configuration defaults](#) for the associated instance type.
 - **Managed Disk Volume Size (GB) per Volume per Available Node** : Volume size for each node. This value is populated with the [volume configuration defaults](#) for the associated instance type.
5. Select **Next** . On Specify additional storage and label info, supply the following:
 - **Database Catalog Path** : The path to a persistent storage location.
 - **Managed Disk Volume Type** : Volume type for the database catalog.
 - **Managed Disk Volume Size (GB) per Available Node** : Volume size for the database catalog.
 - **Database Temp Path** : The path to an ephemeral storage location if the node instance type includes the ephemeral storage option.
 - (E16_v4 VMs only) **Managed Disk Volume Type** : Volume type for the database temp storage location.
 - (E16_v4 VMs only) **Managed Disk Volume Size (GB) per Available Node** : Volume size for the database temp storage location.
 - **Label Instances** : Optional. Assign distinctive, searchable metadata tags to the instances in your new subcluster. Existing tags are displayed.
6. Select **Next** . On **Review Information** , confirm the configuration details for your new subcluster.
7. Select **Add Subcluster** to create the subcluster.

After the subcluster is created, The **Subcluster** page displays. The MC automatically subscribes the nodes in your new subcluster to shards so that the nodes are ready to use.

On-premises

For an Eon Mode database on-premises, you can use MC to create additional subclusters. MC displays all available Vertica hosts that are not part of the database. It configures the ones you select to become the nodes in the new subcluster in your database.

1. On the **Manage > Subclusters** tab, click **Create Subcluster** at top left. MC opens the **Create Subcluster** wizard.
2. In the first screen, respond in the following fields:
 - o **Subcluster Name:** Enter a name for the new subcluster.
 - o **Subcluster type dropdown (unlabeled):** Select **Primary** or **Secondary** .
 - o **Select nodes that will be added to a subcluster:** Select from the list of IP addresses. MC displays all available Vertica hosts within the cluster that are not currently members of a database.
 - o **Confirmation:** Click the **Confirmation** check box to indicate that you want to create the named subcluster, to include the Vertica hosts you selected as nodes.
3. After you click the **Confirmation** check box, the **Proceed** button becomes active. Click **Proceed** .

MC displays a progress screen while it creates the requested subcluster. Wait for all steps to complete.

See also

[Subcluster action rules in MC](#)

Rebalancing data using Management Console

Vertica can rebalance your subcluster when you add or remove nodes. If you notice data skew where one node shows more activity than another (for example, most queries processing data on a single node), you can manually rebalance the subcluster using MC if the database is imported into the MC interface.

On the Management Console **Manage** page in the **Subclusters** tab, click **Rebalance** above the subcluster to initiate the rebalance operation.

During a rebalance operation, you cannot perform any other activities on the database, such as start, stop, add, or remove nodes.

Subcluster action rules in MC

The table below summarizes when each subcluster action is available for the primary subcluster or a secondary subcluster.

For Eon Mode databases, MC supports actions for subcluster and node management for the following public and private cloud providers:

- [Amazon Web Services](#) (AWS)
- [Google Cloud Platform](#) (GCP)
- [Microsoft Azure](#)
- [Pure Storage FlashBlade](#)

Note

Enterprise Mode does not support subclusters.

In the cloud

The explanations in this table apply to subcluster actions in the cloud. For the differences on-premises, see [On-Premises](#) further below.

Subcluster Action	Primary Subcluster	Secondary Subcluster
Add Subcluster	<p>Allowed.</p> <p>Must include at least one node. The subcluster cannot be empty.</p> <p>Vertica recommends having only one primary subcluster.</p> <p>You can add a second primary subcluster in order to stop the original primary. Be sure to make the replacement primary subcluster at least one node larger than the original. (If you make them the same size, they both count equally toward the quorum, and stopping either would violate the quorum, so you cannot stop either one. For more information, see Data integrity and high availability in an Eon Mode database.)</p>	<p>Allowed. Creates a new subcluster.</p> <p>Provisions cloud instance(s).</p> <p>Adds nodes to that subcluster.</p> <p>Defaults to minimum of one node.</p>

<p>Rebalance</p> <ul style="list-style-type: none"> This button applies to shard subscriptions in Eon Mode. 	<p>Always allowed.</p> <div style="background-color: #e1f5fe; padding: 10px; border: 1px solid #cfcfcf;"> <p>Note</p> <p>When you scale down a subcluster, Vertica rebalances the shards automatically, whereas when you scale up a subcluster, you must rebalance the shards yourself.</p> </div>	<p>Always allowed.</p> <p>See note for primary subcluster.</p>
<p>Start Subcluster</p> <ul style="list-style-type: none"> Includes starting cloud instances if not already running. 	<p>Available if primary subcluster is stopped.</p>	<p>Available if:</p> <ul style="list-style-type: none"> Secondary subcluster is stopped. Primary subcluster is running.
<p>Stop Subcluster</p> <ul style="list-style-type: none"> Includes stopping cloud instances. 	<p>Stop Subcluster is available for the primary subcluster only under certain conditions:</p> <ul style="list-style-type: none"> The primary subcluster must be running. One or more additional primary subclusters must exist in the database. It must be true that stopping this primary subcluster will shut down less than 50% of the primary nodes in the database. 	<p>Available if running.</p>
<p>Scale Up</p> <ul style="list-style-type: none"> Adds cloud instances which become added nodes. 	<p>Always allowed.</p> <ul style="list-style-type: none"> Vertica adds nodes that are the same instance type as the existing nodes that are already in the target subcluster. 	<p>Always allowed.</p>
<p>Scale Down</p> <ul style="list-style-type: none"> Removes nodes. Terminates instances. 	<p>Allowed only under the following conditions:</p> <ul style="list-style-type: none"> If K-safety is ≥ 1, the remaining number of nodes after scaling down the primary subcluster must be ≥ 3. The number of nodes you remove must be fewer than half the nodes. 	<p>Same as for primary.</p>
<p>Terminate Subcluster</p> <ul style="list-style-type: none"> Drops subcluster from database. Terminates instances. 	<p>Available if another primary subcluster exists in the database.</p>	<p>Always allowed.</p> <ul style="list-style-type: none"> Removes subcluster entry from SUBCLUSTERS table.

On-premises

When you start or stop a subcluster in an Eon Mode database on-premises, MC starts or stops the subcluster nodes on the Vertica host machines, but not the machines themselves.

When you scale up a subcluster on-premises, the MC wizard displays a list of the available Vertica host machines that are not currently part of a database. You select the ones you want to add to the subcluster as nodes, then confirm that you want to scale up the subcluster.

When you scale down a subcluster on-premises, MC removes the nodes from the subcluster in the database, but does not terminate the Vertica host machines. The hosts are now available for scaling up other subclusters.

Starting and stopping subclusters in MC

For Eon Mode databases, MC supports actions for subcluster and node management for the following public and private cloud providers:

- [Amazon Web Services \(AWS\)](#)
- [Google Cloud Platform \(GCP\)](#)
- [Microsoft Azure](#)
- [Pure Storage FlashBlade](#)

Note

Enterprise Mode does not support subclusters.

On the **Manage > Subclusters** tab, the tool bar displays the available subcluster actions above each subcluster. For example, the screen capture below shows the available actions for the default subcluster, which is also the primary subcluster: **Rebalance**, **Stop** (grayed out), **Scale Up**, **Scale Down**, and **Terminate** (grayed out).

Note

Terminate Subcluster is available for Eon Mode databases only in the cloud, not on premises.

Overview Activity Manage Design Load Query Execution Query Plan License Settings

Why are some actions grayed out?

Stop and **Terminate** are grayed out in this example because if you stopped or terminated the only primary subcluster, the database would shut down. For each subcluster, **Stop** displays if the subcluster is currently running, or **Start** displays if the subcluster is currently stopped. Both **Stop** and **Terminate** are grayed out if their execution would be unsafe for the database.

Starting a subcluster in the cloud

You can start any subcluster that is currently stopped.

1. In the **Manage > Subclusters** tab, locate the subcluster you want to start.
2. Just above it on the right, click **Start**.
3. In the **Start Subcluster** screen, click the check box to confirm you want to start the subcluster.
MC displays a progress screen while the startup tasks are executing.
4. When all the tasks are checked, click **Close**.
The **Manage > Subclusters** tab shows that your subcluster is started and its nodes are up.

Stopping a subcluster in the cloud

Important

Stopping a subcluster does not warn you if there are active user sessions connected to the subcluster. This behavior is the same as stopping an individual node. Before stopping a subcluster, verify that no users are connected to it.

You can stop a primary subcluster only if there is another primary subcluster in the database with node count greater at least by 1 node, to maintain K-safety.

You can add a second primary subcluster in order to stop the original primary. Be sure to make the replacement primary subcluster at least one node larger than the original. (If you make them the same size, they both count equally toward the quorum, and stopping either would violate the quorum, so you cannot stop either one. For more information, see [Data integrity and high availability in an Eon Mode database.](#))

You can stop a secondary subcluster anytime, to save money on cloud resources.

1. In the **Manage > Subclusters** tab, locate the subcluster you want to stop.
If the **Stop** button is displayed but grayed out, you cannot stop this subcluster because doing so would shut down the database.
2. Just above the subcluster on the right, click **Stop**.
3. In the **Stop Subcluster** window, click the check box to confirm you want to stop the subcluster.
MC displays a progress screen while the subcluster stopping tasks are executing.
4. When all the tasks are checked, click **Close**.
The **Manage > Subclusters** tab shows that your subcluster is stopped and its nodes are down.

Starting or stopping a subcluster on premises

When you start or stop a subcluster in an Eon Mode database on-premises, MC starts or stops the subcluster nodes on the Vertica host machines, but not the machines themselves.

See also

[Subcluster action rules in MC](#)

Scaling subclusters in MC

You can scale an Eon Mode subcluster [up](#) or [down](#), to increase or decrease the number of nodes in the subcluster. This lets you add compute capacity when you need it, and reduce it to save money or redirect resources when you don't.

For Eon Mode databases, MC supports actions for subcluster and node management for the following public and private cloud providers:

- [Amazon Web Services](#) (AWS)
- [Google Cloud Platform](#) (GCP)
- [Microsoft Azure](#)
- [Pure Storage FlashBlade](#)

Note

Enterprise Mode does not support subclusters.

Scaling up in the cloud

When you scale up a subcluster, MC adds one or more cloud instances to your database cluster as hosts, and adds them to your subcluster as nodes.

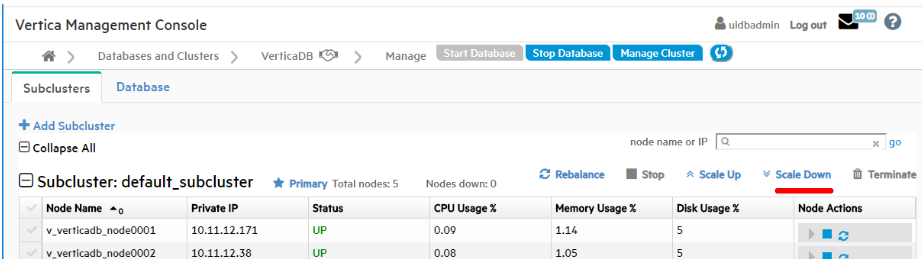

1. On the **Manage > Subclusters** tab, click **Scale Up** immediately above the subcluster you want to enlarge. MC launches the Scale Up wizard.
2. Wait a moment or two while MC pre-populates the fields on the **Enter AWS Credentials and preferences** screen with your credentials, then click **Next**.
3. On the **Specify Subcluster information** screen, enter the number of instances you want to add to the subcluster in **Number of Instances to Add**. MC pre-populates the number of existing hosts in the cluster.
4. Click **Browse** and select your Vertica license to insert in the license field, then click **Next**.
5. The **Specify cloud instance and data storage info** screen has fields that specify the cloud instance and data storage information. MC sets all the fields to the same values as the existing instances in your subcluster. Select **Next** to accept the existing values.
6. The **Specify additional storage and tag info** screen displays any tags you specified for your instances when you created the database cluster. You can use the same tags for the instances you are adding, or use the fields on the screen to add new tags for these instances. You can keep and apply or delete the existing tags. If you delete tags, they are not used for the instances you are adding now. When you are done modifying the tags, click **Next**.
7. MC displays the **Review 'Scale Up' information** screen for your approval. If the information is correct, click **Scale Up** to add the instances to the subcluster.
8. Wait until all operations on the progress screen show check marks, then click **Close**.

Scaling down in the cloud

When you scale down a subcluster, MC removes the requested number of nodes from the subcluster, and removes their hosts from the database cluster. It then terminates the underlying cloud instances. Scaling down a subcluster is allowed only when doing so will not cause the database to shut down.

For details on when Scale Down is or is not available for a subcluster, see [Subcluster action rules in MC](#).

1. On the **Manage > Subclusters** tab, click **Scale Down** above the subcluster to launch the Scale Down page:

2. In the **Number of hosts to remove** field, enter the number of hosts you would like to remove from the subcluster.
3. Under **Confirmation**, click the checkbox to affirm that you want to scale down the named subcluster, and terminate the instances the nodes were using.
4. Click **Scaledown Subcluster**.
The scale down operation may take a little time. When it finishes, the progress screen displays the details about the removed nodes and their hosts and the terminated instances.
5. When all steps show check marks, click **Close**.

Scaling on-premises

When you scale up a subcluster on-premises, the MC wizard displays a list of the available Vertica host machines that are not currently part of a database. You select the ones you want to add to the subcluster as nodes, then confirm that you want to scale up the subcluster.

When you scale down a subcluster on-premises, MC removes the nodes from the subcluster in the database, but does not terminate the Vertica host machines. The hosts are now available for scaling up other subclusters.

Terminating subclusters in MC

For Eon Mode databases, MC supports actions for subcluster and node management for the following public and private cloud providers:

- [Amazon Web Services](#) (AWS)
- [Google Cloud Platform](#) (GCP)
- [Microsoft Azure](#)
- [Pure Storage FlashBlade](#)

Note

Enterprise Mode does not support subclusters.

In the cloud

The **Terminate** action for subclusters is available for Eon Mode databases only in the cloud.

You can terminate any subcluster that will not cause the database to go down. You can terminate:

- Any secondary subcluster.
- A primary subcluster, provided that:
 - There is at least one other primary subcluster in the database.
 - The other primary subcluster is at least one node larger than the one you want to terminate.

Terminate a subcluster

1. On the **Manage > Subclusters** tab, click **Terminate** immediately above the target subcluster.
2. In the **Terminate Subcluster** window, click the check box to confirm you want to delete the chosen subcluster and terminate its instances.
3. Click **Terminate Subcluster**.
MC displays a progress window that shows the steps it is executing to terminate the subcluster.
4. When all the steps are checked, click **Close**.

On-premises

The **Terminate** action for subclusters is not available for Eon Mode on-premises. You can stop a subcluster on-premises, provided doing so will not bring down the database. You cannot terminate a subcluster on-premises, because terminating a subcluster stops the nodes and then terminates the cloud instances those nodes reside on. MC cannot terminate on-premises Vertica host machines.

To free up some of the Vertica host machines in an on-premises subcluster, scale down the subcluster.

See also

[Subcluster action rules in MC](#)

Node action rules in MC

The table below summarizes when each node action is available for nodes in the primary subcluster or in a secondary subcluster.

For Eon Mode databases, MC supports actions for subcluster and node management for the following public and private cloud providers:

- [Amazon Web Services](#) (AWS)
- [Google Cloud Platform](#) (GCP)
- [Microsoft Azure](#)
- [Pure Storage FlashBlade](#)

Note

Enterprise Mode does not support subclusters.

For Enterprise Mode databases, MC supports these actions:

- In the cloud on AWS: Add Node action, Add Instance action.
- On-premises: Add Node action.

Note

In the cloud on GCP, Enterprise Mode databases are not supported.

Node Action	Primary Subcluster	Secondary Subcluster
Start Node Starts instance if needed.	Always allowed.	Always allowed.
Stop Node Stops the instance on a cloud platform.	<ul style="list-style-type: none">• Allowed when K-safety is ≥ 1. After the node is stopped, there must be 3 or more remaining UP nodes.• Not allowed when K-safety is 0.	<ul style="list-style-type: none">• Allowed when K-safety is ≥ 1. After the node is stopped, there must be 3 or more remaining UP nodes.• Allowed when K-safety is 0.
Restart Node	<ul style="list-style-type: none">• Always allowed in the cloud.• Not available on premises.	<ul style="list-style-type: none">• Always allowed in the cloud.• Not available on premises.

The **Remove Node** action has been deleted from existing actions for all nodes. Use [Scale Down](#) subcluster instead.

When you start or stop a node on-premises, MC starts or stops the node in the database, but does not start or stop the Vertica host machine. The Restart Node action is not available for on-premises Eon Mode databases.

See also

[Starting, stopping, and restarting nodes in MC](#)

Starting, stopping, and restarting nodes in MC

In MC you can start, stop, and restart nodes in a subcluster in your database. This allows you to tailor the amount of compute power you are using to the current demands for the workload assigned to that subcluster.

For Eon Mode databases, MC supports actions for subcluster and node management for the following public and private cloud providers:

- [Amazon Web Services](#) (AWS)
- [Google Cloud Platform](#) (GCP)
- [Microsoft Azure](#)
- [Pure Storage FlashBlade](#)

Note

Enterprise Mode does not support subclusters.

For Enterprise Mode databases, MC supports these actions:

- In the cloud on AWS: Add Node action, Add Instance action.
- On-premises: Add Node action.

Note

In the cloud on GCP, Enterprise Mode databases are not supported.

On the **Manage > Subcluster** page in the right column, the **Node Actions** column displays icons that let you start, stop, or restart a node and the underlying cloud machine. Hover over an icon to read the action it performs. If an icon is grayed out, that action is not available for that node.

- **Start Node** . Start an individual node in the subcluster.
- **Stop Node** . Stop an individual node in the subcluster.
- **Restart Node (GCP only)** . Restart an individual node in the subcluster.

Eon Mode on-premises

In this section

- [Reviving an Eon Mode database on premises with FlashBlade using MC](#)
- [Creating an Eon Mode database on premises with FlashBlade in MC](#)

Reviving an Eon Mode database on premises with FlashBlade using MC

An [Eon Mode database](#) keeps an up-to-date version of its data and metadata in its communal storage location. After a cluster hosting an Eon Mode database is terminated, this data and metadata continue to reside in communal storage. When you revive the database later, Vertica uses the data in this location to restore the database in the same state on a newly provisioned cluster.

(For details on how to stop or terminate a cluster using Management Console, see [Viewing and managing your cluster](#).)

Prerequisites

You can revive a *terminated* Eon Mode database on premises that uses a Pure Storage FlashBlade appliance as its communal storage location if you have the following facts available:

- The endpoint IP address of the FlashBlade.
- The endpoint port for the FlashBlade.
- The access key and secret key for FlashBlade.
- The S3 URL for the FlashBlade.
- The name of the stopped database stored on the FlashBlade, that you wish to revive.

Revive an Eon Mode database from communal storage on FlashBlade

1. On the MC Infrastructure page, click the box for the cluster you wish to revive. MC displays a pop-up with cluster details and action buttons.
2. Click **Revive Database** . MC launches the **Revive an Eon Mode Database** wizard.
3. In the **S3 Communal Storage Information** screen, enter the following fields, then click **Next**:

S3-compatible End Point IP	The IP address of the Pure Storage FlashBlade appliance.
End Point IP	The port for the FlashBlade.
Access ID	The access key for the FlashBlade.
Secret Key	The secret key for the FlashBlade.

4. When you click **Next** , MC validates your credentials. If validation is successful, MC reads the list of S3 buckets on the end point (the FlashBlade).
5. In the **Path for Database Communal Location** screen, enter the following field , then click **Discover** .

<p>S3 path for Communal Storage of database(s)</p>	<p>Enter the complete S3 bucket URL for the database you wish to revive, in the following format:</p> <p><i>s3:// bucket-name / subfolder-name</i></p>
---	--

6. MC populates the table under the Discover button with the database names and complete S3 URLs of all the databases it finds on the S3 location.

1. Click the radio button for the database you want to revive, then click **Next** .
2. In the **Details of Selected Database to Revive** screen, MC pre-fills most of the fields. Enter and confirm your password:

Vertica Database Name	Database name is pre-entered.
Original Database Version	Database Vertica version is pre-filled.
Cluster Vertica Version	Cluster Vertica version is pre-filled.
Database size	Number of nodes is pre-filled.
Original Vertica Database Super User Name	Database super user name is pre-filled.
Password	Enter the database password.
Confirm Password	Re-enter the password to confirm.

3. MC validates the information. If validation is successful, the **Next** button changes from grayed out to active. Click **Next** .
4. In the **Eon Mode Database** screen, select the IP addresses of the nodes in the cluster on which you wish to revive the database. MC fills in the **Number of Nodes** field and displays the catalog path and depot path that were configured for the database when it was created.
5. In the **Temp Path** field, enter the complete path for the Temp directory. Then click **Next** .
6. MC displays the **S3 Provider Details** screen with a summary of all the information you have entered to revive the database. Review the information to verify it is correct. Then click **Revive Database** .
7. MC displays a progress screen indicating the database revival tasks that have been completed and the overall percentage of the revival that is complete. Wait until the revive is 100% complete, then click **Close** .

When the work is complete, Vertica displays the MC landing page.

Creating an Eon Mode database on premises with FlashBlade in MC

This topic describes how to create an Eon Mode database using only on-premises machines, with Pure Storage FlashBlade as the communal storage reservoir, using Management Console.

Step 1: create a bucket and credentials on the Pure Storage FlashBlade

To use a Pure Storage FlashBlade appliance as a communal storage location for an Eon Mode database you must have:

- The IP address of the FlashBlade appliance. You must also have the connection port number if your FlashBlade is not using the standard port 80

or 443 to access the bucket. All of the nodes in your Vertica cluster must be able to access this IP address. Make sure any firewalls between the FlashBlade appliance and the nodes are configured to allow access.

- The name of the bucket on the FlashBlade to use for communal storage.
- An access key and secret key for a user account that has read and write access to the bucket.

See the [Pure Storage support site](#) for instructions on how to create the bucket and the access keys needed for a communal storage location.

Step 2: install and configure MC

[Install](#) and [configure](#) Management Console on one of the on-premises machines.

Step 3: create or import a Vertica cluster

In MC, [create a Vertica cluster](#) on a group of on-premises machines, or import a previously created cluster to MC.

Step 4: create an Eon Mode database with FlashBlade as communal storage

Create an Eon Mode database on the on-premises cluster, using Pure Storage FlashBlade as your S3-compatible communal storage, as explained below.

1. In MC on the **Infrastructure** page, click the square for the specific cluster where you want to create the database. MC displays a pop-up with cluster details and action buttons.
2. Click **Create Database**. MC launches the **Create a New Database** wizard.
3. In the **Vertica Database Mode** screen, click the icon for **Eon Mode Database**, then click **Next**.
4. In the **S3 Communal Storage Information** screen, enter the following information, then click **Next**:

S3-compatible End Point IP	Enter the IP address of the Pure Storage FlashBlade appliance.
End Point Port	Enter the port of the FlashBlade appliance for a valid connection with the Management Console (80 for an unencrypted connection or 443 for an encrypted connection).
Access ID	Enter the access key for the FlashBlade.
Secret Key	Enter secret key for the FlashBlade.
Communal Location URL	Enter a communal location URL beginning with <code>s3://</code> that points to the third-party storage appliance you will be using, for example Pure Storage FlashBlade. For example, <code>s3:// bucket / subfolder</code> or <code>s3:// bucket / folder / subfolder</code> . The <i>bucket</i> must already exist, and the <i>subfolder</i> must not exist.

5. In the **Database Parameters** screen, enter these fields, then click **Next**:

Database Name	Enter 1-30 letters, numbers, and underscores. The first character must be alphabetic.
Password	Enter a new administrator password for the new Eon Mode database. Allowed characters: Alphanumeric (letters and digits) and ASCII special characters. Maximum is 100 characters.
Confirm Password	Enter the same password again to confirm it.
Port	Currently, Vertica supports only port 5433.
Catalog Path	Enter the directory path for the catalog of the Eon Mode database. The catalog should always reside on persistent storage. This path must exist on the host machines. If the path does not exist on the host machines you must create it manually before specifying it in this wizard.
Depot Path	Enter the directory path for the Eon Mode depot. MC populates the depot with recently used data. Queries that find their data in the depot get better performance. The directory must exist on the filesystem that was mounted during cluster creation. If the path does not exist on the host machines you must create it manually before specifying it in this wizard.
Depot Size	Enter the percentage of total disk space to use for the Eon Mode depot. The default is 60% of available disk. The maximum is 99,999T, or the equivalent in G or M units.

Temp Path	Directory path to use for temp data. This path must exist on the host machines. If the path does not exist on the host machines you must create it manually before specifying it in this wizard. For Temp, you may want to use a scratch disk.
------------------	--

6. In the **Specify Node Preferences** screen, select the IP addresses of the hosts for the database nodes. Then enter these fields, and click **Next** :

Number of nodes selected for the database	This value is set automatically. Always equal to the number of IP addresses you select.
Data Segmentation Shards	The number of shards is the number of segments that the data will be divided into in communal storage. For best performance, Vertica recommends you choose a number of shards that is a multiple of the number of nodes in the database. Vertica requires a minimum of 1 and allows a maximum of 960 shards. A good strategy is to choose an even number divisible by multiple factors. Consider the future growth of your database, as Vertica requires that the number of nodes be no greater than the number of shards, and you add nodes later but you cannot change the number of shards later.

7. MC displays a confirmation screen labeled **S3 Provider Details** , that summarizes all of your choices for configuring the Eon database. Verify the details are correct, then click **Create Database** .

8. MC creates the database, displaying a progress indicator screen. Wait for all steps to complete, which may take several minutes.

When the work is complete, navigate to the MC landing page to use your new database.

Managing queries using MC

Management Console allows you to view the query plan of an active query or a manually entered query specified by the user.

1. On the MC Home Page, click the database you want to view the **Overview** page.
2. Select the **Activity** tab to view the query activity.
3. Click the **Explain** tab to access the query plan.

See [Working with query plans in MC](#) and [Accessing query plans in Management Console](#) for further information.

Management Console provides two options for viewing the query plan: **Path Information** and **Tree Path** . For details on each, refer [Query plan view options](#) .

Additionally, you can also [Viewing projection and column metadata](#) using the **MC Explain** tab.

See also

- [Expanding and collapsing query paths](#)
- [Clearing query data](#)

In this section

- [About profile data in Management Console](#)
- [Profiling queries using MC](#)
- [Viewing profile data in MC](#)

About profile data in Management Console

After you profile a specific query, the Management Console Explain page displays profile data like query duration, projection metadata, execution events, optimizer events, and metrics in a pie chart.

See the following links for more information on the kinds of profile data you can review on the Management Console Explain page:

- [Projection metadata](#)
- [Query phase duration](#)
- [Profile metrics](#)
- [Execution events](#)
- [Optimizer events](#)

In this section

- [Projection metadata](#)
- [Query phase duration](#)
- [Profile metrics](#)
- [Execution events](#)

- [Optimizer events](#)

Projection metadata

To view projection metadata for a specific projection, click the projection name in the EXPLAIN output. Metadata for that projection opens in a pop-up window.

To view projection data for all projections accessed by that query, click the **View Projection Metadata** button at the top of the **Explain** page. The metadata for all projections opens in a new browser window.

Note

If the **View Projection Metadata** button is not enabled, click **Profile** to retrieve the profile data, including the projection metadata.

The projection metadata includes the following information:

- Projection ID
- Schema name
- Whether or not it is a superprojection
- Sort columns
- IDs of the nodes the projection is stored on
- Whether or not it is segmented
- Whether or not it is up to date
- Whether or not it has statistics
- Owner name
- Anchor table name

To display a SQL script that can recreate the projection on a different cluster, click **Click to get export data** . This script is identical to the output of the [EXPORT_OBJECTS](#) function. The SQL script opens in a pop-up window.

Copy and paste the command from this window, and click **Close** .

Query phase duration

This pie chart appears in the upper-right corner of the Query Plan window. It shows what percentage of total query processing was spent in each phase of processing the query.

The phases included in the pie chart (when applicable) are:

- Plan
- InitPlan
- SerializePlan
- PopulateVirtualProjection
- PreparePlan
- CompilePlan
- ExecutePlan
- AbandonPlan

Hover over the slices on the pie chart or over the names of the phases in the box to get additional information. You can see the approximate number of milliseconds (ms) and percentage used during each phase.

Note

The time data in the profile metrics might not match the times in the query phase duration. These times can differ because the query phase duration graph uses the longest execution time for a given phase from all the nodes. Network latency can add more data, which is not taken into account in these calculations.

Profile metrics

In the **Path Information** view, the area to the right of each query path contains profile metrics for that path.

- **Disk** —Bytes of data accessed from disk by each query path. If none of the query paths accessed the disk data, all the values are 0.

- **Memory** —Bytes of data accessed from memory by each query path.
- **Sent** —Bytes of data sent across the cluster by each query path.
- **Received** —Bytes of data received across the cluster by each query path.
- **Time** —Number of milliseconds (ms) that the query path took to process on a given node, shown on progress bars. The sum of this data does not match the total time required to execute the query. This mismatch occurs because many tasks are executed in parallel on different nodes. Hover over the progress bars to get more information, such as total bytes and percentages.

Note

The time data in the profile metrics might not match the times in the [Query phase duration](#) chart. These times can differ because the query phase duration graph uses the longest execution time for a given phase from all the nodes. Network latency can add more data, which is not taken into account in these calculations.

Execution events

To help you monitor your database system, Vertica logs significant events that affect database performance and functionality. Click **View Execution Events** to see information about the events that took place while the query was executing.

If the **View Execution Events** button is not enabled, click **Profile** to retrieve the profile data, including the execution events.

The arrows on the header of each column allow you to sort the table in ascending or descending order of that column.

The execution events are described in the following table.

Event Characteristic	Details
Time	Clock time when the event took place.
Node Name	Name of the node for which information is listed.
Session ID	Identifier of the session for which profile information is captured.
User ID	Identifier of the user who initiated the query.
Request ID	Unique identifier of the query request in the user session.
Event Type	Type of event processed by the execution engine. For a list of events and their descriptions, see Initial process for improving query performance .
Event Description	Generic description of the event.
Operator Name	<p>Name of the Execution Engine component that generated the event. Examples include but are not limited to:</p> <ul style="list-style-type: none"> • DataSource • DataTarget • NetworkSend • NetworkRecv • StorageUnion <p>Values from the Operator name and Path ID columns let you tie a query event back to a particular operator in the query plan. If the event did not come from a specific operator, then this column is NULL.</p>
Path ID	Unique identifier that Vertica assigns to a query operation or a path in a query plan. If the event did not come from a specific operator, this column is NULL.
Event OID	A unique ID that identifies the specific event.
Event Details	A brief description of the event and details pertinent to the specific situation.

Suggested Action	Recommended actions (if any) to improve query processing.
------------------	---

Optimizer events

To help you monitor your database system, Vertica logs significant events that affect database performance and functionality. Click **View Optimizer Events** to see a table of the events that took place while the optimizer was planning the query.

If the **View Optimizer Events** button is not enabled, click **Profile** to retrieve the profile data, including the optimizer events.

The arrows on the header of each column allow you to sort the table in ascending or descending order of that column.

The following types of optimizer events may appear in the table:

Event characteristic	Details
Time	Clock time when the event took place.
Node Name	Name of the node for which information is listed.
Session ID	Identifier of the session for which profile information is captured.
User ID	Identifier of the user who initiated the query.
Request ID	Unique identifier of the query request in the user session.
Event Type	Type of event processed by the optimizer.
Event Description	Generic description of the event.
Event OID	A unique ID that identifies the specific event.
Event Details	A brief description of the event and details pertinent to the specific situation.
Suggested Action	Recommended actions (if any) to improve query processing.

Profiling queries using MC

Management Console allows you to view profile data for a query.

- On the MC Home Page, click the database to view the **Overview** page.
- Click the **Explain** tab to perform tasks related to profiling a query.

See [Viewing profile data in MC](#) for further details.

On the **Explain** tab, you can view the following profile data using MC:

- [Query phase duration](#)
- [Projection metadata](#)
- [Execution events](#)
- [Optimizer events](#)
- [Profile metrics](#)

You can use any of the four different formats to view the profile data:

- Path Information view
- Query Drilldown view
- Tree Path view
- Profile Analysis view

See [Viewing different profile outputs](#) for detailed explanation of each view.

Additionally, Management Console supports different color codes for viewing the progress of profiling a query. For an explanation of these color codes, see [Monitoring profiling progress](#).

See also

- [Viewing profile data in MC](#)

Viewing profile data in MC

Management Console allows you to view profile data about a single query. You can:

- Review the profile data in multiple views
- View details about projection metadata, execution events, and optimizer events
- Identify how much time was spent in each phase of query execution and which phases took the most amount of time

After you select the database you want to use, you can view the profile data using Management Console in either of two ways:

- Focus on specific areas of database activity, such as spikes in CPU usage
- Review the profile data for a specific query

To focus on specific areas of database activity:

1. At the bottom of the Management Console window, click the **Activity** tab.
2. From the list at the top of the page, select **Queries**.
3. On the activity graph, click the data point that corresponds to the query you want to view.
4. In the **View Plan** column, click **Profile** next to the command for which you want to view the query plan. Only certain queries, like SELECT, INSERT, UPDATE, and DELETE, have profile data.
5. In The **Explain Plan** window, Vertica profiles the query.
6. You can view the output in Path Information view, Query Plan Drilldown view, Tree Path view, or Profile Analysis view. To do so, click the respective buttons on the left of the output box.

To review the profile data for a specific query:

1. In the **Explain** window, type or paste the query text into the text box. Additionally, you can monitor queries that are currently running. To do so, perform one of the following. In the **Find a Query By ID** input window:
 - Enter the query statement and transaction ID
 - Click the **Browse Running Queries** link

Caution

If you enter more than one query, Management Console profiles only the first query.

2. To receive periodic updates about the query's progress and resources used, select the **Enable Monitoring** check box. As a best practice, avoid specifying an interval time of less than 60 seconds because doing so may slow your query's progress.
3. Click the **Profile** button.

While Vertica is profiling the query, a **Cancel Query** button is enabled briefly, allowing you to cancel the query and profiling task. If the **Cancel Query** button is disabled, that means Management Console does not have the proper information to cancel the query or the query is no longer running in the database.

When processing completes, the profile data and metrics display below the text box. You can view the output in Path Information view, Query Plan Drilldown view, Tree Path view, or Profile Analysis view. To do so, click the respective view buttons on the left of the output box.

In this section

- [Viewing different profile outputs](#)
- [Monitoring profiling progress](#)
- [Expanding and collapsing query path profile data](#)

Viewing different profile outputs

Vertica Management Console allows you to examine the results of your query profile in multiple views. You can view your profile in the following formats:

- Path Information view
- Query Drilldown view
- Tree Path view
- Profile Analysis view

You can change the query profile output using the icons on the bottom portion of the **Explain** page.

Path Information [Clear All](#) | [Expand All](#) | [Collapse All](#)

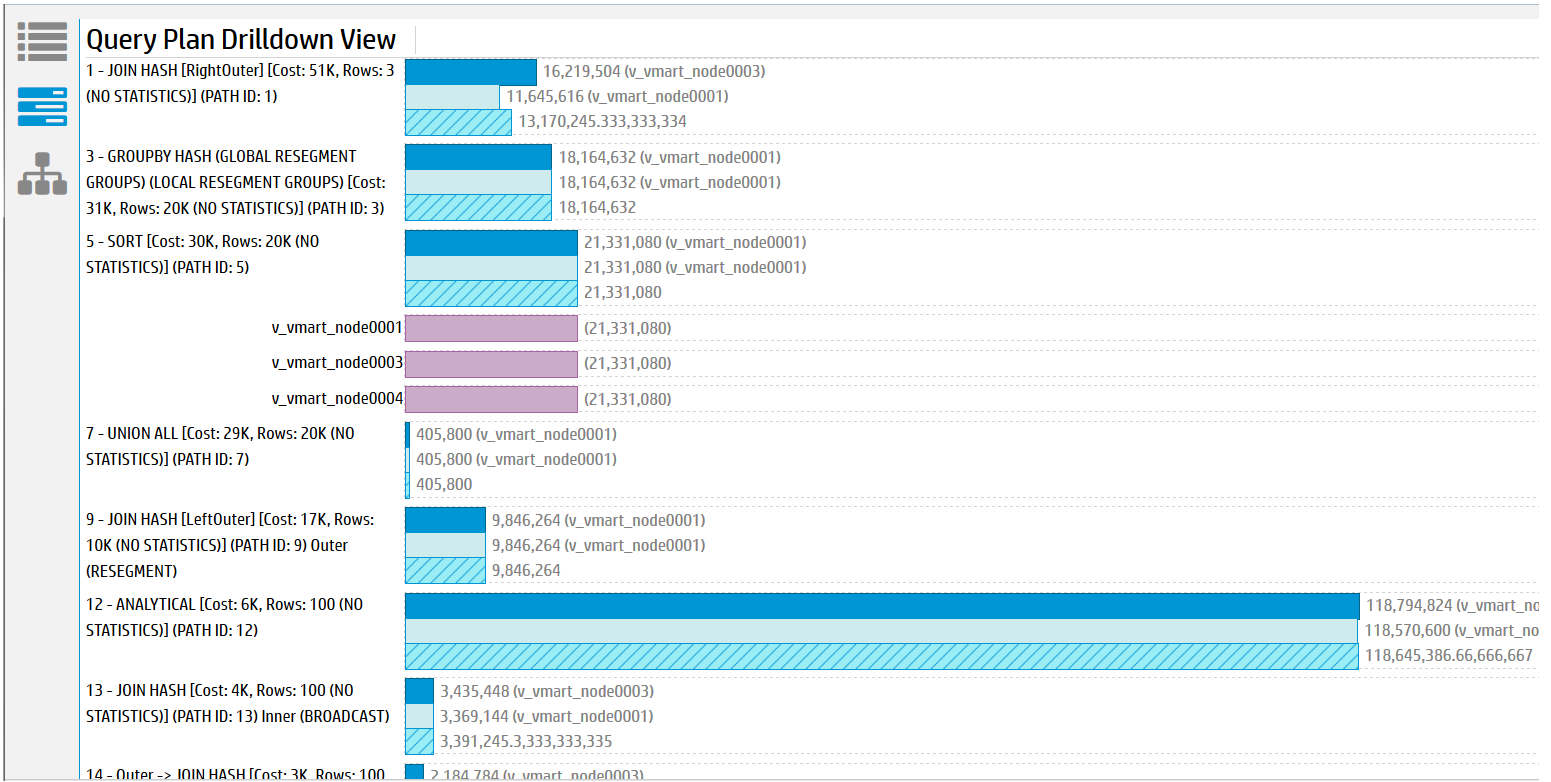

- Query Plan Drilldown View
- Tree Path View
- Profile Analysis

The **Path Information** view displays the query plan path along with metric data. If you enable profile monitoring, the data will update at the specified interval. To view metadata for a projection or a column, click the object name in the path output. A pop-up window displays the metadata if it is available.

Path Information [Clear All](#) | [Expand All](#) | [Collapse All](#)

	Disk	Memory	Sent	Received	Tired
+-JOIN HASH [RightOuter] [Cost: 51K, Rows: 3 (NO STATISTICS)] (PATH ID: 1) Join Cond: (a.design_name = dep_err.ddy) Execute on: All Nodes					
+----> GROUPBY HASH (GLOBAL RESEGMENT GROUPS) (LOCAL RESEGMENT GROUPS) [Cost: 31K, Rows: 20K (NO STATISTICS)] (PATH ID: 3) Aggregates: count(*) Group By: deploy_status.deploy_name Execute on: All Nodes Runtime Filter: (SIP21(HashJoin): dep_err.ddy) Execute on: All Nodes					
+----> SORT [Cost: 30K, Rows: 20K (NO STATISTICS)] (PATH ID: 5) Order: T."time" ASC Execute on: All Nodes Execute on: All Nodes					
+----> UNION ALL [Cost: 29K, Rows: 20K (NO STATISTICS)] (PATH ID: 7) Execute on: All Nodes Execute on: All Nodes					
+----> JOIN HASH [LeftOuter] [Cost: 17K, Rows: 10K (NO STATISTICS)] (PATH ID: 9) Outer (RESEGMENT) Join Cond: (ds.deployment_step = pr.projection_basename) Execute on: All Nodes					
+----> ANALYTICAL [Cost: 6K, Rows: 100 (NO STATISTICS)] (PATH ID: 12) Analytic Group Functions: rank() Group Global Resegment: ds.projection_id Group Sort: ds.projection_id ASC, ds."time" DESC NULLS FIRST Execute on: All Nodes					

The **Query Plan Drilldown** view shows detailed counter information at the node and operator level.

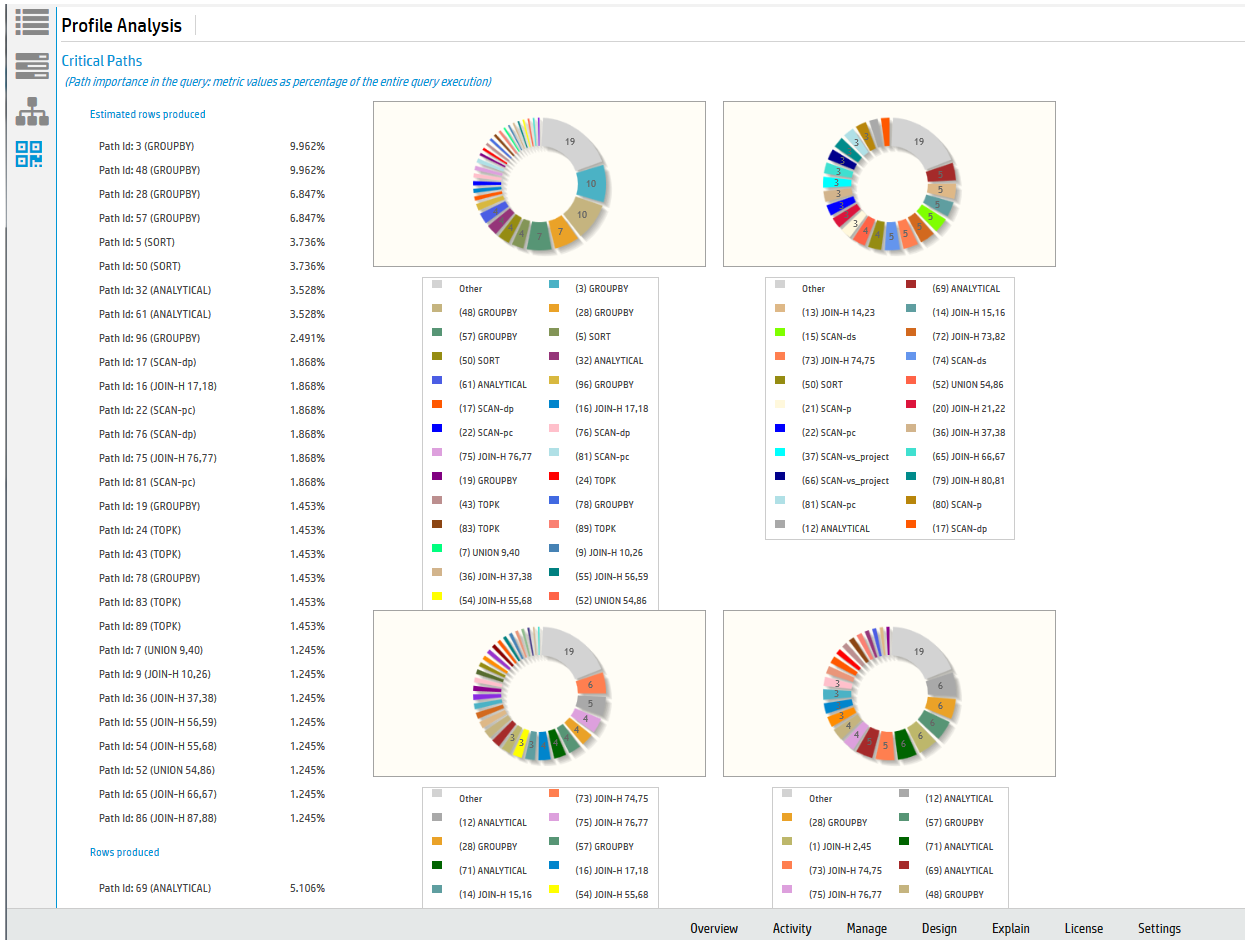

For each path, the path number is listed along with statistical information on the node and operator level. This view allows you to see which nodes are acting as outliers. Click on any of the bars to expand details for that node.

The **Tree Path** details the query plan in the form of a tree. If you enable monitoring, the state of the path blocks will change depending on whether the path is running, done, or has not started. Metric information is displayed in each path block for the counters you specified in the Profile Settings.

The **Profile Analysis** view allows you to identify any resource outliers. You can compare the estimated rows produced count with the actual rows produced count, view execution time per path, and identify memory usage per path.

When you profile a query, you will also see a pie chart detailing the query phase duration. You can also view projection metadata, execution events, and optimizer events by clicking on the respective buttons next to the pie chart.

Monitoring profiling progress

While loading profile data for a query, Management Console can provide updates about the query's progress and resources used.

To enable profiling progress updates, select the Enable Monitoring check box when profiling a query. See [Viewing Profile Data in Management Console](#).

The default interval time is 60 seconds. At the specified interval, Management Console displays an updated view of the query's progress. Note that interval times of less than 60 seconds may slow down your query.

Viewing updated profile metrics

At every interval, Management Console displays a new set of profile metrics. You can view these metrics in Path Information view, Query Plan Drilldown view, or Tree view by clicking the respective view buttons on the left of the output box.

- A dark blue bar indicates the current metric percentage.
- When a metric bar has decreased, a dark blue line indicates the previous metric percentage.
- When a metric bar has increased, a light blue bar indicates the added percentage. The previous percentage appears as a dark blue bar.
- A metric bar highlighted in yellow indicates it has changed since the last interval.
- A metric bar highlighted in red indicates the absolute value of the metric has decreased. This typically means Vertica reported the previous value incorrectly, and has readjusted. (For example, if Vertica previously reported path's Time value as 75 seconds, then reports it as 50 seconds at the next interval, the metric bar turns red to indicate the decrease in absolute Time value.)

Expanding and collapsing query path profile data

When you have a query on the EXPLAIN window, the profile data displays in the right-hand side of the lower half of the window. The query path information can be lengthy, so you can collapse path information that is uninteresting, or expand paths that you want to focus on.

- To collapse all the query paths, click **Collapse All** .
- To expand all the query paths, click **Expand All** .
- To expand an individual query path so you can see details about that step in processing the query, click the first line of the path information. Click the first line again to collapse the path data.

For information about what the profile data means, see [About profile data in Management Console](#) .

Working with query plans in MC

Management Console can show you a query plan in easy-to-read format, where you can review the optimizer's strategy for executing a specific query. You can view a query plan in either of two ways:

- View the plan of an active query.
- View the plan for any query that you manually specify.

Access the plan of an active query

1. At the bottom of the Management Console window, click the **Activity** tab.
2. From the list at the top of the page, select **Queries** .
3. On the activity graph, click the data point that corresponds to the query you want to view.
4. In the View Plan column, click **Explain** next to the command for which you want to view the query plan. Only certain queries use query plans—for example, SELECT, INSERT, DELETE, and UPDATE.
5. In the Explain Plan window, click **Explain** . Vertica generates the query plan.
6. (Optional) View the output in Path Information view or Tree Path view. To do so, click the respective view buttons on the left of the output box.

Access the plan for a specific query

1. Locate the query for which you want to see the query plan in either of the following ways:
 - **Queries Not Running** — In the Explain window, type or paste the query text into the text box.
 - **Queries Currently Running** — In the Find a Query By ID input window, perform one of the following actions:
 - Enter the query statement and transaction ID.
 - Click the **Browse Running Queries** link.

Caution

Entering the word EXPLAIN before the query results in a syntax error.

2. Click **Explain** . Vertica generates the plan.

If the query is invalid, Management Console highlights in red the parts of your query that might have caused a syntax error.

3. (Optional) View the output in Path Information view or Tree Path view. To do so, click the respective view buttons on the left of the output box.

In this section

- [Accessing query plans in Management Console](#)
- [Query plan view options](#)
- [Expanding and collapsing query paths](#)
- [Clearing query data](#)
- [Viewing projection and column metadata](#)

Accessing query plans in Management Console

You can access query plans in Management Console in two ways:

- In the Detail page for query-related charts on the database's Activity page, click **Explain** next to a query to view a plan for that query.
- Enter a query manually on the Explain page and click **Explain Plan** .

In both cases, the following window opens:

You can also enter the transaction ID and statement ID or browse running or completed queries in the Find a Query input window:

In the output window, you can perform the following tasks related to the query you entered:

- [Expand and collapse query paths.](#)
- [Clearing query data.](#)
- [View projection and column metadata.](#)
- [Use different query plan views.](#)

Query plan view options

Vertica Management Console provides two views for displaying query plans:

- Path Information
- Tree Path

Note

Query Plan Drilldown and Profile Analysis output views are only available when you run [PROFILE](#).

You can change the query plan view using the icons on the bottom portion of the **Explain** page.

The **Path Information** view displays the query plan path. You can expand or collapse the view to see different levels of detail. To view metadata for a projection or a column, click the object name in the path output. A pop-up window displays the metadata, if it is available.

Path Information

[Clear All](#) | [Expand All](#) | [Collapse All](#)

```

The **Tree Path** view details the query plan in the form of a tree. When you run EXPLAIN, the tree view does not contain any metrics because the query has not yet executed.

Tree Path View

Legends

Metrics

Node States

- Waiting
- Running
- Finished
- Non-operator

Expanding and collapsing query paths

The EXPLAIN window initially displays the full query plan as generated by the [EXPLAIN](#) command. Query plans can be lengthy, so you might want to modify the display so you can focus only on areas of interest:

- Collapse All collapses all query paths, and displays only a summary of each path.
- Expand All expands all query paths.
- Click the first line of a path to display details for that path. To collapse that path, click its first line again.

For details about EXPLAIN command output, see [EXPLAIN-Generated query plans](#).

Clearing query data

After you finish reviewing the current query data, click Clear All to clear the query text and data. Alternatively, to display information about another query, enter the query text and click Explain or Profile.

Viewing projection and column metadata

In the Management Console EXPLAIN window, when query paths are expanded in the Path Information view, Projection lines contain a projection name and Materialize lines contain one or more column names.

To view metadata for a projection or a column, click the object name. A pop-up window displays the metadata. The following image on the left shows example projection metadata and the image on the right shows example column metadata.

Note

Most system tables do not have metadata.

Details	
name	online_sales_fa
id	450359962765!
owner	uidbadmin
schema	online_sales
node	null
anchor_table	online_sales_fa
isprejoin	false
create_type	DESIGNER
verified_fault_tolerance	0
isuptodate	true
hasstatistics	true
issegmented	true
issuperprojection	true

Details	
name	cc_name
max	Southwest
position	3
min	California
ndv	11
sort_order	4

When you are done viewing the metadata, close the pop-up window.

Creating a database design in Management Console

[Database Designer](#) creates a design that provides excellent performance for ad-hoc queries and specific queries while using disk space efficiently. Database Designer analyzes the logical schema definition, sample data, and sample queries, and creates a physical schema that you can deploy.

For more about how Database Designer works, see the [Creating a database design](#) section of the documentation, and [About Database Designer](#).

To use Management Console to create an optimized design for your database, you must be a DBADMIN user or have been assigned the DBDUSER role.

Management Console provides two ways to create a design:

- **Wizard** —This option walks you through the process of configuring a new design. Click **Back** and **Next** to navigate through the Wizard steps, or **Cancel** to cancel creating a new design.
To learn how to use the Wizard to create a design, see [Using the wizard to create a design](#).
- **Manual** —This option creates and saves a design with the default parameters.
To learn how to create a design manually, see [Creating a design manually](#).

Tip

If you have many design tables that you want Database Designer to consider, it might be easier to use the Wizard to create your design. In the Wizard, you can submit all the tables in a schema at once; creating a design manually requires that you submit the design tables one at a time.

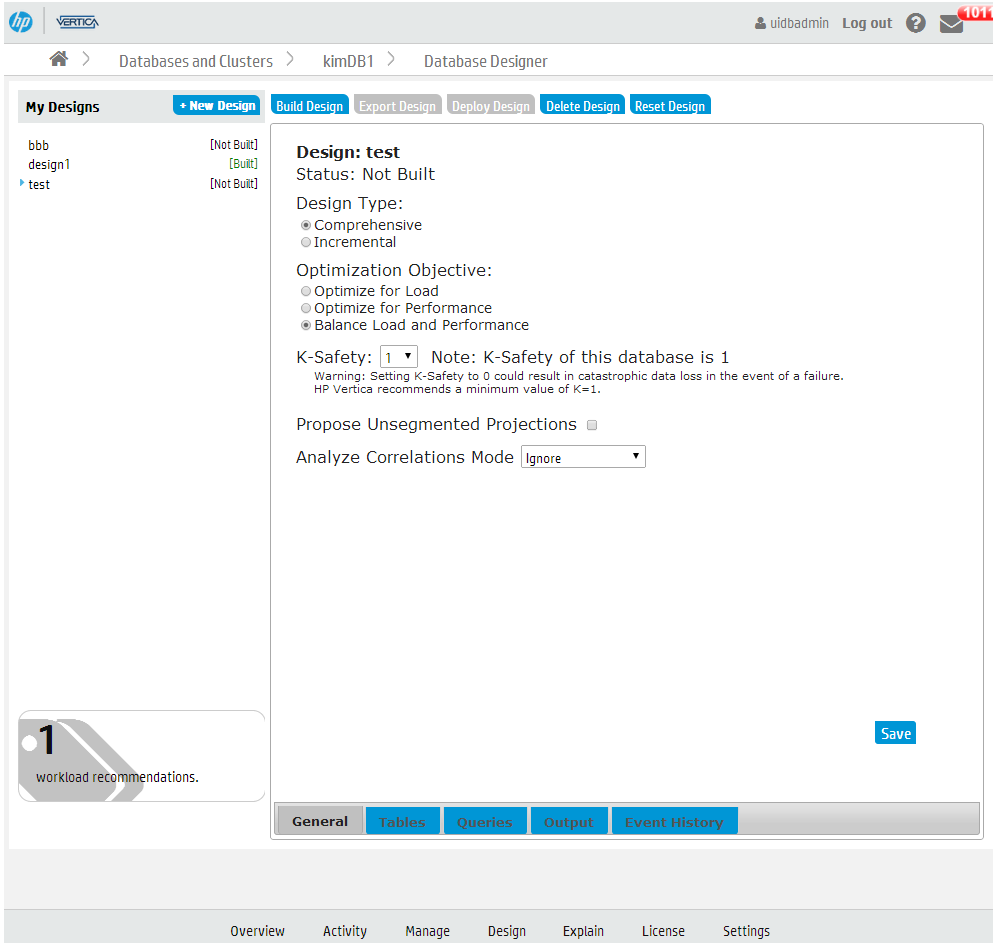

In this section

- [Using the wizard to create a design](#)
- [Creating a design manually](#)

Using the wizard to create a design

Take these steps to create a design using the Management Console's Wizard:

1. On your database's dashboard, click the **Design** tab at the bottom of the page to navigate to the Database Designer page.
The left side of the Database Designer page lists the database designs you own, with the most recent design you worked on highlighted. That pane also lists the current status of the design. Details about the most recent design appear in the main pane.
The main pane contains details about the selected design.

2. To create a new design, click **New Design** .
3. Enter a name for your design, and click **Wizard** .
4. Navigate through the Wizard using the **Back** and **Next** buttons.
5. To build the design immediately after exiting the Wizard, on the **Execution Options** window, select **Auto-build** .

Important

Vertica does not recommend that you auto-deploy the design from the Wizard. There might be a delay in adding the queries to the design, so if the design is deployed but the queries have not yet loaded, deployment might fail. If this happens, reset the design, check the **Queries** tab to make sure the queries are loaded, and deploy the design.

6. After you enter all the information, the Wizard displays a summary of your choices. Click **Submit Design** to build your design.

Summary

Review these design choices. Click Submit Design when you finish configuring your design.

Design Name: **VMart_design**
Design Type: **comprehensive**
Optimization Objective: **balanced**
Schemas: **public, store, online_sales**
K-Safety: **1**
Analyze Correlation Mode: **Ignore**
Propose Unsegmented Projections: **true**
Query File to Upload:
User Query Repository: **true**
Execution Options - Analyze Statistics: **true**
Execution Options - Auto-build: **true**
Execution Options - Auto-deploy: **false**

[Back](#) [Submit Design](#) [Cancel](#)

See also

- [About Database Designer](#)
- [Creating a design manually](#)

Creating a design manually

To create a design using Management Console and specify the configuration, take these steps.

1. On your database's dashboard, click the **Design** tab at the bottom of the page to navigate to the Database Designer page. The left side of the Database Designer page lists the database designs you own, with the most recent design you worked on highlighted. That pane also lists the current status of the design. Details about the most recent design appear in the main pane. The main pane contains details about the selected design.

The screenshot shows the HP Vertica Database Designer interface. At the top, there's a navigation bar with 'Databases and Clusters > kimDB1 > Database Designer'. Below that, a 'My Designs' sidebar lists 'bbb [Not Built]', 'design1 [Built]', and 'test [Not Built]'. The main area is titled 'Design: test' with 'Status: Not Built'. It includes configuration options: Design Type (Comprehensive selected), Optimization Objective (Balance Load and Performance selected), K-Safety (1 selected), Propose Unsegmented Projections (checkbox), and Analyze Correlations Mode (Ignore selected). A 'Save' button is at the bottom right. A 'workload recommendations' callout is visible in the bottom left. The bottom navigation bar includes Overview, Activity, Manage, Design, Explain, License, and Settings.

2. To create a new design, click **New Design**.
3. Enter a name for your design and select **Manual**.

The main **Database Design** window opens, displaying the default design parameters. Vertica has created and saved a design with the name you specified, and assigned it the default parameters.

4. On the **General** window, modify the design type, optimization objectives, K-safety, Analyze Correlations Mode, and the setting that allows Database Designer to create unsegmented projections.
If you choose **Incremental**, the design automatically optimizes for the desired queries, and the K-safety defaults to the value of the cluster K-safety; you cannot change these values for an incremental design.
Analyze Correlations Mode determines if Database Designer analyzes and considers column correlations when creating the design.
5. Click the **Tables** tab. You must submit tables to your design.
6. To add tables of sample data to your design, click **Add Tables**. A list of available tables appears; select the tables you want and click **Save**. If you want to remove tables from your design, click the tables you want to remove, and click **Remove Selected**.
If a design table has been dropped from the database, a red circle with a white exclamation point appears next to the table name. Before you can build or deploy the design, you must remove any dropped tables from the design. To do this, select the dropped tables and click **Remove Selected**. You cannot build or deploy a design if any of the design tables have been dropped.
7. Click the **Queries** tab. To add queries to your design, do one of the following:
 - To add queries from the [QUERY_REQUESTS](#) system table, click **Query Repository**. In the Queries Repository dialog that appears, you can sort queries by most recent, most frequently executed, and longest running. Select the desired queries and click **Save**. All valid queries that you selected appear in the **Queries** window.Database Designer checks the validity of the queries when you add the queries to the design and again when you build the design. If it finds invalid queries, it ignores them.
If you have a large number of queries, it may take time to load them. Make sure that all the queries you want Database Designer to consider when creating the design are listed in the **Queries** window.
8. Once you have specified all the parameters for your design, you should build the design. To do this, select your design and click **Build Design**.
9. Select **Analyze Statistics** if you want Database Designer to analyze the statistics before building the design.
For more information see [Statistics Analysis](#).
10. If you do not need to review the design before deploying it, select **Deploy Immediately**. Otherwise, leave that option unselected.
11. Click **Start**. On the left-hand pane, the status of your design displays as **Building** until it is complete.
12. To follow the progress of a build, click **Event History**. Status messages appear in this window and you can see the current phase of the build operation. The information in the Event History tab contains data from the [OUTPUT_EVENT_HISTORY](#) system table.
13. When the build completes, the left-hand pane displays **Built**. To view the deployment script, select your design and click **Output**.
14. After you deploy the design using Management Console, the deployment script is deleted. To keep a permanent copy of the deployment script, copy and paste the SQL commands from the **Output** window to a file.
15. Once you have reviewed your design and are ready to deploy it, select the design and click **Deploy Design**.
16. To follow the progress of the deployment, click **Event History**. Status messages appear in this window and you can see the current phase of the deployment operation.
In the Event History window, while the design is running, you can do one of the following:
 - Click the blue button next to the design name to refresh the event history listing.
 - Click **Cancel Design Run** to cancel the design in progress.
 - Click **Force Delete Design** to cancel and delete the design in progress.
17. When the deployment completes, the left-hand pane displays **Deployment Completed**. To view the deployment script, select your design and click **Output**.

Your database is now optimized according to the parameters you set.

Running queries in Management Console

You can use the Query Runner to run SQL queries on your database through Management Console (MC). After executing a query, you can also get the query plan and profile information for the query on this page.

To reach the Query Runner, select your database from the Home page or the Databases and Clusters page to view your database's Overview page. Select Query Execution at the bottom of the Overview page.

Home > Databases and Clusters > VMart > Query Runner

Query History

Clear all

Filter previous queries

SELECT sales_quantity, sales_dollar_amount, transaction_type, cc_name FROM online_sales.online_

SELECT sales_quantity, sales_dollar_amount, transaction_type, cc_name FROM online_sales.online_

SELECT sales_quantity, sales_dollar_amount, transaction_type, cc_name FROM online_sales.online_

SELECT sales_quantity, sales_dollar_amount, transaction_type, cc_name FROM online_sales.online_

SELECT sales_quantity, sales_dollar_amount, transaction_type, cc_name FROM online_sales.online_

```

1 SELECT sales_quantity, sales_dollar_amount, transaction_type, cc_name
2 FROM online_sales.online_sales_fact
3 INNER JOIN online_sales.call_center_dimension
4 ON (online_sales.online_sales_fact.call_center_key
5     = online_sales.call_center_dimension.call_center_key

Settings

To familiarize yourself with how queries work in Vertica, you can refer to the [Queries](#) section of the documentation, as well as the [SQL reference](#).

Limitations

You cannot execute COPY LOCAL statements using the Query Runner. To do so, use the vsql client installed on the server. See [Using vsql](#). (To use MC to import data from Amazon S3 storage to your Vertica database, see [Loading data from Amazon S3 using MC](#).)

Manually commit any transactions (INSERT and COPY statements) you perform by adding the COMMIT statement in the text box after the transaction statements. If you do not do so, the transaction rolls back.

In the following example, to insert values into table1, include a COMMIT statement in the text box and execute the two statements together: **INSERT**

INSERT INTO table1 VALUES (1,2); COMMIT;

```

1 INSERT INTO table1 VALUES (4,5);
2 COMMIT;

```

Execute Queries

Format

To input a series of queries, delimit them with a semicolon (;).

To automatically format the SQL text you have input, click the Format icon (</>).

Privileges

It is important when running queries in MC that the database administrator has correctly set up MC user privileges. The administrator must map all MC user profiles to their corresponding database user.

The Query Runner only permits MC users to perform actions that their corresponding Vertica database roles allow.

To set up user mappings, go to Home > MC Settings > User Management.

For more about how mapping MC user profiles to database users works, see [Database privileges](#). For information about database-level users and privileges, see the [Database users and privileges](#) section of the documentation.

Execute a query

The Query Runner provides several ways to input a query to run:

- **Input text.** Enter the text for a query or series of queries into the text box.
- **Import a SQL script.** Click the Upload icon () to the top right of the text box to upload a SQL script (plain text file, typically with an extension of .sql). The queries from that file appears in the text box.

- **Enter a previous query from the Query History tab.** The Query History tab, on the left side of the page, displays the last 100 queries you have executed using the Query Runner on your current device and browser. Click any previous query in this tab to enter that query into the text box.

Hover over a query in the Query History tab to view all the query text. To clear queries from your history, hover over an individual query and click **x**, or click **Clear all** at the top of the tab. Click the star to the left of any query to favorite it, so it won't be cleared when you click **Clear all**.

Click **Execute Query** to run the queries you have input.

You can also execute only a portion of the text entered into the text box, as long as the selected text is a valid query. To do so, select that portion of the text. The **Execute selected text as query** button then appears below the text box.

For example, you might execute only a part of the entered text if you have uploaded a SQL script that containing multiple queries, but you decide to run only one of those queries.

To customize your execution settings, click the Settings icon () at the top right of the text box:

- **Row Limit:** Set the maximum number of rows to return. By default, the limit is 10000 rows.
- **Search Path:** Specify the schema to query.

```

1 SELECT sales_quantity, sales_dollar_amount, transaction_type, cc_name
2 FROM online_sales.online_sales_fact
3 INNER JOIN online_sales.call_center_dimension
4 ON (online_sales.online_sales_fact.call_center_key
5     = online_sales.call_center_dimension.call_center_key
6     AND sale_date_key = 156)
7 ORDER BY sales_dollar_amount DESC;
8 SELECT order_number, date_ordered
9 FROM store.store_orders_fact orders
10 WHERE orders.store_key IN (
11     SELECT store_key
12     FROM store.store_dimension
13     WHERE store_state = 'MA')
14     AND orders.vendor_key NOT IN (
15     SELECT vendor_key
16     FROM public.vendor_dimension
17     WHERE vendor_state = 'MA')
18     AND date_ordered < '2012-03-01';
19 SELECT store_key, order_number, date_ordered

```

Execute Queries Execute selected text as query

Get query results

The Query Runner returns results in a table format. If you ran multiple queries simultaneously, the results window displays a tab for each set of results. View the number of rows returned and the query execution time at the bottom of the results window.

If your result returns many columns, you can click **Auto-resize all columns** in the top right of the results window for a better fit, or click and drag column borders to manually resize individual columns.

Sort results by clicking on a column name, or use the search bar to narrow down results.

Execute Queries			
SELECT fat_cont	SELECT sales_qu		↑ ↓
Query Results	Query Plan	Query Profile	Export Data Auto-Resize all columns Search query results
sales_quantity	sales_dollar_amount	transaction_type	cc_name
8	589	purchase	California
7	589	purchase	Central Midwest
8	589	purchase	South Midwest
1	587	purchase	New England
1	586	purchase	Other

2514 rows | Execution time: 0.176s

Query plans and profiles

Each query result also displays an option to retrieve the plan or profile for that query.

After retrieving a plan or profile, you can expand or collapse the results view to see different levels of detail. To view metadata for a projection or a column, click the object name in the path output. A pop-up window displays the metadata, if it is available.

```

SELECT sales_qu SELECT order_nu SELECT store_ke
Query Results Query Plan Query Profile Expand All Collapse All
+-SELECT LIMIT 10K [Cost: 263K, Rows: 10K (NO STATISTICS)] (PATH ID: 0)
Output Only: 10000 tuples
+----> SORT [TOPK] [Cost: 263K, Rows: 5M (NO STATISTICS)] (PATH ID: 1)
Order: online_sales_fact.sales_dollar_amount DESC
Output Only: 10000 tuples
+----> JOIN HASH [Cost: 16K, Rows: 5M (NO STATISTICS)] (PATH ID: 2)
Join Cond: (online_sales_fact.call_center_key = call_center_dimension.call_center_key)
Materialize at Output: online_sales_fact.sales_quantity, online_sales_fact.sales_dollar_amount, online_sales_fact.transaction_type
+-- Outer -> STORAGE ACCESS for online_sales_fact [Cost: 9K, Rows: 5M (NO STATISTICS)] (PATH ID: 3)

```

Note that the Query Runner does not automatically provide query profiles for queries that run for less than 1 second. To do so, prepend the word PROFILE to the query and run it.

You can also profile your query on the **Query Plan** page. The Query Plan page provides more details about both plan and profile results, including a query plan drilldown by node, a tree path view, and a profile analysis.

Keyboard shortcuts

The Query Runner provides the following keyboard shortcuts:

- **?** : Press the question mark to display or dismiss a list of the available keyboard shortcuts. (You can also click the question mark icon at the top right of the text box to view this list.)
- **alt + ↑** : Press alt + up arrow to decrease the height of the text box.
- **alt + ↓** : Press alt + down arrow to increase the height of the text box.
- **ctrl + enter** : Press ctrl + enter to run the query.
- **ctrl + shift + enter** : Press ctrl + shift + enter to run selected text.

Working with workload analyzer recommendations in MC

If queries perform sub-optimally, use [Workload Analyzer](#) to get tuning recommendations and hints about optimizing database objects.

Workload Analyzer is a Vertica utility that analyzes system information in Vertica system tables. It then returns a set of tuning recommendations based on statistics, system and data collector events, and database/table/projection design. You can use these recommendations to tune query performance.

Configuring the workload analyzer execution time

By default, Workload Analyzer runs each day at 2 AM. To optimize when Workload Analyzer uses resources, you can set Workload Analyzer to run at a different time for any or all databases that Management Console monitors. Alternately, you can set Management Console to never run Workload Analyzer automatically.

Note

Workload Analyzer automatically begins monitoring data one minute after the Management Console process starts. Workload Analyzer then runs once per day, or immediately after you import a database to Management Console. It continually gathers data in the background as long as the database is running. If you have not yet created a database, or if the database is down, Workload Analyzer does nothing until the database is back up.

1. On the Home page, click **MC Settings** .
2. Click the **Monitoring** tab.
3. Under the **Workload Analyzer Assistant** section of the Monitoring page, select your time zone.
4. Select the radio button for one of the options:

- **All Databases:** Select a time from the list. Workload Analyzer will run at that time on all databases that MC monitors.
 - **Specific Database at Specific Time:** Select a database and a time from the list. At the time you specify, Workload Analyzer will run at that time on the database you selected.
 - **Do Not Run Workload Analyzer On Any Database:** MC will never run Workload Analyzer automatically on any database it monitors.
5. Click **Apply** at the top right of the page.

For additional information about tuning recommendations and their triggering event, see [Workload analyzer recommendations](#).

View workload analyzer recommendations

Workload Analyzer recommendations are available from the Quick Stats sidebar on the right of the database's **Overview** page. The Workload Analyzer module displays the number of tuning recommendations that the Workload Analyzer has generated.

To view the Workload Analyzer Results on the Database Designer page, click the number in the Workload Analyzer module.

The Workload Analyzer Results window allows you to view details about and perform actions using current and processed recommendations.

Click the **Current Recommendations** radio button to display available Workload Analyzer recommendations. When [ANALYZE_STATISTICS](#) is returned as a tuning recommendation, select the check mark to the left of the row and click **Run Selected Recommendations** to execute the recommendation automatically.

Total commands submitted for execution: 1 (Selected rows for clearing from database: 1)

1 of 1 items

You can force the Workload Analyzer task to run immediately by clicking **Update Recommendations**, located above the **Status** column.

The total recommendations and the number of recommendations currently selected to run are displayed under the recommendations grid. Use the settings under the grid to view more recommendations per page or to cycle through the recommendations that do not fit on the page.

The following columns are used to describe recommendations:

- **Tuning Description** — Describes the Workload Analyzer recommendation.
- **Tuning Cost** — Resource cost of running each command (LOW, MEDIUM, or HIGH).

Tip
When the tuning cost is HIGH, consider running the recommended tuning during off-peak load times.

- **Tuning Command** — SQL command used to execute the recommendation.
- **Last Executed On** — Date that the recommendation was last run. In MM/DD/YYYY format.
- **Status** — Describes the execution stage of a tuning recommendation ran from Workload Analyzer Results.

For more information about tuning recommendations, see [Getting tuning recommendations](#) and [ANALYZE_WORKLOAD](#).

Running workload analyzer recommendations to optimize a query

When the Workload Analyzer recommends that you run [ANALYZE_STATISTICS](#) to optimize a query, you can run the recommendation automatically from Workload Analyzer Results.

1. Record the data source and execution time for a query that is running sub-optimally.
 1. Click the **Query Execution** tab at the bottom.
 2. Use the Query Runner to execute a query that you want to optimize.
 3. Record the database table or tables in the query's **FROM** clause, and record the **Execution time**, located under the **Query Results** table.

431 rows | Execution time: 14.805s

2. Click the **Overview** tab at the bottom of the window.
3. On the **Overview** page, click the number in the **Workload Analyzer** box on the right.

Workload Analyzer Results opens.

4. To filter the recommendations, enter the sub-optimal query's database table or tables in the field at the top of the **Tuning Description** column.

- Select one or more **ANALYZE_STATISTICS** recommendations by clicking the check mark to the left of the row. To select all of the filtered **ANALYZE_STATISTICS** recommendations, click the check mark to the left of the **Tuning Description** column header.

✓	Tuning Description	Tuning Cost	Tuning Command	Last Executed On	Status
	public.testInsert				
	run database designer on table public.testInsert	HIGH			
✓	analyze statistics on table column public.testInsert.a	MEDIUM	select analyze_statistics('public.testInsert.a');		

- Click **Run Selected Recommendations**, located in the bottom-right of the window. This process might take several minutes.
- After the tuning recommendations are completed, click the **Processed Recommendations** radio button at the top of the window. The previously executed recommendations are displayed.
- Locate any recommendations that you just executed, and verify that the **Status** column says **COMPLETED**.
- Verify that the query was optimized.
 - Click the **Query Execution** tab at the bottom of the Management Console.
 - Execute the query that was performing sub-optimally. Note the **Execution time** under the query results to verify the performance increase.

431 rows | Execution time: 0.312s

Running Database Designer using MC

You can use Database Designer to create a comprehensive design, which allows you to create new projections for all tables in your database.

Additionally, you can use Database Designer to create an incremental design. An incremental design creates projections for all tables referenced in the queries you supply.

To run Database Designer using MC, follow the steps listed at [Running Database Designer with Management Console](#).

Using the Management Console to replace nodes

On the MC **Manage** page, you can quickly replace a DOWN node in the database by selecting one of the STANDBY nodes in the cluster.

A DOWN node shows up as a red node in the cluster. Click the DOWN node and the Replace node button in the Node List becomes activated, as long as there is at least one node in the cluster that is not participating in the database. The STANDBY node will be your replacement node for the node you want to retire; it will appear gray (empty) until it has been added to the database, when it turns green.

Tip

You can resize the Node List by clicking its margins and dragging to the size you want.

When you highlight a node and click **Replace**, MC provides a list of possible STANDBY nodes to use as a replacement. After you select the replacement node, the process begins. A node replacement could be a long-running task.

MC transitions the DOWN node to a STANDBY state, while the node you selected as the replacement will assume the identity of the original node, using the same node name, and will be started.

Assuming a successful startup, the new node will appear orange with a status of RECOVERING until the recovery procedure is complete. When the recovery process completes, the replacement node will turn green and show a state of UP.

Import and monitor a database in a Hadoop environment

You can use Management Console to connect to and monitor a Vertica database that resides in an Apache Hadoop environment. To monitor the database in the Hadoop environment, you must connect to an Apache Ambari server.

Prerequisites

Before you begin, you must:

- Install Vertica on a Hadoop cluster
- Install Apache Ambari version 1.6.1 or 2.1.0
- Enable Ganglia on your Hadoop cluster, to get the most information from your Hadoop environment

Importing Vertica within a Hadoop environment

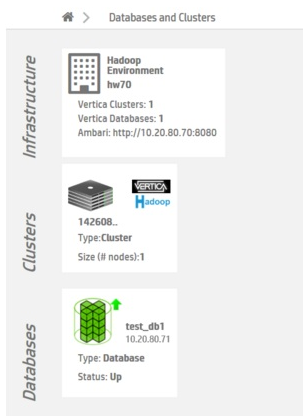

To import your Vertica database that resides in a Hadoop environment, connect to that Hadoop environment in Management Console through an Apache Ambari server.

1. From the Management Console home page, select **Additional import options** .
2. In **Provisioning** , select **Connect using an Ambari server to import Vertica within a Hadoop environment** .
3. The **Provision Access Within Hadoop Environment** window provides the following options:
 - **Connect to a new Ambari server** : Choose this option to create a enter your username and password for a new Ambari server connection.
 - **Known Ambari URLs** : If you have a pre-existing Ambari connection that you want to use, select it from the drop-down list.
4. In the next window, select the Hadoop cluster with the Vertica database that you want to monitor.
Management Console automatically discovers Hadoop clusters that are currently monitored by the Ambari server that you specify. If Management Console does not monitor Vertica clusters in the specified Hadoop environment, you can import clusters at this time.
After you select the Hadoop cluster, you receive confirmation that your Hadoop cluster is saved.
5. Enter the IP address for the Vertica database you want to import and monitor. If Vertica is running on multiple hosts, enter the IP address of one of them.
6. Enter the API key for the Vertica cluster. The API key is generated during Vertica installation, and you can find it in the [/opt/vertica/config/apikeys.dat](#) file.
7. The next window displays the discovered databases. Select one or more databases you want to import, and enter the corresponding username and password.
8. If the import is successful, you receive a success message. Click **Done** to go to the **Existing Infrastructure** page.

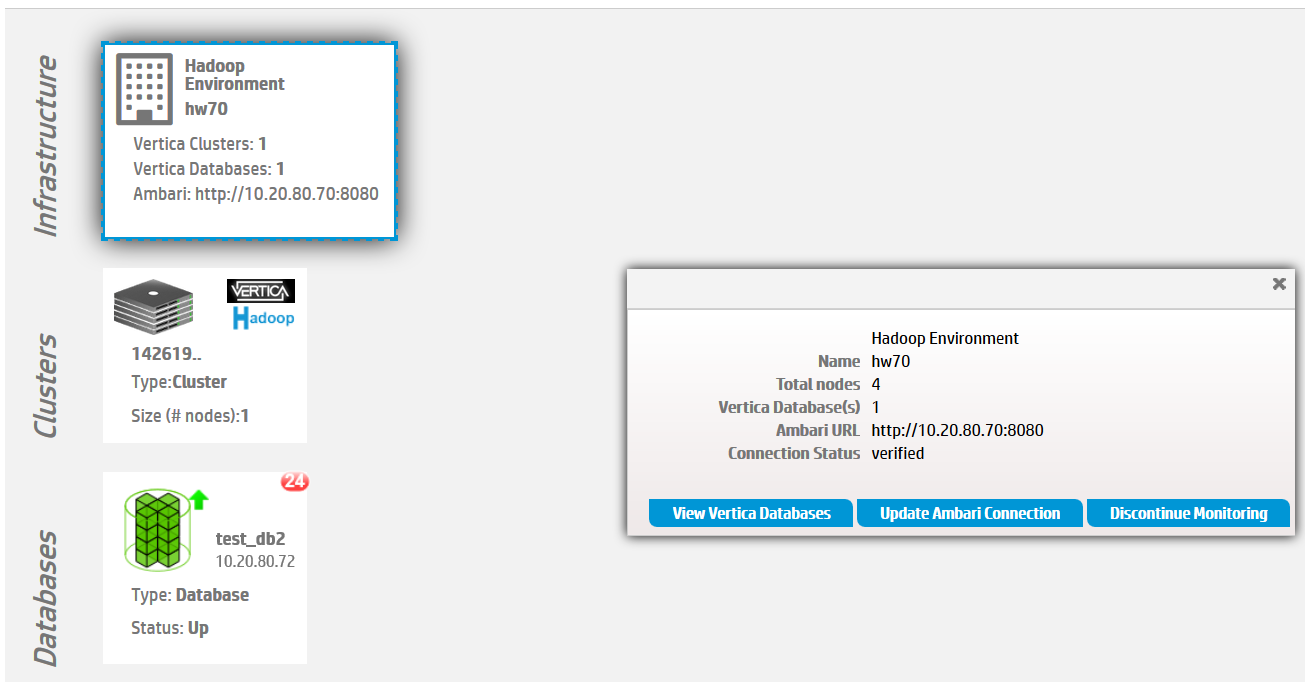

To import an additional Vertica cluster within a Hadoop environment, click **Import Cluster or database using IP address discovery** under **Provisioning** . Management Console will automatically associate the cluster with the existing Hadoop environment.

Monitoring Vertica within a Hadoop environment

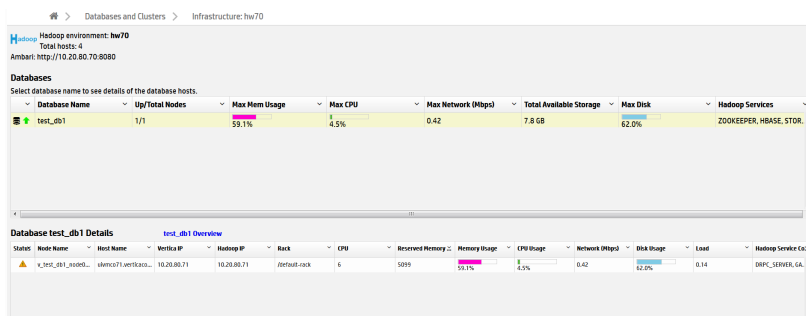

To monitor the Vertica clusters in a Hadoop environment, navigate to the **Existing Infrastructure** page:

Click to select the Hadoop environment, and then click **View Vertica Databases** .

The Management Console displays information about the Vertica databases that reside in a Hadoop environment:

You can monitor information like resource usage, Hadoop services, and database and connection status.

Update or remove an ambari connection

To update or remove an existing Ambari connection, go to the MC **Existing Infrastructure** page, and click on the relevant Hadoop environment.

To update a connection, click **Update Ambari Connection** . Step through the wizard to update the connection.

To remove a connection, select **Update Ambari Connection** and choose **Remove Connection** , or click **Discontinue Monitoring** and then confirm that you want to remove the connection. Removing the connection also removes all Vertica databases associated with this connection from MC monitoring. You can re-import the databases later if needed.

[Apache Hadoop integration](#)

Cloud platforms

Vertica supports Eon Mode database, subcluster, and node actions for the following cloud providers:

- Amazon Web Services (AWS)
- Google Cloud Platform (GCP)
- Microsoft Azure
- [Private on-premises cloud storage](#)

Management Console provides workflows that simplify resource provisioning and database management. Additionally, Vertica provides configuration defaults and recommendations for each cloud provider.

In this section

- [Managing an Eon Mode database in the cloud](#)
- [Amazon Web Services in MC](#)
- [Microsoft Azure in MC](#)

- [Google Cloud Platform in MC](#)

Managing an Eon Mode database in the cloud

After you provision your cluster and database in the cloud, the screens and techniques you use to monitor the database are the same regardless of the database mode or cluster platform. (Exceptions are noted in the documentation for particular features.)

Using MC to monitor your cluster, you can monitor the nodes in your subcluster, load data, run queries, and perform all other monitoring tasks for subclusters and nodes.

For details about Vertica and the supported cloud providers, see [Set up Vertica on the cloud](#).

Monitoring primary and secondary subclusters

The **Cluster > Manage** page **Database** tab lets you monitor your database nodes in visual format. MC supports only the monitoring features on the Database tab, as described in [Viewing and managing your cluster](#).

You can use the **Manage > Subclusters** tab to monitor your subcluster and nodes:

Node Name	Private IP	Status	CPU Usage %	Memory Usage %	Disk Usage %	Node Actions
v_verticadb_node0001	10.142.0.117	UP	0.1	2.48	5	N/A
v_verticadb_node0002	10.142.0.118	UP	0.08	2.21	5	N/A
v_verticadb_node0003	10.142.0.120	UP	0.07	2.23	5	N/A

The **Subclusters** tab displays the following subcluster information:

- Subcluster name
- Whether it is primary or secondary
- Total number of nodes
- Number of down nodes in that subcluster

In addition, the tab displays the following node information:

- Node name
- Private IP address
- UP or DOWN status
- CPU
- Memory
- Disk usage percentages
- Available node actions

Searching for nodes

On the **Manage > Subclusters** tab in MC, you can search for a specific node or group of nodes.

In the node name or IP field above the subcluster:

- To find a single node, enter a complete node name or IP address.
- To find a related group of nodes, enter a partial node name or IP address that those nodes share.

Amazon Web Services in MC

Management Console provides specific resources for managing database clusters on AWS.

You can provision an [Eon Mode](#) or [Enterprise Mode](#) database cluster on AWS.

You can revive an Eon Mode database cluster on AWS. For more information, see [Reviving an Eon Mode database on AWS in MC](#).

The MC provision and revive wizards for AWS configure separate volumes for the data, depot, catalog, and temp database directories. The specific volumes it uses for each directory depend upon the mode and the specific AWS instance type you select when you provision or revive the cluster. For details on the volumes configured for clusters on AWS, see:

- [Eon Mode volume configuration defaults for AWS](#)

- [Enterprise Mode volume configuration defaults for AWS](#)

In this section

- [Creating an Eon Mode database in AWS with MC](#)
- [Creating an Enterprise Mode database in AWS with MC](#)
- [Reviving an Eon Mode database on AWS in MC](#)
- [Eon Mode volume configuration defaults for AWS](#)
- [Enterprise Mode volume configuration defaults for AWS](#)
- [Add nodes to a cluster in AWS using Management Console](#)
- [Loading data from Amazon S3 using MC](#)

Creating an Eon Mode database in AWS with MC

After you deploy Management Console on Amazon Web Services (AWS) with a [CloudFormation Template](#), you can provision a cluster and database. Vertica clusters are provisioned in the same Virtual Private Cloud (VPC) as the Vertica Management Console. You can create an initial cluster of up to 60 hosts.

Note

See [Creating a cluster using MC](#) if you installed Management Console with an RPM, or to provision an on-premises database and cluster.

Prerequisites

Before you begin, complete or obtain the following:

- [Deploy MC and AWS resources with a CloudFormation template](#)
- AWS credentials and environment details
- S3 communal storage URL
- Vertica credentials
- [Vertica Management Console Credentials](#)

Choose one of the following setup options:

- **Quick Setup**: Select your cluster size based on your estimated compressed [working data size](#). The Management Console calculates the volume size per node, and reserves part of the disk for catalog and temp storage.
- **Advanced Setup**: This option provides more granular control over configuration settings related to subnet, Node IP, and depot, temp, and catalog volume sizes.

Quick setup

1. Log in to the Vertica Management Console.
2. On the Management Console home page, select **Create new database**.
3. On **Database Storage Mode**, click Eon Mode.
4. Click **Next**. On Vertica **License**, select one of the following license mode options:
 - **Community Edition**: A free Vertica license to preview Vertica functionality. This license provides limited features. If you use a Community Edition license for your deployment, you can upgrade the license later to expand your cluster load. See [Managing licenses](#) for more information.
 - **Premium Edition**: Use your Vertica license. After you select this option, click **Browse** to locate and upload your Vertica license key file, or manually enter it in the field.
1. Click **Next**. On **Setup Path**, select **Quick Setup**.
2. Click **Next**. In the Vertica **Settings** section, select the desired Vertica database version. You can select from the latest hotfix of recent Vertica releases. For each database version, you can also select the operating system. See [Choose a Vertica AMI Operating Systems](#) for available OS and major version options.
3. In the **AWS EC2 Instance Type** section, select from one of the following instance types:
 - Ephemeral Depot
 - EBS Depot
4. In the **Cluster Size** section, select the number of instances to deploy with your cluster based on your working data size. For details about working data size, see [Configuring your Vertica cluster for Eon Mode](#).

Note

If you are using a Community Edition license, your cluster size selections are limited to **Small**, **Medium**, and **Large**.

5. In the **Database Parameters** section, supply the following information:
 - **Database Name** : The name for your new database. See [Creating a database name and password](#) for database name requirements.
 - **Administrator Username** : The name of the [database superuser](#).
 - **Administrator Password** : The password for the database administrator user account. For details, see [Password guidelines](#).
 - **Confirm Password** : Reenter the **Administrator Password** .
 - **Load Sample Data** : Optional. Click the slider to the right to preload your database with example clickstream data. This option is useful if you are testing features and want some preloaded data in the database to query.
6. In the **AWS Environment** section, supply the following information:
 - **AWS Key Pair** : Your Amazon key pair for SSH access to EC2 instances.
 - **IP Access** : The cluster IP address range for SSH and client access to cluster hosts.
 - **S3 Communal Storage URL** : The path to a new subfolder in your existing AWS S3 bucket for Communal Storage of your Eon Mode database. Vertica creates the subfolder in the existing S3 bucket.
Important
Use an existing S3 bucket in the same region as your Management Console instance. In addition, you must use the S3 bucket that you specified when you [deployed the CloudFormation template](#).
 - **Tag EC2 Instances** : Optional. Assign distinct, searchable metadata tags to the instances in this cluster. Many organizations use labels to organize, track responsibility, and assign costs for instances.
To add a tag, click the slider to the right to display the **Tag Name** and **Tag Value** fields. Click **Add** to create the tag. Added tags are displayed below the fields.
7. Click **Create Database Cluster** to create a Eon Mode cluster on AWS.

Advanced setup

1. Log in to the Vertica Management Console.
2. On the Management Console home page, select **Create new database** .
3. On **Database Storage Mode** , click Eon Mode.
4. Click **Next** . On Vertica **License** , select one of the following license mode options:
 - **Community Edition** : A free Vertica license to preview Vertica functionality. This license provides limited features. If you use a Community Edition license for your deployment, you can upgrade the license later to expand your cluster load. See [Managing licenses](#) form more information.
 - **Premium Edition** : Use your Vertica license. After you select this option, click **Browse** to locate and upload your Vertica license key file, or manually enter it in the field.
1. Click **Next** . On **Setup Path** , select **Advanced Setup** .
2. Click **Next** . On **AWS Environment** , supply the following information:
 - **AWS Key Pair** : Your Amazon key pair for SSH access to EC2 instances.
 - **AWS Subnet** : The subnet for your cluster. By default, Vertica creates your cluster in the same subnet as your MC instance.
Important
Use security groups and network access control lists (ACLs) to secure your subnet. For details, see the [Amazon documentation](#) .
 - **IP Access** : The cluster IP address range for SSH and client access to cluster hosts.
 - **Node IP Setting** : Select **Private** , **Public** , or **Elastic** . For details about each option, see the [Amazon documentation](#) .
 - **S3 Communal Storage URL** : The path to a new subfolder in your existing AWS S3 bucket for Communal Storage of your Eon Mode database. Vertica creates the subfolder in the existing S3 bucket.

Note

Use an existing S3 bucket in the same region as your Management Console instance.

- **Tag EC2 Instances** : Optional. Assign distinct, searchable metadata tags to the instances in this cluster. Many organizations use labels to organize, track responsibility, and assign costs for instances.
To add a tag, click the slider to the right to display the **Tag Name** and **Tag Value** fields. Click **Add** to create the tag. Added tags are displayed below the fields.
3. Click **Next** . **Database Parameters** accepts information about your Vertica license. Supply the following information:
 - **Database Name** : The name for your new database. See [Creating a database name and password](#) for database name requirements.
 - **Administrator Username** : The name of the [database superuser](#).
 - **Administrator Password** : The password for the database administrator user account. For details, see [Password guidelines](#).
 - **Confirm Password** : Reenter the **Administrator Password** .

- **Vertica Version** : Select the desired Vertica database version. You can select from the latest hotfix of recent Vertica releases. For each database version, you can also select the operating system. See [Choose a Vertica AMI Operating Systems](#) for available OS and major version options.
 - **Load Sample Data** : Optional. Click the slider to the right to preload your database with example clickstream data. This option is useful if you are testing features and want some preloaded data in the database to query.
4. Click **Next** . On **AWS Configuration** , supply the following information:
 - **Number of Nodes** : The initial number of nodes for your database.
 - **Number of Vertica Database Shards** : Sets the number of [shards](#) in your database. Vertica suggests a number of shards automatically, based on your node count. After you set this value, you cannot change it later. The shard count must be greater than or equal to the maximum subcluster count. Be sure to allow for node growth. See [Configuring your Vertica cluster for Eon Mode](#) for recommendations.
 - **EC2 Instance Type** : The instance types used for the nodes. See [Choosing AWS Eon Mode Instance Types](#) for a list of recommended AWS instances. For details about each instance type, see the [Amazon EC2 Instance Types](#) documentation.
 - **Local Storage** : Customize your cluster according to your storage needs. For guidance, see [Eon Mode volume configuration defaults for AWS](#) for the Vertica default settings for each supported instance.
 5. Click **Next** . On **Review** , confirm your selections. Click **Edit** to return to a previous section and make changes.
 6. When you are satisfied with your selections, click the **I accept the terms and conditions** checkbox.
 7. Click **Create Cluster** to create a Eon Mode cluster on AWS.

After creating the database

After you create the database, click **Get Started** to view the [Databases](#) page. To view your database, select **Manage and View Your Vertica Database** to go to the database **Overview** .

You can also view your database from the **Recent Databases** section of the MC home page.

For additional information about managing your cluster, instances, and database using Management Console, see [Managing database clusters](#) .

Creating an Enterprise Mode database in AWS with MC

After you deploy Management Console on Amazon Web Services (AWS) with a [CloudFormation Template](#) , you can provision a cluster and database. Vertica clusters are provisioned in the same Virtual Private Cloud (VPC) as the Vertica Management Console. You can create an initial cluster of up to 60 hosts.

Note

See [Creating a cluster using MC](#) if you installed Management Console with an RPM, or to provision an on-premises database and cluster.

Prerequisites

Before you begin, complete or obtain the following:

- [Deploy MC and AWS resources with a CloudFormation template](#)
- AWS credentials and environment details
- S3 communal storage URL
- Vertica credentials
- [Vertica Management Console Credentials](#)

Provisioning a cluster and database

1. Log in to the Vertica Management Console.
2. On the Management Console home page, select **Create new database** .
3. On **Database Storage Mode** , click Enterprise Mode.
4. Click **Next** . **Create a New Vertica Cluster | mode: Enterprise** provides you with two workflow options for creating your database. Select one of the following:
 - **Quick Create** : Vertica configures your EC2 instances with default settings.
 - **Custom Create** : You can specify EC2 instance types and other database settings.
5. Click **Next** . On **Enter AWS Credentials and preferences** , **AWS Region** is filled with the region of the Management Console host. Supply the following information:
 - **AWS Subnet** : Under **Show Advanced Options** . Select the subnet used to create your cluster.
 - **AWS Access Key ID** : Displayed if MC was configured to use the AWS Access Keys authentication method. Enter your access key.
 - **AWS Secret Access Key** : Displayed if MC was configured to use the AWS Access Keys authentication method. Enter the password associated with the **AWS Access Key ID** .
 - **AWS Key Pair** : Your Amazon key pair for SSH access to EC2 instances.
 - **CIDR Range** : The cluster IP address range for SSH and client access to cluster hosts.

6. Click **Next** . **Enter Vertica database name and login credentials** accepts information about your Vertica license. Supply the following information:
 - Vertica **Database Name** : The name for your new database. See [Creating a database name and password](#) for database name requirements.
 - Vertica **Version : Custom Create** mode only. Select the desired Vertica database version. You can select from the latest hotfix of recent Vertica releases. For each database version, you can also select the operating system. See [Choose a Vertica AMI Operating Systems](#) for available OS and major version options.
 - Vertica **Database User Name** : The name of the [database superuser](#) .
 - **Password** : The password associated with the database username. For details, see [Password guidelines](#) .
 - **Confirm Password** : Reenter the **Password** .
 - **Database Node Count** : The number of nodes that you want to deploy in this cluster. **Quick Create** mode provides options for 1 or 3 database node counts.
 - **Vertica License : Custom Create** mode only. Click **Browse** to locate and upload your Vertica license key file. If you do not supply a license key file here, the wizard deploys your database with a Vertica Community Edition license. This license has a three node limit, so the value in the Database Size field cannot be larger than 3 if you do not supply a license. If you use a Community Edition license for your deployment, you can upgrade the license later to expand your cluster load more than 1TB of data. See [Managing licenses](#) form more information.
 - **Load example test data** : Optional. Click the checkbox to preload your database with example clickstream data. This option is useful if you are testing features and want some preloaded data in the database to query.
7. Click **Next** . **Specify cloud instance and main data storage info** provides options to let you customize your instance configuration. In **Quick Create** mode, the options on this screen are pre-selected and read-only. **Database Data Path** is filled with the path to your persistent database storage. **EBS Volume Type** and **EBS Volume Size (GB) per Volume per Available Node** fields are filled with default values for the selected **EC2 Instance Type** . See [Eon Mode volume configuration defaults for AWS](#) for more information. In **Custom Create** mode, supply information for the following:
 - **EC2 Instance Type** : The instance type your cluster deploys. See [Supported AWS instance types](#) for more information.
 - **EBS Volume Type** : The block-level storage type for each node in your cluster. See [Enterprise Mode volume configuration defaults for AWS](#) for recommendations about supported volume types.
 - **EBS Volume Size (GB) per Volume per Available Node** : The amount of disk space available on each disk attached to each node in your cluster. This field shows you the total disk space available per node in your cluster.
 - **Enable EBS Volume Encryption** : Optional. Select the checkbox if you want server-level encryption on your EC2 instances. With AWS, only 4th and 5th generation instance types (c4/5, r4/5, and m4/5) support encryption.
 - **Node IP setting** : Select **Private** , **Public** , or **Elastic** . For details about each option, see the [Amazon documentation](#) .
8. Click **Next** . **Specify additional storage and tag info** lets you allocate additional storage for your cluster. In **Quick Create** mode, the options on this screen are pre-selected and read-only.
 - **Database Catalog Path** is the location of the local copy of the database catalog. **Database Temp Path** is the temporary storage space for each node, if the node instance type includes the temporary storage option.
 - In **Custom Create** mode, select or enter a value for **EBS Volume Type** , **EBS Volume Size (GB) per Volume per Available Node** , and **Enable EBS Volume Encryption** under each path. Each field has the same definition as described in the previous step.
 - **Tag EC2 instances** : Optional. Assign distinct, searchable metadata tags to the instances in this cluster. Many organizations use labels to organize, track responsibility, and assign costs for instances. After you click the checkbox, the **Tag Name** and **Tag Value** fields are displayed. Click **Add** to create the tag. Added tags are displayed below the fields.
9. Click **Next** . On the **Review** screen, confirm your selections. To edit your selections, click **Back** until you reach the screen containing information that you want to edit.
10. When you are satisfied with your selections, click the **Accept terms and conditions of the "Software Only Terms" for your territory** checkbox.
11. Click **Create** to create an Enterprise Mode cluster on AWS.

After the cluster and database is successfully created, click **Get Started** to view the [Databases](#) page. To view your database, select **Manage and View Your Vertica Database** to go to the database **Overview** .

You can also view your database from the **Recent Databases** section of the MC home page.

See [Managing database clusters](#) for further managing your cluster, instances, and database using Management Console.

Reviving an Eon Mode database on AWS in MC

Important

You can also revive a database using [admintools](#) . You must use admintools in order to revive a database on an existing cluster. For example, use admintools if you stopped a cluster whose hosts use instance storage where data is not persistently stored, and plan to bring back the database on the same cluster.

An [Eon Mode database](#) keeps an up-to-date version of its data and metadata in its communal storage location. After a cluster hosting an Eon Mode database is terminated, this data and metadata continue to reside in communal storage. When you revive the database later, Vertica uses the data in

this location to restore the database in the same state on a newly provisioned cluster.

If Management Console has been installed [using a CloudFormation template](#) from the AWS Marketplace, you can use the Provision and Revive wizard in Management Console.

During a revive of your database, when you select a Vertica version that is higher than the version of the original database in the communal storage, Vertica upgrades your database to match the Vertica version you selected. This upgrade may cause the database revive to take longer. To bypass this upgrade, select the Vertica version of your original database.

Note

After upgrading a Vertica database, you can not revert to an earlier version.

Prerequisites

- Communal storage location (an AWS S3 bucket) of the stopped Eon Mode database you plan to revive. For guidance, see [Viewing and managing your cluster](#).
- Username and password of the Eon Mode database you plan to revive.
- AWS account with permissions to create a VPC, subnet, security group, instances, and roles.
- Amazon key pair for SSH access to an instance.

Revive the database on the cloud

You use a wizard in Management Console to provision a new cluster on AWS and revive a database onto it. For the new cluster, Management Console automatically provisions the same number of AWS instances used by the database when it was last shut down.

Caution

You should not use the same communal storage location for running multiple databases, as it causes data corruption. To avoid corruption, you should also never use the revive functionality to simultaneously run the same Eon Mode database on different clusters.

1. From the Management Console home page, select **Revive Eon Mode Database**. The Revive an Eon Mode Database wizard opens.
2. Enter your cloud credentials and cluster preferences. Your cluster must be in the same region as your communal storage location's S3 bucket. To revive the cluster in a new region, you must:
 - Create an S3 bucket in the new region.
 - Copy the previous S3 bucket's contents into it.
 - Provide the new S3 bucket URL in Step 3.
3. By default, Vertica creates your cluster in the same subnet as your Management Console instance. If you want to manage all Vertica clusters in the same VPC, you can provision your Vertica database in a different subnet than the Management Console instance. To do so, on the **AWS Credentials** page, select **Show Advanced Options** and enter a value in the **Subnet** field.

Important

If you specify a different subnet for your database, make sure to secure the subnet.

4. Enter the S3 URL of the database that you are reviving. You can only revive databases that use an S3 bucket that you specified when you [deployed the CloudFormation template](#).
When you enter an S3 bucket location, Management Console discovers all known Eon Mode databases.
5. Select the correct database to revive.
6. Provide the database administrator credentials for the database you are reviving. These credentials are the same as the ones used by the database in the previous cluster.
7. In the **Database Version** field, choose the desired Vertica database version. Select from the latest hotfix of recent Vertica releases. For each Vertica version, you can select from a list of associated Linux operating systems.
If you select a Vertica version that is higher than the version of the original database in the communal storage, Vertica upgrades your database to match the Vertica version you selected. This upgrade may cause the database revive to take longer. To bypass this upgrade, select the Vertica version of your original database.

Note

After your Vertica database has been upgraded, you can not downgrade your database later.

8. Choose instance types for the cluster. Management Console provisions the same number of instances used by the database when it was last shut down.

The MC populates the existing paths for the depot, catalog, and temp directories.

Note

You cannot persist the catalog with ephemeral instances.

The last step displays a confirmation page showing the configured volumes. For details on the volume configurations that MC provides, see [Eon Mode volume configuration defaults for AWS](#) and [Enterprise Mode volume configuration defaults for AWS](#).

Caution

To ensure against data loss, choose instances that use EBS storage. EBS storage is durable, while instance store is temporary. For Eon mode, Management Console displays an alert to inform the user of the potential data loss when terminating instances that support instance store.

9. Choose whether to encrypt your EBS volumes. With AWS, only 4th and 5th generation instance types (c4, r4, and m4; c5, r5, and m5) support encrypting EBS volumes.
10. Optionally, you can tag the instances. In the **Tag EC2 instances** field, if another cluster is already running, Management Console fills those fields with the tag values for the first instance in the cluster. You can accept the defaults, or enter new tag values.
11. Review your choices, accept the license agreement, and click **Create** to revive the database on a new cluster. If the version of Management Console you use to revive is higher than that of the database, Management Console first notifies you that it is about to automatically upgrade the database. After starting the revive process, the wizard displays its progress. After a successful revive, the database starts automatically.

Important
If the database fails to start automatically, check the `controlmode` setting in `/opt/vertica/config/admintools.conf`. This setting must be compatible with the network messaging requirements of your Eon implementation. AWS relies on unicast messaging, which is compatible with a `controlmode` setting of `point-to-point` (pt2pt). If the source database `controlmode` setting was `broadcast` and you migrate to S3/AWS communal storage, you must change `controlmode` with `admintools`:

```
$ admintools -t re_ip -d dbname -T
```

When the revive process is complete, click **Get Started** to navigate to the [Databases](#) page.

Eon Mode volume configuration defaults for AWS

When you provision or revive an Eon Mode database cluster, Management Console configures separate volumes for the depot, catalog, and temp directories. The specific volumes and sizes that Management Console configures vary depending on the AWS instance type you select when provisioning or reviving the cluster.

MC follows these rules when allocating resources for these directories for an Eon Mode database cluster:

- Depot: Allocate instance store if available with the selected instance type. Otherwise, allocate EBS volumes. (In Eon Mode on AWS, S3 is the backup.)
- Catalog: Always allocate an EBS volume, to ensure the catalog is durable.
- Temp: Allocate instance store if available with the selected instance type. Otherwise, allocate EBS volumes.

Note

Table below includes all instances types that include instance store.

Instance Type API Name	Instance Storage	Depot	Catalog	Temp
Supported EBS Volumes	N/A	Configurable 8 EBS volumes Default to 75G per volume	Configurable 1 EBS volume Default to 50G	Configurable 1 EBS volume Default to 100G

c3.4xlarge	320 G (2 * 160 GiB SSD)	Configurable 8 EBS volumes Default to 75G per volume	Configurable 1 EBS volume Default to 50G	Instance store 2x160G
c3.8xlarge	640 G (2 * 320 GiB SSD)	Configurable 8 EBS volumes Default to 75G per volume	Configurable 1 EBS volume Default to 50G	Instance store 2x320G
c5d.4xlarge	4000 G (1 * 400 GiB SSD)	Configurable 8 EBS volumes Default to 75G per volume	Configurable 1 EBS volume Default to 50G	Instance store 1x400G
i3.4xlarge	3800 G (2 * 1900 GiB NVMe SSD)	Instance store 1x1900G	Configurable 1 EBS volume Default to 50G	Instance store 1x1900G

Enterprise Mode volume configuration defaults for AWS

When you provision an Enterprise Mode database cluster, Management Console configures separate volumes for the data, catalog, and temp directories.

The specific volumes and sizes that MC uses vary depending on the AWS instance type you select when provisioning the cluster.

MC follows these rules when selecting resources for these directories for an Enterprise Mode database cluster:

- Data: Always use EBS volumes, to ensure the data is durable.
- Catalog: Always use an EBS volume, to ensure the catalog is durable.
- Temp: If the chosen instance type offers instance store, then use volumes from instance store.

Note

Table below includes all instance types that include instance store.

Instance Type API Name	Instance Storage	Data	Catalog	Temp
------------------------	------------------	------	---------	------

Supported EBS Volumes	N/A	Configurable 8 EBS volumes Default to 75G per volume	Configurable 1 EBS volume Default to 50G	Configurable 1 EBS volume Default to 100G
c3.4xlarge	320 G (2 * 160 GiB SSD)	Configurable 8 EBS volumes Default to 75G per volume	Configurable 1 EBS volume Default to 50G	Instance Store 2x160G
c3.8xlarge	640 G (2 * 320 GiB SSD)	Configurable 8 EBS volumes Default to 75G per volume	Configurable 1 EBS volume Default to 50G	Instance Store 2x320G
c5d.4xlarge	400 G (1 * 400 GiB SSD)	Configurable 8 EBS volumes Default to 75G per volume	Configurable 1 EBS volume Default to 50G	Instance Store 1x400G
i3.4xlarge	3800 G (2 * 1900 GiB NVMe SSD)	Configurable 8 EBS volumes Default to 75G per volume	Configurable 1 EBS volume Default to 50G	Instance Store 2x1900G
i3.8xlarge	7600 G (4 * 1900 GiB NVMe SSD)	Configurable 8 EBS volumes Default to 75G per volume	Configurable 1 EBS volume Default to 50G	Instance Store 4x1900G
i3.16xlarge	15200 G (8 * 1900 GiB NVMe SSD)	Configurable 8 EBS volumes Default to 75G per volume	Configurable 1 EBS volume Default to 50G	Instance Store 8x1900G
i3en.3xlarge	7500 G (1 * 7500 GiB NVMe SSD)	Configurable 8 EBS volumes Default to 75G per volume	Configurable 1 EBS volume Default to 50G	Instance Store 1x7500G
i3en.6xlarge	15000 G (2 * 7500 GiB NVMe SSD)	Configurable 8 EBS volumes Default to 75G per volume	Configurable 1 EBS volume Default to 50G	Instance Store 2x7500G

i3en.12xlarge	30000 G (4 * 7500 GiB NVMe SSD)	Configurable 8 EBS volumes Default to 75G per volume	Configurable 1 EBS volume Default to 50G	Instance Store 4x7500G
i4i.4xlarge	3750 G (1 * 3750 GiB NVMe SSD)	Configurable 8 EBS volumes Default to 75G per volume	Configurable 1 EBS volume Default to 50G	Instance Store 1x3750G
i4i.8xlarge	7500 G (2 * 3750 GiB NVMe SSD)	Configurable 8 EBS volumes Default to 75G per volume	Configurable 1 EBS volume Default to 50G	Instance Store 2x3750G
i4i.16xlarge	15000 G (4 * 3750 GiB NVMe SSD)	Configurable 8 EBS volumes Default to 75G per volume	Configurable 1 EBS volume Default to 50G	Instance Store 4x3750G
r3.4xlarge	320 G (1 * 320 GiB SSD)	Configurable 8 EBS volumes Default to 75G per volume	Configurable 1 EBS volume Default to 50G	Instance Store 320G
m5d.4xlarge	600 G (2 * 300 GiB NVMe SSD)	Configurable 8 EBS volumes Default to 75G per volume	Configurable 1 EBS volume Default to 50G	Instance Store 2x300G
m5d.8xlarge	1200 G (2 * 600 GiB NVMe SSD)	Configurable 8 EBS volumes Default to 75G per volume	Configurable 1 EBS volume Default to 50G	Instance Store 2x600G
m5d.12xlarge	1800 G (2 * 900 GiB NVMe SSD)	Configurable 8 EBS volumes Default to 75G per volume	Configurable 1 EBS volume Default to 50G	Instance Store 2x900G
m5d.16xlarge	2400 G (4 * 600 GiB NVMe SSD)	Configurable 8 EBS volumes Default to 75G per volume	Configurable 1 EBS volume Default to 50G	Instance Store 4x600G

Add nodes to a cluster in AWS using Management Console

When you use MC to add nodes to a cluster in the cloud, MC provisions the instances, adds the new instances to the existing Vertica cluster, and then adds those hosts to the database.

In the Vertica Management Console, you can add nodes in several ways, depending on your database mode.

For Eon Mode databases, MC supports actions for subcluster and node management for the following public and private cloud providers:

- [Amazon Web Services](#) (AWS)
- [Google Cloud Platform](#) (GCP)
- [Microsoft Azure](#)
- [Pure Storage FlashBlade](#)

Note

Enterprise Mode does not support subclusters.

For Enterprise Mode databases, MC supports these actions:

- In the cloud on AWS: Add Node action, Add Instance action.
- On-premises: Add Node action.

Note

In the cloud on GCP, Enterprise Mode databases are not supported.

Adding nodes in an Eon Mode database

In an Eon Mode database, every node must belong to a [subcluster](#). To add nodes, you always add them to one of the subclusters in the database:

- By [scaling up an existing subcluster](#) by one or more nodes.
- By [adding a new subcluster](#) of one or more nodes.

Adding nodes in an Enterprise Mode database on AWS

In an Enterprise Mode database on AWS, to add an instance to your cluster:

1. On the MC Home page, click **View Infrastructure** to go to the [Infrastructure page](#). This page lists all the clusters the MC is monitoring.
2. Click any cluster shown on the Infrastructure page.
3. Select **View** or **Manage** from the dialog that displays, to view its Cluster page. (In a cloud environment, if MC was deployed from a cloud template the button says "Manage". Otherwise, the button says "View".)

Note

You can click the pencil icon beside the cluster name to rename the cluster. Enter a name that is unique within MC.

The screenshot shows the Vertica Management Console interface. At the top, it says 'Vertica Management Console' and 'Cluster:qiongw_1505765368461'. Below this, there are several tabs: 'Start Cluster', 'Stop Cluster', 'Advanced', 'Show Cluster Summary', and 'Show Node List'. The main area displays a cluster diagram with four nodes (two private and two public) and an Instance List on the right. The Instance List has an Add (+) icon. The page also shows a 'Cluster' sidebar with details like 'Vertica Version: 9.0.0', 'Hosts: 4', and 'CPU Type: Intel(R) Xeon(R) CPU E5-2680 v2 @ 2.80GHz'. There is also a 'Databases' section showing 'Monitored: Eon (4)'. At the bottom right, there is a 'Zoom Level: 10' indicator.

1. Click the Add (+) icon on the **Instance List** on the **Cluster Management** page.

MC adds a node to the selected cluster.

Loading data from Amazon S3 using MC

You can use the Data Load Activity page in Management Console to import data from Amazon S3 storage to an existing Vertica table. When you run a load job, Vertica appends rows to the target table you provide. If the job fails, or you cancel the job, Vertica commits no rows to the target table.

When you view your load history on the Instance tab, loading jobs initiated in MC using Amazon S3 have the name MC_S3_Load in the Stream Name column.

Prerequisites

To use the MC Load feature, you must have:

- Access to an Amazon S3 storage account.
- An existing table in your Vertica database to which you can copy your data. You must be the owner of the table.
- (For non-CloudFormation Template installs) An S3 gateway endpoint.

If you aren't using a CloudFormation Template (CFT) to install Vertica, you must create an S3 gateway endpoint in your VPC. For more information, see [the AWS documentation](#).

For example, the Vertica CFT has the following VPC endpoint:

```
"S3Endpoint" : {
  "Type" : "AWS::EC2::VPCEndpoint",
  "Properties" : {
    "PolicyDocument" : {
      "Version":"2012-10-17",
      "Statement":[{"Effect":"Allow",
        "Principal": "*",
        "Action":["***"],
        "Resource":["***"]}
    ]
  },
  "RouteTableIds" : [ {"Ref" : "RouteTable"} ],
  "ServiceName" : { "Fn::Join": [ "", [ "com.amazonaws.", { "Ref": "AWS::Region" }, ".s3" ] ] },
  "VpcId" : {"Ref" : "VPC"}
}
```

Create a loading job

To load data from an Amazon S3 bucket to an existing table in your target database:

1. On the target database MC dashboard, click on the Load tab at the bottom of the page to view the Data Load Activity page.
2. Click on the Instance tab.
3. Click New S3 Data Load at the top-right of the tab. The Create New Amazon S3 Loading Job dialog box opens.
4. Enter your AWS account credentials and your target location information in the required fields, which are indicated by asterisks (*). Use the format S3:// for the bucket name.
5. (Optional) Specify additional options by completing the following fields:
 - COPY Parameters
 - Capture rejected data in a table
 - Reject max

For more about using these fields, see [About configuring a data load from S3](#).

Cancel an initiated loading job

If a loading job is in progress, you can cancel it using the Cancel option in the Load History tab's Cancel column. Click Cancel to cancel the loading job. When you cancel a job, Vertica rolls back all rows and does not commit any data to the target table.

Status	Time Started	User	Schema Name	Table Name	Execution Time (ms)	Accepted Rows	Rejected Rows	Stream Name	Cancel
Running	Mar 28, 2016 1:...	uidbadadmin	v_dbd_foo	vs_designs	0	0	N/A		Cancel
Success	Mar 28, 2016 1:...	natalia	store	store_orders_fact	10707	299994	Details	MC_S3_Load	
Failure	Mar 28, 2016 1:...	natalia	store	store_orders_fact	581	0	Details	MC_S3_Load	
Success	Mar 28, 2016 12:...	natalia	store	store_orders_fact	1299	11	N/A	S3_Data_load	
Failure	Mar 28, 2016 12:...	natalia			2	0	N/A	S3_Data_load	
Success	Mar 25, 2016 3:...	uidbadadmin	store	store_orders_fact	17990	300000	Details	MC_S3_Load

In this section

- [About configuring a data load from S3](#)
- [Viewing load history](#)

About configuring a data load from S3

When you create an S3 Data Load using MC, you have the option of further configuring the load operation. You can optionally specify the following:

- [Add COPY Parameters](#)
- [Capture Rejected Data in a Table](#)
- [Set a Rejected Records Maximum](#)

Add COPY parameters

MC performs the load operation with [COPY](#). You can use the COPY Parameters field to further configure the COPY operation. This field accepts parameters that are specified after the COPY statement's FROM clause. For details on these parameters and special requirements, see [Parameters](#).

Note

The FILTER and PARSER parameters must appear in that order and precede all other parameters.

For example, you can specify the DELIMITER and SKIP parameters to separate columns with a comma, and skip one record of input data, respectively:

```
DELIMITER ',' SKIP 1
```

You can also add comments in this field with [standard C comment notation](#).

Note

This field does not support SQL comment notation (double hyphen --).

Capture rejected data in a table

Set **Capture rejected data in a table** to Yes to create a table that contains rejected row data. You can view this data in the Load History tab.

This table uses the following naming convention:

```
schema.s3_load_rejections_target-table-name
```

You must have CREATE privilege on the schema if the table doesn't already exist. When you invoke multiple load processes for the same target table, MC appends all rejections data to the same table. For details, see [Saving rejected data to a table](#).

Set a rejected records maximum

Set **Reject Max** to the maximum number of rows that can be rejected before the load operation fails. If COPY rejects the specified maximum rows, Vertica rolls back the entire load operation.

See also

- [Loading data from Amazon S3 using MC](#)
- [Viewing load history](#)

Viewing load history

You can view a history of all your continuous and instance loading jobs in Vertica on the Data Load Activity page.

- **Continuous jobs:** Loading jobs that continuously monitor a source and stream data from the source.
- **Instance jobs:** Loading jobs that batch load from a source. Instance jobs are of a fixed length and shorter-term than continuous loads.

View continuous loads

The Continuous tab on the Data Load Activity page displays history of your database's continuous loading jobs. For example, you can see loading jobs you create using the Vertica integration with Kafka (see [Apache Kafka integration](#)). Additionally, if you enable the MC extended monitoring feature, the Continuous tab displays the continuous jobs that stream data from your monitored database to a storage database. (See [Extended monitoring](#) for more on how MC can use Kafka to monitor databases externally.)

Use the Continuous tab to view details about continuous jobs, such as their source, target tables, and other microbatch configuration details.

If extended monitoring is enabled, jobs streaming to the MC storage database show mc_dc_kafka_config as the scheduler name. Deselect **Show MC data collector monitoring streams** at the top of the tab to remove these jobs from the display.

In the Continuous tab, click the labels in the **Scheduler**, **Microbatch**, and **Errors Last Hour** to view additional details about those loading jobs.

For more on continuous data streaming terminology, see [Data streaming integration terms](#).

View load instances

In the Instance tab, you can see a history of your database's one-time loading jobs. For example, you can view instance jobs you created using the COPY command in vsql (see [COPY](#)), or instance jobs you created in MC to copy data from an Amazon S3 bucket. (For more about initiating loading jobs in MC, see [Loading data from Amazon S3 using MC](#).)

In the Instance tab, click the labels in the Status column and Rejected Rows column to view more details about completed jobs. For more about rejected rows, see [Handling messy data](#).

Continuous Instance

Load history for the past: 1 hour New S3 Data Load

Status	Source File	Time Started	User	Schema Name	Table Name	Execution Time (ms)	Accepted Rows	Rejected Rows	Stream Name	Cancel
Success	mcqbucket/cs...	Nov 4, 2016 5:34:05 PM	fred	public	townsfile	277	234	4	MC_S3_Load	
Success	mcqbucket/cs...	Nov 4, 2016 5:31:43 PM	fred	public	townsfile	2286	238	0	MC_S3_Load	

The number of load history results on the Instance tab depends on the [Data collector](#) retention policy for Requests Issued and Requests Completed. To change the retention policy, see [Configuring data retention policies](#).

Microsoft Azure in MC

Management Console (MC) supports both Eon Mode and Enterprise Mode clusters on Microsoft Azure as described in the following table:

Architecture	Description
Eon Mode	Deploy an MC instance, and then provision and create an Eon Mode database from the MC. For more details, see the following: <ul style="list-style-type: none">• Creating an Eon Mode cluster and database in Azure in MC• Adding subclusters in MC
Enterprise Mode	Deploy a four-node database comprised of one MC instance and three database nodes. In Enterprise Mode, the database uses the MC primarily as a monitoring tool. For example, you cannot provision and create a database with an Enterprise Mode MC. For information about creating and managing an Enterprise Mode database, see Create a database using administration tools .

For additional details, see [Vertica on Microsoft Azure](#).

Provision and monitor clusters

You can use MC to provision an Eon Mode database cluster on Azure. For details, see [Creating an Eon Mode cluster and database in Azure in MC](#).

MC provides specific resources for monitoring database clusters on Azure. For details, see [Managing an Eon Mode database in the cloud](#).

You can revive a stopped Eon Mode database on Azure using MC. For details, see [Reviving an Eon Mode database on Azure in MC](#).

Managing your cluster in MC

1. On the MC home page, click **View Infrastructure**. MC displays the Database and Cluster View. This view shows your infrastructure platform, cluster, and database.
2. On the left side of the screen next to **Clusters**, click the square for the cluster you want to manage. MC displays a window with your cluster name, an information summary, and several buttons.
3. Click **Manage**. The **Cluster** page displays.
4. On the **Cluster** page, you can view the following information:
 - The instances in your cluster in visual format.
 - The status of each instance, whether it is running.
 - The private and public IP address for each cluster instance.
 - The Vertica version that is running, your region, and your instance type in the **Cluster** pane.

Cluster actions on Azure in MC

On the **Cluster** page, you can perform the following cluster actions:

- **Start Cluster**: Starts the instances, then starts the database. For Eon Mode databases, MC repopulates the nodes with data from the storage account container.
- **Stop Cluster**: Stops the nodes in the database, then stops their cloud instances.
- **Advanced > Terminate**: Stops the database, then terminates the cloud instances.

Subcluster management

You can add, Scale Up, Scale Down, remove, and terminate subclusters with MC. For details, see the following:

- [Subclusters in MC](#)
- [Scaling subclusters in MC](#)
- [Subcluster action rules in MC](#)

Node management

You add or delete nodes by scaling subclusters up or down. You can also start, stop, and restart nodes. For details, see the following:

- [Add nodes to a cluster in AWS using Management Console](#)

- [Starting, stopping, and restarting nodes in MC](#)
- [Node action rules in MC](#)

Restrictions

You cannot revive an Eon Mode database with the MC.

In this section

- [Creating an Eon Mode cluster and database in Azure in MC](#)
- [Eon Mode volume configuration defaults for Azure](#)
- [Reviving an Eon Mode database on Azure in MC](#)

Creating an Eon Mode cluster and database in Azure in MC

After you deploy a Management Console instance on Azure, you can provision a cluster and create an Eon Mode database.

Prerequisites

Before you begin, complete or obtain the following:

- Complete [Deploy Vertica from the Azure Marketplace](#)
- Complete the cluster and storage requirements described in [Eon Mode on Azure prerequisites](#)
- [SSH public key](#) used when deploying the MC instance
- Review [Recommended Azure VM types and operating systems](#)
- Vertica credentials
- Vertica Management Console credentials

Creating the database

Complete the following steps from the Management Console:

1. Log in to the Vertica Management Console.
2. On the Management Console home page, select **Create new database**.
3. On Vertica License, select one of the following license mode options:
 - **Community Edition** : A free Vertica license to preview Vertica functionality. This license provides limited features. If you use a Community Edition license for your deployment, you can upgrade the license later to expand your cluster load. See [Managing licenses](#) for more information.
 - **Premium Edition** : Use your Vertica license. After you select this option, click **Browse** to locate and upload your Vertica license key file, or manually enter it in the field.
4. Click **Next**. On **Azure Environment**, supply the following information:
 - **SSH Public Key** : Paste the same public key used when you deployed the MC instance in the Azure Marketplace.
 - **Azure Subnet** : The subnet for your cluster. Select the same subnet used when you deployed the MC instance in the Azure Marketplace. If your organization requires multiple subnets for security purposes, see the [Azure documentation](#) for additional information.
 - **CIDR Range** : The range of IP addresses for client and SSH access. Azure requires that the last octet is 0 and the prefix is 24. For example, 10.20.30.0/24.
 - **Node IP Setting** : Choose **Public IP - Dynamic**, **Public IP - Static**, or **Private IP**. For details, see the [Azure documentation](#).
 - **Communal Storage URL** : The path to a new subfolder in your existing Azure Blob storage account and container. The subfolder must not already exist.
 - **Tag Azure Resources** : Optional. Assign distinct, searchable metadata tags to the instances in this cluster. Many organizations use labels to organize, track responsibility, and assign costs for instances. To add a tag, click the slider to the right to display the **Tag Name** and **Tag Value** fields. Click **Add** to create the tag. Added tags are displayed below the fields. Vertica recommends that you use lowercase characters in tag fields.
5. Click **Next**. **Database Parameters** accepts identifying information about your database and OS version:
 - **Database Name** : The name for your new database. See [Creating a database name and password](#) for database name requirements.
 - **Administrator Username** : The name of the [database superuser](#).
 - **Administrator Password** : The password for the database administrator user account. For details, see [Password guidelines](#).
 - **Confirm Password** : Reenter the **Administrator Password**.
 - **Vertica Version** : Select the desired Vertica database version. You can select from the latest hotfix of recent Vertica releases. For each database version, you can also select the operating system. For available OS and major version options, see [Recommended Azure Operating Systems](#).
 - **Load Sample Data** : Optional. Click the slider to the right to preload your database with example clickstream data. This option is useful if you are testing features and want some preloaded data in the database to query.
6. Click **Next**. On Azure configuration, supply the following information:
 - **Number of Nodes** : The initial number of nodes for your database.

- **Number of Vertica Database Shards** : Sets the number of [shards](#) in your database. Vertica suggests a number of shards automatically, based on your node count. After you set this value, you cannot change it later. The shard count must be greater than or equal to the maximum subcluster count. Be sure to allow for node growth. See [Configuring your Vertica cluster for Eon Mode](#) for recommendations.
 - **Virtual machine (VM) size** : The instance types used for the nodes. For a list of recommended instances, see [Recommended Azure VM types and operating systems](#) .
 - **Local Storage per Node** : Customize your cluster according to your storage needs. For the Vertica default settings for each supported instance, see [Eon Mode volume configuration defaults for Azure](#) .
7. Click **Next** . On **Review** , confirm your selections. Click **Edit** to return to a previous section and make changes.
 8. When you are satisfied with your selections, click the **I accept the terms and conditions** checkbox.
 9. Click **Create Cluster** to create a Eon Mode cluster on Azure.

After creating the database

After you create the database, click **Get Started** to view the [Databases](#) page. To view your database, select **Manage and View Your Vertica Database** to go to the database **Overview** .

You can also view your database from the **Recent Databases** section of the MC home page.

For additional information about managing your cluster, instances, and database using Management Console, see [Managing database clusters](#) .

Eon Mode volume configuration defaults for Azure

When you provision an Eon Mode database cluster, Management Console (MC) configures separate volumes for the depot, catalog, and temp directories. The specific volumes and sizes that Management Console configures vary depending on the Azure instance type that you select when provisioning the cluster.

MC follows these rules when allocating resources for these directories for an Eon Mode database cluster:

- Depot: Use Standard or Premium LRS to ensure the data is durable.
- Catalog: Use Standard or Premium LRS to ensure the data is durable.
- Temp: Allocate instance store if available with the selected instance type. Otherwise, allocate Standard or Premium LRS volumes.

If NVMe or Local SSD are displayed as volume types for an instance, there are no other choices. You must choose a different VM to change the volume type.

For details about each disk type, see the [Azure documentation](#) .

Instance Type	Instance Storage	Depot	Catalog	Temp
E16ds v4	1 x 600GB	Configurable 8 Data Disks/Managed Disk/Remote Storage 8 x 75 GB Premium/Standard LRS Default: Premium LRS	Data Disk 50 GB Premium/Standard LRS - Durable Default: Premium LRS	1 x 600GB Temporary local SSD (ephemeral) Display: "Local SSD"
E20ds v4	1 x 750 GB	Data Disk 8 x 75 GB	Data Disk 50 GB	1 x 600GB Temporary local SSD (ephemeral) Display: "Local SSD"
E32ds v4	1 x 1200 GB	Data Disk 8 x 75 GB	Data Disk 50 GB	1 x 600GB Temporary local SSD (ephemeral) Display: "Local SSD"

E48ds v4	1 x 1800 GB	Data Disk 8 x 75 GB	Data Disk 50 GB	1 x 600GB Temporary local SSD (ephemeral) Display: "Local SSD"
E64ds v4	1 x 2400 GB	Data Disk 8 x 75 GB	Data Disk 50 GB	1 x 600GB Temporary local SSD (ephemeral) Display: "Local SSD"
E80ids v4	1 x 2400 GB	Data Disk 8 x 75 GB	Data Disk 50 GB	1 x 600GB Temporary local SSD (ephemeral) Display: "Local SSD"
E16s v4	Instance Store not supported	Configurable 8 Data Disks 8 x 75 GB (user defined)	Data Disk 50 GB	Data Disks 1 x 300 GB (user-defined) No less than 300 GB Premium/Standard LRS - Durable Default: Premium LRS 300GB Min : 50 GB Max : 10000 GB Note This instance type supports Remote storage only. Temp uses Data Disks.
E20s v4	Instance Store not supported	Data Disk 8 x 75 GB	Data Disk 50 GB	Data Disks 1 x 300 GB (user-defined) No less than 300 GB Premium/Standard LRS - Durable Default: Premium LRS 300GB Min : 50 GB Max : 10000 GB

E32s v4	Instance Store not supported	Data Disk 8 x 75 GB	Data Disk 50 GB	Data Disks 1 x 300 GB (user-defined) No less than 300 GB Premium/Standard LRS - Durable Default: Premium LRS 300GB Min : 50 GB Max : 10000 GB
E48s v4	Instance Store not supported	Data Disk 8 x 75 GB	Data Disk 50 GB	Data Disks 1 x 300 GB (user-defined) No less than 300 GB Premium/Standard LRS - Durable Default: Premium LRS 300GB Min : 50 GB Max : 10000 GB
E64s v4	Instance Store not supported	Data Disk 8 x 75 GB	Data Disk 50 GB	Data Disks 1 x 300 GB (user-defined) No less than 300 GB Premium/Standard LRS - Durable Default: Premium LRS 300GB Min : 50 GB Max : 10000 GB
E80s v4	Instance Store not supported	Data Disk 8 x 75 GB	Data Disk 50 GB	Data Disks 1 x 300 GB (user-defined) No less than 300 GB Premium/Standard LRS - Durable Default: Premium LRS 300GB Min : 50 GB Max : 10000 GB
E80s v4	Instance Store not supported	Data Disk 8 x 75 GB	Data Disk 50 GB	Data Disks 1 x 300 GB (user-defined) No less than 300 GB Premium/Standard LRS - Durable Default: Premium LRS 300GB Min : 50 GB Max : 10000 GB
E16s v3	1 x 256 GB	Data Disk 8 x 75 GB	Data Disk 50 GB	1 x 256 GB Use Temporary local SSD (instance store is ephemeral)

Note

You cannot use this type to revive an Eon Mode database.

E20s v3	1 x 320 GB	Data Disk 8 x 75 GB	Data Disk 50 GB	1 x 320 GB Use Temporary local SSD (instance store is ephemeral)
E32s v3	1 x 512 GB	Data Disk 8 x 75 GB	Data Disk 50 GB	1 x 512 GB Use Temporary local SSD (instance store is ephemeral)
E48s v3	1 x 768 GB	Data Disk 8 x 75 GB	Data Disk 50 GB	1 x 768 GB Use Temporary local SSD (instance store is ephemeral)
E64s v3	1 x 864 GB	Data Disk 8 x 75 GB	Data Disk 50 GB	1 x 864 GB Use Temporary local SSD (instance store is ephemeral)
E64is v3	1 x 864 GB	Data Disk 8 x 75 GB	Data Disk 50 GB	1 x 864 GB Use Temporary local SSD (instance store is ephemeral)

Note
You cannot use this type to revive an Eon Mode database.

Reviving an Eon Mode database on Azure in MC

An [Eon Mode database](#) keeps an up-to-date version of its data and metadata in its communal storage location. After a cluster hosting an Eon Mode database is terminated, this data and metadata continue to reside in communal storage. When you revive the database later, Vertica uses the data in this location to restore the database in the same state on a newly provisioned cluster.

Many of the fields in the revive workflow are populated with information provided during provisioning. For details about fields with existing values, see [Creating an Eon Mode cluster and database in Azure in MC](#).

The following steps revive an Eon Mode database on Azure:

1. On the MC home page, select **Revive Eon Mode database**.
2. On **Specify cluster access preferences**, supply the following information:
 - **Azure Subnet**: The subnet for your cluster. Select the same subnet used when you deployed the MC instance in the Azure Marketplace. If your organization requires multiple subnets for security purposes, see the [Azure documentation](#) for additional information.
 - **SSH Public Key**: Paste the same public key used when you deployed the MC instance in the Azure Marketplace.
 - **CIDR Range**: The range of IP addresses for client and SSH access.
3. Select **Next**. On **Specify Azure AZB path for Communal Storage of database**, you can enter a parent directory to list all available Eon Mode databases within that directory:
 1. Enter the directory name. At minimum, you must provide the account and container name, and optionally subfolder names in the following format:
`azb:// storage-account / container [/ subfolder-name /...]`
 2. Select **Discover**. The MC lists all available Eon Mode databases within the container or subfolder.
 3. Select the database that you want to revive from the list.
4. Select **Next**. On **Enter revive database configurations**, supply the following information:
 - **Revive to Vertica Version**: Lists the currently available Vertica versions. If you select a version that is later than the version that you used to provision the database, the MC upgrades the database version automatically.
 - **Password**: The password for the [database superuser](#).

- **Confirm Password** : Reenter **Password** .
5. Select **Next** . On **Specify cloud instance and depot data storage** , supply the following information about the [depot](#) :
 - **Virtual Machine (VM) Size** : The machine types used for the nodes. For recommended machine types, see the memory optimized machine types in [Recommended Azure VM types and operating systems](#) .
 - **Managed Disk Volume Type** : Available for Azure managed disks only. For details about each disk type, see the [Azure documentation](#) .
 - **Managed Disk Volume Size (GB) per Volume per Available Node** : Volume size for each node. This value is populated with the [volume configuration defaults](#) for the associated instance type.
 - **Node IP Setting** : Choose **Public IP - Dynamic** , **Public IP - Static** , or **Private IP** . For details, see the [Azure documentation](#) .
 6. Select **Next** . On **Specify additional storage and tag info** , supply the following information:
 - **Managed Volume Type** : Available only for Azure managed disks. For details about each disk type, see the [Azure documentation](#) .
 - For the [catalog and temp](#) paths, provide the following information:
 - **Managed Disk Volume Type** : Available only for Azure managed disks. For details about each disk type, see the [Azure documentation](#) .
 - **Managed Disk Volume Size (GB) per Available Node** : Volume size for each node. This value is populated with the [volume configuration defaults](#) for the associated VM type.
 - **Tag Azure Resources** : Optional. Assign distinct, searchable metadata tags to the instances in this cluster. Many organizations use labels to organize, track responsibility, and assign costs for instances.
To add a tag, select the checkbox to make the **Tag Name** and **Tag Value** available. Click **Add** to create the tag. Tags are displayed below the fields. Vertica recommends that you use lowercase characters in tag fields.
 7. Select **Next** . On **Review revive information** , confirm your selections. Select **Back** to return to a previous section and make changes.
 8. When you are satisfied with your selections, select the **Accept terms and conditions** checkbox.
 9. Select **Revive Database** to revive the Eon Mode database on Azure.

For details about database clusters in Management Console, see [Managing database clusters](#) .

Google Cloud Platform in MC

Management Console (MC) supports cluster, subcluster, and node actions on Google Cloud Platform (GCP).

Provision, monitor, and revive clusters

You can use MC to provision an Eon Mode database cluster on GCP. For details, see [Provision an Eon Mode cluster and database on GCP in MC](#) .

MC provides specific resources for monitoring database clusters on GCP. For details, see [Managing an Eon Mode database in the cloud](#) .

You can revive a stopped Eon Mode database on GCP using MC. For details, see [Reviving an Eon Mode database on GCP in MC](#) .

Managing your cluster in MC

1. On the MC home page, click **View Infrastructure** . MC displays the Database and Cluster View. This view shows your infrastructure platform, cluster, and database.
2. On the left side of the screen next to **Clusters** , click the square for the cluster you want to manage. MC displays a window with your cluster name, an information summary, and several buttons.
3. Click **Manage** . The **Cluster** page displays.
4. On the **Cluster** page, you can view the following information:
 - The instances in your cluster in visual format.
 - The status of each instance, whether it is running.
 - The private and public IP address for each cluster instance.
 - The Vertica version that is running, your region, and your instance type in the **Cluster** pane.

Cluster actions on GCP in MC

On the **Cluster** page, you can perform the following cluster actions:

- **Start Cluster** : Starts the instances, then starts the database. For Eon Mode databases, MC repopulates the nodes with data from the storage account container.
- **Stop Cluster** : Stops the nodes in the database, then stops their cloud instances.
- **Advanced > Terminate** : Stops the database, then terminates the cloud instances.

Note

If a GCP instance has a local SSD attached, Google does not allow you to stop the instance. If you do shut down an instance with a local SSD through the guest operating system, you will not be able to restart the instance, and the data on the local SSD will be lost.

Subcluster management

You can add, Scale Up, Scale Down, remove, and terminate subclusters with MC. For details, see the following:

- [Subclusters in MC](#)
- [Scaling subclusters in MC](#)
- [Subcluster action rules in MC](#)

Node management

You add or delete nodes by scaling subclusters up or down. You can also start, stop, and restart nodes. For details, see the following:

- [Add nodes to a cluster in AWS using Management Console](#)
- [Starting, stopping, and restarting nodes in MC](#)
- [Node action rules in MC](#)

Restrictions

- Subclusters are supported in Eon Mode only, not in Enterprise Mode.
- Node actions are not supported in MC on GCP.

See also

[Vertica on Google Cloud Platform](#)

In this section

- [GCP Eon Mode instance recommendations](#)
- [Custom GCP image](#)
- [Provision an Eon Mode cluster and database on GCP in MC](#)
- [Reviving an Eon Mode database on GCP in MC](#)
- [Eon Mode volume configuration defaults for GCP](#)

GCP Eon Mode instance recommendations

When you use the MC to deploy an Eon Mode database to the Google Cloud Platform (GCP), you choose the instance type to deploy as the database's nodes. The default instance settings in the MC are the more conservative option (currently, n1-standard-16). They are sufficient for most workloads. However, you may choose instances with more memory (such as n1-highmem-16) if your queries perform complex joins that may otherwise spill to disk. You can also choose instances with more cores (such as n1-standard-32), if you perform highly-complex compute-intensive analysis. The following links provide additional information about GCP machine type instances and Vertica:

- [Machine types](#): Google Cloud's documentation that describes configuration details for each instance option.
- [Supported GCP machine types](#): Available machine types when deploying Vertica to GCP.
- [Eon Mode volume configuration defaults for GCP](#): Details about Vertica's default volume configurations.

The more powerful instance you choose, the higher the cost per hour. You need to balance whether you want to use fewer, higher-powered but more expensive instances vs. relying on more lower-powered instances that cost less. Thanks to Eon Mode's elasticity, if you choose to use the less-powerful instances, you can always add more nodes to meet peak demands. When you reduce the number of instances to a minimum during off-peak times, you'll spend less than if you had a similar number of more-powerful instances.

Storage options

The MC's deployment wizard also asks you to select the type of local storage for your instances. You can select different options for each type of local storage that Vertica uses: the catalog, the depot, and temporary space. For all of these storage locations, you choose the type of disks to use (standard vs. SSD). You will see the best performance with SSD disks. However, SSD disks cost more.

For the depot, you also choose whether to use local or persistent disks. The local option is faster, as it resides directly on the virtual machine host. However, whenever you shut down the node, this storage is wiped clean. The persistent storage is slower than the local option, as it is not stored directly on the machine hosting the instance. However, it is not wiped out whenever you shut down the instance. See the Google Cloud documentation's [Storage options](#) page for more information.

Which of these options you choose depends on how much [depot warming](#) the nodes must perform when starting. If the content of your node's depots change little over time (or you tend to frequently start and stop instances), using persistent storage makes sense. In this case, the depot's warming period will be shorter because most of the data the node needs to participate in queries may still be in its depot when it starts. It will perform fewer fetches of data from communal storage while participating in queries.

If your working data set is rapidly changing or you tend to leave nodes stopped for extended periods of time, your best choice is usually to use local storage. In this scenario, the data in the node's depot when it restarts is usually stale. To participate in queries, the node must fetch much of the data it needs from communal storage, resulting in slower performance until it has warmed its depot. Using local ephemeral storage makes sense here, because you will get the benefit of having faster depot storage. Because your nodes have to warm their depots anyhow, there is less of a downside of having the depot on ephemeral storage.

For general guidelines on scaling your cluster for Eon Mode database, see [Configuring your Vertica cluster for Eon Mode](#).

Custom GCP image

Vertica publishes a Google Cloud Platform (GCP) image that contains third-party libraries and other software that is required to install and operate the Management Console (MC) instance and Vertica database cluster instances. In some circumstances, you might need to add customizations to your MC environment, such as monitoring or security updates.

You cannot modify the published Vertica image directly, but you can create a custom image from the published image with your customizations. You can select this custom image when you create or revive a cluster.

Prerequisites

GCP account with administrative rights.

Create a custom GCP image

To create a custom GCP image, you must launch a base Virtual Machine (VM) instance from the published Vertica image so that you can make your changes. After you create this base instance, you can save it as a custom image.

Create the base instance

To begin, you must create an instance that includes the published Vertica image. This is a temporary instance that you can delete after you [create the custom image](#):

1. Log in to GCP.
2. From the GCP console, go to **Compute Engine**.
3. In the side navigation bar, go to **Storage > Images**.
4. Filter the images table for the published Vertica image that you want to use in the base instance. For example, filter for `vertica-23-4-0` to customize the 23.4.0-x image.
5. Copy the name of the published Vertica image and save it for later use.
6. Go to **Virtual machines > VM instances** in the side navigation bar.
7. Select **CREATE INSTANCE**.
8. Enter a name for your instance.
9. Select a region.
10. Scroll down to **Boot disk**, and select **CHANGE**.
11. In the **Boot disk** window, select the **CUSTOM IMAGES** tab.
12. In the **image** field, paste the name of the published Vertica image to filter the image list.
13. Select **SELECT**. The **Boot disk** window closes and you return to **Create an instance**.
14. Select **CREATE** to create the base instance.

After you select **CREATE**, you return to **Virtual machines > VM instances** in **Compute Engine**. When GCP finishes creating the base instance, you have a running instance that you can access and customize.

Customize the base instance

Note

This section requires access to a separate machine and its public SSH key so you can connect to the base instance and install customizations. You cannot customize the base instance with SSH on the GCP portal or gcloud compute SSH.

To generate a public and private keypair, use the `ssh-keygen` command, and answer the prompts:

```
$ ssh-keygen -t rsa -b 4096 -C gcpAdminUsername
Generating public/private rsa key pair.
Enter file in which to save the key: /path/to/gcp_custom_keys
...
Your public key has been saved in /path/to/gcp_custom_keys.pub
...
```

The preceding `ssh-keygen` command includes the following options:

- **t**: Type of key to create. This example creates a key with the `rsa` algorithm.
- **b**: Number of bits in the key. This example creates a key with 4096 bits.

- **C** : Adds a comment to help identify the key. Specify your GCP administrator username with this option. If you do not use this option, the command generates the comment as `user@hostname`, and you must manually remove the `@hostname` portion.

After you create the base instance, add the contents of your public key to the instance so you can SSH into the machine to add customizations or configurations:

1. In **Virtual machines > VM instances**, filter for the base instance.
2. Select the instance name. The instance **Details** tab displays.
3. Select **EDIT** in the top menu.
4. In **Security and access > SSH Keys**, select **ADD ITEM**.
5. In the **SSH key 1 *** field, paste the contents of the public SSH key that you just created.
Important
If you use public key with the default comment format, do not include the `@hostname` portion of the comment. The key that you paste into **SSH key 1 *** must end with `username`.
6. Select **SAVE**.
7. Return to the **VM instances** window, go to the **Network interfaces** section and retrieve the **External IP address** for the base instance.
8. Remotely log in to the base instance with the user string from the public key. The `-i` option uses the local machine's private key for authentication:

```
ssh -i path/to/ssh-private-key username@baseInstanceExternalIPAddress
```

9. Add custom configurations to the base instance environment.

Now, the base instance includes the published Vertica base image, and any custom configurations.

Create the custom image

After you customize the base instance, you can create a new image that includes the published Vertica base image and your customizations:

1. On **Virtual Machines > VM instances**, select the base instance and select **STOP**.
2. After the instance stops, select the instance name in the list. The image **DETAILS** tab displays.
3. Scroll to the **Boot disk** section. In the **Name** column, select the instance name.
4. In the top navigation bar, select **CREATE IMAGE**. The **Create an image** page displays.
5. In the **Name** field, enter a name for the instance. You must use the following naming convention, or the MC cannot identify the image when you create or revive a cluster:

```
vertica-major-minor-servicepack-hotfix-imageName
```

For example, the following name uses Vertica version 12, minor release 0, service pack 0, hotfix zero:

```
vertica-12-0-0-0-customImageName
```

6. Verify that **Source disk** lists the base instance name.
7. Select **CREATE**.
8. Record the name of the image that you just created so you can enter it in the MC.

After GCP creates the image, you have a custom image that includes the published Vertica base image, and any environment customizations. This custom image is available in the current GCP project.

If you no longer need the customized base instance, you can delete it from your GCP VM instances.

Select the custom image in MC

Important

This section requires that you enter the custom image name in the MC. To retrieve the name, log in to the GCP portal and go to **Compute Engine > Storage > Images**.

After you create the custom image in GCP, return to the MC and use the custom image in a workflow:

1. Log into the MC and begin one of the following workflows:
 - Create database cluster
 - Revive cluster
2. On the wizard page **Enter Vertica database name and login credentials**, select the **Use Custom Image** box.
3. In **Custom Image Name**, enter the custom image name. For example, `vertica-23-4-0-0- customImageName`.
4. Complete the create or revive workflow.

After you complete the workflow, any new or revived Vertica database cluster instances run the custom image. If you scale a new or revived cluster, the added instances use the same custom image.

Provision an Eon Mode cluster and database on GCP in MC

You can use Google Marketplace and MC to provision an Eon Mode database on GCP. The sections below give an overview of how to set up an Eon Mode database on GCP, with links to the detailed procedures

Prerequisites

- [GCP Eon Mode instance recommendations](#)
- [Eon Mode on GCP prerequisites](#)

Step 1: provision an MC instance using Google marketplace

These steps are an overview of the procedure. For more detailed instructions, see [Deploy an MC instance in GCP for Eon Mode](#).

In Google Marketplace:

1. Select the Vertica Eon Mode solution.
2. Fill in the fields to configure a GCP MC instance.
3. Click the **Deploy** button to provision the MC instance.
4. Connect to and log into the MC instance.

You are now in the new MC instance running on GCP, and the MC home page appears.

Step 2: use the MC instance to provision an Eon Mode database on GCP

To use the MC to provision and deploy a new Eon Mode database on GCP:

1. From the MC home screen, click **Create new database** to launch the Create a Vertica Cluster on Google Cloud wizard.
2. On the first page of the wizard enter the following information:
 - **Google Cloud Storage HMAC Access Key** and **HMAC Secret Key** : Copy and paste the HMAC access key and secret you created earlier. You find these values on the Interoperability tab of the of the Storage Settings page. See [Eon Mode on GCP prerequisites](#) for details.
 - **Zone** : This value defaults to the zone containing your MC instance. Make this value is the same as the zone containing the Google Cloud Storage bucket that your database will use for communal storage.

Caution

You will see significant performance issues if you choose different zones for cluster instances, storage, or the MC.

- **CIDR Range** : The IP address range for clients to whom you want to grant access to your database. Make this range as restrictive as possible to limit access to your database.
3. Click **Next** , and supply the following information:
 - **Vertica Database Name** : the name for your new database. See [Creating a database name and password](#) for database name requirements.
 - **Vertica Version** : select the desired Vertica database version. You can select from the latest hotfix of recent Vertica releases. For each database version, you can also select the operating system.
 - **Vertica Database User Name** : the name of the [database superuser](#). This name defaults to dbadmin, but you can enter another user name here.
For details about using a custom GCP instance, see [Custom GCP image](#).
 - **Password** and **Confirm Password** : Enter a password for the database superuser account.
 - **Database Size** : The number of nodes in your initial database. If you specify more than three nodes here, you must supply a valid Vertica license file in the Vertica License field (below).
 - **Vertica License** : Click **Browse** to locate and upload your Vertica license key file. If you do not supply a license key file here, the wizard deploys your database with a Vertica Community Edition license. This license has a three node limit, so the value in the Database Size field cannot be larger than 3 if you do not supply a license. If you use a Community Edition license for your deployment, you can upgrade the license later to expand your cluster load more than 1TB of data. See [Managing licenses](#) form more information.

Note

This field does not appear if you created your MC instance using a by-the-hour (BTH) launcher. The BTH license is automatically applied to all clusters you create using a BTH MC instance. For a by-the-hour license, cloud vendors charge the customer for licensed Vertica usage along with their cloud infrastructure charges.

- **Load example data** : Check this box if you want your deployed database to load some example clickstream data. This option is useful if you are testing features and just want some preloaded data in the database to query.
4. Click **Next** and supply the following information:
- **Instance Type** : the specifications of the virtual machine instances the MC will use to deploy your database nodes. See the Google Cloud documentation's [Machine types](#) page for details of each instance type. Also see [GCP Eon Mode instance recommendations](#) .
 - **Database Depot Path** and **Disk Type** : the local mount point for the depot, and the type and number of local disks dedicated to the [depot](#) for each node. You cannot change the mount path for the depot. The disks you select in the **Disk Type** field are only used to store the depot. On the next page of the wizard, you will configure disks for the catalog and temporary disk space. You will see the best performance when using SSD disks, although at a higher cost. You can choose to use faster local storage for your depot. However, local storage is ephemeral—GCP wipes the disk clean whenever you stop the instance. This means each time you start a node, it will have to [warm its depot](#) from scratch, rather than taking advantage of any still-current data in its depot. See the Google Cloud documentation's [Storage options](#) page for more information about the local disk options.
 - **Volume Size** : the amount of disk space available on each disk attached to each node in your cluster. This field shows you the total disk space available per node in your cluster. For the best practices on choosing the amount of disk space for your nodes, see [Configuring your Vertica cluster for Eon Mode](#) .
 - **Data Segmentation Shards** : sets the number of [shards](#) in your database. After you set this value, you cannot change it later. See [Configuring your Vertica cluster for Eon Mode](#) for recommendations. The default value is based on the number of nodes you entered in the Database size you specified earlier. It is usually sufficient, unless you anticipate greatly expanding your cluster beyond your initial node count.
 - **Communal Location** : a Google Cloud Storage URL that specifies where to store your database's communal data. The storage bucket must use the [Standard storage class](#) . See [Eon Mode on GCP prerequisites](#) for additional requirements.
 - **Instance IP settings** : specify whether the nodes in your database will have static or ephemeral network addresses that are accessible from the internet, or addresses that are only accessible from within the internal virtual network.
5. Click **Next** . The wizard validates your communal storage location URL. If there is an problem with the URL you entered, it displays an error message and prompts you to fix the URL.

After your communal storage URL passes validation, fill in the following information:

- **Database Catalog Path , Disk Type , and Size (GB) per Available Node** : the mount point disk type, and disk size for the local copy of the database [catalog](#) on each node. You cannot edit the mount point. You choose the type of local disk to use for the catalog, and its size. You can only choose persistent disk storage for the catalog. SSD drives are faster, but more expensive than standard disks. The default setting for the disk size is adequate for most medium size databases. Increase the size if you anticipate maintaining a large database.
 - **Database Temp Path , Disk Type , and Size (GB) per Available Node** : the mount point disk type, and disk size for the temporary storage space on each node. You cannot edit the mount point. You choose the type of local disk to use, and its size. You can only choose persistent disk storage for the temporary disk space. SSD drives are faster, but more expensive than standard disks. The default setting is adequate for most databases. Consider increasing the temporary space if you perform many complex merges that spill to disk.
 - **Label Instances** : check this box to enable adding labels to your node's instances. Many organizations use labels to organize, track responsibility, and assign costs for instances. See the Google Cloud documentation's [Labeling resources](#) page for more information. If you choose to add labels, enter the label name and value, and click **Add** .
6. Click **Next** . Review the summary of all your database settings. If you need to make a correction, use the Back button to step back to previous pages of the wizard.
7. When you are satisfied with the database settings, check **Accept terms and conditions** and click **Create** .

The process of provisioning and creating the database takes several minutes. After it completes successfully, the MC displays a **Get Started** button. This button leads to a page of useful links for getting started with your new database.

- [Reviving an Eon Mode database cluster](#)

Reviving an Eon Mode database on GCP in MC

An [Eon Mode database](#) keeps an up-to-date version of its data and metadata in its communal storage location. After a cluster hosting an Eon Mode database is terminated, this data and metadata continue to reside in communal storage. When you revive the database later, Vertica uses the data in this location to restore the database in the same state on a newly provisioned cluster.

Follow these steps to revive an Eon Mode database on GCP:

1. On the MC home page, click **Revive Eon Mode Database** . MC launches the Provision and Revive an Eon Mode Database wizard.
2. On the first page of the wizard, enter the following information:
 - **Google Cloud Storage HMAC Access Key** and **HMAC Secret Key** : Copy and paste the HMAC access key and secret you created when you created the database. See [Eon Mode on GCP prerequisites](#) for details.
 - **Zone** : This value defaults to the zone containing your MC instance. Make this value the same as zone containing the Google Cloud Storage bucket your database will use for communal storage. You will see significant performance issues if you choose different zones for cluster instances, storage, or the MC.

- **CIDR Range** : The IP address range for clients you want to grant access to your database. Make this range as restrictive as possible to limit the exposure of your database.
3. Click **Next** . On the second page of the wizard, set **Google Storage Path for Communal Storage of Database** to the URL of the communal storage bucket for the Eon Mode database to revive. For requirements, see [Eon Mode on GCP prerequisites](#) .
 4. Click **Discover** . MC displays a list of all Eon Mode databases available on the specified communal storage location.
 5. Select the database to revive. MC prepopulates the choices for the Data, Depot, and Temp catalogs, using the same machine types and configuration choices used when the database was created.
 6. Click **Next** . Review the summary of all your database settings. If you need to make a correction, use the Back button to step back to previous pages of the wizard.
 7. When you are satisfied with the database settings, check the **Accept terms and conditions** box and click **Revive Database** .

MC displays a progress screen while creating the cluster and reviving the database onto it, a process which takes several minutes. After it completes successfully, the MC displays a **Get Started** button. This button leads to a page of useful links for getting started with your new database.

Eon Mode volume configuration defaults for GCP

Vertica supports a variety of disk volume resources for provisioning instances on Google Cloud Platform (GCP).

All data is secured with Google-managed data encryption. Management Console does not support user-managed data encryption.

For performance information, see Google's [Block storage performance](#) documentation.

Persistent disk defaults

You can allocate up to 128 persistent disks (PDs). The following table describes the default persistent disk volume resources that Vertica provides:

Instance Types	Catalog	Depot	Temp
n1-standard/highmem-16	Configurable 1 PD (Standard/SSD) volume	Configurable 8 PD (Standard/SSD) volume	Configurable 1 PD (Standard/SSD) volume
n1-standard/highmem-32	Default: 50 GB	Default: 600 GB	Default: 100 GB
n1-standard/highmem-64			
n2-standard/highmem-16			
n2-standard/highmem-32			
n2-standard/highmem-48			
n2-standard/highmem-64			

Local SSD defaults (ephemeral storage)

Allocate up to 24 local SSDs for ephemeral storage with the following considerations:

- There is an extra cost for each local SSD.
- All local SSD are 375G fixed size, with the option of SCSI or NVMe interface. An NVMe disk has twice the input/output operations per second (IOPs) compared to a SCSI disk.

Important

When the local SSD is in use, you cannot stop or start the instance or a cluster containing local SSD instances. If you do shut down an instance with a local SSD through the guest operating system, you will not be able to restart the instance and the data on the local SSD will be lost.

For details, see Google's [Adding Local SSDs](#) page.

The following table describes the default local SSD disk volume resources that Vertica provides:

Total Local SSDs	Instance Types	Catalog (Persistent)	Depot (Ephemeral)	Temp (Ephemeral)
4	n1-standard/highmem-16 n1-standard/highmem-32 n1-standard/highmem-64 n2-standard/highmem-16 n2-standard/highmem-32	Configurable 1 PD (Standard/SSD) volume Default: 50 GB	3 x 375 GB	1 x 375 GB
5	n1-standard/highmem-16 n1-standard/highmem-32 n1-standard/highmem-64	Configurable 1 PD (Standard/SSD) volume Default: 50 GB	4 x 375 GB	1 x 375 GB
6	n1-standard/highmem-16 n1-standard/highmem-32 n1-standard/highmem-64	Configurable 1 PD (Standard/SSD) volume Default: 50 GB	5 x 375 GB	1 x 375 GB
8	n1-standard/highmem-16 n1-standard/highmem-32 n1-standard/highmem-64 n2-standard/highmem-16 n2-standard/highmem-32 n2-standard/highmem-48 n2-standard/highmem-64	Configurable 1 PD (Standard/SSD) volume Default: 50 GB	6 x 375 GB	2 x 375 GB
16	n1-standard/highmem-16 n1-standard/highmem-32 n1-standard/highmem-64 n2-standard/highmem-16 n2-standard/highmem-32 n2-standard/highmem-48 n2-standard/highmem-64	Configurable 1 PD (Standard/SSD) volume Default: 50 GB	12 x 375 GB	4 x 375 GB

24	n1-standard/highmem-16	Configurable 1 PD (Standard/SSD) volume Default: 50 GB	20 x 375 GB	4 x 375 GB
	n1-standard/highmem-32			
	n1-standard/highmem-64			
	n2-standard/highmem-16			
	n2-standard/highmem-32			
	n2-standard/highmem-48			
	n2-standard/highmem-64			

Monitoring with MC

Management Console gathers and retains history of important system activities about your MC-managed database cluster, such as performance and resource utilization. You can use MC charts to locate performance bottlenecks on a particular node, to identify potential improvements to Vertica configuration, and as a reference for what actions users have taken on the MC interface.

Note

MC directly queries Data Collector tables on the MC-monitored databases themselves. See [Management Console architecture](#). For how to set up MC to query an alternative database for monitoring data, see [Extended monitoring](#).

The following list describes some of the areas you can monitor and troubleshoot through the MC interface:

- Multiple database cluster states and key performance indicators that report on the cluster's overall health
- Information on individual cluster nodes specific to resources
- Database activity in relation to CPU/memory, networking, and disk I/O usage
- Layout of [subclusters](#), and resource utilization and query workload on subclusters. (Available in Eon mode databases only, where the database includes one default subcluster, and may include additional user-defined subclusters.)
- Query concurrency and internal/user sessions that report on important events in time
- Cluster-wide messages
- Database and agent log entries
- MC user activity (what users are doing while logged in to MC)
- Issues related to the MC process
- Error handling and feedback

About chart updates

MC retrieves statistical data from the production database to keep the charts updated. The charts also update dynamically with text, color, and messages that Management Console receives from the [agents](#) on the database cluster. This information can help you quickly resolve problems.

Each client session to MC uses a connection from [MaxClientSessions](#), a database configuration parameter. This parameter determines the maximum number of sessions that can run on a single database cluster node. Sometimes multiple MC users, mapped to the same database account, are concurrently monitoring the Overview and Activity pages.

Tip

You can increase the value for [MaxClientSessions](#) on an MC-monitored database to account for extra sessions. See [Managing sessions](#) for details.

In this section

- [Viewing the overview page](#)
- [Monitoring same-name databases with MC](#)
- [Monitoring cluster nodes with MC](#)
- [Monitoring node activity with MC](#)

- [Extended monitoring](#)

Viewing the overview page

The Overview page displays a dynamic dashboard view of your database.

The page provides three tabs: Status Summary, System Health, and Query Synopsis. Access these tabs by clicking one of the three icons at the top left of the Overview page. Each tab contains charts and filters displaying information about your cluster. The QuickStats widgets on the right of the page display alerts and statistics about the state of your cluster.

Information on this page updates every two minutes, however you can adjust that value in the MC Settings page on the Monitoring tab. You can postpone updates by deselecting Auto Refresh in the toolbar.

Chart viewing options

You can specify time frames for some charts, which display a calendar icon in their title bars. Click the calendar icon to specify the time frame for that module.

On the Status Summary tab, you can select **Synchronize charts** to simultaneously apply the specified time frame to all charts on that tab.

If you have enabled extended monitoring on your database, MC can display longer ranges of data in certain charts. See [Extended monitoring](#). If a chart is using extended monitoring data, the rocket ship icon appears in the title bar:

You can expand some charts to view them in larger windows. Click the expand icon in the title bar to do so:

Changing what the chart displays

The charts on the Overview page can display information about the nodes in your database, or the activity in all your database subclusters, in a single subcluster, or on the nodes that are not assigned to a subcluster. Use the dropdown in the title bar to select the type of information you want to display in the chart.

Note

The dropdown list in the CPU/Memory/Disk I/O chart below, and all other MC charts, appears only for Eon Mode databases, and only if subclusters are defined.

Zooming to show chart details

There are several steps you can take to show increasing levels of detail in a chart.

You can click the expand icon in the title bar to view the chart in a larger window:

You can use the cursor to outline a small area you want to expand, shown as a gray rectangle below:

When you release the cursor, the detail area expands to full size:

Hover over any line or point on the chart to see details about those specific data points. This works before or after you expand the chart:

What the lines and dots on the chart represent

The legend below the CPU/Memory/Disk I/O chart explains what the lines and dots on the chart represent.

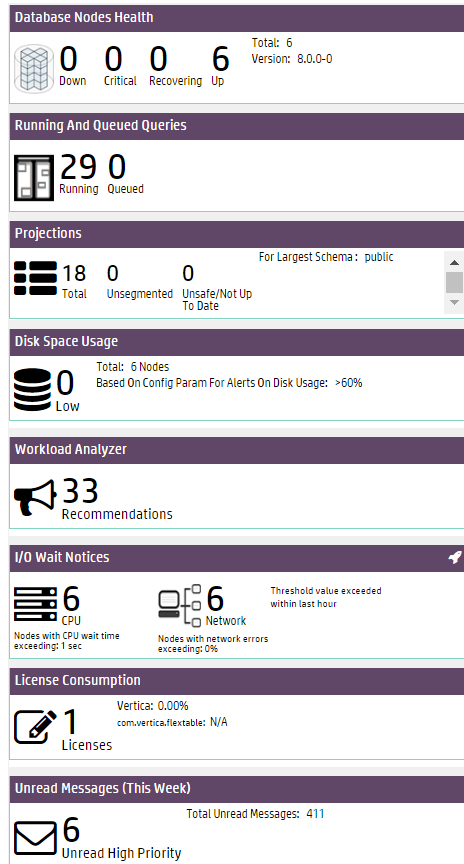

Each line represents the average of the nodes you selected in the dropdown. If you selected Database - Nodes, the line represents the average for all the nodes in the database. If you selected one subcluster, the line represents the average for the nodes in that subcluster.

Each dot represents an individual entity within your dropdown choice. If you chose Database - Nodes, each dot represents one node in the database. If you chose Database - Subclusters, each dot represents one subcluster in the database. If you chose a single subcluster or the unassigned subclusters, each dot represents an individual node within that set.

You can hover over any line or dot to see a summary about it. You can click on a dot to display the Node Details page for that dot.

Quick stats

The Quick Stats sidebar on the right of the page provides instant alerts and information about your cluster's status.

- **Database Nodes Health** displays which nodes are down, critical, recovering, or up. Critical and recovering nodes are included in the total nodes considered "up" by the database. Click a node value to open the Manage page.
- **Running and Queued Queries** displays current queries in the database. Click the query values to open the Query Monitoring charts.
- **Projections** displays the number of total projections, unsegmented projections, and unsafe projections for the database schema with the most projections. Click a value to open the Table Treemap chart.
- **Disk Space Usage** alerts you to the number of nodes that are low on disk space. Click the value to go to the Manage page. On the Manage page, the Storage Used KPI View is displayed.
- **Workload Analyzer** analyzes system information retained in [SQL system tables](#) and provides tuning recommendations, along with the cost (low, medium, or high) of running the command. See [Analyzing workloads](#) for more information.
- **I/O Wait Notices** displays the number of nodes that, in the last hour, have recorded Disk I/O waits and Network I/O waits exceeding the wait threshold (1 second for Disk and 0 seconds for Network).
- **License Consumption** displays the number of licenses your database uses, and the percentage of your Vertica Community Edition or Premium Edition license being used.
- **Unread Messages** display the number of unread messages and alerts for the database. This count differs from the number of total messages across all your databases. Click the value to open the Message Center.

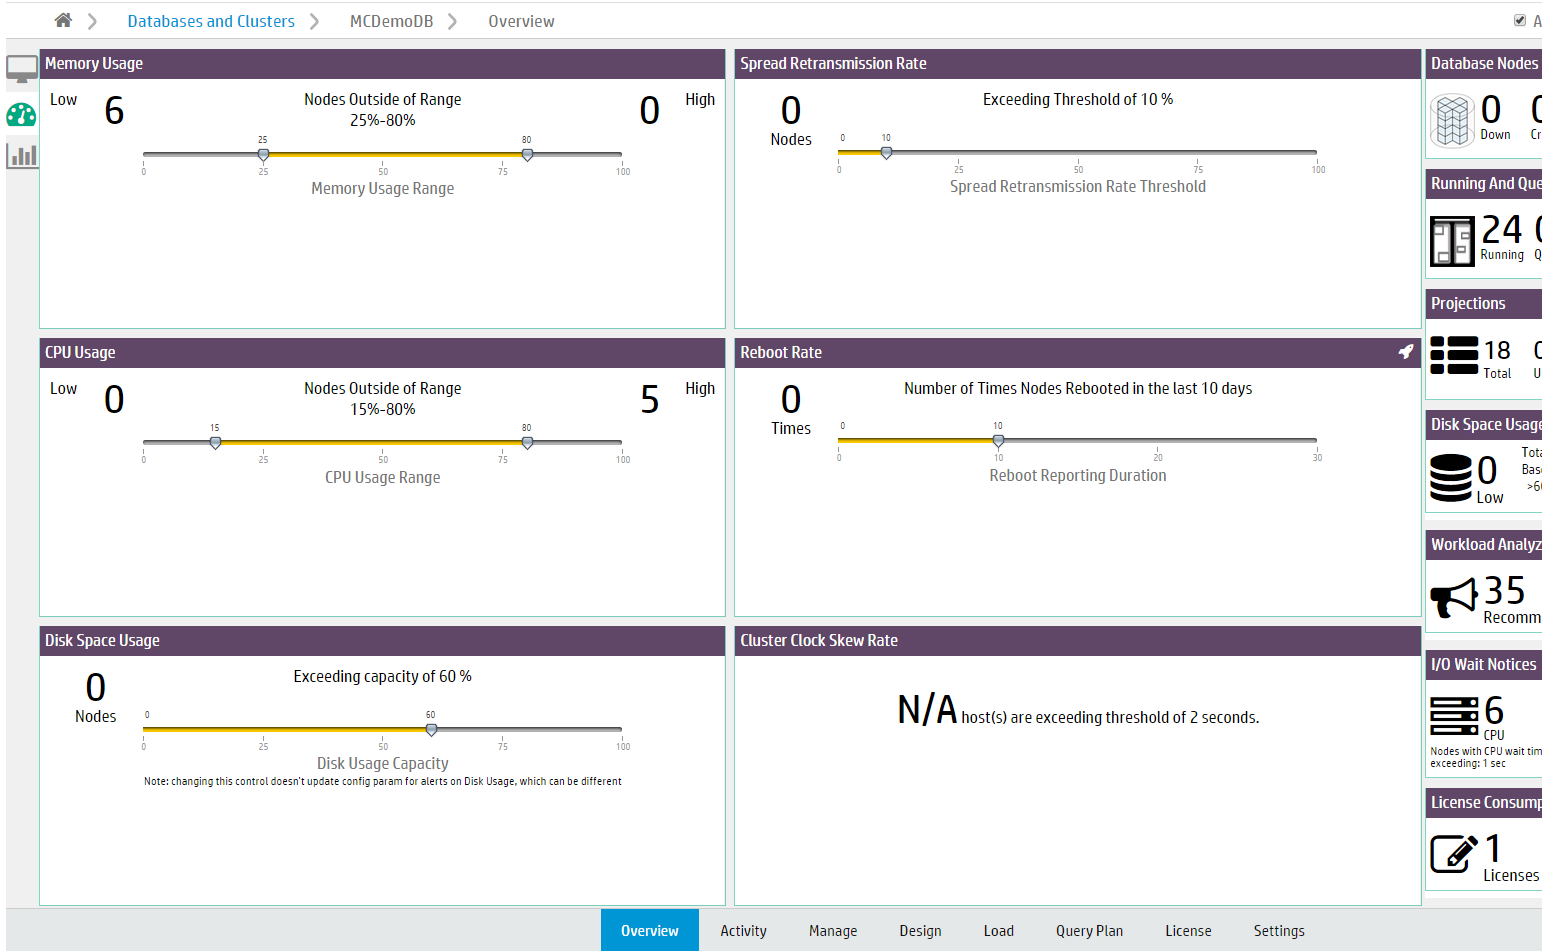

Status summary

The Status Summary tab displays four modules that provide a general overview of the status of your cluster:

- The **CPU/Memory/Disk I/O Usage** module shows cluster resource usage. The chart displays the number of nodes in the database cluster and plots average and per-node percentages for CPU, memory, and disk I/O usage.
 - Select a resource type from the legend to remove or add it from the chart display.
 - Click a data point (which represents a node) to open the Manage page. See [Monitoring cluster CPU and Memory with MC](#).
- The **General Pool Activity** module displays GENERAL pool activity. The chart displays average query queue times, average GENERAL pool free memory, and resource rejections. Use this chart to see how much free memory there is in GENERAL pool, or if there have been high queue times.
 - Click the dropdown in the title bar to view the GENERAL pool usage for the entire database (the default), for a specific subcluster, or for the nodes not assigned to a subcluster.
 - Click the expand icon in the title bar to open the chart in a bigger window.
 - Click a data point to open the [Resource Pools Monitoring](#) chart. See [Managing workloads](#).
- The **Thresholds Notifications** module displays alerts generated when a threshold has been exceeded in the database. Notifications are categorized by System Health and Performance.
 - In the module, you can acknowledge an alert (which marks it as read) or click the X to stop monitoring that threshold (which stops you receiving similar alerts in the future).
 - Customize thresholds and alert priorities for these notifications in the Thresholds tab of the database Settings page. See [Customizing Message Thresholds](#).
- The **Queries** module displays query statistics. The first pie chart displays running and queued queries in the last 24 hours. The second chart displays completed and failed queries for the time frame you specify. Click a query count number above the chart to open the Query Monitoring chart. See [Monitoring running queries with MC](#).

System health

The System Health tab provides a summary of your system resource usage and node information, with filters that allow you to view resource usage within the ranges you specify.

Note

Note: Adjusting the filters on the System Health tab does not affect any database or MC settings.

- The **Memory Usage** filter displays the number of nodes with high and low memory usage. Move the sliders to adjust the memory usage range filter. For example, if you specify a range of 25% to 75% memory usage, the filter displays how many nodes are using less than 25% of memory (Low) and how many are using more than 75% (High). Hover your cursor over the Low and High values to see lists of what nodes fall, respectively, below or above the memory usage range you specified. Click a node value to go to the Manage page, which displays the Memory Utilization KPI View.
- The **Spread Retransmission Rate** filter displays the number of nodes with high spread retransmission rates. When a node's retransmission rate is too high, it is not communicating properly with other nodes. Move the slider to adjust the retransmission rate filter. Hover your cursor over the Nodes value to see a list of what nodes exceeded the spread retransmission rate you specified. Click the node value to view spread retransmit rate alerts in the Message Center.
- The **CPU Usage** chart displays the number of nodes with high and low CPU usage. Move the sliders to adjust the CPU usage range filter. Hover your cursor over the Low and High values to see lists of what nodes are below or above range you specified. Click a node value to go to the Manage page, which displays the CPU Utilization KPI View.
- The **Reboot Rate** filter displays the number of times nodes in the cluster have rebooted within the specified time frame. Use this filter to discover if nodes have gone down recently, or if there have been an unusual number of reboots. Move the slider to adjust the number of days. Hover over the Times value to see a list of the nodes that have rebooted and the times at which they did so.
- The **Disk Space Usage** filter displays the number of nodes with high disk space usage. Move the slider to adjust the disk usage filter. Hover your cursor over the Nodes value to see a list of what nodes exceed the acceptable range. Click the nodes value to go to the Manage page, which displays the Storage Used KPI View.
- The **Cluster Clock Skew Rate** module displays the number of nodes that exceed a clock skew threshold. Nodes in a cluster whose clocks are not in sync can interfere with time-related database functions, the accuracy of database queries, and Management Console's monitoring of cluster activity.

The Query Synopsis page provides two modules that report system query activity and resource pool usage:

- The **Query Statistics** module displays four bar charts that provide an overview of running, queued queries, failed, and completed queries in the past 24 hours.
 - Select one of the options at the top of the module to group the queries by **Resource Pools**, **Users**, **Nodes**, or **Subclusters**.
 - Click a bar on the chart to view details about those queries the [Query Monitoring](#) activity chart.
- The **User Query Type Distribution** chart provides an overview of user and system query activity. The chart reports the types of operations that ran. The default is to display the types of operations that ran on all nodes in the database. Use the dropdown in the title bar to display the types of operations that ran on the nodes in a specific subcluster, or on the nodes not assigned to a subcluster.
 - Hover your cursor over chart points for more details.
 - Select a type of operation from the legend to remove or add it from the chart display.
 - To zoom to a certain time frame, you can adjust the sliders at the bottom of the chart.
 - Click a bar in the graph to open the [Queries](#) chart.

Monitoring same-name databases with MC

If you are monitoring two databases with identical names on different clusters, you can determine which database is associated with which cluster by clicking the database icon on MC's Databases and Clusters page to view its dialog box. Information in the dialog displays the cluster on which the selected database is associated.

Monitoring cluster nodes with MC

For a visual overview of all cluster nodes, click the running database on the Databases and Clusters page and click the **Manage** tab at the bottom of the page to open the cluster status page.

The cluster status page displays the nodes in your cluster.

Home > Databases and Clusters > VMart > Manage

Start Stop Rebalance

Node List

Health filter: 0

KPI View Node State

Zoom level: 10

Overview Activity **Manage** Design Load Query Plan License Settings

The appearance of the nodes indicate the following states:

- **Healthy:** The nodes appear green.
- **Up:** A small arrow to the right of the node points upward.
- **Critical:** The node appears yellow and displays a warning icon to the right.
- **Down:** The node appears red. To the right of the node, a red arrow points downwards.
- **Unplugged:** An orange outlet and plug icon appears to the right. This is displayed when the MC cannot communicate with the [agent](#) running on the node.

You can get information about a particular node by clicking it, an action that opens the [node details](#) page.

Filtering what you see

If you have a large cluster, where it might be difficult to view dozens to hundreds of nodes on the MC interface, you can filter what you see. The Zoom filter shows more or less detail on the cluster overall, and the Health Filter lets you view specific node activity; for example, you can slide the bar all the way to the right to show only nodes that are down. A message next to the health filter indicates how many nodes in the cluster are hidden from view.

On this page, you can perform the following actions on your database cluster:

- Add, remove and replace nodes
- Rebalance data across all nodes
- Stop or start (or restart) the database
- Refresh the view from information MC gathers from the production database
- View key performance indicators (KPI) on node state, CPU, memory, and storage utilization (see [Monitoring cluster performance with MC](#) for details)

Note

Starting, stopping, adding, and dropping nodes and rebalancing data across nodes works with the same functionality and restrictions as those same tasks performed through the [Administration tools](#).

If you don't see what you expect

If the cluster grid does not accurately reflect the current state of the database (for example if the MC interface shows a node in INITIALIZING state, but when you use the Administration Tools to View Database Cluster State, you see that all nodes are UP), click the Refresh button in the toolbar. Doing so forces MC to immediately synchronize with the agents and update MC with new data.

Don't press the F5 key, which redisplay the page using data from MC and ignores data from the agent. It can take several seconds for MC to enable all database action buttons.

Monitoring node activity with MC

If a node fails on an MC-managed cluster or you notice one node is using higher resources than other cluster nodes—which you might observe when monitoring the [Overview page](#)—open the **Manage** page and click the node you want to investigate.

The Node Details page opens and provides summary information for the node (state, name, total memory, and so on), as well as resources the selected node has been consuming for the last three hours, such as average CPU, memory, disk I/O percent usage, network consumption in kilobytes, and the percentage of disk storage the running queries have been using. You can also browse and export log-level data from AgentTools and Vertica log files. MC retains a maximum of 2000 log records.

For a more detailed view of node activity, use the mouse to drag-select around a problem area in one of the graphs, such as the large spike in network traffic in the above image. Then hover over the high data point for a summary.

- [Monitoring cluster performance with MC](#)

Monitoring cluster performance with MC

Key Performance Indicators (KPIs) are a type of performance measurement that let you quickly view the health of your database cluster through MC's **Manage** page. These metrics, which determine a node's color, make it easy for you to quickly identify problem nodes.

Metrics on the database are computed and averaged over the latest 30 seconds of activity and dynamically updated on the cluster grid.

How to get metrics on your cluster

To view metrics for a particular state, click the menu next to the **KPI View** label at the bottom of the Manage page, and select a state.

MC reports KPI scores for:

- **Node state** —(default view) shows node status (up, down, k-safety critical) by color; you can filter which nodes appear on the page by sliding the health filter from left to right
- **CPU Utilization** —average CPU utilization

- **Memory Utilization** —average percent RAM used
- **Storage Utilization** —average percent storage used

After you make a selection, there is a brief delay while MC transmits information back to the requesting client. You can also click **Sync** in the toolbar to force synchronization between MC and the client.

Node colors and what they mean

Nodes in the database cluster appear in color. Green is the most healthy and red is the least healthy, with varying color values in between.

Each node has an attached information dialog box that summarizes its score. It is the score's position within a range of 0 (healthiest) to 100 (least healthy) that determines the node's color *bias*. Color bias means that, depending on the value of the health score, the final color could be slightly biased; for example, a node with score 0 will be more green than a node with a score of 32, which is still within the green range but influenced by the next base color, which is yellow. Similarly, a node with a score of 80 appears as a dull shade of red, because it is influenced by orange.

MC computes scores for each node's color bias as follows:

- 0-33: green and shades of green
- 34-66: yellow and shades of yellow
- 67-100: red and shades of red shades

If the unhealthy node were to consume additional resources, its color would change from a dull orange-red to a brighter red.

Filtering nodes from the view

The health filter is the slider in the lower left area of page. You can slide it left to right to show or hide nodes; for example, you might want to hide nodes with a score smaller than a certain value so the UI displays only the unhealthy nodes that require immediate attention. Wherever you land on the health filter, an informational message appears to the right of the filter, indicating how many nodes are hidden from view.

Filtering is useful if you have many nodes and want to see only the ones that need attention, so you can quickly resolve issues on them.

Monitoring cluster CPU and Memory with MC

On the MC Overview page, the **CPU/Memory** subsection provides a graph-based overview of cluster resources during the last hour, which lets you quickly monitor resource distribution across nodes.

This chart plots average and per-node percentages for both CPU and memory with updates every minute—unless you clear Auto Refresh Charts in the toolbar. You can also filter what the chart displays by clicking components in the legend at the bottom of the subsection to show/hide those components. Yellow data points represent individual nodes in the cluster at that point in time.

Investigating areas of concern

While viewing cluster resources, you might wonder why resources among nodes become skewed. To zoom in, use your mouse to drag around the problem area surrounding the time block of interest.

After you release the mouse, the chart refreshes to display a more detailed view of the selected area. If you hover your cursor over the node that looks like it's consuming the most resources, a dialog box summarizes that node's percent usage.

For more information, click a data point (node) on the graph to open MC's node details page. To return to the previous view, click **Reset zoom**.

- [Monitoring node activity with MC](#)

Monitoring database storage with MC

The Infrastructure page's **Storage View** provides a summary of the amount of data stored in your database, and the persistent location of that data. Use this view to monitor how much of your storage capacity your databases are using.

For a database running in Eon Mode, MC also displays bar charts in the Storage View that illustrate shard subscription status. Use these charts to determine if your current subscription layout is optimal for querying your Eon Mode database. For information about using subscription status charts, see [Monitoring subscription status in Eon Mode](#).

Database Name: IP	Database Size: 0	Database Mode	Storage Type	View
jarjarbinks:10.20.150.24	Load Size	Eon	Communal	Communal/Depot Storage Communal Storage Subscription
test_crash_and_recovery_npj:10.20.150.24 (Data...	N/A	N/A	N/A	N/A
vdb2:10.20.102.83	Load Size	Enterprise	Linux	Vertica Tables Storage
vdb:10.20.102.83 (Database is Down)	N/A	N/A	N/A	N/A

Monitor storage usage

The storage summary table lists all databases currently monitored by MC and information about their storage:

- **Database Size** . Click [Load Size](#) to calculate the total size of the database.
- **Database Mode** . Vertica databases run in Enterprise Mode, or [Eon Mode](#) .
- **Storage Type** . Enterprise Mode databases list the OS of the local nodes where data is stored. Eon Mode databases list the type of communal storage location where it stores its data. Eon Mode currently supports only S3-compatible storage locations.
- **View** . The options displayed in this column depend on the database mode and type of data on the database.
 - **Vertica Tables Storage** : For Enterprise Mode databases only. Click for a dialog listing the node and local directories where Vertica table data is stored.
 - **Communal/Depot Storage** : For Eon Mode databases only. Click for a dialog displaying location paths for your depot and communal storage.
 - **Communal Storage Subscription** : For Eon Mode databases only. Click to view bar charts at the bottom of the Storage View page, illustrating shard subscription status. For more about these charts, [Monitoring subscription status in Eon Mode](#) .
 - **External Tables** : Available when there are [external](#) tables in your database. Click for a dialog displaying details about all external tables. (Also see [Monitoring table utilization and projections with MC](#) .)
 - **HCatalog Details** : Available when your Vertica database has access to Hive tables. (See [Using the HCatalog Connector](#) .) Click for a dialog displaying details about HCatalog schemas. For any HCatalog schema, click View Tables for details about all tables accessible through that schema. (Also see [Monitoring table utilization and projections with MC](#) .)

In front of Eon Mode database names in the list, a plus icon displays. Click the icon to expand more details about the database's depot capacity and usage. The depot is cache-like storage where Eon Mode databases keep local copies of communal storage data for faster query access.

- Click **Percentage Used** to view the [Depot Activity](#) chart for that database.
- Click **View Depot Details by Nodes** to see a dialog displaying location paths and depot usage information.

Monitoring subscription status in Eon Mode

To view subscription charts for any Eon Mode database you monitor, click **View Your Infrastructure** on the MC Home page. Then click the **Storage View** tab.

Click the **Details** action for that database in the storage summary list (highlighted in red in the image below).

Database and Cluster View		Storage View		
Database Name: IP	Database Size: 0	Database Mode	Storage Type	View
jarjarbinks:10.20.150.24	0.3GB	Eon	Communal	Communal/Depot Storage Communal Storage Subscription
test_crash_and_recovery_npj:10.20.150.24 (Data...	N/A	N/A	N/A	N/A

When you click **Details**, two charts become available on the bottom half of the page: The Sharding Subscription chart, and the Node Subscription chart. You can switch between these two charts using the drop down menu to the right of the chart title.

Why monitor shard and node subscriptions?

Shards are segments of the data that is stored persistently in your Eon Mode database's communal storage location, for example Amazon S3 in the cloud or PureStorage if your cluster is on premises. Each node in the database subscribes to a subset of those shards. In this way, the node gets updated on when to populate its depot with new data from communal storage. (See [Namespaces and shards](#).)

For K-safety in an Eon Mode database, shards should have multiple node subscribers to ensure that even if a node goes down or is being used by another query, the data on that shard is still available on other nodes. If a shard has no node subscribers, that could indicate that data loss is occurring.

Subscriptions go through several transitions, which are illustrated by colors in the subscription charts:

- **Pending (Yellow).** The node is ready to subscribe to a certain shard. It cannot yet serve queries because it is not actively subscribed to the shard yet.
- **Passive (Blue/Teal).** The node could potentially serve queries for a shard it is passively subscribed to, but its depot contents for that shard may not yet be up to date, which could negatively impact query performance. The passively subscribed node is waiting for an active node subscriber of the shard to send it the most recent data.
- **Active (Green).** The node is actively subscribed to the shard, can load new data from communal storage, and can serve queries for data in that shard. The actively subscribed node sends data from that shard to other subscribed nodes.
- **Removing (Dark Red/Maroon).** The node is unsubscribing from the shard. It may have the most recent data from that shard, but that state is temporary until data from that shard is cleaned up.
- **Inactive (Red).** The subscribed node is down. It can no longer serve queries for that shard.

Operations such as adding or removing nodes or rebalancing shards can change which nodes subscribe to which shards. Shard subscription changes can prevent object-level restore from backups, though full restore is always possible. If shard subscriptions change, consider making a backup with the new configuration.

Monitor sharding subscription

The Sharding Subscription chart displays how many nodes are subscribed to each shard in your database, and what type of subscription it is.

You can hover over any bar in the chart to see which nodes are subscribed to the shard. Click on a subscription type in the legend to show or hide it in the chart display.

The example below shows the shard subscription status for a running Eon Mode database. The database has three nodes that are up, and one node (Node 4) that has been added to the cluster, but is down.

You can hover over any bar in the chart to see which nodes are subscribed to the shard. In this example, nodes 1 and 3 have active subscriptions to the first shard (green); nodes 1 and 2 to the second shard; and nodes 2 and 3 to the third shard.

The active subscriptions are evenly spread across the shards. This is a k-safe Eon Mode database.

Node 4 was subscribed to two shards; however, because it is down, its subscriptions to the shards are now inactive (red).

Monitor node subscriptions

Use this chart to view how many shards each node in your database is subscribed to, and the state of those subscriptions. The number of shards each node is subscribed to should be about the same to prevent overworking any given node.

Hover over any bar to see the shards it is subscribed to. The color of the bar indicates the state of each subscription. Click on a subscription type in the legend to show or hide it in the chart display.

The example below shows the same database from the Sharding Subscription example above. Nodes 1 through 3 are each actively subscribed to two shards (green). At least two nodes are subscribed to every shard in the database (which you can double check using the Sharding Subscription chart), ensuring that even if one of the nodes is down or being used in a query, another node is still actively subscribed and can access the data of that shard.

Since Node 4 is down, the chart shows that both its shard subscriptions are now inactive.

Monitoring system resources with MC

MC's **Activity** page provides immediate visual insight into potential problem areas in your database's health by giving you graph-based views of query and user activity, hardware and memory impact, table and projection usage, system bottlenecks, and resource pool usage.

Select one of the following charts in the toolbar menu:

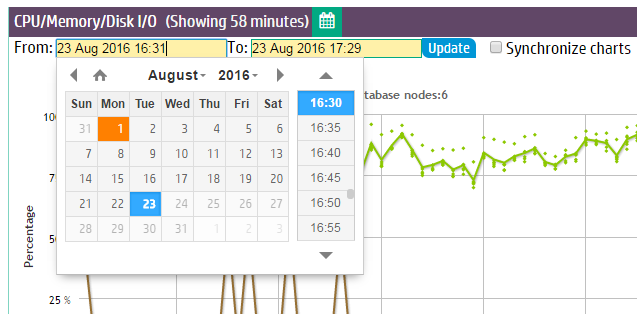

- [Queries](#)
- [Internal Sessions](#)
- [User Sessions](#)
- [Memory Usage](#)
- [System Bottlenecks](#)
- [User Query Phases](#)
- [Monitoring table utilization and projections with MC](#)
- [Query Monitoring](#)
- [Resource Pool Monitoring](#)
- [Monitoring catalog memory with MC](#)

How up to date is the information?

System-level activity charts automatically update every five minutes, unless you clear Auto Refresh in the toolbar. Depending on your system, it could take several moments for the charts to display when you first access the page or change the kind of resource you want to view.

Chart viewing options

You can specify time frames for some charts, which display a calendar icon in their title bars. Click the calendar icon to specify the time frame for that module.

If you have enabled extended monitoring on your database, MC can display longer ranges of data in certain charts. See [Extended monitoring](#). If a chart is using extended monitoring data, the rocket ship icon appears in the title bar:

You can expand some charts to view them in larger windows. Click the expand icon in the title bar to do so:

In this section

- [Monitoring query activity with MC](#)
- [Monitoring internal sessions with MC](#)
- [Monitoring user sessions with MC](#)
- [Monitoring system memory usage with MC](#)
- [Monitoring system bottlenecks with MC](#)
- [Monitoring user query phases with MC](#)
- [Monitoring table utilization and projections with MC](#)
- [Monitoring running queries with MC](#)
- [Monitoring catalog memory with MC](#)

Monitoring query activity with MC

The Queries chart displays information about query concurrency and average resource usage for CPU/memory, network activity, and disk I/O percent based on maximum rated bandwidth.

Hover over a data point for more information about percent usage for each of the resource types.

If you click a data point, MC opens a details page for that point in time, summarizing the number of user queries and system queries. This page can help you identify long-running queries, along with the query type. You can sort table columns and export the report to a file.

Monitoring key events

On the main Queries page, MC reports when a key event occurred, such as a Workload Analyzer or rebalance operation, by posting a **Workload Analyzer** (Workload Analyzer) and/or **RBL** (rebalance) label on the resource section of the chart.

Filtering chart results

The default query concurrency is over the last hour. The chart automatically refreshes every five minutes, unless you clear the Auto Refresh option in the toolbar. You can filter results for 1 hour, 1 day, or up to 1 week, along with corresponding average resource usage. You can also click different resources in the legend to show or hide those resources.

To return to the main Queries page, use the slider bar or click the 1h button.

Viewing more detail

To zoom in for detail, click-drag the mouse around a section or use the sliding selector bar at the bottom of the chart. After the detailed area displays, hover your cursor over a data point to view the resources anchored to that point in time.

For more detail about user or system queries, click a data point on one of the peaks. A **Detail** page opens to provide information about the queries in tabular format, including the query type, session ID, node name, query type, date, time, and the actual query that ran.

The bottom of the page indicates the number of queries it is showing on the current page, with Previous and Next buttons to navigate through the pages. You can sort the columns and export contents of the table to a file.

To return to the main Queries page, click **<database name> Activity** in the navigation bar.

Monitoring internal sessions with MC

The Internal Sessions chart provides information about Vertica system activities, such as Tuple Mover and rebalance cluster operations, along with their corresponding resources, such as CPU/memory, networking, and disk I/O percent used.

Hover your cursor over a bar for more information. A dialog box appears and provides details.

Filtering chart results

You can filter what the chart displays by selecting options for the following components. As you filter, the **Records Requested** number changes:

- **Category:** Filter which internal session types (mergeout, rebalance cluster) appear in the graph. The number in parentheses indicates how many sessions are running on that operation.

- Session duration: Lists time, in milliseconds, for all sessions that appear on the graph. The minimum/maximum values on which you can filter (0 ms to n ms) represent the minimum/maximum elapsed times within all sessions currently displayed on the graph. After you choose a value, the chart refreshes to show only the internal sessions that were greater than or equal to the value you select.
- Records requested: Represents the total combined sessions for the Category and Session Duration filters.

Monitoring user sessions with MC

The User Sessions charts provide information about Vertica user activities for all user connections open to MC.

Choose **User Sessions** from the menu at the top of your database's Activity page to view these charts.

View open sessions

The Open Sessions tab displays a table of currently open sessions for each user. You can close a session or cancel a query on this tab by selecting that option from the **Actions** column.

View all user sessions

The All Sessions tab displays a history of all user sessions in a swim lane chart.

What chart colors mean

Bars outlined with a dotted line are currently running sessions.

Sessions are divided into two colors, yellow and blue.

- Yellow bars represent user (system) sessions. If you click a yellow bar, MC opens a Detail page that shows all queries that ran or are still running within that session.
- Blue bars represent user requests (transactions within the session). If you click a blue bar in the graph, MC opens a Detail page that includes information for that query request only.

When you hover your mouse over a transaction bar, a dialog box provides summary information about that request, such as which user ran the query, how long the transaction took to complete, or whether the transaction is still running.

Filter chart results

Extremely busy systems will show a lot of activity on the interface, perhaps more than you can interpret at a glance. You can filter chart results in several ways:

- **Zoom.** The context chart at the bottom of the page highlights in blue which section of the All Sessions chart you are viewing. Click and drag the blue box left or right to view earlier or later user sessions. Click and drag the edges of the blue box to zoom in or out.
- **Select fewer users.** Click the filter icon () at the top of the page. A menu of a menu of all available users appears below. Deselect users to exclude from the chart.

- **Change the session duration (how long a session took to run).** Click the Filter icon () at the top of the page. The **Filter sessions and queries by duration** field appears below. Enter the minimum session length (in seconds) to display on the chart and click **Update** .

- **Specify a time frame.** Click the Calendar icon () at the top of the page to display the From and To fields. Using the fields, select the time frame to display in the chart and click **Update** .

Monitoring system memory usage with MC

The Memory Usage chart shows how system memory is used on individual nodes over time. Information the chart displays is stored based on [Data collector](#) retention policies, which a superuser can configure. See [Configuring data retention policies](#).

The first time you access the Memory Usage chart, MC displays the first node in the cluster. MC remembers the node you last viewed and displays that node when you access the Activity page again. To choose a different node, select one from the Nodes drop-down list at the bottom of the chart. The chart automatically refreshes every five minutes unless you disable the Auto Refresh option.

Tip

On busy systems, the Node list might cover part of the graph you want to see. You can move the list out of the way by dragging it to another area on the page.

Types of system memory

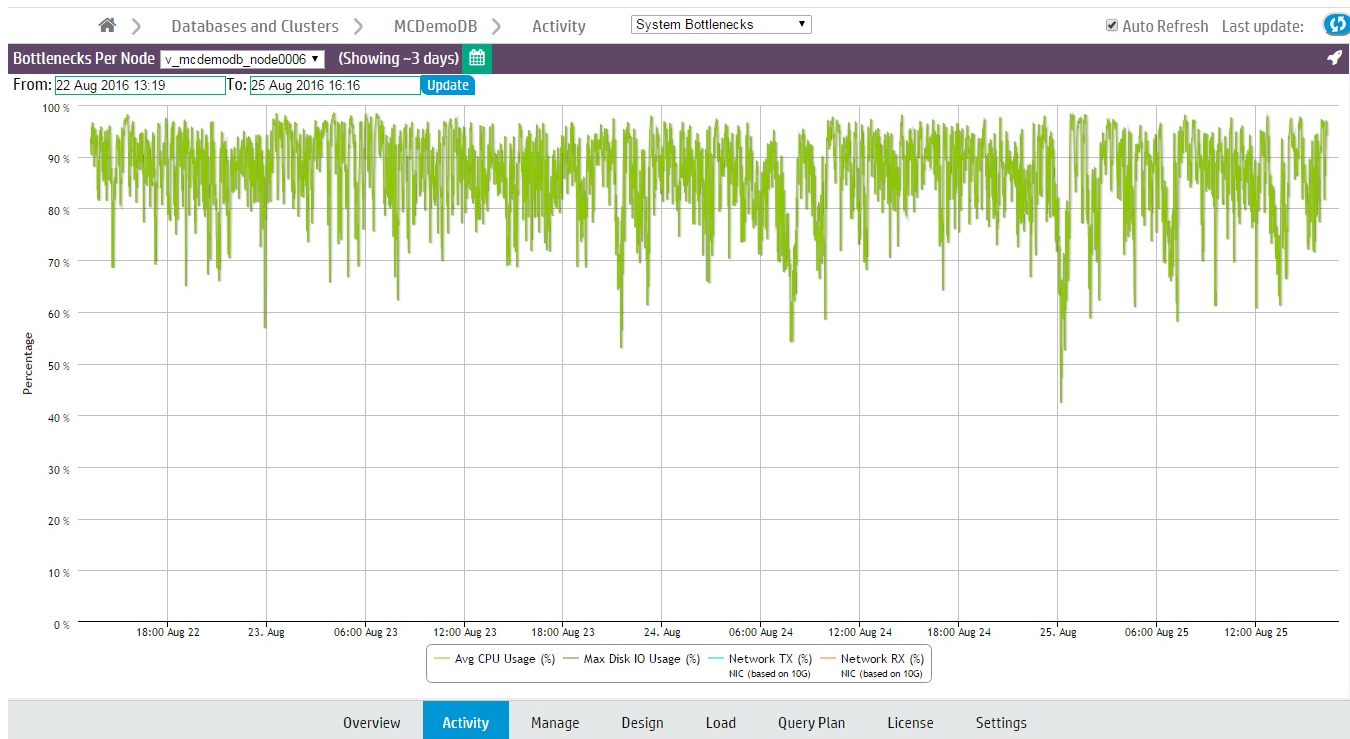

The Memory Usage chart displays a stacking area for the following memory types:

- swap
- free
- fcache (file cache)
- buffer
- other (memory in use by all other processes running on the system besides the main Vertica process, such as the MC process or [agents](#).)
- Vertica
- rcache (Vertica ROS cache)
- catalog

When you hover over a data point, a dialog box displays percentage of memory used during that time period for the selected node.

Monitoring system bottlenecks with MC

The System Bottlenecks chart helps you quickly locate performance bottlenecks on a particular node. The first time you access the Activity page, MC displays the first node in the cluster. To choose a different node, select one from the Nodes drop-down list at the bottom of the chart.

The System Bottlenecks chart reports what MC identifies as the most problematic resource during a given time interval. You can use this chart as a starting point for investigation.

How MC gathers system bottleneck data

Every 15 minutes, MC takes the maximum percent values from various system resources and plots a single line with a data point for the component that used the highest resources at that point in time. When a different component uses the highest resources, MC displays a new data point and changes the line color to make the change in resources obvious. Very busy databases can cause frequent changes in the top resources consumed, so you might notice heavy chart activity.

In the following example, at 08:24 the maximum resources used changed from Disk I/O to CPU. The System Bottlenecks charts denotes this with a change in line color from brown to green.

The components MC reports on

MC reports maximum percent values for the following system components:

- Average percent CPU usage
- Average percent memory usage
- Maximum percent disk I/O usage
- Percent data sent over the network (TX)
- Percent data received over the network (RX)

How MC handles conflicts in resources

If MC encounters two metrics with the same maximum percent value, it displays one at random. If two metrics are very close in value, MC displays the higher of the two.

Monitoring user query phases with MC

The User Query Phases chart provides information about the query execution phases that a query goes through before completion. Viewing this chart helps you identify at a glance queries possibly delayed because of resource contention.

Note

For a list of query phases, see [Query phase duration](#).

Each bar, bound by a gray box, represents an individual query. Within a query, a different color represents each query phase. The chart does not show phases for queries with durations of less than 4 seconds. Blank spaces within a query represent waiting times, as in the image below.

Hover over a phase in the query for information on the phase type and duration.

The chart shows queries run over the last 15 minutes. The chart automatically refreshes every five minutes, unless you clear the Auto Refresh option in the toolbar.

Filtering chart results

You can filter what the chart displays by selecting options for the user running the query, minimum query duration, and minimum phase duration.

Viewing more detail

To zoom in for detail, click-drag the mouse around a section of the chart. Click Reset Zoom, located at the top right corner of the chart, to restore the chart to its original view.

For more detail, click a query bar. The Detail page opens to provide information about the queries in tabular format, including the query type, session ID, node name, query type, date, time, the actual query that ran, and an option to run Explain Plan or profile the query. Click a table column header to sort the queries by that category.

To export the contents of the table to a file, click Export, located at the upper right of the page.

To return to the main Queries page, click Activity in the navigation bar.

Monitoring table utilization and projections with MC

The Table Utilization activity page helps you monitor tables and projections in your database by schema.

Use the [Table Utilization charts](#) for a listing of all the tables in a schema, which you can filter and sort; or view them by size and usage in a treemap visualization. These charts allow you to identify outliers among your tables, such as those that are large or overused.

The [Projections Summary](#), located on the right side of the page, provides an overview of the projections in the schema. You can use this summary to help identify if projections are evenly distributed across nodes.

Visualize tables

MC shows you the public schema by default. To specify which schema to view, choose one from the **Schemas** menu at the top of the activity page. The summary of tables and projections in that schema appear on the page.

MC visualizes your available tables by schema in a [table chart](#) or as a [treemap chart](#). From the **Show As** menu, choose **Table** for a tabular chart or **Map** for a treemap chart. By default, MC displays the Table chart.

Show as:  **Table** |  Map

Depending on the number of tables in the schema, the chart may be crowded. To narrow it down, use the **Show Only** filter at the top of the page to display only the largest 100 tables, smallest 100 tables, or external tables.

View the table chart

The Table chart is a tabular view of the schema's table data. Use the tabular view to filter or sort on any columns, and view the explicit values for row counts and utilization.

The columns display each table's:

- **Table Name** . Click this name to see the [Table Details](#) page.
- **Table Type** : Internal, [Working with external data](#) or [HCatalog](#). (Details such as row count and usage are not available for external and HCatalog types.)
- **Row Count** .
- **Usage in Queries** , by percentage of time the table is queried.
- **Row count and Usage** , visualized as a bar. The length of the bar indicates row count; a darker color indicates higher usage.
- **Table Definition** . The COPY statement table definition, only applicable to external tables.

Hover over any row in the chart to view the table's properties (shown for `inventory_fact` in the screen capture below). Click the table name to view its more in-depth [Table Details](#) page.

Table Name	Table Type	Row Count	Usage in Queries	Row count and Usage	Table Definition

Projections Summary

Schema: public
(Click numbers for details.)

- 46 Total Projections (including 'buddies')
- 46 / 23 Segmented (total/distinct) Projections
- 0 / 0 Unsegmented (total/distinct) Projections
- 4 Projections Showing Distribution Skew >= 1%
- 0 Projections Having >= 304 containers per node
- 0 Unsafe Projections
- 0 Unused Projections
- 0 Not Up To Date Projections

View the treemap chart

In the Treemap visualization, tables are represented by boxes, nested by size and colored by usage. Darker colors indicate higher table usage.

Hover over a table to view more details, or click to view its [Table Details](#) page.

View table details

The Table Details page displays a detailed overview of internal Vertica tables. (This is not available for external and HCatalog tables.) Click a table name on the Table Utilization Activity page to open its Table Details page in a new window.

You can view the following details:

- **Table Properties** . Table properties (such as row count and owner).
- **Projections** . The properties of the table's columns and projections.
- **Storage by Node** . The table's storage utilization per node, in MB.
- **# Deleted Rows by Node** . Vertica [allocates physical storage to deleted rows](#) until they are purged by the Tuple Mover.
- **# Delete Vectors by Node** . Vertica creates small containers called delete vectors when DELETE or UPDATE statements run on a table. A large number of delete vectors can adversely impact performance. (See [Deletion marker mergeout](#).)

Home > Databases and Clusters > VMart activity > Table details Auto Refresh Last update: 1

Table Properties For Public.Customer_dimension

Storage By Node

Deleted Rows By Node

Delete Vectors By Node

Note

Note: If you have deleted table rows recently, Management Console may not display the most recent row count. MC updates the row count when mergeout occurs. See [Mergeout](#).

Projections summary

The Projections Summary is located in a side bar on the right side of the Table Utilization page. It displays the following statistics of all projections in a schema:

- **Total projections** .
- **Segmented projections** , the number of projections segmented across multiple nodes.
- **Unsegmented projections** , the number of projections that are not segmented across multiple nodes.
- **Projections Showing Distribution Skew** , the number of projections unevenly distributed across nodes. Tables with fewer than 1000 rows are not counted. Move the slider to configure filter by distribution skew percentage.
- **Projections Having >= Containers Per Node** . Move the slider to specify the minimum number of containers.
- **Unsafe Projections** , the number of projections with a K-safety less than the database's K-safety.
- **Unused Projections** .
- **Not Up to Date Projections** .

Click a projections number to view a list of the specified projections and their properties. For more about projections, see [Projections](#).

Monitoring running queries with MC

The **Query Monitoring** activity page displays the status of recent and currently running queries, and resource information by user and node. For Eon Mode databases, you can also display the status of queries by subcluster. From this page, you can profile a query or cancel a running query.

Use this page to check the status of your queries, and to quickly cancel running or queued queries to free up system resources. This page can help you identify where resources are being used, and which queries, users, nodes, or subclusters are using the most resources.

The **Query Monitoring** page includes four tables, displayed as tabs:

- Running queries
- Queued queries
- Completed queries
- Failed queries

Home > Databases and Clusters > verticaDB > Activity > Query Monitoring Auto Refresh

Running Queries (2) | Queued Queries (0) | Completed Queries (63) | Failed Queries (0)

Running Queries	Query Label	User	Initiator Node	Transaction ID	Session
Search queries	(All)	(All)	(All)	Transaction Id	Session
select /*+label(myselectquery)*/ count(*) from online_sales.online_sales_fact t1 join online_...	myselectquery	uidbadmin	v_verticadb_node0001	45035996273916614	v_vertic 321
SELECT replace(replace(current_statement, E'\n', ' '), E'\t', ' ') as current_statement , s.trans...		uidbadmin	v_verticadb_node0001	45035996273916652	v_vertic 321

From the **Actions** column you can:

- **Cancel** . Cancel a running or queued query.
- **Close session** . Close a session for a running or queued query.
- **Explain** . Open the **Query Plan** page for any query.
- **Profile** . Profile any query on the **Query Plan** page.

The four bar charts at the bottom of the page display aggregate query usage by node or user. Hover over a bar with your cursor to see its value. When sorted by value, the left-most bar in each chart represents the node or user with the highest value.

The Query Monitoring page refreshes every 20 seconds by default. To change the refresh interval, click the **Page Settings** button in the upper-right corner of the page. A dialog appears. Type the new refresh interval, in milliseconds, in the text box.

Page Settings

Refresh Interval: ms (Update)

Sorting or searching queries by session ID or client label

The Query Monitoring Activity > Running Queries page includes columns that display the **Session ID** and **Client Label** for each query. You can sort the queries by Session ID or Client Label, or use the search field below either column to search for queries with a specific Session ID or Client Label.

Filtering chart results

Use the search field below each column title to narrow down your chart results. (For example, if you enter the text `SELECT product_description` in the **Search Queries** field and select a specific node in the **Initiator Node** column, the chart returns only queries which both contain that text and were initiated on the node you specified.)

Click a column title to sort the order of the queries by that category.

There may be a large number of results for Completed and Failed Queries. Use the **Customize** section at the top of these two tabs to further filter your chart results. For either tab, you can select a custom date and time range for your results.

Customize: Date | |

From: To:

In the Completed Queries tab, click **Data** to enter additional query information to filter based on any of the following fields:

- User
- Request
- Request Duration
- Node
- Request label

Viewing more details

Click a query to view the entire query.

Running Queries

Search queries

SELECT DISTINCT s.product_key, p.product_description FROM store.store_sales_fact s, public.product_dimension p WHERE ... dt

SELECT DISTINCT s.product_key, p.product_description FROM store.store_sales_fact s, public.product_dimension p WHERE s.product_key = p.product_key AND s.product_version = p.product_version AND s.store_key IN (SELECT store_key FROM store.store_dimension WHERE store_state = 'MA') ORDER BY s.product_key;

In the **Failed Queries** chart, click the **plus (+)** icon next to a failed query to see the failure details for each node involved in the query's execution.

To export the data in one of the **Query Monitoring** tables, click the table's tab, then click the **Export** () button in the upper-right corner of the page. The browser downloads the data for that chart in a .dat file. The data exported includes columns that may not be visible in the MC, including the minimum and maximum values for Memory, Thread Count, and Open File Handles.

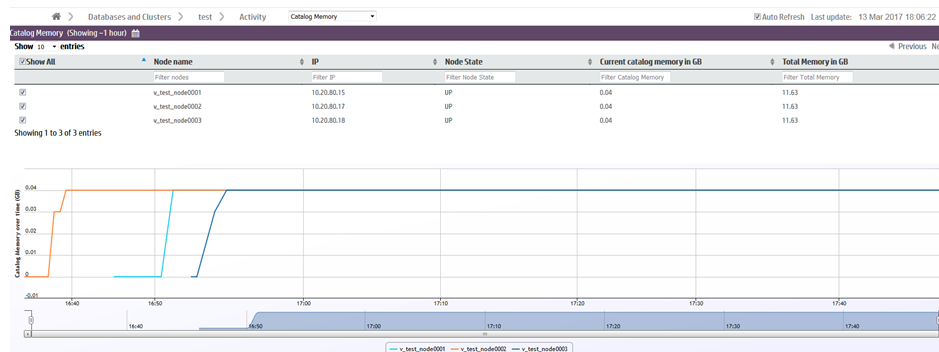

Monitoring catalog memory with MC

The Catalog Memory activity page displays the catalog memory for each node. Use this page to check for sudden changes in catalog memory, or discrepancies in memory distribution across your nodes.

The Catalog Memory page displays:

- **A node details table.** The table lists the details of each node in the database, including their current catalog memory and total memory usage.
- **A catalog memory chart.** A line graph visualization of each node's catalog memory usage over time. Each line represents a node. The color legend at the bottom of the chart indicates the color of each node's line.

In the image below, catalog memory begins at 0GB for all three nodes. Over the next twenty minutes, catalog memory increases to 0.04GB in the second node (orange), then the first node (cyan), and finally in the third node (dark blue). Starting at 16:55, note that the three overlapping node lines appear as one line when all three nodes have the same catalog memory.

Filtering chart results

If you have many nodes in your database, you may want to display only certain nodes in the catalog memory chart. You can remove nodes from the chart in two ways:

- Deselect the node's check box in the node details table.
- Deselect the node in the color legend below the chart.

Viewing more details

Hover over any line in the chart to view the time, node name, and catalog size.

At the bottom of the chart is a summary bar that shows a quick overview of the catalog memory over time. Move the sliders on either side of the chart to zoom in on a specific time frame in the chart. When zoomed in, you can use the scrollbar to move forward or backward in time.

Monitoring resource pools with MC

Management Console allows database administrators to monitor and configure resource pools through the **Activity** and **Configuration** pages. These pages help you manage workloads by providing visual representations of resource usage as well as resource pool configuration options.

Monitoring resource pools charts

You can monitor your resource pools using the **Resource Pools Monitoring** charts, accessible through the Management Console **Activity** page.

Select a resource pool to view using the **Resource Pool** menu, located in the leftmost sidebar. In the sidebar, **Current Usage Activity** displays the pool's real-time statistics.

Monitor the selected resource pool using the following charts, which display the pool's historic data:

- **Resource Usages for Pool:** Shows the historically averaged acquired memory usage by each pool across all nodes. The graph uses two y-axes, one that shows memory size, and a second that shows the total number of running queries. Data is collected every hour. Hover over a data point for a summary of the memory usage at that specific point.
- **Memory Usage in Node:** Shows the historically acquired memory usages by all pools across all nodes. Data is collected every hour. Hover over a data point for a summary of the memory usage at that specific point. Use the title bar dropdown to display the memory usage for a specific node. For Eon mode databases, you can also display the memory usage for a specific [subcluster](#), all subclusters, or nodes not assigned to a subcluster. An Eon mode database has one default subcluster, and may have additional user-defined subclusters.
- **Average Query Execution and Query Time in Pool:** Shows the averaged query queue time plotted against the query execution time by each pool across all nodes. Data is collected every minute. Hover over data to get the average query execution and queue time in the specified pool. Click a data point to show detailed individual query information.
- **Resource Rejections in Pool:** Shows the historical total number of resource requests that were rejected in each pool across all nodes. Data is collected every hour. Click a data point to show rejection details and reasons in a pop-up window.

Configuring resource pools in MC

Database administrators can view information about resource pool parameters and make changes to existing parameters through the Management Console **Configuration** page. You can also create and remove new resource pools, assign resource pool users, and assign cascading pools.

See [Configuring Resource Pools in Management Console](#)

Permissions

Only the database administrator can monitor and configure resource pools in Management Console.

See also

- [Configuring Resource Pools in Management Console](#)

In this section

- [Configuring resource pools with MC](#)

Configuring resource pools with MC

Database administrators can view information about resource pool parameters and make changes to existing parameters in MC through the Resource Pools Configuration page. You can also create and remove new resource pools, assign resource pool users, and assign cascading pools.

Access the Resource Pools Configuration page from the Settings page by selecting the Resource Pools tab.

You can also access the Configuration page from the Resource Pools Monitoring chart, accessible through the Management Console Activity page. Click the tools icon on the top of the leftmost sidebar.

Permissions for monitoring and configuring resource pools

Only the database administrator can monitor and configure resource pools in Management Console.

Modify resource pool parameters

1. On the Resource Pools Configuration page, choose a resource pool from the Resource Pools field. Parameter fields for that resource pool appear.
2. Use the parameter fields to view and modify parameters for the resource pool. Hover your cursor in the parameter field to display information about that parameter.
3. Click **Apply** to save your changes. A success message appears

Modify resource pool users

To add or remove resource pool users:

1. On the Resource Pools Configuration page, select a resource pool from the Resource Pools field.
2. Next to the Pool Users field, click **Add/Remove Pool Users** . The Modify Users for Resource Pool dialog appears.

3. The dialog displays users assigned to the resource pool in the Current Pool Users list. The Other Users list displays all other resource pool users are displayed, along with the pool to which they are currently assigned.
 1. To add users to the resource pool: Select the desired users from Other Users list and click **Add** .
 2. To remove users from the resource pool: Select the users to be removed from the Current Pool Users list and click **Remove** .
4. Click **Apply** to save your changes. A success message appears.

Create and remove resource pools

Database administrators can use MC to create resource pools and assign resource pool users, and remove user-generated resource pools.

To create a resource pool:

1. On the Resource Pools Configuration page, click **Create Pool** . Fields pre-populated with pool parameter default values appear.
2. Enter the new resource pool's parameters in the fields.
3. Click **Create Pool** . A success message appears.

To remove a resource pool:

1. First, remove all users from the resource pool to be deleted. This can be done on the Resource Pool Configuration Page.

2. When all users have been removed from the resource pool, choose the resource pool from the Resource Pools field on the Resource Pool Configuration Page. Parameter fields for that resource pool appear.
3. Click **Remove Pool** . A Confirm dialog appears.
4. Click **OK** in the Confirm dialog. A success message appears.

Monitoring database messages and alerts with MC

Management Console periodically checks system health and performance. When an important event occurs or system performance fluctuates beyond user- or system-defined limits, the Management Console generates a message to alert you about the state of your system. View and manage alerts in the [Message Center](#) .

Message alert notifications

Management Console uses multiple methods to communicate alert notifications to ensure that you are immediately aware of any changes to your database that might require attention. You receive message [notifications by email](#) , and you can view notifications using the following components:

- **Message envelope icon** : This icon is located by the **MC Help** icon, in the top-right of any database-specific page. Select this icon display the **Message Center** quick view, and perform archive, read, and delete message actions. For details about message actions and alerts, see [Message center](#) .
- **Unread Messages (This Week)** widget: On the database **Overview** tab, this widget is located in the quick stats sidebar. It displays unread, high-priority messages. Select the number (including 0) in the widget to go to the **Message Center** .

Pre-configured alerts

Management Console provides pre-configured alerts to provide system monitoring capabilities without manual setup. Each alert has a pre-configured threshold that defines the acceptable performance limit, and MC sends a message notification when the database exceeds that threshold.

By default, pre-configured alerts are not active and require minimal initial setup. For details on how to set pre-configured alert properties, see [Alert configuration](#) .

Node health

Vertica provides the following pre-configured alerts to monitor node health:

- Node CPU
- Node Memory
- Node Disk Usage
- Node Disk I/O
- Node CPU I/O Wait
- Node Reboot Rate
- Node State Change
- Node Catalog Memory

Network health

Vertica provides the Network I/O Error pre-configured alert to monitor network health.

Query

Vertica provides the following pre-configured alerts to monitor queries:

- Queued Query
- NumberFailed
- Query Number
- Spilled Query Number
- Retried Query Number
- Query Running Time

License status

Vertica provides the License Usage pre-configured alert to monitor the status of your Vertica license.

Resource pool

MC can send alerts when an individual resource pool reaches a specified state or usage level. For details about resource pool configuration parameters, see [Built-in resource pools configuration](#) .

Important

Default settings for resource pool alerts apply to the GENERAL pool only.

You can configure the MC to send the following resource pool alerts:

- **Queries Reaching the Max Allowed Execution Time** : Triggers an alert when the specified number of queries reach the RUNTIMECAP execution threshold for the resource pool. You cannot set this alert if the resource pool does not have a RUNTIMECAP threshold set, or if the resource pool has a [secondary resource pool](#).
- **Queries With Resource Rejections** : Triggers an alert when the specified number of queries exceed a specified number of [resource rejections](#) within a set period of time.
- **Minimum Starting Resource Value** : Triggers an alert when the resource pool reaches the minimum amount of resources allocated for the MEMORYSIZE value.

Note

By default, you cannot set MEMORYSIZE for the GENERAL pool. The GENERAL pool must have at least 1GB of memory and it cannot be smaller than 25% of the entire system memory.

- **Maximum Allowed Resource Value** : Triggers an alert when the resource pool reaches the MAXMEMORYSIZE value.
- **Ended Query With Queue Time Exceeding Limit** : Triggers an alert when the specified number of completed queries were queued for a specified length of time within a timeframe.
- **Ended Query With Run Time Exceeding Limit** : Triggers an alert when the specified number of completed queries ran for a specified length of time within a timeframe.

Custom alerts

Create custom alerts to measure system performance metrics that are not monitored by the pre-configured alerts. Create a dynamic SQL query that triggers an alert when it returns any results. You can configure how often an alert is generated, the alert priority, and who receives email alerts. For example, you can create custom alerts that monitor the following:

- Failed logins within a configurable time period
- Idle Vertica user sessions using a configurable time limit
- Database node is DOWN

For details about creating and managing custom alerts, including a tutorial on how to create a custom alert that monitors failed logins, see [Custom alerts](#).

Default notifications

Management Console generates the following messages about the database that appear only in the [Message Center](#):

- Low disk space
- Read-only file system
- Loss of [K-safety](#)
- Current fault tolerance at critical level
- Too many ROS containers
- Change in node state
- Recovery error
- Recovery failure
- Recovery lock error
- Recovery projection retrieval error
- Refresh error
- Refresh lock error
- [Workload analyzer](#) operations
- [Tuple Mover](#) error
- Timer service task error
- [Last Good Epoch](#) (LGE) lag
- License size compliance
- License term compliance

Disk space check and cleanup

When the Management Console checks alerts, it generates a result set and saves it to disk. If you use aggressive alert configurations, the result set might use a large amount of disk space. By default, Vertica reserves 500MB of disk space to save result sets.

Vertica checks the free disk space 2 times each day and cleans alerts that are older than 7 days. If the available disk space is low, custom alerts are disabled. Notifications and emails are generated when an alert is disabled due to insufficient disk space.

The `/opt/console/vconsole/config/console.properties` file contains these settings. Edit the following values to configure the how the MC manages your disk space:

Property	Description
<code>console.diskspace.threshold</code>	The amount of disk space Vertica reserves to save result sets. Default: 500MB
<code>customthreshold.alerts.toKeepInDays</code>	The number of days that alerts are retained on disk. Default: 7

In this section

- [Message center](#)
- [Alert configuration](#)
- [Setting up SMTP for email alerts](#)
- [Custom alerts](#)
- [Exporting MC-managed database messages and logs](#)

Message center

The **Message Center** organizes system performance alerts to help you effectively monitor the state of your database. [Pre-configured](#) and [custom alerts](#) generate messages when the component they measure exceeds the specified threshold.

Access the **Message Center** in the following ways:

- On the MC Home page, select **Message Center** in the **MC Tools** section.
- Select the message envelope icon in the top-right of any database-specific page, then select **Message Center** in the quick view.
- On the database **Overview** tab, select the number (including 0) in the **Unread Messages (This Week)** widget.

Date: Yesterday 0	There are no unread messages for yesterday :)		
Date: This Week 0	There are no unread messages for this week :)		

The Message Center can retrieve up to 10,000 of the most recent messages generated for a database. By default, it lists up to 600 messages generated in the previous week. For details on how to retrieve messages that predate the previous week, see [Date Filtering](#).

Note

To adjust the maximum number of messages listed in the Message Center, edit the `messageCenter.maxEntries` value in the `/opt/vconsole/config/console.properties` file from the command line. For example, the following value increases the number of alerts listed in the Message Center to 5000:

```
messageCenter.maxEntries=5000
```

Filter the messages grid

The Management Console provides options that filter the messages that populate the messages grid by database, keyword, message type, and date. Use one or more of these options to view only the messages that you want to manage.

Database filtering

Select **Showing** to list the databases that are associated with the logged in user account. Choose a specific database to view only messages for that database, or select **(All DBs)** to view and manage messages across all of your databases.

Keyword filtering

Use the search bar at the top-right of the screen to list messages that contain the entered text. For example, if you enter 29, the grid lists any messages that contain those characters within the message title or message details available when you click the plus (+) icon to expand the message row.

Message type filtering

After you select a value for **Showing**, the number of messages for that value are totaled and grouped by type near the top-right corner of the screen, below the search bar. These message types use the [syslog standard](#) to define severity levels. The MC message types are defined as follows:

- **All Messages** : Messages that are not archived or deleted, and are within `messageCenter.maxEntries` for the previous week.
- **High Priority** : Messages that you [assigned a High Priority](#) alert priority on the **Alerts** tab. These messages correspond to syslog levels 0 and 1.
- **Need Attention** : Critical or error messages that indicate that correspond to syslog levels 2 and 3.
- **Informational** : Warning, notice, informational, or debugging messages that correspond to syslog levels 4, 5, 6, and 7.

To populate the grid with only a single message type, select the number or message type description.

Date filtering

Select **Retrieve Older Messages** to enter **From** and **To** dates to list messages that were generated before the previous week. Vertica stores 10,000 of the most recent database messages so that you can retrieve older messages when necessary.

Message groups

The Message Center groups messages and notifications as **Recent Messages**, **Threshold Messages**, and **Archived Messages**. All message groups use the following priority levels and color codes:

- Critical (Red)
- Warning (Orange)
- Notice (Green)
- Info (Blue)

Recent messages and threshold messages

Recent Messages include the most recent messages generated within the previous week within the `messageCenter.maxEntries` value. Threshold messages include messages that are generated when the database exceeds a pre-configured, custom, or default alert threshold.

Recent Messages and Threshold Messages are listed using the message type, database name, a description of the message, and the date and time that the message was generated. Additionally, there are collapsible grid headings that group the alerts by **Today**, **Yesterday**, and **This Week**.

Archived messages

Archived messages are messages that you manually saved for later. When you select the check icon for an individual message or select **Archive All**, MC marks the message as read and archives it. Archived messages do not have the same date or `messageCenter.maxEntries` restrictions as **Recent Messages** or **Threshold Messages**.

The **Archived Messages** tab contains the following tools to refine search result filters:

- Use the **From** and **To** boxes above the grid to define a time frame for the archived message search. To combine multiple time frames, select the **Do not clear existing search results** checkbox.
- Sort or filter messages even further using the **Type**, **Database Name**, **Description**, and **Date** columns.

Message actions

Perform actions on all, multiple, or individual messages. To execute actions on all messages at the same time, use the **Select All** or **Select None** buttons near the top-right of the screen by the search bar.

Each message row has a checkbox so that you can perform actions on one or more messages simultaneously. Select the plus (+) icon to expand the message row and display the following message details:

- Summary
- Host IP
- Time of occurrence
- Number occurrences of this message
- Description

For additional information about each message, query [EVENT_CONFIGURATIONS](#).

When you select the **X** icon or select multiple messages and click the **Delete Msgs** or **Delete all** buttons, the message is permanently deleted.

Alert configuration

Enable and customize settings for pre-configured or custom alerts for each database. For example, you can set the **Threshold Value** for **Node Disk Usage** to a 20% minimum or 80% maximum. If any node exceeds either of those thresholds, the MC generates a message and you receive a notification. Take action on alerts in the [Message center](#).

To access the **Alerts** tab, log in to the Management Console, then select **Go to database > Settings > Alerts**.

Configurable settings

To configure any alert, you must toggle the switch on the left of the row to the on position. **Node State Change** is the only pre-configured alert turned on by default. By default, custom alerts are toggled off.

Pre-configured and custom alerts have the following settings:

- **Query variables** : Custom alerts only. Query variables are the variables that you added when you [created the alert](#). You must provide a value for each variable. The query variable is not validated after you create the alert. If you update the variable to a value that results in an invalid query, the alert is silently disabled during the next execution.
To view the original SQL query, hover the mouse over the alert name to display the alert in a tooltip.
- **Threshold Value** : Pre-configured alerts only. You can add a lower and upper limit on acceptable operating values for the component.
- **Check Interval** : This value determines how often Vertica executes the underlying SQL for the alert.
- **Alert Priority** : You can assign one of the following priority labels to determine how the alert is distributed:
 - **Alert and Critical** : Displays the message using the [message alert notification](#) mechanisms on the **Overview** page and creates a message in the **Message Center**.
 - **Warning** : Creates a message in the [Message center](#).
- **Alert Email Recipients** : Configure email notifications for any alert priority when the alert is triggered. You must have [SMTP configured](#). For details about adding email recipients to alerts, see [Custom alerts](#).
- **Vertical ellipses** : For custom alerts and new resource pool alerts, click the vertical ellipses to delete the alert. You must have [MC ADMIN role](#) privileges to delete an alert.

Configuring resource pool alerts

Resource pool alerts use the same configurable settings as the other alerts, but you can set alerts per resource pool. By default, pre-configured alerts are set for the [GENERAL](#) pool only.

Note

Only users with [MC ADMIN role](#) privileges can add alerts for resource pools other than the GENERAL pool.

1. Log in to the Management Console and select **Databases > Settings > Alerts**.
2. In the top row labeled **Resource Pool**, select the blue box with a plus (+) symbol on the far right of the row. When you hover over the button, the button expands and displays **Add Resource Pool Alert +**.
The **New Resource Pool Alert** window opens.
3. In **Alert Name**, choose the alert that you want to add to a resource pool.
4. In **Resource Pool**, choose the resource pool that you want to add this alert to.
5. When you are finished configuring the remaining settings, select **Create Alert**.

Edit **Check Interval**, **Alert Priority**, and Alert Email Recipients as you would other alerts. For guidance, see [Configurable Settings](#) or [Custom alerts](#).

To delete the alert, select the vertical ellipses at the right of the row, and select **Delete**. You must have [MC ADMIN role](#) privileges to delete an alert.

Setting up SMTP for email alerts

Management Console can generate [email notifications](#) when your database exceeds high-priority alert thresholds. To receive email alerts, you must configure your SMTP settings in MC.

You must be an administrator to provide SMTP settings. To set up MC to send email:

1. Select the **Email Gateway** tab on the MC Settings page.
2. Provide the following information about your SMTP server:
 - **Email Server (Hostname)** : the hostname or IP of the SMTP server
 - **Port** : the port of the SMTP server
 - **Session Type** : the type of connection to use (e.g. SSL)
 - **SMTP Username (optional)** : the username credential for connecting to the server
 - **SMTP Password (optional)** : the password credential for connecting to the server
 - **Sender Address** : The sender address for your server when it sends email alerts
 - **Trust SSL Certificate** : Whether to automatically trust the SMTP server's certificate
3. Click **Test** at the top of the page. MC validates your SMTP settings and sends a test email to the inbox of the email alias you provided.
4. Verify that you successfully received the test email.
5. Click **Apply** at the top-right of the page to save the settings.

After you set up SMTP for email, you can configure MC to send high-priority threshold alerts through email. For details, see [Alert configuration](#) or [Custom alerts](#).

Custom alerts

Create custom events-based alerts to track abnormalities and performance fluctuations for node health, queries, and resource pools using your own database schemas and tables. When the database triggers an active alert, you receive notifications according to the alert priority, and can take action in the [Message center](#).

Creating a custom alert

You must have [MC ADMIN role](#) privileges to create a custom alert.

The following steps create a custom alert named **Failed logins within a X time period** to track the number of failed logins in the previous two hours, per user. This alert might indicate a possible distributed denial-of-service (DDoS) attack, or an application behaving inappropriately. The underlying SQL query uses a variable to create a dynamic threshold value that you can fine-tune after you create the alert.

1. Log in to the Management Console, then select **Go to database > Settings > Alerts** .
2. In the **Custom Alerts** row at the top of the page, click the blue box with a plus (+) symbol on the far right of the row. When you hover over the button, the button expands and displays **Create Custom Alert +** .
The **Create custom alert** window displays.
3. In **Alert Name** , enter **Failed logins within X time period** .
4. In **SQL Query** , enter the following SQL query:

```
SELECT
  login_timestamp,
  user_name,
  node_name,
  client_hostname,
  reason
FROM
  login_failures
WHERE
  reason in ('INVALID USER', 'FAILED', 'INVALID DATABASE')
  AND login_timestamp > sysdate - INTERVAL '{{Time_Interval}}'
```

The AND clause of the preceding query encloses the variable of type String named **Time_Interval** in double curly braces to represent a valid SQL syntax element.

A variable is a dynamic value that is evaluated at runtime that you can configure after you save the alert. You can add up to 6 variables per custom alert. Variable names may consist of a maximum of 14 alpha-numeric characters, including underscores. Verify that the variable uses the correct data type and format. Variables of type String require single quotes around the curly braces.

A SQL query triggers an alert if it returns one or more rows. Use the formatting or full screen buttons above and to the right of the **SQL Query** box as needed.

5. A box displays below the **SQL Query** box containing placeholder text that corresponds to each variable name. To test the alert, enter **2 Hours** in this box.
6. Select **Run Query** . The **Query Results** section displays any rows returned from your query. Alternatively, you might encounter one of the following issues:
 - If you use invalid SQL syntax, you receive an error.
 - If the query returns more than 5 columns or 100 rows, you receive a warning. Because every query result set is saved to disk, it is important to be aware of the size of your result set. For more information, see [Monitoring database messages and alerts with MC](#).

A long-running query runs until it succeeds or returns a Query Error that indicates that there are insufficient resources to continue. To stop a long-running query, select **Cancel Query** .

7. When you are satisfied with the query results, select **Create Alert** .

The **Create custom alert** window closes and the alert you just created is listed in the **Custom Alerts** section on the **Alerts** page. When you point the mouse on the query name, the query is displayed in a tooltip. Under the query name, there are editable boxes that correspond to the variables you added when creating the alert.

8. In the **Time Interval** variable box, enter **2 Hours** .

9. Select a value for **Check Interval** . The default setting is **10 minutes** . This value determines how often the query is executed.

Important

To prevent the scheduled query from impacting system performance, each query has a default runtime threshold of 30 seconds. If the query runtime exceeds this threshold once, the alert is automatically disabled.

To adjust the timeout threshold, edit the `threshold_query.disable_time_out` setting in the `/opt/vconsole/config/console.properties` file.

10. Select a value for **Alert Priority** . By default, the alert is assigned the **Critical** value priority.
11. Optionally, select the **Manage Emails** icon under **Alert Email Recipients** to send an email alert to specific users when the alert is triggered. To register a user to receive email alerts, complete the steps in [Setting up SMTP for email alerts](#) .
12. Complete the following steps in the **Manage Email Recipient** window:
 1. To add an existing user to an alert, click the checkbox beside the existing MC user, or select the box at the top to add all. For non-existing MC users, enter their email address at the bottom of the window.
 2. In **Email Interval** , select how often the email is sent:
 - **Immediately**
 - **One hour**: The hour starts when you make the alert.
 - **One day** : Users receive the alert 24 hours after you create the alert.For example, if you select **One hour** , an email is sent every hour, even if the alert is triggered multiple times within the hour.
 3. Click **Save** .

After you create the alert, toggle it on or off using switch at the far left of the alert row.

Editing a custom alert

You must have [MC ADMIN role](#) privileges to edit a custom alert.

1. Log in to the Management Console, then select **Go to database > Settings > Alerts** .
2. In the **Custom Alerts** row at the top of the page, locate the custom alert that you want to edit.
3. Select the vertical ellipses, and select **Edit** .

The **Edit custom alert** window opens and displays the previously saved values for the custom alert.

4. Edit the alert. You can edit any of the following alert properties:
 - Alert Name
 - SQL Query
 - Any variable values
5. Select **Run Query** . The **Query Results** section displays any rows returned from your query. Alternatively, you might encounter one of the following issues:
 - If you use invalid SQL syntax, you receive an error.
 - If the query returns more than 5 columns or 100 rows, you receive a warning. Because every query result set is saved to disk, it is important to be aware of the size of your result set. For more information, see [Monitoring database messages and alerts with MC](#) .

A long-running query runs until it succeeds or returns a Query Error that indicates that there are insufficient resources to continue. To stop a long-running query, select **Cancel Query** .

6. When you are satisfied with the query results, select **Update Alert** .

Deleting an alert

To delete a custom alert, select the vertical ellipses at the right of the row, and select **Delete** . You must have [MC ADMIN role](#) privileges to delete an alert.

Exporting MC-managed database messages and logs

You can export the contents of database messages, log details, query details, and MC user activity to a file.

Information comes directly from the MC interface. This means that if the last five minutes of `vertica.log` information displays on the interface, you can save that five minutes of data to a file, not the entire log. When you filter messages or logs, MC exports only the filtered results.

Depending on how you set your browser preferences, when you export messages you can view the output immediately or specify a location to save the file. System-generated file names include a timestamp for uniqueness.

The following table shows, by record type, the MC pages that contain content you can export, the name of the system-generated file, and what that file's output contains:

Message type	Where you can export on MC	System-generated filename	Contents of exported file
All db-related message types	Message Center page	<i>vertica-alerts-< timestamp >sv</i>	Exports messages in the Message Center to a .csv file. Message contents are saved under the following headings: <ul style="list-style-type: none"> • Create time • Severity • Database • Summary (of message) • Description (more details)
MC log files	Diagnostics page	<i>mconsole-< timestamp >.log</i>	Exports MC log search results from MC to a ** .log file under the following headings: <ul style="list-style-type: none"> • Time • Type (message severity) • Component (such as TM, Txn, Recover, and so on) • Message
Vertica logs	Manage page Double-click any node to get to the details and then click the VerticaLog tab	<i>vertica-vertica-< db >-< timestamp >.log</i>	Exports vertica log search results from MC to a .log file under the following headings: <ul style="list-style-type: none"> • Time • Type (message severity) • Component (such as TM, Txn, Recover, and so on) • Message
Agent logs	Manage page Click any node to get to the details and then click the AgentTools Log tab.	<i>vertica-agent-< db >-< timestamp >.log</i>	Exports agent log search results from MC to a .log file under the following headings: <ul style="list-style-type: none"> • Time • Type (message severity) • Component (such as TM, Txn, Recover, and so on) • Message
Query details	Activity page Click any query spike in the Queries graph to get to the Detail page.	<i>vertica-querydetails-< db >-< timestamp >.dat</i>	Exports query details for the database between <i>< timestamp ></i> and <i>< timestamp ></i> as a tab-delimited .dat file. Content is saved under the following headings: <ul style="list-style-type: none"> • Query type • Session ID • Node name • Started • Elapsed • User name • Request/Query

MC user activity	Diagnostics page Click the Audit Log task	<code>vertica_audit<timestamp>.csv</code>	Exports MC user-activity results to a <code>.csv</code> file. Content is saved under the following headings: <ul style="list-style-type: none"> • Time • MC User • Resource • Target User • Client IP • Activity
------------------	---	---	--

Monitoring MC user activity using audit log

When an MC user makes changes on the MC interface, whether to an MC-managed database or to the MC itself, their action generates a log entry that records a timestamp, the MC user name, the database and client host (if applicable), and the operation the user performed. You monitor user activity on the **Diagnostics > Audit Log** page.

MC records the following types of user operations:

- User log-on/log-off activities
- Database creation
- Database connection through the console interface
- Start/stop a database
- Remove a database from the console view
- Drop a database
- Database rebalance across the cluster
- License activity views on a database, as well as new license uploads
- [Workload analyzer](#) views on a database
- Database password changes
- Database settings changes (individual settings are tracked in the audit record)
- Syncing the database with the cluster (who clicked Sync on grid view)
- Query detail viewings of a database
- Closing sessions
- Node changes (add, start, stop, replace)
- User management (add, edit, enable, disable, delete)
- LDAP authentication (enable/disable)
- Management Console setting changes (individual settings are tracked in the audit record)
- SSL certificate uploads
- Message deletion and number deleted
- Console restart from the browser interface
- Factory reset from the browser interface
- Upgrade MC from the browser interface

Background cleanup of audit records

An internal MC job starts every day and, if required, clears audit records that exceed a specified timeframe and size. The default is 90 days and 2K in log size. MC clears whichever limit is first reached.

You can adjust the time and size limits by editing the following lines in the `/opt/vconsole/config/console.properties` file:

```
vertica.audit.maxDays=90vertica.audit.maxRecords=2000
```

Filter and export results

You can manipulate the output of the audit log by sorting column headings, scrolling through the log, refining your search to a specific date/time and you can export audit contents to a file.

If you want to export the log, see [Exporting the user audit log](#).

If you perform a factory reset

If you perform a factory reset on MC's Diagnostics page (restore it to its pre-configured state), MC prompts you to export audit records before the reset occurs.

Monitoring external data sources with MC

By default, Management Console monitors a database using information from that database's Data Collector (DC) tables. MC can also monitor DC tables you have copied into Vertica tables, locally or remotely.

MC administrators provide mappings to local schemas or to an external database containing the corresponding DC data. MC can then render its charts and graphs from the new repository instead of from local DC tables. This offers the benefit of loading larger sets of data faster in MC, and retaining historical data long term.

Note

Note: MC also offers [External Monitoring](#), which allows you to set up a Vertica storage database through the MC interface, then use Kafka to stream your data to the storage database. You can use the Data Source mapping process below if you prefer to set up your own alternative data source, or do not plan to use Kafka streaming.

Map an alternative data source

1. On the MC Settings page, navigate to the Data Source tab.
2. Select the database for which you are creating the data source mapping.
3. Choose the database user for which you want to create the mapping.
4. Set Repository Location to Local or Remote.
5. If Remote is selected, provide JDBC connection parameters for the remote database repository. Click **Validate Connection Properties** to confirm a successful connection.
6. Enter the schema mappings for v_internal and v_catalog. MC does not support mapping the v_monitor schema.
7. Input your table mappings in one of the following ways:
 - Click **Auto Discover**. MC retrieves the table mappings based on the database and schema mappings you provided.
 - Click **Manual Entry**. Manually input table mappings.
 - Click **Load Configurations**. If you previously saved a data source configuration for the database in a file, import the file to use that configuration for the currently selected user.
8. Optionally, click **Save Configurations** to export this configuration file. You can create a mapping for another database user with this configuration file later.
9. Click **Apply** to save and apply your configuration settings.

Reports using unmapped schemas

If a report in MC needs to access a locally stored schema or table that is unmapped, MC includes information from the local DC tables for that schema to complete the report.

For remote configurations, if a report depends on an unmapped schema or table, the entire report is run against the local DC tables. If the remote database is down when MC attempts to run a report against it, MC reruns the report against the local database.

When the MC runs a report, it records missing mappings in the MC log under the INFO severity level.

Monitoring depot activity with MC

The [depot](#) is a cache-like component on each node that downloads and stores local copies of table data. Queries that can access the data that they need on the depot, instead of fetching it from communal storage, generally execute much faster. If your database is in Eon Mode, you can use the Depot Activity page to view depot settings and evaluate how efficiently it handles queries and load activity.

To view depot settings and activity, navigate to **Database > Activity > Depot Activity Monitoring**. The Depot Activity page has the following tabs:

- [At A Glance](#)
- [Depot Efficiency](#)
- **[Depot Content](#)**
- [Depot Pinning](#)

In this section

- [Why monitor the depot?](#)
- [Viewing depot activity](#)
- [Viewing depot efficiency](#)
- [Viewing depot content in MC](#)
- [Managing depot pinning policies](#)

Why monitor the depot?

If you run an Eon Mode database on a cloud platform such as AWS, monitoring your depot in MC can help you tune performance and reduce expenses. MC can help address the following questions:

- [How often do queries hit the depot versus the S3 bucket?](#)
- [Is the depot optimally sized?](#)
- [How many API calls are queries executing on the S3 bucket?](#)
- [What is the current depot usage on each node?](#)
- [Are projections and partitions tuned for best query performance?](#)

To access depot monitoring capabilities: from the MC home page, navigate to **Database > Activity > Depot Activity Monitoring**. See [Monitoring depot activity with MC](#).

How often do queries hit the depot versus the S3 bucket?

Queries run faster when they access node-based depot data rather than fetch it from communal storage. For details, see [Query Depot Hits and Misses](#)

Is the depot optimally sized?

To optimize your queries for speed, you might want to [resize the depot](#) to fit your query workload. This ensures that queries do not need to spend extra time fetching data from the communal repository on S3. The Eon meta-function [ALTER_LOCATION_SIZE](#) lets you change depot size on one node, all nodes in a subcluster, or all nodes in the database. The following statement resizes all depots in the database to 80MB:

```
=> SELECT alter_location_size('depot', ',','80%');
alter_location_size
-----
depotSize changed.
(1 row)
```

How many API calls on the SP3 bucket are related to queries?

On the Depot Activity Monitoring screen, in the Communal Storage Access Calls chart, MC displays how many of each type of API call your queries executed in a given timespan. To see details on which queries were running, click on any point on the chart.

What is the current depot usage on each node?

The Depot Content tab of the Depot Activity Monitoring page provides detailed information about how each table is using the depot space on the cluster nodes.

Tables, projections, partitions in Depot

 1 of 1 items

Are projections and partitions tuned for best query performance?

On the Depot Content tab, when you select a row, you are selecting the table depot content on a node. MC loads the details for that table for that node in the bottom section of the page, to show depot content for the selected table, broken down by either projections or partitions on a given node.

Viewing depot activity

The At A Glance screen provides a high level view of depot activity. The screen is divided into several sections:

- [Current Depot Usage](#) summarizes depot attributes and usage statistics.
- [Depot Configuration](#) shows how the depot is configured.
- [User Queries Depot Hits and Misses](#) shows how queries have interacted with the depot over time.
- [Communal Storage Access Calls](#) shows frequency of calls to communal storage.

The screenshot displays the 'At A Glance' interface with the following sections:

- Current Depot Usage:**
 - Overall:**
 - Depot Capacity: 8 TB
 - Depot in Use: 3 KB (0%)
 - Database Size: [Calculate](#)
 - [View More on Database Storage](#)
 - Usage by Node:** [View Details](#)
 - ...node0001: 1 KB (0%)
 - ...node0002: 1 KB (0%)
 - ...node0003: 1 KB (0%)
 - ...node0004: 0 Bytes (0%)
- Depot Configuration:**
 - Participating Nodes: all
 - Max Depot Limit: 2 TB
 - Depot for Writes: enabled
 - Depot for Reads: enabled
 - Depot Operations For Query: ALL
 - [View documentation on Depot configuration](#)
 - Note: retention policies of the [following DC tables](#) affect how much data is available to be displayed.
- User Queries Depot Hits And Misses (Showing ~23 hours):** A line chart showing 'Queries' on the y-axis (0 to 2) and time on the x-axis (15:45 to 16:00). Zoom options: 10m, 1h, All. A legend indicates 'Only from Communal'.
- Communal Storage Access Calls (Showing ~23 hours):** A line chart showing 'Count' on the y-axis and time on the x-axis (15:45 to 16:00). Zoom options: 10m, 1h, All. A legend indicates 'Data Reads (GET)'.

Navigation tabs at the bottom: Overview, **Activity**, Manage, Design, Load.

Current depot usage

Displays a summary of depot attributes and usage statistics:

Overall

- **Depot Capacity:** Total depot capacity for all nodes in the database, added together.
- **Depot in Use:** Total depot space currently in use, on all nodes in the database added together.
- **Database Size:** Select **Calculate** to show the total size of the database, in GB.
- **View More on Database Storage:** Click to see the Storage View tab, with details on the storage for this database.

Usage by node

- Lists the number of bytes in the depot and percentage used, for each node in the database.
- **View More:** Click to display depot usage for individual nodes.

Depot configuration

Provides information about how the depot is configured:

- **Participating Nodes:** Number of nodes covered by these statistics.
- **Max Depot Limit:** Total amount of depot space on all participating nodes.
- **Depot for Writes:** Specifies whether the depot is Enabled or Disabled for write operations.
- **Depot for Reads:** Specifies whether the depot is Enabled or Disabled for read operations.
- **Depot Operations for Query:** Displays how system parameter DepotOperationsForQuery is set. This parameter specifies behavior when the depot does not contain queried file data, one of the following:
 - **ALL** (default): Fetch file data from communal storage, if necessary displace existing files by evicting them from the depot.
 - **FETCHES** : Fetch file data from communal storage only if space is available; otherwise, read the queried data directly from communal storage.
 - **NONE** : Do not fetch file data to the depot, read the queried data directly from communal storage.
- A link for querying internal DC tables, to obtain retention limits on depot activity such as Depot Reads.

User queries depot hits and misses

For optimal performance, the majority of queries should access data that is locally stored on the depot. To maximize depot access, make sure that your depot is large enough to accommodate frequently accessed data. Otherwise, Vertica must access communal storage more often to retrieve required data, which can significantly affect query performance.

User Queries Depot Hits and Misses helps you evaluate how queries have interacted with the depot over time.

- Color-coded graph lines show how many queries were accessing the depot or communal storage, or both, at any given time.
- The left y-axis indicates the number of queries.

Depot fetches and evictions

When a query fetches data from communal storage to a depot that lacks enough space for the new data, Vertica attempts to evict older data. The User Queries Depot Hits and Misses chart can help you monitor churn—that is, how many files are evicted from the depot, and how often:

- Colored bars show the moments of depot fetches and evictions, as measured in megabytes.
- The right y-axis shows how much data was fetched or evicted.

If you observe that queries are consistently slower due to accessing communal storage, and notice the depot keeps experiencing frequent churn, it's likely that you need to [increase depot size](#).

Depot query details

- Hover over a point on the query line to see details about the number of queries that ran.
- Hover over a Fetches or Evictions bar graph to see details about the number of bytes fetched or evicted.
- Click the line or bar to view the Query Details page, which provides information about every query that ran in the selected timespan.

The following Bytes example shows a depot size sufficient to run all queries in the depot:

The next example shows what happens when the depot is too small for ongoing query activity, so a number of queries are forced to fetch their data from communal storage.

If you click on any point on the line, MC opens a Query Detail window that shows:

- All queries represented by that point
- Details for each query

Communal storage access calls

Shows how many communal storage access calls (for example, AWS S3 API calls) of each type your database has executed over a given time span, one of the following:

- Data Reads (GET)
- Data Writes (PUT)
- Metadata Reads (LIST)
- Metadata Writes (POST, DELETE, COPY)

Hover over any point on the Communal Storage Access Calls chart, to view a summary of data about that point. For example, if your cluster is on AWS, the summary lists how many of each AWS S3 API call type were executed in the selected timespan.

Click on any point on the bar graph to view details on:

- All queries that ran during the selected timespan. These queries executed the API calls listed for that timespan on the Communal Storage Access Calls chart.
- Details on each query.

For example:

Vertica Management Console uidbadmin Log out 3.00 ?

Viewing depot efficiency

The Depot Efficiency tab provides several graphics that can help users quickly determine whether the depot is properly tuned.

- [File reads by location](#)
- [Top 10 re-fetches in depot](#)
- [Depot pinning](#)
- [Number of tables in depot by age](#)
- [Number of tables in depot by access count](#)
- [Number of tables in depot by size](#)

File reads by location

Shows the percentage of reads from depot and communal storage over the specified time span. In general, you want the majority of queries and other read operations to obtain their data from the depot rather than communal storage, as verified by the chart below. If communal storage shows a large percentage of file reads, it's likely that you need to increase the depot size.

**Reads from
Communal: 6%**

Majority of reads from Depot is an indication of repeated reads

Top 10 re-fetches in depot

Vertica evicts data from the depot as needed to provide room for new data, and expedite request processing. Depot fetches and evictions are expected in a busy database. However, you generally want to avoid repeated evictions and fetches of the same table data. If this happens, consider increasing the depot size, or [pinning](#) the table or frequently accessed partitions to the depot.

Top 10 Re-Fetches Into Depot (SQL)

15%

Consider pinning tables with high re

Depot pinning

It's often advisable to pin a table or table partitions whose data is frequently queried. Doing so reduces their exposure to eviction from the depot. However, you should also be careful not to use up too much depot storage with pinned data. If too much depot space is claimed by pinned objects (as shown below), the depot might be unable to handle load operations on unpinned objects.

Depot Pinning

Depot capacity: 15

By byte

Not Pinned: 12% (145 MB)

Number of tables in depot by age

Tables should typically reside in the depot for as long as their data are required. A short average lifespan of table residency might indicate frequent depot eviction, which can adversely impact overall performance. If this happens, consider increasing the depot size, or [pinning](#) frequently accessed table data.

Number Of Tables In Depot By Age

Large count of tables staying in Depot for long time. This database was experiencing high churn. This database was

Number of tables in depot by access count

In general, the depot should largely be populated by tables that are frequently accessed, both pinned and unpinned.

Viewing depot content in MC

You can view in detail how the nodes in your Eon database are using the depot:

- Display a list of tables with the largest amount of data in the depot.
- Use the filter fields to list the tables most frequently or most recently accessed in the depot.
- Display details about how frequently the projections and partitions for a specific table access the depot, and the last time the depot was accessed.

The **Depot Activity Monitoring > Depot Content** tab opens showing a default list of the top 25 tables in the database, as ranked by each table's total bytes in the depot. The list shows all the nodes for each of those top tables. The nodes are sorted solely based on most bytes in depot, so the nodes for a given table do not necessarily appear together.

Filter the list

You can use the filter fields above the table to focus the list more narrowly. The filters let you select:

- The number of top tables
- Whether the tables are selected by most bytes in depot, the highest number of times their depot was accessed, or the most recent last access time
- Tables in all schemas, or only in a specific schema
- All tables, or only a specific table
- All nodes, or only a specific node

In the Schema, Table, and Node filter fields, you can enter a text string to select all items whose names include that text string.

Select a node to see the breakdown of depot data in projections and partitions

Select a row in the top table. MC then loads the details to show how that table's depot content is distributed across the projections and the partitions for that table, that are on that node. The Projection and Partition panes show these details for the selected node:

- **Projection:** Number of bytes of data for the selected table that each projection has in the depot on the selected node.
- **Partition:** If the table is partitioned, this pane shows the number of bytes of data for the selected table that each partition has in the depot on the selected node.

For each projection and each partition, MC also displays the total number of times, that the projection or partition has accessed the depot on that node, and the last access time.

For more information about projections, see [Projections](#).

For more information about partitions, see [Partitioning tables](#).

Steps to monitor depot content

1. From the MC home page, open a database, select the **Activity** tab from the bottom menu, select **Depot Activity Monitoring** in the top selection box, and select the **Depot Content** tab. MC displays the top N tables (25 by default), ranked by the number of bytes of data each table has in the depot on all its nodes.

Managing depot pinning policies

Vertica [evicts](#) data from depots as needed to provide room for new data, and expedite request processing. You can pin database objects to reduce the risk of depot eviction. Three object types can be pinned: tables, projections, and table partitions.

The Depot Pinning tab lets you perform the following tasks:

- [List and modify current pinning policies.](#)
- [Create and remove pinning policies.](#)
- [View tables that are frequently fetched from communal storage.](#)

For details on pinning policies, see [Managing depot caching](#).

Listing pinning policies

To list existing depot pinning policies:

1. Select Display Existing Pinning Policies.

2. Click Search. Vertica lists all tables that are currently pinned to the depot, under Existing Pinning Policies:

Vertica Management Console

Databases

At a Glance

Depot Efficiency

Depot Pinning

Use the following selection to view details

Display Existing Pinning Policies

Top Refetched Table(s)

Existing Pinning Policies Bulk

Existing Filtering Policies BULK

Schema	Table
<input type="text"/>	<input type="text"/>
CLICKSTREAM	Customer_Dimension
CLICKSTREAM	Session_Dimension
public	store_orders

3. If desired, filter and sort the list of policies by setting the following fields:

Filter on:

- Schema: Full or partial name of the desired schema
- Table: Full or partial name of the desired table
- Policy Type: Table or Partition
- Policy Scope: Database Level or subcluster name
- Partitioned Table: Y (yes) or N (no)

Sort on (in ascending/descending order):

- Size in Depot: Absolute size (in MB) of cached data -% of Depot: Percentage of depot storage used by the cached data
- Total Access Count: Number of times that cached data from this table has been queried or otherwise accessed
- Last Access Time: Last time cached data of this table or partition was queried or otherwise accessed

Removing existing policies

You can also use the result set under Existing Pinning Policies to remove one or more policies.

To remove one or more table policies:

- From the policy list, select the check boxes of policies to remove.

Note

Policy Type of all selected policies must be set to Table.

- Click Bulk Remove Table Policies.

To remove a table's partition policies:

1. On the policy to remove, click Modify Policy.
2. In the Modify Pinning Policy dialog, perform one of the following actions:
 - Click Remove Policy on the desired policy.
 - Select the check boxes of one or more policies, then click Remove Selected Policies.
3. Click Close.

Creating pinning policies

You can create a policy that pins table data to a subcluster depot or to all database depots. You can specify the following policy types:

- Table: Pins all table data
- Partition: Pins the specified range of partition keys.

Find candidates for pinning

1. Select Create or Modify Pinning Policies.
2. Optionally filter the search by specifying a schema and the full or (for wildcard searches) partial name of a table.
3. Click Search.

Tip

To further refine and sort the result set, [set one or more of the search fields above the table list](#).

You can use the filtered data to determine which tables or partitions are good candidates for depot pinning. For example, a high total access count relative to other tables (Total Access Count) might argue in favor of pinning. This can be evaluated against data storage requirements (% of Depot) and age of the cached data. For example, if pinned objects claim too much storage, a depot might be required to:

- Route large load operations directly to communal storage for processing.
- Increase frequency of evictions.
- Increase frequency of fetches from communal storage to handle queries on non-pinned objects.

All these cases can adversely affect overall database [performance](#).

Tip

To minimize contention over depot usage, consider the following guidelines:

- Pin only those objects that are most active in DML operations and queries.
- Minimize the size of pinned data by setting policies at the smallest effective level—for example, pin only the data of a table's [active partition](#).

For details on how Vertica handles depot storage and turnover, see [Managing depot caching](#).

Create a table or partition pinning policy

To create a pinning policy for a single table or table partition:

1. Under the Create or Modify Pinning Policies list , find the table to pin.
2. Click Create Policy. The Create a Pinning Policy dialog opens.
3. Select the desired policy scope, one of the following:
 - Database
 - An available subcluster
4. Select the desired policy type: [Table Policy](#) or [Partition Policy](#).

Table Policy

Click Create:

Create a Pinning Policy:

Policy Scope

- Database Level
- default_subcluster

Policy Type

- Table Policy

○ Partition Policy

Create

Depot Policies for public

✓	Schema	▼	Table
	<input type="text"/>		<input type="text"/>

Partition Policy (available only if the table is partitioned)

- Enter the minimum and maximum partition keys.

Note

The MC shows a sample range of valid keys for this partition.

For example:

Create a Pinning Policy:

Policy Scope ?

- Database Level
- default_subcluster

Policy Type ?

- Table Policy
- Partition Policy Between

Sample partition input values: 2

Create

- Click Create.

Vertica displays the new pinning policy:

Depot Pinning

Use the following selection to view details

- Display Existing Pinning Policies
- Create or Modify pinning Policies
- Top Refetched Table(s)

Create or Modify Pinning policy

<input type="checkbox"/>	Schema <input type="checkbox"/>	Table
<input type="checkbox"/>	<input type="text"/>	<input type="text"/>
<input checked="" type="checkbox"/>	public	store_orders

- Optionally, add more partition-level policies on the same table by setting new partition keys.
5. When finished, click Close.

If partition pinning policies on the same table specify overlapping key ranges, Vertica collates the partition ranges. For example, if you create two partition pinning policies with key ranges of 1-3 and 2-4, Vertica creates a single policy with a key range of 1-4.

Create pinning policies on multiple tables

To create a pinning policy on multiple tables:

1. On Create or Modify Pinning Policies, select the check boxes of the tables to pin.

Note

All checked tables must be unassigned to a pinning policy, as indicated by their Create Policy link.

2. Click Bulk Create Table Policies. The Bulk Create Table Policies dialog opens.
3. Select the desired policy scope, one of the following:
 - Database
 - subcluster (choose the desired subcluster)
4. Click Create, then click Close.

Removing a pinning policy

To remove an existing pinning policy:

1. On Create or Modify Pinning Policies, find the table with the policy to remove.
2. Click Modify Policy.
3. In the Modify Pinning Policy dialog, perform one of the following actions:
 - Click Remove Policy on the policy to remove.
 - Select the check boxes of one or more policies, then click Remove Selected Policies.
4. Click Close.

Remove pinning policies from multiple tables

To bulk-remove pinning policies from one or more tables:

1. On Create or Modify Pinning Policies, select the target table check boxes.

Note

All checked tables must comply with the following requirements:

- They must be assigned to a pinning policy as indicated by their Modify Policy link.
- Their pinning policy type must be set to Table.

2. Click Bulk Remove Table Policies. The Bulk Remove Table Policies dialog opens.
3. Click Remove, then click Close.

Viewing frequently fetched tables

You can query the depot for tables that are most frequently fetched from communal storage. This can help you quickly identify potential candidates for depot pinning:

1. Select Top *num* Refetched Tables(s) from Depot.
2. Specify the maximum number of results to return (by default 10), and the range of dates to query.

Tip

To further refine and sort the result set, [set one or more of the search fields above the table list](#).

From the list, you can perform the following tasks:

- Create or remove pinning policies on individual tables and partitions by clicking on the desired action— [Create Policy](#) or [Modify Policy](#) .
- Select multiple tables and then remove their pinning policies. See [Remove Pinning Policies from Multiple Tables](#) .

Monitoring depot storage with MC

To display detailed storage monitoring information for your Eon database:

1. From the MC home page, select **View Your Infrastructure**.
2. On the Infrastructure page, select the **Storage View** tab. MC displays the **Storage View** screen, with details about the database storage and links to further detail screens:

3. To see the loaded size of the database, click **Load Size**.
4. To see communal storage details for the database, such as its location and size, and the IP addresses of the nodes, click **Communal/Depot Storage**.

Node IP	Location Path(s)
10.20.150.24	• /scratch_b/qa/jarjardepot/jarjarbinks/v_jarjarbinks_node0001_depot
10.20.150.25	• /scratch_b/qa/jarjardepot/jarjarbinks/v_jarjarbinks_node0002_depot
10.20.150.26	• /scratch_b/qa/jarjardepot/jarjarbinks/v_jarjarbinks_node0003_depot
10.20.150.27	• /scratch_b/qa/jarjardepot/jarjarbinks/v_jarjarbinks_node0004_depot

5. To view the shard subscriptions for your Eon nodes, click **Communal Storage Subscription** . MC displays the shard type, how many nodes are subscribed to each shard, and the status of each shard subscription (Active, Inactive, Passive, Pending, Removing).

Database Name	Database Size	Database Mode	Storage Type	View
jarjarbinks: 10.20.150.24	7.79 TB	Eon	Communal	Communal/Depot Storage Communal Storage Subscription
test_crash_and_recovery_npj: 10.20.150.24 (Data...)	N/A	N/A	N/A	N/A
vdb2: 10.20.102.83	N/A	Enterprise	Linux	Vertica Tables Storage
vdb: 10.20.102.83 (Database is Down)	N/A	N/A	N/A	N/A

There are two views:

- **Sharding Subscription** displays how many nodes store each shard.
- **Node Subscription** displays how many shards are on each node.

Hover over a bar to display the details.

6. To display the depot details for all nodes in the database, click **View Depot Details by Nodes** . MC lists the nodes by node name, and for each node shows the number of bytes the node has in its depot, the total capacity of the depot, the percent used, and the path to the node's depot.

Depot Location Details				
Depot Details:				
Node Name	In Use	Depot Capacity	% Used	Path
v_verticadb_node0001	82.98 MB	83.89 MB	98.9%	/vertica/data/VerticaDB/v_verticadb_node0001_depot
v_verticadb_node0002	81.28 MB	83.89 MB	96.9%	/vertica/data/VerticaDB/v_verticadb_node0002_depot

[Monitoring depot activity with MC](#)

Extended monitoring

Enabling extended monitoring allows you to monitor a longer range of data through MC. This can offer insight into long-term trends in your database's health. MC can also continue to display your monitored database's dashboard while it is down.

Extended monitoring uses Kafka to stream monitoring data from your monitored databases to a single MC storage database. MC can query the storage database instead of your monitored database to render some of its charts, reducing impact on your monitored database's performance.

How extended monitoring works

By default, MC monitors your database by querying it directly for monitoring data about system activities, performance, and resource utilization. Typically, the [Data collector](#) stores all monitoring data in data collector (DC) tables. However, DC tables have limited retention periods. See [Data Collector utility](#).

Extended monitoring stores your database's monitoring data in a dedicated storage database. Vertica streams data from your database's DC tables through Kafka servers to the storage database. To use extended monitoring, you must have access to a running Kafka server. For more how Vertica integrates with Kafka, see [Apache Kafka integration](#).

After you set up and enable extended monitoring for a monitored database, MC renders several of your database's charts and graphs by querying the MC storage database instead of directly querying the database you are monitoring.

You can enable extended monitoring for any, or all, of your monitored databases. The MC storage database provides a single repository for monitoring data from every database that uses enabled extended monitoring.

In the following example, Kafka streams system data from two monitored databases to the storage database. MC uses the storage database to render individual dashboards for each monitored database. Be aware that MC always creates a dashboard that monitors the MC storage database.

Use extended monitoring

Important

Important: To use extended monitoring, OpenText recommends installing Management Console on a host without any other Vertica databases.

When a database has extended monitoring enabled, the MC charts that use the feature display a rocket ship icon in the corner. You can use these charts to access longer-term data about your database's health or performance.

To view historical information in these charts, click the calendar icon to specify the timeframe to display. For example, if your database has been down for several hours, your charts do not display recent activity in your database. You could use the timeframe filter in the System Bottlenecks chart to see unusual resource usage occurred in your database in the hour it went down.

You can view a history of the Kafka streaming jobs loading data into the storage database. MC displays these jobs on the Load tab of your storage database's dashboard. See [Viewing load history](#).

Set up extended monitoring

To set up extended monitoring, see [Managing the storage database](#) and [Managing extended monitoring on a database](#).

See also

- [Managing the storage database](#)
- [Managing extended monitoring on a database](#)
- [Viewing load history](#)
- [Apache Kafka integration](#)
- [Data Collector utility](#)

In this section

- [Managing the storage database](#)
- [Managing extended monitoring on a database](#)
- [Managing streaming services for extended monitoring](#)

Managing the storage database

Extended Monitoring stores your Vertica database's monitoring data in a dedicated MC storage database.

To use Extended Monitoring, you must first set up the storage database and configure it for Kafka streaming. Then, turn on Extended Monitoring for any or all monitored databases.

MC automatically configures a schema for the storage database, named dcschema, which is synced with DC tables on your monitored databases.

Caution

Do not alter dcschema after MC has configured it. Altering it could cause the storage database to lose data or supply incorrect monitoring information to MC.

MC preparation

First verify that MC is not installed on the same host as a Vertica database. When Extended Monitoring is enabled, MC sharing a host with a production database can affect performance.

You must also increase the allocation of memory for the MC application server, as described in the next section. Tune the memory allocation options based on:

- The demands of your database.
- The amount of monitoring data you plan to view in MC charts at the same time.

For example, MC requires more memory to display a week of data in a chart.

Modify memory allocation

To modify memory allocation:

1. In Management Console, select the **Configuration** tab on the MC Settings page.
2. Modify the following fields under **Application Server JVM Settings** to increase the allocation of memory for the JVM:
 - **Initial Heap Size:** For Extended Monitoring, a minimum value of 2 GB is recommended. (The default value is 1 GB.)
 - **Maximum Heap Size:** For Extended Monitoring, a minimum value of 4 GB is recommended. (The default value is 2 GB.)
3. Click **Apply** at the top right of the page. A prompt appears to restart MC.
4. Click **OK** to restart MC and save your changes.

Storage database requirements

To set up storage for Extended Monitoring, your system must meet the following prerequisites:

- An available host, or available database whose Vertica version is the same version or a higher version of the database you plan to monitor.
- Configured MC for Extended Monitoring (See [Prepare MC to Use Extended Monitoring](#).)
- Access to a deployed Kafka server (For details on installing Kafka, see the [Apache Kafka site](#).)

Set up the storage database

To configure the storage database for Extended Monitoring, on the MC Settings page, select the MC Storage DB Setup tab. Modify the settings in each of the three areas:

- 1) Kafka Broker>

Enter the host name or IP addresses and ports for one or more of your deployed Kafka servers.

2) MC external storage database

Designate the storage database. You can create a new database or use an existing database.

- **Create a new database:** To create a new single node cluster on an available host using a Community Edition license of Vertica, choose this option. Doing so does not affect your normal Vertica license usage.
- **Use an existing database known to MC:** To designate a database you have already imported to MC, choose this option. If the schema 'dcschema' exists in the database, a dialog appears. Depending on your system needs, do one of the following:
 - To keep the existing schema's data, click **Append** . For example, if you have already used this database for Extended Monitoring storage and are reimporting it, you can use this option to retain its historical data for continued use.
 - To clear the existing schema from the database and create a fresh version of dcschema configured for Extended Monitoring storage, click **Remove** .

At the **Database name** prompt:

1. Select the database you want to use from the drop-down list.
2. To use that database for Extended Monitoring, click **Prepare MC Storage database** .

Advanced Streaming Options:

To change the value of the Scheduler Frame Duration, click **Advanced Streaming Options** . Management Console displays the **Streaming Options** window, which allows you to modify the Scheduler Frame Duration default that Management Console uses for Extended Monitoring..

The **Scheduler Frame Duration** is the amount of time given to the Kafka scheduler for each individual frame to process and run the COPY statements, after which [KafkaSource](#) terminates the COPY statements. Vertica must have enough time to complete COPY tasks within this duration.

If the frame duration is too small, you would see data loss, as the scheduler does not have sufficient time to process all the data. You may see errors or messages on Management Console's Load page for microbatches that are not able to process the data.

On the contrary, if the frame duration is too large, the scheduler will have too much time to process the incoming data and after it has finished processing the data, it might wait for the frame duration to expire. In this case, you may see some latency in the data getting processed. In addition, the charts in Management Console may not show the data in real time and may show some latency.

You can approximate the average available time per COPY using the following equation:

$$TimePerCopy=(FrameDuration \text{ Parallelism})/Microbatches^*$$

This equation provides only a rough estimate. There are many factors that impact the amount of time that each COPY statement needs to run.

Vertica requires at least 100 milliseconds per COPY to function.

Note

The **Advanced Scheduler options** button is enabled when the Streaming is turned off. If Kafka Streaming is enabled, the **Advanced Scheduler options** button is disabled.

3) enable extended monitoring

Click **Select database(s) for extended monitoring** .

Note

For more information, see [Managing extended monitoring on a database](#) .

Restart the storage database

If you stop the storage database while streaming is enabled, streaming to the storage database stops automatically. You must re-enable streaming on the MC Storage DB Setup tab after you restart the storage database.

If streaming to the MC storage database is disabled while Extended Monitoring on your database is on, the Kafka retention policy determines how long streaming can remain disabled without data loss. See [Managing streaming services for extended monitoring](#) .

Discontinue the storage database

1. Select the Extended Monitoring tab in MC Settings.
2. Set Extended Monitoring for all databases to **OFF** .

3. Select the MC Storage DB Setup tab in MC Settings.
4. Click **Disable Streaming** in the MC External Storage Database section to de-activate your storage database.
5. Click **Remove** in the MC External Storage Database section to remove the MC Storage Database from MC.
6. Choose whether to keep or remove the data your storage database has collected:
 - **Keep Data:** Existing data will not removed. If you re-use this database for Extended Monitoring storage, you can choose to append new collected monitoring data to this existing data.
 - **Remove Data:** MC deletes its customized storage schema from the database.

Configure storage database memory usage

On the Resource Pools tab of the storage database, you can optionally increase the memory size of SYSQUERY and KAFKA_DEFAULT_POOL. For setting resource pool parameters in MC, see [Configuring resource pools with MC](#).

- **SYSQUERY:** Reserved for temporary storage of intermediate results of queries against system monitoring and catalog tables. Default setting is 1G. For best performance for MC, set to 2G or higher.
- **KAFKA_DEFAULT_POOL:** Reserved for all queries executed by the Kafka scheduler. Default setting is 30%, which is the recommended setting. By default, queries spill to the general pool when they exceed the 30% memory size.

Manage disk space

The storage database uses a customized schema, named dcschema. You can monitor these tables on MC, using the Table Utilization chart on the storage database's Activity tab. The Table Utilization chart lists all the tables in dcschema and their details, such as row counts and column properties. You can sort by row count to determine if certain tables use more disk space on your storage database. See [Monitoring table utilization and projections with MC](#).

You should regularly drop partitions from dcschema if you have limited disk space for the MC storage database. MC does not automatically drop partitions from the storage database. For more information on dropping partitions, see [Dropping partitions](#).

The table dc_execution_engine_profiles is partitioned by day. Because this table typically contains the most rows, as a best practice you should drop partitions from this table more often. The following example shows how you can specify partition key 2016-08-22 to drop a partition from dc_execution_engine_profiles.

```
=> SELECT DROP_PARTITIONS
('dcschema.dc_execution_engine_profiles', 2016-08-2, 2016-08-22);
```

Other than dc_execution_engine_profiles, all other tables in dcschema are partitioned by week. The next example shows you how you can drop a partition from the table dc_cpu_aggregate_by_minute, specifying the thirty-fourth week of 2016.

```
=> SELECT DROP_PARTITION
('dcschema.dc_cpu_aggregate_by_minute', 201634, 201634);
```

Manage client sessions

By default Vertica allows 50 client sessions and an additional five administrator sessions per node. If you reach the limit on the storage database, MC switches back to default monitoring, and does not use Extended Monitoring data from the storage database.

You can optionally configure the maximum number of client sessions that can run on a single database cluster node on your MC storage database's Settings page:

1. On the storage database dashboard, click the **Settings** page.
2. Choose the **General** tab.
3. Enter a value in the **Maximum client sessions** field. Valid values are 0–1000.

For more details about managing client connections in MC, see [Configuring Management Console](#).

- [Create a private key file](#)

Managing extended monitoring on a database

When you enable extended monitoring on your Vertica database, monitoring data from your database streams through Kafka servers to the MC storage database.

You can enable streaming for any or all databases that MC monitors.

Extended monitoring prerequisites

Before you can enable extended monitoring, your system must meet these prerequisites:

- The versions of MC and Vertica must match.
- Deployed Kafka server(s)
- Configured MC for extended monitoring (See [Managing the storage database](#).)
- Deployed MC storage database (See [Managing the storage database](#).)

Enable extended monitoring

1. Select the Extended Monitoring tab on MC Settings.

The Extended Monitoring page displays all databases monitored by MC.

2. In the Memory Limit field for the database of your choice, set the maximum amount of memory the database can use for streaming monitoring data. For more about the memory limit, see [Managing streaming services for extended monitoring](#).
3. In the Extended Monitoring column, select **ON** to enable streaming for the database of your choice.

The database begins streaming its monitoring data to the Kafka server.

User access

When you change user permissions for a database using extended monitoring, the user access policy on the storage database does not automatically update. On the Extended Monitoring page, in the user access column for your database, click Refresh to sync the policy.

If you rename a Vertica user, you must re-map the user in MC Settings before refreshing the user access policy.

Managing streaming services for extended monitoring

When extended monitoring is enabled, Vertica streams data from your database through Kafka servers to the storage database.

For additional parameters that optimize the performance of Kafka with Vertica, see [Kafka and Vertica configuration settings](#).

View streaming details in MC

Click the Load tab on your database's MC dashboard to see the Data Load Activity page. On this page, the Continuous tab displays details about all continuous loading jobs for extended monitoring. You can use this page to monitor whether your extended monitoring data is streaming successfully to the MC storage database.

See [Viewing load history](#) for more about the Data Load Activity page.

Tip

Tip: If you do not see loading jobs for extended monitoring, verify that you have selected **Show MC data collector monitoring streams** at the top of the Continuous tab.

Prevent data loss

The Memory Limit buffer allows you to restart the Kafka server without data loss. Vertica queues the streamed data until you restart the Kafka server. When the Kafka server remains down for an extended period of time, data loss occurs when the queue of streamed data exceeds the buffer. You set the buffer size on the Extended Monitoring tab when you enable extended monitoring for a database. See [Managing extended monitoring on a database](#).

The Kafka retention policy determines when data loss occurs during the following scenarios:

- Restarting the MC storage database (see [Managing the storage database](#).)
- Disabling streaming on the MC storage database (see [Managing the storage database](#).)
- Restart a micro-batch (see [Viewing load history](#).)

The Kafka retention policy can allow you to restart these extended monitoring components without data loss. The Kafka server retains the data while the listed components are disabled. Data loss occurs when the streamed data exceeds the Kafka retention policy's log size or retention time limits. See the [Apache Kafka documentation](#) for how to configure the retention policy.

If you perform an MC factory reset (restore MC to its pre-configured state), you automatically have the opportunity to export audit records before the reset occurs.

To manually export MC user activity

1. From the MC Home page, click **Diagnostics** and then click **Audit Log**.
2. On the Audit log viewer page, click **Export** and save the file to a location on the server.

To see what types of user operations the audit logger records, see [Monitoring MC user activity using audit log](#).

Restarting MC

You might need to restart the MC web/application server for a number of reasons, such as after you change port assignments, use the MC interface to import a new SSL certificate, or if the MC interface or Vertica-related tasks become unresponsive.

Restarting MC requires ADMIN Role (MC) or SUPER Role (MC) privileges. For details about these roles, see [Configuration roles in MC](#).

How to restart MC through the MC interface (using your browser)

1. Open a web browser and [connect to MC](#) as an administrator.
2. On MC's Home page, click **Diagnostics**.
3. Click **Restart Console** and then click OK to continue or Cancel to return to the Diagnostics page..

The MC process shuts down for a few seconds and automatically restarts. After the process completes, you are directed back to the sign-in page.

How to restart MC at the command line

If you are unable to connect to MC through a web browser for any reason, such as if the MC interface or Vertica-related tasks become unresponsive, you can run the `vertica-console` script with `start`, `stop`, or `restart` arguments.

Follow these steps to start, stop, or restart MC.

1. As root, open a terminal window on the server on which MC is installed.
2. Run the `vertica-console` script:

```
# /etc/init.d/vertica-console { stop | start | restart }
```

For versions CentOS 7 and above, run:

```
# systemctl { stop | start | restart } vertica-console
```

Important

The `systemctl` function requires you to both start and stop services explicitly. If you kill or stop the `vertica-console` process without using `systemctl stop`, you cannot start the MC process again with the original `systemctl start` command. Instead, you must run `systemctl stop vertica-console` before running `systemctl start vertica-console`.

<code>stop</code>	Stops the MC application/web server.
<code>start</code>	Starts the MC application/web server. Caution: Use <code>start</code> only if you are certain MC is not already running. As a best practice, stop MC before you issue the <code>start</code> command.
<code>restart</code>	Restarts the MC application/web server. This process will report that the stop didn't work if MC is not already running.

How to restart MC on an AMI

You can use the following steps to restart an MC AMI instance.

1. SSH into the MC host as user `dbadmin`:

```
$ ssh -i example.pem dbadmin@52.xx.xx.xx
```

1. Run the `vertica-console` script using `sudo`:

```
# sudo /etc/init.d/vertica-console { stop | start | restart }
```

Starting over

If you need to return MC to its original state (a "factory reset"), see [Resetting MC to pre-configured state](#).

Resetting MC to pre-configured state

If you decide to reset MC to its original, preconfigured state, you can do so on the **Diagnostics** page by clicking **Factory Reset**.

Tip

Consider trying one of the options described in [Restarting MC](#) first.

A factory reset removes all metadata (about a week's worth of database monitoring/configuration information and MC users) from storage and forces you to reconfigure MC again, as described in [Configuring MC](#).

After you click Factory Reset, you have the chance to export audit records to a file by clicking Yes. If you click No (do not export audit records), the process begins. There is no undo.

Keep the following in mind concerning user accounts and the MC.

- When you first configure MC, during the configuration process you create an MC superuser (a Linux account). Issuing a Factory Reset on the MC does not create a new MC superuser, nor does it delete the existing MC superuser. When initializing after a Factory Reset, you must logon using the original MC superuser account.
- Note that, once MC is configured, you can add users that are specific to MC. Users created through the MC interface are MC specific. When you subsequently change a password through the MC, you only change the password for the specific MC user. Passwords external to MC (i.e., system Linux users and Vertica database passwords) remain unchanged.

For information on MC users, refer to the sections, [Creating an MC User](#) and [MC configuration privileges](#).

Avoiding MC self-signed certificate expiration

When you [connect to MC](#) through a client browser, Vertica assigns each HTTPS request a self-signed certificate, which includes a timestamp. To increase security and protect against password replay attacks, the timestamp is valid for several seconds only, after which it expires.

To avoid being blocked out of MC, synchronize time on the hosts in your Vertica cluster, and on the MC host if it resides on a dedicated server. To recover from loss or lack of synchronization, resync system time and the Network Time Protocol.

Uninstalling Management Console

The uninstall command shuts down Management Console (MC) and removes most of the files that MC installation script installed.

1. Log in to the target server as root.
2. Stop Management Console:

```
# /etc/init.d/vertica-constoled stop
```

For versions of Red Hat 7/CentOS 7 and above, use:

```
# systemctl stop vertica-constoled
```

3. Look for previously-installed versions of MC and note the version:

RPM

```
# rpm -qa | grep vertica
```

DEB

```
# dpkg -l | grep vertica
```

4. Remove the package:

RPM

```
# rpm -e vertica-console
```

DEB

```
# dpkg -r vertica-console
```

5. Optionally, delete the MC directory and all subdirectories:

```
# rm -rf /opt/vconsole
```

Administrator's guide

Welcome to the Vertica Administrator's Guide. This document describes how to set up and maintain a Vertica Analytics Platform database.

Prerequisites

This document makes the following assumptions:

- You are familiar with the concepts discussed in [Architecture](#).
- Performed the following procedures as described in [Setup](#):
 - Constructed a hardware platform.
 - Installed Linux.
 - Installed Vertica and configured a cluster of hosts.

In this section

- [Administration overview](#)
- [Managing licenses](#)
- [Configuring the database](#)
- [Database users and privileges](#)
- [Using the administration tools](#)
- [Operating the database](#)
- [Working with native tables](#)

- [About locale](#)
- [Appendix: creating native binary format files](#)

Administration overview

This document describes the functions performed by a Vertica database administrator (DBA). Perform these tasks using only the dedicated database administrator account that was created when you installed Vertica. The examples in this documentation set assume that the administrative account name is dbadmin.

- To perform certain cluster configuration and administration tasks, the DBA (users of the administrative account) must be able to supply the root password for those hosts. If this requirement conflicts with your organization's security policies, these functions must be performed by your IT staff.
- If you perform administrative functions using a different account from the account provided during installation, Vertica encounters file ownership problems.
- If you share the administrative account password, make sure that only one user runs the [Administration tools](#) at any time. Otherwise, automatic configuration propagation does not work correctly.
- The Administration Tools require that the calling user's shell be `/bin/bash`. Other shells give unexpected results and are not supported.

Managing licenses

You must license Vertica in order to use it. Vertica supplies your license in the form of one or more license files, which encode the terms of your license.

To prevent introducing special characters that invalidate the license, do not open the license files in an editor. Opening the file in this way can introduce special characters, such as line endings and file terminators, that may not be visible within the editor. Whether visible or not, these characters invalidate the license.

Applying license files

Be careful not to change the license key file in any way when copying the file between Windows and Linux, or to any other location. To help prevent applications from trying to alter the file, enclose the license file in an archive file (such as a .zip or .tar file). You should keep a back up of your license key file. OpenText recommends that you keep the backup in /opt/vertica.

After copying the license file from one location to another, check that the copied file size is identical to that of the one you received from Vertica.

Obtaining a license key file

Follow these steps to obtain a license key file:

1. Log in to the [Software Entitlement Key site](#) using your passport login information. If you do not have a passport login, create one.
2. On the Request Access page, enter your order number and select a role.
3. Enter your request access reasoning.
4. Click **Submit**.
5. After your request is approved, you will receive a confirmation email. On the site, click the **Entitlements** tab to see your Vertica software.
6. Under the Action tab, click **Activate**. You may select more than one product.
7. The License Activation page opens. Enter your Target Name.
8. Select you Vertica version and the quantity you want to activate.
9. Click **Next**.
10. Confirm your activation details and click Submit.
11. The Activation Results page displays. Follow the instructions in [New Vertica license installations](#) or [Vertica license changes](#) to complete your installation or upgrade.

Your Vertica Community Edition download package includes the Community Edition license, which allows three nodes and 1TB of data. The Vertica Community Edition license does not expire.

Understanding Vertica licenses

Vertica has flexible licensing terms. It can be licensed on the following bases:

- Term-based (valid until a specific date).
- Size-based (valid to store up to a specified amount of raw data).
- Both term- and size-based.
- Unlimited duration and data storage.
- Node-based with an unlimited number of CPUs and users (one node is a server acting as a single computer system, whether physical or virtual).
- A pay-as-you-go model where you pay for only the number of hours you use. This license is available on your cloud provider's marketplace.

Your license key has your licensing bases encoded into it. If you are unsure of your current license, you can [view your license information from within Vertica](#).

Note

Vertica does not support license downgrades.

Community edition license

Vertica Community Edition (CE) is free and allows customers to create databases with the following limits:

- up to 3 of nodes
- up to 1 terabyte of data

Community Edition licenses cannot be installed co-located in a Hadoop infrastructure and used to query data stored in Hadoop formats.

As part of the CE license, you agree to the collection of some anonymous, non-identifying usage data. This data lets Vertica understand how customers use the product, and helps guide the development of new features. None of your personal data is collected. For details on what is collected, see the Community Edition [End User License Agreement](#).

Vertica for SQL on Apache Hadoop license

Vertica for SQL on Apache Hadoop is a separate product with its own license. This documentation covers both products. Consult your license agreement for details about available features and limitations.

Installing or upgrading a license key

The steps you follow to apply your Vertica license key vary, depending on the type of license you are applying and whether you are upgrading your license.

In this section

- [New Vertica license installations](#)
- [Vertica license changes](#)

New Vertica license installations

Follow these steps to install a new Vertica license:

1. Copy the license key file you generated from the Software Entitlement Key site to your [Administration host](#).
2. Ensure the license key's file permissions are set to 400 (read permissions).
3. Install Vertica as described in the Installing Vertica if you have not already done so. The interface prompts you for the license key file.
4. To install Community Edition, leave the default path blank and click **OK**. To apply your evaluation or Premium Edition license, enter the absolute path of the license key file you downloaded to your Administration Host and press **OK**. The first time you log in as the [Database Superuser](#) and run the [Administration tools](#), the interface prompts you to accept the End-User License Agreement (EULA).

Note

If you installed [Management Console](#), the MC administrator can point to the location of the license key during Management Console configuration.

5. Choose **View EULA**.
6. Exit the EULA and choose **Accept EULA** to officially accept the EULA and continue installing the license, or choose **Reject EULA** to reject the EULA and return to the Advanced Menu.

Vertica license changes

If your license is expiring or you want your database to grow beyond your licensed data size, you must renew or upgrade your license. After you obtain your renewal or upgraded license key file, you can install it using Administration Tools or Management Console.

Upgrading does not require a new license unless you are increasing the capacity of your database. You can add-on capacity to your database using the Software Entitlement Key. You do not need uninstall and reinstall the license to add-on capacity.

Uploading or upgrading a license key using administration tools

1. Copy the license key file you generated from the Software Entitlement Key site to your [Administration host](#).
2. Ensure the license key's file permissions are set to 400 (read permissions).
3. Start your database, if it is not already running.
4. In the Administration Tools, select Advanced > Upgrade License Key and click OK.
5. Enter the absolute path to your new license key file and click OK. The interface prompts you to accept the End-User License Agreement (EULA).
6. Choose View EULA.
7. Exit the EULA and choose Accept EULA to officially accept the EULA and continue installing the license, or choose Reject EULA to reject the EULA and return to the Advanced Menu.

Uploading or upgrading a license key using Management Console

1. From your database's Overview page in Management Console, click the License tab. The License page displays. You can view your installed licenses on this page.
2. Click Install New License at the top of the License page.
3. Browse to the location of the license key from your local computer and upload the file.

4. Click Apply at the top of the page. Management Console prompts you to accept the End-User License Agreement (EULA).
5. Select the check box to officially accept the EULA and continue installing the license, or click Cancel to exit.

Note

As soon as you renew or upgrade your license key from either your [Administration host](#) or Management Console, Vertica applies the license update. No further warnings appear.

Adding capacity

If you are adding capacity to your database, you do not need to uninstall and reinstall the license. Instead, you can install multiple licenses to increase the size of your database. This additive capacity only works for licenses with the same format, such as adding a Premium license capacity to an existing Premium license type. When you add capacity, the size of license will be the total of both licenses; the previous license is not overwritten. You cannot add capacity using two different license formats, such as adding Hadoop license capacity to an existing Premium license.

You can run the [AUDIT\(\)](#) function to verify the license capacity was added on. The reflection of add-on capacity to your license will run during the automatic run of the audit function. If you want to see the immediate result of the add-on capacity, run the [AUDIT\(\)](#) function to refresh.

Note

If you have an expired license, you must drop the expired license before you can continue to use Vertica. For more information, see [DROP_LICENSE](#).

Viewing your license status

You can use several functions to display your license terms and current status.

Examining your license key

Use the [DISPLAY_LICENSE](#) SQL function to display the license information. This function displays the dates for which your license is valid (or [Perpetual](#) if your license does not expire) and any raw data allowance. For example:

```
=> SELECT DISPLAY_LICENSE();
      DISPLAY_LICENSE
```

```
-----
Vertica Systems, Inc.
2007-08-03
Perpetual
500GB
```

```
(1 row)
```

You can also query the [LICENSES](#) system table to view information about your installed licenses. This table displays your license types, the dates for which your licenses are valid, and the size and node limits your licenses impose.

Alternatively, use the [LICENSES](#) table in Management Console. On your database Overview page, click the License tab to view information about your installed licenses.

Viewing your license compliance

If your license includes a raw data size allowance, Vertica periodically audits your database's size to ensure it remains compliant with the license agreement. If your license has a term limit, Vertica also periodically checks to see if the license has expired. You can see the result of the latest audits using the [GET_COMPLIANCE_STATUS](#) function.

```
=> select GET_COMPLIANCE_STATUS();
       GET_COMPLIANCE_STATUS
```

```
-----
Raw Data Size: 2.00GB +/- 0.003GB
License Size : 4.000GB
Utilization  : 50%
Audit Time   : 2011-03-09 09:54:09.538704+00
Compliance Status : The database is in compliance with respect to raw data size.
License End Date: 04/06/2011
Days Remaining: 28.59
(1 row)
```

To see how your ORC/Parquet data is affecting your license compliance, see [Viewing license compliance for Hadoop file formats](#).

Viewing your license status through MC

Information about license usage is on the Settings page. See [Monitoring database size for license compliance](#).

Viewing license compliance for Hadoop file formats

You can use the [EXTERNAL_TABLE_DETAILS](#) system table to gather information about all of your tables based on Hadoop file formats. This information can help you understand how much of your license's data allowance is used by ORC and Parquet-based data.

Vertica computes the values in this table at query time, so to avoid performance problems, restrict your queries to filter by table_schema, table_name, or source_format. These three columns are the only columns you can use in a predicate, but you may use all of the usual predicate operators.

```
=> SELECT * FROM EXTERNAL_TABLE_DETAILS
     WHERE source_format = 'PARQUET' OR source_format = 'ORC';
```

```
-[ RECORD 1 ]-----+
```

```
-----
schema_oid      | 45035996273704978
table_schema    | public
table_oid       | 45035996273760390
table_name      | ORC_demo
source_format   | ORC
total_file_count | 5
total_file_size_bytes | 789
source_statement | COPY FROM 'ORC_demo/*' ORC
file_access_error |
```

```
-[ RECORD 2 ]-----+
```

```
-----
schema_oid      | 45035196277204374
table_schema    | public
table_oid       | 45035996274460352
table_name      | Parquet_demo
source_format   | PARQUET
total_file_count | 3
total_file_size_bytes | 498
source_statement | COPY FROM 'Parquet_demo/*' PARQUET
file_access_error |
```

When computing the size of an external table, Vertica counts all data found in the location specified by the COPY FROM clause. If you have a directory that contains ORC and delimited files, for example, and you define your external table with "COPY FROM *" instead of "COPY FROM *.orc", this table includes the size of the delimited files. (You would probably also encounter errors when querying that external table.) When you query this table Vertica does not validate your table definition; it just uses the path to find files to report.

You can also use the [AUDIT](#) function to find the size of a specific table or schema. When using the AUDIT function on ORC or PARQUET external tables, the error tolerance and confidence level parameters are ignored. Instead, the AUDIT always returns the size of the ORC or Parquet files on disk.

```
=> select AUDIT('customers_orc');
   AUDIT
-----
619080883
(1 row)
```

Moving a cloud installation from by the hour (BTH) to bring your own license (BYOL)

Vertica offers two licensing options for some of the entries in the [Amazon Web Services Marketplace](#) and [Google Cloud Marketplace](#):

- **Bring Your Own License (BYOL)** : a long-term license that you [obtain through an online licensing portal](#). These deployments also work with a free Community Edition license. Vertica uses a community license automatically if you do not install a license that you purchased. (For more about Vertica licenses, see [Managing licenses](#) and [Understanding Vertica licenses](#).)
- Vertica **by the Hour (BTH)** : a pay-as-you-go environment where you are charged an hourly fee for both the use of Vertica and the cost of the instances it runs on. The Vertica by the hour deployment offers an alternative to purchasing a term license. If you want to crunch large volumes of data within a short period of time, this option might work better for you. The BTH license is automatically applied to all clusters you create using a BTH MC instance.

If you start out with an hourly license, you can later decide to use a long-term license for your database. The support for an hourly versus a long-term license is built into the instances running your database. To move your database from an hourly license to a long-term license, you must create a new database cluster with a new set of instances.

To move from an hourly to a long-term license, follow these steps:

1. Purchase a BYOL license. Follow the process described in [Obtaining a license key file](#).
2. Apply the new license to your database.
3. Shut down your database.
4. Create a new database cluster using a BYOL marketplace entry.
5. Revive your database onto the new cluster.

The exact steps you must take depend on your database mode and your preferred tool for managing your database:

- **Eon Mode databases:** Use either [the command line](#) or [Management Console](#).
- **Enterprise Mode databases:** [Use the command line](#) to switch licenses.

Moving an Eon Mode database from BTH to BYOL using the command line

Follow these steps to move an Eon Mode database from an hourly to a long-term license.

Obtain a long-term BYOL license from the online licensing portal, described in [Obtaining a license key file](#). Upload the license file to a node in your database. Note the absolute path in the node's filesystem, as you will need this later when installing the license. Connect to the node you uploaded the license file to in the previous step. Connect to your database using [vsq](#) and view the licenses table:

```
=> SELECT * FROM licenses;
```

Note the name of the hourly license listed in the NAME column, so you can check if it is still present later.

Install the license in the database using the [INSTALL_LICENSE](#) function with the absolute path to the license file you uploaded in step 2:

```
=> SELECT install_license('absolute path to BYOL license');
```

View the licenses table again:

```
=> SELECT * FROM licenses;
```

If only the new BYOL license appears in the table, skip to step 8. If the hourly license whose name you noted in step 4 is still in the table, copy the name and proceed to step 7.

Call the [DROP_LICENSE](#) function to drop the hourly license:

```
=> SELECT drop_license('hourly license name');
```

1. You will need the path for your cluster's communal storage in a later step. If you do not already know the path, you can find this information by executing this query:

```
=> SELECT location_path FROM V_CATALOG.STORAGE_LOCATIONS
WHERE sharing_type = 'COMMUNAL';
```

2. Synchronize your database's metadata. See [Synchronizing metadata](#).

3. Shut down the database by calling the [SHUTDOWN](#) function:

```
=> SELECT SHUTDOWN();
```

4. You now need to create a new BYOL cluster onto which you will revive your database. Deploy a new cluster including a new MC instance using a BYOL entry in the marketplace of your chosen cloud platform. See:
 - [Deploy MC and AWS resources with a CloudFormation template](#)
 - [Deploy an MC instance in GCP for Eon Mode](#)

Important

Your new BYOL cluster must have the same number of primary nodes as your existing hourly license cluster.

5. Revive your database onto the new cluster. For instructions, see [Reviving an Eon Mode database cluster](#). Because you created the new cluster using a BYOL entry in the marketplace, the database uses the BYOL you applied earlier.
6. After reviving the database on your new BYOL cluster, terminate the instances for your hourly license cluster and MC. For instructions, see your cloud provider's documentation.

Moving an Eon Mode database from BTH to BYOL using the MC

Follow this procedure to move to BYOL and revive your database using MC:

1. Purchase a long-term BYOL license from the online licensing portal, following the steps detailed in [Obtaining a license key file](#). Save the file to a location on your computer.
2. You now need to install the new license on your database. Log into MC and click your database in the Recent Databases list.
3. At the bottom of your database's Overview page, click the **License** tab.
4. Under the Installed Licenses list, note the name of the BTH license in the License Name column. You will need this later to check whether it is still present after installing the new long-term license.
5. In the ribbon at the top of the License History page, click the **Install New License** button. The Settings: License page opens.
6. Click the **Browse** button next to the **Upload a new license box**.
7. Locate the license file you obtained in step 1, and click **Open**.
8. Click the **Apply** button on the top right of the page.
9. Select the checkbox to agree to the EULA terms and click **OK**.
10. After Vertica installs the license, click the **Close** button.
11. Click the **License** tab at the bottom of the page.
12. If only the new long-term license appears in the **Installed Licenses** list, skip to Step 16. If the by-the-hour license also appears in the list, copy down its name from the **License Name** column.
13. You must drop the by-the-hour license before you can proceed. At the bottom of the page, click the **Query Execution** tab.
14. In the query editor, enter the following statement:

```
SELECT DROP_LICENSE('hourly license name');
```

15. Click **Execute Query**. The query should complete indicating that the license has been dropped.
16. You will need the path for your cluster's communal storage in a later step. If you do not already know the path, you can find this information by executing this query in the Query Execution tab:

```
SELECT location_path FROM V_CATALOG.STORAGE_LOCATIONS  
WHERE sharing_type = 'COMMUNAL';
```

17. Synchronize your database's metadata. See [Synchronizing metadata](#).
18. You must now stop your by-the-hour database cluster. At the bottom of the page, click the **Manage** tab.
19. In the banner at the top of the page, click **Stop Database** and then click **OK** to confirm.
20. From the [Amazon Web Services Marketplace](#) or the [Google Cloud Marketplace](#), deploy a new Vertica Management Console using a BYOL entry. Do not deploy a full cluster. You just need an MC deployment.
21. Log into your new MC instance and revive the database. See [Reviving an Eon Mode database on AWS in MC](#) for detailed instructions.
22. After reviving the database on your new environment, terminate the instances for your hourly license environment. To do so, on the [AWS CloudFormation Stacks page](#), select the hourly environment's stack (its collection of AWS resources) and click **Actions > Delete Stack**.

Moving an Enterprise Mode database from hourly to BYOL using backup and restore

Note

Currently, AWS is the only platform supported for Enterprise Mode databases using hourly licenses.

In an Enterprise Mode database, follow this procedure to move to BYOL, and then back up and restore your database:

Obtain a long-term BYOL license from the online licensing portal, described in [Obtaining a license key file](#). Upload the license file to a node in your database. Note the absolute path in the node's filesystem, as you will need this later when installing the license. Connect to the node you uploaded the license file to in the previous step. Connect to your database using [vsq](#) and view the licenses table:

```
=> SELECT * FROM licenses;
```

Note the name of the hourly license listed in the NAME column, so you can check if it is still present later.

Install the license in the database using the [INSTALL_LICENSE](#) function with the absolute path to the license file you uploaded in step 2:

```
=> SELECT install_license('absolute path to BYOL license');
```

View the licenses table again:

```
=> SELECT * FROM licenses;
```

If only the new BYOL license appears in the table, skip to step 8. If the hourly license whose name you noted in step 4 is still in the table, copy the name and proceed to step 7.

Call the [DROP_LICENSE](#) function to drop the hourly license:

```
=> SELECT drop_license('hourly license name');
```

1. Back up the database. See [Backing up and restoring the database](#).
2. Deploy a new cluster for your database using one of the BYOL entries in the [Amazon Web Services Marketplace](#).
3. Restore the database from the backup you created earlier. See [Backing up and restoring the database](#). When you restore the database, it will use the BYOL you loaded earlier.
4. After restoring the database on your new environment, terminate the instances for your hourly license environment. To do so, on the [AWS CloudFormation Stacks page](#), select the hourly environment's stack (its collection of AWS resources) and click **Actions > Delete Stack**.

After completing one of these procedures, see [Viewing your license status](#) to confirm the license drop and install were successful.

Auditing database size

You can use your Vertica software until columnar data reaches the maximum raw data size that your license agreement allows. Vertica periodically runs an audit of the columnar data size to verify that your database complies with this agreement. You can also run your own audits of database size with two functions:

- [AUDIT](#): Estimates the raw data size of a database, schema, or table.
- [AUDIT_FLEX](#): Estimates the size of one or more flexible tables in a database, schema, or projection.

The following two examples audit the database and one schema:

```
=> SELECT AUDIT('', 'database');
```

```
AUDIT
-----
76376696
(1 row)
```

```
=> SELECT AUDIT('online_sales', 'schema');
```

```
AUDIT
-----
35716504
(1 row)
```

Raw data size

[AUDIT](#) and [AUDIT_FLEX](#) use statistical sampling to estimate the raw data size of data stored in tables—that is, the uncompressed data that the database stores. For most data types, Vertica evaluates the raw data size as if the data were exported from the database in text format, rather than as compressed data. For details, see [Evaluating Data Type Footprint](#).

By using statistical sampling, the audit minimizes its impact on database performance. The tradeoff between accuracy and performance impact is a small margin of error. Reports on your database size include the margin of error, so you can assess the accuracy of the estimate.

Data in ORC and Parquet-based external tables are also audited whether they are stored locally in the Vertica cluster's file system or remotely in S3 or on a Hadoop cluster. [AUDIT](#) always uses the file size of the underlying data files as the amount of data in the table. For example, suppose you have an external table based on 1GB of ORC files stored in HDFS. Then an audit of the table reports it as being 1GB in size.

Note

The Vertica audit does not verify that these files contain actual ORC or Parquet data. It just checks the size of the files that correspond to the external table definition.

Unaudited data

Table data that appears in multiple projections is counted only once. An audit also excludes the following data:

- Temporary table data.
- Data in [SET USING](#) columns.
- Non-columnar data accessible through external table definitions. Data in columnar formats such as ORC and Parquet count against your totals.
- Data that was deleted but not yet [purged](#).
- Data stored in system and work tables such as monitoring tables, [Data collector](#) tables, and Database Designer tables.
- Delimiter characters.

Evaluating data type footprint

Vertica evaluates the footprint of different data types as follows:

- Strings and binary types—CHAR, VARCHAR, BINARY, VARBINARY—are counted as their actual size in bytes using UTF-8 encoding.
- Numeric data types are evaluated as if they were printed. Each digit counts as a byte, as does any decimal point, sign, or scientific notation. For example, `-123.456` counts as eight bytes—six digits plus the decimal point and minus sign.
- Date/time data types are evaluated as if they were converted to text, including hyphens, spaces, and colons. For example, `vsq1` prints a timestamp value of `2011-07-04 12:00:00` as 19 characters, or 19 bytes.
- Complex types are evaluated as the sum of the sizes of their component parts. An array is counted as the total size of all elements, and a ROW is counted as the total size of all fields.

Controlling audit accuracy

[AUDIT](#) can specify the level of an audit's error tolerance and confidence, by default set to 5 and 99 percent, respectively. For example, you can obtain a high level of audit accuracy by setting error tolerance and confidence level to 0 and 100 percent, respectively. Unlike estimating raw data size with statistical sampling, Vertica dumps all audited data to a raw format to calculate its size.

Caution

Vertica discourages database-wide audits at this level. Doing so can have a significant adverse impact on database performance.

The following example audits the database with 25% error tolerance:

```
=> SELECT AUDIT(", 25);
AUDIT
-----
75797126
(1 row)
```

The following example audits the database with 25% level of tolerance and 90% confidence level:

```
=> SELECT AUDIT(",25,90);
AUDIT
-----
76402672
(1 row)
```

Note

These accuracy settings have no effect on audits of external tables based on ORC or Parquet files. Audits of external tables based on these formats always use the file size of ORC or Parquet files.

Monitoring database size for license compliance

Your Vertica license can include a data storage allowance. The allowance can consist of data in columnar tables, flex tables, or both types of data. The `AUDIT()` function estimates the columnar table data size and any flex table materialized columns. The `AUDIT_FLEX()` function estimates the amount of `__raw__` column data in flex or columnar tables. In regards to license data limits, data in `__raw__` columns is calculated at 1/10th the size of structured data. Monitoring data sizes for columnar and flex tables lets you plan either to schedule deleting old data to keep your database in compliance with your license, or to consider a license upgrade for additional data storage.

Note

An audit of columnar data includes flex table real and materialized columns, but not `__raw__` column data.

Viewing your license compliance status

Vertica periodically runs an audit of the columnar data size to verify that your database is compliant with your license terms. You can view the results of the most recent audit by calling the `GET_COMPLIANCE_STATUS` function.

```
=> select GET_COMPLIANCE_STATUS();
       GET_COMPLIANCE_STATUS
```

```
-----
Raw Data Size: 2.00GB +/- 0.003GB
License Size : 4.000GB
Utilization  : 50%
Audit Time   : 2011-03-09 09:54:09.538704+00
Compliance Status : The database is in compliance with respect to raw data size.
License End Date: 04/06/2011
Days Remaining: 28.59
(1 row)
```

Periodically running `GET_COMPLIANCE_STATUS` to monitor your database's license status is usually enough to ensure that your database remains compliant with your license. If your database begins to near its columnar data allowance, you can use the other auditing functions described below to determine where your database is growing and how recent deletes affect the database size.

Manually auditing columnar data usage

You can manually check license compliance for all columnar data in your database using the `AUDIT_LICENSE_SIZE` function. This function performs the same audit that Vertica periodically performs automatically. The `AUDIT_LICENSE_SIZE` check runs in the background, so the function returns immediately. You can then query the results using `GET_COMPLIANCE_STATUS`.

Note

When you audit columnar data, the results include any flex table real and materialized columns, but not data in the `__raw__` column. Materialized columns are virtual columns that you have promoted to real columns. Columns that you define when creating a flex table, or which you add with `ALTER TABLE...ADD COLUMN` statements are real columns. All `__raw__` columns are real columns. However, since they consist of unstructured or semi-structured data, they are audited separately.

An alternative to `AUDIT_LICENSE_SIZE` is to use the `AUDIT` function to audit the size of the columnar tables in your entire database by passing an empty string to the function. This function operates synchronously, returning when it has estimated the size of the database.

```
=> SELECT AUDIT("");
       AUDIT
-----
76376696
(1 row)
```

The size of the database is reported in bytes. The `AUDIT` function also allows you to control the accuracy of the estimated database size using additional parameters. See the entry for the `AUDIT` function for full details. Vertica does not count the `AUDIT` function results as an official audit. It takes no license compliance actions based on the results.

Note

The results of the `AUDIT` function do not include flex table data in `__raw__` columns. Use the `AUDIT_FLEX` function to monitor data usage flex tables.

Manually auditing __raw__ column data

You can use the [AUDIT_FLEX](#) function to manually audit data usage for flex or columnar tables with a [__raw__](#) column. The function calculates the encoded, compressed data stored in ROS containers for any [__raw__](#) columns. Materialized columns in flex tables are calculated by the [AUDIT](#) function. The [AUDIT_FLEX](#) results do not include data in the [__raw__](#) columns of temporary flex tables.

Targeted auditing

If audits determine that the columnar table estimates are unexpectedly large, consider schemas, tables, or partitions that are using the most storage. You can use the [AUDIT](#) function to perform targeted audits of schemas, tables, or partitions by supplying the name of the entity whose size you want to find. For example, to find the size of the `online_sales` schema in the [VMart](#) example database, run the following command:

```
=> SELECT AUDIT('online_sales');
  AUDIT
-----
35716504
(1 row)
```

You can also change the granularity of an audit to report the size of each object in a larger entity (for example, each table in a schema) by using the `granularity` argument of the [AUDIT](#) function. See the [AUDIT](#) function.

Using Management Console to monitor license compliance

You can also get information about data storage of columnar data (for columnar tables and for materialized columns in flex tables) through the Management Console. This information is available in the database Overview page, which displays a grid view of the database's overall health.

- The needle in the license meter adjusts to reflect the amount used in megabytes.
- The grace period represents the term portion of the license.
- The Audit button returns the same information as the `AUDIT()` function in a graphical representation.
- The Details link within the License grid (next to the Audit button) provides historical information about license usage. This page also shows a progress meter of percent used toward your license limit.

Managing license warnings and limits

Term license warnings and expiration

The term portion of a Vertica license is easy to manage—you are licensed to use Vertica until a specific date. If the term of your license expires, Vertica alerts you with messages appearing in the [Administration tools](#) and [vsqL](#). For example:

```
=> CREATE TABLE T (A INT);
NOTICE 8723: Vertica license 432d8e57-5a13-4266-a60d-759275416eb2 is in its grace period; grace period expires in 28 days
HINT: Renew at https://softwaresupport.softwaregrp.com/
CREATE TABLE
```

Contact Vertica at <https://softwaresupport.softwaregrp.com/> as soon as possible to renew your license, and then [install the new license](#). After the grace period expires, Vertica stops processing DML queries and allows DDL queries with a warning message. If a license expires and one or more valid alternative licenses are installed, Vertica uses the alternative licenses.

Data size license warnings and remedies

If your Vertica columnar license includes a raw data size allowance, Vertica periodically audits the size of your database to ensure it remains compliant with the license agreement. For details of this audit, see [Auditing database size](#). You should also monitor your database size to know when it will approach licensed usage. Monitoring the database size helps you plan to either upgrade your license to allow for continued database growth or delete data from the database so you remain compliant with your license. See [Monitoring database size for license compliance](#) for details.

If your database's size approaches your licensed usage allowance (above 75% of license limits), you will see warnings in the [Administration tools](#), [vsqL](#), and Management Console. You have two options to eliminate these warnings:

- Upgrade your license to a larger data size allowance.
- Delete data from your database to remain under your licensed raw data size allowance. The warnings disappear after Vertica's next audit of the database size shows that it is no longer close to or over the licensed amount. You can also manually run a database audit (see [Monitoring database size for license compliance](#) for details).

If your database continues to grow after you receive warnings that its size is approaching your licensed size allowance, Vertica displays additional warnings in more parts of the system after a grace period passes. Use the [GET_COMPLIANCE_STATUS](#) function to check the status of your license.

If your Vertica premium edition database size exceeds your licensed limits

If your Premium Edition database size exceeds your licensed data allowance, all successful queries from ODBC and JDBC clients return with a status of `SUCCESS_WITH_INFO` instead of the usual `SUCCESS`. The message sent with the results contains a warning about the database size. Your ODBC and JDBC clients should be prepared to handle these messages instead of assuming that successful requests always return `SUCCESS`.

Note

These warnings for Premium Edition are in addition to any warnings you see in Administration Tools, vsql, and Management Console.

If your Vertica community edition database size exceeds 1 terabyte

If your Community Edition database size exceeds the limit of 1 terabyte, Vertica stops processing DML queries and allows DDL queries with a warning message.

To bring your database under compliance, you can choose to:

- Drop database tables. You can also consider truncating a table or dropping a partition. See [TRUNCATE TABLE](#) or [DROP PARTITIONS](#).
- Upgrade to Vertica Premium Edition (or an evaluation license).

Exporting license audit results to CSV

You can use `admintools` to audit a database for license compliance and export the results in CSV format, as follows:

```
admintools -t license_audit [--password=password] --database=database] [--file=csv-file] [--quiet]
```

where:

- `database` must be a running database. If the database is password protected, you must also supply the password.
- `--file csv-file` directs output to the specified file. If `csv-file` already exists, the tool returns an error message. If this option is unspecified, output is directed to `stdout`.
- `--quiet` specifies that the tool should run in quiet mode; if unspecified, status messages are sent to `stdout`.

Running the `license_audit` tool is equivalent to invoking the following SQL statements:

```
select audit("");
select audit_flex("");
select * from dc_features_used;
select * from v_catalog.license_audits;
select * from v_catalog.user_audits;
```

Audit results include the following information:

- Log of used Vertica features
- Estimated database size
- Raw data size allowed by your Vertica license
- Percentage of licensed allowance that the database currently uses
- Audit timestamps

The following truncated example shows the raw CSV output that `license_audit` generates:

FEATURES_USED

```
features_used,feature,date,sum
features_used,metafunction::get_compliance_status,2014-08-04,1
features_used,metafunction::bootstrap_license,2014-08-04,1
...
```

LICENSE_AUDITS

```
license_audits,database_size_bytes,license_size_bytes,usage_percent,audit_start_timestamp,audit_end_timestamp,confidence_level_percent,error_tolerance_percent,used_sampling,confidence_interval_lower_bound_bytes,confidence_interval_upper_bound_bytes,sample_count,cell_count,license_name

Configuring the database

Before reading the topics in this section, you should be familiar with the material in [Getting started](#) and are familiar with creating and configuring a fully-functioning example database.

See also

- [Security and authentication](#)
- [Implement locales for international data sets](#)

In this section

- [Configuration procedure](#)
- [Configuration parameter management](#)
- [Designing a logical schema](#)
- [Creating a database design](#)

Configuration procedure

This section describes the tasks required to set up a Vertica database. It assumes that you have a valid license key file, installed the Vertica rpm package, and ran the installation script as described.

You complete the configuration procedure using:

- [Administration tools](#)
If you are unfamiliar with Dialog-based user interfaces, read [Using the administration tools interface](#) before you begin. See also the [Administration tools reference](#) for details.
- [vsq](#) interactive interface
- Database Designer, described in [Creating a database design](#)

Note

You can also perform certain tasks using [Management Console](#). Those tasks point to the appropriate topic.

Continuing configuring

Follow the configuration procedure sequentially as this section describes.

Vertica strongly recommends that you first experiment with [creating and configuring a database](#).

You can use this generic configuration procedure several times during the development process, modifying it to fit your changing goals. You can omit steps such as preparing actual data files and sample queries, and run the Database Designer without optimizing for queries. For example, you can create, load, and query a database several times for development and testing purposes, then one final time to create and load the production database.

In this section

- [Prepare disk storage locations](#)
- [Disk space requirements for Vertica](#)
- [Disk space requirements for Management Console](#)

- [Create an empty database](#)
- [Create the logical schema](#)
- [Perform a partial data load](#)
- [Test the database](#)
- [Optimize query performance](#)
- [Complete the data load](#)
- [Test the optimized database](#)
- [Implement locales for international data sets](#)
- [Using time zones with Vertica](#)
- [Change transaction isolation levels](#)

Prepare disk storage locations

You must create and specify directories in which to store your catalog and data files ([physical schema](#)). You can specify these locations when you install or configure the database, or later during database operations. Both the catalog and data directories must be owned by the [database superuser](#).

The directory you specify for database catalog files (the catalog path) is used across all nodes in the cluster. For example, if you specify `/home/catalog` as the catalog directory, Vertica uses that catalog path on all nodes. The catalog directory should always be separate from any data file directories.

Note

Do not use a shared directory for more than one node. Data and catalog directories must be distinct for each node. Multiple nodes must not be allowed to write to the same data or catalog directory.

The data path you designate is also used across all nodes in the cluster. Specifying that data should be stored in `/home/data`, Vertica uses this path on all database nodes.

Do not use a single directory to contain both catalog and data files. You can store the catalog and data directories on different drives, which can be either on drives local to the host (recommended for the catalog directory) or on a shared storage location, such as an external disk enclosure or a SAN.

Before you specify a catalog or data path, be sure the parent directory exists on all nodes of your database. Creating a database in admintools also creates the catalog and data directories, but the parent directory must exist on each node.

You do not need to specify a disk storage location during installation. However, you can do so by using the `--data-dir` parameter to the `install_vertica` script. See [Specifying disk storage location during installation](#).

In this section

- [Specifying disk storage location during database creation](#)
- [Specifying disk storage location on MC](#)
- [Configuring disk usage to optimize performance](#)
- [Using shared storage with Vertica](#)
- [Viewing database storage information](#)
- [Anti-virus scanning exclusions](#)

Specifying disk storage location during database creation

When you invoke the [Create Database](#) command in the [Administration tools](#), a dialog box allows you to specify the catalog and data locations. These locations must exist on each host in the cluster and must be owned by the database administrator.

When you click **OK**, Vertica automatically creates the following subdirectories:

```
catalog-pathname/database-name/node-name_catalog/data-pathname/database-name/node-name_data/
```

For example, if you use the default value (the database administrator's home directory) of `/home/dbadmin` for the Stock Exchange example database, the catalog and data directories are created on each node in the cluster as follows:

```
/home/dbadmin/Stock_Schema/stock_schema_node1_host01_catalog/home/dbadmin/Stock_Schema/stock_schema_node1_host01_data
```

Notes

- Catalog and data path names must contain only alphanumeric characters and cannot have leading space characters. Failure to comply with these restrictions will result in database creation failure.
- Vertica refuses to overwrite a directory if it appears to be in use by another database. Therefore, if you created a database for evaluation purposes, dropped the database, and want to reuse the database name, make sure that the disk storage location previously used has been completely cleaned up. See [Managing storage locations](#) for details.

Specifying disk storage location on MC

You can use the MC interface to specify where you want to store database metadata on the cluster in the following ways:

- When you configure MC the first time
- When you create new databases using on MC

See also

[Configuring Management Console](#).

Configuring disk usage to optimize performance

Once you have created your initial storage location, you can add additional storage locations to the database later. Not only does this provide additional space, it lets you control disk usage and increase I/O performance by isolating files that have different I/O or access patterns. For example, consider:

- Isolating execution engine temporary files from data files by creating a separate storage location for [temp space](#).
- Creating labeled storage locations and storage policies, in which selected database objects are stored on different storage locations based on measured performance statistics or predicted access patterns.

See also

[Managing storage locations](#)

Using shared storage with Vertica

If using shared SAN storage, ensure there is no contention among the nodes for disk space or bandwidth.

- Each host must have its own catalog and data locations. Hosts cannot share catalog or data locations.
- Configure the storage so that there is enough I/O bandwidth for each node to access the storage independently.

Viewing database storage information

You can view node-specific information on your Vertica cluster through the [Management Console](#). See [Monitoring Vertica Using Management Console](#) for details.

Anti-virus scanning exclusions

You should exclude the Vertica catalog and data directories from anti-virus scanning. Certain anti-virus products have been identified as targeting Vertica directories, and sometimes lock or delete files in them. This can adversely affect Vertica performance and data integrity.

Identified anti-virus products include the following:

- ClamAV
- SentinelOne
- Sophos
- Symantec
- Twistlock

Important

This list is not comprehensive.

Disk space requirements for Vertica

In addition to actual data stored in the database, Vertica requires disk space for several data reorganization operations, such as [mergeout](#) and [managing nodes](#) in the cluster. For best results, Vertica recommends that disk utilization per node be no more than sixty percent (60%) for a [K-Safe=1](#) database to allow such operations to proceed.

In addition, disk space is temporarily required by certain query execution operators, such as hash joins and sorts, in the case when they cannot be completed in memory (RAM). Such operators might be encountered during queries, recovery, refreshing projections, and so on. The amount of disk space needed (known as [temp space](#)) depends on the nature of the queries, amount of data on the node and number of concurrent users on the system. By default, any unused disk space on the data disk can be used as temp space. However, Vertica recommends provisioning temp space separate from data disk space.

See also

[Configuring disk usage to optimize performance](#).

Disk space requirements for Management Console

You can install Management Console on any node in the cluster, so it has no special disk requirements other than [disk space you allocate for your database cluster](#).

Prepare the logical schema script

Designing a logical schema for a Vertica database is no different from designing one for any other SQL database. Details are described more fully in [Designing a logical schema](#).

To create your logical schema, prepare a SQL script (plain text file, typically with an extension of `.sql`) that:

1. Creates additional schemas (as necessary). See [Using multiple schemas](#).
2. Creates the tables and column [constraints](#) in your database using the [CREATE TABLE](#) command.
3. Defines the necessary table constraints using the [ALTER TABLE](#) command.
4. Defines any views on the table using the [CREATE VIEW](#) command.

You can generate a script file using:

- A schema designer application.
- A schema extracted from an existing database.
- A text editor.
- One of the example database `example-name_define_schema.sql` scripts as a template. (See the example database directories in [/opt/vertica/examples](#).)

In your script file, make sure that:

- Each statement ends with a semicolon.
- You use [data types](#) supported by Vertica, as described in the SQL Reference Manual.

Once you have created a database, you can test your schema script by executing it as described in [Create the logical schema](#). If you encounter errors, drop all tables, correct the errors, and run the script again.

Prepare data files

Prepare two sets of data files:

- Test data files. Use test files to test the database after the partial data load. If possible, use part of the actual data files to prepare the test data files.

- Actual data files. Once the database has been tested and optimized, use your data files for your initial [Data load](#).

How to name data files

Name each data file to match the corresponding table in the logical schema. Case does not matter.

Use the extension `.tbl` or whatever you prefer. For example, if a table is named `Stock_Dimension`, name the corresponding data file `stock_dimension.tbl`. When using multiple data files, append `_nnn` (where `nnn` is a positive integer in the range 001 to 999) to the file name. For example, `stock_dimension.tbl_001`, `stock_dimension.tbl_002`, and so on.

Prepare load scripts

Note

You can postpone this step if your goal is to test a logical schema design for validity.

Prepare SQL scripts to load data directly into physical storage using [COPY on vsql](#), or through [ODBC](#).

You need scripts that load:

- Large tables
- Small tables

Vertica recommends that you load large tables using multiple files. To test the load process, use files of 10GB to 50GB in size. This size provides several advantages:

- You can use one of the data files as a sample data file for the [Database Designer](#).
- You can load just enough data to [Perform a partial data load](#) before you load the remainder.
- If a single load fails and rolls back, you do not lose an excessive amount of time.
- Once the load process is tested, for multi-terabyte tables, break up the full load in file sizes of 250–500GB.

See also

- [Data load](#)
- [Using load scripts](#)
- [Distributing a load](#)
- [Constraint enforcement](#)
- [Handling messy data](#)

Tip

You can use the load scripts included in the example databases as templates.

Create an optional sample query script

The purpose of a sample query script is to test your schema and load scripts for errors.

Include a sample of queries your users are likely to run against the database. If you don't have any real queries, just write simple SQL that collects counts on each of your tables. Alternatively, you can skip this step.

Create an empty database

Two options are available for creating an empty database:

- Using the [Management Console](#). For details, see [Creating a database using MC](#).
- Using [Administration tools](#).

Although you can create more than one database (for example, one for production and one for testing), there can be only one active database for each installation of Vertica Analytic Database.

In this section

- [Creating a database name and password](#)
- [Create a database using administration tools](#)

Creating a database name and password

Database names

Database names must conform to the following rules:

- Be between 1-30 characters
- Begin with a letter
- Follow with any combination of letters (upper and lowercase), numbers, and/or underscores.

Database names are case sensitive; however, Vertica strongly recommends that you do not create databases with names that differ only in case. For example, do not create a database called `mydatabase` and another called `MyDataBase`.

Database passwords

Database passwords can contain letters, digits, and special characters listed in the next table. Passwords cannot include non-ASCII Unicode characters.

The allowed password length is between 0-100 characters. The database superuser can change a Vertica user's maximum password length using [ALTER PROFILE](#).

You use [Profiles](#) to specify and control password definitions. For instance, a profile can define the maximum length, reuse time, and the minimum number or required digits for a password, as well as other details.

The following special (ASCII) characters are valid in passwords. Special characters can appear anywhere in a password string. For example, `mypas$word` or `$mypassword` are both valid, while `±mypassword` is not. Using special characters other than the ones listed below can cause database instability.

- #
- ?
- =
- _
- ' (single quote)
-)
- (
- @
- \
- /
- !
- ,
- ~
- :
- %

- {
- }
- |
- *
- \$
- " (double quote)

See also

- [Password guidelines](#)
- [ALTER PROFILE](#)
- [CREATE PROFILE](#)
- [DROP PROFILE](#)

Create a database using administration tools

1. Run the [Administration tools](#) from your [Administration host](#) as follows:

```
$ /opt/vertica/bin/admintools
```

If you are using a remote terminal application, such as PuTTY or a Cygwin bash shell, see [Notes for remote terminal users](#).

2. Accept the license agreement and specify the location of your license file. For more information see [Managing licenses](#) for more information. This step is necessary only if it is the first time you have run the Administration Tools
3. On the Main Menu, click **Configuration Menu**, and click **OK**.
4. On the Configuration Menu, click **Create Database**, and click **OK**.
5. Enter the name of the database and an optional comment, and click **OK**. See [Creating a database name and password](#) for naming guidelines and restrictions.
6. Establish the superuser password for your database.
 - To provide a password enter the password and click **OK**. Confirm the password by entering it again, and then click **OK**.
 - If you don't want to provide the password, leave it blank and click **OK**. If you don't set a password, Vertica prompts you to verify that you truly do not want to establish a superuser password for this database. Click **Yes** to create the database without a password or **No** to establish the password.

Caution

If you do not enter a password at this point, the superuser password is set to empty. Unless the database is for evaluation or academic purposes, Vertica strongly recommends that you enter a superuser password. See [Creating a database name and password](#) for guidelines.

7. Select the hosts to include in the database from the list of hosts specified when Vertica was installed (`install_vertica -s`), and click **OK**.
8. Specify the directories in which to store the data and [catalog](#) files, and click **OK**.

Note

Do not use a shared directory for more than one node. Data and catalog directories must be distinct for each node. Multiple nodes must not be allowed to write to the same data or catalog directory.

9. Catalog and data path names must contain only alphanumeric characters and cannot have leading spaces. Failure to comply with these restrictions results in database creation failure.
For example:
Catalog pathname: /home/dbadmin
Data Pathname: /home/dbadmin
10. Review the **Current Database Definition** screen to verify that it represents the database you want to create, and then click **Yes** to proceed or **No** to modify the database definition.
11. If you click **Yes**, Vertica creates the database you defined and then displays a message to indicate that the database was successfully created.

Note

For databases created with 3 or more nodes, Vertica automatically sets [K-safety](#) to 1 to ensure that the database is fault tolerant in case a node fails. For more information, see [Failure recovery](#) in the Administrator's Guide and [MARK DESIGN_KSAFE](#).

12. Click **OK** to acknowledge the message.

Create the logical schema

1. **Connect to the database**.
In the Administration Tools Main Menu, click **Connect to Database** and click **OK**.
See [Connecting to the Database](#) for details.
The vsql welcome script appears:

```
Welcome to vsql, the Vertica Analytic Database interactive terminal.
```

```
Type: \h or \? for help with vsql commands
```

```
\g or terminate with semicolon to execute query
```

```
\q to quit
```

```
=>
```

2. Run the logical schema script

Using the [\i meta-command](#) in vsql to run the SQL [logical schema script](#) that you prepared earlier.

3. Disconnect from the database

Use the [\q](#) meta-command in vsql to return to the Administration Tools.

Perform a partial data load

Vertica recommends that for large tables, you perform a partial data load and then test your database before completing a full data load. This load should load a representative amount of data.

1. Load the small tables.

Load the small table data files using the SQL [load scripts](#) and [data files](#) you prepared earlier.

2. Partially load the large tables.

Load 10GB to 50GB of table data for each table using the SQL [load scripts](#) and [data files](#) that you prepared earlier.

For more information about projections, see [Projections](#).

Test the database

Test the database to verify that it is running as expected.

Check queries for syntax errors and execution times.

1. Use the vsql [\timing meta-command](#) to enable the display of query execution time in milliseconds.
2. Execute the SQL sample query script that you prepared earlier.
3. Execute several ad hoc queries.

Optimize query performance

Optimizing the database consists of optimizing for compression and tuning for queries. (See [Creating a database design](#).)

To optimize the database, use the Database Designer to create and deploy a design for optimizing the database. See [Using Database Designer to create a comprehensive design](#).

After you run the Database Designer, use the techniques described in [Query optimization](#) to improve the performance of certain types of queries.

Note

The database response time depends on factors such as type and size of the application query, database design, data size and data types stored, available computational power, and network bandwidth. Adding nodes to a database cluster does not necessarily improve the system response time for every query, especially if the response time is already short, e.g., less than 10 seconds, or the response time is not hardware bound.

Complete the data load

To complete the load:

1. Monitor system resource usage.

Continue to run the [top](#), [free](#), and [df](#) utilities and watch them while your load scripts are running (as described in [Monitoring Linux resource usage](#)). You can do this on any or all nodes in the cluster. Make sure that the system is not swapping excessively (watch [kswapd](#) in [top](#)) or running out of swap space (watch for a large amount of used swap space in [free](#)).

Note

Vertica requires a dedicated server. If your loader or other processes take up significant amounts of RAM, it can result in swapping.

2. Complete the large table loads.
Run the remainder of the large table load scripts.

Test the optimized database

Check query execution times to test your optimized design:

1. Use the `vsq|` [timing](#) meta-command to enable the display of query execution time in milliseconds.
Execute a SQL sample query script to test your schema and load scripts for errors.

Note

Include a sample of queries your users are likely to run against the database. If you don't have any real queries, just write simple SQL that collects counts on each of your tables. Alternatively, you can skip this step.

2. Execute several ad hoc queries
 1. Run [Administration tools](#) and select [Connect to Database](#).
 2. Use the `\i` meta-command to execute the query script; for example:

```
vmartdb=> \i vmart_query_03.sql customer_name | annual_income
-----+-----
James M. McNulty |    999979
Emily G. Vogel   |    999998
(2 rows)
Time: First fetch (2 rows): 58.411 ms. All rows formatted: 58.448 ms
vmartdb=> \i vmart_query_06.sql
store_key | order_number | date_ordered
-----+-----+-----
 45 |    202416 | 2004-01-04
 113 |     66017 | 2004-01-04
 121 |   251417 | 2004-01-04
 24 |   250295 | 2004-01-04
 9 |   188567 | 2004-01-04
166 |    36008 | 2004-01-04
 27 |   150241 | 2004-01-04
148 |   182207 | 2004-01-04
198 |    75716 | 2004-01-04
(9 rows)
Time: First fetch (9 rows): 25.342 ms. All rows formatted: 25.383 ms
```

Once the database is optimized, it should run queries efficiently. If you discover queries that you want to optimize, you can modify and update the design [incrementally](#).

Implement locales for international data sets

Locale specifies the user's language, country, and any special variant preferences, such as collation. Vertica uses locale to determine the behavior of certain string functions. Locale also determines the collation for various SQL commands that require ordering and comparison, such as aggregate **GROUP BY** and **ORDER BY** clauses, joins, and the analytic **ORDER BY** clause.

The default locale for a Vertica database is `en_US@collation=binary` (English US). You can define a new default locale that is used for all sessions on the database. You can also override the locale for individual sessions. However, projections are always collated using the default `en_US@collation=binary` collation, regardless of the session collation. Any locale-specific collation is applied at query time.

If you set the locale to null, Vertica sets the locale to `en_US_POSIX`. You can set the locale back to the default locale and collation by issuing the `vsq|` meta-command `\locale`. For example:

Note

```
=> set locale to ";
INFO 2567: Canonical locale: 'en_US_POSIX'
Standard collation: 'LEN'
English (United States, Computer)
SET
=> \locale en_US@collation=binary;
INFO 2567: Canonical locale: 'en_US'
Standard collation: 'LEN_KBINARY'
English (United States)
=> \locale
en_US@collation-binary;
```

You can set locale through [ODBC](#), [JDBC](#), and [ADO.net](#).

ICU locale support

Vertica uses the ICU library for locale support; you must specify locale using the ICU locale syntax. The locale used by the database session is not derived from the operating system (through the [LANG](#) variable), so Vertica recommends that you set the [LANG](#) for each node running vsql, as described in the next section.

While ICU library services can specify collation, currency, and calendar preferences, Vertica supports only the collation component. Any keywords not relating to collation are rejected. Projections are always collated using the [en_US@collation=binary](#) collation regardless of the session collation. Any locale-specific collation is applied at query time.

The [SET DATESTYLE TO ...](#) command provides some aspects of the calendar, but Vertica supports only dollars as currency.

Changing DB locale for a session

This examples sets the session locale to Thai.

1. At the operating-system level for each node running vsql, set the [LANG](#) variable to the locale language as follows:

```
export LANG=th_TH.UTF-8
```

Note

If setting the [LANG=](#) as shown does not work, the operating system support for locales may not be installed.

2. For each Vertica session (from ODBC/JDBC or vsql) set the language locale.

From vsql:

```
\locale th_TH
```

3. From ODBC/JDBC:

```
"SET LOCALE TO th_TH;"
```

4. In PUTTY (or ssh terminal), change the settings as follows:

```
settings > window > translation > UTF-8
```

5. Click **Apply** and then click **Save**.

All data loaded must be in UTF-8 format, not an ISO format, as described in [Delimited data](#). Character sets like ISO 8859-1 (Latin1), which are incompatible with UTF-8, are not supported, so functions like SUBSTRING do not work correctly for multibyte characters. Thus, settings for locale should *not* work correctly. If the translation setting ISO-8859-11:2001 (Latin/Thai) works, the data is loaded incorrectly. To convert data correctly, use a utility program such as Linux [iconv](#).

Note

The maximum length parameter for VARCHAR and CHAR data type refers to the number of octets (bytes) that can be stored in that field, not the number of characters. When using multi-byte UTF-8 characters, make sure to size fields to accommodate from 1 to 4 bytes per character, depending on the data.

- [Supported locales](#)
- [About locale](#)
- [SET LOCALE](#)
- [ICU User Guide](#)

In this section

- [Specify the default locale for the database](#)
- [Override the default locale for a session](#)
- [Server versus client locale settings](#)

Specify the default locale for the database

After you start the database, the default locale configuration parameter, `DefaultSessionLocale`, sets the initial locale. You can override this value for individual sessions.

To set the locale for the database, use the configuration parameter as follows:

```
=> ALTER DATABASE DEFAULT SET DefaultSessionLocale = 'ICU-locale-identifier';
```

For example:

```
=> ALTER DATABASE DEFAULT SET DefaultSessionLocale = 'en_GB';
```

Override the default locale for a session

You can override the default locale for the current session in two ways:

- VSQL command `\locale`. For example:

```
=> \locale en_GBINFO:
INFO 2567: Canonical locale: 'en_GB'
Standard collation: 'LEN'
English (United Kingdom)
```

- SQL statement `SET LOCALE`. For example:

```
=> SET LOCALE TO en_GB;
INFO 2567: Canonical locale: 'en_GB'
Standard collation: 'LEN'
English (United Kingdom)
```

Both methods accept locale [short](#) and [long](#) forms. For example:

```
=> SET LOCALE TO LEN;
INFO 2567: Canonical locale: 'en'
Standard collation: 'LEN'
English
```

```
=> \locale LEN
INFO 2567: Canonical locale: 'en'
Standard collation: 'LEN'
English
```

- [SET LOCALE](#)

Server versus client locale settings

Vertica differentiates database server locale settings from client application locale settings:

- Server locale settings only impact collation behavior for server-side query processing.
- Client applications verify that locale is set appropriately in order to display characters correctly.

The following sections describe best practices to ensure predictable results.

Server locale

The server session locale should be set as described in [Specify the default locale for the database](#). If locales vary across different sessions, set the server locale at the start of each session from your client.

vsq client

- If the database does not have a default session locale, [set the server locale for the session to the desired locale](#).
- The locale setting in the terminal emulator where the vsq client runs should be set to be equivalent to session locale setting on the server side (ICU locale). By doing so, the data is collated correctly on the server and displayed correctly on the client.
- All input data for vsq should be in UTF-8, and all output data is encoded in UTF-8
- Vertica does not support non UTF-8 encodings and associated locale values; .
- For instructions on setting locale and encoding, refer to your terminal emulator documentation.

ODBC clients

- ODBC applications can be either in ANSI or Unicode mode. If the user application is Unicode, the encoding used by ODBC is UCS-2. If the user application is ANSI, the data must be in single-byte ASCII, which is compatible with UTF-8 used on the database server. The ODBC driver converts UCS-2 to UTF-8 when passing to the Vertica server and converts data sent by the Vertica server from UTF-8 to UCS-2.
- If the user application is not already in UCS-2, the application must convert the input data to UCS-2, or unexpected results could occur. For example:
 - For non-UCS-2 data passed to ODBC APIs, when it is interpreted as UCS-2, it could result in an invalid UCS-2 symbol being passed to the APIs, resulting in errors.
 - The symbol provided in the alternate encoding could be a valid UCS-2 symbol. If this occurs, incorrect data is inserted into the database.
- If the database does not have a default session locale, ODBC applications should set the desired server session locale using `SQLSetConnectAttr` (if different from database wide setting). By doing so, you get the expected collation and string functions behavior on the server.

JDBC and ADO.NET clients

- JDBC and ADO.NET applications use a UTF-16 character set encoding and are responsible for converting any non-UTF-16 encoded data to UTF-16. The same cautions apply as for ODBC if this encoding is violated.
- The JDBC and ADO.NET drivers convert UTF-16 data to UTF-8 when passing to the Vertica server and convert data sent by Vertica server from UTF-8 to UTF-16.
- If there is no default session locale at the database level, JDBC and ADO.NET applications should set the correct server session locale by executing the `SET LOCALE TO` command in order to get the expected collation and string functions behavior on the server. For more information, see [SET LOCALE](#).

Using time zones with Vertica

Vertica uses the public-domain [tz database](#) (time zone database), which contains code and data that represent the history of local time for locations around the globe. This database organizes time zone and daylight saving time data by partitioning the world into timezones whose clocks all agree on timestamps that are later than the POSIX Epoch (1970-01-01 00:00:00 UTC). Each timezone has a unique identifier. Identifiers typically follow the convention `area / location`, where `area` is a continent or ocean, and `location` is a specific location within the area—for example, Africa/Cairo, America/New_York, and Pacific/Honolulu.

Important

IANA acknowledge that 1970 is an arbitrary cutoff. They note the problems that face moving the cutoff earlier "due to the wide variety of local practices before computer timekeeping became prevalent." IANA's own description of the tz database suggests that users should regard historical dates and times, especially those that predate the POSIX epoch date, with a healthy measure of skepticism. For details, see [Theory and pragmatics of the tz code and data](#).

Vertica uses the `TZ` environment variable (if set) on each node for the default current time zone. Otherwise, Vertica uses the operating system time zone.

The `TZ` variable can be set by the operating system during login (see `/etc/profile`, `/etc/profile.d`, or `/etc/bashrc`) or by the user in `.profile`, `.bashrc` or `.bash-profile`. `TZ` must be set to the same value on each node when you start Vertica.

The following command returns the current time zone for your database:

```
=> SHOW TIMEZONE;
name | setting
-----+-----
timezone | America/New_York
(1 row)
```

You can also set the time zone for a single session with [SET TIME ZONE](#).

Conversion and storage of date/time data

There is no database default time zone. [TIMESTAMPTZ](#) (TIMESTAMP WITH TIMEZONE) data is converted from the current local time and stored as GMT/UTC (Greenwich Mean Time/Coordinated Universal Time).

When TIMESTAMPTZ data is used, data is converted back to the current local time zone, which might be different from the local time zone where the data was stored. This conversion takes into account daylight saving time (summer time), depending on the year and date to determine when daylight saving time begins and ends.

TIMESTAMP WITHOUT TIMEZONE data stores the timestamp as given, and retrieves it exactly as given. The current time zone is ignored. The same is true for TIME WITHOUT TIMEZONE. For TIME WITH TIMEZONE (TIMETZ), however, the current time zone setting is stored along with the given time, and that time zone is used on retrieval.

Note

Vertica recommends that you use TIMESTAMPTZ, not TIMETZ.

Querying data/time data

TIMESTAMPTZ uses the current time zone on both input and output, as in the following example:

```
=> CREATE TEMP TABLE s (tstz TIMESTAMPTZ);=> SET TIMEZONE TO 'America/New_York';
=> INSERT INTO s VALUES ('2009-02-01 00:00:00');
=> INSERT INTO s VALUES ('2009-05-12 12:00:00');
=> SELECT tstz AS 'Local timezone', tstz AT TIMEZONE 'America/New_York' AS 'America/New_York',
   tstz AT TIMEZONE 'GMT' AS 'GMT' FROM s;
   Local timezone | America/New_York | GMT
-----+-----+-----
2009-02-01 00:00:00-05 | 2009-02-01 00:00:00 | 2009-02-01 05:00:00
2009-05-12 12:00:00-04 | 2009-05-12 12:00:00 | 2009-05-12 16:00:00
(2 rows)
```

The **-05** in the Local time zone column shows that the data is displayed in EST, while **-04** indicates EDT. The other two columns show the TIMESTAMP WITHOUT TIMEZONE at the specified time zone.

The next example shows what happens if the current time zone is changed to GMT:

```
=> SET TIMEZONE TO 'GMT';=> SELECT tstz AS 'Local timezone', tstz AT TIMEZONE 'America/New_York' AS
   'America/New_York', tstz AT TIMEZONE 'GMT' as 'GMT' FROM s;
   Local timezone | America/New_York | GMT
-----+-----+-----
2009-02-01 05:00:00+00 | 2009-02-01 00:00:00 | 2009-02-01 05:00:00
2009-05-12 16:00:00+00 | 2009-05-12 12:00:00 | 2009-05-12 16:00:00
(2 rows)
```

The **+00** in the Local time zone column indicates that TIMESTAMPTZ is displayed in GMT.

The approach of using TIMESTAMPTZ fields to record events captures the GMT of the event, as expressed in terms of the local time zone. Later, it allows for easy conversion to any other time zone, either by setting the local time zone or by specifying an explicit AT TIMEZONE clause.

The following example shows how TIMESTAMP WITHOUT TIMEZONE fields work in Vertica.

```
=> CREATE TEMP TABLE tnoz (ts TIMESTAMP);=> INSERT INTO tnoz VALUES('2009-02-01 00:00:00');
=> INSERT INTO tnoz VALUES('2009-05-12 12:00:00');
=> SET TIMEZONE TO 'GMT';
=> SELECT ts AS 'No timezone', ts AT TIMEZONE 'America/New_York' AS
   'America/New_York', ts AT TIMEZONE 'GMT' AS 'GMT' FROM tnoz;
   No timezone | America/New_York | GMT
-----+-----+-----
2009-02-01 00:00:00 | 2009-02-01 05:00:00+00 | 2009-02-01 00:00:00+00
2009-05-12 12:00:00 | 2009-05-12 16:00:00+00 | 2009-05-12 12:00:00+00
(2 rows)
```

The `+00` at the end of a timestamp indicates that the setting is `TIMESTAMP WITH TIMEZONE` in GMT (the current time zone). The `America/New_York` column shows what the GMT setting was when you recorded the time, assuming you read a normal clock in the `America/New_York` time zone. What this shows is that if it is midnight in the `America/New_York` time zone, then it is 5 am GMT.

Note

00:00:00 Sunday February 1, 2009 in `America/New_York` converts to 05:00:00 Sunday February 1, 2009 in GMT.

The `GMT` column displays the GMT time, assuming the input data was captured in GMT.

If you don't set the time zone to GMT, and you use another time zone, for example `America/New_York`, then the results display in `America/New_York` with a `-05` and `-04`, showing the difference between that time zone and GMT.

```
=> SET TIMEZONE TO 'America/New_York';
=> SHOW TIMEZONE;
  name |  setting
-----+-----
 timezone | America/New_York
(1 row)
=> SELECT ts AS 'No timezone', ts AT TIMEZONE 'America/New_York' AS
 'America/New_York', ts AT TIMEZONE 'GMT' AS 'GMT' FROM tnoz;
  No timezone | America/New_York |  GMT
-----+-----+-----
2009-02-01 00:00:00 | 2009-02-01 00:00:00-05 | 2009-01-31 19:00:00-05
2009-05-12 12:00:00 | 2009-05-12 12:00:00-04 | 2009-05-12 08:00:00-04
(2 rows)
```

In this case, the last column is interesting in that it returns the time in New York, given that the data was captured in GMT.

- [SET TIME ZONE](#)
- [Date/time data types](#)

Change transaction isolation levels

By default, Vertica uses the `READ COMMITTED` isolation level for all sessions. You can change the default isolation level for the database or for a given session.

A transaction retains its isolation level until it completes, even if the session's isolation level changes during the transaction. Vertica internal processes (such as the [Tuple Mover](#) and [refresh](#) operations) and DDL operations always run at the `SERIALIZABLE` isolation level to ensure consistency.

Database isolation level

The configuration parameter [TransactionIsolationLevel](#) specifies the database isolation level, and is used as the default for all sessions. Use [ALTER DATABASE](#) to change the default isolation level. For example:

```
=> ALTER DATABASE DEFAULT SET TransactionIsolationLevel = 'SERIALIZABLE';
ALTER DATABASE
=> ALTER DATABASE DEFAULT SET TransactionIsolationLevel = 'READ COMMITTED';
ALTER DATABASE
```

Changes to the database isolation level only apply to future sessions. Existing sessions and their transactions continue to use their original isolation level.

Use [SHOW CURRENT](#) to view the database isolation level:

```
=> SHOW CURRENT TransactionIsolationLevel;
 level |  name      |  setting
-----+-----
 DATABASE | TransactionIsolationLevel | READ COMMITTED
(1 row)
```

Session isolation level

[SET SESSION CHARACTERISTICS AS TRANSACTION](#) changes the isolation level for a specific session. For example:

```
=> SET SESSION CHARACTERISTICS AS TRANSACTION ISOLATION LEVEL SERIALIZABLE;
SET
```

Use [SHOW](#) to view the current session's isolation level:

```
=> SHOW TRANSACTION_ISOLATION;
```

See also

[Transactions](#)

Configuration parameter management

Vertica supports a wide variety of configuration parameters that affect many facets of database behavior. These parameters can be set with the appropriate ALTER statements at one or more levels, listed here in descending order of precedence:

1. User ([ALTER USER](#))
2. Session ([ALTER SESSION](#))
3. Node ([ALTER NODE](#))
4. Database ([ALTER DATABASE](#))

Not all parameters can be set at all levels. Consult the documentation of individual parameters for restrictions.

You can query the [CONFIGURATION_PARAMETERS](#) system table to obtain the current settings for all user-accessible parameters. For example, the following query returns settings for partitioning parameters: their current and default values, which levels they can be set at, and whether changes require a database restart to take effect:

```
=> SELECT parameter_name, current_value, default_value, allowed_levels, change_requires_restart
FROM configuration_parameters WHERE parameter_name ILIKE '%partitioncount%';
parameter_name | current_value | default_value | allowed_levels | change_requires_restart
-----+-----+-----+-----+-----
MaxPartitionCount | 1024 | 1024 | NODE, DATABASE | F
ActivePartitionCount | 1 | 1 | NODE, DATABASE | F
(2 rows)
```

For details about individual configuration parameters grouped by category, see [Configuration parameters](#).

Setting and clearing configuration parameters

You change specific configuration parameters with the appropriate ALTER statements; the same statements also let you reset configuration parameters to their default values. For example, the following ALTER statements change ActivePartitionCount at the database level from 1 to 2, and DisablePartitionCount at the session level from 0 to 1:

```
=> ALTER DATABASE DEFAULT SET ActivePartitionCount = 2;
ALTER DATABASE
=> ALTER SESSION SET DisableAutopartition = 1;
ALTER SESSION
=> SELECT parameter_name, current_value, default_value FROM configuration_parameters
WHERE parameter_name IN ('ActivePartitionCount', 'DisableAutopartition');
parameter_name | current_value | default_value
-----+-----+-----
ActivePartitionCount | 2 | 1
DisableAutopartition | 1 | 0
(2 rows)
```

You can later reset the same configuration parameters to their default values:

```

=> ALTER DATABASE DEFAULT CLEAR ActivePartitionCount;
ALTER DATABASE
=> ALTER SESSION CLEAR DisableAutopartition;
ALTER DATABASE
=> SELECT parameter_name, current_value, default_value FROM configuration_parameters
   WHERE parameter_name IN ('ActivePartitionCount', 'DisableAutopartition');
parameter_name | current_value | default_value
-----+-----+-----
DisableAutopartition | 0          | 0
ActivePartitionCount | 1          | 1
(2 rows)

```

Caution

Vertica is designed to operate with minimal configuration changes. Be careful to change configuration parameters according to documented guidelines.

In this section

- [Viewing configuration parameter values](#)

Viewing configuration parameter values

You can view active configuration parameter values in two ways:

- [SHOW statements](#)
- [Query related system tables](#)

SHOW statements

Use the following **SHOW** statements to view active configuration parameters:

- **SHOW CURRENT**: Returns settings of active configuration parameter values. Vertica checks settings at all levels, in the following ascending order of precedence:
 - session
 - node
 - database
 If no values are set at any scope, SHOW CURRENT returns the parameter's default value.
- **SHOW DATABASE**: Displays configuration parameter values set for the database.
- **SHOW USER**: Displays configuration parameters set for the specified user, and for all users.
- **SHOW SESSION**: Displays configuration parameter values set for the current session.
- **SHOW NODE**: Displays configuration parameter values set for a node.

If a configuration parameter requires a restart to take effect, the values in a **SHOW CURRENT** statement might differ from values in other **SHOW** statements. To see which parameters require restart, query the [CONFIGURATION_PARAMETERS](#) system table.

System tables

You can query several system tables for configuration parameters:

- [SESSION_PARAMETERS](#) returns session-scope parameters.
- [CONFIGURATION_PARAMETERS](#) returns parameters for all scopes: database, node, and session.
- [USER_CONFIGURATION_PARAMETERS](#) provides information about [user-level configuration parameters](#) that are in effect for database users.

Designing a logical schema

Designing a logical schema for a Vertica database is the same as designing for any other SQL database. A logical schema consists of objects such as schemas, tables, [views](#) and [referential integrity constraints](#) that are visible to SQL users. Vertica supports any relational schema design that you choose.

In this section

- [Using multiple schemas](#)
- [Tables in schemas](#)

Using multiple schemas

Using a single schema is effective if there is only one database user or if a few users cooperate in sharing the database. In many cases, however, it makes sense to use additional schemas to allow users and their applications to create and access tables in separate namespaces. For example, using additional schemas allows:

- Many users to access the database without interfering with one another. Individual schemas can be configured to grant specific users access to the schema and its tables while restricting others.
- Third-party applications to create tables that have the same name in different schemas, preventing table collisions.

Unlike other RDBMS, a schema in a Vertica database is not a collection of objects bound to one user.

In this section

- [Multiple schema examples](#)
- [Creating schemas](#)
- [Specifying objects in multiple schemas](#)
- [Setting search paths](#)
- [Creating objects that span multiple schemas](#)

Multiple schema examples

This section provides examples of when and how you might want to use multiple schemas to separate database users. These examples fall into two categories: using multiple private schemas and using a combination of private schemas (i.e. schemas limited to a single user) and shared schemas (i.e. schemas shared across multiple users).

Using multiple private schemas

Using multiple private schemas is an effective way of separating database users from one another when sensitive information is involved. Typically a user is granted access to only one schema and its contents, thus providing database security at the schema level. Database users can be running different applications, multiple copies of the same application, or even multiple instances of the same application. This enables you to consolidate applications on one database to reduce management overhead and use resources more effectively. The following examples highlight using multiple private schemas.

Using multiple schemas to separate users and their unique applications

In this example, both database users work for the same company. One user (HRUser) uses a Human Resource (HR) application with access to sensitive personal data, such as salaries, while another user (MedUser) accesses information regarding company healthcare costs through a healthcare management application. HRUser should not be able to access company healthcare cost information and MedUser should not be able to view personal employee data.

To grant these users access to data they need while restricting them from data they should not see, two schemas are created with appropriate user access, as follows:

- HRSchema—A schema owned by HRUser that is accessed by the HR application.
- HealthSchema—A schema owned by MedUser that is accessed by the healthcare management application.

Using multiple schemas to support multitenancy

This example is similar to the last example in that access to sensitive data is limited by separating users into different schemas. In this case, however, each user is using a virtual instance of the same application.

An example of this is a retail marketing analytics company that provides data and software as a service (SaaS) to large retailers to help them determine which promotional methods they use are most effective at driving customer sales.

In this example, each database user equates to a retailer, and each user only has access to its own schema. The retail marketing analytics company provides a virtual instance of the same application to each retail customer, and each instance points to the user's specific schema in which to create and update tables. The tables in these schemas use the same names because they are created by instances of the same application, but they do not conflict because they are in separate schemas.

Example of schemas in this database could be:

- MartSchema—A schema owned by MartUser, a large department store chain.
- PharmSchema—A schema owned by PharmUser, a large drug store chain.

Using multiple schemas to migrate to a newer version of an application

Using multiple schemas is an effective way of migrating to a new version of a software application. In this case, a new schema is created to support the new version of the software, and the old schema is kept as long as necessary to support the original version of the software. This is called a “rolling application upgrade.”

For example, a company might use a HR application to store employee data. The following schemas could be used for the original and updated versions of the software:

- HRSchema—A schema owned by HRUser, the schema user for the original HR application.
- V2HRSchema—A schema owned by V2HRUser, the schema user for the new version of the HR application.

Combining private and shared schemas

The previous examples illustrate cases in which all schemas in the database are private and no information is shared between users. However, users might want to share common data. In the retail case, for example, MartUser and PharmUser might want to compare their per store sales of a particular product against the industry per store sales average. Since this information is an industry average and is not specific to any retail chain, it can be placed in a schema on which both users are granted [USAGE privileges](#).

Example of schemas in this database might be:

- MartSchema—A schema owned by MartUser, a large department store chain.
- PharmSchema—A schema owned by PharmUser, a large drug store chain.
- IndustrySchema—A schema owned by DBUser (from the retail marketing analytics company) on which both MartUser and PharmUser have USAGE privileges. It is unlikely that retailers would be given any privileges beyond USAGE on the schema and SELECT on one or more of its tables.

Creating schemas

You can create as many schemas as necessary for your database. For example, you could create a schema for each database user. However, schemas and users are not synonymous as they are in Oracle.

By default, only a superuser can create a schema or give a user the right to create a schema. (See [GRANT \(database\)](#) in the SQL Reference Manual.)

To create a schema use the [CREATE SCHEMA](#) statement, as described in the SQL Reference Manual.

Specifying objects in multiple schemas

Once you create two or more schemas, each SQL statement or function must identify the schema associated with the object you are referencing. You can specify an object within multiple schemas by:

- Qualifying the object name by using the schema name and object name separated by a dot. For example, to specify `MyTable`, located in `Schema1`, qualify the name as `Schema1.MyTable`.
- Using a search path that includes the desired schemas when a referenced object is unqualified. By [Setting search paths](#), Vertica will automatically search the specified schemas to find the object.

Setting search paths

Each user session has a search path of schemas. Vertica uses this search path to find tables and user-defined functions (UDFs) that are unqualified by their schema name. A session search path is initially set from the user's profile. You can change the session's search path at any time by calling [SET SEARCH_PATH](#). This search path remains in effect until the next [SET SEARCH_PATH](#) statement, or the session ends.

Viewing the current search path

[SHOW SEARCH_PATH](#) returns the session's current search path. For example:

```
=> SHOW SEARCH_PATH;
 name |          setting
-----+-----
search_path | "$user", public, v_catalog, v_monitor, v_internal
```

Schemas are listed in descending order of precedence. The first schema has the highest precedence in the search order. If this schema exists, it is also defined as the current schema, which is used for tables that are created with unqualified names. You can identify the current schema by calling the function [CURRENT_SCHEMA](#):

```
=> SELECT CURRENT_SCHEMA;
```

```
current_schema
```

```
public
```

```
(1 row)
```

Setting the user search path

A session search path is initially set from the user's profile. If the search path in a user profile is not set by [CREATE USER](#) or [ALTER USER](#), it is set to the database default:

```
=> CREATE USER agent007;
```

```
CREATE USER
```

```
=> \c - agent007
```

```
You are now connected as user "agent007".
```

```
=> SHOW SEARCH_PATH;
```

```
name | setting
```

```
search_path | "$user", public, v_catalog, v_monitor, v_internal
```

`$user` resolves to the session user name—in this case, `agent007`—and has the highest precedence. If a schema `agent007` exists, Vertica begins searches for unqualified tables in that schema. Also, calls to [CURRENT_SCHEMA](#) return this schema. Otherwise, Vertica uses `public` as the current schema and begins searches in it.

Use [ALTER USER](#) to modify an existing user's search path. These changes overwrite all non-system schemas in the search path, including `$USER`. System schemas are untouched. Changes to a user's search path take effect only when the user starts a new session; current sessions are unaffected.

Important

After modifying the user's search path, [verify that the user has access privileges](#) to all schemas that are on the updated search path.

For example, the following statements modify `agent007`'s search path, and grant access privileges to schemas and tables that are on the new search path:

```
=> ALTER USER agent007 SEARCH_PATH store, public;
```

```
ALTER USER
```

```
=> GRANT ALL ON SCHEMA store, public TO agent007;
```

```
GRANT PRIVILEGE
```

```
=> GRANT SELECT ON ALL TABLES IN SCHEMA store, public TO agent007;
```

```
GRANT PRIVILEGE
```

```
=> \c - agent007
```

```
You are now connected as user "agent007".
```

```
=> SHOW SEARCH_PATH;
```

```
name | setting
```

```
search_path | store, public, v_catalog, v_monitor, v_internal
```

```
(1 row)
```

To verify a user's search path, query the system table [USERS](#):

```
=> SELECT search_path FROM USERS WHERE user_name='agent007';
```

```
search_path
```

```
store, public, v_catalog, v_monitor, v_internal
```

```
(1 row)
```

To revert a user's search path to the database default settings, call [ALTER USER](#) and set the search path to `DEFAULT`. For example:

```

=> ALTER USER agent007 SEARCH_PATH DEFAULT;
ALTER USER
=> SELECT search_path FROM USERS WHERE user_name='agent007';
      search_path
-----
"$user", public, v_catalog, v_monitor, v_internal
(1 row)

```

Ignored search path schemas

Vertica only searches among existing schemas to which the current user has access privileges. If a schema in the search path does not exist or the user lacks access privileges to it, Vertica silently excludes it from the search. For example, if `agent007` lacks `SELECT` privileges to schema `public`, Vertica silently skips this schema. Vertica returns with an error only if it cannot find the table anywhere on the search path.

Setting session search path

Vertica initially sets a session's search path from the user's profile. You can change the current session's search path with [SET SEARCH_PATH](#). You can use [SET SEARCH_PATH](#) in two ways:

- Explicitly set the session search path to one or more schemas. For example:

```

=> \c - agent007
You are now connected as user "agent007".
dbadmin=> SHOW SEARCH_PATH;
  name |          setting
-----+-----
search_path | "$user", public, v_catalog, v_monitor, v_internal
(1 row)

=> SET SEARCH_PATH TO store, public;
SET
=> SHOW SEARCH_PATH;
  name |          setting
-----+-----
search_path | store, public, v_catalog, v_monitor, v_internal
(1 row)

```

- Set the session search path to the database default:

```

=> SET SEARCH_PATH TO DEFAULT;
SET
=> SHOW SEARCH_PATH;
  name |          setting
-----+-----
search_path | "$user", public, v_catalog, v_monitor, v_internal
(1 row)

```

[SET SEARCH_PATH](#) overwrites all non-system schemas in the search path, including `$USER`. System schemas are untouched.

Creating objects that span multiple schemas

Vertica supports [views](#) that reference tables across multiple schemas. For example, a user might need to compare employee salaries to industry averages. In this case, the application queries two schemas:

- Shared schema `IndustrySchema` for salary averages
- Private schema `HRSchema` for company-specific salary information

Best Practice: When creating objects that span schemas, use qualified table names. This naming convention avoids confusion if the query path or table structure within the schemas changes at a later date.

Tables in schemas

In Vertica you can create persistent and temporary tables, through [CREATE TABLE](#) and [CREATE TEMPORARY TABLE](#), respectively.

For detailed information on both types, see [Creating Tables](#) and [Creating temporary tables](#).

Persistent tables

[CREATE TABLE](#) creates a table in the Vertica [logical schema](#). For example:

```
CREATE TABLE vendor_dimension (
  vendor_key    INTEGER    NOT NULL PRIMARY KEY,
  vendor_name   VARCHAR(64),
  vendor_address VARCHAR(64),
  vendor_city   VARCHAR(64),
  vendor_state  CHAR(2),
  vendor_region VARCHAR(32),
  deal_size     INTEGER,
  last_deal_update DATE
);
```

For detailed information, see [Creating Tables](#).

Temporary tables

[CREATE TEMPORARY TABLE](#) creates a table whose data persists only during the current session. Temporary table data is never visible to other sessions.

Temporary tables can be used to divide complex query processing into multiple steps. Typically, a reporting tool holds intermediate results while reports are generated—for example, the tool first gets a result set, then queries the result set, and so on.

[CREATE TEMPORARY TABLE](#) can create tables at two scopes, global and local, through the keywords [GLOBAL](#) and [LOCAL](#), respectively:

- [GLOBAL](#) (default): The table definition is visible to all sessions. However, table data is session-scoped.
- [LOCAL](#): The table definition is visible only to the session in which it is created. When the session ends, Vertica automatically drops the table.

For detailed information, see [Creating temporary tables](#).

Creating a database design

A *design* is a physical storage plan that optimizes query performance. Data in Vertica is physically stored in projections. When you initially load data into a table using `INSERT`, `COPY` (or `COPY LOCAL`), Vertica creates a default [superprojection](#) for the table. This superprojection ensures that all of the data is available for queries. However, these superprojections might not optimize database performance, resulting in slow query performance and low data compression.

To improve performance, create a design for your Vertica database that optimizes query performance and data compression. You can create a design in several ways:

- [Use Database Designer](#), a tool that recommends a design for optimal performance.
- [Manually create a design](#)
- Use Database Designer to create an initial design and then manually modify it.

Database Designer can help you minimize how much time you spend on manual database tuning. You can also use Database Designer to redesign the database incrementally as requirements such as workloads change over time.

Database Designer runs as a background process. This is useful if you have a large design that you want to run overnight. An active SSH session is not required, so design and deploy operations continue to run uninterrupted if the session ends.

Tip

Vertica recommends that you first globally optimize your database using the Comprehensive setting in Database Designer. If the performance of the comprehensive design is not adequate, you can design custom projections using an incremental design and manually, as described in [Creating custom designs](#).

In this section

- [About Database Designer](#)
- [How Database Designer creates a design](#)
- [Database Designer access requirements](#)
- [Logging projection data for Database Designer](#)
- [General design settings](#)
- [Building a design](#)
- [Resetting a design](#)
- [Deploying a design](#)
- [How to create a design](#)
- [Running Database Designer programmatically](#)
- [Creating custom designs](#)

About Database Designer

Vertica Database Designer uses sophisticated strategies to create a design that provides excellent performance for ad-hoc queries and specific queries while using disk space efficiently.

During the design process, Database Designer analyzes the logical schema definition, sample data, and sample queries, and creates a physical schema ([projections](#)) in the form of a SQL script that you deploy automatically or manually. This script creates a minimal set of superprojections to ensure K-safety.

In most cases, the projections that Database Designer creates provide excellent query performance within physical constraints while using disk space efficiently.

General design options

When you run Database Designer, several general options are available:

- Create a comprehensive or incremental design.
- Optimize for query execution, load, or a balance of both.
- Require K-safety.
- Recommend unsegmented projections when feasible.
- Analyze statistics before creating the design.

Design input

Database Designer bases its design on the following information that you provide:

- **Design queries** that you typically run during normal database operations.
- **Design tables** that contain sample data.

Output

Database Designer yields the following output:

- [Design script](#) that creates the projections for the design in a way that meets the optimization objectives and distributes data uniformly across the cluster.
- [Deployment script](#) that creates and refreshes the projections for your design. For comprehensive designs, the deployment script contains commands that remove non-optimized projections. The deployment script includes the full design script.
- [Backup script](#) that contains SQL statements to deploy the design that existed on the system before deployment. This file is useful in case you need to revert to the pre-deployment design.

Design restrictions

Database Designer-generated designs:

- Exclude live aggregate or Top-K projections. You must create these manually. See [CREATE PROJECTION](#).

- Do not sort, segment, or partition projections on LONG VARBINARY and LONG VARCHAR columns.
- Do not support operations on complex types.

Post-design options

While running Database Designer, you can choose to deploy your design automatically after the deployment script is created, or to deploy it manually, after you have reviewed and tested the design. Vertica recommends that you test the design on a non-production server before deploying the design to your production server.

How Database Designer creates a design

Design recommendations

Database Designer-generated designs can include the following recommendations:

- Sort [buddy projections](#) in the same order, which can significantly improve load, recovery, and site node performance. All buddy projections have the same base name so that they can be identified as a group.

Note

If you manually create projections, Database Designer recommends a buddy with the same sort order, if one does not already exist. By default, Database Designer recommends both super and non-super segmented projections with a buddy of the same sort order and segmentation.

- Accepts unlimited queries for a comprehensive design.
- Identifies similar design queries and assigns them a signature.
For queries with the same signature, Database Designer weights the queries, depending on how many queries have that signature. It then considers the weighted query when creating a design.
- Recommends and creates projections in a way that minimizes data skew by distributing data uniformly across the cluster.
- Produces higher quality designs by considering UPDATE, DELETE, and SELECT statements.

Database Designer access requirements

By default, only users with the DBADMIN role can run Database Designer. Non-DBADMIN users can run Database Designer only if they are granted the necessary privileges and DBDUSER role, as described below. You can also enable users to run Database Designer on the Management Console (see [Enabling Users to run Database Designer on Management Console](#)).

1. Add a temporary folder to all cluster nodes with [CREATE LOCATION](#) :

```
=> CREATE LOCATION '/tmp/dbd' ALL NODES;
```

2. Grant the desired user CREATE privileges to create schemas on the current (DEFAULT) database, with [GRANT DATABASE](#) :

```
=> GRANT CREATE ON DATABASE DEFAULT TO dbd-user;
```

3. Grant the DBDUSER role to *dbd-user* with [GRANT ROLE](#) :

```
=> GRANT DBDUSER TO dbd-user;
```

4. On all nodes in the cluster, grant *dbd-user* access to the temporary folder with [GRANT LOCATION](#) :

```
=> GRANT ALL ON LOCATION '/tmp/dbd' TO dbd-user;
```

5. Grant *dbd-user* privileges on one or more database schemas and their tables, with [GRANT SCHEMA](#) and [GRANT TABLE](#) , respectively:

```
=> GRANT ALL ON SCHEMA this-schema[...] TO dbd-user;
```

```
=> GRANT ALL ON ALL TABLES IN SCHEMA this-schema[...] TO dbd-user;
```

6. Enable the DBDUSER role on *dbd-user* in one of the following ways:

- As *dbd-user* , enable the DBDUSER role with [SET ROLE](#) :

```
=> SET ROLE DBDUSER;
```

- As DBADMIN, automatically enable the DBDUSER role for *dbd-user* on each login, with [ALTER USER](#) :

```
=> ALTER USER dbd-user DEFAULT ROLE DBDUSER;
```

Important

When you grant the DBDUSER role, be sure to [associate a resource pool with that user](#) to manage resources while Database Designer runs.

Multiple users can run Database Designer concurrently without interfering with each other or exhausting cluster resources. When a user runs Database Designer, either with Management Console or programmatically, execution is generally contained by the user's resource pool, but might spill over into system resource pools for less-intensive tasks.

Enabling users to run Database Designer on Management Console

Users who are already granted the DBDUSER role and required privileges, as described [above](#), can also be enabled to run Database Designer on [Management Console](#):

1. Log in as a superuser to Management Console.
2. Click **MC Settings**.
3. Click **User Management**.
4. Specify an MC user:
 - To create an MC user, click **Add**.
 - To use an existing MC user, select the user and click **Edit**.
5. Next to the **DB access level** window, click **Add**.
6. In the **Add Permissions** window:
 1. From the **Choose a database** drop-down list, select the database on which to create a design.
 2. In the **Database username** field, enter the *dbd-user* user name that you created [earlier](#).
 3. In the Database password field, enter the database password.
 4. In the **Restrict access** drop-down list, select the level of MC user for this user.
7. Click **OK** to save your changes.
8. Log out of the MC Super user account.

The MC user is now mapped to *dbd-user*. Log in as the MC user and use Database Designer to create an optimized design for your database.

DBDUSER capabilities and limitations

As a DBDUSER, the following constraints apply:

- Designs must set K-safety to be equal to system K-safety. If a design violates K-safety by lacking enough buddy projections for tables, the design does not complete.
- You cannot explicitly advance the ancient history mark (AHM)—for example, call [MAKE_AHM_NOW](#)—until after deploying the design.

When you create a design, you automatically have privileges to manipulate that design. Other tasks might require additional privileges:

Task	Required privileges
Submit design tables	<ul style="list-style-type: none"> • USAGE on the design table schema • OWNER on the design table
Submit a single design query	<ul style="list-style-type: none"> • EXECUTE on the design query
Submit a file of design queries	<ul style="list-style-type: none"> • READ privilege on the storage location that contains the query file • EXECUTE privilege on all queries in the file
Submit design queries from results of a user query	<ul style="list-style-type: none"> • EXECUTE privilege on the user queries • EXECUTE privilege on each design query retrieved from the results of the user query
Create design and deployment scripts	<ul style="list-style-type: none"> • WRITE privilege on the storage location of the design script • WRITE privilege on the storage location of the deployment script

Logging projection data for Database Designer

When you run Database Designer, the Optimizer proposes a set of ideal projections based on the options that you specify. When you deploy the design, Database Designer creates the design based on these projections. However, space or budget constraints may prevent Database Designer from creating all the proposed projections. In addition, Database Designer may not be able to implement the projections using ideal criteria.

To get information about the projections, first enable the Database Designer logging capability. When enabled, Database Designer stores information about the proposed projections in two Data Collector tables. After Database Designer deploys the design, these logs contain information about which proposed projections were actually created. After deployment, the logs contain information about:

- Projections that the Optimizer proposed
- Projections that Database Designer actually created when the design was deployed
- Projections that Database Designer created, but not with the ideal criteria that the Optimizer identified.
- The DDL used to create all the projections
- Column optimizations

If you do not deploy the design immediately, review the log to determine if you want to make any changes. If the design has been deployed, you can still manually create some of the projections that Database Designer did not create.

To enable the Database Designer logging capability, see [Enabling logging for Database Designer](#).

To view the logged information, see [Viewing Database Designer logs](#).

In this section

- [Enabling logging for Database Designer](#)
- [Viewing Database Designer logs](#)
- [Database Designer logs: example data](#)

Enabling logging for Database Designer

By default, Database Designer does not log information about the projections that the Optimizer proposed and the Database Designer deploys.

To enable Database Designer logging, enter the following command:

```
=> ALTER DATABASE DEFAULT SET DBDLogInternalDesignProcess = 1;
```

To disable Database Designer logging, enter the following command:

```
=> ALTER DATABASE DEFAULT SET DBDLogInternalDesignProcess = 0;
```

See also

- [Logging projection data for Database Designer](#)
- [Viewing Database Designer logs](#)

Viewing Database Designer logs

You can find data about the projections that Database Designer considered and deployed in two Data Collector tables:

- DC_DESIGN_PROJECTION_CANDIDATES
- DC_DESIGN_QUERY_PROJECTION_CANDIDATES

DC_DESIGN_PROJECTION_CANDIDATES

The DC_DESIGN_PROJECTION_CANDIDATES table contains information about all the projections that the Optimizer proposed. This table also includes the DDL that creates them. The `is_a_winner` field indicates if that projection was part of the actual deployed design. To view the DC_DESIGN_PROJECTION_CANDIDATES table, enter:

```
=> SELECT * FROM DC_DESIGN_PROJECTION_CANDIDATES;
```

DC_DESIGN_QUERY_PROJECTION_CANDIDATES

The DC_DESIGN_QUERY_PROJECTION_CANDIDATES table lists plan features for all design queries.

Possible features are:

- FULLY DISTRIBUTED JOIN
- MERGE JOIN
- GROUPBY PIPE
- FULLY DISTRIBUTED GROUPBY
- RLE PREDICATE
- VALUE INDEX PREDICATE
- LATE MATERIALIZATION

For all design queries, the DC_DESIGN_QUERY_PROJECTION_CANDIDATES table includes the following plan feature information:

- Optimizer path cost.
- Database Designer benefits.
- Ideal plan feature and its description, which identifies how the referenced projection should be optimized.
- If the design was deployed, the actual plan feature and its description is included in the table. This information identifies how the referenced projection was actually optimized.

Because most projections have multiple optimizations, each projection usually has multiple rows. To view the DC_DESIGN_QUERY_PROJECTION_CANDIDATES table, enter:

```
=> SELECT * FROM DC_DESIGN_QUERY_PROJECTION_CANDIDATES;
```

To see example data from these tables, see [Database Designer logs: example data](#).

Database Designer logs: example data

In the following example, Database Designer created the logs after creating a comprehensive design for the VMart sample database. The output shows two records from the DC_DESIGN_PROJECTION_CANDIDATES table.

The first record contains information about the customer_dimension_dbd_1_sort_\$customer_gender__\$annual_income\$ projection. The record includes the CREATE PROJECTION statement that Database Designer used to create the projection. The **is_a_winner** column is **t**, indicating that Database Designer created this projection when it deployed the design.

The second record contains information about the product_dimension_dbd_2_sort_\$product_version__\$product_key\$ projection. For this projection, the **is_a_winner** column is **f**. The Optimizer recommended that Database Designer create this projection as part of the design. However, Database Designer did not create the projection when it deployed the design. The log includes the DDL for the CREATE PROJECTION statement. If you want to add the projection manually, you can use that DDL. For more information, see [Creating a design manually](#).

The next example shows the contents of two records in the DC_DESIGN_QUERY_PROJECTION_CANDIDATES. Both of these rows apply to projection id 45035996273726626.

In the first record, the Optimizer recommends that Database Designer optimize the **customer_gender** column for the GROUPBY PIPE algorithm.

In the second record, the Optimizer recommends that Database Designer optimize the public.customer_dimension table for late materialization. Late materialization can improve the performance of joins that might spill to disk.

```

=> SELECT * FROM dc_design_query_projection_candidates;

```

General design settings

Before you run Database Designer, you must provide specific information on the design to create.

Design name

All designs that you create with Database Designer must have unique names that conform to the conventions described in [Identifiers](#), and are no more than 32 characters long (16 characters if you use Database Designer in Administration Tools or Management Console).

The design name is incorporated into the names of files that Database Designer generates, such as its deployment script. This can help you differentiate files that are associated with different designs.

Design type

Database Designer can create two distinct design types: comprehensive or incremental.

Comprehensive design

A comprehensive design creates an initial or replacement design for all the tables in the specified schemas. Create a comprehensive design when you are creating a new database.

To help Database Designer create an efficient design, load representative data into the tables before you begin the design process. When you load data into a table, Vertica creates an unoptimized [superprojection](#) so that Database Designer has projections to optimize. If a table has no data, Database Designer cannot optimize it.

Optionally, supply Database Designer with representative queries that you plan to use so Database Designer can optimize the design for them. If you do not supply any queries, Database Designer creates a generic optimization of the superprojections that minimizes storage, with no query-specific projections.

During a comprehensive design, Database Designer creates deployment scripts that:

- Create projections to optimize query performance.
- Create replacement buddy projections when Database Designer changes the encoding of existing projections that it decides to keep.

Incremental design

After you create and deploy a comprehensive database design, your database is likely to change over time in various ways. Consider using Database Designer periodically to create incremental designs that address these changes. Changes that warrant an incremental design can include:

- Significant data additions or updates
- New or modified queries that you run regularly
- Performance issues with one or more queries
- Schema changes

Optimization objective

Database Designer can optimize the design for one of three objectives:

- **Load** : Designs that are optimized for loads minimize database size, potentially at the expense of query performance.
- **Query** : Designs that are optimized for query performance. These designs typically favor fast query execution over load optimization, and thus result in a larger storage footprint.
- **Balanced** : Designs that are balanced between database size and query performance.

A fully optimized query has an optimization ratio of 0.99. Optimization ratio is the ratio of a query's benefits achieved in the design produced by the Database Designer to that achieved in the ideal plan. The optimization ratio is set in the `OptRatio` parameter in `designer.log`.

Design tables

Database Designer needs one or more tables with a moderate amount of sample data—approximately 10 GB—to create optimal designs. Design tables with large amounts of data adversely affect Database Designer performance. Design tables with too little data prevent Database Designer from creating an optimized design. If a design table has no data, Database Designer ignores it.

Note

If you drop a table after adding it to the design, Database Designer cannot build or deploy the design.

Design queries

A database design that is optimized for query performance requires a set of representative queries, or *design queries*. Design queries are required for incremental designs, and optional for comprehensive designs. You list design queries in a SQL file that you supply as input to Database Designer. Database Designer checks the validity of the queries when you add them to your design, and again when it builds the design. If a query is invalid, Database Designer ignores it.

If you use Management Console to create a database design, you can submit queries either from an input file or from the system table `QUERY_REQUESTS`. For details, see [Creating a design manually](#).

The maximum number of design queries depends on the design type: ≤200 queries for a comprehensive design, ≤100 queries for an incremental design. Optionally, you can assign weights to the design queries that signify their relative importance. Database Designer uses those weights to prioritize the queries in its design.

Segmented and unsegmented projections

When creating a comprehensive design, Database Designer creates projections based on data statistics and queries. It also reviews the submitted design tables to decide whether projections should be [segmented](#) (distributed across the cluster nodes) or [unsegmented](#) (replicated on all cluster nodes).

By default, Database Designer recommends only segmented projections. You can enable Database Designer to recommend unsegmented projections. In this case, Database Designer recommends segmented superprojections for large tables when deploying to multi-node clusters, and unsegmented superprojections for smaller tables.

Database Designer uses the following algorithm to determine whether to recommend unsegmented projections. Assuming that *largest-row-count* equals the number of rows in the design table with the largest number of rows, Database Designer recommends unsegmented projections if any of the following conditions is true:

- *largest-row-count* < 1,000,000 AND *number-table-rows* ≤ 10%*largest-row-count*
- *largest-row-count* ≥ 10,000,000 AND *number-table-rows* ≤ 1%*largest-row-count*
- 1,000,000 ≤ *largest-row-count* < 10,000,000 AND *number-table-rows* ≤ 100,000

Database Designer does not segment projections on:

- Single-node clusters
- LONG VARCHAR and LONG VARBINARY columns

For more information, see [High availability with projections](#).

Statistics analysis

By default, Database Designer analyzes statistics for design tables when they are added to the design. Accurate statistics help Database Designer optimize compression and query performance.

Analyzing statistics takes time and resources. If you are certain that design table statistics are up to date, you can specify to skip this step and avoid the overhead otherwise incurred.

For more information, see [Collecting Statistics](#).

Building a design

After you have created design tables and loaded data into them, and then specified the parameters you want Database Designer to use when creating the physical schema, direct Database Designer to create the scripts necessary to build the design.

Note

You cannot stop a running database if Database Designer is building a database design.

When you build a database design, Vertica generates two scripts:

- **Deployment script** : *design-name*_deploy.sql—Contains the SQL statements that create projections for the design you are deploying, deploy the design, and drop unused projections. When the deployment script runs, it creates the optimized design. For details about how to run this script and deploy the design, see [Deploying a Design](#).
- **Design script** : *design-name*_design.sql—Contains the **CREATE PROJECTION** statements that Database Designer uses to create the design. Review this script to make sure you are happy with the design. The design script is a subset of the deployment script. It serves as a backup of the DDL for the projections that the deployment script creates.

When you create a design using Management Console:

- If you submit a large number of queries to your design and build it right immediately, a timing issue could cause the queries not to load before deployment starts. If this occurs, you might see one of the following errors:
 - **No queries to optimize for**
 - **No tables to design projections for**

To accommodate this timing issue, you may need to reset the design, check the **Queries** tab to make sure the queries have been loaded, and then rebuild the design. Detailed instructions are in:

- [Using the wizard to create a design](#)
- [Creating a design manually](#)
- The scripts are deleted when deployment completes. To save a copy of the deployment script after the design is built but before the deployment completes, go to the **Output** window and copy and paste the SQL statements to a file.

Resetting a design

You must reset a design when:

- You build a design and the output scripts described in [Building a Design](#) are not created.
- You build a design but Database Designer cannot complete the design because the queries it expects are not loaded.

Resetting a design discards all the run-specific information of the previous Database Designer build, but retains its configuration (design type, optimization objectives, K-safety, etc.) and tables and queries.

After you reset a design, review the design to see what changes you need to make. For example, you can fix errors, change parameters, or check for and add additional tables or queries. Then you can rebuild the design.

You can only reset a design in Management Console or by using the [DESIGNER_RESET_DESIGN](#) function.

Deploying a design

After running Database Designer to generate a deployment script, Vertica recommends that you test your design on a non-production server before you deploy it to your production server.

Both the design and deployment processes run in the background. This is useful if you have a large design that you want to run overnight. Because an active SSH session is not required, the design/deploy operations continue to run uninterrupted, even if the session is terminated.

Note

You cannot stop a running database if Database Designer is building or deploying a database design.

Database Designer runs as a background process. Multiple users can run Database Designer concurrently without interfering with each other or using up all the cluster resources. However, if multiple users are deploying a design on the same tables at the same time, Database Designer may not be able to complete the deployment. To avoid problems, consider the following:

- Schedule potentially conflicting Database Designer processes to run sequentially overnight so that there are no concurrency problems.
- Avoid scheduling Database Designer runs on the same set of tables at the same time.

There are two ways to deploy your design:

- [Deploying Designs Using Database Designer](#)
- [Deploying Designs Manually](#)

In this section

- [Deploying designs using Database Designer](#)
- [Deploying designs manually](#)

Deploying designs using Database Designer

OpenText recommends that you run Database Designer and deploy optimized projections right after loading your tables with sample data because Database Designer provides projections optimized for the current state of your database.

If you choose to allow Database Designer to automatically deploy your script during a comprehensive design and are running Administrative Tools, Database Designer creates a backup script of your database's current design. This script helps you re-create the design of projections that may have been dropped by the new design. The backup script is located in the output directory you specified during the design process.

If you choose not to have Database Designer automatically run the deployment script (for example, if you want to maintain projections from a pre-existing deployment), you can manually run the deployment script later. See [Deploying designs manually](#).

To deploy a design while running Database Designer, do one of the following:

- In Management Console, select the design and click **Deploy Design**.
- In the Administration Tools, select **Deploy design** in the **Design Options** window.

If you are running Database Designer programmatically, use [DESIGNER_RUN_POPULATE_DESIGN_AND_DEPLOY](#) and set the `deploy` parameter to 'true'.

Once you have deployed your design, query the [DEPLOY_STATUS](#) system table to see the steps that the deployment took:

```
vmartdb=> SELECT * FROM V_MONITOR.DEPLOY_STATUS;
```

Deploying designs manually

If you choose not to have Database Designer deploy your design at design time, you can deploy the design later using the deployment script:

1. Make sure that the target database contains the same tables and projections as the database where you ran Database Designer. The database should also contain sample data.
2. To deploy the projections to a test or production environment, execute the deployment script in vsql with the meta-command `\i` as follows, where *design-name* is the name of the database design:

```
=> \i design-name_deploy.sql
```

3. For a [K-safe](#) database, call Vertica meta-function [GET_PROJECTIONS](#) on tables of the new projections. Check the output to verify that all projections have enough buddies to be identified as safe.
4. If you create projections for tables that already contains data, call [REFRESH](#) or [START_REFRESH](#) to update new projections. Otherwise, these projections are not available for query processing.
5. Call [MAKE_AHM_NOW](#) to set the [Ancient History Mark](#) (AHM) to the most recent epoch.
6. Call [DROP_PROJECTION](#) on projections that are no longer needed, and would otherwise waste disk space and reduce load speed.
7. Call [ANALYZE_STATISTICS](#) on all database projections:

```
=> SELECT ANALYZE_STATISTICS ("");
```

This function collects and aggregates data samples and storage information from all nodes on which a projection is stored, and then writes statistics into the catalog.

How to create a design

There are three ways to create a design using Database Designer:

- From Management Console, open a database and select the **Design** page at the bottom of the window.
For details about using Management Console to create a design, see [Creating a database design in Management Console](#)
- Programmatically, using the techniques described in [About Running Database Designer Programmatically](#). To run Database Designer programmatically, you must be a [DBADMIN](#) or have been granted the [DBDUSER](#) role and enabled that role.
- From the Administration Tools menu, by selecting **Configuration Menu > Run Database Designer**. You must be a DBADMIN user to run Database Designer from the Administration Tools.
For details about using Administration Tools to create a design, see [Using administration tools to create a design](#).

The following table shows what Database Designer capabilities are available in each tool:

Database Designer Capability	Management Console	Running Database Designer Programmatically	Administrative Tools
Create design	Yes	Yes	Yes
Design name length (# of characters)	16	32	16
Build design (create design and deployment scripts)	Yes	Yes	Yes
Create backup script			Yes
Set design type (comprehensive or incremental)	Yes	Yes	Yes
Set optimization objective	Yes	Yes	Yes
Add design tables	Yes	Yes	Yes
Add design queries file	Yes	Yes	Yes
Add single design query		Yes	
Use query repository	Yes	Yes	
Set K-safety	Yes	Yes	Yes
Analyze statistics	Yes	Yes	Yes
Require all unsegmented projections	Yes	Yes	
View event history	Yes	Yes	
Set correlation analysis mode (Default = 0)		Yes	

In this section

- [Using administration tools to create a design](#)

Using administration tools to create a design

To use the Administration Tools interface to create an optimized design for your database, you must be a DBADMIN user. Follow these steps:

1. Log in as the dbadmin user and start Administration Tools.
2. From the main menu, start the database for which you want to create a design. The database must be running before you can create a design for it.
3. On the main menu, select **Configuration Menu** and click **OK**.
4. On the Configuration Menu, select **Run Database Designer** and click **OK**.
5. On the **Select a database to design** window, enter the name of the database for which you are creating a design and click **OK**.

6. On the **Enter the directory for Database Designer output** window, enter the full path to the directory to contain the design script, deployment script, backup script, and log files, and click **OK** .
For information about the scripts, see [Building a design](#) .
7. On the **Database Designer** window, enter a name for the design and click **OK** .
8. On the **Design Type** window, choose which type of design to create and click **OK** .
For details, see [Design Types](#) .
9. The **Select schema(s) to add to query search path** window lists all the schemas in the database that you selected. Select the schemas that contain representative data that you want Database Designer to consider when creating the design and click **OK** .
For details about choosing schema and tables to submit to Database Designer, see [Design Tables with Sample Data](#) .
10. On the **Optimization Objectives** window, select the objective you want for the database optimization:
 - [Optimize with Queries](#)
 - [Update statistics](#)
 - [Deploy design](#)
11. The final window summarizes the choices you have made and offers you two choices:
 - **Proceed** with building the design, and deploying it if you specified to deploy it immediately. If you did not specify to deploy, you can review the design and deployment scripts and deploy them manually, as described in [Deploying designs manually](#) .
 - **Cancel** the design and go back to change some of the parameters as needed.
12. Creating a design can take a long time. To cancel a running design from the Administration Tools window, enter **Ctrl+C** .

To create a design for the VMart example database, see [Using Database Designer to create a comprehensive design](#) in Getting Started.

Running Database Designer programmatically

Vertica provides a set of meta-functions that enable programmatic access to Database Designer functionality. Run Database Designer programmatically to perform the following tasks:

- Optimize performance on tables that you own.
- Create or update a design without requiring superuser or DBADMIN intervention.
- Add individual queries and tables, or add data to your design, and then rerun Database Designer to update the design based on this new information.
- Customize the design.
- Use recently executed queries to set up your database to run Database Designer automatically on a regular basis.
- Assign each design query a *query weight* that indicates the importance of that query in creating the design. Assign a higher weight to queries that you run frequently so that Database Designer prioritizes those queries in creating the design.

For more details about Database Designer functions, see [Database Designer function categories](#) .

In this section

- [Database Designer function categories](#)
- [Workflow for running Database Designer programmatically](#)
- [Privileges for running Database Designer functions](#)
- [Resource pool for Database Designer users](#)

Database Designer function categories

Database Designer functions perform the following operations, generally performed in the following order:

1. [Create a design](#) .
2. [Set design properties](#) .
3. [Populate a design](#) .
4. [Create design and deployment scripts](#) .
5. [Get design data](#) .
6. [Clean up](#) .

Important

You can also use meta-function [DESIGNER_SINGLE_RUN](#) , which encapsulates all of these steps with a single call. The meta-function iterates over all queries within a specified timespan, and returns with a design ready for deployment.

For detailed information, see [Workflow for running Database Designer programmatically](#) . For information on required privileges, see [Privileges for running Database Designer functions](#) .

Caution

Before running Database Designer functions on an existing schema, back up the current design by calling [EXPORT_CATALOG](#) .

Create a design

[DESIGNER_CREATE_DESIGN](#) directs Database Designer to create a design.

Set design properties

The following functions let you specify design properties:

- [DESIGNER_SET_DESIGN_TYPE](#): Specifies whether the design is comprehensive or incremental.
- [DESIGNER_DESIGN_PROJECTION_ENCODINGS](#): Analyzes encoding in the specified projections and creates a script that implements encoding recommendations.
- [DESIGNER_SET_DESIGN_KSAFETY](#): Sets the *K-safety* value for a comprehensive design.
- [DESIGNER_SET_OPTIMIZATION_OBJECTIVE](#): Specifies whether the design optimizes for query or load performance.
- [DESIGNER_SET_PROPOSE_UNSEGMENTED_PROJECTIONS](#): Enables inclusion of unsegmented projections in the design.

Populate a design

The following functions let you add tables and queries to your Database Designer design:

- [DESIGNER_ADD_DESIGN_TABLES](#): Adds the specified tables to a design.
- [DESIGNER_ADD_DESIGN_QUERY](#), [DESIGNER_ADD_DESIGN_QUERIES](#), [DESIGNER_ADD_DESIGN_QUERIES_FROM_RESULTS](#): Adds queries to the design and weights them.

Create design and deployment scripts

The following functions populate the Database Designer workspace and create design and deployment scripts. You can also analyze statistics, deploy the design automatically, and drop the workspace after the deployment:

- [DESIGNER_RUN_POPULATE_DESIGN_AND_DEPLOY](#): Populates the design and creates design and deployment scripts.
- [DESIGNER_WAIT_FOR_DESIGN](#): Waits for a currently running design to complete.

Reset a design

[DESIGNER_RESET_DESIGN](#) discards all the run-specific information of the previous Database Designer build or deployment of the specified design but retains its configuration.

Get design data

The following functions display information about projections and scripts that the Database Designer created:

- [DESIGNER_OUTPUT_ALL_DESIGN_PROJECTIONS](#): Sends to standard output DDL statements that define design projections.
- [DESIGNER_OUTPUT_DEPLOYMENT_SCRIPT](#): Sends to standard output a design's deployment script.

Cleanup

The following functions cancel any running Database Designer operation or drop a Database Designer design and all its contents:

- [DESIGNER_CANCEL_POPULATE_DESIGN](#): Cancels population or deployment operation for the specified design if it is currently running.
- [DESIGNER_DROP_DESIGN](#): Removes the schema associated with the specified design and all its contents.
- [DESIGNER_DROP_ALL_DESIGNS](#): Removes all Database Designer-related schemas associated with the current user.

Workflow for running Database Designer programmatically

The following example shows the steps you take to create a design by running Database Designer programmatically.

Important

Before running Database Designer functions on an existing schema, back up the current design by calling function [EXPORT_CATALOG](#).

Before you run this example, you should have the DBDUSER role, and you should have enabled that role using the SET ROLE DBDUSER command:

1. Create a table in the public schema:

```
=> CREATE TABLE T(  
  x INT,  
  y INT,  
  z INT,  
  u INT,  
  v INT,  
  w INT PRIMARY KEY  
);
```

2. Add data to the table:

```
\\ perl -e 'for ($i=0; $i<100000; ++$i) {printf("%d, %d, %d, %d, %d, %d\n", $i/10000, $i/100, $i/10, $i/2, $i, $i);}'  
| vsql -c "COPY T FROM STDIN DELIMITER ',' DIRECT;"
```

3. Create a second table in the public schema:

```
=> CREATE TABLE T2(  
  x INT,  
  y INT,  
  z INT,  
  u INT,  
  v INT,  
  w INT PRIMARY KEY  
);
```

4. Copy the data from table **T1** to table **T2** and commit the changes:

```
=> INSERT /*+DIRECT*/ INTO T2 SELECT * FROM T;  
=> COMMIT;
```

5. Create a new design:

```
=> SELECT DESIGNER_CREATE_DESIGN('my_design');
```

This command adds information to the [DESIGNS](#) system table in the V_MONITOR schema.

6. Add tables from the public schema to the design :

```
=> SELECT DESIGNER_ADD_DESIGN_TABLES('my_design', 'public.t');  
=> SELECT DESIGNER_ADD_DESIGN_TABLES('my_design', 'public.t2');
```

These commands add information to the [DESIGN_TABLES](#) system table.

7. Create a file named **queries.txt** in **/tmp/examples** , or another directory where you have READ and WRITE privileges. Add the following two queries in that file and save it. Database Designer uses these queries to create the design:

```
SELECT DISTINCT T2.u FROM T JOIN T2 ON T.z=T2.z-1 WHERE T2.u > 0;  
SELECT DISTINCT w FROM T;
```

8. Add the queries file to the design and display the results—the numbers of accepted queries, non-design queries, and unoptimizable queries:

```
=> SELECT DESIGNER_ADD_DESIGN_QUERIES  
('my_design',  
 '/tmp/examples/queries.txt',  
 'true'  
);
```

The results show that both queries were accepted:

```
Number of accepted queries          =2  
Number of queries referencing non-design tables =0  
Number of unsupported queries      =0  
Number of illegal queries          =0
```

The DESIGNER_ADD_DESIGN_QUERIES function populates the [DESIGN_QUERIES](#) system table.

9. Set the design type to **comprehensive** . (This is the default.) A comprehensive design creates an initial or replacement design for all the design tables:

```
=> SELECT DESIGNER_SET_DESIGN_TYPE('my_design', 'comprehensive');
```

10. Set the optimization objective to **query** . This setting creates a design that focuses on faster query performance, which might recommend additional projections. These projections could result in a larger database storage footprint:

```
=> SELECT DESIGNER_SET_OPTIMIZATION_OBJECTIVE('my_design', 'query');
```

11. Create the design and save the design and deployment scripts in `/tmp/examples`, or another directory where you have READ and WRITE privileges.

The following command:

- Analyzes statistics
- Doesn't deploy the design.
- Doesn't drop the design after deployment.
- Stops if it encounters an error.

```
=> SELECT DESIGNER_RUN_POPULATE_DESIGN_AND_DEPLOY
('my_design',
'/tmp/examples/my_design_projections.sql',
'/tmp/examples/my_design_deploy.sql',
'True',
'False',
'False',
'False'
);
```

This command adds information to the following system tables:

- [DEPLOYMENT_PROJECTION_STATEMENTS](#)
- [DEPLOYMENT_PROJECTIONS](#)
- [OUTPUT_DEPLOYMENT_STATUS](#)

12. Examine the status of the Database Designer run to see what projections Database Designer recommends. In the `deployment_projection_name` column:

- `rep` indicates a replicated projection
- `super` indicates a superprojection

The `deployment_status` column is `pending` because the design has not yet been deployed.

For this example, Database Designer recommends four projections:

```
=> \x
Expanded display is on.
=> SELECT * FROM OUTPUT_DEPLOYMENT_STATUS;
-[ RECORD 1 ]-----+-----
deployment_id      | 45035996273795970
deployment_projection_id | 1
deployment_projection_name | T_DBD_1_rep_my_design
deployment_status   | pending
error_message       | N/A
-[ RECORD 2 ]-----+-----
deployment_id      | 45035996273795970
deployment_projection_id | 2
deployment_projection_name | T2_DBD_2_rep_my_design
deployment_status   | pending
error_message       | N/A
-[ RECORD 3 ]-----+-----

deployment_status   | pending
error_message       | N/A
```

13. View the script `/tmp/examples/my_design_deploy.sql` to see how these projections are created when you run the deployment script. In this example, the script also assigns the encoding schemes RLE and COMMONDELTA_COMP to columns where appropriate.

14. Deploy the design from the directory where you saved it:

```
=> \i /tmp/examples/my_design_deploy.sql
```

15. Now that the design is deployed, delete the design:

```
=> SELECT DESIGNER_DROP_DESIGN('my_design');
```

Privileges for running Database Designer functions

Non-DBADMIN users with the [DBDUSER role](#) can run Database Designer functions. Two steps are required to enable users to run these functions:

1. A DBADMIN or superuser grants the user the DBDUSER role:

```
=> GRANT DBDUSER TO username;
```

This role persists until the DBADMIN revokes it.

2. Before the DBDUSER can run Database Designer functions, one of the following must occur:

- The user enables the DBDUSER role:

```
=> SET ROLE DBDUSER;
```

- The superuser sets the user's default role to DBDUSER:

```
=> ALTER USER username DEFAULT ROLE DBDUSER;
```

General DBDUSER limitations

As a DBDUSER, the following restrictions apply:

- You can set a design's [K-safety](#) to a value less than or equal to system K-safety. You cannot change system K-safety.
- You cannot explicitly change the ancient history mark (AHM), even during design deployment.

Design dependencies and privileges

Individual design tasks are likely to have dependencies that require specific privileges:

Task	Required privileges
Add tables to a design	<ul style="list-style-type: none">• USAGE privilege on the design table schema• OWNER privilege on the design table
Add a single design query to the design	<ul style="list-style-type: none">• Privilege to execute the design query
Add a query file to the design	<ul style="list-style-type: none">• Read privilege on the storage location that contains the query file• Privilege to execute all the queries in the file
Add queries from the result of a user query to the design	<ul style="list-style-type: none">• Privilege to execute the user query• Privilege to execute each design query retrieved from the results of the user query
Create design and deployment scripts	<ul style="list-style-type: none">• WRITE privilege on the storage location of the design script• WRITE privilege on the storage location of the deployment script

Resource pool for Database Designer users

When you grant a user the DBDUSER role, be sure to associate a resource pool with that user to manage resources during Database Designer runs. This allows multiple users to run Database Designer concurrently without interfering with each other or using up all cluster resources.

Note

When a user runs Database Designer, execution is mostly contained in the user's resource pool. However, Vertica might also use other system resource pools to perform less-intensive tasks.

Creating custom designs

Vertica strongly recommends that you use the physical schema design produced by [Database Designer](#), which provides [K-safety](#), excellent query performance, and efficient use of storage space. If any queries run less as efficiently than you expect, consider using the Database Designer incremental design process to optimize the database design for the query.

If the projections created by Database Designer still do not meet your needs, you can write custom projections, from scratch or based on projection designs created by Database Designer.

If you are unfamiliar with writing custom projections, start by modifying an existing design generated by Database Designer.

In this section

- [Custom design process](#)
- [Planning your design](#)
- [Design fundamentals](#)

Custom design process

To create a custom design or customize an existing one:

1. Plan the new design or modifications to an existing one. See [Planning your design](#).
2. Create or modify projections. See [Design fundamentals](#) and [CREATE PROJECTION](#) for more detail.
3. Deploy projections to a test environment. See [Writing and deploying custom projections](#).
4. Test and modify projections as needed.
5. After you finalize the design, deploy projections to the production environment.

Planning your design

The syntax for creating a design is easy for anyone who is familiar with SQL. As with any successful project, however, a successful design requires some initial planning. Before you create your first design:

- Become familiar with standard design requirements and plan your design to include them. See [Design requirements](#).
- Determine how many projections you need to include in the design. See [Determining the number of projections to use](#).
- Determine the type of compression and encoding to use for columns. See [Architecture](#).
- Determine whether or not you want the database to be K-safe. Vertica recommends that all production databases have a minimum K-safety of one (K=1). Valid K-safety values are 0, 1, and 2. See [Designing for K-safety](#).

In this section

- [Design requirements](#)
- [Determining the number of projections to use](#)
- [Designing for K-safety](#)
- [Designing for segmentation](#)

Design requirements

A physical schema design is a script that contains CREATE PROJECTION statements. These statements determine which columns are included in projections and how they are optimized.

If you use Database Designer as a starting point, it automatically creates designs that meet all fundamental design requirements. If you intend to create or modify designs manually, be aware that all designs must meet the following requirements:

- Every design must create at least one superprojection for every table in the database that is used by the client application. These projections provide complete coverage that enables users to perform ad-hoc queries as needed. They can contain joins and they are usually configured to maximize performance through sort order, compression, and encoding.
- Query-specific projections are optional. If you are satisfied with the performance provided through superprojections, you do not need to create additional projections. However, you can maximize performance by tuning for specific query work loads.
- Vertica recommends that all production databases have a minimum K-safety of one (K=1) to support high availability and recovery. (K-safety can be set to 0, 1, or 2.) See [High availability with projections](#) and [Designing for K-safety](#).
- Vertica recommends that if you have more than 20 nodes, but small tables, do not create replicated projections. If you create replicated projections, the catalog becomes very large and performance may degrade. Instead, consider segmenting those projections.

Determining the number of projections to use

In many cases, a design that consists of a set of superprojections (and their buddies) provides satisfactory performance through compression and encoding. This is especially true if the sort orders for the projections have been used to maximize performance for one or more query predicates (WHERE clauses).

However, you might want to add additional query-specific projections to increase the performance of queries that run slowly, are used frequently, or are run as part of business-critical reporting. The number of additional projections (and their buddies) that you create should be determined by:

- Your organization's needs
- The amount of disk space you have available on each node in the cluster
- The amount of time available for loading data into the database

As the number of projections that are tuned for specific queries increases, the performance of these queries improves. However, the amount of disk space used and the amount of time required to load data increases as well. Therefore, you should create and test designs to determine the optimum number of projections for your database configuration. On average, organizations that choose to implement query-specific projections achieve optimal performance through the addition of a few query-specific projections.

Designing for K-safety

Vertica recommends that all production databases have a minimum K-safety of one (K=1). Valid K-safety values for production databases are 1 and 2. Non-production databases do not have to be K-safe and can be set to 0.

A K-safe database must have at least three nodes, as shown in the following table:

K-safety level	Number of required nodes
1	3+
2	5+

Note

Vertica only supports K-safety levels 1 and 2.

You can set K-safety to 1 or 2 only when the physical schema design meets certain redundancy requirements. See [Requirements for a K-safe physical schema design](#).

Using Database Designer

To create designs that are K-safe, Vertica recommends that you use the [Database Designer](#). When creating projections with Database Designer, projection definitions that meet K-safe design requirements are recommended and marked with a K-safety level. Database Designer creates a script that uses the [MARK_DESIGN_KSAFE](#) function to set the K-safety of the physical schema to 1. For example:

```
=> \i VMart_Schema_design_opt_1.sql
CREATE PROJECTION
CREATE PROJECTION
mark_design_ksafe
-----
Marked design 1-safe
(1 row)
```

By default, Vertica creates K-safe superprojections when database K-safety is greater than 0.

Monitoring K-safety

Monitoring tables can be accessed programmatically to enable external actions, such as alerts. You monitor the K-safety level by querying the [SYSTEM](#) table for settings in columns [DESIGNED_FAULT_TOLERANCE](#) and [CURRENT_FAULT_TOLERANCE](#).

Loss of K-safety

When K nodes in your cluster fail, your database continues to run, although performance is affected. Further node failures could potentially cause the database to shut down if the failed node's data is not available from another functioning node in the cluster.

[K-safety in an Enterprise Mode database](#)

In this section

- [Requirements for a K-safe physical schema design](#)
- [Requirements for a physical schema design with no K-safety](#)
- [Designing segmented projections for K-safety](#)
- [Designing unsegmented projections for K-Safety](#)

Requirements for a K-safe physical schema design

Database Designer automatically generates designs with a K-safety of 1 for clusters that contain at least three nodes. (If your cluster has one or two nodes, it generates designs with a K-safety of 0. You can modify a design created for a three-node (or greater) cluster, and the K-safe requirements are already set.

If you create custom projections, your physical schema design must meet the following requirements to be able to successfully recover the database in the event of a failure:

- Segmented projections must be [segmented](#) across all nodes. Refer to [Designing for segmentation](#) and [Designing segmented projections for K-safety](#).
- Replicated projections must be replicated on all nodes. See [Designing unsegmented projections for K-Safety](#).
- Segmented projections must have K+1 [buddy](#) projections—projections with identical columns and segmentation criteria, where corresponding segments are placed on different nodes.

You can use the [MARK DESIGN_KSAFE](#) function to find out whether your schema design meets requirements for K-safety.

Requirements for a physical schema design with no K-safety

If you use Database Designer to generate an comprehensive design that you can modify and you do not want the design to be K-safe, set K-safety level to 0 (zero).

If you want to start from scratch, do the following to establish minimal projection requirements for a functioning database with no K-safety (K=0):

1. Define at least one [superprojection](#) for each table in the [logical schema](#).
2. Replicate (define an exact copy of) each dimension table superprojection on each [node](#).

Designing segmented projections for K-safety

Projections must comply with database K-safety requirements. In general, you must create buddy projections for each segmented projection, where the number of buddy projections is K+1. Thus, if system K-safety is set to 1, each projection segment must be duplicated by one buddy; if K-safety is set to 2, each segment must be duplicated by two buddies.

Automatic creation of buddy projections

You can use [CREATE PROJECTION](#) so it automatically creates the number of buddy projections required to satisfy K-safety, by including [SEGMENTED BY ... ALL NODES](#) . If [CREATE PROJECTION](#) specifies K-safety ([KSAFE= n](#)) , Vertica uses that setting; if the statement omits [KSAFE](#) , Vertica uses system K-safety.

In the following example, [CREATE PROJECTION](#) creates segmented projection [ttd_p1](#) for table [ttd](#) . Because system K-safety is set to 1, Vertica requires a buddy projection for each segmented projection. The [CREATE PROJECTION](#) statement omits [KSAFE](#) , so Vertica uses system K-safety and creates two buddy projections: [ttd_p1_b0](#) and [ttd_p1_b1](#) :

```
=> SELECT mark_design_ksafe(1);

mark_design_ksafe
-----
Marked design 1-safe
(1 row)

=> CREATE TABLE ttd (a int, b int);
WARNING 6978: Table "ttd" will include privileges from schema "public"
CREATE TABLE

=> CREATE PROJECTION ttd_p1 as SELECT * FROM ttd SEGMENTED BY HASH(a) ALL NODES;
CREATE PROJECTION

=> SELECT projection_name from projections WHERE anchor_table_name='ttd';
projection_name
-----
ttd_p1_b0
ttd_p1_b1
(2 rows)
```

Vertica automatically names buddy projections by appending the suffix [_b n](#) to the projection base name—for example [ttd_p1_b0](#) .

Manual creation of buddy projections

If you create a projection on a single node, and system K-safety is greater than 0, you must manually create the number of buddies required for K-safety. For example, you can create projection [xxx_p1](#) for table [xxx](#) on a single node, as follows:

```
=> CREATE TABLE xxx (a int, b int);
WARNING 6978: Table "xxx" will include privileges from schema "public"
CREATE TABLE
```

```
=> CREATE PROJECTION xxx_p1 AS SELECT * FROM xxx SEGMENTED BY HASH(a) NODES v_vmart_node0001;
CREATE PROJECTION
```

Because K-safety is set to 1, a single instance of this projection is not K-safe. Attempts to insert data into its anchor table `xxx` return with an error like this:

```
=> INSERT INTO xxx VALUES (1, 2);
ERROR 3586: Insufficient projections to answer query
DETAIL: No projections that satisfy K-safety found for table xxx
HINT: Define buddy projections for table xxx
```

In order to comply with K-safety, you must create a buddy projection for projection `xxx_p1` . For example:

```
=> CREATE PROJECTION xxx_p1_buddy AS SELECT * FROM xxx SEGMENTED BY HASH(a) NODES v_vmart_node0002;
CREATE PROJECTION
```

Table `xxx` now complies with K-safety and accepts DML statements such as `INSERT` :

```
VMart=> INSERT INTO xxx VALUES (1, 2);
OUTPUT
-----
 1
(1 row)
```

See also

For general information about segmented projections and buddies, see [Segmented projections](#) . For information about designing for K-safety, see [Designing for K-safety](#) and [Designing for segmentation](#) .

Designing unsegmented projections for K-Safety

In many cases, dimension tables are relatively small, so you do not need to segment them. Accordingly, you should design a K-safe database so projections for its dimension tables are replicated without segmentation on all cluster nodes. You create these projections with a [CREATE PROJECTION](#) statement that includes the keywords `UNSEGMENTED ALL NODES` . These keywords specify to create identical instances of the projection on all cluster nodes.

The following example shows how to create an unsegmented projection for the table `store.store_dimension` :

```
=> CREATE PROJECTION store.store_dimension_proj (storekey, name, city, state)
      AS SELECT store_key, store_name, store_city, store_state
      FROM store.store_dimension
      UNSEGMENTED ALL NODES;
CREATE PROJECTION
```

Vertica uses the same name to identify all instances of the unsegmented projection—in this example, `store.store_dimension_proj` . The keyword `ALL NODES` specifies to replicate the projection on all nodes:

```
=> \dj store.store_dimension_proj
      List of projections
Schema |      Name      | Owner | Node      | Comment
-----+-----+-----+-----+-----
store  | store_dimension_proj | dbadmin | v_vmart_node0001 |
store  | store_dimension_proj | dbadmin | v_vmart_node0002 |
store  | store_dimension_proj | dbadmin | v_vmart_node0003 |
(3 rows)
```

For more information about projection name conventions, see [Projection naming](#) .

Designing for segmentation

You segment projections using hash segmentation. Hash segmentation allows you to segment a projection based on a built-in hash function that provides even distribution of data across multiple nodes, resulting in optimal query execution. In a projection, the data to be hashed consists of one or more column values, each having a large number of unique values and an acceptable amount of skew in the value distribution. Primary key columns that meet the criteria could be an excellent choice for hash segmentation.

Note

For detailed information about using hash segmentation in a projection, see [CREATE PROJECTION](#) in the SQL Reference Manual.

When segmenting projections, determine which columns to use to segment the projection. Choose one or more columns that have a large number of unique data values and acceptable skew in their data distribution. Primary key columns are an excellent choice for hash segmentation. The columns must be unique across all the tables being used in a query.

Design fundamentals

Although you can write custom projections from scratch, Vertica recommends that you use Database Designer to create a design to use as a starting point. This ensures that you have projections that meet basic requirements.

In this section

- [Writing and deploying custom projections](#)
- [Designing superprojections](#)
- [Sort order benefits](#)
- [Choosing sort order: best practices](#)
- [Prioritizing column access speed](#)

Writing and deploying custom projections

Before you write custom projections, review the topics in [Planning your design](#) carefully. Failure to follow these considerations can result in non-functional projections.

To manually modify or create a projection:

1. Write a script with [CREATE PROJECTION](#) statements to create the desired projections.
2. Run the script in vsql with the meta-command `\i`.

Note

You must have a database loaded with a logical schema.

3. For a [K-safe](#) database, call Vertica meta-function [GET_PROJECTIONS](#) on tables of the new projections. Check the output to verify that all projections have enough buddies to be identified as safe.
4. If you create projections for tables that already contains data, call [REFRESH](#) or [START_REFRESH](#) to update new projections. Otherwise, these projections are not available for query processing.
5. Call [MAKE_AHM_NOW](#) to set the [Ancient History Mark](#) (AHM) to the most recent epoch.
6. Call [DROP PROJECTION](#) on projections that are no longer needed, and would otherwise waste disk space and reduce load speed.
7. Call [ANALYZE_STATISTICS](#) on all database projections:

```
=> SELECT ANALYZE_STATISTICS ("");
```

This function collects and aggregates data samples and storage information from all nodes on which a projection is stored, and then writes statistics into the catalog.

Designing superprojections

Superprojections have the following requirements:

- They must contain every column within the table.
- For a K-safe design, superprojections must either be replicated on all nodes within the database cluster (for dimension tables) or paired with buddies and segmented across all nodes (for very large tables and medium large tables). See [Projections](#) and [High availability with projections](#) for an overview of projections and how they are stored. See [Designing for K-safety](#) for design specifics.

To provide maximum usability, superprojections need to minimize storage requirements while maximizing query performance. To achieve this, the sort order for columns in superprojections is based on storage requirements and commonly used queries.

Sort order benefits

Column sort order is an important factor in minimizing storage requirements, and maximizing query performance.

Minimize storage requirements

Minimizing storage saves on physical resources and increases performance by reducing disk I/O. You can minimize projection storage by prioritizing low-cardinality columns in its sort order. This reduces the number of rows Vertica stores and accesses to retrieve query results.

After identifying projection sort columns, analyze their data and choose the most effective encoding method. The Vertica optimizer gives preference to columns with run-length encoding (RLE), so be sure to use it whenever appropriate. Run-length encoding replaces sequences (runs) of identical values with a single pair that contains the value and number of occurrences. Therefore, it is especially appropriate to use it for low-cardinality columns whose run length is large.

Maximize query performance

You can facilitate query performance through column sort order as follows:

- Where possible, sort order should prioritize columns with the lowest cardinality.
- Do not sort projections on columns of type LONG VARBINARY and LONG VARCHAR.

See also

[Choosing sort order: best practices](#)

Choosing sort order: best practices

When choosing sort orders for your projections, Vertica has several recommendations that can help you achieve maximum query performance, as illustrated in the following examples.

Combine RLE and sort order

When dealing with predicates on low-cardinality columns, use a combination of RLE and sorting to minimize storage requirements and maximize query performance.

Suppose you have a `students` table contain the following values and encoding types:

Column	# of Distinct Values	Encoded With
<code>gender</code>	2 (M or F)	RLE
<code>pass_fail</code>	2 (P or F)	RLE
<code>class</code>	4 (freshman, sophomore, junior, or senior)	RLE
<code>name</code>	10000 (too many to list)	Auto

You might have queries similar to this one:

```
SELECT name FROM students WHERE gender = 'M' AND pass_fail = 'P' AND class = 'senior';
```

The fastest way to access the data is to work through the low-cardinality columns with the smallest number of distinct values before the high-cardinality columns. The following sort order minimizes storage and maximizes query performance for queries that have equality restrictions on `gender`, `class`, `pass_fail`, and `name`. Specify the ORDER BY clause of the projection as follows:

```
ORDER BY students.gender, students.pass_fail, students.class, students.name
```

In this example, the `gender` column is represented by two RLE entries, the `pass_fail` column is represented by four entries, and the `class` column is represented by 16 entries, regardless of the cardinality of the `students` table. Vertica efficiently finds the set of rows that satisfy all the predicates, resulting in a huge reduction of search effort for RLE encoded columns that occur early in the sort order. Consequently, if you use low-cardinality columns in local predicates, as in the previous example, put those columns early in the projection sort order, in increasing order of distinct cardinality (that is, in increasing order of the number of distinct values in each column).

If you sort this table with `student.class` first, you improve the performance of queries that restrict only on the `student.class` column, and you improve the compression of the `student.class` column (which contains the largest number of distinct values), but the other columns do not compress as well. Determining which projection is better depends on the specific queries in your workload, and their relative importance.

Storage savings with compression decrease as the cardinality of the column increases; however, storage savings with compression increase as the number of bytes required to store values in that column increases.

Maximize the advantages of RLE

To maximize the advantages of RLE encoding, use it only when the average run length of a column is greater than 10 when sorted. For example, suppose you have a table with the following columns, sorted in order of cardinality from low to high:

```
address.country, address.region, address.state, address.city, address.zipcode
```

The `zipcode` column might not have 10 sorted entries in a row with the same zip code, so there is probably no advantage to run-length encoding that column, and it could make compression worse. But there are likely to be more than 10 countries in a sorted run length, so applying RLE to the country column can improve performance.

Put lower cardinality column first for functional dependencies

In general, put columns that you use for local predicates (as in the previous example) earlier in the join order to make predicate evaluation more efficient. In addition, if a lower cardinality column is uniquely determined by a higher cardinality column (like `city_id` uniquely determining a `state_id`), it is always better to put the lower cardinality, functionally determined column earlier in the sort order than the higher cardinality column.

For example, in the following sort order, the `Area_Code` column is sorted before the `Number` column in the `customer_info` table:

```
ORDER BY = customer_info.Area_Code, customer_info.Number, customer_info.Address
```

In the query, put the `Area_Code` column first, so that only the values in the `Number` column that start with 978 are scanned.

```
=> SELECT Address FROM customer_info WHERE Area_Code='978' AND Number='9780123457';
```

Sort for merge joins

When processing a join, the Vertica optimizer chooses from two algorithms:

- **Merge join** —If both inputs are pre-sorted on the join column, the optimizer chooses a merge join, which is faster and uses less memory.
- **Hash join** —Using the hash join algorithm, Vertica uses the smaller (inner) joined table to build an in-memory hash table on the join column. A hash join has no sort requirement, but it consumes more memory because Vertica builds a hash table with the values in the inner table. The optimizer chooses a hash join when projections are not sorted on the join columns.

If both inputs are pre-sorted, merge joins do not have to do any pre-processing, making the join perform faster. Vertica uses the term sort-merge join to refer to the case when at least one of the inputs must be sorted prior to the merge join. Vertica sorts the inner input side but only if the outer input side is already sorted on the join columns.

To give the Vertica query optimizer the option to use an efficient merge join for a particular join, create projections on both sides of the join that put the join column first in their respective projections. This is primarily important to do if both tables are so large that neither table fits into memory. If all tables that a table will be joined to can be expected to fit into memory simultaneously, the benefits of merge join over hash join are sufficiently small that it probably isn't worth creating a projection for any one join column.

Sort on columns in important queries

If you have an important query, one that you run on a regular basis, you can save time by putting the columns specified in the `WHERE` clause or the `GROUP BY` clause of that query early in the sort order.

If that query uses a high-cardinality column such as Social Security number, you may sacrifice storage by placing this column early in the sort order of a projection, but your most important query will be optimized.

Sort columns of equal cardinality by size

If you have two columns of equal cardinality, put the column that is larger first in the sort order. For example, a `CHAR(20)` column takes up 20 bytes, but an `INTEGER` column takes up 8 bytes. By putting the `CHAR(20)` column ahead of the `INTEGER` column, your projection compresses better.

Sort foreign key columns first, from low to high distinct cardinality

Suppose you have a fact table where the first four columns in the sort order make up a foreign key to another table. For best compression, choose a sort order for the fact table such that the foreign keys appear first, and in increasing order of distinct cardinality. Other factors also apply to the design of projections for fact tables, such as partitioning by a time dimension, if any.

In the following example, the table `inventory` stores inventory data, and `product_key` and `warehouse_key` are foreign keys to the `product_dimension` and `warehouse_dimension` tables:

```

=> CREATE TABLE inventory (
  date_key INTEGER NOT NULL,
  product_key INTEGER NOT NULL,
  warehouse_key INTEGER NOT NULL,
  ...
);
=> ALTER TABLE inventory
  ADD CONSTRAINT fk_inventory_warehouse FOREIGN KEY(warehouse_key)
  REFERENCES warehouse_dimension(warehouse_key);
ALTER TABLE inventory
  ADD CONSTRAINT fk_inventory_product FOREIGN KEY(product_key)
  REFERENCES product_dimension(product_key);

```

The inventory table should be sorted by warehouse_key and then product, since the cardinality of the `warehouse_key` column is probably lower than the cardinality of the `product_key`.

Prioritizing column access speed

If you measure and set the performance of storage locations within your cluster, Vertica uses this information to determine where to store columns based on their rank. For more information, see [Setting storage performance](#).

How columns are ranked

Vertica stores columns included in the projection sort order on the fastest available storage locations. Columns not included in the projection sort order are stored on slower disks. Columns for each projection are ranked as follows:

- Columns in the sort order are given the highest priority (numbers > 1000).
- The last column in the sort order is given the rank number 1001.
- The next-to-last column in the sort order is given the rank number 1002, and so on until the first column in the sort order is given 1000 + # of sort columns.
- The remaining columns are given numbers from 1000-1, starting with 1000 and decrementing by one per column.

Vertica then stores columns on disk from the highest ranking to the lowest ranking. It places highest-ranking columns on the fastest disks and the lowest-ranking columns on the slowest disks.

Overriding default column ranking

You can modify which columns are stored on fast disks by manually overriding the default ranks for these columns. To accomplish this, set the `ACCESSRANK` keyword in the column list. Make sure to use an integer that is not already being used for another column. For example, if you want to give a column the fastest access rank, use a number that is significantly higher than 1000 + the number of sort columns. This allows you to enter more columns over time without bumping into the access rank you set.

The following example sets column `store_key`'s access rank to 1500:

```

CREATE PROJECTION retail_sales_fact_p (
  store_key ENCODING RLE ACCESSRANK 1500,
  pos_transaction_number ENCODING RLE,
  sales_dollar_amount,
  cost_dollar_amount )
AS SELECT
  store_key,
  pos_transaction_number,
  sales_dollar_amount,
  cost_dollar_amount
FROM store.store_sales_fact
ORDER BY store_key
SEGMENTED BY HASH(pos_transaction_number) ALL NODES;

```

Database users and privileges

Database users should only have access to the database resources that they need to perform their tasks. For example, most users should be able to read data but not modify or insert new data. A smaller number of users typically need permission to perform a wider range of database tasks—for example, create and modify schemas, tables, and views. A very small number of users can perform administrative tasks, such as rebalance nodes on a cluster, or start or stop a database. You can also let certain users extend their own privileges to other users.

Client authentication controls what database objects users can access and change in the database. You specify access for specific users or roles with GRANT statements.

In this section

- [Database users](#)
- [Database roles](#)
- [Database privileges](#)
- [Access policies](#)

Database users

Every Vertica database has one or more users. When users connect to a database, they must log on with valid credentials (username and password) that a superuser defined in the database.

Database users own the objects they create in a database, such as tables, procedures, and storage locations.

Note

By default, users have the right to [create temporary tables](#) in a database.

In this section

- [Types of database users](#)
- [Creating a database user](#)
- [User-level configuration parameters](#)
- [Locking user accounts](#)
- [Setting and changing user passwords](#)

Types of database users

In a Vertica database, there are three types of users:

- Database administrator (DBADMIN)
- Object owner
- Everyone else (PUBLIC)

Note

External to a Vertica database, an MC administrator can create users through the Management Console and grant them database access. See [User administration in MC](#) for details.

In this section

- [Database administration user](#)
- [Object owner](#)
- [PUBLIC user](#)

Database administration user

On installation, a new Vertica database automatically contains a user with [superuser privileges](#). Unless explicitly named [during installation](#), this user is identified as `dbadmin`. This user cannot be dropped and has the following irrevocable roles:

- [DBADMIN](#)
- [DBDUSER](#)
- [PSEUDOSUPERUSER](#)

With these roles, the `dbadmin` user can perform all database operations. This user can also create other users with administrative privileges.

Important

Do not confuse the `dbadmin` user with the [DBADMIN role](#). The DBADMIN role is a set of privileges that can be assigned to one or more users.

The Vertica documentation often references the `dbadmin` user as a superuser. This reference is unrelated to Linux superusers.

Creating additional database administrators

As the **dbadmin** user, you can create other users with the same privileges:

1. Create a user:

```
=> CREATE USER DataBaseAdmin2;  
CREATE USER
```

2. Grant the appropriate roles to new user **DataBaseAdmin2** :

```
=> GRANT dbduser, dbadmin, pseudosuperuser to DataBaseAdmin2;  
GRANT ROLE
```

User **DataBaseAdmin2** now has the same privileges granted to the original dbadmin user.

3. As **DataBaseAdmin2** , enable your assigned roles with [SET ROLE](#) :

```
=> \c - DataBaseAdmin2;  
You are now connected to database "VMart" as user "DataBaseAdmin2".  
=> SET ROLE dbadmin, dbduser, pseudosuperuser;  
SET ROLE
```

4. Confirm the roles are enabled:

```
=> SHOW ENABLED ROLES;  
name      | setting  
-----  
enabled roles | dbduser, dbadmin, pseudosuperuser
```

Object owner

An object owner is the user who creates a particular database object and can perform any operation on that object. By default, only an owner (or a [superuser](#)) can act on a database object. In order to allow other users to use an object, the owner or superuser must grant privileges to those users using one of the [GRANT statements](#).

Note

Object owners are [PUBLIC users](#) for objects that other users own.

See [Database privileges](#) for more information.

PUBLIC user

All non-DBA (superuser) or object owners are PUBLIC users.

Note

Object owners are PUBLIC users for objects that other users own.

Newly-created users do not have access to schema PUBLIC by default. Make sure to GRANT USAGE ON SCHEMA PUBLIC to all users you create.

See also

- [PUBLIC](#)

Creating a database user

To create a database user:

1. From [vsqL](#), connect to the database as a superuser.
2. Issue the [CREATE USER](#) statement with optional parameters.
3. Run a series of [GRANT statements](#) to grant the new user privileges.

To create a user on MC, see [User administration in MC](#) in Management Console

New user privileges

By default, new database users have the right to create temporary tables in the database.

New users do not have access to schema **PUBLIC** by default. Be sure to call **GRANT USAGE ON SCHEMA PUBLIC** to all users you create.

Modifying users

You can change information about a user, such as his or her password, by using the **ALTER USER** statement. If you want to configure a user to not have any password authentication, you can set the empty password " in **CREATE USER** or **ALTER USER** statements, or omit the **IDENTIFIED BY** parameter in **CREATE USER** .

Example

The following series of commands add user Fred to a database with password 'password'. The second command grants USAGE privileges to Fred on the public schema:

```
=> CREATE USER Fred IDENTIFIED BY 'password';
=> GRANT USAGE ON SCHEMA PUBLIC to Fred;
```

User names created with double-quotes are case sensitive. For example:

```
=> CREATE USER "FrEd1";
```

In the above example, the logon name must be an exact match. If the user name was created without double-quotes (for example, **FRED1**), then the user can log on as **FRED1** , **FrEd1** , **fred1** , and so on.

See also

- [Granting and revoking privileges](#)
- [Granting database roles](#)

User-level configuration parameters

ALTER USER lets you set user-level configuration parameters on individual users. These settings override database- or session-level settings on the same parameters. For example, the following **ALTER USER** statement sets DepotOperationsForQuery for users Yvonne and Ahmed to **FETCHES**, thus overriding the default setting of **ALL**:

```
=> SELECT user_name, parameter_name, current_value, default_value FROM user_configuration_parameters
   WHERE user_name IN('Ahmed', 'Yvonne') AND parameter_name = 'DepotOperationsForQuery';
user_name | parameter_name | current_value | default_value
-----+-----+-----+-----
Ahmed    | DepotOperationsForQuery | ALL          | ALL
Yvonne   | DepotOperationsForQuery | ALL          | ALL
(2 rows)

=> ALTER USER Ahmed SET DepotOperationsForQuery='FETCHES';
ALTER USER
=> ALTER USER Yvonne SET DepotOperationsForQuery='FETCHES';
ALTER USER
```

Identifying user-level parameters

To identify user-level configuration parameters, query the **allowed_levels** column of system table **CONFIGURATION_PARAMETERS**. For example, the following query identifies user-level parameters that affect depot usage:

```
n=> SELECT parameter_name, allowed_levels, default_value, current_level, current_value
   FROM configuration_parameters WHERE allowed_levels ilike '%USER%' AND parameter_name ilike '%depot%';
parameter_name | allowed_levels | default_value | current_level | current_value
-----+-----+-----+-----+-----
UseDepotForReads | SESSION, USER, DATABASE | 1          | DEFAULT      | 1
DepotOperationsForQuery | SESSION, USER, DATABASE | ALL        | DEFAULT      | ALL
UseDepotForWrites | SESSION, USER, DATABASE | 1          | DEFAULT      | 1
(3 rows)
```

Viewing user parameter settings

You can obtain user settings in two ways:

- Query system table [USER_CONFIGURATION_PARAMETERS](#) :

```
=> SELECT * FROM user_configuration_parameters;
user_name | parameter_name | current_value | default_value
-----+-----+-----+-----
Ahmed    | DepotOperationsForQuery | FETCHES    | ALL
Yvonne   | DepotOperationsForQuery | FETCHES    | ALL
Yvonne   | LoadSourceStatisticsLimit | 512        | 256
(3 rows)
```

- Use [SHOW USER](#) :

```
=> SHOW USER Yvonne PARAMETER ALL;
user | parameter | setting
-----+-----+-----
Yvonne | DepotOperationsForQuery | FETCHES
Yvonne | LoadSourceStatisticsLimit | 512
(2 rows)

=> SHOW USER ALL PARAMETER ALL;
user | parameter | setting
-----+-----+-----
Yvonne | DepotOperationsForQuery | FETCHES
Yvonne | LoadSourceStatisticsLimit | 512
Ahmed | DepotOperationsForQuery | FETCHES
(3 rows)
```

Locking user accounts

As a superuser, you can manually lock and unlock a database user account with [ALTER USER...ACCOUNT LOCK](#) and [ALTER USER...ACCOUNT UNLOCK](#), respectively. For example, the following command prevents user Fred from logging in to the database:

```
=> ALTER USER Fred ACCOUNT LOCK;
=> \c - Fred
FATAL 4974: The user account "Fred" is locked
HINT: Please contact the database administrator
```

The following example unlocks access to Fred's user account:

```
=> ALTER USER Fred ACCOUNT UNLOCK;
=> \c - Fred
You are now connected as user "Fred".
```

Locking new accounts

[CREATE USER](#) can specify to lock a new account. Like any locked account, it can be unlocked with [ALTER USER...ACCOUNT UNLOCK](#).

```
=> CREATE USER Bob ACCOUNT LOCK;
CREATE USER
```

Locking accounts for failed login attempts

A user's [profile](#) can specify to lock an account after a certain number of failed login attempts.

Setting and changing user passwords

As a superuser, you can set any user's password when you create that user with [CREATE USER](#), or later with [ALTER USER](#). Non-superusers can also change their own passwords with [ALTER USER](#). One exception applies: users who are added to the Vertica database with the LDAPLink service cannot change their passwords with [ALTER USER](#).

You can also give a user a pre-hashed password if you provide its associated salt. The salt must be a hex string. This method bypasses [password complexity requirements](#).

To view password hashes and salts of existing users, see the [PASSWORDS](#) system table.

Changing a user's password has no effect on their current session.

Setting user passwords in VSQL

In this example, the user 'Bob' is created with the password 'mypassword.'

```
=> CREATE USER Bob IDENTIFIED BY 'mypassword';  
CREATE USER
```

The password is then changed to 'Orca.'

```
=> ALTER USER Bob IDENTIFIED BY 'Orca' REPLACE 'mypassword';  
ALTER USER
```

In this example, the user 'Alice' is created with a pre-hashed password and salt.

```
=> CREATE USER Alice IDENTIFIED BY  
'sha512e0299de83ecfaa0b6c9cbb1feabf0b3c82a1495875cd9ec1c4b09016f09b42c1'  
SALT '465a4aec38a85d6ecea5a0ac8f2d36d8';
```

Setting user passwords in Management Console

On Management Console, users with ADMIN or IT privileges can reset a user's non-LDAP password:

1. Sign in to Management Console and navigate to **MC Settings > User management** .
2. Click to select the user to modify and click **Edit** .
3. Click **Edit password** and enter the new password twice.
4. Click **OK** and then **Save** .

Database roles

A role is a collection of privileges that can be [granted](#) to one or more users or other roles. Roles help you grant and manage sets of privileges for various categories of users, rather than grant those privileges to each user individually.

For example, several users might require administrative privileges. You can grant these privileges to them as follows:

1. [Create](#) an administrator role with [CREATE ROLE](#) :

```
CREATE ROLE administrator;
```
2. [Grant the role](#) to the appropriate users.
3. [Grant](#) the appropriate privileges to this role with one or more [GRANT](#) statements. You can later add and remove privileges as needed. Changes in role privileges are automatically propagated to the users who have that role.

After users are assigned roles, they can either [enable](#) those roles themselves, or you can [automatically enable](#) their roles for them.

In this section

- [Predefined database roles](#)
- [Role hierarchy](#)
- [Creating and dropping roles](#)
- [Granting privileges to roles](#)
- [Granting database roles](#)
- [Revoking database roles](#)
- [Enabling roles](#)
- [Enabling roles automatically](#)
- [Viewing user roles](#)

Predefined database roles

Vertica has the following predefined roles:

- [DBADMIN](#)
- [PSEUDOSUPERUSER](#)
- [DBDUSER](#)
- [SYSMONITOR](#)
- [UDXDEVELOPER](#)
- [MLSUPERVISOR](#)
- [PUBLIC](#)

Automatic role grants

On installation, Vertica automatically grants and enables predefined roles as follows:

- The DBADMIN, PSEUDOSUPERUSER, and DBDUSER roles are irrevocably granted to the [dbadmin user](#). These roles are always enabled for `dbadmin`, and can never be dropped.
- PUBLIC is granted to `dbadmin`, and to all other users as they are created. This role is always enabled and cannot be dropped or revoked.

Granting predefined roles

After installation, the `dbadmin` user and users with the PSEUDOSUPERUSER role can grant one or more predefined roles to any user or non-predefined role. For example, the following set of statements creates the `userdba` role and grants it the predefined role DBADMIN:

```
=> CREATE ROLE userdba;
CREATE ROLE
=> GRANT DBADMIN TO userdba WITH ADMIN OPTION;
GRANT ROLE
```

Users and roles that are granted a predefined role can extend that role to other users, if the original [GRANT \(Role\)](#) statement includes WITH ADMIN OPTION. One exception applies: if you grant a user the PSEUDOSUPERUSER role and omit WITH ADMIN OPTION, the grantee can grant any role, including all predefined roles, to other users.

For example, the `userdba` role was previously granted the DBADMIN role. Because the GRANT statement includes WITH ADMIN OPTION, users who are assigned the `userdba` role can grant the DBADMIN role to other users:

```
=> GRANT userdba TO fred;
GRANT ROLE
=> \c - fred
You are now connected as user "fred".
=> SET ROLE userdba;
SET
=> GRANT dbadmin TO alice;
GRANT ROLE
```

Modifying predefined Roles

Excluding SYSMONITOR, you can grant predefined roles privileges on individual database objects, such as tables or schemas. For example:

```
=> CREATE SCHEMA s1;
CREATE SCHEMA
=> GRANT ALL ON SCHEMA s1 to PUBLIC;
GRANT PRIVILEGE
```

You can grant PUBLIC any role, including predefined roles. For example:

```
=> CREATE ROLE r1;
CREATE ROLE
=> GRANT r1 TO PUBLIC;
GRANT ROLE
```

You cannot modify any other predefined role by granting another role to it. Attempts to do so return a rollback error:

```
=> CREATE ROLE r2;
CREATE ROLE
=> GRANT r2 TO PSEUDOSUPERUSER;
ROLLBACK 2347: Cannot alter predefined role "pseudosuperuser"
```

In this section

- [DBADMIN](#)
- [PSEUDOSUPERUSER](#)
- [DBDUSER](#)
- [SYSMONITOR](#)
- [UDXDEVELOPER](#)
- [MLSUPERVISOR](#)
- [PUBLIC](#)

DBADMIN

The `DBADMIN` role is a predefined role that is assigned to the [dbadmin user](#) on database installation. Thereafter, the `dbadmin` user and users with the

[PSEUDOSUPERUSER](#) role can grant any role to any user or non-predefined role.

For example, superuser `dbadmin` creates role `fred` and grants `fred` the `DBADMIN` role:

```
=> CREATE USER fred;
CREATE USER
=> GRANT DBADMIN TO fred WITH ADMIN OPTION;
GRANT ROLE
```

After user `fred` [enables](#) its `DBADMIN` role, he can exercise his `DBADMIN` privileges by creating user `alice`. Because the `GRANT` statement includes `WITH ADMIN OPTION`, `fred` can also grant the `DBADMIN` role to user `alice`:

```
=> \c - fred
You are now connected as user "fred".
=> SET ROLE dbadmin;
SET
CREATE USER alice;
CREATE USER
=> GRANT DBADMIN TO alice;
GRANT ROLE
```

DBADMIN privileges

The following table lists privileges that are supported for the `DBADMIN` role:

- Create users and roles, and grant them roles and privileges
- Create and drop schemas
- View all system tables
- View and terminate user sessions
- Access all data created by any user

PSEUDOSUPERUSER

The [PSEUDOSUPERUSER](#) role is a predefined role that is automatically assigned to the `dbadmin` user on database installation. The `dbadmin` can grant this role to any user or non-predefined role. Thereafter, [PSEUDOSUPERUSER](#) users can grant any role, including predefined roles, to other users.

PSEUDOSUPERUSER privileges

Users with the [PSEUDOSUPERUSER](#) role are entitled to complete administrative privileges, which cannot be revoked. Role privileges include:

- Bypass all `GRANT/REVOKE` authorization
- Create schemas and tables
- Create users and roles, and grant privileges to them
- Modify user accounts—for example, set user account's passwords, and lock/unlock accounts.
- Create or drop a UDF library and function, or any external procedure

DBDUSER

The [DBDUSER](#) role is a predefined role that is assigned to the `dbadmin_user` on database installation. The `dbadmin` and any [PSEUDOSUPERUSER](#) can grant this role to any user or non-predefined role. Users who have this role and enable it can call [Database Designer functions](#) from the command line.

Note

Non-`DBADMIN` users with the `DBDUSER` role cannot run Database Designer through Administration Tools. Only [DBADMIN](#) users can run Administration Tools.

Associating `DBDUSER` with resource pools

Be sure to associate a resource pool with the [DBDUSER](#) role, to facilitate resource management when you run Database Designer. Multiple users can run Database Designer concurrently without interfering with each other or exhausting all the cluster resources. Whether you run Database Designer programmatically or with Administration Tools, design execution is generally contained by the user's resource pool, but might spill over into system resource pools for less-intensive tasks.

SYSMONITOR

An organization's database administrator may have many responsibilities outside of maintaining Vertica as a DBADMIN user. In this case, as the DBADMIN you may want to delegate some Vertica administrative tasks to another Vertica user.

The DBADMIN can assign a delegate the SYSMONITOR role to grant access to system tables without granting full [DBADMIN](#) access.

The SYSMONITOR role provides the following privileges.

- View all system tables that are marked as monitorable. You can see a list of all the monitorable tables by issuing the statement:

```
=> SELECT * FROM system_tables WHERE is_monitorable='t';
```

- If **WITH ADMIN OPTION** was included when granting SYSMONITOR to the user or role, that user or role can then grant SYSMONITOR privileges to other users and roles.

Grant a SYSMONITOR role

To grant a user or role the SYSMONITOR role, you must be one of the following:

- a DBADMIN user
- a user assigned the SYSMONITOR who has the ADMIN OPTION

Use the [GRANT \(Role\)](#) SQL statement to assign a user the SYSMONITOR role. This example shows how to grant the SYSMONITOR role to user1 and includes administration privileges by using the WITH ADMIN OPTION parameter. The ADMIN OPTION grants the SYSMONITOR role administrative privileges:

```
=> GRANT SYSMONITOR TO user1 WITH ADMIN OPTION;
```

This example shows how to revoke the ADMIN OPTION from the SYSMONITOR role for user1:

```
=> REVOKE ADMIN OPTION for SYSMONITOR FROM user1;
```

Use CASCADE to revoke ADMIN OPTION privileges for all users assigned the SYSMONITOR role:

```
=> REVOKE ADMIN OPTION for SYSMONITOR FROM PUBLIC CASCADE;
```

Example

This example shows how to:

- Create a user
- Create a role
- Grant SYSMONITOR privileges to the new role
- Grant the role to the user

```
=> CREATE USER user1;
=> CREATE ROLE monitor;
=> GRANT SYSMONITOR TO monitor;
=> GRANT monitor TO user1;
```

Assign SYSMONITOR privileges

This example uses the user and role created in the Grant SYSMONITOR Role example and shows how to:

- Create a table called personal_data
- Log in as user1
- Grant user1 the monitor role. (You already granted the monitor SYSMONITOR privileges in the Grant a SYSMONITOR Role example.)
- Run a SELECT statement as user1

The results of the operations are based on the privilege already granted to user1.

```
=> CREATE TABLE personal_data (SSN varchar (256));
=> \c -user1;
=> SET ROLE monitor;
=> SELECT COUNT(*) FROM TABLES;
COUNT
-----
 1
(1 row)
```

Because you assigned the SYSMONITOR role, user1 can see the number of rows in the Tables system table. In this simple example, there is only one table (personal_data) in the database so the SELECT COUNT returns one row. In actual conditions, the SYSMONITOR role would see all the tables in the database.

Check if a table is accessible by SYSMONITOR

To check if a system table can be accessed by a user assigned the SYSMONITOR role:

```
=> SELECT table_name, is_monitorable FROM system_tables WHERE table_name='table_name'
```

For example, the following statement shows that the [CURRENT_SESSION](#) system table is accessible by the SYSMONITOR:

```
=> SELECT table_name, is_monitorable FROM system_tables WHERE table_name='current_session';
table_name | is_monitorable
-----+-----
current_session | t
(1 row)
```

UDXDEVELOPER

The UDXDEVELOPER role is a predefined role that enables users to create and replace user-defined libraries. The [dbadmin](#) can grant this role to any user or non-predefined role.

UDXDEVELOPER privileges

Users with the UDXDEVELOPER role can perform the following actions:

- [CREATE LIBRARY](#)
- If library owner or with the DROP privilege:
 - CREATE OR REPLACE LIBRARY
 - [DROP LIBRARY](#)
 - [ALTER LIBRARY](#)

To use the privileges of this role, you must explicitly enable it using [SET ROLE](#).

Security considerations

A user with the UDXDEVELOPER role can create libraries and, therefore, can install any UDx function in the database. UDx functions run as the Linux user that owns the database, and therefore have access to resources that Vertica has access to.

A poorly-written function can degrade database performance. Give this role only to users you trust to use UDxs responsibly. You can limit the memory that a UDx can consume by running UDxs in fenced mode and by setting the [FencedUDxMemoryLimitMB](#) configuration parameter.

MLSUPERVISOR

The [MLSUPERVISOR](#) role is a predefined role to which all the ML-model management privileges of [DBADMIN](#) are delegated. An [MLSUPERVISOR](#) can manage all models in the [V_CATALOG.MODELS](#) table on behalf of [dbadmin](#).

In the following example, user [alice](#) uses her [MLSUPERVISOR](#) privileges to reassign ownership of the model [my_model](#) from user [bob](#) to user [nina](#) :

```

=> \c - alice
You are now connected as user "alice".

=> SELECT model_name, schema_name, owner_name FROM models;
model_name | schema_name | owner_name
-----+-----+-----
my_model   | public     | bob
mylinearreg | myschema2  | alice
(2 rows)

=> SET ROLE MLSUPERVISOR;

=> ALTER MODEL my_model OWNER to nina;

=> SELECT model_name, schema_name, owner_name FROM models;
model_name | schema_name | owner_name
-----+-----+-----
my_model   | public     | nina
mylinearreg | myschema2  | alice
(2 rows)

=> DROP MODEL my_model;

```

MLSUPERVISOR privileges

The following privileges are supported for the MLSUPERVISOR role:

- ML-model management privileges of DBADMIN
- Management (USAGE, ALTER, DROP) of all models in V_CATALOG.MODELS

To use the privileges of this role, you must explicitly enable it using [SET ROLE](#).

See also

- [Model versioning](#)
- [REGISTER_MODEL](#)
- [CHANGE_MODEL_STATUS](#)

PUBLIC

The **PUBLIC** role is a predefined role that is automatically assigned to all new users. It is always [enabled](#) and cannot be dropped or revoked. Use this role to grant all database users the same minimum set of privileges.

Like any role, the **PUBLIC** role can be granted privileges to individual objects and other roles. The following example grants the **PUBLIC** role INSERT and SELECT privileges on table `publicdata`. This enables all users to read data in that table and insert new data:

```

=> CREATE TABLE publicdata (a INT, b VARCHAR);
CREATE TABLE
=> GRANT INSERT, SELECT ON publicdata TO PUBLIC;
GRANT PRIVILEGE
=> CREATE PROJECTION publicdataproj AS (SELECT * FROM publicdata);
CREATE PROJECTION
=> \c - bob
You are now connected as user "bob".
=> INSERT INTO publicdata VALUES (10, 'Hello World');
OUTPUT
-----
 1
(1 row)

```

The following example grants **PUBLIC** the `employee` role, so all database users have `employee` privileges:

```

=> GRANT employee TO public;
GRANT ROLE

```

Important

The clause **WITH ADMIN OPTION** is invalid for any **GRANT** statement that specifies **PUBLIC** as grantee.

Role hierarchy

By granting roles to other roles, you can build a hierarchy of roles, where roles lower in the hierarchy have a narrow range of privileges, while roles higher in the hierarchy are granted combinations of roles and their privileges. When you organize roles hierarchically, any privileges that you add to lower-level roles are automatically propagated to the roles above them.

Creating hierarchical roles

The following example creates two roles, assigns them privileges, then assigns both roles to another role.

1. Create table **applog** :

```
=> CREATE TABLE applog (id int, sourceID VARCHAR(32), data TIMESTAMP, event VARCHAR(256));
```

2. Create the **logreader** role and grant it read-only privileges on table **applog** :

```
=> CREATE ROLE logreader;
CREATE ROLE
=> GRANT SELECT ON applog TO logreader;
GRANT PRIVILEGE
```

3. Create the **logwriter** role and grant it write privileges on table **applog** :

```
=> CREATE ROLE logwriter;
CREATE ROLE
=> GRANT INSERT, UPDATE ON applog to logwriter;
GRANT PRIVILEGE
```

4. Create the **logadmin** role and grant it DELETE privilege on table **applog** :

```
=> CREATE ROLE logadmin;
CREATE ROLE
=> GRANT DELETE ON applog to logadmin;
GRANT PRIVILEGE
```

5. Grant the **logreader** and **logwriter** roles to role **logadmin** :

```
=> GRANT logreader, logwriter TO logadmin;
```

6. Create user **bob** and grant him the **logadmin** role:

```
=> CREATE USER bob;
CREATE USER
=> GRANT logadmin TO bob;
GRANT PRIVILEGE
```

7. Modify user **bob** 's account so his **logadmin** role is [automatically enabled](#) on login:

```
=> ALTER USER bob DEFAULT ROLE logadmin;
ALTER USER
=> \c - bob
You are now connected as user "bob".
=> SHOW ENABLED_ROLES;
 name | setting
-----+-----
enabled roles | logadmin
(1 row)
```

Enabling hierarchical roles

Only roles that are explicitly granted to a user can be enabled for that user. In the previous example, roles **logreader** or **logwriter** cannot be enabled for **bob** . They can only be enabled indirectly, by enabling **logadmin** .

Hierarchical role grants and WITH ADMIN OPTION

If one or more roles are granted to another role using **WITH ADMIN OPTION** , then users who are granted the 'higher' role inherit administrative access to the subordinate roles.

For example, you might modify the earlier grants of roles `logreader` and `logwriter` to `logadmin` as follows:

```
=> GRANT logreader, logwriter TO logadmin WITH ADMIN OPTION;
NOTICE 4617: Role "logreader" was already granted to role "logadmin"
NOTICE 4617: Role "logwriter" was already granted to role "logadmin"
GRANT ROLE
```

User `bob`, through his `logadmin` role, is now authorized to grant its two subordinate roles to other users—in this case, role `logreader` to user `Alice` :

```
=> \c - bob;
You are now connected as user "bob".
=> GRANT logreader TO Alice;
GRANT ROLE
=> \c - alice;
You are now connected as user "alice".
=> show available_roles;
  name  | setting
-----+-----
available roles | logreader
(1 row)
```

Note

Because the grant of the `logadmin` role to `bob` did not include `WITH ADMIN OPTION`, he cannot grant that role to `alice` :

```
=> \c - bob;
You are now connected as user "bob".
=> GRANT logadmin TO alice;
ROLLBACK 4925: The role "logadmin" cannot be granted to "alice"
```

Creating and dropping roles

As a superuser with the `DBADMIN` or `PSEUDOSUPERUSER` role, you can create and drop roles with `CREATE ROLE` and `DROP ROLE`, respectively.

```
=> CREATE ROLE administrator;
CREATE ROLE
```

A new role has no privileges or roles granted to it. Only superusers can [grant privileges](#) and [access](#) to the role.

Dropping database roles with dependencies

If you try to drop a role that is granted to users or other roles Vertica returns a rollback message:

```
=> DROP ROLE administrator;
NOTICE: User Bob depends on Role administrator
ROLLBACK: DROP ROLE failed due to dependencies
DETAIL:  Cannot drop Role administrator because other objects depend on it
HINT:  Use DROP ROLE ... CASCADE to remove granted roles from the dependent users/roles
```

To force the drop operation, qualify the `DROP ROLE` statement with `CASCADE` :

```
=> DROP ROLE administrator CASCADE;
DROP ROLE
```

Granting privileges to roles

You can use [GRANT statements](#) to assign privileges to a role, just as you assign privileges to users. See [Database privileges](#) for information about which privileges can be granted.

Granting a privilege to a role immediately affects active user sessions. When you grant a privilege to a role, it becomes immediately available to all users with that role enabled.

The following example creates two roles and assigns them different privileges on the same table.

1. Create table **applog** :

```
=> CREATE TABLE applog (id int, sourceID VARCHAR(32), data TIMESTAMP, event VARCHAR(256));
```

2. Create roles **logreader** and **logwriter** :

```
=> CREATE ROLE logreader;  
CREATE ROLE  
=> CREATE ROLE logwriter;  
CREATE ROLE
```

3. Grant read-only privileges on **applog** to **logreader** , and write privileges to **logwriter** :

```
=> GRANT SELECT ON applog TO logreader;  
GRANT PRIVILEGE  
=> GRANT INSERT ON applog TO logwriter;  
GRANT PRIVILEGE
```

Revoking privileges from roles

Use [REVOKE statements](#) to revoke a privilege from a role. Revoking a privilege from a role immediately affects active user sessions. When you revoke a privilege from a role, it is no longer available to users who have the privilege through that role.

For example:

```
=> REVOKE INSERT ON applog FROM logwriter;  
REVOKE PRIVILEGE
```

Granting database roles

You can assign one or more roles to a user or another role with [GRANT \(Role\)](#):

```
GRANT role[,...] TO grantee[,...] [ WITH ADMIN OPTION ]
```

For example, you might create three roles— **appdata** , **applogs** , and **appadmin** —and grant **appadmin** to user **bob** :

```
=> CREATE ROLE appdata;  
CREATE ROLE  
=> CREATE ROLE applogs;  
CREATE ROLE  
=> CREATE ROLE appadmin;  
CREATE ROLE  
=> GRANT appadmin TO bob;  
GRANT ROLE
```

Granting roles to another role

GRANT can assign one or more roles to another role. For example, the following **GRANT** statement grants roles **appdata** and **applogs** to role **appadmin** :

```
=> GRANT appdata, applogs TO appadmin;  
-- grant to other roles  
GRANT ROLE
```

Because user bob was previously assigned the role **appadmin** , he now has all privileges that are granted to roles **appdata** and **applogs** .

When you grant one role to another role, Vertica checks for circular references. In the previous example, role **appdata** is assigned to the **appadmin** role. Thus, subsequent attempts to assign **appadmin** to **appdata** fail, returning with the following warning:

```
=> GRANT appadmin TO appdata;  
WARNING: Circular assignment of roles is not allowed  
HINT: Cannot grant appadmin to appdata  
GRANT ROLE
```

Enabling roles

After granting a role to a user, the role must be enabled. You can enable a role for the current session:

```
=> SET ROLE appdata;  
SET ROLE
```

You can also enable a role as part of the user's login, by modifying the user's profile with [ALTER USER...DEFAULT ROLE](#) :

```
=> ALTER USER bob DEFAULT ROLE appdata;  
ALTER USER
```

For details, see [Enabling roles](#) and [Enabling roles automatically](#).

Granting administrative privileges

You can delegate to non-superusers users administrative access to a role by qualifying the [GRANT \(Role\)](#) statement with the option **WITH ADMIN OPTION** . Users with administrative access can manage access to the role for other users, including granting them administrative access. In the following example, a superuser grants the **appadmin** role with administrative privileges to users **bob** and **alice**.

```
=> GRANT appadmin TO bob, alice WITH ADMIN OPTION;  
GRANT ROLE
```

Now, both users can exercise their administrative privileges to grant the **appadmin** role to other users, or revoke it. For example, user **bob** can now revoke the **appadmin** role from user **alice** :

```
=> \connect - bob  
You are now connected as user "bob".  
=> REVOKE appadmin FROM alice;  
REVOKE ROLE
```

Caution

As with all user privilege models, database superusers should be cautious when granting any user a role with administrative privileges. For example, if the database superuser grants two users a role with administrative privileges, either user can revoke that role from the other user.

Example

The following example creates a role called **commenter** and grants that role to user **bob** :

1. Create the **comments** table:

```
=> CREATE TABLE comments (id INT, comment VARCHAR);
```

2. Create the **commenter** role:

```
=> CREATE ROLE commenter;
```

3. Grant to **commenter** INSERT and SELECT privileges on the **comments** table:

```
=> GRANT INSERT, SELECT ON comments TO commenter;
```

4. Grant the **commenter** role to user **bob** .

```
=> GRANT commenter TO bob;
```

5. In order to access the role and its associated privileges, **bob** enables the newly-granted role for himself:

```
=> \c - bob  
=> SET ROLE commenter;
```

6. Because **bob** has INSERT and SELECT privileges on the **comments** table, he can perform the following actions:

```
=> INSERT INTO comments VALUES (1, 'Hello World');
OUTPUT
-----
   1
(1 row)
=> SELECT * FROM comments;
id | comment
---+-----
  1 | Hello World
(1 row)
=> COMMIT;
COMMIT
```

7. Because **bob** 's role lacks DELETE privileges, the following statement returns an error:

```
=> DELETE FROM comments WHERE id=1;
ERROR 4367: Permission denied for relation comments
```

See also

[Database privileges](#)

Revoking database roles

[REVOKE \(Role\)](#) can revoke roles from one or more grantees—that is, from users or roles:

```
REVOKE [ ADMIN OPTION FOR ] role[...] FROM grantees[...] [ CASCADE ]
```

For example, the following statement revokes the **commenter** role from user **bob** :

```
=> \c
You are now connected as user "dbadmin".
=> REVOKE commenter FROM bob;
REVOKE ROLE
```

Revoking administrative access from a role

You can qualify [REVOKE \(Role\)](#) with the clause **ADMIN OPTION FOR** . This clause revokes from the grantees the authority (granted by an earlier **GRANT (Role)...WITH ADMIN OPTION** statement) to grant the specified roles to other users or roles. Current roles for the grantees are unaffected.

The following example revokes user Alice's authority to grant and revoke the **commenter** role:

```
=> \c
You are now connected as user "dbadmin".
=> REVOKE ADMIN OPTION FOR commenter FROM alice;
REVOKE ROLE
```

Enabling roles

When you enable a role in a session, you obtain all privileges assigned to that role. You can enable multiple roles simultaneously, thereby gaining all privileges of those roles, plus any privileges that are already granted to you directly.

By default, only [predefined roles](#) are [enabled automatically](#) for users. Otherwise, on starting a session, you must explicitly enable [assigned roles](#) with the Vertica function [SET ROLE](#) .

For example, the dbadmin creates the **logreader** role and assigns it to user **alice** :

```
=> \c
You are now connected as user "dbadmin".
=> CREATE ROLE logreader;
CREATE ROLE
=> GRANT SELECT ON TABLE applog TO logreader;
GRANT PRIVILEGE
=> GRANT logreader TO alice;
GRANT ROLE
```

User **alice** must enable the new role before she can view the **applog** table:

```

=> \c - alice
You are now connected as user "alice".
=> SELECT * FROM applog;
ERROR: permission denied for relation applog
=> SET ROLE logreader;
SET
=> SELECT * FROM applog;
id | sourceID | data | event
-----+-----+-----+-----
 1 | Loader | 2011-03-31 11:00:38.494226 | Error: Failed to open source file
 2 | Reporter | 2011-03-31 11:00:38.494226 | Warning: Low disk space on volume /scratch-a
(2 rows)

```

Enabling all user roles

You can enable all roles available to your user account with **SET ROLE ALL** :

```

=> SET ROLE ALL;
SET
=> SHOW ENABLED_ROLES;
 name | setting
-----+-----
enabled roles | logreader, logwriter
(1 row)

```

Important

You can also enable user roles on login. For more information, see [Enabling roles automatically](#).

Disabling roles

A user can disable all roles with **SET ROLE NONE**. This statement disables all roles for the current session, excluding predefined roles:

```

=> SET ROLE NONE;
=> SHOW ENABLED_ROLES;
 name | setting
-----+-----
enabled roles |
(1 row)

```

Enabling roles automatically

By default, new users are assigned the **PUBLIC**, which is automatically enabled when a new session starts. Typically, other roles are created and users are assigned to them, but these are not automatically enabled. Instead, users must explicitly **enable** their assigned roles with each new session, with **SET ROLE**.

You can automatically enable roles for users in two ways:

- Enable roles for individual users on login
- Enable all roles for all users on login

Enable roles for individual users

After assigning roles to users, you can set one or more default roles for each user by modifying their profiles, with **ALTER USER...DEFAULT ROLE**. User default roles are automatically enabled at the start of the user session. You should consider setting default roles for users if they typically rely on the privileges of those roles to carry out routine tasks.

Important

ALTER USER...DEFAULT ROLE overwrites previous default role settings.

The following example shows how to set **regional_manager** as the default role for user **LilyCP** :

```

=> \c
You are now connected as user "dbadmin".
=> GRANT regional_manager TO LilyCP;
GRANT ROLE
=> ALTER USER LilyCP DEFAULT ROLE regional_manager;
ALTER USER
=> \c - LilyCP
You are now connected as user "LilyCP".
=> SHOW ENABLED_ROLES;
  name  |  setting
-----+-----
enabled roles | regional_manager
(1 row)

```

Enable all roles for all users

Configuration parameter [EnableAllRolesOnLogin](#) specifies whether to enable all roles for all database users on login. By default, this parameter is set to 0. If set to 1, Vertica enables the roles of all users when they log in to the database.

Clearing default roles

You can clear all default role assignments for a user with [ALTER USER...DEFAULT ROLE NONE](#). For example:

```

=> ALTER USER fred DEFAULT ROLE NONE;
ALTER USER
=> SELECT user_name, default_roles, all_roles FROM users WHERE user_name = 'fred';
 user_name | default_roles | all_roles
-----+-----+-----
fred      |               | logreader
(1 row)

```

Viewing user roles

You can obtain information about roles in three ways:

- [Verify specific role assignments](#) with the function [HAS_ROLE](#).
- [View all available \(granted\) and enabled roles](#).
- [Obtain comprehensive information](#) about roles, the users assigned to them, and the privileges granted to those users and roles by querying system tables [ROLES](#), [USERS](#), AND [GRANTS](#), respectively.

Note

System tables do not show whether a role is available to a user indirectly through other roles. Call [HAS_ROLE](#) to obtain that information.

Verifying role assignments

The function [HAS_ROLE](#) checks whether a Vertica role is granted to the specified user or role. Non-superusers can use this function to check their own role membership. Superusers can use it to determine role assignments for other users and roles. You can also use Management Console to [check role assignments](#).

In the following example, a [dbadmin](#) user checks whether user [MikeL](#) is assigned the [administrator](#) role:

```

=> \c
You are now connected as user "dbadmin".
=> SELECT HAS_ROLE('MikeL', 'administrator');
HAS_ROLE
-----
t
(1 row)

```

User [MikeL](#) checks whether he has the [regional_manager](#) role:

```

=> \c - MikeL
You are now connected as user "MikeL".
=> SELECT HAS_ROLE('regional_manager');
HAS_ROLE
-----
f
(1 row)

```

The dbadmin grants the [regional_manager](#) role to the [administrator](#) role. On checking again, [MikeL](#) verifies that he now has the [regional_manager](#) role:

```

dbadmin=> \c
You are now connected as user "dbadmin".
dbadmin=> GRANT regional_manager to administrator;
GRANT ROLE
dbadmin=> \c - MikeL
You are now connected as user "MikeL".
dbadmin=> SELECT HAS_ROLE('regional_manager');
HAS_ROLE
-----
t
(1 row)

```

Viewing available and enabled roles

[SHOW AVAILABLE ROLES](#) lists all roles granted to you:

```

=> SHOW AVAILABLE ROLES;
 name | setting
-----+-----
available roles | logreader, logwriter
(1 row)

```

[SHOW ENABLED ROLES](#) lists the roles enabled in your session:

```

=> SHOW ENABLED ROLES;
 name | setting
-----+-----
enabled roles | logreader
(1 row)

```

Querying system tables

You can query tables [ROLES](#), [USERS](#), AND [GRANTS](#), either separately or joined, to obtain detailed information about user roles, users assigned to those roles, and the privileges granted explicitly to users and implicitly through roles.

The following query on [ROLES](#) returns the names of all roles users can access, and the roles granted (assigned) to those roles. An asterisk (*) appended to a role indicates that the user can grant the role to other users:

```

=> SELECT * FROM roles;
 name | assigned_roles
-----+-----
public |
dbduser |
dbadmin | dbduser*
pseudosuperuser | dbadmin*
logreader |
logwriter |
logadmin | logreader, logwriter
(7 rows)

```

The following query on system table [USERS](#) returns all users with the DBADMIN role. An asterisk (*) appended to a role indicates that the user can grant the role to other users:

```
=> SELECT user_name, is_super_user, default_roles, all_roles FROM v_catalog.users WHERE all_roles ILIKE '%dbadmin%';
user_name | is_super_user | default_roles | all_roles
-----+-----+-----+-----
dbadmin | t | dbduser*, dbadmin*, pseudosuperuser* | dbduser*, dbadmin*, pseudosuperuser*
u1 | f | | dbadmin*
u2 | f | | dbadmin
(3 rows)
```

The following query on system table [GRANTS](#) returns the privileges granted to user Jane or role R1. An asterisk (*) appended to a privilege indicates that the user can grant the privilege to other users:

```
=> SELECT grantor,privileges_description,object_name,object_type,grantee FROM grants WHERE grantee='Jane' OR grantee='R1';
grantor | privileges_description | object_name | object_type | grantee
-----+-----+-----+-----+-----
dbadmin | USAGE | general | RESOURCEPOOL | Jane
dbadmin | | R1 | ROLE | Jane
dbadmin | USAGE* | s1 | SCHEMA | Jane
dbadmin | USAGE, CREATE* | s1 | SCHEMA | R1
(4 rows)
```

Database privileges

When a database object is created, such as a schema, table, or view, ownership of that object is assigned to the user who created it. By default, only the object's owner, and users with superuser privileges such as database administrators, have privileges on a new object. Only these users (and other users whom they explicitly authorize) can grant object privileges to other users

Privileges are granted and revoked by [GRANT](#) and [REVOKE](#) statements, respectively. The privileges that can be granted on a given object are specific to its type. For example, table privileges include SELECT, INSERT, and UPDATE, while library and resource pool privileges have USAGE privileges only. For a summary of object privileges, see [Database object privileges](#).

Because privileges on database objects can come from several different sources like explicit grants, roles, and inheritance, privileges can be difficult to monitor. Use the [GET_PRIVILEGES_DESCRIPTION](#) meta-function to check the current user's [effective privileges](#) across all sources on a specified database object.

In this section

- [Ownership and implicit privileges](#)
- [Inherited privileges](#)
- [Default user privileges](#)
- [Effective privileges](#)
- [Privileges required for common database operations](#)
- [Database object privileges](#)
- [Granting and revoking privileges](#)
- [Modifying privileges](#)
- [Viewing privileges granted on objects](#)

Ownership and implicit privileges

All users have *implicit* privileges on the objects that they own. On creating an object, its owner automatically is granted all privileges associated with the object's type (see [Database object privileges](#)). Regardless of object type, the following privileges are inseparable from ownership and cannot be revoked, not even by the owner:

- Authority to grant all object privileges to other users, and revoke them
- ALTER (where applicable) and DROP
- Extension of privilege granting authority on their objects to other users, and revoking that authority

Object owners can revoke all non-implicit, or *ordinary*, privileges from themselves. For example, on creating a table, its owner is automatically granted all implicit and ordinary privileges:

Implicit table privileges

Ordinary table privileges

ALTER
DROP

DELETE
INSERT
REFERENCES
SELECT
TRUNCATE
UPDATE

If user **Joan** creates table **t1**, she can revoke ordinary privileges UPDATE and INSERT from herself, which effectively makes this table read-only:

```
=> \c - Joan
You are now connected as user "Joan".
=> CREATE TABLE t1 (a int);
CREATE TABLE
=> INSERT INTO t1 VALUES (1);
OUTPUT
-----
   1
(1 row)

=> COMMIT;
COMMIT
=> REVOKE UPDATE, INSERT ON TABLE t1 FROM Joan;
REVOKE PRIVILEGE
=> INSERT INTO t1 VALUES (3);
ERROR 4367: Permission denied for relation t1
=> SELECT * FROM t1;
 a
---
 1
(1 row)
```

Joan can subsequently restore UPDATE and INSERT privileges to herself:

```
=> GRANT UPDATE, INSERT on TABLE t1 TO Joan;
GRANT PRIVILEGE
dbadmin=> INSERT INTO t1 VALUES (3);
OUTPUT
-----
   1
(1 row)

=> COMMIT;
COMMIT
dbadmin=> SELECT * FROM t1;
 a
---
 1
 3
(2 rows)
```

Inherited privileges

You can manage inheritance of privileges at three levels:

- Database
- Schema
- Tables, views, and models

By default, inherited privileges are enabled at the database level and disabled at the schema level. If privilege inheritance is enabled at both levels, newly created tables, views, and models automatically inherit their parent schema's privileges. You can also disable privilege inheritance on individual objects with the following statements:

- [CREATE TABLE / ALTER TABLE](#)
- [CREATE VIEW / ALTER VIEW](#)
- [ALTER MODEL](#)

In this section

- [Enabling database inheritance](#)
- [Enabling schema inheritance](#)
- [Setting privilege inheritance on tables and views](#)
- [Example usage: implementing inherited privileges](#)

Enabling database inheritance

By default, inherited privileges are enabled at the database level. You can toggle database-level inherited privileges with the `DisableInheritedPrivileges` [configuration parameter](#).

To enable inherited privileges:

```
=> ALTER DATABASE database_name SET DisableInheritedPrivileges = 0;
```

To disable inherited privileges:

```
=> ALTER DATABASE database_name SET DisableInheritedPrivileges = 1;
```

Enabling schema inheritance

Caution

Enabling inherited privileges with `ALTER SCHEMA ... DEFAULT INCLUDE PRIVILEGES` only affects *newly* created tables, views, and models.

This setting does not affect existing tables, views, and models.

By default, inherited privileges are disabled at the schema level. If inherited privileges are enabled at the database level, you can enable inheritance at the schema level with [CREATE SCHEMA](#) and [ALTER SCHEMA](#). For example, the following statement creates the schema `my_schema` with schema inheritance enabled:

To create a schema with schema inheritance enabled:

```
=> CREATE SCHEMA my_schema DEFAULT INCLUDE PRIVILEGES;
```

To enable schema inheritance for an existing schema:

```
=> ALTER SCHEMA my_schema DEFAULT INCLUDE SCHEMA PRIVILEGES;
```

After schema-level privilege inheritance is enabled, privileges granted on the schema are automatically inherited by all newly created tables, views, and models in that schema. You can explicitly exclude a table, view, or model from privilege inheritance with the following statements:

- [CREATE TABLE / ALTER TABLE](#)
- [CREATE VIEW / ALTER VIEW](#)
- [ALTER MODEL](#)

For example, to prevent `my_table` from inheriting the privileges of `my_schema`:

```
=> ALTER TABLE my_schema.my_table EXCLUDE SCHEMA PRIVILEGES;
```

For information about which objects inherit privileges from which schemas, see [INHERITING OBJECTS](#).

For information about which privileges each object inherits, see [INHERITED PRIVILEGES](#).

Note

If inherited privileges are disabled for the database, enabling inheritance on its schemas has no effect. Attempts to do so return the following message:

```
Inherited privileges are globally disabled; schema parameter is set but has no effect.
```

Schema inheritance for existing objects

Enabling schema inheritance on an existing schema only affects newly created tables, views, and models in that schema. To allow an existing objects to inherit the privileges from their parent schema, you must explicitly set schema inheritance on each object with [ALTER TABLE](#), [ALTER VIEW](#), or [ALTER MODEL](#).

For example, my_schema contains my_table, my_view, and my_model. Enabling schema inheritance on my_schema does not affect the privileges of my_table and my_view. The following statements explicitly set schema inheritance on these objects:

```
=> ALTER VIEW my_schema.my_view INCLUDE SCHEMA PRIVILEGES;
=> ALTER TABLE my_schema.my_table INCLUDE SCHEMA PRIVILEGES;
=> ALTER MODEL my_schema.my_model INCLUDE SCHEMA PRIVILEGES;
```

After enabling inherited privileges on a schema, you can grant privileges on it to users and roles with [GRANT \(schema\)](#). The specified user or role then implicitly has these same privileges on the objects in the schema:

```
=> GRANT USAGE, CREATE, SELECT, INSERT ON SCHEMA my_schema TO PUBLIC;
GRANT PRIVILEGE
```

See also

- [Setting privilege inheritance on tables and views](#)
- [Granting and revoking privileges](#)

Setting privilege inheritance on tables and views

Caution

Enabling inherited privileges with ALTER SCHEMA ... DEFAULT INCLUDE PRIVILEGES only affects *newly* created tables, views, and models.

This setting does not affect existing tables, views, and models .

If inherited privileges are enabled for the database and a schema, privileges granted to the schema are automatically granted to all new tables and views in it. You can also explicitly exclude tables and views from inheriting schema privileges.

For information about which tables and views inherit privileges from which schemas, see [INHERITING_OBJECTS](#).

For information about which privileges each table or view inherits, see the [INHERITED_PRIVILEGES](#).

Set privileges inheritance on tables and views

[CREATE TABLE](#) / [ALTER TABLE](#) and [CREATE VIEW](#) / [ALTER VIEW](#) can allow tables and views to inherit privileges from their parent schemas. For example, the following statements enable inheritance on schema s1, so new table s1.t1 and view s1.myview automatically inherit the privileges set on that schema as applicable:

```
=> CREATE SCHEMA s1 DEFAULT INCLUDE PRIVILEGES;
CREATE SCHEMA
=> GRANT USAGE, CREATE, SELECT, INSERT ON SCHEMA S1 TO PUBLIC;
GRANT PRIVILEGE
=> CREATE TABLE s1.t1 ( ID int, f_name varchar(16), l_name(24));
WARNING 6978: Table "t1" will include privileges from schema "s1"
CREATE TABLE
=> CREATE VIEW s1.myview AS SELECT ID, l_name FROM s1.t1
WARNING 6978: View "myview" will include privileges from schema "s1"
CREATE VIEW
```

Note

Both CREATE statements omit the clause INCLUDE SCHEMA PRIVILEGES, so they return a warning message that the new objects will inherit

schema privileges. CREATE statements that include this clause do not return a warning message.

If the schema already exists, you can use ALTER SCHEMA to have all *newly created tables and views* inherit the privileges of the schema. Tables and views created on the schema before this statement, however, are not affected:

```
=> CREATE SCHEMA s2;
CREATE SCHEMA
=> CREATE TABLE s2.t22 ( a int );
CREATE TABLE
...
=> ALTER SCHEMA S2 DEFAULT INCLUDE PRIVILEGES;
ALTER SCHEMA
```

In this case, inherited privileges were enabled on schema s2 after it already contained table s2.t22. To set inheritance on this table and other existing tables and views, you must explicitly set schema inheritance on them with [ALTER TABLE](#) and [ALTER VIEW](#) :

```
=> ALTER TABLE s2.t22 INCLUDE SCHEMA PRIVILEGES;
```

Exclude privileges inheritance from tables and views

You can use [CREATE TABLE / ALTER TABLE](#) and [CREATE VIEW / ALTER VIEW](#) to prevent table and views from inheriting schema privileges.

The following example shows how to create a table that does not inherit schema privileges:

```
=> CREATE TABLE s1.t1 ( x int) EXCLUDE SCHEMA PRIVILEGES;
```

You can modify an existing table so it does not inherit schema privileges:

```
=> ALTER TABLE s1.t1 EXCLUDE SCHEMA PRIVILEGES;
```

Example usage: implementing inherited privileges

The following steps show how user **Joe** enables inheritance of privileges on a given schema so other users can access tables in that schema.

1. **Joe** creates schema **schema1** , and creates table **table1** in it:

```
=>\c - Joe
You are now connected as user Joe
=> CREATE SCHEMA schema1;
CRDEATE SCHEMA
=> CREATE TABLE schema1.table1 (id int);
CREATE TABLE
```

2. **Joe** grants USAGE and CREATE privileges on **schema1** to **Myra** :

```
=> GRANT USAGE, CREATE ON SCHEMA schema1 to Myra;
GRANT PRIVILEGE
```

3. **Myra** queries **schema1.table1** , but the query fails:

```
=>\c - Myra
You are now connected as user Myra
=> SELECT * FROM schema1.table1;
ERROR 4367: Permission denied for relation table1
```

4. **Joe** grants **Myra SELECT ON SCHEMA** privileges on **schema1** :

```
=>\c - Joe
You are now connected as user Joe
=> GRANT SELECT ON SCHEMA schema1 to Myra;
GRANT PRIVILEGE
```

5. **Joe** uses **ALTER TABLE** to include SCHEMA privileges for **table1** :

```
=> ALTER TABLE schema1.table1 INCLUDE SCHEMA PRIVILEGES;  
ALTER TABLE
```

6. Myra 's query now succeeds:

```
=>\c - Myra  
You are now connected as user Myra  
=> SELECT * FROM schema1.table1;  
id  
---  
(0 rows)
```

7. Joe modifies `schema1` to include privileges so all tables created in `schema1` inherit schema privileges:

```
=>\c - Joe  
You are now connected as user Joe  
=> ALTER SCHEMA schema1 DEFAULT INCLUDE PRIVILEGES;  
ALTER SCHEMA  
=> CREATE TABLE schema1.table2 (id int);  
CREATE TABLE
```

8. With inherited privileges enabled, Myra can query `table2` without Joe having to explicitly grant privileges on the table:

```
=>\c - Myra  
You are now connected as user Myra  
=> SELECT * FROM schema1.table2;  
id  
---  
(0 rows)
```

Default user privileges

To set the minimum level of privilege for all users, Vertica has the special [PUBLIC](#), which it grants to each user automatically. This role is automatically enabled, but the database administrator or a [superuser](#) can also grant higher privileges to users separately using GRANT statements.

Default privileges for MC users

Privileges on Management Console (MC) are managed through roles, which determine a user's access to MC and to MC-managed Vertica databases through the MC interface. MC privileges do not alter or override Vertica privileges or roles. See [Users, roles, and privileges in MC](#) for details.

Effective privileges

A user's *effective privileges* on an object encompass privileges of all types, including:

- [Implicit privileges](#) through object ownership
- [Explicit privileges](#) through GRANT statements on objects
- [Inherited privileges](#) through privileges on objects with inheritance enabled

You can view your effective privileges on an object with the [GET_PRIVILEGES_DESCRIPTION](#) meta-function.

Privileges required for common database operations

This topic lists the required privileges for database objects in Vertica.

Unless otherwise noted, [superusers](#) can perform all operations shown in the following tables. Object owners always can perform operations on their own objects.

Note

Certain actions, such as [setting another user's resource pool](#) or [selecting a view](#), depend on the [effective privileges](#) of other users. If that other user acquires these prerequisite privileges through a role, it must be a default role for the action to succeed.

For more information on changing a user's default roles, see [Enabling roles automatically](#).

Schemas

The PUBLIC schema is present in any newly-created Vertica database. Newly-created users must be granted access to this schema:

```
=> GRANT USAGE ON SCHEMA public TO user;
```

A database superuser must also explicitly grant new users CREATE privileges, as well as grant them individual object privileges so the new users can create or look up objects in the PUBLIC schema.

Operation	Required Privileges
CREATE SCHEMA	Database: CREATE
DROP SCHEMA	Schema: owner
ALTER SCHEMA	Database: CREATE

Tables

Operation	Required Privileges
CREATE TABLE	Schema: CREATE Note Referencing sequences in the CREATE TABLE statement requires the following privileges: <ul style="list-style-type: none">• Sequence schema: USAGE• Sequence: SELECT
DROP TABLE	Schema: USAGE or schema owner
TRUNCATE TABLE	Schema: USAGE or schema owner
ALTER TABLE ADD/DROP/ RENAME/ALTER-TYPE COLUMN	Schema: USAGE
ALTER TABLE ADD/DROP CONSTRAINT	Schema: USAGE
ALTER TABLE PARTITION (REORGANIZE)	Schema: USAGE
ALTER TABLE RENAME	USAGE and CREATE privilege on the schema that contains the table
ALTER TABLE...SET SCHEMA	<ul style="list-style-type: none">• New schema: CREATE• Old Schema: USAGE
SELECT	<ul style="list-style-type: none">• Schema: USAGE• SELECT privilege on table
INSERT	<ul style="list-style-type: none">• Table: INSERT• Schema: USAGE

DELETE	<ul style="list-style-type: none"> • Schema: USAGE • Table: DELETE, SELECT when executing DELETE that references table column values in a WHERE or SET clause
UPDATE	<ul style="list-style-type: none"> • Schema: USAGE • Table: UPDATE, SELECT when executing UPDATE that references table column values in a WHERE or SET clause
REFERENCES	<ul style="list-style-type: none"> • Schema: USAGE on schema that contains constrained table and source of foreign key • Table: REFERENCES to create foreign key constraints that reference this table
ANALYZE_STATISTICS ANALYZE_STATISTICS_PARTITION	<ul style="list-style-type: none"> • Schema: USAGE • Table: One of INSERT, DELETE, or UPDATE
DROP_STATISTICS	<ul style="list-style-type: none"> • Schema: USAGE • Table: One of INSERT, DELETE, or UPDATE
DROP_PARTITIONS	Schema: USAGE

Views

Operation	Required Privileges
CREATE VIEW	<ul style="list-style-type: none"> • Schema: CREATE on view schema, USAGE on schema with base objects • Base objects: SELECT
DROP VIEW	<ul style="list-style-type: none"> • Schema: USAGE or owner • View: Owner
SELECT	<ul style="list-style-type: none"> • Base table: View owner must have SELECT...WITH GRANT OPTION • Schema: USAGE • View: SELECT

Projections

Operation	Required Privileges
CREATE PROJECTION	<ul style="list-style-type: none"> • Anchor table: SELECT • Schema: USAGE and CREATE, or owner <div style="background-color: #e1f5fe; padding: 10px; margin-top: 10px;"> <p>Note If a projection is implicitly created with the table, no additional privilege is needed other than privileges for table creation.</p> </div>
AUTO/DELAYED PROJECTION	<p>On projections created during INSERT...SELECT or COPY operations:</p> <ul style="list-style-type: none"> • Schema: USAGE • Anchor table: SELECT
ALTER PROJECTION	Schema: USAGE and CREATE
DROP PROJECTION	Schema: USAGE or owner

External procedures

Operation	Required Privileges
CREATE PROCEDURE (external)	Superuser
DROP PROCEDURE (external)	Superuser
EXECUTE	<ul style="list-style-type: none"> • Schema: USAGE • Procedure: EXECUTE

Stored procedures

Operation	Required Privileges
CREATE PROCEDURE (stored)	Schema: CREATE

Triggers

Operation	Required Privileges
CREATE TRIGGER	Superuser

Schedules

Operation	Required Privileges
CREATE SCHEDULE	Superuser

Libraries

Operation	Required Privileges
CREATE LIBRARY	Superuser
DROP LIBRARY	Superuser

User-defined functions

Note

The following table uses these abbreviations:

- UDF = Scalar
- UDT = Transform
- UDAnF= Analytic
- UDAF = Aggregate

Operation	Required Privileges
CREATE FUNCTION (SQL) CREATE FUNCTION (scalar) CREATE TRANSFORM FUNCTION CREATE ANALYTIC FUNCTION (UDAnF) CREATE AGGREGATE FUNCTION (UDAF)	<ul style="list-style-type: none"> • Schema: CREATE • Base library: USAGE (if applicable)
DROP FUNCTION DROP TRANSFORM FUNCTION DROP AGGREGATE FUNCTION DROP ANALYTIC FUNCTION	<ul style="list-style-type: none"> • Schema: USAGE privilege • Function: owner

ALTER FUNCTION (scalar)... RENAME TO	Schema: USAGE and CREATE
ALTER FUNCTION (scalar)... SET SCHEMA	<ul style="list-style-type: none"> • Old schema: USAGE • New Schema: CREATE
EXECUTE (SQL/UDF/UDT/ ADAF/UDAnF) function	<ul style="list-style-type: none"> • Schema: USAGE • Function: EXECUTE

Sequences

Operation	Required Privileges
CREATE SEQUENCE	Schema: CREATE
DROP SEQUENCE	Schema: USAGE or owner
ALTER SEQUENCE	Schema: USAGE and CREATE
ALTER SEQUENCE ... SET SCHEMA	<ul style="list-style-type: none"> • Old schema: USAGE • New schema: CREATE

ALTER USER ALTER PROFILE ALTER ROLE	Superuser
DROP USER DROP PROFILE DROP ROLE	Superuser

Object visibility

You can use one or a combination of vsql [\d meta commands](#) and [SQL system tables](#) to view objects on which you have privileges to view.

- Use \dn to view schema names and owners
- Use \dt to view all tables in the database, as well as the system table [V_CATALOG.TABLES](#)
- Use \dj to view projections showing the schema, projection name, owner, and node, as well as the system table [V_CATALOG.PROJECTIONS](#)

Operation	Required Privileges
Look up schema	Schema: At least one privilege
Look up object in schema or in system tables	<ul style="list-style-type: none"> • Schema: USAGE • At least one privilege on any of the following objects: <ul style="list-style-type: none"> ◦ TABLE ◦ VIEW ◦ FUNCTION ◦ PROCEDURE ◦ SEQUENCE
Look up projection	All anchor tables: At least one privilege Schema (all anchor tables): USAGE
Look up resource pool	Resource pool: SELECT
Existence of object	Schema: USAGE

I/O operations

Operation	Required Privileges
CONNECT TO VERTICA DISCONNECT	None
EXPORT TO VERTICA	<ul style="list-style-type: none"> • Source table: SELECT • Source schema: USAGE • Destination table: INSERT • Destination schema: USAGE
COPY FROM VERTICA	<ul style="list-style-type: none"> • Source/destination schema: USAGE • Source table: SELECT • Destination table: INSERT
COPY FROM file	Superuser
COPY FROM STDIN	<ul style="list-style-type: none"> • Schema: USAGE • Table: INSERT

EXPLAIN	Same privileges required to run the query for which you use the EXPLAIN keyword

TLS configuration

Operation	Required Privileges
ALTER	ALTER privileges on the TLS Configuration
DROP	DROP privileges on the TLS Configuration
Add certificates to a TLS Configuration	USAGE on the certificate's private key

Cryptographic key

Operation	Required Privileges
Create a certificate from the key	USAGE privileges on the key
DROP	DROP privileges on the key

Certificate

Operation	Required Privileges
Add certificate to TLS Configuration	ALTER privileges on the TLS Configuration and one of the following: <ul style="list-style-type: none"> • USAGE privileges on the certificate • USAGE privileges on the certificate's private key
DROP	DROP privileges on the certificate's private key

Database object privileges

Privileges can be granted explicitly on most user-visible objects in a Vertica database, such as tables and models. For some objects such as projections, privileges are implicitly derived from other objects.

Explicitly granted privileges

The following table provides an overview of privileges that can be explicitly granted on Vertica database objects:

Database Object	Privileges											
	ALTER	DROP	CREATE	DELETE	EXECUTE	INSERT	READ	REFERENCES	SELECT	TEMP	TRUNCATE	UPDATI
Database			•							•

Key	•	•																			
TLS Configuration	•																				

Implicitly granted privileges

Metadata privileges

Superusers have unrestricted access to all non-[cryptographic](#) database metadata. For non-superusers, access to the metadata of specific objects depends on their privileges on those objects:

Metadata	User access
Catalog objects: <ul style="list-style-type: none"> • Tables • Columns • Constraints • Sequences • External procedures • Projections • ROS containers 	Users must possess USAGE privilege on the schema and any type of access (SELECT) or modify privilege on the object to see catalog metadata about the object. For internal objects such as projections and ROS containers, which have no access privileges directly associated with them, you must have the requisite privileges on the associated schema and tables to view their metadata. For example, to determine whether a table has any projection data, you must have USAGE on the table schema and SELECT on the table.
User sessions and functions, and system tables related to these sessions	Non-superusers can access information about their own (current) sessions only, using the following functions: <ul style="list-style-type: none"> • CURRENT_DATABASE • CURRENT_SCHEMA • CURRENT_USER / SESSION_USER • HAS_TABLE_PRIVILEGE

Projection privileges

Projections, which store table data, do not have an owner or privileges directly associated with them. Instead, the privileges to create, access, or alter a projection are derived from the privileges that are set on its anchor tables and respective schemas.

Cryptographic privileges

Unless they have ownership, superusers only have implicit DROP privileges on keys, certificates, and TLS Configurations. This allows superusers to see the existence of these objects in their respective system tables ([CRYPTOGRAPHIC_KEYS](#), [CERTIFICATES](#), and [TLS_CONFIGURATIONS](#)) and DROP them, but does not allow them to see the key or certificate texts.

For details on granting additional privileges, see [GRANT \(key\)](#) and [GRANT \(TLS configuration\)](#).

Granting and revoking privileges

Vertica supports [GRANT](#) and [REVOKE](#) statements to control user access to database objects—for example, [GRANT \(schema\)](#) and [REVOKE \(schema\)](#), [GRANT \(table\)](#) and [REVOKE \(table\)](#), and so on. Typically, a superuser creates [users](#) and [roles](#) shortly after creating the database, and then uses GRANT statements to assign them privileges.

Where applicable, GRANT statements require USAGE privileges on the object schema. The following users can grant and revoke privileges:

- Superusers: all privileges on all database objects, including the database itself
- Non-superusers: all privileges on objects that they own
- Grantees of privileges that include WITH GRANT OPTION: the same privileges on that object

In the following example, a dbadmin (with superuser privileges) creates user **Carol**. Subsequent GRANT statements grant **Carol** schema and table privileges:

- CREATE and USAGE privileges on schema **PUBLIC**
- SELECT, INSERT, and UPDATE privileges on table **public.applog**. This GRANT statement also includes **WITH GRANT OPTION**. This enables **Carol** to grant the same privileges on this table to other users—in this case, SELECT privileges to user **Tom**:

```
=> CREATE USER Carol;
CREATE USER
=> GRANT CREATE, USAGE ON SCHEMA PUBLIC to Carol;
GRANT PRIVILEGE
=> GRANT SELECT, INSERT, UPDATE ON TABLE public.applog TO Carol WITH GRANT OPTION;
GRANT PRIVILEGE
=> GRANT SELECT ON TABLE public.applog TO Tom;
GRANT PRIVILEGE
```

In this section

- [Superuser privileges](#)
- [Schema owner privileges](#)
- [Object owner privileges](#)
- [Granting privileges](#)
- [Revoking privileges](#)
- [Privilege ownership chains](#)

Superuser privileges

A Vertica superuser is a database user—by default, [named dbadmin](#)—that is automatically created on installation. Vertica superusers have complete and irrevocable authority over database users, privileges, and roles.

Important

Vertica superusers are not the same as Linux superusers with (root) privileges.

Superusers can change the privileges of any user and role, as well as override any privileges that are granted by users with the [PSEUDOSUPERUSER](#) role. They can also grant and revoke privileges on any user-owned object, and reassign object ownership.

Note

A superuser always changes a user's privileges on an object on behalf of the object owner. Thus, the **grantor** setting in system table [V_CATALOG.GRANTS](#) always shows the object owner rather than the superuser who issued the GRANT statement.

Cryptographic privileges

For most catalog objects, superusers have all possible privileges. However, for [keys](#), [certificates](#), and [TLS Configurations](#) superusers only get DROP privileges by default and must be granted the other privileges by their owners. For details, see [GRANT \(key\)](#) and [GRANT \(TLS configuration\)](#).

Superusers can see the existence of all [keys](#), [certificates](#), and [TLS Configurations](#), but they cannot see the text of keys or certificates unless they are granted USAGE privileges.

See also

[DBADMIN](#)

Schema owner privileges

The schema owner is typically the user who creates the schema. By default, the schema owner has privileges to create objects within a schema. The owner can also alter the schema: reassign ownership, rename it, and [enable or disable](#) inheritance of schema privileges.

Schema ownership does not necessarily grant the owner access to objects in that schema. Access to objects depends on the privileges that are granted on them.

All other users and roles must be explicitly [granted access to a schema](#) by its owner or a superuser.

Object owner privileges

The database, along with every object in it, has an owner. The object owner is usually the person who created the object, although a superuser can alter ownership of objects, such as table and sequence.

Object owners must have appropriate schema privilege to access, alter, rename, move or drop any object it owns without any additional privileges.

An object owner can also:

- **Grant privileges on their own object to other users**

The WITH GRANT OPTION clause specifies that a user can grant the permission to other users. For example, if user Bob creates a table, Bob can grant privileges on that table to users Ted, Alice, and so on.

- **Grant privileges to [roles](#)**

Users who are granted the role gain the privilege.

Granting privileges

As described in [Granting and revoking privileges](#), specific users grant privileges using the GRANT statement with or without the optional WITH GRANT OPTION, which allows the user to grant the same privileges to other users.

- A [superuser](#) can grant privileges on all object types to other users.
- A superuser or object owner can grant privileges to [roles](#). Users who have been granted the role then gain the privilege.
- An object owner can grant privileges on the object to other users using the optional WITH GRANT OPTION clause.
- The user needs to have USAGE privilege on schema and appropriate privileges on the object.

When a user grants an explicit list of privileges, such as **GRANT INSERT, DELETE, REFERENCES ON applog TO Bob** :

- The GRANT statement succeeds only if all the roles are granted successfully. If any grant operation fails, the entire statement rolls back.
- Vertica will return ERROR if the user does not have grant options for the privileges listed.

When a user grants ALL privileges, such as **GRANT ALL ON applog TO Bob**, the statement always succeeds. Vertica grants all the privileges on which the grantor has the WITH GRANT OPTION and skips those privileges without the optional WITH GRANT OPTION.

For example, if the user Bob has delete privileges with the optional grant option on the applog table, only DELETE privileges are granted to Bob, and the statement succeeds:

```
=> GRANT DELETE ON applog TO Bob WITH GRANT OPTION;GRANT PRIVILEGE
```

For details, see the [GRANT statements](#).

Revoking privileges

The following non-superusers can revoke privileges on an object:

- Object owner
- Grantor of the object privileges

The user also must have USAGE privilege on the object's schema.

For example, the following query on system table [V_CATALOG.GRANTS](#) shows that users **u1**, **u2**, and **u3** have the following privileges on schema **s1** and table **s1.t1** :

```
=> SELECT object_type, object_name, grantee, grantor, privileges_description FROM v_catalog.grants
WHERE object_name IN ('s1', 't1') AND grantee IN ('u1', 'u2', 'u3');
```

```
object_type | object_name | grantee | grantor | privileges_description
-----+-----+-----+-----+-----
SCHEMA      | s1          | u1      | dbadmin | USAGE, CREATE
SCHEMA      | s1          | u2      | dbadmin | USAGE, CREATE
SCHEMA      | s1          | u3      | dbadmin | USAGE
TABLE       | t1          | u1      | dbadmin | INSERT*, SELECT*, UPDATE*
TABLE       | t1          | u2      | u1      | INSERT*, SELECT*, UPDATE*
TABLE       | t1          | u3      | u2      | SELECT*
(6 rows)
```

Note

The asterisks (*) on privileges under `privileges_description` indicate that the grantee can grant these privileges to other users.

In the following statements, `u2` revokes the SELECT privileges that it granted on `s1.t1` to `u3`. Subsequent attempts by `u3` to query this table return an error:

```
=> \c - u2
You are now connected as user "u2".
=> REVOKE SELECT ON s1.t1 FROM u3;
REVOKE PRIVILEGE
=> \c - u3
You are now connected as user "u2".
=> SELECT * FROM s1.t1;
ERROR 4367: Permission denied for relation t1
```

Revoking grant option

If you revoke privileges on an object from a user, that user can no longer act as grantor of those same privileges to other users. If that user previously granted the revoked privileges to other users, the `REVOKE` statement must include the `CASCADE` option to revoke the privilege from those users too; otherwise, it returns with an error.

For example, user `u2` can grant SELECT, INSERT, and UPDATE privileges, and grants those privileges to user `u4`:

```
=> \c - u2
You are now connected as user "u2".
=> GRANT SELECT, INSERT, UPDATE on TABLE s1.t1 to u4;
GRANT PRIVILEGE
```

If you query `V_CATALOG.GRANTS` for privileges on table `s1.t1`, it returns the following result set:

```
=> \c
You are now connected as user "dbadmin".
=> SELECT object_type, object_name, grantee, grantor, privileges_description FROM v_catalog.grants
       WHERE object_name IN ('t1') ORDER BY grantee;
object_type | object_name | grantee | grantor | privileges_description
-----+-----+-----+-----+-----
TABLE      | t1         | dbadmin | dbadmin | INSERT*, SELECT*, UPDATE*, DELETE*, REFERENCES*, TRUNCATE*
TABLE      | t1         | u1      | dbadmin | INSERT*, SELECT*, UPDATE*
TABLE      | t1         | u2      | u1      | INSERT*, SELECT*, UPDATE*
TABLE      | t1         | u4      | u2      | INSERT, SELECT, UPDATE
(3 rows)
```

Now, if user `u1` wants to revoke UPDATE privileges from user `u2`, the revoke operation must cascade to user `u4`, who also has UPDATE privileges that were granted by `u2`; otherwise, the `REVOKE` statement returns with an error:

```

=> \c - u1
=> REVOKE update ON TABLE s1.t1 FROM u2;
ROLLBACK 3052: Dependent privileges exist
HINT: Use CASCADE to revoke them too
=> REVOKE update ON TABLE s1.t1 FROM u2 CASCADE;
REVOKE PRIVILEGE
=> \c
You are now connected as user "dbadmin".
=> SELECT object_type, object_name, grantee, grantor, privileges_description FROM v_catalog.grants
   WHERE object_name IN ('t1') ORDER BY grantee;
object_type | object_name | grantee | grantor |          privileges_description
-----+-----+-----+-----+-----
TABLE      | t1         | dbadmin | dbadmin | INSERT*, SELECT*, UPDATE*, DELETE*, REFERENCES*, TRUNCATE*
TABLE      | t1         | u1      | dbadmin | INSERT*, SELECT*, UPDATE*
TABLE      | t1         | u2      | u1      | INSERT*, SELECT*
TABLE      | t1         | u4      | u2      | INSERT, SELECT
(4 rows)

```

You can also revoke grantor privileges from a user without revoking those privileges. For example, user **u1** can prevent user **u2** from granting INSERT privileges to other users, but allow user **u2** to retain that privilege:

```

=> \c - u1
You are now connected as user "u1".
=> REVOKE GRANT OPTION FOR INSERT ON TABLE s1.t1 FROM U2 CASCADE;
REVOKE PRIVILEGE

```

Note

The REVOKE statement must include the CASCADE, because user **u2** previously granted user **u4** INSERT privileges on table **s1.t1** . When you revoke **u2** 's ability to grant this privilege, that privilege must be removed from any its grantees—in this case, user **u4** .

You can confirm results of the revoke operation by querying **V_CATALOG.GRANTS** for privileges on table **s1.t1** :

```

=> \c
You are now connected as user "dbadmin".
=> SELECT object_type, object_name, grantee, grantor, privileges_description FROM v_catalog.grants
   WHERE object_name IN ('t1') ORDER BY grantee;
object_type | object_name | grantee | grantor |          privileges_description
-----+-----+-----+-----+-----
TABLE      | t1         | dbadmin | dbadmin | INSERT*, SELECT*, UPDATE*, DELETE*, REFERENCES*, TRUNCATE*
TABLE      | t1         | u1      | dbadmin | INSERT*, SELECT*, UPDATE*
TABLE      | t1         | u2      | u1      | INSERT, SELECT*
TABLE      | t1         | u4      | u2      | SELECT
(4 rows)

```

The query results show:

- User **u2** retains INSERT privileges on the table but can no longer grant INSERT privileges to other users (as indicated by absence of an asterisk).
- The revoke operation cascaded down to grantee **u4** , who now lacks INSERT privileges.

See also

[REVOKE \(table\)](#)

Privilege ownership chains

The ability to revoke privileges on objects can cascade throughout an organization. If the grant option was revoked from a user, the privilege that this user granted to other users will also be revoked.

If a privilege was granted to a user or role by multiple grantors, to completely revoke this privilege from the grantee the privilege has to be revoked by each original grantor. The only exception is a superuser may revoke privileges granted by an object owner, with the reverse being true, as well.

In the following example, the SELECT privilege on table t1 is granted through a chain of users, from a superuser through User3.

- A superuser grants User1 CREATE privileges on the schema s1:

```
=> \c - dbadmin
You are now connected as user "dbadmin".
=> CREATE USER User1;
CREATE USER
=> CREATE USER User2;
CREATE USER
=> CREATE USER User3;
CREATE USER
=> CREATE SCHEMA s1;
CREATE SCHEMA
=> GRANT USAGE on SCHEMA s1 TO User1, User2, User3;
GRANT PRIVILEGE
=> CREATE ROLE reviewer;
CREATE ROLE
=> GRANT CREATE ON SCHEMA s1 TO User1;
GRANT PRIVILEGE
```

- User1 creates new table t1 within schema s1 and then grants SELECT WITH GRANT OPTION privilege on s1.t1 to User2:

```
=> \c - User1
You are now connected as user "User1".
=> CREATE TABLE s1.t1(id int, sourceID VARCHAR(8));
CREATE TABLE
=> GRANT SELECT on s1.t1 to User2 WITH GRANT OPTION;
GRANT PRIVILEGE
```

- User2 grants SELECT WITH GRANT OPTION privilege on s1.t1 to User3:

```
=> \c - User2
You are now connected as user "User2".
=> GRANT SELECT on s1.t1 to User3 WITH GRANT OPTION;
GRANT PRIVILEGE
```

- User3 grants SELECT privilege on s1.t1 to the reviewer role:

```
=> \c - User3
You are now connected as user "User3".
=> GRANT SELECT on s1.t1 to reviewer;
GRANT PRIVILEGE
```

Users cannot revoke privileges upstream in the chain. For example, User2 did not grant privileges on User1, so when User1 runs the following REVOKE command, Vertica rolls back the command:

```
=> \c - User2
You are now connected as user "User2".
=> REVOKE CREATE ON SCHEMA s1 FROM User1;
ROLLBACK 0: "CREATE" privilege(s) for schema "s1" could not be revoked from "User1"
```

Users can revoke privileges indirectly from users who received privileges through a cascading chain, like the one shown in the example above. Here, users can use the CASCADE option to revoke privileges from all users "downstream" in the chain. A superuser or User1 can use the CASCADE option to revoke the SELECT privilege on table s1.t1 from all users. For example, a superuser or User1 can execute the following statement to revoke the SELECT privilege from all users and roles within the chain:

```
=> \c - User1
You are now connected as user "User1".
=> REVOKE SELECT ON s1.t1 FROM User2 CASCADE;
REVOKE PRIVILEGE
```

When a superuser or User1 executes the above statement, the SELECT privilege on table s1.t1 is revoked from User2, User3, and the reviewer role. The GRANT privilege is also revoked from User2 and User3, which a superuser can verify by querying the [V_CATALOG.GRANTS](#) system table.

```
=> SELECT * FROM grants WHERE object_name = 's1' AND grantee ILIKE 'User%';
grantor | privileges_description | object_schema | object_name | grantee
-----+-----+-----+-----+-----
dbadmin | USAGE                | s1            | User1
dbadmin | USAGE                | s1            | User2
dbadmin | USAGE                | s1            | User3
(3 rows)
```

Modifying privileges

A [superuser](#) or object owner can use one of the ALTER statements to modify a privilege, such as changing a [sequence owner](#) or [table owner](#). Reassignment to the new owner does not transfer grants from the original owner to the new owner; grants made by the original owner are dropped.

Viewing privileges granted on objects

You can view information about privileges, grantors, grantees, and objects by querying these system tables:

- [GRANTS](#)
- [INHERITED_PRIVILEGES](#)
- [INHERITING_OBJECTS](#)

An asterisk (*) appended to a privilege indicates that the user can grant the privilege to other users.

You can also view the [effective privileges](#) on a specified database object by using the [GET_PRIVILEGES_DESCRIPTION](#) meta-function.

Viewing explicitly granted privileges

To view explicitly granted privileges on objects, query the GRANTS table.

The following query returns the explicit privileges for the schema, myschema.

```
=> SELECT grantee, privileges_description FROM grants WHERE object_name='myschema';
grantee | privileges_description
-----+-----
Bob    | USAGE, CREATE
Alice  | CREATE
(2 rows)
```

Viewing inherited privileges

To view which tables and views inherit privileges from which schemas, query the INHERITING_OBJECTS table.

The following query returns the tables and views that inherit their privileges from their parent schema, customers.

```
=> SELECT * FROM inheriting_objects WHERE object_schema='customers';
object_id | schema_id | object_schema | object_name | object_type
-----+-----+-----+-----+-----
45035996273980908 | 45035996273980902 | customers | cust_info | table
45035996273980984 | 45035996273980902 | customers | shipping_info | table
45035996273980980 | 45035996273980902 | customers | cust_set | view
(3 rows)
```

To view the specific privileges inherited by tables and views and information on their associated grant statements, query the INHERITED_PRIVILEGES table.

The following query returns the privileges that the tables and views inherit from their parent schema, customers.

```
=> SELECT object_schema,object_name,object_type,privileges_description,principal,grantor FROM inherited_privileges WHERE
object_schema='customers';
```

object_schema	object_name	object_type	privileges_description	principal	grantor
customers	cust_info	Table	INSERT*, SELECT*, UPDATE*, DELETE*, ALTER*, REFERENCES*, DROP*, TRUNCATE*	dbadmin	dbadmin
customers	shipping_info	Table	INSERT*, SELECT*, UPDATE*, DELETE*, ALTER*, REFERENCES*, DROP*, TRUNCATE*	dbadmin	dbadmin
customers	cust_set	View	SELECT*, ALTER*, DROP*	dbadmin	dbadmin
customers	cust_info	Table	SELECT	Val	dbadmin
customers	shipping_info	Table	SELECT	Val	dbadmin
customers	cust_set	View	SELECT	Val	dbadmin
customers	cust_info	Table	INSERT	Pooja	dbadmin
customers	shipping_info	Table	INSERT	Pooja	dbadmin

(8 rows)

Viewing effective privileges on an object

To view the current user's effective privileges on a specified database object, use the GET_PRIVILEGES_DESCRIPTION meta-function.

In the following example, user Glenn has set the REPORTER role and wants to check his effective privileges on schema **s1** and table **s1.articles**.

- Table **s1.articles** inherits privileges from its schema (**s1**).
- The REPORTER role has the following privileges:
 - SELECT on schema **s1**
 - INSERT WITH GRANT OPTION on table **s1.articles**
- User Glenn has the following privileges:
 - UPDATE and USAGE on schema **s1**.
 - DELETE on table **s1.articles**.

GET_PRIVILEGES_DESCRIPTION returns the following effective privileges for Glenn on schema **s1**:

```
=> SELECT GET_PRIVILEGES_DESCRIPTION('schema', 's1');
GET_PRIVILEGES_DESCRIPTION
-----
SELECT, UPDATE, USAGE
(1 row)
```

GET_PRIVILEGES_DESCRIPTION returns the following effective privileges for Glenn on table **s1.articles**:

```
=> SELECT GET_PRIVILEGES_DESCRIPTION('table', 's1.articles');
GET_PRIVILEGES_DESCRIPTION
-----
INSERT*, SELECT, UPDATE, DELETE
(1 row)
```

Access policies

[CREATE ACCESS POLICY](#) lets you create access policies on tables that specify how much data certain users and roles can query from those tables. Access policies typically prevent these users from viewing the data of specific columns and rows of a table. You can apply access policies to table [columns](#) and [rows](#). If a table has access policies on both, Vertica filters row access policies first, then filters the column access policies.

You can create most access policies for any table type—columnar, external, or [flex](#). (You cannot create column access policies on flex tables.) You can also create access policies on any column type, including joins.

In this section

- [Creating column access policies](#)
- [Creating row access policies](#)
- [Access policies and DML operations](#)
- [Access policies and query optimization](#)
- [Managing access policies](#)

Creating column access policies

[CREATE ACCESS POLICY](#) can create access policies on individual table columns, one policy per column. Each column access policy lets you specify, for different users and roles, various levels of access to the data of that column. The column access expression can also specify how to render column data for users and roles.

The following example creates an access policy on the `customer_address` column in the `client_dimension` table. This access policy gives non-superusers with the `administrator` role full access to all data in that column, but masks customer address data from all other users:

```
=> CREATE ACCESS POLICY ON public.customer_dimension FOR COLUMN customer_address
-> CASE
-> WHEN ENABLED_ROLE('administrator') THEN customer_address
-> ELSE '*****'
-> END ENABLE;
CREATE ACCESS POLICY
```

Note

Vertica roles are compatible with LDAP users. You do not need separate LDAP roles to use column access policies with LDAP users.

Vertica uses this policy to determine the access it gives to users MaxineT and MikeL, who are assigned `employee` and `administrator` roles, respectively. When these users query the `customer_dimension` table, Vertica applies the column access policy expression as follows:

```
=> \c - MaxineT;
You are now connected as user "MaxineT".
=> SET ROLE employee;
SET
=> SELECT customer_type, customer_name, customer_gender, customer_address, customer_city FROM customer_dimension;
customer_type | customer_name | customer_gender | customer_address | customer_city
-----+-----+-----+-----+-----
Individual | Craig S. Robinson | Male | ***** | Fayetteville
Individual | Mark M. Kramer | Male | ***** | Joliet
Individual | Barbara S. Farmer | Female | ***** | Alexandria
Individual | Julie S. McNulty | Female | ***** | Grand Prairie
...

=> \c - MikeL
You are now connected as user "MikeL".
=> SET ROLE administrator;
SET
=> SELECT customer_type, customer_name, customer_gender, customer_address, customer_city FROM customer_dimension;
customer_type | customer_name | customer_gender | customer_address | customer_city
-----+-----+-----+-----+-----
Individual | Craig S. Robinson | Male | 138 Alden Ave | Fayetteville
Individual | Mark M. Kramer | Male | 311 Green St | Joliet
Individual | Barbara S. Farmer | Female | 256 Cherry St | Alexandria
Individual | Julie S. McNulty | Female | 459 Essex St | Grand Prairie
...
```

Restrictions

The following limitations apply to access policies:

- A column can have only one access policy.
- Column access policies cannot be set on columns of complex types other than native arrays.
- Column access policies cannot be set for materialized columns on flex tables. While it is possible to set an access policy for the `__raw__` column, doing so restricts access to the whole table.
- Row access policies are invalid on temporary tables and tables with aggregate projections.
- Access policy expressions cannot contain:
 - Subqueries
 - Aggregate functions
 - Analytic functions

- User-defined transform functions (UDTF)
- If the query optimizer cannot replace a deterministic expression that involves only constants with their computed values, it blocks all DML operations such as INSERT .

Creating row access policies

[CREATE ACCESS POLICY](#) can create a single row access policy for a given table. This policy lets you specify for different users and roles various levels of access to table row data. When a user launches a query, Vertica evaluates the access policy's WHERE expression against all table rows. The query returns with only those rows where the expression evaluates to true for the current user or role.

For example, you might want to specify different levels of access to table `store.store_store_sales` for four roles:

- **employee** : Users with this role should only access sales records that identify them as the employee, in column `employee_key` . The following query shows how many sales records (in `store.store_sales_fact`) are associated with each user (in `public.emp_dimension`):

```
=> SELECT COUNT(sf.employee_key) AS 'Total Sales', sf.employee_key, ed.user_name FROM store.store_sales_fact sf
      JOIN emp_dimension ed ON sf.employee_key=ed.employee_key
      WHERE ed.job_title='Sales Associate' GROUP BY sf.employee_key, ed.user_name ORDER BY sf.employee_key
```

Total Sales | employee_key | user_name

```
-----+-----+-----
533 |    111 | LucasLC
442 |    124 | JohnSN
487 |    127 | SamNS
477 |    132 | MeghanMD
545 |    140 | HaroldON
...
563 |   1991 | MidoriMG
367 |   1993 | ThomZM
```

(318 rows)

- **regional_manager** : Users with this role (`public.emp_dimension`) should only access sales records for the sales region that they manage (`store.store_dimension`):

```
=> SELECT distinct sd.store_region, ed.user_name, ed.employee_key, ed.job_title FROM store.store_dimension sd
      JOIN emp_dimension ed ON sd.store_region=ed.employee_region WHERE ed.job_title = 'Regional Manager';
```

```
store_region | user_name | employee_key | job_title
-----+-----+-----+-----
West        | JamesGD  |    1070 | Regional Manager
South       | SharonDM |    1710 | Regional Manager
East        | BenOV    |    593  | Regional Manager
MidWest     | LilyCP   |    611  | Regional Manager
NorthWest   | CarlaTG  |   1058 | Regional Manager
SouthWest   | MarcusNK |    150  | Regional Manager
```

(6 rows)

- **dbadmin** and **administrator** : Users with these roles have unlimited access to all table data.

Given these users and the data associated with them, you can create a row access policy on `store.store_store_sales` that looks like this:

```
CREATE ACCESS POLICY ON store.store_sales_fact FOR ROWS WHERE
(ENABLED_ROLE('employee')) AND (store.store_sales_fact.employee_key IN
(SELECT employee_key FROM public.emp_dimension WHERE user_name=CURRENT_USER()))
OR
(ENABLED_ROLE('regional_manager')) AND (store.store_sales_fact.store_key IN
(SELECT sd.store_key FROM store.store_dimension sd
JOIN emp_dimension ed ON sd.store_region=ed.employee_region WHERE ed.user_name = CURRENT_USER()))
OR ENABLED_ROLE('dbadmin')
OR ENABLED_ROLE ('administrator')
ENABLE;
```

Important

In this example, the row policy limits access to a set of roles that are explicitly included in policy's WHERE expression. All other roles and users are implicitly denied access to the table data.

The following examples indicate the different levels of access that are available to users with the specified roles:

- **dbadmin** has access to all rows in `store.store_sales_fact` :

```
=> \c
You are now connected as user "dbadmin".
=> SELECT count(*) FROM store.store_sales_fact;
count
-----
5000000
(1 row)
```

- User **LilyCP** has the role of `regional_manager` , so she can access all sales data of the Midwest region that she manages:

```
=> \c - LilyCP;
You are now connected as user "LilyCP".
=> SET ROLE regional_manager;
SET
=> SELECT count(*) FROM store.store_sales_fact;
count
-----
782272
(1 row)
```

- User **SamRJ** has the role of `employee` , so he can access only the sales data that he is associated with:

```
=> \c - SamRJ;
You are now connected as user "SamRJ".
=> SET ROLE employee;
SET
=> SELECT count(*) FROM store.store_sales_fact;
count
-----
417
(1 row)
```

Restrictions

The following limitations apply to row access policies:

- A table can have only one row access policy.
- Row access policies are invalid on the following tables:
 - Tables with aggregate projections
 - Temporary tables
 - System tables
 - Views
- You cannot create [directed queries](#) on a table with a row access policy.

Access policies and DML operations

By default, Vertica abides by a rule that a user can only edit what they can see. That is, you must be able to view all rows and columns in the table in their original values (as stored in the table) and in their originally defined data types to perform actions that modify data on a table. For example, if a column is defined as `VARCHAR(9)` and an access policy on that column specifies the same column as `VARCHAR(10)`, users using the access policy will be unable to perform the following operations:

- INSERT
- UPDATE
- DELETE
- MERGE
- COPY

You can override this behavior by specifying `GRANT TRUSTED` in a [new](#) or [existing](#) access policy. This option forces the access policy to defer entirely to explicit `GRANT` statements when assessing whether a user can perform the above operations.

You can view existing access policies with the [ACCESS_POLICY](#) system table.

Row access

On tables where a row access policy is enabled, you can only perform DML operations when the condition in the row access policy evaluates to TRUE. For example:

t1 appears as follows:

A	B
1	1
2	2
3	3

Create the following row access policy on t1:

```
=> CREATE ACCESS POLICY ON t1 FOR ROWS
WHERE enabled_role('manager')
OR
A<2
ENABLE;
```

With this policy enabled, the following behavior exists for users who want to perform DML operations:

- A user with the manager role can perform DML on all rows in the table, because the WHERE clause in the policy evaluates to TRUE.
- Users with non-manager roles can only perform a SELECT to return data in column A that has a value of less than two. If the access policy has to read the data in the table to confirm a condition, it does not allow DML operations.

Column access

On tables where a column access policy is enabled, you can perform DML operations if you can view the entire column in its originally defined type.

Suppose table t1 is created with the following data types and values:

```
=> CREATE TABLE t1 (A int, B int);
=> INSERT INTO t1 VALUES (1,2);
=> SELECT * FROM t1;
A | B
---+---
1 | 2
(1 row)
```

Suppose the following access policy is created, which coerces the data type of column A from INT to VARCHAR(20) at execution time.

```
=> CREATE ACCESS POLICY on t1 FOR column A A::VARCHAR(20) ENABLE;
Column "A" is of type int but expression in Access Policy is of type varchar(20). It will be coerced at execution time
```

In this case, u1 can view column A in its entirety, but because the active access policy doesn't specify column A's original data type, u1 cannot perform DML operations on column A.

```
=> \c - u1
You are now connected as user "u1".
=> SELECT A FROM t1;
A
---
1
(1 row)

=> INSERT INTO t1 VALUES (3);
ERROR 6538: Unable to INSERT: "Access denied due to active access policy on table "t1" for column "A"
```

Overriding default behavior with GRANT TRUSTED

Specifying GRANT TRUSTED in an access policy overrides the default behavior ("users can only edit what they can see") and instructs the access policy to defer entirely to explicit GRANT statements when assessing whether a user can perform a DML operation.

Important

GRANT TRUSTED can allow users to make changes to tables even if the data is obscured by the access policy. In these cases, certain users who are constrained by the access policy but also have GRANTS on the table can make changes to the data that they cannot view or verify.

GRANT TRUSTED is useful in cases where the form the data is stored in doesn't match its semantically "true" form.

For example, when integrating with [Voltage SecureData](#), a common use case is storing encrypted data with [VoltageSecureProtect](#), where decryption is left to a case expression in an access policy that calls [VoltageSecureAccess](#). In this case, while the decrypted form is intuitively understood to be the data's "true" form, it's still stored in the table in its encrypted form; users who can view the decrypted data wouldn't see the data as it was stored and therefore wouldn't be able to perform DML operations. You can use GRANT TRUSTED to override this behavior and allow users to perform these operations if they have the grants.

In this example, the customer_info table contains columns for the customer first and last name and SSN. SSNs are sensitive and access to it should be controlled, so it is encrypted with [VoltageSecureProtect](#) as it is inserted into the table:

```
=> CREATE TABLE customer_info(first_name VARCHAR, last_name VARCHAR, ssn VARCHAR);
=> INSERT INTO customer_info SELECT 'Alice', 'Smith', VoltageSecureProtect('998-42-4910' USING PARAMETERS format='ssn');
=> INSERT INTO customer_info SELECT 'Robert', 'Eve', VoltageSecureProtect('899-28-1303' USING PARAMETERS format='ssn');
=> SELECT * FROM customer_info;
first_name | last_name | ssn
-----+-----+-----
Alice      | Smith    | 967-63-8030
Robert     | Eve      | 486-41-3371
(2 rows)
```

In this system, the role "trusted_ssn" identifies privileged users for which Vertica will decrypt the values of the "ssn" column with [VoltageSecureAccess](#). To allow these privileged users to perform DML operations for which they have grants, you might use the following access policy:

```
=> CREATE ACCESS POLICY ON customer_info FOR COLUMN ssn
CASE WHEN enabled_role('trusted_ssn') THEN VoltageSecureAccess(ssn USING PARAMETERS format='ssn')
ELSE ssn END
GRANT TRUSTED
ENABLE;
```

Again, note that GRANT TRUSTED allows *all* users with GRANTS on the table to perform the specified operations, including users without the "trusted_ssn" role.

Access policies and query optimization

Access policies affect the projection designs that the Vertica Database Designer produces, and the plans that the optimizer creates for query execution.

Projection designs

When Database Designer creates projections for a given table, it takes into account access policies that apply to the current user. The set of projections that Database Designer produces for the table are optimized for that user's access privileges, and other users with similar access privileges. However, these projections might be less than optimal for users with different access privileges. These differences might have some effect on how efficiently Vertica processes queries for the second group of users. When you evaluate projection designs for a table, choose a design that optimizes access for all authorized users.

Query rewrite

The Vertica optimizer enforces access policies by rewriting user queries in its query plan, which can affect query performance. For example, the clients table has row and column access policies, both enabled. When a user queries this table, the query optimizer produces a plan that rewrites the query so it includes both policies:

```
=> SELECT * FROM clients;
```

The query optimizer produces a query plan that rewrites the query as follows:

```
SELECT * FROM (
SELECT custID, password, CASE WHEN enabled_role('manager') THEN SSN ELSE substr(SSN, 8, 4) END AS SSN FROM clients
WHERE enabled_role('broker') AND
clients.clientID IN (SELECT brokers.clientID FROM brokers WHERE broker_name = CURRENT_USER())
) clients;
```

Managing access policies

By default, you can only manage access policies on tables that you own. You can optionally restrict access policy management to superusers with the `AccessPolicyManagementSuperuserOnly` parameter (false by default):

```
=> ALTER DATABASE DEFAULT SET PARAMETER AccessPolicyManagementSuperuserOnly = 1;
ALTER DATABASE
```

You can view and manage access policies for tables in several ways:

- [View access policies](#)
- [Modify the expression of an access policy](#)
- [Enable or disable access policies](#)
- [Copy access policies to another table](#)

Viewing access policies

You can view access policies in two ways:

- Query system table [ACCESS_POLICY](#). For example, the following query returns all access policies on table `public.customer_dimension` :

```
=> \x
=> SELECT policy_type, is_policy_enabled, table_name, column_name, expression FROM access_policy WHERE table_name =
'public.customer_dimension';
-[ RECORD 1 ]-----+-----
policy_type      | Column Policy
is_policy_enabled | Enabled
table_name       | public.customer_dimension
column_name      | customer_address
expression       | CASE WHEN enabled_role('administrator') THEN customer_address ELSE ***** END
```

- Export table DDL from the database catalog with [EXPORT_TABLES](#), [EXPORT_OBJECTS](#), or [EXPORT_CATALOG](#). For example:

```
=> SELECT export_tables('', 'customer_dimension');
          export_tables
-----
CREATE TABLE public.customer_dimension
(
  customer_key int NOT NULL,
  customer_type varchar(16),
  customer_name varchar(256),
  customer_gender varchar(8),
  ...
  CONSTRAINT C_PRIMARY PRIMARY KEY (customer_key) DISABLED
);

CREATE ACCESS POLICY ON public.customer_dimension FOR COLUMN customer_address CASE WHEN enabled_role('administrator') THEN
customer_address ELSE ***** END ENABLE;
```

Modifying access policy expression

`ALTER ACCESS POLICY` can modify the expression of an existing access policy. For example, you can modify the access policy in the earlier example by extending access to the `dbadmin` role:

```
=> ALTER ACCESS POLICY ON public.customer_dimension FOR COLUMN customer_address
CASE WHEN enabled_role('dbadmin') THEN customer_address
  WHEN enabled_role('administrator') THEN customer_address
  ELSE ***** END ENABLE;
ALTER ACCESS POLICY
```

Querying system table `ACCESS_POLICY` confirms this change:

```
=> SELECT policy_type, is_policy_enabled, table_name, column_name, expression FROM access_policy
WHERE table_name = 'public.customer_dimension' AND column_name='customer_address';
-[ RECORD 1 ]-----+-----
policy_type   | Column Policy
is_policy_enabled | Enabled
table_name    | public.customer_dimension
column_name   | customer_address
expression    | CASE WHEN enabled_role('dbadmin') THEN customer_address WHEN enabled_role('administrator') THEN customer_address ELSE
***** END
```

Enabling and disabling access policies

Owners of a table can enable and disable its row and column access policies.

Row access policies

You enable and disable row access policies on a table:

```
ALTER ACCESS POLICY ON [schema.]table FOR ROWS { ENABLE | DISABLE }
```

The following examples disable and then re-enable the row access policy on table `customer_dimension` :

```
=> ALTER ACCESS POLICY ON customer_dimension FOR ROWS DISABLE;
ALTER ACCESS POLICY
=> ALTER ACCESS POLICY ON customer_dimension FOR ROWS ENABLE;
ALTER ACCESS POLICY
```

Column access policies

You enable and disable access policies on a table column as follows:

```
ALTER ACCESS POLICY ON [schema.]table FOR COLUMN column { ENABLE | DISABLE }
```

The following examples disable and then re-enable the same column access policy on `customer_dimension.customer_address` :

```
=> ALTER ACCESS POLICY ON public.customer_dimension FOR COLUMN customer_address DISABLE;
ALTER ACCESS POLICY
=> ALTER ACCESS POLICY ON public.customer_dimension FOR COLUMN customer_address ENABLE;
ALTER ACCESS POLICY
```

Copying access policies

You copy access policies from one table to another as follows. Non-superusers must have ownership of both the source and destination tables:

```
ALTER ACCESS POLICY ON [schema.]table { FOR COLUMN column | FOR ROWS } COPY TO TABLE table
```

When you create a copy of a table or move its contents with the following functions (but not [CREATE TABLE AS SELECT](#) or [CREATE TABLE LIKE](#)), the access policies of the original table are copied to the new/destination table:

- [COPY TABLE](#)
- [COPY PARTITIONS TO TABLE](#)
- [MOVE PARTITIONS TO TABLE](#)
- [SWAP PARTITIONS BETWEEN TABLES](#)

To copy access policies to another table, use [ALTER ACCESS POLICY](#).

Note

If you rename a table with [ALTER TABLE...RENAME TO](#), the access policies that were stored under the previous name are stored under the table's new name.

For example, you can copy a row access policy as follows:

```
=> ALTER ACCESS POLICY ON public.emp_dimension FOR ROWS COPY TO TABLE public.regional_managers_dimension;
```

The following statement copies the access policy on column `employee_key` from table `public.emp_dimension` to `store.store_sales_fact` :

```
=> ALTER ACCESS POLICY ON public.emp_dimension FOR COLUMN employee_key COPY TO TABLE store.store_sales_fact;
```

Note

The copied policy retains the source policy's enabled/disabled settings.

Using the administration tools

The Vertica Administration tools allow you to easily perform administrative tasks. You can perform most Vertica database administration tasks with Administration Tools.

Run Administration Tools using the [Database Superuser](#) account on the [Administration host](#), if possible. Make sure that no other Administration Tools processes are running.

If the Administration host is unresponsive, run Administration Tools on a different node in the cluster. That node permanently takes over the role of Administration host.

In this section

- [Running the administration tools](#)
- [First login as database administrator](#)
- [Using the administration tools interface](#)
- [Notes for remote terminal users](#)
- [Using administration tools help](#)
- [Distributing changes made to the administration tools metadata](#)
- [Administration tools and Management Console](#)
- [Administration tools reference](#)

Running the administration tools

Administration tools, or "admintools," supports various commands to manage your database.

To run admintools, you must have SSH and local connections enabled for the [dbadmin](#) user.

Syntax

```
/opt/vertica/bin/admintools [--debug ][  
  { -h | --help }  
  | { -a | --help_all }  
  | { -t | --tool } name_of_tool [options]  
]
```

--debug

If you include this option, Vertica logs debug information.

Note

You can specify the **debug** option with or without naming a specific tool. If you specify **debug** with a specific tool, Vertica logs debug information during tool execution. If you do not specify a tool, Vertica logs debug information when you run tools through the admintools user interface.

-h
--help

Outputs abbreviated help.

-a
--help_all

Outputs verbose help, which lists all command-line sub-commands and options.

```
{-t|--tool}  
name_of_tool  
[options]
```

Specifies the tool to run, where *name_of_tool* is one of the tools described in the help output, and *options* are one or more comma-delimited tool arguments.

Note

Enter `admintools -h` to see the list of tools available. Enter `admintools -t name_of_tool --help` to review a specific tool's options.

An unqualified `admintools` command displays the Main Menu dialog box.

If you are unfamiliar with this type of interface, read [Using the administration tools interface](#).

Privileges

`dbadmin` user

First login as database administrator

The first time you log in as the [Database Superuser](#) and run the Administration Tools, the user interface displays.

1. In the end-user license agreement (EULA) window, type `accept` to proceed.
A window displays, requesting the location of the license key file you downloaded from the Vertica website. The default path is `/tmp/vlicense.dat`.
2. Type the absolute path to your license key (for example,

Using the administration tools interface

The Vertica Administration Tools are implemented using Dialog, a graphical user interface that works in terminal (character-cell) windows. The interface responds to mouse clicks in some terminal windows, particularly local Linux windows, but you might find that it responds only to keystrokes. Thus, this section describes how to use the Administration Tools using only keystrokes.

Note

This section does not describe every possible combination of keystrokes you can use to accomplish a particular task. Feel free to experiment and to use whatever keystrokes you prefer.

Enter [return]

In all dialogs, when you are ready to run a command, select a file, or cancel the dialog, press the **Enter** key. The command descriptions in this section do not explicitly instruct you to press Enter.

OK - cancel - help

The OK, Cancel, and Help buttons are present on virtually all dialogs. Use the tab, space bar, or right and left arrow keys to select an option and then press Enter. The same keystrokes apply to dialogs that present a choice of Yes or No.

Menu dialogs

Some dialogs require that you choose one command from a menu. Type the alphanumeric character shown or use the up and down arrow keys to select a command and then press Enter.

List dialogs

In a list dialog, use the up and down arrow keys to highlight items, then use the space bar to select the items (which marks them with an X). Some list dialogs allow you to select multiple items. When you have finished selecting items, press Enter.

Form dialogs

In a form dialog (also referred to as a dialog box), use the tab key to cycle between **OK**, **Cancel**, **Help**, and the form field area. Once the cursor is in the form field area, use the up and down arrow keys to select an individual field (highlighted) and enter information. When you have finished entering information in all fields, press Enter.

Help buttons

Online help is provided in the form of text dialogs. If you have trouble viewing the help, see [Notes for remote terminal users](#).

Notes for remote terminal users

The appearance of the graphical interface depends on the color and font settings used by your terminal window. The screen captures in this document were made using the default color and font settings in a PuTTY terminal application running on a Windows platform.

Note

If you are using a remote terminal application, such as PuTTY or a Cygwin bash shell, make sure your window is at least 81 characters wide and 23 characters high.

If you are using PuTTY, you can make the Administration Tools look like the screen captures in this document:

1. In a PuTTY window, right click the title area and select Change Settings.
2. Create or load a saved session.
3. In the Category dialog, click Window > Appearance.
4. In the Font settings, click the Change... button.
5. Select Font: Courier New: Regular Size: 10
6. Click Apply.

Repeat these steps for each existing session that you use to run the Administration Tools.

You can also change the translation to support UTF-8:

1. In a PuTTY window, right click the title area and select Change Settings.
2. Create or load a saved session.
3. In the Category dialog, click Window > Translation.
4. In the "Received data assumed to be in which character set" drop-down menu, select UTF-8.
5. Click Apply.

Using administration tools help

The **Help on Using the Administration Tools** command displays a help screen about using the Administration Tools.

Most of the online help in the Administration Tools is context-sensitive. For example, if you use up/down arrows to select a command, press tab to move to the Help button, and press return, you get help on the selected command.

In a menu dialog

1. Use the up and down arrow keys to choose the command for which you want help.
2. Use the Tab key to move the cursor to the Help button.
3. Press Enter (Return).

In a dialog box

1. Use the up and down arrow keys to choose the field on which you want help.
2. Use the Tab key to move the cursor to the Help button.
3. Press Enter (Return).

Scrolling

Some help files are too long for a single screen. Use the up and down arrow keys to scroll through the text.

Distributing changes made to the administration tools metadata

Administration Tools-specific metadata for a failed node will fall out of synchronization with other cluster nodes if you make the following changes:

- Modify the restart policy
- Add one or more nodes
- Drop one or more nodes.

When you restore the node to the database cluster, you can use the Administration Tools to update the node with the latest Administration Tools metadata:

1. Log on to a host that contains the metadata you want to transfer and start the Administration Tools. (See [Using the administration tools.](#))
2. On the **Main Menu** in the Administration Tools, select **Configuration Menu** and click **OK** .
3. On the **Configuration Menu** , select **Distribute Config Files** and click **OK** .
4. Select **AdminTools Meta-Data** .
The Administration Tools metadata is distributed to every host in the cluster.
5. [Restart the database](#) .

Administration tools and Management Console

You can perform most database administration tasks using the Administration Tools, but you have the additional option of using the more visual and dynamic [Management Console](#) .

The following table compares the functionality available in both interfaces. Continue to use Administration Tools and the command line to perform actions not yet supported by Management Console.

Vertica Functionality	Management Console	Administration Tools
Use a Web interface for the administration of Vertica	Yes	No
Manage/monitor one or more databases and clusters through a UI	Yes	No
Manage multiple databases on different clusters	Yes	Yes
View database cluster state	Yes	Yes
View multiple cluster states	Yes	No
Connect to the database	Yes	Yes
Start/stop an existing database	Yes	Yes
Stop/restart Vertica on host	Yes	Yes
Kill a Vertica process on host	No	Yes
Create one or more databases	Yes	Yes
View databases	Yes	Yes
Remove a database from view	Yes	No
Drop a database	Yes	Yes
Create a physical schema design (Database Designer)	Yes	Yes
Modify a physical schema design (Database Designer)	Yes	Yes
Set the restart policy	No	Yes
Roll back database to the Last Good Epoch	No	Yes

Manage clusters (add, replace, remove hosts)	Yes	Yes
Rebalance data across nodes in the database	Yes	Yes
Configure database parameters dynamically	Yes	No
View database activity in relation to physical resource usage	Yes	No
View alerts and messages dynamically	Yes	No
View current database size usage statistics	Yes	No
View database size usage statistics over time	Yes	No
Upload/upgrade a license file	Yes	Yes
Warn users about license violation on login	Yes	Yes
Create, edit, manage, and delete users/user information	Yes	No
Use LDAP to authenticate users with company credentials	Yes	Yes
Manage user access to MC through roles	Yes	No
Map Management Console users to a Vertica database	Yes	No
Enable and disable user access to MC and/or the database	Yes	No
Audit user activity on database	Yes	No
Hide features unavailable to a user through roles	Yes	No
Generate new user (non-LDAP) passwords	Yes	No

Management Console Provides some, but Not All of the Functionality Provided By the Administration Tools. MC Also Provides Functionality Not Available in the Administration Tools.

- [Monitoring Vertica Using Management Console](#)

Administration tools reference

Administration Tools, or "admintools," uses the open-source [vertica-python client](#) to perform operations on the database.

The follow sections explain in detail all the steps you can perform with Vertica Administration Tools:

In this section

- [Viewing database cluster state](#)
- [Connecting to the database](#)
- [Restarting Vertica on host](#)
- [Configuration menu options](#)
- [Advanced menu options](#)
- [Administration tools connection behavior and requirements](#)
- [Writing administration tools scripts](#)

Viewing database cluster state

This tool shows the current state of the nodes in the database.

1. On the Main Menu, select **View Database Cluster State** , and click **OK** .
The normal state of a running database is ALL UP. The normal state of a stopped database is ALL DOWN.

2. If some hosts are UP and some DOWN, restart the specific host that is down using **Restart Vertica on Host** from the Administration Tools, or you can start the database as described in [Starting and Stopping the Database](#) (unless you have a known node failure and want to continue in that state.)

Nodes shown as INITIALIZING or RECOVERING indicate that [Failure recovery](#) is in progress.

Nodes in other states (such as NEEDS_CATCHUP) are transitional and can be ignored unless they persist.

See also

- [Advanced menu options](#)

Connecting to the database

This tool connects to a running [database](#) with [vsqL](#). You can use the Administration Tools to connect to a database from any node within the database while logged in to any user account with access privileges. You cannot use the Administration Tools to connect from a host that is not a database node. To connect from other hosts, run vsqL as described in [Connecting from the command line](#).

1. On the Main Menu, click **Connect to Database**, and then click **OK**.
2. Supply the database password if asked:

Password:

When you create a new user with the [CREATE USER](#) command, you can configure the password or leave it empty. You cannot bypass the password if the user was created with a password configured. You can change a user's password using the [ALTER USER](#) command.

The Administration Tools connect to the database and transfer control to [vsqL](#).

Welcome to vsqL, the Vertica Analytic Database interactive terminal.

Type: \h or \? for help with vsqL commands

\g or terminate with semicolon to execute query

\q to quit

=>

See [Using vsqL](#) for more information.

Note

After entering your password, you may be prompted to change your password if it has expired. See [Configuring client authentication](#) for details of password security.

See also

- [CREATE USER](#)
- [ALTER USER](#)

Restarting Vertica on host

This tool restarts the Vertica process on one or more hosts in a running database. Use this tool if the Vertica process stopped or was killed on the host.

1. To view the current state nodes in cluster, on the Main Menu, select **View Database Cluster State**.
2. Click **OK** to return to the Main Menu.
3. If one or more nodes are down, select **Restart Vertica on Host**, and click **OK**.
4. Select the database that contains the host that you want to restart, and click **OK**.
5. Select the one or more hosts to restart, and click **OK**.
6. Enter the database password.
7. Select **View Database Cluster State** again to verify all nodes are up.

Configuration menu options

The Configuration Menu allows you to perform the following tasks:

In this section

- [Creating a database](#)
- [Dropping a database](#)

Creating a database

Use the procedures below to create either an Enterprise Mode or Eon Mode database with admintools. To create a database with an in-browser wizard in Management Console, see [Creating a database using MC](#). For details about creating a database with admintools through the command line, see [Writing administration tools scripts](#).

Create an Enterprise Mode database

1. On the Configuration Menu, click Create Database. Click OK.
2. Select Enterprise Mode as your database mode.
3. Enter the name of the database and an optional comment. Click OK.
4. Enter a password. See [Creating a database name and password](#) for rules.
If you do not enter a password, you are prompted to confirm: Yes to enter a superuser password, No to create a database without one.

Caution

If you do not enter a password at this point, superuser password is set to empty. Unless the database is for evaluation or academic purposes, Vertica strongly recommends that you enter a superuser password.

5. If you entered a password, enter the password again.
6. Select the hosts to include in the database. The hosts in this list are the ones that were specified at installation time (`install_vertica - s`).

7. Specify the directories in which to store the catalog and data files.

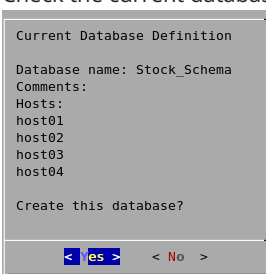

Note

Catalog and data paths must contain only alphanumeric characters and cannot have leading space characters. Failure to comply with these restrictions could result in database creation failure.

Note

Do not use a shared directory for more than one node. Data and catalog directories must be distinct for each node. Multiple nodes must not be allowed to write to the same data or catalog directory.

8. Check the current database definition for correctness. Click Yes to proceed.

9. A message indicates that you have successfully created a database. Click OK.

You can also create an Enterprise Mode database using admintools through the command line, for example:

```
$ admintools -t create_db --data_path=/home/dbadmin --catalog_path=/home/dbadmin --database=verticadb --password=password --hosts=localhost
```

For more information, see [Writing administration tools scripts](#).

Create an Eon Mode database

Note

Currently, the admintools menu interface does not support creating an Eon Mode database on Google Cloud Platform. Use the MC or the admintools command line to create an Eon Mode database instead.

1. On the Configuration Menu, click Create Database. Click OK.
2. Select Eon Mode as your database mode.
3. Enter the name of the database and an optional comment. Click OK.
4. Enter a password. See [Creating a database name and password](#) for rules.
AWS only: If you do not enter a password, you are prompted to confirm: Yes to enter a superuser password, No to create a database without one.

Caution

If you do not enter a password at this point, superuser password is set to empty. Unless the database is for evaluation or academic purposes, Vertica strongly recommends that you enter a superuser password.

5. If you entered a password, enter the password again.
6. Select the hosts to include in the database. The hosts in this list are those specified at installation time (`install_vertica -s`).
7. Specify the directories in which to store the catalog and depot, depot size, communal storage location, and number of shards.
 - **Depot Size:** Use an integer followed by %, K, G, or T. Default is 60% of the disk total disk space of the filesystem storing the depot.
 - **Communal Storage:** Use an existing Amazon S3 bucket in the same region as your instances. Specify a new subfolder name, which Vertica will dynamically create within the existing S3 bucket. For example, `s3://existingbucket/newstorage1` . You can create a new subfolder within existing ones, but database creation will roll back if you do not specify any new subfolder name.
 - **Number of Shards:** Use a whole number. The default is equal to the number of nodes. For optimal performance, the number of shards should be no greater than 2x the number of nodes. When the number of nodes is greater than the number of shards (with ETS), the throughput of dashboard queries improves. When the number of shards exceeds the number of nodes, you can expand the cluster in the future to improve the performance of long analytic queries.

Note

Catalog and depot paths must contain only alphanumeric characters and cannot have leading space characters. Failure to comply with these restrictions could result in database creation failure.

8. Check the current database definition for correctness. Click Yes to proceed.
9. A message indicates that you successfully created a database. Click OK.

In on-premises, AWS, and Azure environments, you can create an Eon Mode database using admintools through the command line. For instructions specific to your environment, see [Create a database in Eon Mode](#).

Dropping a database

This tool drops an existing [database](#). Only the [Database Superuser](#) is allowed to drop a database.

1. [Stop the database](#).
2. On the **Configuration Menu**, click **Drop Database** and then click **OK**.
3. Select the database to drop and click **OK**.
4. Click **Yes** to confirm that you want to drop the database.

5. Type **yes** and click **OK** to reconfirm that you really want to drop the database.
6. A message indicates that you have successfully dropped the database. Click **OK**.

When Vertica drops the database, it also automatically drops the node definitions that refer to the database. The following exceptions apply:

- Another database uses a node definition. If another database refers to any of these node definitions, none of the node definitions are dropped.
- A node definition is the only node defined for the host. (Vertica uses node definitions to locate hosts that are available for database creation, so removing the only node defined for a host would make the host unavailable for new databases.)

Viewing a database

This tool displays the characteristics of an existing [database](#).

1. On the **Configuration Menu**, select **View Database** and click **OK**.
2. Select the database to view.
3. Vertica displays the following information about the database:
 - The name of the database.
 - The name and location of the log file for the database.
 - The hosts within the database cluster.
 - The value of the restart policy setting.
Note: This setting determines whether nodes within a K-Safe database are restarted when they are rebooted. See [Setting the restart policy](#).
 - The database port.
 - The name and location of the catalog directory.

Setting the restart policy

The Restart Policy enables you to determine whether or not nodes in a K-Safe [database](#) are automatically restarted when they are rebooted. Since this feature does not automatically restart nodes if the entire database is DOWN, it is not useful for databases that are not K-Safe.

To set the Restart Policy for a database:

1. Open the Administration Tools.
2. On the Main Menu, select **Configuration Menu**, and click **OK**.
3. In the Configuration Menu, select **Set Restart Policy**, and click **OK**.
4. Select the database for which you want to set the Restart Policy, and click **OK**.
5. Select one of the following policies for the database:
 - **Never** — Nodes are never restarted automatically.
 - **K-Safe** — Nodes are automatically restarted if the database cluster is still UP. This is the default setting.
 - **Always** — Node on a single node database is restarted automatically.

Note

Always does not work if a single node database was not shutdown cleanly or crashed.

6. Click **OK**.

Best practice for restoring failed hardware

Following this procedure will prevent Vertica from misdiagnosing missing disk or bad mounts as data corruptions, which would result in a time-consuming, full-node recovery.

If a server fails due to hardware issues, for example a bad disk or a failed controller, upon repairing the hardware:

1. Reboot the machine into runlevel 1, which is a root and console-only mode.
Runlevel 1 prevents network connectivity and keeps Vertica from attempting to reconnect to the cluster.
2. In runlevel 1, validate that the hardware has been repaired, the controllers are online, and any RAID recover is able to proceed.

Note

You do not need to initialize RAID recover in runlevel 1; simply validate that it can recover.

3. Once the hardware is confirmed consistent, only then reboot to runlevel 3 or higher.

At this point, the network activates, and Vertica rejoins the cluster and automatically recovers any missing data. Note that, on a single-node database, if any files that were associated with a projection have been deleted or corrupted, Vertica will delete all files associated with that projection, which could result in data loss.

Installing external procedure executable files

1. Run the [Administration tools](#).

```
$ /opt/vertica/bin/adminTools
```

2. On the AdminTools **Main Menu**, click **Configuration Menu**, and then click **OK**.
3. On the **Configuration Menu**, click **Install External Procedure** and then click **OK**.
4. Select the database on which you want to install the external procedure.
5. Either select the file to install or manually type the complete file path, and then click **OK**.
6. If you are not the superuser, you are prompted to enter your password and click **OK**.
The Administration Tools automatically create the `database-name /procedures` directory on each node in the database and installs the external procedure in these directories for you.
7. Click **OK** in the dialog that indicates that the installation was successful.

Advanced menu options

The Advanced Menu options allow you to perform the following tasks:

In this section

- [Rolling back the database to the last good epoch](#)
- [Stopping Vertica on host](#)
- [Killing the Vertica process on host](#)
- [Upgrading a Vertica license key](#)
- [Managing clusters](#)
- [Getting help on administration tools](#)
- [Administration tools metadata](#)

Rolling back the database to the last good epoch

Vertica provides the ability to roll the entire database back to a specific [epoch](#) primarily to assist in the correction of human errors during data loads or other accidental corruptions. For example, suppose that you have been performing a bulk load and the cluster went down during a particular [COPY](#) command. You might want to discard all epochs back to the point at which the previous COPY command committed and run the one that did not finish again. You can determine that point by examining the log files (see [Monitoring the Log Files](#)).

1. On the Advanced Menu, select **Roll Back Database to Last Good Epoch**.
2. Select the database to roll back. The database must be stopped.
3. Accept the suggested restart epoch or specify a different one.
4. Confirm that you want to discard the changes after the specified epoch.

The database restarts successfully.

Important

The default value of `HistoryRetentionTime` is 0, which means that Vertica only keeps historical data when nodes are down. This settings prevents the use of the [Administration tools](#) 'Roll Back Database to Last Good Epoch' option because the [AHM](#) remains close to the current epoch. Vertica cannot roll back to an epoch that precedes the AHM.

If you rely on the Roll Back option to remove recently loaded data, consider setting a day-wide window for removing loaded data. For example:

```
=> ALTER DATABASE DEFAULT SET HistoryRetentionTime = 86400;
```

Stopping Vertica on host

This command attempts to gracefully shut down the Vertica process on a single node.

Caution

Do not use this command to shut down the entire cluster. Instead, [stop the database](#) to perform a clean shutdown that minimizes data loss.

1. On the Advanced Menu, select **Stop Vertica on Host** and click **OK** .
2. Select the hosts to stop.
3. Confirm that you want to stop the hosts.
If the command succeeds [View Database Cluster State](#) shows that the selected hosts are DOWN.
If the command fails to stop any selected nodes, proceed to [Killing Vertica Process on Host](#).

Killing the Vertica process on host

This command sends a kill signal to the Vertica process on a node.

Caution

Use this command only after you tried to [stop the database](#) and [stop Vertica on a node](#) and both were unsuccessful.

1. On the Advanced menu, select **Kill Vertica Process on Host** and click **OK** .
2. Select the hosts on which to kill the Vertica process.
3. Confirm that you want to stop the processes.
4. If the command succeeds, [View Database Cluster State](#) shows that the selected hosts are DOWN.

Upgrading a Vertica license key

The following steps are for licensed Vertica users. Completing the steps copies a license key file into the database. See [Managing licenses](#) for more information.

1. On the Advanced menu select **Upgrade License Key** . Click **OK** .
2. Select the database for which to upgrade the license key.
3. Enter the absolute pathname of your downloaded license key file (for example, `/tmp/vlicense.dat`). Click **OK** .
4. Click OK when you see a message indicating that the upgrade succeeded.

Note

If you are using Vertica Community Edition, follow the instructions in [Vertica license changes](#) for instructions to upgrade to a Vertica Premium Edition license key.

Managing clusters

Cluster Management lets you add, replace, or remove hosts from a database cluster. These processes are usually part of a larger process of [adding](#), [removing](#), or [replacing](#) a database node.

Note

View the database state to verify that it is running. See [View Database Cluster State](#) . If the database isn't running, restart it. See [Starting the database](#) .

Using cluster management

To use Cluster Management:

1. From the **Main Menu** , select Advanced Menu, and then click **OK** .
2. In the Advanced Menu, select **Cluster Management** , and then click **OK** .
3. Select one of the following, and then click **OK** .
 - **Add Hosts to Database:** See [Adding Hosts to a Database](#) .
 - **Re-balance Data:** See [Rebalancing Data](#) .
 - **Replace Host:** See [Replacing Hosts](#) .
 - **Remove Host from Database:** See [Removing Hosts from a Database](#) .

Getting help on administration tools

The **Help Using the Administration Tools** command displays a help screen about using the Administration Tools.

Most of the online help in the Administration Tools is context-sensitive. For example, if you use the up/down arrows to select a command, press tab to move to the Help button, and press return, you get help on the selected command.

Administration tools metadata

The Administration Tools configuration data (metadata) contains information that databases need to start, such as the hostname/IP address of each participating host in the database cluster.

To facilitate hostname resolution within the Administration Tools, at the command line, and inside the installation utility, Vertica enforces all hostnames you provide through the Administration Tools to use IP addresses:

- **During installation**

Vertica immediately converts any hostname you provide through command line options `--hosts`, `-add-hosts` or `--remove-hosts` to its IP address equivalent.

- If you provide a hostname during installation that resolves to multiple IP addresses (such as in multi-homed systems), the installer prompts you to choose one IP address.
- Vertica retains the name you give for messages and prompts only; internally it stores these hostnames as IP addresses.

- **Within the Administration Tools**

All hosts are in IP form to allow for direct comparisons (for example `db = database = database.example.com`).

- **At the command line**

Vertica converts any hostname value to an IP address that it uses to look up the host in the configuration metadata. If a host has multiple IP addresses that are resolved, Vertica tests each IP address to see if it resides in the metadata, choosing the first match. No match indicates that the host is not part of the database cluster.

Metadata is more portable because Vertica does not require the names of the hosts in the cluster to be exactly the same when you install or upgrade your database.

Administration tools connection behavior and requirements

The behavior of admintools when it connects to and performs operations on a database may vary based on your configuration. In particular, admintools considers its connection to other nodes, the status of those nodes, and the authentication method used by dbadmin.

Connection requirements and authentication

- admintools uses passwordless SSH connections between cluster hosts for most operations, which is configured or confirmed during installation with the `install_vertica` script
- For most situations, when issuing commands to the database, admintools prefers to use its SSH connection to a target host and uses a localhost client connection to the Vertica database
- The incoming IP address determines the [authentication method](#) used. That is, a client connection may have different behavior from a local connection, which may be trusted by default
- dbadmin should have a [local trust or password-based](#) authentication method
- When deciding which host to use for multi-step operations, admintools prefers localhost, and then to reconnect to known-to-be-good nodes

K-safety support

The Administration Tools allow certain operations on a [K-Safe](#) database, even if some nodes are unresponsive.

The database must have been marked as K-Safe using the [MARK_DESIGN_KSAFE](#) function.

The following management functions within the Administration Tools are operational when some nodes are unresponsive.

Note

Vertica users can perform much of the below functionality using the Management Console interface. See [Management Console and Administration Tools](#) for details.

- View database cluster state
- Connect to database
- Start database (including manual recovery)
- Stop database
- Replace node (assuming node that is down is the one being replaced)
- View database parameters
- Upgrade license key

The following management functions within the Administration Tools require that all nodes be UP in order to be operational:

- Create database
- Run the Database Designer
- Drop database
- Set restart policy
- Roll back database to [Last Good Epoch](#)

Writing administration tools scripts

You can invoke most Administration Tools from the command line or a shell script.

Syntax

```
/opt/vertica/bin/admintools {
  { -h | --help }
  | { -a | --help_all }
  | { [--debug] { -t | --tool } toolname [ tool-args ] }
}
```

Note

For convenience, add `/opt/vertica/bin` to your search path.

Parameters

<code>-h</code> <code>-help</code>	Outputs abbreviated help.
<code>-a</code> <code>-help_all</code>	Outputs verbose help, which lists all command-line sub-commands and options.
<code>[debug] { -t - tool } <i>toolname</i> [<i>args</i>]</code>	Specifies the tool to run, where <i>toolname</i> is one of the tools listed in the help output described below, and <i>args</i> is one or more comma-delimited <i>toolname</i> arguments. If you include the <code>debug</code> option, Vertica logs debug information during tool execution.

Tools

To return a list of all available tools, enter `admintools -h` at a command prompt.

Note

To create a database or password, see [Creating a database name and password](#) for naming rules.

To display help for a specific tool and its options or commands, qualify the specified tool name with `--help` or `-h`, as shown in the example below:

```
$ admintools -t connect_db --help
Usage: connect_db [options]

Options:
-h, --help          show this help message and exit
-d DB, --database=DB Name of database to connect
-p DBPASSWORD, --password=DBPASSWORD
                   Database password in single quotes
```

To list all available tools and their commands and options in individual help text, enter `admintools -a`.

```
Usage:
  adminTools [-t | --tool] toolName [options]

Valid tools are:
  command_host
  connect_db
  create_db
  db_add_node
```

db_add_subcluster
db_remove_node
db_remove_subcluster
db_replace_node
db_status

view_cluster

Usage: command_host [options]

Options:

-h, --help show this help message and exit
-c CMD, --command=CMD
Command to run
-F, --force Provide the force cleanup flag. Only applies to start,
restart, condrestart. For other options it is ignored.

Usage: connect_db [options]

Options:

-h, --help show this help message and exit
-d DB, --database=DB Name of database to connect
-p DBPASSWORD, --password=DBPASSWORD
Database password in single quotes

Usage: create_db [options]

Options:

-h, --help show this help message and exit
-D DATA, --data_path=DATA

Path of data directory[optional] if not using compat21

-c CATALOG, --catalog_path=CATALOG
Path of catalog directory[optional] if not using
compat21

--compat21 (deprecated) Use Vertica 2.1 method using node names
instead of hostnames

-d DB, --database=DB Name of database to be created

-l LICENSEFILE, --license=LICENSEFILE
Database license [optional]

-p DBPASSWORD, --password=DBPASSWORD
Database password in single quotes [optional]

-P POLICY, --policy=POLICY
Database restart policy [optional]

-s HOSTS, --hosts=HOSTS
comma-separated list of hosts to participate in
database

--shard-count=SHARD_COUNT
[Eon only] Number of shards in the database

--communal-storage-location=COMMUNAL_STORAGE_LOCATION
[Eon only] Location of communal storage

-x COMMUNAL_STORAGE_PARAMS, --communal-storage-params=COMMUNAL_STORAGE_PARAMS
[Eon only] Location of communal storage parameter file

--depot-path=DEPOT_PATH
[Eon only] Path to depot directory

--depot-size=DEPOT_SIZE
[Eon only] Size of depot

--force-cleanup-on-failure
Force removal of existing directories on failure of
command

--force-removal-at-creation
Force removal of existing directories before creating
the database

--timeout=NONINTERACTIVE_TIMEOUT
set a timeout (in seconds) to wait for actions to
complete ('never') will wait forever (implicitly sets
-i)

-i, --noprompts do not stop and wait for user input(default false).
Setting this implies a timeout of 20 min.

Usage: db_add_node [options]

Options:

-h, --help show this help message and exit

-d DB, --database=DB Name of the database

-s HOSTS, --hosts=HOSTS
Comma separated list of hosts to add to database

-p DBPASSWORD, --password=DBPASSWORD
Database password in single quotes

-a AHOSTS, --add=AHOSTS
Comma separated list of hosts to add to database

-c SCNAME, --subcluster=SCNAME
Name of subcluster for the new node

--timeout=NONINTERACTIVE_TIMEOUT
set a timeout (in seconds) to wait for actions to
complete ('never') will wait forever (implicitly sets
-i)

-i, --noprompts do not stop and wait for user input(default false).
Setting this implies a timeout of 20 min.

--compat21 (deprecated) Use Vertica 2.1 method using node names
instead of hostnames

Usage: db_add_subcluster [options]

Options:

- h, --help show this help message and exit
 - d DB, --database=DB Name of database to be modified
 - s HOSTS, --hosts=HOSTS
Comma separated list of hosts to add to the subcluster
 - p DBPASSWORD, --password=DBPASSWORD
Database password in single quotes
 - c SCNAME, --subcluster=SCNAME
Name of the new subcluster for the new node
 - is-primary Create primary subcluster
 - is-secondary Create secondary subcluster
 - control-set-size=CONTROLSETSIZE
Set the number of nodes that will run spread within
the subcluster
 - like=CLONESUBCLUSTER
Name of an existing subcluster from which to clone
properties for the new subcluster
 - timeout=NONINTERACTIVE_TIMEOUT
set a timeout (in seconds) to wait for actions to
complete ('never') will wait forever (implicitly sets
-i)
 - i, --noprompts do not stop and wait for user input(default false).
Setting this implies a timeout of 20 min.
-

Usage: db_remove_node [options]

Options:

- h, --help show this help message and exit
 - d DB, --database=DB Name of database to be modified
 - s HOSTS, --hosts=HOSTS
Name of the host to remove from the db
 - p DBPASSWORD, --password=DBPASSWORD
Database password in single quotes
 - timeout=NONINTERACTIVE_TIMEOUT
set a timeout (in seconds) to wait for actions to
complete ('never') will wait forever (implicitly sets
-i)
 - i, --noprompts do not stop and wait for user input(default false).
Setting this implies a timeout of 20 min.
 - compat21 (deprecated) Use Vertica 2.1 method using node names
instead of hostnames
 - skip-directory-cleanup
Caution: this option will force you to do a manual
cleanup. This option skips directory deletion during
remove node. This is best used in a cloud environment
where the hosts being removed will be subsequently
discarded.
-

Usage: db_remove_subcluster [options]

Options:

- h, --help show this help message and exit
- d DB, --database=DB Name of database to be modified
- c SCNAME, --subcluster=SCNAME
Name of subcluster to be removed
- p DBPASSWORD, --password=DBPASSWORD
Database password in single quotes
- timeout=NONINTERACTIVE_TIMEOUT
set a timeout (in seconds) to wait for actions to

complete ('never') will wait forever (implicitly sets
-i)

-i, --noprompts do not stop and wait for user input(default false).
Setting this implies a timeout of 20 min.

--skip-directory-cleanup

Caution: this option will force you to do a manual
cleanup. This option skips directory deletion during
remove subcluster. This is best used in a cloud
environment where the hosts being removed will be
subsequently discarded.

Usage: db_replace_node [options]

Options:

-h, --help show this help message and exit
-d DB, --database=DB Name of the database
-o ORIGINAL, --original=ORIGINAL
Name of host you wish to replace
-n NEWHOST, --new=NEWHOST
Name of the replacement host
-p DBPASSWORD, --password=DBPASSWORD
Database password in single quotes
--timeout=NONINTERACTIVE_TIMEOUT
set a timeout (in seconds) to wait for actions to
complete ('never') will wait forever (implicitly sets
-i)
-i, --noprompts do not stop and wait for user input(default false).
Setting this implies a timeout of 20 min.

Usage: db_status [options]

Options:

-h, --help show this help message and exit
-s STATUS, --status=STATUS
Database status UP,DOWN or ALL(list running dbs -
UP,list down dbs - DOWN list all dbs - ALL

Usage: distribute_config_files

Sends admintools.conf from local host to all other hosts in the cluster

Options:

-h, --help show this help message and exit

Usage: drop_db [options]

Options:

-h, --help show this help message and exit
-d DB, --database=DB Database to be dropped

Usage: host_to_node [options]

Options:

-h, --help show this help message and exit
-s HOST, --host=HOST comma separated list of hostnames which is to be
converted into its corresponding nodenames
-d DB, --database=DB show only node/host mapping for this database.

Usage: admintools -t install_package --package PACKAGE -d DB -p PASSWORD

Examples:

admintools -t install_package -d mydb -p 'mypasswd' --package default
(above) install all default packages that aren't currently installed

```
admintools -t install_package -d mydb -p 'mypasswd' --package default --force-reinstall
# (above) upgrade (re-install) all default packages to the current version
```

```
admintools -t install_package -d mydb -p 'mypasswd' --package hcat
# (above) install package hcat
```

See also: `admintools -t list_packages`

Options:

```
-h, --help          show this help message and exit
-d DBNAME, --dbname=DBNAME
                    database name
-p PASSWORD, --password=PASSWORD
                    database admin password
-P PACKAGE, --package=PACKAGE
                    specify package or 'all' or 'default'
--force-reinstall  Force a package to be re-installed even if it is
                    already installed.
```

Usage: `install_procedure` [options]

Options:

```
-h, --help          show this help message and exit
-d DBNAME, --database=DBNAME
                    Name of database for installed procedure
-f PROCPATH, --file=PROCPATH
                    Path of procedure file to install
-p OWNERPASSWORD, --password=OWNERPASSWORD
                    Password of procedure file owner
```

Usage: `kill_host` [options]

Options:

```
-h, --help          show this help message and exit
-s HOSTS, --hosts=HOSTS
                    comma-separated list of hosts on which the vertica
                    process is to be killed using a SIGKILL signal
--compat21          (deprecated) Use Vertica 2.1 method using node names
                    instead of hostnames
```

Usage: `kill_node` [options]

Options:

```
-h, --help          show this help message and exit
-s HOSTS, --hosts=HOSTS
                    comma-separated list of hosts on which the vertica
                    process is to be killed using a SIGKILL signal
--compat21          (deprecated) Use Vertica 2.1 method using node names
                    instead of hostnames
```

Usage: `license_audit` --dbname DB_NAME [OPTIONS]

Runs audit and collects audit results.

Options:

```
-h, --help          show this help message and exit
-d DATABASE, --database=DATABASE
                    Name of the database to retrieve audit results
-p PASSWORD, --password=PASSWORD
                    Password for database admin
-q, --quiet          Do not print status messages.
-f FILE, --file=FILE
                    Output results to FILE
```

-t FILE, --file=FILE Output results to FILE.

Usage: list_allnodes [options]

Options:

-h, --help show this help message and exit

Usage: list_db [options]

Options:

-h, --help show this help message and exit
-d DB, --database=DB Name of database to be listed

Usage: list_host [options]

Options:

-h, --help show this help message and exit

Usage: list_node [options]

Options:

-h, --help show this help message and exit
-n NODENAME, --node=NODENAME
Name of the node to be listed

Usage: admintools -t list_packages [OPTIONS]

Examples:

admintools -t list_packages # lists all available packages
admintools -t list_packages --package all # lists all available packages
admintools -t list_packages --package default # list all packages installed by default
admintools -t list_packages -d mydb --password 'mypasswd' # list the status of all packages in mydb

Options:

-h, --help show this help message and exit
-d DBNAME, --dbname=DBNAME
database name
-p PASSWORD, --password=PASSWORD
database admin password
-P PACKAGE, --package=PACKAGE
specify package or 'all' or 'default'

Usage: logrotateconfig [options]

Options:

-h, --help show this help message and exit
-d DBNAME, --dbname=DBNAME
database name
-r ROTATION, --rotation=ROTATION
set how often the log is rotated.
daily|weekly|monthly]
-s MAXLOGSZ, --maxsize=MAXLOGSZ
set maximum log size before rotation is forced.
-k KEEP, --keep=KEEP set # of old logs to keep

Usage: node_map [options]

Options:

-h, --help show this help message and exit
-d DB, --database=DB List only data for this database.

Usage: re_ip [options]

Replaces the IP addresses of hosts and databases in a cluster, or changes the control messaging mode/addresses of a database.

Options:

- h, --help show this help message and exit
- f MAPFILE, --file=MAPFILE
A text file with IP mapping information. If the -O option is not used, the command replaces the IP addresses of the hosts in the cluster and all databases for those hosts. In this case, the format of each line in MAPFILE is: [oldIPAddress newIPAddress] or [oldIPAddress newIPAddress, newControlAddress, newControlBroadcast]. If the former, 'newControlAddress' and 'newControlBroadcast' would set to default values. Usage: \$ admintools -t re_ip -f <mapfile>
- O, --db-only Updates the control messaging addresses of a database. Also used for error recovery (when re_ip encounters some certain errors, a mapfile is auto-generated). Format of each line in MAPFILE: [NodeName AssociatedNodeIPAddress, newControlAddress, newControlBroadcast]. 'NodeName' and 'AssociatedNodeIPAddress' must be consistent with admintools.conf. Usage: \$ admintools -t re_ip -f <mapfile> -O -d <db_name>
- i, --noprompts System does not prompt for the validation of the new settings before performing the re_ip operation. Prompting is on by default.
- T, --point-to-point Sets the control messaging mode of a database to point-to-point. Usage: \$ admintools -t re_ip -d <db_name> -T
- U, --broadcast Sets the control messaging mode of a database to broadcast. Usage: \$ admintools -t re_ip -d <db_name> -U
- d DB, --database=DB Name of a database. Required with the following options: -O, -T, -U.

Usage: rebalance_data [options]

Options:

- h, --help show this help message and exit
- d DBNAME, --dbname=DBNAME
database name
- k KSAFETY, --ksafety=KSAFETY
specify the new k value to use
- p PASSWORD, --password=PASSWORD
- script Don't re-balance the data, just provide a script for later use.

Usage: restart_db [options]

Options:

- h, --help show this help message and exit
- d DB, --database=DB Name of database to be restarted
- e EPOCH, --epoch=EPOCH
Epoch at which the database is to be restarted. If 'last' is given as argument the db is restarted from the last good epoch.
- p DBPASSWORD, --password=DBPASSWORD
Database password in single quotes
- k --allow-fallback-keygen

Generate spread encryption key from Vertica. Use under support guidance only.

--timeout=NONINTERACTIVE_TIMEOUT
set a timeout (in seconds) to wait for actions to complete ('never') will wait forever (implicitly sets -i)

-i, --noprompts do not stop and wait for user input(default false).
Setting this implies a timeout of 20 min.

Usage: restart_node [options]

Options:

-h, --help show this help message and exit

-s HOSTS, --hosts=HOSTS
comma-separated list of hosts to be restarted

-d DB, --database=DB Name of database whose node is to be restarted

-p DBPASSWORD, --password=DBPASSWORD
Database password in single quotes

--new-host-ips=NEWHOSTS
comma-separated list of new IPs for the hosts to be restarted

--timeout=NONINTERACTIVE_TIMEOUT
set a timeout (in seconds) to wait for actions to complete ('never') will wait forever (implicitly sets -i)

-i, --noprompts do not stop and wait for user input(default false).
Setting this implies a timeout of 20 min.

-F, --force force the node to start and auto recover if necessary

--compat21 (deprecated) Use Vertica 2.1 method using node names instead of hostnames

--waitfordown-timeout=WAITTIME
Seconds to wait until nodes to be restarted are down

Usage: restart_subcluster [options]

Options:

-h, --help show this help message and exit

-d DB, --database=DB Name of database whose subcluster is to be restarted

-c SCNAME, --subcluster=SCNAME
Name of subcluster to be restarted

-p DBPASSWORD, --password=DBPASSWORD
Database password in single quotes

-s NEWHOSTS, --hosts=NEWHOSTS
Comma separated list of new hosts to rebind to the nodes

--timeout=NONINTERACTIVE_TIMEOUT
set a timeout (in seconds) to wait for actions to complete ('never') will wait forever (implicitly sets -i)

-i, --noprompts do not stop and wait for user input(default false).
Setting this implies a timeout of 20 min.

-F, --force Force the nodes in the subcluster to start and auto recover if necessary

Usage: return_epoch [options]

Options:

-h, --help show this help message and exit

-d DB, --database=DB Name of database

-p PASSWORD, --password=PASSWORD
Database password in single quotes

Usage: revive_db [options]

Options:

-h, --help show this help message and exit
-s HOSTS, --hosts=HOSTS
comma-separated list of hosts to participate in
database
-n NODEHOST, --node-and-host=NODEHOST
pair of nodename-hostname values delimited by "|" eg:
"v_testdb_node0001|10.0.0.1"Note: Each node-host pair
has to be specified as a new argument
--communal-storage-location=COMMUNAL_STORAGE_LOCATION
Location of communal storage
-x COMMUNAL_STORAGE_PARAMS, --communal-storage-params=COMMUNAL_STORAGE_PARAMS
Location of communal storage parameter file
-d DBNAME, --database=DBNAME
Name of database to be revived
--force Force cleanup of existing catalog directory
--display-only Describe the database on communal storage, and exit
--strict-validation Print warnings instead of raising errors while
validating cluster_config.json

Usage: sandbox_subcluster [options]

Options:

-h, --help show this help message and exit
-d DB, --database=DB Name of database to be modified
-p DBPASSWORD, --password=DBPASSWORD
Database password in single quotes
-c SCNAME, --subcluster=SCNAME
Name of subcluster to be sandboxed
-b SBNAME, --sandbox=SBNAME
Name of the sandbox
--timeout=NONINTERACTIVE_TIMEOUT
set a timeout (in seconds) to wait for actions to
complete ('never') will wait forever (implicitly sets
-i)
-i, --noprompts do not stop and wait for user input(default false).
Setting this implies a timeout of 20 min.

Usage: set_restart_policy [options]

Options:

-h, --help show this help message and exit
-d DB, --database=DB Name of database for which to set policy
-p POLICY, --policy=POLICY
Restart policy: ('never', 'ksafe', 'always')

Usage: set_ssl_params [options]

Options:

-h, --help show this help message and exit
-d DB, --database=DB Name of database whose parameters will be set
-k KEYFILE, --ssl-key-file=KEYFILE
Path to SSL private key file
-c CERTFILE, --ssl-cert-file=CERTFILE
Path to SSL certificate file
-a CAFILE, --ssl-ca-file=CAFILE
Path to SSL CA file
-p DBPASSWORD, --password=DBPASSWORD

Database password in single quotes

Usage: show_active_db [options]

Options:

-h, --help show this help message and exit

Usage: start_db [options]

Options:

-h, --help show this help message and exit

-d DB, --database=DB Name of database to be started

-p DBPASSWORD, --password=DBPASSWORD
Database password in single quotes

--timeout=NONINTERACTIVE_TIMEOUT
set a timeout (in seconds) to wait for actions to complete ('never') will wait forever (implicitly sets -i)

-i, --noprompts do not stop and wait for user input(default false).
Setting this implies a timeout of 20 min.

-F, --force force the database to start at an epoch before data consistency problems were detected.

-U, --unsafe Start database unsafely, skipping recovery. Use under support guidance only.

-k, --allow-fallback-keygen
Generate spread encryption key from Vertica. Use under support guidance only.

-s HOSTS, --hosts=HOSTS
comma-separated list of hosts to be started

--fast Attempt fast startup on un-encrypted eon db. Fast startup will use startup information from cluster_config.json

Usage: stop_db [options]

Options:

-h, --help show this help message and exit

-d DB, --database=DB Name of database to be stopped

-p DBPASSWORD, --password=DBPASSWORD
Database password in single quotes

-F, --force Force the databases to shutdown, even if users are connected.

-z, --if-no-users Only shutdown if no users are connected.
If any users are connected, exit with an error.

-n DRAIN_SECONDS, --drain-seconds=DRAIN_SECONDS
Eon db only: seconds to wait for user connections to close.
Default value is 60 seconds.
When the time expires, connections will be forcibly closed and the db will shut down.

--timeout=NONINTERACTIVE_TIMEOUT
set a timeout (in seconds) to wait for actions to complete ('never') will wait forever (implicitly sets -i)

-i, --noprompts do not stop and wait for user input(default false).
Setting this implies a timeout of 20 min.

Usage: stop_host [options]

Options:

-h, --help show this help message and exit

-s HOSTS, --hosts=HOSTS

comma-separated list of hosts on which the vertica process is to be killed using a SIGTERM signal

--compat21 (deprecated) Use Vertica 2.1 method using node names instead of hostnames

Usage: stop_node [options]

Options:

-h, --help show this help message and exit
-s HOSTS, --hosts=HOSTS
comma-separated list of hosts on which the vertica process is to be killed using a SIGTERM signal
--compat21 (deprecated) Use Vertica 2.1 method using node names instead of hostnames

Usage: stop_subcluster [options]

Options:

-h, --help show this help message and exit
-d DB, --database=DB Name of database whose subcluster is to be stopped
-c SCNAME, --subcluster=SCNAME
Name of subcluster to be stopped
-p DBPASSWORD, --password=DBPASSWORD
Database password in single quotes
-n DRAIN_SECONDS, --drain-seconds=DRAIN_SECONDS
Seconds to wait for user connections to close.
Default value is 60 seconds.
When the time expires, connections will be forcibly closed and the db will shut down.
-F, --force Force the subcluster to shutdown immediately, even if users are connected.
--timeout=NONINTERACTIVE_TIMEOUT
set a timeout (in seconds) to wait for actions to complete ('never') will wait forever (implicitly sets -i)
-i, --noprompts do not stop and wait for user input(default false).
Setting this implies a timeout of 20 min.

Usage: uninstall_package [options]

Options:

-h, --help show this help message and exit
-d DBNAME, --dbname=DBNAME
database name
-p PASSWORD, --password=PASSWORD
database admin password
-P PACKAGE, --package=PACKAGE
specify package or 'all' or 'default'

Usage: unsandbox_subcluster [options]

Options:

-h, --help show this help message and exit
-d DB, --database=DB Name of database to be modified
-p DBPASSWORD, --password=DBPASSWORD
Database password in single quotes
-c SCNAME, --subcluster=SCNAME
Name of subcluster to be un-sandboxed
--timeout=NONINTERACTIVE_TIMEOUT
set a timeout (in seconds) to wait for actions to complete ('never') will wait forever (implicitly sets

-i)

-i, --noprompts do not stop and wait for user input(default false).
Setting this implies a timeout of 20 min.

Usage: upgrade_license_key --database mydb --license my_license.key
upgrade_license_key --install --license my_license.key

Updates the vertica license.

Without '--install', updates the license used by the database and the admintools license cache.

With '--install', updates the license cache in admintools that is used for creating new databases.

Options:

-h, --help show this help message and exit
-d DB, --database=DB Name of database. Cannot be used with --install.
-l LICENSE, --license=LICENSE
Required - path to the license.
-i, --install When option is included, command will only update the admintools license cache. Cannot be used with --database.
-p PASSWORD, --password=PASSWORD
Database password.

Usage: view_cluster [options]

Options:

-h, --help show this help message and exit
-x, --xpannd show the full cluster state, node by node
-d DB, --database=DB filter the output for a single database

Operating the database

This topic explains how to start and stop your Vertica database, and how to use the database index tool.

In this section

- [Starting the database](#)
- [Stopping the database](#)
- [CRC and sort order check](#)

Starting the database

You can start a database through one of the following:

- [Management Console](#)
- [Administration Tools](#)
- [Command Line](#)

Administration tools

You can start a database with the Vertica [Administration Tools](#) :

1. Open the Administration Tools and select [View Database Cluster State](#) to make sure all nodes are down and no other database is running.
2. Open the Administration Tools. See [Using the administration tools](#) for information about accessing the Administration Tools.
3. On the **Main Menu** , select **Start Database** ,and then select **OK** .
4. Select the database to start, and then click **OK** .

Caution

Start only one database at a time. If you start more than one database at a given time, results can be unpredictable: users are liable to encounter resource conflicts, or perform operations on the wrong database.

5. Enter the database password and click **OK** .
6. When prompted that the database started successfully, click **OK** .
7. Check the log files to make sure that no startup problems occurred.

Command line

You can start a database with the [command line tool start_db](#) :

```
$ /opt/vertica/bin/admintools -t start_db -d db-name
  [-p password]
  [-s host1[,...] | --hosts=host1[,...]]
  [--timeout seconds]
  [-i | --noprompts]
  [--fast]
  [-F | --force]
```

Option	Description
-d --database	Name of database to start.
-p --password	<p>Required only during database creation, when you install a new license.</p> <p>If the license is valid, the option -p (or --password) is not required to start the database and is silently ignored. This is by design, as the database can only be started by the user who (as part of the verticadba UNIX user group) initially created the database or who has root or su privileges.</p> <p>If the license is invalid, Vertica uses the -p password argument to attempt to upgrade the license with the license file stored in /opt/vertica/config/share/license.key .</p>
-s --hosts	<p>(Eon Mode only) Comma delimited list of primary node host names or IP addresses. If you use this option, start_db attempts to start the database using just the nodes in the list. If omitted, start_db starts all database nodes.</p> <p>For details, see Start Just the Primary Nodes in an Eon Mode Database below.</p>
--timeout	The number of seconds a timeout in seconds to await startup completion. If set to never , start_db never times out (implicitly sets -i)
-i --noprompts	Startup does not pause to await user input. Setting -i implies a timeout of 1200 seconds.
--fast	(Eon Mode only) Attempts fast startup on a database using startup information from cluster_config.json . This option can only be used with databases that do not use Spread encryption .
-F --force	Forces the database to start at an epoch before data consistency problems were detected.

The following example uses **start_db** to start a single-node database:

```
$ /opt/vertica/bin/admintools -t start_db -d VMart
```

Info:

```
no password specified, using none
Node Status: v_vmart_node0001: (DOWN)
Node Status: v_vmart_node0001: (DOWN)
Node Status: v_vmart_node0001: (DOWN)
Node Status: v_vmart_node0001: (DOWN)
Node Status: v_vmart_node0001: (DOWN)
Node Status: v_vmart_node0001: (DOWN)
Node Status: v_vmart_node0001: (DOWN)
Node Status: v_vmart_node0001: (DOWN)
Node Status: v_vmart_node0001: (DOWN)
Node Status: v_vmart_node0001: (UP)
Database VMart started successfully
```

Eon Mode database node startup

On starting an Eon Mode database, you can start all primary nodes, or a subset of them. In both cases, pass `start_db` the list of the primary nodes to start with the `-s` option.

The following requirements apply:

- Primary node hosts must already be up to start the database.
- The `start_db` tool cannot start stopped hosts such as cloud-based VMs. You must either manually start the hosts or use the MC to start the cluster.

The following example starts the three primary nodes in a six-node Eon Mode database:

```
$ admintools -t start_db -d verticadb -p 'password' \
```

```
-s 10.11.12.10,10.11.12.20,10.11.12.30
```

Starting nodes:

```
v_verticadb_node0001 (10.11.12.10)
```

```
v_verticadb_node0002 (10.11.12.20)
```

```
v_verticadb_node0003 (10.11.12.30)
```

Starting Vertica on all nodes. Please wait, databases with a large catalog may take a while to initialize.

```
Node Status: v_verticadb_node0001: (DOWN) v_verticadb_node0002: (DOWN) v_verticadb_node0003: (DOWN)
```

```
Node Status: v_verticadb_node0001: (DOWN) v_verticadb_node0002: (DOWN) v_verticadb_node0003: (DOWN)
```

```
Node Status: v_verticadb_node0001: (DOWN) v_verticadb_node0002: (DOWN) v_verticadb_node0003: (DOWN)
```

```
Node Status: v_verticadb_node0001: (DOWN) v_verticadb_node0002: (DOWN) v_verticadb_node0003: (DOWN)
```

```
Node Status: v_verticadb_node0001: (DOWN) v_verticadb_node0002: (DOWN) v_verticadb_node0003: (DOWN)
```

```
Node Status: v_verticadb_node0001: (DOWN) v_verticadb_node0002: (DOWN) v_verticadb_node0003: (DOWN)
```

```
Node Status: v_verticadb_node0001: (UP) v_verticadb_node0002: (UP) v_verticadb_node0003: (UP)
```

Syncing catalog on verticadb with 2000 attempts.

Database verticadb: Startup Succeeded. All Nodes are UP

After the database starts, the [secondary subclusters](#) are down. You can choose to start them as needed. See [Starting a Subcluster](#).

Starting the database with a subset of primary nodes

As a best practice, Vertica recommends that you always start an Eon Mode database with all primary nodes. Occasionally, you might be unable to start the hosts for all primary nodes. In that case, you might need to start the database with a subset of its primary nodes.

If `start_db` specifies a subset of database primary nodes, the following requirements apply:

- The nodes must comprise a quorum: at least 50% + 1 of all primary nodes in the cluster.
- Collectively, the nodes must provide coverage for all shards in communal storage. The primary nodes you use to start the database do not attempt to rebalance shard subscriptions while starting up.

If either or both of these conditions are not met, `start_db` returns an error. In the following example, `start_db` specifies three primary nodes in a database with nine primary nodes. The command returns an error that it cannot start the database with fewer than five primary nodes:

```
$ admintools -t start_db -d verticadb -p 'password' \  
-s 10.11.12.10,10.11.12.20,10.11.12.30  
Starting nodes:  
v_verticadb_node0001 (10.11.12.10)  
v_verticadb_node0002 (10.11.12.20)  
v_verticadb_node0003 (10.11.12.30)  
Error: Quorum not satisfied for verticadb.  
3 < minimum 5 of 9 primary nodes.  
Attempted to start the following nodes:  
Primary  
v_verticadb_node0001 (10.11.12.10)  
v_verticadb_node0003 (10.11.12.30)  
v_verticadb_node0002 (10.11.12.20)  
Secondary  
  
hint: you may want to start all primary nodes in the database  
Database start up failed. Cluster partitioned.
```

If you try to start the database with fewer than the full set of primary nodes and the cluster fails to start, Vertica processes might continue to run on some of the hosts. If so, subsequent attempts to start the database will return with an error like this:

```
Error: the vertica process for the database is running on the following hosts:  
10.11.12.10  
10.11.12.20  
10.11.12.30  
This may be because the process has not completed previous shutdown activities. Please wait and retry again.  
Database start up failed. Processes still running.  
Database verticadb did not start successfully: Processes still running.. Hint: you may need to start all primary nodes.
```

Before you can start the database, you must stop the Vertica server process on the hosts listed in the error message, either with the [admintools menus](#) or the admintools command line's [stop_host](#) tool:

```
$ admintools -t stop_host -s 10.11.12.10,10.11.12.20,10.11.12.30
```

Stopping the database

There are many occasions when you must stop a database, for example, before an upgrade or performing various maintenance tasks. You can stop a running database through one of the following:

- [Management Console](#)
- [Administration Tools interface](#)
- [Vertica functions](#)
- [Command line](#)

You cannot stop a running database if any users are connected or Database Designer is building or deploying a database design.

Administration tools

To stop a running database with admintools:

1. [Verify that all cluster nodes are up](#). If any nodes are down, [identify and restart them](#).
2. Close all user sessions:
 - Identify all users with active sessions by querying the [SESSIONS](#) system table. Notify users of the impending shutdown and request them to shut down their sessions.
 - Prevent users from starting new sessions by temporarily resetting configuration parameter [MaxClientSessions](#) to 0:

```
=> ALTER DATABASE DEFAULT SET MaxClientSessions = 0;
```
 - Close all remaining user sessions with Vertica functions [CLOSE_SESSION](#) and [CLOSE_ALL_SESSIONS](#).

Note

You can also force a database shutdown and block new sessions with the function [SHUTDOWN](#).

3. Open Vertica [Administration Tools](#).
4. From the Main Menu:
 - Select Stop Database
 - Click **OK**
5. Select the database to stop and click **OK**.
6. Enter the password (if asked) and click **OK**.
7. When prompted that database shutdown is complete, click **OK**.

Vertica functions

You can stop a database with the [SHUTDOWN](#) function. By default, the shutdown fails if any users are connected. To force a shutdown regardless of active user connections, call SHUTDOWN with an argument of `true` :

```
=> SELECT SHUTDOWN('true');
      SHUTDOWN
```

```
-----
Shutdown: sync complete
(1 row)
```

In Eon Mode databases, you can stop subclusters with the [SHUTDOWN_SUBCLUSTER](#) and [SHUTDOWN_WITH_DRAIN](#) functions. SHUTDOWN_SUBCLUSTER shuts down subclusters immediately, whereas SHUTDOWN_WITH_DRAIN performs a graceful shutdown that drains client connections from subclusters before shutting them down. For more information, see [Starting and stopping subclusters](#).

The following example demonstrates how you can shut down all subclusters in an Eon Mode database using SHUTDOWN_WITH_DRAIN:

```
=> SELECT SHUTDOWN_WITH_DRAIN("", 0);
NOTICE 0: Begin shutdown of subcluster (default_subcluster, analytics)
      SHUTDOWN_WITH_DRAIN
```

```
-----
Shutdown message sent to subcluster (default_subcluster, analytics)
(1 row)
```

Command line

You can stop a database with the [admintools command stop_db](#) :

```
$$$ admintools -t stop_db --help
Usage: stop_db [options]
```

Options:

- h, --help Show this help message and exit.
- d DB, --database=DB Name of database to be stopped.
- p DBPASSWORD, --password=DBPASSWORD Database password in single quotes.
- F, --force Force the database to shutdown, even if users are connected.
- z, --if-no-users Only shutdown if no users are connected. If any users are connected, exit with an error.
- n DRAIN_SECONDS, --drain-seconds=DRAIN_SECONDS Eon db only: seconds to wait for user connections to close. Default value is 60 seconds. When the time expires, connections will be forcibly closed and the db will shut down.
- timeout=NONINTERACTIVE_TIMEOUT Set a timeout (in seconds) to wait for actions to complete ('never') will wait forever (implicitly sets -i).
- i, --noprompts Do not stop and wait for user input(default false). Setting this implies a timeout of 20 min.

Note

You cannot use both the `-z` (`--if-no-users`) and `-F` (or `--force`) options in the same `stop_db` call.

`stop_db` behavior depends on whether it stops an [Eon Mode](#) or [Enterprise Mode](#) database.

Stopping an Eon Mode database

In Eon Mode databases, the default behavior of `stop_db` is to call `SHUTDOWN_WITH_DRAIN` to [gracefully shut down](#) all subclusters in the database. This graceful shutdown process drains client connections from subclusters before shutting them down.

The `stop_db` option `-n (--drain-seconds)` lets you specify the number of seconds to wait—by default, 60—before forcefully closing client connections and shutting down all subclusters. If you set a negative `-n` value, the subclusters are marked as draining but do not shut down until all active user sessions disconnect.

In the following example, the database initially has an active client session, but the session closes before the timeout limit is reached and the database shuts down:

```
$ admintools -t stop_db -d verticadb --password password --drain-seconds 200
Shutdown will use connection draining.
Shutdown will wait for all client sessions to complete, up to 200 seconds
Then it will force a shutdown.
Poller has been running for 0:00:00.000025 seconds since 2022-07-27 17:10:08.292919

1                |1          |v_verticadb_node0001
Stopping poller drain_status because it was canceled
Shutdown metafunction complete. Polling until database processes have stopped.
Database verticadb stopped successfully
```

If you use the `-z (--if-no-users)` option, the database shuts down immediately if there are no active user sessions. Otherwise, the `stop_db` command returns an error:

```
$ admintools -t stop_db -d verticadb --password password --if-no-users
Running shutdown metafunction. Not using connection draining

      Active session details
| Session id      | Host Ip    | Connected User |
|-----|-----|-----|
| v_verticadb_node0001-107720:0x257 | 192.168.111.31 | analyst      |
Database verticadb not stopped successfully for the following reason:
Shutdown did not complete. Message: Shutdown: aborting shutdown
Active sessions prevented shutdown.
Omit the option --if-no-users to close sessions. See stop_db --help.
```

You can use the `-F (or --force)` option to shut down all subclusters immediately, without checking for active user sessions or draining the subclusters.

Stopping an Enterprise Mode database

In Enterprise Mode databases, the default behavior of `stop_db` is to shut down the database only if there are no active sessions. If users are connected to the database, the command aborts with an error message and lists all active sessions. For example:

```
$ /opt/vertica/bin/admintools -t stop_db -d VMart
```

```
Info: no password specified, using none
```

Active session details

```
| Session id          | Host Ip    | Connected User |
|-----|-----|-----|
| v_vmart_node0001-91901:0x162 | 10.20.100.247 | analyst      |
Database VMart not stopped successfully for the following reason:
Unexpected output from shutdown: Shutdown: aborting shutdown
NOTICE: Cannot shut down while users are connected
```

You can use the **-F** (or **--force**) option to override user connections and force a shutdown.

CRC and sort order check

As a superuser, you can run the Index tool on a Vertica database to perform two tasks:

- Run a cyclic redundancy check (CRC) on each block of existing data storage to check the data integrity of ROS data blocks.
- Check that the sort order in ROS containers is correct.

If the database is down, invoke the Index tool from the Linux command line. If the database is up, invoke from VSQL with Vertica meta-function [RUN_INDEX_TOOL](#) :

Operation	Database down	Database up
Run CRC	<code>/opt/vertica/bin/vertica -D catalog-path -v</code>	<code>SELECT RUN_INDEX_TOOL ('checkcrc',...);</code>
Check sort order	<code>/opt/vertica/bin/vertica -D catalog-path -l</code>	<code>SELECT RUN_INDEX_TOOL ('checksort',...);</code>

If invoked from the command line, the Index tool runs only on the current node. However, you can run the Index tool on multiple nodes simultaneously.

Result output

The Index tool writes summary information about its operation to standard output; detailed information on results is logged in one of two locations, depending on the environment where you invoke the tool:

Invoked from:	Results written to:
Linux command line	<code>indextool.log</code> in the database catalog directory
VSQL	<code>vertica.log</code> on the current node

For information about evaluating output for possible errors, see:

- [Evaluating CRC errors](#)
- [Evaluating sort order errors](#)

Optimizing performance

You can optimize meta-function performance by narrowing the scope of the operation to one or more projections, and specifying the number of threads used to execute the function. For details, see [RUN_INDEX_TOOL](#).

In this section

- [Evaluating CRC errors](#)
- [Evaluating sort order errors](#)

Evaluating CRC errors

Vertica evaluates the CRC values in each ROS data block each time it fetches data disk to process a query. If CRC errors occur while fetching data, the following information is written to the `vertica.log` file:

CRC Check Failure Details:File Name:

File Offset:

Compressed size in file:

Memory Address of Read Buffer:

Pointer to Compressed Data:

Memory Contents:

The Event Manager is also notified of CRC errors, so you can use an SNMP trap to capture CRC errors:

```
"CRC mismatch detected on file <file_path>. File may be corrupted. Please check hardware and drivers."
```

If you run a query from vsql, ODBC, or JDBC, the query returns a **FileColumnReader ERROR** . This message indicates that a specific block's CRC does not match a given record as follows:

hint: Data file may be corrupt. Ensure that all hardware (disk and memory) is working properly.

Possible solutions are to delete the file *<pathname>* while the node is down, and then allow the node to recover, or truncate the table data.code: ERRCODE_DATA_CORRUPTED

Evaluating sort order errors

If ROS data is not sorted correctly in the projection's order, query results that rely on sorted data will be incorrect. You can use the Index tool to check the ROS sort order if you suspect or detect incorrect query results. The Index tool evaluates each ROS row to determine whether it is sorted correctly. If the check locates a row that is not in order, it writes an error message to the log file with the row number and contents of the unsorted row.

Reviewing errors

1. Open the **indextool.log** file. For example:

```
$ cd VMart/v_check_node0001_catalog
```

2. Look for error messages that include an OID number and the string **Sort Order Violation** . For example:

```
<INFO> ...on oid 45035996273723545: Sort Order Violation:
```

3. Find detailed information about the sort order violation string by running **grep** on **indextool.log** . For example, the following command returns the line before each string (**-B1**), and the four lines that follow (**-A4**):

```
[15:07:55][vertica-s1]: grep -B1 -A4 'Sort Order Violation:' /my_host/databases/check/v_check_node0001_catalog/indextool.log
2012-06-14 14:07:13.686 unknown:0x7fe1da7a1950 [EE] <INFO> An error occurred when running index tool thread on oid 45035996273723537:
Sort Order Violation:
Row Position: 624
Column Index: 0
Last Row: 2576000
This Row: 2575000
--
2012-06-14 14:07:13.687 unknown:0x7fe1dafa2950 [EE] <INFO> An error occurred when running index tool thread on oid 45035996273723545:
Sort Order Violation:
Row Position: 3
Column Index: 0
Last Row: 4
This Row: 2
--
```

4. Find the projection where a sort order violation occurred by querying system table **STORAGE_CONTAINERS** . Use a **storage_oid** equal to the OID value listed in **indextool.log** . For example:

```
=> SELECT * FROM storage_containers WHERE storage_oid = 45035996273723545;
```

Working with native tables

You can create two types of native tables in Vertica (ROS format), columnar and flexible. You can create both types as persistent or temporary. You can also create views that query a specific set of table columns.

The tables described in this section store their data in and are managed by the Vertica database. Vertica also supports external tables, which are defined in the database and store their data externally. For more information about external tables, see [Working with external data](#) .

In this section

- [Creating tables](#)

- [Creating temporary tables](#)
- [Creating a table from other tables](#)
- [Immutable tables](#)
- [Disk quotas](#)
- [Managing table columns](#)
- [Altering table definitions](#)
- [Sequences](#)
- [Merging table data](#)
- [Removing table data](#)
- [Rebuilding tables](#)
- [Dropping tables](#)

Creating tables

Use the [CREATE TABLE](#) statement to create a native table in the Vertica [logical schema](#). You can specify the columns directly, as in the following example, or you can derive a table definition from another table using a LIKE or AS clause. You can specify constraints, partitioning, segmentation, and other factors. For details and restrictions, see the reference page.

The following example shows a basic table definition:

```
=> CREATE TABLE orders(  
  orderkey INT,  
  custkey INT,  
  prodkey ARRAY[VARCHAR(10)],  
  orderprices ARRAY[DECIMAL(12,2)],  
  orderdate DATE  
);
```

Table data storage

Unlike traditional databases that store data in tables, Vertica physically stores table data in [projections](#), which are collections of table columns. Projections store data in a format that optimizes query execution. Similar to materialized views, they store result sets on disk rather than compute them each time they are used in a query.

In order to query or perform any operation on a Vertica table, the table must have one or more [projections](#) associated with it. For more information, see [Projections](#).

Deriving a table definition from the data

You can use the [INFER_TABLE_DDL](#) function to inspect Parquet, ORC, JSON, or Avro data and produce a starting point for a table definition. This function returns a CREATE TABLE statement, which might require further editing. For columns where the function could not infer the data type, the function labels the type as unknown and emits a warning. For VARCHAR and VARBINARY columns, you might need to adjust the length. Always review the statement the function returns, but especially for tables with many columns, using this function can save time and effort.

Parquet, ORC, and Avro files include schema information, but JSON files do not. For JSON, the function inspects the raw data to produce one or more candidate table definitions. See the function reference page for JSON examples.

In the following example, the function infers a complete table definition from Parquet input, but the VARCHAR columns use the default size and might need to be adjusted:

```

=> SELECT INFER_TABLE_DDL('/data/people/*.parquet'
      USING PARAMETERS format = 'parquet', table_name = 'employees');
WARNING 9311: This generated statement contains one or more varchar/varbinary columns which default to length 80
      INFER_TABLE_DDL
-----
create table "employees"(
  "employeeID" int,
  "personal" Row(
    "name" varchar,
    "address" Row(
      "street" varchar,
      "city" varchar,
      "zipcode" int
    ),
    "taxID" int
  ),
  "department" varchar
);
(1 row)

```

For Parquet files, you can use the [GET_METADATA](#) function to inspect a file and report metadata including information about columns.

- [Creating external tables](#)

Creating temporary tables

[CREATE TEMPORARY TABLE](#) creates a table whose data persists only during the current session. Temporary table data is never visible to other sessions.

By default, all temporary table data is transaction-scoped—that is, the data is discarded when a COMMIT statement ends the current transaction. If CREATE TEMPORARY TABLE includes the parameter ON COMMIT PRESERVE ROWS , table data is retained until the current session ends.

Temporary tables can be used to divide complex query processing into multiple steps. Typically, a reporting tool holds intermediate results while reports are generated—for example, the tool first gets a result set, then queries the result set, and so on.

When you create a temporary table, Vertica automatically generates a default [projection](#) for it. For more information, see [Auto-projections](#).

Global versus local tables

CREATE TEMPORARY TABLE can create tables at two scopes, global and local, through the keywords GLOBAL and LOCAL , respectively:

Global temporary tables	Vertica creates global temporary tables in the public schema. Definitions of these tables are visible to all sessions, and persist across sessions until they are explicitly dropped. Multiple users can access the table concurrently. Table data is session-scoped, so it is visible only to the session user, and is discarded when the session ends.
Local temporary tables	Vertica creates local temporary tables in the <code>V_TEMP_SCHEMA</code> namespace and inserts them transparently into the user's search path. These tables are visible only to the session where they are created. When the session ends, Vertica automatically drops the table and its data.

Data retention

You can specify whether temporary table data is transaction- or session-scoped:

- [ON COMMIT DELETE ROWS](#) (default): Vertica automatically removes all table data when each transaction ends.
- [ON COMMIT PRESERVE ROWS](#): Vertica preserves table data across transactions in the current session. Vertica automatically truncates the table when the session ends.

Note

If you create a temporary table with ON COMMIT PRESERVE ROWS , you cannot add projections for that table if it contains data. You must first remove all data from that table with [TRUNCATE TABLE](#).

You can create projections for temporary tables created with ON COMMIT DELETE ROWS , whether populated with data or not. However, CREATE PROJECTION ends any transaction where you might have added data, so projections are always empty.

ON COMMIT DELETE ROWS

By default, Vertica removes all data from a temporary table, whether global or local, when the current transaction ends.

For example:

```
=> CREATE TEMPORARY TABLE tempDelete (a int, b int);
```

```
CREATE TABLE
```

```
=> INSERT INTO tempDelete VALUES(1,2);
```

```
OUTPUT
```

```
-----
```

```
    1  
(1 row)
```

```
=> SELECT * FROM tempDelete;
```

```
a | b
```

```
---+---
```

```
  1 | 2  
(1 row)
```

```
=> COMMIT;
```

```
COMMIT
```

```
=> SELECT * FROM tempDelete;
```

```
a | b
```

```
---+---
```

```
(0 rows)
```

If desired, you can use [DELETE](#) within the same transaction multiple times, to refresh table data repeatedly.

ON COMMIT PRESERVE ROWS

You can specify that a temporary table retain data across transactions in the current session, by defining the table with the keywords ON COMMIT PRESERVE ROWS . Vertica automatically removes all data from the table only when the current session ends.

For example:

```

=> CREATE TEMPORARY TABLE tempPreserve (a int, b int) ON COMMIT PRESERVE ROWS;
CREATE TABLE
=> INSERT INTO tempPreserve VALUES (1,2);
OUTPUT
-----
 1
(1 row)

=> COMMIT;
COMMIT
=> SELECT * FROM tempPreserve;
a | b
---+---
 1 | 2
(1 row)

=> INSERT INTO tempPreserve VALUES (3,4);
OUTPUT
-----
 1
(1 row)

=> COMMIT;
COMMIT
=> SELECT * FROM tempPreserve;
a | b
---+---
 1 | 2
 3 | 4
(2 rows)

```

Eon restrictions

The following Eon Mode restrictions apply to temporary tables:

- K-safety of temporary tables is always set to 0, regardless of system K-safety. If a **CREATE TEMPORARY TABLE** statement sets *k-num* greater than 0, Vertica returns an warning.
- If subscriptions to the current session change, temporary tables in that session becomes inaccessible. Causes for session subscription changes include:
 - A node left the list of participating nodes.
 - A new node appeared in the list of participating nodes.
 - An active node changed for one or more shards.
 - A [mergeout](#) operation in the same session that is triggered by a user explicitly invoking `DO_TM_TASK('mergeout')`, or changing a column data type with `ALTER TABLE...ALTER COLUMN`.

Note

Background mergeout operations have no effect on session subscriptions.

Creating a table from other tables

You can create a table from other tables in two ways:

- [Replicate an existing table](#) through `CREATE TABLE...LIKE`.
- [Create a table from a query](#) through `CREATE TABLE...AS`.

Important

You can also copy one table to another with the Vertica function `COPY_TABLE`.

In this section

- [Replicating a table](#)

- [Creating a table from a query](#)

Replicating a table

You can create a table from an existing one using [CREATE TABLE](#) with the [LIKE clause](#):

```
CREATE TABLE [ IF NOT EXISTS ] [[ { namespace. | database. } ]schema.]table
LIKE [[ { namespace. | database. } ]schema.]existing-table
[ { INCLUDING | EXCLUDING } PROJECTIONS ]
[ { INCLUDE | EXCLUDE } [SCHEMA] PRIVILEGES ]
```

Creating a table with [LIKE](#) replicates the source table definition and any [storage policy](#) associated with it. Table data and expressions on columns are not copied to the new table.

The user performing the operation owns the new table.

The source table cannot have out-of-date projections and cannot be a temporary table.

Copying constraints

[CREATE TABLE LIKE](#) copies all table constraints except for:

- Foreign key constraints.
- Sequence column constraints.

For any column that obtains its values from a sequence, including [IDENTITY](#) columns, Vertica copies the column values into the new table, but removes the original constraint. For example, the following table definition sets an [IDENTITY](#) constraint on the ID column:

```
=> CREATE TABLE public.Premium_Customer
(
  ID IDENTITY,
  lname varchar(25),
  fname varchar(25),
  store_membership_card int
);
```

The following [CREATE TABLE LIKE](#) statement uses the source table [Premium_Customer](#) to create the replica [All_Customers](#). Vertica removes the [IDENTITY](#) constraint, changing the column to an integer column with a [NOT NULL](#) constraint:

```
=> CREATE TABLE All_Customers LIKE Premium_Customer;
CREATE TABLE

=> SELECT export_tables('All_Customers');
export_tables

-----
CREATE TABLE public.All_Customers
(
  ID int NOT NULL,
  lname varchar(25),
  fname varchar(25),
  store_membership_card int
)
(1 row)
```

Including projections

You can qualify the [LIKE](#) clause with [INCLUDING PROJECTIONS](#) or [EXCLUDING PROJECTIONS](#), which specify whether to copy projections from the source table:

- [EXCLUDING PROJECTIONS](#) (default): Do not copy projections from the source table.
- [INCLUDING PROJECTIONS](#): Copy current projections from the source table. Vertica names the new projections according to Vertica [naming conventions](#), to avoid name conflicts with existing objects.

Including schema privileges

You can specify default inheritance of schema privileges for the new table:

- **EXCLUDE [SCHEMA] PRIVILEGES** (default) disables inheritance of privileges from the schema
- **INCLUDE [SCHEMA] PRIVILEGES** grants the table the same privileges granted to its schema

For more information see [Setting privilege inheritance on tables and views](#).

Examples

1. Create the table **states** :

```
=> CREATE TABLE states (
  state char(2) NOT NULL, bird varchar(20), tree varchar (20), tax float, stateDate char (20))
PARTITION BY state;
```

2. Populate the table with data:

```
INSERT INTO states VALUES ('MA', 'chickadee', 'american_elm', 5.675, '07-04-1620');
INSERT INTO states VALUES ('VT', 'Hermit_Thrasher', 'Sugar_Maple', 6.0, '07-04-1610');
INSERT INTO states VALUES ('NH', 'Purple_Finch', 'White_Birch', 0, '07-04-1615');
INSERT INTO states VALUES ('ME', 'Black_Cap_Chickadee', 'Pine_Tree', 5, '07-04-1615');
INSERT INTO states VALUES ('CT', 'American_Robin', 'White_Oak', 6.35, '07-04-1618');
INSERT INTO states VALUES ('RI', 'Rhode_Island_Red', 'Red_Maple', 5, '07-04-1619');
```

3. View the table contents:

```
=> SELECT * FROM states;
state |      bird      | tree | tax | stateDate
-----+-----+-----+-----+-----
VT | Hermit_Thrasher | Sugar_Maple | 6 | 07-04-1610
CT | American_Robin | White_Oak | 6.35 | 07-04-1618
RI | Rhode_Island_Red | Red_Maple | 5 | 07-04-1619
MA | chickadee | american_elm | 5.675 | 07-04-1620
NH | Purple_Finch | White_Birch | 0 | 07-04-1615
ME | Black_Cap_Chickadee | Pine_Tree | 5 | 07-04-1615
(6 rows)
```

4. Create a sample projection and refresh:

```
=> CREATE PROJECTION states_p AS SELECT state FROM states;
=> SELECT START_REFRESH();
```

5. Create a table like the **states** table and include its projections:

```
=> CREATE TABLE newstates LIKE states INCLUDING PROJECTIONS;
```

6. View projections for the two tables. Vertica has copied projections from **states** to **newstates** :

```
=> \d|
          List of projections
 Schema      | Name | Owner | Node | Comment
-----+-----+-----+-----+-----
public       | newstates_b0 | dbadmin | |
public       | newstates_b1 | dbadmin | |
public       | newstates_p_b0 | dbadmin | |
public       | newstates_p_b1 | dbadmin | |
public       | states_b0 | dbadmin | |
public       | states_b1 | dbadmin | |
public       | states_p_b0 | dbadmin | |
public       | states_p_b1 | dbadmin | |
```

7. Query the new table:

```
=> SELECT * FROM newstates;
state | bird | tree | tax | stateDate
-----+-----+-----+-----+-----
(0 rows)
```

When you use the **CREATE TABLE LIKE** statement, storage policy objects associated with the table are also copied. Data added to the new table use the same labeled storage location as the source table, unless you change the storage policy. For more information, see [Working With Storage Locations](#).

See also

- [Creating tables](#)
- [Creating temporary tables](#)
- [Creating external tables](#)
- [Creating a table from a query](#)

Creating a table from a query

[CREATE TABLE](#) can specify an AS clause to create a table from a query, as follows:

```
CREATE [TEMPORARY] TABLE [schema.]table-name
  [ ( column-name-list ) ]
  [ {INCLUDE | EXCLUDE} [SCHEMA] PRIVILEGES ]
AS [ /*+ LABEL */ ] [ AT epoch ] query [ ENCODED BY column-ref-list ]
```

Vertica creates a table from the query results and loads the result set into it. For example:

```
-> CREATE TABLE cust_basic_profile AS SELECT
  customer_key, customer_gender, customer_age, marital_status, annual_income, occupation
  FROM customer_dimension WHERE customer_age > 18 AND customer_gender != 'M';
CREATE TABLE
-> SELECT customer_age, annual_income, occupation FROM cust_basic_profile
  WHERE customer_age > 23 ORDER BY customer_age;
customer_age | annual_income | occupation
-----
24 | 469210 | Hairdresser
24 | 140833 | Butler
24 | 558867 | Lumberjack
24 | 529117 | Mechanic
24 | 322062 | Acrobat
24 | 213734 | Writer
...
```

AS clause options

You can qualify an AS clause with one or both of the following options:

- [LABEL](#) hint that identifies a statement for profiling and debugging
- AT *epoch* clause to specify that the query return historical data

Labeling the AS clause

You can embed a [LABEL](#) hint in an AS clause in two places:

- Immediately after the keyword AS :

```
CREATE TABLE myTable AS /*+LABEL myLabel*/...
```

- In the SELECT statement:

```
CREATE TABLE myTable AS SELECT /*+LABEL myLabel*/
```

If the AS clause contains a LABEL hint in both places, the first label has precedence.

Note

Labels are invalid for external tables.

Loading historical data

You can qualify a CREATE TABLE AS query with an AT *epoch* clause, to specify that the query return historical data, where *epoch* is one of the following:

- EPOCH LATEST : Return data up to but not including the current epoch. The result set includes data from the latest committed DML transaction.
- EPOCH *integer* : Return data up to and including the *integer*-specified epoch.
- TIME '*timestamp*' : Return data from the *timestamp*-specified epoch.

Note

These options are ignored if used to query temporary or external tables.

See [Epochs](#) for additional information about how Vertica uses epochs.

For details, see [Historical queries](#).

Zero-width column handling

If the query returns a column with zero width, Vertica automatically converts it to a VARCHAR(80) column. For example:

```
=> CREATE TABLE example AS SELECT " AS X;
CREATE TABLE
=> SELECT EXPORT_TABLES (" , 'example');
      EXPORT_TABLES
-----
CREATE TEMPORARY TABLE public.example
(
  X varchar(80)
);
```

Requirements and restrictions

- If you create a temporary table from a query, you must specify ON COMMIT PRESERVE ROWS in order to load the result set into the table. Otherwise, Vertica creates an empty table.
- If the query output has expressions other than simple columns, such as constants or functions, you must specify an alias for that expression, or list all columns in the column name list.
- You cannot use CREATE TABLE AS SELECT with a SELECT that returns values of [complex types](#). You can, however, use CREATE TABLE LIKE .

See also

- [Creating tables](#)
- [Creating temporary tables](#)
- [Creating external tables](#)
- [Replicating a table](#)

Immutable tables

Many secure systems contain records that must be provably immune to change. Protective strategies such as row and block checksums incur high overhead. Moreover, these approaches are not foolproof against unauthorized changes, whether deliberate or inadvertent, by database administrators or other users with sufficient privileges.

Immutable tables are insert-only tables in which existing data cannot be modified, regardless of user privileges. Updating row values and deleting rows are prohibited. Certain changes to table metadata—for example, renaming table columns—are also prohibited, in order to prevent attempts to circumvent these restrictions. [Flattened](#) or [external](#) tables, which obtain their data from outside sources, cannot be set to be immutable.

You define an existing table as immutable with [ALTER TABLE](#) :

```
ALTER TABLE table SET IMMUTABLE ROWS;
```

Once set, table immutability cannot be reverted, and is immediately applied to all existing table data, and all data that is loaded thereafter. In order to modify the data of an immutable table, you must copy the data to a new table—for example, with [COPY](#), [CREATE TABLE...AS](#), or [COPY_TABLE](#).

When you execute ALTER TABLE...SET IMMUTABLE ROWS on a table, Vertica sets two columns for that table in the system table [TABLES](#). Together, these columns show when the table was made immutable:

- `immutable_rows_since_timestamp` : Server system time when immutability was applied. This is valuable for long-term timestamp retrieval and efficient comparison.
- `immutable_rows_since_epoch` : The epoch that was [current](#) when immutability was applied. This setting can help protect the table from attempts to pre-insert records with a future timestamp, so that row's epoch is less than the table's immutability epoch.

Enforcement

The following operations are prohibited on immutable tables:

- [UPDATE](#)
- [DELETE](#)
- [ALTER TABLE...DROP COLUMN](#)

- [ALTER TABLE...RENAME COLUMN](#)
- [ALTER TABLE...ADD COLUMN](#) where the new column is defined with a [SET USING clause](#).

The following partition management functions are disallowed when the target table is immutable:

- [COPY_PARTITIONS_TO_TABLE](#)
- [MOVE_PARTITIONS_TO_TABLE](#)
- [SWAP_PARTITIONS_BETWEEN_TABLES](#)

Allowed operations

In general, you can execute any DML operation on an immutable table that does not affect existing row data—for example, add rows with [COPY](#) or [INSERT](#). After you add data to an immutable table, it cannot be changed.

Tip

A table's immutability can render meaningless certain operations that are otherwise permitted on an immutable table. For example, you can add a column to an immutable table with [ALTER TABLE...ADD COLUMN](#). However, all values in the new column are set to NULL (unless the column is defined with a [DEFAULT](#) value), and they cannot be updated.

Other allowed operations fall generally into two categories:

- Changes to a table's DDL that have no effect on its data:
 - [ALTER TABLE...SET SCHEMA](#): Change the table schema.
 - [ALTER TABLE...OWNER TO](#): Transfer table ownership.
 - [ALTER TABLE...ALTER COLUMN...SET DATATYPE](#): Change a column's data type. [Column data type changes](#) are allowed only if they have no effect on the column's stored data.
- Block operations on multiple table rows, or the entire table:
 - [DROP PARTITIONS](#)
 - [TRUNCATE TABLE](#)
 - [DROP TABLE](#)

Disk quotas

By default, schemas and tables are limited only by available disk space and license capacity. You can set disk quotas for schemas or individual tables, for example, to support multi-tenancy. Setting, modifying, or removing a disk quota requires superuser privileges.

Most user operations that increase storage size enforce disk quotas. A table can temporarily exceed its quota during some operations such as recovery. If you lower a quota below the current usage, no data is lost but you cannot add more. Treat quotas as advisory, not as hard limits

A schema quota, if set, must be larger than the largest table quota within it.

A disk quota is a string composed of an integer and a unit of measure (K, M, G, or T), such as '15G' or '1T'. Do not use a space between the number and the unit. No other units of measure are supported.

To set a quota at creation time, use the DISK_QUOTA option for [CREATE SCHEMA](#) or [CREATE TABLE](#):

```
=> CREATE SCHEMA internal DISK_QUOTA '10T';
CREATE SCHEMA

=> CREATE TABLE internal.sales (...) DISK_QUOTA '5T';
CREATE TABLE

=> CREATE TABLE internal.leads (...) DISK_QUOTA '12T';
ROLLBACK 0: Table can not have a greater disk quota than its Schema
```

To modify, add, or remove a quota on an existing schema or table, use [ALTER SCHEMA](#) or [ALTER TABLE](#):

```
=> ALTER SCHEMA internal DISK_QUOTA '20T';
ALTER SCHEMA

=> ALTER TABLE internal.sales DISK_QUOTA SET NULL;
ALTER TABLE
```

You can set a quota that is lower than the current usage. The ALTER operation succeeds, the schema or table is temporarily over quota, and you cannot perform operations that increase data usage.

Data that is counted

In Eon Mode, disk usage is an aggregate of all space used by all shards for the schema or table. This value is computed for primary subscriptions only.

In Enterprise Mode, disk usage is the sum space used by all storage containers on all nodes for the schema or table. This sum excludes buddy projections but includes all other projections.

Disk usage is calculated based on compressed size.

When quotas are applied

Quotas, if present, affect most DML and ILM operations, including:

- [COPY](#), [INSERT](#), [UPDATE](#), and [MERGE](#)
- Adding or refreshing columns (see [ALTER COLUMN](#))
- [REFRESH](#) and [START_REFRESH](#)
- [Subset restore of a table](#), if it would exceed the schema quota

The following example shows a failure caused by exceeding a table's quota:

```
=> CREATE TABLE stats(score int) DISK_QUOTA '1k';
CREATE TABLE

=> COPY stats FROM STDIN;
1
2
3
4
5
\
ERROR 0: Disk Quota Exceeded for the Table object public.stats
HINT: Delete data and PURGE or increase disk quota at the table level
```

[DELETE](#) does not free space, because deleted data is still preserved in the storage containers. The delete vector that is added by a delete operation does not count against a quota, so deleting is a quota-neutral operation. Disk space for deleted data is reclaimed when you purge it; see [Removing table data](#).

Some uncommon operations, such as [ADD COLUMN](#), [RESTORE](#), and [SWAP PARTITION](#), can create new storage containers during the transaction. These operations clean up the extra locations upon completion, but while the operation is in progress, a table or schema could exceed its quota. If you get disk-quota errors during these operations, you can temporarily increase the quota, perform the operation, and then reset it.

Quotas do not affect recovery, rebalancing, or Tuple Mover operations.

Monitoring

The [DISK_QUOTA_USAGES](#) system table shows current disk usage for tables and schemas that have quotas. This table does not report on objects that do not have quotas.

You can use this table to monitor usage and make decisions about adjusting quotas:

```
=> SELECT * FROM DISK_QUOTA_USAGES;
  object_oid | object_name | is_schema | total_disk_usage_in_bytes | disk_quota_in_bytes
-----+-----+-----+-----+-----
45035996273705100 | s      | t      |          307 |          10240
45035996273705104 | public.t | f      |           64 |           1024
45035996273705108 | s.t     | f      |          307 |           2048
(3 rows)
```

Managing table columns

After you define a table, you can use [ALTER TABLE](#) to modify existing table columns. You can perform the following operations on a column:

In this section

- [Renaming columns](#)
- [Changing scalar column data type](#)

- [Adding a new field to a complex type column](#)
- [Defining column values](#)

Renaming columns

You rename a column with **ALTER TABLE** as follows:

```
ALTER TABLE [schema.]table-name RENAME [ COLUMN ] column-name TO new-column-name
```

The following example renames a column in the **Retail.Product_Dimension** table from **Product_description** to **Item_description** :

```
=> ALTER TABLE Retail.Product_Dimension
  RENAME COLUMN Product_description TO Item_description;
```

If you rename a column that is referenced by a view, the column does not appear in the result set of the view even if the view uses the wild card (*) to represent all columns in the table. Recreate the view to incorporate the column's new name.

Changing scalar column data type

In general, you can change a column's data type with **ALTER TABLE** if doing so does not require storage reorganization. After you modify a column's data type, data that you load conforms to the new definition.

The sections that follow describe requirements and restrictions associated with changing a column with a scalar (primitive) data type. For information on modifying complex type columns, see [Adding a new field to a complex type column](#).

Supported data type conversions

Vertica supports conversion for the following data types:

Data Types	Supported Conversions
Binary	Expansion and contraction.
Character	All conversions between CHAR, VARCHAR, and LONG VARCHAR.
Exact numeric	All conversions between the following numeric data types: integer data types—INTEGER, INT, BIGINT, TINYINT, INT8, SMALLINT—and NUMERIC values of scale <=18 and precision 0. You cannot modify the scale of NUMERIC data types; however, you can change precision in the ranges (0-18), (19-37), and so on.
Collection	The following conversions are supported: <ul style="list-style-type: none"> • Collection of one element type to collection of another element type, if the source element type can be coerced to the target element type. • Between arrays and sets. • Collection type to the same type (array to array or set to set), to change bounds or binary size. For details, see Changing Collection Columns .

Unsupported data type conversions

Vertica does not allow data type conversion on types that require storage reorganization:

- Boolean
- DATE/TIME
- Approximate numeric type
- BINARY to VARBINARY and vice versa

You also cannot change a column's data type if the column is one of the following:

- Primary key
- Foreign key
- Included in the SEGMENTED BY clause of any projection for that table.

You can work around some of these restrictions. For details, see [Working with column data conversions](#).

In this section

- [Changing column width](#)
- [Working with column data conversions](#)

Changing column width

You can expand columns within the same class of data type. Doing so is useful for storing larger items in a column. Vertica validates the data before it performs the conversion.

In general, you can also reduce column widths within the data type class. This is useful to reclaim storage if the original declaration was longer than you need, particularly with strings. You can reduce column width only if the following conditions are true:

- Existing column data is no greater than the new width.
- All nodes in the database cluster are up.

Otherwise, Vertica returns an error and the conversion fails. For example, if you try to convert a column from `varchar(25)` to `varchar(10)` Vertica allows the conversion as long as all column data is no more than 10 characters.

In the following example, columns `y` and `z` are initially defined as `VARCHAR` data types, and loaded with values `12345` and `654321`, respectively. The attempt to reduce column `z`'s width to 5 fails because it contains six-character data. The attempt to reduce column `y`'s width to 5 succeeds because its content conforms with the new width:

```
=> CREATE TABLE t (x int, y VARCHAR, z VARCHAR);
CREATE TABLE
=> CREATE PROJECTION t_p1 AS SELECT * FROM t SEGMENTED BY hash(x) ALL NODES;
CREATE PROJECTION
=> INSERT INTO t values(1,'12345','654321');
OUTPUT
-----
      1
(1 row)

=> SELECT * FROM t;
x | y | z
---+---+-----
 1 | 12345 | 654321
(1 row)

=> ALTER TABLE t ALTER COLUMN z SET DATA TYPE char(5);
ROLLBACK 2378: Cannot convert column "z" to type "char(5)"
HINT: Verify that the data in the column conforms to the new type
=> ALTER TABLE t ALTER COLUMN y SET DATA TYPE char(5);
ALTER TABLE
```

Changing collection columns

If a column is a collection data type, you can use `ALTER TABLE` to change either its bounds or its maximum binary size. These properties are set at table creation time and can then be altered.

You can make a collection bounded, setting its maximum number of elements, as in the following example.

```
=> ALTER TABLE test.t1 ALTER COLUMN arr SET DATA TYPE array[int,10];
ALTER TABLE

=> \d test.t1

                List of Fields by Tables
Schema | Table | Column | Type | Size | Default | Not Null | Primary Key | Foreign Key
-----+-----+-----+-----+-----+-----+-----+-----+-----
test | t1 | arr | array[int8, 10] | 80 | | f | f | |
(1 row)
```

Alternatively, you can set the binary size for the entire collection instead of setting bounds. Binary size is set either explicitly or from the `DefaultArrayBinarySize` configuration parameter. The following example creates an array column from the default, changes the default, and then uses

ALTER TABLE to change it to the new default.

```
=> SELECT get_config_parameter('DefaultArrayBinarySize');
get_config_parameter
-----
100
(1 row)

=> CREATE TABLE test.t1 (arr array[int]);
CREATE TABLE

=> \d test.t1

                List of Fields by Tables
Schema | Table | Column | Type      | Size | Default | Not Null | Primary Key | Foreign Key
-----+-----+-----+-----+-----+-----+-----+-----+-----
test | t1 | arr | array[int8](96) | 96 | | f | f | |
(1 row)

=> ALTER DATABASE DEFAULT SET DefaultArrayBinarySize=200;
ALTER DATABASE

=> ALTER TABLE test.t1 ALTER COLUMN arr SET DATA TYPE array[int];
ALTER TABLE

=> \d test.t1

                List of Fields by Tables
Schema | Table | Column | Type      | Size | Default | Not Null | Primary Key | Foreign Key
-----+-----+-----+-----+-----+-----+-----+-----+-----
test | t1 | arr | array[int8](200) | 200 | | f | f | |
(1 row)
```

Alternatively, you can set the binary size explicitly instead of using the default value.

```
=> ALTER TABLE test.t1 ALTER COLUMN arr SET DATA TYPE array[int](300);
```

Purging historical data

You cannot reduce a column's width if Vertica retains any historical data that exceeds the new width. To reduce the column width, first remove that data from the table:

1. Advance the AHM to an epoch more recent than the historical data that needs to be removed from the table.
2. Purge the table of all historical data that precedes the AHM with the function [PURGE_TABLE](#).

For example, given the previous example, you can update the data in column `t.z` as follows:

```
=> UPDATE t SET z = '54321';
OUTPUT
-----
1
(1 row)

=> SELECT * FROM t;
x | y | z
---+---+---
1 | 12345 | 54321
(1 row)
```

Although no data in column `z` now exceeds 5 characters, Vertica retains the history of its earlier data, so attempts to reduce the column width to 5 return an error:

```
=> ALTER TABLE t ALTER COLUMN z SET DATA TYPE char(5);
ROLLBACK 2378: Cannot convert column "z" to type "char(5)"
HINT: Verify that the data in the column conforms to the new type
```

You can reduce the column width by purging the table's historical data as follows:

```
=> SELECT MAKE_AHM_NOW();
      MAKE_AHM_NOW
-----
AHM set (New AHM Epoch: 6350)
(1 row)

=> SELECT PURGE_TABLE('t');
      PURGE_TABLE
-----
Task: purge operation
(Table: public.t) (Projection: public.t_p1_b0)
(Table: public.t) (Projection: public.t_p1_b1)

(1 row)

=> ALTER TABLE t ALTER COLUMN z SET DATA TYPE char(5);
ALTER TABLE
```

Working with column data conversions

Vertica conforms to the SQL standard by disallowing certain data conversions for table columns. However, you sometimes need to work around this restriction when you convert data from a non-SQL database. The following examples describe one such workaround, using the following table:

```
=> CREATE TABLE sales(id INT, price VARCHAR) UNSEGMENTED ALL NODES;
CREATE TABLE
=> INSERT INTO sales VALUES (1, '$50.00');
OUTPUT
-----
  1
(1 row)

=> INSERT INTO sales VALUES (2, '$100.00');
OUTPUT
-----
  1
(1 row)

=> COMMIT;
COMMIT
=> SELECT * FROM SALES;
id | price
---+-----
 1 | $50.00
 2 | $100.00
(2 rows)
```

To convert the `price` column's existing data type from VARCHAR to NUMERIC, complete these steps:

1. [Add a new column for temporary use](#). Assign the column a NUMERIC data type, and derive its default value from the existing price column.
2. [Drop the original price column](#).
3. [Rename the new column to the original column](#).

Add a new column for temporary use

1. Add a column `temp_price` to table `sales`. You can use the new column temporarily, setting its data type to what you want (NUMERIC), and deriving its default value from the `price` column. Cast the default value for the new column to a NUMERIC data type and query the table:

```
=> ALTER TABLE sales ADD COLUMN temp_price NUMERIC(10,2) DEFAULT
SUBSTR(sales.price, 2)::NUMERIC;
ALTER TABLE
```

```
=> SELECT * FROM SALES;
id | price | temp_price
-----+-----
 1 | $50.00 | 50.00
 2 | $100.00 | 100.00
(2 rows)
```

2. Use ALTER TABLE to drop the default expression from the new column `temp_price` . Vertica retains the values stored in this column:

```
=> ALTER TABLE sales ALTER COLUMN temp_price DROP DEFAULT;
ALTER TABLE
```

Drop the original price column

Drop the extraneous `price` column. Before doing so, you must first advance the [AHM](#) to purge historical data that would otherwise prevent the drop operation:

1. Advance the AHM:

```
=> SELECT MAKE_AHM_NOW();
MAKE_AHM_NOW
-----
AHM set (New AHM Epoch: 6354)
(1 row)
```

2. Drop the original price column:

```
=> ALTER TABLE sales DROP COLUMN price CASCADE;
ALTER COLUMN
```

Rename the new column to the original column

You can now rename the `temp_price` column to `price` :

1. Use **ALTER TABLE** to rename the column:

```
=> ALTER TABLE sales RENAME COLUMN temp_price to price;
```

2. Query the sales table again:

```
=> SELECT * FROM sales;
id | price
-----+-----
 1 | 50.00
 2 | 100.00
(2 rows)
```

Adding a new field to a complex type column

You can add new fields to columns of complex types (any combination or nesting of arrays and structs) in native tables. To add a field to an existing table's column, use a single [ALTER TABLE](#) statement.

Requirements and restrictions

The following are requirements and restrictions associated with adding a new field to a complex type column:

- New fields can only be added to rows/structs.
- The new type definition must contain all of the existing fields in the complex type column. Dropping existing fields from the complex type is not allowed. All of the existing fields in the new type must exactly match their definitions in the old type. This requirement also means that existing fields cannot be renamed.
- New fields can only be added to columns of native (non-external) tables.
- New fields can be added at any level within a nested complex type. For example, if you have a column defined as `ROW(id INT, name ROW(given_name VARCHAR(20), family_name VARCHAR(20)))` , you can add a `middle_name` field to the nested ROW.
- New fields can be of any type, either complex or primitive.
- Blank field names are not allowed when adding new fields. Note that blank field names in complex type columns are allowed when creating the table. Vertica automatically assigns a name to each unnamed field.
- If you change the ordering of existing fields using ALTER TABLE, the change affects existing data in addition to new data. This means it is possible

to reorder existing fields.

- When you call ALTER COLUMN ... SET DATA TYPE to add a field to a complex type column, Vertica will place an O lock on the table preventing DELETE, UPDATE, INSERT, and COPY statements from accessing the table and blocking SELECT statements issued at SERIALIZABLE isolation level, until the operation completes.
- Performance is slower when adding a field to an array element than when adding a field to an element not nested in an array.

Examples

Adding a field

Consider a company storing customer data:

```
=> CREATE TABLE customers(id INT, name VARCHAR, address ROW(street VARCHAR, city VARCHAR, zip INT));
CREATE TABLE
```

The company has just decided to expand internationally, so now needs to add a country field:

```
=> ALTER TABLE customers ALTER COLUMN address
SET DATA TYPE ROW(street VARCHAR, city VARCHAR, zip INT, country VARCHAR);
ALTER TABLE
```

You can view the table definition to confirm the change:

```
=> \d customers
List of Fields by Tables
Schema | Table | Column | Type | Size | Default | Not Null | Primary Key | Foreign Key
-----+-----+-----+-----+-----+-----+-----+-----+-----
public | customers | id | int | 8 | | f | f | |
public | customers | name | varchar(80) | 80 | | f | f | |
public | customers | address | ROW(street varchar(80),city varchar(80),zip int,country varchar(80)) | -1 | | f | f | |
(3 rows)
```

You can also see that the country field remains null for existing customers:

```
=> SELECT * FROM customers;
id | name | address
---+-----+-----
1 | mina | {"street":"1 allegheny square east","city":"hamden","zip":6518,"country":null}
(1 row)
```

Common error messages

While you can add one or more fields with a single ALTER TABLE statement, existing fields cannot be removed. The following example throws an error because the city field is missing:

```
=> ALTER TABLE customers ALTER COLUMN address SET DATA TYPE ROW(street VARCHAR, state VARCHAR, zip INT, country VARCHAR);
ROLLBACK 2377: Cannot convert column "address" from "ROW(varchar(80),varchar(80),int,varchar(80))" to type "ROW(varchar(80),varchar(80),int,varchar(80))"
```

Similarly, you cannot alter the type of an existing field. The following example will throw an error because the zip field's type cannot be altered:

```
=> ALTER TABLE customers ALTER COLUMN address SET DATA TYPE ROW(street VARCHAR, city VARCHAR, zip VARCHAR, country VARCHAR);
ROLLBACK 2377: Cannot convert column "address" from "ROW(varchar(80),varchar(80),int,varchar(80))" to type "ROW(varchar(80),varchar(80),varchar(80),varchar(80))"
```

Additional properties

A complex type column's field order follows the order specified in the ALTER command, allowing you to reorder a column's existing fields. The following example reorders the fields of the address column:

```
=> ALTER TABLE customers ALTER COLUMN address
SET DATA TYPE ROW(street VARCHAR, country VARCHAR, city VARCHAR, zip INT);
ALTER TABLE
```

The table definition shows the address column's fields have been reordered:

```
=> \d customers
```

List of Fields by Tables

Schema	Table	Column	Type	Size	Default	Not Null	Primary Key	Foreign Key
public	customers	id	int	8	f	f		
public	customers	name	varchar(80)	80	f	f		
public	customers	address	ROW(street varchar(80),country varchar(80),city varchar(80),zip int)	-1		f	f	

(3 rows)

Note that you cannot add new fields with empty names. When creating a complex table, however, you can omit field names, and Vertica automatically assigns a name to each unnamed field:

```
=> CREATE TABLE products(name VARCHAR, description ROW(VARCHAR));  
CREATE TABLE
```

Because the field created in the `description` column has not been named, Vertica assigns it a default name. This default name can be checked in the table definition:

```
=> \d products
```

List of Fields by Tables

Schema	Table	Column	Type	Size	Default	Not Null	Primary Key	Foreign Key
public	products	name	varchar(80)	80	f	f		
public	products	description	ROW(f0 varchar(80))	-1		f	f	

(2 rows)

Above, we see that the VARCHAR field in the `description` column was automatically assigned the name `f0`. When adding new fields, you must specify the existing Vertica-assigned field name:

```
=> ALTER TABLE products ALTER COLUMN description  
SET DATA TYPE ROW(f0 VARCHAR(80), expanded_description VARCHAR(200));  
ALTER TABLE
```

Defining column values

You can define a column so Vertica automatically sets its value from an expression through one of the following clauses:

- DEFAULT
- SET USING
- DEFAULT USING

DEFAULT

The DEFAULT option sets column values to a specified value. It has the following syntax:

```
DEFAULT default-expression
```

Default values are set when you:

- Load new rows into a table, for example, with [INSERT](#) or [COPY](#). Vertica populates DEFAULT columns in new rows with their default values. Values in existing rows, including columns with DEFAULT expressions, remain unchanged.
- Execute [UPDATE](#) on a table and set the value of a DEFAULT column to **DEFAULT**:

```
=> UPDATE table-name SET column-name=DEFAULT;
```

- Add a column with a DEFAULT expression to an existing table. Vertica populates the new column with its default values when it is added to the table.

Note

Altering an existing table column to specify a DEFAULT expression has no effect on existing values in that column. Vertica applies the DEFAULT expression only on new rows when they are added to the table, through load operations such as INSERT and COPY. To refresh all values in a column with the column's DEFAULT expression, update the column as shown above.

Restrictions

DEFAULT expressions cannot specify volatile functions with ALTER TABLE...ADD COLUMN. To specify volatile functions, use CREATE TABLE or ALTER TABLE...ALTER COLUMN statements.

SET USING

The SET USING option sets the column value to an expression when the function [REFRESH_COLUMNS](#) is invoked on that column. This option has the following syntax:

```
SET USING using-expression
```

This approach is useful for large denormalized ([flattened](#)) tables, where multiple columns get their values by querying other tables.

Restrictions

SET USING has the following restrictions:

- Volatile functions are not allowed.
- The expression cannot specify a sequence.
- Vertica limits the use of several meta-functions that copy table data: [COPY_TABLE](#), [COPY_PARTITIONS_TO_TABLE](#), [MOVE_PARTITIONS_TO_TABLE](#), and [SWAP_PARTITIONS_BETWEEN_TABLES](#) :
 - If the source and target tables both have SET USING columns, the operation is permitted only if each source SET USING column has a corresponding target SET USING column.
 - If only the source table has SET USING columns, [SWAP_PARTITIONS_BETWEEN_TABLES](#) is disallowed.
 - If only the target table has SET USING columns, the operation is disallowed.

DEFAULT USING

The DEFAULT USING option sets DEFAULT and SET USING constraints on a column, equivalent to using DEFAULT and SET USING separately with the same expression on the same column. It has the following syntax:

```
DEFAULT USING expression
```

For example, the following column definitions are effectively identical:

```
=> ALTER TABLE public.orderFact ADD COLUMN cust_name varchar(20)
    DEFAULT USING (SELECT name FROM public.custDim WHERE (custDim.cid = orderFact.cid));
```

```
=> ALTER TABLE public.orderFact ADD COLUMN cust_name varchar(20)
    DEFAULT (SELECT name FROM public.custDim WHERE (custDim.cid = orderFact.cid))
    SET USING (SELECT name FROM public.custDim WHERE (custDim.cid = orderFact.cid));
```

DEFAULT USING supports the same expressions as SET USING and is subject to the same [restrictions](#).

Supported expressions

DEFAULT and SET USING generally support the same expressions. These include:

- Queries
- Other columns in the same table
- [Literals](#) (constants)
- All [operators](#) supported by Vertica
- The following categories of functions:
 - [Null-handling](#)
 - [User-defined scalar](#)
 - [System information](#)
 - [String](#)
 - [Mathematical](#)
 - [Formatting](#)

Expression restrictions

The following restrictions apply to DEFAULT and SET USING expressions:

- The return value data type must match or be cast to the column data type.
- The expression must return a value that conforms to the column bounds. For example, a column that is defined as a [VARCHAR\(1\)](#) cannot be set to a default string of `abc`.
- In a temporary table, DEFAULT and SET USING do not support subqueries. If you try to create a temporary table where DEFAULT or SET USING use subquery expressions, Vertica returns an error.

- A column's SET USING expression cannot specify another column in the same table that also sets its value with SET USING. Similarly, a column's DEFAULT expression cannot specify another column in the same table that also sets its value with DEFAULT, or whose value is automatically set to a [sequence](#). However, a column's SET USING expression can specify another column that sets its value with DEFAULT.

Note

You can set a column's DEFAULT expression from another column in the same table that sets its value with SET USING. However, the DEFAULT column is typically set to **NULL**, as it is only set on load operations that initially set the SET USING column to **NULL**.

- DEFAULT and SET USING expressions only support one SELECT statement; attempts to include multiple SELECT statements in the expression return an error. For example, given table **t1**:

```
=> SELECT * FROM t1;
a | b
---+-----
1 | hello
2 | world
(2 rows)
```

Attempting to create table **t2** with the following DEFAULT expression returns with an error:

```
=> CREATE TABLE t2 (aa int, bb varchar(30) DEFAULT (SELECT 'I said ')||((SELECT b FROM t1 where t1.a = t2.aa));
ERROR 9745: Expressions with multiple SELECT statements cannot be used in 'set using' query definitions
```

Disambiguating predicate columns

If a SET USING or DEFAULT query expression joins two columns with the same name, the column names must include their table names. Otherwise, Vertica assumes that both columns reference the dimension table, and the predicate always evaluates to true.

For example, tables **orderFact** and **custDim** both include column **cid**. Flattened table **orderFact** defines column **cust_name** with a SET USING query expression. Because the query predicate references columns **cid** from both tables, the column names are fully qualified:

```
=> CREATE TABLE public.orderFact
(
  ...
  cid int REFERENCES public.custDim(cid),
  cust_name varchar(20) SET USING (
    SELECT name FROM public.custDim WHERE (custDIM.cid = orderFact.cid)),
  ...
)
```

Examples

Derive a column's default value from another column

1. Create table **t** with two columns, **date** and **state**, and insert a row of data:

```
=> CREATE TABLE t (date DATE, state VARCHAR(2));
CREATE TABLE
=> INSERT INTO t VALUES (CURRENT_DATE, 'MA');
OUTPUT
-----
 1
(1 row)

=> COMMIT;
COMMMIT
SELECT * FROM t;
  date | state
-----+-----
2017-12-28 | MA
(1 row)
```

2. Use ALTER TABLE to add a third column that extracts the integer month value from column **date**:

```
=> ALTER TABLE t ADD COLUMN month INTEGER DEFAULT date_part('month', date);
ALTER TABLE
```

- When you query table `t`, Vertica returns the number of the month in column `date` :

```
=> SELECT * FROM t;
  date | state | month
-----+-----+-----
2017-12-28 | MA | 12
(1 row)
```

Update default column values

- Update table `t` by subtracting 30 days from `date` :

```
=> UPDATE t SET date = date-30;
OUTPUT
-----
  1
(1 row)

=> COMMIT;
COMMIT
=> SELECT * FROM t;
  date | state | month
-----+-----+-----
2017-11-28 | MA | 12
(1 row)
```

The value in `month` remains unchanged.

- Refresh the default value in `month` from column `date` :

```
=> UPDATE t SET month=DEFAULT;
OUTPUT
-----
  1
(1 row)

=> COMMIT;
COMMIT
=> SELECT * FROM t;
  date | state | month
-----+-----+-----
2017-11-28 | MA | 11
(1 row)
```

Derive a default column value from user-defined scalar function

This example shows a user-defined scalar function that adds two integer values. The function is called `add2ints` and takes two arguments.

- Develop and deploy the function, as described in [Scalar functions \(UDSFs\)](#).
- Create a sample table, `t1`, with two integer columns:

```
=> CREATE TABLE t1 ( x int, y int );
CREATE TABLE
```

- Insert some values into `t1`:

```
=> insert into t1 values (1,2);
OUTPUT
-----
  1
(1 row)
=> insert into t1 values (3,4);
OUTPUT
-----
  1
(1 row)
```

- Use `ALTER TABLE` to add a column to `t1`, with the default column value derived from the UDSF `add2ints` :

```
alter table t1 add column z int default add2ints(x,y);
ALTER TABLE
```

5. List the new column:

```
select z from t1;
z
----
3
7
(2 rows)
```

Table with a SET USING column that queries another table for its values

1. Define tables **t1** and **t2** . Column **t2.b** is defined to get its data from column **t1.b** , through the query in its SET USING clause:

```
=> CREATE TABLE t1 (a INT PRIMARY KEY ENABLED, b INT);
CREATE TABLE

=> CREATE TABLE t2 (a INT, alpha VARCHAR(10),
  b INT SET USING (SELECT t1.b FROM t1 WHERE t1.a=t2.a))
  ORDER BY a SEGMENTED BY HASH(a) ALL NODES;
CREATE TABLE
```

Important

The definition for table **t2** includes SEGMENTED BY and ORDER BY clauses that exclude SET USING column **b** . If these clauses are omitted, Vertica creates an [auto-projection](#) for this table that specifies column **b** in its SEGMENTED BY and ORDER BY clauses . Inclusion of a SET USING column in any projection's segmentation or sort order prevents function REFRESH_COLUMNS from populating this column. Instead, it returns with an error.

For details on this and other restrictions, see [REFRESH_COLUMNS](#) .

2. Populate the tables with data:

```
=> INSERT INTO t1 VALUES(1,11),(2,22),(3,33),(4,44);
=> INSERT INTO t2 VALUES (1,'aa'),('2','bb');
=> COMMIT;
COMMIT
```

3. View the data in table **t2** : Column in SET USING column **b** is empty, pending invocation of Vertica function REFRESH_COLUMNS:

```
=> SELECT * FROM t2;
a | alpha | b
-----+-----
1 | aa   |
2 | bb   |
(2 rows)
```

4. Refresh the column data in table **t2** by calling function REFRESH_COLUMNS:

```
=> SELECT REFRESH_COLUMNS ('t2','b', 'REBUILD');
  REFRESH_COLUMNS
-----
refresh_columns completed
(1 row)
```

In this example, REFRESH_COLUMNS is called with the optional argument REBUILD. This argument specifies to replace all data in SET USING column **b** . It is generally good practice to call REFRESH_COLUMNS with REBUILD on any new SET USING column. For details, see [REFRESH_COLUMNS](#) .

5. View data in refreshed column **b** , whose data is obtained from table **t1** as specified in the column's SET USING query:

```
=> SELECT * FROM t2 ORDER BY a;
a | alpha | b
-----+-----
1 | aa   | 11
2 | bb   | 22
(2 rows)
```

DEFAULT and SET USING expressions support subqueries that can obtain values from other tables, and use those with values in the current table to compute column values. The following example adds a column `gmt_delivery_time` to fact table `customer_orders`. The column specifies a DEFAULT expression to set values in the new column as follows:

1. Calls meta-function [NEW_TIME](#), which performs the following tasks:
 - Uses customer keys in `customer_orders` to query the `customers` dimension table for customer time zones.
 - Uses the queried time zone data to convert local delivery times to GMT.
2. Populates the `gmt_delivery_time` column with the converted values.

```
=> CREATE TABLE public.customers(  
  customer_key int,  
  customer_name varchar(64),  
  customer_address varchar(64),  
  customer_tz varchar(5),  
  ...);  
  
=> CREATE TABLE public.customer_orders(  
  customer_key int,  
  order_number int,  
  product_key int,  
  product_version int,  
  quantity_ordered int,  
  store_key int,  
  date_ordered date,  
  date_shipped date,  
  expected_delivery_date date,  
  local_delivery_time timestamptz,  
  ...);  
  
=> ALTER TABLE customer_orders ADD COLUMN gmt_delivery_time timestamp  
  DEFAULT NEW_TIME(customer_orders.local_delivery_time,  
    (SELECT c.customer_tz FROM customers c WHERE (c.customer_key = customer_orders.customer_key)),  
    'GMT');
```

Altering table definitions

You can modify a table's definition with [ALTER TABLE](#), in response to evolving database schema requirements. Changing a table definition is often more efficient than staging data in a temporary table, consuming fewer resources and less storage.

For information on making column-level changes, see [Managing table columns](#). For details about changing and reorganizing table partitions, see [Partitioning existing table data](#).

In this section

- [Adding table columns](#)
- [Dropping table columns](#)
- [Altering constraint enforcement](#)
- [Renaming tables](#)
- [Moving tables to another schema](#)
- [Changing table ownership](#)

Adding table columns

You add a column to a persistent table with [ALTER TABLE...ADD COLUMN](#):

```
ALTER TABLE ...  
ADD COLUMN [IF NOT EXISTS] column datatype  
  [column-constraint]  
  [ENCODING encoding-type]  
  [PROJECTIONS (projections-list) | ALL PROJECTIONS ]
```

An ALTER TABLE statement can include more than one ADD COLUMN clause, separated by commas:

```
ALTER TABLE...
ADD COLUMN pid INT NOT NULL,
ADD COLUMN desc VARCHAR(200),
ADD COLUMN region INT DEFAULT 1
```

Columns that use DEFAULT with static values, as shown in the previous example, can be added in a single ALTER TABLE statement. Columns that use non-static DEFAULT values must be added in separate ALTER TABLE statements.

Before you add columns to a table, verify that all its superprojections are up to date.

Table locking

When you use ADD COLUMN to alter a table, Vertica takes an O lock on the table until the operation completes. The lock prevents DELETE, UPDATE, INSERT, and COPY statements from accessing the table. The lock also blocks SELECT statements issued at SERIALIZABLE isolation level, until the operation completes.

Adding a column to a table does not affect [K-safety](#) of the [physical schema](#) design.

You can add columns when nodes are down.

Adding new columns to projections

When you add a column to a table, Vertica automatically adds the column to [superprojections](#) of that table. The ADD COLUMN clause can also specify to add the column to one or more non-superprojections, with one of these options:

- **PROJECTIONS (*projections-list*)**: Adds the new column to one or more projections of this table, specified as a comma-delimited list of projection [base names](#). Vertica adds the column to all buddies of each projection. The projection list cannot include projections with [pre-aggregated data](#) such as live aggregate projections; otherwise, Vertica rolls back the ALTER TABLE statement.
- **ALL PROJECTIONS** adds the column to all projections of this table, excluding projections with pre-aggregated data.

For example, the `store_orders` table has two projections, a superprojection (`store_orders_super`) and a user-created projection (`store_orders_p`). The following ALTER TABLE...ADD COLUMN statement adds a column to the `store_orders` table. Because the statement omits the PROJECTIONS option, Vertica adds the column only to the table's superprojection:

```
=> ALTER TABLE public.store_orders ADD COLUMN expected_ship_date date;
ALTER TABLE
=> SELECT projection_column_name, projection_name FROM projection_columns WHERE table_name ILIKE 'store_orders'
ORDER BY projection_name , projection_column_name;
projection_column_name | projection_name
-----+-----
order_date             | store_orders_p_b0
order_no               | store_orders_p_b0
ship_date              | store_orders_p_b0
order_date             | store_orders_p_b1
order_no               | store_orders_p_b1
ship_date              | store_orders_p_b1
expected_ship_date   | store_orders_super
order_date             | store_orders_super
order_no               | store_orders_super
ship_date              | store_orders_super
shipper                | store_orders_super
(11 rows)
```

The following ALTER TABLE...ADD COLUMN statement includes the PROJECTIONS option. This specifies to include projection `store_orders_p` in the add operation. Vertica adds the new column to this projection and the table's superprojection:

```

=> ALTER TABLE public.store_orders ADD COLUMN delivery_date date PROJECTIONS (store_orders_p);
=> SELECT projection_column_name, projection_name FROM projection_columns WHERE table_name ILIKE 'store_orders'
   ORDER BY projection_name, projection_column_name;
projection_column_name | projection_name
-----+-----
delivery_date         | store_orders_p_b0
order_date            | store_orders_p_b0
order_no              | store_orders_p_b0
ship_date             | store_orders_p_b0
delivery_date         | store_orders_p_b1
order_date            | store_orders_p_b1
order_no              | store_orders_p_b1
ship_date             | store_orders_p_b1
delivery_date         | store_orders_super
expected_ship_date   | store_orders_super
order_date            | store_orders_super
order_no              | store_orders_super
ship_date             | store_orders_super
shipper               | store_orders_super
(14 rows)

```

Updating associated table views

Adding new columns to a table that has an associated view does not update the view's result set, even if the view uses a wildcard (*) to represent all table columns. To incorporate new columns, you must [recreate the view](#).

Dropping table columns

[ALTER TABLE...DROP COLUMN](#) drops the specified table column and the ROS containers that correspond to the dropped column:

```
ALTER TABLE [schema.]table DROP [ COLUMN ] [IF EXISTS] column [CASCADE | RESTRICT]
```

After the drop operation completes, data backed up from the current epoch onward recovers without the column. Data recovered from a backup that precedes the current epoch re-add the table column. Because drop operations physically purge object storage and catalog definitions (table history) from the table, AT EPOCH (historical) queries return nothing for the dropped column.

The altered table retains its object ID.

Note

Drop column operations can be fast because these catalog-level changes do not require data reorganization, so Vertica can quickly reclaim disk storage.

Restrictions

- You cannot drop or alter a primary key column or a column that participates in the table partitioning clause.
- You cannot drop the first column of any projection sort order, or columns that participate in a projection segmentation expression.
- In Enterprise Mode, all nodes must be up. This restriction does not apply to Eon mode.
- You cannot drop a column associated with an access policy. Attempts to do so produce the following error:
ERROR 6482: Failed to parse Access Policies for table "t1"

Using CASCADE to force a drop

If the table column to drop has dependencies, you must qualify the DROP COLUMN clause with the CASCADE option. For example, the target column might be specified in a projection sort order. In this and other cases, DROP COLUMN...CASCADE handles the dependency by reorganizing catalog definitions or dropping a projection. In all cases, CASCADE performs the minimal reorganization required to drop the column.

Use CASCADE to drop a column with the following dependencies:

Dropped column dependency	CASCADE behavior
---------------------------	------------------

Any constraint	Vertica drops the column when a FOREIGN KEY constraint depends on a UNIQUE or PRIMARY KEY constraint on the referenced columns.
Specified in projection sort order	Vertica truncates projection sort order up to and including the projection that is dropped without impact on physical storage for other columns and then drops the specified column. For example if a projection's columns are in sort order (a,b,c), dropping column b causes the projection's sort order to be just (a), omitting column (c).
Specified in a projection segmentation expression	The column to drop is integral to the projection definition. If possible, Vertica drops the projection as long as doing so does not compromise K-safety; otherwise, the transaction rolls back.
Referenced as default value of another column	See Dropping a Column Referenced as Default , below.

Dropping a column referenced as default

You might want to drop a table column that is referenced by another column as its default value. For example, the following table is defined with two columns, **a** and **b** ;, where **b** gets its default value from column **a** :

```
=> CREATE TABLE x (a int) UNSEGMENTED ALL NODES;
CREATE TABLE
=> ALTER TABLE x ADD COLUMN b int DEFAULT a;
ALTER TABLE
```

In this case, dropping column **a** requires the following procedure:

1. Remove the default dependency through ALTER COLUMN..DROP DEFAULT :

```
=> ALTER TABLE x ALTER COLUMN b DROP DEFAULT;
```

2. Create a replacement superprojection for the target table if one or both of the following conditions is true:

- o The target column is the table's first sort order column. If the table has no explicit sort order, the default table sort order specifies the first table column as the first sort order column. In this case, the new superprojection must specify a sort order that excludes the target column.
- o If the table is segmented, the target column is specified in the segmentation expression. In this case, the new superprojection must specify a segmentation expression that excludes the target column.

Given the previous example, table **x** has a default sort order of (a,b). Because column **a** is the table's first sort order column, you must create a replacement superprojection that is sorted on column **b** :

```
=> CREATE PROJECTION x_p1 as select * FROM x ORDER BY b UNSEGMENTED ALL NODES;
```

3. Run [START_REFRESH](#) :

```
=> SELECT START_REFRESH();
        START_REFRESH
-----
Starting refresh background process.

(1 row)
```

4. Run [MAKE_AHM_NOW](#) :

```
=> SELECT MAKE_AHM_NOW();
        MAKE_AHM_NOW
-----
AHM set (New AHM Epoch: 1231)

(1 row)
```

5. Drop the column:

```
=> ALTER TABLE x DROP COLUMN a CASCADE;
```

Vertica implements the CASCADE directive as follows:

- Drops the original superprojection for table **x** (**x_super**).
- Updates the replacement superprojection **x_p1** by dropping column **a** .

Examples

The following series of commands successfully drops a BYTEA data type column:

```
=> CREATE TABLE t (x BYTEA(65000), y BYTEA, z BYTEA(1));
CREATE TABLE
=> ALTER TABLE t DROP COLUMN y;
ALTER TABLE
=> SELECT y FROM t;
ERROR 2624: Column "y" does not exist
=> ALTER TABLE t DROP COLUMN x RESTRICT;
ALTER TABLE
=> SELECT x FROM t;
ERROR 2624: Column "x" does not exist
=> SELECT * FROM t;
z
---
(0 rows)
=> DROP TABLE t CASCADE;
DROP TABLE
```

The following series of commands tries to drop a FLOAT(8) column and fails because there are not enough projections to maintain K-safety.

```
=> CREATE TABLE t (x FLOAT(8),y FLOAT(08));
CREATE TABLE
=> ALTER TABLE t DROP COLUMN y RESTRICT;
ALTER TABLE
=> SELECT y FROM t;
ERROR 2624: Column "y" does not exist
=> ALTER TABLE t DROP x CASCADE;
ROLLBACK 2409: Cannot drop any more columns in t
=> DROP TABLE t CASCADE;
```

Altering constraint enforcement

[ALTER TABLE...ALTER CONSTRAINT](#) can enable or disable enforcement of [primary key](#), [unique](#), and [check](#) constraints. You must qualify this clause with the keyword **ENABLED** or **DISABLED** :

- **ENABLED** enforces the specified constraint.
- **DISABLED** disables enforcement of the specified constraint.

For example:

```
ALTER TABLE public.new_sales ALTER CONSTRAINT C_PRIMARY ENABLED;
```

For details, see [Constraint enforcement](#).

Renaming tables

[ALTER TABLE...RENAME TO](#) renames one or more tables. Renamed tables retain their original OIDs.

You rename multiple tables by supplying two comma-delimited lists. Vertica maps the names according to their order in the two lists. Only the first list can qualify table names with a schema. For example:

```
=> ALTER TABLE S1.T1, S1.T2 RENAME TO U1, U2;
```

The **RENAME TO** parameter is applied atomically: all tables are renamed, or none of them. For example, if the number of tables to rename does not match the number of new names, none of the tables is renamed.

Caution

If a table is referenced by a view, renaming it causes the view to fail, unless you create another table with the previous name to replace the renamed table.

Using rename to swap tables within a schema

You can use [ALTER TABLE...RENAME TO](#) to swap tables within the same schema, without actually moving data. You cannot swap tables across schemas.

The following example swaps the data in tables **T1** and **T2** through intermediary table **temp** :

1. **t1 to temp**
2. **t2 to t1**
3. **temp to t2**

```
=> DROP TABLE IF EXISTS temp, t1, t2;
DROP TABLE
=> CREATE TABLE t1 (original_name varchar(24));
CREATE TABLE
=> CREATE TABLE t2 (original_name varchar(24));
CREATE TABLE
=> INSERT INTO t1 VALUES ('original name t1');
OUTPUT
-----
 1
(1 row)
=> INSERT INTO t2 VALUES ('original name t2');
OUTPUT
-----
 1
(1 row)
=> COMMIT;
COMMIT
=> ALTER TABLE t1, t2, temp RENAME TO temp, t1, t2;
ALTER TABLE
=> SELECT * FROM t1, t2;
 original_name | original_name
-----+-----
original name t2 | original name t1
(1 row)
```

Moving tables to another schema

[ALTER TABLE...SET SCHEMA](#) moves a table from one schema to another. Vertica automatically moves all projections that are anchored to the source table to the destination schema. It also moves all [IDENTITY](#) columns to the destination schema.

Moving a table across schemas requires that you have **USAGE** privileges on the current schema and **CREATE** privileges on destination schema. You can move only one table between schemas at a time. You cannot move temporary tables across schemas.

Name conflicts

If a table of the same name or any of the projections that you want to move already exist in the new schema, the statement rolls back and does not move either the table or any projections. To work around name conflicts:

1. Rename any conflicting table or projections that you want to move.
2. Run [ALTER TABLE...SET SCHEMA](#) again.

Note

Vertica lets you move system tables to system schemas. Moving system tables could be necessary to support designs created through the [Database Designer](#).

Example

The following example moves table **T1** from schema **S1** to schema **S2**. All projections that are anchored on table **T1** automatically move to schema **S2** :

```
=> ALTER TABLE S1.T1 SET SCHEMA S2;
```

Changing table ownership

As a superuser or table owner, you can reassign table ownership with [ALTER TABLE...OWNER TO](#), as follows:

```
ALTER TABLE [schema.]table-name OWNER TO owner-name
```

Changing table ownership is useful when moving a table from one schema to another. Ownership reassignment is also useful when a table owner leaves the company or changes job responsibilities. Because you can change the table owner, the tables won't have to be completely rewritten, you can avoid loss in productivity.

Changing table ownership automatically causes the following changes:

- Grants on the table that were made by the original owner are dropped and all existing privileges on the table are revoked from the previous owner. Changes in table ownership has no effect on schema privileges.
- Ownership of dependent [IDENTITY](#) sequences are transferred with the table. However, ownership does not change for named sequences created with [CREATE SEQUENCE](#). To transfer ownership of these sequences, use [ALTER SEQUENCE](#).
- New table ownership is propagated to its projections.

Example

In this example, user Bob connects to the database, looks up the tables, and transfers ownership of table `t33` from himself to user Alice.

```
=> \c - Bob
You are now connected as user "Bob".
=> \d
Schema | Name | Kind | Owner | Comment
-----+-----+-----+-----+-----
public | applog | table | dbadmin |
public | t33 | table | Bob |
(2 rows)
=> ALTER TABLE t33 OWNER TO Alice;
ALTER TABLE
```

When Bob looks up database tables again, he no longer sees table `t33` :

```
=> \d
List of tables
List of tables
Schema | Name | Kind | Owner | Comment
-----+-----+-----+-----+-----
public | applog | table | dbadmin |
(1 row)
```

When user Alice connects to the database and looks up tables, she sees she is the owner of table `t33` .

```
=> \c - Alice
You are now connected as user "Alice".
=> \d
List of tables
Schema | Name | Kind | Owner | Comment
-----+-----+-----+-----+-----
public | t33 | table | Alice |
(2 rows)
```

Alice or a superuser can transfer table ownership back to Bob. In the following case a superuser performs the transfer.

```
=> \c - dbadmin
You are now connected as user "dbadmin".
=> ALTER TABLE t33 OWNER TO Bob;
ALTER TABLE
=> \d
      List of tables
Schema | Name | Kind | Owner | Comment
-----+-----+-----+-----+-----
public | applog | table | dbadmin |
public | comments | table | dbadmin |
public | t33 | table | Bob |
s1 | t1 | table | User1 |
(4 rows)
```

You can also query system table [TABLES](#) to view table and owner information. Note that a change in ownership does not change the table ID.

In the below series of commands, the superuser changes table ownership back to Alice and queries the [TABLES](#) system table.

```
=> ALTER TABLE t33 OWNER TO Alice;
ALTER TABLE
=> SELECT table_schema_id, table_schema, table_id, table_name, owner_id, owner_name FROM tables;
 table_schema_id | table_schema | table_id | table_name | owner_id | owner_name
-----+-----+-----+-----+-----+-----
45035996273704968 | public | 45035996273713634 | applog | 45035996273704962 | dbadmin
45035996273704968 | public | 45035996273724496 | comments | 45035996273704962 | dbadmin
45035996273730528 | s1 | 45035996273730548 | t1 | 45035996273730516 | User1
45035996273704968 | public | 45035996273795846 | t33 | 45035996273724576 | Alice
(5 rows)
```

Now the superuser changes table ownership back to Bob and queries the [TABLES](#) table again. Nothing changes but the `owner_name` row, from Alice to Bob.

```
=> ALTER TABLE t33 OWNER TO Bob;
ALTER TABLE
=> SELECT table_schema_id, table_schema, table_id, table_name, owner_id, owner_name FROM tables;
 table_schema_id | table_schema | table_id | table_name | owner_id | owner_name
-----+-----+-----+-----+-----+-----
45035996273704968 | public | 45035996273713634 | applog | 45035996273704962 | dbadmin
45035996273704968 | public | 45035996273724496 | comments | 45035996273704962 | dbadmin
45035996273730528 | s1 | 45035996273730548 | t1 | 45035996273730516 | User1
45035996273704968 | public | 45035996273793876 | foo | 45035996273724576 | Alice
45035996273704968 | public | 45035996273795846 | t33 | 45035996273714428 | Bob
(5 rows)
```

Sequences

Sequences can be used to set the default values of columns to sequential integer values. Sequences guarantee uniqueness, and help avoid constraint enforcement problems and overhead. Sequences are especially useful for primary key columns.

While sequence object values are guaranteed to be unique, they are not guaranteed to be contiguous. For example, two nodes can increment a sequence at different rates. The node with a heavier processing load increments the sequence, but the values are not contiguous with those being incremented on a node with less processing. For details, see [Distributing sequences](#).

Vertica supports the following sequence types:

- [Named sequences](#) are database objects that generates unique numbers in sequential ascending or descending order. Named sequences are defined independently through [CREATE SEQUENCE](#) statements, and are managed independently of the tables that reference them. A table can set the default values of one or more columns to named sequences.
- [IDENTITY column sequences](#) increment or decrement column's value as new rows are added. Unlike named sequences, IDENTITY sequence types are defined in a table's DDL, so they do not persist independently of that table. A table can contain only one IDENTITY column.

In this section

- [Sequence types compared](#)
- [Named sequences](#)
- [IDENTITY sequences](#)
- [Sequence caching](#)

Sequence types compared

The following table lists the differences between the two sequence types:

Supported Behavior	Named Sequence	IDENTITY
Default cache value 250K	•	•
Set initial cache	•	•
Define start value	•	•
Specify increment unit	•	•
Exists as an independent object	•	
Exists only as part of table		•
Create as column constraint		•
Requires name	•	
Use in expressions	•	
Unique across tables	•	
Change parameters	•	
Move to different schema	•	
Set to increment or decrement	•	
Grant privileges to object	•	
Specify minimum value	•	
Specify maximum value	•	

Named sequences

Named sequences are sequences that are defined by [CREATE SEQUENCE](#) . Unlike [IDENTITY sequences](#) , which are defined in a table's DDL, you create a named sequence as an independent object, and then set it as the default value of a table column.

Named sequences are used most often when an application requires a unique identifier in a table or an expression. After a named sequence returns a value, it never returns the same value again in the same session.

In this section

- [Creating and using named sequences](#)
- [Distributing sequences](#)
- [Altering sequences](#)
- [Dropping sequences](#)

Creating and using named sequences

You create a named sequence with [CREATE SEQUENCE](#) . The statement requires only a sequence name; all other parameters are optional. To create a sequence, a user must have CREATE privileges on a schema that contains the sequence.

The following example creates an ascending named sequence, `my_seq`, starting at the value 100:

```
=> CREATE SEQUENCE my_seq START 100;
CREATE SEQUENCE
```

Incrementing and decrementing a sequence

When you create a named sequence object, you can also specify its increment or decrement value by setting its `INCREMENT` parameter. If you omit this parameter, as in the previous example, the default is set to 1.

You increment or decrement a sequence by calling the function `NEXTVAL` on it—either directly on the sequence itself, or indirectly by adding new rows to a table that [references the sequence](#). When called for the first time on a new sequence, `NEXTVAL` initializes the sequence to its start value. Vertica also [creates a cache](#) for the sequence. Subsequent `NEXTVAL` calls on the sequence increment its value.

The following call to `NEXTVAL` initializes the new `my_seq` sequence to 100:

```
=> SELECT NEXTVAL('my_seq');
nextval
-----
    100
(1 row)
```

Getting a sequence's current value

You can obtain the current value of a sequence by calling `CURRVAL` on it. For example:

```
=> SELECT CURRVAL('my_seq');
CURRVAL
-----
    100
(1 row)
```

Note

`CURRVAL` returns an error if you call it on a new sequence that has not yet been initialized by `NEXTVAL`, or an existing sequence that has not yet been accessed in a new session. For example:

```
=> CREATE SEQUENCE seq2;
CREATE SEQUENCE
=> SELECT currval('seq2');
ERROR 4700: Sequence seq2 has not been accessed in the session
```

Referencing sequences in tables

A table can set the [default values](#) of any column to a named sequence. The table creator must have the following privileges: `SELECT` on the sequence, and `USAGE` on its schema.

In the following example, column `id` gets its default values from named sequence `my_seq`:

```
=> CREATE TABLE customer(id INTEGER DEFAULT my_seq.NEXTVAL,
  Iname VARCHAR(25),
  fname VARCHAR(25),
  membership_card INTEGER
);
```

For each row that you insert into table `customer`, the sequence invokes the `NEXTVAL` function to set the value of the `id` column. For example:

```
=> INSERT INTO customer VALUES (default, 'Carr', 'Mary', 87432);
=> INSERT INTO customer VALUES (default, 'Diem', 'Nga', 87433);
=> COMMIT;
```

For each row, the insert operation invokes `NEXTVAL` on the sequence `my_seq`, which increments the sequence to 101 and 102, and sets the `id` column to those values:

```
=> SELECT * FROM customer;
id | lname | fname | membership_card
-----+-----+-----+-----
101 | Carr | Mary | 87432
102 | Diem | Nga | 87433
(1 row)
```

Distributing sequences

When you create a sequence, its **CACHE** parameter determines the number of sequence values each node maintains during a session. The default cache value is 250K, so each node reserves 250,000 values per session for each sequence. The default cache size provides an efficient means for large insert or copy operations.

If sequence caching is set to a low number, nodes are liable to request a new set of cache values more frequently. While it supplies a new cache, Vertica must lock the catalog. Until Vertica releases the lock, other database activities such as table inserts are blocked, which can adversely affect overall performance.

When a new session starts, node caches are initially empty. By default, the initiator node requests and reserves cache for all nodes in a cluster. You can change this default so each node requests its own cache, by setting configuration parameter **ClusterSequenceCacheMode** to 0.

For information on how Vertica requests and distributes cache among all nodes in a cluster, refer to [Sequence caching](#).

Effects of distributed sessions

Vertica distributes a session across all nodes. The first time a cluster node calls the function **NEXTVAL** on a sequence to increment (or decrement) its value, the node requests its own cache of sequence values. The node then maintains that cache for the current session. As other nodes call **NEXTVAL**, they too create and maintain their own cache of sequence values.

During a session, nodes call **NEXTVAL** independently and at different frequencies. Each node uses its own cache to populate the sequence. All sequence values are guaranteed to be unique, but can be out of order with a **NEXTVAL** statement executed on another node. As a result, sequence values are often non-contiguous.

In all cases, increments a sequence only once per row. Thus, if the same sequence is referenced by multiple columns, **NEXTVAL** sets all columns in that row to the same value. This applies to rows of joined tables.

Calculating sequences

Vertica calculates the current value of a sequence as follows:

- At the end of every statement, the state of all sequences used in the session is returned to the initiator node.
- The initiator node calculates the maximum **CURRVAL** of each sequence across all states on all nodes.
- This maximum value is used as **CURRVAL** in subsequent statements until another **NEXTVAL** is invoked.

Losing sequence values

Sequence values in cache can be lost in the following situations:

- If a statement fails after **NEXTVAL** is called (thereby consuming a sequence value from the cache), the value is lost.
- If a disconnect occurs (for example, dropped session), any remaining values in cache that have not been returned through **NEXTVAL** are lost.
- When the initiator node distributes a new block of cache to each node where one or more nodes has not used up its current cache allotment. For information on this scenario, refer to [Sequence caching](#).

You can recover lost sequence values by using **ALTER SEQUENCE...RESTART**, which resets the sequence to the specified value in the next session.

Caution

Using **ALTER SEQUENCE** to set a sequence start value below its **current value** can result in duplicate keys.

Altering sequences

ALTER SEQUENCE can change sequences in two ways:

- Changes values that control sequence behavior—for example, its start value and range of minimum and maximum values. These changes take effect only when you start a new database session.
- Changes sequence name, schema, or ownership. These changes take effect immediately.

Note

The same ALTER SEQUENCE statement cannot make both types of changes.

Changing sequence behavior

ALTER SEQUENCE can change one or more sequence attributes through the following parameters:

These parameters...	Control...
INCREMENT	How much to increment or decrement the sequence on each call to NEXTVAL .
MINVALUE / MAXVALUE	Range of valid integers.
RESTART	Sequence value on its next call to NEXTVAL.
CACHE / NO CACHE	How many sequence numbers are pre-allocated and stored in memory for faster access.
CYCLE / NO CYCLE	Whether the sequence wraps when its minimum or maximum values are reached.

These changes take effect only when you start a new database session. For example, if you create a named sequence `my_sequence` that starts at 10 and increments by 1 (the default), each sequence call to NEXTVAL increments its value by 1:

```
=> CREATE SEQUENCE my_sequence START 10;
=> SELECT NEXTVAL('my_sequence');
nextval
-----
    10
(1 row)
=> SELECT NEXTVAL('my_sequence');
nextval
-----
    11
(1 row)
```

The following ALTER SEQUENCE statement specifies to restart the sequence at 50:

```
=>ALTER SEQUENCE my_sequence RESTART WITH 50;
```

However, this change has no effect in the current session. The next call to NEXTVAL increments the sequence to 12:

```
=> SELECT NEXTVAL('my_sequence');
NEXTVAL
-----
    12
(1 row)
```

The sequence restarts at 50 only after you start a new database session:

```
=> \q
$ vsql
Welcome to vsql, the Vertica Analytic Database interactive terminal.

=> SELECT NEXTVAL('my_sequence');
NEXTVAL
-----
    50
(1 row)
```

Changing sequence name, schema, and ownership

You can use ALTER SEQUENCE to make the following changes to a sequence:

- Rename it (supported only for [named sequences](#)).
- Move it to another schema (supported only for named sequences).
- Reassign ownership.

Each of these changes requires separate ALTER SEQUENCE statements. These changes take effect immediately.

For example, the following statement renames a sequence from `my_seq` to `serial` :

```
=> ALTER SEQUENCE s1.my_seq RENAME TO s1.serial;
```

This statement moves sequence `s1.serial` to schema `s2` :

```
=> ALTER SEQUENCE s1.my_seq SET SCHEMA TO s2;
```

The following statement reassigns ownership of `s2.serial` to another user:

```
=> ALTER SEQUENCE s2.serial OWNER TO bertie;
```

Note

Only a superuser or the sequence owner can change its ownership. Reassignment does not transfer grants from the original owner to the new owner. Grants made by the original owner are dropped.

Dropping sequences

Use [DROP SEQUENCE](#) to remove a named sequence. For example:

```
=> DROP SEQUENCE my_sequence;
```

You cannot drop a sequence if one of the following conditions is true:

- Other objects depend on the sequence. [DROP SEQUENCE](#) does not support cascade operations.
- A column's [DEFAULT](#) expression references the sequence. Before dropping the sequence, you must remove all column references to it.

IDENTITY sequences

IDENTITY (synonymous with AUTO_INCREMENT) columns are defined with a sequence that automatically increments column values as new rows are added. You define an IDENTITY column in a table as follows:

```
CREATE TABLE table-name...
(column-name {IDENTITY | AUTO_INCREMENT}
 ([ cache-size | start, increment [, cache-size ] ] )
```

Settings

<i>start</i>	<p>First value to set for this column.</p> <p>Default: 1</p>
<i>increment</i>	<p>Positive or negative integer that specifies how much to increment or decrement the sequence on each new row insertion from the previous row value, by default set to 1. To decrement sequence values, specify a negative value.</p> <div style="background-color: #e6f2ff; padding: 10px; margin-top: 10px;"> <p>Note</p> <p>The actual amount by which column values are incremented or decremented might be larger than the <i>increment</i> setting, unless sequence caching is disabled.</p> </div> <p>Default: 1</p>

cache-size How many unique numbers each node caches per session. A value of 0 or 1 disables sequence caching. For details, see [Sequence caching](#).

Default: 250,000

Managing settings

Like [named sequences](#), you can manage an IDENTITY column with [ALTER SEQUENCE](#)—for example, reset its start integer. Two exceptions apply: because the sequence is defined as part of a table column, you cannot change the sequence name or schema. You can query the [SEQUENCES](#) system table for the name of an IDENTITY column's sequence. This name is automatically created when you define the table, and conforms to the following convention:

```
table-name_col-name_seq
```

For example, you can change the maximum value of an IDENTITY column that is defined in the `testAutold` table:

```
=> SELECT * FROM sequences WHERE identity_table_name = 'testAutold';
-[ RECORD 1 ]-----+-----
sequence_schema | public
sequence_name   | testAutold_autoldCol_seq
owner_name      | dbadmin
identity_table_name | testAutold
session_cache_count | 250000
allow_cycle     | f
output_ordered  | f
increment_by    | 1
minimum        | 1
maximum        | 1000
current_value   | 1
sequence_schema_id | 45035996273704980
sequence_id     | 45035996274278950
owner_id        | 45035996273704962
identity_table_id | 45035996274278948

=> ALTER SEQUENCE testAutold_autoldCol_seq maxvalue 10000;
ALTER SEQUENCE
```

This change, like other changes to a sequence, take effect only when you start a new database session. One exception applies: changes to the sequence owner take effect immediately.

You can obtain the last value generated for an IDENTITY column by calling [LAST_INSERT_ID](#).

Restrictions

The following restrictions apply to IDENTITY columns:

- A table can contain only one IDENTITY column.
- IDENTITY column values automatically increment before the current transaction is committed; rolling back the transaction does not revert the change.
- You cannot change the value of an IDENTITY column.

Examples

The following example shows how to use the IDENTITY column-constraint to create a table with an ID column. The ID column has an initial value of 1. It is incremented by 1 every time a row is inserted.

1. Create table `Premium_Customer` :

```
=> CREATE TABLE Premium_Customer(
  ID IDENTITY(1,1),
  lname VARCHAR(25),
  fname VARCHAR(25),
  store_membership_card INTEGER
);
=> INSERT INTO Premium_Customer (lname, fname, store_membership_card )
VALUES ('Gupta', 'Saleem', 475987);
```

The IDENTITY column has a seed of 1, which specifies the value for the first row loaded into the table, and an increment of 1, which specifies the value that is added to the IDENTITY value of the previous row.

2. Confirm the row you added and see the ID value:

```
=> SELECT * FROM Premium_Customer;
ID | lname | fname | store_membership_card
-----+-----+-----+-----
1 | Gupta | Saleem | 475987
(1 row)
```

3. Add another row:

```
=> INSERT INTO Premium_Customer (lname, fname, store_membership_card)
VALUES ('Lee', 'Chen', 598742);
```

4. Call the Vertica function [LAST_INSERT_ID](#). The function returns value 2 because you previously inserted a new customer (Chen Lee), and this value is incremented each time a row is inserted:

```
=> SELECT LAST_INSERT_ID();
last_insert_id
-----
2
(1 row)
```

5. View all the ID values in the [Premium_Customer](#) table:

```
=> SELECT * FROM Premium_Customer;
ID | lname | fname | store_membership_card
-----+-----+-----+-----
1 | Gupta | Saleem | 475987
2 | Lee | Chen | 598742
(2 rows)
```

The next three examples illustrate the three valid ways to use IDENTITY arguments.

The first example uses a cache of 100, and the defaults for start value (1) and increment value (1):

```
=> CREATE TABLE t1(x IDENTITY(100), y INT);
```

The next example specifies the start and increment values as 1, and defaults to a cache value of 250,000:

```
=> CREATE TABLE t2(y IDENTITY(1,1), x INT);
```

The third example specifies start and increment values of 1, and a cache value of 100:

```
=> CREATE TABLE t3(z IDENTITY(1,1,100), zx INT);
```

Sequence caching

Caching is similar for all sequence types: [named sequences](#) and [IDENTITY column](#) sequences. To allocate cache among the nodes in a cluster for a given sequence, Vertica uses the following process.

1. By default, when a session begins, the cluster initiator node requests cache for itself and other nodes in the cluster.
2. The initiator node distributes cache to other nodes when it distributes the execution plan.
3. Because the initiator node requests caching for all nodes, only the initiator locks the global catalog for the cache request.

This approach is optimal for handling large INSERT-SELECT and COPY operations. The following figure shows how the initiator request and distributes cache for a named sequence in a three-node cluster, where caching for that sequence is set to 250 K:

First Request for Cache in a Session

Nodes run out of cache at different times. While executing the same query, nodes individually request additional cache as needed.

For new queries in the same session, the initiator might have an empty cache if it used all of its cache to execute the previous query execution. In this case, the initiator requests cache for all nodes.

Configuring sequence caching

You can change how nodes obtain sequence caches by setting the configuration parameter [ClusterSequenceCacheMode](#) to 0 (disabled). When this parameter is set to 0, all nodes in the cluster request their own cache and catalog lock. However, for initial large INSERT-SELECT and COPY operations, when the cache is empty for all nodes, each node requests cache at the same time. These multiple requests result in simultaneous locks on the global catalog, which can adversely affect performance. For this reason, [ClusterSequenceCacheMode](#) should remain set to its default value of 1 (enabled).

The following example compares how different settings of [ClusterSequenceCacheMode](#) affect how Vertica manages sequence caching. The example assumes a three-node cluster, 250 K caches for each node (the default), and sequence ID values that increment by 1.

Workflow step	ClusterSequenceCacheMode = 1	ClusterSequenceCacheMode = 0
1	Cache is empty for all nodes. Initiator node requests 250 K cache for each node.	Cache is empty for all nodes. Each node, including initiator, requests its own 250 K cache.
2	Blocks of cache are distributed to each node as follows: <ul style="list-style-type: none"> • Node 1: 0-250 K • Node 2: 250 K + 1 to 500 K • Node 3: 500 K + 1 to 750 K Each node begins to use its cache as it processes sequence updates.	
3	Initiator node and node 3 run out of cache. Node 2 only uses 250 K + 1 to 400 K, 100 K of cache remains from 400 K + 1 to 500 K.	

4	<p>Executing same statement:</p> <ul style="list-style-type: none"> • As each node uses up its cache, it requests a new cache allocation. • If node 2 never uses its cache, the 100-K unused cache becomes a gap in sequence IDs. <p>Executing a new statement in same session, if initiator node cache is empty:</p> <ul style="list-style-type: none"> • It requests and distributes new cache blocks for all nodes. • Nodes receive a new cache before the old cache is used, creating a gap in ID sequencing. 	<p>Executing same or new statement:</p> <ul style="list-style-type: none"> • As each node uses up its cache, it requests a new cache allocation. • If node 2 never uses its cache, the 100 K unused cache becomes a gap in sequence IDs.
---	---	--

Merging table data

MERGE statements can perform [update](#) and [insert](#) operations on a target table based on the results of a join with a source data set. The join can match a source row with only one target row; otherwise, Vertica returns an error.

MERGE has the following syntax:

```
MERGE INTO target-table USING source-dataset ON join-condition
matching-clause[ matching-clause ]
```

Merge operations have at least three components:

- The target table on which to perform update and insert operations. **MERGE** takes an X (exclusive) lock on the target table until the merge operation is complete.
- [Join to another data set](#), one of the following: a table, view, or subquery result set.
- One or both matching clauses: [WHEN MATCHED THEN UPDATE SET](#) and [WHEN NOT MATCHED THEN INSERT](#).

In this section

- [Basic MERGE example](#)
- [MERGE source options](#)
- [MERGE matching clauses](#)
- [Update and insert filters](#)
- [MERGE optimization](#)
- [MERGE restrictions](#)

Basic MERGE example

In this example, a merge operation involves two tables:

- **visits_daily** logs daily restaurant traffic, and is updated with each customer visit. Data in this table is refreshed every 24 hours.
- **visits_history** stores the history of customer visits to various restaurants, accumulated over an indefinite time span.

Each night, you merge the daily visit count from **visits_daily** into **visits_history**. The merge operation modifies the target table in two ways:

- Updates existing customer data.
- Inserts new rows of data for first-time customers.

One **MERGE** statement executes both operations as a single (upsert) transaction.

Source and target tables

The source and target tables **visits_daily** and **visits_history** are defined as follows:

```
CREATE TABLE public.visits_daily
(
  customer_id int,
  location_name varchar(20),
  visit_time time(0) DEFAULT (now())::timetz(6)
);

CREATE TABLE public.visits_history
(
  customer_id int,
  location_name varchar(20),
  visit_count int
);
```

Table `visits_history` contains rows of three customers who between them visited two restaurants, Etoile and LaRosa:

```
=> SELECT * FROM visits_history ORDER BY customer_id, location_name;
customer_id | location_name | visit_count
-----+-----+-----
 1001 | Etoile      |          2
 1002 | La Rosa    |          4
 1004 | Etoile      |          1
(3 rows)
```

By close of business, table `visits_daily` contains three rows of restaurant visits:

```
=> SELECT * FROM visits_daily ORDER BY customer_id, location_name;
customer_id | location_name | visit_time
-----+-----+-----
 1001 | Etoile      | 18:19:29
 1003 | Lux Cafe    | 08:07:00
 1004 | La Rosa     | 11:49:20
(3 rows)
```

Table data merge

The following `MERGE` statement merges `visits_daily` data into `visits_history` :

- For matching customers, `MERGE` updates the occurrence count.
- For non-matching customers, `MERGE` inserts new rows.

```
=> MERGE INTO visits_history h USING visits_daily d
  ON (h.customer_id=d.customer_id AND h.location_name=d.location_name)
  WHEN MATCHED THEN UPDATE SET visit_count = h.visit_count + 1
  WHEN NOT MATCHED THEN INSERT (customer_id, location_name, visit_count)
  VALUES (d.customer_id, d.location_name, 1);
OUTPUT
-----
 3
(1 row)
```

`MERGE` returns the number of rows updated and inserted. In this case, the returned value specifies three updates and inserts:

- Customer `1001` 's third visit to Etoile
- New customer `1003` 's first visit to new restaurant Lux Cafe
- Customer `1004` 's first visit to La Rosa

If you now query table `visits_history` , the result set shows the merged (updated and inserted) data. Updated and new rows are highlighted:

```
=> SELECT * FROM visits_history ORDER BY customer_id, location_name
customer_id | location_name | visit_count
-----+-----+-----
 1001 | Etoile      |          3
 1002 | La Rosa    |          4
 1003 | Lux Cafe    |          1
 1004 | Etoile      |          1
 1004 | La Rosa     |          1
(5 rows)
```

MERGE source options

A **MERGE** operation joins the target table to one of the following data sources:

- Another table
- View
- Subquery result set

Merging from table and view data

You merge data from one table into another as follows:

```
MERGE INTO target-table USING { source-table | source-view } join-condition
  matching-clause[ matching-clause ]
```

If you specify a view, Vertica expands the view name to the query that it encapsulates, and uses the result set as the merge source data.

For example, the VMart table `public.product_dimension` contains current and discontinued products. You can move all discontinued products into a separate table `public.product_dimension_discontinued`, as follows:

```
=> CREATE TABLE public.product_dimension_discontinued (
  product_key int,
  product_version int,
  sku_number char(32),
  category_description char(32),
  product_description varchar(128));

=> MERGE INTO product_dimension_discontinued tgt
  USING product_dimension src ON tgt.product_key = src.product_key
    AND tgt.product_version = src.product_version
  WHEN NOT MATCHED AND src.discontinued_flag='1' THEN INSERT VALUES
  (src.product_key,
   src.product_version,
   src.sku_number,
   src.category_description,
   src.product_description);

OUTPUT
-----
  1186
(1 row)
```

Source table `product_dimension` uses two columns, `product_key` and `product_version`, to identify unique products. The **MERGE** statement joins the source and target tables on these columns in order to return single instances of non-matching rows. The **WHEN NOT MATCHED** clause includes a [filter](#) (`src.discontinued_flag='1'`), which reduces the result set to include only discontinued products. The remaining rows are inserted into target table `product_dimension_discontinued`.

Merging from a subquery result set

You can merge into a table the result set that is returned by a subquery, as follows:

```
MERGE INTO target-table USING (subquery) sq-alias join-condition
  matching-clause[ matching-clause ]
```

For example, the VMart table `public.product_dimension` is defined as follows (DDL truncated):

```
CREATE TABLE public.product_dimension
(
  product_key int NOT NULL,
  product_version int NOT NULL,
  product_description varchar(128),
  sku_number char(32),
  ...
)
ALTER TABLE public.product_dimension
  ADD CONSTRAINT C_PRIMARY PRIMARY KEY (product_key, product_version) DISABLED;
```

Columns `product_key` and `product_version` comprise the table's primary key. You can modify this table so it contains a single column that concatenates the values of these two columns. This column can be used to uniquely identify each product, while also maintaining the original values from `product_key` and `product_version`.

You populate the new column with a `MERGE` statement that queries the other two columns:

```
=> ALTER TABLE public.product_dimension ADD COLUMN product_ID numeric(8,2);
ALTER TABLE

=> MERGE INTO product_dimension tgt
  USING (SELECT (product_key||'.0'||product_version)::numeric(8,2) AS pid, sku_number
  FROM product_dimension) src
  ON tgt.product_key||'.0'||product_version::numeric=src.pid
  WHEN MATCHED THEN UPDATE SET product_ID = src.pid;
OUTPUT
-----
60000
(1 row)
```

The following query verifies that the new column values correspond to the values in `product_key` and `product_version`:

```
=> SELECT product_ID, product_key, product_version, product_description
  FROM product_dimension
  WHERE category_description = 'Medical'
  AND product_description ILIKE '%diabetes%'
  AND discontinued_flag = 1 ORDER BY product_ID;
product_ID | product_key | product_version | product_description
-----+-----+-----+-----
5836.02 | 5836 | 2 | Brand #17487 diabetes blood testing kit
14320.02 | 14320 | 2 | Brand #43046 diabetes blood testing kit
18881.01 | 18881 | 1 | Brand #56743 diabetes blood testing kit
(3 rows)
```

MERGE matching clauses

`MERGE` supports one instance of the following matching clauses:

-
-

Each matching clause can specify an additional filter, as described in [Update and insert filters](#).

WHEN MATCHED THEN UPDATE SET

Updates all target table rows that are joined to the source table, typically with data from the source table:

```
WHEN MATCHED [ AND update-filter ] THEN UPDATE
  SET { target-column = expression }[,...]
```

Vertica can execute the join only on unique values in the source table's join column. If the source table's join column contains more than one matching value, the `MERGE` statement returns with a run-time error.

WHEN NOT MATCHED THEN INSERT

`WHEN NOT MATCHED THEN INSERT` inserts into the target table a new row for each source table row that is excluded from the join:

```
WHEN NOT MATCHED [ AND insert-filter ] THEN INSERT
  [ ( column-list ) ] VALUES ( values-list )
```

`column-list` is a comma-delimited list of one or more target columns in the target table, listed in any order. `MERGE` maps `column-list` columns to `values-list` values in the same order, and each column-value pair must be [compatible](#). If you omit `column-list`, Vertica maps `values-list` values to columns according to column order in the table definition.

For example, given the following source and target table definitions:

```
CREATE TABLE t1 (a int, b int, c int);
CREATE TABLE t2 (x int, y int, z int);
```

The following **WHEN NOT MATCHED** clause implicitly sets the values of the target table columns **a**, **b**, and **c** in the newly inserted rows:

```
MERGE INTO t1 USING t2 ON t1.a=t2.x
  WHEN NOT MATCHED THEN INSERT VALUES (t2.x, t2.y, t2.z);
```

In contrast, the following **WHEN NOT MATCHED** clause excludes columns **t1.b** and **t2.y** from the merge operation. The **WHEN NOT MATCHED** clause explicitly pairs two sets of columns from the target and source tables: **t1.a** to **t2.x**, and **t1.c** to **t2.z**. Vertica sets excluded column **t1.b** to null:

```
MERGE INTO t1 USING t2 ON t1.a=t2.x
  WHEN NOT MATCHED THEN INSERT (a, c) VALUES (t2.x, t2.z);
```

Update and insert filters

Each **WHEN MATCHED** and **WHEN NOT MATCHED** clause in a **MERGE** statement can optionally specify an update filter and insert filter, respectively:

```
WHEN MATCHED AND update-filter THEN UPDATE ...
WHEN NOT MATCHED AND insert-filter THEN INSERT ...
```

Vertica also supports Oracle syntax for specifying update and insert filters:

```
WHEN MATCHED THEN UPDATE SET column-updates WHERE update-filter
WHEN NOT MATCHED THEN INSERT column-values WHERE insert-filter
```

Each filter can specify multiple conditions. Vertica handles the filters as follows:

- An update filter is applied to the set of matching rows in the target table that are returned by the **MERGE** join. For each row where the update filter evaluates to true, Vertica updates the specified columns.
- An insert filter is applied to the set of source table rows that are excluded from the **MERGE** join. For each row where the insert filter evaluates to true, Vertica adds a new row to the target table with the specified values.

For example, given the following data in tables **t11** and **t22**:

```
=> SELECT * from t11 ORDER BY pk;
```

```
pk | col1 | col2 | SKIP_ME_FLAG
```

```
-----+-----+-----
```

```
1 | 2 | 3 | t
2 | 3 | 4 | t
3 | 4 | 5 | f
4 |   | 6 | f
5 | 6 | 7 | t
6 |   | 8 | f
7 | 8 |   | t
```

```
(7 rows)
```

```
=> SELECT * FROM t22 ORDER BY pk;
```

```
pk | col1 | col2
```

```
-----+-----+-----
```

```
1 | 2 | 4
2 | 4 | 8
3 | 6 |
4 | 8 | 16
```

```
(4 rows)
```

You can merge data from table **t11** into table **t22** with the following **MERGE** statement, which includes update and insert filters:

```
=> MERGE INTO t22 USING t11 ON ( t11.pk=t22.pk )
  WHEN MATCHED
    AND t11.SKIP_ME_FLAG=FALSE AND (
      COALESCE (t22.col1<>t11.col1, (t22.col1 is null)<>(t11.col1 is null))
    )
  THEN UPDATE SET col1=t11.col1, col2=t11.col2
  WHEN NOT MATCHED
    AND t11.SKIP_ME_FLAG=FALSE
  THEN INSERT (pk, col1, col2) VALUES (t11.pk, t11.col1, t11.col2);
OUTPUT
```

```
-----
  3
(1 row)
```

```
=> SELECT * FROM t22 ORDER BY pk;
```

```
pk | col1 | col2
-----+-----+-----
 1 |  2 |  4
 2 |  4 |  8
 3 |  4 |  5
 4 |   |  6
 6 |   |  8
(5 rows)
```

Vertica uses the update and insert filters as follows:

- Evaluates all matching rows against the update filter conditions. Vertica updates each row where the following two conditions both evaluate to true:
 - Source column `t11.SKIP_ME_FLAG` is set to false.
 - The `COALESCE` function evaluates to true.
- Evaluates all non-matching rows in the source table against the insert filter. For each row where column `t11.SKIP_ME_FLAG` is set to false, Vertica inserts a new row in the target table.

MERGE optimization

You can improve `MERGE` performance in several ways:

- [Design projections for optimal MERGE performance.](#)
- [Facilitate creation of optimized query plans.](#)
- Use source tables that are smaller than target tables.

Projections for MERGE operations

The Vertica query optimizer automatically chooses the best projections to implement a merge operation. A good projection design strategy provides projections that help the query optimizer avoid extra sort and data transfer operations, and facilitate `MERGE` performance.

Tip

You can rely on [Database Designer](#) to generate projections that address merge requirements. You can then [customize these projections](#) as needed.

For example, the following `MERGE` statement fragment joins source and target tables `tgt` and `src`, respectively, on columns `tgt.a` and `src.b`:

```
=> MERGE INTO tgt USING src ON tgt.a = src.b ...
```

Vertica can use a local merge join if projections for tables `tgt` and `src` use one of the following projection designs, where inputs are presorted by projection `ORDER BY` clauses:

- Replicated projections are sorted on:
 - Column `a` for table `tgt`
 - Column `b` for table `src`
- [Segmented](#) projections are [identically segmented](#) on:

- Column **a** for table **tgt**
- Column **b** for table **src**
- Corresponding segmented columns

Optimizing MERGE query plans

Vertica prepares an optimized query plan if the following conditions are all true:

- The **MERGE** statement contains both matching clauses [WHEN MATCHED THEN UPDATE SET](#) and [WHEN NOT MATCHED THEN INSERT](#). If the **MERGE** statement contains only one matching clause, it uses a non-optimized query plan.
- The **MERGE** statement excludes [update and insert filters](#).
- The target table join column has a unique or primary key constraint. This requirement does not apply to the source table join column.
- Both matching clauses specify all columns in the target table.
- Both matching clauses specify identical source values.

For details on evaluating an [EXPLAIN](#) -generated query plan, see [MERGE path](#).

The examples that follow use a simple schema to illustrate some of the conditions under which Vertica prepares or does not prepare an optimized query plan for **MERGE** :

```
CREATE TABLE target(a INT PRIMARY KEY, b INT, c INT) ORDER BY b,a;
CREATE TABLE source(a INT, b INT, c INT) ORDER BY b,a;
INSERT INTO target VALUES(1,2,3);
INSERT INTO target VALUES(2,4,7);
INSERT INTO source VALUES(3,4,5);
INSERT INTO source VALUES(4,6,9);
COMMIT;
```

Optimized MERGE statement

Vertica can prepare an optimized query plan for the following **MERGE** statement because:

- The target table's join column **t.a** has a primary key constraint.
- All columns in the target table (**a,b,c**) are included in the **UPDATE** and **INSERT** clauses.
- The **UPDATE** and **INSERT** clauses specify identical source values: **s.a** , **s.b** , and **s.c** .

```
MERGE INTO target t USING source s ON t.a = s.a
WHEN MATCHED THEN UPDATE SET a=s.a, b=s.b, c=s.c
WHEN NOT MATCHED THEN INSERT(a,b,c) VALUES(s.a, s.b, s.c);
```

OUTPUT

```
-----
2
(1 row)
```

The output value of 2 indicates success and denotes the number of rows updated/inserted from the source into the target.

Non-optimized MERGE statement

In the next example, the **MERGE** statement runs without optimization because the source values in the **UPDATE/INSERT** clauses are not identical. Specifically, the **UPDATE** clause includes constants for columns **s.a** and **s.c** and the **INSERT** clause does not:

```
MERGE INTO target t USING source s ON t.a = s.a
WHEN MATCHED THEN UPDATE SET a=s.a + 1, b=s.b, c=s.c - 1
WHEN NOT MATCHED THEN INSERT(a,b,c) VALUES(s.a, s.b, s.c);
```

To make the previous **MERGE** statement eligible for optimization, rewrite the statement so that the source values in the **UPDATE** and **INSERT** clauses are identical:

```
MERGE INTO target t USING source s ON t.a = s.a
WHEN MATCHED THEN UPDATE SET a=s.a + 1, b=s.b, c=s.c -1
WHEN NOT MATCHED THEN INSERT(a,b,c) VALUES(s.a + 1, s.b, s.c - 1);
```

MERGE restrictions

The following restrictions apply to updating and inserting table data with [MERGE](#).

Constraint enforcement

If primary key, unique key, or check constraints are enabled for automatic enforcement in the target table, Vertica enforces those constraints when you load new data. If a violation occurs, Vertica rolls back the operation and returns an error.

Caution

If you run MERGE multiple times using the same target and source table, each iteration is liable to introduce duplicate values into the target columns and return with an error.

Columns prohibited from merge

The following columns cannot be specified in a merge operation; attempts to do so return with an error:

- [IDENTITY](#) columns, or columns whose default value is set to a [named sequence](#).
- Vmap columns such as `__raw__` in flex tables.
- Columns of complex types ARRAY, SET, or ROW.

Removing table data

Vertica provides several ways to remove data from a table:

Delete operation	Description
Drop a table	Permanently remove a table and its definition, optionally remove associated views and projections .
Delete table rows	Mark rows with delete vectors and store them so data can be rolled back to a previous epoch. The data must be purged to reclaim disk space.
Truncate table data	Remove all storage and history associated with a table. The table structure is preserved for future use.
Purge data	Permanently remove historical data from physical storage and free disk space for reuse.
Drop partitions	Remove one or more partitions from a table. Each partition contains a related subset of data in the table. Dropping partitioned data is efficient, and provides query performance benefits.

In this section

- [Data removal operations compared](#)
- [Optimizing DELETE and UPDATE](#)
- [Purging deleted data](#)
- [Truncating tables](#)

Data removal operations compared

The following table summarizes differences between various data removal operations.

Operations and options	Performance	Auto commits	Saves history
<code>DELETE FROM ``table</code>	Normal	No	Yes
<code>DELETE FROM ``temp-table</code>	High	No	No
<code>DELETE FROM table where-clause</code>	Normal	No	Yes
<code>DELETE FROM temp-table where-clause</code>	Normal	No	Yes

<code>DELETE FROM <i>temp-table</i> where-clause ON COMMIT PRESERVE ROWS</code>	Normal	No	Yes
<code>DELETE FROM <i>temp-table</i> where-clause ON COMMIT DELETE ROWS</code>	High	Yes	No
<code>DROP <i>table</i></code>	High	Yes	No
<code>TRUNCATE <i>table</i></code>	High	Yes	No
<code>TRUNCATE <i>temp-table</i></code>	High	Yes	No
<code>SELECT DROP_PARTITIONS (...)</code>	High	Yes	No

Choosing the best operation

The following table can help you decide which operation is best for removing table data:

If you want to...	Use...
Delete both table data and definitions and start from scratch.	DROP TABLE
Quickly drop data while preserving table definitions, and reload data.	TRUNCATE TABLE
Regularly perform bulk delete operations on logical sets of data.	DROP_PARTITIONS
Occasionally perform small deletes with the option to roll back or review history.	DELETE

Optimizing DELETE and UPDATE

Vertica is optimized for query-intensive workloads, so DELETE and UPDATE queries might not achieve the same level of performance as other queries. A DELETE and UPDATE operation must update all projections, so the operation can only be as fast as the slowest projection.

To improve the performance of DELETE and UPDATE queries, consider the following issues:

- **Query performance after large DELETE operations** : Vertica's implementation of DELETE differs from traditional databases: it does not delete data from disk storage; rather, it marks rows as deleted so they are available for historical queries. Deletion of 10% or more of the total rows in a table can adversely affect queries on that table. In that case, consider [purging those rows](#) to improve performance.
- **Recovery performance** : Recovery is the action required for a cluster to restore K-safety after a crash. Large numbers of deleted records can degrade the performance of a recovery. To improve recovery performance, [purge the deleted rows](#) .
- **Concurrency** : DELETE and UPDATE take exclusive locks on the table. Only one DELETE or UPDATE transaction on a table can be in progress at a time and only when no load operations are in progress. Delete and update operations on different tables can run concurrently.

Tip

To optimize large bulk deletion, consider [dropping partitions](#) where possible.

Projection column requirements for optimized delete

A projection is optimized for delete and update operations if it contains all columns required by the query predicate. In general, DML operations are significantly faster when performed on optimized projections than on non-optimized projections.

For example, consider the following table and projections:

```
=> CREATE TABLE t (a INTEGER, b INTEGER, c INTEGER);
=> CREATE PROJECTION p1 (a, b, c) AS SELECT * FROM t ORDER BY a;
=> CREATE PROJECTION p2 (a, c) AS SELECT a, c FROM t ORDER BY c, a;
```

In the following query, both **p1** and **p2** are eligible for DELETE and UPDATE optimization because column **a** is available:

```
=> DELETE from t WHERE a = 1;
```

In the following example, only projection **p1** is eligible for DELETE and UPDATE optimization because the b column is not available in **p2** :

```
=> DELETE from t WHERE b = 1;
```

Optimized DELETE in subqueries

To be eligible for DELETE optimization, all target table columns referenced in a DELETE or UPDATE statement's WHERE clause must be in the projection definition.

For example, the following simple schema has two tables and three projections:

```
=> CREATE TABLE tb1 (a INT, b INT, c INT, d INT);
```

```
=> CREATE TABLE tb2 (g INT, h INT, i INT, j INT);
```

The first projection references all columns in **tb1** and sorts on column **a** :

```
=> CREATE PROJECTION tb1_p AS SELECT a, b, c, d FROM tb1 ORDER BY a;
```

The buddy projection references and sorts on column **a** in **tb1** :

```
=> CREATE PROJECTION tb1_p_2 AS SELECT a FROM tb1 ORDER BY a;
```

This projection references all columns in **tb2** and sorts on column **i** :

```
=> CREATE PROJECTION tb2_p AS SELECT g, h, i, j FROM tb2 ORDER BY i;
```

Consider the following DML statement, which references **tb1.a** in its **WHERE** clause. Since both projections on **tb1** contain column **a** , both are eligible for the optimized DELETE:

```
=> DELETE FROM tb1 WHERE tb1.a IN (SELECT tb2.i FROM tb2);
```

Restrictions

Optimized DELETE operations are not supported under the following conditions:

- With replicated projections if subqueries reference the target table. For example, the following syntax is not supported:

```
=> DELETE FROM tb1 WHERE tb1.a IN (SELECT e FROM tb2, tb2 WHERE tb2.e = tb1.e);
```

- With subqueries that do not return multiple rows. For example, the following syntax is not supported:

```
=> DELETE FROM tb1 WHERE tb1.a = (SELECT k from tb2);
```

Projection sort order for optimizing DELETE

Design your projections so that frequently-used DELETE or UPDATE predicate columns appear in the sort order of all projections for large DELETE and UPDATE operations.

For example, suppose most of the DELETE queries you perform on a projection look like the following:

```
=> DELETE from t where time_key < '1-1-2007'
```

To optimize the delete operations, make **time_key** appear in the ORDER BY clause of all projections. This schema design results in better performance of the delete operation.

In addition, add sort columns to the sort order such that each combination of the sort key values uniquely identifies a row or a small set of rows. For more information, see [Choosing sort order: best practices](#). To analyze projections for sort order issues, use the [EVALUATE_DELETE_PERFORMANCE](#) function.

Purging deleted data

In Vertica, delete operations do not remove rows from physical storage. **DELETE** marks rows as deleted, as does **UPDATE** , which combines delete and insert operations. In both cases, Vertica retains discarded rows as historical data, which remains accessible to [historical queries](#) until it is purged.

The cost of retaining historical data is twofold:

- Disk space is allocated to deleted rows and delete markers.
- Typical (non-historical) queries must read and skip over deleted data, which can impact performance.

A purge operation permanently removes historical data from physical storage and frees disk space for reuse. Only historical data that precedes the [Ancient History Mark](#) (AHM) is eligible to be purged.

You can purge data in two ways:

- [Set a purge policy](#).
- [Manually purge data](#).

In both cases, Vertica purges all historical data up to and including the AHM epoch and resets the AHM. See [Epochs](#) for additional information about how Vertica uses epochs.

Caution

Large delete and purge operations can take a long time to complete, so use them sparingly. If your application requires deleting data on a regular basis, such as by month or year, consider designing tables that take advantage of [table partitioning](#). If partitioning is not suitable, consider [rebuilding the table](#).

In this section

- [Setting a purge policy](#)
- [Manually purging data](#)

Setting a purge policy

The preferred method for purging data is to establish a policy that determines which deleted data is eligible to be purged. Eligible data is automatically purged when the [Tuple Mover](#) performs [mergeout](#) operations.

Vertica provides two methods for determining when deleted data is eligible to be purged:

- Specifying the time for which delete data is saved
- Specifying the number of [epochs](#) that are saved

Specifying the time for which delete data is saved

Specifying the time for which delete data is saved is the preferred method for determining which deleted data can be purged. By default, Vertica saves historical data only when nodes are down.

To change the specified time for saving deleted data, use the [HistoryRetentionTime configuration parameter](#):

```
=> ALTER DATABASE DEFAULT SET HistoryRetentionTime = {seconds | -1};
```

In the above syntax:

- *seconds* is the amount of time (in seconds) for which to save deleted data.
- *-1* indicates that you do not want to use the [HistoryRetentionTime](#) configuration parameter to determine which deleted data is eligible to be purged. Use this setting if you prefer to use the other method ([HistoryRetentionEpochs](#)) for determining which deleted data can be purged.

The following example sets the history epoch retention level to 240 seconds:

```
=> ALTER DATABASE DEFAULT SET HistoryRetentionTime = 240;
```

Specifying the number of epochs that are saved

Unless you have a reason to limit the number of epochs, Vertica recommends that you specify the time over which delete data is saved.

To specify the number of historical epoch to save through the [HistoryRetentionEpochs](#) configuration parameter:

1. Turn off the [HistoryRetentionTime](#) configuration parameter:

```
=> ALTER DATABASE DEFAULT SET HistoryRetentionTime = -1;
```

2. Set the history epoch retention level through the [HistoryRetentionEpochs](#) configuration parameter:

```
=> ALTER DATABASE DEFAULT SET HistoryRetentionEpochs = {num_epochs | -1};
```

- *num_epochs* is the number of historical epochs to save.
- *-1* indicates that you do not want to use the [HistoryRetentionEpochs](#) configuration parameter to trim historical epochs from the epoch map. By default, [HistoryRetentionEpochs](#) is set to *-1*.

The following example sets the number of historical epochs to save to 40:

```
=> ALTER DATABASE DEFAULT SET HistoryRetentionEpochs = 40;
```

Modifications are immediately implemented across all nodes within the database cluster. You do not need to restart the database.

Note

If both [HistoryRetentionTime](#) and [HistoryRetentionEpochs](#) are specified, [HistoryRetentionTime](#) takes precedence.

See [Epoch management parameters](#) for additional details. See [Epochs](#) for information about how Vertica uses epochs.

Disabling purge

If you want to preserve all historical data, set the value of both historical epoch retention parameters to -1, as follows:

```
=> ALTER DATABASE mydb SET HistoryRetentionTime = -1;
=> ALTER DATABASE DEFAULT SET HistoryRetentionEpochs = -1;
```

Manually purging data

You manually purge deleted data as follows:

1. Set the cut-off date for purging deleted data. First, call one of the following functions to verify the current ancient history mark ([AHM](#)):
 - [GET_AHM_TIME](#) returns a `TIMESTAMP` value of the AHM.
 - [GET_AHM_EPOCH](#) returns the number of the epoch in which the AHM is located.
2. Set the AHM to the desired cut-off date with one of the following functions:
 - [SET_AHM_TIME](#) sets the AHM to the [epoch](#) that includes the specified `TIMESTAMP` value on the [initiator node](#).
 - [SET_AHM_EPOCH](#) sets the AHM to the specified epoch.
 - [MAKE_AHM_NOW](#) sets the AHM to the greatest allowable value. This lets you purge all deleted data.

If you call [SET_AHM_TIME](#), keep in mind that the timestamp you specify is mapped to an epoch, which by default has a three-minute granularity. Thus, if you specify an AHM time of `2008-01-01 00:00:00.00`, Vertica might purge data from the first three minutes of 2008, or retain data from last three minutes of 2007.

Note

You cannot advance the AHM beyond a point where Vertica is unable to recover data for a down node.

3. Purge deleted data from the desired projections with one of the following functions:
 - [PURGE](#) purges all projections in the physical schema.
 - [PURGE_TABLE](#) purges all projections anchored to the specified table.
 - [PURGE_PROJECTION](#) purges the specified projection.
 - [PURGE_PARTITION](#) purges a specified partition.

The [tuple mover](#) performs a [mergeout](#) operation to purge the data. Vertica periodically invokes the tuple mover to perform mergeout operations, as configured by [tuple mover parameters](#). You can manually invoke the tuple mover by calling the function [DO_TM_TASK](#).

Caution

Manual purge operations can take a long time.

See [Epochs](#) for additional information about how Vertica uses epochs.

Truncating tables

[TRUNCATE TABLE](#) removes all storage associated with the target table and its projections. Vertica preserves the table and the projection definitions. If the truncated table has out-of-date projections, those projections are cleared and marked up-to-date when `TRUNCATE TABLE` returns.

`TRUNCATE TABLE` commits the entire transaction after statement execution, even if truncating the table fails. You cannot roll back a `TRUNCATE TABLE` statement.

Use `TRUNCATE TABLE` for testing purposes. You can use it to remove all data from a table and load it with fresh data, without recreating the table and its projections.

Table locking

TRUNCATE TABLE takes an O (owner) lock on the table until the truncation process completes. The savepoint is then released.

If the operation cannot obtain an [O lock](#) on the target table, Vertica tries to close any internal [Tuple Mover](#) sessions that are running on that table. If successful, the operation can proceed. Explicit Tuple Mover operations that are running in user sessions do not close. If an explicit Tuple Mover operation is running on the table, the operation proceeds only when the operation is complete.

Restrictions

You cannot truncate an external table.

Examples

```
=> INSERT INTO sample_table (a) VALUES (3);
=> SELECT * FROM sample_table;
a
---
3
(1 row)
=> TRUNCATE TABLE sample_table;
TRUNCATE TABLE
=> SELECT * FROM sample_table;
a
---
(0 rows)
```

Rebuilding tables

You can reclaim disk space on a large scale by rebuilding tables, as follows:

1. Create a table with the same (or similar) definition as the table to rebuild.
2. Create projections for the new table.
3. Copy data from the target table into the new one with [INSERT...SELECT](#).
4. Drop the old table and its projections.

Note

Rather than dropping the old table, you can rename it and use it as a backup copy. Before doing so, verify that you have sufficient disk space for both the new and old tables.

5. Rename the new table with [ALTER TABLE...RENAME](#), using the name of the old table.

Caution

When you rebuild a table, Vertica purges the table of all delete vectors that precede the AHM. This prevents historical queries on any older epoch.

Projection considerations

- You must have enough disk space to contain the old and new projections at the same time. If necessary, you can drop some of the old projections before loading the new table. You must, however, retain at least one [superprojection](#) of the old table (or two [buddy](#) superprojections to maintain K-safety) until the new table is loaded. (See [Prepare disk storage locations](#) for disk space requirements.)
- You can specify different names for the new projections or use [ALTER TABLE...RENAME](#) to change the names of the old projections.
- The relationship between tables and projections does not depend on object names. Instead, it depends on object identifiers that are not affected by rename operations. Thus, if you rename a table, its projections continue to work normally.

Dropping tables

[DROP TABLE](#) drops a table from the database catalog. If any projections are associated with the table, [DROP TABLE](#) returns an error message unless it also includes the [CASCADE](#) option. One exception applies: the table only has an [auto-generated superprojection](#) (auto-projection) associated with it.

Using CASCADE

In the following example, **DROP TABLE** tries to remove a table that has several projections associated with it. Because it omits the **CASCADE** option, Vertica returns an error:

```
=> DROP TABLE d1;
NOTICE: Constraint - depends on Table d1
NOTICE: Projection d1p1 depends on Table d1
NOTICE: Projection d1p2 depends on Table d1
NOTICE: Projection d1p3 depends on Table d1
NOTICE: Projection f1d1p1 depends on Table d1
NOTICE: Projection f1d1p2 depends on Table d1
NOTICE: Projection f1d1p3 depends on Table d1
ERROR: DROP failed due to dependencies: Cannot drop Table d1 because other objects depend on it
HINT: Use DROP ... CASCADE to drop the dependent objects too.
=> DROP TABLE d1 CASCADE;
DROP TABLE
=> CREATE TABLE mytable (a INT, b VARCHAR(256));
CREATE TABLE
=> DROP TABLE IF EXISTS mytable;
DROP TABLE
=> DROP TABLE IF EXISTS mytable; -- Doesn't exist
NOTICE: Nothing was dropped
DROP TABLE
```

The next attempt includes the **CASCADE** option and succeeds:

```
=> DROP TABLE d1 CASCADE;
DROP TABLE
=> CREATE TABLE mytable (a INT, b VARCHAR(256));
CREATE TABLE
=> DROP TABLE IF EXISTS mytable;
DROP TABLE
=> DROP TABLE IF EXISTS mytable; -- Doesn't exist
NOTICE: Nothing was dropped
DROP TABLE
```

Using IF EXISTS

In the following example, **DROP TABLE** includes the option **IF EXISTS**. This option specifies not to report an error if one or more of the tables to drop does not exist. This clause is useful in SQL scripts—for example, to ensure that a table is dropped before you try to recreate it:

```
=> DROP TABLE IF EXISTS mytable;
DROP TABLE
=> DROP TABLE IF EXISTS mytable; -- Table doesn't exist
NOTICE: Nothing was dropped
DROP TABLE
```

Dropping and restoring view tables

Views that reference a table that is dropped and then replaced by another table with the same name continue to function and use the contents of the new table. The new table must have the same column definitions.

Managing client connections

Vertica provides several settings to control client connections:

- Limit the number of client connections a user can have open at the same time.
- Limit the time a client connection can be idle before being automatically disconnected.
- Use connection load balancing to spread the overhead of servicing client connections among nodes.
- Detect unresponsive clients with TCP keepalive.
- Drain a subcluster to reject any new client connections to that subcluster. For details, see [Drain client connections](#).
- Route client connections to subclusters based on their workloads. For details, see [Workload routing](#).

Total client connections to a given node cannot exceed the limits set in MaxClientSessions.

Changes to a client's **MAXCONNECTIONS** property have no effect on current sessions; these changes apply only to new sessions. For example, if you change user's connection mode from **DATABASE** to **NODE**, current node connections are unaffected. This change applies only to new sessions, which are reserved on the invoking node.

When Vertica closes a client connection, the client's ongoing operations, if any, are canceled.

In this section

- [Limiting the number and length of client connections](#)
- [Drain client connections](#)
- [Connection load balancing](#)

Limiting the number and length of client connections

You can manage how many active sessions a user can open to the server, and the duration of those sessions. Doing so helps prevent overuse of available resources, and can improve overall throughput.

You can define connection limits at two levels:

- Set the **MAXCONNECTIONS** property on individual users. This property specifies how many sessions a user can open concurrently on individual nodes, or across the database cluster. For example, the following ALTER USER statement allows user Joe up to 10 concurrent sessions:

```
=> ALTER USER Joe MAXCONNECTIONS 10 ON DATABASE;
```

- Set the configuration parameter **MaxClientSessions** on the database or individual nodes. This parameter specifies the maximum number of client sessions that can run on nodes in the database cluster, by default set to 50. An extra five sessions are always reserved to dbadmin users. This enables them to log in when the total number of client sessions equals MaxClientSessions.

Total client connections to a given node cannot exceed the limits set in MaxClientSessions.

Changes to a client's MAXCONNECTIONS property have no effect on current sessions; these changes apply only to new sessions. For example, if you change user's connection mode from DATABASE to NODE, current node connections are unaffected. This change applies only to new sessions, which are reserved on the invoking node.

Managing TCP keepalive settings

Vertica uses kernel TCP keepalive parameters to detect unresponsive clients and determine when the connection should be closed. Vertica also supports a set of equivalent KeepAlive parameters that can override TCP keepalive parameter settings. By default, all Vertica KeepAlive parameters are set to 0, which signifies to use TCP keepalive settings. To override TCP keepalive settings, set the equivalent parameters at the database level with [ALTER DATABASE](#), or for the current session with [ALTER SESSION](#).

TCP keepalive Parameter	Vertica Parameter	Description
tcp_keepalive_time	KeepAliveIdleTime	Length (in seconds) of the idle period before the first TCP keepalive probe is sent to ensure that the client is still connected.
tcp_keepalive_probes	KeepAliveProbeCount	Number of consecutive keepalive probes that must go unacknowledged by the client before the client connection is considered lost and closed
tcp_keepalive_intvl	KeepAliveProbeInterval	Time interval (in seconds) between keepalive probes.

Examples

The following examples show how to use Vertica KeepAlive parameters to override TCP keepalive parameters as follows:

- After 600 seconds (ten minutes), the first keepalive probe is sent to the client.
- Consecutive keepalive probes are sent every 30 seconds.
- If the client fails to respond to 10 keepalive probes, the connection is considered lost and is closed.

To make this the default policy for client connections, use [ALTER DATABASE](#):

```
=> ALTER DATABASE DEFAULT SET KeepAliveIdleTime = 600;  
=> ALTER DATABASE DEFAULT SET KeepAliveProbeInterval = 30;  
=> ALTER DATABASE DEFAULT SET KeepAliveProbeCount = 10;
```

To override database-level policies for the current session, use [ALTER SESSION](#):

```
=> ALTER SESSION SET KeepAliveIdleTime = 400;
=> ALTER SESSION SET KeepAliveProbeInterval = 72;
=> ALTER SESSION SET KeepAliveProbeCount = 60;
```

Query system table CONFIGURATION_PARAMETERS to verify database and session settings of the three Vertica KeepAlive parameters:

```
=> SELECT parameter_name, database_value, current_value FROM configuration_parameters WHERE parameter_name ILIKE 'KeepAlive%';
 parameter_name | database_value | current_value
-----+-----+-----
KeepAliveProbeCount | 10           | 60
KeepAliveIdleTime   | 600          | 400
KeepAliveProbeInterval | 30          | 72
(3 rows)
```

Limiting idle session length

If a client continues to respond to [TCP keepalive probes](#), but is not running any queries, the client's session is considered idle. Idle sessions eventually time out. The maximum time that sessions are allowed to idle can be set at three levels, in descending order of precedence:

- As dbadmin, set the [IDLESESSIONTIMEOUT](#) property for individual users. This property overrides all other session timeout settings.
- Users can limit the idle time of the current session with [SET SESSION IDLESESSIONTIMEOUT](#). Non-superusers can only set their session idle time to a value equal to or lower than their own IDLESESSIONTIMEOUT setting. If no session idle time is explicitly set for a user, the session idle time for that user is inherited from the node or database settings.
- As dbadmin, set configuration parameter [DEFAULTIDLESESSIONTIMEOUT](#) on the database or on individual nodes. This You can limit the default database cluster or individual nodes, with configuration parameter [DEFAULTIDLESESSIONTIMEOUT](#). This parameter sets the default timeout value for all non-superusers.

All settings apply to sessions that are continuously idle—that is, sessions where no queries are running. If a client is slow or unresponsive during query execution, that time does not apply to timeouts. For example, the time that is required for a streaming batch insert is not counted towards timeout. The server identifies a session as idle starting from the moment it starts to wait for any type of message from that session.

Viewing session settings

The following sections demonstrate how you can query the database for details about the session and connection limits.

Session length limits

Use [SHOW DATABASE](#) to view the session length limit for the database:

```
=> SHOW DATABASE DEFAULT DEFAULTIDLESESSIONTIMEOUT;
 name      | setting
-----+-----
DefaultIdleSessionTimeout | 2 day
(1 row)
```

Use [SHOW](#) to view the length limit for the current session:

```
=> SHOW IDLESESSIONTIMEOUT;
 name      | setting
-----+-----
idlesessiontimeout | 1
(1 row)
```

Connection limits

Use [SHOW DATABASE](#) to view the connection limits for the database:

```
=> SHOW DATABASE DEFAULT MaxClientSessions;
 name      | setting
-----+-----
MaxClientSessions | 50
(1 row)
```

Query [USERS](#) to view the connection limits for users:

```
=> SELECT user_name, max_connections, connection_limit_mode FROM users
      WHERE user_name != 'dbadmin';
user_name | max_connections | connection_limit_mode
-----+-----+-----
SuzyX    | 3              | database
Joe      | 10             | database
(2 rows)
```

Closing user sessions

To manually close a user session, use [CLOSE_USER_SESSIONS](#) :

```
=> SELECT CLOSE_USER_SESSIONS ('Joe');
      close_user_sessions
-----
Close all sessions for user Joe sent. Check v_monitor.sessions for progress.
(1 row)
```

Example

A user executes a query, and for some reason the query takes an unusually long time to finish (for example, because of server traffic or query complexity). In this case, the user might think the query failed, and opens another session to run the same query. Now, two sessions run the same query, using an extra connection.

To prevent this situation, you can limit how many sessions individual users can run, by modifying their MAXCONNECTIONS user property. This can help minimize the chances of running redundant queries. It also helps prevent users from consuming all available connections, as set by the database. For example, the following setting on user [SuzyQ](#) limits her to two database sessions at any time:

```
=> CREATE USER SuzyQ MAXCONNECTIONS 2 ON DATABASE;
```

Limiting Another issue setting client connections prevents is when a user connects to the server many times. Too many user connections exhausts the number of allowable connections set by database configuration parameter [MaxClientSessions](#).

Note

No user can have a MAXCONNECTIONS limit greater than the MaxClientSessions setting.

Cluster changes and connections

Behavior changes can occur with client connection limits when the following changes occur to a cluster:

- You add or remove a node.
- A node goes down or comes back up.

Changes in node availability between connection requests have little impact on connection limits.

In terms of honoring connection limits, no significant impact exists when nodes go down or come up in between connection requests. No special actions are needed to handle this. However, if a node goes down, its active session exits and other nodes in the cluster also drop their sessions. This frees up connections. The query may hang in which case the blocked sessions are reasonable and as expected.

Drain client connections

Eon Mode only

Draining client connections in a subclusters prepares the subcluster for shutdown by marking all nodes in the subcluster as draining. Work from existing user sessions continues on draining nodes, but the nodes refuse new client connections and are excluded from load-balancing operations. If clients attempt to connect to a draining node, they receive an error that informs them of the draining status. Load balancing operations exclude draining nodes, so clients that opt-in to connection load balancing should receive a connection error only if all nodes in the load balancing policy are draining. You do not need to change any connection load balancing configurations to use this feature. dbadmin can still connect to draining nodes.

To drain client connections before shutting down a subcluster, you can use the [SHUTDOWN_WITH_DRAIN](#) function. This function performs a [Graceful Shutdown](#) that marks a subcluster as draining until either the existing connections complete their work and close or a user-specified timeout is reached. When one of these conditions is met, the function proceeds to shutdown the subcluster. Vertica provides several meta-functions that allow you to independently perform each step of the SHUTDOWN_WITH_DRAIN process. You can use the [START_DRAIN_SUBCLUSTER](#) function to mark a subcluster as draining and then the [SHUTDOWN_SUBCLUSTER](#) function to shut down a subcluster once its connections have closed.

You can use the [CANCEL_DRAIN_SUBCLUSTER](#) function to mark all nodes in a subcluster as not draining. As soon as a node is both UP and not draining, the node accepts new client connections. If all nodes in a draining subcluster are down, the draining status of its nodes is automatically reset to not draining.

You can query the [DRAINING_STATUS](#) system table to monitor the draining status of each node as well as client connection information, such as the number of active user sessions on each node.

The following example drains a subcluster named `analytics`, then cancels the draining of the subcluster.

To mark the `analytics` subcluster as draining, call `SHUTDOWN_WITH_DRAIN` with a negative timeout value:

```
=> SELECT SHUTDOWN_WITH_DRAIN('analytics', -1);
NOTICE 0: Draining has started on subcluster (analytics)
```

You can confirm that the subcluster is draining by querying the `DRAINING_STATUS` system table:

```
=> SELECT node_name, subcluster_name, is_draining FROM draining_status ORDER BY 1;
node_name      | subcluster_name | is_draining
-----+-----+-----
verticadb_node0001 | default_subcluster | f
verticadb_node0002 | default_subcluster | f
verticadb_node0003 | default_subcluster | f
verticadb_node0004 | analytics       | t
verticadb_node0005 | analytics       | t
verticadb_node0006 | analytics       | t
```

If a client attempts to connect directly to a node in the draining subcluster, they receive the following error message:

```
$ /opt/vertica/bin/vsql -h noelP --password password verticadb analyst
vsql: FATAL 10611: New session rejected because subcluster to which this node belongs is draining connections
```

To cancel the graceful shutdown of the `analytics` subcluster, you can type `Ctrl+C`:

```
=> SELECT SHUTDOWN_WITH_DRAIN('analytics', -1);
NOTICE 0: Draining has started on subcluster (analytics)
^Ccancel request sent
ERROR 0: Cancel received after draining started and before shutdown issued. Nodes will not be shut down. The subclusters are still in the draining state.
HINT: Run cancel_drain_subcluster("") to restore all nodes to the 'not_draining' state
```

As mentioned in the above hint, you can run `CANCEL_DRAIN_SUBCLUSTER` to reset the status of the draining nodes in the subcluster to not draining:

```
=> SELECT CANCEL_DRAIN_SUBCLUSTER('analytics');
          CANCEL_DRAIN_SUBCLUSTER
-----+-----+-----
Targeted subcluster: 'analytics'
Action: CANCEL DRAIN

(1 row)
```

To confirm that the subcluster is no longer draining, you can again query the `DRAINING_STATUS` system table:

```
=> SELECT node_name, subcluster_name, is_draining FROM draining_status ORDER BY 1;
node_name      | subcluster_name | is_draining
-----+-----+-----
verticadb_node0001 | default_subcluster | f
verticadb_node0002 | default_subcluster | f
verticadb_node0003 | default_subcluster | f
verticadb_node0004 | analytics       | f
verticadb_node0005 | analytics       | f
verticadb_node0006 | analytics       | f
(6 rows)
```

Each client connection to a host in the Vertica cluster requires a small overhead in memory and processor time. If many clients connect to a single host, this overhead can begin to affect the performance of the database. You can spread the overhead of client connections by dictating that certain clients connect to specific hosts in the cluster. However, this manual balancing becomes difficult as new clients and hosts are added to your environment.

Connection load balancing helps automatically spread the overhead of client connections across the cluster by having hosts redirect client connections to other hosts. By redirecting connections, the overhead from client connections is spread across the cluster without having to manually assign particular hosts to individual clients. Clients can connect to a small handful of hosts, and they are naturally redirected to other hosts in the cluster. Load balancing does not redirect connections to draining hosts. For more information see, [Drain client connections](#).

Native connection load balancing

Native connection load balancing is a feature built into the Vertica Analytic Database server and client libraries as well as [vsqL](#). Both the server and the client need to enable load balancing for it to function. If connection load balancing is enabled, a host in the database cluster can redirect a client's attempt to connect to it to another currently-active host in the cluster. This redirection is based on a load balancing policy. This redirection only takes place once, so a client is not bounced from one host to another.

Because native connection load balancing is incorporated into the Vertica client libraries, any client application that connects to Vertica transparently takes advantage of it simply by setting a connection parameter.

How you choose to implement connection load balancing depends on your network environment. Since native load connection balancing is easier to implement, you should use it unless your network configuration requires that clients be separated from the hosts in the Vertica database by a firewall.

For more about native connection load balancing, see [About Native Connection Load Balancing](#).

Workload routing

Workload routing lets you [create rules](#) for routing client connections to particular subclusters based on their workloads.

The primary advantages of this type of load balancing is as follows:

- Database administrators can associate certain subclusters with certain workloads (as opposed to client IP addresses).
- Clients do not need to know anything about the subcluster they will be routed to, only the type of workload they have.
- Database administrators can change workload routing policies at any time, and these changes are transparent to all clients.

For details, see [Workload routing](#).

In this section

- [Classic connection load balancing](#)
- [Connection load balancing policies](#)
- [Workload routing](#)

About native connection load balancing

Native connection load balancing is a feature built into the Vertica server and client libraries that helps spread the CPU and memory overhead caused by client connections across the hosts in the database. It can prevent unequal distribution of client connections among hosts in the cluster.

There are two types of native connection load balancing:

- Cluster-wide balancing—This method the legacy method of connection load balancing. It was the only type of load balancing prior to Vertica version 9.2. Using this method, you apply a single load balancing policy across the entire cluster. All connection to the cluster are handled the same way.
- Load balancing policies—This method lets you set different load balancing policies depending on the source of client connection. For example, you can have a policy that redirects connections from outside of your local network to one set of nodes in your cluster, and connections from within your local network to another set of nodes.

Classic connection load balancing

The classic connection load balancing feature applies a single policy for all client connections to your database. Both your database and the client must enable the load balancing option in order for connections to be load balanced. When both client and server enable load balancing, the following process takes place when the client attempts to open a connection to Vertica:

1. The client connects to a host in the database cluster, with a connection parameter indicating that it is requesting a load-balanced connection.
2. The host chooses a host from the list of currently up hosts in the cluster, according to the [current load balancing scheme](#). Under all schemes, it is possible for a host to select itself.
3. The host tells the client which host it selected to handle the client's connection.

4. If the host chose another host in the database to handle the client connection, the client disconnects from the initial host. Otherwise, the client jumps to step 6.
5. The client establishes a connection to the host that will handle its connection. The client sets this second connection request so that the second host does not interpret the connection as a request for load balancing.
6. The client connection proceeds as usual, (negotiating encryption if the connection has SSL enabled, and proceeding to authenticating the user).

This process is transparent to the client application. The client driver automatically disconnects from the initial host and reconnects to the host selected for load balancing.

Requirements

- In mixed IPv4 and IPv6 environments, balancing only works for the address family for which you have configured native load balancing. For example, if you have configured load balancing using an IPv4 address, then IPv6 clients cannot use load balancing, however the IPv6 clients can still connect, but load balancing does not occur.
- The native load balancer returns an IP address for the client to use. This address must be one that the client can reach. If your nodes are on a private network, native load-balancing requires you to publish a public address in one of two ways:
 - Set the public address on each node. Vertica saves that address in the `export_address` field in the `NODES` system table.
 - Set the subnet on the database. Vertica saves that address in the `export_subnet` field in the `DATABASES` system table.

Load balancing schemes

The load balancing scheme controls how a host selects which host to handle a client connection. There are three available schemes:

- **NONE** (default): Disables native connection load balancing.
- **ROUNDROBIN** : Chooses the next host from a circular list of hosts in the cluster that are up—for example, in a three-node cluster, iterates over node1, node2, and node3, then wraps back to node1. Each host in the cluster maintains its own pointer to the next host in the circular list, rather than there being a single cluster-wide state.
- **RANDOM** : Randomly chooses a host from among all hosts in the cluster that are up.

You set the native connection load balancing scheme using the `SET_LOAD_BALANCE_POLICY` function. See [Enabling and Disabling Native Connection Load Balancing](#) for instructions.

Driver notes

- Native connection load balancing works with the ADO.NET driver's connection pooling. The connection the client makes to the initial host, and the final connection to the load-balanced host, use pooled connections if they are available.
- If a client application uses the JDBC and ODBC driver with third-party connection pooling solutions, the initial connection is not pooled because it is not a full client connection. The final connection is pooled because it is a standard client connection.

Connection failover

The client libraries include a failover feature that allow them to connect to backup hosts if the host specified in the connection properties is unreachable. When using native connection load balancing, this failover feature is only used for the initial connection to the database. If the host to which the client was redirected does not respond to the client's connection request, the client does not attempt to connect to a backup host and instead returns a connection error to the user.

Clients are redirected only to hosts that are known to be up. Thus, this sort of connection failure should only occur if the targeted host goes down at the same moment the client is redirected to it. For more information, see [ADO.NET connection failover](#), [JDBC connection failover](#), and [Connection failover](#).

- [Monitoring legacy connection load balancing](#)

Enabling and disabling classic connection load balancing

Only a database `superuser` can enable or disable classic cluster-wide connection load balancing. To enable or disable load balancing, use the `SET_LOAD_BALANCE_POLICY` function to set the load balance policy. Setting the load balance policy to anything other than 'NONE' enables load balancing on the server. The following example enables native connection load balancing by setting the load balancing policy to ROUNDROBIN.

```
=> SELECT SET_LOAD_BALANCE_POLICY('ROUNDROBIN');
       SET_LOAD_BALANCE_POLICY
-----
Successfully changed the client initiator load balancing policy to: roundrobin
(1 row)
```

To disable native connection load balancing, use `SET_LOAD_BALANCE_POLICY` to set the policy to 'NONE':

```
=> SELECT SET_LOAD_BALANCE_POLICY('NONE');
SET_LOAD_BALANCE_POLICY
```

Successfully changed the client initiator load balancing policy to: none

(1 row)

Note

When a client makes a connection, the native load-balancer chooses a node and returns the value from the `export_address` column in the `NODES` table. The client then uses the `export_address` to connect. The `node_address` specifies the address to use for inter-node and spread communications. When a database is installed, the `export_address` and `node_address` are set to the same value. If you installed Vertica on a private address, then you must set the `export_address` to a *public* address for each node.

By default, client connections are not load balanced, even when connection load balancing is enabled on the server. Clients must set a connection parameter to indicate they are willing to have their connection request load balanced. See [Load balancing in ADO.NET](#), [Load balancing in JDBC](#), and [Load balancing](#), for information on enabling load balancing on the client. For vsql, use the `-C` command-line option to enable load balancing.

Important

In mixed IPv4 and IPv6 environments, balancing only works for the address family for which you have configured load balancing. For example, if you have configured load balancing using an IPv4 address, then IPv6 clients cannot use load balancing, however the IPv6 clients can still connect, but load balancing does not occur.

Resetting the load balancing state

When the load balancing policy is ROUNDROBIN, each host in the Vertica cluster maintains its own state of which host it will select to handle the next client connection. You can reset this state to its initial value (usually, the host with the lowest-node id) using the [RESET_LOAD_BALANCE_POLICY](#) function:

```
=> SELECT RESET_LOAD_BALANCE_POLICY();
RESET_LOAD_BALANCE_POLICY
```

Successfully reset stateful client load balance policies: "roundrobin".

Monitoring legacy connection load balancing

Query the `LOAD_BALANCE_POLICY` column of the `V_CATALOG.DATABASES` to determine the state of native connection load balancing on your server:

```
=> SELECT LOAD_BALANCE_POLICY FROM V_CATALOG.DATABASES;
LOAD_BALANCE_POLICY
```

roundrobin

(1 row)

Determining to which node a client has connected

A client can determine the node to which it has connected by querying the `NODE_NAME` column of the `V_MONITOR.CURRENT_SESSION` table:

```
=> SELECT NODE_NAME FROM V_MONITOR.CURRENT_SESSION;
NODE_NAME
```

v_vmart_node0002

(1 row)

Connection load balancing policies

Connection load balancing policies help spread the load of servicing client connections by redirecting connections based on the connection's origin. These policies can also help prevent nodes reaching their client connection limits and rejecting new connections by spreading connections among nodes. See [Limiting the number and length of client connections](#) for more information about client connection limits.

A load balancing policy consists of:

- **Network addresses** that identify particular IP address and port number combinations on a node.
- One or more **connection load balancing groups** that consists of network addresses that you want to handle client connections. You define load balancing groups using [fault groups](#), [subclusters](#), or a list of network addresses.
- One or more **routing rules** that map a range of client IP addresses to a connection load balancing group.

When a client connects to a node in the database with load balancing enabled, the node evaluates all of the routing rules based on the client's IP address to determine if any match. If more than one rule matches the IP address, the node applies the most specific rule (the one that affects the fewest IP addresses).

If the node finds a matching rule, it uses the rule to determine the pool of potential nodes to handle the client connection. When evaluating potential target nodes, it always ensures that the nodes are currently up. The initially-contacted node then chooses one of the nodes in the group based on the group's distribution scheme. This scheme can be either choosing a node at random, or choosing a node in a rotating "round-robin" order. For example, in a three-node cluster, the round robin order would be node 1, then node 2, then node 3, and then back to node 1 again.

After it processes the rules, if the node determines that another node should handle the client's connection, it tells the client which node it has chosen. The client disconnects from the initial node and connects to the chosen node to continue with the connection process (either negotiating encryption if the connection has TLS/SSL enabled, or authentication).

If the initial node chooses itself based on the routing rules, it tells the client to proceed to the next step of the connection process.

If no routing rule matches the incoming IP address, the node checks to see if classic connection load balancing is enabled by both Vertica and the client. If so, it handles the connection according to the classic load balancing policy. See [Classic connection load balancing](#) for more information.

Finally, if the database is running in Eon Mode, the node tries to apply a default interior load balancing rule. See [Default Subcluster Interior Load Balancing Policy](#) below.

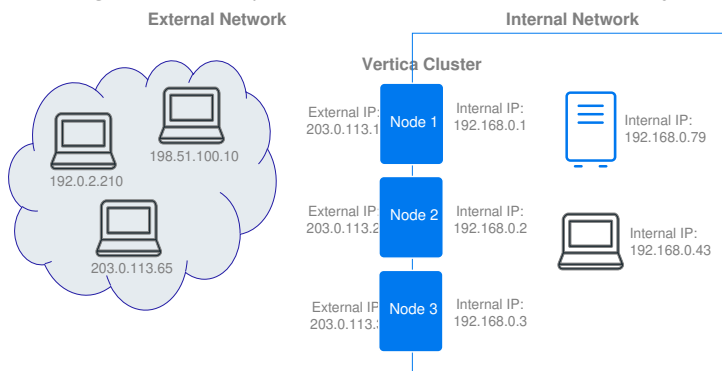

If no routing rule matches the incoming IP address and classic load balancing and the default subcluster interior load balancing rule did not apply, the node handles the connection itself. It also handles the connection itself if it cannot follow the load balancing rule. For example, if all nodes in the load balancing group targeted by the rule are down, then the initially-contacted node handles the client connection itself. In this case, the node does not

attempt to apply any other less-restrictive load balancing rules that would apply to the incoming connection. It only attempts to apply a single load balancing rule.

Use cases

Using load balancing policies you can:

- Ensure connections originating from inside or outside of your internal network are directed to a valid IP address for the client. For example, suppose your Vertica nodes have two IP addresses: one for the external network and another for the internal network. These networks are mutually exclusive. You cannot reach the private network from the public, and you cannot reach the public network from the private. Your load balancing rules need to provide the client with an IP address they can actually reach.

- Enable access to multiple nodes of a Vertica cluster that are behind a NAT router. A NAT router is accessible from the outside network via a single IP address. Systems within the NAT router's private network can be accessed on this single IP address using different port numbers. You can create a load balancing policy that redirects a client connection to the NAT's IP address but with a different port number.

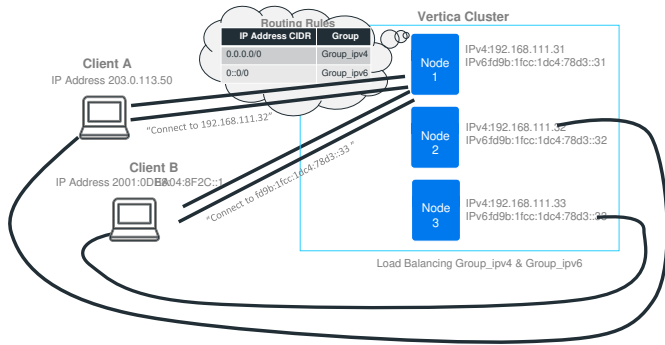

- Designate sets of nodes to service client connections from an IP address range. For example, if your ETL systems have a set range of IP addresses, you could limit their client connections to an arbitrary set of Vertica nodes, a subcluster, or a fault group. This technique lets you isolate the overhead of servicing client connections to a few nodes. It is useful when you are using subclusters in an Eon Mode database to isolate workloads (see [Subclusters](#) for more information).

Using connection load balancing policies with IPv4 and IPv6

Connection load balancing policies work with both IPv4 and IPv6. As far as the load balancing policies are concerned, the two address families represent separate networks. If you want your load balancing policy to handle both IPv4 and IPv6 addresses, you must create separate sets of network addresses, load balancing groups, and rules for each protocol. When a client opens a connection to a node in the cluster, the addressing protocol it uses determines which set of rules Vertica consults when deciding whether and how to balance the connection.

Default subcluster interior load balancing policy

Databases running in Eon Mode have a default connection load balancing policy that helps spread the load of handling client connections among the nodes in a subcluster. When a client connects to a node while opting into connection load balancing, the node checks for load balancing policies that apply to the client's IP address. If it does not find any applicable load balancing rule, and classic load balancing is not enabled, the node falls back to the default interior load balancing rule. This rule distributes connections among the nodes in the same subcluster as the initially-contacted node.

As with other connection load balancing policies, the nodes in the subcluster must have a network address defined for them to be eligible to handle the client connection. If no nodes in the subcluster have a network address, the node does not apply the default subcluster interior load balancing rule, and the connection is not load balanced.

This default rule is convenient when you are primarily interested in load balancing connections within each subcluster. You just create network addresses for the nodes in your subcluster. You do not need to create load balancing groups or rules. Clients that opt-in to load balancing are then automatically balanced among the nodes in the subcluster.

Interior load balancing policy with multiple network addresses

If your nodes have multiple network addresses, the default subcluster interior load balancing rule chooses the address that was created first as the target of load balancing rule. For example, suppose you create a network address on a node for the private IP address 192.168.1.10. Then you create another network address for the node for the public IP address 233.252.0.1. The default subcluster interior connection load balancing rule always selects 192.168.1.10 as the target of the rule.

If you want the default interior load balancing rule to choose a different network address as its target, drop the other network addresses on the node and then recreate them. Deleting and recreating other addresses makes the address you want the rule to select the oldest address. For example, suppose you want the rule to use a public address (233.252.0.1) that was created after a private address (192.168.1.10). In this case, you can drop the address for 192.168.1.10 and then recreate it. The rule then defaults to the older public 233.252.0.1 address.

If you intend to create multiple network addresses for the nodes in your subcluster, create the network addresses you want to use with the default subcluster interior load balancing first. For example, suppose you want to use the default interior load balancing subcluster rule to load balance most client connections. However, you also want to create a connection load balancing policy to manage connections coming in from a group of ETL systems. In this case, create the network addresses you want to use for the default interior load balancing rule first, then create the network addresses for the ETL systems.

Load balancing policies vs. classic load balancing

There are several differences between the classic load balancing feature and the load balancing policy feature:

- In classic connection load balancing, you just enable the load balancing option on both client and server, and load balancing is enabled. There are more steps to implement load balancing policies: you have to create addresses, groups, and rules and then enable load balancing on the client.
- Classic connection load balancing only supports a single, cluster-wide policy for redirecting connections. With connection load balancing policies, you get to choose which nodes handle client connections based on the connection's origin. This gives you more flexibility to handle complex situations. Examples include routing connections through a NAT-based router or having nodes that are accessible via multiple IP addresses on different networks.
- In classic connection load balancing, each node in the cluster can only be reached via a single IP address. This address is set in the `EXPORT_ADDRESS` column of the `NODES` system table. With connection load balancing policies, you can create a network address for each IP address associated with a node. Then you create rules that redirect to those addresses.

Steps to create a load balancing policy

There are three steps you must follow to create a load balancing policy:

1. Create one or more network addresses for each node that you want to participate in the connection load balancing policies.

2. Create one or more load balancing groups to be the target of the routing rules. Load balancing groups can target a collection of specific network addresses. Alternatively, you can create a group from a fault group or subcluster. You can limit the members of the load balance group to a subset of the fault group or subcluster using an IP address filter.
3. Create one or more routing rules.

While not absolutely necessary, it is always a good idea to test your load balancing policy to ensure it works the way you expect it to.

After following these steps, Vertica will apply the load balancing policies to client connections that opt into connection load balancing. See [Load balancing in ADO.NET](#), [Load balancing in JDBC](#), and [Load balancing](#), for information on enabling load balancing on the client. For vsq, use the `-C` command-line option to enable load balancing.

These steps are explained in the other topics in this section.

Creating network addresses

Network addresses assign a name to an IP address and port number on a node. You use these addresses when you define load balancing groups. A node can have multiple network addresses associated with it. For example, suppose a node has one IP address that is only accessible from outside of the local network, and another that is accessible only from inside the network. In this case, you can define one network address using the external IP address, and another using the internal address. You can then create two different load balancing policies, one for external clients, and another for internal clients.

Note

You must create network addresses for your nodes, even if you intend to base your connection load balance groups on fault groups or subclusters. Load balancing rules can only select nodes that have a network address defined for them.

You create a network address using the CREATE NETWORK ADDRESS statement. This statement takes:

- The name to assign to the network address
- The name of the node
- The IP address of the node to associate with the network address
- The port number the node uses to accept client connections (optional)

Note

You can use hostnames instead of IP addresses when creating network addresses. However, doing so may lead to confusion if you are not sure which IP address a hostname resolves to. Using hostnames can also cause problems if your DNS server maps the hostname to multiple IP addresses.

The following example demonstrates creating three network addresses, one for each node in a three-node database.

```
=> SELECT node_name,node_address,node_address_family FROM v_catalog.nodes;
 node_name | node_address | node_address_family
-----+-----+-----
v_vmart_node0001 | 10.20.110.21 | ipv4
v_vmart_node0002 | 10.20.110.22 | ipv4
v_vmart_node0003 | 10.20.110.23 | ipv4
(4 rows)
```

```
=> CREATE NETWORK ADDRESS node01 ON v_vmart_node0001 WITH '10.20.110.21';
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS node02 ON v_vmart_node0002 WITH '10.20.110.22';
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS node03 on v_vmart_node0003 WITH '10.20.110.23';
CREATE NETWORK ADDRESS
```

Creating network addresses for IPv6 addresses works the same way:

```
=> CREATE NETWORK ADDRESS node1_ipv6 ON v_vmart_node0001 WITH '2001:0DB8:7D5F:7433::';
CREATE NETWORK ADDRESS
```

Vertica does not perform any tests on the IP address you supply in the CREATE NETWORK ADDRESS statement. You must test the IP addresses you supply to this statement to confirm they correspond to the right node.

Vertica does not restrict the address you supply because it is often not aware of all the network addresses through which the node is accessible. For example, your node may be accessible from an external network via an IP address that Vertica is not configured to use. Or, your node can have both an IPv4 and an IPv6 address, only one of which Vertica is aware of.

For example, suppose v_vmart_node0003 from the previous example is **not** accessible via the IP address 192.168.1.5. You can still create a network address for it using that address:

```
=> CREATE NETWORK ADDRESS node04 ON v_vmart_node0003 WITH '192.168.1.5';
CREATE NETWORK ADDRESS
```

If you create a network group and routing rule that targets this address, client connections would either connect to the wrong node, or fail due to being connected to a host that's not part of a Vertica cluster.

Specifying a port number in a network address

By default, the CREATE NETWORK ADDRESS statement assumes the port number for the node's client connection is the default 5433. Sometimes, you may have a node listening for client connections on a different port. You can supply an alternate port number for the network address using the PORT keyword.

For example, suppose your nodes are behind a NAT router. In this case, you can have your nodes listen on different port numbers so the NAT router can route connections to them. When creating network addresses for these nodes, you supply the IP address of the NAT router and the port number the node is listening on. For example:

```
=> CREATE NETWORK ADDRESS node1_nat ON v_vmart_node0001 WITH '192.168.10.10' PORT 5433;
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS node2_nat ON v_vmart_node0002 with '192.168.10.10' PORT 5434;
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS node3_nat ON v_vmart_node0003 with '192.168.10.10' PORT 5435;
CREATE NETWORK ADDRESS
```

Creating connection load balance groups

After you have created network addresses for nodes, you create collections of them so you can target them with routing rules. These collections of network addresses are called load balancing groups. You have two ways to select the addresses to include in a load balancing group:

- A list of network addresses
- The name of one or more [fault groups](#) or [subclusters](#), plus an IP address range in CIDR format. The address range selects which network addresses in the fault groups or subclusters Vertica adds to the load balancing group. Only the network addresses that are within the IP address range you supply are added to the load balance group. This filter lets you base your load balance group on a portion of the nodes that make up the fault group or subcluster.

Note

Load balance groups can only be based on fault groups or subclusters, or contain an arbitrary list of network addresses. You cannot mix these sources. For example, if you create a load balance group based on one or more fault groups, then you can only add additional fault groups to it. Vertica will return an error if you try to add a network address or subcluster to the load balance group.

You create a load balancing group using the [CREATE LOAD BALANCE GROUP](#) statement. When basing your group on a list of addresses, this statement takes the name for the group and the list of addresses. The following example demonstrates creating addresses for four nodes, and then creating two groups based on those nodes.

```
=> CREATE NETWORK ADDRESS addr01 ON v_vmart_node0001 WITH '10.20.110.21';
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS addr02 ON v_vmart_node0002 WITH '10.20.110.22';
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS addr03 on v_vmart_node0003 WITH '10.20.110.23';

```

A network address can be a part of as many load balancing groups as you like. However, each group can only have a single network address per node. You cannot add two network addresses belonging to the same node to the same load balancing group.

Creating load balancing groups from fault groups

To create a load balancing group from one or more fault groups, you supply:

- The name for the load balancing group
- The name of one or more fault groups
- An IP address filter in CIDR format that filters the fault groups to be added to the load balancing group based on their IP addresses. Vertica excludes any network addresses in the fault group that do not fall within this range. If you want all of the nodes in the fault groups to be added to the load balance group, specify the filter 0.0.0.0/0.

This example creates two load balancing groups from a fault group. The first includes all network addresses in the group by using the CIDR notation for all IP addresses. The second limits the fault group to three of the four nodes in the fault group by using the IP address filter.

```

=> CREATE FAULT GROUP fault_1;
CREATE FAULT GROUP
=> ALTER FAULT GROUP fault_1 ADD NODE v_vmart_node0001;
ALTER FAULT GROUP
=> ALTER FAULT GROUP fault_1 ADD NODE v_vmart_node0002;
ALTER FAULT GROUP
=> ALTER FAULT GROUP fault_1 ADD NODE v_vmart_node0003;
ALTER FAULT GROUP
=> ALTER FAULT GROUP fault_1 ADD NODE v_vmart_node0004;
ALTER FAULT GROUP
=> SELECT node_name,node_address,node_address_family,export_address
FROM v_catalog.nodes;
node_name | node_address | node_address_family | export_address
-----+-----+-----+-----
v_vmart_node0001 | 10.20.110.21 | ipv4 | 10.20.110.21
v_vmart_node0002 | 10.20.110.22 | ipv4 | 10.20.110.22
v_vmart_node0003 | 10.20.110.23 | ipv4 | 10.20.110.23
v_vmart_node0004 | 10.20.110.24 | ipv4 | 10.20.110.24
(4 rows)

```

```

=> CREATE LOAD BALANCE GROUP group_all WITH FAULT GROUP fault_1 FILTER
'0.0.0.0/0';
CREATE LOAD BALANCE GROUP
=> CREATE LOAD BALANCE GROUP group_some WITH FAULT GROUP fault_1 FILTER
'10.20.110.21/30';
CREATE LOAD BALANCE GROUP
=> SELECT * FROM LOAD_BALANCE_GROUPS;
name | policy | filter | type | object_name
-----+-----+-----+-----+-----
group_all | ROUNDROBIN | 0.0.0.0/0 | Fault Group | fault_1
group_some | ROUNDROBIN | 10.20.110.21/30 | Fault Group | fault_1
(2 rows)

```

You can also supply multiple fault groups to the CREATE LOAD BALANCE GROUP statement:

```

=> CREATE LOAD BALANCE GROUP group_2_faults WITH FAULT GROUP
fault_2, fault_3 FILTER '0.0.0.0/0';
CREATE LOAD BALANCE GROUP

```

Note

If you supply a filter range that does not match any network addresses of the nodes in the fault groups, Vertica creates an empty load balancing group. Any routing rules that direct connections to the empty load balance group will fail, because no nodes are set to handle connections for the group. In this case, the node that the client connected to initially handles the client connection itself.

Creating load balance groups from subclusters

Creating a load balance group from a subcluster is similar to creating a load balance group from a fault group. You just use WITH SUBCLUSTER instead of WITH FAULT GROUP in the CREATE LOAD BALANCE GROUP statement.

```
=> SELECT node_name,node_address,node_address_family,subcluster_name
FROM v_catalog.nodes;
node_name | node_address | node_address_family | subcluster_name
-----+-----+-----+-----
v_verticadb_node0001 | 10.11.12.10 | ipv4 | load_subcluster
v_verticadb_node0002 | 10.11.12.20 | ipv4 | load_subcluster
v_verticadb_node0003 | 10.11.12.30 | ipv4 | load_subcluster
v_verticadb_node0004 | 10.11.12.40 | ipv4 | analytics_subcluster
v_verticadb_node0005 | 10.11.12.50 | ipv4 | analytics_subcluster
v_verticadb_node0006 | 10.11.12.60 | ipv4 | analytics_subcluster
(6 rows)
```

```
=> CREATE NETWORK ADDRESS node01 ON v_verticadb_node0001 WITH '10.11.12.10';
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS node02 ON v_verticadb_node0002 WITH '10.11.12.20';
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS node03 ON v_verticadb_node0003 WITH '10.11.12.30';
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS node04 ON v_verticadb_node0004 WITH '10.11.12.40';
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS node05 ON v_verticadb_node0005 WITH '10.11.12.50';
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS node06 ON v_verticadb_node0006 WITH '10.11.12.60';
CREATE NETWORK ADDRESS

=> CREATE LOAD BALANCE GROUP load_subcluster WITH SUBCLUSTER load_subcluster
FILTER '0.0.0.0/0';
CREATE LOAD BALANCE GROUP
=> CREATE LOAD BALANCE GROUP analytics_subcluster WITH SUBCLUSTER
analytics_subcluster FILTER '0.0.0.0/0';
CREATE LOAD BALANCE GROUP
```

Setting the group's distribution policy

A load balancing group has a policy setting that determines how the initially-contacted node chooses a target from the group. CREATE LOAD BALANCE GROUP supports three policies:

- ROUNDROBIN (default) rotates among the available members of the load balancing group. The initially-contacted node keeps track of which node it chose last time, and chooses the next one in the cluster.

Note

Each node in the cluster maintains its own round-robin pointer that indicates which node it should pick next for each load-balancing group. Therefore, if clients connect to different initial nodes, they may be redirected to the same node.

- RANDOM chooses an available node from the group randomly.
- NONE disables load balancing.

The following example demonstrates creating a load balancing group with a RANDOM distribution policy.

```
=> CREATE LOAD BALANCE GROUP group_random WITH ADDRESS node01, node02,
node03, node04 POLICY 'RANDOM';
CREATE LOAD BALANCE GROUP
```

The next step

After creating the load balancing group, you must add a load balancing routing rule that tells Vertica how incoming connections should be redirected to the groups. See [Creating load balancing routing rules](#).

Creating load balancing routing rules

Once you have created one or more connection load balancing groups, you are ready to create load balancing routing rules. These rules tell Vertica how to redirect client connections based on their IP addresses.

You create routing rules using the [CREATE ROUTING RULE](#) statement. You pass this statement:

- The name for the rule
- The source IP address range (either IPv4 or IPv6) in CIDR format the rule applies to
- The name of the load balancing group to handle the connection

The following example creates two rules. The first redirects connections coming from the IP address range 192.168.1.0 through 192.168.1.255 to a load balancing group named `group_1`. The second routes connections from the IP range 10.20.1.0 through 10.20.1.255 to the load balancing group named `group_2`.

```
=> CREATE ROUTING RULE internal_clients ROUTE '192.168.1.0/24' TO group_1;
CREATE ROUTING RULE

=> CREATE ROUTING RULE external_clients ROUTE '10.20.1.0/24' TO group_2;
CREATE ROUTING RULE
```

Creating a catch-all routing rule

Vertica applies routing rules in most specific to least specific order. This behavior lets you create a "catch-all" rule that handles all incoming connections. Then you can create rules to handle smaller IP address ranges for specific purposes. For example, suppose you wanted to create a catch-all rule that worked with the rules created in the previous example. Then you can create a new rule that routes 0.0.0.0/0 (the CIDR notation for all IP addresses) to a group that should handle connections that aren't handled by either of the previously-created rules. For example:

```
=> CREATE LOAD BALANCE GROUP group_all WITH ADDRESS node01, node02, node03, node04;
CREATE LOAD BALANCE GROUP

=> CREATE ROUTING RULE catch_all ROUTE '0.0.0.0/0' TO group_all;
CREATE ROUTING RULE
```

After running the above statements, any connection that does not originate from the IP address ranges 192.168.1.* or 10.20.1.* are routed to the `group_all` group.

Testing connection load balancing policies

After creating your routing rules, you should test them to verify that they perform the way you expect. The best way to test your rules is to call the [DESCRIBE_LOAD_BALANCE_DECISION](#) function with an IP address. This function evaluates the routing rules and reports back how Vertica would route a client connection from the IP address. It uses the same logic that Vertica uses when handling client connections, so the results reflect the actual connection load balancing result you will see from client connections. It also reflects the current state of the your Vertica cluster, so it will not redirect connections to down nodes.

The following example demonstrates testing a set of rules. One rule handles all connections from the range 192.168.1.0 to 192.168.1.255, while the other handles all connections originating from the 192 subnet. The third call demonstrates what happens when no rules apply to the IP address you supply.

```
=> SELECT describe_load_balance_decision('192.168.1.25');
        describe_load_balance_decision
```

```

No rules matched. Falling back to classic load balancing.

Classic load balance decision: Success. Load balance redirect to: [10.20.100.247] port [5433]

(1 row)

Note

The DESCRIBE_LOAD_BALANCE_DECISION function assumes the client connection has opted to be load balanced. In reality, clients may not enable load balancing. This setting prevents the load-balancing features from redirecting the connection.

The function can also help you debug connection issues you notice after going live with your load balancing policy. For example, if you notice that one node is handling a large number of client connections, you can test the client IP addresses against your policies to see why the connections are not being balanced.

Load balancing policy examples

The following examples demonstrate some common use cases for connection load balancing policies.

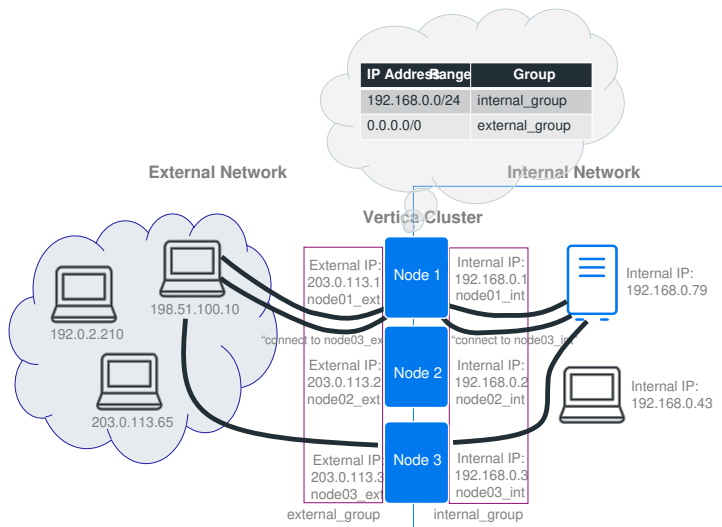

Enabling client connections from multiple networks

Suppose you have a Vertica cluster that is accessible from two (or more) different networks. Some examples of this situation are:

- You have an internal and an external network. In this configuration, your database nodes usually have two or more IP addresses, which each address only accessible from one of the networks. This configuration is common when running Vertica in a cloud environment. In many cases, you can create a catch-all rule that applies to all IP addresses, and then add additional routing rules for the internal subnets.
- You want clients to be load balanced whether they use IPv4 or IPv6 protocols. From the database's perspective, IPv4 and IPv6 connections are separate networks because each node has a separate IPv4 and IPv6 IP address.

When creating a load balancing policy for a database that is accessible from multiple networks, client connections must be directed to IP addresses on the network they can access. The best solution is to create load balancing groups for each set of IP addresses assigned to a node. Then create routing rules that redirect client connections to the IP addresses that are accessible from their network.

The following example:

1. Creates two sets of network addresses: one for the internal network and another for the external network.
2. Creates two load balance groups: one for the internal network and one for the external.
3. Creates three routing rules: one for the internal network, and two for the external. The internal routing rule covers a subset of the network covered by one of the external rules.
4. Tests the routing rules using internal and external IP addresses.

```
=> CREATE NETWORK ADDRESS node01_int ON v_vmart_node0001 WITH '192.168.0.1';

Isolating workloads

You may want to control which nodes in your cluster are used by specific types of clients. For example, you may want to limit clients that perform data-loading tasks to one set of nodes, and reserve the rest of the nodes for running queries. This separation of workloads is especially common for Eon Mode databases. See [Controlling Where a Query Runs](#) for an example of using load balancing policies in an Eon Mode database to control which subcluster a client connects to.

You can create client load balancing policies that support workload isolation if clients performing certain types of tasks always originate from a limited IP address range. For example, if the clients that load data into your system always fall into a specific subnet, you can create a policy that limits which nodes those clients can access.

In the following example:

- There are two fault groups (group_a and group_b) that separate workloads in an Eon Mode database. These groups are used as the basis of the load balancing groups.
- The ETL client connections all originate from the 203.0.113.0/24 subnet.
- User connections originate in the range of 192.0.0.0 to 199.255.255.255.

Enabling the default subcluster interior load balancing policy

Vertica attempts to apply the default subcluster interior load balancing policy if no other load balancing policy applies to an incoming connection and classic load balancing is not enabled. See [Default Subcluster Interior Load Balancing Policy](#) for a description of this rule.

To enable default subcluster interior load balancing, you must create network addresses for the nodes in a subcluster. Once you create the addresses, Vertica attempts to apply this rule to load balance connections within a subcluster when no other rules apply.

The following example confirms the database has no load balancing groups or rules. Then it adds publicly-accessible network addresses to the nodes in the primary subcluster. When these addresses are added, Vertica applies the default subcluster interior load balancing policy.

```

=> SELECT * FROM LOAD_BALANCE_GROUPS;
name | policy | filter | type | object_name

```

Load balance both IPv4 and IPv6 connections

Connection load balancing policies regard IPv4 and IPv6 connections as separate networks. To load balance both types of incoming client connections, create two sets of network addresses, at least two load balancing groups, and two load balancing , once for each network address family.

This example creates two load balancing policies for the default subcluster: one for the IPv4 network addresses (192.168.111.31 to 192.168.111.33) and one for the IPv6 network addresses (fd9b:1fcc:1dc4:78d3::31 to fd9b:1fcc:1dc4:78d3::33).

```

=> SELECT node_name,node_address,subcluster_name FROM NODES;
node_name | node_address | subcluster_name

Other examples

For other examples of using connection load balancing, see the following topics:

- [Using connection load balancing with the Kafka scheduler](#)
- [Distributing Clients Among the Throughput Subclusters](#)

Viewing load balancing policy configurations

Query the following system tables in the [V_CATALOG schema](#) to see the load balance policies defined in your database:

- [NETWORK_ADDRESSES](#) lists all of the network addresses defined in your database.
- [LOAD_BALANCE_GROUPS](#) lists the contents of your load balance groups.

Note

This table does not directly lists all of your database's load balance groups. Instead, it lists the contents of the load balance groups. It is possible for your database to have load balancing groups that are not in this table because they do not contain any network addresses or fault groups.

- [ROUTING_RULES](#) lists all of the routing rules defined in your database.

This example demonstrates querying each of the load balancing policy system tables.

```

Maintaining load balancing policies

Once you have created load balancing policies, you maintain them using the following statements:

- [ALTER NETWORK ADDRESS](#) lets you: rename, change the IP address, and enable or disable a network address.
- [ALTER LOAD BALANCE GROUP](#) lets you rename, add or remove network addresses or fault groups, change the fault group IP address filter, or change the policy of a load balance group.
- [ALTER ROUTING RULE](#) lets you rename, change the source IP address, and the target load balance group of a rule.

See the reference pages for these statements for examples.

Deleting load balancing policy objects

You can also delete existing load balance policy objects using the following statements:

- [DROP NETWORK ADDRESS](#)
- [DROP LOAD BALANCE GROUP](#)
- [DROP ROUTING RULE](#)

Workload routing

Workload routing routes client connections to [subclusters](#). This lets you reserve subclusters for certain types of tasks.

When a client connects to Vertica, they connect to a [Connection node](#), which then routes the client to the correct subcluster based on the client's specified workload, [user](#), or [role](#) and the database's [routing rules](#). If multiple subclusters are associated with the same workload, the client is randomly routed to one of those subclusters.

In this context, "routing" refers to the connection node acting as a proxy for the client and the [Execution node](#) in the target subcluster. All queries and query results are first sent to the connection node and then passed on to the execution node and client, respectively.

The primary advantages of this type of load balancing are as follows:

- Database administrators can associate certain subclusters with certain workloads and roles (as opposed to client IP addresses).
- Clients do not need to know anything about the subcluster they will be routed to, only the type of workload they have or the role they should use.

Workload routing depends on actions from both the database administrator and the client:

- The database administrator must create rules for handling various workloads.
- The client must either specify the type of workload they have or have an enabled role (either from a manual [SET ROLE](#) or [default role](#).) associated with a routing rule.

View the current workload

To view the workload associated with the current session, use [SHOW WORKLOAD](#):

```
=> SHOW WORKLOAD;
 name | setting
-----+-----
 workload | my_workload
(1 row)
```

Create workload routing rules

Routing rules apply to a client's specified workload and either user or role. If you specify more than one subcluster in a routing rule, the client is randomly routed to one of those subclusters.

If multiple routing rules could apply to a client's session, the rule with the highest priority is used. For details, see [Priorities](#).

To view existing routing rules, see [WORKLOAD_ROUTING_RULES](#).

To view workloads available to you and your [enabled roles](#), use [SHOW AVAILABLE WORKLOADS](#):

```
-> SHOW AVAILABLE WORKLOADS;
      name | setting
-----
available workloads | reporting, analytics
(1 row)
```

Workload-based routing

[Workload-based routing rules](#) apply to clients that specify a particular workload, routing them to one of the subclusters listed in the rule. In this example, when a client connects to the database and specifies the **analytics** workload, their connection is randomly routed to either **sc_analytics** or **sc_analytics_2**:

```
-> CREATE ROUTING RULE ROUTE WORKLOAD analytics TO SUBCLUSTER sc_analytics, sc_analytics_2;
```

To alter a routing rule, use [ALTER ROUTING RULE](#). For example, to route **analytics** workloads to **sc_analytics**:

```
-> ALTER ROUTING RULE FOR WORKLOAD analytics SET SUBCLUSTER TO sc_analytics;
```

To add or remove a subcluster, use [ALTER ROUTING RULE](#). For example:

1. To add a subcluster **sc_01**:

```
-> ALTER ROUTING RULE FOR WORKLOAD analytics ADD SUBCLUSTER sc_01;
```

2. To remove a subcluster **sc_01**:

```
-> ALTER ROUTING RULE FOR WORKLOAD analytics REMOVE SUBCLUSTER sc_01;
```

To drop a routing rule, use [DROP ROUTING RULE](#) and specify the workload. For example, to drop the routing rule for the **analytics** workload:

```
-> DROP ROUTING RULE FOR WORKLOAD analytics;
```

User- and role-based routing

You can [grant](#) USAGE privileges to a [user](#) or [role](#) to let them route their queries to one of the subclusters listed in the routing rule. In this example, when a client connects to the database and enables the **analytics_role** role, their connection is randomly routed to either **sc_analytics** or **sc_analytics_2**:

```
-> CREATE ROUTING RULE ROUTE WORKLOAD analytics TO SUBCLUSTER sc_analytics, sc_analytics_2;
-> GRANT USAGE ON ROUTING RULE analytics TO analytics_role;
```

Users can then [enable](#) the role and set their workload to **analytics** for the session:

```
-> SET ROLE analytics_role;
-> SET SESSION WORKLOAD analytics;
```

Users can also enable the role automatically by setting it as a default role and then specify the workload when they connect. For details on default roles, see [Enabling roles automatically](#).

Similarly, in this example, when a client connects to the database as user **analytics_user**, they are randomly routed to either **sc_analytics** or **sc_analytics_2**:

```
-> CREATE ROUTING RULE ROUTE WORKLOAD analytics TO SUBCLUSTER sc_analytics, sc_analytics_2;
-> GRANT USAGE ON ROUTING RULE analytics TO analytics_user;
```

Priorities

Only one workload routing rule can apply to a session at any given time. If multiple routing rules are [granted](#) to a user or role, the priority associated with the rule determines which one applies. If multiple rules have the highest priority, Vertica chooses one of those rules randomly.

You can force a routing rule to apply to your session, ignoring priority, by using [SET SESSION WORKLOAD](#).

In this example, the user Gunther is granted usage on the routing rule for workload **reporting** . The following statement does not specify a priority, so the priority defaults to 0:

```
=> GRANT USAGE ON WORKLOAD reporting TO Gunther;
```

Gunther also has the roles **analytics_role** and **qa_role** , each of which are granted their own routing rules:

```
=> GRANT USAGE ON WORKLOAD analytics TO analytics_role;
=> GRANT USAGE ON WORKLOAD qa TO qa_role;
```

When Gunther first connects to Vertica, the routing rule for **reporting** applies. If Gunther then [enables](#) the **analytics_role** and **qa_role** , the routing rule for **qa_role** applies instead because it has the greatest priority value.

Similarly, if the priority of the routing rule for **reporting** is changed to 3 with [ALTER ROUTING RULE](#) , that rule applies instead:

```
=> ALTER ROUTING RULE FOR WORKLOAD reporting SET PRIORITY TO 3;
```

To ignore priorities and force the session to use the **analytics** rule, Gunther can use [SET SESSION WORKLOAD](#) :

```
=> SET SESSION WORKLOAD analytics;
```

Specify a workload

The workload for a given connection can be reported by the client when they connect. The method for specifying a workload depends on the client.

The following examples set the workload to **analytics** for several clients. After you connect, you can verify that the workload was set with [SHOW WORKLOAD](#) .

[vsq](#) uses **--workload** :

```
$ vsq --dbname databaseName --host node01.example.com --username Bob --password my_pwd --workload analytics
```

[JDBC](#) uses **workload** :

```
jdbc:vertica://node01.example.com:5443/databaseName?user=analytics_user&password=***&workload=analytics
```

[ODBC](#) uses **Workload** :

```
Database=databaseName;Servername=node01.mydomain.com;Port=5433;UID=analytics_user;PWD=***;Workload=analytics
```

[ADO.NET](#) uses **Workload** :

```
Database=databaseName;Host=node01.mydomain.com;Port=5433;User=analytics_user;Password=***;Workload=analytics
```

[vertica-sql-go](#) uses **Workload** :

```
var query = url.URL{
    Scheme: "vertica",
    User:   url.UserPassword(user, password),
    Host:   fmt.Sprintf("%s:%d", host, port),
    Path:   databaseName,
    Workload: "analytics",
    RawQuery: rawQuery.Encode(),
}
```

[vertica-python](#) uses **workload** :

```
conn_info = {'host': '127.0.0.1',
            'port': 5433,
            'user': 'some_user',
            'password': 'my_pwd',
            'database': 'databaseName',
            'workload': 'analytics',
            # autogenerated session label by default,
            'session_label': 'some_label',
            # default throw error on invalid UTF-8 results
            'unicode_error': 'strict',
            # SSL is disabled by default
            'ssl': False,
            # autocommit is off by default
            'autocommit': True,
            # using server-side prepared statements is disabled by default
            'use_prepared_statements': False,
            # connection timeout is not enabled by default
            # 5 seconds timeout for a socket operation (Establishing a TCP connection or read/write operation)
            'connection_timeout': 5}
```

[vertica-nodejs](#) uses **workload** :

```
const client = new Client({
  user: "vertica_user",
  host: "node01.example.com",
  database: "verticadb",
  password: "",
  port: "5433",
  workload: "analytics",
})
```

Clients can also change their workload type after they connect with [SET SESSION WORKLOAD](#) :

```
-> SET SESSION WORKLOAD my_workload;
```

Projections

Unlike traditional databases that store data in tables, Vertica physically stores table data in [projections](#), which are collections of table columns.

Projections store data in a format that optimizes query execution. Similar to materialized views, they store result sets on disk rather than compute them each time they are used in a query. Vertica automatically refreshes these result sets with updated or new data.

Projections provide the following benefits:

- Compress and encode data to reduce storage space. Vertica also operates on the encoded data representation whenever possible to avoid the cost of decoding. This combination of compression and encoding optimizes disk space while maximizing query performance.
- Facilitate distribution across the database cluster. Depending on their size, projections can be segmented or replicated across cluster nodes. For instance, projections for large tables can be segmented and distributed across all nodes. Unsegmented projections for small tables can be replicated across all nodes.
- Transparent to end-users. The Vertica query optimizer automatically picks the best projection to execute a given query.
- Provide high availability and recovery. Vertica duplicates table columns on at least K+1 nodes in the cluster. If one machine fails in a [K-Safe](#) environment, the database continues to operate using replicated data on the remaining nodes. When the node resumes normal operation, it automatically queries other nodes to recover data and lost objects. For more information, see [High availability with fault groups](#) and [High availability with projections](#).

In this section

- [Projection types](#)
- [Creating projections](#)
- [Projection naming](#)
- [Auto-projections](#)
- [Unsegmented projections](#)
- [Segmented projections](#)
- [K-safe database projections](#)

- [Partition range projections](#)
- [Refreshing projections](#)
- [Dropping projections](#)

Projection types

A Vertica table typically has multiple projections, each defined to contain different content. Content for the projections of a given table can differ in scope and organization. These differences can generally be divided into the following projection types:

- [Superprojections](#)
- [Query-specific projections](#)
- [Aggregate projections](#)

Superprojections

For each table in the database, Vertica requires at least one superprojection that contains all columns in the table. In the absence of a query-specific projection, Vertica uses the table's superprojection, which can support any query and DML operation.

Under certain conditions, Vertica [automatically creates a table's superprojection](#) immediately on table creation. Vertica also creates a superprojection when you first load data into that table, if none already exists. [CREATE PROJECTION](#) can create a superprojection if it specifies to include all table columns. A table can have multiple superprojections.

While superprojections can support all queries on a table, they do not facilitate optimal execution of specific queries.

Query-specific projections

A query-specific projection is a projection that contains only the subset of table columns needed to process a given query. Query-specific projections significantly improve performance of queries for which they are optimized.

Aggregate projections

Queries that include expressions or aggregate functions, such as [SUM](#) and [COUNT](#), can perform more efficiently when using projections that already contain the aggregated data. This is especially true for queries on large quantities of data.

Vertica provides several types of projections for storing data that is returned from aggregate functions or expressions:

- [Live aggregate projection](#): Projection that contains columns with values that are aggregated from columns in its anchor table. You can also define live aggregate projections that include [user-defined transform functions](#).
- [Top-K projection](#): Type of live aggregate projection that returns the top *k* rows from a partition of selected rows. Create a Top-K projection that satisfies the criteria for a Top-K query.
- [Projection that pre-aggregates UDTF results](#): Live aggregate projection that invokes user-defined transform functions (UDTFs). To minimize overhead when you query those projections of this type, Vertica processes the UDTF functions in the background and stores their results on disk.
- [Projection that contains expressions](#): Projection with columns whose values are calculated from anchor table columns.

For more information, see [Pre-aggregating data in projections](#).

Creating projections

Vertica supports two methods for creating projections: Database Designer and the `CREATE PROJECTION` statement.

Creating projections with Database Designer

Vertica recommends that you use Database Designer to design your physical schema, by running it on a representative sample of your data. Database Designer generates SQL for creating projections as follows:

1. Analyzes your [logical schema](#), sample data, and sample queries (optional).
2. Designs a [physical schema](#) in the form of a SQL script that you can deploy automatically or manually.

For more information, see [Creating a database design](#).

Manually creating projections

[CREATE PROJECTION](#) defines a projection, as in the following example:

```
=> CREATE PROJECTION retail_sales_fact_p (
  store_key ENCODING RLE,
  pos_transaction_number ENCODING RLE,
  sales_dollar_amount,
  cost_dollar_amount )
AS SELECT
  store_key,
  pos_transaction_number,
  sales_dollar_amount,
  cost_dollar_amount
FROM store.store_sales_fact
ORDER BY store_key
SEGMENTED BY HASH(pos_transaction_number) ALL NODES;
```

A projection definition includes the following components:

- [Column List and Encoding](#)
- [Base Query](#)
- [Sort Order](#)
- [Segmentation](#)

Column list and encoding

This portion of the SQL statement lists every column in the projection and defines the encoding for each column. Vertica supports encoded data, which helps query execution to incur less disk I/O.

```
CREATE PROJECTION retail_sales_fact_P (
  store_key ENCODING RLE,
  pos_transaction_number ENCODING RLE,
  sales_dollar_amount,
  cost_dollar_amount )
```

Base query

A projection's base query clause identifies which columns to include in the projection.

```
AS SELECT
  store_key,
  pos_transaction_number,
  sales_dollar_amount,
  cost_dollar_amount
```

Sort order

A projection's **ORDER BY** clause determines how to sort projection data. The sort order localizes logically grouped values so a disk read can identify many results at once. For maximum performance, do not sort projections on LONG VARBINARY and LONG VARCHAR columns. For more information see [ORDER BY clause](#).

```
ORDER BY store_key
```

Segmentation

A projection's segmentation clause specifies how to distribute projection data across all nodes in the database. Even load distribution helps maximize access to projection data. For large tables, distribute projection data in segments with **SEGMENTED BY HASH**. For example:

```
SEGMENTED BY HASH(pos_transaction_number) ALL NODES;
```

For small tables, use the **UNSEGMENTED** keyword to replicate table data. Vertica creates identical copies of an unsegmented projection on all cluster nodes. Replication ensures high availability and recovery.

For maximum performance, do not segment projections on LONG VARBINARY and LONG VARCHAR columns.

For more design considerations, see [Creating custom designs](#).

Projection naming

Vertica identifies projections according to the following conventions, where *proj-basename* is the name assigned to this projection by [CREATE PROJECTION](#).

Unsegmented projections

Unsegmented projections conform to the following naming conventions:

<i>proj-basename</i> <i>_super</i>	The auto projection that Vertica creates when data is loaded for the first time into a new unsegmented table. Vertica uses the anchor table name to create the projection base name <i>proj-basename</i> and appends the string <i>_super</i> . The auto projection is always a superprojection.
<i>proj-basename</i> <i>_unseg</i>	An unsegmented projection, where <i>proj-basename</i> and the anchor table name are identical. If no other projection was previously created with this base name (including an auto projection), Vertica appends the string <i>_unseg</i> to the projection name. If the projection is copied on all nodes, this projection name maps to all instances.

Segmented projections

Enterprise Mode

In Enterprise Mode, segmented projections use the following naming convention:

```
proj-basename_offset
```

This name identifies buddy projections for a segmented projection, where *offset* is the projection's node location relative to all other buddy projections. All buddy projections share the same project base name. For example:

```
=> SELECT projection_basename, projection_name FROM projections WHERE anchor_table_name = 'store_orders';
projection_basename | projection_name
-----+-----
store_orders      | store_orders_b0
store_orders      | store_orders_b1
(2 rows)
```

One exception applies: Vertica uses the following convention to name live aggregate projections: *proj-basename*, *proj-basename_b1*, and so on.

Eon Mode

In Eon Mode, segmented projections use the following naming convention:

```
proj-basename
```

Note

Eon Mode uses shards in communal storage to segment table data, which are functionally equivalent to Enterprise Mode buddy projections. For details, see [Namespaces and shards](#).

Projections of renamed and copied tables

Vertica uses the same logic to rename existing projections in two cases:

- You rename a table with [ALTER TABLE...RENAME TABLE](#).
- You create a table from an existing one with [CREATE TABLE LIKE...INCLUDING PROJECTIONS](#).

In both cases, Vertica uses the following algorithm to rename projections:

- Iterate over all projections anchored on the renamed or new table, and check whether their names are prefixed by the original table name:
 - No: Retain projection name
 - Yes: Rename projection
- If yes, compare the original table name and projection base name:
 - If the new base name is the same as the original table name, then replace the base name with the new table name in the table and projection names.
 - If the new base name is prefixed by the original table name, then replace the prefix with the new table name, remove any version strings that were appended to the old base name (such as *old-basename_v1*), and generate projection names with the new base name.
- Check whether the new projection names already exist. If not, save them. Otherwise, resolve name conflicts by appending version numbers as needed to the new base name— *new-basename_v1*, *new-basename_v2*, and so on.

Examples

An auto projection is always a superprojection:

```
=> CREATE TABLE store.store_dimension
  store_key int NOT NULL,
  store_name varchar(64),
  ...
) UNSEGMENTED ALL NODES;
CREATE TABLE
=> COPY store.store_dim FROM '/home/dbadmin/store_dimension_data.txt';
50
=> SELECT anchor_table_name, projection_basename, projection_name FROM projections WHERE anchor_table_name = 'store_dimension';
anchor_table_name | projection_basename | projection_name
-----+-----+-----
store_dimension | store_dimension | store_dimension_super
store_dimension | store_dimension | store_dimension_super
store_dimension | store_dimension | store_dimension_super
(3 rows)
```

An unsegmented projection name has the `_unseg` suffix on all nodes:

```
=> CREATE TABLE store.store_dimension(
  store_key int NOT NULL,
  store_name varchar(64),
  ...
);
CREATE TABLE
=> CREATE PROJECTION store_dimension AS SELECT * FROM store.store_dimension UNSEGMENTED ALL NODES;
WARNING 6922: Projection name was changed to store_dimension_unseg because it conflicts with the basename of the table store_dimension
CREATE PROJECTION
=> SELECT anchor_table_name, projection_basename, projection_name FROM projections WHERE anchor_table_name = 'store_dimension';
anchor_table_name | projection_basename | projection_name
-----+-----+-----
store_dimension | store_dimension | store_dimension_unseg
store_dimension | store_dimension | store_dimension_unseg
store_dimension | store_dimension | store_dimension_unseg
(3 rows)
```

The following example creates the segmented table `testRenameSeg` and populates it with data:

```
=> CREATE TABLE testRenameSeg (a int, b int);
CREATE TABLE
dbadmin=> INSERT INTO testRenameSeg VALUES (1,2);
OUTPUT
-----
  1
(1 row)

dbadmin=> COMMIT;
COMMIT
```

Vertica automatically creates two buddy superprojections for this table:

```
=> \dj testRename*
      List of projections
Schema | Name | Owner | Node | Comment
-----+-----+-----+-----+-----
public | testRenameSeg_b0 | dbadmin | |
public | testRenameSeg_b1 | dbadmin | |
```

The following `CREATE PROJECTION` statements explicitly create additional projections for the table:

```
=> CREATE PROJECTION nameTestRenameSeg_p AS SELECT * FROM testRenameSeg;
=> CREATE PROJECTION testRenameSeg_p AS SELECT * FROM testRenameSeg;
=> CREATE PROJECTION testRenameSeg_pLap AS SELECT b, MAX(a) a FROM testRenameSeg GROUP BY b;
=> CREATE PROJECTION newTestRenameSeg AS SELECT * FROM testRenameSeg;
=> \dj *testRenameSeg*
```

```
List of projections
Schema | Name | Owner | Node | Comment
-----+-----+-----+-----+-----
public | nameTestRenameSeg_p_b0 | dbadmin | |
public | nameTestRenameSeg_p_b1 | dbadmin | |
public | newTestRenameSeg_b0 | dbadmin | |
public | newTestRenameSeg_b1 | dbadmin | |
public | testRenameSeg_b0 | dbadmin | |
public | testRenameSeg_b1 | dbadmin | |
public | testRenameSeg_pLap | dbadmin | |
public | testRenameSeg_pLap_b1 | dbadmin | |
public | testRenameSeg_p_b0 | dbadmin | |
public | testRenameSeg_p_b1 | dbadmin | |
(10 rows)
```

If you rename the anchor table, Vertica also renames its projections:

```
=> ALTER TABLE testRenameSeg RENAME TO newTestRenameSeg;
ALTER TABLE=> \dj *testRenameSeg*
```

```
List of projections
Schema | Name | Owner | Node | Comment
-----+-----+-----+-----+-----
public | nameTestRenameSeg_p_b0 | dbadmin | |
public | nameTestRenameSeg_p_b1 | dbadmin | |
public | newTestRenameSeg_b0 | dbadmin | |
public | newTestRenameSeg_b1 | dbadmin | |
public | newTestRenameSeg_pLap_b0 | dbadmin | |
public | newTestRenameSeg_pLap_b1 | dbadmin | |
public | newTestRenameSeg_p_b0 | dbadmin | |
public | newTestRenameSeg_p_b1 | dbadmin | |
public | newTestRenameSeg_v1_b0 | dbadmin | |
public | newTestRenameSeg_v1_b1 | dbadmin | |
(10 rows)
```

Two sets of buddy projections are not renamed, as their names are not prefixed by the original table name:

- [nameTestRenameSeg_p_b0](#)
- [nameTestRenameSeg_p_b1](#)
- [newTestRenameSeg_b0](#)
- [newTestRenameSeg_b1](#)

When renaming the other projections, Vertica identified a potential conflict between the table's superprojection—originally [testRenameSeg](#)—and existing projection [newTestRenameSeg](#). It resolved this conflict by appending version numbers [_v1](#) and [_v2](#) to the superprojection's new name:

- [newTestRenameSeg_v1_b0](#)
- [newTestRenameSeg_v1_b1](#)

Auto-projections

Auto-projections are [superprojections](#) that Vertica automatically generates for tables, both temporary and persistent. In general, if no projections have been defined for a table, Vertica automatically creates projections for that table when you first load data into it. The following rules apply to all auto-projections:

- Vertica creates the auto-projection in the same schema as the table.
- Auto-projections conform to encoding, sort order, segmentation, and K-safety as specified in the table's creation statement.
- If the table creation statement contains an [AS SELECT](#) clause, Vertica uses some properties of the projection definition's underlying query.

Auto-projection triggers

The conditions for creating auto-projections differ, depending on whether the table is temporary or persistent:

Table type	Auto-projection trigger
Temporary	CREATE TEMPORARY TABLE statement, unless it includes NO PROJECTION .
Persistent	<p>CREATE TABLE statement contains one of these clauses:</p> <ul style="list-style-type: none"> • AS SELECT • ENCODED BY • ORDER BY • SEGMENTED BY / UNSEGMENTED • KSAFE <p>If none of these conditions are true, Vertica automatically creates a superprojection (if one does not already exist) when you first load data into the table with INSERT or COPY .</p>

Default segmentation and sort order

If **CREATE TABLE** or **CREATE TEMPORARY TABLE** omits a segmentation (**SEGMENTED BY** or **UNSEGMENTED**) or **ORDER BY** clause, Vertica segments and sorts auto-projections as follows:

1. If the table creation statement omits a segmentation ([SEGMENTED BY](#) or **UNSEGMENTED**) clause, Vertica checks configuration parameter **SegmentAutoProjection** to determine whether to create an auto projection that is segmented or unsegmented. By default, this parameter is set to 1 (enable).
2. If **SegmentAutoProjection** is enabled and a table's creation statement also omits an **ORDER BY** clause, Vertica segments and sorts the table's auto-projection according to the table's manner of creation:
 - If **CREATE [TEMPORARY] TABLE** contains an [AS SELECT](#) clause and the query output is segmented, the auto-projection uses the same segmentation. If the result set is already sorted, the projection uses the same sort order.
 - In all other cases, Vertica evaluates table column constraints to determine how to sort and segment the projection, as shown below:

Constraints	Sorted by:	Segmented by:
Primary key	Primary key	Primary key
Primary and foreign keys	<ol style="list-style-type: none"> 1. Foreign keys 2. Primary key 	Primary key
Foreign keys only	<ol style="list-style-type: none"> 1. Foreign keys 2. Remaining columns excluding LONG data types , up to the limit set in configuration parameter MaxAutoSortColumns (by default 8). 	<p>All columns excluding LONG data types , up to the limit set in configuration parameter MaxAutoSegColumns (by default 8).</p> <p>Vertica orders segmentation as follows:</p>
None	All columns excluding LONG data types , in the order specified by CREATE TABLE .	<div style="border: 1px solid black; padding: 5px;"> <ol style="list-style-type: none"> 1. Small (≤ 8 byte) data type columns: Columns are specified in the same order as they are defined in the table CREATE statement. 1. Large (> 8 byte) data type columns: Columns are ordered by ascending size. </div>

For example, the following table is defined with no primary or foreign keys:

```
=> CREATE TABLE testAutoProj(c10 char (10), v1 varchar(140) DEFAULT v2||v3, i int, c5 char(5), v3 varchar (80), d timestamp, v2 varchar(60), c1 char(1));
CREATE TABLE
=> INSERT INTO testAutoProj VALUES
('1234567890',
DEFAULT,
1,
'abcde',
'Lorem ipsum dolor sit amet, consectetur adipiscing elit, sed do eiusmod tempor ',
current_timestamp,
'incididunt ut labore et dolore magna aliqua. Eu scelerisque',
'a');
OUTPUT
-----
1
(1 row)
=> COMMIT;
COMMIT
```

Before the INSERT statement loads data into this table for the first time, Vertica automatically creates a superprojection for the table:

```
=> SELECT export_objects("", 'testAutoProj_b0');
-----
CREATE PROJECTION public.testAutoProj_b0 /*+basename(testAutoProj),createtype(L)*/
(c10, v1, i, c5, v3, d, v2, c1 )
AS
SELECT testAutoProj.c10,
testAutoProj.v1,
testAutoProj.i,
testAutoProj.c5,
testAutoProj.v3,
testAutoProj.d,
testAutoProj.v2,
testAutoProj.c1
FROM public.testAutoProj
ORDER BY testAutoProj.c10,
testAutoProj.v1,
testAutoProj.i,
testAutoProj.c5,
testAutoProj.v3,
testAutoProj.d,
testAutoProj.v2,
testAutoProj.c1
SEGMENTED BY hash(testAutoProj.i, testAutoProj.c5, testAutoProj.d, testAutoProj.c1, testAutoProj.c10, testAutoProj.v2, testAutoProj.v3, testAutoProj.v1)
ALL NODES OFFSET 0;

SELECT MARK_DESIGN_KSAFE(1);

(1 row)
```

Unsegmented projections

In many cases, dimension tables are relatively small, so you do not need to segment them. Accordingly, you should design a K-safe database so projections for its dimension tables are replicated without segmentation on all cluster nodes. You create unsegmented projections with a [CREATE PROJECTION](#) statement that includes the clause **UNSEGMENTED ALL NODES** . This clause specifies to create identical instances of the projection on all cluster nodes.

The following example shows how to create an unsegmented projection for the table `store.store_dimension` :

```
=> CREATE PROJECTION store.store_dimension_proj (storekey, name, city, state)
      AS SELECT store_key, store_name, store_city, store_state
      FROM store.store_dimension
      UNSEGMENTED ALL NODES;
CREATE PROJECTION
```

Vertica uses the same name to identify all instances of the unsegmented projection—in this example, `store.store_dimension_proj`. The keyword **ALL NODES** specifies to replicate the projection on all nodes:

```
=> \dj store.store_dimension_proj
      List of projections
Schema |      Name      | Owner | Node      | Comment
-----+-----+-----+-----+-----
store  | store_dimension_proj | dbadmin | v_vmart_node0001 |
store  | store_dimension_proj | dbadmin | v_vmart_node0002 |
store  | store_dimension_proj | dbadmin | v_vmart_node0003 |
(3 rows)
```

For more information about projection name conventions, see [Projection naming](#).

Segmented projections

You typically create segmented projections for large fact tables. Vertica splits segmented projections into chunks (segments) of similar size and distributes these segments evenly across the cluster. System K-safety determines how many duplicates (*buddies*) of each segment are created and maintained on different nodes.

Projection segmentation achieves the following goals:

- Ensures high availability and recovery.
- Spreads the query execution workload across multiple nodes.
- Allows each node to be optimized for different query workloads.

Hash Segmentation

Vertica uses hash segmentation to segment large projections. Hash segmentation allows you to segment a projection based on a built-in hash function that provides even distribution of data across multiple nodes, resulting in optimal query execution. In a projection, the data to be hashed consists of one or more column values, each having a large number of unique values and an acceptable amount of skew in the value distribution. Primary key columns typically meet these criteria, so they are often used as hash function arguments.

You create segmented projections with a [CREATE PROJECTION](#) statement that includes a [SEGMENTED BY clause](#).

The following **CREATE PROJECTION** statement creates projection `public.employee_dimension_super`. It specifies to include all columns in table `public.employee_dimension`. The hash segmentation clause invokes the Vertica **HASH** function to segment projection data on the column `employee_key`; it also includes the **ALL NODES** clause, which specifies to distribute projection data evenly across all nodes in the cluster:

```
=> CREATE PROJECTION public.employee_dimension_super
      AS SELECT * FROM public.employee_dimension
      ORDER BY employee_key
      SEGMENTED BY hash(employee_key) ALL NODES;
```

If the database is K-safe, Vertica creates multiple buddies for this projection and distributes them on different nodes across the cluster. In this case, database K-safety is set to 1, so Vertica creates two buddies for this projection. It uses the projection name `employee_dimension_super` as the basename for the two buddy identifiers it creates—in this example, `employee_dimension_super_b0` and `employee_dimension_super_b1`:

```
=> SELECT projection_name FROM projections WHERE projection_basename='employee_dimension_super';
      projection_name
-----
employee_dimension_super_b0
employee_dimension_super_b1
(2 rows)
```

K-safe database projections

K-safety is implemented differently for segmented and unsegmented projections, as described below. Examples assume database K-safety is set to 1 in a 3-node database, and uses projections for two tables:

- `store.store_orders_fact` is a large fact table. The projection for this table should be segmented. Vertica distributes projection segments uniformly across the cluster.
- `store.store_dimension` is a smaller dimension table. The projection for this table should be unsegmented. Vertica copies a complete instance of this projection on each cluster node.

Segmented projections

In a K-safe database, the database requires K+1 instances, or buddies, of each projection segment. For example, if database K-safety is set to 1, the database requires two instances, or buddies, of each projection segment.

You can set K-safety on individual segmented projections through the `CREATE PROJECTION` option `KSAFE`. Projection K-safety must be equal to or greater than database K-safety. If you omit setting `KSAFE`, the projection obtains K-safety from the database.

The following `CREATE PROJECTION` defines a segmented projection for the fact table `store.store_orders_fact`:

```
=> CREATE PROJECTION store.store_orders_fact
      (prodkey, ordernum, storekey, total)
      AS SELECT product_key, order_number, store_key, quantity_ordered*unit_price
      FROM store.store_orders_fact
      SEGMENTED BY HASH(product_key, order_number) ALL NODES KSAFE 1;
CREATE PROJECTION
```

The following keywords in the `CREATE PROJECTION` statement pertain to setting projection K-safety:

SEGMENTED BY	Specifies how to segment projection data for distribution across the cluster. In this example, the segmentation expression specifies Vertica's built-in <code>HASH</code> function.
ALL NODES	Specifies to distribute projection segments across all cluster nodes.
K-SAFE 1	Sets K-safety to 1. Vertica creates two projection buddies with these identifiers: <ul style="list-style-type: none">• <code>store.store_orders_fact_b0</code>• <code>store.store_orders_fact_b1</code>

Unsegmented projections

In a K-safe database, unsegmented projections must be replicated on all nodes. Thus, the `CREATE PROJECTION` statement for an unsegmented projection must include the segmentation clause `UNSEGMENTED ALL NODES`. This instructs Vertica to create identical instances (buddies) of the projection on all cluster nodes. If you create an unsegmented projection on a single node, Vertica regards it unsafe and does not use it.

The following example shows how to create an unsegmented projection for the table `store.store_dimension`:

```
=> CREATE PROJECTION store.store_dimension_proj (storekey, name, city, state)
      AS SELECT store_key, store_name, store_city, store_state
      FROM store.store_dimension
      UNSEGMENTED ALL NODES;
CREATE PROJECTION
```

Vertica uses the same name to identify all instances of the unsegmented projection—in this example, `store.store_dimension_proj`. The keyword `ALL NODES` specifies to replicate the projection on all nodes:

```

=> \dj store.store_dimension_proj
      List of projections
Schema |      Name      | Owner |      Node      | Comment
-----+-----+-----+-----+-----
store | store_dimension_proj | dbadmin | v_vmart_node0001 |
store | store_dimension_proj | dbadmin | v_vmart_node0002 |
store | store_dimension_proj | dbadmin | v_vmart_node0003 |
(3 rows)

```

For more information about projection name conventions, see [Projection naming](#).

Partition range projections

Vertica supports projections that specify a range of partition keys. By default, projections store all rows of partitioned table data. Over time, this requirement can incur increasing overhead:

- As data accumulates, increasing amounts of storage are required for large amounts of data that are queried infrequently, if at all.
- Large projections can deter optimizations such as better encodings, or changes to the projection sort order or segmentation. Changes to the projection's DDL like these require you to refresh the entire projection. Depending on the projection size, this refresh operation might span hours or even days.

You can minimize these problems by creating projections for partitioned tables that specify a relatively narrow range of partition keys. For example, the table `store_orders` is partitioned on `order_date`, as follows:

```

=> CREATE TABLE public.store_orders(order_no int, order_date timestamp NOT NULL, shipper varchar(20), ship_date date);
CREATE TABLE
=> ALTER TABLE store_orders PARTITION BY order_date::DATE GROUP BY date_trunc('month', (order_date)::DATE);
ALTER TABLE

```

If desired, you can create a projection of `store_orders` that specifies a contiguous range of the table's partition keys. In the following example, the projection `ytd_orders` specifies to include only orders that were placed since the first day of the year:

```

=> CREATE PROJECTION ytd_orders AS SELECT * FROM store_orders ORDER BY order_date
  ON PARTITION RANGE BETWEEN date_trunc('year',now())::date AND NULL;
WARNING 4468: Projection <public.ytd_orders_b0> is not available for query processing. Execute the select start_refresh() function to copy data into this projection.
  The projection must have a sufficient number of buddy projections and all nodes must be up before starting a refresh
WARNING 4468: Projection <public.ytd_orders_b1> is not available for query processing. Execute the select start_refresh() function to copy data into this projection.
  The projection must have a sufficient number of buddy projections and all nodes must be up before starting a refresh
CREATE PROJECTION
=> SELECT refresh();

          refresh
-----
Refresh completed with the following outcomes:
Projection Name: [Anchor Table] [Status] [Refresh Method] [Error Count] [Duration (sec)]
-----
"public"."ytd_orders_b1": [store_orders] [refreshed] [scratch] [0] [0]
"public"."ytd_orders_b0": [store_orders] [refreshed] [scratch] [0] [0]
(1 row)

```

Each `ytd_orders` buddy projection requires only 7 ROS containers per node, versus the 77 containers required by the anchor table's superprojection:

```
=> SELECT COUNT (DISTINCT ros_id) NumROS, projection_name, node_name FROM PARTITIONS WHERE projection_name ilike 'store_orders_b%'
GROUP BY node_name, projection_name ORDER BY node_name;
```

```
NumROS | projection_name | node_name
```

```
+-----+-----+-----
```

```
77 | store_orders_b0 | v_vmart_node0001
77 | store_orders_b1 | v_vmart_node0001
77 | store_orders_b0 | v_vmart_node0002
77 | store_orders_b1 | v_vmart_node0002
77 | store_orders_b0 | v_vmart_node0003
77 | store_orders_b1 | v_vmart_node0003
```

```
(6 rows)
```

```
=> SELECT COUNT (DISTINCT ros_id) NumROS, projection_name, node_name FROM PARTITIONS WHERE projection_name ilike 'ytd_orders%' GROUP
BY node_name, projection_name ORDER BY node_name;
```

```
NumROS | projection_name | node_name
```

```
+-----+-----+-----
```

```
7 | ytd_orders_b0 | v_vmart_node0001
7 | ytd_orders_b1 | v_vmart_node0001
7 | ytd_orders_b0 | v_vmart_node0002
7 | ytd_orders_b1 | v_vmart_node0002
7 | ytd_orders_b0 | v_vmart_node0003
7 | ytd_orders_b1 | v_vmart_node0003
```

```
(6 rows)
```

Partition range requirements

Partition range expressions must conform with requirements that apply to [table-level partitioning](#)—for example, partition key format and data type validation.

The following requirements and constraints specifically apply to partition range projections:

- The anchor table must already be partitioned.
- Partition range expressions must be compatible with the table's partition expression.
- The first range expression must resolve to a partition key that is smaller or equal to the second expression.
- If the projection is unsegmented, at least one superprojection of the anchor table must also be unsegmented. If not, Vertica adds the projection to the database catalog, but throws a warning that this projection cannot be used to process queries until you create an unsegmented superprojection.
- Partition range expressions do not support subqueries.

Anchor table dependencies

As noted earlier, a partition range projection depends on the anchor table being partitioned on the same expression. If you remove table partitioning from the projection's anchor table, Vertica drops the dependent projection. Similarly, if you modify the anchor table's partition clause, Vertica drops the projection.

The following exception applies: if the anchor table's new partition clause leaves the partition expression unchanged, the dependent projection is not dropped and remains available for queries. For example, the table `store_orders` and its projection `ytd_orders` were originally partitioned as follows:

```
=> ALTER TABLE store_orders PARTITION BY order_date::DATE GROUP BY DATE_TRUNC('month', (order_date)::DATE);
```

```
...
```

```
=> CREATE PROJECTION ytd_orders AS SELECT * FROM store_orders ORDER BY order_date
ON PARTITION RANGE BETWEEN date_trunc('year',now())::date AND NULL;
```

If you now modify `store_orders` to use hierarchical partitioning, Vertica repartitions the table data as well as its partition range projection:

```
=> ALTER TABLE store_orders PARTITION BY order_date::DATE GROUP BY CALENDAR_HIERARCHY_DAY(order_date::DATE, 2, 2) REORGANIZE;
NOTICE 4785: Started background repartition table task
ALTER TABLE
```

Because both `store_orders` and the `ytd_orders` projection remain partitioned on the `order_date` column, the `ytd_orders` projection remains valid. Also, the scope of projection data remains unchanged, so the projection requires no refresh. However, in the background, the Tuple Mover silently reorganizes the projection ROS containers as per the new hierarchical partitioning of its anchor table:

```
=> SELECT COUNT (DISTINCT ros_id) NumROS, projection_name, node_name FROM PARTITIONS WHERE projection_name ilike 'ytd_orders%' GROUP BY node_name, projection_name ORDER BY node_name;
```

```
NumROS | projection_name | node_name
```

```
+-----+-----+-----+
38 | ytd_orders_b0 | v_vmart_node0001
38 | ytd_orders_b1 | v_vmart_node0001
38 | ytd_orders_b0 | v_vmart_node0002
38 | ytd_orders_b1 | v_vmart_node0002
38 | ytd_orders_b0 | v_vmart_node0003
38 | ytd_orders_b1 | v_vmart_node0003
```

```
(6 rows)
```

Modifying existing projections

You can modify the partition range of a projection with [ALTER PROJECTION](#). No refresh is required if the new range is within the previous range. Otherwise, a refresh is required before the projection reflects the modified partition range. Prior to refreshing, the projection continues to return data within the unmodified range.

For example, projection `ytd_orders` [previously specified](#) a partition range that starts on the first day of the current year. The following ALTER PROJECTION statement changes the range to start on October 1 of last year. The new range precedes the previous one, so Vertica issues a warning to refresh the specified projection `ytd_orders_b0` and its buddy projection `ytd_orders_b1` :

```
=> ALTER PROJECTION ytd_orders_b0 ON PARTITION RANGE BETWEEN
```

```
add_months(date_trunc('year',now())::date, -3) AND NULL;
```

```
WARNING 10001: Projection "public.ytd_orders_b0" changed to out-of-date state as new partition range is not covered by existing partition range
```

```
HINT: Call refresh() or start_refresh() to refresh the projections
```

```
WARNING 10001: Projection "public.ytd_orders_b1" changed to out-of-date state as new partition range is not covered by existing partition range
```

```
HINT: Call refresh() or start_refresh() to refresh the projections
```

```
ALTER PROJECTION
```

You can change a regular projection to a partition range projection provided no history or data loss will occur, such as by doing the following:

```
=> ALTER PROJECTION foo ON PARTITION RANGE BETWEEN '22' AND NULL;
```

Dynamic partition ranges

A projection's partition range can be static, set by expressions that always resolve to the same value. For example, the following projection specifies a static range between 06/01/21 and 06/30/21:

```
=> CREATE PROJECTION last_month_orders AS SELECT * FROM store_orders ORDER BY order_date ON PARTITION RANGE BETWEEN '2021-06-01' AND '2021-06-30';
```

```
...
```

```
CREATE PROJECTION
```

More typically, partition range expressions use stable date functions such as [ADD_MONTHS](#), [DATE_TRUNC](#) and [NOW](#) to specify a dynamic range. In the following example, the partition range is set from the first day of the previous month. As the calendar date advances to the next month, the partition range advances with it:

```
=> ALTER PROJECTION last_month_orders_b0 ON PARTITION RANGE BETWEEN
```

```
add_months(date_trunc('month', now())::date, -1) AND NULL;
```

```
ALTER PROJECTION
```

As a best practice, always leave the maximum range open-ended by setting it to NULL, and rely on queries to determine the maximum amount of data to fetch. For example, a query that fetches all store orders placed last month might look like this:

```
=> SELECT * from store_orders WHERE order_date BETWEEN
```

```
add_months(date_trunc('month', now())::date, -1) AND
```

```
add_months(date_trunc('month', now())::date + dayofmonth(now()), -1);
```

The query plan generated to execute this query shows that it uses the partition range projection `last_month_orders` :

```
=> EXPLAIN SELECT * from store_orders WHERE order_date BETWEEN
add_months(date_trunc('month', now())::date, -1) AND
add_months(date_trunc('month', now())::date + dayofmonth(now()), -1);
```

Access Path:

```
+STORAGE ACCESS for store_orders [Cost: 34, Rows: 763 (NO STATISTICS)] (PATH ID: 1)
| Projection: public.last_month_orders_b0
| Materialize: store_orders.order_date, store_orders.order_no, store_orders.shipper, store_orders.ship_date
| Filter: ((store_orders.order_date >= '2021-06-01 00:00:00'::timestamp(0)) AND (store_orders.order_date <= '2021-06-30 00:00:00'::timestamp(0)))
| Execute on: All Nodes
```

Dynamic partition range maintenance

The Projection Maintainer is a background service that checks projections with projection range expressions hourly. If the value of either expression in a projection changes, the Projection Maintainer compares the new and old values in `PARTITION_RANGE_MIN` and `PARTITION_RANGE_MAX` to determine whether the partition range contracted or expanded:

- If the partition range contracted in either direction—that is, `PARTITION_RANGE_MIN` is greater, or `PARTITION_RANGE_MAX` is smaller than its previous value—then the Projection Maintainer acts as follows:
 - Updates the system table `PROJECTIONS` with new values in columns `PARTITION_RANGE_MIN` and `PARTITION_RANGE_MAX`.
 - Queues a `MERGEOUT request` to purge unused data from this range. The projection remains available to execute queries within the updated range.
- If the partition range expanded in either direction—that is, `PARTITION_RANGE_MIN` is smaller, or `PARTITION_RANGE_MAX` is greater than its previous value—then the Projection Maintainer leaves the projection and the `PROJECTIONS` table unchanged. Because the partition range remains unchanged, Vertica regards the existing projection data as up to date, so it also can never be refreshed.

For example, the following projection creates a partition range that includes all orders in the current month:

```
=> CREATE PROJECTION mtd_orders AS SELECT * FROM store_orders ON PARTITION RANGE BETWEEN
date_trunc('month', now())::date AND NULL;
```

If you create this partition in July of 2021, the minimum partition range expression—`date_trunc('month', now())::date`—initially resolves to the first day of the month: 2021-07-01. At the start of the following month, sometime between 2021-08-01 00:00 and 2021-08-01 01:00, the Projection Maintainer compares the minimum range expression against system time. It then acts as follows:

1. Updates the `PROJECTIONS` table and sets `PARTITION_RANGE_MIN` for projection `mtd_orders` to 2021-08-01.
2. Queues a `MERGEOUT request` to purge from this projection's partition range all rows with keys that predate 2021-08-01.

Important

Given the example shown above, you might consider setting the projection's maximum partition range expression as follows:

```
add_months(date_trunc('month', now()), 1) - 1
```

This expression would always resolve to the last day of the current month. With each new month, the maximum partition range would be one month greater than its earlier value. As noted earlier, the Projection Maintainer ignores any expansion of a partition range, so it would leave the minimum and maximum partition range values for `mtd_orders` unchanged. To avoid issues like this, always set the maximum partition expression to `NULL`.

Refreshing projections

When you create a projection for a table that already contains data, Vertica does not automatically load that data into the new projection. Instead, you must explicitly refresh that projection. Until you do so, the projection cannot participate in executing queries on its anchor table.

You can refresh a projection with one of the following functions:

- `START_REFRESH` refreshes projections in the `current schema` with the latest data of their respective `anchor tables`. `START_REFRESH` runs asynchronously in the background.
- `REFRESH` synchronously refreshes one or more table projections in the foreground.

Both functions update system tables that maintain information about a projection's refresh status: `PROJECTION_REFRESHES`, `PROJECTIONS`, and `PROJECTION_CHECKPOINT_EPOCHS`.

If a refresh would violate a table or schema disk quota, the operation fails. For more information, see [Disk quotas](#).

Getting projection refresh information

You can query the [PROJECTION_REFRESHES](#) and [PROJECTIONS](#) system tables to view the progress of the refresh operation. You can also call the [GET_PROJECTIONS](#) function to view the final status of projection refreshes for a given table:

```
=> SELECT GET_PROJECTIONS('customer_dimension');
          GET_PROJECTIONS
-----
Current system K is 1.
# of Nodes: 3.
Table public.customer_dimension has 2 projections.

Projection Name: [Segmented] [Seg Cols] [# of Buddies] [Buddy Projections] [Safe] [UptoDate] [Stats]
-----
public.customer_dimension_b1 [Segmented: Yes] [Seg Cols: "public.customer_dimension.customer_key"] [K: 1]
    [public.customer_dimension_b0] [Safe: Yes] [UptoDate: Yes] [Stats: RowCounts]
public.customer_dimension_b0 [Segmented: Yes] [Seg Cols: "public.customer_dimension.customer_key"] [K: 1]
    [public.customer_dimension_b1] [Safe: Yes] [UptoDate: Yes] [Stats: RowCounts]

(1 row)
```

Refresh methods

Vertica can refresh a projection from one of its buddies, if one is available. In this case, the target projection gets the source buddy's historical data. Otherwise, the projection is refreshed from scratch with data of the latest epoch at the time of the refresh operation. In this case, the projection cannot participate in historical queries on any epoch that precedes the refresh operation.

Vertica can perform incremental refreshes when the following conditions are met:

- The table being refreshed is partitioned.
- The table does not contain any unpartitioned data.
- The operation is a full projection refresh (not a partition range projection refresh).

In an incremental refresh, the refresh operation first loads data from the partition with the highest range of keys. After refreshing this partition, Vertica begins to refresh the partition with next highest partition range. This process continues until all projection partitions are refreshed. While the refresh operation is in progress, projection partitions that have completed the refresh process become available to process query requests.

The method used to refresh a given projection is recorded in the `REFRESH_METHOD` column of the [PROJECTION_REFRESHES](#) system table.

Dropping projections

Projections can be dropped explicitly through the [DROP_PROJECTION](#) statement. They are also implicitly dropped when you drop their anchor table.

Partitioning tables

Data partitioning is [defined as a table property](#), and is implemented on all projections of that table. On all load, refresh, and recovery operations, the Vertica [Tuple Mover](#) automatically partitions data into separate ROS containers. Each ROS container contains data for a single partition or [partition group](#); depending on space requirements, a partition or partition group can span multiple ROS containers.

For example, it is common to partition data by time slices. If a table contains decades of data, you can partition it by year. If the table contains only one year of data, you can partition it by month.

Logical divisions of data can significantly improve query execution. For example, if you query a table on a column that is in the table's partition clause, the query optimizer can quickly isolate the relevant ROS containers (see [Partition pruning](#)).

Partitions can also facilitate DML operations. For example, given a table that is partitioned by months, you might drop all data for the oldest month when a new month begins. In this case, Vertica can easily identify the ROS containers that store the partition data to drop. For details, see [Managing partitions](#).

In this section

- [Defining partitions](#)
- [Hierarchical partitioning](#)
- [Partitioning and segmentation](#)
- [Managing partitions](#)
- [Active and inactive partitions](#)
- [Partition pruning](#)

Defining partitions

You can specify partitioning for new and existing tables:

- [Define partitioning for a table](#) with [CREATE TABLE](#).
- [Specify partitioning for an existing table](#) by modifying its definition with [ALTER TABLE](#).
- [Create partition groups to consolidate partitions into logical subsets](#), minimizing the use of ROS storage.

In this section

- [Partitioning a new table](#)
- [Partitioning existing table data](#)
- [Partition grouping](#)

Partitioning a new table

Use [CREATE TABLE](#) to partition a new table, as specified by the [PARTITION BY clause](#):

```
CREATE TABLE table-name... PARTITION BY partition-expression [ GROUP BY group-expression ] [ REORGANIZE ];
```

The following statements create the `store_orders` table and load data into it. The CREATE TABLE statement includes a simple partition clause that specifies to partition data by year:

```
=> CREATE TABLE public.store_orders
(
  order_no int,
  order_date timestamp NOT NULL,
  shipper varchar(20),
  ship_date date
)
UNSEGMENTED ALL NODES
PARTITION BY YEAR(order_date);
CREATE TABLE
=> COPY store_orders FROM '/home/dbadmin/export_store_orders_data.txt';
41834
```

As COPY loads the new table data into ROS storage, the Tuple Mover executes the table's partition clause by dividing orders for each year into separate partitions, and consolidating these partitions in ROS containers.

In this case, the Tuple Mover creates four partition keys for the loaded data—2017, 2016, 2015, and 2014—and divides the data into separate ROS containers accordingly:

```

=> SELECT dump_table_partition_keys('store_orders');
... Partition keys on node v_vmart_node0001
Projection 'store_orders_super'
Storage [ROS container]
  No of partition keys: 1
  Partition keys: 2017
Storage [ROS container]
  No of partition keys: 1
  Partition keys: 2016
Storage [ROS container]
  No of partition keys: 1
  Partition keys: 2015
Storage [ROS container]
  No of partition keys: 1
  Partition keys: 2014

Partition keys on node v_vmart_node0002
Projection 'store_orders_super'
Storage [ROS container]
  No of partition keys: 1
  Partition keys: 2017
...
(1 row)

```

As new data is loaded into `store_orders`, the Tuple Mover merges it into the appropriate partitions, creating partition keys as needed for new years.

Partitioning existing table data

Use [ALTER TABLE](#) to partition or repartition an existing table, as specified by the `PARTITION BY` clause:

```
ALTER TABLE table-name PARTITION BY partition-expression [ GROUP BY group-expression ] [ REORGANIZE ];
```

For example, you might repartition the `store_orders` table, [defined earlier](#). The following ALTER TABLE divides all `store_orders` data into monthly partitions for each year, each partition key identifying the order date year and month:

```

=> ALTER TABLE store_orders
  PARTITION BY EXTRACT(YEAR FROM order_date)*100 + EXTRACT(MONTH FROM order_date)
  GROUP BY EXTRACT(YEAR FROM order_date)*100 + EXTRACT(MONTH FROM order_date);
NOTICE 8364: The new partitioning scheme will produce partitions in 42 physical storage containers per projection
WARNING 6100: Using PARTITION expression that returns a Numeric value
HINT: This PARTITION expression may cause too many data partitions. Use of an expression that returns a more accurate value, such as a regular
VARCHAR or INT, is encouraged
WARNING 4493: Queries using table "store_orders" may not perform optimally since the data may not be repartitioned in accordance with the new partition
expression
HINT: Use "ALTER TABLE public.store_orders REORGANIZE;" to repartition the data

```

After executing this statement, Vertica drops existing partition keys. However, the partition clause omits [REORGANIZE](#), so existing data remains stored according to the previous partition clause. This can put table partitioning in an inconsistent state and adversely affect query performance, [DROP PARTITIONS](#), and node recovery. In this case, you must explicitly request Vertica to reorganize existing data into new partitions, in one of the following ways:

- Issue ALTER TABLE...REORGANIZE:

```
ALTER TABLE table-name REORGANIZE;
```

- Call the Vertica meta-function [PARTITION_TABLE](#).

For example:

```

=> ALTER TABLE store_orders REORGANIZE;
NOTICE 4785: Started background repartition table task
ALTER TABLE

```

ALTER TABLE...REORGANIZE and PARTITION_TABLE operate identically: both split any ROS containers where partition keys do not conform with the

new partition clause. On executing its next mergeout, the Tuple Mover merges partitions into the appropriate ROS containers.

Partition grouping

Partition groups consolidate partitions into logical subsets that minimize use of ROS storage. Reducing the number of ROS containers to store partitioned data helps facilitate DML operations such as **DELETE** and **UPDATE**, and avoid ROS pushback. For example, you can group date partitions by year. By doing so, the Tuple Mover allocates ROS containers for each year group, and merges individual partitions into these ROS containers accordingly.

Creating partition groups

You create partition groups by qualifying the **PARTITION BY** clause with a **GROUP BY** clause:

```
ALTER TABLE table-name PARTITION BY partition-expression [ GROUP BY group-expression ]
```

The **GROUP BY** clause specifies how to consolidate partition keys into groups, where each group is identified by a unique partition group key. For example, the following **ALTER TABLE** statement specifies to repartition the `store_orders` table (shown in [Partitioning a new table](#)) by order dates, grouping partition keys by year. The group expression— `DATE_TRUNC('year', (order_date)::DATE)` —uses the partition expression `order_date::DATE` to generate partition group keys:

```
=> ALTER TABLE store_orders
PARTITION BY order_date::DATE GROUP BY DATE_TRUNC('year', (order_date)::DATE) REORGANIZE;
NOTICE 8364: The new partitioning scheme will produce partitions in 4 physical storage containers per projection
NOTICE 4785: Started background repartition table task
```

In this case, the `order_date` column dates span four years. The Tuple Mover creates four partition group keys, and merges `store_orders` partitions into group-specific ROS storage containers accordingly:

```
=> SELECT DUMP_TABLE_PARTITION_KEYS('store_orders');
...
Partition keys on node v_vmart_node0001
Projection 'store_orders_super'
Storage [ROS container]
No of partition keys: 173
Partition keys: 2017-01-02 2017-01-03 2017-01-04 ... 2017-09-25 2017-09-26 2017-09-27
Storage [ROS container]
No of partition keys: 212
Partition keys: 2016-01-01 2016-01-04 2016-01-05 ... 2016-11-23 2016-11-24 2016-11-25
Storage [ROS container]
No of partition keys: 213
Partition keys: 2015-01-01 2015-01-02 2015-01-05 ... 2015-11-23 2015-11-24 2015-11-25
2015-11-26 2015-11-27
Storage [ROS container]
No of partition keys: 211
Partition keys: 2014-01-01 2014-01-02 2014-01-03 ... 2014-11-25 2014-11-26 2014-11-27
Projection 'store_orders_super'
Storage [ROS container]
No of partition keys: 173
...
```

Caution

This example demonstrates how partition grouping can facilitate more efficient use of ROS storage. However, grouping all partitions into several large and static ROS containers can adversely affect performance, especially for a table that is subject to frequent DML operations. Frequent load operations in particular can incur considerable merge overhead, which, in turn, reduces performance.

Vertica recommends that you use `CALENDAR_HIERARCHY_DAY`, as a partition clause's group expression. This function automatically groups **DATE** partition keys into a dynamic hierarchy of years, months, and days. Doing so helps minimize merge-related issues. For details, see [Hierarchical partitioning](#).

You can use various [partition management functions](#), such as [DROP_PARTITIONS](#) or [MOVE_PARTITIONS_TO_TABLE](#), to target a range of order dates within a given partition group, or across multiple partition groups. In the previous example, each group contains partition keys of different dates within a given year. You can use [DROP_PARTITIONS](#) to drop order dates that span two years, 2014 and 2015:

```
=> SELECT DROP_PARTITIONS('store_orders', '2014-05-30', '2015-01-15', 'true');
```

Important

The drop operation requires Vertica to [split the ROS containers that store partition groups](#) for these two years. To do so, the function's [force_split](#) parameter must be set to true.

Hierarchical partitioning

Hierarchical partitions organize data into [partition groups](#) for more efficient storage. When partitioning by date, the oldest partitions are grouped by year, more recent partitions are grouped by month, and the most recent partitions remain ungrouped. Grouping is dynamic: as recent data ages, the Tuple Mover merges those partitions into month groups, and eventually into year groups. Hierarchical partitioning reduces the number of ROS files Vertica uses and thus reduces ROS pushback.

Use the [CALENDAR_HIERARCHY_DAY](#) function as the partitioning [GROUP BY](#) expression in a table's [PARTITION BY](#) clause, as in the following example:

```
=> CREATE TABLE public.store_orders(
  order_no int,
  order_date timestamp NOT NULL,
  shipper varchar(20),
  ship_date date )
PARTITION BY order_date::DATE
GROUP BY CALENDAR_HIERARCHY_DAY(order_date::DATE, 3, 2);
```

Managing timestamped data

Partition consolidation strategies are especially important for managing timestamped data, where the number of partitions can quickly escalate and risk ROS pushback. For example, the following statements create the [store_orders](#) table and load data into it. The [CREATE TABLE](#) statement includes a simple [partition clause](#) that partitions data by date:

```
=> DROP TABLE IF EXISTS public.store_orders CASCADE;

=> CREATE TABLE public.store_orders(
  order_no int,
  order_date timestamp NOT NULL,
  shipper varchar(20),
  ship_date date )
UNSEGMENTED ALL NODES PARTITION BY order_date::DATE;

=> COPY store_orders FROM '/home/dbadmin/export_store_orders_data.txt';
```

As COPY loads the new table data into ROS storage, it executes this table's partition clause by dividing daily orders into separate partitions, where each partition requires its own ROS container:

```
=> SELECT COUNT (DISTINCT ros_id) NumROS, node_name FROM PARTITIONS
  WHERE projection_name ilike '%store_orders_super%'
  GROUP BY node_name ORDER BY node_name;
NumROS | node_name
-----+-----
  809 | v_vmart_node0001
  809 | v_vmart_node0002
  809 | v_vmart_node0003
(3 rows)
```

This is far above the recommended maximum of 50 partitions per projection. This number is also close to the default system limit of 1024 ROS containers per projection, risking ROS pushback in the near future.

You can approach this problem in several ways:

- Consolidate table data into larger partitions—for example, partition by month instead of day. However, partitioning data at this level might limit effective use of [partition management functions](#).
- Regularly [archive older partitions](#), and thereby minimize the number of accumulated partitions. However, this requires an extra layer of data management, and also inhibits access to historical data.

Alternatively, you can use [CALENDAR_HIERARCHY_DAY](#) to automatically merge partitions into a date-based hierarchy of partition groups. Each partition group is stored in its own set of ROS containers, apart from other groups. You specify this function in the table partition clause as follows:

```
PARTITION BY partition-expression
GROUP BY CALENDAR_HIERARCHY_DAY( partition-expression [, active-months [, active-years] ] )
```

For example, given the previous table, you can repartition it as follows:

```
-> ALTER TABLE public.store_orders
PARTITION BY order_date::DATE
GROUP BY CALENDAR_HIERARCHY_DAY(order_date::DATE, 2, 2) REORGANIZE;
```

The partition expression must match the expression used in the **GROUP BY** expression. When using [CALENDAR_HIERARCHY_DAY](#), the expression must be a [DATE](#).

Important
The [CALENDAR_HIERARCHY_DAY algorithm](#) assumes that most table activity is focused on recent dates. Setting *active-years* and *active-months* to a low number ≥ 2 serves to isolate most merge activity to date-specific containers, and incurs minimal overhead. Vertica recommends that you use the default setting of 2 for *active-years* and *active-months*. For most users, these settings achieve an optimal balance between ROS storage and performance.

As a best practice, never set *active-years* and *active-months* to 0.

Grouping DATE data hierarchically

[CALENDAR_HIERARCHY_DAY](#) creates hierarchies of partition groups and merges partitions into the appropriate groups. It does so by evaluating the partition expression of each table row with the following algorithm, to determine its partition group key:

```
GROUP BY (
CASE WHEN DATEDIFF('YEAR', NOW()::TIMESTAMPTZ(6)) >=
THEN DATE_TRUNC('YEAR', :DATE)
WHEN DATEDIFF('MONTH', NOW()::TIMESTAMPTZ(6)) >=
THEN DATE_TRUNC('MONTH', :DATE)
ELSE DATE_TRUNC('DAY', :DATE) END);
```

In this example, the algorithm compares *order_date* in each row to the current date as follows:

1. Determines if *order_date* is in an inactive year. If it is, the row is merged into a ROS container for that year.
2. Otherwise, for an active year, [CALENDAR_HIERARCHY_DAY](#) evaluates *order_date* to determine if it is in an inactive month. If it is, the row is merged into a ROS container for that month.
3. Otherwise, for an active month, the row is merged into a ROS container for that day. Any rows where *order_date* is a future date is treated in the same way.

For example, if the current date is 2017-09-26, [CALENDAR_HIERARCHY_DAY](#) resolves *active-years* and *active-months* to the following date spans:

- *active-years* : 2016-01-01 to 2017-12-31. Partitions in active years are grouped into monthly ROS containers or are merged into daily ROS containers. Partitions from earlier years are regarded as inactive and merged into yearly ROS containers.
- *active-months* : 2017-08-01 to 2017-09-30. Partitions in active months are merged into daily ROS containers.

Now, the total number of ROS containers is reduced to 40 per projection:

```

-> SELECT COUNT (DISTINCT ros_id) NumROS, node_name FROM PARTITIONS
   WHERE projection_name ilike '%store_orders_super%'
   GROUP BY node_name ORDER BY node_name;
NumROS | node_name
-----|-----
    40 | v_vmart_node0001
    40 | v_vmart_node0002
    40 | v_vmart_node0003
(3 rows)

```

Regardless of how the Tuple Mover groups and merges partitions, it always identifies one or more partitions or partition groups as active. For details, see [Active and inactive partitions](#).

Dynamic regrouping

As shown earlier, CALENDAR_HIERARCHY_DAY references the current date when it creates partition group keys and merges partitions. As the calendar advances, the Tuple Mover reevaluates the partition group keys of tables that are partitioned with this function, and moves partitions as needed to different ROS containers.

Thus, given the previous example, on 2017-10-01 the Tuple Mover creates a monthly ROS container for August partitions. All partition keys between 2017-08-01 and 2017-08-31 are merged into the new ROS container 2017-08:

Likewise, on 2018-01-01, the Tuple Mover creates a ROS container for 2016 partitions. All partition keys between 2016-01-01 and 2016-12-31 that were previously grouped by month are merged into the new yearly ROS container:

Caution

After older partitions are grouped into months and years, any partition operation that acts on a subset of older partition groups is likely to split

ROS containers into smaller ROS containers for each partition—for example, [MOVE PARTITIONS TO TABLE](#), where *force-split* is set to true. These operations can lead to ROS pushback. If you anticipate frequent partition operations on hierarchically grouped partitions, [consider modifying the partition expression](#) so partitions are grouped no higher than months.

Customizing partition group hierarchies

Vertica provides a single function, `CALENDAR_HIERARCHY_DAY`, to facilitate hierarchical partitioning. Vertica stores the `GROUP BY` clause as a `CASE` statement that you can edit to suit your own requirements.

For example, Vertica stores the `store_orders` partition clause as follows:

```
=> SELECT EXPORT_TABLES('store_orders');
...
CREATE TABLE public.store_orders ( ... )
...
PARTITION BY ((store_orders.order_date)::date)
GROUP BY (
CASE WHEN ("datediff"('year', (store_orders.order_date)::date, ((now())::timestamp(6)::date) >= 2)
  THEN (date_trunc('year', (store_orders.order_date)::date)::date)
  WHEN ("datediff"('month', (store_orders.order_date)::date, ((now())::timestamp(6)::date) >= 2)
  THEN (date_trunc('month', (store_orders.order_date)::date)::date)
  ELSE (store_orders.order_date)::date END);
```

You can modify the `CASE` statement to customize the hierarchy of partition groups. For example, the following `CASE` statement creates a hierarchy of months, days, and hours:

```
=> ALTER TABLE store_orders
PARTITION BY (store_orders.order_date)
GROUP BY (
CASE
  WHEN DATEDIFF('MONTH', store_orders.order_date, NOW())::TIMESTAMPTZ(6) >= 2
  THEN DATE_TRUNC('MONTH', store_orders.order_date::DATE)
  WHEN DATEDIFF('DAY', store_orders.order_date, NOW())::TIMESTAMPTZ(6) >= 2
  THEN DATE_TRUNC('DAY', store_orders.order_date::DATE)
  ELSE DATE_TRUNC('hour', store_orders.order_date::DATE) END);
```

Alternatively, you can write a [user-defined SQL function](#) to partition values in different ways. The following example defines a function that partitions timestamps by hour:

```
=> CREATE OR REPLACE FUNCTION public.My_Calendar_By_Hour
( tsz timestamp(0)
, p1 int
, p2 int
)
return timestamp(0)
as
begin
return (case
  when datediff('day', trunc(tsz, 'hh'), now() at time zone 'utc') > p1
  then date_trunc('month', trunc(tsz, 'hh'))
  when datediff('day', trunc(tsz, 'hh'), now() at time zone 'utc') > p2
  then date_trunc('day', trunc(tsz, 'hh'))
  else date_trunc('hour', trunc(tsz, 'hh'))
end);
end;
```

You can then use this function in the partition clause:

```
=> ALTER TABLE store_orders
PARTITION BY ((col2 at time zone 'utc')::timestamp(0))
GROUP BY My_Calendar_By_Hour((col2 at time zone 'utc')::timestamp(0), 31, 1)
REORGANIZE;
```

Partitioning and segmentation

In Vertica, partitioning and segmentation are separate concepts and achieve different goals to localize data:

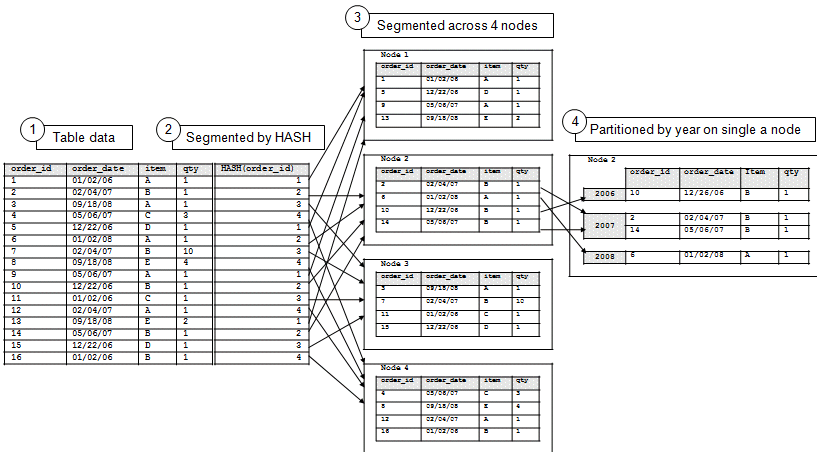

- **Segmentation** refers to organizing and distributing data across cluster nodes for fast data purges and query performance. Segmentation aims to distribute data evenly across multiple database nodes so all nodes participate in query execution. You specify segmentation with the [CREATE PROJECTION](#) statement's [hash segmentation clause](#).
- **Partitioning** specifies how to organize data within individual nodes for distributed computing. Node partitions let you easily identify data you wish to drop and help reclaim disk space. You specify partitioning with the [CREATE TABLE](#) statement's [PARTITION BY](#) clause.

For example: partitioning data by year makes sense for retaining and dropping annual data. However, segmenting the same data by year would be inefficient, because the node holding data for the current year would likely answer far more queries than the other nodes.

The following diagram illustrates the flow of segmentation and partitioning on a four-node database cluster:

1. Example table data
2. Data segmented by [HASH\(order_id\)](#)
3. Data segmented by hash across four nodes
4. Data partitioned by year on a single node

While partitioning occurs on all four nodes, the illustration shows partitioned data on one node for simplicity.

- [Segmented projections](#)
- [Unsegmented projections](#)
- [CREATE PROJECTION](#)
- [CREATE TABLE](#)

Managing partitions

You can manage partitions with the following operations:

- [Drop partitions](#)
- [Archive partitions](#)
- [Swap partitions](#)
- [Minimize partitions](#)
- [View partition storage](#)

In this section

- [Dropping partitions](#)
- [Archiving partitions](#)
- [Swapping partitions](#)
- [Minimizing partitions](#)
- [Viewing partition storage data](#)

Dropping partitions

Use the [DROP_PARTITIONS](#) function to drop one or more partition keys for a given table. You can specify a single partition key or a range of partition keys.

For example, the table shown in [Partitioning a new table](#) is partitioned by column `order_date` :

```
=> CREATE TABLE public.store_orders
(
  order_no int,
  order_date timestamp NOT NULL,
  shipper varchar(20),
  ship_date date
)
PARTITION BY YEAR(order_date);
```

Given this table definition, Vertica creates a partition key for each unique `order_date` year—in this case, 2017, 2016, 2015, and 2014—and divides the data into separate ROS containers accordingly.

The following `DROP_PARTITIONS` statement drops from table `store_orders` all order records associated with partition key 2014:

```
=> SELECT DROP_PARTITIONS ('store_orders', 2014, 2014);
Partition dropped
```

Splitting partition groups

If a table partition clause includes a `GROUP BY` clause, partitions are consolidated in the ROS by their partition group keys. `DROP_PARTITIONS` can then specify a range of partition keys within a given partition group, or across multiple partition groups. In either case, the drop operation requires Vertica to split the ROS containers that store these partitions. To do so, the function's `force_split` parameter must be set to true.

For example, the `store_orders` table shown above can be repartitioned with a `GROUP BY` clause as follows:

```
=> ALTER TABLE store_orders
PARTITION BY order_date::DATE GROUP BY DATE_TRUNC('year', (order_date)::DATE) REORGANIZE;
```

With all 2014 order records having been dropped earlier, `order_date` values now span three years—2017, 2016, and 2015. Accordingly, the Tuple Mover creates three partition group keys for each year, and designates one or more ROS containers for each group. It then merges `store_orders` partitions into the appropriate groups.

The following `DROP_PARTITIONS` statement specifies to drop order dates that span two years, 2014 and 2015:

```
=> SELECT DROP_PARTITIONS('store_orders', '2015-05-30', '2016-01-16', 'true');
Partition dropped
```

The drop operation requires Vertica to drop partitions from two partition groups—2015 and 2016. These groups span at least two ROS containers, which must be split in order to remove the target partitions. Accordingly, the function's `force_split` parameter is set to true.

Scheduling partition drops

If your hardware has fixed disk space, you might need to configure a regular process to roll out old data by dropping partitions.

For example, if you have only enough space to store data for a fixed number of days, configure Vertica to drop the oldest partition keys. To do so, create a time-based job scheduler such as `cron` to schedule dropping the partition keys during low-load periods.

If the ingest rate for data has peaks and valleys, you can use two techniques to manage how you drop partition keys:

- Set up a process to check the disk space on a regular (daily) basis. If the percentage of used disk space exceeds a certain threshold—for example, 80%—drop the oldest partition keys.
- Add an artificial column in a partition that increments based on a metric like row count. For example, that column might increment each time the row count increases by 100 rows. Set up a process that queries this column on a regular (daily) basis. If the value in the new column exceeds a certain threshold—for example, 100—drop the oldest partition keys, and set the column value back to 0.

Table locking

`DROP_PARTITIONS` requires an exclusive [D lock](#) on the target table. This lock is only compatible with I-lock operations, so only table load operations such as `INSERT` and `COPY` are allowed during drop partition operations.

Archiving partitions

You can move partitions from one table to another with the Vertica function [MOVE_PARTITIONS_TO_TABLE](#). This function is useful for archiving old partitions, as part of the following procedure:

1. Identify the partitions to archive, and [move them to a temporary staging table](#) with [MOVE_PARTITIONS_TO_TABLE](#).
2. [Back up the staging table](#).
3. [Drop the staging table](#).

You [restore archived partitions](#) at any time.

Move partitions to staging tables

You archive historical data by identifying the partitions you wish to remove from a table. You then move each partition (or group of partitions) to a temporary staging table.

Before calling [MOVE_PARTITIONS_TO_TABLE](#) :

- Refresh all out-of-date projections.

The following recommendations apply to staging tables:

- To facilitate the backup process, create a unique schema for the staging table of each archiving operation.
- Specify new names for staging tables. This ensures that they do not contain partitions from previous move operations.

If the table does not exist, Vertica creates a table from the source table's definition, by calling [CREATE TABLE](#) with [LIKE](#) and [INCLUDING PROJECTIONS](#) clause. The new table inherits ownership from the source table. For details, see [Replicating a table](#).

- Use staging names that enable other users to easily identify partition contents. For example, if a table is partitioned by dates, use a name that specifies a date or date range.

In the following example, [MOVE_PARTITIONS_TO_TABLE](#) specifies to move a single partition to the staging table `partn_backup.trades_200801`.

```
=> SELECT MOVE_PARTITIONS_TO_TABLE (  
    'prod_trades',  
    '200801',  
    '200801',  
    'partn_backup.trades_200801');  
MOVE_PARTITIONS_TO_TABLE  
-----  
1 distinct partition values moved at epoch 15.  
(1 row)
```

Back up the staging table

After you create a staging table, you archive it through an object-level backup using a [vbr](#) configuration file. For detailed information, see [Backing up and restoring the database](#).

Important
Vertica recommends performing a full database backup before the object-level backup, as a precaution against data loss. You can only restore object-level backups to the original database.

Drop the staging tables

After the backup is complete, you can drop the staging table as described in [Dropping tables](#).

Restoring archived partitions

You can restore partitions that you previously moved to an intermediate table, archived as an object-level backup, and then dropped.

Note

Restoring an archived partition requires that the original table definition is unchanged since the partition was archived and dropped. If the table definition changed, you can restore an archived partition with `INSERT...SELECT` statements, which are not described here.

These are the steps to restoring archived partitions:

1. Restore the backup of the intermediate table you saved when you moved one or more partitions to archive (see [Archiving partitions](#)).
2. Move the restored partitions from the intermediate table to the original table.

- Drop the intermediate table.

Swapping partitions

[SWAP_PARTITIONS_BETWEEN_TABLES](#) combines the operations of [DROP_PARTITIONS](#) and [MOVE_PARTITIONS_TO_TABLE](#) as a single transaction. [SWAP_PARTITIONS_BETWEEN_TABLES](#) is useful if you regularly load partitioned data from one table into another and need to refresh partitions in the second table.

For example, you might have a table of revenue that is partitioned by date, and you routinely move data into it from a staging table. Occasionally, the staging table contains data for dates that are already in the target table. In this case, you must first remove partitions from the target table for those dates, then replace them with the corresponding partitions from the staging table. You can accomplish both tasks with a single call to [SWAP_PARTITIONS_BETWEEN_TABLES](#).

By wrapping the drop and move operations within a single transaction, [SWAP_PARTITIONS_BETWEEN_TABLES](#) maintains integrity of the swapped data. If any task in the swap operation fails, the entire operation fails and is rolled back.

Example

The following example creates two partitioned tables and then swaps certain partitions between them.

Both tables have the same definition and have partitions for various **year** values. You swap the partitions where **year** = 2008 and **year** = 2009. Both tables have at least two rows to swap.

- Create the **customer_info** table:

```
=> CREATE TABLE customer_info (  
  customer_id INT NOT NULL,  
  first_name VARCHAR(25),  
  last_name VARCHAR(35),  
  city VARCHAR(25),  
  year INT NOT NULL)  
  ORDER BY last_name  
  PARTITION BY year;
```

- Insert data into the **customer_info** table:

```
INSERT INTO customer_info VALUES  
(1,'Joe','Smith','Denver',2008),  
(2,'Bob','Jones','Boston',2008),  
(3,'Silke','Muller','Frankfurt',2007),  
(4,'Simone','Bernard','Paris',2014),  
(5,'Vijay','Kumar','New Delhi',2010);  
OUTPUT  
-----  
 5  
(1 row)  
  
=> COMMIT;
```

- View the table data:

```
=> SELECT * FROM customer_info ORDER BY year DESC;  
customer_id | first_name | last_name | city | year  
-----+-----+-----+-----+-----  
 4 | Simone | Bernard | Paris | 2014  
 5 | Vijay | Kumar | New Delhi | 2010  
 2 | Bob | Jones | Boston | 2008  
 1 | Joe | Smith | Denver | 2008  
 3 | Silke | Muller | Frankfurt | 2007  
(5 rows)
```

- Create a second table, **member_info**, that has the same definition as **customer_info**:

```
=> CREATE TABLE member_info LIKE customer_info INCLUDING PROJECTIONS;  
CREATE TABLE
```

- Insert data into the **member_info** table:

```
=> INSERT INTO member_info VALUES
```

```
(1,'Jane','Doe','Miami',2001),  
(2,'Mike','Brown','Chicago',2014),  
(3,'Patrick','OMalley','Dublin',2008),  
(4,'Ana','Lopez','Madrid',2009),  
(5,'Mike','Green','New York',2008);
```

```
OUTPUT
```

```
-----  
5  
(1 row)  
=> COMMIT;  
COMMIT
```

6. View the data in the `member_info` table:

```
=> SELECT * FROM member_info ORDER BY year DESC;
```

```
customer_id | first_name | last_name | city | year
```

```
-----+-----+-----+-----  
2 | Mike | Brown | Chicago | 2014  
4 | Ana | Lopez | Madrid | 2009  
5 | Mike | Green | New York | 2008  
3 | Patrick | OMalley | Dublin | 2008  
1 | Jane | Doe | Miami | 2001
```

```
(5 rows)
```

7. To swap the partitions, run the `SWAP_PARTITIONS_BETWEEN_TABLES` function:

```
=> SELECT SWAP_PARTITIONS_BETWEEN_TABLES('customer_info', 2008, 2009, 'member_info');
```

```
SWAP_PARTITIONS_BETWEEN_TABLES
```

```
-----  
1 partition values from table customer_info and 2 partition values from table member_info are swapped at epoch 1045.
```

```
(1 row)
```

8. Query both tables to confirm that they swapped their respective 2008 and 2009 records:

```
=> SELECT * FROM customer_info ORDER BY year DESC;
```

```
customer_id | first_name | last_name | city | year
```

```
-----+-----+-----+-----  
4 | Simone | Bernard | Paris | 2014  
5 | Vijay | Kumar | New Delhi | 2010  
4 | Ana | Lopez | Madrid | 2009  
3 | Patrick | OMalley | Dublin | 2008  
5 | Mike | Green | New York | 2008  
3 | Silke | Muller | Frankfurt | 2007
```

```
(6 rows)
```

```
=> SELECT * FROM member_info ORDER BY year DESC;
```

```
customer_id | first_name | last_name | city | year
```

```
-----+-----+-----+-----  
2 | Mike | Brown | Chicago | 2014  
2 | Bob | Jones | Boston | 2008  
1 | Joe | Smith | Denver | 2008  
1 | Jane | Doe | Miami | 2001
```

```
(4 rows)
```

Minimizing partitions

By default, Vertica supports up to 1024 ROS containers to store partitions for a given projection (see [Projection parameters](#)). A ROS container contains data that share the same partition key, or the same partition group key. Depending on the amount of data per partition, a partition or partition group can span multiple ROS containers.

Given this limit, it is inadvisable to partition a table on highly granular data—for example, on a `TIMESTAMP` column. Doing so can generate a very high number of partitions. If the number of partitions requires more than 1024 ROS containers, Vertica issues a ROS pushback warning and refuses to load more table data. A large number of ROS containers also can adversely affect DML operations such as `DELETE`, which requires Vertica to open all ROS containers.

In practice, it is unlikely you will approach this maximum. For optimal performance, Vertica recommends that the number of ungrouped partitions range between 10 and 20, and not exceed 50. This range is typically compatible with most business requirements.

You can also reduce the number of ROS containers by grouping partitions. For more information, see [Partition grouping](#) and [Hierarchical partitioning](#).

Viewing partition storage data

Vertica provides various ways to view how your table partitions are organized and stored:

- Query the [PARTITIONS](#) system table.
- Dump partition keys.

Querying PARTITIONS table

The following table and projection definitions partition `store_order` data on order dates, and groups together partitions of the same year:

```
=> CREATE TABLE public.store_orders
  (order_no int, order_date timestamp NOT NULL, shipper varchar(20), ship_date date)
  PARTITION BY ((order_date)::date) GROUP BY (date_trunc('year', (order_date)::date));

=> CREATE PROJECTION public.store_orders_super
  AS SELECT order_no, order_date, shipper, ship_date FROM store_orders
  ORDER BY order_no, order_date, shipper, ship_date UNSEGMENTED ALL NODES;

=> COPY store_orders FROM '/home/dbadmin/export_store_orders_data.txt';
```

After loading data into this table, you can query the `PARTITIONS` table to determine how many ROS containers store the grouped partitions for projection `store_orders_unseg`, across all nodes. Each node has eight ROS containers, each container storing partitions of one partition group:

```
=> SELECT COUNT (partition_key) NumPartitions, ros_id, node_name FROM PARTITIONS
  WHERE projection_name ilike 'store_orders%' GROUP BY ros_id, node_name ORDER BY node_name, NumPartitions;
NumPartitions |  ros_id  |  node_name
-----+-----+-----
      173 | 45035996274562779 | v_vmart_node0001
      211 | 45035996274562791 | v_vmart_node0001
      212 | 45035996274562783 | v_vmart_node0001
      213 | 45035996274562787 | v_vmart_node0001
      173 | 49539595901916471 | v_vmart_node0002
      211 | 49539595901916483 | v_vmart_node0002
      212 | 49539595901916475 | v_vmart_node0002
      213 | 49539595901916479 | v_vmart_node0002
      173 | 54043195529286985 | v_vmart_node0003
      211 | 54043195529286997 | v_vmart_node0003
      212 | 54043195529286989 | v_vmart_node0003
      213 | 54043195529286993 | v_vmart_node0003
(12 rows)
```

Dumping partition keys

Vertica provides several functions that let you inspect how individual partitions are stored on the cluster, at several levels:

- [DUMP_PARTITION_KEYS](#) dumps partition keys of all projections in the system.
- [DUMP_TABLE_PARTITION_KEYS](#) dumps partition keys of all projections for the specified table.
- [DUMP_PROJECTION_PARTITION_KEYS](#) dumps partition keys of the specified projection.

Given the previous table and projection, `DUMP_PROJECTION_PARTITION_KEYS` shows the contents of four ROS containers on each node:

```

=> SELECT DUMP_PROJECTION_PARTITION_KEYS('store_orders_super');
...
Partition keys on node v_vmart_node0001

```

Active and inactive partitions

The Tuple Mover assumes that all loads and updates to a partitioned table are targeted to one or more partitions that it identifies as *active*. In general, the partitions with the largest partition keys—typically, the most recently created partitions—are regarded as active. As the partition ages, its workload typically shrinks and becomes mostly read-only.

Setting active partition count

You can specify how many partitions are active for partitioned tables at two levels, in ascending order of precedence:

- Configuration parameter [ActivePartitionCount](#) determines how many partitions are active for partitioned tables in the database. By default, ActivePartitionCount is set to 1. The Tuple Mover applies this setting to all tables that do not set their own active partition count.
- Individual tables can supersede ActivePartitionCount by setting their own active partition count with [CREATE TABLE](#) and [ALTER TABLE](#).

Partitioned tables in the same database can be subject to different distributions of update and load activity. When these differences are significant, it might make sense for some tables to set their own active partition counts.

For example, table `store_orders` is partitioned by month and gets its active partition count from configuration parameter `ActivePartitionCount`. If the parameter is set to 1, the Tuple Mover identifies the latest month—typically, the current one—as the table's active partition. If `store_orders` is subject to frequent activity on data for the current month and the one before it, you might want the table to supersede the configuration parameter, and set its active partition count to 2:

```
ALTER TABLE public.store_orders SET ACTIVEPARTITIONCOUNT 2;
```

Note

For tables partitioned by non-temporal attributes, set its active partition count to reflect the number of partitions that are subject to a high level of activity—for example, frequent loads or queries.

Identifying the active partition

The Tuple Mover typically identifies the active partition as the one most recently created. Vertica uses the following algorithm to determine which partitions are older than others:

1. If partition X was created before partition Y, partition X is older.
2. If partitions X and Y were created at the same time, but partition X was last updated before partition Y, partition X is older.
3. If partitions X and Y were created and last updated at the same time, the partition with the smaller key is older.

You can obtain the active partitions for a table by joining system tables `PARTITIONS` and `STRATA` and querying on its projections. For example, the following query gets the active partition for projection `store_orders_super`:

```
=> SELECT p.node_name, p.partition_key, p.ros_id, p.ros_size_bytes, p.ros_row_count, ROS_container_count
FROM partitions p JOIN strata s ON p.partition_key = s.stratum_key AND p.node_name=s.node_name
WHERE p.projection_name = 'store_orders_super' ORDER BY p.node_name, p.partition_key;
node_name | partition_key | ros_id | ros_size_bytes | ros_row_count | ROS_container_count
-----+-----+-----+-----+-----+-----
v_vmart_node0001 | 2017-09-01 | 45035996279322851 | 6905 | 960 | 1
v_vmart_node0002 | 2017-09-01 | 49539595906590663 | 6905 | 960 | 1
v_vmart_node0003 | 2017-09-01 | 54043195533961159 | 6905 | 960 | 1
(3 rows)
```

Active partition groups

If a table's partition clause includes a `GROUP BY` expression, Vertica applies the table's active partition count to its largest partition group key, and regards all the partitions in that group as active. If you group partitions with Vertica meta-function `CALENDAR_HIERARCHY_DAY`, the most recent date partitions are also grouped by day. Thus, the largest partition group key and largest partition key are identical. In effect, this means that only the most recent partitions are active.

For more information about partition grouping, see [Partition grouping](#) and [Hierarchical partitioning](#).

Partition pruning

If a query predicate specifies a partitioning expression, the query optimizer evaluates the predicate against the `ROS` containers of the partitioned data. Each `ROS` container maintains the minimum and maximum values of its partition key data. The query optimizer uses this metadata to determine which `ROS` containers it needs to execute the query, and omits, or *prunes*, the remaining containers from the query plan. By minimizing the number of `ROS` containers that it must scan, the query optimizer enables faster execution of the query.

For example, a table might be partitioned by year as follows:

```
=> CREATE TABLE ... PARTITION BY EXTRACT(year FROM date);
```

Given this table definition, its projection data is partitioned into `ROS` containers according to year, one for each year—in this case, 2007, 2008, 2009.

The following query specifies the partition expression `date`:

```
=> SELECT ... WHERE date = '12-2-2009';
```

Given this query, the `ROS` containers that contain data for 2007 and 2008 fall outside the boundaries of the requested year (2009). The query optimizer prunes these containers from the query plan before the query executes:

Examples

Assume a table that is partitioned by time and will use queries that restrict data on time.

```
=> CREATE TABLE time ( tdate DATE NOT NULL, tnum INTEGER)
PARTITION BY EXTRACT(year FROM tdate);
=> CREATE PROJECTION time_p (tdate, tnum) AS
=> SELECT * FROM time ORDER BY tdate, tnum UNSEGMENTED ALL NODES;
```

Note

Projection sort order has no effect on partition pruning.

```
=> INSERT INTO time VALUES ('03/15/04' , 1);
=> INSERT INTO time VALUES ('03/15/05' , 2);
=> INSERT INTO time VALUES ('03/15/06' , 3);
=> INSERT INTO time VALUES ('03/15/06' , 4);
```

The data inserted in the previous series of commands are loaded into three ROS containers, one per year, as that is how the data is partitioned:

```
=> SELECT * FROM time ORDER BY tnum;
 tdate | tnum
-----+-----
2004-03-15 | 1 --ROS1 (min 03/01/04, max 03/15/04)
2005-03-15 | 2 --ROS2 (min 03/15/05, max 03/15/05)
2006-03-15 | 3 --ROS3 (min 03/15/06, max 03/15/06)
2006-03-15 | 4 --ROS3 (min 03/15/06, max 03/15/06)
(4 rows)
```

Here's what happens when you query the `time` table:

- In this query, Vertica can omit container ROS2 because it is only looking for year 2004:

```
=> SELECT COUNT(*) FROM time WHERE tdate = '05/07/2004';
```

- In the next query, Vertica can omit two containers, ROS1 and ROS3:

```
=> SELECT COUNT(*) FROM time WHERE tdate = '10/07/2005';
```

- The following query has an additional predicate on the `tnum` column for which no minimum/maximum values are maintained. In addition, the use of logical operator OR is not supported, so no ROS elimination occurs:

```
=> SELECT COUNT(*) FROM time WHERE tdate = '05/07/2004' OR tnum = 7;
```

Constraints

Constraints set rules on what data is allowed in table columns. Using constraints can help maintain data integrity. For example, you can constrain a column to allow only unique values, or to disallow NULL values. Constraints such as primary keys also help the optimizer generate query plans that facilitate faster data access, particularly for joins.

You set constraints on a new table and an existing one with [CREATE TABLE](#) and [ALTER TABLE...ADD CONSTRAINT](#), respectively.

To view current constraints, see [Column-constraint](#).

In this section

- [Supported constraints](#)
- [Setting constraints](#)
- [Dropping constraints](#)
- [Naming constraints](#)
- [Detecting constraint violations](#)
- [Constraint enforcement](#)

Supported constraints

Vertica supports standard SQL constraints, as described in this section.

In this section

- [Primary key constraints](#)

- [Foreign key constraints](#)
- [Unique constraints](#)
- [Check constraints](#)
- [NOT NULL constraints](#)

Primary key constraints

A primary key comprises one or multiple columns of primitive types, whose values can uniquely identify table rows. A table can specify only one primary key. You identify a table's primary key when you create the table, or in an existing table with [ALTER TABLE](#). You cannot designate a column with a collection type as a key.

For example, the following [CREATE TABLE](#) statement defines the `order_no` column as the primary key of the `store_orders` table:

```
=> CREATE TABLE public.store_orders(
  order_no int PRIMARY KEY,
  order_date timestamp NOT NULL,
  shipper varchar(20),
  ship_date date,
  product_key int,
  product_version int
)
PARTITION BY ((date_part('year', order_date))::int);
CREATE TABLE
```

Multi-column primary keys

A primary key can comprise multiple columns. In this case, the [CREATE TABLE](#) statement must specify the constraint after all columns are defined, as follows:

```
=> CREATE TABLE public.product_dimension(
  product_key int,
  product_version int,
  product_description varchar(128),
  sku_number char(32) UNIQUE,
  category_description char(32),
  CONSTRAINT pk PRIMARY KEY (product_key, product_version) ENABLED
);
CREATE TABLE
```

Alternatively, you can specify the table's primary key with a separate [ALTER TABLE...ADD CONSTRAINT](#) statement, as follows:

```
=> ALTER TABLE product_dimension ADD CONSTRAINT pk PRIMARY KEY (product_key, product_version) ENABLED;
ALTER TABLE
```

Enforcing primary keys

You can prevent loading duplicate values into primary keys by enforcing the primary key constraint. Doing so allows you to join tables on their primary and [foreign keys](#). When a query joins a dimension table to a fact table, each primary key in the dimension table must uniquely match each foreign key value in the fact table. Otherwise, attempts to join these tables return a key enforcement error.

You enforce primary key constraints globally with configuration parameter [EnableNewPrimaryKeysByDefault](#). You can also enforce primary key constraints for specific tables by qualifying the constraint with the keyword [ENABLED](#). In both cases, Vertica checks key values as they are loaded into tables, and returns errors on any constraint violations. Alternatively, use [ANALYZE_CONSTRAINTS](#) to validate primary keys after updating table contents. For details, see [Constraint enforcement](#).

Tip

Consider using [sequences](#) for primary key columns to guarantee uniqueness, and avoid the resource overhead that primary key constraints can incur.

Setting NOT NULL on primary keys

When you define a primary key , Vertica automatically sets the primary key columns to **NOT NULL** . For example, when you create the table `product_dimension` as shown [earlier](#) , Vertica sets primary key columns `product_key` and `product_version` to **NOT NULL** , and stores them in the catalog accordingly:

```
> SELECT EXPORT_TABLES('', 'product_dimension');
...
CREATE TABLE public.product_dimension
(
  product_key int NOT NULL,
  product_version int NOT NULL,
  product_description varchar(128),
  sku_number char(32),
  category_description char(32),
  CONSTRAINT C_UNIQUE UNIQUE (sku_number) DISABLED,
  CONSTRAINT pk PRIMARY KEY (product_key, product_version) ENABLED
);
(1 row)
```

If you specify a primary key for an existing table with **ALTER TABLE** , Vertica notifies you that it set the primary key columns to **NOT NULL** :

```
WARNING 2623: Column "column-name" definition changed to NOT NULL
```

Note

If you drop a primary key constraint, the columns that comprised it remain set to **NOT NULL** . This constraint can only be removed explicitly, through [ALTER TABLE...ALTER COLUMN](#) .

Foreign key constraints

A foreign key joins a table to another table by referencing its primary key. A foreign key constraint specifies that the key can only contain values that are in the referenced primary key, and thus ensures the referential integrity of data that is joined on the two keys.

You can identify a table's foreign key when you create the table, or in an existing table with [ALTER TABLE](#) . For example, the following **CREATE TABLE** statement defines two foreign key constraints: `fk_store_orders_store` and `fk_store_orders_vendor` :

```
=> CREATE TABLE store.store_orders_fact(
  product_key int NOT NULL,
  product_version int NOT NULL,
  store_key int NOT NULL CONSTRAINT fk_store_orders_store REFERENCES store.store_dimension (store_key),
  vendor_key int NOT NULL CONSTRAINT fk_store_orders_vendor REFERENCES public.vendor_dimension (vendor_key),
  employee_key int NOT NULL,
  order_number int NOT NULL,
  date_ordered date,
  date_shipped date,
  expected_delivery_date date,
  date_delivered date,
  quantity_ordered int,
  quantity_delivered int,
  shipper_name varchar(32),
  unit_price int,
  shipping_cost int,
  total_order_cost int,
  quantity_in_stock int,
  reorder_level int,
  overstock_ceiling int
);
```

The following **ALTER TABLE** statement adds foreign key constraint `fk_store_orders_employee` to the same table:

```
=> ALTER TABLE store.store_orders_fact ADD CONSTRAINT fk_store_orders_employee
    FOREIGN KEY (employee_key) REFERENCES public.employee_dimension (employee_key);
```

The **REFERENCES** clause can omit the name of the referenced column if it is the same as the foreign key column name. For example, the following **ALTER TABLE** statement is equivalent to the one above:

```
=> ALTER TABLE store.store_orders_fact ADD CONSTRAINT fk_store_orders_employee
    FOREIGN KEY (employee_key) REFERENCES public.employee_dimension;
```

Multi-column foreign keys

If a foreign key references a primary key that contains multiple columns, the foreign key must contain the same number of columns. For example, the primary key for table `public.product_dimension` contains two columns, `product_key` and `product_version`. In this case, **CREATE TABLE** can define a foreign key constraint that references this primary key as follows:

```
=> CREATE TABLE store.store_orders_fact3(
    product_key int NOT NULL,
    product_version int NOT NULL,
    ...
    CONSTRAINT fk_store_orders_product
    FOREIGN KEY (product_key, product_version) REFERENCES public.product_dimension (product_key, product_version)
);

CREATE TABLE
```

CREATE TABLE can specify multi-column foreign keys only after all table columns are defined. You can also specify the table's foreign key with a separate **ALTER TABLE...ADD CONSTRAINT** statement:

```
=> ALTER TABLE store.store_orders_fact ADD CONSTRAINT fk_store_orders_product
    FOREIGN KEY (product_key, product_version) REFERENCES public.product_dimension (product_key, product_version);
```

In both examples, the constraint specifies the columns in the referenced table. If the referenced column names are the same as the foreign key column names, the **REFERENCES** clause can omit them. For example, the following **ALTER TABLE** statement is equivalent to the previous one:

```
=> ALTER TABLE store.store_orders_fact ADD CONSTRAINT fk_store_orders_product
    FOREIGN KEY (product_key, product_version) REFERENCES public.product_dimension;
```

NULL values in foreign key

A foreign key that whose columns omit **NOT NULL** can contain NULL values, even if the primary key contains no NULL values. Thus, you can insert rows into the table even if their foreign key is not yet known.

Unique constraints

You can specify a unique constraint on a column so each value in that column is unique among all other values. You can define a unique constraint when you create a table, or you can add a unique constraint to an existing table with **ALTER TABLE**. You cannot use a uniqueness constraint on a column with a collection type.

For example, the following **ALTER TABLE** statement defines the `sku_number` column in the `product_dimensions` table as unique:

```
=> ALTER TABLE public.product_dimension ADD UNIQUE(sku_number);
WARNING 4887: Table product_dimension has data. Queries using this table may give wrong results
if the data does not satisfy this constraint
HINT: Use analyze_constraints() to check constraint violation on data
```

Enforcing unique constraints

You enforce unique constraints globally with configuration parameter `EnableNewUniqueKeysByDefault`. You can also enforce unique constraints for specific tables by qualifying their unique constraints with the keyword `ENABLED`. In both cases, Vertica checks values as they are loaded into unique columns, and returns with errors on any constraint violations. Alternatively, you can use **ANALYZE CONSTRAINTS** to validate unique constraints after updating table contents. For details, see [Constraint enforcement](#).

For example, the previous example does not enforce the unique constraint in column `sku_number`. The following statement enables this constraint:

```
=> ALTER TABLE public.product_dimension ALTER CONSTRAINT C_UNIQUE ENABLED;
ALTER TABLE
```

Multi-column unique constraints

You can define a unique constraint that is comprised of multiple columns. The following **CREATE TABLE** statement specifies that the combined values of columns `c1` and `c2` in each row must be unique among all other rows:

```
CREATE TABLE dim1 (c1 INTEGER,
  c2 INTEGER,
  c3 INTEGER,
  UNIQUE (c1, c2) ENABLED
);
```

Check constraints

A *check constraint* specifies a Boolean expression that evaluates a column's value on each row. If the expression resolves to false for a given row, the column value is regarded as violating the constraint.

For example, the following table specifies two named check constraints:

- **IsYear2018** specifies to allow only 2018 dates in column `order_date` .
- **Ship5dAfterOrder** specifies to check whether each `ship_date` value is no more than 5 days after `order_date` .

```
CREATE TABLE public.store_orders_2018 (
  order_no int CONSTRAINT pk PRIMARY KEY,
  product_key int,
  product_version int,
  order_date timestamp NOT NULL,
  shipper varchar(20),
  ship_date date,
  CONSTRAINT IsYear2018 CHECK (DATE_PART('year', order_date)::int = 2018),
  CONSTRAINT Ship5dAfterOrder CHECK (DAYOFYEAR(ship_date) - DAYOFYEAR(order_date) <=5)
);
```

When Vertica checks the data in `store_orders_2018` for constraint violations, it evaluates the values of `order_date` and `ship_date` on each row, to determine whether they comply with their respective check constraints.

Check expressions

A check expression can only reference the current table row; it cannot access data stored in other tables or database objects, such as sequences. It also cannot access data in other table rows.

A check constraint expression can include:

- Arithmetic and concatenated string operators
- Logical operators such as **AND** , **OR** , **NOT**
- WHERE prepositions such as **CASE** , **IN** , **LIKE** , **BETWEEN** , **IS [NOT] NULL**
- Calls to the following function types:
 - Immutable built-in SQL functions such as **LENGTH**
 - Immutable SQL macros (see [Check Constraints and SQL Macros](#) below)
 - User-defined scalar functions that are marked as immutable in the component factory (see [Check Constraints and UDSFs](#) below)

Example check expressions

The following check expressions assume that the table contains all referenced columns and that they have the appropriate data types:

- **CONSTRAINT chk_pos_quant CHECK (quantity > 0)**
- **CONSTRAINT chk_pqe CHECK (price*quantity = extended_price)**
- **CONSTRAINT size_sml CHECK (size in ('s', 'm', 'l', 'xl'))**
- **CHECK (regexp_like(dept_name, '^([a-z]+)\$', 'i') OR (dept_name = 'inside sales'))**

Check expression restrictions

A check expression must evaluate to a Boolean value. However, Vertica does not support implicit conversions to Boolean values. For example, the following check expressions are invalid:

- **CHECK (1)**
- **CHECK ('hello')**

A check expression cannot include the following elements:

- Subqueries—for example, `CHECK (dept_id in (SELECT id FROM dept))`
- Aggregates—for example, `CHECK (quantity < sum(quantity)/2)`
- Window functions—for example, `CHECK (RANK() over () < 3)`
- SQL meta-functions—for example, `CHECK (START_REFRESH() = 0)`
- References to the epoch column
- References to other tables or objects (for example, sequences), or system context
- Invocation of functions that are not immutable in time and space

Enforcing check constraints

You can enforce check constraints globally with configuration parameter `EnableNewCheckConstraintsByDefault`. You can also enforce check constraints for specific tables by qualifying unique constraints with the keyword `ENABLED`. In both cases, Vertica evaluates check constraints as new values are loaded into the table, and returns with errors on any constraint violations. Alternatively, you can use `ANALYZE_CONSTRAINTS` to validate check constraints after updating the table contents. For details, see [Constraint enforcement](#).

For example, you can enable the constraints shown earlier with `ALTER TABLE...ALTER CONSTRAINT`:

```
=> ALTER TABLE store_orders_2018 ALTER CONSTRAINT IsYear2018 ENABLED;
ALTER TABLE
=> ALTER TABLE store_orders_2018 ALTER CONSTRAINT Ship5dAfterOrder ENABLED;
ALTER TABLE
```

Check constraints and nulls

If a check expression evaluates to unknown for a given row because a column within the expression contains a null, the row passes the constraint condition. Vertica evaluates the expression and considers it satisfied if it resolves to either true or unknown. For example, `check (quantity > 0)` passes validation if `quantity` is null. This result differs from how a `WHERE` clause works. With a `WHERE` clause, the row would not be included in the result set.

You can prohibit nulls in a check constraint by explicitly including a null check in the check constraint expression. For example: `CHECK (quantity IS NOT NULL AND (quantity > 0))`

Tip

Alternatively, set a `NOT NULL` constraint on the same column.

Check constraints and SQL macros

A check constraint can call a SQL macro (a function written in SQL) if the macro is immutable. An immutable macro always returns the same value for a given set of arguments.

When a DDL statement specifies a macro in a check expression, Vertica determines if it is immutable. If it is not, Vertica rolls back the statement.

The following example creates the macro `mycompute` and then uses it in a check expression:

```
=> CREATE OR REPLACE FUNCTION mycompute(j int, name1 varchar)
RETURN int AS BEGIN RETURN (j + length(name1)); END;
=> ALTER TABLE sampletable
ADD CONSTRAINT chk_compute
CHECK(mycompute(weekly_hours, name1))<50;
```

Check constraints and UDSFs

A check constraint can call [user-defined scalar functions](#) (UDSFs). The following requirements apply:

- The UDSF must be marked as immutable in the UDx factory.
- The constraint handles null values properly.

Caution

Vertica evaluates an enabled check constraint on every row that is loaded or updated. Invoking a computationally expensive check constraint on a large table is liable to incur considerable system overhead.

For a usage example, see [C++ example: calling a UDSF from a check constraint](#).

NOT NULL constraints

A NOT NULL constraint specifies that a column cannot contain a null value. All table updates must specify values in columns with this constraint. You can set a **NOT NULL** constraint on columns when you create a table, or set the constraint on an existing table with [ALTER TABLE](#).

The following CREATE TABLE statement defines three columns as NOT NULL. You cannot store any NULL values in those columns.

```
=> CREATE TABLE inventory ( date_key INTEGER NOT NULL,
                             product_key INTEGER NOT NULL,
                             warehouse_key INTEGER NOT NULL, ... );
```

The following ALTER TABLE statement defines column sku_number in table product_dimensions as NOT NULL:

```
=> ALTER TABLE public.product_dimension ALTER COLUMN sku_number SET NOT NULL;
ALTER TABLE
```

Enforcing NOT NULL constraints

You cannot enable [enforcement](#) of a NOT NULL constraint. You must use [ANALYZE CONSTRAINTS](#) to determine whether column data contains null values, and then manually fix any constraint violations that the function finds.

NOT NULL and primary keys

When you define a primary key, Vertica automatically sets the primary key columns to NOT NULL. If you drop a primary key constraint, the columns that comprised it remain set to NOT NULL. This constraint can only be removed explicitly, through [ALTER TABLE...ALTER COLUMN](#).

Setting constraints

You can set constraints on a new table and an existing one with [CREATE TABLE](#) and [ALTER TABLE...ADD CONSTRAINT](#), respectively.

Setting constraints on a new table

CREATE TABLE can specify a constraint in two ways: as part of the column definition, or following all column definitions.

For example, the following **CREATE TABLE** statement sets two constraints on column `sku_number`, **NOT NULL** and **UNIQUE**. After all columns are defined, the statement also sets a primary key that is composed of two columns, `product_key` and `product_version`:

```
=> CREATE TABLE public.prod_dimension(
  product_key int,
  product_version int,
  product_description varchar(128),
  sku_number char(32) NOT NULL UNIQUE,
  category_description char(32),
  CONSTRAINT pk PRIMARY KEY (product_key, product_version) ENABLED
);
CREATE TABLE
```

Setting constraints on an existing table

[ALTER TABLE...ADD CONSTRAINT](#) adds a constraint to an existing table. For example, the following statement specifies unique values for column `product_version`:

```
=> ALTER TABLE prod_dimension ADD CONSTRAINT u_product_versions UNIQUE (product_version) ENABLED;
ALTER TABLE
```

Validating existing data

When you add a constraint on a column that already contains data, Vertica immediately validates column values if the following conditions are both true:

- The constraint is a [primary key](#), [unique](#), or [check](#) constraint.
- The constraint is [enforced](#).

If either of these conditions is not true, Vertica does not validate the column values. In this case, you must call [ANALYZE CONSTRAINTS](#) to find constraint violations. Otherwise, queries are liable to return unexpected results. For details, see [Detecting constraint violations](#).

Exporting table constraints

Whether you specify constraints in the column definition or on the table, Vertica stores the table DDL as part of the **CREATE** statement and exports them as such. One exception applies: foreign keys are stored and [exported](#) as **ALTER TABLE** statements.

For example:

```
=> SELECT EXPORT_TABLES('', 'prod_dimension');
...
CREATE TABLE public.prod_dimension
(
  product_key int NOT NULL,
  product_version int NOT NULL,
  product_description varchar(128),
  sku_number char(32) NOT NULL,
  category_description char(32),
  CONSTRAINT C_UNIQUE UNIQUE (sku_number) DISABLED,
  CONSTRAINT pk PRIMARY KEY (product_key, product_version) ENABLED,
  CONSTRAINT u_product_versions UNIQUE (product_version) ENABLED
);
(1 row)
```

Dropping constraints

[ALTER TABLE](#) drops constraints from tables in two ways:

- [ALTER TABLE...DROP CONSTRAINT](#) removes a named table constraint.
- [ALTER TABLE...ALTER COLUMN](#) removes a column's **NOT NULL** constraint.

For example, table `store_orders_2018` specifies the following constraints:

- Named constraint `pk` identifies column `order_no` as a primary key.
- Named constraint `IsYear2018` specifies a check constraint that allows only 2018 dates in column `order_date`.
- Named constraint `Ship5dAfterOrder` specifies a check constraint that disallows any `ship_date` value that is more than 5 days after `order_date`.
- Columns `order_no` and `order_date` are set to **NOT NULL**.

```
CREATE TABLE public.store_orders_2018 (
  order_no int NOT NULL CONSTRAINT pk PRIMARY KEY,
  product_key int,
  product_version int,
  order_date timestamp NOT NULL,
  shipper varchar(20),
  ship_date date,
  CONSTRAINT IsYear2018 CHECK (DATE_PART('year', order_date)::int = 2018),
  CONSTRAINT Ship5dAfterOrder CHECK (DAYOFYEAR(ship_date) - DAYOFYEAR(order_date) <=5)
);
```

Dropping named constraints

You remove primary, foreign key, check, and unique constraints with [ALTER TABLE...DROP CONSTRAINT](#), which requires you to supply their names.

For example, you remove the primary key constraint in table `store_orders_2018` as follows:

```
=> ALTER TABLE store_orders_2018 DROP CONSTRAINT pk;
ALTER TABLE
=> SELECT export_tables("", 'store_orders_2018');
           export_tables
```

```
CREATE TABLE public.store_orders_2018
(
  order_no int NOT NULL,
  product_key int,
  product_version int,
  order_date timestamp NOT NULL,
  shipper varchar(20),
  ship_date date,
  CONSTRAINT IsYear2018 CHECK (((date_part('year', store_orders_2018.order_date))::int = 2018)) ENABLED,
  CONSTRAINT Ship5dAfterOrder CHECK (((dayofyear(store_orders_2018.ship_date) - dayofyear(store_orders_2018.order_date)) <= 5)) ENABLED
);
```

Important

If you do not explicitly name a constraint, Vertica [assigns its own name](#). You can obtain all constraint names from the Vertica catalog with [EXPORT_TABLES](#), or by querying the following system tables:

- [CONSTRAINT_COLUMNS](#)
- [TABLE_CONSTRAINTS](#)
- [PRIMARY_KEYS](#)

Dropping NOT NULL constraints

You drop a column's **NOT NULL** constraint with [ALTER TABLE...ALTER COLUMN](#), as in the following example:

```
=> ALTER TABLE store_orders_2018 ALTER COLUMN order_date DROP NOT NULL;
ALTER TABLE
```

Dropping primary keys

You cannot drop a primary key constraint if another table has a foreign key constraint that references the primary key. To drop the primary key, you must first drop all foreign keys that reference it.

Dropping constraint-referenced columns

If you try to drop a column that is referenced by a constraint in the same table, the drop operation returns with an error. For example, check constraint [Ship5dAfterOrder](#) references two columns, [order_date](#) and [ship_date](#). If you try to drop either column, Vertica returns the following error message:

```
=> ALTER TABLE public.store_orders_2018 DROP COLUMN ship_date;
ROLLBACK 3128: DROP failed due to dependencies
DETAIL:
Constraint Ship5dAfterOrder references column ship_date
HINT: Use DROP .. CASCADE to drop or modify the dependent objects
```

In this case, you must qualify the **DROP COLUMN** clause with the **CASCADE** option, which specifies to drop the column and its dependent objects—in this case, constraint [Ship5dAfterOrder](#) :

```
=> ALTER TABLE public.store_orders_2018 DROP COLUMN ship_date CASCADE;
ALTER TABLE
```

A call to Vertica function [EXPORT_TABLES](#) confirms that the column and the constraint were both removed:

```
=> ALTER TABLE public.store_orders_2018 DROP COLUMN ship_date CASCADE;
ALTER TABLE
dbadmin=> SELECT export_tables('',store_orders_2018);
        export_tables
-----
CREATE TABLE public.store_orders_2018
(
  order_no int NOT NULL,
  product_key int,
  product_version int,
  order_date timestamp,
  shipper varchar(20),
  CONSTRAINT IsYear2018 CHECK (((date_part('year', store_orders_2018.order_date))::int = 2018)) ENABLED
);
(1 row)
```

Naming constraints

The following constraints must be named.

- **PRIMARY KEY**
- **REFERENCES** (foreign key)
- **CHECK**
- **UNIQUE**

You name these constraints when you define them. If you omit assigning a name, Vertica automatically assigns one.

User-assigned constraint names

You assign names to constraints when you define them with [CREATE TABLE](#) or [ALTER TABLE...ADD CONSTRAINT](#). For example, the following [CREATE TABLE](#) statement names primary key and check constraints `pk` and `date_c`, respectively:

```
=> CREATE TABLE public.store_orders_2016
(
  order_no int CONSTRAINT pk PRIMARY KEY,
  product_key int,
  product_version int,
  order_date timestamp NOT NULL,
  shipper varchar(20),
  ship_date date,
  CONSTRAINT date_c CHECK (date_part('year', order_date)::int = 2016)
)
PARTITION BY ((date_part('year', order_date))::int);
CREATE TABLE
```

The following [ALTER TABLE](#) statement adds foreign key constraint `fk`:

```
=> ALTER TABLE public.store_orders_2016 ADD CONSTRAINT fk
  FOREIGN KEY (product_key, product_version)
  REFERENCES public.product_dimension (product_key, product_version);
```

Auto-assigned constraint names

Naming a constraint is optional. If you omit assigning a name to a constraint, Vertica assigns its own name using the following convention:

```
C_constraint-type[_integer]
```

For example, the following table defines two columns `a` and `b` and constrains them to contain unique values:

```
=> CREATE TABLE t1 (a int UNIQUE, b int UNIQUE );
CREATE TABLE
```

When you export the table's DDL with [EXPORT_TABLES](#), the function output shows that Vertica assigned constraint names `C_UNIQUE` and `C_UNIQUE_1` to columns `a` and `b`, respectively:

```
=> SELECT EXPORT_TABLES('', 't1');
CREATE TABLE public.t1
(
  a int,
  b int,
  CONSTRAINT C_UNIQUE UNIQUE (a) DISABLED,
  CONSTRAINT C_UNIQUE_1 UNIQUE (b) DISABLED
);

(1 row)
```

Viewing constraint names

You can view the names of table constraints by exporting the table's DDL with [EXPORT_TABLES](#), as shown earlier. You can also query the following system tables:

- [CONSTRAINT_COLUMNS](#)
- [TABLE_CONSTRAINTS](#)
- [PRIMARY_KEYS](#)

For example, the following query gets the names of all primary and foreign key constraints in schema `online_sales`:

```
=> SELECT table_name, constraint_name, column_name, constraint_type FROM constraint_columns
WHERE constraint_type in ('p','f') AND table_schema='online_sales'
ORDER BY table_name, constraint_type, constraint_name;
table_name | constraint_name | column_name | constraint_type
-----+-----+-----+-----
call_center_dimension | C_PRIMARY | call_center_key | p
online_page_dimension | C_PRIMARY | online_page_key | p
online_sales_fact | fk_online_sales_cc | call_center_key | f
online_sales_fact | fk_online_sales_customer | customer_key | f
online_sales_fact | fk_online_sales_op | online_page_key | f
online_sales_fact | fk_online_sales_product | product_version | f
online_sales_fact | fk_online_sales_product | product_key | f
online_sales_fact | fk_online_sales_promotion | promotion_key | f
online_sales_fact | fk_online_sales_saledate | sale_date_key | f
online_sales_fact | fk_online_sales_shipdate | ship_date_key | f
online_sales_fact | fk_online_sales_shipping | shipping_key | f
online_sales_fact | fk_online_sales_warehouse | warehouse_key | f
(12 rows)
```

Using constraint names

You must reference a constraint name in order to perform the following tasks:

- Enable or disable constraint enforcement.
- Drop a constraint.

For example, the following `ALTER TABLE` statement enables enforcement of constraint `pk` in table `store_orders_2016`:

```
=> ALTER TABLE public.store_orders_2016 ALTER CONSTRAINT pk ENABLED;
ALTER TABLE
```

The following statement drops another constraint in the same table:

```
=> ALTER TABLE public.store_orders_2016 DROP CONSTRAINT date_c;
ALTER TABLE
```

Detecting constraint violations

[ANALYZE_CONSTRAINTS](#) analyzes and reports on table constraint violations within a given schema. You can use [ANALYZE_CONSTRAINTS](#) to analyze an individual table, specific columns within a table, or all tables within a schema. You typically use this function on tables where primary key, unique, or check constraints are not enforced. You can also use [ANALYZE_CONSTRAINTS](#) to check the referential integrity of foreign keys.

In the simplest use case, [ANALYZE_CONSTRAINTS](#) is a two-step process:

1. Run [ANALYZE_CONSTRAINTS](#) on the desired table. [ANALYZE_CONSTRAINTS](#) reports all rows that violate constraints.
2. Use the report to fix violations.

You can also use [ANALYZE_CONSTRAINTS](#) in the following cases:

- Analyze tables with enforced constraints.
- Detect constraint violations introduced by a [COPY](#) operation and address them before the copy transaction is committed.

Analyzing tables with enforced constraints

If constraints are enforced on a table and a DML operation returns constraint violations, Vertica reports on a limited number of constraint violations before it rolls back the operation. This can be problematic when you try to load a large amount of data that includes many constraint violations—for example, duplicate key values. In this case, use [ANALYZE_CONSTRAINTS](#) as follows:

1. Temporarily disable enforcement of all constraints on the target table.
2. Run the DML operation.
3. After the operation returns, run [ANALYZE_CONSTRAINTS](#) on the table. [ANALYZE_CONSTRAINTS](#) reports all rows that violate constraints.
4. Use the report to fix the violations.
5. Re-enable constraint enforcement on the table.

Using [ANALYZE_CONSTRAINTS](#) in a [COPY](#) transaction

Use [ANALYZE_CONSTRAINTS](#) to detect and address constraint violations introduced by a [COPY](#) operation as follows:

1. Copy the source data into the target table with [COPY...NO COMMIT](#) .
2. Call [ANALYZE_CONSTRAINTS](#) to check the target table with its uncommitted updates.
3. If [ANALYZE_CONSTRAINTS](#) reports constraint violations, roll back the copy transaction.
4. Use the report to fix the violations, and then re-execute the copy operation.

For details about using [COPY...NO COMMIT](#) , see [Using transactions to stage a load](#) .

Distributing constraint analysis

[ANALYZE_CONSTRAINTS](#) runs as an atomic operation—that is, it does not return until it evaluates all constraints within the specified scope. For example, if you run [ANALYZE_CONSTRAINTS](#) against a table, the function returns only after it evaluates all column constraints against column data. If the table has a large number of columns with constraints, and contains a very large data set, [ANALYZE_CONSTRAINTS](#) is liable to exhaust all available memory and return with an out-of-memory error. This risk is increased by running [ANALYZE_CONSTRAINTS](#) against multiple tables simultaneously, or against the entire database.

You can minimize the risk of out-of-memory errors by setting configuration parameter [MaxConstraintChecksPerQuery](#) (by default set to -1) to a positive integer. For example, if this parameter is set to 20, and you run [ANALYZE_CONSTRAINTS](#) on a table that contains 38 column constraints, the function divides its work into two separate queries. [ANALYZE_CONSTRAINTS](#) creates a temporary table for loading and compiling results from the two queries, and then returns the composite result set.

[MaxConstraintChecksPerQuery](#) can only be set at the database level, and can incur a certain amount of overhead. When set, commits to the temporary table created by [ANALYZE_CONSTRAINTS](#) cause all pending database transactions to auto-commit. Setting this parameter to a reasonable number such as 20 should minimize its performance impact.

Constraint enforcement

You can enforce the following constraints:

- [PRIMARY KEY](#)
- [UNIQUE](#)
- [CHECK](#)

When you enable constraint enforcement on a table, Vertica applies that constraint immediately to the table's current content, and to all content that is added or updated later.

Operations that invoke constraint enforcement

The following DDL and DML operations invoke constraint enforcement:

- [ALTER TABLE...ADD CONSTRAINT](#) and [ALTER TABLE...ALTER CONSTRAINT](#)
- [INSERT](#) and [INSERT...SELECT](#)
- [COPY](#)
- [UPDATE](#)
- [MERGE](#)
- Partitioning functions:
 - [COPY_PARTITIONS_TO_TABLE](#)
 - [MOVE_PARTITIONS_TO_TABLE](#)
 - [SWAP_PARTITIONS_BETWEEN_TABLES](#)

Benefits and costs

Enabling constraint enforcement can help minimize post-load maintenance tasks, such as validating data separately with [ANALYZE_CONSTRAINTS](#), and then dealing with the constraint violations that it returns.

Enforcing key constraints, particularly on primary keys, can help the optimizer produce faster query plans, particularly for joins. When a primary key constraint is enforced on a table, the optimizer assumes that no rows in that table contain duplicate key values.

Under certain circumstances, widespread constraint enforcement, especially in large fact tables, can incur significant system overhead. For details, see [Constraint enforcement and performance](#).

In this section

- [Levels of constraint enforcement](#)
- [Verifying constraint enforcement](#)
- [Reporting constraint violations](#)
- [Constraint enforcement and locking](#)
- [Constraint enforcement and performance](#)
- [Projections for enforced constraints](#)
- [Constraint enforcement limitations](#)

Levels of constraint enforcement

Constraints can be enforced at two levels:

- [Database configuration parameters](#)
- [Table constraints](#)

Constraint enforcement parameters

Vertica supports three Boolean parameters to enforce constraints:

Enforcement parameter	Default setting
EnableNewPrimaryKeysByDefault	0 (false/disabled)
EnableNewUniqueKeysByDefault	0 (false/disabled)
EnableNewCheckConstraintsByDefault	1 (true/enabled)

Table constraint enforcement

You set constraint enforcement on tables through [CREATE TABLE](#) and [ALTER TABLE](#), by qualifying the constraints with the keywords **ENABLED** or **DISABLED**. The following [CREATE TABLE](#) statement enables enforcement of a check constraint in its definition of column `order_qty`:

```
=> CREATE TABLE new_orders (  
  cust_id int,  
  order_date timestamp DEFAULT CURRENT_TIMESTAMP,  
  product_id varchar(12),  
  order_qty int CHECK(order_qty > 0) ENABLED,  
  PRIMARY KEY(cust_id, order_date) ENABLED  
);  
CREATE TABLE
```

ALTER TABLE can enable enforcement on existing constraints. The following statement modifies table `customer_dimension` by enabling enforcement on named constraint `C_UNIQUE` :

```
=> ALTER TABLE public.customer_dimension ALTER CONSTRAINT C_UNIQUE ENABLED;
ALTER TABLE
```

Enforcement level precedence

Table and column enforcement settings have precedence over enforcement parameter settings. If a table or column constraint omits `ENABLED` or `DISABLED` , Vertica uses the current settings of the pertinent configuration parameters.

Important
Changing constraint enforcement parameters has no effect on existing table constraints that omit `ENABLED` or `DISABLED` . These table constraints retain the enforcement settings that they previously acquired. You can change the enforcement settings on these constraints only with [ALTER TABLE...ALTER CONSTRAINT](#) .

The following **CREATE TABLE** statement creates table `new_sales` with columns `order_id` and `order_qty` , which are defined with constraints `PRIMARY KEY` and `CHECK` , respectively:

```
=> CREATE TABLE new_sales ( order_id int PRIMARY KEY, order_qty int CHECK (order_qty > 0) );
```

Neither constraint is explicitly enabled or disabled, so Vertica uses configuration parameters `EnableNewPrimaryKeysByDefault` and `EnableNewCheckConstraintsByDefault` to set enforcement in the table definition:

```
=> SHOW CURRENT EnableNewPrimaryKeysByDefault, EnableNewCheckConstraintsByDefault;
```

level	name	setting
DEFAULT	EnableNewPrimaryKeysByDefault	0
DEFAULT	EnableNewCheckConstraintsByDefault	1

(2 rows)

```
=> SELECT EXPORT_TABLES('new_sales');
```

```
...
CREATE TABLE public.new_sales
(
  order_id int NOT NULL,
  order_qty int,
  CONSTRAINT C_PRIMARY PRIMARY KEY (order_id) DISABLED,
  CONSTRAINT C_CHECK CHECK ((new_sales.order_qty > 0)) ENABLED
);
(1 row)
```

In this case, changing `EnableNewPrimaryKeysByDefault` to 1 (enabled) has no effect on the `C_PRIMARY` constraint in table `new_sales` . You can enforce this constraint with [ALTER TABLE...ALTER CONSTRAINT](#) :

```
=> ALTER TABLE public.new_sales ALTER CONSTRAINT C_PRIMARY ENABLED;
ALTER TABLE
```

Verifying constraint enforcement

`SHOW CURRENT` can return the settings of constraint enforcement parameters:

```
=> SHOW CURRENT EnableNewCheckConstraintsByDefault, EnableNewUniqueKeysByDefault, EnableNewPrimaryKeysByDefault;
```

level	name	setting
DEFAULT	EnableNewCheckConstraintsByDefault	1
DEFAULT	EnableNewUniqueKeysByDefault	0
DATABASE	EnableNewPrimaryKeysByDefault	1

(3 rows)

You can also query the following system tables to check table enforcement settings:

- [CONSTRAINT_COLUMNS](#)
- [TABLE_CONSTRAINTS](#)
- [PRIMARY_KEYS](#)

For example, the following statement queries [TABLE_CONSTRAINTS](#) and returns all constraints in database tables. Column `is_enabled` is set to true or false for all constraints that can be enabled or disabled— [PRIMARY KEY](#) , [UNIQUE](#) , and [CHECK](#) :

```
=> SELECT constraint_name, table_name, constraint_type, is_enabled FROM table_constraints ORDER BY is_enabled, table_name;
```

constraint_name	table_name	constraint_type	is_enabled
C_PRIMARY	call_center_dimension	p	f
C_PRIMARY	date_dimension	p	f
C_PRIMARY	employee_dimension	p	f
C_PRIMARY	online_page_dimension	p	f
C_PRIMARY	product_dimension	p	f
C_PRIMARY	promotion_dimension	p	f
C_PRIMARY	shipping_dimension	p	f
C_PRIMARY	store_dimension	p	f
C_UNIQUE_1	tabletemp	u	f
C_PRIMARY	vendor_dimension	p	f
C_PRIMARY	warehouse_dimension	p	f
C_PRIMARY	customer_dimension	p	t
C_PRIMARY	new_sales	p	t
C_CHECK	new_sales	c	t
fk_inventory_date	inventory_fact	f	
fk_inventory_product	inventory_fact	f	
fk_inventory_warehouse	inventory_fact	f	
...			

The following query returns all tables that have primary key, unique, and check constraints, and shows whether the constraints are enabled:

```
=> SELECT table_name, constraint_name, constraint_type, is_enabled FROM constraint_columns  
WHERE constraint_type in ('p', 'u', 'c')  
ORDER BY table_name, constraint_type;
```

```
=> SELECT table_name, constraint_name, constraint_type, is_enabled FROM constraint_columns WHERE constraint_type in ('p', 'u', 'c') ORDER BY  
table_name, constraint_type;
```

table_name	constraint_name	constraint_type	is_enabled
call_center_dimension	C_PRIMARY	p	f
customer_dimension	C_PRIMARY	p	t
customer_dimension2	C_PRIMARY	p	t
customer_dimension2	C_PRIMARY	p	t
date_dimension	C_PRIMARY	p	f
employee_dimension	C_PRIMARY	p	f
new_sales	C_CHECK	c	t
new_sales	C_PRIMARY	p	t
...			

Reporting constraint violations

Vertica reports constraint violations in two cases:

- [ALTER TABLE](#) tries to enable constraint enforcement on a table that already contains data, and the data does not comply with the constraint.
- A DML operation tries to add or update data on a table with enforced constraints, and the new data does not comply with one or more constraints.

DDL constraint violations

When you enable constraint enforcement on an existing table with [ALTER TABLE...ADD CONSTRAINT](#) or [ALTER TABLE...ALTER CONSTRAINT](#) , Vertica applies that constraint immediately to the table's current content. If Vertica detects constraint violations, Vertica returns with an error that reports on violations and then rolls back the [ALTER TABLE](#) statement.

For example:

```
=> ALTER TABLE public.customer_dimension ADD CONSTRAINT unique_cust_types UNIQUE (customer_type) ENABLED;
ERROR 6745: Duplicate key values: 'customer_type=Company'
-- violates constraint 'public.customer_dimension.unique_cust_types'
DETAIL: Additional violations:
Constraint 'public.customer_dimension.unique_cust_types':
duplicate key values: 'customer_type=Individual'
```

DML constraint violations

When you invoke [DML operations](#) that add or update data on a table with enforced constraints, Vertica checks that the new data complies with these constraints. If Vertica detects constraint violations, the operation returns with an error that reports on violations, and then rolls back.

For example, table `store_orders` and `store_orders_2015` are defined with the same primary key and check constraints. Both tables enable enforcement of the primary key constraint; only `store_orders_2015` enforces the check constraint:

```
CREATE TABLE public.store_orders
(
  order_no int NOT NULL,
  order_date timestamp NOT NULL,
  shipper varchar(20),
  ship_date date
)
PARTITION BY ((date_part('year', store_orders.order_date))::int);

ALTER TABLE public.store_orders ADD CONSTRAINT C_PRIMARY PRIMARY KEY (order_no) ENABLED;
ALTER TABLE public.store_orders ADD CONSTRAINT C_CHECK CHECK (((date_part('year', store_orders.order_date))::int = 2014)) DISABLED;

CREATE TABLE public.store_orders_2015
(
  order_no int NOT NULL,
  order_date timestamp NOT NULL,
  shipper varchar(20),
  ship_date date
)
PARTITION BY ((date_part('year', store_orders_2015.order_date))::int);

ALTER TABLE public.store_orders_2015 ADD CONSTRAINT C_PRIMARY PRIMARY KEY (order_no) ENABLED;
ALTER TABLE public.store_orders_2015 ADD CONSTRAINT C_CHECK CHECK (((date_part('year', store_orders_2015.order_date))::int = 2015))
ENABLED;
```

If you try to insert data with duplicate key values into `store_orders`, the insert operation returns with an error message. The message contains detailed information about the first violation. It also returns abbreviated information about subsequent violations, up to the first 30. If necessary, the error message also includes a note that more than 30 violations occurred:

```
=> INSERT INTO store_orders SELECT order_number, date_ordered, shipper_name, date_shipped FROM store.store_orders_fact;
ERROR 6745: Duplicate key values: 'order_no=10' -- violates constraint 'public.store_orders.C_PRIMARY'
DETAIL: Additional violations:
Constraint 'public.store_orders.C_PRIMARY':
duplicate key values:
'order_no=11'; 'order_no=12'; 'order_no=13'; 'order_no=14'; 'order_no=15'; 'order_no=17';
'order_no=21'; 'order_no=23'; 'order_no=26'; 'order_no=27'; 'order_no=29'; 'order_no=33';
'order_no=35'; 'order_no=38'; 'order_no=39'; 'order_no=4'; 'order_no=41'; 'order_no=46';
'order_no=49'; 'order_no=6'; 'order_no=62'; 'order_no=67'; 'order_no=68'; 'order_no=70';
'order_no=72'; 'order_no=75'; 'order_no=76'; 'order_no=77'; 'order_no=79';
Note: there were additional errors
```

Similarly, the following attempt to copy data from `store_orders` into `store_orders_2015` violates the table's check constraint. It returns with an error message like the one shown earlier:

```
=> SELECT COPY_TABLE('store_orders', 'store_orders_2015');
NOTICE 7636: Validating enabled constraints on table 'public.store_orders_2015'...
ERROR 7231: Check constraint 'public.store_orders_2015.C_CHECK' ((date_part('year', store_orders_2015.order_date)::int = 2015)
violation in table 'public.store_orders_2015': 'order_no=101,order_date=2007-05-02 00:00:00'
DETAIL: Additional violations:
Check constraint 'public.store_orders_2015.C_CHECK':violations:
'order_no=106,order_date=2016-07-01 00:00:00'; 'order_no=119,order_date=2016-01-04 00:00:00';
'order_no=14,order_date=2016-07-01 00:00:00'; 'order_no=154,order_date=2016-11-06 00:00:00';
'order_no=156,order_date=2016-04-10 00:00:00'; 'order_no=171,order_date=2016-10-08 00:00:00';
'order_no=203,order_date=2016-03-01 00:00:00'; 'order_no=204,order_date=2016-06-09 00:00:00';
'order_no=209,order_date=2016-09-07 00:00:00'; 'order_no=214,order_date=2016-11-02 00:00:00';
'order_no=223,order_date=2016-12-08 00:00:00'; 'order_no=227,order_date=2016-08-02 00:00:00';
'order_no=240,order_date=2016-03-09 00:00:00'; 'order_no=262,order_date=2016-02-09 00:00:00';
'order_no=280,order_date=2016-10-10 00:00:00';
Note: there were additional errors
```

[Partition management functions](#) that add or update table content must also respect enforced constraints in the target table. For example, the following [MOVE_PARTITIONS_TO_TABLE](#) operation attempts to move a partition from `store_orders` into `store_orders_2015`. However, the source partition includes data that violates the target table's check constraint. Thus, the function returns with results that indicate it failed to move any data:

```
=> SELECT MOVE_PARTITIONS_TO_TABLE ('store_orders','2014','2014','store_orders_2015');
NOTICE 7636: Validating enabled constraints on table 'public.store_orders_2015'...
      MOVE_PARTITIONS_TO_TABLE
-----
0 distinct partition values moved at epoch 204.
```

Constraint enforcement and locking

Vertica uses an insert/validate (IV) lock for [DML operations](#) that require validation for enabled primary key and unique constraints.

When you run these operations on tables that enforce primary or unique key constraints, Vertica sets locks on the tables as follows:

1. Sets an I (insert) lock in order to load data. Multiple sessions can acquire an I lock on the same table simultaneously, and load data concurrently.
2. Sets an IV lock on the table to validate the loaded data against table primary and unique constraints. Only one session at a time can acquire an IV lock on a given table. Other sessions that need to access this table are blocked until the IV lock is released. A session retains its IV lock until one of two events occur:
 - Validation is complete and the DML operation is committed.
 - A constraint violation is detected and the operation is rolled back.

In either case, Vertica releases the IV lock.

IV lock blocking

While Vertica validates a table's primary or unique key constraints, it temporarily blocks other DML operations on the table. These delays can be especially noticeable when multiple sessions concurrently try to perform extensive changes to data on the same table.

For example, each of three concurrent sessions attempts to load data into table `t1`, as follows:

1. All three session acquire an I lock on `t1` and begin to load data into the table.
2. Session 2 acquires an exclusive IV lock on `t1` to validate table constraints on the data that it loaded. Only one session at a time can acquire an IV lock on a table, so sessions 1 and 3 must wait for session 2 to complete validation before they can begin their own validation.
3. Session 2 successfully validates all data that it loaded into `t1`. On committing its load transaction, it releases its IV lock on the table.
4. Session 1 acquires an IV lock on `t1` and begins to validate the data that it loaded. In this case, Vertica detects a constraint violation and rolls back the load transaction. Session 1 releases its IV lock on `t1`.
5. Session 3 now acquires an IV lock on `t1` and begins to validate the data that it loaded. On completing validation, session 3 commits its load transaction and releases the IV lock on `t1`. The table is now available for other DML operations.

See also

For information on lock modes and compatibility and conversion matrices, see [Lock modes](#). See also [LOCKS](#) and [LOCK_USAGE](#).

Constraint enforcement and performance

In some cases, constraint enforcement can significantly affect overall system performance. This is especially true when constraints are enforced on large fact tables that are subject to frequent and concurrent bulk updates. Every update operation that [invokes constraint enforcement](#) requires

Vertica to check each table row for all constraint violations. Thus, enforcing multiple constraints on a table with a large amount of data can cause noticeable delays.

To minimize the overhead incurred by enforcing constraints, omit constraint enforcement on large, often updated tables. You can evaluate these tables for constraint violations by running [ANALYZE_CONSTRAINTS](#) during off-peak hours.

Several aspects of constraint enforcement have specific impact on system performance. These include:

- [Table locking](#)
- [Projections for enforced constraints](#)
- [Constraint-triggered rollback within transactions](#)

Table locking

If a table enforces constraints, Vertica sets an insert/validate (IV) lock on that table during a DML operation while it undergoes validation. Only one session at a time can acquire an IV lock on that table. As long as the session retains this lock, no other session can access the table. Lengthy loads is liable to cause performance bottlenecks, especially if multiple sessions try to load the same table simultaneously. For details, see [Constraint enforcement and locking](#).

Enforced constraint projections

To enforce primary key and unique constraints, Vertica creates [special projections](#) that it uses to validate data. Depending on the amount of data in the anchor table, creating the projection might incur significant system overhead.

Rollback in transactions

Vertica validates enforced constraints for each SQL statement, and rolls back each statement that encounters a constraint violation. You cannot defer enforcement until the transaction commits. Thus, if multiple DML statements comprise a single transaction, Vertica validates each statement separately for constraint compliance, and rolls back any statement that fails validation. It commits the transaction only after all statements in it return.

For example, you might issue ten **INSERT** statements as a single transaction on a table that enforces **UNIQUE** on one of its columns. If the sixth statement attempts to insert a duplicate value in that column, that statement is rolled back. However, the other statements can commit.

Projections for enforced constraints

To enforce primary key and unique constraints, Vertica creates special constraint enforcement projections that it uses to validate new and updated data. If you add a constraint on an empty table, Vertica creates a constraint enforcement projection for that table only when data is added to it. If you add a primary key or unique constraint to a populated table and enable enforcement, Vertica chooses an existing projection to enforce the constraint, if one exists. Otherwise, Vertica creates a projection for that constraint. If a constraint violation occurs, Vertica rolls back the statement and any projection it created for the constraint.

If you drop an enforced primary key or unique constraint, Vertica automatically drops the projection associated with that constraint. You can also explicitly drop constraint projections with [DROP PROJECTION](#). If the statement omits **CASCADE**, Vertica issues a warning about dropping this projection for an enabled constraint; otherwise, it silently drops the projection. In either case, the next time Vertica needs to enforce this constraint, it recreates the projection. Depending on the amount of data in the anchor table, creating the projection can incur significant overhead.

You can query system table [PROJECTIONS](#) on Boolean column **IS_KEY_CONSTRAINT_PROJECTION** to obtain constraint-specific projections.

Note

Constraint enforcement projections in a table can significantly facilitate its analysis by [ANALYZE_CONSTRAINTS](#).

Constraint enforcement limitations

Vertica does not support constraint enforcement for foreign keys or external tables. Restrictions also apply to temporary tables.

Foreign keys

Vertica does not support enforcement of foreign keys and referential integrity. Thus, it is possible to load data that can return errors in the following cases:

- An inner join query is processed.
- An outer join is treated as an inner join due to the presence of foreign keys.

To validate foreign key constraints, use [ANALYZE_CONSTRAINTS](#).

External tables

Vertica does not support automatic enforcement of constraints on external tables.

Local temporary tables

ALTER TABLE can set enforcement on a primary key or unique constraint in a local temporary table only if the table contains no data. If you try to enforce a constraint in a table that contains data, **ALTER TABLE** returns an error.

Global temporary tables

In a global temporary table, you set enforcement on a primary key or unique constraint only with **CREATE TEMPORARY TABLE**. **ALTER TABLE** returns an error if you try to set enforcement on a primary key or unique constraint in an existing table, whether populated or empty.

Note

You can always use **ALTER TABLE...DROP CONSTRAINT** to disable primary and unique key constraints in local and global temporary tables.

Managing queries

This section covers the following topics:

- [Query plans](#): Describes how Vertica creates and uses query plans, which optimize access to information in the Vertica database.
- [Directed queries](#): Shows how to save query plan information.

In this section

- [Query plans](#)
- [Directed queries](#)

Query plans

When you submit a query, the query optimizer quickly chooses the projections to use, optimizes and plans the query execution, and logs the SQL statement to its log. This planning results in an *query plan*, which maps out the steps the query performs.

A query plan is a sequence of step-like [paths](#) that the Vertica cost-based query optimizer uses to execute queries. Vertica can produce different query plans for a given query. For each query plan, the query optimizer evaluates the data to be queried: number of rows, column statistics such as number of distinct values (cardinality), distribution of data across nodes. It also evaluates available resources such as CPUs and network topology, and other environment factors. The query optimizer uses this information to develop several potential plans. It then compares plans and chooses one, generally the plan with the [lowest cost](#).

The optimizer breaks down the query plan into smaller [local plans](#) and distributes them to [executor nodes](#). [The executor nodes process the smaller plans in parallel. Tasks associated with a query are recorded in the executor's log files.](#)

In the final stages of query plan execution, the initiator node performs the following tasks:

- Combines results in a grouping operation.
- Merges multiple sorted partial result sets from all the executors.
- Formats the results to return to the client.

Before executing a query, you can [view its plan](#) in by embedding the query in an **EXPLAIN** statement; you can also view it in the Management Console.

In this section

- [Viewing query plans](#)
- [Query plan cost estimation](#)
- [Query plan information and structure](#)

Viewing query plans

You can obtain query plans in two ways:

- The **EXPLAIN** statement outputs query plans in various text formats (see [below](#)).
- Management Console provides a graphical interface for viewing query plans. For detailed information, see [Working with query plans in MC](#).

You can also observe the real-time flow of data through a query plan by querying the system table [QUERY_PLAN_PROFILES](#). For more information, see [Profiling query plans](#).

EXPLAIN output options

By default, EXPLAIN output represents the query plan as a hierarchy, where each level, or [path](#), represents a single database operation that the optimizer uses to execute a query. EXPLAIN output also appends DOT language source so you can display this output graphically with open source [Graphviz](#) tools.

EXPLAIN supports options for producing [verbose](#) and [JSON](#) output. You can also show the [local query plans](#) that are assigned to each node, which together comprise the total (global) query plan.

EXPLAIN also supports an ANNOTATED option. EXPLAIN ANNOTATED returns a query with embedded optimizer hints, which encapsulate the query plan for this query. For an example of usage, see [Using optimizer-generated and custom directed queries together](#).

In this section

- [EXPLAIN-Generated query plans](#)
- [JSON-Formatted query plans](#)
- [Verbose query plans](#)
- [Local query plans](#)

EXPLAIN-Generated query plans

[EXPLAIN](#) returns the optimizer's query plan for executing a specified query. For example:

```
QUERY PLAN DESCRIPTION:
-----

EXPLAIN SELECT customer_name, customer_state FROM customer_dimension WHERE customer_state IN ('MA','NH') AND customer_gender='Male'
ORDER BY customer_name LIMIT 10;

Access Path:
+-SELECT LIMIT 10 [Cost: 365, Rows: 10] (PATH ID: 0)
| Output Only: 10 tuples
| Execute on: Query Initiator
| +---> SORT [TOPK] [Cost: 365, Rows: 544] (PATH ID: 1)
|| Order: customer_dimension.customer_name ASC
|| Output Only: 10 tuples
|| Execute on: Query Initiator
|| +---> STORAGE ACCESS for customer_dimension [Cost: 326, Rows: 544] (PATH ID: 2)
||| Projection: public.customer_dimension_DBD_1_rep_VMartDesign_node0001
||| Materialize: customer_dimension.customer_state, customer_dimension.customer_name
||| Filter: (customer_dimension.customer_gender = 'Male')
||| Filter: (customer_dimension.customer_state = ANY (ARRAY['MA', 'NH']))
||| Execute on: Query Initiator
||| Runtime Filter: (SIP1(TopK): customer_dimension.customer_name)
```

You can use [EXPLAIN](#) to evaluate choices that the optimizer makes with respect to a given query. If you think query performance is less than optimal, run it through the Database Designer. For more information, see [Incremental Design](#) and [Reducing query run time](#).

JSON-Formatted query plans

[EXPLAIN JSON](#) returns a query plan in JSON format. For example:

```

=> EXPLAIN JSON SELECT customer_name, customer_state FROM customer_dimension
WHERE customer_state IN ('MA','NH') AND customer_gender='Male' ORDER BY customer_name LIMIT 10;
-----
{
  "PARAMETERS" : {
    "QUERY_STRING" : "EXPLAIN JSON SELECT customer_name, customer_state FROM customer_dimension \n
WHERE customer_state IN ('MA','NH') AND customer_gender='Male' ORDER BY customer_name LIMIT 10;"
  },
  "PLAN" : {
    "PATH_ID" : 0,
    "PATH_NAME" : "SELECT",
    "EXTRA" : " LIMIT 10",
    "COST" : 2114.000000,
    "ROWS" : 10.000000,
    "COST_STATUS" : "NO_STATISTICS",
    "TUPLE_LIMIT" : 10,
    "EXECUTE_NODE" : "Query Initiator",
    "INPUT" : {
      "PATH_ID" : 1,
      "PATH_NAME" : "SORT",
      "EXTRA" : "[TOPK]",
      "COST" : 2114.000000,
      "ROWS" : 49998.000000,
      "COST_STATUS" : "NO_STATISTICS",
      "ORDER" : ["customer_dimension.customer_name", "customer_dimension.customer_state"],
      "TUPLE_LIMIT" : 10,
      "EXECUTE_NODE" : "All Nodes",

        "PATH_NAME" : "STORAGE ACCESS",
        "EXTRA" : "for customer_dimension",
        "COST" : 252.000000,
        "ROWS" : 49998.000000,
        "COST_STATUS" : "NO_STATISTICS",
        "TABLE" : "public.customer_dimension",
        "PROJECTION" : "public.customer_dimension_b0",
        "MATERIALIZATION" : ["customer_dimension.customer_name", "customer_dimension.customer_state"],
        "FILTER" : ["(customer_dimension.customer_state = ANY (ARRAY['MA', 'NH']))", "(customer_dimension.customer_gender = 'Male')"],
        "EXECUTE_NODE" : "All Nodes"
      }
    }
  }
}
(40 rows)

```

Verbose query plans

You can qualify **EXPLAIN** with the **VERBOSE** option. This option, valid for default and **JSON** output, increases the amount of detail in the rendered query plan

For example, the following **EXPLAIN** statement specifies to produce verbose output. Added information is set off in bold:

```
=> EXPLAIN VERBOSE SELECT customer_name, customer_state FROM customer_dimension
WHERE customer_state IN ('MA','NH') AND customer_gender='Male' ORDER BY customer_name LIMIT 10;
```

QUERY PLAN DESCRIPTION:

Opt Vertica Options

PLAN_OUTPUT_SUPER_VERBOSE

```
EXPLAIN VERBOSE SELECT customer_name, customer_state FROM customer_dimension
WHERE customer_state IN ('MA','NH') AND customer_gender='Male'
ORDER BY customer_name LIMIT 10;
```

Access Path:

```
+--SELECT LIMIT 10 [Cost: 756.000000, Rows: 10.000000 Disk(B): 0.000000 CPU(B): 0.000000 Memory(B): 0.000000 Netwrk(B): 0.000000 Parallelism:

```

Local query plans

EXPLAIN LOCAL (on a multi-node database) shows the local query plans assigned to each node, which together comprise the total (global) query plan. If you omit this option, Vertica shows only the global query plan. Local query plans are shown only in DOT language source, which can be rendered in [Graphviz](#).

For example, the following **EXPLAIN** statement includes the **LOCAL** option:

```
=> EXPLAIN LOCAL SELECT store_name, store_city, store_state
FROM store.store_dimension ORDER BY store_state ASC, store_city ASC;
```

The output includes GraphViz source, which describes the local query plans assigned to each node. For example, output for this statement on a three-node database includes a GraphViz description of the following query plan for one node (`v_vmart_node0003`):

PLAN: v_vmart_node0003 (GraphViz Format)

```
digraph G {
graph [rankdir=BT, label = "v_vmart_node0003\n", labelloc=t, labeljust=l ordering=out]
0[label = "NewEENode \nOutBlk=[UncTuple(3)]", color = "green", shape = "box"];
1[label = "Send\nSend to: v_vmart_node0001\nNet id: 1000\nMerge\n\nUnc: Char(2)\nUnc: Varchar(64)\nUnc: Varchar(64)", color = "green", shape = "box"];
2[label = "Sort: (keys = A,A,N)\nUnc: Char(2)\nUnc: Varchar(64)\nUnc: Varchar(64)", color = "green", shape = "box"];
3[label = "ExprEval: \n store_dimension.store_state\n store_dimension.store_city\n store_dimension.store_name\nUnc: Char(2)\nUnc: Varchar(64)\nUnc: Varchar(64)", color = "green", shape = "box"];
4[label = "StorageUnionStep: store_dimension_p_b0\nUnc: Varchar(64)\nUnc: Varchar(64)\nUnc: Char(2)", color = "purple", shape = "box"];
5[label = "ScanStep: store_dimension_p_b0\nstore_key (not emitted)\nstore_name\nstore_city\nstore_state\nUnc: Varchar(64)\nUnc: Varchar(64)\nUnc: Char(2)", color = "brown", shape = "box"];
1->0 [label = "0",color = "blue"];
2->1 [label = "0",color = "blue"];
3->2 [label = "0",color = "blue"];
4->3 [label = "0",color = "blue"];
5->4 [label = "0",color = "blue"];
}
```

GraphViz renders this output as follows:

Query plan cost estimation

The query optimizer chooses a query plan based on cost estimates. The query optimizer uses information from a number of sources to develop potential plans and determine their relative costs. These include:

- Number of table rows
- Column statistics, including: number of distinct values (cardinality), minimum/maximum values, distribution of values, and disk space usage
- Access path that is likely to require fewest I/O operations, and lowest CPU, memory, and network usage
- Available eligible projections
- Join options: join types (merge versus hash joins), join order
- Query predicates
- Data segmentation across cluster nodes

Many important optimizer decisions rely on statistics, which the query optimizer uses to determine the final plan to execute a query. Therefore, it is important that statistics be up to date. Without reasonably accurate statistics, the optimizer could choose a suboptimal plan, which might affect query performance.

Vertica provides hints about statistics in the query plan. See [Query plan statistics](#).

Cost versus execution runtime

Although costs correlate to query runtime, they do not provide an *estimate* of actual runtime. For example, if the optimizer determines that Plan A costs twice as much as Plan B, it is likely that Plan A will require more time to run. However, this cost estimate does not necessarily indicate that Plan A will run twice as long as Plan B.

Also, plan costs for different queries are not directly comparable. For example, if the estimated cost of Plan X for query1 is greater than the cost of Plan Y for query2, it is not necessarily true that Plan X's runtime is greater than Plan Y's runtime.

Query plan information and structure

Depending on the query and database schema, **EXPLAIN** output includes the following information:

- Tables referenced by the statement
- Estimated costs
- Estimated row cardinality
- Path ID, an integer that links to error messages and profiling counters so you troubleshoot performance issues more easily. For more information, see [Profiling query plans](#).
- Data operations such as **SORT**, **FILTER**, **LIMIT**, and **GROUP BY**
- Projections used
- Information about statistics—for example, whether they are current or out of range
- Algorithms chosen for operations into the query, such as **HASH / MERGE** or **GROUPBY HASH / GROUPBY PIPELINED**
- Data redistribution (broadcast, segmentation) across cluster nodes

Example

In the **EXPLAIN** output that follows, the optimizer processes a query in three steps, where each step identified by a unique path ID:

- 0: Limit
- 1: Sort
- 2: Storage access and filter

```
QUERY PLAN DESCRIPTION:
-----
EXPLAIN SELECT customer_name, customer_state FROM customer_dimension
WHERE customer_state IN ('MA','NH') AND customer_gender = 'Male'
ORDER BY customer_name LIMIT 10;

Access Path:
+-SELECT LIMIT 10 [Cost: 365, Rows: 10] (PATH ID: 0) ← Limit
| Output Only: 10 tuples
| Execute on: Query Initiator
| +---> SORT [TOPK] [Cost: 365, Rows: 544] (PATH ID: 1) ← Sort
| | Order: customer_dimension.customer_name ASC
| | Output Only: 10 tuples
| | Execute on: Query Initiator
| | +---> STORAGE ACCESS for customer_dimension [Cost: 326, Rows: 544] (PATH ID: 2)
| | | Projection: public.customer_dimension.DBD_1_rep_WmartDesign_node0001
| | | Materialize: customer_dimension.customer_state, customer_dimension.customer_name
| | | Filter: (customer_dimension.customer_gender = 'Male')
| | | Filter: (customer_dimension.customer_state = ANY (ARRAY['MA', 'NH']))
| | | Execute on: Query Initiator
| | | Storage access and filter
```

Note

A storage access operation can scan more than the columns in the **SELECT** list— for example, columns referenced in **WHERE** clause.

Query plan statistics

If you query a table whose statistics are unavailable or out-of-date, the optimizer might choose a sub-optimal query plan.

You can resolve many issues related to table statistics by calling [ANALYZE STATISTICS](#). This function let you update statistics at various scopes: one or more table columns, a single table, or all database tables.

If you update statistics and find that the query still performs sub-optimally, run your query through Database Designer and choose incremental design as the design type.

For detailed information about updating database statistics, see [Collecting database statistics](#).

Statistics hints in query plans

Query plans can contain information about table statistics through two hints: **NO STATISTICS** and **STALE STATISTICS**. For example, the following query plan fragment includes **NO STATISTICS** to indicate that histograms are unavailable:

```
|| +-- Outer -> STORAGE ACCESS for fact [Cost: 604, Rows: 10K (NO STATISTICS)]
```

The following query plan fragment includes **STALE STATISTICS** to indicate that the predicate has fallen outside the histogram range:

```
|| +-- Outer -> STORAGE ACCESS for fact [Cost: 35, Rows: 1 (STALE STATISTICS)]
```

Cost and rows path

The following EXPLAIN output shows the **Cost** operator:

```
Access Path: +-SELECT LIMIT 10 [Cost: 370, Rows: 10] (PATH ID: 0)
| Output Only: 10 tuples
| Execute on: Query Initiator
| +---> SORT [Cost: 370, Rows: 544] (PATH ID: 1)
|| Order: customer_dimension.customer_name ASC
|| Output Only: 10 tuples
|| Execute on: Query Initiator
|| +---> STORAGE ACCESS for customer_dimension [Cost: 331, Rows: 544] (PATH ID: 2)
||| Projection: public.customer_dimension_DBD_1_rep_vmartdb_design_vmartdb_design_node0001
||| Materialize: customer_dimension.customer_state, customer_dimension.customer_name
||| Filter: (customer_dimension.customer_gender = 'Male')
||| Filter: (customer_dimension.customer_state = ANY (ARRAY['MA', 'NH']))
||| Execute on: Query Initiator
```

The **Row** operator is the number of rows the optimizer estimates the query will return. Letters after numbers refer to the units of measure (K=thousand, M=million, B=billion, T=trillion), so the output for the following query indicates that the number of rows to return is 50 *thousand*.

```
=> EXPLAIN SELECT customer_gender FROM customer_dimension;
Access Path:
+-STORAGE ACCESS for customer_dimension [Cost: 17, Rows: 50K (3 RLE)] (PATH ID: 1)
| Projection: public.customer_dimension_DBD_1_rep_vmartdb_design_vmartdb_design_node0001
| Materialize: customer_dimension.customer_gender
| Execute on: Query Initiator
```

The reference to (3 RLE) in the STORAGE ACCESS path means that the optimizer estimates that the storage access operator returns 50K rows. Because the column is run-length encoded (RLE), the real number of RLE rows returned is only three rows:

- 1 row for female
- 1 row for male
- 1 row that represents unknown (NULL) gender

Note

See [Query plans](#) for more information about how the optimizer estimates cost.

Projection path

You can see which [projections](#) the optimizer chose for the query plan by looking at the [Projection](#) path in the textual output:

```
EXPLAIN SELECT
  customer_name,
  customer_state
FROM customer_dimension
WHERE customer_state in ('MA','NH')
AND customer_gender = 'Male'
ORDER BY customer_name
LIMIT 10;
Access Path:
+-SELECT LIMIT 10 [Cost: 370, Rows: 10] (PATH ID: 0)
| Output Only: 10 tuples
| Execute on: Query Initiator
| +---> SORT [Cost: 370, Rows: 544] (PATH ID: 1)
|| Order: customer_dimension.customer_name ASC
|| Output Only: 10 tuples
|| Execute on: Query Initiator
|| +---> STORAGE ACCESS for customer_dimension [Cost: 331, Rows: 544] (PATH ID: 2)
||| Projection: public.customer_dimension_DBD_1_rep_vmart_vmart_node0001
||| Materialize: customer_dimension.customer_state, customer_dimension.customer_name
||| Filter: (customer_dimension.customer_gender = 'Male')
||| Filter: (customer_dimension.customer_state = ANY (ARRAY['MA', 'NH']))
||| Execute on: Query Initiator
```

The query optimizer automatically picks the best projections, but without reasonably accurate statistics, the optimizer could choose a suboptimal projection or join order for a query. For details, see [Collecting Statistics](#).

Vertica considers which projection to choose for a plan by considering the following aspects:

- How columns are joined in the query
- How the projections are grouped or sorted
- Whether SQL analytic operations applied
- Any column information from a projection's storage on disk

As Vertica scans the possibilities for each plan, projections with the higher initial costs could end up in the final plan because they make joins cheaper. For example, a query can be answered with many possible plans, which the optimizer considers before choosing one of them. For efficiency, the optimizer uses sophisticated algorithms to prune intermediate partial plan fragments with higher cost. The optimizer knows that intermediate plan fragments might initially look bad (due to high storage access cost) but which produce excellent final plans due to other optimizations that it allows.

If your statistics are up to date but the query still performs poorly, run the query through the Database Designer. For details, see [Incremental Design](#).

Tips

- To test different segmented projections, refer to the projection by name in the query.
- For optimal performance, write queries so the columns are sorted the same way that the projection columns are sorted.

See also

- [Reducing query run time](#)
- [Creating custom designs](#)
- [Projections](#)

Join path

Just like a join query, which references two or more tables, the [Join](#) step in a query plan has two input branches:

- The left input, which is the outer table of the join
- The right input, which is the inner table of the join

In the following query, the **T1** table is the left input because it is on the left side of the JOIN keyword, and the **T2** table is the right input, because it is on the right side of the JOIN keyword:

```
SELECT * FROM T1 JOIN T2 ON T1.x = T2.x;
```

Outer versus inner join

Query performance is better if the small table is used as the inner input to the join. The query optimizer automatically reorders the inputs to joins to ensure that this is the case unless the join in question is an outer join.

Note

If the configuration parameter `EnableForceOuter` is set to 1, you can control join inputs for specific tables through `ALTER TABLE..FORCE OUTER`. For details, see [Controlling join inputs](#).

The following example shows a query and its plan for a left outer join:

```
=> EXPLAIN SELECT CD.annual_income,OSI.sale_date_key
-> FROM online_sales.online_sales_fact OSI
-> LEFT OUTER JOIN customer_dimension CD ON CD.customer_key = OSI.customer_key;
Access Path:
+-JOIN HASH [LeftOuter] [Cost: 4K, Rows: 5M] (PATH ID: 1)
| Join Cond: (CD.customer_key = OSI.customer_key)
| Materialize at Output: OSI.sale_date_key
| Execute on: All Nodes
| +- Outer -> STORAGE ACCESS for OSI [Cost: 3K, Rows: 5M] (PATH ID: 2)
|| Projection: online_sales.online_sales_fact_DBD_12_seg_vmartdb_design_vmartdb_design
|| Materialize: OSI.customer_key
|| Execute on: All Nodes
| +- Inner -> STORAGE ACCESS for CD [Cost: 264, Rows: 50K] (PATH ID: 3)
|| Projection: public.customer_dimension_DBD_1_rep_vmartdb_design_vmartdb_design_node0001
|| Materialize: CD.annual_income, CD.customer_key
|| Execute on: All Nodes
```

The following example shows a query and its plan for a full outer join:

```
=> EXPLAIN SELECT CD.annual_income,OSI.sale_date_key
-> FROM online_sales.online_sales_fact OSI
-> FULL OUTER JOIN customer_dimension CD ON CD.customer_key = OSI.customer_key;
Access Path:
+-JOIN HASH [FullOuter] [Cost: 18K, Rows: 5M] (PATH ID: 1) Outer (RESEGMENT) Inner (FILTER)
| Join Cond: (CD.customer_key = OSI.customer_key)
| Execute on: All Nodes
| +- Outer -> STORAGE ACCESS for OSI [Cost: 3K, Rows: 5M] (PATH ID: 2)
|| Projection: online_sales.online_sales_fact_DBD_12_seg_vmartdb_design_vmartdb_design
|| Materialize: OSI.sale_date_key, OSI.customer_key
|| Execute on: All Nodes
| +- Inner -> STORAGE ACCESS for CD [Cost: 264, Rows: 50K] (PATH ID: 3)
|| Projection: public.customer_dimension_DBD_1_rep_vmartdb_design_vmartdb_design_node0001
|| Materialize: CD.annual_income, CD.customer_key
|| Execute on: All Nodes
```

Hash and merge joins

Vertica has two join algorithms to choose from: merge join and hash join. The optimizer automatically chooses the most appropriate algorithm, given the query and projections in a system.

For the following query, the optimizer chooses a hash join.

```

=> EXPLAIN SELECT CD.annual_income,OSI.sale_date_key
-> FROM online_sales.online_sales_fact OSI
-> INNER JOIN customer_dimension CD ON CD.customer_key = OSI.customer_key;
Access Path:
+-JOIN HASH [Cost: 4K, Rows: 5M] (PATH ID: 1)
| Join Cond: (CD.customer_key = OSI.customer_key)
| Materialize at Output: OSI.sale_date_key
| Execute on: All Nodes
| +- Outer -> STORAGE ACCESS for OSI [Cost: 3K, Rows: 5M] (PATH ID: 2)
|| Projection: online_sales.online_sales_fact_DBD_12_seg_vmartdb_design_vmartdb_design
|| Materialize: OSI.customer_key
|| Execute on: All Nodes
| +- Inner -> STORAGE ACCESS for CD [Cost: 264, Rows: 50K] (PATH ID: 3)
|| Projection: public.customer_dimension_DBD_1_rep_vmartdb_design_vmartdb_design_node0001
|| Materialize: CD.annual_income, CD.customer_key
|| Execute on: All Nodes

```

Tip

If you get a hash join when you are expecting a merge join, it means that at least one of the projections is not sorted on the join column (for example, [customer_key](#) in the preceding query). To facilitate a merge join, you might need to create different projections that are sorted on the join columns.

In the next example, the optimizer chooses a merge join. The optimizer's first pass performs a merge join because the inputs are presorted, and then it performs a hash join.

```

=> EXPLAIN SELECT count(*) FROM online_sales.online_sales_fact OSI
-> INNER JOIN customer_dimension CD ON CD.customer_key = OSI.customer_key
-> INNER JOIN product_dimension PD ON PD.product_key = OSI.product_key;
Access Path:
+-GROUPBY NOTHING [Cost: 8K, Rows: 1] (PATH ID: 1)
| Aggregates: count(*)
| Execute on: All Nodes
| +---> JOIN HASH [Cost: 7K, Rows: 5M] (PATH ID: 2)
|| Join Cond: (PD.product_key = OSI.product_key)
|| Materialize at Input: OSI.product_key
|| Execute on: All Nodes
|| +- Outer -> JOIN MERGEJOIN(inputs presorted) [Cost: 4K, Rows: 5M] (PATH ID: 3)
||| Join Cond: (CD.customer_key = OSI.customer_key)
||| Execute on: All Nodes
||| +- Outer -> STORAGE ACCESS for OSI [Cost: 3K, Rows: 5M] (PATH ID: 4)
||| Projection: online_sales.online_sales_fact_DBD_12_seg_vmartdb_design_vmartdb_design
||| Materialize: OSI.customer_key
||| Execute on: All Nodes
||| +- Inner -> STORAGE ACCESS for CD [Cost: 132, Rows: 50K] (PATH ID: 5)
||| Projection: public.customer_dimension_DBD_1_rep_vmartdb_design_vmartdb_design_node0001
||| Materialize: CD.customer_key
||| Execute on: All Nodes
|| +- Inner -> STORAGE ACCESS for PD [Cost: 152, Rows: 60K] (PATH ID: 6)
|| Projection: public.product_dimension_DBD_2_rep_vmartdb_design_vmartdb_design_node0001
|| Materialize: PD.product_key
|| Execute on: All Nodes

```

Inequality joins

Vertica processes joins with equality predicates very efficiently. The query plan shows equality join predicates as join condition ([Join Cond](#)).

```

=> EXPLAIN SELECT CD.annual_income, OSI.sale_date_key
-> FROM online_sales.online_sales_fact OSI
-> INNER JOIN customer_dimension CD
-> ON CD.customer_key = OSI.customer_key;
Access Path:
+-JOIN HASH [Cost: 4K, Rows: 5M] (PATH ID: 1)
| Join Cond: (CD.customer_key = OSI.customer_key)
| Materialize at Output: OSI.sale_date_key
| Execute on: All Nodes
| +- Outer -> STORAGE ACCESS for OSI [Cost: 3K, Rows: 5M] (PATH ID: 2)
|| Projection: online_sales.online_sales_fact_DBD_12_seg_vmartdb_design_vmartdb_design
|| Materialize: OSI.customer_key
|| Execute on: All Nodes
| +- Inner -> STORAGE ACCESS for CD [Cost: 264, Rows: 50K] (PATH ID: 3)
|| Projection: public.customer_dimension_DBD_1_rep_vmartdb_design_vmartdb_design_node0001
|| Materialize: CD.annual_income, CD.customer_key
|| Execute on: All Nodes

```

However, inequality joins are treated like cross joins and can run less efficiently, which you can see by the change in cost between the two queries:

```

=> EXPLAIN SELECT CD.annual_income, OSI.sale_date_key
-> FROM online_sales.online_sales_fact OSI
-> INNER JOIN customer_dimension CD
-> ON CD.customer_key < OSI.customer_key;
Access Path:
+-JOIN HASH [Cost: 98M, Rows: 5M] (PATH ID: 1)
| Join Filter: (CD.customer_key < OSI.customer_key)
| Materialize at Output: CD.annual_income
| Execute on: All Nodes
| +- Outer -> STORAGE ACCESS for CD [Cost: 132, Rows: 50K] (PATH ID: 2)
|| Projection: public.customer_dimension_DBD_1_rep_vmartdb_design_vmartdb_design_node0001
|| Materialize: CD.customer_key
|| Execute on: All Nodes
| +- Inner -> STORAGE ACCESS for OSI [Cost: 3K, Rows: 5M] (PATH ID: 3)
|| Projection: online_sales.online_sales_fact_DBD_12_seg_vmartdb_design_vmartdb_design
|| Materialize: OSI.sale_date_key, OSI.customer_key
|| Execute on: All Nodes

```

Event series joins

Event series joins are denoted by the **INTERPOLATED** path.

```

=> EXPLAIN SELECT * FROM hTicks h FULL OUTER JOIN aTicks a -> ON (h.time INTERPOLATE PREVIOUS
Access Path:
+-JOIN (INTERPOLATED) [FullOuter] [Cost: 31, Rows: 4 (NO STATISTICS)] (PATH ID: 1)
Outer (SORT ON JOIN KEY) Inner (SORT ON JOIN KEY)
| Join Cond: (h."time" = a."time")
| Execute on: Query Initiator
| +- Outer -> STORAGE ACCESS for h [Cost: 15, Rows: 4 (NO STATISTICS)] (PATH ID: 2)
|| Projection: public.hTicks_node0004
|| Materialize: h.stock, h."time", h.price
|| Execute on: Query Initiator
| +- Inner -> STORAGE ACCESS for a [Cost: 15, Rows: 4 (NO STATISTICS)] (PATH ID: 3)
|| Projection: public.aTicks_node0004
|| Materialize: a.stock, a."time", a.price
|| Execute on: Query Initiator

```

Path ID

The **PATH ID** is a unique identifier that Vertica assigns to each operation (path) within a query plan. The same identifier is shared by:

- [Query plans](#)
- Join error messages

- System tables [EXECUTION_ENGINE_PROFILES](#) and [QUERY_PLAN_PROFILES](#)

Path IDs can help you trace issues to their root cause. For example, if a query returns a join error, preface the query with **EXPLAIN** and look for **PATH ID *n*** in the query plan to see which join in the query had the problem.

For example, the following **EXPLAIN** output shows the path ID for each path in the optimizer's query plan:

```
=> EXPLAIN SELECT * FROM fact JOIN dim ON x=y JOIN ext on y=z;
Access Path:
+-JOIN MERGEJOIN(inputs presorted) [Cost: 815, Rows: 10K (NO STATISTICS)] (PATH ID: 1)
| Join Cond: (dim.y = ext.z)
| Materialize at Output: fact.x
| Execute on: All Nodes
| +- Outer -> JOIN MERGEJOIN(inputs presorted) [Cost: 408, Rows: 10K (NO STATISTICS)] (PATH ID: 2)
| | Join Cond: (fact.x = dim.y)
| | Execute on: All Nodes
| | +- Outer -> STORAGE ACCESS for fact [Cost: 202, Rows: 10K (NO STATISTICS)] (PATH ID: 3)
| | | Projection: public.fact_super
| | | Materialize: fact.x
| | | Execute on: All Nodes
| | +- Inner -> STORAGE ACCESS for dim [Cost: 202, Rows: 10K (NO STATISTICS)] (PATH ID: 4)
| | | Projection: public.dim_super
| | | Materialize: dim.y
| | | Execute on: All Nodes
| +- Inner -> STORAGE ACCESS for ext [Cost: 202, Rows: 10K (NO STATISTICS)] (PATH ID: 5)
| | Projection: public.ext_super
| | Materialize: ext.z
| | Execute on: All Nodes
```

Filter path

The **Filter** step evaluates predicates on a single table. It accepts a set of rows, eliminates some of them (based on the criteria you provide in your query), and returns the rest. For example, the optimizer can filter local data of a join input that will be joined with another re-segmented join input.

The following statement queries the **customer_dimension** table and uses the WHERE clause to filter the results only for male customers in Massachusetts and New Hampshire.

```
EXPLAIN SELECT
  CD.customer_name,
  CD.customer_state,
  AVG(CD.customer_age) AS avg_age,
  COUNT(*) AS count
FROM customer_dimension CD
WHERE CD.customer_state in ('MA','NH') AND CD.customer_gender = 'Male'
GROUP BY CD.customer_state, CD.customer_name;
```

The query plan output is as follows:

```
Access Path:
+-GROUPBY HASH [Cost: 378, Rows: 544] (PATH ID: 1)
| Aggregates: sum_float(CD.customer_age), count(CD.customer_age), count(*)
| Group By: CD.customer_state, CD.customer_name
| Execute on: Query Initiator
| +---> STORAGE ACCESS for CD [Cost: 372, Rows: 544] (PATH ID: 2)
| | Projection: public.customer_dimension_DBD_1_rep_vmartdb_design_vmartdb_design_node0001
| | Materialize: CD.customer_state, CD.customer_name, CD.customer_age
| | Filter: (CD.customer_gender = 'Male')
| | Filter: (CD.customer_state = ANY (ARRAY['MA', 'NH']))
| | Execute on: Query Initiator
```

GROUP BY paths

A GROUP BY operation has two algorithms:

- [GROUPBY HASH](#) input is not sorted by the group columns, so Vertica builds a hash table on those group columns in order to process the aggregates and group by expressions.
- [GROUPBY PIPELINED](#) requires that inputs be presorted on the columns specified in the group, which means that Vertica need only retain data in the current group in memory. GROUPBY PIPELINED operations are preferred because they are generally faster and require less memory than GROUPBY HASH. GROUPBY PIPELINED is especially useful for queries that process large numbers of high-cardinality group by columns or [DISTINCT](#) aggregates.

If possible, the query optimizer chooses the faster algorithm GROUPBY PIPELINED over GROUPBY HASH.

Note

For details, see [GROUP BY implementation options](#).

In this section

- [GROUPBY HASH query plan](#)
- [GROUPBY PIPELINED query plan](#)

GROUPBY HASH query plan

Here's an example of how [GROUPBY HASH](#) operations look in [EXPLAIN](#) output.

```
=> EXPLAIN SELECT COUNT(DISTINCT annual_income)
FROM customer_dimension
WHERE customer_region='NorthWest';
```

The output shows that the optimizer chose the less efficient [GROUPBY HASH](#) path, which means the projection was not presorted on the [annual_income](#) column. If such a projection is available, the optimizer would choose the [GROUPBY PIPELINED](#) algorithm.

```
Access Path:
+-GROUPBY NOTHING [Cost: 256, Rows: 1 (NO STATISTICS)] (PATH ID: 1)
| Aggregates: count(DISTINCT customer_dimension.annual_income)
| +----> GROUPBY HASH (LOCAL RESEGMENT GROUPS) [Cost: 253, Rows: 10K (NO STATISTICS)] (PATH ID: 2)
| |   Group By: customer_dimension.annual_income
| | +----> STORAGE ACCESS for customer_dimension [Cost: 227, Rows: 50K (NO STATISTICS)] (PATH ID: 3)
| | |   Projection: public.customer_dimension_super
| | |   Materialize: customer_dimension.annual_income
| | |   Filter: (customer_dimension.customer_region = 'NorthWest')
| | ...
```

GROUPBY PIPELINED query plan

If you have a projection that is already sorted on the [customer_gender](#) column, the optimizer chooses the faster [GROUPBY PIPELINED](#) operation:

```
=> EXPLAIN SELECT COUNT(distinct customer_gender) from customer_dimension;
Access Path:
+-GROUPBY NOTHING [Cost: 22, Rows: 1] (PATH ID: 1)
| Aggregates: count(DISTINCT customer_dimension.customer_gender)
| Execute on: Query Initiator
| +----> GROUPBY PIPELINED [Cost: 20, Rows: 10K] (PATH ID: 2)
| |   Group By: customer_dimension.customer_gender
| |   Execute on: Query Initiator
| | +----> STORAGE ACCESS for customer_dimension [Cost: 17, Rows: 50K (3 RLE)] (PATH ID: 3)
| | |   Projection: public.customer_dimension_DBD_1_rep_vmartdb_design_vmartdb_design_node0001
| | |   Materialize: customer_dimension.customer_gender
| | |   Execute on: Query Initiator
```

Similarly, the use of an equality predicate, such as in the following query, preserves [GROUPBY PIPELINED](#) :

```
=> EXPLAIN SELECT COUNT(DISTINCT annual_income) FROM customer_dimension
WHERE customer_gender = 'Female';
```

```
Access Path: +-GROUPBY NOTHING [Cost: 161, Rows: 1] (PATH ID: 1)
| Aggregates: count(DISTINCT customer_dimension.annual_income)
| +----> GROUPBY PIPELINED [Cost: 158, Rows: 10K] (PATH ID: 2)
|| Group By: customer_dimension.annual_income
|| +----> STORAGE ACCESS for customer_dimension [Cost: 144, Rows: 47K] (PATH ID: 3)
||| Projection: public.customer_dimension_DBD_1_rep_vmartdb_design_vmartdb_design_node0001
||| Materialize: customer_dimension.annual_income
||| Filter: (customer_dimension.customer_gender = 'Female')
```

Tip
If **EXPLAIN** reports **GROUPBY HASH**, modify the projection design to force it to use **GROUPBY PIPELINED**.

Sort path

The **SORT** operator sorts the data according to a specified list of columns. The EXPLAIN output indicates the sort expressions and if the sort order is ascending (ASC) or descending (DESC).

For example, the following query plan shows the column list nature of the SORT operator:

```
EXPLAIN SELECT
  CD.customer_name,
  CD.customer_state,
  AVG(CD.customer_age) AS avg_age,
  COUNT(*) AS count
FROM customer_dimension CD
WHERE CD.customer_state in ('MA','NH')
  AND CD.customer_gender = 'Male'
GROUP BY CD.customer_state, CD.customer_name
ORDER BY avg_age, customer_name;
Access Path:
+-SORT [Cost: 422, Rows: 544] (PATH ID: 1)
| Order: (<SVAR> / float8(<SVAR>)) ASC, CD.customer_name ASC
| Execute on: Query Initiator
| +----> GROUPBY HASH [Cost: 378, Rows: 544] (PATH ID: 2)
|| Aggregates: sum_float(CD.customer_age), count(CD.customer_age), count(*)
|| Group By: CD.customer_state, CD.customer_name
|| Execute on: Query Initiator
|| +----> STORAGE ACCESS for CD [Cost: 372, Rows: 544] (PATH ID: 3)
||| Projection: public.customer_dimension_DBD_1_rep_vmart_vmart_node0001
||| Materialize: CD.customer_state, CD.customer_name, CD.customer_age
||| Filter: (CD.customer_gender = 'Male')
||| Filter: (CD.customer_state = ANY (ARRAY['MA', 'NH']))
||| Execute on: Query Initiator
```

If you change the sort order to descending, the change appears in the query plan:

```

EXPLAIN SELECT
  CD.customer_name,
  CD.customer_state,
  AVG(CD.customer_age) AS avg_age,
  COUNT(*) AS count
FROM customer_dimension CD
WHERE CD.customer_state in ('MA','NH')
  AND CD.customer_gender = 'Male'
GROUP BY CD.customer_state, CD.customer_name
ORDER BY avg_age DESC, customer_name;
Access Path:
+-SORT [Cost: 422, Rows: 544] (PATH ID: 1)
| Order: (<SVAR> / float8(<SVAR>)) DESC, CD.customer_name ASC
| Execute on: Query Initiator
| +---> GROUPBY HASH [Cost: 378, Rows: 544] (PATH ID: 2)
|| Aggregates: sum_float(CD.customer_age), count(CD.customer_age), count(*)
|| Group By: CD.customer_state, CD.customer_name
|| Execute on: Query Initiator
|| +---> STORAGE ACCESS for CD [Cost: 372, Rows: 544] (PATH ID: 3)
||| Projection: public.customer_dimension_DBD_1_rep_vmart_vmart_node0001
||| Materialize: CD.customer_state, CD.customer_name, CD.customer_age
||| Filter: (CD.customer_gender = 'Male')
||| Filter: (CD.customer_state = ANY (ARRAY['MA', 'NH']))
||| Execute on: Query Initiator

```

Limit path

The **LIMIT** path restricts the number of result rows based on the LIMIT clause in the query. Using the **LIMIT** clause in queries with thousands of rows might increase query performance.

The optimizer pushes the **LIMIT** operation as far down as possible in queries. A single **LIMIT** clause in the query can generate multiple **Output Only** plan annotations.

```

=> EXPLAIN SELECT COUNT(DISTINCT annual_income) FROM customer_dimension LIMIT 10;
Access Path:
+-SELECT LIMIT 10 [Cost: 161, Rows: 10] (PATH ID: 0)
| Output Only: 10 tuples
| +---> GROUPBY NOTHING [Cost: 161, Rows: 1] (PATH ID: 1)
|| Aggregates: count(DISTINCT customer_dimension.annual_income)
|| Output Only: 10 tuples
|| +---> GROUPBY HASH (SORT OUTPUT) [Cost: 158, Rows: 10K] (PATH ID: 2)
||| Group By: customer_dimension.annual_income
||| +---> STORAGE ACCESS for customer_dimension [Cost: 132, Rows: 50K] (PATH ID: 3)
||| Projection: public.customer_dimension_DBD_1_rep_vmartdb_design_vmartdb_design_node0001
||| Materialize: customer_dimension.annual_income

```

Data redistribution path

The optimizer can redistribute join data in two ways:

- Broadcasting
- Resegmentation

Broadcasting

Broadcasting sends a complete copy of an intermediate result to all nodes in the cluster. Broadcast is used for joins in the following cases:

- One table is very small (usually the inner table) compared to the other.
- Vertica can avoid other large upstream resegmentation operations.
- Outer join or subquery semantics require one side of the join to be replicated.

For example:

```
=> EXPLAIN SELECT * FROM T1 LEFT JOIN T2 ON T1.a > T2.y;
Access Path:
+-JOIN HASH [LeftOuter] [Cost: 40K, Rows: 10K (NO STATISTICS)] (PATH ID: 1) Inner (BROADCAST)
| Join Filter: (T1.a > T2.y)
| Materialize at Output: T1.b
| Execute on: All Nodes
| +- Outer -> STORAGE ACCESS for T1 [Cost: 151, Rows: 10K (NO STATISTICS)] (PATH ID: 2)
|| Projection: public.T1_b0
|| Materialize: T1.a
|| Execute on: All Nodes
| +- Inner -> STORAGE ACCESS for T2 [Cost: 302, Rows: 10K (NO STATISTICS)] (PATH ID: 3)
|| Projection: public.T2_b0
|| Materialize: T2.x, T2.y
|| Execute on: All Nodes
```

Resegmentation

Resegmentation takes an existing projection or intermediate relation and resegments the data evenly across all cluster nodes. At the end of the resegmentation operation, every row from the input relation is on exactly one node. Resegmentation is the operation used most often for distributed joins in Vertica if the data is not already segmented for local joins. For more detail, see [Identical segmentation](#).

For example:

```
=> CREATE TABLE T1 (a INT, b INT) SEGMENTED BY HASH(a) ALL NODES;
=> CREATE TABLE T2 (x INT, y INT) SEGMENTED BY HASH(x) ALL NODES;
=> EXPLAIN SELECT * FROM T1 JOIN T2 ON T1.a = T2.y;

----- QUERY PLAN DESCRIPTION: -----
Access Path:
+-JOIN HASH [Cost: 639, Rows: 10K (NO STATISTICS)] (PATH ID: 1) Inner (RESEGMENT)
| Join Cond: (T1.a = T2.y)
| Materialize at Output: T1.b
| Execute on: All Nodes
| +- Outer -> STORAGE ACCESS for T1 [Cost: 151, Rows: 10K (NO STATISTICS)] (PATH ID: 2)
|| Projection: public.T1_b0
|| Materialize: T1.a
|| Execute on: All Nodes
| +- Inner -> STORAGE ACCESS for T2 [Cost: 302, Rows: 10K (NO STATISTICS)] (PATH ID: 3)
|| Projection: public.T2_b0
|| Materialize: T2.x, T2.y
|| Execute on: All Nodes
```

Analytic function path

Vertica attempts to optimize multiple SQL-99 [Analytic functions](#) from the same query by grouping them together in [Analytic Group](#) areas.

For each analytical group, Vertica performs a distributed sort and resegment of the data, if necessary.

You can tell how many sorts and resegments are required based on the query plan.

For example, the following query plan shows that the [FIRST_VALUE](#) and [LAST_VALUE](#) functions are in the same analytic group because their [OVER](#) clause is the same. In contrast, [ROW_NUMBER\(\)](#) has a different [ORDER BY](#) clause, so it is in a different analytic group. Because both groups share the same [PARTITION BY deal_stage](#) clause, the data does not need to be resegmented between groups :

EXPLAIN SELECT

```
first_value(deal_size) OVER (PARTITION BY deal_stage
ORDER BY deal_size),
last_value(deal_size) OVER (PARTITION BY deal_stage
ORDER BY deal_size),
row_number() OVER (PARTITION BY deal_stage
ORDER BY largest_bill_amount)
FROM customer_dimension;
```

Access Path:

```
+--ANALYTICAL [Cost: 1K, Rows: 50K] (PATH ID: 1)
| Analytic Group
| Functions: row_number()
| Group Sort: customer_dimension.deal_stage ASC, customer_dimension.largest_bill_amount ASC NULLS LAST
| Analytic Group
| Functions: first_value(), last_value()
| Group Filter: customer_dimension.deal_stage
| Group Sort: customer_dimension.deal_stage ASC, customer_dimension.deal_size ASC NULL LAST
| Execute on: All Nodes
| +---> STORAGE ACCESS for customer_dimension [Cost: 263, Rows: 50K]
|   (PATH ID: 2)
|| Projection: public.customer_dimension_DBD_1_rep_vmart_vmart_node0001
|| Materialize: customer_dimension.largest_bill_amount,
||               customer_dimension.deal_stage, customer_dimension.deal_size
|| Execute on: All Nodes
```

[Invoking analytic functions](#)

Node down information

Vertica provides performance optimization when cluster nodes fail by distributing the work of the down nodes uniformly among available nodes throughout the cluster.

When a node in your cluster is down, the query plan identifies which node the query will execute on. To help you quickly identify down nodes on large clusters, **EXPLAIN** output lists up to six nodes, if the number of running nodes is less than or equal to six, and lists only down nodes if the number of running nodes is more than six.

Note

The node that executes down node queries is not always the same one.

The following table provides more detail:

Node state	EXPLAIN output
If all nodes are up, EXPLAIN output indicates All Nodes .	Execute on: All Nodes
If fewer than 6 nodes are up, EXPLAIN lists up to six running nodes.	Execute on: [node_list].
If more than 6 nodes are up, EXPLAIN lists only non-running nodes.	Execute on: All Nodes Except [node_list]
If the node list contains non-ephemeral nodes, the EXPLAIN output indicates All Permanent Nodes .	Execute on: All Permanent Nodes
If the path is being run on the query initiator, the EXPLAIN output indicates Query Initiator .	Execute on: Query Initiator

Examples

In the following example, the down node is `v_vmart_node0005` , and the node `v_vmart_node0006` will execute this run of the query.

```
=> EXPLAIN SELECT * FROM test;
QUERY PLAN
```

```
-----
QUERY PLAN DESCRIPTION:
-----
```

```
EXPLAIN SELECT * FROM my1table;
```

```
Access Path:
```

```
+STORAGE ACCESS for my1table [Cost: 10, Rows: 2] (PATH ID: 1)
```

```
| Projection: public.my1table_b0
```

```
| Materialize: my1table.c1, my1table.c2
```

```
| Execute on: All Except v_vmart_node0005
```

```
+STORAGE ACCESS for my1table (REPLACEMENT FOR DOWN NODE) [Cost: 66, Rows: 2]
```

```
| Projection: public.my1table_b1
```

```
| Materialize: my1table.c1, my1table.c2
```

```
| Execute on: v_vmart_node0006
```

The **All Permanent Nodes** output in the following example fragment denotes that the node list is for permanent (non-ephemeral) nodes only:

```
=> EXPLAIN SELECT * FROM my2table;
```

```
Access Path:
```

```
+STORAGE ACCESS for my2table [Cost: 18, Rows:6 (NO STATISTICS)] (PATH ID: 1)
```

```
| Projection: public.my2tablee_b0
```

```
| Materialize: my2table.x, my2table.y, my2table.z
```

```
| Execute on: All Permanent Nodes
```

MERGE path

Vertica prepares an optimized query plan for a [MERGE](#) statement if the statement and its tables meet the criteria described in [MERGE optimization](#).

Use the [EXPLAIN](#) keyword to determine whether Vertica can produce an optimized query plan for a given **MERGE** statement. If optimization is possible, the **EXPLAIN** -generated output contains a **[Semi]** path, as shown in the following sample fragment:

```
...
Access Path:
+-DML DELETE [Cost: 0, Rows: 0]
| Target Projection: public.A_b1 (DELETE ON CONTAINER)
| Target Prep:
| Execute on: All Nodes
| +---> JOIN MERGEJOIN(inputs presorted) [Semi] [Cost: 6, Rows: 1 (NO STATISTICS)] (PATH ID: 1)
|   Inner (RESEGMENT)
| |   Join Cond: (A.a1 = VAL(2))
| |   Execute on: All Nodes
| | +- Outer -> STORAGE ACCESS for A [Cost: 2, Rows: 2 (NO STATISTICS)] (PATH ID: 2)
...

```

Conversely, if Vertica cannot create an optimized plan, **EXPLAIN** -generated output contains **RightOuter** path:

```
...
Access Path: +-DML MERGE
| Target Projection: public.locations_b1
| Target Projection: public.locations_b0
| Target Prep:
| Execute on: All Nodes
| +---> JOIN MERGEJOIN(inputs presorted) [RightOuter] [Cost: 28, Rows: 3 (NO STATISTICS)] (PATH ID: 1) Outer (RESEGMENT) Inner (RESEGMENT)
| |   Join Cond: (locations.user_id = VAL(2)) AND (locations.location_x = VAL(2)) AND (locations.location_y = VAL(2))
| |   Execute on: All Nodes
| | +- Outer -> STORAGE ACCESS for <No Alias> [Cost: 15, Rows: 2 (NO STATISTICS)] (PATH ID: 2)
...

```

Directed queries

Directed queries encapsulate information that the optimizer can use to create a query plan. Directed queries can serve the following goals:

- Preserve current query plans before a scheduled upgrade. In most instances, queries perform more efficiently after a Vertica upgrade. In the few cases where this is not so, you can use directed queries that you created before upgrading, to recreate query plans from the earlier version.
- Enable you to create query plans that improve optimizer performance. Occasionally, you might want to influence the optimizer to make better choices in executing a given query. For example, you can choose a different projection, or force a different join order. In this case, you can use a directed query to create a query plan that preempts any plan that the optimizer might otherwise create.
- Redirect an input query to a query that uses different semantics—for example, [map a join query to a SELECT statement that queries a flattened table](#).

Directed query components

A directed query pairs two components:

- **Input query** : A query that triggers use of this directed query when it is active.
- **Annotated query** : A SQL statement with embedded optimizer hints, which instruct the optimizer how to create a query plan for the specified input query. These hints specify important query plan elements, such as join order and projection choices.

Tip

You can also use most optimizer hints directly in vsql. For details, see [Hints](#).

Vertica provides two methods for creating directed queries:

- The optimizer can generate an annotated query from a given input query and pair the two as a directed query.
- You can write your own annotated query and pair it with an input query.

For a description of both methods, see [Creating directed queries](#).

In this section

- [Creating directed queries](#)
- [Setting hints in annotated queries](#)
- [Ignoring constants in directed queries](#)
- [Rewriting queries](#)
- [Managing directed queries](#)
- [Batch query plan export](#)
- [Half join and cross join semantics](#)
- [Directed query restrictions](#)

Creating directed queries

CREATE DIRECTED QUERY associates an input query with a query annotated with optimizer hints. It stores the association under a unique identifier.

CREATE DIRECTED QUERY has two variants:

- [CREATE DIRECTED QUERY OPTIMIZER](#) directs the query optimizer to generate annotated SQL from the specified input query. The annotated query contains hints that the optimizer can use to recreate its current query plan for that input query.
- [CREATE DIRECTED QUERY CUSTOM](#) specifies an annotated query supplied by the user. Vertica associates the annotated query with the input query specified by the last [SAVE QUERY](#) statement.

In both cases, Vertica associates the annotated query and input query, and registers their association in the system table [DIRECTED_QUERIES](#) under `query_name`.

[The two approaches can be used together](#): you can use the annotated SQL that the optimizer creates as the basis for creating your own (custom) directed queries.

In this section

- [Optimizer-generated directed queries](#)
- [Custom directed queries](#)
- [Using optimizer-generated and custom directed queries together](#)

Optimizer-generated directed queries

[CREATE DIRECTED QUERY OPTIMIZER](#) passes an input query to the optimizer, which generates an annotated query from its own query plan. It then pairs the input and annotated queries and saves them as a directed query. This directed query can be used to handle other queries that are identical

except for the predicate strings on which query results are filtered.

You can use optimizer-generated directed queries to capture query plans before you upgrade. Doing so can be especially useful if you detect diminished performance of a given query after the upgrade. In this case, you can use the corresponding directed query to recreate an earlier query plan, and compare its performance to the plan generated by the current optimizer.

You can also create multiple optimizer-generated directed queries from the most frequently executed queries, by invoking the meta-function [SAVE_PLANS](#). For details, see [Bulk-Creation of Directed Queries](#).

Example

The following SQL statements create and activate the directed query `findEmployeesCityJobTitle_OPT` :

```
=> CREATE DIRECTED QUERY OPTIMIZER 'findEmployeesCityJobTitle_OPT'
  SELECT employee_first_name, employee_last_name FROM public.employee_dimension
  WHERE employee_city='Boston' and job_title='Cashier' ORDER BY employee_last_name, employee_first_name;
CREATE DIRECTED QUERY

=> ACTIVATE DIRECTED QUERY findEmployeesCityJobTitle_OPT;
ACTIVATE DIRECTED QUERY
```

After this directed query plan is activated, the optimizer uses it to generate a query plan for all subsequent invocations of this input query, and others like it. You can view the optimizer-generated annotated query by calling [GET DIRECTED QUERY](#) or querying system table [DIRECTED_QUERIES](#) :

```
=> SELECT input_query, annotated_query FROM V_CATALOG.DIRECTED_QUERIES
  WHERE query_name = 'findEmployeesCityJobTitle_OPT';
-[ RECORD 1 ]---+-----
input_query   | SELECT employee_dimension.employee_first_name, employee_dimension.employee_last_name FROM public.employee_dimension
WHERE ((employee_dimension.employee_city = 'Boston'::varchar(6) /*+:v(1)*/) AND (employee_dimension.job_title = 'Cashier'::varchar(7) /*+:v(2)*/))
ORDER BY employee_dimension.employee_last_name, employee_dimension.employee_first_name
annotated_query | SELECT /*+verbatim*/ employee_dimension.employee_first_name AS employee_first_name, employee_dimension.employee_last_name
AS employee_last_name FROM public.employee_dimension AS employee_dimension/*+projs('public.employee_dimension')*/
WHERE (employee_dimension.employee_city = 'Boston'::varchar(6) /*+:v(1)*/) AND (employee_dimension.job_title = 'Cashier'::varchar(7) /*+:v(2)*/)
ORDER BY 2 ASC, 1 ASC
```

In this case, the annotated query includes the following hints:

- `/*+verbatim*/` specifies to execute the annotated query exactly as written and produce a query plan accordingly.
- `/*+projs('public.Emp_Dimension')*/` directs the optimizer to create a query plan that uses the projection `public.Emp_Dimension`.
- `/*+:v(n)*/` (alias of `/*+IGNORECONST(n)*/`) is included several times in the annotated and input queries. These hints qualify two constants in the query predicates: `Boston` and `Cashier`. Each `:v` hint has an integer argument `n` that pairs corresponding constants in the input and annotated query queries: `/*+:v(1)*/` for `Boston`, and `/*+:v(2)*/` for `Cashier`. The hints tell the optimizer to disregard these constants when it decides whether to apply this directed query to other input queries that are similar. Thus, ignore constant hints can let you use the same directed query for different input queries.

The following query uses different values for the columns `employee_city` and `job_title`, but is otherwise identical to the original input query of directed query `EmployeesCityJobTitle_OPT` :

```
=> SELECT employee_first_name, employee_last_name FROM public.employee_dimension
  WHERE employee_city = 'San Francisco' and job_title = 'Branch Manager' ORDER BY employee_last_name, employee_first_name;
```

If the directed query `EmployeesCityJobTitle_OPT` is active, the optimizer can use it for this query:

```

=> EXPLAIN SELECT employee_first_name, employee_last_name FROM employee_dimension
    WHERE employee_city='San Francisco' AND job_title='Branch Manager' ORDER BY employee_last_name, employee_first_name;
...
-----
QUERY PLAN DESCRIPTION:
-----
EXPLAIN SELECT employee_first_name, employee_last_name FROM employee_dimension WHERE employee_city='San Francisco' AND job_title='Branch
Manager' ORDER BY employee_last_name, employee_first_name;

The following active directed query(query name: findEmployeesCityJobTitle_OPT) is being executed:
SELECT /*+verbatim*/ employee_dimension.employee_first_name, employee_dimension.employee_last_name
FROM public.employee_dimension employee_dimension/*+projs('public.employee_dimension')*/
WHERE ((employee_dimension.employee_city = 'San Francisco'::varchar(13)) AND (employee_dimension.job_title = 'Branch Manager'::varchar(14)))
ORDER BY employee_dimension.employee_last_name, employee_dimension.employee_first_name

Access Path:
+-SORT [Cost: 222, Rows: 10K (NO STATISTICS)] (PATH ID: 1)
| Order: employee_dimension.employee_last_name ASC, employee_dimension.employee_first_name ASC
| Execute on: All Nodes
| +---> STORAGE ACCESS for employee_dimension [Cost: 60, Rows: 10K (NO STATISTICS)] (PATH ID: 2)
|| Projection: public.employee_dimension_super
|| Materialize: employee_dimension.employee_first_name, employee_dimension.employee_last_name
|| Filter: (employee_dimension.employee_city = 'San Francisco')
|| Filter: (employee_dimension.job_title = 'Branch Manager')
|| Execute on: All Nodes
...

```

Bulk-creation of directed queries

The meta-function [SAVE_PLANS](#) lets you create multiple optimizer-generated directed queries from the most frequently executed queries.

SAVE_PLANS works as follows:

1. Iterates over all queries in the data collector table `dc_requests_issued` and selects the most-frequently requested queries, up to the maximum specified by its `query-budget` argument. If the meta-function's `since-date` argument is also set, then SAVE_PLANS iterates only over queries that were issued on or after the specified date.
As SAVE_PLANS iterates over `dc_requests_issued`, it tests queries against various restrictions. In general, directed queries support only SELECT statements as input. Within this broad requirement, input queries are subject to other [restrictions](#).
2. Calls CREATE DIRECTED QUERY OPTIMIZER on all qualifying input queries, which creates a directed query for each unique input query as described [above](#).
3. Saves metadata on the new set of directed queries to system table [DIRECTED_QUERIES](#), where all directed queries of that set share the same `SAVE_PLANS_VERSION` integer. This integer is computed from the highest `SAVE_PLANS_VERSION` + 1.

You can later use `SAVE_PLANS_VERSION` identifiers to bulk [activate](#), [deactivate](#), and [drop](#) directed queries. For example:

```
=> SELECT save_plans (40);
```

```
save_plans
```

9 directed query supported queries out of 40 most frequently run queries were saved under the save_plans_version 3.

To view the saved queries, run:

```
SELECT * FROM directed_queries WHERE save_plans_version = '3';
```

To drop the saved queries, run:

```
DROP DIRECTED QUERY WHERE save_plans_version = '3';
```

(1 row)

```
=> SELECT input_query::VARCHAR(60) FROM directed_queries WHERE save_plans_version = 3 AND input_query ILIKE '%line_search%';
```

```
input_query
```

```
SELECT public.line_search_logistic2(udtf1.deviance, udtf1.G
```

```
SELECT public.line_search_logistic2(udtf1.deviance, udtf1.G
```

(2 rows)

```
=> ACTIVATE DIRECTED QUERY WHERE save_plans_version = 3 AND input_query ILIKE '%line_search%';
```

```
ACTIVATE DIRECTED QUERY
```

```
=> SELECT query_name, input_query::VARCHAR(60), is_active FROM directed_queries WHERE save_plans_version = 3 AND input_query ILIKE '%line_search%';
```

```
query_name | input_query | is_active
```

```
save_plans_nolabel_3_3 | SELECT public.line_search_logistic2(udtf1.deviance, udtf1.G | t
```

```
save_plans_nolabel_6_3 | SELECT public.line_search_logistic2(udtf1.deviance, udtf1.G | t
```

(2 rows)

Note

`query_name` values are concatenated from the following strings:

```
save_plans_query-label_query-number_save-plans-version
```

where:

- `query-label` is a [LABEL](#) hint embedded in the input query associated with this directed query. If the input query contains no label, then this string is set to `nolabel`.
- `query-number` is an integer in a continuous sequence between 0 and `budget-query`, which uniquely identifies this directed query from others in the same SAVE_PLANS-generated set.
- `[save-plans-version]/[sql-reference/system-tables/v-catalog-schema/directed-queries.html#SAVE_PLANS_VERSION]` identifies the set of directed queries to which this directed query belongs.

Custom directed queries

[CREATE DIRECTED QUERY CUSTOM](#) specifies an annotated query and pairs it to an input query previously saved by [SAVE QUERY](#). You must issue both statements in the same user session.

For example, you might want a query to use a specific projection:

1. Specify the query with SAVE QUERY:

```
=> SAVE QUERY SELECT employee_first_name, employee_last_name FROM employee_dimension
```

```
WHERE employee_city='Boston' AND job_title='Cashier';
```

```
SAVE QUERY
```

Note

The input query that you supply to SAVE QUERY only supports the [:v](#) hint.

2. Create a custom directed query with CREATE DIRECTED QUERY CUSTOM, which specifies an annotated query and associates it with the saved query. The annotated query includes a `/*+projs*/` hint, which instructs the optimizer to use the projection `public.emp_dimension_unseg` when users call the saved query:

```
=> CREATE DIRECTED QUERY CUSTOM 'findBostonCashiers_CUSTOM'  
  SELECT employee_first_name, employee_last_name  
  FROM employee_dimension /*+Projs('public.emp_dimension_unseg')*/  
  WHERE employee_city='Boston' AND job_title='Cashier';  
CREATE DIRECTED QUERY
```

Caution

Vertica associates a saved query and annotated query without checking whether the input and annotated queries are compatible. Be careful to sequence SAVE QUERY and CREATE DIRECTED QUERY CUSTOM statements so the saved and directed queries are correctly matched.

3. Activate the directed query:

```
=> ACTIVATE DIRECTED QUERY findBostonCashiers_CUSTOM;  
ACTIVATE DIRECTED QUERY
```

4. After activation, the optimizer uses this directed query to generate a query plan for all subsequent invocations of its input query. The following EXPLAIN output verifies the optimizer's use of this directed query and the projection it specifies:

```
=> EXPLAIN SELECT employee_first_name, employee_last_name FROM employee_dimension  
  WHERE employee_city='Boston' AND job_title='Cashier';  
  
QUERY PLAN  
-----  
QUERY PLAN DESCRIPTION:  
-----  
EXPLAIN SELECT employee_first_name, employee_last_name FROM employee_dimension where employee_city='Boston' AND job_title='Cashier';  
  
The following active directed query(query name: findBostonCashiers_CUSTOM) is being executed:  
SELECT employee_dimension.employee_first_name, employee_dimension.employee_last_name  
FROM public.employee_dimension/*+Projs('public.emp_dimension_unseg')*/  
WHERE ((employee_dimension.employee_city = 'Boston'::varchar(6)) AND (employee_dimension.job_title = 'Cashier'::varchar(7)))  
  
Access Path:  
+STORAGE ACCESS for employee_dimension [Cost: 158, Rows: 10K (NO STATISTICS)] (PATH ID: 1)  
| Projection: public.emp_dimension_unseg  
| Materialize: employee_dimension.employee_first_name, employee_dimension.employee_last_name  
| Filter: (employee_dimension.employee_city = 'Boston')  
| Filter: (employee_dimension.job_title = 'Cashier')  
| Execute on: Query Initiator
```

[Rewriting Join Queries](#)

Using optimizer-generated and custom directed queries together

You can use the annotated SQL that the optimizer creates as the basis for creating your own custom directed queries. This approach can be especially useful in evaluating the plan that the optimizer creates to handle a given query, and testing plan modifications.

For example, you might want to modify how the optimizer implements the following query:

```
=> SELECT COUNT(customer_name) Total, customer_region Region
FROM (store_sales s JOIN customer_dimension c ON c.customer_key = s.customer_key)
JOIN product_dimension p ON s.product_key = p.product_key
WHERE p.category_description ilike '%Medical%'
AND p.product_description ilike '%antibiotics%'
AND c.customer_age <= 30 AND YEAR(s.sales_date)=2017
GROUP BY customer_region;
```

When you run EXPLAIN on this query, you discover that the optimizer uses projection `customers_proj_age` for the `customer_dimension` table. This projection is sorted on column `customer_age`. Consequently, the optimizer hash-joins the tables `store_sales` and `customer_dimension` on `customer_key`.

After analyzing `customer_dimension` table data, you observe that most customers are under 30, so it makes more sense to use projection `customer_proj_id` for the `customer_dimension` table, which is sorted on `customer_key`:

You can create a directed query that encapsulates this change as follows:

1. Obtain optimizer-generated annotations on the query with EXPLAIN ANNOTATED:

```
=> \o annotatedQuery
=> EXPLAIN ANNOTATED SELECT COUNT(customer_name) Total, customer_region Region
FROM (store_sales s JOIN customer_dimension c ON c.customer_key = s.customer_key)
JOIN product_dimension p ON s.product_key = p.product_key
WHERE p.category_description ilike '%Medical%'
AND p.product_description ilike '%antibiotics%'
AND c.customer_age <= 30 AND YEAR(s.sales_date)=2017
GROUP BY customer_region;
=> \o
=> \! cat annotatedQuery
...
SELECT /*+syntactic_join,verbatim*/ count(c.customer_name) AS Total, c.customer_region AS Region
FROM ((public.store_sales AS s/*+projs('public.store_sales_super')*/
JOIN /*+Distrib(L,B),JType(H)*/ public.customer_dimension AS c/*+projs('public.customers_proj_age')*/
ON (c.customer_key = s.customer_key))
JOIN /*+Distrib(L,B),JType(M)*/ public.product_dimension AS p/*+projs('public.product_dimension')*/
ON (s.product_key = p.product_key))
WHERE ((date_part('year':varchar(4), (s.sales_date)::timestamp(0))):int = 2017)
AND (c.customer_age <= 30)
AND ((p.category_description)::varchar(32) ~~~ '%Medical%':varchar(9))
AND (p.product_description ~~~ '%antibiotics%':varchar(13))
GROUP BY /*+GByType(Hash)*/ 2
(4 rows)
```

2. Modify the annotated query:

```
SELECT /*+syntactic_join,verbatim*/ count(c.customer_name) AS Total, c.customer_region AS Region
FROM ((public.store_sales AS s/*+projs('public.store_sales_super')*/
JOIN /*+Distrib(L,B),JType(H)*/ public.customer_dimension AS c/*+projs('public.customer_proj_id')*/
ON (c.customer_key = s.customer_key))
JOIN /*+Distrib(L,B),JType(H)*/ public.product_dimension AS p/*+projs('public.product_dimension')*/
ON (s.product_key = p.product_key))
WHERE ((date_part('year':varchar(4), (s.sales_date)::timestamp(0))):int = 2017)
AND (c.customer_age <= 30)
AND ((p.category_description)::varchar(32) ~~~ '%Medical%':varchar(9))
AND (p.product_description ~~~ '%antibiotics%':varchar(13))
GROUP BY /*+GByType(Hash)*/ 2
```

3. Use the modified annotated query to create the desired directed query:

- o Save the desired input query with [SAVE QUERY](#):

```
=> SAVE QUERY SELECT COUNT(customer_name) Total, customer_region Region
FROM (store_sales s JOIN customer_dimension c ON c.customer_key = s.customer_key)
JOIN product_dimension p ON s.product_key = p.product_key
WHERE p.category_description ilike '%Medical%'
      AND p.product_description ilike '%antibiotics%'
      AND c.customer_age <= 30 AND YEAR(s.sales_date)=2017
GROUP BY customer_region;
```

- Create a custom directed query that associates the saved input query with the modified annotated query:

```
=> CREATE DIRECTED QUERY CUSTOM 'getCustomersUnder31'
SELECT /*+syntactic_join,verbatim*/ count(c.customer_name) AS Total, c.customer_region AS Region
FROM ((public.store_sales AS s/*+projs('public.store_sales_super')*/
JOIN /*+Distrib(L,B),JType(H)*/ public.customer_dimension AS c/*+projs('public.customer_proj_id')*/
      ON (c.customer_key = s.customer_key))
JOIN /*+Distrib(L,B),JType(H)*/ public.product_dimension AS p/*+projs('public.product_dimension')*/
      ON (s.product_key = p.product_key))
WHERE ((date_part('year'::varchar(4), (s.sales_date)::timestamp(0)))::int = 2017)
      AND (c.customer_age <= 30)
      AND ((p.category_description)::varchar(32) ~~* '%Medical%':::varchar(9))
      AND (p.product_description ~~* '%antibiotics%':::varchar(13))
GROUP BY /*+GByType(Hash)*/ 2;
CREATE DIRECTED QUERY
```

4. Activate this directed query:

```
=> ACTIVATE DIRECTED QUERY getCustomersUnder31;
ACTIVATE DIRECTED QUERY
```

When the optimizer processes a query that matches this directed query's input query, it uses the directed query's annotated query to generate a query plan:

```
=> EXPLAIN SELECT COUNT(customer_name) Total, customer_region Region
FROM (store_sales s JOIN customer_dimension c ON c.customer_key = s.customer_key)
JOIN product_dimension p ON s.product_key = p.product_key
WHERE p.category_description ilike '%Medical%'
      AND p.product_description ilike '%antibiotics%'
      AND c.customer_age <= 30 AND YEAR(s.sales_date)=2017
GROUP BY customer_region;
```

The following active directed query(query name: getCustomersUnder31) is being executed:

...

Setting hints in annotated queries

The hints in a directed query's annotated query provide the optimizer with instructions how to execute an input query. Annotated queries support the following hints:

- *Join hints* specify join order, join type, and join data distribution: [SYNTACTIC_JOIN](#), [DISTRIB](#), [JTYPE](#), [UTYPE](#).
- *Table hints* specify which projections to include and exclude in the query plan: [PROJS](#), [SKIP_PROJS](#).
- [v](#) and its alias [IGNORECONSTANT](#) marks predicate string constants that you want the optimizer to ignore when it decides whether to use a directed query for a given input query. For details, see [Ignoring constants in directed queries](#).
- [:c](#) hints mark predicate [constants that must not be ignored](#).
- [VERBATIM](#) enforces execution of an annotated query exactly as written.

Other hints in annotated queries such as [DIRECT](#) or [LABEL](#) have no effect.

You can use hints in a vsql query the same as in an annotated query, with two exceptions: [:v](#) ([IGNORECONSTANT](#)) and [VERBATIM](#).

Ignoring constants in directed queries

Optimizer-generated directed queries generally include one or more `:v` (alias of `IGNORECONSTANT`) hints, which mark predicate string constants that you want the optimizer to ignore when it decides whether to use a directed query for a given input query. `:v` hints enable multiple queries to use the same directed query, provided the queries are identical in all respects except their predicate strings.

For example, the following two queries are identical, except for the string constants `Boston|San Francisco` and `Cashier|Branch Manager`, which are specified for columns `employee_city` and `job_title`, respectively:

```
=> SELECT employee_first_name, employee_last_name FROM public.employee_dimension
    WHERE employee_city='Boston' and job_title ='Cashier' ORDER BY employee_last_name, employee_first_name;

=> SELECT employee_first_name, employee_last_name FROM public.employee_dimension
    WHERE employee_city = 'San Francisco' and job_title = 'Branch Manager' ORDER BY employee_last_name, employee_first_name;
```

In this case, an optimizer-generated directed query that you create from one query can be used for both:

```
=> CREATE DIRECTED QUERY OPTIMIZER 'findEmployeesCityJobTitle_OPT'
    SELECT employee_first_name, employee_last_name FROM public.employee_dimension
    WHERE employee_city='Boston' and job_title='Cashier' ORDER BY employee_last_name, employee_first_name;
CREATE DIRECTED QUERY

=> ACTIVATE DIRECTED QUERY findEmployeesCityJobTitle_OPT;
ACTIVATE DIRECTED QUERY
```

The directed query's input and annotated queries both include `:v` hints:

```
=> SELECT input_query, annotated_query FROM V_CATALOG.DIRECTED_QUERIES
    WHERE query_name = 'findEmployeesCityJobTitle_OPT';
-[ RECORD 1 ]--+-+-----
input_query  | SELECT employee_dimension.employee_first_name, employee_dimension.employee_last_name FROM public.employee_dimension
WHERE ((employee_dimension.employee_city = 'Boston'::varchar(6) /*+:v(1)*/) AND (employee_dimension.job_title = 'Cashier'::varchar(7) /*+:v(2)*/))
ORDER BY employee_dimension.employee_last_name, employee_dimension.employee_first_name
annotated_query | SELECT /*+verbatim*/ employee_dimension.employee_first_name AS employee_first_name, employee_dimension.employee_last_name
AS employee_last_name FROM public.employee_dimension AS employee_dimension/*+projs('public.employee_dimension')*/
WHERE (employee_dimension.employee_city = 'Boston'::varchar(6) /*+:v(1)*/) AND (employee_dimension.job_title = 'Cashier'::varchar(7) /*+:v(2)*/)
ORDER BY 2 ASC, 1 ASC
```

The hint arguments in the input and annotated queries pair two predicate constants:

- `/*+:v(1)*/` pairs input and annotated query settings for `employee_city`.
- `/*+:v(2)*/` pairs input and annotated query settings for `job_title`.

The `:v` hints tell the optimizer to ignore values for these two columns when it decides whether it can use this directed query for a given input query.

For example, the following query uses different values for `employee_city` and `job_title`, but is otherwise identical to the query used to create the directed query `EmployeesCityJobTitle_OPT`:

```
=> SELECT employee_first_name, employee_last_name FROM public.employee_dimension
    WHERE employee_city = 'San Francisco' and job_title = 'Branch Manager' ORDER BY employee_last_name, employee_first_name;
```

If the directed query `EmployeesCityJobTitle_OPT` is active, the optimizer can use it in its query plan for this query:

```
=> EXPLAIN SELECT employee_first_name, employee_last_name FROM employee_dimension
  WHERE employee_city='San Francisco' AND job_title='Branch Manager' ORDER BY employee_last_name, employee_first_name;
...
-----
QUERY PLAN DESCRIPTION:
-----
EXPLAIN SELECT employee_first_name, employee_last_name FROM employee_dimension WHERE employee_city='San Francisco' AND job_title='Branch
Manager' ORDER BY employee_last_name, employee_first_name;

The following active directed query(query name: findEmployeesCityJobTitle_OPT) is being executed:
SELECT /*+verbatim*/ employee_dimension.employee_first_name, employee_dimension.employee_last_name
FROM public.employee_dimension employee_dimension/*+projs('public.employee_dimension')*/
WHERE ((employee_dimension.employee_city = 'San Francisco'::varchar(13)) AND (employee_dimension.job_title = 'Branch Manager'::varchar(14)))
ORDER BY employee_dimension.employee_last_name, employee_dimension.employee_first_name

Access Path:
+-SORT [Cost: 222, Rows: 10K (NO STATISTICS)] (PATH ID: 1)
| Order: employee_dimension.employee_last_name ASC, employee_dimension.employee_first_name ASC
| Execute on: All Nodes
| +---> STORAGE ACCESS for employee_dimension [Cost: 60, Rows: 10K (NO STATISTICS)] (PATH ID: 2)
|| Projection: public.employee_dimension_super
|| Materialize: employee_dimension.employee_first_name, employee_dimension.employee_last_name
|| Filter: (employee_dimension.employee_city = 'San Francisco')
|| Filter: (employee_dimension.job_title = 'Branch Manager')
|| Execute on: All Nodes
...

```

Mapping one-to-many :v hints

The examples shown so far demonstrate one-to-one pairings of :v hints. You can also use :v hints to map one input constant to multiple constants in an annotated query. This approach can be especially useful when you want to provide the optimizer with explicit instructions how to execute a query that joins tables.

For example, the following query joins two tables:

```
SELECT * FROM S JOIN T ON S.a = T.b WHERE S.a = 8;
```

In this case, the optimizer can infer that **S.a** and **T.b** have the same value and implements the join accordingly:

```
<a name="simpleJoinExample"></a>=> CREATE DIRECTED QUERY OPTIMIZER simpleJoin SELECT * FROM S JOIN T ON S.a = T.b WHERE S.a = 8;
CREATE DIRECTED QUERY
=> SELECT input_query, annotated_query FROM directed_queries WHERE query_name = 'simpleJoin';
-[ RECORD 1 ]---+-----
input_query   | SELECT S.a, T.b FROM (public.S JOIN public.T ON ((S.a = T.b))) WHERE (S.a = 8 /*+:v(1)*/)
annotated_query | SELECT /*+syntactic_join,verbatim*/ S.a AS a, T.b AS b
FROM (public.S AS S/*+projs('public.S')*/ JOIN /*+Distrib(L,L),JType(M)*/ public.T AS T/*+projs('public.T')*/ ON (S.a = T.b))
WHERE (S.a = 8 /*+:v(1)*/) AND (T.b = 8 /*+:v(1)*/)
(1 row)

=> ACTIVATE DIRECTED QUERY simpleJoin;
ACTIVATED DIRECTED QUERY

```

Now, given the following input query:

```
SELECT * FROM S JOIN T ON S.a = T.b WHERE S.a = 3;
```

the optimizer disregards the join predicate constants and uses the directed query **simpleJoin** in its query plan:

QUERY PLAN DESCRIPTION:

```
EXPLAIN SELECT * FROM S JOIN T ON S.a = T.b WHERE S.a = 3;
```

The following active directed query(query name: simpleJoin) is being executed:

```
SELECT /*+syntactic_join,verbatim*/ S.a, T.b FROM (public.S S/*+projs('public.S')*/ JOIN /*+Distrib('L', 'L'), JType('M')*/public.T T/*+projs('public.T')*/ ON ((S.a = T.b))) WHERE ((S.a = 3) AND (T.b = 3))
```

Access Path:

```
+--JOIN MERGEJOIN(inputs presorted) [Cost: 21, Rows: 4 (NO STATISTICS)] (PATH ID: 1)
| Join Cond: (S.a = T.b)
| Execute on: Query Initiator
| +-- Outer -> STORAGE ACCESS for S [Cost: 12, Rows: 4 (NO STATISTICS)] (PATH ID: 2)
|| Projection: public.S_b0
|| Materialize: S.a
|| Filter: (S.a = 3)
|| Execute on: Query Initiator
|| Runtime Filter: (SIP1(MergeJoin): S.a)
| +-- Inner -> STORAGE ACCESS for T [Cost: 8, Rows: 3 (NO STATISTICS)] (PATH ID: 3)
|| Projection: public.T_b0
|| Materialize: T.b
|| Filter: (T.b = 3)
|| Execute on: Query Initiator
...

```

Conserving predicate constants in directed queries

By default, optimizer-generated directed queries set `:v` hints on predicate constants. You can override this behavior by marking predicate constants that must not be ignored with `:c` hints. For example, the following statement creates a directed query that can be used only for input queries where the join predicate constant is the same as in the original input query— **8** :

```
=> CREATE DIRECTED QUERY OPTIMIZER simpleJoin_KeepPredicateConstant SELECT * FROM S JOIN T ON S.a = T.b WHERE S.a = 8 /*+:c*/;
CREATE DIRECTED QUERY
=> ACTIVATE DIRECTED QUERY simpleJoin_KeepPredicateConstant;
```

The following query on system table DIRECTED_QUERIES compares directed queries `simpleJoin` (created in an [earlier example](#)) and `simpleJoin_KeepPredicateConstant` . Unlike `simpleJoin` , the join predicate of the input and annotated queries for `simpleJoin_KeepPredicateConstant` omit `:v` hints:

```
=> SELECT query_name, input_query, annotated_query FROM directed_queries WHERE query_name ILIKE'%simpleJoin%';
-[ RECORD 1 ]---+
query_name      | simpleJoin
input_query     | SELECT S.a, T.b FROM (public.S JOIN public.T ON ((S.a = T.b))) WHERE (S.a = 8 /*+:v(1)*/)
annotated_query | SELECT /*+syntactic_join,verbatim*/ S.a AS a, T.b AS b
FROM (public.S AS S/*+projs('public.S')*/ JOIN /*+Distrib(L,L),JType(M)*/ public.T AS T/*+projs('public.T')*/ ON (S.a = T.b))
WHERE (S.a = 8 /*+:v(1)*/) AND (T.b = 8 /*+:v(1)*/)
-[ RECORD 2 ]---+
query_name      | simpleJoin_KeepPredicateConstant
input_query     | SELECT S.a, T.b FROM (public.S JOIN public.T ON ((S.a = T.b))) WHERE (S.a = 8)
annotated_query | SELECT /*+syntactic_join,verbatim*/ S.a AS a, T.b AS b
FROM (public.S AS S/*+projs('public.S')*/ JOIN /*+Distrib(L,L),JType(M)*/ public.T AS T/*+projs('public.T')*/ ON (S.a = T.b))
WHERE (S.a = 8) AND (T.b = 8)
```

If you deactivate directed query `simpleJoin` (which would otherwise have precedence over `simpleJoin_KeepPredicateConstant` because it was created earlier), Vertica only applies `simpleJoin_KeepPredicateConstant` on input queries where the join predicate constant is the same as in the original input query. For example, compare the following two query plans:

```
=> EXPLAIN SELECT * FROM S JOIN T ON S.a = T.b WHERE S.a = 8;
```

...

QUERY PLAN DESCRIPTION:

```
EXPLAIN SELECT * FROM S JOIN T ON S.a = T.b WHERE S.a = 8;
```

The following active directed query(query name: simpleJoin_KeepPredicateConstant) is being executed:

```
SELECT /*+syntactic_join,verbatim*/ S.a, T.b FROM (public.S S/*+projs('public.S')*/ JOIN /*+Distrib('L', 'L'), JType('M')*/public.T T/*+projs('public.T')*/ ON ((S.a = T.b))) WHERE ((S.a = 8) AND (T.b = 8))
```

Access Path:

```
+--JOIN MERGEJOIN(inputs presorted) [Cost: 21, Rows: 4 (NO STATISTICS)] (PATH ID: 1)
|  Join Cond: (S.a = T.b)
```

...

```
=> EXPLAIN SELECT * FROM S JOIN T ON S.a = T.b WHERE S.a = 3
```

...

QUERY PLAN DESCRIPTION:

```
EXPLAIN SELECT * FROM S JOIN T ON S.a = T.b WHERE S.a = 3;
```

Access Path:

```
+--JOIN MERGEJOIN(inputs presorted) [Cost: 21, Rows: 4 (NO STATISTICS)] (PATH ID: 1)
|  Join Cond: (S.a = T.b)
```

...

Rewriting queries

You can use directed queries to change the semantics of a given query—that is, substitute one query for another. This can be especially important when you have little or no control over the content and format of input queries that your Vertica database processes. You can map these queries to directed queries that rewrite the original input for optimal execution.

The following sections describe two use cases:

- [Rewriting Join Queries](#)
- [Creating Query Templates](#)

Rewriting join queries

Many of your input queries join multiple tables. You've determined that in many cases, it would be more efficient to denormalize much of your data in several [flattened tables](#) and query those tables directly. You cannot revise the input queries themselves. However, you can use directed queries to redirect join queries to the flattened table data.

For example, the following query aggregates regional sales of wine products by joining three tables in the VMart database:

```
=> SELECT SD.store_region AS Region, SD.store_city AS City, SUM(SF.gross_profit_dollar_amount) Total
FROM store.store_sales_fact SF
JOIN store.store_dimension SD ON SF.store_key=SD.store_key
JOIN product_dimension P ON SF.product_key||SF.product_version=P.product_key||P.product_version
WHERE P.product_description ILIKE '%wine%'
GROUP BY ROLLUP (SD.store_region, SD.store_city)
ORDER BY Region,Total DESC;
```

You can consolidate the joined table data in a single flattened table, and query this table instead. By doing so, you can access the same data faster. You can create the flattened table with the following DDL statements:

```

=> CREATE TABLE store.store_sales_wide AS SELECT * FROM store.store_sales_fact;
=> ALTER TABLE store.store_sales_wide ADD COLUMN store_name VARCHAR(64)
    SET USING (SELECT store_name FROM store.store_dimension WHERE store.store_sales_wide.store_key=store.store_dimension.store_key);
=> ALTER TABLE store.store_sales_wide ADD COLUMN store_city varchar(64)
    SET USING (SELECT store_city FROM store.store_dimension WHERE store.store_sales_wide.store_key=store.store_dimension.store_key);
=> ALTER TABLE store.store_sales_wide ADD COLUMN store_state char(2)
    SET USING (SELECT store_state char FROM store.store_dimension WHERE store.store_sales_wide.store_key=store.store_dimension.store_key)
=> ALTER TABLE store.store_sales_wide ADD COLUMN store_region varchar(64)
    SET USING (SELECT store_region FROM store.store_dimension WHERE store.store_sales_wide.store_key=store.store_dimension.store_key);
=> ALTER TABLE store.store_sales_wide ADD column product_description VARCHAR(128)
    SET USING (SELECT product_description FROM public.product_dimension
    WHERE store_sales_wide.product_key||store_sales_wide.product_version = product_dimension.product_key||product_dimension.product_version);
=> ALTER TABLE store.store_sales_wide ADD COLUMN sku_number char(32)
    SET USING (SELECT sku_number char FROM product_dimension
    WHERE store_sales_wide.product_key||store_sales_wide.product_version = product_dimension.product_key||product_dimension.product_version);
=> SELECT REFRESH_COLUMNS ('store.store_sales_wide',", 'rebuild');

```

After creating this table and refreshing its **SET USING** columns, you can rewrite the earlier query as follows:

```

=> SELECT SD.store_region AS Region, SD.store_city AS City, SUM(SF.gross_profit_dollar_amount) Total
FROM store.store_sales_fact SF
JOIN store.store_dimension SD ON SF.store_key=SD.store_key
JOIN product_dimension P ON SF.product_key||SF.product_version=P.product_key||P.product_version
WHERE P.product_description ILIKE '%wine%'
GROUP BY ROLLUP (SD.store_region, SD.store_city)
ORDER BY Region,Total DESC;

```

Region	City	Total
East		1679788
East	Boston	138494
East	Elizabeth	138071
East	Sterling Heights	137719
East	Allentown	137122

MidWest	Lansing	145616
MidWest	Livonia	129349

--More--

Querying the flattened table is more efficient; however, you still must account for input queries that continue to use the earlier join syntax. You can do so by creating a [custom directed query](#), which redirects these input queries to syntax that targets the flattened table:

1. [Save the input query](#) :

```
=> SAVE QUERY SELECT SD.store_region AS Region, SD.store_city AS City, SUM(SF.gross_profit_dollar_amount) Total
FROM store.store_sales_fact SF
JOIN store.store_dimension SD ON SF.store_key=SD.store_key
JOIN product_dimension P ON SF.product_key||SF.product_version=P.product_key||P.product_version
WHERE P.product_description ILIKE '%wine%'
GROUP BY ROLLUP (SD.store_region, SD.store_city)
ORDER BY Region,Total DESC;
SAVE QUERY
```

2. Map the saved query to a directed query with the desired syntax, and [activate](#) the directed query:

```
=> CREATE DIRECTED QUERY CUSTOM 'RegionalSalesWine'
SELECT store_region AS Region,
store_city AS City,
SUM(gross_profit_dollar_amount) AS Total
FROM store.store_sales_wide
WHERE product_description ILIKE '%wine%'
GROUP BY ROLLUP (region, city)
ORDER BY Region,Total DESC;
CREATE DIRECTED QUERY

=> ACTIVATE DIRECTED QUERY RegionalSalesWine;
ACTIVATE DIRECTED QUERY
```

When directed query **RegionalSalesWine** is active, the query optimizer maps all queries that match the original input format to the directed query, as shown in the following query plan:

```
=> EXPLAIN SELECT SD.store_region AS Region, SD.store_city AS City, SUM(SF.gross_profit_dollar_amount) Total
FROM store.store_sales_fact SF
JOIN store.store_dimension SD ON SF.store_key=SD.store_key
JOIN product_dimension P ON SF.product_key||SF.product_version=P.product_key||P.product_version
WHERE P.product_description ILIKE '%wine%'
GROUP BY ROLLUP (SD.store_region, SD.store_city)
ORDER BY Region,Total DESC;
...

```

The following active directed query(query name: RegionalSalesWine) is being executed:

```
SELECT store_sales_wide.store_region AS Region, store_sales_wide.store_city AS City, sum(store_sales_wide.gross_profit_dollar_amount) AS Total
FROM store.store_sales_wide WHERE (store_sales_wide.product_description ~~* '%wine%':::varchar(6))
GROUP BY GROUPING SETS((store_sales_wide.store_region, store_sales_wide.store_city), (store_sales_wide.store_region),())
ORDER BY store_sales_wide.store_region, sum(store_sales_wide.gross_profit_dollar_amount) DESC
```

Access Path:

```
+--SORT [Cost: 2K, Rows: 10K (NO STATISTICS)] (PATH ID: 1)
| Order: store_sales_wide.store_region ASC, sum(store_sales_wide.gross_profit_dollar_amount) DESC
| Execute on: All Nodes
| +---> GROUPBY HASH (GLOBAL RESEGMENT GROUPS) (LOCAL RESEGMENT GROUPS) [Cost: 2K, Rows: 10K (NO STATISTICS)] (PATH ID: 2)
|| Aggregates: sum(store_sales_wide.gross_profit_dollar_amount)
|| Group By: store_sales_wide.store_region, store_sales_wide.store_city
|| Grouping Sets: (store_sales_wide.store_region, store_sales_wide.store_city, <SVAR>), (store_sales_wide.store_region, <SVAR>), (<SVAR>)
|| Execute on: All Nodes
|| +---> STORAGE ACCESS for store_sales_wide [Cost: 864, Rows: 10K (NO STATISTICS)] (PATH ID: 3)
||| Projection: store.store_sales_wide_b0
||| Materialize: store_sales_wide.gross_profit_dollar_amount, store_sales_wide.store_city, store_sales_wide.store_region
||| Filter: (store_sales_wide.product_description ~~* '%wine%')
||| Execute on: All Nodes
```

To compare the costs of executing the directed query and executing the original input query, deactivate the directed query and use EXPLAIN on the original input query. The optimizer reverts to creating a plan for the input query that incurs significantly greater cost—188K versus 2K:

```

=> DEACTIVATE DIRECTED QUERY RegionalSalesWine;
DEACTIVATE DIRECTED QUERY
=> EXPLAIN SELECT SD.store_region AS Region, SD.store_city AS City, SUM(SF.gross_profit_dollar_amount) Total
  FROM store.store_sales_fact SF
  JOIN store.store_dimension SD ON SF.store_key=SD.store_key
  JOIN product_dimension P ON SF.product_key||SF.product_version=P.product_key||P.product_version
 WHERE P.product_description ILIKE '%wine%'
 GROUP BY ROLLUP (SD.store_region, SD.store_city)
 ORDER BY Region,Total DESC;
...
Access Path:
+-SORT [Cost: 188K, Rows: 10K (NO STATISTICS)] (PATH ID: 1)
| Order: SD.store_region ASC, sum(SF.gross_profit_dollar_amount) DESC
| Execute on: All Nodes
| +---> GROUPBY HASH (GLOBAL RESEGMENT GROUPS) (LOCAL RESEGMENT GROUPS) [Cost: 188K, Rows: 10K (NO STATISTICS)] (PATH ID: 2)
|| Aggregates: sum(SF.gross_profit_dollar_amount)
|| Group By: SD.store_region, SD.store_city
|| Grouping Sets: (SD.store_region, SD.store_city, <SVAR>), (SD.store_region, <SVAR>), (<SVAR>)
|| Execute on: All Nodes
|| +---> JOIN HASH [Cost: 12K, Rows: 5M (NO STATISTICS)] (PATH ID: 3) Inner (BROADCAST)
||| Join Cond: (concat((SF.product_key)::varchar, (SF.product_version)::varchar) = concat((P.product_key)::varchar, (P.product_version)::varchar))
||| Materialize at Input: SF.product_key, SF.product_version
||| Materialize at Output: SF.gross_profit_dollar_amount
||| Execute on: All Nodes
||| +- Outer -> JOIN HASH [Cost: 2K, Rows: 5M (NO STATISTICS)] (PATH ID: 4) Inner (BROADCAST)
|||| Join Cond: (SF.store_key = SD.store_key)
|||| Execute on: All Nodes
|||| +- Outer -> STORAGE ACCESS for SF [Cost: 1K, Rows: 5M (NO STATISTICS)] (PATH ID: 5)
||||| Projection: store.store_sales_fact_super
||||| Materialize: SF.store_key
||||| Execute on: All Nodes
||||| Runtime Filters: (SIP2(HashJoin): SF.store_key), (SIP1(HashJoin): concat((SF.product_key)::varchar, (SF.product_version)::varchar))
|||| +- Inner -> STORAGE ACCESS for SD [Cost: 13, Rows: 250 (NO STATISTICS)] (PATH ID: 6)

||||| Projection: public.product_dimension_super
||||| Materialize: P.product_key, P.product_version
||||| Filter: (P.product_description ~~* '%wine%')
||||| Execute on: All Nodes

```

Creating query templates

You can use directed queries to implement multiple queries that are identical except for the predicate strings on which query results are filtered. For example, directed query [RegionalSalesWine](#) only handles input queries that filter on [product_description](#) values that contain the string [wine](#) . You can create a modified version of this directed query that matches the syntax of multiple input queries, which differ only in their input values—for example, [tuna](#) .

Create this query template in the following steps:

1. Create two [optimizer-generated directed queries](#) :

- From the original query on the joined tables:

```

=> CREATE DIRECTED QUERY OPTIMIZER RegionalSalesProducts_JoinTables
  SELECT SD.store_region AS Region, SD.store_city AS City, SUM(SF.gross_profit_dollar_amount) Total
  FROM store.store_sales_fact SF
  JOIN store.store_dimension SD ON SF.store_key=SD.store_key
  JOIN product_dimension P ON SF.product_key||SF.product_version=P.product_key||P.product_version
  WHERE P.product_description ILIKE '%wine%'
  GROUP BY ROLLUP (SD.store_region, SD.store_city)
  ORDER BY Region,Total DESC;
CREATE DIRECTED QUERY

```

- o From the query on the flattened table:

```
=> CREATE DIRECTED QUERY OPTIMIZER RegionalSalesProduct
SELECT store_region AS Region, store_city AS City, SUM(gross_profit_dollar_amount) AS Total
FROM store.store_sales_wide
WHERE product_description ILIKE '%wine%'
GROUP BY ROLLUP (region, city)
ORDER BY Region,Total DESC;
CREATE DIRECTED QUERY
```

2. Query system table DIRECTED_QUERIES and copy the input query for directed query [RegionalSalesProducts_JoinTables](#) :

```
SELECT input_query FROM directed_queries WHERE query_name = 'RegionalSalesProducts_JoinTables';
```

3. Use the copied input query with SAVE QUERY:

```
SAVE QUERY SELECT SD.store_region AS Region, SD.store_city AS City, sum(SF.gross_profit_dollar_amount) AS Total
FROM ((store.store_sales_fact SF
JOIN store.store_dimension SD ON ((SF.store_key = SD.store_key)))
JOIN public.product_dimension P ON ((concat((SF.product_key)::varchar, (SF.product_version)::varchar) = concat((P.product_key)::varchar,
(P.product_version)::varchar))))
WHERE (P.product_description ~~* '%wine%':::varchar(6) /*+:v(1)*/)
GROUP BY GROUPING SETS((SD.store_region, SD.store_city), (SD.store_region), ())
ORDER BY SD.store_region, sum(SF.gross_profit_dollar_amount) DESC
(1 row)
```

4. Query system table DIRECTED_QUERIES and copy the annotated query for directed query [RegionalSalesProducts_FlatTables](#) :

```
SELECT input_query FROM directed_queries WHERE query_name = 'RegionalSalesProducts_JoinTables';
```

5. Use the copied annotated query to create a [custom directed query](#):

```
=> CREATE DIRECTED QUERY CUSTOM RegionalSalesProduct SELECT /*+verbatim*/ store_sales_wide.store_region AS Region,
store_sales_wide.store_city AS City, sum(store_sales_wide.gross_profit_dollar_amount) AS Total
FROM store.store_sales_wide AS store_sales_wide/*+projs('store.store_sales_wide')*/
WHERE (store_sales_wide.product_description ~~* '%wine%':::varchar(6) /*+:v(1)*/)
GROUP BY /*+GByType(Hash)*/ GROUPING SETS((1, 2), (1), ())
ORDER BY 1 ASC, 3 DESC;
CREATE DIRECTED QUERY
```

6. Activate the directed query:

```
ACTIVATE DIRECTED QUERY RegionalSalesProduct;
```

After activating this directed query, Vertica can use it for input queries that match the template, differing only in the predicate value for [product_description](#) :

```
=> EXPLAIN SELECT SD.store_region AS Region, SD.store_city AS City, SUM(SF.gross_profit_dollar_amount) Total
FROM store.store_sales_fact SF
JOIN store.store_dimension SD ON SF.store_key=SD.store_key
JOIN product_dimension P ON SF.product_key||SF.product_version=P.product_key||P.product_version
WHERE P.product_description ILIKE '%tuna%'
GROUP BY ROLLUP (SD.store_region, SD.store_city)
ORDER BY Region,Total DESC;
```

...

The following active directed query(query name: RegionalSalesProduct) is being executed:

```
SELECT /*+verbatim*/ store_sales_wide.store_region AS Region, store_sales_wide.store_city AS City, sum(store_sales_wide.gross_profit_dollar_amount)
AS Total
FROM store.store_sales_wide store_sales_wide/*+projs('store.store_sales_wide')*/
WHERE (store_sales_wide.product_description ~~* '%tuna%'::varchar(6))
GROUP BY /*+GByType(Hash)*/ GROUPING SETS((store_sales_wide.store_region, store_sales_wide.store_city), (store_sales_wide.store_region), ())
ORDER BY store_sales_wide.store_region, sum(store_sales_wide.gross_profit_dollar_amount) DESC
```

Access Path:

```
+--SORT [Cost: 2K, Rows: 10K (NO STATISTICS)] (PATH ID: 1)
| Order: store_sales_wide.store_region ASC, sum(store_sales_wide.gross_profit_dollar_amount) DESC
| Execute on: All Nodes
| +---> GROUPBY HASH (GLOBAL RESEGMENT GROUPS) (LOCAL RESEGMENT GROUPS) [Cost: 2K, Rows: 10K (NO STATISTICS)] (PATH ID: 2)
|| Aggregates: sum(store_sales_wide.gross_profit_dollar_amount)
|| Group By: store_sales_wide.store_region, store_sales_wide.store_city
|| Grouping Sets: (store_sales_wide.store_region, store_sales_wide.store_city, <SVAR>), (store_sales_wide.store_region, <SVAR>), (<SVAR>)
|| Execute on: All Nodes
|| +---> STORAGE ACCESS for store_sales_wide [Cost: 864, Rows: 10K (NO STATISTICS)] (PATH ID: 3)
||| Projection: store.store_sales_wide_b0
||| Materialize: store_sales_wide.gross_profit_dollar_amount, store_sales_wide.store_city, store_sales_wide.store_region
||| Filter: (store_sales_wide.product_description ~~* '%tuna%')
||| Execute on: All Nodes
```

When you execute this query, it returns with the following results:

Region	City	Total
East		1564582
East	Elizabeth	131328
East	Allentown	129704
East	Boston	128188
East	Sterling Heights	125877

--More--		

Managing directed queries

Vertica provides the following ways to manage directed queries:

- [Listing defined directed queries](#) and [identifying which ones are active](#)
- [Activating and deactivating directed queries](#)
- [Exporting directed queries](#), especially before upgrading Vertica
- [Dropping directed queries](#)

Listing directed queries

You can use [GET DIRECTED QUERY](#) to look up queries in the [DIRECTED_QUERIES](#) system table. The statement returns details of all directed queries that map to the input SELECT statement. For example:

```

-> GET DIRECTED QUERY
   SELECT employee_first_name, employee_last_name
   FROM employee_dimension
   WHERE employee_city='Boston' AND job_title='Cashier'
   ORDER BY employee_last_name, employee_first_name;
{ RECORD 1 }--+
query_name    | findEmployeesCityJobTitle_OPT
is_active     | 1
vertica_version | Vertica Analytic Database v11.0.1-20210815
comment       | Optimizer-generated directed query
creation_date  | 2021-08-20 14:53:42.323963
annotated_query | SELECT /*+verbatim*/ employee_dimension.employee_first_name, employee_dimension.employee_last_name FROM public.employee_d

```

You can also query the system table directly:

```

-> SELECT query_name, is_active
   FROM V_CATALOG.DIRECTED_QUERIES
  WHERE query_name ILIKE '%findEmployeesCityJobTitle%';
      query_name      | is_active
-----+-----
findEmployeesCityJobTitle_OPT | t
(1 row)

```

Identifying active directed queries

Multiple directed queries can map to the same input query. If more than one directed query is active, the optimizer uses the one that was created first. The [DIRECTED_QUERIES](#) system table records when queries were created and whether they are active. You can also use [EXPLAIN](#) to identify which directed query is active.

It is good practice to activate only one directed query at a time for a given input query.

The following query finds all active directed queries where the input query contains the name of the queried table:

```

-> SELECT * FROM DIRECTED_QUERIES
   WHERE input_query ILIKE ('%employee_dimension%') AND is_active=1;
{ RECORD 1 }----+
query_name      | findEmployeesCityJobTitle_OPT
is_active       | t
vertica_version | Vertica Analytic Database v11.0.1-20210815
comment         | Optimizer-generated directed query
save_plans_version | 0
username        | dbadmin
creation_date   | 2021-08-20 14:53:42.323963
since_date      |
input_query     | SELECT employee_dimension.employee_first_name, employee_dimension.employee_last_name FROM public.employee_dimension WHERE
associated_query | SELECT /*+verbatim*/ employee_dimension.employee_first_name, employee_dimension.employee_last_name FROM public.employee

```

If you run [EXPLAIN](#) on the input query, it returns with a query plan that confirms use of this directed query:

```

-> EXPLAIN SELECT employee_first_name, employee_last_name
   FROM employee_dimension
  WHERE employee_city='Boston' AND job_title = 'Cashier'
  ORDER BY employee_last_name, employee_first_name;

The following active directed query(query name: findEmployeesCityJobTitle_OPT) is being executed:
SELECT /*+verbatim*/ employee_dimension.employee_first_name, employee_dimension.employee_last_name FROM public.employee_dimension employee

```

Activating and deactivating directed queries

The optimizer uses only directed queries that are active. If multiple directed queries share the same input query, the optimizer uses the first one to be created.

Use [ACTIVATE DIRECTED QUERY](#) and [DEACTIVATE DIRECTED QUERY](#) to activate and deactivate queries. The following example replaces a directed query:

```

-> DEACTIVATE DIRECTED QUERY RegionalSalesProducts_JoinTables;
DEACTIVATE DIRECTED QUERY;

-> ACTIVATE DIRECTED QUERY RegionalSalesProduct;
ACTIVATE DIRECTED QUERY;

```

[ACTIVATE DIRECTED QUERY](#) and [DEACTIVATE DIRECTED QUERY](#) can also activate and deactivate multiple directed queries that are filtered from [DIRECTED_QUERIES](#). In the following example, [DEACTIVATE DIRECTED QUERY](#) deactivates all directed queries with the same [save_plans_version](#) identifier:

```

-> DEACTIVATE DIRECTED QUERY WHERE save_plans_version = 21;

```

Vertica uses the active directed query for a given query across all sessions until it is explicitly deactivated by [DEACTIVATE DIRECTED QUERY](#) or removed from storage by [DROP DIRECTED QUERY](#). If a directed query is active at the time of database shutdown, Vertica automatically reactivates it when you restart the database.

After a directed query is deactivated, the query optimizer handles subsequent invocations of the input query by using another directed query, if one is available. Otherwise, it generates its own query plan.

Exporting directed queries from the catalog

Before upgrading to a new version of Vertica, you can export directed queries for those queries whose optimal performance is critical to your system:

Use [EXPORT_CATALOG](#) with the [DIRECTED_QUERIES](#) argument to export from the database catalog all current directed queries and their current activation status:

```
-> SELECT EXPORT_CATALOG('././export_directedqueries', 'DIRECTED_QUERIES');
EXPORT_CATALOG
-----
Catalog data exported successfully
```

EXPORT_CATALOG creates a script to recreate the directed queries, as in the following example:

```
SAVE QUERY SELECT employee_dimension.employee_first_name, employee_dimension.employee_last_name FROM public.employee_dimension WHERE
CREATE DIRECTED QUERY CUSTOM findEmployeesCityJobTitle_OPT COMMENT 'Optimizer-generated directed query' OPTVER 'Vertica Analytic Databa
FROM public.employee_dimension employee_dimension"+projs('public.employee_dimension')?
WHERE ((employee_dimension.employee_city = 'Boston':varchar(6) /'+v(1)?') AND (employee_dimension.job_title = 'Cashier':varchar(7) /'+v(2)?')
ORDER BY employee_dimension.employee_last_name, employee_dimension.employee_first_name;
ACTIVATE DIRECTED QUERY findEmployeesCityJobTitle_OPT;
```

Note

The script that [EXPORT_CATALOG](#) creates recreates all directed queries with CREATE DIRECTED QUERY CUSTOM, regardless of how they were created originally.

After the upgrade is complete, remove each directed query from the database catalog with [DROP DIRECTED QUERY](#). Alternatively, edit the export script and insert a DROP DIRECTED QUERY statement before each CREATE DIRECTED QUERY statement.

When you run this script, Vertica recreates the directed queries and restores their activation status:

```
-> \! /home/dbadmin/export_directedqueries
SAVE QUERY
DROP DIRECTED QUERY
CREATE DIRECTED QUERY
ACTIVATE DIRECTED QUERY
```

You can also export query plans as directed queries to an external SQL file. See [Batch query plan export](#).

Dropping directed queries

[DROP DIRECTED QUERY](#) removes one or more directed queries from the database catalog. If the directed query is active, Vertica deactivates it before removal.

For example:

```
-> DROP DIRECTED QUERY findBostonCashiers_CUSTOM;
DROP DIRECTED QUERY
```

DROP DIRECTED QUERY can drop multiple directed queries that are filtered from [DIRECTED_QUERIES](#). In the following example, DROP DIRECTED QUERY drops all directed queries with the same [save_plans_version](#) identifier:

```
-> DROP DIRECTED QUERY WHERE save_plans_version = 21;
```

Batch query plan export

Before upgrading to a new Vertica version, you might want to use directed queries to save query plans for possible reuse in the new database. You cannot predict which query plans are likely candidates for reuse, so you probably want to save query plans for many, or all, database queries.

However, you run hundreds of queries each day. Saving query plans for each one to the database catalog through repetitive calls to [CREATE DIRECTED QUERY](#) is impractical. Moreover, doing so can significantly increase catalog size and possibly impact performance.

In this case, you can bypass the database catalog and batch export query plans as directed queries to an external SQL file. By offloading query plan storage, you can save any number of query plans from the current database without impacting catalog size and performance. After the upgrade, you can decide which query plans you wish to retain in the new database, and selectively import the corresponding directed queries.

Vertica provides a set of meta-functions that support this approach:

- [EXPORT_DIRECTED_QUERIES](#) generates query plans from a set of input queries, and writes SQL for creating directed queries that encapsulate those plans.
- [IMPORT_DIRECTED_QUERIES](#) imports directed queries to the database catalog from a SQL file that was generated by [EXPORT_DIRECTED_QUERIES](#).

In this section

- [Exporting directed queries](#)
- [Importing directed queries](#)

Exporting directed queries

You can batch export any number of query plans as directed queries to an external SQL file, as follows:

1. Create a SQL file that contains the input queries whose query plans you wish to save. See [Input Format](#) below.
2. Call the meta-function [EXPORT_DIRECTED_QUERIES](#) on that SQL file. The meta-function takes two arguments:
 - [Input queries file](#).
 - Optionally, the name of an [output file](#). [EXPORT_DIRECTED_QUERIES](#) writes SQL for creating directed queries to this file. If you supply an empty string, Vertica writes the SQL to standard output.

For example, the following [EXPORT_DIRECTED_QUERIES](#) statement specifies input file `inputQueries` and output file `outputQueries` :

```
=> SELECT EXPORT_DIRECTED_QUERIES('/home/dbadmin/inputQueries','/home/dbadmin/outputQueries');
      EXPORT_DIRECTED_QUERIES
```

```
-----
1 queries successfully exported.
Queries exported to /home/dbadmin/outputQueries.
```

```
(1 row)
```

Input file

The input file that you supply to [EXPORT_DIRECTED_QUERIES](#) contains one or more input queries. For each input query, you can optionally specify two fields that are used in the generated directed query:

- `DirQueryName` provides the directed query's unique identifier, a string that conforms to conventions described in [Identifiers](#).
- `DirQueryComment` specifies a quote-delimited string, up to 128 characters.

You format each input query as follows:

```
--DirQueryName=query-name
--DirQueryComment='comment'
input-query
```

For example, a file can specify one input query as follows:

```
/* Query: findEmployeesCityJobTitle_OPT */
/* Comment: This query finds all employees of a given city and job title, ordered by employee name */
SELECT employee_dimension.employee_first_name, employee_dimension.employee_last_name, employee_dimension.job_title FROM
public.employee_dimension WHERE (employee_dimension.employee_city = 'Boston'::varchar(6)) ORDER BY employee_dimension.job_title;
```

Output file

[EXPORT_DIRECTED_QUERIES](#) generates SQL for creating directed queries, and writes the SQL to the specified file or to standard output. In both cases, output conforms to the following format:

```
/* Query: directed-query-name */
/* Comment: directed-query-comment */
SAVE QUERY input-query;
CREATE DIRECTED QUERY CUSTOM 'directed-query-name'
COMMENT 'directed-query-comment'
OPTVER 'vertica-release-num'
PSDATE 'timestamp'
annotated-query
```

For example, given the previous input, Vertica writes the following output to `/home/dbadmin/outputQueries` :

```
/* Query: findEmployeesCityJobTitle_OPT */
/* Comment: This query finds all employees of a given city and job title, ordered by employee name */
SAVE QUERY SELECT employee_dimension.employee_first_name, employee_dimension.employee_last_name FROM public.employee_dimension
WHERE ((employee_dimension.employee_city = 'Boston'::varchar(6) /*+:v(1)*/) AND (employee_dimension.job_title = 'Cashier'::varchar(7) /*+:v(2)*/))
ORDER BY employee_dimension.employee_last_name, employee_dimension.employee_first_name;
CREATE DIRECTED QUERY CUSTOM 'findEmployeesCityJobTitle_OPT'
COMMENT 'This query finds all employees of a given city and job title, ordered by employee name'
OPTVER 'Vertica Analytic Database v11.1.0-20220102'
PSDATE '2022-01-06 13:45:17.430254'
SELECT /*+verbatim*/ employee_dimension.employee_first_name AS employee_first_name, employee_dimension.employee_last_name AS
employee_last_name
FROM public.employee_dimension AS employee_dimension/*+projs('public.employee_dimension')*/
WHERE (employee_dimension.employee_city = 'Boston'::varchar(6) /*+:v(1)*/) AND (employee_dimension.job_title = 'Cashier'::varchar(7) /*+:v(2)*/)
ORDER BY 2 ASC, 1 ASC;
```

If a given input query omits `DirQueryName` and `DirQueryComment` fields, `EXPORT_DIRECTED_QUERIES` automatically generates the following output:

- `/* Query: Autoname: timestamp . n */`, where `n` is a zero-based integer index that ensures uniqueness among auto-generated names with the same timestamp.
- `/* Comment: Optimizer-generated directed query */`

For example, the following input file contains one `SELECT` statement, and omits the `DirQueryName` and `DirQueryComment` fields:

```
SELECT employee_dimension.employee_first_name, employee_dimension.employee_last_name
FROM public.employee_dimension WHERE (employee_dimension.employee_city = 'Boston'::varchar(6))
ORDER BY employee_dimension.job_title;
```

Given this file, `EXPORT_DIRECTED_QUERIES` returns with a warning about the missing input fields, which it also writes to an [error file](#):

```
> SELECT EXPORT_DIRECTED_QUERIES('/home/dbadmin/inputQueries2', '/home/dbadmin/outputQueries3');
EXPORT_DIRECTED_QUERIES
```

```
-----
1 queries successfully exported.
1 warning message was generated.
Queries exported to /home/dbadmin/outputQueries3.
See error report, /home/dbadmin/outputQueries3.err for details.
(1 row)
```

The output file contains the following content:

```

/* Query: Autaname:2022-01-06 14:11:23.071559.0 */
/* Comment: Optimizer-generated directed query */
SAVE QUERY SELECT employee_dimension.employee_first_name, employee_dimension.employee_last_name FROM public.employee_dimension
WHERE (employee_dimension.employee_city = 'Boston'::varchar(6) /*+:v(1)*/) ORDER BY employee_dimension.job_title;
CREATE DIRECTED QUERY CUSTOM 'Autaname:2022-01-06 14:11:23.071559.0'
COMMENT 'Optimizer-generated directed query'
OPTVER 'Vertica Analytic Database v11.1.0-20220102'
PSDATE '2022-01-06 14:11:23.071559'
SELECT /*+verbatim*/ employee_dimension.employee_first_name AS employee_first_name, employee_dimension.employee_last_name AS
employee_last_name
FROM public.employee_dimension AS employee_dimension/*+projs('public.employee_dimension')*/
WHERE (employee_dimension.employee_city = 'Boston'::varchar(6) /*+:v(1)*/)
ORDER BY employee_dimension.job_title ASC;

```

Error file

If any errors or warnings occur during EXPORT_DIRECTED_QUERIES execution, it returns with a message like this one:

```

1 queries successfully exported.
1 warning message was generated.
Queries exported to /home/dbadmin/outputQueries.
See error report, /home/dbadmin/outputQueries.err for details.

```

EXPORT_DIRECTED_QUERIES writes all errors and warnings to a file that it creates on the same path as the output file, and uses the output file's base name.

In the previous example, the output filename is `/home/dbadmin/outputQueries`, so EXPORT_DIRECTED_QUERIES writes errors to `/home/dbadmin/outputQueries.err`.

The error file can capture a number of errors and warnings, such as all instances where EXPORT_DIRECTED_QUERIES was unable to create a directed query. In the following example, the error file contains a warning that no name field was supplied for the specified input query, and records the name that was auto-generated for it:

```

-----
WARNING: Name field not supplied. Using auto-generated name: 'Autaname:2016-10-13 09:44:33.527548.0'
Input Query: SELECT employee_dimension.employee_first_name, employee_dimension.employee_last_name, employee_dimension.job_title FROM
public.employee_dimension WHERE (employee_dimension.employee_city = 'Boston'::varchar(6)) ORDER BY employee_dimension.job_title;
END WARNING

```

Importing directed queries

After you determine which exported query plans you wish to use in the current database, you import them with [IMPORT_DIRECTED_QUERIES](#). You supply this function with the name of the export file that you created with EXPORT_DIRECTED_QUERIES, and the names of directed queries you wish to import. For example:

```

=> SELECT IMPORT_DIRECTED_QUERIES('/home/dbadmin/outputQueries','FindEmployeesBoston');
      IMPORT_DIRECTED_QUERIES

```

```

-----
1 directed queries successfully imported.
To activate a query named 'my_query1':
=> ACTIVATE DIRECTED QUERY 'my_query1';

```

(1 row)

After importing the desired directed queries, you must activate them with [ACTIVATE DIRECTED QUERY](#) before you can use them to create query plans.

Half join and cross join semantics

The Vertica optimizer uses several keywords in directed queries to recreate cross join and half join subqueries. It also supports an additional set of keywords to express complex cross joins and half joins. You can also use these keywords in queries that you execute directly in vsql.

Caution

These keywords do not conform with standard SQL; they are intended for use only by the Vertica optimizer.

For details, see the following topics:

- [Half-join subquery semantics](#)
- [Complex join semantics](#)

In this section

- [Half-join subquery semantics](#)
- [Complex join semantics](#)

Half-join subquery semantics

The Vertica optimizer uses several keywords in directed queries to recreate half-join subqueries with certain search operators, such as [ANY](#) or [NOT IN](#).

SEMI JOIN

Recreates a query that contains a subquery preceded by an [IN](#), [EXISTS](#), or [ANY](#) operator and executes a semi-join.

Input query

```
SELECT product_description FROM product_dimension
WHERE product_dimension.product_key IN (SELECT qty_in_stock from inventory_fact);
```

Query plan

QUERY PLAN DESCRIPTION:

```
explain SELECT product_description FROM product_dimension WHERE product_dimension.product_key IN (SELECT qty_in_stock from inventory_fact);
```

Access Path:

```
+--JOIN HASH [Semi] [Cost: 1K, Rows: 30K] (PATH ID: 1) Outer (FILTER) Inner (RESEGMENT)
| Join Cond: (product_dimension.product_key = VAL(2))
| Materialize at Output: product_dimension.product_description
| Execute on: All Nodes
| +- Outer -> STORAGE ACCESS for product_dimension [Cost: 152, Rows: 60K] (PATH ID: 2)
|| Projection: public.product_dimension
|| Materialize: product_dimension.product_key
|| Execute on: All Nodes
|| Runtime Filter: (SIP1(HashJoin): product_dimension.product_key)
| +- Inner -> SELECT [Cost: 248, Rows: 300K] (PATH ID: 3)
|| Execute on: All Nodes
| +-> STORAGE ACCESS for inventory_fact [Cost: 248, Rows: 300K] (PATH ID: 4)
|| Projection: public.inventory_fact_b0
|| Materialize: inventory_fact.qty_in_stock
|| Execute on: All Nodes
```

Optimizer-generated annotated query

```
SELECT /*+ syntactic_join */ product_dimension.product_description AS product_description
FROM (public.product_dimension AS product_dimension/*+projs('public.product_dimension')*/
SEMI JOIN /*+Distrib(F,R),JType(H)*/ (SELECT inventory_fact.qty_in_stock AS qty_in_stock
FROM public.inventory_fact AS inventory_fact/*+projs('public.inventory_fact')*/) AS subQ_1
ON (product_dimension.product_key = subQ_1.qty_in_stock))
```

NULLAWARE ANTI JOIN

Recreates a query that contains a subquery preceded by a [NOT IN](#) or `!=ALL` operator, and executes a null-aware anti-join.

Input query

```
SELECT product_description FROM product_dimension
WHERE product_dimension.product_key NOT IN (SELECT qty_in_stock from inventory_fact);
```

Query plan

QUERY PLAN DESCRIPTION:

EXPLAIN SELECT product_description FROM product_dimension WHERE product_dimension.product_key not IN (SELECT qty_in_stock from inventory_fact);

Access Path:

```
+--JOIN HASH [Anti][NotInAnti] [Cost: 7K, Rows: 30K] (PATH ID: 1) Inner (BROADCAST)
| Join Cond: (product_dimension.product_key = VAL(2))
| Materialize at Output: product_dimension.product_description
| Execute on: Query Initiator
| +- Outer -> STORAGE ACCESS for product_dimension [Cost: 152, Rows: 60K] (PATH ID: 2)
|| Projection: public.product_dimension_DBD_2_rep_VMartDesign
|| Materialize: product_dimension.product_key
|| Execute on: Query Initiator
| +- Inner -> SELECT [Cost: 248, Rows: 300K] (PATH ID: 3)
|| Execute on: All Nodes
|| +--> STORAGE ACCESS for inventory_fact [Cost: 248, Rows: 300K] (PATH ID: 4)
||| Projection: public.inventory_fact_DBD_9_seg_VMartDesign_b0
||| Materialize: inventory_fact.qty_in_stock
||| Execute on: All Nodes
```

Optimizer-generated annotated query

```
SELECT /*+ syntactic_join */ product_dimension.product_description AS product_description
FROM (public.product_dimension AS product_dimension/*+projs('public.product_dimension')*/
NULLAWARE ANTI JOIN /*+Distrib(L,B),JType(H)*/ (SELECT inventory_fact.qty_in_stock AS qty_in_stock
FROM public.inventory_fact AS inventory_fact/*+projs('public.inventory_fact')*/) AS subQ_1
ON (product_dimension.product_key = subQ_1.qty_in_stock))
```

SEMIALL JOIN

Recreates a query that contains a subquery preceded by an [ALL](#) operator, and executes a semi-all join.

Input query

```
SELECT product_key, product_description FROM product_dimension
WHERE product_dimension.product_key > ALL (SELECT product_key from inventory_fact);
```

Query plan

QUERY PLAN DESCRIPTION:

explain SELECT product_key, product_description FROM product_dimension WHERE product_dimension.product_key > ALL (SELECT product_key from inventory_fact);

Access Path:

```
+--JOIN HASH [Semi][All] [Cost: 7M, Rows: 30K] (PATH ID: 1) Outer (FILTER) Inner (BROADCAST)
| Join Filter: (product_dimension.product_key > VAL(2))
| Materialize at Output: product_dimension.product_description
| Execute on: All Nodes
|-- Outer -> STORAGE ACCESS for product_dimension [Cost: 152, Rows: 60K] (PATH ID: 2)
| | Projection: public.product_dimension
| | Materialize: product_dimension.product_key
| | Execute on: All Nodes
|-- Inner -> SELECT [Cost: 248, Rows: 300K] (PATH ID: 3)
| | Execute on: All Nodes
| |--> STORAGE ACCESS for inventory_fact [Cost: 248, Rows: 300K] (PATH ID: 4)
| | | Projection: public.inventory_fact_b0
| | | Materialize: inventory_fact.product_key
| | | Execute on: All Nodes
```

Optimizer-generated annotated query

```
SELECT /*+ syntactic_join */ product_dimension.product_key AS product_key, product_dimension.product_description AS product_description
FROM (public.product_dimension AS product_dimension/*+projs('public.product_dimension')*/
SEMIALL JOIN /*+Distrib(F,B),JType(H)*/ (SELECT inventory_fact.product_key AS product_key FROM public.inventory_fact AS
inventory_fact/*+projs('public.inventory_fact')*/) AS subQ_1
ON (product_dimension.product_key > subQ_1.product_key))
```

ANTI JOIN

Recreates a query that contains a subquery preceded by a [NOT EXISTS](#) operator, and executes an anti-join.

Input query

```
SELECT product_key, product_description FROM product_dimension
WHERE NOT EXISTS (SELECT inventory_fact.product_key FROM inventory_fact
WHERE inventory_fact.product_key=product_dimension.product_key);
```

Query plan

QUERY PLAN DESCRIPTION:

```
-----  
  
explain SELECT product_key, product_description FROM product_dimension WHERE NOT EXISTS (SELECT inventory_fact.product_key FROM inventory_fact WHERE inventory_fact.product_key=product_dimension.product_key);
```

Access Path:

```
+--JOIN HASH [Anti] [Cost: 703, Rows: 30K] (PATH ID: 1) Outer (FILTER)  
| Join Cond: (VAL(1) = product_dimension.product_key)  
| Materialize at Output: product_dimension.product_description  
| Execute on: All Nodes  
| +-- Outer -> STORAGE ACCESS for product_dimension [Cost: 152, Rows: 60K] (PATH ID: 2)  
|| Projection: public.product_dimension_DBD_2_rep_VMartDesign  
|| Materialize: product_dimension.product_key  
|| Execute on: All Nodes  
| +-- Inner -> SELECT [Cost: 248, Rows: 300K] (PATH ID: 3)  
|| Execute on: All Nodes  
| +---> STORAGE ACCESS for inventory_fact [Cost: 248, Rows: 300K] (PATH ID: 4)  
||| Projection: public.inventory_fact_DBD_9_seg_VMartDesign_b0  
||| Materialize: inventory_fact.product_key  
||| Execute on: All Nodes
```

Optimizer-generated annotated query

```
SELECT /*+ syntactic_join */ product_dimension.product_key AS product_key, product_dimension.product_description AS product_description  
FROM (public.product_dimension AS product_dimension/*+projs('public.product_dimension')*/  
ANTI JOIN /*+Distrib(F,L),JType(H)*/ (SELECT inventory_fact.product_key AS "inventory_fact.product_key"  
FROM public.inventory_fact AS inventory_fact/*+projs('public.inventory_fact')*/) AS subQ_1  
ON (subQ_1."inventory_fact.product_key" = product_dimension.product_key))
```

Complex join semantics

The optimizer uses a set of keywords to express [complex cross joins](#) and [half joins](#). All complex joins are indicated by the keyword **COMPLEX**, which is inserted before the keyword **JOIN** —for example, **CROSS COMPLEX JOIN**. Semantics for complex half joins have an additional requirement, which is detailed [below](#).

Complex cross join

Vertica uses the keyword phrase **CROSS COMPLEX JOIN** to describe all complex cross joins. For example:

Input query

```
SELECT  
(SELECT max(sales_quantity) FROM store.store_sales_fact) *  
(SELECT max(sales_quantity) FROM online_sales.online_sales_fact);
```

Query plan

QUERY PLAN DESCRIPTION:

EXPLAIN SELECT

```
(SELECT max(sales_quantity) FROM store.store_sales_fact) *  
(SELECT max(sales_quantity) FROM online_sales.online_sales_fact);
```

Access Path:

```
+--JOIN (CROSS JOIN) [Cost: 4K, Rows: 1 (NO STATISTICS)] (PATH ID: 1)  
| Execute on: Query Initiator  
| +-- Outer -> JOIN (CROSS JOIN) [Cost: 2K, Rows: 1 (NO STATISTICS)] (PATH ID: 2)  
|| Execute on: Query Initiator  
|| +-- Outer -> STORAGE ACCESS for dual [Cost: 10, Rows: 1] (PATH ID: 3)  
||| Projection: v_catalog.dual_p  
||| Materialize: dual.dummy  
||| Execute on: Query Initiator  
|| +-- Inner -> SELECT [Cost: 2K, Rows: 1 (NO STATISTICS)] (PATH ID: 4)  
||| Execute on: Query Initiator  
||| +---> GROUPBY NOTHING [Cost: 2K, Rows: 1 (NO STATISTICS)] (PATH ID: 5)  
|||| Aggregates: max(store_sales_fact.sales_quantity)  
|||| Execute on: All Nodes  
|||| +---> STORAGE ACCESS for store_sales_fact [Cost: 1K, Rows: 5M (NO STATISTICS)] (PATH ID: 6)  
||||| Projection: store.store_sales_fact_super  
||||| Materialize: store_sales_fact.sales_quantity  
||||| Execute on: All Nodes  
| +-- Inner -> SELECT [Cost: 2K, Rows: 1 (NO STATISTICS)] (PATH ID: 7)  
|| Execute on: Query Initiator  
|| +---> GROUPBY NOTHING [Cost: 2K, Rows: 1 (NO STATISTICS)] (PATH ID: 8)  
||| Aggregates: max(online_sales_fact.sales_quantity)  
||| Execute on: All Nodes  
|| +---> STORAGE ACCESS for online_sales_fact [Cost: 1K, Rows: 5M (NO STATISTICS)] (PATH ID: 9)  
||| Projection: online_sales.online_sales_fact_super  
||| Materialize: online_sales_fact.sales_quantity  
||| Execute on: All Nodes
```

Optimizer-generated annotated query

The following annotated query returns the same results as the input query shown earlier. As with all optimizer-generated annotated queries, you can execute this query directly in vsql, either as written or with modifications:

```
SELECT /*+syntactic_join,verbatim*/ (subQ_1.max * subQ_2.max) AS "?column?"  
FROM ((v_catalog.dual AS dual CROSS COMPLEX JOIN /*+Distrib(L,L),JType(H)*/  
(SELECT max(store_sales_fact.sales_quantity) AS max  
FROM store.store_sales_fact AS store_sales_fact/*+projs('store.store_sales_fact')*/) AS subQ_1 )  
CROSS COMPLEX JOIN /*+Distrib(L,L),JType(H)*/ (SELECT max(online_sales_fact.sales_quantity) AS max  
FROM online_sales.online_sales_fact AS online_sales_fact/*+projs('online_sales.online_sales_fact')*/) AS subQ_2 )
```

Complex half join

Complex half joins are expressed by one of the following keywords:

- **SEMI COMPLEX JOIN**
- **NULLAWARE ANTI COMPLEX JOIN**
- **SEMIALL COMPLEX JOIN**
- **ANTI COMPLEX JOIN**

An additional requirement applies to all complex half joins: each subquery's **SELECT** list ends with a dummy column (labeled as **false**) that invokes the Vertica meta-function **complex_join_marker()**. As the subquery processes each row, **complex_join_marker()** returns **true** or **false** to indicate the row's inclusion or exclusion from the result set. The result set returns with this flag to the outer query, which can use the flag from this and other subqueries to filter its own result set.

For example, the query optimizer rewrites the following input query as a **NULLAWARE ANTI COMPLEX JOIN** . The join returns all rows from the subquery with their `complex_join_marker()` flag set to the appropriate Boolean value.

Input query

```
SELECT product_dimension.product_description FROM public.product_dimension
WHERE (NOT (product_dimension.product_key NOT IN (SELECT inventory_fact.qty_in_stock FROM public.inventory_fact)));
```

Query plan

QUERY PLAN DESCRIPTION:

```
EXPLAIN SELECT product_dimension.product_description FROM public.product_dimension
WHERE (NOT (product_dimension.product_key NOT IN (SELECT inventory_fact.qty_in_stock FROM public.inventory_fact)));
```

Access Path:

```
+--JOIN HASH [Anti][NotInAnti] [Cost: 3K, Rows: 30K] (PATH ID: 1) Inner (BROADCAST)
| Join Cond: (product_dimension.product_key = VAL(2))
| Materialize at Output: product_dimension.product_description
| Filter: (NOT VAL(2))
| Execute on: All Nodes
| +- Outer -> STORAGE ACCESS for product_dimension [Cost: 56, Rows: 60K] (PATH ID: 2)
|| Projection: public.product_dimension_super
|| Materialize: product_dimension.product_key
|| Execute on: All Nodes
| +- Inner -> SELECT [Cost: 248, Rows: 300K] (PATH ID: 3)
|| Execute on: All Nodes
|| +--> STORAGE ACCESS for inventory_fact [Cost: 248, Rows: 300K] (PATH ID: 4)
||| Projection: public.inventory_fact_super
||| Materialize: inventory_fact.qty_in_stock
||| Execute on: All Nodes
```

Optimizer-generated annotated query

The following annotated query returns the same results as the input query shown earlier. As with all optimizer-generated annotated queries, you can execute this query directly in vsql, either as written or with modifications. For example, you can control the outer query's output by modifying how its predicate evaluates the flag `subQ_1."false"` .

```
SELECT /*+syntactic_join,verbatim*/ product_dimension.product_description AS product_description
FROM (public.product_dimension AS product_dimension/*+projs('public.product_dimension')*/
NULLAWARE ANTI COMPLEX JOIN /*+Distrib(L,B),JType(H)*/
(SELECT inventory_fact.qty_in_stock AS qty_in_stock, complex_join_marker() AS "false"
FROM public.inventory_fact AS inventory_fact/*+projs('public.inventory_fact')*/ AS subQ_1
ON (product_dimension.product_key = subQ_1.qty_in_stock)) WHERE (NOT subQ_1."false"))
```

Directed query restrictions

In general, directed queries support only SELECT statements as input. Within that broad restriction, a number of specific restrictions apply to input queries. Vertica handles all restrictions through optimizer-generated warnings. The sections below divide these restrictions into several categories.

Tables, views, and projections

Input queries cannot query the following objects:

- Tables without projections
- Tables with access policies
- System and data collector tables, except explicit and implicit references to [V_CATALOG.DUAL](#)
- Views
- Projections

Functions

Input queries cannot include the following functions:

- Vertica meta-functions

- [Pattern-matching functions](#)
- [GROUPING_ID](#) with no arguments

Language elements

Input queries cannot include the following:

- [Hints](#)
- [WITH](#) clauses [when materialization is enabled](#)
- [Date/time literals](#) that reference the current time, such as **NOW** or **YESTERDAY**

Data types

Input queries cannot include the following data types:

- [Spatial data types](#): GEOMETRY and GEOGRAPHY
- [Complex data types](#): [non-native arrays](#), [rows](#), and [sets](#)

Transactions

When [transactions](#) in multiple user sessions concurrently access the same data, session-scoped isolation levels determine what data each transaction can access.

A transaction retains its isolation level until it completes, even if the session's isolation level changes during the transaction. Vertica internal processes (such as the [Tuple Mover](#) and [refresh](#) operations) and DDL operations always run at the SERIALIZABLE isolation level to ensure consistency.

The Vertica query parser supports standard ANSI SQL-92 isolation levels as follows:

- [READ COMMITTED](#) (default)
- READ UNCOMMITTED: Automatically interpreted as READ COMMITTED.
- REPEATABLE READ: Automatically interpreted as SERIALIZABLE
- [SERIALIZABLE](#)

Transaction isolation levels READ COMMITTED and SERIALIZABLE differ as follows:

Isolation level	Dirty read	Non-repeatable read	Phantom read
READ COMMITTED	Not Possible	Possible	Possible
SERIALIZABLE	Not Possible	Not Possible	Not Possible

You can [set separate isolation levels](#) for the database and individual transactions.

Implementation details

Vertica supports conventional SQL transactions with standard ACID properties:

- ANSI SQL 92 style-implicit transactions. You do not need to run a BEGIN or START TRANSACTION command.
- No redo/undo log or two-phase commits.
- The [COPY](#) command automatically commits itself and any current transaction (except when loading temporary tables). It is generally good practice to commit or roll back the current transaction before you use COPY. This step is optional for DDL statements, which are auto-committed.

In this section

- [Rollback](#)
- [Savepoints](#)
- [READ COMMITTED isolation](#)
- [SERIALIZABLE isolation](#)

Rollback

Transaction rollbacks restore a database to an earlier state by discarding changes made by that transaction. Statement-level rollbacks discard only the changes initiated by the reverted statements. Transaction-level rollbacks discard all changes made by the transaction.

With a **ROLLBACK** statement, you can explicitly roll back to a named savepoint within the transaction, or discard the entire transaction. Vertica can also initiate automatic rollbacks in two cases:

- An individual statement returns an **ERROR** message. In this case, Vertica rolls back the statement.

- DDL errors, systemic failures, dead locks, and resource constraints return a **ROLLBACK** message. In this case, Vertica rolls back the entire transaction.

Explicit and automatic rollbacks always release any locks that the transaction holds.

Savepoints

A *savepoint* is a special marker inside a transaction that allows commands that execute after the savepoint to be rolled back. The transaction is restored to the state that preceded the savepoint.

Vertica supports two types of savepoints:

- An *implicit savepoint* is automatically established after each successful command within a transaction. This savepoint is used to roll back the next statement if it returns an error. A transaction maintains one implicit savepoint, which it rolls forward with each successful command. Implicit savepoints are available to Vertica only and cannot be referenced directly.
- Named savepoints* are labeled markers within a transaction that you set through [SAVEPOINT](#) statements. A named savepoint can later be referenced in the same transaction through [RELEASE SAVEPOINT](#), which destroys it, and [ROLLBACK TO SAVEPOINT](#), which rolls back all operations that followed the savepoint. Named savepoints can be especially useful in nested transactions: a nested transaction that begins with a savepoint can be rolled back entirely, if necessary.

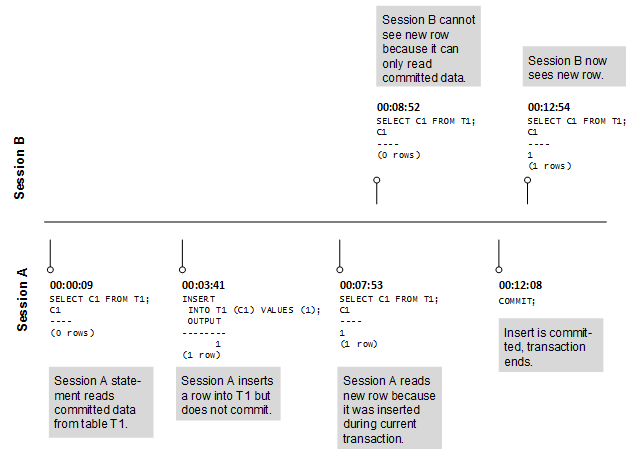

READ COMMITTED isolation

When you use the isolation level **READ COMMITTED**, a **SELECT** query obtains a backup of committed data at the transaction's start. Subsequent queries during the current transaction also see the results of uncommitted updates that already executed in the same transaction.

When you use DML statements, your query acquires write locks to prevent other **READ COMMITTED** transactions from modifying the same data. However, be aware that **SELECT** statements do not acquire locks, so concurrent transactions can obtain read and write access to the same selection.

READ COMMITTED is the default isolation level. For most queries, this isolation level balances database consistency and concurrency. However, this isolation level can allow one transaction to change the data that another transaction is in the process of accessing. Such changes can yield [nonrepeatable](#) and [phantom reads](#). You may have applications with complex queries and updates that require a more consistent view of the database. If so, use [SERIALIZABLE isolation](#) instead.

The following figure shows how **READ COMMITTED** isolation might control how concurrent transactions read and write the same data:

READ COMMITTED isolation maintains exclusive write locks until a transaction ends, as shown in the following graphic:

See also

- [Vertica database locks](#)
- [LOCKS](#)
- [SET SESSION CHARACTERISTICS AS TRANSACTION](#)

SERIALIZABLE isolation

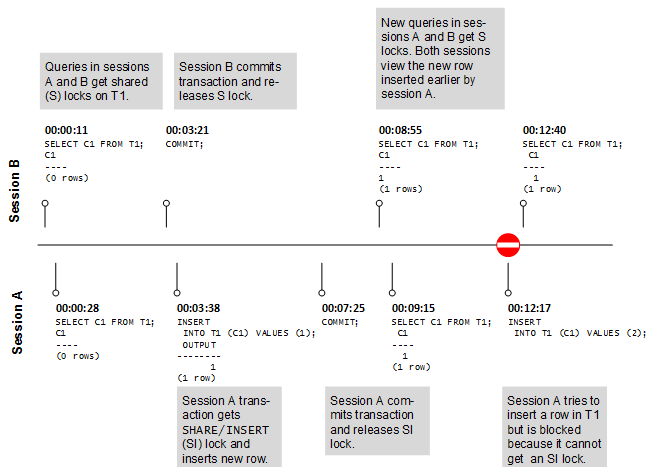

SERIALIZABLE is the strictest SQL transaction isolation level. While this isolation level permits transactions to run concurrently, it creates the effect that transactions are running in serial order. Transactions acquire locks for read and write operations. Thus, successive **SELECT** commands within a single transaction always produce the same results. Because **SERIALIZABLE** isolation provides a consistent view of data, it is useful for applications that require complex queries and updates. However, serializable isolation reduces concurrency. For example, it blocks queries during a bulk load.

SERIALIZABLE isolation establishes the following locks:

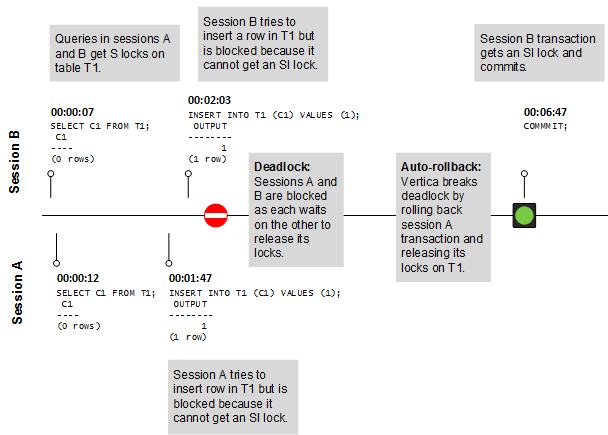

- Table-level read locks: Vertica acquires table-level read locks on selected tables and releases them when the transaction ends. This behavior prevents one transaction from modifying rows while they are being read by another transaction.
- Table-level write lock: Vertica acquires table-level write locks on update and releases them when the transaction ends. This behavior prevents one transaction from reading another transaction's changes to rows before those changes are committed.

At the start of a transaction, a **SELECT** statement obtains a backup of the selection's committed data. The transaction also sees the results of updates that are run within the transaction before they are committed.

The following figure shows how concurrent transactions that both have **SERIALIZABLE** isolation levels handle locking:

Applications that use **SERIALIZABLE** must be prepared to retry transactions due to serialization failures. Such failures often result from deadlocks. When a deadlock occurs, any transaction awaiting a lock automatically times out after 5 minutes. The following figure shows how deadlock might occur and how Vertica handles it:

Note

SERIALIZABLE isolation does not apply to temporary tables. No locks are required for these tables because they are isolated by their transaction scope.

- [Vertica Database Locks](#)
- [LOCKS](#)

Vertica database locks

When multiple users concurrently access the same database information, data manipulation can cause conflicts and threaten data integrity. Conflicts occur because some transactions block other operations until the transaction completes. Because transactions committed at the same time should produce consistent results, Vertica uses locks to maintain data concurrency and consistency. Vertica automatically controls locking by limiting the actions a user can take on an object, depending on the state of that object.

Vertica uses object locks and system locks. *Object locks* are used on objects, such as tables and projections. *System locks* include global catalog locks, local catalog locks, and elastic cluster locks. Vertica supports a full range of standard SQL [lock modes](#), such as shared (S) and exclusive (X).

For related information about lock usage in different transaction isolation levels, see [READ COMMITTED isolation](#) and [SERIALIZABLE isolation](#).

In this section

- [Lock modes](#)
- [Lock examples](#)
- [Deadlocks](#)
- [Troubleshooting locks](#)

Lock modes

Vertica has different lock modes that determine how a lock acts on an object. Each lock mode is unique in its compatibility with other lock modes; each lock mode has its own strength vis a vis other lock modes, which determines whether Each lock mode has a lock compatibility and strength that reflect how it interacts with other locks in the same environment.

Lock mode	Description
Usage (U)	Vertica uses usage (U) locks for Tuple Mover mergeout operations. These Tuple Mover operations run automatically in the background, therefore, other operations on a table except those requiring an O or D locks can run when the object is locked in U mode.
Tuple Mover (T)	Vertica uses Tuple Mover (T) locks for operations on delete vectors. Tuple Mover operations upgrade the table lock mode from U to T when work on delete vectors starts so that no other updates or deletes can happen concurrently.

Shared (S)	Use a shared (S) lock for SELECT queries that run at the serialized transaction isolation level. This allows queries to run concurrently, but the S lock creates the effect that transactions are running in serial order. The S lock ensures that one transaction does not affect another transaction until one transaction completes and its S lock is released. Select operations in READ COMMITTED transaction mode do not require S table locks. See Transactions for more information.
Insert (I)	Vertica requires an insert (I) lock to insert data into a table. Multiple transactions can lock an object in insert mode simultaneously, enabling multiple inserts and bulk loads to occur at the same time. This behavior is critical for parallel loads and high ingestion rates.
Insert Validate (IV)	An insert validate (IV) lock is required for insert operations where the system performs constraint validation for enabled PRIMARY or UNIQUE key constraints.
Shared Insert (SI)	Vertica requires a shared insert (SI) lock when both a read and an insert occur in a transaction. SI mode prohibits delete/update operations. An SI lock also results from lock promotion.
Exclusive (X)	Vertica uses exclusive (X) locks when performing deletes and updates. Only Tuple Mover mergeout operations (U locks) can run concurrently on objects with X locks.
Drop Partition (D)	DROP_PARTITIONS requires a D lock on the target table. This lock is only compatible with I-lock operations, so only table load operations such as INSERT and COPY are allowed during drop partition operations.
Owner (O)	An owner (O) lock is the strongest Vertica lock mode. An object acquires an O lock when it undergoes changes in both data and structure. Such changes can occur in some DDL operations, such as DROP_PARTITIONS, TRUNCATE TABLE, and ADD COLUMN. When an object is locked in O mode, it cannot be locked simultaneously by another transaction in any mode.

Lock compatibility

Bulleted (•) cells in the following matrix shows which locks can be used on the same object simultaneously. Empty cells indicate that a query's requested mode is not granted until the current (granted) mode releases its lock on the object.

Requested mode	Granted mode								
	U	T	S	I	IV	SI	X	D	O
U	•	•	•	•	•	•	•		
T	•	•	•	•	•	•			
S	•	•	•						
I	•	•		•	•			•	
IV	•	•		•					
SI	•	•							
X	•								
D				•					
O									

Lock conversion

Often, the same object is the target of concurrent lock requests from different sessions. The matrix below shows how Vertica responds to multiple lock requests on the same object, one of the following:

- Locks are granted to concurrent requests on an object if the respective lock modes are [compatible](#). For example, D (drop partition) and I (insert)

locks are compatible, so Vertica can grant multiple lock requests on the same table for concurrent load and drop partition operations.

- Lock modes for concurrent requests on an object are incompatible, but the requests also support a higher ([stronger](#)) lock mode. In this case, Vertica converts (upgrades) the lock modes for these requests—for example, S and I to SI. The upgraded lock mode enables requests on the object to proceed concurrently.
- Lock modes for concurrent requests on an object are incompatible, and none can be upgraded to a common lock mode. In this case, object lock requests are queued and granted in sequence.

Requested mode	Granted mode									
	U	T	S	I	IV	SI	X	D	O	
U	U	T	S	I	IV	SI	X	D	O	
T	T	T	S	I	IV	SI	X	D	O	
S	S	S	S	SI	SI	SI	X	O	O	
I	I	I	SI	I	IV	SI	X	D	O	
IV	IV	IV	SI	IV	IV	SI	X	D	O	
SI	SI	SI	SI	SI	SI	SI	X	O	O	
X	X	X	X	X	X	X	X	O	O	
D	D	D	O	D	D	O	O	D	O	
O	O	O	O	O	O	O	O	O	O	

Lock strength

Lock strength refers to the ability of a lock mode to interact with another lock mode. O locks are strongest and are incompatible with all other locks. Conversely, U locks are weakest and can run concurrently with all other locks except D and O locks.

The following figure depicts the spectrum of lock mode strength:

See also

- [Vertica database locks](#)
- [LOCKS](#)

Lock examples

Automatic locks

In this example, two sessions (A and B) attempt to perform operations on table T1. These operations automatically acquire the necessary locks.

At the beginning of the example, table T1 has one column (C1) and no rows.

The steps here represent a possible series of transactions from sessions A and B:

1. Transactions in both sessions acquire S locks to read from Table T1.
2. Session B releases its S lock with the COMMIT statement.
3. Session A can upgrade to an SI lock and insert into T1 because Session B released its S lock.
4. Session A releases its SI lock with a COMMIT statement.
5. Both sessions can acquire S locks because Session A released its SI lock.
6. Session A cannot acquire an SI lock because Session B has not released its S lock. SI locks are incompatible with S locks.
7. Session B releases its S lock with the COMMIT statement.
8. Session A can now upgrade to an SI lock and insert into T1.
9. Session B attempts to delete a row from T1 but can't acquire an X lock because Session A has not released its SI lock. SI locks are incompatible with X locks.
10. Session A continues to insert into T1.

11. Session A releases its SI lock.
12. Session B can now acquire an X lock and perform the delete.

This figure illustrates the previous steps:

Session A Transactions

Manual locks

In this example, Alice attempts to manually lock table `customer_info` with `LOCK TABLE` while Bob runs an `INSERT` statement:

Bob runs the following `INSERT` statement to acquire an INSERT lock and insert a row:

```
=> INSERT INTO customer_info VALUES(37189,'Albert','Quinlan','Frankfurt',2022);
```

In another session, Alice attempts to acquire a SHARE lock with `LOCK TABLE`. As shown in the [lock compatibility table](#), the INSERT lock is incompatible with SHARE locks (among others), so Alice cannot acquire a SHARE lock until Bob finishes his transaction:

```
=> LOCK customer_info IN SHARE MODE NOWAIT;  
ERROR 5157: Unavailable: [Txn 0xa00000001c48e3] S lock table - timeout error Timed out S locking Table:public.customer_info. I held by [user Bob (LOCK TABLE)]. Your current transaction isolation level is READ COMMITTED
```

Bob then releases the lock by calling `COMMIT`:

```
=> COMMIT;  
COMMIT
```

Alice can now acquire the SHARE lock:

```
=> LOCK customer_info IN SHARE MODE NOWAIT;  
LOCK TABLE
```

Bob tries to insert another row into the table, but because Alice has the SHARE lock, the statement enters a queue and appears to hang; after Alice finishes her transaction, the `INSERT` statement will automatically acquire the INSERT lock:

```
=> INSERT INTO customer_info VALUES(17441,'Kara','Shen','Cairo',2022);
```

Alice calls `COMMIT`, ending her transaction and releasing the SHARE lock:

```
=> COMMIT;  
COMMIT;
```

Bob's `INSERT` statement automatically acquires the lock and completes the operation:

```
=> INSERT INTO customer_info VALUES(17441,'Kara','Shen','Cairo',2022);  
OUTPUT  
-----  
   1  
(1 row)
```

Bob calls `COMMIT`, ending his transaction and releasing the INSERT lock:

```
=> COMMIT;  
COMMIT
```

Deadlocks

Deadlocks can occur when two or more sessions with locks on a table attempt to elevate to lock types incompatible with the lock owned by another session. For example, suppose Bob and Alice each run an `INSERT` statement:

```
--Alice's session  
=> INSERT INTO customer_info VALUES(92837,'Alexander','Lamar','Boston',2022);  
  
--Bob's session  
=> INSERT INTO customer_info VALUES(76658,'Midori','Tanaka','Osaka',2021);
```

`INSERT (I)` locks are [compatible](#), so both Alice and Bob have the lock:

```

=> SELECT * FROM locks;
-[ RECORD 1 ]-----+-----
node_names      | v_vmart_node0001,v_vmart_node0002,v_vmart_node0003
object_name     | Table:public.customer_info
object_id       | 45035996274212656
transaction_id  | 45035996275578544
transaction_description | Txn: a0000001c96b0 'INSERT INTO customer_info VALUES(92837,'Alexander','Lamar','Boston',2022);'
lock_mode       | I
lock_scope      | TRANSACTION
request_timestamp | 2022-10-05 12:57:49.039967-04
grant_timestamp  | 2022-10-05 12:57:49.039971-04
-[ RECORD 2 ]-----+-----
node_names      | v_vmart_node0001,v_vmart_node0002,v_vmart_node0003
object_name     | Table:public.customer_info
object_id       | 45035996274212656
transaction_id  | 45035996275578546
transaction_description | Txn: a0000001c96b2 'INSERT INTO customer_info VALUES(76658,'Midori','Tanaka','Osaka',2021);'
lock_mode       | I
lock_scope      | TRANSACTION
request_timestamp | 2022-10-05 12:57:56.599637-04
grant_timestamp  | 2022-10-05 12:57:56.599641-04

```

Alice then runs an UPDATE statement, attempting to elevate her existing INSERT lock into an EXCLUSIVE (X) lock. However, because EXCLUSIVE locks are [incompatible](#) with the INSERT lock in Bob's session, the UPDATE is added to a queue for the lock and appears to hang:

```

=> UPDATE customer_info SET city='Cambridge' WHERE customer_id=92837;

```

A deadlock occurs when Bob runs an UPDATE statement while Alice's UPDATE is still waiting. Vertica detects the deadlock and terminates Bob's entire transaction (which includes his INSERT), allowing Alice to elevate to an EXCLUSIVE lock and complete her UPDATE:

```

=> UPDATE customer_info SET city='Shibuya' WHERE customer_id=76658;
ROLLBACK 3010: Deadlock: initiator locks for query - Deadlock X locking Table:public.customer_info. I held by [user Alice (INSERT INTO customer_info VALUES(92837,'Alexander','Lamar','Boston',2022);)]. Your current transaction isolation level is SERIALIZABLE

```

Preventing deadlocks

You can avoid deadlocks by acquiring the elevated lock earlier in the transaction, ensuring that your session has exclusive access to the table. You can do this in several ways:

- [SELECT...FOR UPDATE](#): You should prefer this method when possible for your transaction.
- [LOCK TABLE...IN EXCLUSIVE MODE](#)

To prevent a deadlock in the previous example, Alice and Bob should both begin their transactions with LOCK TABLE. The first session to request the lock will lock the table, and the other waits for the first session to release the lock or until a [user-specified timeout](#):

```

=> LOCK TABLE customer_info IN EXCLUSIVE MODE;

```

Troubleshooting locks

The [LOCKS](#) and [LOCK_USAGE](#) system tables can help identify problems you may encounter with Vertica database locks.

This example shows one row from the LOCKS system table. From this table you can see what types of locks are active on specific objects and nodes.

```

=> SELECT node_names, object_name, lock_mode, lock_scope FROM LOCKS;
node_names      | object_name          | lock_mode | lock_scope
-----+-----+-----+-----
v_vmart_node0001 | Table:public.customer_dimension | X        | TRANSACTION

```

This example shows two rows from the LOCKS_USAGE system table. You can also use this table to see what locks are in use on specific objects and nodes.

```
=> SELECT node_name, object_name, mode FROM LOCK_USAGE;
```

```
node_name      | object_name      | mode  
-----+-----+-----  
v_vmart_node0001 | Cluster Topology | S  
v_vmart_node0001 | Global Catalog   | X
```

Using text search

Text search allows you to quickly search the contents of a single CHAR, VARCHAR, LONG VARCHAR, VARBINARY, or LONG VARBINARY field within a table to locate a specific keyword.

You can use this feature on columns that are queried repeatedly regarding their contents. After you create the text index, DML operations become slightly slower on the source table. This performance change results from syncing the text index and source table. Any time an operation is performed on the source table, the text index updates in the background. Regular queries on the source table are not affected.

The text index contains all of the words from the source table's text field and any other additional columns you included during index creation. Additional columns are not indexed—their values are just passed through to the text index. The text index is like any other Vertica table, except it is linked to the source table internally.

First, create a text index on the table you plan to search. Then, after you have indexed your table, run a query against the text index for a specific keyword. This query returns a doc_id for each instance of the keyword. After querying the text index, joining the text index back to the source table should give a significant performance improvement over directly querying the source table about the contents of its text field.

Important

Do not alter the contents or definitions of the text index. If you alter the contents or definitions of the text index, the results do not appropriately match the source table.

In this section

- [Creating a text index](#)
- [Creating a text index on a flex table](#)
- [Searching a text index](#)
- [Dropping a text index](#)
- [Stemmers and tokenizers](#)

Creating a text index

In the following example, you perform a text search using a source table called t_log. This source table has two columns:

- One column containing the table's primary key
- Another column containing log file information

You must associate a projection with the source table. Use a projection that is sorted by the primary key and either segmented by hash(id) or unsegmented. You can define this projection on the source table, along with any other existing projections.

Create a text index on the table for which you want to perform a text search.

```
=> CREATE TEXT INDEX text_index ON t_log (id, text);
```

The text index contains two columns:

- doc_id uses the unique identifier from the source table.
- token is populated with text strings from the designated column from the source table. The word column results from tokenizing and stemming the words found in the text column.

If your table is partitioned then your text index also contains a third column named *partition*.

```
=> SELECT * FROM text_index;
  token | doc_id | partition
-----+-----+-----
<info> | 6 | 2014
<warning> | 2 | 2014
<warning> | 3 | 2014
<warning> | 4 | 2014
<warning> | 5 | 2014
database | 6 | 2014
execute: | 6 | 2014
object | 4 | 2014
object | 5 | 2014
[catalog] | 4 | 2014
[catalog] | 5 | 2014
```

You create a text index on a source table only once. In the future, you do not have to re-create the text index each time the source table is updated or changed.

Your text index stays synchronized to the contents of the source table through any operation that is run on the source table. These operations include, but are not limited to:

- COPY
- INSERT
- UPDATE
- DELETE
- DROP PARTITION
- MOVE_PARTITIONS_TO_TABLE

When you move or swap partitions in a source table that is indexed, verify that the destination table already exists and is indexed in the same way.

Creating a text index on a flex table

In the following example, you create a text index on a flex table. The example assumes that you have created a flex table called `mountains`. See [Getting started](#) in Using Flex Tables to create the flex table used in this example.

Before you can create a text index on your flex table, add a primary key constraint to the flex table.

```
=> ALTER TABLE mountains ADD PRIMARY KEY (__identity__);
```

Create a text index on the table for which you want to perform a text search. Tokenize the `__raw__` column with the `FlexTokenizer` and specify the data type as `LONG VARBINARY`. It is important to use the `FlexTokenizer` when creating text indices on flex tables because the data type of the `__raw__` column differs from the default `StringTokenizer`.

```
=> CREATE TEXT INDEX flex_text_index ON mountains(__identity__, __raw__) TOKENIZER public.FlexTokenizer(long varbinary);
```

The text index contains two columns:

- `doc_id` uses the unique identifier from the source table.
- `token` is populated with text strings from the designated column from the source table. The word column results from tokenizing and stemming the words found in the text column.

If your table is partitioned then your text index also contains a third column named `partition`.

```
=> SELECT * FROM flex_text_index;
```

token	doc_id
50.6	5
Mt	5
Washington	5
mountain	5
12.2	3
15.4	2
17000	3
29029	2
Denali	3
Helen	2
Mt	2
St	2
mountain	3
volcano	2
29029	1
34.1	1
Everest	1
mountain	1
14000	4
Kilimanjaro	4
mountain	4

(21 rows)

You create a text index on a source table only once. In the future, you do not have to re-create the text index each time the source table is updated or changed.

Your text index stays synchronized to the contents of the source table through any operation that is run on the source table. These operations include, but are not limited to:

- COPY
- INSERT
- UPDATE
- DELETE
- DROP PARTITION
- MOVE_PARTITIONS_TO_TABLE

When you move or swap partitions in a source table that is indexed, verify that the destination table already exists and is indexed in the same way.

Searching a text index

After you create a text index, write a query to run against the index to search for a specific keyword.

In the following example, you use a WHERE clause to search for the keyword <WARNING> in the text index. The WHERE clause should use the stemmer you used to create the text index. When you use the STEMMER keyword, it stems the keyword to match the keywords in your text index. If you did not use the STEMMER keyword, then the default stemmer is v_txtindex.StemmerCaseInsensitive. If you used STEMMER NONE, then you can omit STEMMER keyword from the WHERE clause.

```
=> SELECT * FROM text_index WHERE token = v_txtindex.StemmerCaseInsensitive('<WARNING>');
```

token	doc_id
<warning>	2
<warning>	3
<warning>	4
<warning>	5

(4 rows)

Next, write a query to display the full contents of the source table that match the keyword you searched for in the text index.

```
=> SELECT * FROM t_log WHERE id IN (SELECT doc_id FROM text_index WHERE token = v_txtindex.StemmerCaseInsensitive('<WARNING>'));
id | date | text
-----+-----
4 | 2014-06-04 | 11:00:49.568 unknown:0x7f9207607700 [Catalog] <WARNING> validateDependencies: Object 45035968
5 | 2014-06-04 | 11:00:49.568 unknown:0x7f9207607700 [Catalog] <WARNING> validateDependencies: Object 45030
2 | 2013-06-04 | 11:00:49.568 unknown:0x7f9207607700 [Catalog] <WARNING> validateDependencies: Object 4503
3 | 2013-06-04 | 11:00:49.568 unknown:0x7f9207607700 [Catalog] <WARNING> validateDependencies: Object 45066
(4 rows)
```

Use the doc_id to find the exact location of the keyword in the source table. The doc_id matches the unique identifier from the source table. This matching allows you to quickly find the instance of the keyword in your table.

Performing a case-sensitive and case-insensitive text search query

Your text index is optimized to match all instances of words depending upon your stemmer. By default, the case insensitive stemmer is applied to all text indices that do not specify a stemmer. Therefore, if the queries you plan to write against your text index are case sensitive, then Vertica recommends you use a case sensitive stemmer to build your text index.

The following examples show queries that match case-sensitive and case-insensitive words that you can use when performing a text search.

This query finds case-insensitive records in a case insensitive text index:

```
=> SELECT * FROM t_log WHERE id IN (SELECT doc_id FROM text_index WHERE token = v_txtindex.StemmerCaseInsensitive('warning'));
```

This query finds case-sensitive records in a case sensitive text index:

```
=> SELECT * FROM t_log_case_sensitive WHERE id IN (SELECT doc_id FROM text_index WHERE token = v_txtindex.StemmerCaseSensitive('Warning'));
```

Including and excluding keywords in a text search query

Your text index also allows you to perform more detailed queries to find multiple keywords or omit results with other keywords. The following example shows a more detailed query that you can use when performing a text search.

In this example, t_log is the source table, and text_index is the text index. The query finds records that either contain:

- Both the words '<WARNING>' and 'validate'
- Only the word '[Log]' and does not contain 'validateDependencies'

```
SELECT * FROM t_log where (
  id IN (SELECT doc_id FROM text_index WHERE token = v_txtindex.StemmerCaseSensitive('<WARNING>'))
  AND ( id IN (SELECT doc_id FROM text_index WHERE token = v_txtindex.StemmerCaseSensitive('validate')
  OR id IN (SELECT doc_id FROM text_index WHERE token = v_txtindex.StemmerCaseSensitive('[Log]'))
  AND NOT (id IN (SELECT doc_id FROM text_index WHERE token = v_txtindex.StemmerCaseSensitive('validateDependencies'))));
```

This query returns the following results:

```
id | date | text
-----+-----
11 | 2014-05-04 | 11:00:49.568 unknown:0x7f9207607702 [Log] <WARNING> validate: Object 4503 via fld num_all_roles
13 | 2014-05-04 | 11:00:49.568 unknown:0x7f9207607706 [Log] <WARNING> validate: Object 45035 refers to root_i3
14 | 2014-05-04 | 11:00:49.568 unknown:0x7f9207607708 [Log] <WARNING> validate: Object 4503 refers to int_2
17 | 2014-05-04 | 11:00:49.568 unknown:0x7f9207607700 [Txn] <WARNING> Begin validate Txn: fff0ed17 catalog editor
(4 rows)
```

Dropping a text index

Dropping a text index removes the specified text index from the database.

You can drop a text index when:

- It is no longer queried frequently.
- An administrative task needs to be performed on the source table and requires the text index to be dropped.

Dropping the text index does not drop the source table associated with the text index. However, if you drop the source table associated with a text index, then that text index is also dropped. Vertica considers the text index a dependent object.

The following example illustrates how to drop a text index named text_index:

```
=> DROP TEXT INDEX text_index;  
DROP INDEX
```

Stemmers and tokenizers

Vertica provides default stemmers and tokenizers. You can also create your own custom stemmers and tokenizers. The following topics explain the default stemmers and tokenizers, and the requirements for creating custom stemmers and tokenizers in Vertica.

- [Vertica stemmers](#)
- [Vertica tokenizers](#)
- [Configuring a tokenizer](#)
- [Requirements for custom stemmers and tokenizers](#)

In this section

- [Vertica stemmers](#)
- [Vertica tokenizers](#)
- [Configuring a tokenizer](#)
- [Requirements for custom stemmers and tokenizers](#)

Vertica stemmers

Vertica *stemmers* use the Porter stemming algorithm to find words derived from the same base/root word. For example, if you perform a search on a text index for the keyword *database*, you might also want to get results containing the word *databases*.

To achieve this type of matching, Vertica stores words in their stemmed form when using any of the `v_txtindex` stemmers.

The Vertica Analytics Platform provides the following stemmers:

Name	Description
<code>v_txtindex.Stemmer(long varchar)</code>	Not sensitive to case; outputs lowercase words. Stems strings from a Vertica table. Alias of <code>StemmerCaseInsensitive</code> .
<code>v_txtindex.StemmerCaseSensitive(long varchar)</code>	Sensitive to case. Stems strings from a Vertica table.
<code>v_txtindex.StemmerCaseInsensitive(long varchar)</code>	Default stemmer used if no stemmer is specified when creating a text index. Not sensitive to case; outputs lowercase words. Stems strings from a Vertica table.
<code>v_txtindex.caseInsensitiveNoStemming(long varchar)</code>	Not sensitive to case; outputs lowercase words. Does not use the Porter Stemming algorithm.

Examples

The following examples show how to use a stemmer when creating a text index.

Create a text index using the `StemmerCaseInsensitive` stemmer:

```
=> CREATE TEXT INDEX idx_100 ON top_100 (id, feedback) STEMMER v_txtindex.StemmerCaseInsensitive(long varchar)  
      TOKENIZER v_txtindex.StringTokenizer(long varchar);
```

Create a text index using the `StemmerCaseSensitive` stemmer:

```
=> CREATE TEXT INDEX idx_unstruc ON unstruc_data (__identity__, __raw__) STEMMER v_txtindex.StemmerCaseSensitive(long varchar)  
      TOKENIZER public.FlexTokenizer(long varbinary);
```

Create a text index without using a stemmer:

```
=> CREATE TEXT INDEX idx_logs FROM sys_logs ON (id, message) STEMMER NONE TOKENIZER v_txtindex.StringTokenizer(long varchar);
```

Vertica tokenizers

A tokenizer does the following:

- Receives a stream of characters.
- Breaks the stream into individual tokens that usually correspond to individual words.
- Returns a stream of tokens.

In this section

- [Preconfigured tokenizers](#)
- [ICU tokenizer](#)

Preconfigured tokenizers

The Vertica Analytics Platform provides the following preconfigured tokenizers:

public.FlexTokenizer(LONG VARBINARY)

Splits the values in your flex table by white space.

v_txtindex.StringTokenizer(LONG VARCHAR)

Splits the string into words by splitting on white space.

v_txtindex.StringTokenizerDelim(LONG VARCHAR, CHAR(1))

Splits a string into tokens using the specified delimiter character.

Vertica also provides the following tokenizer, which is not preconfigured:

v_txtindex.ICUTokenizer

Supports multiple languages. Tokenizes based on the conventions of the language you set in the locale parameter. For more information, see ICU Tokenizer.

Examples

The following examples show how you can use a preconfigured tokenizer when creating a text index.

Use the StringTokenizer to create an index from the top_100:

```
=> CREATE TEXT INDEX idx_100 FROM top_100 on (id, feedback)
      TOKENIZER v_txtindex.StringTokenizer(long varchar)
      STEMMER v_txtindex.StemmerCaseInsensitive(long varchar);
```

Use the FlexTokenizer to create an index from unstructured data:

```
=> CREATE TEXT INDEX idx_unstruc FROM unstruc_data on (__identity__, __raw__)
      TOKENIZER public.FlexTokenizer(long varbinary)
      STEMMER v_txtindex.StemmerCaseSensitive(long varchar);
```

Use the StringTokenizerDelim to split a string at the specified delimiter:

```

=> CREATE TABLE string_table (word VARCHAR(100), delim VARCHAR);
CREATE TABLE
=> COPY string_table FROM STDIN DELIMITER ';';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>>
>> SingleWord,dd
>> Break On Spaces,' '
>> Break:On:Colons,:
>> \.
=> SELECT * FROM string_table;
      word | delim
-----+-----
      SingleWord | dd
Break On Spaces |
Break:On:Colons | :
(3 rows)

=> SELECT v_txtindex.StringTokenizerDelim(word,delim) OVER () FROM string_table;
      words
-----
Break
On
Colons
SingleWor
Break
On
Spaces
(7 rows)

=> SELECT v_txtindex.StringTokenizerDelim(word,delim) OVER (PARTITION BY word), word as input FROM string_table;
      words | input
-----+-----
      Break | Break:On:Colons
           | On | Break:On:Colons
      Colons | Break:On:Colons
SingleWor | SingleWord
           | Break | Break On Spaces
           | On | Break On Spaces
      Spaces | Break On Spaces
(7 rows)

```

ICU tokenizer

Supports multiple languages. You can use this tokenizer to identify word boundaries in languages other than English, including Asian languages that are not separated by whitespace.

The ICU Tokenizer is not pre-configured. You configure the tokenizer by first creating a user-defined transform Function (UDTF). Then set the parameter, locale, to identify the language to tokenizer.

Important

If you create a database with no tables and the k-safety has increased, you must rebalance your data using [REBALANCE_CLUSTER](#) before using a Vertica tokenizer.

Parameters

Parameter Name	Parameter Value
----------------	-----------------

locale	<p>Uses the POSIX naming convention: language[_COUNTRY]</p> <p>Identify the language using its ISO-639 code, and the country using its ISO-3166 code. For example, the parameter value for simplified Chinese is zh_CN, and the value for Spanish is es_ES.</p> <p>The default value is English if you do not specify a locale.</p>
--------	---

Example

The following example steps show how you can configure the ICU Tokenizer for simplified Chinese, then create a text index from the table foo, which contains Chinese characters.

For more on how to configure tokenizers, see [Configuring a tokenizer](#).

1. Create the tokenizer using a UDTF. The example tokenizer is named ICUChineseTokenizer.

```
VMart=> CREATE OR REPLACE TRANSFORM FUNCTION v_txtindex.ICUChineseTokenizer AS LANGUAGE 'C++' NAME 'ICUTokenizerFactory'
LIBRARY v_txtindex.logSearchLib NOT FENCED;
CREATE TRANSFORM FUNCTION
```

2. Get the procedure ID of the tokenizer.

```
VMart=> SELECT proc_oid from vs_procedures where procedure_name = 'ICUChineseTokenizer';
proc_oid
-----
45035996280452894
(1 row)
```

3. Set the parameter, locale, to simplified Chinese. Identify the tokenizer using its procedure ID.

```
VMart=> SELECT v_txtindex.SET_TOKENIZER_PARAMETER('locale','zh_CN' using parameters proc_oid='45035996280452894');
SET_TOKENIZER_PARAMETER
-----
t
(1 row)
```

4. Lock the tokenizer.

```
VMart=> SELECT v_txtindex.SET_TOKENIZER_PARAMETER('used','true' using parameters proc_oid='45035996273762696');
SET_TOKENIZER_PARAMETER
-----
t
(1 row)
```

5. Create an example table, foo, containing simplified Chinese text to index.

```
VMart=> CREATE TABLE foo(doc_id integer primary key not null,text varchar(250));
CREATE TABLE

VMart=> INSERT INTO foo values(1, u&'\4E2D\534E\4EBA\6C11\5171\548C\56FD');
OUTPUT
-----
1
```

6. Create an index, index_example, on the table foo. The example creates the index without a stemmer; Vertica stemmers work only on English text. Using a stemmer for English on non-English text can cause incorrect tokenization.

```
VMart=> CREATE TEXT INDEX index_example ON foo (doc_id, text) TOKENIZER v_txtindex.ICUChineseTokenizer(long varchar) stemmer none;
CREATE INDEX
```

7. View the new index.

```
VMart=> SELECT * FROM index_example ORDER BY token,doc_id;
token | doc_id
-----+-----
中华 | 1
人民 | 1
共和国 | 1
(3 rows)
```

Configuring a tokenizer

You configure a tokenizer by creating a user-defined transform function (UDTF) using one of the two base UDTFs in the [v_txtindex.AdvTxtSearchLib](#) library. The library contains two base tokenizers: one for Log Words and one for Ngrams. You can configure each base function with or without positional relevance.

In this section

- [Tokenizer base configuration](#)
- [RetrieveTokenizerproc_oid](#)
- [Set tokenizer parameters](#)
- [View tokenizer parameters](#)
- [Delete tokenizer config file](#)

Tokenizer base configuration

You can choose among two tokenizer base configurations:

- Ngram with position: [logNgramTokenizerPositionFactory](#)
- Ngram without position: [logNgramTokenizerFactory](#)

The following example creates an Ngram tokenizer without positional relevance:

```
=> CREATE TRANSFORM FUNCTION v_txtindex.myNgramTokenizer
AS LANGUAGE 'C++'
NAME 'logNgramTokenizerFactory'
LIBRARY v_txtindex.logNgramSearchLib NOT FENCED;
```

RetrieveTokenizerproc_oid

After you create the tokenizer, Vertica writes the name and proc_oid to the system table vs_procedures. You must retrieve the tokenizer's proc_oid to perform additional configuration.

Enter the following query, substituting your own tokenizer name:

```
=> SELECT proc_oid FROM vs_procedures WHERE procedure_name = 'fooTokenizer';
```

Set tokenizer parameters

Use the tokenizer's proc_oid to configure the tokenizer. See [Configuring a tokenizer](#) for more information about getting the proc_oid of your tokenizer. The following examples show how you can configure each of the tokenizer parameters:

Configure stop words:

```
=> SELECT v_txtindex.SET_TOKENIZER_PARAMETER('stopwordscaseinsensitive','for,the' USING PARAMETERS proc_oid='45035996274128376');
```

Configure major separators:

```
=> SELECT v_txtindex.SET_TOKENIZER_PARAMETER('majorseparators', 'E'{}&[]' USING PARAMETERS proc_oid='45035996274128376');
```

Configure minor separators:

```
=> SELECT v_txtindex.SET_TOKENIZER_PARAMETER('minorseparators', '-,$' USING PARAMETERS proc_oid='45035996274128376');
```

Configure minimum length:

```
=> SELECT v_txtindex.SET_TOKENIZER_PARAMETER('minlength', '1' USING PARAMETERS proc_oid='45035996274128376');
```

Configure maximum length:

```
=> SELECT v_txtindex.SET_TOKENIZER_PARAMETER('maxlength', '140' USING PARAMETERS proc_oid='45035996274128376');
```

Configure ngramssize:

```
=> SELECT v_txtindex.SET_TOKENIZER_PARAMETER('ngramssize', '2' USING PARAMETERS proc_oid='45035996274128376');
```

Lock tokenizer parameters

When you finish configuring the tokenizer, set the parameter, `used`, to `True` . After changing this setting, you are no longer able to alter the parameters of the tokenizer. At this point, the tokenizer is ready for you to use to create a text index.

Configure the `used` parameter:

```
=> SELECT v_txtindex.SET_TOKENIZER_PARAMETER('used', 'True' USING PARAMETERS proc_oid='45035996274128376');
```

See also

[SET_TOKENIZER_PARAMETER](#)

View tokenizer parameters

After creating a custom tokenizer, you can view the tokenizer's parameter settings in either of two ways:

- Use the `GET_TOKENIZER_PARAMETER` — [View individual tokenizer parameter settings](#) .
- Use the `READ_CONFIG_FILE` — [View all tokenizer parameter settings](#) .

View individual tokenizer parameter settings

If you need to see an individual parameter setting for a tokenizer, you can use `GET_TOKENIZER_PARAMETER` to see specific tokenizer parameter settings:

```
=> SELECT v_txtindex.GET_TOKENIZER_PARAMETER('majorseparators' USING PARAMETERS proc_oid='45035996274126984');
getTokenizerParameter
-----
{}()&[]
(1 row)
```

For more information, see [GET_TOKENIZER_PARAMETER](#) .

View all tokenizer parameter settings

If you need to see all of the parameters for a tokenizer, you can use `READ_CONFIG_FILE` to see all of the parameter settings for your tokenizer:

```
=> SELECT v_txtindex.READ_CONFIG_FILE( USING PARAMETERS proc_oid='45035996274126984') OVER();
config_key | config_value
-----+-----
majorseparators | {}()&[]
maxlength | 140
minlength | 1
minorseparators | -, $
stopwordscaseinsensitive | for,the
type | 1
used | true
(7 rows)
```

If the parameter, `used`, is set to `False` , then you can only view the parameters that have been applied to the tokenizer.

Note

Vertica automatically supplies the value for `Type`, unless you are using an ngram tokenizer, which allows you to set it.

For more information, see [READ_CONFIG_FILE](#) .

Delete tokenizer config file

Use the `DELETE_TOKENIZER_CONFIG_FILE` function to delete a tokenizer configuration file. This function does not delete the User- Defined Transform Function (UDTF). It only deletes the configuration file associated with the UDTF.

Delete the tokenizer configuration file when the parameter, `used`, is set to `False` :

```
=> SELECT v_txtindex.DELETE_TOKENIZER_CONFIG_FILE(USING PARAMETERS proc_oid='45035996274127086');
```

Delete the tokenizer configuration file with the parameter, `confirm`, set to `True` . This setting forces the configuration file deletion, even if the parameter, `used`, is also set to `True` :

```
=> SELECT v_txtindex.DELETE_TOKENIZER_CONFIG_FILE(USING PARAMETERS proc_oid='45035996274126984', confirm='true');
```

For more information, see [DELETE_TOKENIZER_CONFIG_FILE](#).

Requirements for custom stemmers and tokenizers

Sometimes, you may want specific tokenization or stemming behavior that differs from what Vertica provides. In such cases, you can to implement your own custom User Defined Extensions (UDx) to replace the stemmer or tokenizer. For more information about building custom UDxs see [Developing user-defined extensions \(UDxs\)](#).

Before implementing a custom stemmer or tokenizer in Vertica verify that the UDx extension meets these requirements.

Note

Custom tokenizers can return multi-column text indices.

Vertica stemmer requirements

Comply with these requirements when you create custom stemmers:

- Must be a User Defined Scalar Function (UDSF) or a SQL Function
- Can be written in C++, Java, or R
- Volatility set to stable or immutable

Supported Data Input Types :

- Varchar
- Long varchar

Supported Data Output Types :

- Varchar
- Long varchar

Vertica tokenizer requirements

To create custom tokenizers, follow these requirements:

- Must be a User Defined Transform Function (UDTF)
- Can be written in C++, Java, or R
- Input type must match the type of the input text

Supported Data Input Types :

- Char
- Varchar
- Long varchar
- Varbinary
- Long varbinary

Supported Data Output Types :

- Varchar
- Long varchar

Managing storage locations

Vertica *storage locations* are paths to file destinations that you designate to store data and temporary files. Each cluster node requires at least two storage locations: one to store data, and another to store database catalog files. You set up these locations as part of installation and setup. (See [Prepare disk storage locations](#) for disk space requirements.)

Important

While no technical issue prevents you from using CREATE LOCATION to add one or more Network File System (NFS) storage locations, Vertica does not support NFS data or catalog storage except for MapR mount points. You will be unable to run queries against any other NFS data. When creating locations on MapR file systems, you must specify ALL NODES SHARED.

How Vertica uses storage locations

When you add data to the database or perform a DML operation, the new data is added to storage locations on disk as ROS containers. Depending on the configuration of your database, many ROS containers are likely to exist.

You can label the storage locations that you create, in order to reference them for object storage policies. If an object has no storage policy associated with it, Vertica uses default storage algorithms to store its data in available storage locations. If the object has a storage policy, Vertica stores the data at the object's designated storage location. You can [retire](#) or [drop](#) storage locations when you no longer need them.

Local storage locations

By default, Vertica stores data in unique locations on each node. Each location is in a directory in a file system that the node can access, and is often in the node's own file system. You can create a local storage location for a single node or for all nodes in the cluster. Cluster-wide storage locations are the most common type of storage. Vertica defaults to using a local cluster-wide storage location for storing all data. If you want it to store data differently, you must create additional storage locations.

Shared storage locations

You can create shared storage locations, where data is stored on a single file system to which all cluster nodes in the cluster have access. This shared file system is often hosted outside of the cluster, such as on a distributed file system like HDFS. Currently, Vertica supports only HDFS shared storage locations. You cannot use NFS as a Vertica shared storage location except when using MapR mount points. See [Vertica Storage Location for HDFS](#) for more information.

When you create a shared storage location for DATA and/or TEMP usage, each node in the Vertica cluster creates its own subdirectory in the shared location. The separate directories prevent nodes from overwriting each other's data.

Deprecated

SHARED DATA and SHARED DATA,TEMP storage locations are deprecated.

For databases running in Eon Mode, the [STORAGE_LOCATIONS](#) system table shows a third type of location, communal.

In this section

- [Viewing storage locations and policies](#)
- [Creating storage locations](#)
- [Storage locations on HDFS](#)
- [Altering location use](#)
- [Altering location labels](#)
- [Creating storage policies](#)
- [Creating storage policies for low-priority data](#)
- [Moving data storage locations](#)
- [Clearing storage policies](#)
- [Measuring storage performance](#)
- [Setting storage performance](#)
- [Retiring storage locations](#)
- [Restoring retired storage locations](#)
- [Dropping storage locations](#)

Viewing storage locations and policies

You can monitor information about available storage location labels and your current storage policies.

Viewing disk storage information

Query the [V_MONITOR.DISK_STORAGE](#) system table for disk storage information on each database node. For more information, see [Using system tables](#) and [Altering location use](#). The [V_MONITOR.DISK_STORAGE](#) system table includes a CATALOG annotation, indicating that the location is used to store catalog files.

Note

You cannot add or remove a catalog storage location. Vertica creates and manages this storage location internally, and the area exists in the same location on each cluster node.

Viewing location labels

Three system tables have information about storage location labels in their [location_labels](#) columns:

- [storage_containers](#)
- [storage_locations](#)
- [partitions](#)

Use a query such as the following for relevant columns of the [storage_containers](#) system table:

```
VMart=> select node_name,projection_name, location_label from v_monitor.storage_containers;
 node_name | projection_name | location_label
-----+-----+-----
v_vmart_node0001 | states_p |
v_vmart_node0001 | states_p |
v_vmart_node0001 | t1_b1 |
v_vmart_node0001 | newstates_b0 | FAST3
v_vmart_node0001 | newstates_b0 | FAST3
v_vmart_node0001 | newstates_b1 | FAST3
v_vmart_node0001 | newstates_b1 | FAST3
v_vmart_node0001 | newstates_b1 | FAST3
.
.
.
```

Use a query such as the following for columns of the [v_catalog.storage_locations](#) system table:

```
VMart=> select node_name, location_path, location_usage, location_label from storage_locations;
 node_name | location_path | location_usage | location_label
-----+-----+-----+-----
v_vmart_node0001 | /home/dbadmin/VMart/v_vmart_node0001_data | DATA,TEMP |
v_vmart_node0001 | /home/dbadmin/SSD/schemas | DATA |
v_vmart_node0001 | /home/dbadmin/SSD/tables | DATA | SSD
v_vmart_node0001 | /home/dbadmin/SSD/schemas | DATA | Schema
v_vmart_node0002 | /home/dbadmin/VMart/v_vmart_node0002_data | DATA,TEMP |
v_vmart_node0002 | /home/dbadmin/SSD/tables | DATA |
v_vmart_node0002 | /home/dbadmin/SSD/schemas | DATA |
v_vmart_node0003 | /home/dbadmin/VMart/v_vmart_node0003_data | DATA,TEMP |
v_vmart_node0003 | /home/dbadmin/SSD/tables | DATA |
v_vmart_node0003 | /home/dbadmin/SSD/schemas | DATA |
(10 rows)
```

Use a query such as the following for columns of the [v_monitor.partitions](#) system table:

```
VMart=> select partition_key, projection_name, location_label from v_monitor.partitions;
partition_key | projection_name | location_label
-----+-----+-----
NH | states_b0 | FAST3
MA | states_b0 | FAST3
VT | states_b1 | FAST3
ME | states_b1 | FAST3
CT | states_b1 | FAST3
.
.
.
```

Viewing storage tiers

Query the [storage_tiers](#) system table to see both the labeled and unlabeled storage containers and information about them:

```
VMart=> select * from v_monitor.storage_tiers;
location_label | node_count | location_count | ros_container_count | total_occupied_size
-----+-----+-----+-----+-----
SSD | 1 | 2 | 17 | 297039391
Schema | 1 | 1 | 9 | 1506
(3 rows)
```

Viewing storage policies

Query the `storage_policies` system table to view the current storage policy in place.

```
VMART=> select * from v_monitor.storage_policies;
schema_name | object_name | policy_details | location_label
-----+-----+-----+-----
      public | Schema      | F4
public | lineorder | Partition [4, 4] | M3
(2 rows)
```

Creating storage locations

You can use [CREATE LOCATION](#) to add and configure storage locations (other than the required defaults) to provide storage for these purposes:

- Isolating execution engine temporary files from data files.
- Creating [labeled locations](#) to use in storage policies.
- Creating storage locations based on predicted or measured access patterns.
- Creating USER storage locations for specific users or user groups.

Important

While no technical issue prevents you from using `CREATE LOCATION` to add one or more Network File System (NFS) storage locations, Vertica does not support NFS data or catalog storage except for MapR mount points. You will be unable to run queries against any other NFS data. When creating locations on MapR file systems, you must specify `ALL NODES SHARED`.

You can add a new storage location from one node to another node or from a single node to all cluster nodes. However, do not use a shared directory on one node for other cluster nodes to access.

Planning storage locations

Before adding a storage location, perform the following steps:

1. Verify that the directory you plan to use for a storage location destination is an empty directory with write permissions for the Vertica process.
2. Plan the labels to use if you want to label the location as you create it.
3. Determine the type of information to store in the storage location:
 - **DATA,TEMP** (default): The storage location can store persistent and temporary DML-generated data, and data for temporary tables.
 - **TEMP**: A *path*-specified location to store DML-generated temporary data. If *path* is set to S3, then this location is used only when the `RemoteStorageForTemp` configuration parameter is set to 1, and **TEMP** must be qualified with `ALL NODES SHARED`. For details, see [S3 Storage of Temporary Data](#).
 - **DATA**: The storage location can only store persistent data.
 - **USER**: Users with `READ` and `WRITE` [privileges](#) can access data and [external tables](#) of this storage location.
 - **DEPOT**: The storage location is used in [Eon Mode](#) to store the depot. Only create **DEPOT** storage locations on local Linux file systems. Vertica allows a single **DEPOT** storage location per node. If you want to move your depot to different location (on a different file system, for example) you must first drop the old depot storage location, then create the new location.

Storing temp and data files in different storage locations is advantageous because the two types of data have different disk I/O access patterns. Temp files are distributed across locations based on available storage space. However, data files can be stored on different storage locations, based on storage policy, to reflect predicted or measured access patterns.

If you plan to place storage locations on HDFS, see [Requirements for HDFS storage locations](#) for additional requirements.

Creating unlabeled local storage locations

This example shows a three-node cluster, each with a `vertica/SSD` directory for storage.

On each node in the cluster, create a directory where the node stores its data. For example:

```
$ mkdir /home/dbadmin/vertica/SSD
```

Vertica recommends that you create the same directory path on each node. Use this path when creating a storage location.

Use the [CREATE LOCATION](#) statement to add a storage location. Specify the following information:

- The path on the node where Vertica stores the data.
Important
Vertica does not validate the path that you specify. Confirm that the path value points to a valid location.
- The node where the location is available, or ALL NODES. If you specify ALL NODES, the statement creates the storage locations on all nodes in the cluster in a single transaction.
- The type of information to be stored.

To give unprivileged (non-dbadmin) Linux users access to data, you must create a USER storage location. You can also use a USER storage location to give users without their own credentials access to shared file systems and object stores like HDFS and S3. See [Creating a Storage Location for USER Access](#).

The following example shows how to add a location available on all nodes to store only data:

```
=> CREATE LOCATION '/home/dbadmin/vertica/SSD/' ALL NODES USAGE 'DATA';
```

The following example shows how to add a location that is available on the v_vmart_node0001 node to store data and temporary files:

```
=> CREATE LOCATION '/home/dbadmin/vertica/SSD/' NODE 'v_vmart_node0001';
```

Suppose you are using a storage location for data files and want to create ranked storage locations. In this ranking, columns are stored on different disks based on their measured performance. To create ranked storage locations, see [Measuring storage performance](#) and [Setting storage performance](#).

After you create a storage location, you can alter the type of information it stores, with some restrictions. See [Altering location use](#).

Storage location subdirectories

You cannot create a storage location in a subdirectory of an existing storage location. Doing so results in an error similar to the following:

```
=> CREATE LOCATION '/tmp/myloc' ALL NODES USAGE 'TEMP';  
CREATE LOCATION  
=> CREATE LOCATION '/tmp/myloc/ssd' ALL NODES USAGE 'TEMP';  
ERROR 5615: Location [/tmp/myloc/ssd] conflicts with existing location  
[/tmp/myloc] on node v_vmart_node0001
```

Creating labeled storage locations

You can add a storage location with a descriptive label using the CREATE LOCATION statement's LABEL keyword. You use labeled locations to set up storage policies. See [Creating storage policies](#).

This example shows how to create a storage location on v_vmart_node0002 with the label SSD:

```
=> CREATE LOCATION '/home/dbadmin/SSD/schemas' NODE 'v_vmart_node0002'  
USAGE 'DATA' LABEL 'SSD';
```

This example shows you how to create a storage location on all nodes. Specifying the ALL NODES keyword adds the storage location to all nodes in a single transaction:

```
=> CREATE LOCATION '/home/dbadmin/SSD/schemas' ALL NODES  
USAGE 'DATA' LABEL 'SSD';
```

The new storage location is listed in the [DISK_STORAGE](#) system table:

```
=> SELECT * FROM v_monitor.disk_storage;
```

```
.  
.  
-[ RECORD 7 ]-----+-----  
node_name          | v_vmart_node0002  
storage_path       | /home/dbadmin/SSD/schemas  
storage_usage      | DATA  
rank               | 0  
throughput         | 0  
latency            | 0  
storage_status     | Active  
disk_block_size_bytes | 4096  
disk_space_used_blocks | 1549437  
disk_space_used_mb   | 6053  
disk_space_free_blocks | 13380004  
disk_space_free_mb   | 52265  
disk_space_free_percent | 89%  
...  
.
```

Creating a storage location for USER access

To give unprivileged (non-dbadmin) Linux users access to data, you must create a USER storage location.

By default, Vertica uses user-provided credentials to access external file systems such as HDFS and cloud object stores. You can override this default and create a USER storage location to manage access to these locations. To override the default, set the [UseServerIdentityOverUserIdentity](#) configuration parameter.

After you create a USER storage location, you can grant one or more users access to it. USER storage locations grant access only to data files, not temp files. You cannot assign a USER storage location to a storage policy. You cannot change an existing storage location to have USER access.

The following example shows how to create a USER storage location on a specific node:

```
=> CREATE LOCATION '/home/dbadmin/UserStorage/BobStore' NODE  
'v_mcdb_node0007' USAGE 'USER';
```

The following example shows how to grant a specific user read and write permissions to the location:

```
=> GRANT ALL ON LOCATION '/home/dbadmin/UserStorage/BobStore' TO Bob;  
GRANT PRIVILEGE
```

The following example shows how to use a USER storage location to grant access to locations on S3. Vertica uses the server credential to access the location:

```
-- set database-level credential (once).  
-> ALTER DATABASE DEFAULT SET AWSSAuth = 'myaccesskeyid123456:mysecretaccesskey123456789012345678901234';  
  
-> CREATE LOCATION 's3://datalake' SHARED USAGE 'USER' LABEL 's3user';  
  
-> CREATE ROLE ExtUsers;  
-- Assign users to this role using GRANT (Role).  
  
-> GRANT READ ON LOCATION 's3://datalake' TO ExtUsers;
```

For more information about configuring user privileges, see [Database users and privileges](#) and the [GRANT \(storage location\)](#) and [REVOKE \(storage location\)](#) reference pages.

Shared versus local storage

The SHARED keyword indicates that the location is shared by all nodes. Most remote file systems such as HDFS and S3 are shared. For these file systems, the *path* argument represents a single location in the remote file system where all nodes store data. Each node creates its own subdirectory in the shared storage location for its own files. Doing so prevents one node from overwriting files that belong to other nodes.

If using a remote file system, you must specify SHARED, even for one-node clusters. If the location is declared as USER, Vertica does not create subdirectories for each node. The setting of USER takes precedence over SHARED.

If you create a location and omit this keyword, the new storage location is treated as local. Each node must have unique access to the specified path. This location is usually a path in the node's own file system. Storage locations in file systems that are local to each node, such as Linux, are always local.

Deprecated

SHARED DATA storage locations are deprecated.

S3 storage of temporary data in Eon Mode

If you are using Vertica in Eon Mode and have limited local disk space, that space might be insufficient to handle the large quantities of temporary data that some DML operations can generate. This is especially true for large load operations and refresh operations.

You can leverage S3 storage to handle temporary data, as follows:

1. Create a remote storage location with [CREATE LOCATION](#), where *path* is set to S3 as follows:

```
=> CREATE LOCATION 's3://bucket/path' ALL NODES SHARED USAGE 'TEMP';
```

2. Set the RemoteStorageForTemp session configuration parameter to 1:

```
=> ALTER SESSION SET RemoteStorageForTemp= 1;
```

A temporary storage location must already exist on S3 before you set this parameter to 1; otherwise, Vertica throws an error and hint to create the storage location.

3. Run the queries that require extra temporary storage.
4. Reset RemoteStorageForTemp to its default value:

```
=> ALTER SESSION DEFAULT CLEAR RemoteStorageForTemp;
```

When you set RemoteStorageForTemp, Vertica redirects temporary data for all DML operations to the specified remote location. The parameter setting remains in effect until it is explicitly reset to its default value (0), or the current session ends.

Important

Redirecting temporary data to S3 is liable to affect performance and require extra S3 API calls. Use it only for DML operations that involve large quantities of data.

Storage locations on HDFS

You can place storage locations in HDFS, in addition to on the local Linux file system. Because HDFS storage locations are not local, querying them can be slower. You might use HDFS storage locations for lower-priority data or data that is rarely queried (cold data). Moving lower-priority data to HDFS frees space on your Vertica cluster for higher-priority data.

If you are using Vertica for SQL on Apache Hadoop, you typically place storage locations only on HDFS.

In this section

- [Requirements for HDFS storage locations](#)
- [How the HDFS storage location stores data](#)
- [Best practices for Vertica for SQL on Apache Hadoop](#)
- [Troubleshooting HDFS storage locations](#)

Requirements for HDFS storage locations

Caution

If you use HDFS storage locations, the HDFS data must be available when you start Vertica. Your HDFS cluster must be operational, and the ROS files must be present. If you moved data files, or they are corrupted, or your HDFS cluster is not responsive, Vertica cannot start.

To store Vertica's data on HDFS, verify that:

- Your Hadoop cluster has WebHDFS enabled.
- All of the nodes in your Vertica cluster can connect to all of the nodes in your Hadoop cluster. Any firewall between the two clusters must allow connections on the ports used by HDFS.

- If your HDFS cluster is unsecured, you have a Hadoop user whose username matches the name of the Vertica [database superuser](#) (usually named dbadmin). This Hadoop user must have read and write access to the HDFS directory where you want Vertica to store its data.
- If your HDFS cluster uses Kerberos authentication:
 - You have a Kerberos principal for Vertica, and it has read and write access to the HDFS directory that will be used for the storage location. See [Kerberos](#) below for instructions.
 - The Kerberos KDC is running.
- Your HDFS cluster has enough storage available for Vertica data. See [Space Requirements](#) below for details.
- The data you store in an HDFS-backed storage location does not expand your database's size beyond any data allowance in your Vertica license. Vertica counts data stored in an HDFS-backed storage location as part of any data allowance set by your license. See [Managing licenses](#) in the Administrator's Guide for more information.

Backup/Restore has [additional requirements](#).

Space requirements

If your Vertica database is [K-safe](#), HDFS-based storage locations contain two copies of the data you store in them. One copy is the primary projection, and the other is the buddy projection. If you have enabled HDFS's data-redundancy feature, Hadoop stores both projections multiple times. This duplication might seem excessive. However, it is similar to how a RAID level 1 or higher stores redundant copies of both the primary and buddy projections. The redundant copies also help the performance of HDFS by enabling multiple nodes to process a request for a file.

Verify that your HDFS installation has sufficient space available for redundant storage of both the primary and buddy projections of your K-safe data. You can adjust the number of duplicates stored by HDFS by setting the [HadoopFSReplication](#) configuration parameter. See [Troubleshooting HDFS Storage Locations](#) for details.

Kerberos

To use a storage location in HDFS with Kerberos, take the following additional steps:

1. Create a Kerberos principal for each Vertica node as explained in [Using Kerberos with Vertica](#).
2. Give all node principals read and write permission to the HDFS directory you will use as a storage location.

If you plan to use [vbr](#) to back up and restore the location, see additional requirements in [Requirements for backing up and restoring HDFS storage locations](#).

Adding HDFS storage locations to new nodes

If you add nodes to your Vertica cluster, they do not automatically have access to existing HDFS storage locations. You must manually create the storage location for the new node using the [CREATE LOCATION](#) statement. Do not use the ALL NODES option in this statement. Instead, use the NODE option with the name of the new node to tell Vertica that just that node needs to add the shared location.

Caution

You must manually create the storage location. Otherwise, the new node uses the default storage policy (usually, storage on the local Linux file system) to store data that the other nodes store in HDFS. As a result, the node can run out of disk space.

Consider an HDFS storage location that was created on a three-node cluster with the following statements:

```
=> CREATE LOCATION 'hdfs://hadoopNS/vertica/colddata' ALL NODES SHARED
  USAGE 'data' LABEL 'coldstorage';

=> SELECT SET_OBJECT_STORAGE_POLICY('SchemaName','coldstorage');
```

The following example shows how to add the storage location to a new cluster node:

```
=> CREATE LOCATION 'hdfs://hadoopNS/vertica/colddata' NODE 'v_vmart_node0004'
  SHARED USAGE 'data' LABEL 'coldstorage';
```

Any [active standby nodes](#) in your cluster when you create an HDFS storage location automatically create their own instances of the location. When the standby node takes over for a down node, it uses its own instance of the location to store data for objects using the HDFS storage policy. Treat standby nodes added after you create the storage location as any other new node. You must manually define the HDFS storage location.

How the HDFS storage location stores data

Vertica stores data in storage locations on HDFS similarly to the way it stores data in the Linux file system. When you create a storage location on HDFS, Vertica stores the [ROS](#) containers holding its data on HDFS. You can choose which data uses the HDFS storage location: from the data for just a single table or partition to all of the database's data.

When Vertica reads data from or writes data to an HDFS storage location, the node storing or retrieving the data contacts the Hadoop cluster directly to transfer the data. If a single ROS container file is split among several HDFS nodes, the Vertica node connects to each of them. The Vertica node retrieves the pieces and reassembles the file. Because each node fetches its own data directly from the source, data transfers are parallel, increasing their efficiency. Having the Vertica nodes directly retrieve the file splits also reduces the impact on the Hadoop cluster.

What you can store in HDFS

Use HDFS storage locations to store only data. You cannot store catalog information in an HDFS storage location.

Caution

While it is possible to use an HDFS storage location for temporary data storage, you must never do so. Using HDFS for temporary storage causes severe performance issues.

What HDFS storage locations cannot do

Because Vertica uses storage locations to store ROS containers in a proprietary format, MapReduce and other Hadoop components cannot access your Vertica ROS data stored in HDFS. Never allow another program that has access to HDFS to write to the ROS files. Any outside modification of these files can lead to data corruption and loss. Applications must use the [Vertica client libraries](#) to access Vertica data. If you want to share ROS data with other Hadoop components, you can export it (see [File export](#)).

Best practices for Vertica for SQL on Apache Hadoop

If you are using the Vertica for SQL on Apache Hadoop product, Vertica recommends the following best practices for storage locations:

- Place only data type storage locations on HDFS storage.
- Place temp space directly on the local Linux file system, not in HDFS.
- For the best performance, place the Vertica catalog directly on the local Linux file system.
- Create the database first on a local Linux file system. Then, you can extend the database to HDFS storage locations and set storage policies that exclusively place data blocks on the HDFS storage location.
- For better performance, if you are running Vertica only on a subset of the HDFS nodes, do not run the HDFS balancer on them. The HDFS balancer can move data blocks farther away, causing Vertica to read non-local data during query execution. Queries run faster if they do not require network I/O.

Generally, HDFS requires approximately 2 GB of memory for each node in the cluster. To support this requirement in your Vertica configuration:

1. Create a 2-GB resource pool.
2. Do not assign any Vertica execution resources to this pool. This approach reserves the space for use by HDFS.

Alternatively, use Ambari or Cloudera Manager to find the maximum heap size required by HDFS and set the size of the resource pool to that value.

For more about how to configure resource pools, see [Managing workloads](#).

Troubleshooting HDFS storage locations

This topic explains some common issues with HDFS storage locations.

HDFS storage disk consumption

By default, HDFS makes three copies of each file it stores. This replication helps prevent data loss due to disk or system failure. It also helps increase performance by allowing several nodes to handle a request for a file.

A Vertica database with a [K-safety](#) value of 1 or greater also stores its data redundantly using buddy projections.

When a K-Safe Vertica database stores data in an HDFS storage location, its data redundancy is compounded by HDFS's redundancy. HDFS stores three copies of the primary projection's data, plus three copies of the buddy projection for a total of six copies of the data.

If you want to reduce the amount of disk storage used by HDFS locations, you can alter the number of copies of data that HDFS stores. The Vertica configuration parameter named `HadoopFSReplication` controls the number of copies of data HDFS stores.

You can determine the current HDFS disk usage by logging into the Hadoop NameNode and issuing the command:

```
$ hdfs dfsadmin -report
```

This command prints the usage for the entire HDFS storage, followed by details for each node in the Hadoop cluster. The following example shows the beginning of the output from this command, with the total disk space highlighted:

```
$ hdfs dfsadmin -report
Configured Capacity: 51495516981 (47.96 GB)
Present Capacity: 32087212032 (29.88 GB)
DFS Remaining: 31565144064 (29.40 GB)
DFS Used: 522067968 (497.88 MB)
DFS Used%: 1.63%
Under replicated blocks: 0
Blocks with corrupt replicas: 0
Missing blocks: 0
...
```

After loading a simple million-row table into a table stored in an HDFS storage location, the report shows greater disk usage:

```
Configured Capacity: 51495516981 (47.96 GB)
Present Capacity: 32085299338 (29.88 GB)
DFS Remaining: 31373565952 (29.22 GB)
DFS Used: 711733386 (678.76 MB)
DFS Used%: 2.22%
Under replicated blocks: 0
Blocks with corrupt replicas: 0
Missing blocks: 0
...
```

The following Vertica example demonstrates:

1. Creating the storage location on HDFS.
2. Dropping the table in Vertica.
3. Setting the HadoopFSReplication configuration option to 1. This tells HDFS to store a single copy of an HDFS storage location's data.
4. Recreating the table and reloading its data.

```
=> CREATE LOCATION 'hdfs://hadoopNS/user/dbadmin' ALL NODES SHARED
  USAGE 'data' LABEL 'hdfs';
CREATE LOCATION

=> DROP TABLE messages;
DROP TABLE

=> ALTER DATABASE DEFAULT SET PARAMETER HadoopFSReplication = 1;

=> CREATE TABLE messages (id INTEGER, text VARCHAR);
CREATE TABLE

=> SELECT SET_OBJECT_STORAGE_POLICY('messages', 'hdfs');
SET_OBJECT_STORAGE_POLICY
-----
Object storage policy set.
(1 row)

=> COPY messages FROM '/home/dbadmin/messages.txt';
Rows Loaded
-----
1000000
```

Running the HDFS report on Hadoop now shows less disk space use:

```
$ hdfs dfsadmin -report
Configured Capacity: 51495516981 (47.96 GB)
Present Capacity: 32086278190 (29.88 GB)
DFS Remaining: 31500988416 (29.34 GB)
DFS Used: 585289774 (558.18 MB)
DFS Used%: 1.82%
Under replicated blocks: 0
Blocks with corrupt replicas: 0
Missing blocks: 0
. . .
```

Caution

Reducing the number of copies of data stored by HDFS increases the risk of data loss. It can also negatively impact the performance of HDFS by reducing the number of nodes that can provide access to a file. This slower performance can impact the performance of Vertica queries that involve data stored in an HDFS storage location.

ERROR 6966: StorageBundleWriter

You might encounter Error 6966 when loading data into a storage location on a small Hadoop cluster (5 or fewer data nodes). This error is caused by the way HDFS manages the write pipeline and replication. You can mitigate this problem by reducing the number of replicas as explained in [HDFS Storage Disk Consumption](#). For configuration changes you can make in the Hadoop cluster instead, see [this blog post from Hortonworks](#).

Kerberos authentication when creating a storage location

If HDFS uses Kerberos authentication, then the CREATE LOCATION statement authenticates using the Vertica keytab principal, not the principal of the user performing the action. If the creation fails with an authentication error, verify that you have followed the steps described in [Kerberos](#) to configure this principal.

When creating an HDFS storage location on a Hadoop cluster using Kerberos, CREATE LOCATION reports the principal being used as in the following example:

```
=> CREATE LOCATION 'hdfs://hadoopNS/user/dbadmin' ALL NODES SHARED
      USAGE 'data' LABEL 'coldstorage';
NOTICE 0: Performing HDFS operations using kerberos principal [vertica/hadoop.example.com]
CREATE LOCATION
```

Backup or restore fails

For issues with backup/restore of HDFS storage locations, see [Troubleshooting backup and restore](#).

Altering location use

[ALTER_LOCATION_USE](#) lets you change the type of files that Vertica stores at a storage location. You typically use labels only for DATA storage locations, not TEMP.

This example shows how to alter the storage location on `v_vmartdb_node0004` to store only data files:

```
=> SELECT ALTER_LOCATION_USE ('/thirdVerticaStorageLocation', 'v_vmartdb_node0004', 'DATA');
```

Altering HDFS storage locations

When altering an HDFS storage location, you must make the change for all nodes in the Vertica cluster. To do so, specify a node value of "", as in the following example:

```
=> SELECT ALTER_LOCATION_USE('hdfs:///user/dbadmin/v_vmart',
      '', 'TEMP');
```

Restrictions

You cannot change a storage location from a USER usage type if you created the location that way, or to a USER type if you did not. You can change a USER storage location to specify DATA (storing TEMP files is not supported). However, doing so does not affect the primary objective of a USER storage location, to be accessible by non-dbadmin users with assigned privileges.

You cannot change a storage location from SHARED TEMP or SHARED USER to SHARED DATA or the reverse.

Effects of altering storage location use

Before altering a storage location use type, be aware that at least one location must remain for storing data and temp files on a node. You can store data and temp files in the same, or separate, storage locations.

Altering an existing storage location has the following effects:

Alter use from...	To store only...	Has this effect...
Temp and data files (or data only)	Temp files	Data content is eventually merged out by the Tuple Mover. You can also manually merge out data from the storage location using DO_TM_TASK . The location stores only temp files from that point forward.
Temp and data files (or temp only)	Data files	Vertica continues to run all statements that use temp files (such as queries and loads). Subsequent statements no longer use the changed storage location for temp files, and the location stores only data files from that point forward.

Altering location labels

[ALTER_LOCATION_LABEL](#) lets you change the label for a storage location in several ways:

- [Add a label to an unlabeled storage location](#).
- [Remove a label](#).
- [Change an existing label](#).

You can perform these operations on individual nodes or cluster-wide.

Adding a location label

You add a location label to an unlabeled storage location with `ALTER_LOCATION_LABEL`. For example, unlabeled storage location `/home/dbadmin/Vertica/SSD` is defined on a three-node cluster:

You can label this storage location as `SSD` on all nodes as follows:

```
=> SELECT ALTER_LOCATION_LABEL('/home/dbadmin/vertica/SSD', '', 'SSD');
```

Caution

If you label a storage location that contains data, Vertica moves the data to an unlabeled location, if one exists. To prevent data movement between storage locations, labels should be applied either to all storage locations or none.

Removing a location label

You can remove a location label only if the following conditions are both true:

- No database object has a storage policy that specifies this label.
- The labeled location is not the last available storage for the objects associated with it.

The following statement removes the `SSD` label from the specified storage location on all nodes:

```
=> SELECT ALTER_LOCATION_LABEL('/home/dbadmin/SSD/tables',"");
ALTER_LOCATION_LABEL
```

```
-----
/home/dbadmin/SSD/tables label changed.
```

```
(1 row)
```

Altering a storage location label

You can relabel a storage location only if no database object has a storage policy that specifies this label.

Creating storage policies

Vertica meta-function [SET_OBJECT_STORAGE_POLICY](#) creates a [storage policy](#) that associates a database object with a labeled storage location. When an object has a storage policy, Vertica uses the labeled location as the default storage location for that object's data.

You can create storage policies for the database, schemas, tables, and partition ranges. Each object can be associated with one storage policy. Each time data is loaded and updated, Vertica checks whether the object has a storage policy. If it does, Vertica uses the labeled storage location. If no storage policy exists for an object or its parent entities, data storage processing continues using standard storage algorithms on available storage locations. If all storage locations are labeled, Vertica uses one of them.

Storage policies let you determine where to store critical data. For example, you might create a storage location with the label **SSD** that represents the fastest available storage on the cluster nodes. You then create storage policies to associate tables with that labeled location. For example, the following [SET_OBJECT_STORAGE_POLICY](#) statement sets a storage policy on table **test** to use the storage location labeled **SSD** as its default location:

```
=> SELECT SET_OBJECT_STORAGE_POLICY('test','ssd', true);
SET_OBJECT_STORAGE_POLICY
```

```
-----
Object storage policy set.
```

```
Task: moving storages
```

```
(Table: public.test) (Projection: public.test_b0)
```

```
(Table: public.test) (Projection: public.test_b1)
```

```
(1 row)
```

Note

You cannot include temporary files in storage policies. Storage policies are for use only with data files on storage locations for DATA. Storage policies are not valid for USER locations.

Creating one or more storage policies does not require that policies exist for all database objects. A site can support objects with or without storage policies. You can add storage policies for a discrete set of priority objects, while letting other objects exist without a policy, so they use available storage.

Creating policies based on storage performance

You can measure the performance of any disk storage location (see [Measuring storage performance](#)). Then, using the performance measurements, set the storage location performance. Vertica uses the performance measurements you set to rank its storage locations and, through ranking, to determine which key projection columns to store on higher performing locations, as described in [Setting storage performance](#).

If you already set the performance of your site's storage locations, and decide to use storage policies, any storage location with an associated policy has a higher priority than the storage ranking setting.

You can use storage policies to move older data to less-expensive storage locations while keeping it available for queries. See [Creating storage policies for low-priority data](#).

Storage hierarchy and precedence

Vertica determines where to store object data according to the following hierarchy of storage policies, listed below in ascending order of precedence:

1. Database
2. Schema
3. Table
4. Table partition

If an object lacks its own storage policy, it uses the storage policy of its parent object. For example, table **Region.Income** in database **Sales** is

partitioned by months. Labeled storage policies **FAST** and **STANDARD** are assigned to the table and database, respectively. No storage policy is assigned to the table's partitions or its parent schema, so these use the storage policies of their parent objects, **FAST** and **STANDARD** , respectively:

Object	Storage policy	Policy precedence	Labeled location	Default location
Sales (database)	YES	4	STANDARD	STANDARD
Region (schema)	NO	3	N/A	STANDARD
Income (table)	YES	2	FAST	FAST
MONTH (partitions)	NO	1	N/A	FAST

When Tuple Mover operations such as mergeout occur, all **Income** data moves to the **FAST** storage location. Other tables in the Region schema use their own storage policy. If a **Region** table lacks its own storage policy, Tuple Mover uses the next storage policy above it—in this case, it uses database storage policy and moves the table data to **STANDARD** .

Querying existing storage policies

You can query existing storage policies, listed in the `location_label` column of system table [STORAGE_CONTAINERS](#) :

```
=> SELECT node_name, projection_name, location_label FROM v_monitor.storage_containers;
```

```
node_name | projection_name | location_label
-----+-----+-----
v_vmart_node0001 | states_p      |
v_vmart_node0001 | states_p      |
v_vmart_node0001 | t1_b1        |
v_vmart_node0001 | newstates_b0  | LEVEL3
v_vmart_node0001 | newstates_b0  | LEVEL3
v_vmart_node0001 | newstates_b1  | LEVEL3
v_vmart_node0001 | newstates_b1  | LEVEL3
v_vmart_node0001 | newstates_b1  | LEVEL3
v_vmart_node0001 | states_p_v1_node0001 | LEVEL3
v_vmart_node0001 | states_p_v1_node0001 | LEVEL3
v_vmart_node0001 | states_p_v1_node0001 | LEVEL3
v_vmart_node0001 | states_p_v1_node0001 | LEVEL3
v_vmart_node0001 | states_p_v1_node0001 | LEVEL3
v_vmart_node0001 | states_p_v1_node0001 | LEVEL3
v_vmart_node0001 | states_b0     | SSD
v_vmart_node0001 | states_b0     | SSD
v_vmart_node0001 | states_b1     | SSD
v_vmart_node0001 | states_b1     | SSD
v_vmart_node0001 | states_b1     | SSD
...
```

Forcing existing data storage to a new storage location

By default, the Tuple Mover enforces object storage policies after all pending mergeout operations are complete. **SET_OBJECT_STORAGE_POLICY** moves existing data storage to a new location immediately, if you set its parameter `enforce-storage-move` to `true` . You might want to force a move, even though it means waiting for the operation to complete before continuing, if the data being moved is old. The Tuple Mover runs less frequently on older data.

Note

If parameter `enforce-storage-move` is set to `true` , **SET_OBJECT_STORAGE_POLICY** performs a cluster-wide operation. If an error occurs on any node, the function displays a warning message and skips that node. It then continues executing the operation on the remaining nodes.

Creating storage policies for low-priority data

If some of your data is in a partitioned table, you can move less-queried partitions to less-expensive storage such as HDFS. The data is still accessible in queries, just at a slower speed. In this scenario, the faster storage is often referred to as "hot storage," and the slower storage is referred to as "cold storage."

Suppose you have a table named `messages` (containing social-media messages) that is partitioned by the year and month of the message's timestamp. You can list the partitions in the table by querying the `PARTITIONS` system table.

```
=> SELECT partition_key, projection_name, node_name, location_label FROM partitions
      ORDER BY partition_key;
```

partition_key	projection_name	node_name	location_label
201309	messages_b1	v_vmart_node0001	
201309	messages_b0	v_vmart_node0003	
201309	messages_b1	v_vmart_node0002	
201309	messages_b1	v_vmart_node0003	
201309	messages_b0	v_vmart_node0001	
201309	messages_b0	v_vmart_node0002	
201310	messages_b0	v_vmart_node0002	
201310	messages_b1	v_vmart_node0003	
201310	messages_b0	v_vmart_node0001	
...			
201405	messages_b0	v_vmart_node0002	
201405	messages_b1	v_vmart_node0003	
201405	messages_b1	v_vmart_node0001	
201405	messages_b0	v_vmart_node0001	

(54 rows)

Next, suppose you find that most queries on this table access only the latest month or two of data. You might decide to move the older data to cold storage in an HDFS-based storage location. After you move the data, it is still available for queries, but with lower query performance.

To move partitions to the HDFS storage location, supply the lowest and highest partition key values to be moved in the [SET_OBJECT_STORAGE_POLICY](#) function call. The following example shows how to move data between two dates. In this example:

- The partition key value 201309 represents September 2013.
- The partition key value 201403 represents March 2014.
- The name, `coldstorage`, is the label of the HDFS-based storage location.
- The final argument, which is optional, is `true`, meaning that the function does not return until the move is complete. By default the function returns immediately and the data is moved when the Tuple Mover next runs. When data is old, however, the Tuple Mover runs less frequently, which would delay recovering the original storage space.

```
=> SELECT SET_OBJECT_STORAGE_POLICY('messages','coldstorage', '201309', '201403', 'true');
```

The partitions within the specified range are moved to the HDFS storage location labeled `coldstorage` the next time the [Tuple Mover](#) runs. This location name now displays in the [PARTITIONS](#) system table's `location_label` column.

```
=> SELECT partition_key, projection_name, node_name, location_label
       FROM partitions ORDER BY partition_key;
partition_key | projection_name | node_name | location_label
-----+-----+-----+-----
201309      | messages_b0    | v_vmart_node0003 | coldstorage
201309      | messages_b1    | v_vmart_node0001 | coldstorage
201309      | messages_b1    | v_vmart_node0002 | coldstorage
201309      | messages_b0    | v_vmart_node0001 | coldstorage
...
201403      | messages_b0    | v_vmart_node0002 | coldstorage
201404      | messages_b0    | v_vmart_node0001 |
201404      | messages_b0    | v_vmart_node0002 |
201404      | messages_b1    | v_vmart_node0001 |
201404      | messages_b1    | v_vmart_node0002 |
201404      | messages_b0    | v_vmart_node0003 |
201404      | messages_b1    | v_vmart_node0003 |
201405      | messages_b0    | v_vmart_node0001 |
201405      | messages_b1    | v_vmart_node0002 |
201405      | messages_b0    | v_vmart_node0002 |
201405      | messages_b0    | v_vmart_node0003 |
201405      | messages_b1    | v_vmart_node0001 |
201405      | messages_b1    | v_vmart_node0003 |
(54 rows)
```

After your initial data move, you can move additional data to the HDFS storage location periodically. You can move individual partitions or a range of partitions from the "hot" storage to the "cold" storage location using the same method:

```
=> SELECT SET_OBJECT_STORAGE_POLICY('messages', 'coldstorage', '201404', '201404', 'true');

=> SELECT projection_name, node_name, location_label
       FROM PARTITIONS WHERE PARTITION_KEY = '201404';
projection_name | node_name | location_label
-----+-----+-----
messages_b0    | v_vmart_node0002 | coldstorage
messages_b0    | v_vmart_node0003 | coldstorage
messages_b1    | v_vmart_node0003 | coldstorage
messages_b0    | v_vmart_node0001 | coldstorage
messages_b1    | v_vmart_node0002 | coldstorage
messages_b1    | v_vmart_node0001 | coldstorage
(6 rows)
```

Moving partitions to a table stored on HDFS

Another method of moving partitions from hot storage to cold storage is to move the partitions' data to a separate table in the other storage location. This method breaks the data into two tables, one containing hot data and the other containing cold data. Use this method if you want to prevent queries from inadvertently accessing data stored in cold storage. To query the older data, you must explicitly query the cold table.

To move partitions:

1. Create a new table whose schema matches that of the existing partitioned table.
2. Set the storage policy of the new table to use the HDFS-based storage location.
3. Use the [MOVE_PARTITIONS_TO_TABLE](#) function to move a range of partitions from the hot table to the cold table. The partitions migrate when the Tuple Mover next runs.

The following example demonstrates these steps. You first create a table named cold_messages. You then assign it the HDFS-based storage location named coldstorage, and, finally, move a range of partitions.

```
=> CREATE TABLE cold_messages LIKE messages INCLUDING PROJECTIONS;
=> SELECT SET_OBJECT_STORAGE_POLICY('cold_messages', 'coldstorage');
=> SELECT MOVE_PARTITIONS_TO_TABLE('messages','201309','201403','cold_messages');
```

Moving data storage locations

[SET_OBJECT_STORAGE_POLICY](#) moves data storage from an existing location (labeled and unlabeled) to another labeled location. This function performs two tasks:

- Creates a storage policy for an object, or changes its current policy.
- Moves all existing data for the specified objects to the target storage location.

Before it moves object data to the specified storage location, Vertica calculates the required storage and checks available space at the target. Before calling `SET_OBJECT_STORAGE_POLICY`, check available space on the new target location. Be aware that checking does not guarantee that this space remains available when the Tuple Mover actually executes the move. If the storage location lacks sufficient free space, the function returns an error.

Note

Moving an object's current storage to a new target is a cluster-wide operation. If a node is unavailable, the function returns a warning message, and then continues to implement the move on other nodes. When the node rejoins the cluster, the Tuple Mover updates it with the storage data.

By default, the Tuple Mover moves object data to the new storage location after all pending mergeout tasks return. You can force the data to move immediately by setting the function's *enforce-storage-move* argument to true. For example, the following statement sets the storage policy for a table and implements the move immediately:

```
=> SELECT SET_OBJECT_STORAGE_POLICY('states', 'SSD', 'true');
      SET_OBJECT_STORAGE_POLICY
```

Object storage policy set.

Task: moving storages

(Table: public.states) (Projection: public.states_p1)

(Table: public.states) (Projection: public.states_p2)

(Table: public.states) (Projection: public.states_p3)

(1 row)

Tip

Consider using the [ENFORCE_OBJECT_STORAGE_POLICY](#) meta-function to relocate the data of multiple database objects as needed, to bring them into compliance with current storage policies. Using this function is equivalent to calling `SET_OBJECT_STORAGE_POLICY` successively on multiple database objects and setting the *enforce-storage-move* argument to true.

Clearing storage policies

The [CLEAR_OBJECT_STORAGE_POLICY](#) meta-function clears a storage policy from a database, schema, table, or table partition. For example, the following statement clears the storage policy for a table:

```
=> SELECT CLEAR_OBJECT_STORAGE_POLICY ('store.store_sales_fact');
      CLEAR_OBJECT_STORAGE_POLICY
```

Object storage policy cleared.

(1 row)

The Tuple Mover moves existing storage containers to the parent storage policy's location, or the default storage location if there is no parent policy. By default, this move occurs after all pending mergeout tasks return.

You can force the data to move immediately by setting the function's *enforce-storage-move* argument to true. For example, the following statement clears the storage policy for a table and implements the move immediately:

```
=> SELECT CLEAR_OBJECT_STORAGE_POLICY ('store.store_orders_fact', 'true');
      CLEAR_OBJECT_STORAGE_POLICY
```

Object storage policy cleared.

Task: moving storages

(Table: store.store_orders_fact) (Projection: store.store_orders_fact_b0)

(Table: store.store_orders_fact) (Projection: store.store_orders_fact_b1)

(1 row)

Tip

Consider using the [ENFORCE_OBJECT_STORAGE_POLICY](#) meta-function to relocate the data of multiple database objects as needed, to bring them into compliance with current storage policies. Using this function is equivalent to calling `CLEAR_OBJECT_STORAGE_POLICY` successively on multiple database objects and setting `enforce-storage-move` to true.

Effects on related elements

Clearing a storage policy at one level, such as a table, does not necessarily affect storage policies at other levels, such as that table's partitions.

For example, the `lineorder` table has a storage policy to store table data at a location labeled `F2`. Various partitions in this table are individually assigned their own storage locations, as verified by querying the [STORAGE_POLICIES](#) system table:

```
=> SELECT * from v_monitor.storage_policies;
schema_name | object_name | policy_details | location_label
-----+-----+-----+-----
      | public | Schema | F4
public | lineorder | Partition [0, 0] | F1
public | lineorder | Partition [1, 1] | F2
public | lineorder | Partition [2, 2] | F4
public | lineorder | Partition [3, 3] | M1
public | lineorder | Partition [4, 4] | M3
(6 rows)
```

Clearing the current storage policy from the `lineorder` table has no effect on the storage policies of its individual partitions. For example, given the following `CLEAR_OBJECT_STORAGE_POLICY` statement:

```
=> SELECT CLEAR_OBJECT_STORAGE_POLICY ('lineorder');
      CLEAR_OBJECT_STORAGE_POLICY
-----
Default storage policy cleared.
(1 row)
```

The individual partitions in the table retain their storage policies:

```
=> SELECT * from v_monitor.storage_policies;
schema_name | object_name | policy_details | location_label
-----+-----+-----+-----
      | public | Schema | F4
public | lineorder | Partition [0, 0] | F1
public | lineorder | Partition [1, 1] | F2
public | lineorder | Partition [2, 2] | F4
public | lineorder | Partition [3, 3] | M1
public | lineorder | Partition [4, 4] | M3
(6 rows)
```

If you clear storage policies from a range of partitions key in a table, the storage policies of parent objects and other partition ranges are unaffected. For example, the following statement clears storage policies from partition keys 0 through 3:

```
=> SELECT CLEAR_OBJECT_STORAGE_POLICY ('lineorder','0','3');
      clear_object_storage_policy
-----
Default storage policy cleared.
(1 row)
=> SELECT * from storage_policies;
schema_name | object_name | policy_details | location_label
-----+-----+-----+-----
      | public | Schema | F4
public | lineorder | Table | F2
public | lineorder | Partition [4, 4] | M3
(2 rows)
```

Measuring storage performance

Vertica lets you measure disk I/O performance on any storage location at your site. You can use the returned measurements to set performance, which automatically provides rank. Depending on your storage needs, you can also use performance to determine the storage locations needed for critical data as part of your site's storage policies. Storage performance measurements apply only to data storage locations, not temporary storage locations.

Measuring storage location performance calculates the time it takes to read and write 1 MB of data from the disk, which equates to:

```
I/O time = time to read/write 1MB + time to seek = 1/throughput + 1/Latency
```

- Throughput is the average throughput of sequential reads/writes (expressed in megabytes per second).
- Latency is for random reads only in seeks (units in seeks per second).

Thus, the I/O time of a faster storage location is less than that of a slower storage location.

Note

Measuring storage location performance requires extensive disk I/O, which is a resource-intensive operation. Consider starting this operation when fewer other operations are running.

Vertica gives you two ways to measure storage location performance, depending on whether the database is running. You can either:

- Measure performance on a running database.
- Measure performance before a cluster is set up.

Both methods return the throughput and latency for the storage location. Record or capture the throughput and latency information so you can use it to set the location performance (see [Setting storage performance](#)).

Measuring performance on a running Vertica database

Use the [MEASURE_LOCATION_PERFORMANCE\(\)](#) function to measure performance for a storage location when the database is running. This function has the following requirements:

- The storage path must already exist in the database.
- You need RAM*2 free space available in a storage location to measure its performance. For example, if you have 16 GB RAM, you need 32 GB of available disk space. If you do not have enough disk space, the function returns an error.

Use the system table [DISK_STORAGE](#) to obtain information about disk storage on each database node.

The following example shows how to measure the performance of a storage location on `v_vmartdb_node0004`:

```
=> SELECT MEASURE_LOCATION_PERFORMANCE('/secondVerticaStorageLocation/', 'v_vmartdb_node0004');
```

```
WARNING: measure_location_performance can take a long time. Please check logs for progress
```

```
measure_location_performance
```

```
-----  
Throughput : 122 MB/sec. Latency : 140 seeks/sec
```

Measuring performance before a cluster is set up

You can measure disk performance before setting up a cluster. This approach is useful when you want to verify that the disk is functioning within normal parameters. To perform this measurement, you must already have Vertica installed.

To measure disk performance, use the following command:

```
opt/vertica/bin/vertica -m <path to disk mount>
```

For example:

```
opt/vertica/bin/vertica -m /secondVerticaStorageLocation/node0004_data
```

Setting storage performance

You can use the measurements returned from the [MEASURE_LOCATION_PERFORMANCE](#) function as input values to the [SET_LOCATION_PERFORMANCE\(\)](#) function.

Note

You must set the throughput and latency parameters of this function to 1 or more.

The following example shows how to set the performance of a storage location on `v_vmartdb_node0004`, using values for this location returned from the [MEASURE_LOCATION_PERFORMANCE](#) function. Set the throughput to 122 MB/second and the latency to 140 seeks/second.

[MEASURE_LOCATION_PERFORMANCE](#)

```
=> SELECT SET_LOCATION_PERFORMANCE('/secondVerticaStorageLocation/', 'node2', '122', '140');
```

Sort order ranking by location performance settings

After you set performance-data parameters, Vertica automatically uses performance data to rank storage locations whenever it stores projection columns.

Vertica stores columns included in the projection sort order on the fastest available storage locations. Columns not included in the projection sort order are stored on slower disks. Columns for each projection are ranked as follows:

- Columns in the sort order are given the highest priority (numbers > 1000).
- The last column in the sort order is given the rank number 1001.
- The next-to-last column in the sort order is given the rank number 1002, and so on until the first column in the sort order is given 1000 + # of sort columns.
- The remaining columns are given numbers from 1000-1, starting with 1000 and decrementing by one per column.

Vertica then stores columns on disk from the highest ranking to the lowest ranking. It places highest-ranking columns on the fastest disks and the lowest-ranking columns on the slowest disks.

Using location performance settings with storage policies

You initially measure location performance and set it in the Vertica database. Then, you can use the performance results to determine the fastest storage to use in your storage policies.

- Set the locations with the highest performance as the default locations for critical data.
- Use slower locations as default locations for older, or less-important data. Such slower locations may not require policies at all, if you do not want to specify default locations.

Vertica determines data storage as follows, depending on whether a storage policy exists:

Storage policy	Label	# Locations	Vertica action
No	No	Multiple	Uses ranking (as described), choosing a location from all locations that exist.
Yes	Yes	Single	Uses that storage location exclusively.
Yes	Yes	Multiple	Ranks storage (as described) among all same-name labeled locations.

Retiring storage locations

You can retire a storage location to stop using it. Retiring a storage location prevents Vertica from storing data or temp files to it, but does not remove the actual location. Any data previously stored on the retired location is eventually [merged out](#) by the Tuple Mover. Use the [RETIRE_LOCATION](#) function to retire a location.

The following example retires a location from a single node:

```
=> SELECT RETIRE_LOCATION('/secondStorageLocation/', 'v_vmartdb_node0004');
```

To retire a storage location on all nodes, use an empty string (`"`) for the second argument. If the location is SHARED, you can retire it only on all nodes.

You can expedite retiring and then dropping a storage location by passing an optional third argument, `enforce`, as `true`. With this directive, the function moves the data out of the storage location instead of waiting for the Tuple Mover, allowing you to drop the location immediately.

You can also use the [ENFORCE_OBJECT_STORAGE_POLICY](#) function to trigger the move for all storage locations at once, which allows you to drop the locations. This approach is equivalent to using the `enforce` argument.

The following example shows how to retire a storage location on all nodes so that it can be immediately dropped:

```
=> SELECT RETIRE_LOCATION('/secondStorageLocation/' , "", true);
```

Note

If the location used in a storage policy is the last available storage for its associated objects, you cannot retire it *unless* you set *enforce* to *true* .

Data and temp files can be stored in one, or multiple separate, storage locations.

For further information on dropping a location after retiring it, see [Dropping storage locations](#) .

Restoring retired storage locations

You can restore a previously retired storage location. After the location is restored, Vertica re-ranks the storage location and uses the restored location to process queries as determined by its rank.

Use the [RESTORE_LOCATION](#) function to restore a retired storage location.

The following example shows how to restore a retired storage location on a single node:

```
=> SELECT RESTORE_LOCATION('/secondStorageLocation/' , 'v_vmartdb_node0004');
```

To restore a storage location on all nodes, use an empty string ("") for the second argument. The following example demonstrates creating, retiring, and restoring a location on all nodes:

```
=> CREATE LOCATION '/tmp/ab1' ALL NODES USAGE 'TEMP';
CREATE LOCATION

=> SELECT RETIRE_LOCATION('/tmp/ab1', "");
retire_location
-----
/tmp/ab1 retired.
(1 row)

=> SELECT location_id, node_name, location_path, location_usage, is_retired
       FROM STORAGE_LOCATIONS WHERE location_path ILIKE '/tmp/ab1';
location_id | node_name      | location_path | location_usage | is_retired
-----+-----+-----+-----+-----
45035996273736724 | v_vmart_node0001 | /tmp/ab1     | TEMP          | t
45035996273736726 | v_vmart_node0002 | /tmp/ab1     | TEMP          | t
45035996273736728 | v_vmart_node0003 | /tmp/ab1     | TEMP          | t
45035996273736730 | v_vmart_node0004 | /tmp/ab1     | TEMP          | t
(4 rows)

=> SELECT RESTORE_LOCATION('/tmp/ab1', "");
restore_location
-----
/tmp/ab1 restored.
(1 row)

=> SELECT location_id, node_name, location_path, location_usage, is_retired
       FROM STORAGE_LOCATIONS WHERE location_path ILIKE '/tmp/ab1';
location_id | node_name      | location_path | location_usage | is_retired
-----+-----+-----+-----+-----
45035996273736724 | v_vmart_node0001 | /tmp/ab1     | TEMP          | f
45035996273736726 | v_vmart_node0002 | /tmp/ab1     | TEMP          | f
45035996273736728 | v_vmart_node0003 | /tmp/ab1     | TEMP          | f
45035996273736730 | v_vmart_node0004 | /tmp/ab1     | TEMP          | f
(4 rows)
```

RESTORE_LOCATION restores the location only on the nodes where the location exists and is retired. The meta-function does not propagate the storage location to nodes where that location did not previously exist.

Restoring on all nodes fails if the location has been dropped on any of them. If you have dropped the location on some nodes, you have two options:

- If you no longer want to use the node where the location was dropped, restore the location individually on each of the other nodes.
- Alternatively, you can re-create the location on the node where you dropped it. To do so, use [CREATE LOCATION](#). After you re-create the location, you can then restore it on all nodes.

The following example demonstrates the failure if you try to restore on nodes where you have dropped the location:

```
=> SELECT RETIRE_LOCATION('/tmp/ab1', '');
retire_location
-----
/tmp/ab1 retired.
(1 row)

=> SELECT DROP_LOCATION('/tmp/ab1', 'v_vmart_node0002');
drop_location
-----
/tmp/ab1 dropped.
(1 row)

==> SELECT location_id, node_name, location_path, location_usage, is_retired
       FROM STORAGE_LOCATIONS WHERE location_path ILIKE '/tmp/ab1';
location_id | node_name      | location_path | location_usage | is_retired
-----+-----+-----+-----+-----
45035996273736724 | v_vmart_node0001 | /tmp/ab1     | TEMP          | t
45035996273736728 | v_vmart_node0003 | /tmp/ab1     | TEMP          | t
45035996273736730 | v_vmart_node0004 | /tmp/ab1     | TEMP          | t
(3 rows)

=> SELECT RESTORE_LOCATION('/tmp/ab1', '');
ERROR 2081: [/tmp/ab1] is not a valid storage location on node v_vmart_node0002
```

Dropping storage locations

To drop a storage location, use the [DROP_LOCATION](#) function. You cannot drop locations with DATA usage, only TEMP or USER usage. (See [Altering Storage Locations Before Dropping Them](#).)

Because dropping a storage location cannot be undone, Vertica recommends that you first retire a storage location (see [Retiring storage locations](#)). Retiring a storage location before dropping it lets you verify that there will be no adverse effects on any data access. If you decide not to drop it, you can restore it (see [Restoring retired storage locations](#)).

The following example shows how to drop a storage location on a single node:

```
=> SELECT DROP_LOCATION('/secondStorageLocation', 'v_vmartdb_node0002');
```

When you drop a storage location, the operation cascades to associated objects including any granted privileges to the storage.

Caution

Dropping a storage location is a permanent operation and cannot be undone. Subsequent queries on storage used for external table access fail with a COPY COMMAND FAILED message.

Altering storage locations before dropping them

You can drop only storage locations containing temp files. Thus, you must alter a storage location to the TEMP usage type before you can drop it. However, if data files still exist in the storage location, Vertica prevents you from dropping it. Deleting data files does not clear the storage location and can result in database corruption. To handle a storage area containing data files so that you can drop it, use one of these options:

- Manually [merge out](#) the data files.
- Wait for the Tuple Mover to merge out the data files automatically.
- Retire the location, and force changes to take effect immediately.
- Manually [drop partitions](#).

Dropping HDFS storage locations

After dropping a storage location on HDFS, clean up residual files and snapshots on HDFS as explained in [Removing HDFS storage locations](#).

Dropping USER storage locations

Storage locations that you create with the USER usage type can contain only data files, not temp files. However, you can drop a USER location, regardless of any remaining data files. This behavior differs from that of a storage location not designated for USER access.

Checking location properties

You can check the properties of a storage location, such as whether it is a USER location or is being used only for TEMP files, in the [STORAGE_LOCATIONS](#) system table. You can also use this table to verify that a location has been retired.

Analyzing workloads

If queries perform suboptimally, use Workload Analyzer to get tuning recommendations for them and hints about optimizing database objects. Workload Analyzer is a Vertica utility that analyzes system information in Vertica [system tables](#).

Workload Analyzer identifies the root causes of poor query performance through intelligent monitoring of query execution, workload history, resources, and configurations. It then returns a set of tuning recommendations based on statistics, system and [data collector](#) events, and database/table/projection design. Use these recommendations to tune query performance, quickly and easily.

You can run Workload Analyzer in two ways:

- Call the Vertica function [ANALYZE_WORKLOAD](#).
- Use the [Management Console interface](#).

See [Workload analyzer recommendations](#) for common issues that Workload Analyzer finds, and recommendations.

In this section

- [Getting tuning recommendations](#)
- [Workload analyzer recommendations](#)

Getting tuning recommendations

Call the function [ANALYZE_WORKLOAD](#) to get tuning recommendations for queries and database objects. The function arguments specify what events to analyze and when.

Setting scope and time span

[ANALYZE_WORKLOAD](#) 's **scope** argument determines what to analyze:

This argument...	Returns Workload Analyzer recommendations for...
" (empty string)	All database objects
Table name	A specific table
Schema name	All objects in the specified schema

The optional **since-time** argument specifies to return values from all in -scope events starting from **since-time** and continuing to the current system status. If you omit **since_time**, [ANALYZE_WORKLOAD](#) returns recommendations for events since the last recorded time that you called the function. You must explicitly cast the **since-time** string value to either **TIMESTAMP** or **TIMESTAMPTZ**.

The following examples show four ways to express the **since-time** argument with different formats. All queries return the same result for workloads on table **t1** since October 4, 2012:

```
=> SELECT ANALYZE_WORKLOAD('t1', TIMESTAMP '2012-10-04 11:18:15');
=> SELECT ANALYZE_WORKLOAD('t1', '2012-10-04 11:18:15'::TIMESTAMPTZ);
=> SELECT ANALYZE_WORKLOAD('t1', 'October 4, 2012'::TIMESTAMP);
=> SELECT ANALYZE_WORKLOAD('t1', '10-04-12'::TIMESTAMPTZ);
```

Saving function results

Instead of analyzing events since a specific time, you can save results from [ANALYZE_WORKLOAD](#), by setting the function's second argument to **true**. The default is **false**, and no results are saved. After saving function results, subsequent calls to [ANALYZE_WORKLOAD](#) analyze only events since you last saved returned data, and ignore all previous events.

For example, the following statement returns recommendations for all database objects in all schemas and records this analysis invocation.

```
=> SELECT ANALYZE_WORKLOAD("", true);
```

The next invocation of **ANALYZE_WORKLOAD** analyzes events from this point forward.

Observation count and time

The **observation_count** column returns an integer that represents the total number of events Workload Analyzer observed for this tuning recommendation. In each case above, Workload Analyzer is making its first recommendation. Null results in **observation_time** only mean that the recommendations are from the current system status instead of from a prior event.

Tuning targets

The **tuning_parameter** column returns the object on which Workload Analyzer recommends that you apply the tuning action. The parameter of **release** in the example above notifies the DBA to set a password for user release.

Tuning recommendations and costs

Workload Analyzer's output returns a brief description of tasks you should consider in the **tuning_description** column, along with a SQL command you can run, where appropriate, in the **tuning_command column** . In records 1 and 2 above, Workload Analyzer recommends that you run the [Database Designer](#) on two tables, and in record 3 recommends setting a user's password. Record 3 also provides the **ALTER USER** command to run because the tuning action is a SQL command.

Output in the **tuning_cost** column indicates the cost of running the recommended tuning command:

- **LOW** : Running the tuning command has minimal impact on resources. You can perform the tuning operation at any time, like changing the user's password in Record 3 above.
- **MEDIUM** : Running the tuning command has moderate impact on resources.
- **HIGH** : Running the tuning command has maximum impact on resources. Depending on the size of your database or table, consider running high-cost operations during off-peak load times.

Examples

The following statement tells Workload Analyzer to analyze all events for the **locations** table:

```
=> SELECT ANALYZE_WORKLOAD('locations');
```

Workload Analyzer returns with a recommendation that you run the Database Designer on the table, an operation that, depending on the size of **locations** , might incur a high cost:

```
-[ RECORD 1 ]-----+-----  
observation_count | 1  
first_observation_time |  
last_observation_time |  
tuning_parameter   | public.locations  
tuning_description  | run database designer on table public.locations  
tuning_command     |  
tuning_cost        | HIGH
```

The following statement analyzes workloads on all tables in the VMart example database since one week before today:

```
=> SELECT ANALYZE_WORKLOAD("", NOW() - INTERVAL '1 week');
```

Workload Analyzer returns with the following results:

```

-[ RECORD 1 ]-----+-----
observation_count | 4
first_observation_time | 2012-02-17 13:57:17.799003-04
last_observation_time | 2011-04-22 12:05:26.856456-04
tuning_parameter   | store.store_orders_fact.date_ordered
tuning_description  | analyze statistics on table column store.store_orders_fact.date_ordered
tuning_command      | select analyze_statistics('store.store_orders_fact.date_ordered');
tuning_cost         | MEDIUM
-[ RECORD 2 ]-----+-----
...
-[ RECORD 14 ]-----+-----
observation_count | 2
first_observation_time | 2012-02-19 17:52:03.022644-04
last_observation_time | 2012-02-19 17:52:03.02301-04
tuning_parameter    | SELECT x FROM t WHERE x > (SELECT SUM(DISTINCT x) FROM
                    | t GROUP BY y) OR x < 9;
tuning_description  | consider incremental design on query
tuning_command      |
tuning_cost         | HIGH

```

Workload Analyzer finds two issues:

- In record 1, the `date_ordered` column in the `store.store_orders_fact` table likely has stale statistics, so Workload Analyzer suggests running [ANALYZE_STATISTICS](#) on that column. The function output also returns the query to run. For example:

```
=> SELECT ANALYZE_STATISTICS('store.store_orders_fact.date_ordered');
```

- In record 14, Workload Analyzer identifies an under-performing query in the `tuning_parameter` column. It recommends to use the Database Designer to run an incremental design. Workload Analyzer rates the potential cost as `HIGH`.

System table recommendations

You can also get tuning recommendations by querying system table [TUNING_RECOMMENDATIONS](#), which returns tuning recommendation results from the last [ANALYZE_WORKLOAD](#) call.

```
=> SELECT * FROM tuning_recommendations;
```

System information that Workload Analyzer uses for its recommendations is held in [SQL system tables](#), so querying the [TUNING_RECOMMENDATIONS](#) system table does not run Workload Analyzer.

See also

[Collecting database statistics](#)

Workload analyzer recommendations

Workload Analyzer monitors database activity and logs recommendations as needed in system table [TUNING_RECOMMENDATIONS](#). When you run Workload Analyzer, the utility returns the following information:

- Description of the object that requires tuning
- Recommended action
- SQL command to implement the recommendation

Common issues and recommendations

Issue	Recommendation
No custom resource pools, user queries are typically handled by the GENERAL resource pool.	Create custom resource pools to handle queries from specific users.
A projection is identified as rarely or never used to execute queries:	Remove the projection with DROP PROJECTION
User with admin privileges has empty password.	Set the password for user with ALTER USER...IDENTIFIED BY .
Table has too many partitions.	Alter the table's partition expression with ALTER TABLE . Also consider grouping partitions and hierarchical partitioning .

Partitioned table data is not fully reorganized after repartitioning.	Reorganize data in the partitioned table with ALTER TABLE...REORGANIZE .
Table has multiple partition keys within the same ROS container.	
Tuple Mover 's MoveOutInterval parameter setting is greater than the default value.	Decrease the parameter setting, or reset the parameter to its default setting.
Average CPU usage exceeds 95% for 20 minutes.	Check system processes, or change resource pool settings of parameters PLANNEDCONCURRENCY and/or MAXCONCURRENCY. For details, see ALTER RESOURCE POOL and Built-in resource pools configuration .
Excessive swap activity; average memory usage exceeds 99% for 10 minutes.	Check system processes
A table does not have any Database Designer-designed projections.	Run database designer on the table. For details, see Incremental Design .
Table statistics are stale.	Run ANALYZE_STATISTICS on table columns. See also Collecting database statistics .
Data distribution in segmented projection is skewed.	Resegment projection on high-cardinality columns. For details, see Designing for segmentation .
Attempts to execute a query generated a GROUP BY spill event.	Consider running an incremental design on the query.
Internal configuration parameter is not the same across nodes.	Reset configuration parameter with ALTER DATABASE...SET
LGE threshold setting is lower than the default setting.	Workload Analyzer does not trigger a tuning recommendation for this scenario unless you altered settings and/or services under the guidance of technical support.
Tuple Mover is disabled.	
Too many ROS containers since the last mergeout operation; configuration parameters are set lower than the default.	
Too many ROS containers since the last mergeout operation; the TM Mergeout service is disabled.	

Managing the database

This section describes how to manage the Vertica database. It includes the following topics:

- [Connection load balancing](#)
- [Managing nodes](#)
- [Adding disk space to a node](#)
- [Tuple mover](#)
- [Managing the tuple mover](#)
- [Managing workloads](#)

In this section

- [Managing nodes](#)

Stop Vertica on a node

In some cases, you need to take down a node to perform maintenance tasks, or upgrade hardware. You can do this with one of the following:

- [Administration Tools](#)
- [Command line](#) admintools stop_node

Important

Before removing a node from a cluster, check that the cluster has the minimum number of nodes required to comply with K-safety. If necessary, [temporarily lower the database K-safety level](#).

Administration tools

1. Run Administration Tools, select **Advanced Menu**, and click **OK**.
2. Select **Stop Vertica on Host** and click **OK**.
3. Choose the host that you want to stop and click **OK**.
4. Return to the Main Menu, select **View Database Cluster State**, and click **OK**. The host you previously stopped should appear DOWN.
5. You can now perform maintenance.

See [Restart Vertica on a Node](#) for details about restarting Vertica on a node.

Command line

You can use the command line tool stop_node to stop Vertica on one or more nodes. stop_node takes one or more node IP addresses as arguments. For example, the following command stops Vertica on two nodes:

```
$ admintools -t stop_node -s 192.0.2.1,192.0.2.2
```

Restart Vertica on a node

After [stopping a node](#) to perform maintenance tasks such as upgrading hardware, you need to restart the node so it can reconnect with the database cluster.

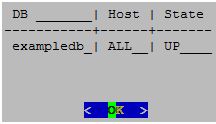

1. Run Administration Tools. From the Main Menu select **Restart Vertica on Host** and click **OK**.
2. Select the database and click **OK**.

3. Select the host that you want to restart and click **OK**.

Note

This process may take a few moments.

4. Return to the Main Menu, select **View Database Cluster State**, and click **OK**. The host you restarted now appears as UP, as shown.

DB	Host	State
exampledb	ALL	UP

Setting node type

When you create a node, Vertica automatically sets its type to **PERMANENT**. This enables Vertica to use this node to store data. You can change a node's type with [ALTER NODE](#), to one of the following:

- **PERMANENT**: (default): A node that stores data.
- **EPHEMERAL**: A node that is in transition from one type to another—typically, from **PERMANENT** to either **STANDBY** or **EXECUTE**.
- **STANDBY**: A node that is reserved to replace any node when it goes down. A standby node stores no segments or data until it is called to replace a down node. When used as a replacement node, Vertica changes its type to **PERMANENT**. For more information, see [Active standby nodes](#).
- **EXECUTE**: A node that is reserved for computation purposes only. An execute node contains no segments or data.

Note

STANDBY and **EXECUTE** node types are supported only in Enterprise Mode.

Active standby nodes

An *active standby node* exists is a node in an Enterprise Mode database that is available to replace any failed node. Unlike permanent Vertica nodes, an standby node does not perform computations or contain data. If a permanent node fails, an active standby node can replace the failed node, after the failed node exceeds the failover time limit. After replacing the failed node, the active standby node contains the projections and performs all calculations of the node it replaced.

In this section

In this section

- [Creating an active standby node](#)
- [Replace a node with an active standby node](#)
- [Revert active standby nodes](#)

Creating an active standby node

You can create active standby nodes in an Enterprise Mode database at the same time that you create the database, or later.

Note

When you create an active standby node, be sure to add any necessary storage locations. For more information, refer to [Adding Storage Locations](#).

Creating an active standby node in a new database

1. [Create a database](#), including the nodes that you intend to use as active standby nodes.
2. Using `vsqll`, connect to a node **other than** the node that you want to use as an active standby node.
3. Use [ALTER NODE](#) to convert the node from a permanent node to an active standby node. For example:

```
=> ALTER NODE v_mart_node5 STANDBY;
```

After you issue the `ALTER NODE` statement, the affected node goes down and restarts as an active standby node.

Creating an active standby node in an existing database

When you create a node to be used as an active standby node, change the new node to ephemeral status as quickly as possible to prevent the cluster from moving data to it.

1. [Add a node to the database](#).

Important

Do not rebalance the database at this stage.

2. Using `vsq`, connect to any other node.

3. Use [ALTER NODE](#) to convert the new node from a permanent node to an ephemeral node. For example:

```
=> ALTER NODE v_mart_node5 EPHEMERAL;
```

4. [Rebalance the cluster](#) to remove all data from the ephemeral node.

5. Use [ALTER NODE](#) on the ephemeral node to convert it to an active standby node. For example:

```
=> ALTER NODE v_mart_node5 STANDBY;
```

Replace a node with an active standby node

A failed node on an Enterprise Mode database can be replaced with an active standby node automatically, or manually.

Important

A node must be down before it can be replaced with an active standby node. Attempts to replace a node that is up return with an error.

Automatic replacement

You can configure automatic replacement of failed nodes with parameter [FailoverToStandbyAfter](#). If enabled, this parameter specifies the length of time that an active standby node waits before taking the place of a failed node. If possible, Vertica selects a standby node from the same fault group as the failed node. Otherwise, Vertica randomly selects an available active standby node.

Manual replacement

As an administrator, you can manually replace a failed node with [ALTER NODE](#):

1. Connect to the database with [Administration Tools](#) or `vsq`.
2. Replace the node with `ALTER NODE...REPLACE`. The `REPLACE` option can specify a standby node. If `REPLACE` is unqualified, then Vertica selects a standby node from the same fault group as the failed node, if one is available; otherwise, it randomly selects an available active standby node.

Revert active standby nodes

When a down node in an Enterprise Mode database is ready for reactivation, you can restore it by reverting its replacement to standby status. You can perform this operation on individual nodes or the entire database, with [ALTER NODE](#) and [ALTER DATABASE](#), respectively:

1. Connect to the database with [Administration Tools](#) or via `vsq`.
2. Revert the standby nodes.

- Individually with `ALTER NODE`:

```
ALTER NODE node-name RESET;
```

- Collectively across the database cluster with `ALTER DATABASE`:

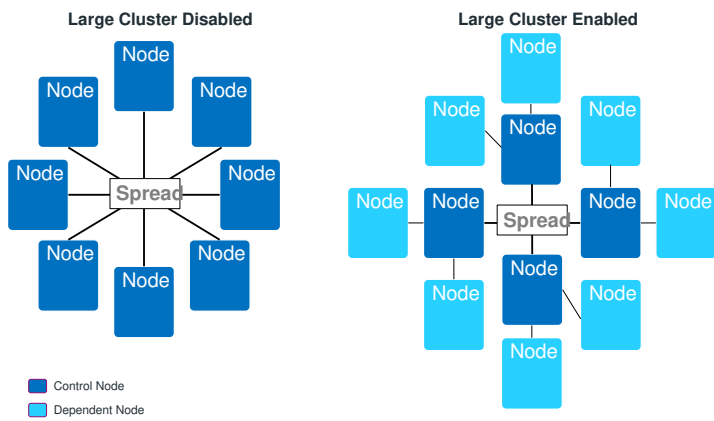

```
ALTER DATABASE DEFAULT RESET STANDBY;
```

If a down node cannot resume operation, Vertica ignores the reset request and leaves the standby node in place.

Large cluster

Vertica uses the Spread service to broadcast control messages between database nodes. This service can limit the growth of a Vertica database cluster. As you increase the number of cluster nodes, the load on the Spread service also increases as more participants exchange messages. This increased load can slow overall cluster performance. Also, network addressing limits the maximum number of participants in the Spread service to 120 (and often far less). In this case, you can use *large cluster* to overcome these Spread limitations.

When large cluster is enabled, a subset of cluster nodes, called *control nodes*, exchange messages using the Spread service. Other nodes in the cluster are assigned to one of these control nodes, and depend on them for cluster-wide communication. Each control node passes messages from the Spread service to its dependent nodes. When a dependent node needs to broadcast a message to other nodes in the cluster, it passes the message to its control node, which in turn sends the message out to its other dependent nodes and the Spread service.

By setting up dependencies between control nodes and other nodes, you can grow the total number of database nodes, and remain in compliance with the Spread limit of 120 nodes.

Note

Technically, when large cluster is disabled, all of the nodes in the cluster are control nodes. In this case, all nodes connect to Spread. When large cluster is enabled, some nodes become dependent on control nodes.

A downside of the large cluster feature is that if a control node fails, its dependent nodes are cut off from the rest of the database cluster. These nodes cannot participate in database activities, and Vertica considers them to be down as well. When the control node recovers, it re-establishes communication between its dependent nodes and the database, so all of the nodes rejoin the cluster.

Note

The Spread service demon runs as an independent process on the control node host. It is not part of the Vertica process. If the Vertica process goes down on the node—for example, you use `admintools` to stop the Vertica process on the host—Spread continues to run. As long as the Spread demon runs on the control node, the node's dependents can communicate with the database cluster and participate in database activity. Normally, the control node only goes down if the node's host has an issue—for example, you shut it down, it becomes disconnected from the network, or a hardware failure occurs.

Large cluster and database growth

When your database has large cluster enabled, Vertica decides whether to make a newly added node into a control or a dependent node as follows:

- In Enterprise Mode, if the number of control nodes configured for the database cluster is greater than the current number of nodes it contains, Vertica makes the new node a control node. In Eon Mode, the number of control nodes is set at the subcluster level. If the number of control nodes set for the subcluster containing the new node is less than this setting, Vertica makes the new node a control node.
- If the Enterprise Mode cluster or Eon Mode subcluster has reached its limit on control nodes, a new node becomes a dependent of an existing control node.

When a newly-added node is a dependent node, Vertica automatically assigns it to a control node. Which control node it chooses is guided by the database mode:

- Enterprise Mode database: Vertica assigns the new node to the control node with the least number of dependents. If you created fault groups in your database, Vertica chooses a control node in the same fault group as the new node. This feature lets you use fault groups to organize control nodes and their dependents to reflect the physical layout of the underlying host hardware. For example, you might want dependent nodes to be in the same rack as their control nodes. Otherwise, a failure that affects the entire rack (such as a power supply failure) will not only cause nodes in the rack to go down, but also nodes in other racks whose control node is in the affected rack. See [Fault groups](#) for more information.
- Eon Mode database: Vertica always adds new nodes to a subcluster. Vertica assigns the new node to the control node with the fewest dependent nodes in that subcluster. Every subcluster in an Eon Mode database with large cluster enabled has at least one control node. Keeping dependent nodes in the same subcluster as their control node maintains subcluster isolation.

Important

In versions of Vertica prior to 10.0.1, nodes in an Eon Mode database with large cluster enabled were not necessarily assigned a control node in their subcluster. If you have upgraded your Eon Mode database from a version of Vertica earlier than 10.0.1 and have large cluster enabled, realign the control nodes in your database. This process reassigns dependent nodes and fixes any cross-subcluster control node dependencies. See [Realigning Control Nodes and Reloading Spread](#) for more information.

Spread's upper limit of 120 participants can cause errors when adding a subcluster to an Eon Mode database. If your database cluster has 120 control nodes, attempting to create a subcluster fails with an error. Every subcluster must have at least one control node. When your cluster has 120 control nodes, Vertica cannot create a control node for the new subcluster. If this error occurs, you must reduce the number of control nodes in your database cluster before adding a subcluster.

When to enable large cluster

Vertica automatically enables large cluster in two cases:

- The database cluster contains 120 or more nodes. This is true for both Enterprise Mode and Eon Mode.
- You create an Eon Mode [subcluster](#) (either a [primary subcluster](#) or a [secondary subcluster](#)) with an initial node count of 16 or more. Vertica does not automatically enable large cluster if you expand an existing subcluster to 16 or more nodes by adding nodes to it.

Note

You can prevent Vertica from automatically enabling large cluster when you create a subcluster with 16 or more nodes by setting the `control-set-size` parameter to `-1`. See [Creating subclusters](#) for details.

You can choose to manually enable large cluster mode before Vertica automatically enables it. Your best practice is to enable large cluster when your database cluster size reaches a threshold:

- For cloud-based databases, enable large cluster when the cluster contains 16 or more nodes. In a cloud environment, your database uses point-to-point network communications. Spread scales poorly in point-to-point communications mode. Enabling large cluster when the database cluster reaches 16 nodes helps limit the impact caused by Spread being in point-to-point mode.
- For on-premises databases, enable large cluster when the cluster reaches 50 to 80 nodes. Spread scales better in an on-premises environment. However, by the time the cluster size reaches 50 to 80 nodes, Spread may begin exhibiting performance issues.

In either cloud or on-premises environments, enable large cluster if you begin to notice Spread-related performance issues. Symptoms of Spread performance issues include:

- The load on the spread service begins to cause performance issues. Because Vertica uses Spread for cluster-wide control messages, Spread performance issues can adversely affect database performance. This is particularly true for cloud-based databases, where Spread performance problems becomes a bottleneck sooner, due to the nature of network broadcasting in the cloud infrastructure. In on-premises databases, broadcast messages are usually less of a concern because messages usually remain within the local subnet. Even so, eventually, Spread usually becomes a bottleneck before Vertica automatically enables large cluster automatically when the cluster reaches 120 nodes.
- The compressed list of addresses in your cluster is too large to fit in a maximum transmission unit (MTU) packet (1478 bytes). The MTU packet has to contain all of the addresses for the nodes participating in the Spread service. Under ideal circumstances (when your nodes have the IP addresses 1.1.1.1, 1.1.1.2 and so on) 120 addresses can fit in this packet. This is why Vertica automatically enables large cluster if your database cluster reaches 120 nodes. In practice, the compressed list of IP addresses will reach the MTU packet size limit at 50 to 80 nodes.

In this section

- [Planning a large cluster](#)
- [Enabling large cluster](#)
- [Changing the number of control nodes and realigning](#)
- [Monitoring large clusters](#)

Planning a large cluster

There are two factors you should consider when planning to expand your database cluster to the point that it needs to use large cluster:

- How many control nodes should your database cluster have?
- How should those control nodes be distributed?

Determining the number of control nodes

When you manually enable large cluster or add enough nodes to trigger Vertica to enable it automatically, a subset of the cluster nodes become control nodes. In subclusters with fewer than 16 nodes, all nodes are control nodes. In many cases, you can set the number of control nodes to the square root of the total number of nodes in the entire Enterprise Mode cluster, or in Eon Mode subclusters with more than 16 nodes. However, this formula for calculating the number of control is not guaranteed to always meet your requirements.

When choosing the number of control nodes in a database cluster, you must balance two competing considerations:

- If a control node fails or is shut down, all nodes that depend on it are cut off from the database. They are also down until the control node rejoins the database. You can reduce the impact of a control node failure by increasing the number of control nodes in your cluster.

- The more control nodes in your cluster, the greater the load on the spread service. In cloud environments, increased complexity of the network environment broadcast can contribute to high latency. This latency can cause messages sent over the spread service to take longer to reach all of the nodes in the cluster.

In a cloud environment, experience has shown that 16 control nodes balances the needs of reliability and performance. In an Eon Mode database, you must have at least one control node per subcluster. Therefore, if you have more than 16 subclusters, you must have more than 16 control nodes.

In an Eon Mode database, whether on-premises or in the cloud, consider adding more control nodes to your primary subclusters than to secondary subclusters. Only nodes in primary subclusters are responsible for [maintaining K-safety](#) in an Eon Mode database. Therefore, a control node failure in a primary subcluster can have greater impact on your database than a control node failure in a secondary subcluster.

In an on-premises Enterprise Mode database, consider the physical layout of the hosts running your database when choosing the number of control nodes. If your hosts are spread across multiple server racks, you want to have enough control nodes to distribute them across the racks. Distributing the control nodes helps ensure reliability in the case of a failure that involves the entire rack (such as a power supply or network switch failure). You can configure your database so no node depends on a control node that is in a separate rack. Limiting dependency to within a rack prevents a failure that affects an entire rack from causing additional node loss outside the rack due to control node loss.

Selecting the number of control nodes based on the physical layout also lets you reduce network traffic across switches. By having dependent nodes on the same racks as their control nodes, the communications between them remain in the rack, rather than traversing a network switch.

You might need to increase the number of control nodes to evenly distribute them across your racks. For example, on-premises Enterprise Mode database has 64 total nodes, spread across three racks. The square root of the number of nodes yields 8 control nodes for this cluster. However, you cannot evenly distribute eight control nodes among the three racks. Instead, you can have 9 control nodes and evenly distribute three control nodes per rack.

Influencing control node placement

After you determine the number of nodes for your cluster, you need to determine how to distribute them among the cluster nodes. Vertica chooses which nodes become control nodes. You can influence how Vertica chooses the control nodes and which nodes become their dependents. The exact process you use depends on your database's mode:

- Enterprise Mode on-premises database: Define fault groups to influence control node placement. Dependent nodes are always in the same fault group as their control node. You usually define fault groups that reflect the physical layout of the hosts running your database. For example, you usually define one or more fault groups for the nodes in a single rack of servers. When the fault groups reflect your physical layout, Vertica places control nodes and dependents in a way that can limit the impact of rack failures. See [Fault groups](#) for more information.
- Eon Mode database: Use subclusters to control the placement of control nodes. Each subcluster must have at least one control node. Dependent nodes are always in the same subcluster as their control nodes. You can set the number of control nodes for each subcluster. Doing so lets you assign more control nodes to primary subclusters, where it's important to minimize the impact of a control node failure.

How Vertica chooses a default number of control nodes

Vertica can automatically choose the number of control nodes in the entire cluster (when in Enterprise Mode) or for a subcluster (when in Eon Mode). It sets a default value in these circumstances:

- When you pass the `default` keyword to the `--large-cluster` option of the `install_vertica` script (see [Enable Large Cluster When Installing Vertica](#)).
- Vertica automatically enables large cluster when your database cluster grows to 120 or more nodes.
- Vertica automatically enables large cluster for an Eon Mode subcluster if you create it with more than 16 nodes. Note that Vertica does not enable large cluster on a subcluster you expand past the 16 node limit. It only enables large clusters that start out larger than 16 nodes.

The number of control nodes Vertica chooses depends on what triggered Vertica to set the value.

If you pass the `--large-cluster default` option to the `install_vertica` script, Vertica sets the number of control nodes to the square root of the number of nodes in the initial cluster.

If your database cluster reaches 120 nodes, Vertica enables large cluster by making any newly-added nodes into dependents. The default value for the limit on the number of control nodes is 120. When you reach this limit, any newly-added nodes are added as dependents. For example, suppose you have a 115 node Enterprise Mode database cluster where you have not manually enabled large cluster. If you add 10 nodes to this cluster, Vertica adds 5 of the nodes as control nodes (bringing you up to the 120-node limit) and the other 5 nodes as dependents.

Important

You should manually enable large cluster before your database reaches 120 nodes.

In an Eon Mode database, each subcluster has its own setting for the number of control nodes. Vertica only automatically sets the number of control nodes when you create a subcluster with more than 16 nodes initially. When this occurs, Vertica sets the number of control nodes for the subcluster to the square root of the number of nodes in the subcluster.

For example, suppose you add a new subcluster with 25 nodes in it. This subcluster starts with more than the 16 node limit, so Vertica sets the number of control nodes for subcluster to 5 (which is the square root of 25). Five of the nodes are added as control nodes, and the remaining 20 are added as dependents of those five nodes.

Even though each subcluster has its own setting for the number of control nodes, an Eon Mode database cluster still has the 120 node limit on the total number of control nodes that it can have.

Enabling large cluster

Vertica enables the large cluster feature automatically when:

- The total number of nodes in the database cluster exceeds 120.
- You create an Eon Mode subcluster with more than 16 nodes.

In most cases, you should consider manually enabling large cluster before your cluster size reaches either of these thresholds. See [Planning a large cluster](#) for guidance on when to enable large cluster.

You can enable large cluster on a [new Vertica database](#), or on [an existing database](#).

Enable large cluster when installing Vertica

You can enable large cluster when installing Vertica onto a new database cluster. This option is useful if you know from the beginning that your database will benefit from large cluster.

The [install_vertica](#) script's `--large-cluster` argument enables large cluster during installation. It takes a single integer value between 1 and 120 that specifies the number of control nodes to create in the new database cluster. Alternatively, this option can take the literal argument `default`. In this case, Vertica enables large cluster mode and sets the number of control nodes to the square root of the number nodes you provide in the `--hosts` argument. For example, if `--hosts` specifies 25 hosts and `--large-cluster` is set to `default`, the install script creates a database cluster with 5 control nodes.

The `--large-cluster` argument has a slightly different effect depending on the database mode you choose when creating your database:

- Enterprise Mode: `--large-cluster` sets the total number of control nodes for the entire database cluster.
- Eon Mode: `--large-cluster` sets the number of control nodes in the initial [default subcluster](#). This setting has no effect on [subclusters](#) that you create later.

Note

You cannot use `--large-cluster` to set the number of control nodes in your initial database to be higher than the number of you pass in the `--hosts` argument. The installer sets the number of control nodes to whichever is the lower value: the value you pass to the `--large-cluster` option or the number of hosts in the `--hosts` option.

You can set the number of control nodes to be higher than the number of nodes currently in an existing database, with the meta-function [SET_CONTROL_SET_SIZE](#) function. You choose to set a higher number to preallocate control nodes when planning for future expansion. For details, see [Changing the number of control nodes and realigning](#).

After the installation process completes, use the [Administration tools](#) or the `[%=Vertica.MC%]` to create a database. See [Create an empty database](#) for details.

If your database is on-premises and running in Enterprise Mode, you usually want to define fault groups that reflect the physical layout of your hosts. They let you define which hosts are in the same server racks, and are dependent on the same infrastructure (such power supplies and network switches). With this knowledge, Vertica can realign the control nodes to make your database better able to cope with hardware failures. See [Fault groups](#) for more information.

After creating a database, any nodes that you add are, by default, dependent nodes. You can [change the number of control nodes](#) in the database with the meta-function [SET_CONTROL_SET_SIZE](#).

Enable large cluster in an existing database

You can manually enable large cluster in an existing database. You usually choose to enable large cluster manually before your database reaches the point where Vertica automatically enables it. See [When To Enable Large Cluster](#) for an explanation of when you should consider enabling large cluster.

Use the meta-function [SET_CONTROL_SET_SIZE](#) to enable large cluster and [set the number of control nodes](#). You pass this function an integer value that sets the number of control nodes in the entire Enterprise Mode cluster, or in an Eon Mode subcluster.

Changing the number of control nodes and realigning

You can change the number of control nodes in the entire database cluster in Enterprise Mode, or the number of control nodes in a subcluster in Eon Mode. You may choose to change the number of control nodes in a cluster or subcluster to reduce the impact of control node loss on your database. See [Planning a large cluster](#) to learn more about when you should change the number of control nodes in your database.

You change the number of control nodes by calling the meta-function [SET_CONTROL_SET_SIZE](#). If large cluster was not enabled before the call to `SET_CONTROL_SET_SIZE`, the function enables large cluster in your database. See [Enabling large cluster](#) for more information.

When you call `SET_CONTROL_SET_SIZE` in an Enterprise Mode database, it sets the number of control nodes in the entire database cluster. In an Eon Mode database, you must supply `SET_CONTROL_SET_SIZE` with the name of a subcluster in addition to the number of control nodes. The function sets the number of control nodes for that subcluster. Other subclusters in the database cluster are unaffected by this call.

Before changing the number of control nodes in an Eon Mode subcluster, verify that the subcluster is running. Changing the number of control nodes of a subcluster while it is down can cause configuration issues that prevent nodes in the subcluster from starting.

Note

You can set the number of control nodes to a value that is higher than the number of nodes currently in the cluster or subcluster. When the number of control nodes is higher than the current node count, newly-added nodes become control nodes until the number of nodes in the cluster or subcluster reaches the number control nodes you set.

You may choose to set the number of control nodes higher than the current node count to plan for future expansion. For example, suppose you have a 4-node subcluster in an Eon Mode database that you plan to expand in the future. You determine that you want limit the number of control nodes in this cluster to 8, even if you expand it beyond that size. In this case, you can choose to set the control node size for the subcluster to 8 now. As you add new nodes to the subcluster, they become control nodes until the size of the subcluster reaches 8. After that point, Vertica assigns newly-added nodes as a dependent of an existing control node in the subcluster.

Realigning control nodes and reloading spread

After you call the `SET_CONTROL_SET_SIZE` function, there are several additional steps you must take before the new setting takes effect.

Important

Follow these steps if you have upgraded your large-cluster enabled Eon Mode database from a version prior to 10.0.1. Earlier versions of Vertica did not restrict control node assignments to be within the same subcluster. When you realign the control nodes after an upgrade, Vertica configures each subcluster to have at least one control node, and assigns nodes to a control node in their own subcluster.

1. Call the [REALIGN_CONTROL_NODES](#) function. This function tells Vertica to re-evaluate the assignment of control nodes and their dependents in your cluster or subcluster. When calling this function in an Eon Mode database, you must supply the name of the subcluster where you changed the control node settings.
2. Call the [RELOAD_SPREAD](#) function. This function updates the control node assignment information in configuration files and triggers Spread to reload.
3. Restart the nodes affected by the change in control nodes. In an Enterprise Mode database, you must restart the entire database to ensure all nodes have updated configuration information. In Eon Mode, restart the subcluster or subclusters affected by your changes. You must restart the entire Eon Mode database if you changed a critical subcluster (such as the only [primary subcluster](#)).

Note

You do not need to restart nodes if the earlier steps didn't change control node assignments. This case usually only happens when you set the number of control nodes in an Eon Mode subcluster to higher than the subcluster's current node count, and all nodes in the subcluster are already control nodes. In this case, no control nodes are added or removed, so node dependencies do not change. Because the dependencies did not change, the nodes do not need to reload the Spread configuration.

4. In an Enterprise Mode database, call [START_REBALANCE_CLUSTER](#) to rebalance the cluster. This process improves your database's fault tolerance by shifting buddy projection assignments to limit the impact of a control node failure. You do not need to take this step in an Eon Mode database.

Enterprise Mode example

The following example makes 4 out of the 8 nodes in an Enterprise Mode database into control nodes. It queries the [LARGE_CLUSTER_CONFIGURATION_STATUS](#) system table which shows control node assignments for each node in the database. At the start, all nodes are their own control nodes. See [Monitoring large clusters](#) for more information the system tables associated with large cluster.

```
=> SELECT * FROM V_CATALOG.LARGE_CLUSTER_CONFIGURATION_STATUS;
```

```
node_name | spread_host_name | control_node_name
-----+-----+-----
v_vmart_node0001 | v_vmart_node0001 | v_vmart_node0001
v_vmart_node0002 | v_vmart_node0002 | v_vmart_node0002
v_vmart_node0003 | v_vmart_node0003 | v_vmart_node0003
v_vmart_node0004 | v_vmart_node0004 | v_vmart_node0004
v_vmart_node0005 | v_vmart_node0005 | v_vmart_node0005
v_vmart_node0006 | v_vmart_node0006 | v_vmart_node0006
v_vmart_node0007 | v_vmart_node0007 | v_vmart_node0007
v_vmart_node0008 | v_vmart_node0008 | v_vmart_node0008
(8 rows)
```

```
=> SELECT SET_CONTROL_SET_SIZE(4);
SET_CONTROL_SET_SIZE
```

```
Control size set
(1 row)
```

```
=> SELECT REALIGN_CONTROL_NODES();
REALIGN_CONTROL_NODES
```

The new control node assignments can be viewed in vs_nodes.
Check vs_cluster_layout to see the proposed new layout. Reboot
all the nodes and call rebalance_cluster now

```
(1 row)
```

```
=> SELECT RELOAD_SPREAD(true);
RELOAD_SPREAD
```

```
Reloaded
(1 row)
```

```
=> SELECT SHUTDOWN();
```

After restarting the database, the final step is to rebalance the cluster and query the LARGE_CLUSTER_CONFIGURATION_STATUS table to see the current control node assignments:

```
=> SELECT START_REBALANCE_CLUSTER();
START_REBALANCE_CLUSTER
```

```
REBALANCING
(1 row)
```

```
=> SELECT * FROM V_CATALOG.LARGE_CLUSTER_CONFIGURATION_STATUS;
node_name | spread_host_name | control_node_name
```

```

v_vmart_node0006 | v_vmart_node0002 | v_vmart_node0002
v_vmart_node0007 | v_vmart_node0003 | v_vmart_node0003
v_vmart_node0008 | v_vmart_node0004 | v_vmart_node0004
(8 rows)
```

Eon Mode example

The following example configures 4 control nodes in an 8-node secondary subcluster named analytics. The primary subcluster is not changed. The primary differences between this example and the previous Enterprise Mode example is the need to specify a subcluster when calling SET_CONTROL_SET_SIZE, not having to restart the entire database, and not having to call START_REBALANCE_CLUSTER.

```
=> SELECT * FROM V_CATALOG.LARGE_CLUSTER_CONFIGURATION_STATUS;
```

node_name	spread_host_name	control_node_name
v_verticadb_node0001	v_verticadb_node0001	v_verticadb_node0001

v_verticadb_node0010	v_verticadb_node0010	v_verticadb_node0010
v_verticadb_node0011	v_verticadb_node0011	v_verticadb_node0011

(11 rows)

```
=> SELECT subcluster_name,node_name,is_primary,control_set_size FROM
V_CATALOG.SUBCLUSTERS;
```

subcluster_name	node_name	is_primary	control_set_size
default_subcluster	v_verticadb_node0001	t	-1
default_subcluster	v_verticadb_node0002	t	-1
default_subcluster	v_verticadb_node0003	t	-1
analytics	v_verticadb_node0004	f	-1
analytics	v_verticadb_node0005	f	-1
analytics	v_verticadb_node0006	f	-1
analytics	v_verticadb_node0007	f	-1
analytics	v_verticadb_node0008	f	-1
analytics	v_verticadb_node0009	f	-1
analytics	v_verticadb_node0010	f	-1
analytics	v_verticadb_node0011	f	-1

(11 rows)

```
=> SELECT SET_CONTROL_SET_SIZE('analytics',4);
SET_CONTROL_SET_SIZE
```

Control size set
(1 row)

```
=> SELECT REALIGN_CONTROL_NODES('analytics');
REALIGN_CONTROL_NODES
```

The new control node assignments can be viewed in vs_nodes. Call reload_spread(true). If the subcluster is critical, restart the database. Otherwise, restart the subcluster

(1 row)

```
=> SELECT RELOAD_SPREAD(true);
RELOAD_SPREAD
```

Reloaded
(1 row)

At this point, the analytics subcluster needs to restart. You have several options to restart it. See [Starting and stopping subclusters](#) for details. This example uses the admintools command line to stop and start the subcluster.

```
$ admintools -t stop_subcluster -d verticadb -c analytics -p password
```

```
*** Forcing subcluster shutdown ***

Disabling large cluster

To disable large cluster, call SET_CONTROL_SET_SIZE with a value of -1. This value is the default for non-large cluster databases. It tells Vertica to make all nodes into control nodes.

In an Eon Mode database, to fully disable large cluster you must to set the number of control nodes to -1 in every subcluster that has a set number of control nodes. You can see which subclusters have a set number of control nodes by querying the CONTROL_SET_SIZE column of the [V_CATALOG.SUBCLUSTERS](#) system table.

The following example resets the number of control nodes set in the previous Eon Mode example.

```
=> SELECT subcluster_name,node_name,is_primary,control_set_size FROM subclusters;
subcluster_name | node_name | is_primary | control_set_size
-----+-----+-----+-----
default_subcluster | v_verticadb_node0001 | t | -1
default_subcluster | v_verticadb_node0002 | t | -1
default_subcluster | v_verticadb_node0003 | t | -1
analytics | v_verticadb_node0004 | f | 4
analytics | v_verticadb_node0005 | f | 4
analytics | v_verticadb_node0006 | f | 4
analytics | v_verticadb_node0007 | f | 4

```

Monitoring large clusters

Monitor large cluster traits by querying the following system tables:

- [V_CATALOG.LARGE_CLUSTER_CONFIGURATION_STATUS](#)—Shows the current spread hosts and the control designations in the catalog so you can see if they match.
- [V_MONITOR.CRITICAL_HOSTS](#)—Lists the hosts whose failure would cause the database to become unsafe and force a shutdown.

The `CRITICAL_HOSTS` view is especially useful for large cluster arrangements. For non-large clusters, query the [CRITICAL_NODES](#) table.

- In an Eon Mode database, the `CONTROL_SET_SIZE` column of the [V_CATALOG.SUBCLUSTERS](#) system table shows the number of control nodes set for each subcluster.

You might also want to query the following system tables:

- [V_CATALOG.FAULT_GROUPS](#)—Shows fault groups and their hierarchy in the cluster.
- [V_CATALOG.CLUSTER_LAYOUT](#)—Shows the relative position of the actual arrangement of the nodes participating in the database cluster and the fault groups that affect them.

Multiple databases on a cluster

Vertica allows you to manage your database workloads by running multiple databases on a single cluster. However, databases cannot share the same node while running.

Example

If you have an 8-node cluster, with database 1 running on nodes 1, 2, 3, 4 and database 2 running on nodes 5, 6, 7, 8, you cannot create a new database in this cluster because all nodes are occupied. But if you stop database 1, you can create a database 3 using nodes 1, 2, 3, 4. Or if you stop both databases 1 and 2, you can create a database 3 using nodes 3, 4, 5, 6. In this latter case, database 1 and database 2 cannot be restarted unless you stop database 3, as they occupy the same nodes.

Fault groups

Note

You cannot create fault groups for an Eon Mode database. Rather, Vertica automatically creates fault groups on a large cluster Eon database; these fault groups are configured around the control nodes and their dependents of each subcluster. These fault groups are managed internally by Vertica and are not accessible to users.

Fault groups let you configure an Enterprise Mode database for your physical cluster layout. Sharing your cluster topology lets you use [terrace routing](#) to reduce the buffer requirements of large queries. It also helps to minimize the risk of correlated failures inherent in your environment, usually caused by shared resources.

Vertica automatically creates fault groups around control nodes (servers that run [spread](#)) in large cluster arrangements, placing nodes that share a control node in the same fault group. Automatic and user-defined fault groups do not include ephemeral nodes because such nodes hold no data.

Consider defining your own fault groups specific to your cluster's physical layout if you want to:

- Use terrace routing to reduce the buffer requirements of large queries.
- Reduce the risk of correlated failures. For example, by defining your rack layout, Vertica can better tolerate a rack failure.
- Influence the placement of control nodes in the cluster.

Vertica supports complex, hierarchical fault groups of different shapes and sizes. The database platform provides a fault group script (DDL generator), SQL statements, system tables, and other monitoring tools.

See [High availability with fault groups](#) for an overview of fault groups with a cluster topology example.

In this section

- [About the fault group script](#)
- [Creating a fault group input file](#)
- [Creating fault groups](#)
- [Monitoring fault groups](#)
- [Dropping fault groups](#)

About the fault group script

To help you define fault groups on your cluster, Vertica provides a script named `fault_group_ddl_generator.py` in the `/opt/vertica/scripts` directory. This script generates the SQL statements you need to run to create fault groups.

The `fault_group_ddl_generator.py` script does not create fault groups for you, but you can copy the output to a file. Then, when you run the helper script, you can use `\i` or `vsqL-f` commands to pass the cluster topology to Vertica.

The fault group script takes the following arguments:

- The database name
- The fault group input file

For example:

```
$ python /opt/vertica/scripts/fault_group_ddl_generator.py VMartdb fault_grp_input.out
```

See also

- [Creating a fault group input file](#)
- [Creating fault groups](#)
- [Dropping fault groups](#)
- [Monitoring fault groups](#)
- [Fault groups](#)

Creating a fault group input file

Use a text editor to create a fault group input file for the targeted cluster.

The following example shows how you can create a fault group input file for a cluster that has 8 racks with 8 nodes on each rack—for a total of 64 nodes in the cluster.

1. On the first line of the file, list the parent (top-level) fault groups, delimited by spaces.

```
rack1 rack2 rack3 rack4 rack5 rack6 rack7 rack8
```

2. On the subsequent lines, list the parent fault group followed by an equals sign (=). After the equals sign, list the nodes or fault groups delimited by spaces.

```
<parent> = <child_1> <child_2> <child_n...>
```

Such as:

```
rack1 = v_vmart_node0001 v_vmart_node0002 v_vmart_node0003 v_vmart_node0004
rack2 = v_vmart_node0005 v_vmart_node0006 v_vmart_node0007 v_vmart_node0008
rack3 = v_vmart_node0009 v_vmart_node0010 v_vmart_node0011 v_vmart_node0012
rack4 = v_vmart_node0013 v_vmart_node0014 v_vmart_node0015 v_vmart_node0016
rack5 = v_vmart_node0017 v_vmart_node0018 v_vmart_node0019 v_vmart_node0020
rack6 = v_vmart_node0021 v_vmart_node0022 v_vmart_node0023 v_vmart_node0024
rack7 = v_vmart_node0025 v_vmart_node0026 v_vmart_node0027 v_vmart_node0028
rack8 = v_vmart_node0029 v_vmart_node0030 v_vmart_node0031 v_vmart_node0032
```

After the first row of parent fault groups, the order in which you write the group descriptions does not matter. All fault groups that you define in this file must refer back to a parent fault group. You can indicate the parent group directly or by specifying the child of a fault group that is the child of a parent fault group.

Such as:

```
rack1 rack2 rack3 rack4 rack5 rack6 rack7 rack8
rack1 = v_vmart_node0001 v_vmart_node0002 v_vmart_node0003 v_vmart_node0004
rack2 = v_vmart_node0005 v_vmart_node0006 v_vmart_node0007 v_vmart_node0008
rack3 = v_vmart_node0009 v_vmart_node0010 v_vmart_node0011 v_vmart_node0012
rack4 = v_vmart_node0013 v_vmart_node0014 v_vmart_node0015 v_vmart_node0016
rack5 = v_vmart_node0017 v_vmart_node0018 v_vmart_node0019 v_vmart_node0020
rack6 = v_vmart_node0021 v_vmart_node0022 v_vmart_node0023 v_vmart_node0024
rack7 = v_vmart_node0025 v_vmart_node0026 v_vmart_node0027 v_vmart_node0028
rack8 = v_vmart_node0029 v_vmart_node0030 v_vmart_node0031 v_vmart_node0032
```

After you create your fault group input file, you are ready to run the `fault_group_ddl_generator.py`. This script generates the DDL statements you need to create fault groups in Vertica.

If your Vertica database is co-located on a Hadoop cluster, and that cluster uses more than one rack, you can use fault groups to improve performance. See [Configuring rack locality](#).

See also

[Creating fault groups](#)

Creating fault groups

When you define fault groups, Vertica distributes data segments across the cluster. This allows the cluster to be aware of your cluster topology so it can tolerate correlated failures inherent in your environment, such as a rack failure. For an overview, see [High Availability With Fault Groups](#).

Important

Defining fault groups requires careful and thorough network planning, and a solid understanding of your network topology.

Prerequisites

To define a fault group, you must have:

- Superuser privileges
- A [fault group input file](#)
- An existing database

Run the fault group script

1. As the database administrator, run the `fault_group_ddl_generator.py` script:

```
python /opt/vertica/scripts/fault_group_ddl_generator.py databasename fault-group-inputfile > sql-filename
```

For example, the following command writes the Python script output to the SQL file `fault_group_ddl.sql`.

```
$ python /opt/vertica/scripts/fault_group_ddl_generator.py  
VMart fault_groups_VMart.out > fault_group_ddl.sql
```

After the script returns, you can run the SQL file, instead of multiple DDL statements individually.

Tip

Consider saving the input file so you can modify fault groups later—for example, after expanding the cluster or changing the distribution of control nodes.

2. Using `vsql`, run the DDL statements in `fault_group_ddl.sql` or execute the commands in the file using `vsql`.

```
=> \i fault_group_ddl.sql
```

3. If large cluster is enabled, realign control nodes with [REALIGN_CONTROL_NODES](#). Otherwise, skip this step.

```
=> SELECT REALIGN_CONTROL_NODES();
```

4. Save cluster changes to the Spread configuration file by calling [RELOAD_SPREAD](#):

```
=> SELECT RELOAD_SPREAD(true);
```

5. Use [Administration tools](#) to restart the database.

6. Save changes to the cluster's data layout by calling [REBALANCE_CLUSTER](#):

```
=> SELECT REBALANCE_CLUSTER();
```

Monitoring fault groups

You can monitor fault groups by querying Vertica system tables or by logging in to the Management Console (MC) interface.

Monitor fault groups using system tables

Use the following system tables to view information about fault groups and cluster vulnerabilities, such as the nodes the cluster cannot lose without the database going down:

- [V_CATALOG.FAULT_GROUPS](#): View the hierarchy of all fault groups in the cluster.
- [V_CATALOG.CLUSTER_LAYOUT](#): Observe the arrangement of the nodes participating in the data business and the fault groups that affect them. Ephemeral nodes do not appear in the cluster layout ring because they hold no data.

Monitoring fault groups using Management Console

An MC administrator can monitor and highlight fault groups of interest by following these steps:

1. Click the running database you want to monitor and click **Manage** in the task bar.
2. Open the **Fault Group View** menu, and select the fault groups you want to view.
3. (Optional) Hide nodes that are not in the selected fault group to focus on fault groups of interest.

Nodes assigned to a fault group each have a colored bubble attached to the upper-left corner of the node icon. Each fault group has a unique color. If the number of fault groups exceeds the number of colors available, MC recycles the colors used previously.

Because Vertica supports complex, hierarchical fault groups of different shapes and sizes, MC displays multiple fault group participation as a stack of different-colored bubbles. The higher bubbles represent a lower-tiered fault group, which means that bubble is closer to the parent fault group, not the child or grandchild fault group.

For more information about fault group hierarchy, see [High Availability With Fault Groups](#).

Dropping fault groups

When you remove a fault group from the cluster, be aware that the drop operation removes the specified fault group and its child fault groups. Vertica places all nodes under the parent of the dropped fault group. To see the current fault group hierarchy in the cluster, query system table [FAULT_GROUPS](#).

Drop a fault group

Use the **DROP FAULT GROUP** statement to remove a fault group from the cluster. The following example shows how you can drop the `group2` fault group:

```
=> DROP FAULT GROUP group2;  
DROP FAULT GROUP
```

Drop all fault groups

Use the **ALTER DATABASE** statement to drop all fault groups, along with any child fault groups, from the specified database cluster.

The following command drops all fault groups from the current database.

```
=> ALTER DATABASE DEFAULT DROP ALL FAULT GROUP;  
ALTER DATABASE
```

Add nodes back to a fault group

To add a node back to a fault group, you must manually reassign it to a new or existing fault group. To do so, use the **CREATE FAULT GROUP** and **ALTER FAULT GROUP..ADD NODE** statements.

Terrace routing

Important

Before you apply terrace routing to your database, be sure you are familiar with [large cluster](#) and [fault groups](#).

Terrace routing can significantly reduce message buffering on a large cluster database. The following sections describe how Vertica implements terrace routing on [Enterprise Mode](#) and [Eon Mode](#) databases.

Terrace routing on Enterprise Mode

Terrace routing on an Enterprise Mode database is implemented through fault groups that define a rack-based topology. In a large cluster with terrace routing disabled, nodes in a Vertica cluster form a fully connected network, where each non-dependent ([control](#)) node sends messages across the database cluster through connections with all other non-dependent nodes, both within and outside its own rack/fault group:

In this case, large Vertica clusters can require many connections on each node, where each connection incurs its own network buffering requirements. The total number of buffers required for each node is calculated as follows:

$$(numRacks * numRackNodes) - 1$$

In a two-rack cluster with 4 nodes per rack as shown above, this resolves to 7 buffers for each node.

With terrace routing enabled, you can considerably reduce large cluster network buffering. Each n th node in a rack/fault group is paired with the corresponding n th node of all other fault groups. For example, with terrace routing enabled, messaging in the same two-rack cluster is now implemented as follows:

Thus, a message that originates from node 2 on rack A (A2) is sent to all other nodes on rack A; each rack A node then conveys the message to its corresponding node on rack B—A1 to B1, A2 to B2, and so on.

With terrace routing enabled, each node of a given rack avoids the overhead of maintaining message buffers to all other nodes. Instead, each node is only responsible for maintaining connections to:

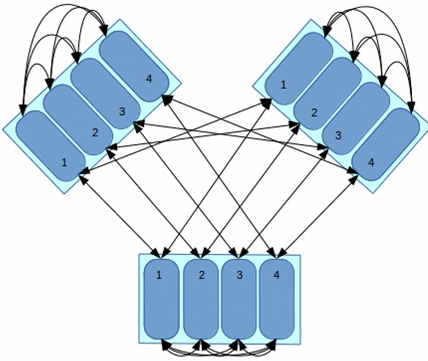

- All other nodes of the same rack ($numRackNodes - 1$)
- One node on each of the other racks ($numRacks - 1$)

Thus, the total number of message buffers required for each node is calculated as follows:

$$(numRackNodes-1) + (numRacks-1)$$

In a two-rack cluster with 4 nodes as shown earlier, this resolves to 4 buffers for each node.

Terrace routing trades time (intra-rack hops) for space (network message buffers). As a cluster expands with additional racks and nodes, the argument favoring this trade off becomes increasingly persuasive:

In this three-rack cluster with 4 nodes per rack, without terrace routing the number of buffers required by each node would be 11. With terrace routing, the number of buffers per node is 5. As a cluster expands with the addition of racks and nodes per rack, the disparity between buffer requirements widens. For example, given a six-rack cluster with 16 nodes per rack, without terrace routing the number of buffers required per node is 95; with terrace routing, 20.

Enabling terrace routing

Terrace routing depends on [fault group definitions](#) that describe a cluster network topology organized around racks and their member nodes. As noted earlier, when terrace routing is enabled, Vertica first distributes data within the rack/fault group; it then uses n th node-to- n th node mappings to forward this data to all other racks in the database cluster.

You enable (or disable) terrace routing for any Enterprise Mode large cluster that implements rack-based fault groups through configuration parameter [TerraceRoutingFactor](#). To enable terrace routing, set this parameter as follows:

$$\text{TerraceRoutingFactor} < \frac{(\text{numRackNodes}-1) + (\text{numRacks}-1)}{(\text{numRacks} * \text{numRackNodes}) - 1}$$

where:

- **numRackNodes** : Number of nodes in a rack
- **numRacks** : Number of racks in the cluster

For example:

#Racks	Nodes/rack	#Connections		Terrace routing enabled if TerraceRoutingFactor less than:
		Without terrace routing	With terrace routing	
2	16	31	16	1.94
4	16	63	18	3.5
6	16	95	20	4.75
8	16	127	22	5.77

By default, TerraceRoutingFactor is set to 2, which generally ensures that terrace routing is enabled for any Enterprise Mode large cluster that implements rack-based fault groups. Vertica recommends enabling terrace routing for any cluster that contains 64 or more nodes, or if queries often require excessive buffer space.

To disable terrace routing, set TerraceRoutingFactor to a large integer such as 1000:

```
=> ALTER DATABASE DEFAULT SET TerraceRoutingFactor = 1000;
```

Terrace routing on Eon Mode

As in Enterprise Mode mode, terrace routing is enabled by default on an Eon Mode database, and is implemented through fault groups. However, you do not create fault groups for an Eon Mode database. Rather, Vertica automatically creates fault groups on a large cluster database; these fault groups are configured around the control nodes and their dependents of each subcluster. These fault groups are managed internally by Vertica and are not

accessible to users.

Elastic cluster

Note

Elastic Cluster is an Enterprise Mode-only feature. For scaling your database under Eon Mode, see [Scaling your Eon Mode database](#).

You can scale your cluster up or down to meet the needs of your database. The most common case is to add nodes to your database cluster to accommodate more data and provide better query performance. However, you can scale down your cluster if you find that it is over-provisioned, or if you need to divert hardware for other uses.

You scale your cluster by adding or removing nodes. Nodes can be added or removed without shutting down or restarting the database. After adding a node or before removing a node, Vertica begins a rebalancing process that moves data around the cluster to populate the new nodes or move data off nodes about to be removed from the database. During this process, nodes can exchange data that are not being added or removed to maintain robust intelligent [K-safety](#). If Vertica determines that the data cannot be rebalanced in a single iteration due to lack of disk space, then the rebalance operation spans multiple iterations.

To help make data rebalancing due to cluster scaling more efficient, Vertica locally segments data storage on each node so it can be easily moved to other nodes in the cluster. When a new node is added to the cluster, existing nodes in the cluster give up some of their data segments to populate the new node. They also exchange segments to minimize the number of nodes that any one node depends upon. This strategy minimizes the number of nodes that might become [critical when a node fails](#). When a node is removed from the cluster, its storage containers are moved to other nodes in the cluster (which also relocates data segments to minimize how many nodes might become critical when a node fails). This method of breaking data into portable segments is referred to as elastic cluster, as it facilitates enlarging or shrinking the cluster.

The alternative to elastic cluster is re-segmenting all projection data and redistributing it evenly among all database nodes any time a node is added or removed. This method requires more processing and more disk space, as it requires all data in all projections to be dumped and reloaded.

Elastic cluster scaling factor

In a new installation, each node has a *scaling factor* that specifies the number of local segments (see [Scaling factor](#)). Rebalance efficiently redistributes data by relocating local segments provided that, after nodes are added or removed, there are sufficient local segments in the cluster to redistribute the data evenly (determined by [MAXIMUM_SKEW_PERCENT](#)). For example, if the scaling factor = 8, and there are initially 5 nodes, then there are a total of 40 local segments cluster-wide.

If you add two additional nodes (seven nodes) Vertica relocates five local segments on two nodes, and six such segments on five nodes, resulting in roughly a 16.7 percent skew. Rebalance relocates local segments only if the resulting skew is less than the allowed threshold, as determined by [MAXIMUM_SKEW_PERCENT](#). Otherwise, segmentation space (and hence data, if uniformly distributed over this space) is evenly distributed among the seven nodes, and new local segment boundaries are drawn for each node, such that each node again has eight local segments.

Note

By default, the scaling factor only has an effect while Vertica rebalances the database. While rebalancing, each node breaks the projection segments it contains into storage containers, which it then moves to other nodes if necessary. After rebalancing, the data is recombined into [ROS](#) containers. It is possible to have Vertica always group data into storage containers. See [Local data segmentation](#) for more information.

Enabling elastic cluster

You enable elastic cluster with [ENABLE_ELASTIC_CLUSTER](#). Query the [ELASTIC_CLUSTER](#) system table to verify that elastic cluster is enabled:

```
=> SELECT is_enabled FROM ELASTIC_CLUSTER;
is_enabled
-----
t
(1 row)
```

In this section

- [Scaling factor](#)
- [Viewing scaling factor settings](#)
- [Setting the scaling factor](#)
- [Local data segmentation](#)
- [Elastic cluster best practices](#)

Scaling factor

To avoid an increased number of ROS containers, do not enable local segmentation and do not change the scaling factor.

Viewing scaling factor settings

To view the scaling factor, query the ELASTIC_CLUSTER table:

```
=> SELECT scaling_factor FROM ELASTIC_CLUSTER;
scaling_factor
-----
         4
(1 row)

=> SELECT SET_SCALING_FACTOR(6);
SET_SCALING_FACTOR
-----
SET
(1 row)

=> SELECT scaling_factor FROM ELASTIC_CLUSTER;
scaling_factor
-----
         6
(1 row)
```

Setting the scaling factor

The scaling factor determines the number of storage containers that Vertica uses to store each projection across the database during rebalancing when local segmentation is enabled. When setting the scaling factor, follow these guidelines:

- The number of storage containers should be greater than or equal to the number of partitions multiplied by the number of local segments:
 $num-storage-containers \geq (num-partitions * num-local-segments)$
- Set the scaling factor high enough so rebalance can transfer local segments to satisfy the skew threshold, but small enough so the number of storage containers does not result in too many ROS containers, and cause [ROS pushback](#). The maximum number of ROS containers (by default 1024) is set by configuration parameter [ContainersPerProjectionLimit](#).

Use the [SET_SCALING_FACTOR](#) function to change your database's scaling factor. The scaling factor can be an integer between 1 and 32.

```
=> SELECT SET_SCALING_FACTOR(12);
SET_SCALING_FACTOR
-----
SET
(1 row)
```

Local data segmentation

By default, the scaling factor only has an effect when Vertica rebalances the database. During rebalancing, nodes break the projection segments they contain into storage containers which they can quickly move to other nodes.

This process is more efficient than re-segmenting the entire projection (in particular, less free disk space is required), but it still has significant overhead, since storage containers have to be separated into local segments, some of which are then transferred to other nodes. This overhead is not a problem if you rarely add or remove nodes from your database.

However, if your database is growing rapidly and is constantly busy, you may find the process of adding nodes becomes disruptive. In this case, you can enable local segmentation, which tells Vertica to always segment its data based on the scaling factor, so the data is always broken into containers that are easily moved. Having the data segmented in this way dramatically speeds up the process of adding or removing nodes, since the data is always in a state that can be quickly relocated to another node. The rebalancing process that Vertica performs after adding or removing a node just has to decide which storage containers to relocate, instead of first having to first break the data into storage containers.

Local data segmentation increases the number of storage containers stored on each node. This is not an issue unless a table contains many partitions. For example, if the table is partitioned by day and contains one or more years. If local data segmentation is enabled, then each of these table partitions is broken into multiple local storage segments, which potentially results in a huge number of files which can lead to ROS "pushback."

Consider your table partitions and the effect enabling local data segmentation may have before enabling the feature.

In this section

- [Enabling and disabling local segmentation](#)

Enabling and disabling local segmentation

To enable local segmentation, use the [ENABLE_LOCAL_SEGMENTS](#) function. To disable local segmentation, use the [DISABLE_LOCAL_SEGMENTATION](#) function:

```
=> SELECT ENABLE_LOCAL_SEGMENTS();
ENABLE_LOCAL_SEGMENTS
-----
ENABLED
(1 row)

=> SELECT is_local_segment_enabled FROM elastic_cluster;
is_enabled
-----
t
(1 row)

=> SELECT DISABLE_LOCAL_SEGMENTS();
DISABLE_LOCAL_SEGMENTS
-----
DISABLED
(1 row)

=> SELECT is_local_segment_enabled FROM ELASTIC_CLUSTER;
is_enabled
-----
f
(1 row)
```

Elastic cluster best practices

The following are some best practices with regard to local segmentation.

Note

You should always perform a database backup before and after performing any of the operations discussed in this topic. You need to back up before changing any elastic cluster or local segmentation settings to guard against a hardware failure causing the rebalance process to leave the database in an unusable state. You should perform a full backup of the database after the rebalance procedure to avoid having to rebalance the database again if you need to restore from a backup.

When to enable local data segmentation

[Local data segmentation](#) can significantly speed up the process of resizing your cluster. You should enable local data segmentation if:

- your database does not contain tables with hundreds of partitions.
- the number of nodes in the database cluster is a power of two.
- you plan to expand or contract the size of your cluster.

Local segmentation can result in an excessive number of storage containers with tables that have hundreds of partitions, or in clusters with a non-power-of-two number of nodes. If your database has these two features, take care when enabling local segmentation.

Adding nodes

There are many reasons to add one or more nodes to a Vertica cluster:

- **Increase system performance or capacity.** Add nodes due to a high query load or load latency, or increase disk space in Enterprise Mode without adding storage locations to existing nodes.

The database response time depends on factors such as type and size of the application query, database design, data size and data types stored, available computational power, and network bandwidth. Adding nodes to a database cluster does not necessarily improve the system response time for every query, especially if the response time is already short or not hardware-bound.

- **Make the database K-safe** ([K-safety](#) =1) or increase K-safety to 2. See [Failure recovery](#) for details.
- **Swap or replace hardware.** Swap out a node to perform maintenance or hardware upgrades.

Important
If you install Vertica on a single node without specifying the IP address or host name (or you used `localhost`), you cannot expand the cluster. You must reinstall Vertica and specify an IP address or host name that is not `localhost/127.0.0.1` .

Adding nodes consists of the following general tasks:

1. [Back up the database](#) .
Vertica strongly recommends that you back up the database before you perform this significant operation because it entails creating new projections, refreshing them, and then deleting the old projections. See [Backing up and restoring the database](#) for more information.
The process of migrating the projection design to include the additional nodes could take a while; however during this time, all user activity on the database can proceed normally, using the old projections.
2. Configure the hosts you want to add to the cluster.
See [Before you Install Vertica](#) . You will also need to edit the hosts configuration file on all of the existing nodes in the cluster to ensure they can resolve the new host.
3. [Add one or more hosts to the cluster](#) .
4. [Add the hosts](#) you added to the cluster (in step 3) to the database.
When you add a host to the database, it becomes a node. You can add nodes to your database using either the [Administration tools](#) or the [Management Console](#) (See [Monitoring with MC](#)). Adding nodes using `admintools` preserves the specific order of the nodes you add.

After you add nodes to the database, Vertica automatically distributes updated configuration files to the rest of the nodes in the cluster and starts the process of rebalancing data in the cluster. See [Rebalancing data across nodes](#) for details.

If you have previously created storage locations using [CREATE LOCATION...ALL NODES](#) , you must create those locations on the new nodes.

In this section

- [Adding hosts to a cluster](#)
- [Adding nodes to a database](#)
- [Add nodes to a cluster in AWS](#)

Adding hosts to a cluster

After you have backed up the database and configured the hosts you want to add to the cluster, you can now add hosts to the cluster using the `update_vertica` script.

You cannot use the MC to add hosts to a cluster in an on-premises environment. However, after the hosts are added to the cluster, the MC does allow you to add the hosts to a database as nodes.

Prerequisites and restrictions

If you installed Vertica on a single node without specifying the IP address or hostname (you used `localhost`), it is not possible to expand the cluster. You must reinstall Vertica and specify an IP address or hostname.

Procedure to add hosts

From one of the existing cluster hosts, run the `update_vertica` script with a minimum of the `--add-hosts host(s)` parameter (where *host(s)* is the hostname or IP address of the system(s) that you are adding to the cluster) and the `--rpm` or `--deb` parameter:

```
# /opt/vertica/sbin/update_vertica --add-hosts host(s) --rpm package
```

Note

See [Install Vertica with the installation script](#) for the full list of parameters. You must also provide the same options you used when originally installing the cluster.

The `update_vertica` ** script uses all the same options as `install_vertica` and:

- Installs the Vertica RPM on the new host.
- Performs post-installation checks, including RPM version and N-way network connectivity checks.

- Modifies spread to encompass the larger cluster.
- Configures the [Administration Tools](#) to work with the larger cluster.

Important Tips:

- Consider using `--large-cluster` with more than 50 nodes.
- A host can be specified by the hostname or IP address of the system you are adding to the cluster. However, internally Vertica stores all host addresses as IP addresses.
- Do not use include spaces in the hostname/IP address list provided with `--add-hosts` if you specified more than one host.
- If a package is specified with `--rpm/--deb`, and that package is newer than the one currently installed on the existing cluster, then, Vertica first installs the new package on the existing cluster hosts before the newly-added hosts.
- Use the same command line parameters for the database administrator username, password, and directory path you used when you installed the cluster originally. Alternatively, you can create a properties file to save the parameters during install and then re-using it on subsequent install and update operations. See [Installing Vertica Silently](#).
- If you are installing using sudo, the database administrator user (dbadmin) must already exist on the hosts you are adding and must be configured with passwords and home directory paths identical to the existing hosts. Vertica sets up passwordless ssh from existing hosts to the new hosts, if needed.
- If you initially used the `--point-to-point` option to configure spread to use direct, point-to-point communication between nodes on the subnet, then use the `--point-to-point` option whenever you run `install_vertica` or `update_vertica`. Otherwise, your cluster's configuration is reverted to the default (`broadcast`), which may impact future databases.
- The maximum number of spread daemons supported in point-to-point communication and broadcast traffic is 80. It is possible to have more than 80 nodes by using large cluster mode, which does not install a spread daemon on each node.

Examples

```
--add-hosts host01 --rpm
--add-hosts 192.168.233.101
--add-hosts host02,host03
```

Adding nodes to a database

After you add one or more hosts to the cluster, you can add them as nodes to the database with one of the following:

- `admintools` command line, to ensure nodes are added in a specific order
- Administration Tools
- Management Console

If you have previously created storage locations using [CREATE LOCATION...ALL NODES](#), you must create those locations on the new nodes.

Command line

With the `admintools db_add_node` tool, you can control the order in which nodes are added to the database cluster. It specifies the hosts of new nodes with its `-s` or `--hosts` option, which takes a comma-delimited argument list. Vertica adds new nodes in the list-specified order. For example, the following command adds three nodes:

```
$ admintools -t db_add_node \
-d VMart \
-p 'password' \
-s 192.0.2.1,192.0.2.2,192.0.2.3
```

Tip

When adding nodes to an Eon Mode database, you can also specify the subcluster that the new nodes should belong to. See [Adding and removing nodes from subclusters](#) for more information.

Administration tools

You add nodes to a database with the Administration Tools as follows:

1. Open the Administration Tools.
2. On the **Main Menu**, select **View Database Cluster State** to verify that the database is running. If it is not, start it.
3. From the **Main Menu**, select **Advanced Menu** and click **OK**.
4. In the **Advanced Menu**, select **Cluster Management** and click **OK**.
5. In the **Cluster Management** menu, select **Add Host(s)** and click **OK**.
6. Select the database to which you want to add one or more hosts, and then select **OK**.

A list of unused hosts is displayed.

7. Select the hosts you want to add to the database and click **OK**.
8. When prompted, click **Yes** to confirm that you want to add the hosts.
9. When prompted, enter the password for the database, and then select **OK**.
10. When prompted that the hosts were successfully added, select **OK**.
11. Vertica now automatically starts the rebalancing process to populate the new node with data. When prompted, enter the path to a temporary directory that the Database Designer can use to rebalance the data in the database and select **OK**.
12. Either press Enter to accept the default [K-safety](#) value, or enter a new higher value for the database and select **OK**.
13. Select whether to [rebalance the database immediately](#), or later. In both cases, Vertica creates a script, which you can use to rebalance at any time. Review the summary of the rebalancing process and select **Proceed**.
If you choose to automatically rebalance, the rebalance process runs. If you chose to create a script, the script is generated and saved. In either case, you are shown a success screen.
14. Select **OK** to complete the Add Node process.

Management Console

To add nodes to an Eon Mode database using MC, see [Add nodes to a cluster in AWS using Management Console](#).

To add hosts to an Enterprise Mode database using MC, see [Adding hosts to a cluster](#)

Add nodes to a cluster in AWS

This section gives an overview on how to add nodes if you are managing your cluster using admintools. Each main step points to another topic with the complete instructions.

Step 1: before you start

Before you add nodes to a cluster, verify that you have an AWS cluster up and running and that you have:

- Created a database.
- Defined a database schema.
- Loaded data.
- Run the Database Designer.
- Connected to your database.

Step 2: launch new instances to add to an existing cluster

Perform the procedure in [Configure and launch an instance](#) to create new instances (hosts) that you then will add to your existing cluster. Be sure to choose the same details you chose when you created the original instances (VPC, placement group, subnet, and security group).

Step 3: include new instances as cluster nodes

You need the IP addresses when you run the `install_vertica` script to include new instances as cluster nodes.

If you are configuring Amazon Elastic Block Store (EBS) volumes, be sure to configure the volumes on the node before you add the node to your cluster.

To add the new instances as nodes to your existing cluster:

1. [Configure and launch your new instances](#).
2. Connect to the instance that is assigned to the Elastic IP. See [Connect to an instance](#) if you need more information.
3. Run the Vertica installation script to add the new instances as nodes to your cluster. Specify the internal IP addresses for your instances and your `*.pem` file name.

```
$ sudo /opt/vertica/sbin/install_vertica --add-hosts instance-ip --dba-user-password-disabled \  
--point-to-point --data-dir /vertica/data --ssh-identity ~/name-of-pem.pem
```

Step 4: add the nodes

After you have added the new instances to your existing cluster, add them as nodes to your cluster, as described in [Adding nodes to a database](#).

Step 5: rebalance the database

After you add nodes to a database, always rebalance the database.

Removing nodes

Although less common than adding a node, permanently removing a node is useful if the host system is obsolete or over-provisioned.

Important

Before removing a node from a cluster, check that the cluster has the minimum number of nodes required to comply with K-safety. If necessary,

[temporarily lower the database K-safety level.](#)

In this section

- [Automatic eviction of unhealthy nodes](#)
- [Lowering K-Safety to enable node removal](#)
- [Removing nodes from a database](#)
- [Removing hosts from a cluster](#)
- [Remove nodes from an AWS cluster](#)

Automatic eviction of unhealthy nodes

To manage the health of the nodes in your cluster, Vertica performs regular health checks by sending and receiving "heartbeats." During a health check, each node in the cluster verifies read-write access to its catalog, catalog disk, and local [storage locations](#) ('TEMP, DATA', TEMP, DATA, and DEPOT). Upon verification, the node sends a heartbeat. If a node fails to send a heartbeat after five intervals (fails five health checks), then the node is evicted from the cluster.

You can control the time between each health check with the DatabaseHeartBeatInterval parameter. By default, DatabaseHeartBeatInterval is set to 120, which allows five 120-second intervals to pass without a heartbeat.

The amount of time allowed before an eviction is:

$$TOT = DHBI * 5$$

where *TOT* is the total time (in seconds) allowed without a heartbeat before eviction, and *DHBI* is equal to the value of DatabaseHeartBeatInterval.

If you set the DatabaseHeartBeatInterval too low, it can cause evictions in cases of brief node health issues. Sometimes, such premature evictions result in lower availability and performance of the Vertica database.

See also

DatabaseHeartbeatInterval in [General parameters](#)

Lowering K-Safety to enable node removal

A database with a K-safety level of 1 requires at least three nodes to operate, and a database with a K-safety level 2 requires at least 5 nodes to operate. You can check the cluster's current K-safety level as follows:

```
=> SELECT current_fault_tolerance FROM system;
current_fault_tolerance
-----
1
(1 row)
```

To remove a node from a cluster with the minimum number of nodes that it requires for K-safety, first lower the K-safety level with [MARK_DESIGN_KSAFE](#).

Caution

Lowering the K-safety level of a database to 0 eliminates Vertica's fault tolerance features. If you must reduce K-safety to 0, first [back up the database](#).

1. Connect to the database with [Administration Tools](#) or [vsqL](#).
2. Call the function [MARK_DESIGN_KSAFE](#) :

```
SELECT MARK_DESIGN_KSAFE(n);
```

where *n* is the new K-safety level for the database.

Removing nodes from a database

Note

In an Eon Mode database, you remove nodes from the subcluster that contains them, rather than from the database. See [Removing Nodes](#) for more information.

As long as there are enough nodes remaining to satisfy the K-Safety requirements, you can remove the node from a database. You cannot drop nodes that are critical for [K-safety](#). See [Lowering K-Safety to enable node removal](#).

You can remove nodes from a database using one of the following:

- Management Console interface
- Administration Tools

Prerequisites

Before removing a node from the database, verify that the database complies with the following requirements:

- It is running.
- It has been [backed up](#).
- The database has the minimum number of nodes required to comply with K-safety. If necessary, [temporarily lower the database K-safety level](#).
- All of the nodes in your database must be either up or in active standby. Vertica reports the error "All nodes must be UP or STANDBY before dropping a node" if you attempt to remove a node while a database node is down. You will get this error, even if you are trying to remove the node that is down.

Management Console

Remove nodes with Management Console from its Manage page:

Remove database nodes as follows:

1. Choose the node to remove.
2. Click **Remove node** in the Node List.

The following restrictions apply:

- You can only remove nodes that belong to the database cluster.
- You cannot remove DOWN nodes.

When you remove a node, its state changes to STANDBY. You can later [add STANDBY nodes back](#) to the database.

Administration tools

To remove unused hosts from the database using Administration Tools:

1. Open the Administration Tools. See [Using the administration tools](#) for information about accessing the Administration Tools.
2. On the Main Menu, select View Database Cluster State to verify that the database is running. If the database is not running, start it.
3. From the Main Menu, choose Advanced Menu and choose OK.
4. In the Advanced menu, choose Cluster Management and choose OK.
5. In the Cluster Management menu, choose Remove Host(s) from Database and choose OK.
6. When warned that you must redesign your database and create projections that exclude the hosts you are going to drop, choose Yes.
7. Select the database from which you want to remove the hosts and choose OK.
A list of currently active hosts appears.
8. Select the hosts you want to remove from the database and choose OK.
9. When prompted, choose OK to confirm that you want to remove the hosts.
10. When informed that the hosts were successfully removed, choose OK.
11. If you removed a host from a [Large Cluster](#) configuration, open a vsql session and run `realign_control_nodes`:

```
SELECT realign_control_nodes();
```

For more details, see [REALIGN_CONTROL_NODES](#).

12. If this host is not used by any other database in the cluster, you can remove the host from the cluster. See [Removing hosts from a cluster](#).

Removing hosts from a cluster

If a host that you removed from the database is not used by any other database, you can remove it from the cluster with `update_vertica`. You can leave the database running during this operation.

When you use `update_vertica` to reduce the size of the cluster, it also performs these tasks:

- Modifies the spread to match the smaller cluster.
- Configures [Administration tools](#) to work with the smaller cluster.

Note

You can use Management Console to [remove hosts from a database](#), but you cannot remove those hosts from a cluster.

From one of the Vertica cluster hosts, run `update_vertica` with the `--remove-hosts` switch. This switch takes an list of comma-separated hosts to remove from the cluster. You can reference hosts by their names or IP addresses. For example, you can remove hosts `host01`, `host02`, and `host03` as follows:

```
# /opt/vertica/sbin/update_vertica --remove-hosts host01,host02,host03 \  
--rpm /tmp/vertica-version.RHEL8.x86_64.rpm \  
--dba-user mydba
```

If `--rpm` specifies a new RPM, then Vertica installs it on the existing cluster hosts before proceeding.

`update_vertica` uses the same options as `install_vertica`. For all options, see [Install Vertica with the installation script](#).

Requirements

- If `-remove-host` s specifies a list of multiple hosts, the list must not embed any spaces between hosts.
- Use the same command line options as in the original installation. If you used non-default values for the database administrator username, password, or directory path, provide the same settings when you remove hosts; otherwise, the procedure fails. Consider saving the original installation options in a properties file that you can reuse on subsequent installation and update operations. See [Install Vertica silently](#).

Remove nodes from an AWS cluster

Use the following procedures to remove instances/nodes from an AWS cluster.

To avoid data loss, Vertica strongly recommends that you back up your database before removing a node. For details, see [Backing up and restoring the database](#).

Remove hosts from the database

Before you remove hosts from the database, verify that you have:

- Backed up the database.
- Lowered the K-safety of the database.

Note

Do not stop the database.

To remove a host from the database:

1. While logged on as `dbadmin`, launch Administration Tools.
`$ /opt/vertica/bin/admintools`
2. From the **Main Menu**, select **Advanced Menu**.
3. From **Advanced Menu**, select **Cluster Management**. Click **OK**.
4. From **Cluster Management**, select **Remove Host(s)**. Click **OK**.
5. From **Select Database**, choose the database from which you plan to remove hosts. Click **OK**.
6. Select the host(s) to remove. Click **OK**.
7. Click **Yes** to confirm removal of the hosts.

Note

Enter a password if necessary. Leave blank if there is no password.

8. Click **OK**. The system displays a message telling you that the hosts have been removed. Automatic rebalancing also occurs.
9. Click **OK** to confirm. Administration Tools brings you back to the **Cluster Management** menu.

Remove nodes from the cluster

To remove nodes from a cluster, run the `update_vertica` script and specify:

- The option `--remove-hosts`, followed by the IP addresses of the nodes you are removing.

- The option `--ssh-identity` , followed by the location and name of your `*pem` file.
- The option `--dba-user-password-disabled` .

The following example removes one node from the cluster:

```
$ sudo /opt/vertica/sbin/update_vertica --remove-hosts 10.0.11.165 --point-to-point \  
--ssh-identity ~/name-of-pem.pem --dba-user-password-disabled
```

Stop the AWS instances

After you have removed one or more nodes from your cluster, to save costs associated with running instances, you can choose to stop the AWS instances that were previously part of your cluster.

To stop an instance in AWS:

1. On AWS, navigate to your **Instances** page.
2. Right-click the instance, and choose **Stop** .

This step is optional because, after you have removed the node from your Vertica cluster, Vertica no longer sees the node as part of the cluster, even though it is still running within AWS.

Replacing nodes

If you have a [K-Safe](#) database, you can replace nodes, as necessary, without bringing the system down. For example, you might want to replace an existing node if you:

- Need to repair an existing host system that no longer functions and restore it to the cluster
- Want to exchange an existing host system for another more powerful system

Note

Vertica does not support replacing a node on a K-safe=0 database. Use the procedures to [add](#) and [remove](#) nodes instead.

The process you use to replace a node depends on whether you are replacing the node with:

- A host that uses the same name and IP address
- A host that uses a different name and IP address
- An active standby node

Prerequisites

- Configure the replacement hosts for Vertica. See [Before you Install Vertica](#) .
- Read the Important **Tips** sections under [Adding hosts to a cluster](#) and [Removing hosts from a cluster](#) .
- Ensure that the database administrator user exists on the new host and is configured identically to the existing hosts. Vertica will setup passwordless ssh as needed.
- Ensure that directories for Catalog Path, Data Path, and any storage locations are added to the database when you create it and/or are mounted correctly on the new host and have read and write access permissions for the database administrator user. Also ensure that there is sufficient disk space.
- Follow the best practice procedure below for introducing the failed hardware back into the cluster to avoid spurious full-node rebuilds.

Best practice for restoring failed hardware

Following this procedure will prevent Vertica from misdiagnosing missing disk or bad mounts as data corruptions, which would result in a time-consuming, full-node recovery.

If a server fails due to hardware issues, for example a bad disk or a failed controller, upon repairing the hardware:

1. Reboot the machine into runlevel 1, which is a root and console-only mode.
Runlevel 1 prevents network connectivity and keeps Vertica from attempting to reconnect to the cluster.
2. In runlevel 1, validate that the hardware has been repaired, the controllers are online, and any RAID recover is able to proceed.

Note

You do not need to initialize RAID recover in runlevel 1; simply validate that it can recover.

3. Once the hardware is confirmed consistent, only then reboot to runlevel 3 or higher.

At this point, the network activates, and Vertica rejoins the cluster and automatically recovers any missing data. Note that, on a single-node database, if any files that were associated with a projection have been deleted or corrupted, Vertica will delete all files associated with that projection, which could result in data loss.

In this section

- [Replacing a host using the same name and IP address](#)
- [Replacing a failed node using a node with a different IP address](#)
- [Replacing a functioning node using a different name and IP address](#)
- [Using the administration tools to replace nodes](#)

Replacing a host using the same name and IP address

If a host of an existing Vertica database is removed you can replace it while the database is running.

Note

Remember a host in Vertica consists of the hardware and operating system on which Vertica software resides, as well as the same network configurations.

You can replace the host with a new host that has the following same characteristics as the old host:

- Name
- IP address
- Operating system
- The OS administrator user
- Directory location

Replacing the host while your database is running prevents system downtime. Before replacing a host, backup your database. See [Backing up and restoring the database](#) for more information.

Replace a host using the same characteristics as follows:

1. Run `install_vertica` from a functioning host using the `--rpm` or `--deb` parameter:

```
$ /opt/vertica/sbin/install_vertica --rpm rpm_package
```

For more information see [Install Vertica using the command line](#).

2. Use Administration Tools from an existing node to restart the new host. See [Restart Vertica on a node](#).

The node automatically joins the database and recovers its data by querying the other nodes in the database. It then transitions to an UP state.

Replacing a failed node using a node with a different IP address

Replacing a failed node with a host system that has a different IP address from the original consists of the following steps:

1. [Back up the database](#).
Vertica recommends that you back up the database before you perform this significant operation because it entails creating new projections, deleting old projections, and reloading data.
2. Add the new host to the cluster. See [Adding hosts to a cluster](#).
3. If Vertica is still running in the node being replaced, then use the Administration Tools to **Stop Vertica on Host** on the host being replaced.
4. Use the Administration Tools to [replace the original host](#) with the new host. If you are using more than one database, replace the original host in all the databases in which it is used. See [Replacing Hosts](#).
5. Use the procedure in [Distributing Configuration Files to the New Host](#) to transfer metadata to the new host.
6. [Remove the host from the cluster](#).
7. Use the Administration Tools to restart Vertica on the host. On the **Main Menu**, select **Restart Vertica on Host**, and click **OK**. See [Starting the database](#) for more information.

Once you have completed this process, the replacement node automatically recovers the data that was stored in the original node by querying other nodes within the database.

Replacing a functioning node using a different name and IP address

Replacing a node with a host system that has a different IP address and host name from the original consists of the following general steps:

1. [Back up the database](#).

Vertica recommends that you back up the database before you perform this significant operation because it entails creating new projections, deleting old projections, and reloading data.

2. [Add the replacement hosts to the cluster](#).

At this point, both the original host that you want to remove and the new replacement host are members of the cluster.

3. Use the Administration Tools to *Stop Vertica on Host* on the host being replaced.

4. Use the Administration Tools to [replace the original host](#) with the new host. If you are using more than one database, replace the original host in all the databases in which it is used. See [Replacing Hosts](#).

5. [Remove the host from the cluster](#).

6. Restart Vertica on the host.

Once you have completed this process, the replacement node automatically recovers the data that was stored in the original node by querying the other nodes within the database. It then transitions to an UP state.

Note

If you do not remove the original host from the cluster and you attempt to restart the database, the host is not invited to join the database because its node address does not match the new address stored in the database catalog. Therefore, it remains in the INITIALIZING state.

Using the administration tools to replace nodes

If you are replacing a node with a host that uses a different name and IP address, use the Administration Tools to replace the original host with the new host. Alternatively, you can [use the Management Console to replace a node](#).

Replace the original host with a new host using the administration tools

To replace the original host with a new host using the Administration Tools:

1. Back up the database. See [Backing up and restoring the database](#).
2. From a node that is up, and is not going to be replaced, open the [Administration tools](#).
3. On the **Main Menu**, select **View Database Cluster State** to verify that the database is running. If it's not running, use the Start Database command on the Main Menu to restart it.
4. On the **Main Menu**, select **Advanced Menu**.
5. In the **Advanced Menu**, select **Stop Vertica on Host**.
6. Select the host you want to replace, and then click **OK** to stop the node.
7. When prompted if you want to stop the host, select **Yes**.
8. In the **Advanced Menu**, select **Cluster Management**, and then click **OK**.
9. In the **Cluster Management** menu, select **Replace Host**, and then click **OK**.
10. Select the database that contains the host you want to replace, and then click **OK**.
A list of all the hosts that are currently being used displays.
11. Select the host you want to replace, and then click **OK**.
12. Select the host you want to use as the replacement, and then click **OK**.
13. When prompted, enter the password for the database, and then click **OK**.
14. When prompted, click **Yes** to confirm that you want to replace the host.
15. When prompted that the host was successfully replaced, click **OK**.
16. In the **Main Menu**, select **View Database Cluster State** to verify that all the hosts are running. You might need to start Vertica on the host you just replaced. Use **Restart Vertica on Host**.
The node enters a RECOVERING state.

Caution

If you are using a [K-Safe](#) database, keep in mind that the recovering node counts as one node down even though it might not yet contain a complete copy of the data. This means that if you have a database in which K safety=1, the current fault tolerance for your database is at a critical level. If you lose one more node, the database shuts down. Be sure that you do not stop any other nodes.

Rebalancing data across nodes

Vertica can rebalance your database when you add or remove nodes. As a superuser, you can manually trigger a rebalance with [Administration Tools](#), [SQL functions](#), or the [Management Console](#).

A rebalance operation can take some time, depending on the cluster size, and the number of projections and the amount of data they contain. You should allow the process to complete uninterrupted. If you must cancel the operation, call [CANCEL_REBALANCE_CLUSTER](#).

Why rebalance?

Rebalancing is useful or even necessary after you perform one of the following operations:

- Change the size of the cluster by adding or removing nodes.
- Mark one or more nodes as ephemeral in preparation of removing them from the cluster.
- Change the [scaling factor](#) of an elastic cluster, which determines the number of storage containers used to store a projection across the database.
- Set the control node size or realign control nodes on a [large cluster](#) layout.
- Specify more than 120 nodes in your initial Vertica cluster configuration.
- Modify a [fault group](#) by adding or removing nodes.

General rebalancing tasks

When you rebalance a database cluster, Vertica performs the following tasks for all projections, segmented and unsegmented alike:

- Distributes data based on:
 - User-defined [fault groups](#), if specified
 - [Large cluster](#) automatic fault groups
- Ignores node-specific distribution specifications in projection definitions. Node rebalancing always distributes data across all nodes.
- When rebalancing is complete, sets the [Ancient History Mark](#) the greatest allowable epoch (now).

Vertica rebalances segmented and unsegmented projections differently, as described below.

Rebalancing segmented projections

For each segmented projection, Vertica performs the following tasks:

1. Copies and renames projection buddies and distributes them evenly across all nodes. The renamed projections share the same base name.
2. Refreshes the new projections.
3. Drops the original projections.

Rebalancing unsegmented projections

For each unsegmented projection, Vertica performs the following tasks:

If adding nodes:

- Creates projection buddies on them.
- Maps the new projections to their shared name in the database catalog.

If dropping nodes : drops the projection buddies from them.

K-safety and rebalancing

Until rebalancing completes, Vertica operates with the existing [K-safe](#) value. After rebalancing completes, Vertica operates with the K-safe value specified during the rebalance operation. The new K-safe value must be equal to or higher than current K-safety. Vertica does not support downgrading K-safety and returns a warning if you try to reduce it from its current value. For more information, see [Lowering K-Safety to enable node removal](#).

Rebalancing failure and projections

If a failure occurs while rebalancing the database, you can rebalance again. If the cause of the failure has been resolved, the rebalance operation continues from where it failed. However, a failed data rebalance can result in projections becoming out of date.

To locate out-of-date projections, query the system table [PROJECTIONS](#) as follows:

```
=> SELECT projection_name, anchor_table_name, is_up_to_date FROM projections
WHERE is_up_to_date = false;
```

To remove out-of-date projections, use [DROP PROJECTION](#).

Temporary tables

Node rebalancing has no effect on projections of temporary tables.

For Detailed Information About Rebalancing

See the [Knowledge Base](#) articles:

- [What Happens During Rebalancing](#)
- [Optimizing for Rebalancing](#)

In this section

- [Rebalancing data using the administration tools UI](#)
- [Rebalancing data using SQL functions](#)

Rebalancing data using the administration tools UI

To rebalance the data in your database:

1. Open the Administration Tools. (See [Using the administration tools.](#))
2. On the **Main Menu** , select **View Database Cluster State** to verify that the database is running. If it is not, start it.
3. From the **Main Menu** , select **Advanced Menu** and click **OK** .
4. In the **Advanced Menu** , select **Cluster Management** and click **OK** .
5. In the **Cluster Management** menu, select **Re-balance Data** and click **OK** .
6. Select the database you want to rebalance, and then select **OK** .
7. Enter the directory for the Database Designer outputs (for example `/tmp`) and click **OK** .
8. Accept the proposed [K-safety](#) value or provide a new value. Valid values are 0 to 2.
9. Review the message and click **Proceed** to begin rebalancing data.

The Database Designer modifies existing projections to rebalance data across all database nodes with the K-safety you provided. A script to rebalance data, which you can run manually at a later time, is also generated and resides in the path you specified; for example `/tmp/extend_catalog_rebalance.sql` .

Important

Rebalancing data can take some time, depending on the number of projections and the amount of data they contain. Vertica recommends that you allow the process to complete. If you must cancel the operation, use Ctrl+C.

The terminal window notifies you when the rebalancing operation is complete.

10. Press **Enter** to return to the Administration Tools.

Rebalancing data using SQL functions

Vertica has three SQL functions for starting and stopping a cluster rebalance. You can call these functions from a script that runs during off-peak hours, rather than manually trigger a rebalance through Administration Tools.

- [REBALANCE_CLUSTER](#) rebalances the database cluster synchronously as a session foreground task.
- [START_REBALANCE_CLUSTER](#) asynchronously rebalances the database cluster as a background task.
- [CANCEL_REBALANCE_CLUSTER](#) stops any rebalance task that is currently in progress or is waiting to execute.

Redistributing configuration files to nodes

The add and remove node processes automatically redistribute the Vertica configuration files. You rarely need to redistribute the configuration files to help resolve configuration issues.

To distribute configuration files to a host:

1. Log on to a host that contains these files and [start Administration Tools](#) .
2. On the Administration Tools **Main Menu** , select **Configuration Menu** and click **OK** .
3. On the **Configuration Menu** , select **Distribute Config Files** and click **OK** .
4. Select **Database Configuration** .
5. Select the database where you want to distribute the files and click **OK** .
Vertica configuration files are distributed to all other database hosts. If the files already existed on a host, they are overwritten.
6. On the **Configuration Menu** , select **Distribute Config Files** and click **OK** .
7. Select **SSL Keys** .
Certifications and keys are distributed to all other database hosts. If they already existed on a host, they are overwritten.
8. On the **Configuration Menu** , select **Distribute Config Files** and click **OK** .
Select **AdminTools Meta-Data** .
Administration Tools metadata is distributed to every host in the cluster.
9. [Restart the database](#) .

Note

To distribute the configuration file `admintools.conf` via the command line or scripts, use the `admintools` option `distribute_config_files` :

```
$ admintools -t distribute_config_files
```

Stopping and starting nodes on MC

You can start and stop one or more database nodes through the **Manage** page by clicking a specific node to select it and then clicking the Start or Stop button in the Node List.

Note

The Stop and Start buttons in the toolbar start and stop the database, not individual nodes.

On the **Databases and Clusters** page, you must click a database first to select it. To stop or start a node on that database, click the **View** button. You'll be directed to the Overview page. Click **Manage** in the applet panel at the bottom of the page and you'll be directed to the database node view.

The Start and Stop database buttons are always active, but the node Start and Stop buttons are active only when one or more nodes of the same status are selected; for example, all nodes are UP or DOWN.

After you click a Start or Stop button, Management Console updates the status and message icons for the nodes or databases you are starting or stopping.

Upgrading your operating system on nodes in your Vertica cluster

If you need to upgrade the operating system on the nodes in your Vertica cluster, check with the documentation for your Linux distribution to make sure they support the particular upgrade you are planning.

For example, the following articles provide information about upgrading Red Hat:

- [How do I upgrade from Red Hat Enterprise Linux 6 to Red Hat Enterprise Linux 7?](#)
- [Upgrading from RHEL 7 to RHEL 8](#)
- [Does Red Hat support upgrades between major versions of Red Hat Enterprise Linux?](#)

After you confirm that you can perform the upgrade, follow the steps at [Best Practices for Upgrading the Operating System on Nodes in a Vertica Cluster](#).

Reconfiguring node messaging

Sometimes, nodes of an existing, operational Vertica database cluster [require new IP addresses](#). Cluster nodes might also need to [change their messaging protocols](#)—for example, from broadcast to point-to-point. The admintools `re_ip` utility performs both tasks.

Note

You cannot change from one address family—IPv4 or IPv6—to another. For example, if hosts in the database cluster are identified by IPv4 network addresses, you can only change host addresses to another set of IPv4 addresses.

Changing IP addresses

You can use `re_ip` to perform two tasks:

- [Update node IP addresses](#)
- [Change node control and broadcast addresses](#)

In both cases, `re_ip` requires a mapping file that identifies the current node IP addresses, which are stored in `admintools.conf`. You can get these addresses in two ways:

- Use the admintools utility `list_allnodes`:

```
$ admintools -t list_allnodes
Node      | Host      | State | Version  | DB
-----+-----+-----+-----+-----
v_vmart_node0001 | 192.0.2.254 | UP   | vertica-12.0.1 | VMart
v_vmart_node0002 | 192.0.2.255 | UP   | vertica-12.0.1 | VMart
v_vmart_node0003 | 192.0.2.256 | UP   | vertica-12.0.1 | VMart
```

Tip

`list_allnodes` can help you identify issues that you might have to access Vertica. For example, if hosts are not communicating with each other,

the **Version** column displays Unavailable.

- Print the content of **admintools.conf** :

```
$ cat /opt/vertica/config/admintools.conf
...
[Cluster]
hosts = 192.0.2.254, 192.0.2.255, 192.0.2.256

[Nodes]
node0001 = 192.0.2.254/home/dbadmin,/home/dbadmin
node0002 = 192.0.2.255/home/dbadmin,/home/dbadmin
node0003 = 192.0.2.256/home/dbadmin,/home/dbadmin
...
```

Update node IP addresses

You can update IP addresses with **re_ip** as described below. **re_ip** automatically backs up **admintools.conf** so you can recover the original settings if necessary.

1. Create a mapping file with lines in the following format:

```
oldIPAddress newIPAddress[, controlAddress, controlBroadcast]
...
```

For example:

```
192.0.2.254 198.51.100.255, 198.51.100.255, 203.0.113.255
192.0.2.255 198.51.100.256, 198.51.100.256, 203.0.113.255
192.0.2.256 198.51.100.257, 198.51.100.257, 203.0.113.255
```

controlAddress and **controlBroadcast** are optional. If omitted:

- **controlAddress** defaults to **newIPAddress** .
- **controlBroadcast** defaults to the host of **newIPAddress** 's broadcast IP address.

2. Stop the database.
3. Run **re_ip** to map old IP addresses to new IP addresses:

```
$ admintools -t re_ip -f mapfile
```

re_ip issues warnings for the following mapping file errors:

- IP addresses are incorrectly formatted.
- Duplicate IP addresses, whether old or new.

If **re_ip** finds no syntax errors, it performs the following tasks:

- Remaps the IP addresses as listed in the mapping file.
- If the **-i** option is omitted, asks to confirm updates to the database.
- Updates required local configuration files with the new IP addresses.
- Distributes the updated configuration files to the hosts using new IP addresses.

For example:

Parsing mapfile...

New settings for Host 192.0.2.254 are:

address: 198.51.100.255

New settings for Host 192.0.2.255 are:

address: 198.51.100.256

New settings for Host 192.0.2.254 are:

address: 198.51.100.257

The following databases would be affected by this tool: Vmart

Checking DB status ...

Enter "yes" to write new settings or "no" to exit > yes

Backing up local admintools.conf ...

Writing new settings to local admintools.conf ...

Writing new settings to the catalogs of database Vmart ...

The change was applied to all nodes.

Success. Change committed on a quorum of nodes.

Initiating admintools.conf distribution ...

Success. Local admintools.conf sent to all hosts in the cluster.

4. Restart the database.

re_ip and export IP address

By default, a node's IP address and its export IP address are identical. For example:

```
=> SELECT node_name, node_address, export_address FROM nodes;
```

```
node_name | node_address | export_address
-----
v_VMartDB_node0001 | 192.168.100.101 | 192.168.100.101
v_VMartDB_node0002 | 192.168.100.102 | 192.168.100.101
v_VMartDB_node0003 | 192.168.100.103 | 192.168.100.101
v_VMartDB_node0004 | 192.168.100.104 | 192.168.100.101
(4 rows)
```

The export address is the IP address of the node on the network. This address provides access to other DBMS systems, and enables you to import and export data across the network.

If node IP and export IP addresses are the same, then running `re_ip` changes both to the new address. Conversely, if you [manually change the export address](#), subsequent `re_ip` operations leave your export address changes untouched.

Change node control and broadcast addresses

You can map IP addresses for the database only, by using the `re_ip` option `-O` (or `--db-only`). Database-only operations are useful for error recovery. The node names and IP addresses that are specified in the mapping file must be the same as the node information in `admintools.conf`. In this case, `admintools.conf` is not updated. Vertica updates only `spread.conf` and the catalog with the changes.

You can also use `re_ip` to change the node control and broadcast addresses. In this case the mapping file must contain the control messaging IP address and associated broadcast address. This task allows nodes on the same host to have different data and control addresses.

1. Create a mapping file with lines in the following format:

```
nodeName nodeIPAddress, controlAddress, controlBroadcast
...
```

Tip

Query the system table `NODES` for node names.

For example:

```
vertica_node001 192.0.2.254, 203.0.113.255, 203.0.113.258
vertica_node002 192.0.2.255, 203.0.113.256, 203.0.113.258
vertica_node003 192.0.2.256, 203.0.113.257, 203.0.113.258
```

2. Stop the database.
3. Run the following command to map the new IP addresses:

```
$ admintools -t re_ip -f mapfile -O -d dbname
```

4. Restart the database.

Changing node messaging protocols

You can use `re_ip` to reconfigure spread messaging between Vertica nodes. `re_ip` configures node messaging to broadcast or point-to-point (unicast) messaging with these options:

- `-U`, `--broadcast` (default)
- `-T`, `--point-to-point`

Both options support up to 80 spread daemons. You can exceed the 80-node limit by using [large cluster](#) mode, which does not install a spread daemon on each node.

For example, to set the database cluster messaging protocol to point-to-point:

```
$ admintools -t re_ip -d dbname -T
```

To set the messaging protocol to broadcast:

```
$ admintools -t re_ip -d dbname -U
```

Setting re_ip timeout

You can configure how long `re_ip` executes a given task before it times out, by editing the setting of `prepare_timeout_sec` in `admintools.conf`. By default, this parameter is set to 7200 (seconds).

In this section

- [re_ip command](#)
- [Restarting a node with new host IPs](#)

re_ip command

Updates database cluster node IP addresses and reconfigures spread messaging between nodes.

Syntax

```
admintools -t re_ip { -h
  | -f mapfile [-O -d dbname]
  | -d dbname { -T | U }
} [-i]
```

Options

Option	Description
<code>-h</code> <code>--help</code>	Displays online help.
<code>-f <i>mapfile</i></code> <code>--file= <i>mapfile</i></code>	Name of the mapping text file used to map old addresses to new ones .
<code>-O</code> <code>--dba-only</code>	Used for error recovery, updates and replaces data on the database cluster catalog and control messaging system. If the mapping file fails, Vertica automatically recreates it when you re-run the command. For details, see Change Node Control and Broadcast Addresses . This option updates only one database at a time, so it requires the <code>-d</code> option.

<p>-T --point-to-point</p>	<p>Sets control messaging to the point-to-point (unicast) protocol. Vertica can change the messaging protocol on only one database at a time, so you must specify the target database with the -d option.</p> <p>Use point-to-point if nodes are not located on the same subnet. Point-to-point supports up to 80 spread daemons. You can exceed the 80-node limit by using large cluster mode, which does not install a spread daemon on each node.</p>
<p>-U --broadcast</p>	<p>Sets control messaging to the broadcast protocol, the default setting. Vertica can change the messaging protocol on only one database at a time, so you must specify the target database with the -d option.</p> <p>Broadcast supports up to 80 spread daemons. You can exceed the 80-node limit by using large cluster mode, which does not install a spread daemon on each node.</p>
<p>-d <i>dbname</i> --database=<i>dbname</i></p>	<p>Database name, required with the following re_ip options:</p> <ul style="list-style-type: none"> • -O • -T • -U
<p>-i --noprompts</p>	<p>System does not prompt to validate new settings before executing the re_ip operation. Prompting is on by default.</p>

Restarting a node with new host IPs

Kubernetes only

Note

For information about remapping node IP addresses on a non-Kubernetes database, see [Reconfiguring node messaging](#).

The node IP addresses of an Eon Mode database on Kubernetes must occasionally be updated—for example, a pod fails, or is added to the cluster or rescheduled. When this happens, you must update the Vertica catalog with the new IP addresses of affected nodes and restart the node.

Note

You cannot switch an existing database cluster from one address family to another. For example, you cannot change the IP addresses of the nodes in your database from IPv4 to IPv6.

Vertica's **restart_node** tool addresses these requirements with its **--new-host-ips** option, which lets you change the node IP addresses of an Eon Mode database running on Kubernetes, and restart the updated nodes. Unlike [remapping node IP addresses](#) on other (non-Kubernetes) databases, you can perform this task on individual nodes in a running database:

```
admintools -t restart_node \
{-d db-name | --database=db-name} [-p password | --password=password] \
{{-s nodes-list | --hosts=nodes-list} --new-host-ips=ip-address-list}
```

- ***nodes-list*** is a comma-delimited list of nodes to restart. All nodes in the list must be down, otherwise admintools returns an error.
- ***ip-address-list*** is a comma-delimited list of new IP addresses or host names to assign to the specified nodes.

Note

Because a host name resolves to an IP address, Vertica recommends that you use the IP address to eliminate unneeded complexity.

The following requirements apply to ***nodes-list*** and ***ip-address-list***:

- The number of node hosts and IP addresses or host names must be the same.
- The lists must not include any embedded spaces.

For example, you can restart node `v_k8s_node0003` with a new IP address:

```
$ admintools -t list_allnodes
Node      | Host      | State | Version  | DB
-----+-----+-----+-----+-----
v_k8s_node0001 | 172.28.1.4 | UP    | vertica-10.1.1 | K8s
v_k8s_node0002 | 172.28.1.5 | UP    | vertica-10.1.1 | K8s
v_k8s_node0003 | 172.28.1.6 | DOWN  | vertica-10.1.1 | K8s

$ admintools -t restart_node -s v_k8s_node0003 --new-host-ips 172.28.1.7 -d K8s
Info: no password specified, using none
*** Updating IP addresses for nodes of database K8s ***

```

Adjusting Spread Daemon timeouts for virtual environments

Vertica relies on [Spread](#) daemons to pass messages between database nodes. Occasionally, nodes fail to respond to messages within the specified Spread timeout. These failures might be caused by spikes in network latency or brief pauses in the node's VM—for example, scheduled [Azure maintenance timeouts](#). In either case, Vertica assumes that the non-responsive nodes are down and starts to remove them from the database, even though they might still be running. You can address this issue by [adjusting the Spread timeout](#) as needed.

Adjusting spread timeout

By default, the Spread timeout depends on the number of configured Spread segments:

Configured Spread segments	Default timeout
1	8 seconds
> 1	25 seconds

Important

If you deploy your Vertica cluster with Azure Marketplace, the default Spread timeout is set to 35 seconds. If you manually create your cluster in Azure, the default Spread timeout is set to 8 or 25 seconds.

If the Spread timeout is likely to elapse before the network or database nodes can respond, increase the timeout to the maximum length of non-responsive time plus five seconds. For example, if Azure memory-preserving maintenance pauses node VMs for up to 30 seconds, set the Spread timeout to 35 seconds.

If you are unsure how long network or node disruptions are liable to last, gradually increase the Spread timeout until fewer instances of UP nodes leave the database.

Important

Vertica cannot react to a node going down or being shut down improperly before the timeout period elapses. Changing Spread's timeout to a value too high can result in longer query restarts if a node goes down.

To see the current setting of the Spread timeout, query system table [SPREAD_STATE](#). For example, the following query shows that the current timeout setting (`token_timeout`) is set to 8000ms:

```
=> SELECT * FROM V_MONITOR.SPREAD_STATE;
 node_name | token_timeout
-----+-----
v_vmart_node0003 |      8000
v_vmart_node0001 |      8000
v_vmart_node0002 |      8000
(3 rows)
```

To change the Spread timeout, call the meta-function [SET_SPREAD_OPTION](#) and set the token timeout to a new value. The following example sets the timeout to 35000ms (35 seconds):

```
=> SELECT SET_SPREAD_OPTION('TokenTimeout', '35000');
NOTICE 9003: Spread has been notified about the change
          SET_SPREAD_OPTION
-----
Spread option 'TokenTimeout' has been set to '35000'.
(1 row)

=> SELECT * FROM V_MONITOR.SPREAD_STATE;
 node_name | token_timeout
-----+-----
v_vmart_node0001 |     35000
v_vmart_node0002 |     35000
v_vmart_node0003 |     35000
(3 rows);
```

Note

Changing Spread settings with `SET_SPREAD_OPTION` has minor impact on your cluster as it pauses while the new settings are propagated across the cluster. Because of this delay, changes to the Spread timeout are not immediately visible in system table [SPREAD_STATE](#).

Azure maintenance and spread timeouts

Azure [scheduled maintenance on virtual machines](#) might pause nodes longer than the Spread timeout period. If so, Vertica is liable to view nodes that do not respond to Spread messages as down and remove them from the database.

The length of Azure maintenance tasks is usually well-defined. For example, memory-preserving updates can pause a VM for up to 30 seconds while performing maintenance on the system hosting the VM. This pause does not disrupt the node, which resumes normal operation after maintenance is complete. To prevent Vertica from removing nodes while they undergo Azure maintenance, [adjust the Spread timeout](#) as needed.

Managing disk space

Vertica detects and reports low disk space conditions in the log file so you can address the issue before serious problems occur. It also detects and reports low disk space conditions via [SNMP traps](#) if enabled.

Critical disk space issues are reported sooner than other issues. For example, running out of catalog space is fatal; therefore, Vertica reports the condition earlier than less critical conditions. To avoid database corruption when the disk space falls beyond a certain threshold, Vertica begins to reject transactions that update the catalog or data.

Caution

A low disk space report indicates one or more hosts are running low on disk space or have a failing disk. It is imperative to add more disk space (or replace a failing disk) as soon as possible.

When Vertica reports a low disk space condition, use the [DISK_RESOURCE_REJECTIONS](#) system table to determine the types of disk space requests that are being rejected and the hosts on which they are being rejected.

To add disk space, see [Adding disk space to a node](#). To replace a failed disk, see [Replacing failed disks](#).

Monitoring disk space usage

You can use these system tables to monitor disk space usage on your cluster:

System table	Description
DISK_STORAGE	Monitors the amount of disk storage used by the database on each node.
COLUMN_STORAGE	Monitors the amount of disk storage used by each column of each projection on each node.
PROJECTION_STORAGE	Monitors the amount of disk storage used by each projection on each node.

In this section

- [Adding disk space to a node](#)
- [Replacing failed disks](#)
- [Catalog and data files](#)
- [Understanding the catalog directory](#)
- [Reclaiming disk space from deleted table data](#)

Adding disk space to a node

This procedure describes how to add disk space to a node in the Vertica cluster.

Note

If you are adding disk space to multiple nodes in the cluster, then use the following procedure for each node, one node at a time.

To add disk space to a node:

1. If you must shut down the hardware to which you are adding disk space, then first shut down Vertica on the host where disk space is being added.
2. Add the new disk to the system as required by the hardware environment. Boot the hardware if it is was shut down.
3. Partition, format, and mount the new disk, as required by the hardware environment.
4. Create a data directory path on the new volume.

For example:

```
mkdir -p /myNewPath/myDB/host01_data2/
```

5. If you shut down the hardware, then restart Vertica on the host.
6. Open a database connection to Vertica and add a [storage location](#) to add the new data directory path. Specify the node in the [CREATE LOCATION](#), otherwise Vertica assumes you are creating the storage location on all nodes.
See [Creating storage locations](#) in this guide and the [CREATE LOCATION](#) statement in the SQL Reference Manual.

Replacing failed disks

If the disk on which the data or catalog directory resides fails, causing full or partial disk loss, perform the following steps:

1. Replace the disk and recreate the data or catalog directory.
2. Distribute the configuration file ([vertica.conf](#)) to the new host. See [Distributing Configuration Files to the New Host](#) for details.

- Restart the Vertica on the host, as described in [Restart Vertica On Host](#).

See [Catalog and data files](#) for information about finding your DATABASE_HOME_DIR.

Catalog and data files

For the recovery process to complete successfully, it is essential that catalog and data files be in the proper directories.

In Vertica, the [catalog](#) is a set of files that contains information (metadata) about the objects in a database, such as the nodes, tables, constraints, and projections. The catalog files are replicated on all nodes in a cluster, while the data files are unique to each node. These files are installed by default in the following directories:

```
/DATABASE_HOME_DIR/DATABASE_NAME/v_db_nodexxxx_catalog/ /DATABASE_HOME_DIR/DATABASE_NAME/v_db_nodexxxx_catalog/
```

Note

DATABASE_HOME_DIR is the path, which you can see from the Administration Tools. See [Using the administration tools](#) in the Administrator's Guide for details on using the interface.

To view the path of your database:

- Run the [Administration tools](#).

```
$ /opt/vertica/bin/admintools
```

- From the Main Menu, select **Configuration Menu** and click **OK**.
- Select **View Database** and click **OK**.
- Select the database you want would like to view and click **OK** to see the database profile.

See [Understanding the catalog directory](#) for an explanation of the contents of the catalog directory.

Understanding the catalog directory

The catalog directory stores metadata and support files for your database. Some of the files within this directory can help you troubleshoot data load or other database issues. See [Catalog and data files](#) for instructions on locating your database's catalog directory. By default, it is located in the database directory. For example, if you created the VMart database in the database administrator's account, the path to the catalog directory is:

```
/home/dbadmin/VMart/v_vmart_nodennnn_catalog
```

where *node nnnn* is the name of the node you are logged into. The name of the catalog directory is unique for each node, although most of the contents of the catalog directory are identical on each node.

The following table explains the files and directories that may appear in the catalog directory.

Note

Do not change or delete any of the files in the catalog directory unless asked to do so by Vertica support.

File or Directory	Description
bootstrap-catalog.log	A log file generated as the Vertica server initially creates the database (in which case, the log file is only created on the node used to create the database) and whenever the database is restored from a backup.
Catalog/	Contains catalog information about the database, such as checkpoints.
CopyErrorLogs/	The default location for the COPY exceptions and rejections files generated when data in a bulk load cannot be inserted into the database. See Handling messy data for more information.
DataCollector/	Log files generated by the Data collector .
debug_log.conf	Debugging information configuration file. For Vertica use only.

Epoch.log	Used during recovery to indicate the latest epoch that contains a complete set of data.
ErrorReport.txt	A stack trace written by Vertica if the server process exits unexpectedly.
Libraries/	Contains user defined library files that have been loaded into the database See Developing user-defined extensions (UDxs) . Do not change or delete these libraries through the file system. Instead, use the CREATE LIBRARY , DROP LIBRARY , and ALTER LIBRARY statements.
Snapshots/	The location where backups are stored.
tmp/	A temporary directory used by Vertica's internal processes.
UDxLogs/	Log files written by user defined functions that run in fenced mode .
vertica.conf	The configuration file for Vertica.
vertica.log	The main log file generated by the Vertica server process.
vertica.pid	The process ID and path to the catalog directory of the Vertica server process running on this node.

Reclaiming disk space from deleted table data

You can reclaim disk space from deleted table data in several ways:

- [Purge deleted records](#).
- [Rebuild the table](#).
- [Drop table partition](#).

Memory usage reporting

Vertica periodically polls its own memory usage to determine whether it is below the threshold that is set by configuration parameter [MemoryPollerReportThreshold](#). Polling occurs at regular intervals—by default, every 2 seconds—as set by configuration parameter [MemoryPollerIntervalSec](#).

The memory poller compares [MemoryPollerReportThreshold](#) with the following expression:

```
RSS / available-memory
```

When this expression evaluates to a value higher than [MemoryPollerReportThreshold](#) —by default, set to 0.93, then the memory poller writes a report to [MemoryReport.log](#), in the Vertica working directory. This report includes information about Vertica memory pools, how much memory is consumed by individual queries and session, and so on. The memory poller also logs the report as an event in system table [MEMORY_EVENTS](#), where it sets [EVENT_TYPE](#) to [MEMORY_REPORT](#).

The memory poller also checks for excessive glibc allocation of free memory (glibc memory bloat). For details, see [Memory trimming](#).

Memory trimming

Under certain workloads, [glibc](#) can accumulate a significant amount of free memory in its allocation arena. This memory consumes physical memory as indicated by its usage of resident set size (RSS), which glibc does not always return to the operating system. High retention of physical memory by glibc—*glibc memory bloat*—can adversely affect other processes, and, under high workloads, can sometimes cause Vertica to run out of memory.

Vertica provides two configuration parameters that let you control how frequently Vertica detects and consolidates much of the glibc-allocated free memory, and then returns it to the operating system:

- [MemoryPollerTrimThreshold](#): Sets the threshold for the memory poller to start checking whether to trim [glibc](#)-allocated memory. The memory poller compares [MemoryPollerTrimThreshold](#) —by default, set to 0.83— with the following expression:

```
RSS / available-memory
```

If this expression evaluates to a value higher than [MemoryPollerTrimThreshold](#), then the memory poller starts checking the next threshold—set in [MemoryPollerMallocBloatThreshold](#) —for glibc memory bloat.

Note

On high-memory machines where very large Vertica RSS values are atypical, consider a higher setting for `MemoryPollerTrimThreshold`. To turn off auto-trimming, set this parameter to 0.

- `MemoryPollerMallocBloatThreshold`: Sets the threshold of glibc memory bloat.

The memory poller calls glibc function `malloc_info()` to obtain the amount of free memory in malloc. It then compares `MemoryPollerMallocBloatThreshold` —by default, set to 0.3—with the following expression:

```
free-memory-in-malloc / RSS
```

If this expression evaluates to a value higher than `MemoryPollerMallocBloatThreshold`, the memory poller calls glibc function `malloc_trim()`. This function reclaims free memory from malloc and returns it to the operating system. Details on calls to `malloc_trim()` are written to system table `MEMORY_EVENTS`.

For example, the memory poller calls `malloc_trim()` when the following conditions are true:

- `MemoryPollerMallocBloatThreshold` is set to 0.5.
- `malloc_info()` returns 15GB memory in malloc free.
- RSS is 30GB.

Note

This parameter is ignored if `MemoryPollerTrimThreshold` is set to 0 (disabled).

Trimming memory manually

If auto-trimming is disabled, you can manually reduce glibc-allocated memory by calling Vertica function `MEMORY_TRIM`. This function calls `malloc_trim()`.

Tuple mover

The Tuple Mover manages ROS data storage. On `mergeout`, it combines small ROS containers into larger ones and purges deleted data. The Tuple Mover automatically performs these tasks in the background.

The database mode affects which nodes perform Tuple Mover operations:

- In an Enterprise Mode database, all nodes run the Tuple Mover to perform mergeout operations on the data they store.
- In Eon Mode, the `primary subscriber` to each `shard` plans Tuple Mover mergeout operations on the ROS containers in the shard. It can delegate the execution of this plan to another node in the cluster.

Tuple Mover operations typically require no intervention. However, Vertica provides various ways to adjust Tuple Mover behavior. For details, see [Managing the tuple mover](#).

The tuple mover in Eon Mode databases

In Eon Mode, the Tuple Mover's operations are broken into two parts: mergeout planning and mergeout execution. Mergeout planning is always carried out by the `primary subscribers` of the shards involved in the mergeout. These primary subscribers are part of same the primary subcluster. As part of its mergeout planning, the primary subscriber chooses a node to execute the mergeout plan. It uses two criteria to decide which node should execute the mergeout:

- Only nodes that have memory allocated to their TM resource pool are eligible to perform a mergeout. The primary subscriber ignores all nodes in subclusters whose TM pool's `MEMORYSIZE` and `MAXMEMORYSIZE` settings are 0.
- From the group of nodes able to execute a mergeout, the primary subscriber chooses the node that has the most ROS containers in its depot that are involved in the mergeout.

Limiting which subclusters perform mergeout tasks

You can prevent a secondary subcluster from being assigned mergeout tasks by changing the `MEMORYSIZE` and `MAXMEMORYSIZE` settings of the its TM pool to 0. These settings prevent the primary subscribers from assigning mergeout tasks to nodes in the subcluster.

Important

Primary subclusters must always be able to execute mergeout tasks. Only change these settings on secondary subclusters.

For example, this statement prevents the subcluster named `dashboard` from running mergeout tasks.

```
=> ALTER RESOURCE POOL TM FOR SUBCLUSTER dashboard MEMORYSIZE '0%'
MAXMEMORYSIZE '0%';
```

In this section

- [Mergeout](#)
- [Managing the tuple mover](#)

Mergeout

Mergeout is a Tuple Mover process that consolidates ROS containers and purges deleted records. DML activities such as COPY and data partitioning generate new ROS containers that typically require consolidation, while deleting and repartitioning data requires reorganization of existing containers. The Tuple Mover constantly monitors these activities, and executes mergeout as needed to consolidate and reorganize containers. By doing so, the Tuple Mover seeks to avoid two problems:

- Performance degradation when column data is fragmented across multiple ROS containers.
- Risk of ROS pushback when ROS containers for a given projection increase faster than the Tuple Mover can handle them. A projection can have up to 1024 ROS containers; when it reaches that limit, Vertica starts to return ROS pushback errors on all attempts to query the projection.

In this section

- [Mergeout request types and precedence](#)
- [Scheduled mergeout](#)
- [User-invoked mergeout](#)
- [Partition mergeout](#)
- [Deletion marker mergeout](#)
- [Disabling mergeout on specific tables](#)
- [Purging ROS containers](#)
- [Mergeout strata algorithm](#)

Mergeout request types and precedence

The Tuple Mover constantly monitors all activity that generates new ROS containers. As it does so, it creates mergeout requests and queues them according to type. These types include, in descending order of precedence:

1. RECOMPUTE_LIMITS: Sets criteria used by the Tuple Mover to determine when to queue new merge requests for a projection. This request type is queued in two cases:
 - When a projection is created.
 - When an existing projection changes—for example, a column is added or dropped, or a configuration parameter changes that affects ROS storage for that projection, such as [ActivePartitionCount](#).
2. MERGEOUT: Consolidate new containers. These containers typically contain data from recent load activity or table partitioning.
3. DVMERGEOUT: Consolidate data marked for deletion, or *delete vectors*.
4. PURGE: Purge aged-out delete vectors from containers.

The Tuple Mover also monitors how frequently containers are created for each projection, to determine which projections might be at risk from ROS pushback. Intense DML activity on projections typically causes a high rate of container creation. The Tuple Mover monitors MERGEOUT and DVMERGEOUT requests and, within each set, prioritizes them according to their level of projection activity. Mergeout requests for projections with the highest rate of container creation get priority for immediate execution.

Note

The Tuple Mover often postpones mergeout for projections with a low level of load activity. Until a projection meets the internal threshold for queuing mergeout requests, mergeout from those projections is liable to remain on hold.

Scheduled mergeout

At regular intervals set by configuration parameter [MergeOutInterval](#), the Tuple Mover checks the mergeout request queue for pending requests:

1. If the queue contains mergeout requests, the Tuple Mover does nothing and goes back to sleep.
2. If the queue is empty, the Tuple Mover:
 - Processes pending storage location move requests.
 - Checks for new unqueued purge requests and adds them to the queue.

It then goes back to sleep.

By default, this parameter is set to 600 (seconds).

Important

Scheduled mergeout is independent of the Tuple Mover service that continuously monitors mergeout requests and executes them as needed.

User-invoked mergeout

You can invoke mergeout at any time on one or more projections, by calling Vertica meta-function [DO_TM_TASK](#):

```
DO_TM_TASK('mergeout', '[[database.]schema.]{table | projection} ]')
```

The function scans the database catalog within the specified scope to identify outstanding mergeout tasks. If no table or projection is specified, [DO_TM_TASK](#) scans the entire catalog. Unlike the continuous TM service, which runs in the TM resource pool, [DO_TM_TASK](#) runs in the GENERAL pool. If [DO_TM_TASK](#) executes mergeout tasks that are pending in the merge request queue, the TM service removes these tasks from the queue with no action taken.

Partition mergeout

Vertica keeps data from different table [partitions](#) or [partition groups](#) separate on disk. The Tuple Mover adheres to this separation policy when it consolidates ROS containers. When a partition is first created, it typically has frequent data loads and requires regular activity from the Tuple Mover. As a partition ages, it commonly transitions to a mostly read-only workload and requires much less activity.

The Tuple Mover has two different policies for managing these different partition workloads:

- *Active partition* is the partition that was most recently created. The Tuple Mover uses a [strata-based algorithm](#) that seeks to minimize the number of times individual tuples undergo mergeout. A table's [active partition count](#) identifies how many partitions are active for that table.
- *Inactive partitions* are those that were not most recently created. The Tuple Mover consolidates ROS containers to a minimal set while avoiding merging containers whose size exceeds [MaxMrgOutROSSizeMB](#).

Note

If you [invoke mergeout](#) with the Vertica meta-function [DO_TM_TASK](#), all partitions are consolidated into the smallest possible number of containers, including active partitions.

For details on how the Tuple Mover identifies active partitions, see [Active and inactive partitions](#).

Partition mergeout thread allocation

The [TM_resource_pool](#) sets the number of threads that are available for mergeout with its `MAXCONCURRENCY` parameter. By default, this parameter is set to 7. Vertica allocates half the threads to active partitions, and the remaining half to active and inactive partitions. If `MAXCONCURRENCY` is set to an uneven integer, Vertica rounds up to favor active partitions.

For example, if `MAXCONCURRENCY` is set to 7, then Vertica allocates four threads exclusively to active partitions, and allocates the remaining three threads to active and inactive partitions as needed. If additional threads are required to avoid ROS pushback, increase `MAXCONCURRENCY` with [ALTER RESOURCE POOL](#).

Deletion marker mergeout

When you delete data from the database, Vertica does not remove it. Instead, it marks the data as deleted. Using many [DELETE](#) statements to mark a small number of rows relative to the size of a table can result in creating many small containers— *delete vectors* —to hold data marked for deletion. Each delete vector container consumes resources, so a large number of such containers can adversely impact performance, especially during recovery.

After the Tuple Mover performs a mergeout, it looks for deletion marker containers that hold few entries. If such containers exist, the Tuple Mover merges them together into a single, larger container. This process helps lower the overhead of tracking deleted data by freeing resources used by multiple, individual containers. The Tuple Mover does not purge or otherwise affect the deleted data, but consolidates delete vectors for greater efficiency.

Tip

Query system table [DELETE_VECTORS](#) to view the number and size of containers that store deleted data.

Disabling mergeout on specific tables

By default, [mergeout](#) is enabled for all tables and their projections. You can disable mergeout on a table with [ALTER TABLE](#). For example:

```
=> ALTER TABLE public.store_orders_temp SET MERGEOUT 0;
ALTER TABLE
```

In general, it is useful to disable mergeout on tables that you create to serve a temporary purpose—for example, staging tables that are used to [archive old partition data](#), or [swap partitions](#) between tables—which are deleted soon after the task is complete. By doing so, you avoid the mergeout-related overhead that the table would otherwise incur.

You can query system table [TABLES](#) to identify tables that have mergeout disabled:

```
=> SELECT table_schema, table_name, is_mergeout_enabled FROM v_catalog.tables WHERE is_mergeout_enabled= 0;
table_schema | table_name | is_mergeout_enabled
-----+-----+-----
public      | store_orders_temp | f
(1 row)
```

Purging ROS containers

Vertica periodically checks ROS storage containers to determine whether delete vectors are eligible for purge, as follows:

1. Counts the number of aged-out delete vectors in each container—that is, delete vectors that are equal to or earlier than the ancient history mark (AHM) epoch.
2. Calculates the percentage of aged-out delete vectors relative to the total number of records in the same ROS container.
3. If this percentage exceeds the threshold set by configuration parameter [PurgeMergeoutPercent](#) (by default, 20 percent), Vertica automatically performs a mergeout on the ROS container that permanently removes all aged-out delete vectors. Vertica uses the TM resource pool's [MAXCONCURRENCY](#) setting to determine how many threads are available for the mergeout operation.

You can also manually purge all aged-out delete vectors from ROS containers with two Vertica meta-functions:

- [DO_TM_TASK\('mergeout'\)](#)
- [PURGE](#)

Both functions remove all aged-out delete vectors from ROS containers, regardless of how many are in a given container.

Mergeout strata algorithm

The mergeout operation uses a strata-based algorithm to verify that each tuple is subjected to a mergeout operation a small, constant number of times, despite the process used to load the data. The mergeout operation uses this algorithm to choose which ROS containers to merge for non-partitioned tables and for active partitions in partitioned tables.

Vertica builds strata for each active partition and for projections anchored to non-partitioned tables. The number of strata, the size of each stratum, and the maximum number of ROS containers in a stratum is computed based on disk size, memory, and the number of columns in a projection.

Merging small ROS containers before merging larger ones provides the maximum benefit during the mergeout process. The algorithm begins at stratum 0 and moves upward. It checks to see if the number of ROS containers in a stratum has reached a value equal to or greater than the maximum ROS containers allowed per stratum. The default value is 32. If the algorithm finds that a stratum is full, it marks the projections and the stratum as eligible for mergeout.

Managing the tuple mover

The Tuple Mover is preconfigured to handle typical workloads. However, some situations might require you to adjust Tuple Mover behavior. You can do so in various ways:

- [Configure the [TM](#) resource pool](#Configur).
- [Manage active data partitions](#).

Configuring the TM resource pool

The Tuple Mover uses the built-in [TM](#) resource pool to handle its workload. Several settings of this resource pool can be adjusted to facilitate handling of high volume loads:

- [MEMORYSIZE](#)

- [MAXMEMORYSIZE](#)
- [MAXCONCURRENCY](#)
- [PLANNEDCONCURRENCY](#)

MEMORYSIZE

Specifies how much memory is reserved for the TM pool per node. The TM pool can grow beyond this lower limit by borrowing from the GENERAL pool. By default, this parameter is set to 5% of available memory. If MEMORYSIZE of the GENERAL resource pool is also set to a percentage, the TM pool can compete with it for memory. This value must always be less than or equal to MAXMEMORYSIZE setting.

Caution

Increasing MEMORYSIZE to a large percentage can cause regressions in memory-sensitive queries that run in the GENERAL pool.

MAXMEMORYSIZE

Sets the upper limit of memory that can be allocated to the TM pool. The TM pool can grow beyond the value set by MEMORYSIZE by borrowing memory from the GENERAL pool. This value must always be equal to or greater than the MEMORYSIZE setting.

In an Eon Mode database, if you set this value to 0 on a subcluster level, the Tuple Mover is disabled on the subcluster.

Important

Never set the TM pool's MAXMEMORYSIZE to 0 on a [primary subcluster](#). Primary subclusters must always run the Tuple Mover.

MAXCONCURRENCY

Sets across all nodes the maximum number of concurrent execution slots available to TM pool. In databases created in Vertica releases ≥ 9.3 , the default value is 7. In databases created in earlier versions, the default is 3. This setting specifies the maximum number of merges that can occur simultaneously on multiple threads.

PLANNEDCONCURRENCY

Specifies the preferred number queries to execute concurrently in the resource pool, across all nodes, by default set to 6. The Resource Manager uses PLANNEDCONCURRENCY to calculate the target memory that is available to a given query:

TM-memory-size / PLANNEDCONCURRENCY

The PLANNEDCONCURRENCY setting must be proportional to the size of RAM, the CPU, and the storage subsystem. Depending on the storage type, increasing PLANNEDCONCURRENCY for Tuple Mover threads might create a storage I/O bottleneck. Monitor the storage subsystem; if it becomes saturated with long I/O queues, more than two I/O queues, and long latency in read and write, adjust the PLANNEDCONCURRENCY parameter to keep the storage subsystem resources below saturation level.

Managing active data partitions

The Tuple Mover assumes that all loads and updates to a partitioned table are targeted to one or more partitions that it identifies as *active*. In general, the partitions with the largest partition keys—typically, the most recently created partitions—are regarded as active. As the partition ages, its workload typically shrinks and becomes mostly read-only.

You can specify how many partitions are active for partitioned tables at two levels, in ascending order of precedence:

- Configuration parameter [ActivePartitionCount](#) determines how many partitions are active for partitioned tables in the database. By default, ActivePartitionCount is set to 1. The Tuple Mover applies this setting to all tables that do not set their own active partition count.
- Individual tables can supersede ActivePartitionCount by setting their own active partition count with [CREATE TABLE](#) and [ALTER TABLE](#).

For details, see [Active and inactive partitions](#).

See also

[Best practices for managing workload resources](#)

Managing workloads

Vertica's resource management scheme allows diverse, concurrent workloads to run efficiently on the database. For basic operations, Vertica pre-configures the built-in [GENERAL pool](#) based on RAM and machine cores. You can customize the General pool to handle specific concurrency requirements.

You can also define new resource pools that you configure to limit memory usage, concurrency, and query priority. You can then optionally assign each database user to use a specific resource pool, which controls memory resources used by their requests.

User-defined pools are useful if you have competing resource requirements across different classes of workloads. Example scenarios include:

- A large batch job takes up all server resources, leaving small jobs that update a web page without enough resources. This can degrade user experience.
In this scenario, create a resource pool to handle web page requests and ensure users get resources they need. Another option is to create a limited resource pool for the batch job, so the job cannot use up all system resources.
- An application has lower priority than other applications and you want to limit the amount of memory and number of concurrent users for the low-priority application.
In this scenario, create a resource pool with an upper limit on the query's memory and associate the pool with users of the low-priority application.

You can also use resource pools to manage resources assigned to running queries. You can assign a run-time priority to a resource pool, as well as a threshold to assign different priorities to queries with different durations. See [Managing resources at query run time](#) for more information.

Enterprise Mode and Eon Mode

In Enterprise Mode, there is one global set of resource pools for the entire database. In Eon Mode, you can allocate resources globally or per subcluster. See [Managing workload resources in an Eon Mode database](#) for more information.

In this section

- [Resource manager](#)
- [Resource pool architecture](#)
- [Managing resources at query run time](#)
- [Restoring resource manager defaults](#)
- [Best practices for managing workload resources](#)
- [Managing system resource usage](#)

Resource manager

On a single-user environment, the system can devote all resources to a single query, getting the most efficient execution for that one query. More likely, your environment needs to run several queries at once, which can cause tension between providing each query the maximum amount of resources (fastest run time) and serving multiple queries simultaneously with a reasonable run time.

The Vertica Resource Manager lets you resolve this tension, while ensuring that every query is eventually serviced and that true system limits are respected at all times.

For example, when the system experiences resource pressure, the Resource Manager might queue queries until the resources become available or a timeout value is reached. In addition, when you configure various Resource Manager settings, you can tune each query's target memory based on the expected number of concurrent queries running against the system.

Resource manager impact on query execution

The Resource Manager impacts individual query execution in various ways. When a query is submitted to the database, the following series of events occur:

1. The query is parsed, optimized to determine an execution plan, and distributed to the participating nodes.
2. The Resource Manager is invoked on each node to estimate resources required to run the query and compare that with the resources currently in use. One of the following will occur:
 - If the memory required by the query alone would exceed the machine's physical memory, the query is rejected - it cannot possibly run. Outside of significantly under-provisioned nodes, this case is very unlikely.
 - If the resource requirements are not currently available, the query is queued. The query will remain on the queue until either sufficient resources are freed up and the query runs or the query times out and is rejected.
 - Otherwise the query is allowed to run.
3. The query starts running when all participating nodes allow it to run.

Note

Once the query is running, the Resource Manager further manages resource allocation using `RUNTIMEPRIORITY` and `RUNTIMEPRIORITYTHRESHOLD` parameters for the resource pool. See [Managing resources at query run time](#) for more information.

Apportioning resources for a specific query and the maximum number of queries allowed to run depends on the resource pool configuration. See [Resource pool architecture](#).

On each node, no resources are reserved or held while the query is in the queue. However, multi-node queries queued on some nodes will hold resources on the other nodes. Vertica makes every effort to avoid deadlocks in this situation.

Resource pool architecture

The Resource Manager handles resources as one or more resource pools, which are a pre-allocated subset of the system resources with an associated queue.

In Enterprise Mode, there is one global set of resource pools that apply to all subclusters in the entire database. In Eon Mode, you can allocate resources globally or per subcluster. Global-level resource pools apply to all subclusters. Subcluster-level resource pools allow you to fine-tune resources for the type of workloads that the subcluster does. If you have both global- and subcluster-level resource pool settings, you can override any memory-related global setting for that subcluster. Global settings are applied to subclusters that do not have subcluster-level resource pool settings. See [Managing workload resources in an Eon Mode database](#) for more information about fine-tuning resource pools per subcluster.

Vertica is preconfigured with a set of [Built-in pools](#) that allocate resources to different request types, where the GENERAL pool allows for a certain concurrency level based on the RAM and cores in the machines.

Modifying and creating resource pools

You can configure the built-in GENERAL pool based on actual concurrency and performance requirements, as described in [Built-in pools](#). You can also create custom pools to handle various classes of workloads and optionally restrict user requests to your custom pools.

You create and modify user-defined resource pools with [CREATE RESOURCE POOL](#) and [ALTER RESOURCE POOL](#), respectively. You can configure these resource pools for memory usage, concurrency, and queue priority. You can also restrict a database user or user session to use a specific resource pool. Doing so allows you to control how memory, CPU, and other resources are allocated.

The following graphic illustrates what database operations are executed in which resource pool. Only three built-in pools are shown.

In this section

- [Defining secondary resource pools](#)
- [Querying resource pool settings](#)
- [User resource allocation](#)
- [Query budgeting](#)

Defining secondary resource pools

You can define secondary resource pools to which running queries can cascade if they exceed their primary pool's [RUNTIMECAP](#).

Identifying a secondary pool

Secondary resource pools designate a place where queries that exceed the [RUNTIMECAP](#) of the pool on which they are running can continue execution. If a query exceeds a pool's [RUNTIMECAP](#), the query can cascade to a pool with a larger [RUNTIMECAP](#) instead of returning with an error. When a query cascades to another pool, the original pool regains the memory used by that query.

Unlike a user's primary resource pool, which requires [USAGE](#) privileges, Vertica does not check for user privileges on secondary resource pools. Thus, a user whose query cascades to a secondary resource pool requires no [USAGE](#) privileges on that resource pool.

You can define a secondary pool so it queues long-running queries if the pool lacks sufficient memory to handle that query immediately, by setting two parameters:

- Set [PRIORITY](#) to HOLD, to queue queries until the pool's [QUEUETIMEOUT](#) interval elapses.
- Set [QUEUETIMEOUT](#) to the appropriate length.

Eon Mode restrictions

In Eon Mode, you can associate user-defined resource pools with a subcluster. The following restrictions apply:

- Global resource pools can cascade only to other global resource pools.
- A subcluster resource pool can cascade to a global resource pool, or to another subcluster-specific resource pool that belongs to the same subcluster. If a subcluster-specific resource pool cascades to a user-defined resource pool that exists on both the global and subcluster level, the subcluster-level resource pool has priority. For example:

```

=> CREATE RESOURCE POOL billing1;
=> CREATE RESOURCE POOL billing1 FOR CURRENT SUBCLUSTER;
=> CREATE RESOURCE POOL billing2 FOR CURRENT SUBCLUSTER CASCADE TO billing1;
WARNING 9613: Resource pool billing1 both exists at both subcluster level and global level, assuming subcluster level
CREATE RESOURCE POOL

```

Query cascade path

Vertica routes queries to a secondary pool when the RUNTIMECAP on an initial pool is reached. Vertica then checks the secondary pool's RUNTIMECAP value. If the secondary pool's RUNTIMECAP is greater than the initial pool's value, the query executes on the secondary pool. If the secondary pool's RUNTIMECAP is less than or equal to the initial pool's value, Vertica retries the query on the next pool in the chain until it finds a pool on which the RUNTIMECAP is greater than the initial pool's value. If the secondary pool does not have sufficient resources available to execute the query at that time, SELECT queries may re-queue, re-plan, and abort on that pool. Other types of queries will fail due to insufficient resources. If no appropriate secondary pool exists for a query, the query will error out.

The following diagram demonstrates the path a query takes to execution.

Query execution time allocation

After Vertica finds an appropriate pool on which to run the query, it continues to execute that query uninterrupted. The query now has the difference of the two pools' RUNTIMECAP limits in which to complete:

```

query execution time allocation = rp2 RUNTIMECAP - rp1 RUNTIMECAP

```

Using CASCADE TO

As a [superuser](#), you can identify an existing resource pool—either user-defined pool or the GENERAL pool—by using the CASCADE TO parameter in the [CREATE RESOURCE POOL](#) or [ALTER RESOURCE POOL](#) statement.

In the following example, two resource pools are created and associated with a user as follows:

1. The `shortUserQueries` resource pool is created with a one-minute RUNTIMECAP
2. The `userOverflow` resource pool is created with a RUNTIMECAP of five minutes.
3. `shortUserQueries` is modified with ALTER RESOURCE POOL...CASCADE to use `userOverflow` to handle queries that require more than one minute to process.
4. The user `molly` is created and configured to use `shortUserQueries` to handle that user's queries.

Given this scenario, queries issued by `molly` are initially directed to `shortUserQueries` for handling; queries that require more than one minute of processing time automatically cascade to the `userOverflow` pool to complete execution. Using the secondary pool frees up space in the primary pool, which is configured to handle short queries:

```
=> CREATE RESOURCE POOL shortUserQueries RUNTIMECAP '1 minutes'  
=> CREATE RESOURCE POOL userOverflow RUNTIMECAP '5 minutes';  
=> ALTER RESOURCE POOL shortUserQueries CASCADE TO userOverflow;  
=> CREATE USER molly RESOURCE POOL shortUserQueries;
```

If desired, you can modify this scenario so `userOverflow` can queue long-running queries until it is available to handle them, by setting the `PRIORITY` and `QUEUETIMEOUT` parameters:

```
=> ALTER RESOURCE POOL userOverflow PRIORITY HOLD QUEUETIMEOUT '10 minutes';
```

In this scenario, a query that cascades to `userOverflow` can be queued up to 10 minutes until `userOverflow` acquires the memory it requires to handle it. After 10 minutes elapse, the query is rejected and returns with an error.

Dropping a secondary pool

If you try to drop a resource pool that is the secondary pool for another resource pool, Vertica returns an error. The error lists the resource pools that depend on the secondary pool you tried to drop. To drop a secondary resource pool, first set the `CASCADE TO` parameter to `DEFAULT` on the primary resource pool, and then drop the secondary pool.

For example, you can drop resource pool `rp2`, which is a secondary pool for `rp1`, as follows:

```
=> ALTER RESOURCE POOL rp1 CASCADE TO DEFAULT;  
=> DROP RESOURCE POOL rp2;
```

Secondary pool parameter dependencies

In general, a secondary pool's parameters are applied to an incoming query. In the case of `RUNTIMEPRIORITY`, the following dependencies apply:

- If the `RUNTIMEPRIORITYTHRESHOLD` timer was not started when the query was running in the primary pool, the query adopts the secondary resource pools' `RUNTIMEPRIORITY` when it cascades. This happens either when the `RUNTIMEPRIORITYTHRESHOLD` is not set for the primary pool or the `RUNTIMEPRIORITY` is set to `HIGH` for the primary pool.
- If the `RUNTIMEPRIORITYTHRESHOLD` was reached in the primary pool, the query adopts the secondary resource pools' `RUNTIMEPRIORITY` when it cascades.
- If the `RUNTIMEPRIORITYTHRESHOLD` was not reached in the primary pool and the secondary pool has no threshold, the query adopts the new pool's `RUNTIMEPRIORITY` when it cascades.
- If the `RUNTIMEPRIORITYTHRESHOLD` was not reached in the primary pool and the secondary pool has a threshold set.
- If the primary pool's `RUNTIMEPRIORITYTHRESHOLD` is greater than or equal to the secondary pool's `RUNTIMEPRIORITYTHRESHOLD`, the query adopts the secondary pool's `RUNTIMEPRIORITY` after the query reaches the `RUNTIMEPRIORITYTHRESHOLD` of the primary pool.

For example:

```
RUNTIMECAP of primary pool = 5 sec  
RUNTIMEPRIORITYTHRESHOLD of primary pool = 8 sec  
RUNTIMTPRIORITYTHRESHOLD of secondary pool = 7 sec
```

In this case, the query runs for 5 seconds on the primary pool and then cascades to the secondary pool. After another 3 seconds, 8 seconds total, the query adopts the `RUNTIMEPRIORITY` of the secondary pool.

- If the primary pool's `RUNTIMEPRIORITYTHRESHOLD` is less than the secondary pool's `RUNTIMEPRIORITYTHRESHOLD`, the query adopts the secondary pool's `RUNTIMEPRIORITY` after the query reaches the `RUNTIMEPRIORITYTHRESHOLD` of the secondary pool.

In this case, the query runs for 5 seconds on the primary pool and then cascades to the secondary pool. After another 7 seconds, 12 seconds total, the query adopts the `RUNTIMEPRIORITY` of the secondary pool:

```
RUNTIMECAP of primary pool = 5 sec  
RUNTIMEPRIORITYTHRESHOLD of primary pool = 8 sec  
RUNTIMTPRIORITYTHRESHOLD of secondary pool = 12 se
```

CASCADE errors

A query that cascades to a secondary resource pool typically returns with an error in the following cases:

- The resource pool cannot acquire the memory it needs to finish processing the query.
- The secondary resource pool parameter `MAXCONCURRENCY` is set to 1 and it is already processing another query.

Querying resource pool settings

You can use the following to get information about resource pools:

- `RESOURCE_POOLS` returns resource pool settings from the Vertica database catalog, as set by `CREATE RESOURCE POOL` and `ALTER RESOURCE POOL`.

- [SUBCLUSTER_RESOURCE_POOL_OVERRIDES](#) displays all subcluster level overrides of global resource pool settings.

For runtime information about resource pools, see [Monitoring resource pools](#).

Querying resource pool settings

The following example queries various settings of two internal resource pools, GENERAL and TM:

```
=> SELECT name, subcluster_oid, subcluster_name, maxmemorysize, memorysize, runtimepriority, runtimeprioritythreshold, queuetimeout
FROM RESOURCE_POOLS WHERE name IN('general', 'tm');
name | subcluster_oid | subcluster_name | maxmemorysize | memorysize | runtimepriority | runtimeprioritythreshold | queuetimeout
-----+-----+-----+-----+-----+-----+-----+-----
general | 0 | | Special: 95% | | MEDIUM | | 2 | 00:05
tm | 0 | | | 3G | MEDIUM | | 60 | 00:05
(2 rows)
```

Viewing overrides to global resource pools

In Eon Mode, you can query `SUBCLUSTER_RESOURCE_POOL_OVERRIDES` in the system tables to view any overrides to global resource pools for individual subclusters. The following query shows an override that sets `MEMORYSIZE` and `MAXMEMORYSIZE` for the built-in resource pool `TM` to 0% in the `analytics_1` subcluster. These settings prevent the subcluster from performing Tuple Mover mergeout tasks.

```
=> SELECT * FROM SUBCLUSTER_RESOURCE_POOL_OVERRIDES;
pool_oid | name | subcluster_oid | subcluster_name | memorysize | maxmemorysize | maxquerymemorysize
-----+-----+-----+-----+-----+-----+-----
45035996273705058 | tm | 45035996273843504 | analytics_1 | 0% | 0% |
(1 row)
```

User resource allocation

You can allocate resources to users in two ways:

- Customize allocation of resources for individual users by setting the appropriate [user parameters](#).
- Assign users to a resource pool. This resource pool is used to process all queries from its assigned users, allocating resources as set by resource pool parameters.

The two methods can complement each other. For example, you can set the `RUNTIMECAP` parameter in the user-defined resource pool `user_rp` to 20 minutes. This setting applies to the queries of all users who are assigned to `user_rp`, including user Bob:

```
=> ALTER RESOURCE POOL user_rp RUNTIMECAP '20 minutes';
ALTER RESOURCE POOL
=> GRANT USAGE ON RESOURCE POOL user_rp to Bob;
GRANT PRIVILEGE
=> ALTER USER Bob RESOURCE POOL pool user_rp;
ALTER USER
```

When Vertica directs any query from user Bob to the `user_rp` resource pool for processing, it allocates resources to the query as configured in the resource pool, including `RUNTIMECAP`. Accordingly, queries in `user_rp` that do not complete execution within 20 minutes [cascade](#) to a secondary resource pool (if one is designated), or return to Bob with an error.

You can also edit Bob's user profile by setting its user-level parameter `RUNTIMECAP` to 10 minutes:

```
=> ALTER USER Bob RUNTIMECAP '10 minutes';
ALTER USER
```

On receiving queries from Bob after this change, the resource pool compares the two `RUNTIMECAP` settings—its own, and Bob's profile setting—and applies the shorter of the two. If you subsequently reassign Bob to another resource pool, the same logic applies, where the new resource pool continues to apply the shorter of the two `RUNTIMECAP` settings.

Precedence of user resource pools

Resource pools can be assigned to users at three levels, in ascending order of precedence:

1. Default user resource pool, set in configuration parameter [DefaultResourcePoolForUsers](#). When a database user is created with [CREATE USER](#), Vertica automatically sets the new user's profile to use this resource pool unless the `CREATE USER` statement specifies otherwise.
- Important

By default, `DefaultResourcePoolForUsers` is set to the `GENERAL` resource pool, on which all new users have `USAGE` privileges. If you reconfigure `DefaultResourcePoolForUsers` to specify a user-defined resource pool, be sure that new users have `USAGE` privileges on it.

2. User resource pool, set in the user's profile by [CREATE USER](#) or [ALTER USER](#) with its `RESOURCE POOL` parameter. If you try to [drop](#) a user's resource pool, Vertica checks whether it can assign that user to the default user resource pool. If the user cannot be assigned to this resource pool—typically, for lack of `USAGE` privileges—Vertica rolls back the drop operation.
3. Current user session resource pool, set by [SET SESSION RESOURCE_POOL](#).

In all cases, users must have `USAGE` privileges on their assigned resource pool; otherwise, they cannot log in to the database.

Resource pool usage in Eon Mode

In an Eon Mode database, you can assign a given resource pool to a subcluster, and then configure user profiles to use that resource pool. When users connect to a subcluster, Vertica determines which resource pool handles their queries as follows:

1. If a user's resource pool and the subcluster resource pool are the same, then the subcluster resource pool handles queries from that user.
2. If a user's resource pool and the subcluster resource pool are different, and the user has privileges on the default user resource pool, then that resource pool handles queries from the user.
3. If a user's resource pool and the subcluster resource pool are different, and the user lacks privileges on the default user resource pool, then no resource pool is available on any node to handle queries from that user, and the queries return with an error.

Examples

For examples of different use cases for managing user resources, see [Managing workloads with resource pools and user profiles](#).

Query budgeting

Before it can execute a query, Vertica devises a query plan, which it sends to each node that will participate in executing the query. The Resource Manager evaluates the plan on each node and estimates how much memory and concurrency the node needs to execute its part of the query. This is the *query budget*, which Vertica stores in the `query_budget_kb` column of system table [V_MONITOR.RESOURCE_POOL_STATUS](#).

A query budget is based on several parameter settings of the resource pool where the query will execute:

- `MEMORYSIZE`
- `MAXMEMORYSIZE`
- `PLANNEDCONCURRENCY`

You can modify `MAXMEMORYSIZE` and `PLANNEDCONCURRENCY` for the `GENERAL` resource pool with [ALTER RESOURCE POOL](#). This resource pool typically executes queries that are not assigned to a user-defined resource pool. You can set all three parameters for any user-defined resource pool when you create it with [CREATE RESOURCE POOL](#), or later with [ALTER RESOURCE POOL](#).

Important

You can also limit how much memory that a pool can allocate at runtime to its queries, by setting parameter `MAXQUERYMEMORYSIZE` on that pool. For more information, see [CREATE RESOURCE POOL](#).

Computing the GENERAL pool query budget

Vertica calculates query budgets in the `GENERAL` pool with the following formula:

$$\text{queryBudget} = \text{queuingThresholdPool} / \text{PLANNEDCONCURRENCY}$$

Note

Vertica calculates the `GENERAL` pool's queuing threshold as 95 percent of its `MAXMEMORYSIZE` setting.

Computing query budgets for user-defined resource pools

For user-defined resource pools, Vertica uses the following algorithm:

1. If `MEMORYSIZE` is set to 0 and `MAXMEMORYSIZE` is not set:

$$\text{queryBudget} = \text{queuingThresholdGeneralPool} / \text{PLANNEDCONCURRENCY}$$

2. If `MEMORYSIZE` is set to 0 and `MAXMEMORYSIZE` is set to a non-default value:

$$\text{query-budget} = \text{queuingThreshold} / \text{PLANNEDCONCURRENCY}$$

Note

Vertica calculates a user-defined pool's queuing threshold as 95 percent of its `MAXMEMORYSIZE` setting.

3. If `MEMORYSIZE` is set to a non-default value:

```
queryBudget = MEMORYSIZE / PLANNEDCONCURRENCY
```

By carefully tuning a resource pool's `MEMORYSIZE` and `PLANNEDCONCURRENCY` parameters, you can control how much memory can be budgeted for queries.

Caution

Query budgets do not typically require tuning. However, if you reduce the `MAXMEMORYSIZE` because you need memory for other purposes, be aware that doing so also reduces the query budget. Reducing the query budget negatively impacts the query performance, particularly if the queries are complex.

To maintain the original query budget for the resource pool, be sure to reduce parameters `MAXMEMORYSIZE` and `PLANNEDCONCURRENCY` together.

[Do You Need to Put Your Query on a Budget?](#) in the [Vertica User Community](#).

Managing resources at query run time

The Resource Manager estimates the resources required for queries to run, and then prioritizes them. You can control how the Resource Manager prioritizes query execution in several ways:

- [Set a resource pool's run-time priority](#) relative to other resource pools.
- [Change a running query's priority](#) relative to other queries in the same resource pool.
- [Move a running query](#) to another resource pool.

In this section

- [Setting runtime priority for the resource pool](#)
- [Changing runtime priority of a running query](#)
- [Manually moving queries to different resource pools](#)

Setting runtime priority for the resource pool

For each resource pool, you can manage resources that are assigned to queries that are already running. You assign each resource pool a runtime priority of HIGH, MEDIUM, or LOW. These settings determine the amount of runtime resources (such as CPU and I/O bandwidth) assigned to queries in the resource pool when they run. Queries in a resource pool with a HIGH priority are assigned greater runtime resources than those in resource pools with MEDIUM or LOW runtime priorities.

Prioritizing queries within a resource pool

While runtime priority helps to manage resources for the resource pool, there may be instances where you want some flexibility within a resource pool. For instance, you may want to ensure that very short queries run at a high priority, while also ensuring that all other queries run at a medium or low priority.

The Resource Manager allows you this flexibility by letting you set a *runtime priority threshold* for the resource pool. With this threshold, you specify a time limit (in seconds) by which a query must finish before it is assigned the runtime priority of the resource pool. All queries begin running with a HIGH priority; once a query's duration exceeds the time limit specified in the runtime priority threshold, it is assigned the runtime priority of the resource pool.

Setting runtime priority and runtime priority threshold

You specify runtime priority and runtime priority threshold by setting two resource pool parameters with [CREATE RESOURCE POOL](#) or [ALTER RESOURCE POOL](#):

- `RUNTIMEPRIORITY`
- `RUNTIMEPRIORITYTHRESHOLD`

Changing runtime priority of a running query

[CHANGE_CURRENT_STATEMENT_RUNTIME_PRIORITY](#) lets you to change a query's runtime priority. You can change the runtime priority of a query that is already executing.

This function takes two arguments:

- The query's transaction ID, obtained from the system table [SESSIONS](#)
- The desired priority, one of the following string values: **HIGH** , **MEDIUM** , or **LOW**

Restrictions

Superusers can change the runtime priority of any query to any priority level. The following restrictions apply to other users:

- They can only change the runtime priority of their own queries.
- They cannot raise the runtime priority of a query to a level higher than that of the resource pools.

Procedure

Changing a query's runtime priority is a two-step procedure:

1. Get the query's transaction ID by querying the system table [SESSIONS](#) . For example, the following statement returns information about all running queries:

```
=> SELECT transaction_id, runtime_priority, transaction_description from SESSIONS;
```

2. Run ``CHANGE_CURRENT_STATEMENT_RUNTIME_PRIORITY```, specifying the query's transaction ID and desired runtime priority:

```
=> SELECT CHANGE_CURRENT_STATEMENT_RUNTIME_PRIORITY(45035996273705748, 'low')
```

Manually moving queries to different resource pools

If you are the database administrator, you can move queries to another resource pool mid-execution using the

[MOVE_STATEMENT_TO_RESOURCE_POOL](#) meta-function.

You might want to use this feature if a single query is using a large amount of resources, preventing smaller queries from executing.

What happens when a query moves to a different resource pool

When a query is moved from one resource pool to another, it continues executing, provided the target pool has enough resources to accommodate the incoming query. If sufficient resources cannot be assigned in the target pool on at least one node, Vertica cancels the query and attempts to re-plan the query. If Vertica cannot re-plan the query, the query is canceled indefinitely.

When you successfully move a query to a target resource pool, its resources will be accounted for by the target pool and released on the first pool.

If you move a query to a resource pool with PRIORITY HOLD, Vertica cancels the query and queues it on the target pool. This cancellation remains in effect until you change the PRIORITY or move the query to another pool without PRIORITY HOLD. You can use this option if you want to store long-running queries for later use.

You can view the [RESOURCE_ACQUISITIONS](#) or [RESOURCE_POOL_STATUS](#) system tables to determine if the target pool can accommodate the query you want to move. Be aware that the system tables may change between the time you query the tables and the time you invoke the [MOVE_STATEMENT_TO_RESOURCE_POOL](#) meta-function.

When a query successfully moves from one resource pool to another mid-execution, it executes until the greater of the existing and new **RUNTIMECAP** is reached. For example, if the **RUNTIMECAP** on the initial pool is greater than that on the target pool, the query can execute until the initial **RUNTIMECAP** is reached. When a query successfully moves from one resource pool to another mid-execution the CPU affinity will change.

Using the MOVE_STATEMENT_TO_RESOURCE_POOL function

To manually move a query from its current resource pool to another resource pool, use the [MOVE_STATEMENT_TO_RESOURCE_POOL](#) meta-function. Provide the session id, transaction id, statement id, and target resource pool name, as shown:

```
=> SELECT MOVE_STATEMENT_TO_RESOURCE_POOL ('v_vmart_node0001.example.-31427:0x82fbm', 45035996273711993, 1, 'my_target_pool');
```

- [Defining secondary resource pools](#)
- [MOVE_STATEMENT_TO_RESOURCE_POOL](#)
- [RESOURCE_POOL_MOVE](#)

Restoring resource manager defaults

System table [RESOURCE_POOL_DEFAULTS](#) stores default values for all parameters for all built-in and user-defined resource pools.

If you have changed the value of any parameter in any of your resource pools and want to restore it to its default, you can simply alter the table and set the parameter to DEFAULT. For example, the following statement sets the RUNTIMEPRIORITY for the resource pool sysquery back to its default value:

```
=> ALTER RESOURCE POOL sysquery RUNTIMEPRIORITY DEFAULT;
```

Best practices for managing workload resources

This section provides general guidelines and best practices on how to set up and tune resource pools for various common scenarios.

Note

The exact settings for resource pool parameters are heavily dependent on your query mix, data size, hardware configuration, and concurrency requirements. Vertica recommends performing your own experiments to determine the optimal configuration for your system.

In this section

- [Basic principles for scalability and concurrency tuning](#)
- [Setting a runtime limit for queries](#)
- [Handling session socket blocking](#)
- [Managing workloads with resource pools and user profiles](#)
- [Tuning built-in pools](#)
- [Reducing query run time](#)
- [Managing workload resources in an Eon Mode database](#)

Basic principles for scalability and concurrency tuning

A Vertica database runs on a cluster of commodity hardware. All loads and queries running against the database take up system resources, such as CPU, memory, disk I/O bandwidth, file handles, and so forth. The performance (run time) of a given query depends on how much resource it has been allocated.

When running more than one query concurrently on the system, both queries are sharing the resources; therefore, each query could take longer to run than if it was running by itself. In an efficient and scalable system, if a query takes up all the resources on the machine and runs in X time, then running two such queries would double the run time of each query to 2X. If the query runs in > 2X, the system is not linearly scalable, and if the query runs in < 2X then the single query was wasteful in its use of resources. Note that the above is true as long as the query obtains the minimum resources necessary for it to run and is limited by CPU cycles. Instead, if the system becomes bottlenecked so the query does not get enough of a particular resource to run, then the system has reached a limit. In order to increase concurrency in such cases, the system must be expanded by adding more of that resource.

In practice, Vertica should achieve near linear scalability in run times, with increasing concurrency, until a system resource limit is reached. When adequate concurrency is reached without hitting bottlenecks, then the system can be considered as ideally sized for the workload.

Note

Typically Vertica queries on segmented tables run on multiple (likely all) nodes of the cluster. Adding more nodes generally improves the run time of the query almost linearly.

Setting a runtime limit for queries

You can set a limit for the amount of time a query is allowed to run. You can set this limit at three levels, listed in descending order of precedence:

1. The resource pool to which the user is assigned.
2. User profile with **RUNTIMECAP** configured by [CREATE USER / ALTER USER](#)
3. Session queries, set by [SET SESSION RUNTIMECAP](#)

In all cases, you set the runtime limit with an **interval** value that does not exceed one year. When you set runtime limit at multiple levels, Vertica always uses the shortest value. If a runtime limit is set for a non-superuser, that user cannot set any session to a longer runtime limit. Superusers can set the runtime limit for other users and for their own sessions, to any value up to one year, inclusive.

Example

user1 is assigned to the **ad_hoc_queries** resource pool:

```
=> CREATE USER user1 RESOURCE POOL ad_hoc_queries;
```

RUNTIMECAP for **user1** is set to 1 hour:

```
=> ALTER USER user1 RUNTIMECAP '60 minutes';
```

RUNTIMECAP for the **ad_hoc_queries** resource pool is set to 30 minutes:

```
=> ALTER RESOURCE POOL ad_hoc_queries RUNTIMECAP '30 minutes';
```

In this example, Vertica terminates **user1**'s queries if they exceed 30 minutes. Although the **user1**'s runtime limit is set to one hour, the pool on which the query runs, which has a 30-minute runtime limit, has precedence.

Note

If a secondary pool for the **ad_hoc_queries** pool is specified using the **CASCADE TO** function, the query executes on that pool when the **RUNTIMECAP** on the **ad_hoc_queries** pool is surpassed.

- [RESOURCE_POOLS](#)
- [Defining secondary resource pools](#)

Handling session socket blocking

A session socket can be blocked while awaiting client input or output for a given query. Session sockets are typically blocked for numerous reasons—for example, when the Vertica execution engine transmits data to the client, or a [COPY LOCAL](#) operation awaits load data from the client.

In rare cases, a session socket can remain indefinitely blocked. For example, a query times out on the client, which tries to forcibly cancel the query, or relies on the session [RUNTIMECAP setting](#) to terminate it. In either case, if the query ends while awaiting messages or data, the socket can remain blocked and the session hang until it is forcibly closed.

Configuring a grace period

You can configure the system with a grace period, during which a lagging client or server can catch up and deliver a pending response. If the socket is blocked for a continuous period that exceeds the grace period setting, the server shuts down the socket and throws a fatal error. The session is then terminated. If no grace period is set, the query can maintain its block on the socket indefinitely.

You should set the session grace period high enough to cover an acceptable range of latency and avoid closing sessions prematurely—for example, normal client-side delays in responding to the server. Very large load operations might require you to adjust the session grace period as needed.

You can set the grace period at four levels, listed in descending order of precedence:

1. Session (highest)
2. User
3. Node
4. Database

Setting grace periods for the database and nodes

At the database and node levels, you set the grace period to any [interval](#) up to 20 days, through configuration parameter **BlockedSocketGracePeriod** :

- **ALTER DATABASE** *db-name* SET **BlockedSocketGracePeriod** = ' *interval* ';
- **ALTER NODE** *node-name* SET **BlockedSocketGracePeriod** = ' *interval* ';

By default, the grace period for both levels is set to an empty string, which allows unlimited blocking.

Setting grace periods for users and sessions

You can set the grace period for individual users and for a given session, as follows:

- { **CREATE** | **ALTER USER** } *user-name* **GRACEPERIOD** { ' *interval* ' | NONE };
- **SET SESSION GRACEPERIOD** { ' *interval* ' | = DEFAULT | NONE };

A user can set a session to any interval equal to or less than the grace period set for that user. Superusers can set the grace period for other users, and for their own sessions, to any value up to 20 days, inclusive.

Examples

Superuser `dbadmin` sets the database grace period to 6 hours. This limit only applies to non-superusers. `dbadmin` can set the session grace period for herself to any value up to 20 days—in this case, 10 hours:

```
=> ALTER DATABASE VMart SET BlockedSocketGracePeriod = '6 hours';
ALTER DATABASE
=> SHOW CURRENT BlockedSocketGracePeriod;
 level |      name      | setting
-----+-----
DATABASE | BlockedSocketGracePeriod | 6 hours
(1 row)

=> SET SESSION GRACEPERIOD '10 hours';
SET
=> SHOW GRACEPERIOD;
 name | setting
-----+-----
 graceperiod | 10:00
(1 row)
```

`dbadmin` creates user `user777` created with no grace period setting. Thus, the effective grace period for `user777` is derived from the database setting of `BlockedSocketGracePeriod`, which is 6 hours. Any attempt by `user777` to set the session grace period to a value greater than 6 hours returns with an error:

```
=> CREATE USER user777;
=> \c - user777
You are now connected as user "user777".
=> SHOW GRACEPERIOD;
 name | setting
-----+-----
 graceperiod | 06:00
(1 row)

=> SET SESSION GRACEPERIOD '7 hours';
ERROR 8175: The new period 07:00 would exceed the database limit of 06:00
```

`dbadmin` sets a grace period of 5 minutes for `user777`. Now, `user777` can set the session grace period to any value equal to or less than the user-level setting:

```
=> \c
You are now connected as user "dbadmin".
=> ALTER USER user777 GRACEPERIOD '5 minutes';
ALTER USER
=> \c - user777
You are now connected as user "user777".
=> SET SESSION GRACEPERIOD '6 minutes';
ERROR 8175: The new period 00:06 would exceed the user limit of 00:05
=> SET SESSION GRACEPERIOD '4 minutes';
SET
```

Managing workloads with resource pools and user profiles

The scenarios in this section describe common workload-management issues, and provide solutions with examples.

In this section

- [Periodic batch loads](#)
- [CEO query](#)
- [Preventing runaway queries](#)
- [Restricting resource usage of ad hoc query application](#)
- [Setting a hard limit on concurrency for an application](#)
- [Handling mixed workloads: batch versus interactive](#)

- [Setting priorities on queries issued by different users](#)
- [Continuous load and query](#)
- [Prioritizing short queries at run time](#)
- [Dropping the runtime priority of long queries](#)

Periodic batch loads

Scenario

You do batch loads every night, or occasionally (infrequently) during the day. When loads are running, it is acceptable to reduce resource usage by queries, but at all other times you want all resources to be available to queries.

Solution

Create a separate resource pool for loads with a higher priority than the preconfigured setting on the build-in GENERAL pool.

In this scenario, nightly loads get preference when borrowing memory from the GENERAL pool. When loads are not running, all memory is automatically available for queries.

Example

Create a resource pool that has higher priority than the GENERAL pool:

1. Create resource pool `load_pool` with PRIORITY set to 10:

```
=> CREATE RESOURCE POOL load_pool PRIORITY 10;
```

2. Modify user `load_user` to use the new resource pool:

```
=> ALTER USER load_user RESOURCE POOL load_pool;
```

CEO query

Scenario

The CEO runs a report every Monday at 9AM, and you want to be sure that the report always runs.

Solution

To ensure that a certain query or class of queries always gets resources, you could create a dedicated pool for it as follows:

1. Using the `PROFILE` command, run the query that the CEO runs every week to determine how much memory should be allocated:

```
=> PROFILE SELECT DISTINCT s.product_key, p.product_description
-> FROM store.store_sales_fact s, public.product_dimension p
-> WHERE s.product_key = p.product_key AND s.product_version = p.product_version
-> AND s.store_key IN (
-> SELECT store_key FROM store.store_dimension
-> WHERE store_state = 'MA')
-> ORDER BY s.product_key;
```

2. At the end of the query, the system returns a notice with resource usage:

```
NOTICE: Statement is being profiled.HINT: select * from v_monitor.execution_engine_profiles where
transaction_id=45035996273751349 and statement_id=6;
NOTICE: Initiator memory estimate for query: [on pool general: 1723648 KB,
minimum: 355920 KB]
```

3. Create a resource pool with MEMORYSIZE reported by the above hint to ensure that the CEO query has at least this memory reserved for it:

```

=> CREATE RESOURCE POOL ceo_pool MEMORYSIZE '1800M' PRIORITY 10;
CREATE RESOURCE POOL
=> \x
Expanded display is on.
=> SELECT * FROM resource_pools WHERE name = 'ceo_pool';
-[ RECORD 1 ]-----+-----
name          | ceo_pool
is_internal   | f
memorysize    | 1800M
maxmemorysize |
priority      | 10
queuetimeout  | 300
plannedconcurrency | 4
maxconcurrency |
singleinitiator | f

```

4. Assuming the CEO report user already exists, associate this user with the above resource pool using ALTER USER statement.

```

=> ALTER USER ceo_user RESOURCE POOL ceo_pool;

```

5. Issue the following command to confirm that the ceo_user is associated with the ceo_pool:

```

=> SELECT * FROM users WHERE user_name = 'ceo_user';
-[ RECORD 1 ]-----+-----
user_id      | 45035996273713548
user_name    | ceo_user
is_super_user | f
resource_pool | ceo_pool
memory_cap_kb | unlimited

```

If the CEO query memory usage is too large, you can ask the Resource Manager to reduce it to fit within a certain budget. See [Query budgeting](#).

Preventing runaway queries

Scenario

Joe, a business analyst often runs big reports in the middle of the day that take up the whole machine's resources. You want to prevent Joe from using more than 100MB of memory, and you want to also limit Joe's queries to run for less than 2 hours.

Solution

[User resource allocation](#) provides a solution to this scenario. To restrict the amount of memory Joe can use at one time, set a MEMORYCAP for Joe to 100MB using the [ALTER USER](#) command. To limit the amount of time that Joe's query can run, set a RUNTIMECAP to 2 hours using the same command. If any query run by Joe takes up more than its cap, Vertica rejects the query.

If you have a whole class of users whose queries you need to limit, you can also create a resource pool for them and set RUNTIMECAP for the resource pool. When you move these users to the resource pool, Vertica limits all queries for these users to the RUNTIMECAP you specified for the resource pool.

Example

```

=> ALTER USER analyst_user MEMORYCAP '100M' RUNTIMECAP '2 hours';

```

If Joe attempts to run a query that exceeds 100MB, the system returns an error that the request exceeds the memory session limit, such as the following example:

```

\i vmart_query_04.sqlvsq:vmart_query_04.sql:12: ERROR: Insufficient resources to initiate plan
on pool general [Request exceeds memory session limit: 137669KB > 102400KB]

```

Only the system database administrator (dbadmin) can increase only the MEMORYCAP setting. Users cannot increase their own MEMORYCAP settings and will see an error like the following if they attempt to edit their MEMORYCAP or RUNTIMECAP settings:

```

ALTER USER analyst_user MEMORYCAP '135M';
ROLLBACK: permission denied

```

Restricting resource usage of ad hoc query application

Scenario

You recently made your data warehouse available to a large group of users who are inexperienced with SQL. Some users run reports that operate on

a large number of rows and overwhelm the system. You want to throttle system usage by these users.

Solution

1. Create a resource pool for ad hoc applications where MAXMEMORYSIZE is equal to MEMORYSIZE. This prevents queries in that resource pool from borrowing resources from the GENERAL pool. Also, set RUNTIMECAP to limit the maximum duration of ad hoc queries:

```
=> CREATE RESOURCE POOL adhoc_pool
MEMORYSIZE '200M'
MAXMEMORYSIZE '200M'
RUNTIMECAP '20 seconds'
PRIORITY 0
QUEUETIMEOUT 300
PLANNEDCONCURRENCY 4;
=> SELECT pool_name, memory_size_kb, queueing_threshold_kb
FROM V_MONITOR.RESOURCE_POOL_STATUS WHERE pool_name='adhoc_pool';
pool_name | memory_size_kb | queueing_threshold_kb
-----+-----+-----
adhoc_pool |      204800 |          153600
(1 row)
```

2. Associate this resource pool with database users who use the application to connect to the database.

```
=> ALTER USER app1_user RESOURCE POOL adhoc_pool;
```

Tip

Other solutions include limiting the memory usage of individual users such as in the [Preventing runaway queries](#).

Setting a hard limit on concurrency for an application

Scenario

For billing purposes, analyst Jane would like to impose a hard limit on concurrency for this application. How can she achieve this?

Solution

The simplest solution is to create a separate resource pool for the users of that application and set its MAXCONCURRENCY to the desired concurrency level. Any queries beyond MAXCONCURRENCY are queued.

Tip

Vertica recommends leaving PLANNEDCONCURRENCY to the default level so the queries get their maximum amount of resources. The system as a whole thus runs with the highest efficiency.

Example

In this example, there are four billing users associated with the billing pool. The objective is to set a hard limit on the resource pool so a maximum of three concurrent queries can be executed at one time. All other queries will queue and complete as resources are freed.

```

=> CREATE RESOURCE POOL billing_pool MAXCONCURRENCY 3 QUEUETIMEOUT 2;
=> CREATE USER bill1_user RESOURCE POOL billing_pool;
=> CREATE USER bill2_user RESOURCE POOL billing_pool;
=> CREATE USER bill3_user RESOURCE POOL billing_pool;
=> CREATE USER bill4_user RESOURCE POOL billing_pool;
=> \x

```

Expanded display is on.

```

=> select maxconcurrency,queuetimeout from resource_pools where name = 'billing_pool';

```

```

maxconcurrency | queuetimeout

```

```

-----+-----
      3 |      2

```

(1 row)

```

> SELECT reason, resource_type, rejection_count FROM RESOURCE_REJECTIONS
WHERE pool_name = 'billing_pool' AND node_name ilike '%node0001';

```

```

reason          | resource_type | rejection_count

```

```

-----+-----+-----

```

```

Timeoutd waiting for resource request | Queries |      16

```

(1 row)

If queries are running and do not complete in the allotted time (default timeout setting is 5 minutes), the next query requested gets an error similar to the following:

```

ERROR: Insufficient resources to initiate plan on pool billing_pool [Timeoutd waiting for resource request: Request exceeds limits:
Queries Exceeded: Requested = 1, Free = 0 (Limit = 3, Used = 3)]

```

The table below shows that there are three active queries on the billing pool.

```

=> SELECT pool_name, thread_count, open_file_handle_count, memory_inuse_kb FROM RESOURCE_ACQUISITIONS

```

```

WHERE pool_name = 'billing_pool';

```

```

pool_name | thread_count | open_file_handle_count | memory_inuse_kb

```

```

-----+-----+-----+-----

```

```

billing_pool |      4 |      5 |    132870

```

```

billing_pool |      4 |      5 |    132870

```

```

billing_pool |      4 |      5 |    132870

```

Handling mixed workloads: batch versus interactive

Scenario

You have a web application with an interactive portal. Sometimes when IT is running batch reports, the web page takes a long time to refresh and users complain, so you want to provide a better experience to your web site users.

Solution

The principles learned from the previous scenarios can be applied to solve this problem. The basic idea is to segregate the queries into two groups associated with different resource pools. The prerequisite is that there are two distinct database users issuing the different types of queries. If this is not the case, do consider this a best practice for application design.

****Method 1**

****Create a dedicated pool for the web page refresh queries where you:**

- Size the pool based on the average resource needs of the queries and expected number of concurrent queries issued from the portal.
- Associate this pool with the database user that runs the web site queries. See [CEO query](#) for information about creating a dedicated pool.

This ensures that the web site queries always run and never queue behind the large batch jobs. Leave the batch jobs to run off the GENERAL pool.

For example, the following pool is based on the average resources needed for the queries running from the web and the expected number of concurrent queries. It also has a higher PRIORITY to the web queries over any running batch jobs and assumes the queries are being tuned to take 250M each:

```
=> CREATE RESOURCE POOL web_pool
MEMORYSIZE '250M'
MAXMEMORYSIZE NONE
PRIORITY 10
MAXCONCURRENCY 5
PLANNEDCONCURRENCY 1;
```

**Method 2

**Create a resource pool with fixed memory size. This limits the amount of memory available to batch reports so memory is always left over for other purposes. For details, see [Restricting resource usage of ad hoc query application](#).

For example:

```
=> CREATE RESOURCE POOL batch_pool
MEMORYSIZE '4G'
MAXMEMORYSIZE '4G'
MAXCONCURRENCY 10;
```

The same principle can be applied if you have three or more distinct classes of workloads.

Setting priorities on queries issued by different users

Scenario

You want user queries from one department to have a higher priority than queries from another department.

Solution

The solution is similar to the [mixed workload case](#). In this scenario, you do not limit resource usage; you set different priorities. To do so, create two different pools, each with MEMORYSIZE=0% and a different PRIORITY parameter. Both pools borrow from the GENERAL pool, however when competing for resources, the priority determine the order in which each pool's request is granted. For example:

```
=> CREATE RESOURCE POOL dept1_pool PRIORITY 5;
=> CREATE RESOURCE POOL dept2_pool PRIORITY 8;
```

If you find this solution to be insufficient, or if one department's queries continuously starves another department's users, you can add a reservation for each pool by setting MEMORYSIZE so some memory is guaranteed to be available for each department.

For example, both resources use the GENERAL pool for memory, so you can allocate some memory to each resource pool by using ALTER RESOURCE POOL to change MEMORYSIZE for each pool:

```
=> ALTER RESOURCE POOL dept1_pool MEMORYSIZE '100M';
=> ALTER RESOURCE POOL dept2_pool MEMORYSIZE '150M';
```

Continuous load and query

Scenario

You want your application to run continuous load streams, but many have up concurrent query streams. You want to ensure that performance is predictable.

Solution

The solution to this scenario depends on your query mix. In all cases, the following approach applies:

1. Determine the number of continuous load streams required. This may be related to the desired load rate if a single stream does not provide adequate throughput, or may be more directly related to the number of sources of data to load. Create a dedicated resource pool for the loads, and associate it with the database user that will perform them. See [CREATE RESOURCE POOL](#) for details.
In general, concurrency settings for the load pool should be less than the number of cores per node. Unless the source processes are slow, it is more efficient to dedicate more memory per load, and have additional loads queue. Adjust the load pool's QUEUETIMEOUT setting if queuing is expected.
2. Run the load workload for a while and observe whether the load performance is as expected. If the Tuple Mover is not tuned adequately to cover the load behavior, see [Managing the tuple mover](#).
3. If there is more than one kind of query in the system—for example, some queries must be answered quickly for interactive users, while others are part of a batch reporting process—follow the guidelines in [Handling mixed workloads: batch versus interactive](#).
4. Let the queries run and observe performance. If some classes of queries do not perform as desired, then you might need to tune the GENERAL pool as outlined in [Restricting resource usage of ad hoc query application](#), or create more dedicated resource pools for those queries. For more information, see [CEO query](#) and [Handling mixed workloads: batch versus interactive](#).

See the sections on [Managing workloads](#) and [CREATE RESOURCE POOL](#) for information on obtaining predictable results in mixed workload environments.

Prioritizing short queries at run time

Scenario

You recently created a resource pool for users who are inexperienced with SQL and who frequently run ad hoc reports. Until now, you managed resource allocation by creating a resource pool where MEMORYSIZE and MAXMEMORYSIZE are equal. This prevented queries in that resource pool from borrowing resources from the GENERAL pool. Now you want to manage resources at run time and prioritize short queries so they are never queued as a result of limited run-time resources.

Solution

- Set **RUNTIMEPRIORITY** for the resource pool to MEDIUM or LOW.
- Set **RUNTIMEPRIORITYTHRESHOLD** for the resource pool to the duration of queries you want to ensure always run at a high priority.

For example:

```
=> ALTER RESOURCE POOL ad_hoc_pool RUNTIMEPRIORITY medium RUNTIMEPRIORITYTHRESHOLD 5;
```

Because **RUNTIMEPRIORITYTHRESHOLD** is set to 5, all queries in resource pool **ad_hoc_pool** that complete within 5 seconds run at high priority. Queries that exceeds 5 seconds drop down to the **RUNTIMEPRIORITY** assigned to the resource pool, MEDIUM.

Dropping the runtime priority of long queries

Scenario

You want most queries in a resource pool to run at a HIGH runtime priority; however, you'd like to be able to drop jobs longer than 1 hour to a lower priority.

Solution

Set the **RUNTIMEPRIORITY** for the resource pool to LOW and set the **RUNTIMEPRIORITYTHRESHOLD** to a number that cuts off only the longest jobs.

Example

To ensure that all queries with a duration of more than 3600 seconds (1 hour) are assigned a low runtime priority, modify the resource pool as follows:

- Set the **RUNTIMEPRIORITY** to LOW.
- Set the **RUNTIMETHRESHOLD** to 3600

```
=> ALTER RESOURCE POOL ad_hoc_pool RUNTIMEPRIORITY low RUNTIMEPRIORITYTHRESHOLD 3600;
```

Tuning built-in pools

The scenarios in this section describe how to tune built-in pools.

- [Restricting Vertica to take only 60% of memory](#)
- [Tuning for recovery](#)
- [Tuning for refresh](#)
- [Tuning tuple mover pool settings](#)
- [Tuning for machine learning](#)

In this section

- [Restricting Vertica to take only 60% of memory](#)
- [Tuning for recovery](#)
- [Tuning for refresh](#)
- [Tuning tuple mover pool settings](#)
- [Tuning for machine learning](#)

Restricting Vertica to take only 60% of memory

Scenario

You have a single node application that embeds Vertica, and some portion of the RAM needs to be devoted to the application process. In this scenario, you want to limit Vertica to use only 60% of the available RAM.

Solution

Set the `MAXMEMORYSIZE` parameter of the `GENERAL` pool to the desired memory size. See [Resource pool architecture](#) for a discussion on resource limits.

Tuning for recovery

Scenario

You have a large database that contains a single large table with two projections, and with default settings, recovery is taking too long. You want to give recovery more memory to improve speed.

Solution

Set `PLANNEDCONCURRENCY` and `MAXCONCURRENCY` in the `RECOVERY` pool to 1, so recovery can take as much memory as possible from the `GENERAL` pool and run only one thread at once.

Caution

This setting can slow down other queries in your system.

Tuning for refresh

Scenario

When a [refresh](#) operation is running, system performance is affected and user queries are rejected. You want to reduce the memory usage of the refresh job.

Solution

Set `MEMORYSIZE` in the `REFRESH` pool to a fixed value. The Resource Manager then tunes the refresh query to only use this amount of memory.

Important

Remember to reset `MEMORYSIZE` in the `REFRESH` pool to 0% after the refresh operation completes, so memory can be used for other operations.

Tuning tuple mover pool settings

Scenario 1

During heavy load operations, you occasionally notice spikes in the number of ROS containers. You would like the Tuple Mover to perform mergeout more aggressively to consolidate ROS containers, and avoid ROS pushback.

Solution

Use [ALTER RESOURCE POOL](#) to increase the setting of `MAXCONCURRENCY` in the [TM resource pools](#). This setting determines how many threads are available for mergeout. By default, this parameter is set to 7. Vertica allocates half the threads to active partitions, and the remaining half to active and inactive partitions as needed. If `MAXCONCURRENCY` is set to an uneven integer, Vertica rounds up to favor active partitions.

For example, if you increase `MAXCONCURRENCY` to 9, then Vertica allocates five threads exclusively to active partitions, and allocates the remaining four threads to active and inactive partitions.

Scenario 2

You have a secondary subcluster that is dedicated to time-sensitive analytic queries. You want to limit any other workloads on this subcluster that could interfere with it processing queries while also freeing up memory to perform queries.

By default, each subcluster has a built-in TM resource pool for Tuple Mover operations that makes it eligible to execute Tuple Mover mergeout operations. The TM pool consumes memory that could be used for queries. In addition, the mergeout operation could add a slight overhead to your subcluster's processing. You want to reallocate the memory consumed by the TM pool, and prevent the subcluster from running mergeout operations.

Solution

Use [ALTER RESOURCE POOL](#) to override the global TM resource pool for the secondary subcluster, and set both its `MAXMEMORYSIZE` and `MEMORYSIZE` to 0. This allows you to use the memory consumed by the global TM pool for use running analytic queries and prevents the subcluster being assigned TM mergeout operations to execute.

Tuning for machine learning

Scenario

A large number of machine learning functions are running, and you want to give them more memory to improve performance.

Solution

Vertica executes machine learning functions in the BLOBDATA resource pool. To improve performance of machine learning functions and avoid spilling queries to disk, increase the pool's MAXMEMORYSIZE setting with [ALTER RESOURCE POOL](#).

For more about tuning query budgets, see [Query budgeting](#).

See also

- [Managing resources at query run time](#)
- [Built-in resource pools configuration](#)

Reducing query run time

Query run time depends on the complexity of the query, the number of operators in the plan, data volumes, and projection design. I/O or CPU bottlenecks can cause queries to run slower than expected. You can often remedy high CPU usage with [better projection design](#). High I/O can often be traced to contention caused by joins and sorts that spill to disk. However, no single solution addresses all queries that incur high CPU or I/O usage. You must analyze and tune each query individually.

You can evaluate a slow-running query in two ways:

- Prefix the query with [EXPLAIN](#) to view the optimizer's query plan.
- Examine the execution profile by querying system tables [QUERY_CONSUMPTION](#) or [EXECUTION_ENGINE_PROFILES](#).

Examining the query plan can reveal one or more of the following:

- Suboptimal projection sort order
- Predicate evaluation on an unsorted or unencoded column
- Use of [GROUPBY HASH](#) instead of [GROUPBY PIPE](#)

Profiling

Vertica provides profiling mechanisms that help you evaluate database performance at different levels. For example, you can collect profiling data for a single statement, a single session, or for all sessions on all nodes. For details, see [Profiling database performance](#).

Managing workload resources in an Eon Mode database

You primarily control workloads in an Eon Mode database using subclusters. For example, you can create subclusters for specific use cases, such as ETL or query workloads, or you can create subclusters for different groups of users to isolate workloads. Within each subcluster, you can create individual resource pools to optimize resource allocation according to workload. See [Managing subclusters](#) for more information about how Vertica uses subclusters.

Global and subcluster-specific resource pools

You can define global resource pool allocations that affect all nodes in the database. You can also create resource pool allocations at the subcluster level. If you create both, the subcluster-level settings override the global settings.

Note

The GENERAL pool requires at least 25% of available memory to function properly. If you attempt to set MEMORYSIZE for a user-defined resource pool to more than 75%, Vertica returns an error.

You can use this feature to remove global resource pools that the subcluster does not need. Additionally, you can create a resource pool with settings that are adequate for most subclusters, and then tailor the settings for specific subclusters as needed.

Optimizing ETL and query subclusters

Overriding resource pool settings at the subcluster level allows you to isolate built-in and user-defined resource pools and optimize them by workload. You often assign specific roles to different subclusters:

- Subclusters dedicated to ETL workloads and DDL statements that alter the database.
- Subclusters dedicated to running in-depth, long-running analytics queries. These queries need more resources allocated for the best performance.
- Subclusters that run many short-running "dashboard" queries that you want to finish quickly and run in parallel.

After you define the type of queries executed by each subcluster, you can create a subcluster-specific resource pool that is optimized to improve efficiency for that workload.

The following scenario optimizes 3 subclusters by workload:

- etl: A subcluster that performs ETL that you want to optimize for Tuple Mover operations.
- dashboard: A subcluster that you want to designate for short-running queries executed by a large number of users to refresh a web page.
- analytics: A subcluster that you want to designate for long-running queries.

See [Best practices for managing workload resources](#) for additional scenarios about resource pool tuning.

Configure an ETL subcluster to improve TM performance

Vertica chooses the subcluster that has the most ROS containers involved in a mergeout operation in its depot to execute a mergeout (see [The Tuple Mover in Eon Mode Databases](#)). Often, a subcluster performing ETL will be the best candidate to perform a mergeout because the data it loaded is involved in the mergeout. You can choose to improve the performance of mergeout operations on a subcluster by altering the TM pool's MAXCONCURRENCY setting to increase the number of threads available for mergeout operations. You cannot change this setting at the subcluster level, so you must set it globally:

```
=> ALTER RESOURCE POOL TM MAXCONCURRENCY 10;
```

See [Tuning tuple mover pool settings](#) for additional information about Tuple Mover resources.

Configure the dashboard query subcluster

By default, secondary subclusters have memory allocated to Tuple Mover resource pools. This pool setting allows Vertica to assign mergeout operations to the subcluster, which can add a small overhead. If you primarily use a secondary subcluster for queries, the best practice is to reclaim the memory used by the TM pool and prevent mergeout operations being assigned to the subcluster.

To optimize your dashboard query secondary subcluster, set their TM pool's MEMORYSIZE and MAXMEMORYSIZE settings to 0:

```
=> ALTER RESOURCE POOL TM FOR SUBCLUSTER dashboard MEMORYSIZE '0%'
    MAXMEMORYSIZE '0%';
```

Important

Do not set the TM pool's MEMORYSIZE and MAXMEMORYSIZE settings to 0 on [primary subclusters](#). They must always be able to run the Tuple Mover.

To confirm the overrides, query the [SUBCLUSTER_RESOURCE_POOL_OVERRIDES](#) table:

```
=> SELECT pool_oid, name, subcluster_name, memorysize, maxmemorysize
    FROM SUBCLUSTER_RESOURCE_POOL_OVERRIDES;
```

```
pool_oid | name | subcluster_name | memorysize | maxmemorysize
-----+-----+-----+-----+-----
45035996273705046 | tm | dashboard | 0% | 0%
(1 row)
```

To optimize the dashboard subcluster for short-running queries on a web page, create a dash_pool subcluster-level resource pool that uses 70% of the subcluster's memory. Additionally, increase PLANNEDCONCURRENCY to use all of the machine's logical cores, and limit EXECUTIONPARALLELISM to no more than half of the machine's available cores:

```
=> CREATE RESOURCE POOL dash_pool FOR SUBCLUSTER dashboard
    MEMORYSIZE '70%'
    PLANNEDCONCURRENCY 16
    EXECUTIONPARALLELISM 8;
```

Configure the analytic query subcluster

To optimize the analytics subcluster for long-running queries, create an analytics_pool subcluster-level resource pool that uses 60% of the subcluster's memory. In this scenario, you cannot allocate more memory to this pool because the nodes in this subcluster still have memory assigned to their TM pools. Additionally, set EXECUTIONPARALLELISM to AUTO to use all cores available on the node to process a query, and limit PLANNEDCONCURRENCY to no more than 8 concurrent queries:

```
=> CREATE RESOURCE POOL analytics_pool FOR SUBCLUSTER analytics
    MEMORYSIZE '60%'
    EXECUTIONPARALLELISM AUTO
    PLANNEDCONCURRENCY 8;
```

Managing system resource usage

You can use the [Using system tables](#) to track overall resource usage on your cluster. These and the other system tables are described in the [Vertica system tables](#).

If your queries are experiencing errors due to resource unavailability, you can use the following system tables to obtain more details:

System Table	Description
RESOURCE_REJECTIONS	Monitors requests for resources that are rejected by the Resource manager .
DISK_RESOURCE_REJECTIONS	Monitors requests for resources that are rejected due to disk space shortages. See Managing disk space for more information.

When requests for resources of a certain type are being rejected, do one of the following:

- Increase the resources available on the node by adding more memory, more disk space, and so on. See [Managing disk space](#).
- Reduce the demand for the resource by reducing the number of users on the system (see [Managing sessions](#)), rescheduling operations, and so on.

The [LAST_REJECTED_VALUE](#) field in [RESOURCE_REJECTIONS](#) indicates the cause of the problem. For example:

- The message [Usage of a single requests exceeds high limit](#) means that the system does not have enough of the resource available for the single request. A common example occurs when the file handle limit is set too low and you are loading a table with a large number of columns.
- The message [Timed out or Canceled waiting for resource reservation](#) usually means that there is too much contention for the resource because the hardware platform cannot support the number of concurrent users using it.

In this section

- [Managing sessions](#)
- [Managing load streams](#)

Managing sessions

Vertica provides several methods for database administrators to view and control sessions. The methods vary according to the type of session:

- External (user) sessions are initiated by vsql or programmatic (ODBC or JDBC) connections and have associated client state.
- Internal (system) sessions are initiated by Vertica and have no client state.

Configuring maximum sessions

The maximum number of per-node user sessions is set by the configuration parameter [MaxClientSessions](#) parameter, by default 50. You can set [MaxClientSessions](#) parameter to any value between 0 and 1000. In addition to this maximum, Vertica also allows up to five administrative sessions per node.

For example:

```
=> ALTER DATABASE DEFAULT SET MaxClientSessions = 100;
```

Note

If you use the Administration Tools "Connect to Database" option, Vertica will attempt connections to other nodes if a local connection does not succeed. These cases can result in more successful "Connect to Database" commands than you would expect given the [MaxClientSessions](#) value.

Viewing sessions

The system table [SESSIONS](#) contains detailed information about user sessions and returns one row per session. Superusers have unrestricted access to all database metadata. Access for other users varies according to their [privileges](#).

Interrupting and closing sessions

You can interrupt a running statement with the Vertica function [INTERRUPT_STATEMENT](#). Interrupting a running statement returns a session to an idle state:

- No statements or transactions are running.
- No locks are held.
- The database is doing no work on behalf of the session.

Closing a user session interrupts the session and disposes of all state related to the session, including client socket connections for the target sessions. The following Vertica functions close one or more user sessions:

- [CLOSE_SESSION](#)
- [CLOSE_ALL_SESSIONS](#)
- [CLOSE_USER_SESSIONS](#)
- [SHUTDOWN](#)

SELECT statements that call these functions return after the interrupt or close message is delivered to all nodes. The function might return before Vertica completes execution of the interrupt or close operation. Thus, there might be a delay after the statement returns and the interrupt or close takes effect throughout the cluster. To determine if the session or transaction ended, query the **SESSIONS** system table.

In order to shut down a database, you must first close all user sessions. For more about database shutdown, see [Stopping the database](#).

Managing load streams

You can use system table [LOAD_STREAMS](#) to monitor data as it is loaded on your cluster. Several columns in this table show metrics for each load stream on each node, including the following:

Column name	Value...
ACCEPTED_ROW_COUNT	Increases during parsing, up to the maximum number of rows in the input file.
PARSE_COMPLETE_PERCENT	Remains zero (0) until all named pipes return an EOF. While COPY awaits an EOF from multiple pipes, it can appear to be hung. However, before canceling the COPY statement, check your system CPU and disk accesses to determine if any activity is in progress. In a typical load, the PARSE_COMPLETE_PERCENT value can either increase slowly or jump quickly to 100%, if you are loading from named pipes or STDIN.
SORT_COMPLETE_PERCENT	Remains at 0 when loading from named pipes or STDIN. After PARSE_COMPLETE_PERCENT reaches 100 percent, SORT_COMPLETE_PERCENT increases to 100 percent.

Depending on the data sizes, a significant lag can occur between the time [PARSE_COMPLETE_PERCENT](#) reaches 100 percent and the time [SORT_COMPLETE_PERCENT](#) begins to increase.

Node Management Agent

The Node Management Agent (NMA) lets you administer your cluster with a REST API. The NMA listens on port 5554 and runs on all nodes.

Start the NMA

To start the NMA on all nodes, run the following on any Vertica node:

```
$ /opt/vertica/bin/manage_node_agent.sh start node_management_agent
```

To verify that the NMA is running, you can send a GET request to `/v1/health`, which returns `{"healthy":"true"}` if the NMA is running.

When you first start the NMA, Vertica recommends that you perform this verification from inside the cluster. While you can and should still verify that the NMA is reachable from outside the cluster, doing it first from inside the cluster removes possible network and environmental interference:

```
$ curl https://localhost:5554/v1/health -k  
{"healthy":"true"}
```

To send this and other requests from outside the cluster, see [Endpoints](#).

If the request to `/v1/health` hangs or otherwise fails, perform the following troubleshooting steps:

- Verify that port 5554 is not being used by any other process on the target node.
- Verify that the host and port 5554 are accessible by the client.
- Open `/opt/vertica/log/node_management_agent.log` and verify that the endpoint can reach the NMA service.

Stop the NMA

To stop the NMA, send a PUT request to [/v1/nma/shutdown](#) :

For simplicity, the following command is run from a Vertica node and specifies paths for certificates generated by the [install_vertica_script](#). To send this and other requests from outside the cluster, see [Endpoints](#) .

```
$ curl -X PUT https://localhost:5554/v1/nma/shutdown -k \
  --key /opt/vertica/config/https_certs/dbadmin.key \
  --cert /opt/vertica/config/https_certs/dbadmin.pem \
  --cacert /opt/vertica/config/https_certs/rootca.pem

{"shutdown_error": "Null", "shutdown_message": "NMA server stopped", "shutdown_scheduled": "NMA server shutdown scheduled"}
```

In this section

- [API Docs](#)
- [Custom certificates](#)
- [Endpoints](#)

Custom certificates

The Node Management Agent (NMA) starts with the following certificates by default. These certificates are automatically generated by the [install_vertica_script](#) in the `/opt/vertica/config/https_certs` directory. The certificate authority (CA) certificate is a self-signed certificate, but is safe to use with the NMA in production environments:

- [vertica_https.key](#) (private key)
- [vertica_https.pem](#) (certificate)
- [rootca.pem](#) (CA certificate)

If you want to use custom certificates or cannot run `install_vertica`, you can specify custom certificates with environment variables. Invalid values for these parameters prevent the NMA from starting, and the failure is logged in `/opt/vertica/log/node_management_agent.log` .

Each category of environment variable (literal certificate or path) must either be set together with valid parameters or not at all. For example, setting only `NMA_ROOTCA` and `NMA_CERT` causes an error. Similarly, setting `NMA_ROOTCA_PATH` , `NMA_CERT_PATH` , and `NMA_KEY_PATH` would also cause an error if `NMA_KEY_PATH` references an invalid path.

Certificate literals

NMA_ROOTCA

A PEM-encoded root CA certificate or concatenated CA certificates.

NMA_CERT

A PEM-encoded server certificate.

NMA_KEY

A PEM-encoded private key.

Certificate paths

Note

In general, you should use absolute paths for the `_PATH` environment variables. Relative paths must be relative to the current working directory of the process.

NMA_ROOTCA_PATH

The path to a file containing either a PEM-encoded root CA certificate or concatenated CA certificates.

NMA_CERT_PATH

The path to a PEM-encoded server certificate.

NMA_KEY_PATH

The path to a PEM-encoded private key.

Configuration precedence

The NMA attempts to use the specified certificates in the following order. If all parameters at a given level are unset, the NMA falls through and attempts to use the parameters, if any, at the next level. However, if the parameters at a given level are only partially set or invalid, the NMA does not fall through and instead produces an error:

1. Environment specifying a literal certificate (`NMA_ROOTCA` , `NMA_CERT` , `NMA_KEY`).
2. Environment variables specifying the path to a certificate (`NMA_ROOTCA_PATH` , `NMA_CERT_PATH` , `NMA_KEY_PATH`).
3. `/opt/vertica/config/https_certs/tls_path_cache.yaml` , which caches the values of the certificate path environment variables. In general, you should not edit this file, but you can delete it to return to Vertica defaults.
4. The default certificates at the default path: `/opt/vertica/config/https_certs` .

Endpoints

The Node Management Agent exposes several endpoints on port 5554 for performing various node operations.

For a static, publicly accessible copy of the documentation for all NMA endpoints, see [NMA API Docs](#) . This can be used as a general reference if you don't have access to a local instance of the NMA and its `/api-docs/` endpoint.

Prerequisites

For all endpoints other than `/api-docs/` and `/v1/health` , the Node Management Agent (NMA) authenticates users of its API with [mutual TLS](#) . The client and Vertica server must each provide the following so that the other party can verify their identity:

- Private key
- Certificate
- Certificate authority (CA) certificate

Server configuration

If you installed Vertica with the [install_vertica script](#) , Vertica should already be configured for mutual TLS for NMA. The `install_vertica` script automatically creates the necessary keys and certificates in `/opt/vertica/config/https_certs` . These certificates are also used by the HTTPS service.

Note

The CA certificate, `rootca.pem` , is a self-signed certificate and is safe to use in production with the NMA. If you want to use custom certificates, see [Custom certificates](#) .

If you do not have files in `/opt/vertica/config/https_certs` , run `install_vertica --generate-https-certs-only` , specifying the hosts of every Vertica node with the `--hosts` option. This generates the keys and certificates in the `/opt/vertica/config/https_certs` directory on each of the specified hosts.

For example, for a Vertica cluster with nodes on hosts `192.0.2.100` , `192.0.2.101` , `192.0.2.102` :

```
$ /opt/vertica/sbin/install_vertica --dba-user dbadmin \  
  --dba-group verticadba \  
  --hosts '192.0.2.100, 192.0.2.101, 192.0.2.102' \  
  --ssh-identity '/home/dbadmin/.ssh/id_rsa' \  
  --generate-https-certs-only
```

Client configuration

Copy the following files from `/opt/vertica/config/https_certs` to client machines that send requests to NMA:

- `dbadmin.key` (private key)
- `dbadmin.pem` (certificate)
- `rootca.pem` (CA certificate)

You can then use these files when sending requests to the NMA. For example, to send a GET request to the `/v1/health` endpoint with `curl` :

```
$ curl https://localhost:5554/v1/health -k \  
  --key /opt/vertica/config/https_certs/dbadmin.key \  
  --cert /opt/vertica/config/https_certs/dbadmin.pem \  
  --cacert /opt/vertica/config/https_certs/rootca.pem
```

If you want to use your browser to send requests to NMA, copy the PKCS #12 file `dbadmin.p12` to your client machine and import it into your browser. This file packages the private key, certificate, and CA certificate together as one file. The steps for importing PKCS #12 files vary between browsers, so consult your browser's documentation for instructions.

Endpoints

The following are basic, general-purpose endpoints for interacting with your database, as opposed to the advanced endpoints exclusively documented by `/api-docs/` .

/v1/health (GET)

Send a GET request to [/v1/health](#) to verify the status of the NMA. This endpoint does not require authentication. If the NMA is running, [/v1/health](#) responds with `{"healthy":"true"}` :

```
$ curl https://localhost:5554/v1/health -k
{"healthy":"true"}
```

In general, [/v1/health](#) cannot return `{"healthy":"false"}` . In cases where NMA is not functioning properly, [/v1/health](#) will either hang or clients will fail to connect entirely:

```
$ curl https://localhost:5554/v1/health -k
curl: (7) Failed connect to localhost:5554: Connection refused
```

/v1/vertica/version (GET)

Send a GET request to [/v1/vertica/version](#) to retrieve the version of Vertica:

```
$ curl https://localhost:5554/v1/vertica/version -k \
  --key /opt/vertica/config/https_certs/dbadmin.key \
  --cert /opt/vertica/config/https_certs/dbadmin.pem \
  --cacert /opt/vertica/config/https_certs/rootca.pem
{"vertica_version":"Vertica Analytic Database v23.3.0-20230613"}
```

/v1/nma/shutdown (PUT)

Send a PUT request to [/v1/shutdown](#) to shut down the NMA:

```
$ curl -X PUT https://localhost:5554/v1/nma/shutdown -k \
  --key /opt/vertica/config/https_certs/dbadmin.key \
  --cert /opt/vertica/config/https_certs/dbadmin.pem \
  --cacert /opt/vertica/config/https_certs/rootca.pem
{"shutdown_error":"Null","shutdown_message":"NMA server stopped","shutdown_scheduled":"NMA server shutdown scheduled"}
```

/v1/vertica-processes/signal-vertica (POST)

Send a POST request to the [/v1/vertica-processes/signal-vertica](#) endpoint to send a KILL or TERM signal to the Vertica process. This endpoint takes the following query parameters:

signal_type

Either `kill` or `term` (default), the signal to send to the Vertica process.

catalog_path

The path of the catalog for the instance of Vertica to signal. Specify the catalog path when there is more than one database running on a single host, or if the NMA must distinguish between Vertica processes. For example, if there are old or stale Vertica processes on the target node.

To terminate the Vertica process:

```
$ curl -X POST https://localhost:5554/v1/vertica-processes/signal-vertica -k \
  --key /opt/vertica/config/https_certs/dbadmin.key \
  --cert /opt/vertica/config/https_certs/dbadmin.pem \
  --cacert /opt/vertica/config/https_certs/rootca.pem
{"status": "Signal has been sent to the Vertica process"}
```

To kill the Vertica process:

```
$ curl -X POST https://localhost:5554/v1/vertica-processes/signal-vertica?signal_type=kill -k \
  --key /opt/vertica/config/https_certs/dbadmin.key \
  --cert /opt/vertica/config/https_certs/dbadmin.pem \
  --cacert /opt/vertica/config/https_certs/rootca.pem
{"status": "Signal has been sent to the Vertica process"}
```

To kill the Vertica process with the catalog path `/home/dbadmin/VMart/v_vmart_node0001_catalog/` :

```
$ curl -X POST https://localhost:5554/v1/vertica-processes/signal-vertica?signal_type=kill&catalog_path=/home/dbadmin/VMart/v_vmart_node0001_catalog/ \
--key /opt/vertica/config/https_certs/dbadmin.key \
--cert /opt/vertica/config/https_certs/dbadmin.pem \
--cacert /opt/vertica/config/https_certs/rootca.pem

{"status": "Signal has been sent to the Vertica process"}
```

/api-docs/ (GET)

Send a GET request to the `/api-docs/` endpoint to get the Swagger UI documentation for all NMA endpoints. This endpoint does not require authentication and serves the documentation in `.json` , `.yaml` , and `.html` formats.

The `/api-docs/` endpoint contains documentation for additional endpoints not listed on this page. These extra endpoints should only be used by advanced users and developers to manage and integrate their Vertica database with applications and scripts.

To retrieve the `.json` -formatted documentation, send a GET request to `/api-docs/nma_swagger.json` :

```
$ curl https://localhost:5554/api-docs/nma_swagger.json -k
```

To retrieve the `.yaml` -formatted documentation, send a GET request to `/api-docs/nma_swagger.yaml` :

```
$ curl https://localhost:5554/api-docs/nma_swagger.yaml -k
```

To retrieve the `.html` -formatted documentation, go to `https://my_vertica_node:5554/api-docs/` with your web browser.

HTTPS service

The HTTPS service lets clients securely access and manage a Vertica database with a REST API. This service listens on [port 8443](#) and runs on all nodes.

Most [HTTPS service endpoints](#) require authentication, and only the `dbadmin` user can authenticate to the HTTPS service. The following endpoints serve documentation on the endpoints and do not require authentication ([unless your TLSMODE is VERIFY_CA](#)):

- `/swagger/ui`
- `/swagger/{RESOURCE}`
- `/api-docs/oas-3.0.0.json`

This service encrypts communications with [mutual TLS \(mTLS\)](#). To configure mTLS, you must alter the `server` TLS configuration with a `server` certificate and a trusted Certificate Authority (CA). For mTLS authentication, each client request must include a certificate that is signed by the CA in the `server` TLS configuration and specifies the `dbadmin` user in the Common Name (CN). For additional details about these TLS components and Vertica, see [TLS protocol](#).

Important

During installation, the [install_vertica script](#) generates self-signed certificates in the `/opt/vertica/config/https_certs` directory. Vertica uses these certificates to bootstrap the HTTPS service on a new cluster—they are not suitable for production. Certificates in the TLS configuration supersede those in the `/opt/vertica/config/https_certs` directory.

Password authentication

The following command connects to the HTTPS service from outside the cluster with the username and password:

```
$ curl -i -u dbadmin:db-password https://10.20.30.40:8443/endpoint
```

Important

Due to security concerns, this request method is not recommended. For example, the command history can save the `dbadmin` password.

Certificate authentication

Client requests authenticate to the HTTPS service with a private key and certificate:

```
$ curl https://10.20.30.40:8443/endpoint \
--key path/to/client_key.key \
--cert path/to/client_cert.pem \
```

When the Vertica server receives the request, it verifies that the client certificate is signed by a trusted CA and specifies the dbadmin user. To establish this workflow, you must complete the following:

- Alter the **server** TLS configuration with a server certificate and a CA.
- Generate a client certificate that is signed by the CA in the **server** TLS configuration. The client certificate **SUBJECT** must specify the dbadmin user.
- Grant TLS access to the database.

Note

To demonstrate a comprehensive setup, the following sections use a self-signed CA certificate that signs both the client and server certificates. In a production environment, you should replace the self-signed CA with a trusted CA.

For details about importing a CA certificate, see [Generating TLS certificates and keys](#).

Create a CA certificate

Important

A self-signed CA certificate is convenient for development purposes, but you should always use a proper certificate authority in a production environment.

A CA is a trusted entity that signs and validates other certificates with its own certificate. The following example generates a self-signed root CA certificate:

1. Generate or import a private key. The following command generates a new private key:

```
=> CREATE KEY ca_private_key TYPE 'RSA' LENGTH 4096;  
CREATE KEY
```

2. Generate the certificate with the following format. Sign the certificate the with the private key that you generated or imported in the previous step:

```
=> CREATE CA CERTIFICATE ca_certificate  
SUBJECT '/C=country_code/ST=state_or_province/L=locality/O=organization/OU=org_unit/CN=Vertica Root CA'  
VALID FOR days_valid  
EXTENSIONS 'authorityKeyIdIdentifier' = 'keyid:always,issuer', 'nsComment' = 'Vertica generated root CA cert'  
KEY ca_private_key;
```

Note

The CA certificate **SUBJECT** must be different from the **SUBJECT** of any certificate that it signs.

For example:

```
=> CREATE CA CERTIFICATE SSCA_cert  
SUBJECT '/C=US/ST=Massachusetts/L=Cambridge/O=OpenText/OU=Vertica/CN=Vertica Root CA'  
VALID FOR 3650  
EXTENSIONS 'nsComment' = 'Self-signed root CA cert'  
KEY SSCA_key;
```

Create the server certificate

The server private key and certificate verify the Vertica server's identity for clients:

1. Generate the server private key:

```
=> CREATE KEY server_private_key TYPE 'RSA' LENGTH 2048;
CREATE KEY
```

2. Generate the server certificate with the following format. Include the *server_private_key* , and sign it with the CA certificate:

```
=> CREATE CERTIFICATE server_certificate
SUBJECT '/C=country_code/ST=state_or_province/L=locality/O=organization/OU=org_unit/CN=Vertica server certificate'
SIGNED BY ca_certificate
KEY server_private_key;
CREATE CERTIFICATE
```

For example:

```
=> CREATE CERTIFICATE server_certificate
SUBJECT '/C=US/ST=Massachusetts/L=Burlington/O=OpenText/OU=Vertica/CN=Vertica server certificate'
SIGNED BY ca_certificate
KEY server_private_key;
CREATE CERTIFICATE
```

Alter the TLS configuration

After you generate the server certificate, you must alter the server's default [TLS configuration](#) with the server certificate and its CA. When you change the **server** TLS configuration, the HTTPS service restarts, and the new keys and certificates are added to the catalog and distributed to the nodes in the cluster:

1. [Alter the default server configuration](#). Mutual TLS requires that you set **TLSMODE** to **TRY_VERIFY** or **VERIFY_CA** . If you use **VERIFY_CA** , all endpoints (including the documentation-related endpoints `/swagger/ui` , `/swagger/{RESOURCE}` , and `/api-docs/oas-3.0.0.json`) require authentication:

```
=> ALTER TLS CONFIGURATION server CERTIFICATE server_certificate ADD CA CERTIFICATES ca_certificate TLSMODE 'VERIFY_CA';
ALTER TLS CONFIGURATION
```

2. Verify the changes on the [TLS configuration object](#) :

```
=> SELECT name, certificate, ca_certificate, mode FROM TLS_CONFIGURATIONS WHERE name='server';
name | certificate | ca_certificate | mode
-----|-----|-----|-----
server | server_certificate | ca_certificate | VERIFY_CA
(1 row)
```

Create the client certificate

The client private key and certificate verify the client's identity for requests. Generate a client private key and a client certificate that specifies the `dbadmin` user, and sign the client certificate with the same CA that signed the server certificate.

The following steps generate a client key and certificate, and then make them available to the client:

1. Generate the client key:

```
=> CREATE KEY client_private_key TYPE 'RSA' LENGTH 2048;
CREATE KEY
```

2. Generate the client certificate. Mutual TLS requires that the Common Name (**CN**) in the **SUBJECT** specifies a database username:

```
=> CREATE CERTIFICATE client_certificate
SUBJECT '/C=US/ST=Massachusetts/L=Cambridge/O=OpenText/OU=Vertica/CN=dbadmin/emailAddress=example@example.com'
SIGNED BY ca_certificate
EXTENSIONS 'nsComment' = 'Vertica client cert', 'extendedKeyUsage' = 'clientAuth'
KEY client_private_key;
CREATE CERTIFICATE
```

3. On the client machine, export the client key and client certificate to the client filesystem. The following commands use the [vsq client](#) :

```
$ vsq -A -c "SELECT key FROM cryptographic_keys WHERE name = 'client_private_key'" -o client_private_key.key
$ vsq -A -c "SELECT certificate_text FROM certificates WHERE name = 'client_certificate'" -o client_cert.pem
```

In the preceding command:

- **-A** : enables unaligned output.
- **-t** : prevents the command from outputting metadata, such as column names.
- **-c** : instructs the shell to run one command and then exit.
- **-o** : writes the query output to the specified filename.

For details about all vsq command line options, see [Command-line options](#)

4. Copy or move the client key and certificate to a location that your client recognizes.

The following commands move the client key and certificate to the hidden directory `~/.client-creds` , and then grants the file owner read and write permissions with `chmod` :

```
$ mkdir ~/.client-creds
$ mv client_private_key.key ~/.client-creds/client_key.key
$ mv client_cert.pem ~/.client-creds/client_cert.pem
$ chmod 600 ~/.client-creds/client_key.key ~/.client-creds/client_cert.pem
```

Create an authentication record

Next, you must create an [authentication record](#) in the database. An authentication record defines a set of authentication and the access methods for the database. You grant this record to a user or role to control how they authenticate to the database:

1. [Create the authentication record](#) . The `tls` method requires that clients authenticate with a certificate whose Common Name (CN) specifies a database username:

```
=> CREATE AUTHENTICATION auth_record METHOD 'tls' HOST TLS '0.0.0.0/0';
CREATE AUTHENTICATION
```

2. [Grant the authentication record](#) to a user or to a role. The following example grants the authentication record to `PUBLIC` , the [default role](#) for all users:

```
=> GRANT AUTHENTICATION auth_record TO PUBLIC;
GRANT AUTHENTICATION
```

After you grant the authentication record, the user or role can access [HTTPS service endpoints](#) .

In this section

- [HTTPS endpoints](#)
- [Prometheus metrics](#)

HTTPS endpoints

The [HTTPS service](#) exposes general-purpose endpoints for interacting with your database. While most endpoints [require authentication](#) with either certificates or the `dbadmin`'s password, the following endpoints for documentation do not:

- `/v1/version`
- `/swagger/ui`

- [/swagger/{RESOURCE}](#)
- [/api-docs/oas-3.0.0.json](#)

To view a list of all endpoints, enter the following URL in your browser:

```
https://database_hostname_or_ip:8443/swagger/ui?urls.primaryName=server_docs
```

`/v1/metrics` (GET)

Vertica exposes time series metrics for [Prometheus](#) monitoring and alerting. These metrics create a detailed model of your database behavior over time to provide valuable performance and troubleshooting insights.

To retrieve time series metrics for a node, send a GET request to `/v1/metrics` :

```
$ curl https://host:8443/v1/metrics \
  --key path/to/client_key.key \
  --cert path/to/client_cert.pem \
```

Vertica scrapes metrics from the node and outputs the metrics in [Prometheus text-based exposition format](#). This format applies context-specific labels to each metric to help group metrics when you visualize your data. It also describes the metric type—Vertica provides [counter, gauge, and histogram metric types](#). The following example outlines the output format:

```
# HELP metric-name metric-definition
# TYPE metric-name metric-type
metric-name{label-key="label-value", ...} metric-value
```

For example, the following example shows a snippet of the request response that provides details about the `vertica_resource_pool_memory_size_actual_kb` metric:

```
$ curl https://10.20.30.40:8443/v1/metrics \
  --key path/to/client_key.key \
  --cert path/to/client_cert.pem \
...
# HELP vertica_resource_pool_memory_size_actual_kb Current amount of memory (in kilobytes) allocated to the resource pool by the resource manager.
# TYPE vertica_resource_pool_memory_size_actual_kb gauge
vertica_resource_pool_memory_size_actual_kb{node_name="v_vmart_node0001",pool_name="metadata",revive_instance_id="114b25c4aab6fec8c26b121cf2b52"}
vertica_resource_pool_memory_size_actual_kb{node_name="v_vmart_node0001",pool_name="blobdata",revive_instance_id="114b25c4aab6fec8c26b121cf2b52"}
vertica_resource_pool_memory_size_actual_kb{node_name="v_vmart_node0001",pool_name="jvm",revive_instance_id="114b25c4aab6fec8c26b121cf2b52"}
vertica_resource_pool_memory_size_actual_kb{node_name="v_vmart_node0001",pool_name="sysquery",revive_instance_id="114b25c4aab6fec8c26b121cf2b52"}
vertica_resource_pool_memory_size_actual_kb{node_name="v_vmart_node0001",pool_name="tm",revive_instance_id="114b25c4aab6fec8c26b121cf2b52"}
vertica_resource_pool_memory_size_actual_kb{node_name="v_vmart_node0001",pool_name="general",revive_instance_id="114b25c4aab6fec8c26b121cf2b52"}
vertica_resource_pool_memory_size_actual_kb{node_name="v_vmart_node0001",pool_name="recovery",revive_instance_id="114b25c4aab6fec8c26b121cf2b52"}
vertica_resource_pool_memory_size_actual_kb{node_name="v_vmart_node0001",pool_name="dbd",revive_instance_id="114b25c4aab6fec8c26b121cf2b52"}
vertica_resource_pool_memory_size_actual_kb{node_name="v_vmart_node0001",pool_name="refresh",revive_instance_id="114b25c4aab6fec8c26b121cf2b52"}
...
```

To get a cluster-wide view of your metrics, you must call the `/v1/metrics` endpoint on each node in your cluster.

For a comprehensive list of metrics, see [Prometheus metrics](#).

Grafana dashboards

You can visualize data exposed at `/v1/metrics` with Grafana dashboards. Vertica provides the following dashboards for metrics that use a Prometheus data source:

- [Vertica Overview \(Prometheus\)](#)
- [Vertica Queries \(Prometheus\)](#)
- [Vertica Resource Management \(Prometheus\)](#)
- [Vertica Depot \(Prometheus\)](#)

You can also download the source for each dashboard from the [vertica/grafana-dashboards repository](#).

Prometheus metrics

The following table describes the metrics available at `https:// host :8443/v1/metrics/`.

Name	Type	Description
vertica_allocator_total_size_bytes	gauge	Amount of bytes consumed in an allocator pool.
vertica_build_info	gauge	Shows information about the Vertica build through labels.
vertica_cpu_aggregate_usage_percentage	gauge	Aggregate CPU usage, expressed as a percentage of total CPU capacity.
vertica_data_size_compressed_mb	gauge	Total compressed size (in megabytes) of the data.
vertica_data_size_estimation_error_mb	gauge	Margin of error (in megabytes) of the estimated raw data size.
vertica_db_info	gauge	Shows information about the current database through labels.
vertica_depot_evictions_bytes	counter	Total size (in bytes) of depot evictions.
vertica_depot_evictions_total	counter	Number of depot evictions.
vertica_depot_fetch_queue_size	gauge	Number of files in the depot's fetch queue.
vertica_depot_fetches_bytes	counter	Total size (in bytes) of successful depot fetches.
vertica_depot_fetches_failures_total	counter	Number of failed depot fetch requests.
vertica_depot_fetches_ms	histogram	Time (in milliseconds) that it takes to fetch files into the depot.
vertica_depot_fetches_requests_total	counter	Number of depot fetch requests.
vertica_depot_lookup_hits_total	counter	Number of cache hits when finding a file in the depot.
vertica_depot_lookup_requests_total	counter	Number of attempts to find a file in the depot.
vertica_depot_max_size_bytes	gauge	Maximum size (in bytes) of the depot.
vertica_depot_size_bytes	gauge	Number of bytes currently used in the depot.
vertica_depot_uploads_bytes	counter	Number of bytes uploaded to persistent storage.
vertica_depot_uploads_failures_total	counter	Number of failures during upload attempts to persistent storage.
vertica_depot_uploads_in_progress_bytes	gauge	Number of bytes in running requests that are uploading a file to persistent storage.
vertica_depot_uploads_in_progress_counter	gauge	Number of requests currently uploading a file to persistent storage.
vertica_depot_uploads_ms	histogram	Time (in milliseconds) it took to upload files to persistent storage.
vertica_depot_uploads_queued_bytes	gauge	Number of bytes in queued requests to upload a file to persistent storage.
vertica_depot_uploads_queued_counter	gauge	Number of queued requests to upload a file to persistent storage.
vertica_depot_uploads_requests_total	counter	Number of file upload attempts to persistent storage.
vertica_depot_usage_percent	gauge	Current size of the depot, expressed as a percentage of max depot size.
vertica_disk_storage_free_mb	gauge	Number of megabytes of free storage available.

<code>vertica_disk_storage_free_percent</code>	gauge	Amount of free storage available, expressed as a percentage of total disk storage.
<code>vertica_disk_storage_latency_seek_per_second</code>	gauge	Measures a storage location's performance in seeks/sec. 1/latency is the time that it takes to seek to the data.
<code>vertica_disk_storage_throughput_mb_per_second</code>	gauge	Measures a storage location's performance in MBps. 1/throughput is the time that it takes to read 1MB of data.
<code>vertica_disk_storage_total_mb</code>	gauge	Number of megabytes of total disk storage.
<code>vertica_disk_storage_used_mb</code>	gauge	Number of megabytes of disk storage in use.
<code>vertica_errors</code>	counter	Number of errors, by error level and error code.
<code>vertica_estimated_data_size_raw_mb</code>	gauge	Estimation (in megabytes) of the total raw data size. This is computed each time there is an audit.
<code>vertica_file_system_attempted_operations_total</code>	gauge	Number of attempted file system operations.
<code>vertica_file_system_data_reads_total</code>	gauge	Number of read operations, such as S3 GET requests, to download files.
<code>vertica_file_system_data_writes_total</code>	gauge	Number of write operations, such as S3 PUT requests, to upload files.
<code>vertica_file_system_downstream_bytes</code>	gauge	Number of bytes received.
<code>vertica_file_system_failed_operations_total</code>	gauge	Number of failed filesystem operations.
<code>vertica_file_system_metadata_reads_total</code>	gauge	Number of requests to read metadata. For example, S3 list bucket and HEAD requests are metadata reads.
<code>vertica_file_system_metadata_writes_total</code>	gauge	Number of requests to write metadata. For example, S3 POST and DELETE requests are metadata writes.
<code>vertica_file_system_open_files_counter</code>	gauge	Number of currently open files.
<code>vertica_file_system_reader_counter</code>	gauge	Number of currently running read operations.
<code>vertica_file_system_retries_total</code>	gauge	Number of retry events.
<code>vertica_file_system_total_request_duration_ms</code>	gauge	Sum of HTTP request latency in milliseconds.
<code>vertica_file_system_upstream_bytes</code>	gauge	Number of bytes sent.
<code>vertica_file_system_writer_counter</code>	gauge	Number of currently running writer operations.
<code>vertica_is_readonly</code>	gauge	Returns whether the nodes are read-only.
<code>vertica_last_audit_end_time</code>	gauge	Time (in milliseconds) that the last audit ended.
<code>vertica_last_catalog_sync_seconds</code>	gauge	Number of seconds elapsed since the most recent catalog sync.
<code>vertica_license_node_count</code>	gauge	If the license limits the number of nodes, the number of nodes that the license allows.
<code>vertica_license_size_mb</code>	gauge	If the license limits the size of the database, the number of megabytes that license allows.

vertica_locked_users	gauge	Number of users that are locked out of their accounts.
vertica_login_attempted_total	counter	Number of login attempts.
vertica_login_failure_total	counter	Number of failed login attempts.
vertica_login_success_total	counter	Number of successful login attempts.
vertica_planned_file_reads_bytes	counter	Total number of bytes read in requests for files (estimated during query planning).
vertica_planned_file_reads_requests_total	counter	Total number of read requests for files (estimated during query planning).
vertica_process_memory_usage_percent	gauge	Total Vertica process memory usage, expressed as a percentage of total usable RAM.
vertica_projections_not_up_to_date_total	gauge	Number of projections that are not up to date.
vertica_projections_segmented_total	gauge	Number of segmented projections.
vertica_projections_total	gauge	Number of projections.
vertica_projections_unsafe_total	gauge	Number of projections whose K-safety is less than the database K-safety.
vertica_projections_unsegmented_total	gauge	Number of unsegmented projections.
vertica_query_requests_attempted_total	counter	Number of attempted query requests.
vertica_query_requests_failed_total	counter	Number of failed query requests.
vertica_query_requests_processed_rows_total	counter	Number of processed rows for each query type.
vertica_query_requests_succeeded_total	counter	Number of successful query requests.
vertica_query_requests_time_ms	histogram	Time (in milliseconds) that it takes to execute query requests in the resource pool.
vertica_queued_requests_failed_reservation_total	counter	Number of queued requests whose resource reservation failed in the resource pool.
vertica_queued_requests_max_memory_kb	gauge	Maximum memory requested for a single queued request in the resource pool.
vertica_queued_requests_total	gauge	Number of requests that are queued in the resource pool.
vertica_queued_requests_total_memory_kb	gauge	Total memory requested for all queued requests in the resource pool.
vertica_queued_requests_wait_time_ms	histogram	Length of time (in microseconds) that a resource pool queues queries.
vertica_resource_pool_general_memory_borrowed_kb	gauge	Amount of memory (in kilobytes) that running requests borrow from the GENERAL pool.
vertica_resource_pool_max_concurrency	gauge	MAXCONCURRENCY parameter setting for the resource pool. When set to -1, the resource pool can have an unlimited number of concurrent execution slots. When set to 0, queries are prevented from running in the pool.
vertica_resource_pool_max_memory_size_kb	gauge	MAXMEMORYSIZE parameter setting (in kilobytes) for the resource pool.

vertica_resource_pool_max_query_memory_size_kb	gauge	MAXQUERYMEMORYSIZE parameter setting (in kilobytes) for the resource pool. When set to -1, the resource pool borrows any amount of available memory from the GENERAL pool, up to vertica_resource_pool_max_memory_size_kb.
vertica_resource_pool_memory_inuse_kb	gauge	Amount of memory (in kilobytes) acquired by requests running against the resource pool.
vertica_resource_pool_memory_size_actual_kb	gauge	Current amount of memory (in kilobytes) allocated to the resource pool by the resource manager.
vertica_resource_pool_planned_concurrency	gauge	PLANNEDCONCURRENCY parameter setting for the resource pool.
vertica_resource_pool_priority	gauge	PRIORITY parameter setting for the resource pool.
vertica_resource_pool_query_budget_kb	gauge	Amount of resource pool memory (in kilobytes) that queries are currently tuned to use. When equal to -1, queries are prevented from running in the pool.
vertica_resource_pool_queue_timeout	gauge	QUEUETIMEOUT parameter setting for the resource pool.
vertica_resource_pool_queueing_threshold_kb	gauge	Limits the amount of memory (in kilobytes) that a resource pool makes available to all requests before it queues requests.
vertica_resource_pool_running_query_count	gauge	Number of queries currently executing in the pool.
vertica_resource_pool_runtime_priority_threshold	gauge	RUNTIMEPRIORITYTHRESHOLD parameter setting for the resource pool.
vertica_sessions_blocked_counter	gauge	Number of sessions that are blocked waiting for locks.
vertica_sessions_running_counter	gauge	Number of active sessions.
vertica_storage_containers_count	gauge	Total number of storage containers.
vertica_subcluster_info	gauge	Shows information about a subcluster through labels.
vertica_system_disk_io_completed_per_second	gauge	Number of successful I/O requests completed per second.
vertica_system_disk_io_in_progress_counter	gauge	Number of I/O requests currently in process.
vertica_system_disk_io_read_kb_per_second	gauge	Measures the I/O bandwidth used to read from disk in KBps.
vertica_system_disk_io_usage_percent	gauge	Percentage of time the disk is processing I/O.
vertica_system_disk_io_write_kb_per_second	gauge	Measures the I/O bandwidth used to write to disk in KBps.
vertica_system_memory_usage_percent	gauge	Total system memory usage, expressed as a percentage of total usable RAM.
vertica_tm_operations_attempted_total	counter	Number of attempted tuple mover operations.
vertica_tm_operations_completed_total	counter	Number of completed tuple mover operations.
vertica_tm_operations_failed_total	counter	Number of aborted tuple mover operations.
vertica_tm_operations_ros_count_total	gauge	Total number of ROS containers in the tuple mover operation.
vertica_tm_operations_ros_used_bytes_total	gauge	Total size (in bytes) of all ROS containers in the mergeout operation.

<code>vertica_tm_operations_running_total</code>	gauge	Number of running tuple mover operations.
<code>vertica_total_nodes_count</code>	gauge	Total number of nodes.
<code>vertica_transactions_completed_total</code>	counter	Number of completed transactions.
<code>vertica_transactions_failed_total</code>	counter	Number of failed transactions.
<code>vertica_transactions_started_total</code>	counter	Number of transactions that have started.
<code>vertica_up_nodes_count</code>	gauge	Number of nodes that have Vertica running and can accept connections.

Monitoring Vertica

You can monitor the activity and health of a Vertica database through various log files and system tables. Vertica provides various [configuration parameters](#) that control monitoring options. You can also use the [Management Console](#) to observe database activity.

In this section

- [Monitoring log files](#)
- [Rotating log files](#)
- [Monitoring process status \(ps\)](#)
- [Monitoring Linux resource usage](#)
- [Monitoring disk space usage](#)
- [Monitoring elastic cluster rebalancing](#)
- [Monitoring events](#)
- [Using system tables](#)
- [Data Collector utility](#)
- [Monitoring partition reorganization](#)
- [Monitoring resource pools](#)
- [Monitoring recovery](#)
- [Clearing projection refresh history](#)
- [Monitoring Vertica using notifiers](#)

Monitoring log files

When a database is running

When a Vertica database is running, each [node](#) in the [cluster](#) writes messages into a file named `vertica.log`. For example, the [Tuple Mover](#) and the transaction manager write INFO messages into `vertica.log` at specific intervals even when there is no mergeout activity.

You configure the location of the `vertica.log` file. By default, the log file is in:

```
catalog-path/database-name/node-name_catalog/vertica.log
```

- `catalog-path` is the path shown in the NODES system table minus the Catalog directory at the end.
- `database-name` is the name of your database.
- `node-name` is the name of the node shown in the NODES system table.

Note

Vertica often changes the format or content of log files in subsequent releases to benefit both customers and customer support.

To monitor one node in a running database in real time:

1. Log in to the database administrator account on any node in the cluster.
2. In a terminal window enter:

```
$ tail -f catalog-path/database-name/node-name_catalog/vertica.log
```

Note

To monitor your overall database (rather than an individual node/host), use the Data Collector, which records system activities and performance.

See [Data Collector utility](#) for more on Data Collector.

<i>catalog-path</i>	The catalog pathname specified when you created the database. See Creating a database .
<i>database-name</i>	The database name (case sensitive)
<i>node-name</i>	The node name, as specified in the database definition. See Viewing a database .

When the database/node is starting up

During system startup, before the Vertica log has been initialized to write messages, each node in the cluster writes messages into a file named `dbLog`. This log is useful to diagnose situations where the database fails to start before it can write messages into `vertica.log`. The `dblog` is located at the following path, using `catalog-path` and `database-name` as described above:

```
catalog-path/database-name/dbLog
```

See also

- [Rotating log files](#)

Rotating log files

The LogRotate service periodically rotates logs and removes old rotated logs. To view previous LogRotate events, see [LOG_ROTATE_EVENTS](#).

If the following files exceed the specified maximum size, they are rotated:

- `vertica.log`
- `UDxFencedProcesses.log`
- `MemoryReport.log`
- `editor.log`
- `dbLog`

Rotated files are compressed and marked with a timestamp in the same location as the original log file: `path/to/logfile.log timestamp.gz`. For example, `/scratch_b/qa/VMart/v_vmart_node0001_catalog/vertica.log` is rotated to `/scratch_b/qa/VMart/v_vmart_node0001_catalog/vertica.log.2023-11-08-14-09-02-381909-05.gz`.

If a log file was rotated, the previously rotated logs (`.gz`) in that directory are checked against the specified maximum age. Rotated logs older than the maximum age are deleted.

Upgrade behavior

The LogRotate service is automatically enabled, but if your database contains the configuration file for the Linux `logrotate` utility at `/opt/vertica/config/logrotate/database_name`, the LogRotate service will not run. If you upgraded from Vertica 23.4 or below, you must delete the configuration file on all nodes to use the LogRotate service.

Automatic rotation

To configure and enable the LogRotate service:

1. Set the maximum allowed size of logs with `LogRotateMaxSize`. Log files larger than this age are rotated (compressed).
2. Set the maximum allowed age of rotated logs with `LogRotateMaxAge`. Rotated (compressed) logs older than this age are deleted.
3. Set how often the service runs with `LogRotateInterval`.
4. Enable the service with `EnableLogRotate`.

For details on these parameters, see [Monitoring parameters](#).

To view the current values for these parameters, query [CONFIGURATION_PARAMETERS](#).

The following example configures the LogRotate service to automatically run every four hours, rotating logs that are larger than 1 kibibyte and removing rotated logs that are older than 12 days:

```
-> ALTER DATABASE DEFAULT SET LogRotateInterval = '4h', LogRotateMaxSize = '1k', LogRotateMaxAge = '12 days';
```

Manual rotation

You can manually rotate the logs on a particular node with the [DO_LOGROTATE_LOCAL](#) meta-function. This function takes optional arguments to force the rotation of all logs and override the values of `LogRotateMaxSize` and `LogRotateMaxAge`.

To rotate logs that are larger than 1 kilobyte, and then remove rotated logs that are older than 1 day:

```
-> SELECT do_logrotate_local('max_size=1K;max_age=1 day');

do_logrotate_local
-----
Doing Logrotate
Considering file /scratch_b/qa/VMart/v_vmart_node0001_catalog/vertica.log
File size: 35753 Bytes

```

Rotating with the Linux logrotate utility

Deprecated

This functionality is deprecated and will be removed in a future release. You should instead use the native LogRotate service.

Most Linux distributions include the `logrotate` utility. By setting up a `logrotate` configuration file, you can use the utility to complete one or more of these tasks automatically:

- Compress and rotate log files
- Remove log files automatically
- Email log files to named recipients

You can configure `logrotate` to complete these tasks at specific intervals, or when log files reach a particular size.

If `logrotate` is present when Vertica is installed, then Vertica automatically sets this utility to look for configuration files. Thus, `logrotate` searches for configuration files in the `/opt/vertica/config/logrotate` directory on each node.

When you create a database, Vertica creates database-specific `logrotate` configurations on each node in your cluster, which are used by the `logrotate` utility. It then creates a file with the path `/opt/vertica/config/logrotate/dbname` for each individual database.

For information about additional settings, use the `man logrotate` command.

Executing the Python script through the `dbadmin logrotate` cron job

During the installation of Vertica, the installer configures a cron job for the `dbadmin` user. This cron job is configured to execute a Python script that runs the `logrotate` utility. You can view the details of this cron job by viewing the `dbadmin.cron` file, which is located in the `/opt/vertica/config` directory.

If you want to customize a cron job to configure `logrotate` for your Vertica database, you *must* create the cron job under the `dbadmin` user.

Using the administration tools `logrotate` utility

You can use the `admintools logrotate` option to help configure `logrotate` scripts for a database and distribute the scripts across the cluster. The `logrotate` option allows you to specify:

- How often to rotate logs
- How large logs can become before being rotated
- How long to keep the logs

Example:

The following example shows you how to set up log rotation on a weekly schedule and keeps for three months (12 logs).

```
$ admintools -t logrotate -d <dbname> -r weekly -k 12
```

See [Writing administration tools scripts](#) for more usage information.

Configure `logrotate` for MC

The Management Console log file is:

```
/opt/vconsole/log/mc/mconsole.log
```

To configure `logrotate` for MC, configure the following file:

```
/opt/vconsole/temp/webapp/WEB-INF/classes/log4j.xml
```

Edit the `log4j.xml` file and set these parameters as follows:

1. Restrict the size of the log:

```
<param name="MaxFileSize" value="1MB"/>
```

2. Restrict the number of file backups for the log:

```
<param name="MaxBackupIndex" value="1"/>
```

3. Restart MC as the root user:

```
# etc/init.d/vertica-console restart
```

Rotating logs manually

To implement a custom log rotation process, follow these steps:

1. Rename or archive the existing `vertica.log` file. For example:

```
$ mv vertica.log vertica.log.1
```

2. Send the Vertica process the `USR1` signal, using either of the following approaches:

```
$ killall -USR1 vertica
```

or

```
$ ps -ef | grep -i vertica
```

```
$ kill -USR1 process-id
```

Monitoring process status (ps)

You can use `ps` to monitor the database and Spread processes running on each node in the cluster. For example:

```
$ ps aux | grep /opt/vertica/bin/vertica
```

```
$ ps aux | grep /opt/vertica/spread/sbin/spread
```

You should see one Vertica process and one Spread process on each node for common configurations. To monitor Administration Tools and connector processes:

```
$ ps aux | grep vertica
```

There can be many connection processes but only one Administration Tools process.

Monitoring Linux resource usage

You should monitor system resource usage on any or all nodes in the cluster. You can use System Activity Reporting (SAR) to monitor resource usage.

Note

OpenText recommends that you install `pstack` and `sysstat` to help monitor Linux resources. The SYSSTAT package contains utilities for monitoring system performance and usage activity, such as `sar`, as well as tools you can schedule via `cron` to collect performance and activity data. See the SYSSTAT Web page for details.

The `pstack` utility lets you print a stack trace of a running process. See the [PSTACK man page](#) for details.

1. Log in to the database administrator account on any node.
2. Run the `top` utility

```
$ top
```

A high CPU percentage in `top` indicates that Vertica is CPU-bound. For example:

```
top - 11:44:28 up 53 days, 23:47, 9 users, load average: 0.91, 0.97, 0.81
Tasks: 123 total, 1 running, 122 sleeping, 0 stopped, 0 zombie
Cpu(s): 26.9%us, 1.3%sy, 0.0%ni, 71.8%id, 0.0%wa, 0.0%hi, 0.0%si, 0.0%st
Mem: 4053136 total, 3882020k used, 171116 free, 407688 buffers
Swap: 4192956 total, 176k used, 4192780 free, 1526436 cached
  PID USER   PR  NI  VIRT  RES  SHR  S %CPU %MEM  TIME+  COMMAND
13703 dbadmin  1   0 1374m 678m 55m  S 99.9 17.1  6:21.70 vertica
2606 root    16   0 32152 11m 2508 S  1.0  0.3  0:16.97 X
   1 root    16   0 4748 552 456 S  0.0  0.0  0:01.51 init
   2 root    RT  -5   0   0  0 S  0.0  0.0  0:04.92 migration/0
   3 root    34  19   0   0  0 S  0.0  0.0  0:11.75 ksoftirqd/0
...
```

Some possible reasons for high CPU usage are:

- The [Tuple Mover](#) runs automatically and thus consumes CPU time even if there are no connections to the database.
- The swappiness kernel parameter may not be set to 0. Execute the following command from the Linux command line to see the value of this parameter:

```
$ cat /proc/sys/vm/swappiness
```

If this value is not 0, change it by following the steps in [Check for swappiness](#).

- Some information sources:
 - [Red Hat](#)
 - [Indiana University Unix Systems Support Group](#)
3. Run the `iostat` utility. A high idle time in `top` at the same time as a high rate of blocks read in `iostat` indicates that Vertica is disk-bound. For example:

```

$ /usr/bin/iostat
Linux 2.6.18-164.el5 (qa01) 02/05/2011
avg-cpu:  %user   %nice %system %iowait  %steal   %idle
           0.77    2.32   0.76   0.68   0.00   95.47

Monitoring disk space usage

You can use these system tables to monitor disk space usage on your cluster:

System table	Description
DISK_STORAGE	Monitors the amount of disk storage used by the database on each node.
COLUMN_STORAGE	Monitors the amount of disk storage used by each column of each projection on each node.
PROJECTION_STORAGE	Monitors the amount of disk storage used by each projection on each node.

Monitoring elastic cluster rebalancing

Vertica includes system tables that can be used to monitor the rebalance status of an elastic cluster and gain general insight to the status of elastic cluster on your nodes.

- [REBALANCE_TABLE_STATUS](#) provides general information about a rebalance. It shows, for each table, the amount of data that has been separated, the amount that is currently being separated, and the amount to be separated. It also shows the amount of data transferred, the amount that is currently being transferred, and the remaining amount to be transferred (or an estimate if storage is not separated).

Note

If multiple rebalance methods were used for a single table (for example, the table has unsegmented and segmented projections), the table may appear multiple times - once for each rebalance method.

- [REBALANCE_PROJECTION_STATUS](#) can be used to gain more insight into the details for a particular projection that is being rebalanced. It provides the same type of information as above, but in terms of a projection instead of a table.

In each table, the columns [SEPARATED_PERCENT](#) and [TRANSFERRED_PERCENT](#) can be used to determine overall progress.

Historical rebalance information

Historical information about work completed is retained, so query with the table column `IS_LATEST` to restrict output to only the most recent or current rebalance activity. Historical data may include information about dropped projections or tables. If a table or projection has been dropped and information about the anchor table is not available, then NULL is displayed for the table ID and `<unknown>` for table name. Information on dropped tables is still useful, for example, in providing justification for the duration of a task.

Monitoring events

To help you monitor your database system, Vertica traps and logs significant events that affect database performance and functionality if you do not address their root causes. This section describes where events are logged, the types of events that Vertica logs, how to respond to these events, the information that Vertica provides for these events, and how to configure event monitoring.

In this section

- [Event logging mechanisms](#)
- [Event codes](#)
- [Event data](#)
- [Configuring event reporting](#)

- [Event reporting examples](#)

Event logging mechanisms

Vertica posts events to the following mechanisms:

Mechanism	Description
vertica.log	All events are automatically posted to vertica.log . See Monitoring the Log Files .
ACTIVE_EVENTS	This SQL system table provides information about all open events. See Using system tables and ACTIVE_EVENTS .
SNMP	To post traps to SNMP, enable global reporting in addition to each individual event you want trapped. See Configuring event reporting .
Syslog	To log events to syslog, enable event reporting for each individual event you want logged. See Configuring event reporting .

Event codes

The following table lists the event codes that Vertica logs to the events system tables.

Event Code	Severity	Event Code Description	Description/Action
0	Warning	Low Disk Space	<p>Warning indicates one of the following issues:</p> <ul style="list-style-type: none"> • Lack of disk space for database • Disk failure • I/O hardware failure <p>Action: Add more disk space, or replace the failing disk or hardware as soon as possible.</p> <p>Check dmesg to see what caused the problem.</p> <p>Also, use the DISK_RESOURCE_REJECTIONS system table to determine the types of disk space requests that are being rejected and the hosts where they are rejected. See Managing disk space for details.</p>
1	Warning	Read Only File System	<p>Database lacks write access to the file system for data or catalog paths. This sometimes occurs if Linux remounts a drive due to a kernel issue.</p> <p>Action: Give the database write access.</p>
2	Emergency	Loss Of K Safety	<p>The database is no longer K-safe because insufficient nodes are functioning within the cluster. Loss of K-safety causes the database to shut down.</p> <p>Action: Recover the system .</p>
3	Critical	Current Fault Tolerance at Critical Level	<p>One or more nodes in the cluster failed. If the database loses one more node, it will no longer be K-safe and shut down.</p> <p>Action: Restore nodes that failed or shut down.</p>

4	Warning	Too Many ROS Containers	<p>Heavy load activity on one or more projections sometimes generates more ROS containers than the Tuple Mover can handle. Vertica allows up to 1024 ROS containers per projection before it rolls back additional load jobs and returns a ROS pushback error message.</p> <p>Action: The Tuple Mover typically catches up with pending mergeout requests and the Optimizer can resume executing queries on affected tables (see Mergeout).</p> <p>If this problem does not resolve quickly, or if it occurs frequently, it is probably related to insufficient RAM allocated to MAXMEMORY in the TM resource pool.</p>
5	Informational	WOS Over Flow	Deprecated
6	Informational	Node State Change	<p>The node state changed.</p> <p>Action: Check node status.</p>
7	Warning	Recovery Failure	<p>Database was not restored to a functional state after a hardware or software related failure.</p> <p>Action: Reasons for the warning can vary, see the event description for details.</p>
8	Warning	Recovery Error	<p>Database encountered an error while attempting to recover. If the number of recovery errors exceeds Max Tries, the Recovery Failure event is triggered.</p> <p>Action: Reasons for the warning can vary, see the event description for details.</p>
9	n/a	Recovery Lock Error	Unused
10	n/a	Recovery Projection Retrieval Error	Unused
11	Warning	Refresh Error	<p>The database encountered an error while attempting to refresh.</p> <p>Action: Reasons for the warning can vary, see the event description for details.</p>
12	n/a	Refresh Lock Error	Unused
13	n/a	Tuple Mover Error	Deprecated
14	Warning	Timer Service Task Error	<p>Error occurred in an internal scheduled task.</p> <p>Action: None, internal use only</p>
15	Warning	Stale Checkpoint	Deprecated
16	Notice	License Size Compliance	<p>Database size exceeds license size allowance.</p> <p>Action: See Monitoring database size for license compliance.</p>
17	Notice	License Term Compliance	<p>Database is not in compliance with your Vertica license.</p> <p>Action: Check compliance status with GET_COMPLIANCE_STATUS.</p>

18	Error	CRC Mismatch	Cyclic Redundancy Check (CRC) returned an error or errors while fetching data. Action: Review the vertica.log file or the SNMP trap utility to evaluate CRC errors .
19	Critical/Warning	Catalog Sync Exceeds Durability Threshold	Severity: Critical when exceeding hard limit, Warning when exceeding soft limit.
20	Critical	Cluster Read-only	Eon Mode) Quorum or primary shard coverage loss forced database into read-only mode . Action: Restart down nodes .

Event data

To help you interpret and solve the issue that triggered an event, each event provides a variety of data, depending upon the event logging mechanism used.

The following table describes the event data and indicates where it is used.

vertica.log	ACTIVE_EVENTS (column names)	SNMP	Syslog	Description
N/A	NODE_NAME	N/A	N/A	The node where the event occurred.
Event Code	EVENT_CODE	Event Type	Event Code	A numeric ID that indicates the type of event. See Event Types in the previous table for a list of event type codes.
Event Id	EVENT_ID	Event OID	Event Id	A unique numeric ID that identifies the specific event.
Event Severity	EVENT_SEVERITY	Event Severity	Event Severity	The severity of the event from highest to lowest. These events are based on standard syslog severity types: 0 – Emergency 1 – Alert 2 – Critical 3 – Error 4 – Warning 5 – Notice 6 – Info 7 – Debug
PostedTimestamp	EVENT_POSTED_TIMESTAMP	N/A	PostedTimestamp	The year, month, day, and time the event was reported. Time is provided as military time.
ExpirationTimestamp	EVENT_EXPIRATION	N/A	ExpirationTimestamp	The time at which this event expires. If the same event is posted again prior to its expiration time, this field gets updated to a new expiration time.

EventCodeDescription	EVENT_CODE_DESCRIPTION	Description	EventCodeDescription	A brief description of the event and details pertinent to the specific situation.
ProblemDescription	EVENT_PROBLEM_DESCRIPTION	Event Short Description	ProblemDescription	A generic description of the event.
N/A	REPORTING_NODE	Node Name	N/A	The name of the node within the cluster that reported the event.
DatabaseName	N/A	Database Name	DatabaseName	The name of the database that is impacted by the event.
N/A	N/A	Host Name	Hostname	The name of the host within the cluster that reported the event.
N/A	N/A	Event Status	N/A	The status of the event. It can be either: 1 – Open 2 – Clear

Configuring event reporting

Event reporting is automatically configured for `vertica.log`, and current events are automatically posted to the `ACTIVE_EVENTS` system table. You can also configure Vertica to post events to `syslog` and `SNMP`.

In this section

- [Configuring reporting for the simple notification service \(SNS\)](#)
- [Configuring reporting for syslog](#)
- [Configuring reporting for SNMP](#)
- [Configuring event trapping for SNMP](#)
- [Verifying SNMP configuration](#)

Configuring reporting for the simple notification service (SNS)

You can monitor `Data collector` (DC) components and send new rows to Amazon Web Services (AWS) Simple Notification Service (SNS). SNS notifiers are configured with `database-level SNS parameters`.

Note

Several `SNS configuration parameters` have and fall back to equivalents for `S3`. This lets you to share configurations between S3 and SNS. For example, if you set the values for `AWSAuth` but not for `SNSAuth`, Vertica automatically uses the `AWSAuth` credentials. For brevity, the procedures on this page will not use this fallback behavior and instead use the SNS configuration parameters.

For details, see `SNS parameters`.

Minimally, to send DC data to SNS topics, you must configure and specify the following:

- An SNS notifier
- A Simple Notification Service (SNS) topic
- An AWS region (SNSRegion)
- An SNS endpoint (SNSEndpoint) (FIPS only)
- Credentials to authenticate to AWS
- Information about how to handle HTTPS

Creating an SNS notifier

To create an SNS notifier, use [CREATE NOTIFIER](#), specifying `sns` as the ACTION.

SNS configuration

SNS topics and their subscribers should be configured with AWS. For details, see the AWS documentation:

- [Creating an Amazon SNS topic](#)
- [Subscribing to an Amazon SNS topic](#)

AWS region and endpoint

In most use cases, you only need to set the AWS region with the `SNSRegion` parameter; if the `SNSEndpoint` is set to an empty string (default) and the `SNSRegion` is set, Vertica automatically finds and uses the appropriate endpoint:

```
=> ALTER DATABASE DEFAULT SET SNSRegion='us-east-1';
=> ALTER DATABASE DEFAULT SET SNSEndpoint=";
```

If you want to specify an endpoint, its region must match the region specified in `SNSRegion`:

```
=> ALTER DATABASE DEFAULT SET SNSEndpoint='sns.us-east-1.amazonaws.com';
```

If you use FIPS, you should manually set `SNSEndpoint` to a [FIPS-compliant endpoint](#):

```
=> ALTER DATABASE DEFAULT SET SNSEndpoint='sns-fips.us-east-1.amazonaws.com';
```

AWS credentials

AWS credentials can be set with `SNSAuth`, which takes an access key and secret access key in the following format:

```
access_key:secret_access_key
```

To set `SNSAuth`:

```
=> ALTER DATABASE DEFAULT SET SNSAuth='VNDDNVOPIUQF917O5PDB:+mcnVONVlbjOnf1ekNis7nm3mE83u9fjdwmlq36Z';
```

Handling HTTPS

The `SNSEnableHttps` parameter determines whether the SNS notifier uses TLS to secure the connection between Vertica and AWS. HTTPS is enabled by default and can be manually enabled with:

```
=> ALTER DATABASE DEFAULT SET SNSEnableHttps=1;
```

If `SNSEnableHttps` is enabled, depending on your configuration, you might need to specify a custom set of CA bundles with `SNSCAFile` or `SNSCAPath`. Amazon root certificates are typically contained in the set of trusted CA certificates already, so you should not have to set these parameters in most environments:

```
=> ALTER DATABASE DEFAULT SET SNSCAFile='path/to/ca/bundle.pem'
=> ALTER DATABASE DEFAULT SET SNSCAPath='path/to/ca/bundles'
```

HTTPS can be manually disabled with:

```
=> ALTER DATABASE DEFAULT SET SNSEnableHttps=0;
```

Examples

The following example creates an SNS topic, subscribes to it with an SQS queue, and then configures an SNS notifier for the DC component `LoginFailures`:

1. [Create an SNS topic](#).
2. [Create an SQS queue](#).
3. [Subscribe the SQS queue to the SNS topic](#).
4. Set `SNSAuth` with your AWS credentials:

```
=> ALTER DATABASE DEFAULT SET SNSAuth='VNDDNVOPIUQF917O5PDB:+mcnVONVlbjOnf1ekNis7nm3mE83u9fjdwmlq36Z';
```

5. Set `SNSRegion`:

```
=> ALTER DATABASE DEFAULT SET SNSRegion='us-east-1'
```

6. Enable HTTPS:

```
=> ALTER DATABASE DEFAULT SET SNSEnableHttps=1;
```

7. [Create](#) an SNS notifier:

```
=> CREATE NOTIFIER v_sns_notifier ACTION 'sns' MAXPAYLOAD '256K' MAXMEMORYSIZE '10M' CHECK COMMITTED;
```

8. Verify that the SNS notifier, SNS topic, and SQS queue are properly configured:

1. Manually send a message from the notifier to the SNS topic with [NOTIFY](#):

```
=> SELECT NOTIFY('test message', 'v_sns_notifier', 'arn:aws:sns:us-east-1:123456789012:MyTopic')
```

2. [Poll the SQS queue](#) for your message.

9. Attach the SNS notifier to the [LoginFailures](#) component with [SET_DATA_COLLECTOR_NOTIFY_POLICY](#):

```
=> SELECT SET_DATA_COLLECTOR_NOTIFY_POLICY('LoginFailures', 'v_sns_notifier', 'Login failed!', true)
```

To disable an SNS notifier:

```
=> SELECT SET_DATA_COLLECTOR_NOTIFY_POLICY('LoginFailures', 'v_sns_notifier', 'Login failed!', false)
```

Configuring reporting for syslog

Syslog is a network-logging utility that issues, stores, and processes log messages. It is a useful way to get heterogeneous data into a single data repository.

To log events to syslog, enable event reporting for each individual event you want logged. Messages are logged, by default, to [/var/log/messages](#).

Configuring event reporting to syslog consists of:

1. Enabling Vertica to trap events for syslog.
2. Defining which events Vertica traps for syslog.
Vertica strongly suggests that you trap the Stale Checkpoint event.
3. Defining which syslog facility to use.

Enabling Vertica to trap events for syslog

To enable event trapping for syslog, issue the following SQL command:

```
=> ALTER DATABASE DEFAULT SET SyslogEnabled = 1;
```

To disable event trapping for syslog, issue the following SQL command:

```
=> ALTER DATABASE DEFAULT SET SyslogEnabled = 0;
```

Defining events to trap for syslog

To define events that generate a syslog entry, issue the following SQL command, one of the events described in the list below the command:

```
=> ALTER DATABASE DEFAULT SET SyslogEvents = 'events-list';
```

where [events-list](#) is a comma-delimited list of events, one or more of the following:

- Low Disk Space
- Read Only File System
- Loss Of K Safety
- Current Fault Tolerance at Critical Level
- Too Many ROS Containers
- Node State Change
- Recovery Failure
- Recovery Error
- Recovery Lock Error
- Recovery Projection Retrieval Error
- Refresh Error
- Refresh Lock Error
- Tuple Mover Error
- Timer Service Task Error
- Stale Checkpoint

The following example generates a syslog entry for low disk space and recovery failure:

```
=> ALTER DATABASE DEFAULT SET SyslogEvents = 'Low Disk Space, Recovery Failure';
```

Defining the SyslogFacility to use for reporting

The syslog mechanism allows for several different general classifications of logging messages, called facilities. Typically, all authentication-related messages are logged with the **auth** (or **authpriv**) facility. These messages are intended to be secure and hidden from unauthorized eyes. Normal operational messages are logged with the **daemon** facility, which is the collector that receives and optionally stores messages.

The SyslogFacility directive allows all logging messages to be directed to a different facility than the default. When the directive is used, *all* logging is done using the specified facility, both authentication (secure) and otherwise.

To define which SyslogFacility Vertica uses, issue the following SQL command:

```
=> ALTER DATABASE DEFAULT SET SyslogFacility = 'Facility_Name';
```

Where the facility-level argument `<Facility_Name>` is one of the following:

- auth
- authpriv (Linux only)
- cron
- uucp (UUCP subsystem)
- daemon
- ftp (Linux only)
- lpr (line printer subsystem)
- mail (mail system)
- news (network news subsystem)
- user (default system)
- local0 (local use 0)
- local1 (local use 1)
- local2 (local use 2)
- local3 (local use 3)
- local4 (local use 4)
- local5 (local use 5)
- local6 (local use 6)
- local7 (local use 7)

Trapping other event types

To trap events other than the ones listed above, [create a syslog notifier](#) and allow it to trap the desired events with [SET_DATA_COLLECTOR_NOTIFY_POLICY](#).

Events monitored by this notifier type are not logged to [MONITORING_EVENTS](#) nor `vertica.log`.

The following example creates a notifier that writes a message to syslog when the [Data collector](#) (DC) component [LoginFailures](#) updates:

1. Enable syslog notifiers for the current database:

```
=> ALTER DATABASE DEFAULT SET SyslogEnabled = 1;
```

2. Create and enable a syslog notifier `v_syslog_notifier` :

```
=> CREATE NOTIFIER v_syslog_notifier ACTION 'syslog'  
ENABLE  
MAXMEMORYSIZE '10M'  
IDENTIFIED BY 'f8b0278a-3282-4e1a-9c86-e0f3f042a971'  
PARAMETERS 'eventSeverity = 5';
```

3. Configure the syslog notifier `v_syslog_notifier` for updates to the [LoginFailures](#) DC component with [SET_DATA_COLLECTOR_NOTIFY_POLICY](#) :

```
=> SELECT SET_DATA_COLLECTOR_NOTIFY_POLICY('LoginFailures','v_syslog_notifier', 'Login failed!', true);
```

This notifier writes the following message to syslog (default location: `/var/log/messages`) when a user fails to authenticate as the user **Bob** :

[Event reporting examples](#)

Configuring reporting for SNMP

Configuring event reporting for SNMP consists of:

1. Configuring Vertica to enable event trapping for SNMP as described below.
2. Importing the Vertica Management Information Base (MIB) file into the SNMP monitoring device.
The Vertica MIB file allows the SNMP trap receiver to understand the traps it receives from Vertica. This, in turn, allows you to configure the actions it takes when it receives traps.
Vertica supports the SNMP V1 trap protocol, and it is located in /opt/vertica/sbin/VERTICA-MIB. See the documentation for your SNMP monitoring device for more information about importing MIB files.
3. Configuring the SNMP trap receiver to handle traps from Vertica.
SNMP trap receiver configuration differs greatly from vendor to vendor. As such, the directions presented here for configuring the SNMP trap receiver to handle traps from Vertica are generic.
Vertica traps are single, generic traps that contain several fields of identifying information. These fields equate to the event data described in [Monitoring events](#). However, the format used for the field names differs slightly. Under SNMP, the field names contain no spaces. Also, field names are pre-pended with "vert". For example, Event Severity becomes vertEventSeverity.
When configuring your trap receiver, be sure to use the same hostname, port, and community string you used to configure event trapping in Vertica.

Examples of network management providers:

- [Network Node Manager i](#)
- IBM Tivoli
- AdventNet
- Net-SNMP (Open Source)
- Nagios (Open Source)

- Open NMS (Open Source)

Configuring event trapping for SNMP

The following events are trapped by default when you configure Vertica to trap events for SNMP:

- Low Disk Space
- Read Only File System
- Loss of K Safety
- Current Fault Tolerance at Critical Level
- Too Many ROS Containers
- Node State Change
- Recovery Failure
- Stale Checkpoint
- CRC Mismatch

To configure Vertica to trap events for SNMP

1. Enable Vertica to trap events for SNMP.
2. Define where Vertica sends the traps.
3. Optionally redefine which SNMP events Vertica traps.

Note

After you complete steps 1 and 2 above, Vertica automatically traps the default SNMP events. Only perform step 3 if you want to redefine which SNMP events are trapped. Vertica recommends that you trap the **Stale Checkpoint** event even if you decide to reduce the number events Vertica traps for SNMP. The specific settings you define have no effect on traps sent to the log. All events are trapped to the log.

To enable event trapping for SNMP

Use the following SQL command:

```
=> ALTER DATABASE DEFAULT SET SnmpTrapsEnabled = 1;
```

To define where Vertica send traps

Use the following SQL command, where Host_name and port identify the computer where SNMP resides, and CommunityString acts like a password to control Vertica's access to the server:

```
=> ALTER DATABASE DEFAULT SET SnmpTrapDestinationsList = 'host_name port CommunityString';
```

For example:

```
=> ALTER DATABASE DEFAULT SET SnmpTrapDestinationsList = 'localhost 162 public';
```

You can also specify multiple destinations by specifying a list of destinations, separated by commas:

```
=> ALTER DATABASE DEFAULT SET SnmpTrapDestinationsList = 'host_name1 port1 CommunityString1, hostname2 port2 CommunityString2';
```

Note

: Setting multiple destinations sends any SNMP trap notification to all destinations listed.

To define which events Vertica traps

Use the following SQL command, where **Event_Name** is one of the events in the list below the command:

```
=> ALTER DATABASE DEFAULT SET SnmpTrapEvents = 'Event_Name1, Even_Name2';
```

- Low Disk Space
- Read Only File System
- Loss Of K Safety
- Current Fault Tolerance at Critical Level
- Too Many ROS Containers
- Node State Change
- Recovery Failure

- Recovery Error
- Recovery Lock Error
- Recovery Projection Retrieval Error
- Refresh Error
- Tuple Mover Error
- Stale Checkpoint
- CRC Mismatch

Note

The above values are case sensitive.

The following example specifies two event names:

```
=> ALTER DATABASE DEFAULT SET SnmpTrapEvents = 'Low Disk Space, Recovery Failure';
```

Verifying SNMP configuration

To create a set of test events that checks SNMP configuration:

1. Set up SNMP trap handlers to catch Vertica events.
2. Test your setup with the following command:

```
SELECT SNMP_TRAP_TEST();
   SNMP_TRAP_TEST
-----
Completed SNMP Trap Test
(1 row)
```

Event reporting examples

Vertica.log

Too many ROS containers exist on this node. DatabaseName: TESTDB Hostname: fc6-1.example.com
```

Using system tables

Vertica system tables provide information about system resources, background processes, workload, and performance—for example, load streams, query profiles, and tuple mover operations. Vertica collects and refreshes this information automatically.

You can query system tables using expressions, predicates, aggregates, analytics, subqueries, and joins. You can also save system table query results into a user table for future analysis. For example, the following query creates a table, `mynode`, selecting three node-related columns from the `NODES` system table:

```
=> CREATE TABLE mynode AS SELECT node_name, node_state, node_address FROM nodes;
```

```
CREATE TABLE
```

```
=> SELECT * FROM mynode;
```

```
node_name | node_state | node_address
```

```
-----+-----+-----
```

```
v_vmart_node0001 | UP | 192.168.223.11
```

```
(1 row)
```

Note

You cannot query system tables if the database cluster is in a recovering state. The database refuses connection requests and cannot be monitored. Vertica also does not support DDL and DML operations on system tables.

Where system tables reside

System tables are grouped into two schemas:

- [V_CATALOG schema](#): Provides information about persistent objects in the catalog
- [V_MONITOR schema](#): Provides information about transient system state

These schemas reside in the default search path. Unless you [change the search path](#) to exclude `V_MONITOR` or `V_CATALOG` or both, queries can specify a system table name that omits its schema.

You can query the `SYSTEM_TABLES` table for all Vertica system tables and their schemas. For example:

```
SELECT * FROM system_tables ORDER BY table_schema, table_name;
```

System table categories

Vertica system tables can be grouped into the following areas:

- System information
- System resources
- Background processes
- Workload and performance

Vertica reserves some memory to help monitor busy systems. Using simple system table queries makes it easier to troubleshoot issues. See also [SYSQUERY](#).

Note

You can use external monitoring tools or scripts to query the system tables and act upon the information, as necessary. For example, when a host failure causes the [K-safety](#) level to fall below the desired level, the tool or script can notify the database administrator and/or appropriate IT personnel of the change, typically in the form of an e-mail.

Privileges

You can GRANT and REVOKE privileges on system tables, with the following restrictions:

- You cannot GRANT privileges on system tables to the SYSMONITOR or PSEUDOSUPERUSER roles.
- You cannot GRANT on system schemas.

Case-sensitive system table data

Some system table data might be stored in mixed case. For example, Vertica stores mixed-case [identifier](#) names the way you specify them in the CREATE statement, even though case is ignored when you reference them in queries. When these object names appear as data in the system tables, you'll encounter errors if you query them with an equality (=) operator because the case must exactly match the stored identifier. In particular, data in columns [TABLE_SCHEMA](#) and [TABLE_NAME](#) in system table [TABLES](#) are case sensitive.

If you don't know how the identifiers are stored, use the case-insensitive operator [ILIKE](#). For example, given the following schema:

```
=> CREATE SCHEMA SS;
=> CREATE TABLE SS.TT (c1 int);
=> CREATE PROJECTION SS.TTP1 AS SELECT * FROM ss.tt UNSEGMENTED ALL NODES;
=> INSERT INTO ss.tt VALUES (1);
```

A query that uses the = operator returns 0 rows:

```
=> SELECT table_schema, table_name FROM v_catalog.tables WHERE table_schema = 'ss';
table_schema | table_name
-----+-----
(0 rows)
```

A query that uses case-insensitive [ILIKE](#) returns the expected results:

```
=> SELECT table_schema, table_name FROM v_catalog.tables WHERE table_schema ILIKE 'ss';
table_schema | table_name
-----+-----
SS          | TT
(1 row)
```

Examples

The following examples illustrate simple ways to use system tables in queries.

```
=> SELECT current_epoch, designed_fault_tolerance, current_fault_tolerance FROM SYSTEM;
```

```
current_epoch | designed_fault_tolerance | current_fault_tolerance
```

```
-----+-----+-----  
492 | 1 | 1
```

```
(1 row)
```

```
=> SELECT node_name, total_user_session_count, executed_query_count FROM query_metrics;
```

```
node_name | total_user_session_count | executed_query_count
```

```
-----+-----+-----  
v_vmart_node0001 | 115 | 353
```

```
v_vmart_node0002 | 114 | 35
```

```
v_vmart_node0003 | 116 | 34
```

```
(3 rows)
```

```
=> SELECT DISTINCT(schema_name), schema_owner FROM schemata;
```

```
schema_name | schema_owner
```

```
-----+-----  
v_catalog | dbadmin
```

```
v_txtindex | dbadmin
```

```
v_func | dbadmin
```

```
TOPSCHEMA | dbadmin
```

```
online_sales | dbadmin
```

```

```

```
v_monitor | dbadmin
```

```
structs | dbadmin
```

```
public | dbadmin
```

```
store | dbadmin
```

```
(10 rows)
```

Data Collector utility

The Data Collector collects and retains history of important system activities and records essential performance and resource utilization counters. The Data Collector propagates information to system tables.

You can use the Data Collector in the following ways:

- Query the past state of system tables and extract aggregate information
- See what actions users have taken
- Locate performance bottlenecks
- Identify potential improvements to Vertica configuration

The Data Collector does not collect data for nodes that are down, so no historical data is available for affected nodes.

The Data Collector works with [Workload Analyzer](#), a tool that intelligently monitors the performance of SQL queries and workloads and recommends tuning actions based on observations of the actual workload history.

Configuring and accessing Data Collector information

The Data Collector retains the data it gathers according to [configurable retention policies](#). The Data Collector is on by default; you can disable it by setting the EnableDataCollector configuration parameter to 0. You can set the parameter at the database level using [ALTER DATABASE](#) or the node level using [ALTER NODE](#). You cannot set it at the session or user level.

You can access metadata on collected data of all components using the [DATA_COLLECTOR](#) system table. This table includes information for each component about current collection policies and how much data is retained in memory and on disk.

Collected data is logged on disk in the [DataCollector](#) directory under the Vertica [/catalog](#) path. You can query logged data from component-specific [Data Collector tables](#). You can also manage logged data with Vertica meta-functions; see [Managing data collection logs](#).

In this section

- [Configuring data retention policies](#)
- [Querying data collector tables](#)
- [Managing data collection logs](#)

Configuring data retention policies

[Data collector](#) maintains retention policies for each Vertica component that it monitors—for example, TupleMoverEvents or DepotEvictions. You can identify monitored components by querying the [DATA_COLLECTOR](#) system table. For example, the following query returns partition activity components:

```
--> SELECT DISTINCT component FROM DATA_COLLECTOR
   WHERE component ILIKE '%partition%';
 component
-----
HiveCustomPartitions
CopyPartitions
MovePartitions
SwapPartitions
(4 rows)
```

Each component has its own retention policy, which consists of several properties:

- **MEMORY_BUFFER_SIZE_KB**: the maximum amount of collected data that the Data Collector buffers in memory before moving it to disk.
- **DISK_SIZE_KB**: the maximum disk space allocated for the component's Data Collector table.
- **INTERVAL_TIME**: how long data of a given component is retained in the component's Data Collector table ([INTERVAL](#) data type).

Vertica sets default values on all properties, which you can modify with the [SET_DATA_COLLECTOR_POLICY \(using parameters\)](#) function or, alternatively, [SET_DATA_COLLECTOR_POLICY](#) and [SET_DATA_COLLECTOR_TIME_POLICY](#).

You can view retention policy settings with [GET_DATA_COLLECTOR_POLICY](#). For example, the following statement returns the retention policy for the TupleMoverEvents component:

```
--> SELECT GET_DATA_COLLECTOR_POLICY('TupleMoverEvents');
   GET_DATA_COLLECTOR_POLICY
-----
1000KB kept in memory, 15000KB kept on disk. Time based retention disabled.
(1 row)
```

Setting retention memory and disk storage

The **MEMORY_BUFFER_SIZE_KB** and **DISK_SIZE_KB** properties combine to determine how much collected data is available at any given time. If **MEMORY_BUFFER_SIZE_KB** is set to 0, the Data Collector does not retain any data for the component either in memory or on disk. If **DISK_SIZE_KB** is set to 0, then the Data Collector retains only as much component data as it can buffer, as set by **MEMORY_BUFFER_SIZE_KB**.

For example, the following statement changes memory and disk setting for the ResourceAcquisitions component from its default setting of 1,000 KB memory and 10,000 KB disk space to 1500 KB and 25000 KB, respectively:

```
--> SELECT SET_DATA_COLLECTOR_POLICY('ResourceAcquisitions', '1500', '25000');
   SET_DATA_COLLECTOR_POLICY
-----
SET
(1 row)
```

Consider setting **MEMORY_BUFFER_SIZE_KB** to a high value in the following cases:

- Unusually high levels of data collection. If **MEMORY_BUFFER_SIZE_KB** is set too low, the Data Collector might be unable to flush buffered data to disk quickly enough to keep up with the activity level, which can lead to loss of in-memory data.
- Very large data collector records—for example, records with very long query strings. The Data Collector uses double-buffering, so it cannot retain in-memory records that are more than half the size of the memory buffer.

Setting time-based retention

By default, all data collected for a given component remains on disk and is accessible in the component's Data Collector table, up to the disk storage limit of that component's retention policy. You can use [SET_DATA_COLLECTOR_POLICY](#) to limit how long data is retained in a component's Data Collector table. The following example sets the **INTERVAL_TIME** property for the TupleMoverEvents component:

```
=> SELECT SET_DATA_COLLECTOR_TIME_POLICY('TupleMoverEvents', '30minutes':INTERVAL);
SET_DATA_COLLECTOR_TIME_POLICY
```

```
SET
(1 row)
```

After this call, the corresponding Data Collector table, **DC_TUPLE_MOVER_EVENTS**, only retains records of activity that occurred in the last 30 minutes. Older data is automatically dropped from this table. For example, after the previous call to SET_DATA_COLLECTOR_TIME_POLICY, the table contains on 30 minutes' worth of data:

```
=> SELECT CURRENT_TIMESTAMP(0) - '30 minutes':INTERVAL AS '30 minutes ago';
```

```
30 minutes ago
```

```
2020-08-13 07:58:21
```

```
(1 row)
```

```
=> SELECT time, node_name, session_id, user_name, transaction_id, operation
FROM DC_TUPLE_MOVER_EVENTS WHERE node_name='v_vmart_node0001'
ORDER BY transaction_id;
```

time	node_name	session_id	user_name	transaction_id	operation

```
(18 rows)
```

After 25 minutes elapse, 12 of these records age out of the 30-minute interval and are dropped:

```
=> SELECT CURRENT_TIMESTAMP(0) - '30 minutes':INTERVAL AS '30 minutes ago';
```

```
30 minutes ago
```

```
2020-08-13 08:23:33
```

```
(1 row)
```

```
=> SELECT time, node_name, session_id, user_name, transaction_id, operation
FROM DC_TUPLE_MOVER_EVENTS WHERE node_name='v_vmart_node0001'
ORDER BY transaction_id;
```

time	node_name	session_id	user_name	transaction_id	operation
2020-08-13 08:25:20.465604-04	v_vmart_node0001	v_vmart_node0001-190508:0x375db	dbadmin	45035996273807890	Mergeout
2020-08-13 08:25:20.497266-04	v_vmart_node0001	v_vmart_node0001-190508:0x375db	dbadmin	45035996273807890	Mergeout
2020-08-13 08:25:20.518839-04	v_vmart_node0001	v_vmart_node0001-190508:0x375db	dbadmin	45035996273807890	Mergeout
2020-08-13 08:25:20.52099-04	v_vmart_node0001	v_vmart_node0001-190508:0x375db	dbadmin	45035996273807893	Mergeout
2020-08-13 08:25:20.549075-04	v_vmart_node0001	v_vmart_node0001-190508:0x375db	dbadmin	45035996273807893	Mergeout
2020-08-13 08:25:20.569072-04	v_vmart_node0001	v_vmart_node0001-190508:0x375db	dbadmin	45035996273807893	Mergeout

```
(6 rows)
```

Note

Setting a component policy's `INTERVAL_TIME` property has no effect on how much data storage the Data Collector retains on disk for that component. Maximum disk storage capacity is determined by the `DISK_SIZE_KB` property. Setting the `INTERVAL_TIME` property only affects how long data is retained by the component's Data Collector table.

You can use `SET_DATA_COLLECTOR_TIME_POLICY` to update `INTERVAL_TIME` for all components by omitting the component argument:

```
=> SELECT SET_DATA_COLLECTOR_TIME_POLICY('1 day':INTERVAL);
SET_DATA_COLLECTOR_TIME_POLICY
-----
SET
(1 row)

=> SELECT DISTINCT component, INTERVAL_SET, INTERVAL_TIME
FROM DATA_COLLECTOR WHERE component ILIKE '%partition%';
 component | INTERVAL_SET | INTERVAL_TIME
-----
HiveCustomPartitions | t          | 1
MovePartitions      | t          | 1
CopyPartitions      | t          | 1
SwapPartitions      | t          | 1
(4 rows)
```

To clear the `INTERVAL_TIME` policy property, call `SET_DATA_COLLECTOR_TIME_POLICY` with a negative integer argument:

```
=> SELECT SET_DATA_COLLECTOR_TIME_POLICY(-1);
SET_DATA_COLLECTOR_TIME_POLICY
-----
SET
(1 row)

=> SELECT DISTINCT component, INTERVAL_SET, INTERVAL_TIME
FROM DATA_COLLECTOR WHERE component ILIKE '%partition%';
 component | INTERVAL_SET | INTERVAL_TIME
-----
MovePartitions | f          | 0
SwapPartitions | f          | 0
HiveCustomPartitions | f          | 0
CopyPartitions | f          | 0
(4 rows)
```

Setting `INTERVAL_TIME` on a retention policy also sets its `INTERVAL_SET` property to true.

Querying data collector tables

Caution

Data Collector tables (prefixed by `DC_`) are in the `V_INTERNAL` schema. If you use Data Collector tables in scripts or monitoring tools, be aware that any Vertica upgrade can remove or change them without notice.

You can obtain component-specific data from Data Collector tables. The Data Collector compiles the component data from its log files in a table format that you can query with standard SQL queries. You can identify Data Collector table names for specific components from the `DATA_COLLECTOR` system table:

```
=> SELECT DISTINCT component, table_name FROM DATA_COLLECTOR
   WHERE component ILIKE 'lock%';
 component | table_name
-----+-----
 LockRequests | dc_lock_requests
 LockReleases | dc_lock_releases
 LockAttempts | dc_lock_attempts
(3 rows)
```

You can then query those Data Collector tables directly:

```
=> SELECT * FROM DC_LOCK_ATTEMPTS
   WHERE description != 'Granted immediately';
[ RECORD 1 ]-----+-----
 time          | 2020-08-17 00:14:07.187607-04
 node_name     | v_vmart_node0001
 session_id    | v_vmart_node0001-319647:0x1d
 user_id       | 45035996273704962
 user_name     | dbadmin
 transaction_id | 45035996273819050
 object        | 0
 object_name   | Global Catalog
 mode          | X
 promoted_mode | X
 scope         | TRANSACTION
 start_time    | 2020-08-17 00:14:07.184663-04
 timeout_in_seconds | 300
 result        | granted
 description   | Granted after waiting
```

Managing data collection logs

On startup, Vertica creates a **DataCollector** directory under the database catalog directory of each node. This directory contains one or more logs for individual components. For example:

```
$ pwd
/home/dbadmin/VMart/v_vmart_node0001_catalog/DataCollector

$ ls -l -g Lock*
-rw----- 1 verticadba 2559879 Aug 17 00:14 LockAttempts_650572441057355.log
-rw----- 1 verticadba 614579 Aug 17 05:28 LockAttempts_650952885486175.log
-rw----- 1 verticadba 2559895 Aug 14 18:31 LockReleases_650306482037650.log
-rw----- 1 verticadba 1411127 Aug 17 05:28 LockReleases_650759468041873.log
```

The **DataCollector** directory also contains a pair of SQL template files for each component:

- **CREATE_ *component* _TABLE.sql** provides DDL for creating a table that you can use to load Data Collector logs for a given component. For example:

```

$ cat CREATE_LockAttempts_TABLE.sql
set dcschema `echo ${DCSCHEMA:-dc}`
CREATE TABLE :dcschema.dc_lock_attempts(
  "time" TIMESTAMP WITH TIME ZONE,
  "node_name" VARCHAR(128),
  "session_id" VARCHAR(128),
  "user_id" INTEGER,
  "user_name" VARCHAR(128),
  "transaction_id" INTEGER,
  "object" INTEGER,
  "object_name" VARCHAR(128),
  "mode" VARCHAR(128),
  "promoted_mode" VARCHAR(128),
  "scope" VARCHAR(128),
  "start_time" TIMESTAMP WITH TIME ZONE,
  "timeout_in_seconds" INTEGER,
  "result" VARCHAR(128),
  "description" VARCHAR(64000)
);

```

- **COPY_component_TABLE.sql** contains SQL for loading (with [COPY](#)) the data log files into the table that the CREATE script creates. For example:

```

$ cat COPY_LockAttempts_TABLE.sql
set dcpath `echo ${DCPATH:-$PWD}`
set dcschema `echo ${DCSCHEMA:-dc}`
set logfile "" :dcpath/LockAttempts_*.log"
COPY :dcschema.dc_lock_attempts(
  LockAttempts_start_filler FILLER VARCHAR(64) DELIMITER E'\n',
  "time_nfiller" FILLER VARCHAR(32) DELIMITER ':',
  "time" FORMAT '_internal' DELIMITER E'\n',
  "node_name_nfiller" FILLER VARCHAR(32) DELIMITER ':',
  "node_name" ESCAPE E'\001' DELIMITER E'\n',
  "session_id_nfiller" FILLER VARCHAR(32) DELIMITER ':',
  "session_id" ESCAPE E'\001' DELIMITER E'\n',
  "user_id_nfiller" FILLER VARCHAR(32) DELIMITER ':',
  "user_id" FORMAT 'd' DELIMITER E'\n',
  "user_name_nfiller" FILLER VARCHAR(32) DELIMITER ':',
  "user_name" ESCAPE E'\001' DELIMITER E'\n',
  "transaction_id_nfiller" FILLER VARCHAR(32) DELIMITER ':',
  "transaction_id" FORMAT 'd' DELIMITER E'\n',
  "object_nfiller" FILLER VARCHAR(32) DELIMITER ':',
  "object" FORMAT 'd' DELIMITER E'\n',
  "object_name_nfiller" FILLER VARCHAR(32) DELIMITER ':',
  "object_name" ESCAPE E'\001' DELIMITER E'\n',
  "mode_nfiller" FILLER VARCHAR(32) DELIMITER ':',
  "mode" ESCAPE E'\001' DELIMITER E'\n',
  "promoted_mode_nfiller" FILLER VARCHAR(32) DELIMITER ':',
  "promoted_mode" ESCAPE E'\001' DELIMITER E'\n',
  "scope_nfiller" FILLER VARCHAR(32) DELIMITER ':',
  "scope" ESCAPE E'\001' DELIMITER E'\n',
  "start_time_nfiller" FILLER VARCHAR(32) DELIMITER ':',
  "start_time" FORMAT '_internal' DELIMITER E'\n',
  "timeout_in_seconds_nfiller" FILLER VARCHAR(32) DELIMITER ':',
  "timeout_in_seconds" FORMAT 'd' DELIMITER E'\n',
  "result_nfiller" FILLER VARCHAR(32) DELIMITER ':',
  "result" ESCAPE E'\001' DELIMITER E'\n',
  "description_nfiller" FILLER VARCHAR(32) DELIMITER ':',
  "description" ESCAPE E'\001'
) FROM :logfile RECORD TERMINATOR E'\n\n' DELIMITER E'\n';

```

Log management functions

You can use two Data Collector functions to manage logs. Both functions can operate on a single component or all components.

- [FLUSH_DATA_COLLECTOR](#) waits until in-memory logs are moved to disk and then flushes the Data Collector, synchronizing the log with disk storage.
- [CLEAR_DATA_COLLECTOR](#) clears all memory and disk records from Data Collector tables and logs and then resets collection statistics in [DATA_COLLECTOR](#).

Monitoring partition reorganization

When you use [ALTER TABLE...REORGANIZE](#), the operation reorganizes the data in the background.

You can monitor details of the reorganization process by polling the following system tables:

- [V_MONITOR.PARTITION_STATUS](#) displays the fraction of each table that is partitioned correctly.
- [V_MONITOR.PARTITION_REORGANIZE_ERRORS](#) logs errors issued by the reorganize process.
- [V_MONITOR.PARTITIONS](#) displays **NULL** in the `partition_key` column for any ROS that was not reorganized.

Note

The corresponding foreground process to [ALTER TABLE...REORGANIZE](#) is [PARTITION_TABLE](#).

Monitoring resource pools

You can use the following to find information about resource pools:

- [RESOURCE_POOL_STATUS](#) returns current data from resource pools—for example, current memory usage, resources requested and acquired by various requests, and state of the queues.
- [RESOURCE_ACQUISITIONS](#) displays all resources granted to the queries that are currently running.
- [SHOW SESSION](#) shows, along with other session-level parameters, the [current session's resource pool](#).

You can also use the Management Console to obtain run-time data on [resource pool usage](#).

Note

The Linux [top command](#) returns data on overall CPU usage and I/O wait time across the system. Because of file system caching, the resident memory size returned by `top` is not the best indicator of actual memory use or available reserves.

Viewing resource pool status

The following example queries [RESOURCE_POOL_STATUS](#) for memory size data:

```
=> SELECT pool_name poolName,
node_name nodeName,
max_query_memory_size_kb maxQueryMemSizeKb,
max_memory_size_kb maxMemSizeKb,
memory_size_actual_kb memSizeActualKb
FROM resource_pool_status WHERE pool_name='ceo_pool';
poolName | nodeName | maxQueryMemSizeKb | maxMemSizeKb | memSizeActualKb
-----+-----+-----+-----+-----
ceo_pool | v_vmart_node0001 | 12179388 | 13532654 | 1843200
ceo_pool | v_vmart_node0002 | 12191191 | 13545768 | 1843200
ceo_pool | v_vmart_node0003 | 12191170 | 13545745 | 1843200
(3 rows)
```

Viewing query resource acquisitions

The following example displays all resources granted to the queries that are currently running. The information shown is stored in system table [RESOURCE_ACQUISITIONS](#) table. You can see that the query execution used 708504 KB of memory from the GENERAL pool.

```
=> SELECT pool_name, thread_count, open_file_handle_count, memory_inuse_kb,
       queue_entry_timestamp, acquisition_timestamp
       FROM V_MONITOR.RESOURCE_ACQUISITIONS WHERE node_name ILIKE '%node0001';
```

```
-[ RECORD 1 ]-----+-----
pool_name      | sysquery
thread_count   | 4
open_file_handle_count | 0
memory_inuse_kb | 4103
queue_entry_timestamp | 2013-12-05 07:07:08.815362-05
acquisition_timestamp | 2013-12-05 07:07:08.815367-05
-[ RECORD 2 ]-----+-----
...
-[ RECORD 8 ]-----+-----
pool_name      | general
thread_count   | 12
open_file_handle_count | 18
memory_inuse_kb | 708504
queue_entry_timestamp | 2013-12-04 12:55:38.566614-05
acquisition_timestamp | 2013-12-04 12:55:38.566623-05
-[ RECORD 9 ]-----+-----
...
```

You can determine how long a query waits in the queue before it can run. To do so, you obtain the difference between `acquisition_timestamp` and `queue_entry_timestamp` using a query as this example shows:

```
=> SELECT pool_name, queue_entry_timestamp, acquisition_timestamp,
       (acquisition_timestamp-queue_entry_timestamp) AS 'queue wait'
       FROM V_MONITOR.RESOURCE_ACQUISITIONS WHERE node_name ILIKE '%node0001';
```

```
-[ RECORD 1 ]-----+-----
pool_name      | sysquery
queue_entry_timestamp | 2013-12-05 07:07:08.815362-05
acquisition_timestamp | 2013-12-05 07:07:08.815367-05
queue wait     | 00:00:00.000005
-[ RECORD 2 ]-----+-----
pool_name      | sysquery
queue_entry_timestamp | 2013-12-05 07:07:14.714412-05
acquisition_timestamp | 2013-12-05 07:07:14.714417-05
queue wait     | 00:00:00.000005
-[ RECORD 3 ]-----+-----
pool_name      | sysquery
queue_entry_timestamp | 2013-12-05 07:09:57.238521-05
acquisition_timestamp | 2013-12-05 07:09:57.281708-05
queue wait     | 00:00:00.043187
-[ RECORD 4 ]-----+-----
...
```

Querying user-defined resource pools

The Boolean column `IS_INTERNAL` in system tables `RESOURCE_POOLS` and `RESOURCE_POOL_STATUS` lets you get data on user-defined resource pools only. For example:

```

SELECT name, subcluster_oid, subcluster_name, memorysize, maxmemorysize, priority, maxconcurrency
dbadmin-> FROM V_CATALOG.RESOURCE_POOLS where is_internal = 'f';
 name      | subcluster_oid | subcluster_name | memorysize | maxmemorysize | priority | maxconcurrency
-----+-----+-----+-----+-----+-----+-----
load_pool  | 72947297254957395 | default        | 0%         |                |         | 10
ceo_pool   | 63570532589529860 | c_subcluster   | 250M       |                |         | 10
ad_hoc_pool | 0                |                | 200M       | 200M           | 0       |
billing_pool | 45579723408647896 | ar_subcluster  | 0%         |                |         | 0 | 3
web_pool   | 0                | analytics_1    | 25M        |                | 10      | 5
batch_pool | 47479274633682648 | default        | 150M       | 150M           | 0       | 10
dept1_pool | 0                | 0%             |            |                | 5       |
dept2_pool | 0                | 0%             |            |                | 8       |
dashboard  | 45035996273843504 | analytics_1    | 0%         |                |         | 0
(9 rows)

```

Monitoring recovery

When your Vertica database is recovering from a failure, it's important to monitor the recovery process. There are several ways to monitor database recovery:

In this section

- [Viewing log files on each node](#)
- [Using system tables to monitor recovery](#)
- [Viewing cluster state and recovery status](#)
- [Monitoring cluster status after recovery](#)

Viewing log files on each node

During database recovery, Vertica adds logging information to the `vertica.log` on each host. Each message is identified with a `[Recover]` string.

Use the `tail` command to monitor recovery progress by viewing the relevant status messages, as follows.

```

$ tail -f catalog-path/database-name/node-name_catalog/vertica.log
01/23/08 10:35:31 thr:Recover:0x2a98700970 [Recover] <INFO> Changing host v_vmart_node0001 startup state from INITIALIZING to RECOVERING
01/23/08 10:35:31 thr:CatchUp:0x1724b80 [Recover] <INFO> Recovering to specified epoch 0x120b6
01/23/08 10:35:31 thr:CatchUp:0x1724b80 [Recover] <INFO> Running 1 split queries
01/23/08 10:35:31 thr:CatchUp:0x1724b80 [Recover] <INFO> Running query: ALTER PROJECTION proj_tradesquotes_0 SPLIT v_vmart_node0001 FROM 73911;

```

Using system tables to monitor recovery

Use the following system tables to monitor recover:

- [RECOVERY_STATUS](#)
- [PROJECTION_RECOVERIES](#)

Specifically, the `recovery_status` system table includes information about the node that is recovering, the epoch being recovered, the current recovery phase, and running status:

```

=>select node_name, recover_epoch, recovery_phase, current_completed, is_running from recovery_status;
 node_name      | recover_epoch | recovery_phase | current_completed | is_running
-----+-----+-----+-----+-----
v_vmart_node0001 |              |                | 0                 | f
v_vmart_node0002 | 0            | historical pass 1 | 0                 | t
v_vmart_node0003 | 1            | current          | 0                 | f

```

The `projection_recoveries` system table maintains history of projection recoveries. To check the recovery status, you can summarize the data for the recovering node, and run the same query several times to see if the counts change. Differing counts indicate that the recovery is working and in the process of recovering all missing data.

```
=> select node_name, status, progress from projection_recoveries;
node_name      | status  | progress
-----+-----+-----
v_vmart_node0001 | running | 61
```

To see a single record from the [projection_recoveries](#) system table, add limit 1 to the query.

After a recovery has completed, Vertica continues to store information from the most recent recovery in these tables.

Viewing cluster state and recovery status

Use the admintools [view_cluster](#) tool from the command line to see the cluster state:

```
$/opt/vertica/bin/admintools -t view_cluster
DB | Host | State
-----+-----+-----
<data_base> | 112.17.31.10 | RECOVERING
<data_base> | 112.17.31.11 | UP
<data_base> | 112.17.31.12 | UP
<data_base> | 112.17.31.17 | UP
```

Monitoring cluster status after recovery

When recovery has completed:

1. Launch Administration Tools.
2. From the Main Menu, select **View Database Cluster** State and click **OK**.
The utility reports your node's status as **UP**.

Note

You can also monitor the state of your database nodes on the Management Console Overview page under the Database section, which tells you the number of nodes that are up, critical, recovering, or down. To get node-specific information, click Manage at the bottom of the page.

Clearing projection refresh history

The [PROJECTION_REFRESHES](#) system table records information about successful and unsuccessful [refresh operations](#). This table normally retains data for a projection until replaced by a new refresh of that projection, but you can also purge the table.

To immediately purge data for all completed refreshes, call [CLEAR_PROJECTION_REFRESHES](#):

```
=> SELECT clear_projection_refreshes();
clear_projection_refreshes
-----+-----+-----
CLEAR
(1 row)
```

This function does not clear data for refreshes that are currently in progress.

Monitoring Vertica using notifiers

A Vertica notifier is a push-based mechanism for sending messages from Vertica to endpoints like Apache Kafka or syslog. For example, you can configure a long-running script to send notifications at various stages and then at the completion of a task.

To use a notifier:

1. Use [CREATE NOTIFIER](#) to create one of the following notifier types:
 - [Syslog](#)
 - [SNS](#)
 - [Kafka](#)
2. Send a notification to the NOTIFIER endpoint with any of the following:
 - [NOTIFY](#): Manually sends a message to the NOTIFIER endpoint.

- [SET_DATA_COLLECTOR_NOTIFY_POLICY](#): Creates a notification policy, which automatically sends a message to the NOTIFIER endpoint when a specified event occurs.

Backing up and restoring the database

Important

Inadequate security on backups can compromise overall database security. Be sure to secure backup locations and strictly limit access to backups only to users who already have permissions to access all database data.

Creating regular database backups is an important part of basic maintenance tasks. Vertica supplies a comprehensive utility, `vbr`, for this purpose. `vbr` lets you perform the following operations. Unless otherwise noted, operations are supported in both Enterprise Mode and Eon Mode:

- Back up a database.
- Back up specific objects (schemas or tables) in a database.
- Restore a database or individual objects from backup.
- Copy a database to another cluster. For example, to promote a test cluster to production (Enterprise Mode only).
- Replicate individual objects (schemas or tables) to another cluster.
- List available backups.

When you run `vbr`, you specify a configuration (.ini) file. In this file you specify all of the configuration parameters for the operation: what to back up, where to back it up, how many backups to keep, whether to encrypt transmissions, and much more. Vertica provides several [Sample vbr configuration files](#) that you can use as templates.

You can use `vbr` to restore a backup created by `vbr`. Typically, you use the same configuration file for both operations. [Common use cases](#) introduces the most common `vbr` operations.

When performing a backup, you can save your data to one of the following locations:

- Local directory on each node
- Remote file system
- Different Vertica cluster (effectively cloning your database)
- Cloud storage

You cannot back up an Enterprise Mode database and restore it in Eon Mode, or vice versa.

Supported cloud storage

Vertica supports backup and restore operations in the following cloud storage locations:

- Amazon Web Services (AWS) S3
- S3-compatible private cloud storage, such as Pure Storage or Minio
- Google Cloud Storage (GCS)
- Azure Blob Storage

If you are backing up an Eon Mode database, you must use a supported cloud storage location.

You cannot perform backup or restore operations between different cloud providers. For example, you cannot back up or restore from GCS to an S3 location.

Additional considerations for HDFS storage locations

If your database has any storage locations on HDFS, additional configuration is required to enable those storage locations for backup operations. See [Requirements for backing up and restoring HDFS storage locations](#).

In this section

- [Common use cases](#)
- [Sample vbr configuration files](#)
- [Eon Mode database requirements](#)
- [Requirements for backing up and restoring HDFS storage locations](#)
- [Setting up backup locations](#)
- [Creating backups](#)
- [Restoring backups](#)
- [Copying the database to another cluster](#)
- [Replicating objects to another database cluster](#)
- [Including and excluding objects](#)
- [Managing backups](#)

- [Troubleshooting backup and restore](#)
- [vbr reference](#)
- [vbr configuration file reference](#)

Common use cases

You can use `vbr` to perform many tasks related to backup and restore. The [vbr reference](#) describes all of the tasks in detail. This section summarizes common use cases. For each of these cases, there are additional requirements not covered here. Be sure to read the linked topics for details.

This is not a complete list of Backup/Restore capabilities.

Routine backups in Enterprise Mode

A full backup stores a copy of your data in another location—ideally a location that is separated from your database location, such as on different hardware or in the cloud. You give the backup a name (the snapshot name), which allows you to have different backups and backup types without interference. In your configuration file, you can map database nodes to backup locations and set some other parameters.

Before your first backup, run the [vbr init task](#).

Use the [vbr backup task](#) to perform a full backup. The [External full backup/restore](#) example provides a starting point for your configuration. For complete documentation of full backups, see [Creating full backups](#).

Routine backups in Eon Mode

For the most part, backups in Eon Mode work the same way as backups in Enterprise Mode. Eon Mode has some additional requirements described in [Eon Mode database requirements](#), and some configuration parameters are different for backups to cloud storage. You can back up or restore Eon Mode databases that run in the cloud or on-premises using a [supported cloud storage](#) location.

Use the [vbr backup task](#) to perform a full backup. The [Backup/restore to cloud storage](#) example provides a starting point for your configuration. For complete documentation of full backups, see [Creating full backups](#).

Checkpoint backups: backing up before a major operation

It is a good idea to back up your database before performing destructive operations such as dropping tables, or before major operations such as upgrading Vertica to a new version.

You can perform a regular full backup for this purpose, but a faster way is to create a hard-link local backup. This kind of backup copies your catalog and links your data files to another location on the local file system on each node. (You can also do a hard-link backup of specific objects rather than the whole database.) A hard-link local backup does not provide the same protection as a backup stored externally. For example, it does not protect you from local system failures. However, for a backup that you expect to need only temporarily, a hard-link local backup is an expedient option. Do not use hard-link local backups as substitutes for regular backups to other nodes.

Hard-link backups use the same [vbr backup task](#) as other backups, but with a different configuration. The [Full hard-link backup/restore](#) example provides a starting point for your configuration. See [Creating hard-link local backups](#) for more information.

Restoring selected objects

Sometimes you need to restore specific objects, such as a table you dropped, rather than the entire database. You can restore individual tables or schemas from any backup that contains them, whether a full backup or an object backup.

Use the [vbr restore task](#) and the `--restore-objects` parameter to specify what to restore. Usually you use the same configuration file that you used to create the backup. See [Restoring individual objects](#) for more information.

Restoring an entire database

You can restore both Enterprise Mode and Eon Mode databases from complete backups. You cannot use restore to change the mode of your database. In Eon Mode, you can restore to the primary subcluster without regard to secondary subclusters.

Use the [vbr restore task](#) to restore a database. As when restoring selected objects, you usually use the same configuration file that you used to create the backup. See [Restoring a database from a full backup](#) and [Restoring hard-link local backups](#) for more information.

Copying a cluster

You might need to copy a database to another cluster of computers, such as when you are promoting a database from a staging environment to production. Copying a database to another cluster is essentially a simultaneous backup and restore operation. The data is backed up from the source database cluster and restored to the destination cluster in a single operation.

Use the [vbr copycluster task](#) to copy a cluster. The [Database copy to an alternate cluster](#) example provides a starting point for your configuration. See [Copying the database to another cluster](#) for more information.

Replicating selected objects to another database

You might want to replicate specific tables or schemas from one database to another. For example, you might do this to copy data from a production database to a test database to investigate a problem in isolation. Another example is when you complete a large data load in one database, replication to another database might be more efficient than repeating the load operation in the other database.

Use the [vbr replicate task](#) to replicate objects. You specify the objects to replicate in the configuration file. The [Object replication to an alternate database](#) example provides a starting point for your configuration. See [Replicating objects to another database cluster](#) for more information.

Sample vbr configuration files

The vbr utility uses configuration files to provide the information it needs to back up and restore a full or object-level backup or copy a cluster. No default configuration file exists. You must always specify a configuration file with the vbr command.

Vertica includes sample configuration files that you can copy, edit, and deploy for various vbr tasks. Vertica automatically installs these files at:

[/opt/vertica/share/vbr/example_configs](#)

In this section

External full backup/restore

backup_restore_full_external.ini

An external (distributed) backup backs up each database node to a distinct backup host. Nodes are mapped to hosts in the [Mapping] section.

To restore, use the same configuration file that you used to create the backup.

```
; This sample vbr configuration file shows full or object backup and restore to a separate remote backup-host for each respective database host.
; Section headings are enclosed by square brackets.
; Comments have leading semicolons (;) or pound signs (#).
; An equal sign separates options and values.
; Specify arguments marked '!!Mandatory!!' explicitly.
; All commented parameters are set to their default value.
```

```
; ----- ;
;;; BASIC PARAMETERS ;;;
; ----- ;
```

[Mapping]

```
; !!Mandatory!! This section defines what host and directory will store the backup for each node.
; node_name = backup_host:backup_dir
; In this "parallel backup" configuration, each node backs up to a distinct external host.
; To backup all database nodes to a single external host, use that single hostname/IP address in each entry below.
v_exampledb_node0001 = 10.20.100.156:/home/dbadmin/backups
v_exampledb_node0002 = 10.20.100.157:/home/dbadmin/backups
v_exampledb_node0003 = 10.20.100.158:/home/dbadmin/backups
v_exampledb_node0004 = 10.20.100.159:/home/dbadmin/backups
```

[Misc]

```
; !!Recommended!! Snapshot name. Object and full backups should always have different snapshot names.
; Backups with the same snapshotName form a time sequence limited by restorePointLimit.
; SnapshotName is used for naming archives in the backup directory, and for monitoring and troubleshooting.
; Valid characters: a-z A-Z 0-9 - _
; snapshotName = backup_snapshot
```

[Database]

; !!Recommended!! If you have more than one database defined on this Vertica cluster, use this parameter to specify which database to backup/restore.

; dbName = current_database

; If this parameter is True, vbr prompts the user for the database password every time.

; If False, specify the location of password config file in 'passwordFile' parameter in [Misc] section.

; dbPromptForPassword = True

; If true, vbr attempts to connect to the database using a local connection.

; dbUseLocalConnection = False

; ----- ;

::: ADVANCED PARAMETERS :::

; ----- ;

[Misc]

; The temp directory location on all database hosts.

; The directory must be readable and writeable by the dbadmin, and must implement POSIX style fcntl lockf locking.

; tempDir = /tmp/vbr

; Specifies the number of historical backups to retain in addition to the most recent backup.

; 1 current + n historical backups

; restorePointLimit = 1

; Full path to the password configuration file

; Store this file in directory readable only by the dbadmin

; (no default)

; passwordFile = /path/to/vbr/pw.txt

; When enabled, Vertica confirms that the specified backup locations contain

; sufficient free space and inodes to allow a successful backup. If a backup

; location has insufficient resources, Vertica displays an error message explaining the shortage and

; cancels the backup. If Vertica cannot determine the amount of available space

; or number of inodes in the backupDir, it displays a warning and continues

; with the backup.

; enableFreeSpaceCheck = True

[Transmission]

; Specifies the default port number for the rsync protocol.

; port_rsync = 50000

; Total bandwidth limit for all backup connections in KBPS, 0 for unlimited. Vertica distributes

; this bandwidth evenly among the number of connections set in concurrency_backup.

; total_bwlimit_backup = 0

; The maximum number of backup TCP rsync connection threads per node.

; Optimum settings depend on your particular environment.

; For best performance, experiment with values between 2 and 16.

; concurrency_backup = 1

; The total bandwidth limit for all restore connections in KBPS, 0 for unlimited

; total_bwlimit_restore = 0

; The maximum number of restore TCP rsync connection threads per node.

; Optimum settings depend on your particular environment.

; For best performance, experiment with values between 2 and 16.

; concurrency_restore = 1

; The maximum number of delete TCP rsync connection threads per node.

; Optimum settings depend on your particular environment.

; For best performance, experiment with values between 2 and 16.

; concurrency_delete = 16

```
[Database]
```

```
; Vertica user name for vbr to connect to the database.  
; This setting is rarely needed since dbUser is normally identical to the database administrator  
; dbUser = current_username
```

Backup/restore to cloud storage

```
backup_restore_cloud_storage.ini
```

You can backup and restore Enterprise Mode and Eon Mode databases to a cloud storage location. You must back up Eon Mode databases to a [supported cloud storage](#) location. Configuration settings in the [\[CloudStorage\]](#) section are identical for both Enterprise Mode and Eon Mode.

There are one-time configurations that you must complete before your first backup to a new cloud storage location. See [Additional considerations for cloud storage](#) for more information.

Backups to on-premises cloud storage destinations require additional configuration for both Enterprise Mode and Eon databases. For details about the additional requirements, see [Configuring cloud storage backups](#).

To restore, use the same configuration file that you used to create the backup. To restore selected objects rather than the entire database, specify the objects to restore on the [vbr command line](#) using `--restore-objects`.

```
; This sample vbr configuration file shows backup to Cloud Storage e.g AWS S3, GCS, HDFS or on-premises (e.g. Pure Storage)  
; This can be used for Vertica databases in Enterprise or Eon mode.  
; Section headings are enclosed by square brackets.  
; Comments have leading semicolons (;) or pound signs (#).  
; Option and values are separated by an equal sign.  
; Only arguments marked as "!!Mandatory!!" must be specified explicitly.  
; All commented parameters are set to their default value.
```

```
;----- ;  
;;; BASIC PARAMETERS ;;;  
;----- ;
```

```
[CloudStorage]
```

```
; This section replaces the [Mapping] section and is required to back up to cloud storage.
```

```
; !!Mandatory!! Backup location on Cloud or HDFS (no default).
```

```
cloud_storage_backup_path = gs://backup_bucket/database_backup_path/  
; cloud_storage_backup_path = s3://backup_bucket/database_backup_path/  
; cloud_storage_backup_path = webhdfs://backup_nameservice/database_backup_path/  
; cloud_storage_backup_path = azb://backup_account/backup_container/
```

```
; !!Mandatory!! directory used to manage locking during a backup (no default). If the directory is mounted on the initiator host, you  
; should use "[]" instead of the local host name. The file system must support POSIX fcntl flock.
```

```
cloud_storage_backup_file_system_path = []:/home/dbadmin/backup_locks_dir/
```

```
[Misc]
```

```
; !!Recommended!! Snapshot name  
; Backups with the same snapshotName form a time sequence limited by restorePointLimit.  
; SnapshotName is used for naming archives in the backup directory, and for monitoring and troubleshooting.  
; Valid values: a-z A-Z 0-9 - _  
; snapshotName = backup_snapshot
```

```
; Specifies how Vertica handles objects of the same name when restoring schema or table backups.  
; objectRestoreMode = createOrReplace
```

```
; Specifies which tables and/or schemas to copy. For tables, the containing schema defaults to public.  
; Note: 'objects' is incompatible with 'includeObjects' and 'excludeObjects'.  
; (no default)
```

```
; objects = mytable, myschema, myothertable
```

```
; Specifies the set of objects to backup/restore; wildcards may be used.
```

```
; Note: 'includeObjects' is incompatible with 'objects'
```

; Note: includeObjects is incompatible with objects.

; includeObjects = public.mytable, customer*, s?

; Subtracts from the set of objects to backup/restore; wildcards may be used

; Note: 'excludeObjects' is incompatible with 'objects'.

; excludeObjects = public.*temp, etl.phase?

[Database]

; !!Recommended!! If you have more than one database defined on this Vertica cluster, use this parameter to specify which database to backup/restore.

```
; dbUser = current_username
```

Full hard-link backup/restore

backup_restore_full_hardlink.ini

The following requirements apply to configuring hard-link local backups:

- Under the [Transmission] section, add the parameter hardLinkLocal :

```
hardLinkLocal = True
```

- The backup directory must be in the same file system as the database data directory.

- Omit the encrypt parameter. If the configuration file sets both parameters encrypt and hardLinkLocal to true, then vbr issues a warning and ignores the encrypt parameter.

```
; This sample vbr configuration file shows backup and restore using hard-links to data files on each database host for that host's backup.
```

```
; Section headings are enclosed by square brackets.
```

```
; Comments have leading semicolons (;) or pound signs (#).
```

Object-level local backup/restore in Enterprise Mode

backup_restore_object_local.ini

An object backup backs up only the schemas or tables that are specified in the [Misc] section by the parameter objects, or parameters includeObjects and excludeObjects.

For an object restore, use the same configuration file that you used to create the backup, and specify the objects to restore with the vbr command-line parameter `--restore-objects`.

```
; This sample vbr configuration file shows object-level backup and restore
; using a file system on each database host for that host's backup.
; Section headings are enclosed by square brackets.
; Comments have leading semicolons (;) or pound signs (#).
; Option and values are separated by an equal sign.
; Only arguments marked as '!!Mandatory!!' must be specified explicitly.
; All commented parameters are set to their default value.
```

```
; ----- ;
;;; BASIC PARAMETERS ;;;
; ----- ;
```

[Mapping]

; There must be one [Mapping] section for all of the nodes in your database cluster.

; !!Mandatory!! Backup host name (no default) and Backup directory (no default)

; dest_dbPassword=destDBsecret
```

Eon Mode database requirements

Eon Mode databases perform the same backup and restore operations as Enterprise Mode databases. Additional requirements pertain to Eon Mode because it uses a different architecture.

Note

These requirements are for cloud storage locations listed in [Backing up and restoring the database](#), and on-premises with communal storage on HDFS.

Cloud storage requirements

Eon Mode databases must be backed up to supported cloud storage locations. The following [\[CloudStorage\]](#) configuration parameters must be set:

- `cloud_storage_backup_path`
- `cloud_storage_backup_file_system_path`

A backup path is valid for one database only. You cannot use the same path to store backups for multiple databases.

Eon Mode databases that use S3-compatible on-premises cloud storage can back up to Amazon Web Services (AWS) S3.

Cloud storage access

In addition to having access to the cloud storage bucket used for the database's communal storage, you must have access to the cloud storage backup location. Verify that the credential you use to access communal storage also has access to the backup location. For more information about configuring cloud storage access for Vertica, see [Configuring cloud storage backups](#).

Note

While an AWS backup location can be in a different region, backup and restore operations across different S3 regions are incompatible with virtual private cloud (VPC) endpoints.

Eon on-premises and private cloud storage

If an Eon database runs on-premises, then communal storage is not on AWS but on another storage platform that uses the S3 or GS protocol. This means there can be two endpoints and two sets of credentials, depending on where you back up. This additional information is stored in [environment variables](#), and not in `vbr` configuration parameters.

Backups of Eon Mode on-premises databases do not support AWS IAM profiles.

HDFS on-premises storage

To back up an Eon Mode database that uses HDFS on-premises storage, the communal storage and backup location must use the same HDFS credentials and domain. All `vbr` operations are supported, except `copycluster`.

Vertica supports Kerberos authentication, High Availability Name Node, and wire encryption for `vbr` operations. Vertica does not support at-rest encryption for Hadoop storage.

For details, see [Configuring backups to and from HDFS](#).

Database restore requirements

When restoring a backup of an Eon Mode database, the target database must satisfy the following requirements:

- Share the same name as the source database.
- Have at least as many nodes as the primary subcluster(s) in the source database.
- Have the same node names as the nodes of the source database.
- Use the same catalog directory location as the source database.
- Use the same port numbers as the source database.
- For object-level restore, if you restore to an existing [target namespace](#), the target namespace and the objects' source namespace must have the same shard count, shard boundaries, and node subscriptions. For details, see [object-level tasks with multiple namespaces](#).

You can restore a full or object backup that was taken from a database with primary and secondary subclusters to the primary subclusters in the target database. The database can have only primary subclusters, or it can also have any number of secondary subclusters. Secondary subclusters do not need to match the backup database. The same is true for replicating a database; only the primary subclusters are required. The requirements are similar to those for [Reviving an Eon Mode database cluster](#).

Use the [\[Mapping\]](#) section in the configuration file to specify the mappings for the primary subcluster.

Object-level tasks with multiple namespaces

Eon Mode databases group schemas and tables into one or more [namespaces](#). By default, Eon databases contain only one namespace, `default_namespace`, which is created during database creation. Unless you have created additional namespaces, the `default_namespace` contains all schemas and tables. If you do not specify the namespace of an object, `vbr` assumes the object belongs to the `default_namespace`. Full database `vbr` tasks are unaffected by the number of namespaces.

Important

For `vbr` tasks, namespaces are prefixed with a period. For example, `.n.s.t` refers to table `t` in schema `s` in namespace `n`.

For object-level backups, you can specify the included objects in the `objects` parameter of your `vbr` configuration file. For example, to create an object-level backup of all objects in the `orders` and `customers` schemas in the `store_1` namespace, add the following lines to your configuration file:

```
objects = .store_1.orders*, .store_1.customers.*
```

Alternatively, you can specify the included and excluded objects using the `includeObjects` and `excludeObjects` parameters. If you set these parameters, the `objects` parameter must be empty.

For object-level restore and replicate `vbr` tasks, you can use the `--target-namespace` argument to specify the namespace to which the objects are restored or replicated.

`vbr` behaves differently depending on whether the target namespace exists:

- **Exists:** `vbr` attempts to restore or replicate the objects to the existing namespace, which must have the same shard count, shard boundaries, and node subscriptions as the source namespace. If these conditions are not met, the `vbr` task fails.
- **Nonexistent:** `vbr` creates a namespace in the target database with the name specified in `--target-namespace` and the shard count of the source namespace, and then replicates or restores the objects to that namespace.

If no target namespace is specified, `vbr` attempts to restore or replicate objects to a namespace with the same name as the source namespace.

You can specify how restore operations handle duplicate objects with `objectRestoreMode` parameter in the `vbr` configuration file.

The following command restores the `store_1.orders` schema of the source database to the `store_2` namespace in the target database:

```
$ vbr --task restore --config-file=db.ini --restore-objects=.store_1.orders.* --target-namespace=store_2
```

If no target namespace is specified, `vbr` attempts to restore the objects to a namespace with the same name as the source namespace. For example, you can omit the `--target-namespace=store_1` argument when restoring the `store_1.orders` schema to the `store_1` namespace:

```
$ vbr --task restore --config-file=db.ini --restore-objects=.store_1.orders.*
```

Requirements for backing up and restoring HDFS storage locations

There are several considerations for backing up and restoring HDFS storage locations:

- The HDFS directory for the storage location must have snapshotting enabled. You can either directly configure this yourself or enable the database administrator's Hadoop account to do it for you automatically. See [Hadoop configuration for backup and restore](#) for more information.
- If the Hadoop cluster uses Kerberos, Vertica nodes must have access to certain Hadoop configuration files. See [Configuring Kerberos](#) below.
- To restore an HDFS storage location, your Vertica cluster must be able to run the Hadoop `distcp` command. See [Configuring distcp on a Vertica Cluster](#) below.
- HDFS storage locations do not support object-level backups. You must perform a full database backup to back up the data in your HDFS storage locations.
- Data in an HDFS storage location is backed up to HDFS. This backup guards against accidental deletion or corruption of data. It does not prevent data loss in the case of a catastrophic failure of the entire Hadoop cluster. To prevent data loss, you must have a backup and disaster recovery plan for your Hadoop cluster.
Data stored on the Linux native file system is still backed up to the location you specify in the backup configuration file. It and the data in HDFS storage locations are handled separately by the `vbr` backup script.

Configuring Kerberos

If HDFS uses Kerberos, then to back up your HDFS storage locations you must take the following additional steps:

1. Grant Hadoop superuser privileges to the Kerberos principals for each Vertica node.

- Copy Hadoop configuration files to your database nodes as explained in [Accessing Hadoop Configuration Files](#). Vertica needs access to `core-site.xml`, `hdfs-site.xml`, and `yarn-site.xml` for backup and restore. If your Vertica nodes are co-located on HDFS nodes, these files are already present.
- Set the `HadoopConfDir` parameter to the location of the directory containing these files. The value can be a path, if the files are in multiple directories. For example:

```
=> ALTER DATABASE exampledb SET HadoopConfDir = '/etc/hadoop/conf:/etc/hadoop/test';
```

All three configuration files must be present on this path on every database node.

If your Vertica nodes are co-located on HDFS nodes and you are using Kerberos, you must also change some Hadoop configuration parameters. These changes are needed in order for restoring from backups to work. In `yarn-site.xml` on every Vertica node, set the following parameters:

Parameter	Value
<code>yarn.resourcemanager.proxy-user-privileges.enabled</code>	true
<code>yarn.resourcemanager.proxyusers.*.groups</code>	•
<code>yarn.resourcemanager.proxyusers.*.hosts</code>	•
<code>yarn.resourcemanager.proxyusers.*.users</code>	•
<code>yarn.timeline-service.http-authentication.proxyusers.*.groups</code>	•
<code>yarn.timeline-service.http-authentication.proxyusers.*.hosts</code>	•
<code>yarn.timeline-service.http-authentication.proxyusers.*.users</code>	•

No changes are needed on HDFS nodes that are not also Vertica nodes.

Configuring distcp on a Vertica cluster

Your Vertica cluster must be able to run the Hadoop `distcp` command to restore a backup of an HDFS storage location. The easiest way to enable your cluster to run this command is to install several Hadoop packages on each node. These packages must be from the same distribution and version of Hadoop that is running on your Hadoop cluster.

The steps you need to take depend on:

- The distribution and version of Hadoop running on the Hadoop cluster containing your HDFS storage location.
- The distribution of Linux running on your Vertica cluster.

Note

Installing the Hadoop packages necessary to run `distcp` does not turn your Vertica database into a Hadoop cluster. This process installs just enough of the Hadoop support files on your cluster to run the `distcp` command. There is no additional overhead placed on the Vertica cluster, aside from a small amount of additional disk space consumed by the Hadoop support files.

Configuration overview

The steps for configuring your Vertica cluster to restore backups for HDFS storage location are:

- If necessary, install and configure a Java runtime on the hosts in the Vertica cluster.
- Find the location of your Hadoop distribution's package repository.
- Add the Hadoop distribution's package repository to the Linux package manager on all hosts in your cluster.
- Install the necessary Hadoop packages on your Vertica hosts.
- Set two configuration parameters in your Vertica database related to Java and Hadoop.
- Confirm that the Hadoop `distcp` command runs on your Vertica hosts.

The following sections describe these steps in greater detail.

Installing a Java runtime

Your Vertica cluster must have a Java Virtual Machine (JVM) installed to run the Hadoop `distcp` command. It already has a JVM installed if you have configured it to:

- Execute user-defined extensions developed in Java. See [Developing user-defined extensions \(UDxs\)](#) for more information.
- Access Hadoop data using the HCatalog Connector. See [Using the HCatalog Connector](#) for more information.

If your Vertica database has a JVM installed, verify that your Hadoop distribution supports it. See your Hadoop distribution's documentation to determine which JVMs it supports.

If the JVM installed on your Vertica cluster is not supported by your Hadoop distribution you must uninstall it. Then you must install a JVM that is supported by both Vertica and your Hadoop distribution. See [Vertica SDKs](#) for a list of the JVMs compatible with Vertica.

If your Vertica cluster does not have a JVM (or its existing JVM is incompatible with your Hadoop distribution), follow the instructions in [Installing the Java runtime on your Vertica cluster](#).

Finding your Hadoop distribution's package repository

Many Hadoop distributions have their own installation system, such as Cloudera Manager or Ambari. However, they also support manual installation using native Linux packages such as RPM and `.deb` files. These package files are maintained in a repository. You can configure your Vertica hosts to access this repository to download and install Hadoop packages.

Consult your Hadoop distribution's documentation to find the location of its Linux package repository. This information is often located in the portion of the documentation covering manual installation techniques.

Each Hadoop distribution maintains separate repositories for each of the major Linux package management systems. Find the specific repository for the Linux distribution running your Vertica cluster. Be sure that the package repository that you select matches the version used by your Hadoop cluster.

Configuring Vertica nodes to access the Hadoop Distribution's package repository

Configure the nodes in your Vertica cluster so they can access your Hadoop distribution's package repository. Your Hadoop distribution's documentation should explain how to add the repositories to your Linux platform. If the documentation does not explain how to add the repository to your packaging system, refer to your Linux distribution's documentation.

The steps you need to take depend on the package management system your Linux platform uses. Usually, the process involves:

- Downloading a configuration file.
- Adding the configuration file to the package management system's configuration directory.
- For Debian-based Linux distributions, adding the Hadoop repository encryption key to the root account keyring.
- Updating the package management system's index to have it discover new packages.

You must add the Hadoop repository to all hosts in your Vertica cluster.

Installing the required Hadoop packages

After configuring the repository, you are ready to install the Hadoop packages. The packages you need to install are:

- `hadoop`
- `hadoop-hdfs`
- `hadoop-client`

The names of the packages are usually the same across all Hadoop and Linux distributions. These packages often have additional dependencies. Always accept any additional packages that the Linux package manager asks to install.

To install these packages, use the package manager command for your Linux distribution. The package manager command you need to use depends on your Linux distribution:

- On Red Hat and CentOS, the package manager command is `yum`.
- On Debian and Ubuntu, the package manager command is `apt-get`.
- On SUSE the package manager command is `zypper`.

Consult your Linux distribution's documentation for instructions on installing packages.

Setting configuration parameters

You must set two [Hadoop configuration parameters](#) to enable Vertica to restore HDFS data:

- `JavaBinaryForUDx` is the path to the Java executable. You may have already set this value to use Java UDxs or the HCatalog Connector. You can find the path for the default Java executable from the Bash command shell using the command:

```
$ which java
```

- HadoopHome is the directory that contains `bin/hadoop` (the bin directory containing the Hadoop executable file). The default value for this parameter is `/usr`. The default value is correct if your Hadoop executable is located at `/usr/bin/hadoop`.

The following example shows how to set and then review the values of these parameters:

```
=> ALTER DATABASE DEFAULT SET PARAMETER JavaBinaryForUDx = '/usr/bin/java';
=> SELECT current_value FROM configuration_parameters WHERE parameter_name = 'JavaBinaryForUDx';
current_value
-----
/usr/bin/java
(1 row)
=> ALTER DATABASE DEFAULT SET HadoopHome = '/usr';
=> SELECT current_value FROM configuration_parameters WHERE parameter_name = 'HadoopHome';
current_value
-----
/usr
(1 row)
```

You can also set the following parameters:

- HadoopFSReadRetryTimeout and HadoopFSWriteRetryTimeout specify how long to wait before failing. The default value for each is 180 seconds. If you are confident that your file system will fail more quickly, you can improve performance by lowering these values.
- HadoopFSReplication specifies the number of replicas HDFS makes. By default, the Hadoop client chooses this; Vertica uses the same value for all nodes.

Caution

Do not change this setting unless directed otherwise by Vertica support.

- HadoopFSBlockSizeBytes is the block size to write to HDFS; larger files are divided into blocks of this size. The default is 64MB.

Confirming that distcp runs

After the packages are installed on all hosts in your cluster, your database should be able to run the Hadoop `distcp` command. To test it:

1. Log into any host in your cluster as the [database superuser](#).
2. At the Bash shell, enter the command:

```
$ hadoop distcp
```

3. The command should print a message similar to the following:

```
usage: distcp OPTIONS [source_path...] <target_path>
      OPTIONS
-async          Should distcp execution be blocking
-atomic         Commit all changes or none
-bandwidth <arg> Specify bandwidth per map in MB
-delete        Delete from target, files missing in source
-f <arg>       List of files that need to be copied
-filelimit <arg> (Deprecated!) Limit number of files copied to <= n
-i            Ignore failures during copy
-log <arg>     Folder on DFS where distcp execution logs are
              saved
-m <arg>      Max number of concurrent maps to use for copy
-mapredSslConf <arg> Configuration for ssl config file, to use with
              https://
-overwrite     Choose to overwrite target files unconditionally,
              even if they exist.
-p <arg>      preserve status (rbugpc)(replication, block-size,
              user, group, permission, checksum-type)
-sizelimit <arg> (Deprecated!) Limit number of files copied to <= n
              bytes
-skipcrccheck  Whether to skip CRC checks between source and
              target paths.
-strategy <arg> Copy strategy to use. Default is dividing work
              based on file sizes
-tmp <arg>    Intermediate work path to be used for atomic
              commit
-update       Update target, copying only missing files or
              directories
```

4. Repeat these steps on the other hosts in your database to verify that all of the hosts can run `distcp` .

Troubleshooting

If you cannot run the `distcp` command, try the following steps:

- If Bash cannot find the `hadoop` command, you may need to manually add Hadoop's `bin` directory to the system search path. An alternative is to create a symbolic link in an existing directory in the search path (such as `/usr/bin`) to the `hadoop` binary.
- Ensure the version of Java installed on your Vertica cluster is compatible with your Hadoop distribution.
- Review the Linux package installation tool's logs for errors. In some cases, packages may not be fully installed, or may not have been downloaded due to network issues.
- Ensure that the database administrator account has permission to execute the `hadoop` command. You might need to add the account to a specific group in order to allow it to run the necessary commands.

Setting up backup locations

Important

Inadequate security on backups can compromise overall database security. Be sure to secure backup locations and strictly limit access to backups only to users who already have permissions to access all database data.

Full and object-level backups reside on *backup hosts* , the computer systems on which backups and archives are stored. On the backup hosts, Vertica saves backups in a specific *backup location* (directory).

You must set up your backup hosts before you can create backups.

The storage format type at your backup locations must support `fcntl lockf` (POSIX) file locking.

In this section

- [Configuring backup hosts and connections](#)
- [Configuring hard-link local backup hosts](#)
- [Configuring cloud storage backups](#)
- [Additional considerations for cloud storage](#)
- [Configuring backups to and from HDFS](#)

Configuring backup hosts and connections

You use **vbr** to back up your database to one or more hosts (known as *backup hosts*) that can be outside of your database cluster.

You can use one or more backup hosts or a single cloud storage bucket to back up your database. Use the **vbr** configuration file to specify which backup host each node in your cluster should use.

Before you back up to hosts outside of the local cluster, configure the target backup locations to work with **vbr** . The backup hosts you use must:

- [Have sufficient backup disk space](#) .
- Be accessible from your database cluster through SSH.
- Have passwordless SSH access for the Database Administrator account.
- Have either the Vertica rpm or Python 3.7 and rsync 3.0.5 or later installed.
- If you are using a stateful firewall, configure your `tcp_keepalive_time` and `tcp_keepalive_intvl` `sysctl` settings to use values less than your firewall timeout value.

Configuring TCP forwarding on database hosts

vbr depends on TCP forwarding to forward connections from database hosts to backup hosts. For copycluster and replication tasks, you must enable TCP forwarding on both sets of hosts. SSH connections to backup hosts do not require SSH forwarding.

If it is not already set by default, set `AllowTcpForwarding = Yes` in `/etc/ssh/sshd_config` and then send a SIGHUP signal to sshd on each host. See the Linux sshd documentation for more information.

If TCP forwarding is not enabled, tasks requiring it fail with the following message: "Errors connecting to remote hosts: Check SSH settings, and that the same Vertica version is installed on all nodes."

On a single-node cluster, **vbr** uses a random high-number port to create a local ssh tunnel. This fails if `PermitOpen` is set to restrict the port. Comment out the `PermitOpen` line in `sshd_config`.

Creating configuration files for backup hosts

Create separate configuration files for full or object-level backups, using distinct names for each configuration file. Also, use the same node, backup host, and directory location pairs. Specify different backup directory locations for each database.

Note

For optimal network performance when creating a backup, Vertica recommends that you give each node in the cluster its own dedicated backup host.

Preparing backup host directories

Before **vbr** can back up a database, you must prepare the target backup directory. Run **vbr** with a task type of `init` to create the necessary manifests for the backup process. You need to perform the init process only once. After that, Vertica maintains the manifests automatically.

Estimating backup host disk requirements

Wherever you plan to save data backups, consider the disk requirements for historical backups at your site. Also, if you use more than one archive, multiple archives potentially require more disk space. Vertica recommends that each backup host have space for at least twice the database node footprint size. Follow this recommendation regardless of the specifics of your site's backup schedule and retention requirements.

To estimate the database size, use the `used_bytes` column of the `storage_containers` system table as in the following example:

```
=> SELECT SUM(used_bytes) FROM storage_containers WHERE node_name='v_mydb_node0001';
total_size
-----
302135743
(1 row)
```

Making backup hosts accessible

You must verify that any firewalls between the source database nodes and the target backup hosts allow connections for SSH and rsync on port 50000.

The backup hosts must be running identical versions of rsync and Python as those supplied in the Vertica installation package.

Setting up passwordless SSH access

For **vbr** to access a backup host, the [database superuser](#) must meet two requirements:

- Have an account on each backup host, with write permissions to the backup directory.
- Have passwordless SSH access from each database cluster host to the corresponding backup host.

How you fulfill these requirements depends on your platform and infrastructure.

SSH access among the backup hosts and access from the backup host to the database node is not necessary.

If your site does not use a centralized login system (such as LDAP), you can usually add a user with the `useradd` command or through a GUI administration tool. See the documentation for your Linux distribution for details.

If your platform supports it, you can enable passwordless SSH logins using the `ssh-copy-id` command to copy a database administrator's SSH identity file to the backup location from one of your database nodes. For example, to copy the SSH identity file from a node to a backup host named `backup01`

:

```
$ ssh-copy-id -i dbadmin@backup01|
Password:
```

Try logging into the machine with "`ssh dbadmin@backup01`". Then, check the contents of the `~/.ssh/authorized_keysfile` to verify that you have not added extra keys that you did not intend to include.

```
$ ssh backup01
Last login: Mon May 23 11:44:23 2011 from host01
```

Repeat the steps to copy a database administrator's SSH identity to all backup hosts you use to back up your database.

After copying a database administrator's SSH identity, you should be able to log in to the backup host from any of the nodes in the cluster without being prompted for a password.

Increasing the SSH maximum connection settings for a backup host

If your configuration requires backing up multiple nodes to one backup host (n:1), increase the number of concurrent SSH connections to the SSH daemon (`sshd`). By default, the number of concurrent SSH connections on each host is `10` , as set in the `sshd_config` file with the `MaxStartups` keyword. The `MaxStartups` value for each backup host should be greater than the total number of hosts being backed up to this backup host. For more information on configuring `MaxStartups` , [refer to the man page for that parameter](#) .

See also

- [vbr configuration file reference](#)
- [Enable secure shell \(SSH\) logins](#)

Configuring hard-link local backup hosts

When specifying the `backupHost` parameter for your hard-link local configuration files, use the database host names (or IP addresses) as known to admintools. Do not use the node names. Host names (or IP addresses) are what you used when setting up the cluster. Do not use `localhost` for the `backupHost` parameter.

Listing host names

To query node names and host names:

```
=> SELECT node_name, host_name FROM node_resources;
 node_name | host_name
-----+-----
v_vmart_node0001 | 192.168.223.11
v_vmart_node0002 | 192.168.223.22
v_vmart_node0003 | 192.168.223.33
(3 rows)
```

Because you are creating a local backup, use square brackets `[]` to map the host to the local host. For more information, refer to [\[mapping\]](#) .

```
[Mapping]
v_vmart_node0001 = []:/home/dbadmin/data/backups
v_vmart_node0002 = []:/home/dbadmin/data/backups
v_vmart_node0003 = []:/home/dbadmin/data/backups
```

Configuring cloud storage backups

Backing up an Enterprise Mode or Eon Mode database to a [supported cloud storage](#) location requires that you add parameters to the backup

configuration file. You can create these backups from the local cluster or from your cloud provider's virtual servers. [Additional cloud storage configuration](#) is required to configure authentication and encryption.

Configuration file requirements

To back up any Eon Mode or Enterprise Mode cluster to a cloud storage destination, the backup configuration file must include a [\[CloudStorage\]](#) section. Vertica provides a sample [cloud storage configuration file](#) that you can copy and edit.

Environment variable requirements

Environment variables securely pass credentials for backup locations. Eon and Enterprise Mode databases require environment variables in the following backup scenarios:

- Vertica on Google Cloud Platform (GCP) to Google Cloud Storage (GCS).
For backups to GCS, you must have a hash-based message authentication code (HMAC) key that contains an access ID and a secret. See [Eon Mode on GCP prerequisites](#) for instructions on how to create your HMAC key.
- On-premises databases to any of the following storage locations:
 - Amazon Web Services (AWS)
 - Any S3-compatible storage
 - Azure Blob Storage (Enterprise Mode only)On-premises database backups require you to pass your credentials with environment variables. You cannot use other methods of credentialing with cross-endpoint backups.
- Any Azure user environment that does not manage resources with Azure managed identities.

The `vbr` log captures when you sent an environment variable. For security purposes, the value that the environment variable represents is not logged. For details about checking `vbr` logs, see [Troubleshooting backup and restore](#).

Enterprise Mode and Eon Mode

All Enterprise Mode and Eon Mode databases require the following environment variables:

Environment Variable	Description
<code>VBR_BACKUP_STORAGE_ACCESS_KEY_ID</code>	Credentials for the backup location.
<code>VBR_BACKUP_STORAGE_SECRET_ACCESS_KEY</code>	Credentials for the backup location.
<code>VBR_BACKUP_STORAGE_ENDPOINT_URL</code>	The endpoint for the on-premises S3 backup location, includes the scheme HTTP or HTTPS. Important Do not set this variable for backup locations on AWS or GCS.

Eon Mode only

Eon Mode databases require the following environment variables:

Environment Variable	Description
<code>VBR_COMMUNAL_STORAGE_ACCESS_KEY_ID</code>	Credentials for the communal storage location.
<code>VBR_COMMUNAL_STORAGE_SECRET_ACCESS_KEY</code>	Credentials for the communal storage location.
<code>VBR_COMMUNAL_STORAGE_ENDPOINT_URL</code>	The endpoint for the communal storage, includes the scheme HTTP or HTTPS. Important Do not set this variable for backup locations on GCS.

Azure Blob Storage only

If the user environment does not manage resources with Azure-managed identities, you must provide credentials with environment variables. If you set environment variables in an environment that uses Azure-managed identities, credentials set with environment variables take precedence over Azure-managed identity credentials.

You can back up and restore between two separate Azure accounts. Cross-account operations require a credential configuration JSON object and an endpoint configuration JSON object for each account. Each environment variable accepts a collection of one or more comma-separated JSON objects.

Cross-account and cross-region backup and restore operations might result in decreased performance. For details about performance and cost, see the [Azure documentation](#).

The Azure Blob Storage environment variables are described in the following table:

Environment Variable	Description
<code>VbrCredentialConfig</code>	Credentials for the backup location. Each JSON object requires values for the following keys: <ul style="list-style-type: none"><code>accountName</code> : Name of the storage account.<code>blobEndpoint</code> : Host address and optional port for the endpoint to use as the backup location.<code>accountKey</code> : Access key for the account.<code>sharedAccessSignature</code> : A token that provides access to the backup endpoint.
<code>VbrEndpointConfig</code>	The endpoint for the backup location. To backup and restore between two separate Azure accounts, provide each set of endpoint information as a JSON object. Each JSON object requires values for the following keys: <ul style="list-style-type: none"><code>accountName</code> : Name of the storage account.<code>blobEndpoint</code> : Host address and optional port for the endpoint to use as the backup location.<code>protocol</code> : HTTPS (default) or HTTP.<code>isMultiAccountEndpoint</code> : Boolean (by default false), indicates whether <code>blobEndpoint</code> supports multiple accounts

The following commands export the Azure Blob Storage environment variables to the current shell session:

```
$ export VbrCredentialConfig=[{"accountName": "account1", "blobEndpoint": "host[:port]", "accountKey": "account-key1", "sharedAccessSignature": "sas-token1"}]
$ export VbrEndpointConfig=[{"accountName": "account1", "blobEndpoint": "host[:port]", "protocol": "http"}]
```

Additional considerations for cloud storage

If you are backing up to a [supported cloud storage](#) location, you need to do some additional one-time configuration. You must also take additional steps if the cluster you are backing up is running on instances in the cloud. For Amazon Web Services (AWS), you might choose to encrypt your backups, which requires additional steps.

By default, bucket access is restricted to the communal storage bucket. For one-time operations with other buckets like backing up and restoring the database, use the appropriate credentials. See [Google Cloud Storage parameters](#) and [S3 parameters](#) for additional information.

Configuring cloud storage for backups

As with any storage location, you must initialize a cloud storage location with the `vbr` task `init`.

Because cloud storage does not support file locking, Vertica uses either your local file system or the cloud storage file system to handle file locks during a backup. You identify this location by setting the `cloud_storage_backup_file_system_path` parameter in your `vbr` configuration file. During a backup, Vertica creates a locked identity file on your local or cloud instance, and a duplicate file in your cloud storage backup location. If the files match, Vertica proceeds with the backup, releasing the lock when the backup is complete. As long as the files remain identical, you can use the cloud storage location for backup and restore tasks.

Reinitializing cloud backup storage

If the files in your locking location become out of sync with the files in your backup location, backup and restore tasks fail with an error message. You can resolve locking inconsistencies by rerunning the `init` task qualified by `--cloud-force-init`:

```
$/opt/vertica/bin/vbr --task init --cloud-force-init -c filename.ini
```

Note

If a backup fails, confirm that your Vertica cluster has permission to access your cloud storage location.

Configuring authentication for Google Cloud Storage

If you are backing up to Google Cloud Storage (GCS) from a Google Cloud Platform-based cluster, you must provide authentication to the GCS communal storage location. Set the environment variables as detailed in [Configuring cloud storage backups](#) to authenticate to GCS storage.

See [Eon Mode on GCP prerequisites](#) for additional authentication information, including how to create your hash-based message authentication code (HMAC) key.

Configuring EC2 authentication for Amazon S3

If you are backing up to S3 from an EC2-based cluster, you must provide authentication to your S3 host. Regardless of the authentication type you choose, your credentials do not leave your EC2 cluster. Vertica supports the following authentication types:

- AWS credential file
- Environment variables
- IAM role

AWS credential file - You can manually create a configuration file on your EC2 initiator host at `~/.aws/credentials`.

```
[default]
aws_access_key_id = YOUR_ACCESS_KEY
aws_secret_access_key = YOUR_SECRET_KEY
```

For more information on credential files, refer to [Amazon Web Services documentation](#).

Environment variables - Amazon Web Services provides the following environment variables:

- AWS_ACCESS_KEY_ID
- AWS_SECRET_ACCESS_KEY

Use these variables on your initiator to provide authentication to your S3 host. When your session ends, AWS deletes these variables. For more information, refer to the [AWS documentation](#).

IAM role - Create an AWS IAM role and grant that role permission to access your EC2 cluster and S3 resources. This method is recommended for managing long-term access. For more information, refer to [Amazon Web Services documentation](#).

Encrypting backups on Amazon S3

Backups made to Amazon S3 can be encrypted using native server-side S3 encryption capability. For more information on Amazon S3 encryption, refer to [Amazon documentation](#).

Note

Vertica supports server-side encryption only. Client-side encryption is not supported.

Vertica supports the following forms of S3 encryption:

- Server-Side Encryption with Amazon S3-Managed Keys (SSE-S3)
 - Encrypts backups with AES-256
 - Amazon manages encryption keys
- Server-Side Encryption with AWS KMS-Managed Keys (SSE-KMS)
 - Encrypts backups with AES-256
 - Requires an encryption key from Amazon Key Management Service
 - Your S3 bucket must be from the same region as your encryption key
 - Allows auditing of user activity

When you enable encryption of your backups, Vertica encrypts backups as it creates them. If you enable encryption after creating an initial backup, only increments added after you enabled encryption are encrypted. To ensure that your backup is entirely encrypted, create new backups after enabling encryption.

To enable encryption, add the following settings to your configuration file:

- `cloud_storage_encrypt_transport`: Encrypts your backups during transmission. You must enable this parameter if you are using SSE-KMS encryption.
- `cloud_storage_encrypt_at_rest`: Enables encryption of your backups. If you enable encryption and do not provide a KMS key, Vertica uses SSE-S3 encryption.
- `cloud_storage_sse_kms_key_id`: If you are using KMS encryption, use this parameter to provide your key ID.

See [\[CloudStorage\]](#) for more information on these settings.

The following example shows a typical configuration for KMS encryption of backups.

```
[CloudStorage]
cloud_storage_encrypt_transport = True
cloud_storage_encrypt_at_rest = sse
cloud_storage_sse_kms_key_id = 6785f412-1234-4321-8888-6a774ba2aaaa
```

Configuring backups to and from HDFS

Eon Mode only

To back up an Eon Mode database that uses HDFS on-premises storage, the communal storage and backup location must use the same HDFS credentials and domain. All vbr operations are supported, except copycluster.

Vertica supports Kerberos authentication, High Availability Name Node, and TLS (wire encryption) for vbr operations.

Creating a cloud storage configuration file

To back up Eon Mode on-premises with communal storage on HDFS, you must provide a [backup configuration file](#). In the [\[CloudStorage\]](#) section, provide the `cloud_storage_backup_path` and `cloud_storage_backup_file_system_path` values.

If you use [Kerberos authentication](#) or [High Availability NameNode](#) with your Hadoop cluster, the vbr utility requires access to the same values set in the bootstrapping file that you created during the [database install](#). Include these values in the [\[misc\]](#) section of the backup file.

The following table maps the vbr configuration option to its associated bootstrap file parameter:

vbr Configuration Option	Bootstrap File Parameter
kerberos_service_name	KerberosServiceName
kerberos_realm	KerberosRealm
kerberos_keytab_file	KerberosKeytabFile
hadoop_conf_dir	HadoopConfDir

For example, if `KerberosServiceName` is set to *principal-name* in the bootstrap file, set `kerberos_service_name` to *principal-name* in the [\[Misc\]](#) section of your configuration file.

Encryption between communal storage and backup locations

Vertica supports vbr operations using wire encryption between your communal storage and backup locations. Use the [cloud_storage_encrypt_transport](#) parameter in the [\[CloudStorage\]](#) section of your [backup configuration file](#) to configure encryption.

To enable encryption:

- Set `cloud_storage_encrypt_transport` to `true`.
- Use the `swbhdfs://` protocol for `cloud_storage_backup_path`.

If you do not use encryption:

- Set `cloud_storage_encrypt_transport` to `false`.
- Use the `wbhdfs://` protocol for `cloud_storage_backup_path`.

Vertica does not support at-rest encryption for Hadoop storage.

Creating backups

Important

Inadequate security on backups can compromise overall database security. Be sure to secure backup locations and strictly limit access to backups only to users who already have permissions to access all database data.

You should perform full backups of your database regularly. You should also perform a full backup under the following circumstances:

Before...

- Upgrading Vertica to another release.
- Dropping a partition.
- Adding, removing, or replacing nodes in the database cluster.

After...

- Loading a large volume of data.
- Adding, removing, or replacing nodes in the database cluster.
- Recovering a cluster from a crash.

If...

- The epoch of the latest backup predates the current ancient history mark.

Ideally, schedule ongoing backups to back up your data. You can run the Vertica `vbr` from a `cron` job or other task scheduler.

You can also back up selected objects. Use object backups to supplement full backups, not to replace them. Backup types are described in [Types of backups](#).

Running `vbr` does not affect active database applications. `vbr` supports creating backups while concurrently running applications that execute DML statements, including COPY, INSERT, UPDATE, DELETE, and SELECT.

Backup locations and contents

Full and object-level backups reside on *backup hosts*, the computer systems on which backups and archives are stored.

Vertica saves backups in a specific *backup location*, the directory on a backup host. This location can contain multiple backups, both full and object-level, including associated archives. The backups are also compatible, allowing you to restore any objects from a full database backup. Backup locations for Eon Mode databases must be on S3.

Note

Vertica does not recommend concurrent backups. If you must run multiple backups concurrently, use separate backup and temp directories for each. Having separate backup directories detracts from the advantage of sharing data among historical backups.

Before beginning a backup, you must prepare your backup locations using the [vbr init task](#), as in the following example:

```
$ vbr -t init -c full_backup.ini
```

For more information about backup locations, see [Setting up backup locations](#).

Backups contain all committed data for the backed-up objects as of the start time of the backup. Backups do not contain uncommitted data or data committed during the backup. Backups do not delay mergeout or load activity.

Backing up HDFS storage locations

If your Vertica cluster uses HDFS storage locations, you must do some additional configuration before you can perform backups. See [Requirements for backing up and restoring HDFS storage locations](#).

HDFS storage locations support only full backup and restore. You cannot perform object backup or restore on a cluster that uses HDFS storage locations.

Impact of backups on Vertica nodes

While a backup is taking place, the backup process can consume additional storage. The amount of space consumed depends on the size of your catalog and any objects that you drop during the backup. The backup process releases this storage when the backup is complete.

Best practices for creating backups

When creating backup configuration files:

- Create separate configuration files to create full and object-level backups.
- Use a unique snapshot name in each configuration file.
- Use the same backup host directory location for both kinds of backups:
 - Because the backups share disk space, they are compatible when performing a restore.
 - Each cluster node must also use the same directory location on its designated backup host.
- For best network performance, use one backup host per cluster node.

- Use one directory on each backup node to store successive backups.
- For future reference, append the major Vertica version number to the configuration file name (`mybackup 9x`).

The selected objects of a backup can include one or more schemas or tables, or a combination of both. For example, you can include schema `S1` and tables `T1` and `T2` in an object-level backup. Multiple backups can be combined into a single backup. A schema-level backup can be integrated with a database backup (and a table backup integrated with a schema-level backup, and so on).

In this section

- [Types of backups](#)
- [Creating full backups](#)
- [Creating object-level backups](#)
- [Creating hard-link local backups](#)
- [Incremental or repeated backups](#)

Types of backups

`vbr` supports the following kinds of backups:

- [Full backups](#)
- [Object-level backups](#)
- [Hard-link local backups](#)

The `vbr` configuration file includes the `snapshotName` parameter. Use different snapshot names for different types of backups, including different combinations of objects in object-level backups. Backups with the same snapshot name form a time sequence limited by `restorePointLimit` . Avoid giving all backups the same snapshot name; otherwise, they eventually interfere with each other.

Full backups

A full backup is a complete copy of the database catalog, its schemas, tables, and other objects. This type of backup provides a consistent image of the database at the time the backup occurred. You can use a full backup for disaster recovery to restore a damaged or incomplete database. You can also [restore individual objects from a full backup](#) .

When a full backup already exists, `vbr` performs incremental backups, whose scope is confined to data that is new or changed since the last full backup occurred. You can specify the number of historical backups to keep.

Archives contain a collection of same-name backups. Each archive can have a different retention policy. For example, `TBak` might be the name of an object-level backup of table `T` . If you create a daily backup each week, the seven backups of a given week become part of the `TBak` archive. Keeping a backup archive lets you revert back to any one of the saved backups.

Object-level backups

An object-level backup consists of one or more schemas or tables or a group of such objects. The conglomerate parts of the object-level backup do not contain the entire database. When an object-level backup exists, you can restore all of its contents or [individual objects](#) .

Note
Object-level backups are not supported for Enterprise Mode databases that use a Hadoop File System (HDFS) storage location.

Object-level backups contain the following object types:

Object Type	Description
Selected objects	Objects you choose to be part of an object-level backup. For example, if you specify tables <code>T1</code> and <code>T2</code> to include in an object-level backup, they are the selected objects.
Dependent objects	Objects that must be included as part of an object-level backup, due to dependencies. Suppose you want to create an object-level backup that includes a table with a foreign key. To do so, table constraints require that you include the primary key table, and <code>vbr</code> enforces this requirement. Projections anchored on a table in the selected objects are also dependent objects.
Principal objects	The objects on which both selected and dependent objects depend are called <i>principal objects</i> . For example, each table and projection has an owner, and each is a <i>principal object</i> .

Hard-link local backups

Valid only for Enterprise Mode, hard-link local backups are saved directly on the database nodes, and can be performed on the entire database or specific objects. Typically you use this kind of backup temporarily before performing a disruptive operation. Do not rely on this kind of backup for long-term use; it cannot protect you from node failures because data and backups are on the same nodes.

A checkpoint backup is a hard-link local backup that comprises a complete copy of the database catalog, and a set of hard file links to corresponding data files. You must save a hard-link local backup on the same file system that is used by the catalog and database files.

Creating full backups

Before you create a database backup, verify the following:

- You have prepared your backup directory with the [vbr init task](#) :

```
$ vbr -t init -c full_backup.ini
```

- Your database is running. It is unnecessary for all nodes to be up in a K-safe database. However, any nodes that are DOWN are not backed up.
- All of the backup hosts are up and available.
- The backup host (either on the database cluster or elsewhere) has sufficient disk space to store the backups.
- The user account of the user who starts **vbr** has write access to the target directories on the host backup location. This user can be **dbadmin** or another assigned role. However, you cannot run **vbr** as root.
- Each backup has a unique file name.
- If you want to keep earlier backups, **restorePointLimit** is set to a number greater than 1 in the configuration file.
- If you are backing up an Eon Mode database, you have met the [Eon Mode database requirements](#).

Run **vbr** from a terminal. Use the database administrator account from an initiator node in your database cluster. The command requires only the **--task backup** and **--config-file** arguments (or their short forms, **-t** and **-c**).

If your configuration file does not contain the database administrator password, **vbr** prompts you to enter the password. It does not display what you type.

vbr requires no further interaction after you invoke it.

The following example shows a full backup:

```
$ vbr -t backup -c full_backup.ini
Starting backup of database VTDB.
Participating nodes: v_vmart_node0001, v_vmart_node0002, v_vmart_node0003, v_vmart_node0004.
Snapshotting database.
Snapshot complete.
Approximate bytes to copy: 2315056043 of 2356089422 total.
[=====] 100%
Copying backup metadata.
Finalizing backup.
Backup complete!
```

By default, no output is displayed, other than the progress bar. To include additional progress information, use the **--debug** option, with a value of 1, 2, or 3.

Creating object-level backups

Use object-level backups to back up individual schemas or tables. Object-level backups are especially useful for multi-tenanted database sites. For example, an international airport could use a multi-tenanted database to represent different airlines in its schemas. Then, tables could maintain various types of information for the airline, including ARRIVALS, DEPARTURES, and PASSENGER information. With such an organization, creating object-level backups of the specific schemas would let you restore by airline tenant, or any other important data segment.

To create one or more object-level backups, create a configuration file specifying the backup location, the object-level backup name, and a list of objects to include. You can use the **includeObjects** and **excludeObjects** parameters together with wildcards to specify the objects of interest. For more information about specifying the objects to include, see [Including and excluding objects](#).

Important

If your Eon Mode database has multiple [namespaces](#), you must specify the namespace to which the objects belong. For **vbr** tasks, namespace names are prefixed with a period. For example, **.n.s.t** refers to table **t** in schema **s** in namespace **n**. See [Eon Mode database requirements](#) for more information.

For more information about configuration files for full or object-level backups, see [Sample vbr configuration files](#) and [vbr configuration file reference](#).

While not required, Vertica recommends that you first create a full backup before creating any object-level backups.

Note

Apache Kafka uses internal configuration settings to maintain the integrity of your data. When backing up your Kafka data, Vertica recommends that you perform a [full database backup](#) rather than an object-level backup.

Performing the backup

Before you can create a backup, you must prepare your backup directory with the [vbr -init task](#). You must also create a configuration file specifying which objects to back up.

Run `vbr` from a terminal using the database administrator account from a node in your database cluster. You cannot run `vbr` as root.

You can create an object-level backup as in the following example.

```
$ vbr --task backup --config-file objectbak.ini
Preparing...
Found Database port: 5433
Copying...
[=====] 100%
All child processes terminated successfully.
Committing changes on all backup sites...
backup done!
```

Naming conventions

Give each object-level backup configuration file a distinct and descriptive name. For instance, at an airport terminal, schema-based backup configuration files use a naming convention with an airline prefix, followed by further description, such as:

`AIR1_daily_arrivals_backup`

`AIR2_hourly_arrivals_backup`

`AIR2_hourly_departures_backup`

`AIR3_daily_departures_backup`

When database and object-level backups exist, you can recover the backup of your choice.

Caution

Do not change object names in an object-level configuration file if a backup already exists. Doing so overwrites the original configuration file, and you cannot restore it from the earlier backup. Instead, create a different configuration file.

Understanding object-level backup contents

Object-level backups comprise only the elements necessary to restore the schema or table, including the selected, dependent, and principal objects. An object-level backup includes the following contents:

- Storage: Data files belonging to any specified objects
- Metadata: Including the cluster topology, timestamp, epoch, AHM, and so on
- Catalog snippet: Persistent catalog objects serialized into the principal and dependent objects

Some of the elements that AIR2 comprises, for instance, are its parent schema, tables, named sequences, primary key and foreign key constraints, and so on. To create such a backup, `vbr` saves the objects directly associated with the table. It also saves any dependencies, such as foreign key (FK) tables, and creates an object map from which to restore the backup.

Note

Because the data in local temp tables persists only within a session, local temporary tables are excluded when you create an object-level backup. For global temporary tables, `vbr` stores the table's definition.

Making changes after an object-level backup

Be aware how changes made after an object-level backup affect subsequent backups. Suppose you create an object-level backup and later drop schemas and tables from the database. In this case, the objects you dropped are also dropped from subsequent backups. If you do not save an archive of the object backup, such objects could be lost permanently.

Changing a table name after creating a table backup does not persist after restoring the backup. Suppose that, after creating a backup, you drop a user who owns any selected or dependent objects in that backup. In this case, restoring the backup re-creates the object and assigns ownership to the user performing the restore. If the owner of a restored object still exists, that user retains ownership of the restored object.

To restore a dropped table from a backup:

1. Rename the newly created table from t1 to t2.
2. Restore the backup containing t1.
3. Restore t1. Tables t1 and t2 now coexist.

For information on how Vertica handles object overwrites, refer to the `objectRestoreMode` parameter in [\[misc\]](#).

K-safety can increase after an object backup. Restoration of a backup fails if *both* of the following conditions occur:

- An increase in K-safety occurs.
- Any table in the backup has insufficient projections.

Changing principal and dependent objects

If you create a backup and then drop a principal object, restoring the backup restores that principal object. If the owner of the restored object has also been dropped, Vertica assigns the restored object to the current dbadmin.

You can specify how Vertica handles object overwrites in the `vbr` configuration file. For more information, refer to the `objectRestoreMode` parameter in [\[misc\]](#).

[IDENTITY](#) sequences are dependent objects because they cannot exist without their tables. An object-level backup includes such objects, along with the tables on which they depend.

Named sequences are not dependent objects because they exist autonomously. A named sequence remains after you drop the table in which the sequence is used. In this case, the named sequence is a principal object. Thus, you must back up the named sequence with the table. Then you can regenerate it, if it does not already exist when you restore the table. If the sequence does exist, `vbr` uses it, unmodified. Sequence values could repeat, if you restore the full database and then restore a table backup to a newer epoch.

Considering constraint references

When database objects are related through constraints, you must back them up together. For example, a schema with tables whose constraints reference only tables in the same schema can be backed up. However, a schema containing a table with an FK/PK constraint on a table in another schema cannot. To back up the second table, you must include the other schema in the list of selected objects.

Configuration files for object-level backups

`vbr` automatically associates configurations with different backup names but uses the same backup location.

Always create a cluster-wide configuration file and one or more object-level configuration files pointing to the same backup location. Storage between backups is shared, preventing multiple copies of the same data. For object-level backups, using the same backup location causes `vbr` to encounter fewer OID conflict prevention techniques. Avoiding OID conflict prevention results in fewer problems when restoring the backup.

When using cluster and object configuration files with the same backup location, `vbr` includes additional provisions to ensure that the object-level backups can be used following a full cluster restore. One approach to restoring a full cluster is to use a full database backup to bootstrap the cluster. After the cluster is operational again, you can restore the most recent object-level backups for schemas and tables.

Attempting to restore a full database using an object-level configuration file fails, resulting in this error:

```
VMart=> /tmp/vbr --config-file=Table2.ini -t restore
Preparing...
Invalid metadata file. Cannot restore.
restore failed!
```

See [Restoring all objects from an object-level backup](#) for more information.

Backup epochs

Each backup includes the epoch to which its contents can be restored. When `vbr` restores data, Vertica updates to the current epoch.

vbr attempts to create an object-level backup five times before an error occurs and the backup fails.

Creating hard-link local backups

You can use the **hardLinkLocal** option to create a full or object-level backup with hard file links on a local database host.

Creating hard-link local backups can provide the following advantages over a remote host backup:

- **Speed** : A hard-link local backup is significantly faster than a remote host backup. When backing up, **vbr** does not copy files if the backup directory exists on the same file system as the database directory.
- **Reduced network activities** : The hard-link local backup minimizes network load because it does not require rsync to copy files to a remote backup host.
- **Less disk space** : The backup includes a copy of the catalog and hard file links. Therefore, the local backup uses significantly less disk space than a backup with copies of database data files. However, a hard-link local backup saves a full copy of the catalog each time you run **vbr** . Thus, the disk size increases with the catalog size over time.

Hard-link local backups can help you during experimental designs and development cycles. Database designers and developers can create hard-link local object backups of schemas and tables on a regular schedule during design and development phases. If any new developments are unsuccessful, developers can restore one or more objects from the backup.

Planning hard-link local backups

If you plan to use hard-link local backups as a standard site procedure, design your database and hardware configuration appropriately. Consider storing all of the data files on one file system per node. Such a configuration has the advantage of being set up automatically for hard-link local backups.

Specifying backup directory locations

The **backupDir** parameter of the configuration file specifies the location of the top-level backup directory. Hard-link local backups require that the backup directory be located on the same Linux file system as the database data. The Linux operating system cannot create hard file links to another file system.

Do not create the hard-link local backup directory in a database data storage location. For example, as a best practice, the database data directory should not be at the top level of the file system, as it is in the following example:

```
/home/dbadmin/data/VMart/v_vmart_node0001
```

Instead, Vertica recommends adding another subdirectory for data above the database level, such as in this example:

```
/home/dbadmin/data/dbdata/VMart/v_vmart_node0001
```

You can then create the hard-link local backups subdirectory as a peer of the data directory you just created, such as in this example:

```
/home/dbadmin/data/backups  
/home/dbadmin/data/dbdata
```

When you specify the hard-link backup location, be sure to avoid these common errors when adding the **hardLinkLocal=True** parameter to the configuration file:

If ...	Then...	Solution
You specify a backup directory on a <i>different</i> node	vbr issues an error message and aborts the backup.	Change the configuration file to include a backup directory on the same host and file system as the database files. Then, run vbr again.
You specify a backup location on the same node, but a backup destination directory on a <i>different</i> file system from the database and catalog files.	vbr issues a warning message and performs the backup by copying (not linking) the files from one file system to the other.	No action required, but copying consumes more disk space and takes longer than linking.

Creating the backup

Before creating a full hard-link local database backup of an Enterprise Mode database, verify the following:

- Your database is running. All nodes need not be up in a K-safe database for **vbr** to run. However, be aware that any nodes that are DOWN are not backed up.
- The user account that starts **vbr** (**dbadmin** or other) has write access to the target backup directories.

Hard-link backups are not supported in Eon Mode.

When you create a full or object-level hard link local backup, that backup contains the following:

Backup	Catalog	Database files
Full backup	Full copy	Hard file links to all database files
Object-level backup	Full copy	Hard file links for all objects listed in the configuration file, and any of their dependent objects

Run the **vbr** script from a terminal using the database administrator account from a node in your database cluster. You cannot run **vbr** as root.

Hard-link backups use the same **vbr** arguments as other backups. Configuring a backup as a hard-link backup is done entirely in the configuration file. The following example shows the syntax:

```
$ vbr --task backup --config fullbak.ini
```

Creating hard-link local backups for external media storage

You can use hard-link local backups as a staging mechanism to back up to tape or other forms of storage media. The following steps present a simplified approach to saving, and then restoring, hard-link local backups from tape storage:

1. Create a configuration file by copying an existing one or one of the samples described in [Sample vbr configuration files](#).
2. Edit the configuration file (**localbak.ini** in this example) to include the **hardLinkLocal=True** parameter in the **[Transmission]** section.
3. Run **vbr** with the configuration file:

```
$ vbr --task backup --config-file localbak.ini
```

4. Copy the hard-link local backup directory with a separate process (not **vbr**) to tape or other external media.
5. If the database becomes corrupted, transfer the backup files from tape to their original backup directory and restore as explained in [Restoring hard-link local backups](#).

Note

Vertica recommends that you preserve the directory containing the hard-link backup after copying it to other media. If you delete the directory and later copy the files back from external media, the copied files will no longer be links. Instead, they will use as much disk space as if you had done a full (not hard-link) backup.

Restoring hard-link local backups requires some additional (manual) steps. Do not use them as a substitute for regular full backups ([Creating full backups](#)).

Hard-link local backups and disaster recovery

Hard-link local backups are only as reliable as the disk on which they are stored. If the local disk becomes corrupt, so does the hard-link local backup. In this case, you are unable to restore the database from the hard-link local backup because it is also corrupt.

All sites should maintain full backups externally for disaster recovery because hard-link local backups do not actually copy any database files.

Incremental or repeated backups

As a best practice, Vertica recommends that you take frequent backups if database contents diverge in significant ways. Always take backups after any event that significantly modifies the database, such as performing a rebalance. Mixing many backups with significant differences can weaken data K-safety. For example, taking backups both before and after a rebalance is not a recommended practice in cases where the backups are all part of one archive.

Each time you back up your database with the same configuration file, **vbr** creates an additional backup and might remove the oldest backup. The backup operation copies new storage containers, which can include:

- Data that existed the last time you performed a database backup
- New and changed data since the last full backup

Use the **restorePointLimit** parameter in the configuration file to increase the number of stored backups. If a backup task would cause this limit to be

exceeded, [vbr](#) deletes the oldest backup after a successful backup.

When you run a backup task, [vbr](#) first creates the new backup in the specified location, which might temporarily exceed the limit. It then checks whether the number of backups exceeds the value of [restorePointLimit](#), and, if necessary, deletes the oldest backups until only [restorePointLimit](#) remain. If the requested backup fails or is interrupted, [vbr](#) does not delete any backups.

When you restore a database, you can choose to restore from any retained backup rather than the most recent, so raise the limit if you expect to need access to older backups.

Restoring backups

You can use the [vbr restore task](#) to restore your full database or selected objects from backups created by [vbr](#). Typically you use the same configuration file for both operations. The minimal restore command is:

```
$ vbr --task restore --config-file config-file
```

You must log in using the database administrator's account (not root).

For full restores, the database must be DOWN. For object restores, the database must be UP.

Usually you restore to the cluster that you backed up, but you can also restore to an alternate cluster if the original one is no longer available.

Restoring must be done on the same architecture as the backup from which you are restoring. You cannot back up an Enterprise Mode database and restore it in Eon Mode or vice versa.

You can perform restore tasks on Permanent node types. You cannot restore data on Ephemeral, Execute, or Standby nodes. To restore or replicate to these nodes, you must first change the [destination node type](#) to PERMANENT. For more information, refer to [Setting node type](#).

Restoring objects to a higher Vertica version

Vertica supports restoration to a database that is no more than one minor version higher than the current database version. For example, you can restore objects from a 12.0.x database to a 12.1.x database.

If restored objects require a UDX library that is not present in the later-version database, Vertica displays the following error:

```
ERROR 2858: Could not find function definition
```

You can resolve this issue by [installing compatible libraries](#) in the target database.

Restoring HDFS storage locations

If your Vertica cluster uses HDFS storage locations, you must do some additional configuration before you can restore. See [Requirements for backing up and restoring HDFS storage locations](#).

HDFS storage locations support only full backup and restore. You cannot perform object backup or restore on a cluster that uses HDFS storage locations.

In this section

- [Restoring a database from a full backup](#)
- [Restoring a database to an alternate cluster](#)
- [Restoring all objects from an object-level backup](#)
- [Restoring individual objects](#)
- [Restoring objects to an alternate cluster](#)
- [Restoring hard-link local backups](#)
- [Ownership of restored objects](#)

Restoring a database from a full backup

You can restore a full database backup to the database that was backed up, or to an alternate cluster with the same architecture. One reason to restore to an alternate cluster is to set up a test cluster to investigate a problem in your production cluster.

To restore a full database backup, you must verify that:

- Database is DOWN. You cannot restore a full backup when the database is running.
- All backup hosts are available.
- Backup directory exists and contains backups of the data to restore.
- Cluster to which you are restoring the backup has:
 - Same number of nodes as used to create the backup (Enterprise Mode), or at least as many nodes as the primary subclusters (Eon Mode)

- Same architecture as the one used to create the backup
- Identical node names
- Target database already exists on the cluster where you are restoring data.
 - Database can be completely empty, without any data or schema.
 - Database name must match the name in the backup
 - All node names in the database must match the names of the nodes in the configuration file.
- The user performing the restore is the database administrator.
- If you are restoring an Eon Mode database, you have met the [Eon Mode database requirements](#).

You can use only a full database backup to restore a complete database. If you have saved multiple backup archives, you can restore from either the last backup or a specific archive.

Restoring from a full database backup injects the OIDs from each backup into the restored catalog of the full database backup. The catalog also receives all archives. Additionally, the OID generator and current epoch are set to the current epoch.

You can also restore a full backup to a different database than the one you backed up. See [Restoring a database to an alternate cluster](#).

Important

When you restore an Eon Mode database to another database, the restore operation copies the source database's communal storage. The original communal storage is unaffected.

Restoring the most recent backup

Usually, when a node or cluster is DOWN, you want to return the cluster to its most-recent state. Doing so requires restoring a full database backup. You can restore any full database backup from the archive by identifying the name in the configuration file.

To restore from the most recent backup, use the [vbr restore task](#) with the configuration file. If your [password configuration file](#) does not contain the database superuser password, **vbr** prompts you to enter it.

The following example shows how you can use the **db.ini** configuration file for restoration:

```
> vbr --task restore --config-file db.ini
Copying...
1871652633 out of 1871652633, 100%
All child processes terminated successfully.
restore done!
```

Restoring an archive

If you saved multiple backups, you can specify an archive to restore. To list the archives that exist to choose one to restore, use the **vbr --listbackup** task, with a specific configuration file. See [Viewing backups](#).

To restore from an archive, add the **--archive** parameter to the command line. The value is the *date_timestamp* suffix of the directory name that identifies the archive to restore. For example:

```
$ vbr --task restore --config-file fullbak.ini --archive=20121111_205841
```

The **--archive** parameter identifies the archive created on 11-11-2012 (**_archive20121111**), at time **205841** (20:58:41). You need specify only the **_archive** suffix, because the configuration file identifies the backup name of the subdirectory, and the OID identifier indicates the backup is an archive.

Restore failures in Eon Mode

When a restore operation fails, **vbr** can leave extra files in the communal storage location. If you use communal storage in the cloud, those extra files cost you money. To remove them, restart the database and call [CLEAN_COMMUNAL_STORAGE](#) with an argument of true.

Restoring a database to an alternate cluster

Vertica supports restoring a full backup to an alternate cluster.

Requirements

The process is similar to the process for [Restoring a database from a full backup](#), with the following additional requirements.

The destination database must:

- Be DOWN.
- Share the same name as the source database.
- Have the same number of nodes as the source database.

- Have the same names as the source nodes.
- Use the same catalog directory location as the source database.
- Use the same port numbers as the source database.

Procedure

1. Copy the [vbr configuration file](#) that you used to create the backup to any node on the destination cluster.
2. If you are using a [stored password](#), copy the password configuration file to the same location as the vbr configuration file.
3. From the destination node, issue a vbr restore command, such as:

```
$ vbr -t restore -c full.ini
```

4. After the restore has completed, [start the restored database](#).

Restoring all objects from an object-level backup

To restore everything in an object-level backup to the database from which it was taken, use the [vbr restore task](#) with the configuration file you used to create the backup, as in the following example:

```
$ vbr --task restore --config-file MySchema.ini
Copying...
1871652633 out of 1871652633, 100%
All child processes terminated successfully.
restore done!
```

The database must be UP.

You can specify how Vertica reacts to duplicate objects by setting the `objectRestoreMode` parameter in the configuration file.

Object-level backup and restore are not supported for HDFS storage locations.

Restoring objects to a changed cluster

Unlike restoring from a full database backup, `vbr` supports restoring object-level backups after adding nodes to the cluster. Any nodes that were not in the cluster when you created the object-level backup do not participate in the restore. You can rebalance your cluster after the restore to distribute data among the new nodes.

You cannot restore an object-level backup after removing nodes, altering node names, or changing IP addresses. Trying to restore an object-level backup after such changes causes `vbr` to fail and display this message:

```
Preparing...
Topology changed after backup; cannot restore.
restore failed!
```

Projection epoch after restore

All object-level backup and restore events are treated as DDL events. If a table does not participate in an object-level backup, possibly because a node is down, restoring the backup affects the projection in the following ways:

- Its epoch is reset to 0.
- It must recover any data that it does not have by comparing epochs and other recovery procedures.

Catalog locks during restore

As with other databases, Vertica transactions follow strict locking protocols to maintain data integrity.

When restoring an object-level backup into a cluster that is UP, `vbr` begins by copying data and managing storage containers. If necessary, `vbr` splits the containers. This process does not require any database locks.

After completing data-copying tasks, `vbr` first requires a table object lock (O-lock) and then a global catalog lock (GCLX).

In some circumstances, other database operations, such as DML statements, are in progress when the process attempts to get an O-lock on the table. In such cases, `vbr` is blocked from progress until the DML statement completes and releases the lock. After securing an O-lock first, and then a GCLX lock, `vbr` blocks other operations that require a lock on the same table.

While `vbr` holds its locks, concurrent table modifications are blocked. Database system operations, such as the Tuple Mover (TM) transferring data from memory to disk, are canceled to permit the object-level restore to complete.

Catalog restore events

Each object-level backup includes a section of the database catalog, or a *snippet*. A snippet contains the selected objects, their dependent objects, and principal objects. A catalog snippet is similar in structure to the database catalog but consists of a subset representing the object information. Objects being restored can be read from the catalog snippet and used to update both global and local catalogs.

Each object from a restored backup is updated in the catalog. If the object no longer exists, **vbr** drops the object from the catalog. Any dependent objects that are not in the backup are also dropped from the catalog.

vbr uses existing dependency verification methods to check the catalog and adds a restore event to the catalog for each restored table. That event also includes the epoch at which the event occurred. If a node misses the restore table event, it recovers projections anchored on the given table.

Reverting object DDL changes

If you restore the database to an epoch that precedes changes to an object's DDL, the restore operation reverts the object to its earlier definition. For example, if you change a table column's data type from **CHAR(8)** to **CHAR(16)** in epoch 10, and then restore the database from epoch 5, the column reverts to **CHAR(8)** data type.

Restoring objects to a higher Vertica version

Vertica supports restoration to a database that is no more than one minor version higher than the current database version. For example, you can restore objects from a 12.0.x database to a 12.1.x database.

If restored objects require a UDX library that is not present in the later-version database, Vertica displays the following error:

```
ERROR 2858: Could not find function definition
```

You can resolve this issue by [installing compatible libraries](#) in the target database.

Catalog size limitations

Object-level restores can fail if your catalog size is greater than five percent of the total memory available in the node performing the restore. In this situation, Vertica recommends restoring individual objects from the backup. For more information, refer to [Restoring individual objects](#).

See also

- [Failure recovery](#)
- [Transactions](#)

Restoring individual objects

You can use **vbr** to restore individual tables and schemas from a full or object-level backup: qualify the **restore** task with **--restore-objects**, and specify the objects to restore as a comma-delimited list:

Important

If your Eon Mode database has multiple [namespaces](#), you must specify the namespace to which the objects belong. For **vbr** tasks, namespace names are prefixed with a period. For example, **.n.s.t** refers to table **t** in schema **s** in namespace **n**. See [Eon Mode database requirements](#) for more information.

```
$ vbr --task restore --config-file=filename --restore-objects='objectname[,...]' [--archive=archive-id] [--target-namespace=namespace-name]
```

The following requirements and restrictions apply:

- The database must be running, and nodes must be UP.
- Tables must include their schema names.
- Do not embed spaces before or after comma delimiters of the **--restore-objects** list; otherwise, **vbr** interprets the space as part of the object name.
- Object-level restore is not supported for HDFS storage locations. To restore an HDFS storage location you must do a full restore.

If the schema has a disk quota and restoring the table would exceed the quota, the operation fails.

By default, **--restore-objects** restores the specified objects from the most recent backup. You can restore from an earlier backup with the **--archive** parameter.

The **--target-namespace** parameter is only valid for Eon Mode databases with multiple namespaces. The parameter specifies the namespace in the target cluster to which objects are restored. For more information, see [Eon Mode database requirements](#).

The following example uses the **db.ini** configuration file, which includes the database administrator's password:

```
> vbr --task restore --config-file=db.ini --restore-objects=saleschema,public.sales_table,public.customer_info
Preparing...
Found Database port: 5433
Copying...
[=====] 100%
All child processes terminated successfully.
All extract object child processes terminated successfully.
Copying...
[=====] 100%
All child processes terminated successfully.
restore done!
```

Object dependencies

When you restore an object, Vertica does not always restore dependent objects. For example, if you restore a schema containing views, Vertica does not automatically restore the tables of those views. One exception applies: if database tables are linked through foreign keys, you must restore them together, unless [drop_foreign_constraints](#) is set in the `vbr` configuration file to true.

Note

You must also set `objectRestoreMode` to `coexist`, otherwise Vertica ignores `drop_foreign_constraints`.

Duplicate objects

You can specify how restore operations handle duplicate objects by configuring `objectRestoreMode`. By default, it is set to `createOrReplace`, so if a duplicate object exists, the restore operation overwrites it with the archived version.

Interactions with data loaders

When doing a restore with `objectRestoreMode` set to `coexist`, `vbr` creates new [data loaders](#) and their corresponding state tables, but does not change the table names in the loader COPY clauses. After the restore, you can use [ALTER DATA LOADER](#) to update the COPY statement in the restored data loader to use the new table name.

Eon Mode considerations

Restoring objects to an Eon Mode database can leave unneeded files in cloud storage. These files have no effect on database performance or data integrity. However, they can incur extra cloud storage expenses. To remove these files, restart the database and call [CLEAN_COMMUNAL_STORAGE](#) with an argument of true.

- [Restoring all objects from an object-level backup](#)
- [Ownership of restored objects](#)
- [Including and excluding objects](#)

Restoring objects to an alternate cluster

You can use the restore task to copy objects from one database to another. You might do this to "promote" tables from a development environment to a production environment, for example. All restrictions described in [Restoring individual objects](#) apply when restoring to an alternate cluster.

To restore to an alternate database, you must make changes to a copy of the configuration file that was used to create the backup. The changes are in the [Mapping] and [NodeMapping] sections. Essentially, you create a configuration file for the restore operation that looks to `vbr` like a backup of the target database, but it actually describes the backup from the source database. See [Restore object from backup to an alternate cluster](#) for an example configuration file.

The following example uses two databases, named source and target. The source database contains a table named sales. The following `source_snapshot.ini` configuration file is used to back up the source database:

```
[Misc]
snapshotName = source_snapshot
restorePointLimit = 2
objectRestoreMode = createOrReplace
```

```
[Database]
dbName = source
dbUser = dbadmin
dbPromptForPassword = True
```

```
[Transmission]
```

```
[Mapping]
v_source_node0001 = 192.168.50.168:/home/dbadmin/backups/
```

The target_snapshot.ini file starts as a copy of source_snapshot.ini. Because the [Mapping] section describes the database that vbr operates on, we must change the node names to point to the target nodes. We must also add the [NodeMapping] section and change the database name:

```
[Misc]
snapshotName = source_snapshot
restorePointLimit = 2
objectRestoreMode = createOrReplace
```

```
[Database]
dbName = target
dbUser = dbadmin
dbPromptForPassword = True
```

```
[Transmission]
```

```
[Mapping]
v_target_node0001 = 192.168.50.151:/home/dbadmin/backups/
[NodeMapping]
v_source_node0001 = v_target_node0001
```

As far as vbr is concerned, we are restoring objects from a backup of the target database. In reality, we are restoring from the source database.

The following command restores the sales table from the source backup into the target database:

```
$ vbr --task restore --config-file target_snapshot.ini --restore-objects sales
Starting object restore of database target.
Participating nodes: v_target_node0001.
Objects to restore: sales.
Enter vertica password:
Restoring from restore point: source_snapshot_20160204_191920
Loading snapshot catalog from backup.
Extracting objects from catalog.
Syncing data from backup to cluster nodes.
[=====] 100%
Finalizing restore.
Restore complete!
```

Restoring hard-link local backups

You restore from hard-link local backups the same way that you restore from full backups, using the restore task. If you used hard-link local backups to back up to external media, you need to take some additional steps.

Transferring backups to and from remote storage

When a full hard-link local backup exists, you can transfer the backup to other storage media, such as tape or a locally-mounted NFS directory. Transferring hard-link local backups to other storage media may copy the data files associated with the hard file links.

You can use a different directory when you return the backup files to the hard-link local backup host. However, you must also change the backupDir parameter value in the configuration file before restoring the backup.

Complete the following steps to restore hard-link local backups from external media:

1. If the original backup directory no longer exists on one or more local backup host nodes, re-create the directory.

The directory structure into which you restore hard-link backup files must be identical to what existed when the backup was created. For example, if you created hard-link local backups at the following backup directory, you can then re-create that directory structure:

```
/home/dbadmin/backups/localbak
```

2. Copy the backup files to their original backup directory, as specified for each node in the configuration file. For more information, refer to [\[Mapping\]](#).
3. Restore the backup, using one of three options:

1. To restore the latest version of the backup, move the backup files to the following directory:

```
/home/dbadmin/backups/localbak/node_name/snapshotname
```

2. To restore a different backup version, move the backup files to this directory:

```
/home/dbadmin/backups/localbak/node_name/snapshotname_archivedate_timestamp
```

4. When the backup files are returned to their original backup directory, use the original configuration file to invoke `vbr`. Verify that the configuration file specifies `hardLinkLocal = true`. Then restore the backup as follows:

```
$ vbr --task restore --config-file localbak.ini
```

Ownership of restored objects

For a full restore, objects have the owners that they had in the backed-up database.

When performing an object restore, Vertica inserts data into existing database objects. By default, the restore does not affect the ownership, storage policies, or permissions of the restored objects. However, if the restored object does not already exist, Vertica re-creates it. In this situation, the restored object is owned by the user performing the restore. Vertica does not restore dependent grants, roles, or client authentications with restored objects.

If the storage policies of a restored object are not valid, `vbr` applies the default storage policy. Restored storage policies can become invalid due to HDFS storage locations, table incompatibility, and unavailable min-max values at restore time.

Sometimes, Vertica encounters a catalog object that it does not need to restore. When this situation occurs, Vertica generates a warning message for that object and the restore continues.

Examples

Suppose you have a full backup, including Schema1, owned by the user Alice. Schema1 contains Table1, owned by Bob, who eventually passes ownership to Chris. The user dbadmin performs the restore. The following scenarios might occur that affect ownership of these objects.

Scenario 1:

Schema1.Table1 has been dropped at some point since the backup was created. When dbadmin performs the restore, Vertica re-creates Schema1.Table1. As the user performing the restore, dbadmin takes ownership of Schema1.Table1. Because Schema1 still exists, Alice retains ownership of the schema.

Scenario 2:

Schema1 is dropped, along with all contained objects. When dbadmin performs the restore, Vertica re-creates the schema and all contained objects. dbadmin takes ownership of Schema1 and Schema1.Table1.

Scenario 3:

Schema1 and Schema1.Table1 both exist in the current database. When dbadmin rolls back to an earlier backup, the ownership of the objects remains unchanged. Alice owns Schema1, and Bob owns Schema1.Table1.

Scenario 4:

Schema1.Table1 exists and dbadmin wants to roll back to an earlier version. In the time since the backup was made, ownership of Schema1.Table1 has changed to Chris. When dbadmin restores Schema1.Table1, Alice remains owner of Schema1 and Chris remains owner of Schema1.Table1. The restore does not revert ownership of Schema1.Table1 from Chris to Bob.

Copying the database to another cluster

Important

Inadequate security on backups can compromise overall database security. Be sure to secure backup locations and strictly limit access to backups

only to users who already have permissions to access all database data.

The `vbr` task `copycluster` combines two other `vbr` tasks— `backup` and `restore` —as a single operation, enabling you to back up an entire data from one Enterprise Mode database cluster and then restore it on another. This can facilitate routine operations, such as copying a database between development and production environments.

Caution

`copycluster` overwrites all existing data in the destination database. To preserve that data, back up the destination database before launching the `copycluster` task.

Restrictions

`copycluster` is invalid with Eon databases. It is also incompatible with HDFS storage locations; Vertica does not transfer data to a remote HDFS cluster as it does for a Linux cluster.

Prerequisites

`copycluster` requires that the target and source database clusters be identical in the following respects:

- Vertica hotfix version—for example, 12.0.1-1
- Number of nodes and node names, as shown in the system table `NODES`:

```
=> SELECT node_name FROM nodes;
node_name
-----
v_vmart_node0001
v_vmart_node0002
v_vmart_node0003
(3 rows)
```

- Database name
- Vertica catalog, data, and temp directory paths as shown in the system table `DISK_STORAGE`:

```
=> SELECT node_name,storage_path,storage_usage FROM disk_storage;
node_name | storage_path | storage_usage
-----+-----+-----
v_vmart_node0001 | /home/dbadmin/VMart/v_vmart_node0001_catalog/Catalog | CATALOG
v_vmart_node0001 | /home/dbadmin/VMart/v_vmart_node0001_data | DATA,TEMP
v_vmart_node0001 | /home/dbadmin/verticadb | DEPOT
v_vmart_node0002 | /home/dbadmin/VMart/v_vmart_node0002_catalog/Catalog | CATALOG
...
```

Note

Directory paths for the catalog, data, and temp storage are the same on all nodes.

- Database administrator accounts

The following requirements also apply:

- The target cluster has adequate disk space for `copycluster` to complete.
- The source cluster's database administrator must be able to log in to all target cluster nodes through SSH without a password.

Note

Passwordless access *within* the cluster is not the same as passwordless access *between* clusters. The SSH ID of the administrator account on the source cluster and the target cluster are likely not the same. You must configure each host in the target cluster to accept the SSH authentication of the source cluster.

Copycluster procedure

1. Create a configuration file for the `copycluster` operation. The Vertica installation includes a sample configuration file:

```
/opt/vertica/share/vbr/example_configs/copycluster.ini
```

For each node in the source database, create a [\[Mapping\]](#) entry that specifies the host name of each destination database node. Unlike other [vbr](#) tasks such as [restore](#) and [backup](#) , mappings for [copycluster](#) only require the destination host name. [copycluster](#) always stores backup data in the catalog and data directories of the destination database.

The following example configures [vbr](#) to copy the [vmart](#) database from its three-node [v_vmart](#) cluster to the [test-host](#) cluster:

```
[Misc]
snapshotName = CopyVmart
tempDir = /tmp/vbr

[Database]
dbName = vmart
dbUser = dbadmin
dbPassword = password
dbPromptForPassword = False

[Transmission]
encrypt = False
port_rsync = 50000

[Mapping]
; backupDir is not used for cluster copy
v_vmart_node0001= test-host01
v_vmart_node0002= test-host02
v_vmart_node0003= test-host03
```

2. Stop the target cluster.
3. As database administrator, invoke the [vbr](#) task [copycluster](#) from a source database node:

```
$ vbr -t copycluster -c copycluster.ini
Starting copy of database VMART.
Participating nodes: vmart_node0001, vmart_node0002, vmart_node0003, vmart_node0004.
Enter vertica password:
Snapshotting database.
Snapshot complete.
Determining what data to copy.
[=====] 100%
Approximate bytes to copy: 987394852 of 987394852 total.
Syncing data to destination cluster.
[=====] 100%
Reinitializing destination catalog.
Copycluster complete!
```

Important

If the [copycluster](#) task is interrupted, the destination cluster retains data files that already transferred. If you retry the operation, Vertica does not resend these files.

Replicating objects to another database cluster

The [vbr](#) task [replicate](#) supports replication of tables and schemas from one database cluster to another. You might consider replication for the following reasons:

- Copy tables and schemas between test, staging, and production clusters. Replicate certain objects immediately after an important change, such as a large table data load, instead of waiting until the next scheduled backup.

In both cases, replicating objects is generally more efficient than exporting and importing them. The first replication of an object replicates the entire object. Subsequent replications copy only data that has changed since the last replication. Vertica replicates data as of the current epoch on the target database. Used with a cron job, you can replicate key objects to create a backup database.

Replicate versus copycluster

[replicate](#) only supports tables, schemas, and—in Eon Mode databases—namespaces. In situations where the target database is down, or you plan to replicate the entire database, Vertica recommends that you use the [copycluster](#) task to copy the database to another cluster. Thereafter, you can use [replicate](#) to update individual objects.

Replication procedure

To replicate objects to another database, perform these actions from the source database:

1. [Verify replication requirements](#).
2. [Identify the objects to replicate and target database](#) in the `vbr` configuration file.
3. [Replicate objects](#).

Verify replication requirements

The following requirements apply to the source and target databases and their respective clusters:

- All nodes in both databases are UP, else DOWN nodes are handled as described [below](#).
- Versions of the two databases must be compatible. Vertica supports object replication to a target database up to one minor version higher than the current database version. For example, you can replicate objects from a 12.0.x database to a 12.1.x database.
- The same Linux user is associated with the dbadmin account of both databases.
- The source cluster database administrator can log on to all target nodes through SSH without a password.

Note

The SSH ID of the administrator account on the source cluster and the target cluster are likely not the same. You must configure each host in the target cluster to accept the SSH authentication of the source cluster.

- Enterprise Mode: The following requirements apply:
 - Both databases have the same number of nodes.
 - Clusters of both databases have the same number of fault groups, where corresponding fault groups in each cluster have the same number of nodes.
- Eon Mode: The following requirements apply:
 - The primary subclusters of both databases have the same node subscriptions.
 - Primary subclusters of the target database have as many or more nodes as primary subclusters of the source database.
 - For databases with multiple namespaces, the target and source namespaces must satisfy the requirements described in [Eon Mode database requirements](#).

Edit vbr configuration file

Tip

As a best practice, create a separate configuration file for each replication task.

Edit the `vbr` configuration file to use for the `replicate` task as follows:

1. In the `[misc]` section, set the `objects` parameter to the objects to be replicated:

```
; Identify the objects that you want to replicate
objects = schema.objectName
```

Important

If your Eon Mode database has multiple [namespaces](#), you must specify the namespace to which the objects belong. For `vbr` tasks, namespace names are prefixed with a period. For example, `.n.s.t` refers to table `t` in schema `s` in namespace `n`. See [Eon Mode database requirements](#) for more information.

2. In the `[misc]` section, set the `snapshotName` parameter to a unique snapshot identifier. Multiple `replicate` tasks can run concurrently with each other and with `backup` tasks, but only if their snapshot names are different.

```
snapshotName = name
```

3. In the `[database]` section, set the following parameters:

```
; parameters used to replicate objects between databases
dest_dbName =
dest_dbUser =
dest_dbPromptForPassword =
```

If you use a stored password, be sure to configure the `dest_dbPassword` parameter in your [password configuration file](#).

4. In the [\[mapping\]](#) section, map source nodes to target hosts:

```
[Mapping]
v_source_node0001 = targethost01
v_source_node0002 = targethost02
v_source_node0003 = targethost03
```

Replicate objects

Run **vbr** with the **replicate** task:

```
vbr -t replicate -c configfile.ini
```

The **replicate** task can run concurrently with **backup** and other **replicate** tasks in either direction, provided all tasks have unique snapshot names. **replicate** cannot run concurrently with other **vbr** tasks.

Handling DOWN nodes

You can replicate objects if some nodes are down in either the source or target database, provided the nodes are visible on the network.

The effect of DOWN nodes on a replication task depends on whether they are present in the source or target database.

Location	Effect on replication
DOWN source nodes	Vertica can replicate objects from a source database containing DOWN nodes. If nodes in the source database are DOWN, set the corresponding nodes in the target database to DOWN as well.
DOWN target nodes	Vertica can replicate objects when the target database has DOWN nodes. If nodes in the target database are DOWN, exclude the corresponding source database nodes using the --nodes parameter on the vbr command line.

Monitoring object replication

You can monitor object replication in the following ways:

- View **vbr** logs on the source database
- Check database logs on the source and target databases
- Query [REMOTE_REPLICATION_STATUS](#) on the source database

Including and excluding objects

You specify objects to include in backup, restore, and replicate operations with the **vbr** configuration and command-line parameters **includeObjects** and **--include-objects**, respectively. You can optionally modify the set of included objects with the **vbr** configuration and command line parameters **excludeObjects** and **--exclude-objects**, respectively. Both parameters support wildcard expressions to include and exclude groups of objects.

Important
If your Eon Mode database has multiple [namespaces](#), you must specify the namespace to which the objects belong. For **vbr** tasks, namespace names are prefixed with a period. For example, **.n.s.t** refers to table **t** in schema **s** in namespace **n**. See [Eon Mode database requirements](#) for more information.

For example, you might back up all tables in the schema **store**, and then exclude from the backup the table **store.orders** and all tables in the same schema whose name includes the string **account**:

```
vbr --task=backup --config-file=db.ini --include-objects 'store.*' --exclude-objects 'store.orders,store.*account*'
```

Wildcard characters

Character	Description
?	Matches any single character. Case-insensitive.
*	Matches 0 or more characters. Case-insensitive.

\	Escapes the next character. To include a literal ? or * in your table or schema name, use the \ character immediately before the escaped character. To escape the \ character itself, use a double \.
"	Escapes the . character. To include a literal . in your table or schema name, wrap the character in double quotation marks.

Matching schemas

Any string pattern without a period (.) character represents a schema. For example, the following `includeObjects` list can match any schema name that starts with the string `customer` , and any two-character schema name that starts with the letter `s` :

```
includeObjects = customer*,s?
```

When a `vbr` operation specifies a schema that is unqualified by table references, the operation includes all tables of that schema. In this case, you cannot exclude individual tables from the same schema. For example, the following `vbr.ini` entries are invalid:

```
; invalid:
includeObjects = VMart
excludeObjects = VMart.?table?
```

You can exclude tables from an included schema by identifying the schema with the pattern `schemaname.*`. In this case, the pattern explicitly specifies to include all tables in that schema with the wildcard `*`. In the following example, the `include-objects` parameter includes all tables in the VMart schema, and then excludes specific tables—specifically, the table `VMart.sales` and all VMart tables that include the string `account` :

```
--include-objects 'VMart.*'
--exclude-objects 'VMart.sales,VMart.*account**'
```

Matching tables

Any pattern that includes a period (.) represents a table. For example, in a configuration file, the following `includeObjects` list matches the table name `sales.newclients` , and any two-character table name in the same schema:

```
includeObjects = sales.newclients,sales.??
```

You can also match all schemas and tables in a database or backup by using the pattern `*.*`. For example, you can restore all tables and schemas in a backup using this command:

```
--include-objects '*.*'
```

Because a `vbr` parameter is evaluated on the command line, you must enclose the wildcards in single quote marks to prevent Linux from misinterpreting them.

Testing wildcard patterns

You can test the results of any pattern by using the `--dry-run` parameter with a backup or restore command. Commands that include `--dry-run` do not affect your database. Instead, `vbr` displays the result of the command without executing it. For more information on `--dry-run` , refer to the [vbr reference](#).

Using wildcards with backups

You can identify objects to include in your object backup tasks using the `includeObjects` and `excludeObjects` parameters in your configuration file. A typical configuration file might include the following content:

```
[Misc]
snapshotName = dbobjects
restorePointLimit = 1
enableFreeSpaceCheck = True
includeObjects = VMart.*,online_sales.*
excludeObjects = *.*temp*
```

In this example, the backup would include all tables from the VMart and `online_sales` schemas, while excluding any table containing the string 'temp' in its name belonging to any schema.

After it evaluates included objects, `vbr` evaluates excluded objects and removes excluded objects from the included set. For example, if you included `schema1.table1` and then excluded `schema1.table1`, that object would be excluded. If no other objects were included in the task, the task would fail. The same is true for wildcards. If an exclusion pattern removes all included objects, the task fails.

Using wildcards with restore

You can identify objects to include in your restore tasks using the `--include-objects` and `--exclude-objects` parameters.

Note

Take extra care when using wildcard patterns to restore database objects. Depending on your object restore mode settings, restored objects can overwrite existing objects. Test the impact of a wildcard restore with the `--dry-run vbr` parameter before performing the actual task.

As with backups, `vbr` evaluates excluded objects after it evaluates included objects and removes excluded objects from the included set. If no objects remain, the task fails.

A typical restore command might include this content. (Line wrapped in the documentation for readability, but this is one command.)

```
$ vbr -t restore -c verticaconfig --include-objects 'customers.* ,sales??'  
--exclude-objects 'customers.199?,customers.200?'
```

This example includes the schema `customers`, minus any tables with names matching `199` and `200` plus one character, as well as all any schema matching `'sales'` plus two characters.

Another typical restore command might include this content.

```
$ vbr -t restore -c replicateconfig --include-objects '*.transactions,flights.*'  
--exclude-objects 'flights.DTW*,flights.LAS*,flights.LAX*'
```

This example includes any table named `transactions`, regardless of schema, and any tables beginning with `DTW`, `LAS`, or `LAX` belonging to the schema `flights`. Although these three-letter airport codes are capitalized in the example, `vbr` is case-insensitive.

Managing backups

Important

Inadequate security on backups can compromise overall database security. Be sure to secure backup locations and strictly limit access to backups only to users who already have permissions to access all database data.

`vbr` provides several tasks related to managing backups: listing them, checking their integrity, selectively deleting them, and more. In addition, `vbr` has parameters to allow you to restrict its use of system resources.

In this section

- [Viewing backups](#)
- [Checking backup integrity](#)
- [Repairing backups](#)
- [Removing backups](#)
- [Estimating log file disk requirements](#)
- [Allocating resources](#)

Viewing backups

You can view backups in three ways:

- `vbr listbackup` task: List backups on the local or remote backup host.
- `DATABASE_BACKUPS` system table: Query for historical information about backups.
- `vbr log file`: Check the status of a backup. The log file resides on the node where you ran `vbr`, in the directory specified by the `vbr` configuration parameter `tempDir`, by default set to `/tmp/vbr`.

`vbr listbackup`

The `vbr` task `listbackup` returns a list of all backups on backup hosts, whether local or remote. If unqualified by task `options`, `listbackup` returns the list to standard output in columnar format.

The following example lists two full backups of a three-node cluster, where each node is mapped to the same backup host, `bkhost`. Backups are listed in reverse chronological order:

```
$ vbr -t listbackup -c fullbackup.ini
backup          backup_type epoch  objects  include_patterns  exclude_patterns  nodes(hosts)
version        file_system_type
backup_snapshot_20220912_131918  full      3915                                v_vmart_node0001(10.20.100.247),
v_vmart_node0002(10.20.100.248), v_vmart_node0003(10.20.100.249) v12.0.2-20220911 [Linux]
backup_snapshot_20220909_122300  full      3910                                v_vmart_node0001(10.20.100.247),
v_vmart_node0002(10.20.100.248), v_vmart_node0003(10.20.100.249) v12.0.2-20220911 [Linux]
```

The following table contains information about output columns that are returned from a [vbr listbackup](#) task:

Column	Description
backup	Identifies a backup by concatenating the configured snapshot_name with the backup timestamp: <i>snapshot-name _ YYYYMMDD _ HHMMSS</i> For example, the following identifier identifies a backup generated by the configuration file that sets <code>snapshotName</code> to <code>monthlyBackup</code> on April 14 2022, at 13:44:52. <code>monthlyBackup_20220414_134452</code> Use the timestamp portion of this identifier— <code>20220414_134452</code> —to specify the archived backup you wish to restore.
backup_type	Type of backup, full or object.
epoch	Epoch when the backup was created.
objects	Objects that were backed up, blank if a full backup.
include_patterns	Wildcard patterns included in object backup tasks using the <code>includeObjects</code> parameter in your configuration file, blank for full backups.
exclude_patterns	Wildcard patterns included in your object backup tasks using the <code>excludeObjects</code> parameter in your configuration file, blank for full backups.
nodes (hosts)	(Enterprise Mode only) Names of database nodes and hosts that received the backup.
version	Version of Vertica used to create the backup.
file_system_type	Storage location file system of the Vertica hosts that comprise this backup—for example, Linux or GCS.
communal_storage	(Eon Mode only) Communal storage location for the backup.

Important

If you try to list backups on a local cluster with no database, the backup configuration node-host mappings must provide full paths. If the configuration maps to local hosts using the [shortcut](#), the `listbackup` task fails.

Listbackup options

You can qualify the `listbackup` task with one or more options:

```
vbr --task listbackup [--list-all] [--json] [--list-output-file filepath] --config-file filepath
```

Option	Description
<code>--list-all</code>	Generate a list of all snapshots stored on the hosts and paths listed in the specified configuration file.
<code>--json</code>	Use JSON delimited format.

`--list-output-file`

Redirect output to the specified file.

The following example qualifies the `listbackup` task with the `--list-all` option. The output shows three nightly backups from nodes `vmart_1` , `vmart_2` , and `v_mart3` , which the configuration file `nightly.ini` maps to their respective hosts `doca01` , `doca02` , and `doca03` . The `listbackup` output shows that these locations contain not only object backups that were generated with `nightly.ini` , but also full backups created with a second configuration file, `weekly.ini` , which maps to the same nodes and host:

```
$ vbr --task listbackup --list-all --config-file /home/dbadmin/nightly.ini
```

backup	backup_type	epoch	objects	include_patterns	exclude_patterns	nodes(hosts)	version	file_system_type
weekly_20220508_183249	full	1720				vmart_1(doca01), vmart_2(doca02), vmart_3(doca03)	v11.0.1	[Linux]
weekly_20220501_182816	full	1403				vmart_1(doca01), vmart_2(doca02), vmart_3(doca03)	v11.0.1	[Linux]
weekly_20220424_192754	full	1109				vmart_1(doca01), vmart_2(doca02), vmart_3(doca03)	v11.0.1	[Linux]
nightly_20220507_183034	object	1705	sales_schema			vmart_1(doca01), vmart_2(doca02), vmart_3(doca03)	v11.0.1	[Linux]
nightly_20220506_181808	object	1692	sales_schema			vmart_1(doca01), vmart_2(doca02), vmart_3(doca03)	v11.0.1	[Linux]
nightly_20220505_193906	object	1632	sales_schema			vmart_1(doca01), vmart_2(doca02), vmart_3(doca03)	v11.0.1	[Linux]

Query backup history

You can query the system table `DATABASE_BACKUPS` to get historical information about backups. The `objects` column lists which objects were included in object-level backups.

Important

Do not use the `backup_timestamp` value to [restore an archive](#). Instead, use the values provided by vbr `listbackup` task.

```

=> SELECT * FROM v_monitor.database_backups;
-[ RECORD 1 ]-----+-----
backup_timestamp | 2013-05-10 14:41:12.673381-04
node_name       | v_vmart_node0003
snapshot_name   | schemabak
backup_epoch    | 174
node_count     | 3
file_system_type | [Linux]
objects        | public, store, online_sales
-[ RECORD 2 ]-----+-----
backup_timestamp | 2013-05-13 11:17:30.913176-04
node_name       | v_vmart_node0003
snapshot_name   | kantibak
backup_epoch    | 175
node_count     | 3
file_system_type | [Linux]
objects        |
-[ RECORD 13 ]----+-----
backup_timestamp | 2013-05-16 07:02:23.721657-04
node_name       | v_vmart_node0003
snapshot_name   | objectbak
backup_epoch    | 180
node_count     | 3
file_system_type | [Linux]
objects        | test, test2
-[ RECORD 14 ]----+-----

snapshot_name   | table1bak
backup_epoch    | 180
node_count     | 3
file_system_type | [Linux]
objects        | test
-[ RECORD 15 ]----+-----
backup_timestamp | 2013-05-16 07:20:18.585076-04
node_name       | v_vmart_node0003
snapshot_name   | table2bak
backup_epoch    | 180
node_count     | 3
file_system_type | [Linux]
objects        | test2

```

Checking backup integrity

Vertica can confirm the integrity of your backup files and the manifest that identifies them. By default, backup integrity checks output their results to the command line.

Quick check

The **quick-check** task gathers all backup metadata from the backup location specified in the configuration file and compares that metadata to the backup manifest. A quick check does not verify the objects themselves. Instead, this task outputs an exceptions list of any discrepancies between objects in the backup location and objects listed in the backup manifest.

Use the following format to perform quick check task:

```
$ vbr -t quick-check -c configfile.ini
```

For example:

```
$ vbr -t quick-check -c backupconfig.ini
```

Full check

The **full-check** task verifies all objects listed in the backup manifest against filesystem metadata. A full check includes the same steps as a quick check. You can include the optional **--report-file** parameter to output results to a delimited JSON file. This task outputs an exceptions list that identifies the following inconsistencies:

- Incomplete restore points
- Damaged restore points
- Missing backup files
- Unreferenced files

Use the following template to perform a full check task:

```
$ vbr -t full-check -c configfile.ini --report-file=path/filename
```

For example:

```
$ vbr -t full-check -c backupconfig.ini --report-file=logging/fullintegritycheck.json
```

Repairing backups

Vertica can reconstruct backup manifests and remove unneeded backup objects.

Quick repair

The **quick-repair** task rebuilds the backup manifest, based on the manifests contained in the backup location.

Use the following template to perform a quick repair task:

```
$ vbr -t quick-repair -c configfile.ini
```

Garbage collection

The **collect-garbage** task rebuilds your backup manifest and deletes any backup objects that do not appear in the manifest. You can include the optional **--report-file** parameter to output results to a delimited JSON file.

Use the following template to perform a garbage collection task:

```
$ vbr -t collect-garbage -c configfile.ini --report-file=path/filename
```

Removing backups

You can remove existing backups and restore points using **vbr**. When you use the **remove** task, **vbr** updates the manifests affected by the removal and maintains their integrity. If the backup archive contains multiple restore points, removing one does not affect the others. When you remove the last restore point, **vbr** removes the backup entirely.

Note

Vertica does not support removing backups through the file system.

Use the following template to perform a remove task:

```
$ vbr -t remove -c configfile.ini --archive timestamp
```

You can remove multiple restore points using the archive parameter. To obtain the timestamp for a particular restore point, [use the listbackup task](#).

- To remove multiple restore points, use a comma separator:

```
--archive="restore-point1,restore-point2"
```

- To remove an inclusive range of restore points, use a colon:

```
--archive="oldest-restore-point:newest-restore-point"
```

- To remove all restore points, specify an archive value of **all**:

```
--archive all
```

The following example shows how you can remove a restore point from an existing backup:

```
$ vbr -t remove -c backup.ini --archive 20160414_134452
Removing restore points: 20160414_134452
Remove complete!
```

Estimating log file disk requirements

One of the **vbr** configuration parameters is [tempDir](#). This parameter specifies the database host location where **vbr** writes its log files and some other temp files (of negligible size). The default location is the `/tmp/vbr` directory on each database host. You can change the default location by specifying a different path in the configuration file.

The temporary storage directory also contains local log files describing the progress, throughput, and any errors encountered for each node. Each time you run **vbr**, the script creates a separate log file, each named with a timestamp. When using default settings, the log file typically uses about 4KB of space per node per backup.

The **vbr** log files are not removed automatically, so you must delete older log files manually, as necessary.

Allocating resources

By default, **vbr** allows a single rsync connection (for Linux file systems), 10 concurrent threads (for cloud storage connections), and unlimited bandwidth for any backup or restore operation. You can change these values in your configuration file. See [vbr configuration file reference](#) for details about these parameters.

Connections

You might want to increase the number of concurrent connections. If you have many Vertica files, more connections can provide a significant performance boost as each connection increases the number of concurrent file transfers.

For more information, refer to the following parameters in [\[transmission\]](#):

- `total_bwlimit_backup`
- `total_bwlimit_restore`
- `concurrency_backup`
- `concurrency_restore`

and the following parameters in [\[CloudStorage\]](#):

- `cloud_storage_concurrency_backup`
- `cloud_storage_concurrency_restore`

Bandwidth limits

You can limit network bandwidth use through the `total_bwlimit_backup` and `total_bwlimit_restore` data transmission parameters. For more information, refer to [\[transmission\]](#).

Troubleshooting backup and restore

These tips can help you avoid issues related to backup and restore with Vertica and to troubleshoot any problems that occur.

Check vbr log
