Vertica server and Management Console

Operating systems and versions

OpenText supports the Vertica Analytic Database 24.2.x running on the following 64-bit operating systems and versions on x86_x64 architecture.

In general, OpenText provides support for the Vertica Analytic Database, not its host operating system, hardware, or other environmental elements. However, OpenText makes an effort to ensure the success of its customers on recent versions of the following popular operating systems for the x86_64 architecture.

When there are multiple minor versions supported for a major operating system release, OpenText recommends that you run Vertica on the latest minor version listed in the supported versions list. For example, if you run Vertica on a Red Hat Enterprise Linux 8.x release, OpenText recommends you upgrade to or be running the latest supported RHEL 8.x release.

Important

Vertica does not support or recommend in-place upgrades from one major version to another major version. For example, you cannot perform in-place upgrades from RHEL/CentOS 8.x to RHEL/CentOS 9.x.

Platform	Processor	Supported Versions	Known Issues
Red Hat Enterprise Linux (RHEL) / CentOS Important For information on how to upgrade your Red Hat Enterprise Linux version, see Upgrading your operating system on nodes in your Vertica cluster . Vertica supports CentOS based on testing and troubleshooting done on the associated Red Hat Enterprise Linux version.	x86_64	8.x: all with known issues RHEL 9.x: all	8.x : To create R extensions, manually install the libgfortran4 package. Download the applicable package from the CentOS Linux and Stream releases page .

Rocky Linux	x86_64	8.x: all	
SUSE Linux Enterprise Server	x86_64	12 SP2 and higher 15.x: all	
openSUSE	x86_64	42.3	
Oracle Enterprise Linux (Red Hat compatible kernels only)	x86_64	7.x: all Deprecated OEL 7.x support is deprecated.	
Debian Linux	x86_64	8.5, 8.9 10.x: with known issues	10.2 : On Vertica 9.3 and higher, you cannot restart the Management Console using the MC Interface in your browser. To restart the Management Console, enter one of the following commands: <ul style="list-style-type: none"> • <code>systemctl restart vertica-console</code>
Ubuntu	x86_64	14.04 LTS and higher with known issues	16.x/18.x : On Vertica 9.3 and higher, you cannot restart the Management Console using the MC Interface in your browser. To restart the Management Console, enter one of the following commands: <ul style="list-style-type: none"> • <code>systemctl restart vertica-console</code> • <code>/etc/init.d/vertica-console restart</code>

Recommended storage format types

Choose the storage format type based on deployment requirements. Vertica recommends the following storage format types where applicable:

- ext3
- ext4
- NFS for backup
- XFS
- Amazon S3 Standard, Azure Blob Storage, or Google Cloud Storage for communal storage and related backup tasks when running in Eon Mode

Note

For the Vertica I/O profile, the ext4 file system is considerably faster than ext3.

The storage format type at your backup and temporary directory locations must support `fcntl lockf` (POSIX) file locking.

You can view the file systems in use on your nodes by querying the system table [STORAGE_USAGE](#).

Vertica users have successfully deployed other file systems, Vertica cannot guarantee or desired outcomes on all storage format types. In certain support situations, you may be asked to migrate to a recommended storage format type to help with troubleshooting or to fix an issue.

Vertica Analytic Database supports Linux Volume Manager (LVM) on all supported operating systems. Your LVM version must be 2.02.66 or later, and must include device-mapper version 1.02.48 or later. For information on requirements and restrictions, see the section, [Vertica Support for LVM](#).

Network address family support

Vertica server supports IPv4 and IPv6 network addresses for both internal and external communications. The database cluster uses IPv4 by default for internal communications. You can choose to have the cluster use IPv6 for its internal communications when you install Vertica and create the cluster.

Vertica supports using IPv6 to identify nodes in the database cluster. However, AWS DNS resolution does not support IPv6. To have a cluster in AWS that uses IPv6, use the IPv6 IP addresses instead of using host names when installing Vertica and forming the cluster.

Currently, Vertica does not support using IPv6 on Google Cloud Platform or Microsoft Azure.

The MC currently does not support IPv6. If your Vertica database uses IPv6 for internal communications, the MC will not be able to connect to or manage the database. The MC must communicate with the database cluster using its own internal network addresses.

Supported browsers for Management Console

Vertica Analytic Database 24.2.x Management Console is supported on the following web browsers:

- Chrome
- Firefox
- Microsoft Edge

Vertica server and Management Console compatibility

Management Console (MC) 24.2.x is compatible with all supported Vertica server versions.

Client drivers support

Vertica provides JDBC, ODBC, OLE DB, Python, vsq, and ADO.NET client drivers. Download the latest drivers from [Vertica Client Drivers](#). Choose from drivers for the following platforms:

Platform	Drivers	See also
Linux/UNIX	ODBC, JDBC, Python, ADO.NET, vsq	Installing the ODBC client driver
Windows	ODBC, JDBC, OLE DB, ADO.NET, vsq	Windows client driver installer
macOS (including M1 and M2 processors)	ODBC, JDBC, ADO.NET, vsq	Installing the ODBC client driver

To view a list of driver and server version compatibility, see [Client driver and server version compatibility](#).

ADO.NET Driver

The ADO.NET and OLE DB drivers are supported on the following platforms:

Platform	Processor	Supported Versions	.NET Requirements
Microsoft Windows	x86 (32-bit)	Windows 10	Microsoft .NET Standard 2.0+ or higher (Microsoft .NET Framework 4.6.1+ and .NET Core 3.1+)
Microsoft Windows	x64 (64-bit)	Windows 10	
Microsoft Windows Server	x64 (64-bit)	2016 2019	
Linux	x64 (64-bit)	For supported distributions, see the Microsoft documentation .	
macOS	x64 (64-bit)	For supported versions, see the Microsoft documentation .	

OLE DB Driver

The ADO.NET and OLE DB drivers are supported on the following platforms:

Platform	Processor	Supported Versions	.NET Requirements
Microsoft Windows	x86 (32-bit)	Windows 10	Microsoft .NET Framework 4.6 or higher service packs
Microsoft Windows	x64 (64-bit)	Windows 10	
Microsoft Windows Server	x64 (64-bit)	2016 2019	

JDBC driver

All non-FIPS JDBC drivers are supported on any Java 8-compliant platform or later (Java 8 is the minimum).

ODBC driver

Vertica Analytic Database provides both 32-bit and 64-bit ODBC drivers. Vertica 24.2.x ODBC drivers are supported on the following platforms:

Platform	Processor	Supported Versions	Driver Manager
Microsoft Windows	x86 (32-bit)	Windows 10	Microsoft ODBC MDAC 2.8
Microsoft Windows	x64 (64-bit)	Windows 10	
Microsoft Windows Server	x64 (64-bit)	2016 2019	
Red Hat Enterprise Linux / CentOS	x86_64	8.0 and later	iODBC 3.52.6 and higher unixODBC 2.3.0 and higher DataDirect 5.3 and 6.1 and higher
FIPS-compliant Red Hat Enterprise Linux	x86_64	8.1 and higher	
SUSE Linux Enterprise	x86_64	12 SP2, 12 SP3, 12 SP4	
openSUSE	x86_64	42.3	
Oracle Enterprise Linux (Red Hat compatible kernel only)	x86_64	7.3 and higher	
Ubuntu	x86_64	14.04 LTS, 16.04 LTS, 18.04 LTS, 19.1	
Amazon Linux	x86_64	2	
Debian Linux	x86_64	8.5, 8.9, 10	
macOS	x86_64, M1, M2	10.15 and higher	

vsq client

The Vertica vsq client is included in all client packages. It is not available as a separate download. The vsq client is supported on the following platforms:

Operating System	Processor	Supported Versions
Microsoft Windows	x86, x64	Windows 2016, 2019: all variants Windows 10
Red Hat Enterprise Linux / CentOS	x86, x64	8.x: all

FIPS-compliant Red Hat Enterprise Linux	x64	8.1 and higher
SUSE Linux Enterprise	x86, x64	12: SP2 and higher
openSUSE	x86, x64	42.3
Oracle Enterprise Linux (Red Hat compatible kernels only)	x86, x64	6.7 and higher 7.x: all
Ubuntu	x86, x64	14.04 LTS, 16.04 LTS, 18.04 LTS, 19.1
Debian Linux	x86, x64	8.5, 8.9
macOS	x86, x64, M1, M2	10.15 and higher
Amazon Linux	x86, x64	2

In this section

- [Perl driver requirements](#)
- [Python driver requirements](#)

Perl driver requirements

To use Perl with Vertica, you must install the Perl driver modules (DBI and DBD::ODBC) and a Vertica ODBC driver on the machine where Perl is installed. The following table lists the Perl versions supported with Vertica 24.2.x.

Later versions of Perl (5.10 and above), DBI, and DBD::ODBC might also work.

Perl Version	Perl Driver Modules	ODBC Requirements
<ul style="list-style-type: none"> • 5.8 • 5.10 	<ul style="list-style-type: none"> • DBI driver version 1.609 • DBD::ODBC version 1.22 	See Client drivers support .

Python driver requirements

To use Python with Vertica, you must install either:

- The vertica-python client.
- The pyodbc module.

For details, see [Installing Python client drivers](#).

The following table lists compatible versions of Python, the Python drivers, and ODBC.

Python Version	Python Driver Module	ODBC Requirements
2.4.6	pyodbc 2.1.6	See Client drivers support .
2.7.x	Vertica Python Client (Linux only)	
2.7.3	pyodbc 3.0.6	
3.3.4	pyodbc 3.0.7	

Vertica SDKs

This section details software requirements for running User Defined Extensions (UDxs) developed using the Vertica SDKs.

C++ SDK

The Vertica cluster does not have any special requirements for running UDxs written in C++.

Java SDK

Your Vertica cluster must have a Java runtime installed to run UDxs developed using the Vertica Java SDK. Vertica has tested the following Java Runtime Environments (JREs) with this version of the Vertica Java SDK:

- Oracle Java Platform Standard Edition 6 (version number 1.6)
- Oracle Java Platform Standard Edition 7 (version number 1.7)
- Oracle Java Platform Standard Edition 8 (version number 1.8)
- OpenJDK 6 (version number 1.6)
- OpenJDK 7 (version number 1.7)
- OpenJDK 8 (version number 1.8)

Python SDK

The Vertica Python SDK does not require any additional configuration or header files.

R language pack

The Vertica R Language Pack provides version 3.5 of the R runtime and associated libraries for interfacing with Vertica. You install the R Language Pack on the Vertica server.

FIPS 140-2 supported platforms

Vertica uses a certified OpenSSL FIPS 140-2 cryptographic module to meet the security standards set by the National Institute of Standards and Technology (NIST) for Federal Agencies in the United States or other countries. Vertica links with the version of OpenSSL on the system to perform cryptographic operations at run time. When operating in FIPS mode, Vertica relies on the operating system's FIPS configuration to ensure a FIPS-certified version of OpenSSL is present in the environment.

OpenText supports running Vertica in FIPS mode on Red Hat Enterprise Linux versions 9.2 and higher with FIPS-compliant versions of OpenSSL 3.0. OpenSSL version 1.1.1k is not supported. For information on downloading FIPS-compliant libraries, see the [OpenSSL documentation](#).

FIPS-enabled Vertica requires the following:

- A user-generated certificate signed by an approved Certificate Authority.
- TLS 1.2 to support the server-client connection for a FIPS-enabled system.

Supported drivers

Vertica supports the following client drivers for FIPS-compliance:

- vsql
- ODBC
- JDBC

Important

FIPS-enablement is not supported in the Management Console.

For more information see [Federal information processing standard](#).

Eon on-premises storage

Vertica supports the following storage platforms for Vertica Eon Mode running on-premises.

Pure Storage FlashBlade

Vertica supports communal storage on Pure Storage FlashBlade version 3.0.0 and later. See [Create an Eon Mode database on-premises with FlashBlade](#) for more information.

Vertica does not support the use of Vertica Management Console or admintools to administer data located on Pure Storage hardware.

For information on configuring Pure Storage, refer to [support.purestorage.com](#).

MinIO

Vertica supports communal storage on MinIO version 2018-12-27T18:33:08Z and later. See [Create an Eon Mode database on-premises with MinIO](#) for more information.

In Eon Mode, Vertica relies on the communal storage platform to manage data safety and integrity. For production use, always use MinIO in a distributed mode cluster. This mode provides high availability and data integrity protection. See the [Distributed MinIO Quickstart Guide](#) for instructions on configuring MinIO in distributed mode.

To ensure MinIO consistency guarantees, MinIO must be configured for read-after-write and list-after-write consistency. For details, see the [MinIO documentation](#).

Vertica does not support the use of Vertica Management Console or admintools to administer data located on MinIO.

See the [MinIO website](#) for more information about MinIO.

HDFS

Vertica supports communal storage on HDFS when accessed through WebHDFS. See [Create an Eon Mode database on-premises with HDFS](#) for more information.

For HDFS, Vertica does not support the following:

- The MapR distribution of HDFS, which is accessed through an NFS mount point and not through WebHDFS.
- Using Vertica Management Console or admintools to administer data located on HDFS.
- Cloudera (CDH) versions 5.x in Eon Mode.
- The copycluster vbr backup and restore utility for communal storage on HDFS.

Other validated object storage

The preceding sections detail storage platforms and versions that Vertica engineering tests under specific performance and load thresholds. In addition to these storage platforms, the Vertica Partner Engineering team validates object storage platforms that meet strict performance requirements.

For details, see [On-Premises](#).

Vertica on Amazon Web Services

For information about deploying Vertica on Amazon Web Services (AWS), see [Vertica on Amazon Web Services](#).

AWS instance types

Vertica supports a range of AWS instance types to deploy cluster hosts or MC hosts on AWS. See [Supported AWS instance types](#) for a complete list of supported instance types.

Amazon machine images

Vertica provides tested and pre-configured Amazon Machine Images (AMIs) to deploy cluster hosts or MC hosts on AWS. The Vertica AMI allows users to configure their own storage using the officially supported version of Vertica Analytic Database for AWS.

See [Choose a Vertica AMI Operating Systems](#) for a list of operating systems currently available in Vertica AMIs.

Consider the following when using the Vertica AMI:

- Vertica develops AMIs on a slightly different schedule than the product release schedule. The AMIs for Vertica releases are available sometime following the initial release of Vertica software.
- Each Vertica AMI comes pre-configured with [default resource limit settings](#).
- Amazon does not support using 32-bit binaries on Amazon Linux 2.0 AMIs. Therefore, you cannot use the Vertica 32-bit client libraries on these AMIs.

IPv6 support

Vertica supports using IPv6 to identify nodes in the database cluster. However, AWS DNS resolution does not support IPv6. To have a cluster in AWS that uses IPv6, use the IPv6 IP addresses instead of using host names when installing Vertica and forming the cluster.

Containerized environments

Vertica supports running in any containerized environment that conforms to the performance requirements for [vioperf](#), [vnetperf](#), and [vcupperf](#).

As Vertica extends our support and deployment in containerized environments including Kubernetes, we cannot test and certify all possible configurations. However, OpenText makes an effort to ensure the success of its customers on recent versions of [supported operating systems](#) for the x86_64 architecture.

Vertica tests containers running on Docker. When the underlying hardware, OS, and container are configured correctly, the database system performs well. In some circumstances, there is a minor performance difference for queries made against a cold- or partially-populated depot when accessing communal storage.

Because your Vertica support contract covers Vertica products only, if you choose to run Vertica on a container configuration and you experience an issue that might not be caused by Vertica products, the Vertica Support team might ask you to reproduce the issue in a different environment, or engage with the support resources for your containerization technology.

For guidelines on how to provision and size your Kubernetes resources for Vertica deployments, see [Recommendations for Sizing Vertica Nodes and Clusters](#) in the Vertica Knowledge Base.

Note
If your Kubernetes cluster is in the cloud or on a managed service, each Vertica node must operate in the same availability zone.

VerticaDB operator and Vertica server version support

The [VerticaDB operator](#) supports Vertica server versions 11.0.0 and higher.

Container orchestration version support

Component	Supported Version
Kubernetes	1.21.1 and higher
Helm	3.5.0 and higher

Communal storage support

Containerized Vertica on Kubernetes supports the following public and private cloud providers:

- Amazon Web Services S3
- S3-compatible storage, such as [MinIO](#)
- Google Cloud Storage
- Azure Blob Storage
- Hadoop File Storage

Managed Kubernetes services support

Vertica supports the following managed Kubernetes services:

- Amazon Elastic Kubernetes Service (EKS)
- Google Kubernetes Engine (GKE)
- Azure Kubernetes Service (AKS)

Cluster management platform support

Vertica supports the Vertica DB operator and Vertica on Kubernetes environment on Red Hat OpenShift versions 4.8 and higher.

Virtualized environments

Vertica supports running in any virtualized environment that conforms to the performance requirements for [vioperf](#), [vnetperf](#), and [vcupperf](#).

Vertica does not support VM Snapshot.

Important
Vertica does not support suspending or migrating virtual machines while Vertica is running. A virtual machine that is suspended or migrated will in all likelihood be marked as DOWN to the Vertica cluster, reducing the overall performance of the cluster, or in a worst-case scenario, cause the cluster to crash.

Vertica has tested VMware, and when the underlying hardware is configured correctly, VMWare performs well. Customers have also deployed other virtualization configurations successfully. If you choose to run Vertica on a different virtualization configuration and you experience an issue, the Vertica Support team may ask you to reproduce the issue using a bare-metal environment to aid in troubleshooting. Depending on the details of the case, the Support team may also ask you to enter a support ticket with your virtualization vendor.

Guidelines for hypervisor and virtual machine configuration

There are many enterprise-grade hypervisors available on the market today, most of which support Linux-based virtual machines (VMs) in support of Vertica. When selecting and configuring your virtual environment, refer to the following guidelines.

- Do not over-subscribe the physical resources (CPU, memory, and network) of the hosting hardware. Many hypervisors allow you to take advantage of scaling out solutions by over-subscribing resources, for example, deploying more virtual CPUs than are physically installed in the host hardware. However, this type of deployment has a negative performance effect on a Vertica cluster.
- Configure the hypervisor to run low-latency, high-performance applications. This means that you should disable power-saving features and CPU frequency scaling on the hypervisor hardware because these technologies contribute to latency in the applications.
- Choose an operating system for the Vertica VMs that is supported by Vertica and by the hypervisor you are using. For some hypervisors, different operating systems may perform better than others. Vertica recommends that you investigate the options with your hypervisor vendor.
- Configure attached storage for high I/O performance. A virtualized Vertica node requires the same amount of disk I/O performance as a non-virtualized one. Vertica recommends that customers use the [vioperf](#) utility to validate the actual performance throughput being achieved on each VM.
- If you are providing storage using a shared storage device, make sure to validate disk I/O performance on the cluster as a whole to ensure that the shared resource(s) do not create a bottleneck. To achieve this validation, run the [vioperf](#) utility on all the cluster nodes simultaneously to determine the maximum disk I/O performance that can be achieved on each VM during times of heavy I/O load.
- Memory recommendations for Vertica running in a virtualized environment are no different than running in a non-virtualized environment. Vertica recommends that you allocate 8 GB of memory per virtual core. Again, do not over-subscribe the memory available in the hypervisor, because this creates contention for the physical resources, causes negative performance impacts, and possibly crashes the VMs.
- Networking requirements for a virtualized Vertica cluster are the same as for a non-virtualized cluster. Each node in the cluster must be able to communicate with all the other nodes, and latency in those communications can have a negative effect on cluster performance. When you are running multiple virtual machines on a single host server, the network communication is very fast. This occurs because the network traffic is virtualized in the memory space of the hypervisor and never leaves the physical server. However, if the cluster expands beyond a single host, the physical networking of that host can become a bottleneck for the cluster. If you are deploying in a virtual environment, that environment has a robust networking infrastructure that can provide the necessary connection speeds between physical hosts. In most cases, there will be multiple 10 GBE networking connections. Use the [vnetperf](#) utility to validate actual network performance speeds between nodes in your Vertica cluster.
- When deploying multiple Vertica VMs per physical host, the fewer the better. The goal of virtualization is to consolidate workloads to reduce overall hardware footprints. However, running multiple Vertica VMs on the same host can place the Vertica cluster in a situation where a single hardware failure can take down multiple nodes in a cluster, and perhaps even the cluster itself. Vertica recommends that when you virtualize a Vertica cluster, spread the VMs across as many physical hosts as possible, with an ideal goal of having one Vertica VM per physical host.
- While virtual networking can be very robust, Vertica has found that UDP broadcast traffic that is used in the spread daemon can be unreliable in most virtual environments, especially when those environments are spread across more than one physical host. In order for Vertica to function effectively in a virtualized environment, use the `--point-to-point` flag when you execute the `/opt/vertica/sbin/install_vertica` script. This flag configures the spread daemons to communicate directly with one another.

Hadoop integrations

OpenText supports Vertica 24.2.x with the following Hadoop distributions. OpenText expects Vertica to work with subsequent Hadoop distributions, and tests these later distributions as soon as practical.

Distribution	Supported Versions	Important Notes
Cloudera Distributed Hadoop (CDH)	<ul style="list-style-type: none">• 5.11 and higher*• 6.x	You cannot use versions 5.x in Eon Mode.
HortonWorks Data Platform (HDP)	<ul style="list-style-type: none">• 2.4 and higher*• 3.0	
Cloudera Data Platform (CDP)	<ul style="list-style-type: none">• 7.x	

* Vertica is phasing out support for this platform. See [End-of-support notices](#) for more information.

You must apply patches for the following issues: HDFS-8855 and HDFS-8696. See your Hadoop vendor documentation for further instructions.

MapR versions 5.2 and later are expected to work. You cannot use MapR in Eon Mode.

Apache Kafka integrations

You can use Vertica with the Apache Kafka message broker. For more information on Kafka integration, refer to [Apache Kafka integration](#).

Kafka versions

Vertica has been tested with different versions of Apache Kafka. The following table lists the Kafka versions that each Vertica version supports:

Apache Kafka Versions	Vertica Versions
2.0, 2.1, 2.2.1, 2.4.1	9.3.1 and higher
2.0, 2.1	9.3.0 and higher
1.0, 1.1, 2.0	9.2.1 and higher
0.11, 1.0, 1.1	9.1.1 and higher

Avro schema registry versions

The Vertica integration for Apache Kafka has been tested with the Avro schema registry distributed with Confluent 3.3.1 and 4.0.0. For more information about Confluent, see the [Confluent website](#).

Java versions

The data streaming job scheduler uses the Vertica JDBC library to connect to the target database, and requires Java 8 or later.

Apache Spark integrations

You can use the Vertica Connector for Apache Spark to transfer data between Vertica and Apache Spark. The following table shows the versions Apache Spark and Scala the Connector supports as well as the name of the Spark Connector JAR file to use for each combination:

Apache Spark Version	Scala Version	Spark Connector JAR file
2.0*	2.11	vertica-spark2.0_scala2.11.jar
2.1*	2.11	vertica-spark2.1_scala2.11.jar
2.2	2.11	vertica-spark2.1_scala2.11.jar
2.3	2.11	vertica-spark2.1_scala2.11.jar
2.4.1	2.11	vertica-spark2.1_scala2.11.jar
2.4.1	2.12	vertica-spark2.4-3.0_scala2.12.jar
3.0	2.12	vertica-spark2.4-3.0_scala2.12.jar

* Vertica is phasing out support for this Apache Spark version. See [End-of-support notices](#) for more information.

Notes

- A Spark Connector JAR file can support multiple versions of Spark. For example, [vertica-spark2.1_scala2.11.jar](#) supports Spark 2.1, 2.2, 2.3, and 2.4.1.
- Vertica recommends you always use the version of the Spark Connector shipped with your version of the Vertica server. When you upgrade your Vertica server, you should also upgrade your version of the Spark Connector.

For more information on Apache Spark integration, refer to [Apache Spark integration](#).

Linux volume manager (LVM)

Vertica 24.2.x supports Linux Volume Manager (LVM) on all supported operating systems.

LVM version supported

Vertica supports LVM version 2.02.66 or later, and must include device-mapper version 1.02.48 or later.

LVM configuration notes

In configuring LVM:

- When you create logical volumes with the `lvcreate` command, use the `readahead` option to set the read ahead sector count to greater than 2048 KB.
- You can use the default settings for all other LVM options.

LVM restrictions

The following limitations apply to LVM support:

- You cannot have physical drives shared across several nodes.
- Vertica supports linear logical volumes only. Vertica does not support striped or mirrored logical volumes.
- Vertica supports extending logical volumes (`lvextend`), but not reducing the size of a logical volume.
- Vertica recommends frequent backups.
- Vertica does not support LVM backup and restore, such as LVM snapshot and merge. Use the Vertica backup utility, `vbr`.
- Vertica does not support LVM space reclamation because space reclamation is duplicated when reducing the size of a logical volume.
- Vertica does not support LVM migration. Use Vertica Copy operations.
- Vertica does not support LVM high availability. Use Vertica high availability capabilities.
- Vertica does not support LVM RAID. Configure RAID at the disk controller level.

End-of-support notices

These end-of-support notices apply to specific client, Linux, Hadoop, and Kafka distributions.

End-of-support notices

Vertica no longer supports the following client platforms and server distributions:

- AIX (all releases)
- Amazon Linux 2017.09
- Debian 7.6, 7.7
- HP-UX (all releases)
- macOS 10.10
- Red Hat Enterprise Linux/CentOS 6.x
- SUSE 11SP3
- Ubuntu 12.04

New features

This guide briefly describes the new features introduced in the most recent releases of Vertica and provides references to detailed information in the documentation set.

For known and fixed issues in the most recent release, see the Vertica [Release Notes](#).

In this section

- [Deprecated and removed functionality](#)
- [New and changed in Vertica 24.2](#)

Deprecated and removed functionality

Vertica retires functionality in two phases:

- **Deprecated** : Vertica announces deprecated features and functionality in a major or minor release. Deprecated features remain in the product and are functional. Published release documentation announces deprecation on this page. When users access this functionality, it may return informational messages about its pending removal.
- **Removed** : Vertica removes a feature in a major or minor release that follows the deprecation announcement. Users can no longer access the functionality, and this page is updated to verify removal (see [History](#), below). Documentation that describes this functionality is removed, but remains in previous documentation versions.

Deprecated

The following functionality was deprecated and will be removed in future versions:

Release	Functionality	Notes
---------	---------------	-------

24.2	<code>OAuth2JITClient</code> security parameter.	Use <code>OAuth2JITRolesClaimName</code> instead.

Backup and restore

vbr target namespace creation

For **vbr** restore and replicate tasks, if the namespace specified in the `--target-namespace` parameter does not exist in the target database, **vbr** creates a namespace with the name specified in `--target-namespace` and the shard count of the source namespace, and then replicates or restores the objects to that namespace. See [Eon Mode database requirements](#) for details.

Client connectivity

Add and remove subclusters from routing rules

You can now [alter](#) a routing rule to add or remove subclusters. For details, see [ALTER ROUTING RULE](#).

Client drivers

OAuth support for ADO.NET

You can now use OAuth to connect to Vertica with ADO.NET.

The ADO.NET driver uses a simplified configuration scheme and takes a single [connection property](#): an access token retrieved by the client from the identity provider. Other flows like token refresh should be handled externally by the driver.

The JDBC and ODBC drivers will follow a similar configuration scheme in future versions.

For details on OAuth, see [OAuth 2.0 authentication](#).

Configuration

S3

Vertica now supports S3 access through a proxy. See the [S3Proxy configuration parameter](#) and the **proxy** field in S3BucketConfig.

Containers and Kubernetes

AWS Secrets Manager support

The VerticaDB operator can access secrets that you store in Amazon Web Service's [AWS Secrets Manager](#). This lets you maintain a single location for all sensitive information that you share between AWS and Vertica on Kubernetes.

For details, see [Secrets management](#).

VerticaRestorePointsQuery custom resource definition

Important

Beta Feature — For Test Environments Only

The VerticaRestorePointsQuery custom resource definition (CRD) retrieves restore points from an archive so that you can restore objects or roll back your database to a previous state. The custom resource (CR) specifies an archive and an optional period of time, and the VerticaDB operator retrieves restore points saved to the archive.

For details, see [VerticaRestorePointsQuery custom resource definition](#) and [Custom resource definition parameters](#).

VerticaDB CRD parameters

The [VerticaDB custom resource definition](#) provides the following CRD parameters to revive from a restore point:

- `restorePoint.archive`
- `restorePoint.id`
- `restorePoint.index`

You can use the [VerticaRestorePointsQuery custom resource definition](#) to retrieve saved restore points. For details about the CRD parameters, see [Custom resource definition parameters](#).

VerticaScrutinize custom resource definition

The VerticaScrutinize CRD runs [scrutinize](#) to collect diagnostic information about a VerticaDB CR. Vertica support might request you provide this diagnostic information while resolving support cases.

For details, see [VerticaScrutinize custom resource definition](#).

Namespace-scoped operators

You can use Helm charts to deploy the VerticaDB operator to watch only resources within a namespace. This requires that you set the following Helm chart parameters during installation:

- `controllers.enable`
- `controllers.scope`

For installation instructions, see [Installing the VerticaDB operator](#). For details about each parameter, see [Helm chart parameters](#).

Node Management Agent (NMA) sidecar

Vertica on Kubernetes runs the [Node Management Agent](#) in a sidecar container. The NMA exposes a REST API the VerticaDB operator uses to administer a cluster.

For details, see [Containerized Vertica on Kubernetes](#).

Support OpenShift restricted-v2 SCC

Vertica on Kubernetes supports the [restricted-v2](#) SCC for OpenShift. This is the most restrictive SCC available.

For details about the Vertica and OpenShift integration, see [Red Hat OpenShift integration](#).

Namespace-scoped operators

You can use Helm charts to deploy the VerticaDB operator to watch only resources within a namespace. This requires that you set the following Helm chart parameters during installation:

- `controllers.enable`
- `controllers.scope`

For installation instructions, see [Installing the VerticaDB operator](#). For details about each parameter, see [Helm chart parameters](#).

Containerized Kafka Scheduler

Vertica on Kubernetes supports the Kafka scheduler, a mechanism that automatically loads data from Kafka into a Vertica database table. Vertica packages the scheduler in a Helm chart so you can easily deploy a scheduler into your Kubernetes environment.

For details, see [Containerized Kafka Scheduler](#).

Data load

Automatic load triggers from AWS

Data loaders can process messages from SQS (Simple Queue Service) queues on AWS to load new files that are added to an S3 bucket. You define a [trigger](#) when creating the data loader, and Vertica automatically runs EXECUTE DATA LOADER in response to events in the queue.

Iceberg version 2

[CREATE EXTERNAL TABLE ICEBERG](#) supports both version 1 and version 2 of the metadata format.

Database management

HTTPS service

For details on the HTTPS service, see [HTTPS service](#).

View client connections

You can now use the [/v1/node/connections](#) endpoint to view the number of client connections to that node.

The following example shows that there are 11 total connections to the node at [127.0.0.1](#), 2 of which are just starting to initialize:

```
$ curl -sk -w "%n" --user dbadmin: "https://127.0.0.1:8443/v1/node/connections"
{
  "total_connections": 11,
  "user_sessions": 9,
  "initializing_connections": 2
}
```

Drain subclusters

You can now use the [/v1/subclusters/ subcluster_name /drain](#) endpoint to drain connections from a subcluster. This functionality was previously limited to the [SHUTDOWN_WITH_DRAIN](#) function. To verify the draining status of your subclusters, query [DRAINING_STATUS](#).

To drain the connections from a subcluster, you can send a POST request with one of the following:

- An empty body
- `{"cancel": false}`

For example:

```
$ curl -i -X POST -d '{"cancel": false}' -ks -w "%n" --user dbadmin: https://127.0.0.1:8443/v1/subclusters/sc_01/drain
HTTP/1.1 200 OK
Content-Type: application/json
Content-Length: 43
Connection: keep-alive
Server: oatpp/1.3.0
```

To stop draining connections, send a POST request with `{"cancel": true}`. For example:

```
$ curl -i -X POST -d '{"cancel": true}' -ks -w "%n" --user dbadmin: https://127.0.0.1:8443/v1/subclusters/sc_01/drain
HTTP/1.1 200 OK
Content-Type: application/json
Content-Length: 47
Connection: keep-alive
Server: oatpp/1.3.0
```

View subscription states

The new [/v1/subscriptions](#) endpoint returns information on a node's subscriptions to shards:

- `node_name`
- `shard_name`: The shard the node is subscribed to
- `subscription_state`: Subscription status (`ACTIVE`, `PENDING`, `PASSIVE`, or `REMOVING`)
- `is_primary`: Whether the subscription is a primary subscription

For example:

```
$ curl -i -sk -w "%n" --user dbadmin:my_password "https://127.0.0.1:8443/v1/subscriptions"
```

```
{
  "subscriptions_list":
  [
    {
      "node_name": "node08",
      "shard_name": "segment0004",
      "subscription_state": "ACTIVE",
      "is_primary": false
    },
    ...
  ]
}
```

Depot and data paths

The following [storage locations](#) fields have been added to the `/v1/nodes` and `/v1/nodes/ node_name` endpoints:

- `data_path` : A list of paths used to store USAGE 'DATA,TEMP' data.
- `depot_path` : The path used to store USAGE 'DEPOT' data.

For example:

Machine learning

Partial least squares (PLS) regression support

Vertica now supports PLS regression models.

Combining aspects of [PCA \(principal component analysis\)](#) and [linear regression](#), the PLS regression algorithm extracts a set of latent components that explain as much covariance as possible between the predictor and response variables, and then performs a regression that predicts response values using the extracted components.

This technique is particularly useful when the number of predictor variables is greater than the number of observations or the predictor variables are highly collinear. If either of these conditions is true of the input relation, ordinary linear regression fails to converge to an accurate model.

The [PLS_REG](#) function creates and trains a PLS model, and the [PREDICT_PLS_REG](#) function makes predictions on an input relation using a PLS model. For an in-depth example, see [PLS regression](#).

Vector autoregression (VAR) support

Vertica now supports VAR models.

VAR is a multivariate autoregressive time series algorithm that captures the relationship between multiple time series variables over time. Unlike AR, which only considers a single variable, VAR models incorporate feedback between different variables in the model, enabling the model to analyze how variables interact across lagged time steps. For example, with two variables—atmospheric pressure and rain accumulation—a VAR model could determine whether a drop in pressure tends to result in rain at a future date.

The [AUTOREGRESSOR](#) function automatically executes the algorithm that fits your input data:

- One value column: the function executes autoregression and returns a trained AR model.
- Multiple value columns: the function executes vector autoregression and returns a trained VAR model.

To make predictions with a VAR model, use the [PREDICT_AUTOREGRESSOR](#) function. See [VAR model example](#) for an extended example.

Security and authentication

OAuth2 security configuration parameters

There are new security configuration parameters that provide more control for users created with just-in-time (JIT) provisioning:

- [OAuth2JITRolesClaimName](#) : Identifies an IdP role claim. JIT-provisioned users are automatically assigned the claim roles as [default roles](#). This parameter replaces [OAuth2JITClient](#).
- [OAuth2JITGroupsClaimName](#) : Identifies an IdP group claim. JIT-provisioned users are automatically assigned the group claim name or group claim roles as default roles.
- [OAuth2JITForbiddenRoles](#) : Restricts the specified roles during automatic role assignment.

For details, see [Security parameters](#).

OAuth authentication parameters

Vertica provides the following OAuth authentication parameters that configure an OAuth authentication record that uses JIT provisioning:

- [groups_claim_name](#)
- [oauth2_jit_authorized_roles](#)
- [role_group_suffix](#)
- [roles_claim_name](#)

For details about each parameter, see [OAuth authentication parameters](#).

Automatic role assignment for JWT validation

Vertica supports automatic role assignment for just-in-time provisioned (JIT) users that use authentication records with the [JWT](#) validation type.

For details, see [Just-in-time user provisioning](#).

Fixed schedules for LDAP Link

The LDAP Link service now supports fixed schedules with [LDAPLinkCron](#). This acts as an alternative to [LDAPLinkInterval](#).

[LDAPLinkInterval](#) calculates the time of the next [synchronization](#) based on the completion time of the last synchronization. For example, suppose [LDAPLinkInterval](#) is set to 24 hours. If synchronization starts at 9:00 AM and finishes in 30 minutes, the next synchronization will occur at 9:30 AM the next day.

The new LDAPLinkCron parameter lets you designate an exact time for the synchronization with a **cron** expression so that the completion time doesn't affect the next runtime. Value separators are not currently supported.

For details, see [LDAP link parameters](#).

For example, to run the LDAP Link synchronization operation on the second day of every month at 7:00 PM:

```
=> ALTER DATABASE DEFAULT SET LDAPLinkCron='0 19 72 * *';
```

Stored procedures

Schedule steps and ranges

[Schedules](#) now support **cron** expressions that use steps and ranges. For details, see [Scheduled execution](#).

Getting started

Welcome to Getting Started. This guide walks you through the process of configuring a Vertica Analytics Platform database and running typical queries.

For short tutorial on how to install Vertica, create a database, and load data, see the [Quickstart guide](#).

In this section

- [Using this guide](#)
- [Quickstart guide](#)
- [Vertica community edition \(CE\)](#)
- [Vertica interfaces](#)
- [Introducing the VMart example database](#)
- [Installing and connecting to the VMart example database](#)
- [Querying data](#)
- [Backing up and restoring the database](#)
- [Using Database Designer to create a comprehensive design](#)
- [Restoring the status of your host](#)
- [Appendix: VMart example database schema, tables, and scripts](#)

Using this guide

This guide shows how to set up a Vertica database and run simple queries that perform common database tasks.

Who should use this guide?

This guide targets anyone who wants to learn how to create and run a Vertica database. This guide requires no special knowledge at this point, although a rudimentary knowledge of basic SQL commands is useful when you begin to run queries.

For short tutorial on how to install Vertica, create a database, and load data, see the [Quickstart guide](#).

What you need

The examples in this guide require one of the following:

- Vertica installed on one host or a cluster of hosts. Vertica recommends a minimum of three hosts in the cluster.
- Vertica installed on a virtual machine (VM).

For further instructions about installation, see [Installing Vertica](#).

Accessing your database

You access your database with an SSH client or the terminal utility in your Linux console, such as vsql. Throughout this guide, you use the following user interfaces:

- Linux command line (shell) interface
- [Administration Tools](#)
- [vsql client interface](#)
- [Management Console](#)

Quickstart guide

This section contains a short guide to setting up an installation environment for Vertica, loading data, and using various client drivers.

Examples in the documentation use `$` to denote a terminal prompt and `=>` to denote a vsql prompt.

Preparing

the Installation Environment

Installing

Vertica

Creating

the Database and Users

Loading

Sample Data

Monitoring

the Database

Connecting

Clients

In this section

- [Preparing the installation environment](#)
- [Installing Vertica](#)
- [Creating a database and users](#)
- [Loading sample data](#)
- [Monitoring the database](#)
- [Connecting clients](#)

Preparing the installation environment

Before installing Vertica, you must configure your environment.

To run Vertica Enterprise on-premises, follow the numbered instructions below.

To run the Vertica in a Virtual Machine instead, see [Vertica community edition \(CE\)](#).

1. Copy the installation file to your home directory. The example shows an `rpm` file for CentOS/RHEL, but you may have a `deb` file for Debian.

```
$ scp vertica-version.RHEL8.x86_64.rpm ~/
```

2. Identify the IP address of the current node.

```
$ ipconfig -a
```

If the `ipconfig` command is not found in your path, you can try running it directly using the paths `/sbin/ipconfig` or `/usr/sbin/ipconfig`. If neither of those work, use the `ip` command:

```
$ ip a
```

Note

The previous commands can return multiple addresses. For example, if your system is configured to use both IPv4 and IPv6 addressing, the commands will list two addresses, one for each address family. In this case, you must determine which address you want to use.

3. Ensure your packages are up to date. Run the command based on your distribution.

On CentOS and RedHat:

```
$ sudo yum update -y
```

On openSUSE:

```
$ sudo zypper up
```

On Debian and Ubuntu:

```
$ sudo apt-get update && sudo apt-get upgrade
```

4. Set swappiness to 0 (recommended).

```
$ sudo systemctl vm.swappiness=0
```

5. Verify that SELinux is running in permissive mode or is disabled.

```
$ sudo setenforce 0
```

6. Disable the system firewall.

```
$ sudo systemctl mask firewalld
$ sudo systemctl disable firewalld
$ sudo systemctl stop firewalld
```

7. [Install Vertica](#).

Installing Vertica

1. To install from the binary, run the command based on your distribution.

On CentOS, RedHat, and openSUSE:

```
$ sudo rpm -Uvh vertica-version.RHEL8.x86_64.rpm
```

On Debian and Ubuntu:

```
$ sudo dpkg -i vertica-version_amd64.deb
```

2. Run the installation script. The following command specifies the localhost, the rpm, a database admin, and home directory.

```
$ sudo /opt/vertica/sbin/install_vertica -s localhost -r vertica-version.RHEL8.x86_64.rpm
-u dbadmin -g dbadmin -d /home/dbadmin -p vertica -L -Y
```

3. Switch to the newly created dbadmin user.

```
$ su dbadmin
```

4. Run admintools and accept the EULA and operating license.

```
$ admintools
```

5. [Creating a database and users](#).

Creating a database and users

The admintools utility included in the installation provides a number of administrative functions. The following steps show how to create a database and users with this utility.

1. View the status of your cluster. It should return an empty table.

```
$ admintools -t view_cluster

DB | Host | State
---+-----+-----
```

2. Create a database called "vdb" in the home directory with the password "vertica". This command also sets the plaintext password "vertica" for both the database and dbadmin.

```
$ admintools -t create_db --data_path=/home/dbadmin --catalog_path=/home/dbadmin --database=vdb --password=vertica --hosts=localhost
```

3. Run vsql and enter "vertica" at the password prompt.

```
$ vsql
```

4. Create a user named "Mike" with the password "inventor."

```
=> CREATE USER Mike IDENTIFIED BY 'inventor';
```

5. Grant the USAGE permission on the public schema.

```
=> GRANT USAGE ON SCHEMA PUBLIC TO Mike;
```

6. [Load sample data](#).

Loading sample data

Vertica offers several solutions for loading files with structured and unstructured data, and from several formats.

Creating a sample data file

Create a sample CSV file called `cities.csv` with the following contents and save it to `/home/dbadmin/cities.csv`.

```
City,State,Zip,Population
Boston,MA,02108,694583
Chicago,IL,60601,2705994
Seattle,WA,98101,744955
Dallas,TX,75201,1345047
New York,NY,10001,8398748
```

Loading structured data from a file

1. Run vsql.

```
$ vsql
```

2. Create the cities table.

```
=> CREATE TABLE cities (
city   varchar(20),
state  char(2),
zip    int,
population int
);
```

3. Use the [COPY](#) statement to load the data from the [cities.csv](#) file. The following command logs exceptions and rejections in the home directory.

```
=> COPY cities FROM LOCAL '/home/dbadmin/cities.csv' DELIMITER ',' NULL '' EXCEPTIONS '/home/dbadmin/cities_exceptions.log'
REJECTED DATA '/home/dbadmin/cities_rejections.log';
```

4. Review the rejections log for what data was excluded. Here, the header was excluded.

```
$ cat /home/dbadmin/cities_rejections.log
```

```
City,State,Zip,Population
```

5. Review the exceptions for details on the error. In this case, the header failed Vertica's integer data type verification.

```
$ cat /home/dbadmin/cities_exceptions.log
```

```
COPY: Input record 1 has been rejected (Invalid integer format 'Zip' for column 3 (zip)).
Please see /home/dbadmin/cities_rejections.log, record 1 for the rejected record. This record was record 1 from cities.csv
```

6. To fix this, add SKIP 1 to the original COPY statement. This excludes the first row.

```
=> COPY cities FROM LOCAL '/home/dbadmin/cities.csv' DELIMITER, 'NULL'
EXCEPTIONS '/home/dbadmin/cities_exceptions.log'
REJECTED DATA '/home/dbadmin/cities_rejections.log' SKIP 1;
```

Loading unstructured data with flex tables

To load data from another source, Vertica uses Flex tables. Flex tables simplify data loading by allowing you to load unstructured or "semi-structured" data without having to create a schema or column definitions.

Supported formats include:

- Avro Data
- CEF
- CSV
- Delimited
- JSON

1. Create a table called `cities_flex`. Notice how it does not include column names or data types.

```
=> CREATE FLEXIBLE TABLE cities_flex();
```

2. Load the CSV file into the table.

```
=> COPY cities_flex FROM '/source/cities.csv' PARSER FDELIMITEDPARSER (delimiter=',');
```

3. Query the `cities_flex` table, specifying the column names from the original CSV file.

```
=> SELECT city, state FROM cities_flex;
```

Monitoring the database

This page includes a collection of general-purpose SQL statements useful for monitoring your database.

Check disk space

Check disk space used by tables.

```
=> SELECT projection_schema, anchor_table_name, to_char(sum(used_bytes)/1024/1024/1024,'999,999.99')
as disk_space_used_gb FROM
projection_storage
GROUP by projection_schema, anchor_table_name ORDER by
disk_space_used_gb desc limit 50;
```

Check total disk space used.

```
=> SELECT to_char(sum(used_bytes)/1024/1024/1024,'999,999.99') AS gb FROM projection_storage;
```

Check the amount of free disk space.

```
=> SELECT to_char(sum(disk_space_free_mb)/1024,'999,999,999') AS
disk_space_free_gb, to_char(sum(disk_space_used_mb)/1024,'999,999,999') AS
disk_space_used_gb FROM disk_storage;
```

Adjust data types

Change the Zip and Population columns from VARCHAR to INT.

```
=> UPDATE cities_flex_keys set data_type_guess='int' WHERE key_name='Zip';
=> UPDATE cities_flex_keys set data_type_guess='int' WHERE key_name='Population';
=> COMMIT;
```

Refresh the cities_flex_view with the new data types

```
=> SELECT build_flextable_view('cities_flex');
```

Materialize the flex table

Materialize the flex table and all columns into a persistent Vertica table.

```
=> CREATE TABLE cities AS SELECT * from cities_flex_view;
```

View user and role information

View user information.

```
=> SELECT user_name, is_super_user, resource_pool, memory_cap_kb, temp_space_cap_kb, run_time_cap FROM users;
```

Identify users.

```
=> SELECT * FROM user_sessions;
```

View queries by user.

```
=> SELECT * FROM query_profiles WHERE user_name ILIKE '%dbadmin%';
```

View roles.

```
=> SELECT * FROM roles;
```

View database information

View resource pool assignments.

```
=> SELECT user_name, resource_pool FROM users;
```

View table information.

```
=> SELECT table_name, is_flextable, is_temp_table, is_system_table, count(*) FROM tables GROUP by 1,2,3,4;
```

View projection information.

```
=> SELECT is_segmented, is_aggregate_projection, has_statistics, is_super_projection, count(*) FROM projections GROUP by 1,2,3,4,5;
```

View update information.

```
=> SELECT substr(query, 0, instr(query, ")")+1) count(*) FROM (SELECT transaction_id, statement_id, upper(query::varchar(30000)) as query FROM query_profiles WHERE regexp_like(query, '^\\s*update\\s','i')) sq GROUP BY 1 ORDER BY 1;
```

View active events.

```
=> SELECT * FROM active_events WHERE event_problem_description NOT ILIKE '%state to UP';
```

View backups.

```
=> SELECT * FROM database_backups;
```

View disk storage.

```
=> SELECT node_name, storage_path, storage_usage, storage_status, disk_space_free_percent FROM disk_storage;
```

View long-running queries

```
=> SELECT query_duration_us/1000000/60 AS query_duration_mins, table_name, user_name, processed_row_count AS rows_processed, substr(query,0,70) FROM query_profiles ORDER BY query_duration_us DESC LIMIT 250;
```

View sizes and counts of Read Optimized Store (ROS) containers.

```
=> SELECT node_name, projection_name, sum(ros_count), sum(ros_used_bytes) FROM projection_storage GROUP BY 1,2 HAVING sum(ros_count) >= 50 ORDER BY 3 DESC LIMIT 250;
```

View license information

View license consumption.

```
=> SELECT GET_COMPLIANCE_STATUS();
```

View how the database complies with your license.

```
=> SELECT AUDIT("");
```

Audit the database to check if it complies with raw storage allowance of your license.

```
=> SELECT AUDIT_LICENSE_SIZE;
```

Compare storage size of database the database and your license.

```
=> SELECT /*+(license_utilization)*/ audit_start_timestamp, database_size_bytes / (1024^3) AS database_size_gb, license_size_bytes / (1024^3) AS license_size_gb, usage_percent FROM v_catalog.license_audits ORDER BY audit_start_timestamp DESC LIMIT 30;
```

Connecting clients

Vertica supports several third-party clients. A list of Vertica client drivers can be found [here](#).

Connecting to DbVisualizer

1. Download the [DbVisualizer client application](#).
2. Create a database. Database Menu -> Create Database Connection.
3. Specify a name for the connection.
4. In the "Driver (JDBC)" field, specify Vertica.
5. In the "Database Server" field, specify an IP address.
6. In the "Database Port" field, specify a port number.
7. In the "Database Name" field, specify a database name.
8. In the "Database Userid" field, specify a username.
9. In the "Database Password" field, specify a password.
10. Use the "ping" function to test the connection.

Connecting to tableau

1. Download [Tableau](#).

2. Open Tableau Desktop.
3. Select Server Connection.
4. Select Vertica as the server type.
5. Set the Server IP.
6. Set the Port to "vdb".
7. Sign into the database.

Vertica community edition (CE)

The Vertica Community Edition (CE) is a free, limited license that Vertica provides users so that they can get a hands-on introduction to the platform. It allows you to deploy up to three nodes using a maximum of 1TB of data.

As part of the CE license, you agree to the collection of some anonymous, non-identifying usage data. This data lets Vertica understand how customers use the product, and helps guide the development of new features. None of your personal data is collected. For details on what is collected, see the Community Edition [End User License Agreement](#).

Vertica provides two options to use the Community Edition:

- CE container image. Container images require a container engine such as Docker Desktop. For installation details, see the [official Docker documentation](#).
- Vertica Community Edition Virtual Machine (Vertica CE VM), which is available for download on the [Vertica website](#).

CE container image

The CE image is a single-node, lightweight alternative to the Vertica CE VM. Vertica provides two options to get the CE container image:

- Pull the image from the [Vertica DockerHub registry](#).
- Build a custom CE image using the [one-node-ce GitHub repository](#). This requires the [free CE trial RPM](#).

The CE container environment includes the following:

- VMart example database
- admintools
- vsql
- Developer libraries

Important

Use the Vertica CE container image with the following limitations:

- There is a two-day verification period before CE licenses are issued.
- CE images expire after 1 year.

For more information about Vertica licensing, see [Managing licenses](#).

Vertica CE VM

The Vertica CE VM is a preconfigured Linux environment that includes:

- Vertica Community Edition with the VMart example database
- Management Console
- admintools
- vsql
- A tutorial that guides you through a series of common tasks

Note

The Vertica CE VM is not supported for production use.

For a preview of the tutorial included in the Vertica CE VM, see the [Vertica CE VM User Guide](#).

To download and install the Vertica CE VM, follow the instructions in the [Vertica CE VM Installation Guide](#).

Vertica interfaces

Vertica provides tools to perform administrative tasks quickly and easily:

- Management Console (MC) provides a unified view of your Vertica cluster through a browser connection.
- Administration Tools provides a simple graphical user interface for you to perform certain tasks such as starting and stopping a database, running Database Designer, and more.

The following sections provide detailed information about both tools.

Management Console

Management Console (MC) is the Vertica in-browser monitoring and management tool. Its graphical user interface provides a unified view of your Vertica database operations. Through user-friendly, step-by-step screens, you can create, configure, manage, and monitor your Vertica databases and their associated clusters. You can use MC to operate your Vertica database in Eon Mode or in Enterprise Mode. You can use MC to provision and deploy a Vertica Eon Mode database.

For detailed instructions, see [Management Console](#).

Administration tools

If possible, always run the Administration Tools using the database administrator account (dbadmin) on the administration host.

When you run Administration Tools, the **Main Menu** dialog box appears with a dark blue background and a title on top. The screen captures used in this documentation set are cropped down to the dialog box itself, as shown in the following screenshot.

The Administration Tools interface responds to mouse clicks in some terminal windows, but it might respond only to keystrokes. The following table is a quick reference to keystroke usage in the Administration Tools interface:

Key	Action
Return	Run selected command.
Tab	Cycle between OK , Cancel , Help , and menu.
Up/Down Arrow	Move cursor up and down in menu, window, or help file.
Space	Select item in list.
Character	Select corresponding command from menu.

For details, see [Using the Administration Tools](#) in the Administrator's Guide.

After your first login

The first time you log in as the database administrator and run the Administration Tools, complete the following steps:

1. Accept the end-user license agreement (EULA) to proceed.
A window displays, requesting the location of the license key file you downloaded from the OpenText website. The default path is `/tmp/vlicense.dat`.
2. Enter the absolute path to your license key and select **OK**.
3. To return to the command line, select **Exit** and click **OK**.

Introducing the VMart example database

Vertica ships with a sample multi-schema database called the VMart Example Database, which represents a database that might be used by a large supermarket (VMart) to access information about its products, customers, employees, and online and physical stores. Using this example, you can create, run, optimize, and test a multi-schema database.

The VMart database contains the following schema:

- **public** (automatically created in any newly created Vertica database)
- **store**
- **online_Sales**

VMart database location and scripts

If you installed Vertica from the RPM package, the VMart schema is installed in the `/opt/vertica/examples/VMart_Schema` directory. This folder contains the following script files that you can use to get started quickly. Use the scripts as templates for your own applications.

Script/file name	Description
vmart_count_data.sql	SQL script that counts rows of all example database tables, which you can use to verify load.
vmart_define_schema.sql	SQL script that defines the logical schema for each table and referential integrity constraints.
vmart_gen.cpp	Data generator source code (C++).
vmart_gen	Data generator executable file.
vmart_load_data.sql	SQL script that loads the generated sample data to the corresponding tables using COPY.
vmart_queries.sql	SQL script that contains concatenated sample queries for use as a training set for the Database Designer.
vmart_query_##.sql	SQL scripts that contain individual queries; for example, vmart_query_01 through vmart_query_09.sql
vmart_schema_drop.sql	SQL script that drops all example database tables.

For more information about the schema, tables, and queries included with the VMart example database, see the [Appendix](#).

Installing and connecting to the VMart example database

Follow the steps in this section to create the fully functioning, multi-schema VMart example database to run sample queries. The number of example databases you create within a single Vertica installation is limited only by the disk space available on your system. However, Vertica strongly recommends that you start only one example database at a time to avoid unpredictable results.

Vertica provides two options to install the example database:

- [Quick Installation Using a Script](#): This option lets you create the example database and start using it immediately. Use this method to bypass the schema and table creation processes and start querying immediately.
- [Advanced Installation](#). The advance option is an advanced-but-simple example database installation using the Administration Tools interface. Use this method to better understand the database creation process and practice creating a schema, creating tables, and loading data.

Note

Both installation methods create a database named VMart. If you try both installation methods, you need to drop the VMart database you created (see [Restoring the Status of Your Host](#)) or create the subsequent database with a new name. However, Vertica strongly recommends that you start only one example database at a time to avoid unpredictable results

This tutorial uses Vertica-provided queries, but if you create your own design and use your own queries, you can follow the same set of procedures.

In this section

- [Quick installation using a script](#)
- [Advanced installation](#)

Quick installation using a script

The script you need to perform a quick installation is located in `/opt/vertica/sbin` and is called `install_example`. This script creates a database on the default port (5433), generates data, creates the schema and a default superprojection, and loads the data. The folder also contains a `delete_example` script, which stops and drops the database.

1. In a terminal window, log in as the database administrator.

```
$ su dbadmin
```

```
Password: (your password)
```

2. Change to the `/examples` directory.
`$ cd /opt/vertica/examples`
3. Run the install script:
`$ /opt/vertica/sbin/install_example VMart`

After installation, you should see the following:

```
[dbadmin@localhost examples]$ /opt/vertica/sbin/install_example VMart
Installing VMart example example database
Mon Jul 22 06:57:40 PDT 2013
Creating Database
Completed
Generating Data. This may take a few minutes.
Completed
Creating schema
Completed
Loading 5 million rows of data. Please stand by.
Completed
Removing generated data files
Example data
```

The example database log files, `ExampleInstall.txt` and `ExampleDelete.txt`, are written to `/opt/vertica/examples/log`.

To start using your database, continue to [Connecting to the Database](#) in this guide. To drop the example database, see [Restoring the Status of Your Host](#) in this guide.

Advanced installation

To perform an advanced-but-simple installation, set up the VMart example database environment and then create the database using the Administration Tools or Management Console.

Note

If you installed the VMart database using the quick installation method, you cannot complete the following steps because the database has already been created.

To try the advanced installation, drop the example database (see [Restoring the Status of Your Host](#) on this guide) and perform the advanced Installation, or create a new example database with a different name. However, Vertica strongly recommends that you install only one example database at a time to avoid unpredictable results.

The advanced installation requires the following steps:

In this section

- [Step 1: setting up the example environment](#)
- [Step 2: creating the example database](#)
- [Step 3: connecting to the database](#)
- [Step 4: defining the database schema](#)
- [Step 5: loading data](#)

Step 1: setting up the example environment

1. Stop all databases running on the same host on which you plan to install your example database.
If you are unsure if other databases are running, run the Administration Tools and select **View Cluster State**. The State column should show DOWN values on pre-existing databases.
If databases are running, click **Stop Database** in the **Main Menu** of the Administration Tools interface and click **OK**.
2. In a terminal window, log in as the database administrator:

```
$ su dbadmin
Password:
```

3. Change to the `/VMart_Schema` directory.

```
$ cd /opt/vertica/examples/VMart_Schema
```

Do not change directories while following this tutorial. Some steps depend on being in a specific directory.

4. Run the sample data generator.

```
$ ./vmart_gen
```

5. Let the program run with the default parameters, which you can review in the README file.

```
Using default parameters
datadirectory = ./
numfiles = 1
seed = 2
null = ''
timefile = Time.txt
numfactsalesrows = 5000000
numfactororderrows = 300000
numprodkeys = 60000
numstorekeys = 250
numpromokeys = 1000
numvendkeys = 50
numcustkeys = 50000
numempkeys = 10000
numwarehousekeys = 100
numshippingkeys = 100
numonlinepagekeys = 1000
numcallcenterkeys = 200
numfactonlinesalesrows = 5000000
numinventoryfactrows = 300000
gen_load_script = false
Data Generated successfully !
Using default parameters
datadirectory = ./
numfiles = 1
seed = 2
null = ''
timefile = Time.txt
numfactsalesrows = 5000000
numfactororderrows = 300000
numprodkeys = 60000
numstorekeys = 250
numpromokeys = 1000
numvendkeys = 50
numcustkeys = 50000
numempkeys = 10000
numwarehousekeys = 100
numshippingkeys = 100
numonlinepagekeys = 1000
numcallcenterkeys = 200
numfactonlinesalesrows = 5000000
numinventoryfactrows = 300000
gen_load_script = false
Data Generated successfully !
```

6. If the `vmart_gen` executable does not work correctly, recompile it as follows, and run the sample data generator script again.

```
$ g++ vmart_gen.cpp -o vmart_gen
$ chmod +x vmart_gen
$ ./vmart_gen
```

Step 2: creating the example database

To create the example database: use the Administration Tools or Management Console, as described in this section.

Creating the example database using the administration tools

In this procedure, you create the example database using the Administration Tools. To use the Management Console, go to the next section.

Note

If you have not used Administration Tools before, see [Vertica interfaces](#).

1. Run the Administration Tools.

```
$ /opt/vertica/bin/admintools
```

or simply type **admintools**

2. From the Administration Tools **Main Menu**, click **Configuration Menu** and click **OK**.
3. Click **Create Database** and click **OK**.
4. Name the database **VMart** and click **OK**.

5. Click **OK** to bypass the password and click **Yes** to confirm.

There is no need for a database administrator password in this tutorial. When you create a production database, however, always specify an administrator password. Otherwise, the database is permanently set to trust authentication (no passwords).

6. Select the hosts you want to include from your Vertica cluster and click **OK**.

This example creates the database on a one-host cluster. Vertica recommends a minimum of three hosts in the cluster. If you are using the Vertica Community Edition, you are limited to three nodes.

7. Click **OK** to select the default paths for the data and catalog directories.

- Catalog and data paths must contain only alphanumeric characters and cannot have leading space characters. Failure to comply with these restrictions could result in database creation failure.
- When you create a production database, you'll likely specify other locations than the default. See [Prepare Disk Storage Locations](#) in the Administrator's Guide for more information.

8. Since this tutorial uses a one-host cluster, a K-safety warning appears. Click **OK**.

9. Click **Yes** to create the database.

During database creation, Vertica automatically creates a set of node definitions based on the database name and the names of the hosts you selected and returns a success message.

10. Click **OK** to close the **Database VMart created successfully** message.

Creating the example database using Management Console

In this procedure, you create the example database using Management Console. To use the Administration Tools, follow the steps in the preceding section.

Note

To use Management Console, the console should already be installed and you should be familiar with its concepts and layout. For details, see

1. Connect to Management Console and log in.
2. On the Home page, click **Infrastructure** to go to the Databases and Clusters page.
3. Click to select the appropriate existing cluster and click **Create Database** .
4. Follow the on-screen wizard, which prompts you to provide the following information:
 - Database name, which must be between 3–25 characters, starting with a letter, and followed by any combination of letters, numbers, or underscores.
 - (Optional) database administrator password for the database you want to create and connect to.
 - IP address of a node in your database cluster, typically the IP address of the administration host.
5. Click **Next** .

Step 3: connecting to the database

Regardless of the installation method you used, follow these steps to connect to the database.

1. As **dbadmin** , run the Administration Tools.
`$/opt/vertica/bin/admintools`
or simply type **admintools** .
2. If you are already in the Administration Tools, navigate to the Main Menu page.
3. Select **Connect to Database** , click **OK** .

To configure and load data into the VMart database, complete the following steps:

- [Step 4: defining the database schema](#)
- [Step 5: loading data](#)

If you installed the VMart database using the Quick Installation method, the schema, tables, and data are already defined. You can choose to drop the example database (see [Restoring the Status of Your Host](#) in this guide) and perform the Advanced Installation, or continue straight to [Querying Your Data](#) in this guide.

Step 4: defining the database schema

The VMart database installs with sample scripts with SQL commands that are intended to represent queries that might be used in a real business. The `vmart_define_schema.sql` script runs a script that defines the VMart schema and creates tables. You must run this script before you load data into the VMart database.

This script performs the following tasks:

- Defines two schemas in the VMart database schema: *online_sales* and *store* .
- Defines tables in both schemas.
- Defines constraints on those tables.

```
Vmart=> \i vmart_define_schema.sql
```

```
CREATE SCHEMA  
CREATE SCHEMA  
CREATE TABLE  
CREATE TABLE  
CREATE TABLE  
CREATE TABLE  
CREATE TABLE  
CREATE TABLE  
CREATE TABLE  
CREATE TABLE  
CREATE TABLE  
ALTER TABLE  
CREATE TABLE  
CREATE TABLE  
ALTER TABLE  
CREATE TABLE  
ALTER TABLE  
CREATE TABLE  
CREATE TABLE  
CREATE TABLE  
ALTER TABLE
```

Step 5: loading data

Now that you have created the schemas and tables, you can load data into a table by running the [vmart_load_data.sql](#) script. This script loads data from the 15 [.tbl](#) text files in [/opt/vertica/examples/VMart_Schema](#) into the tables that [vmart_design_schema.sql](#) created.

It might take several minutes to load the data on a typical hardware cluster. Check the load status by monitoring the [vertica.log](#) file, as described in [Monitoring Log Files](#) in the Administrator's Guide.

```
VMart=> \i vmart_load_data.sql
```

```
Rows Loaded

VMart=>
```

Querying data

The VMart database installs with sample scripts that contain SQL commands that represent queries that might be used in a real business. Use basic SQL commands to query the database, or try out the following command. Once you're comfortable running the example queries, you might want to write your own.

Note

The data that your queries return might differ from the example output shown in this guide because the sample data generator is random.

Type the following SQL command to return the values for five products with the lowest fat content in the Dairy department. The command selects the fat content from Dairy department products in the `product_dimension` table in the `public` schema, orders them from low to high and limits the output to the first five (the five lowest fat contents).

```
VMart => SELECT fat_content
        FROM ( SELECT DISTINCT fat_content
              FROM product_dimension
              WHERE department_description
                IN ('Dairy') ) AS food
        ORDER BY fat_content
        LIMIT 5;
```

Your results will be similar to the following:

```
fat_content
-----
80
81
82
83
84
(5 rows)
```

The preceding example is from the `vmart_query_01.sql` file. You can execute more sample queries using the scripts that installed with the VMart database or write your own. For a list of the sample queries supplied with Vertica, see [Appendix: VMart example database schema, tables, and scripts](#).

Backing up and restoring the database

Important
Inadequate security on backups can compromise overall database security. Be sure to secure backup locations and strictly limit access to backups only to users who already have permissions to access all database data.

Vertica supplies a comprehensive utility, `vbr`, that lets you back up and restore a full database, as well as create backups of specific schema or tables. You should back up your database regularly and before major or destructive operations.

All `vbr` operations rely on a configuration file that describes your database, backup locations, and other parameters. Typically you use the same configuration file for both the backup and restore operations. To create your first configuration file, copy one of the sample files for backup listed in [Sample vbr configuration files](#). Edit the copy to specify a snapshot (backup) name, your database details, and where to back up. The comments in the sample file guide you.

The following example shows a full backup:

```
$ vbr -t backup --config full-backup.ini
Starting backup of database VTDB.
Participating nodes: v_vmart_node0001, v_vmart_node0002, v_vmart_node0003, v_vmart_node0004.
Snapshotting database.
Snapshot complete.
Approximate bytes to copy: 2315056043 of 2356089422 total.
[=====] 100%
Copying backup metadata.
Finalizing backup.
Backup complete!
```

By default, there is no screen output other than the progress bar.

You can restore the entire database or selected schemas and tables. You can also use `vbr` to replicate data from one database to another or to copy an entire cluster. For more information about `vbr`, see [Backing up and restoring the database](#).

Using Database Designer to create a comprehensive design

Vertica Database Designer:

- Analyzes your logical schema, sample data, and, optionally, your sample queries.
- Creates a physical schema design (a set of projections) that can be deployed automatically or manually.
- Does not require specialized database knowledge.
- Can be run and rerun any time for additional optimization without stopping the database.
- Uses strategies to provide optimal query performance and data compression.

Use Database Designer to create a comprehensive design, which allows you to create projections for all tables in your database.

You can also use Database Designer to create an [incremental design](#), which creates projections for all tables referenced in the queries you supply.

You can create a comprehensive design with Database Designer using Management Console or through Administration Tools. You can also choose to run Database Designer [programmatically](#).

In this section

- [Running Database Designer with Management Console](#)
- [Running Database Designer with administration tools](#)

Running Database Designer with Management Console

In this tutorial, you'll create a [comprehensive design](#) with Database Designer through the Management Console interface. If, in the future, you have a query that you want to optimize, you can create an enhanced ([incremental](#)) design with additional projections. You can tune these projections specifically for the query you provide.

Note

To run Database Designer outside Administration Tools, you must be a dbadmin user. If you are not a dbadmin user, you must have the DBDUSER role assigned to you and own the tables for which you are designing projections. For details, see [Database Designer access requirements](#).

You can choose to create the design [manually](#) or use the Management Console wizard, as described below.

Important

Set your browser so it does not cache pages. If a browser caches pages, you might be unable to see the new design added.

Follow these steps to create a comprehensive design with the Management Console wizard:

1. Log in to Management Console.
2. Verify that your database is up and running.
3. Choose the database for which you want to create the design. You can find the database under the **Recent Databases** section or by clicking **Existing Infrastructure** to reach the Databases and Clusters page.
The database overview page opens.
4. At the bottom of the screen, click the **Design** button.
5. In the **New Design** dialog box, enter the design name.
6. Click **Wizard** to continue.
7. Create an initial design. For **Design Type**, select **Comprehensive** and click **Next**.
8. In the **Optimization Objective** window, select **Balance Load and Performance** to create a design that is balanced between database size and query performance. Click **Next**.
9. Select the schemas. Because the VMart design is a multi-schema database, select all three schemas (public, store, and online_sales) for your design in the **Select Sample Data** window. Click **Next**.
If you include a schema that contains tables without data, the design could be suboptimal. You can choose to continue, but Vertica recommends that you deselect the schemas that contain empty tables before you proceed.
10. Choose the K-safety value for your design. The K-Safety value determines the number of buddy projections you want Database Designer to create.
11. Choose Analyze Correlations Mode. Analyze Correlations Mode determines if Database Designer analyzes and considers column correlations when creating the design.
 - **Ignore:** When creating a design, ignore any column correlations in the specified tables.
 - **Consider existing:** Consider the existing correlations in the tables when creating the design. If you set the mode to 1, and there are no existing correlations, Database Designer does not consider correlations.

- **Analyze missing:** Analyze column correlations on tables where the correlation analysis was not previously performed. When creating the design, consider all column correlations (new and existing).
- **Analyze all:** Analyze all column correlations in the tables and consider them when creating the design. Even if correlations exist for a table, reanalyze the table for correlations.

Click **Next** .

12. Submit query files to Database Designer in one of two ways:

- Supply your own query files by selecting the **Browse** button.
- Click **Use Query Repository** , which submits recently executed queries from the QUERY_REQUESTS system table.

Click **Next** .

13. In the **Execution Options** window, select any of the following options:

- **Analyze statistics** : Select this option to run statistics automatically after design deployment, so Database Designer can make better decisions for its proposed design.
- **Auto-build** : Select this option to run Database Designer as soon as you complete the wizard. This option only builds the proposed design.
- **Auto-deploy** : Select this option for auto-build designs that you want to deploy automatically.

14. Click **Submit Design** . The Database Designer page opens:

- If you chose to automatically deploy your design, Database Designer executes in the background.
- If you did not select the **Auto-build** or **Auto-deploy** options, you can click **Build Design** or **Deploy Design** on the Database Designer page.

15. In the **My Designs** pane, view the status of your design:

- When the deployment completes, the **My Design** pane shows **Design Deployed** .
- The event history window shows the details of the design build and deployment.

To run Database Designer with Administration Tools, see [Running Database Designer with administration tools](#) in this guide.

Running Database Designer with administration tools

In this procedure, you create a comprehensive design with Database Designer using the Administration Tools interface. If, in the future, you have a query that you want to optimize, you can create an enhanced (incremental) design with additional projections. You can tune these projections specifically for the query you provide. See [Incremental Design](#) for more information.

Follow these steps to create the comprehensive design using Database Designer in Administration Tools:

1. If you are not in Administration Tools, exit the vsql session and access Administration Tools:
 - Type `\q` to exit vsql.
 - Type `admintools` to access the Administration Tools Main Menu.
2. Start the database for which you want to create a design.
3. From the **Main Menu** , click **Configuration Menu** and then click **OK** .
4. From the **Configuration Menu** , click **Run Database Designer** and then click **OK** .
5. When the **Select a database for design** dialog box opens, select **VMart** and then click **OK** .
If you are prompted to enter the password for the database, click **OK** to bypass the message. Because no password was assigned when you installed the VMart database, you do not need to enter one now.
6. Click **OK** to accept the default directory for storing Database Designer output and log files.
7. In the **Database Designer** window, enter a name for the design, for example, `vmart_design` , and click **OK** . Design names can contain only alphanumeric characters or underscores. No other special characters are allowed.
8. Create a complete initial design. In the **Design Type** window, click **Comprehensive** and click **OK** .
9. Select the schemas. Because the VMart design is a multi-schema database, you can select all three schemas (online_sales, public, and store) for your design. Click **OK** .

If you include a schema that contains tables without data, the Administration Tools notifies you that designing for tables without data could be suboptimal. You can choose to continue, but Vertica recommends that you deselect the schemas that contain empty tables before you proceed.

10. In the **Design Options** window, accept all three options and click **OK** .

The three options are:

- **Optimize with queries:** Supplying the Database Designer with queries is especially important if you want to optimize the database design for query performance. Vertica recommends that you limit the design input to 100 queries.
- **Update statistics:** Accurate statistics help the Database Designer choose the best strategy for data compression. If you select this option, the database statistics are updated to maximize design quality.
- **Deploy design:** The new design deploys automatically. During deployment, new projections are added, some existing projections retained, and any necessary existing projections removed. Any new projections are refreshed to populate them with data.

11. Because you selected the **Optimize with queries** option, you must enter the full path to the file containing the queries that will be run on your database. In this example, it is:

```
/opt/vertica/examples/VMart_Schema/vmart_queries.sql
```

The queries in the query file must be delimited with semicolons (;). The last query must end with a semicolon (;).

12. Choose the K-safety value you want and click **OK** . The design K-Safety determines the number of buddy projections you want Database Designer to create.
If you create a comprehensive design on a single node, you are not prompted to enter a K-safety value.
13. In the **Optimization Objective** window, select **Balanced query/load performance** to create a design that is balanced between database size and query performance. Click **OK** .
14. When the informational message displays, click **Proceed** .
Database Designer automatically performs these actions:
 - Sets up the design session.
 - Examines table data.
 - Loads queries from the query file you provided (in this example, `/opt/vertica/examples/VMart_Schema/vmart_queries.sql`).
 - Creates the design.Deploys the design or saves a SQL file containing the commands to create the design, based on your selections in the Design Options window. Depending on system resources, the design process could take several minutes. You should allow this process to complete uninterrupted. If you must cancel the session, use Ctrl+C.
15. When Database Designer finishes, press **Enter** to return to the Administration Tools menu. Examine the steps taken to create the design. The files are in the directory you specified to store the output and log files. In this example, that directory is `/opt/vertica/examples/VMart_Schema` . For more information about the script files, see [About Database Designer](#) .

For additional information about managing your designs, see [Creating a database design](#) in the Administrator's Guide.

Restoring the status of your host

When you finish the tutorial, you can restore your host machines to their original state. Use the following instructions to clean up your host and start over from scratch.

Stopping and dropping the database

Follow these steps to stop and/or drop your database. A database must be stopped before it can be dropped.

1. If connected to the database, disconnect by typing `\q` .
2. In the Administration Tools **Main Menu** dialog box, click **Stop Database** and click **OK** .
3. In the **Select database to stop** window, select the database you want to stop and click **OK** .
4. After stopping the database, click **Configuration Menu** and click **OK** .
5. Click **Drop Database** and click **OK** .
6. In the **Select database to drop** window, select the database you want to drop and click **OK** .
7. Click **Yes** to confirm.
8. In the next window type `yes` (lowercase) to confirm and click **OK** .

Alternatively, use the `delete_example` script, which stops and drops the database:

1. If connected to the database, disconnect by typing `\q` .
2. In the Administration Tools **Main Menu** dialog box, select **Exit** .
3. Log in as the database administrator.
4. Change to the `/examples` directory.

```
$ cd /opt/vertica/examples
```

5. Run the `delete_example` script.

```
$ /opt/vertica/sbin/delete_example Vmart
```

Uninstalling Vertica

See [Uninstall Vertica](#) .

Optional steps

You can also choose to:

- Remove the `dbadmin` account on all cluster hosts.
- Remove any example database directories you created.

Appendix: VMart example database schema, tables, and scripts

This appendix provides detailed information about the VMart example database's schema, tables, and scripts.

The VMart example database contains three different schemas:

- [public](#)
- [store](#)
- [online_sales](#)

The term “schema” has several related meanings in Vertica:

- In SQL statements, a schema refers to named namespace for a logical schema.
- Logical schema refers to a set of tables and constraints.
- Physical schema refers to a set of projections.

[Tables](#) identifies the three schemas and all the data tables in the VMart database. Each schema contains tables that are created and loaded during database installation. See the schema maps for a list of tables and their contents:

- [Public schema map](#)
- [Store schema map](#)
- [online_sales schema map](#)

[Sample scripts](#) describes the sample scripts that contain SQL commands that represent queries that might be used in a real business using a VMart-like database. Once you’re comfortable running the example queries, you might want to write your own.

In this section

- [Tables](#)
- [Public schema map](#)
- [Store schema map](#)
- [online_sales schema map](#)
- [Sample scripts](#)

Tables

The three schemas in the VMart database include the following tables:

public Schema	store Schema	online_sales Schema
inventory_fact	store_orders_fact	online_sales_fact
customer_dimension	store_sales_fact	call_center_dimension
date_dimension	store_dimension	online_page_dimension
employee_dimension		
product_dimension		
promotion_dimension		
shipping_dimension		
vendor_dimension		
warehouse_dimension		

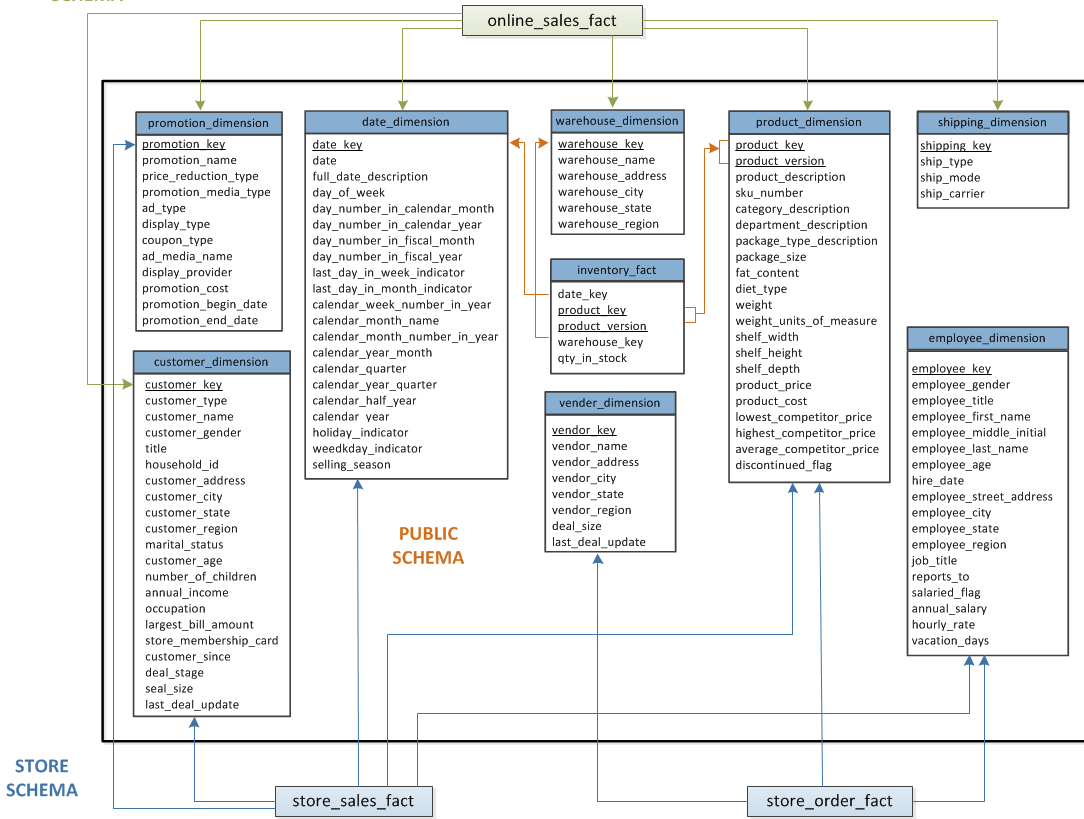

Public schema map

The [public](#) schema is a snowflake schema. The following graphic illustrates the public schema and its relationships with tables in the [online_sales](#) and [store](#) schemas.

The subsequent subsections describe database tables.

ONLINE_SALES SCHEMA

underline indicates relationship

In this section

- [inventory_fact](#)
- [customer_dimension](#)
- [date_dimension](#)
- [employee_dimension](#)
- [product_dimension](#)
- [promotion_dimension](#)
- [shipping_dimension](#)
- [vendor_dimension](#)
- [warehouse_dimension](#)

inventory_fact

This table contains information about each product in inventory.

Column Name	Data Type	NULLs
date_key	INTEGER	No
product_key	INTEGER	No
product_version	INTEGER	No
warehouse_key	INTEGER	No
qty_in_stock	INTEGER	No

customer_dimension

This table contains information about all the retail chain's customers.

Column Name	Data Type	NULLs
-------------	-----------	-------

customer_key	INTEGER	No
customer_type	VARCHAR(16)	Yes
customer_name	VARCHAR(256)	Yes
customer_gender	VARCHAR(8)	Yes
title	VARCHAR(8)	Yes
household_id	INTEGER	Yes
customer_address	VARCHAR(256)	Yes
customer_city	VARCHAR(64)	Yes
customer_state	CHAR(2)	Yes
customer_region	VARCHAR(64)	Yes
marital_status	VARCHAR(32)	Yes
customer_age	INTEGER	Yes
number_of_children	INTEGER	Yes
annual_income	INTEGER	Yes
occupation	VARCHAR(64)	Yes
largest_bill_amount	INTEGER	Yes
store_membership_card	INTEGER	Yes
customer_since	DATE	Yes
deal_stage	VARCHAR(32)	Yes
deal_size	INTEGER	Yes
last_deal_update	DATE	Yes

date_dimension

This table contains information about dates. It is generated from a file containing correct date/time data.

Column Name	Data Type	NULLs
date_key	INTEGER	No
date	DATE	Yes
full_date_description	VARCHAR(18)	Yes
day_of_week	VARCHAR(9)	Yes
day_number_in_calendar_month	INTEGER	Yes

day_number_in_calendar_year	INTEGER	Yes
day_number_in_fiscal_month	INTEGER	Yes
day_number_in_fiscal_year	INTEGER	Yes
last_day_in_week_indicator	INTEGER	Yes
last_day_in_month_indicator	INTEGER	Yes
calendar_week_number_in_year	INTEGER	Yes
calendar_month_name	VARCHAR(9)	Yes
calendar_month_number_in_year	INTEGER	Yes
calendar_year_month	CHAR(7)	Yes
calendar_quarter	INTEGER	Yes
calendar_year_quarter	CHAR(7)	Yes
calendar_half_year	INTEGER	Yes
calendar_year	INTEGER	Yes
holiday_indicator	VARCHAR(10)	Yes
weekday_indicator	CHAR(7)	Yes
selling_season	VARCHAR(32)	Yes

employee_dimension

This table contains information about all the people who work for the retail chain.

Column Name	Data Type	NULLs
employee_key	INTEGER	No
employee_gender	VARCHAR(8)	Yes
courtesy_title	VARCHAR(8)	Yes
employee_first_name	VARCHAR(64)	Yes
employee_middle_initial	VARCHAR(8)	Yes
employee_last_name	VARCHAR(64)	Yes
employee_age	INTEGER	Yes
hire_date	DATE	Yes
employee_street_address	VARCHAR(256)	Yes
employee_city	VARCHAR(64)	Yes

employee_state	CHAR(2)	Yes
employee_region	CHAR(32)	Yes
job_title	VARCHAR(64)	Yes
reports_to	INTEGER	Yes
salaried_flag	INTEGER	Yes
annual_salary	INTEGER	Yes
hourly_rate	FLOAT	Yes
vacation_days	INTEGER	Yes

product_dimension

This table describes all products sold by the department store chain.

Column Name	Data Type	NULLs
product_key	INTEGER	No
product_version	INTEGER	No
product_description	VARCHAR(128)	Yes
sku_number	CHAR(32)	Yes
category_description	CHAR(32)	Yes
department_description	CHAR(32)	Yes
package_type_description	CHAR(32)	Yes
package_size	CHAR(32)	Yes
fat_content	INTEGER	Yes
diet_type	CHAR(32)	Yes
weight	INTEGER	Yes
weight_units_of_measure	CHAR(32)	Yes
shelf_width	INTEGER	Yes
shelf_height	INTEGER	Yes
shelf_depth	INTEGER	Yes
product_price	INTEGER	Yes
product_cost	INTEGER	Yes
lowest_competitor_price	INTEGER	Yes

highest_competitor_price	INTEGER	Yes
average_competitor_price	INTEGER	Yes
discontinued_flag	INTEGER	Yes

promotion_dimension

This table describes every promotion ever done by the retail chain.

Column Name	Data Type	NULLs
promotion_key	INTEGER	No
promotion_name	VARCHAR(128)	Yes
price_reduction_type	VARCHAR(32)	Yes
promotion_media_type	VARCHAR(32)	Yes
ad_type	VARCHAR(32)	Yes
display_type	VARCHAR(32)	Yes
coupon_type	VARCHAR(32)	Yes
ad_media_name	VARCHAR(32)	Yes
display_provider	VARCHAR(128)	Yes
promotion_cost	INTEGER	Yes
promotion_begin_date	DATE	Yes
promotion_end_date	DATE	Yes

shipping_dimension

This table contains information about shipping companies that the retail chain uses.

Column Name	Data Type	NULLs
shipping_key	INTEGER	No
ship_type	CHAR(30)	Yes
ship_mode	CHAR(10)	Yes
ship_carrier	CHAR(20)	Yes

vendor_dimension

This table contains information about each vendor that provides products sold through the retail chain.

Column Name	Data Type	NULLs
-------------	-----------	-------

vendor_key	INTEGER	No
vendor_name	VARCHAR(64)	Yes
vendor_address	VARCHAR(64)	Yes
vendor_city	VARCHAR(64)	Yes
vendor_state	CHAR(2)	Yes
vendor_region	VARCHAR(32)	Yes
deal_size	INTEGER	Yes
last_deal_update	DATE	Yes

warehouse_dimension

This table provides information about each of the chain's warehouses.

Column Name	Data Type	NULLs
warehouse_key	INTEGER	No
warehouse_name	VARCHAR(20)	Yes
warehouse_address	VARCHAR(256)	Yes
warehouse_city	VARCHAR(60)	Yes
warehouse_state	CHAR(2)	Yes
warehouse_region	VARCHAR(32)	Yes

Store schema map

The **store** schema is a snowflake schema that contains information about the retail chain's bricks-and-mortar stores. The following graphic illustrates the **store** schema and its relationship with tables in the **public** schema.

The subsequent subsections describe database tables.

In this section

- [store_orders_fact](#)
- [store_sales_fact](#)
- [store_dimension](#)

store_orders_fact

This table contains information about all orders made at the company's brick-and-mortar stores.

Column Name	Data Type	NULLs
<code>product_key</code>	INTEGER	No
<code>product_version</code>	INTEGER	No
<code>store_key</code>	INTEGER	No
<code>vendor_key</code>	INTEGER	No
<code>employee_key</code>	INTEGER	No
<code>order_number</code>	INTEGER	No
<code>date_ordered</code>	DATE	Yes
<code>date_shipped</code>	DATE	Yes
<code>expected_delivery_date</code>	DATE	Yes
<code>date_delivered</code>	DATE	Yes
<code>quantity_ordered</code>	INTEGER	Yes
<code>quantity_delivered</code>	INTEGER	Yes
<code>shipper_name</code>	VARCHAR(32)	Yes

unit_price	INTEGER	Yes
shipping_cost	INTEGER	Yes
total_order_cost	INTEGER	Yes
quantity_in_stock	INTEGER	Yes
reorder_level	INTEGER	Yes
overstock_ceiling	INTEGER	Yes

store_sales_fact

This table contains information about all sales made at the company's brick-and-mortar stores.

Column Name	Data Type	NULLs
date_key	INTEGER	No
product_key	INTEGER	No
product_version	INTEGER	No
store_key	INTEGER	No
promotion_key	INTEGER	No
customer_key	INTEGER	No
employee_key	INTEGER	No
pos_transaction_number	INTEGER	No
sales_quantity	INTEGER	Yes
sales_dollar_amount	INTEGER	Yes
cost_dollar_amount	INTEGER	Yes
gross_profit_dollar_amount	INTEGER	Yes
transaction_type	VARCHAR(16)	Yes
transaction_time	TIME	Yes
tender_type	VARCHAR(8)	Yes

store_dimension

This table contains information about each brick-and-mortar store within the retail chain.

Column Name	Data Type	NULLs
store_key	INTEGER	No
store_name	VARCHAR(64)	Yes

store_number	INTEGER	Yes
store_address	VARCHAR(256)	Yes
store_city	VARCHAR(64)	Yes
store_state	CHAR(2)	Yes
store_region	VARCHAR(64)	Yes
floor_plan_type	VARCHAR(32)	Yes
photo_processing_type	VARCHAR(32)	Yes
financial_service_type	VARCHAR(32)	Yes
selling_square_footage	INTEGER	Yes
total_square_footage	INTEGER	Yes
first_open_date	DATE	Yes
last_remodel_date	DATE	Yes
number_of_employees	INTEGER	Yes
annual_shrinkage	INTEGER	Yes
foot_traffic	INTEGER	Yes
monthly_rent_cost	INTEGER	Yes

online_sales schema map

The [online_sales](#) schema is a snowflake schema that contains information about the retail chains. The following graphic illustrates the [online_sales](#) schema and its relationship with tables in the [public](#) schema.

The subsequent subsections describe database tables.

PUBLIC SCHEMA

In this section

- [online_sales_fact](#)
- [call_center_dimension](#)
- [online_page_dimension](#)

online_sales_fact

This table describes all the items purchased through the online store front.

Column Name	Data Type	NULLs
sale_date_key	INTEGER	No
ship_date_key	INTEGER	No
product_key	INTEGER	No
product_version	INTEGER	No
customer_key	INTEGER	No
call_center_key	INTEGER	No
online_page_key	INTEGER	No
shipping_key	INTEGER	No
warehouse_key	INTEGER	No
promotion_key	INTEGER	No
pos_transaction_number	INTEGER	No
sales_quantity	INTEGER	Yes
sales_dollar_amount	FLOAT	Yes
ship_dollar_amount	FLOAT	Yes

net_dollar_amount	FLOAT	Yes
cost_dollar_amount	FLOAT	Yes
gross_profit_dollar_amount	FLOAT	Yes
transaction_type	VARCHAR(16)	Yes

call_center_dimension

This table describes all the chain's call centers.

Column Name	Data Type	NULLs
call_center_key	INTEGER	No
cc_closed_date	DATE	Yes
cc_open_date	DATE	Yes
cc_date	VARCHAR(50)	Yes
cc_class	VARCHAR(50)	Yes
cc_employees	INTEGER	Yes
cc_hours	CHAR(20)	Yes
cc_manager	VARCHAR(40)	Yes
cc_address	VARCHAR(256)	Yes
cc_city	VARCHAR(64)	Yes
cc_state	CHAR(2)	Yes
cc_region	VARCHAR(64)	Yes

online_page_dimension

This table describes all the pages in the online store front.

Column Name	Data Type	NULLs
online_page_key	INTEGER	No
start_date	DATE	Yes
end_date	DATE	Yes
page_number	INTEGER	Yes
page_description	VARCHAR(100)	Yes
page_type	VARCHAR(100)	Yes

Sample scripts

You can create your own queries, but the VMart example directory includes sample query script files to help you get started quickly.

You can find the following sample scripts at this path /opt/vertica/examples/VMart_Schema.

To run any of the scripts, enter

```
=> \i <script_name>
```

Alternatively, type the commands from the script file manually.

Note

The data that your queries return might differ from the example output shown in this guide because the sample data generator is random.

vmart_query_01.sql

```
-- vmart_query_01.sql
-- FROM clause subquery
-- Return the values for five products with the
-- lowest-fat content in the Dairy department
SELECT fat_content
FROM (
  SELECT DISTINCT fat_content
  FROM product_dimension
  WHERE department_description
  IN ('Dairy') ) AS food
ORDER BY fat_content
LIMIT 5;
```

Output

```
fat_content
-----
      80
      81
      82
      83
      84
(5 rows)
```

vmart_query_02.sql

```
-- vmart_query_02.sql
-- WHERE clause subquery
-- Asks for all orders placed by stores located in Massachusetts
-- and by vendors located elsewhere before March 1, 2003:
SELECT order_number, date_ordered
FROM store.store_orders_fact orders
WHERE orders.store_key IN (
  SELECT store_key
  FROM store.store_dimension
  WHERE store_state = 'MA')
  AND orders.vendor_key NOT IN (
  SELECT vendor_key
  FROM public.vendor_dimension
  WHERE vendor_state = 'MA')
  AND date_ordered < '2012-03-01';
```

Output

```
order_number | date_ordered
-----+-----

Architecture

Understanding how Vertica works helps you effectively design, build, operate, and maintain a Vertica database. This section assumes that you are familiar with the basic concepts and terminology of relational database management systems and SQL.

Column storage

Vertica stores data in a column format so it can be queried for best performance. Compared to row-based storage, column storage reduces disk I/O, making it ideal for read-intensive workloads. Vertica reads only the columns needed to answer the query. Columns are encoded and compressed to further improve performance.

Vertica uses a number of different encoding strategies, depending on column data type, table cardinality, and sort order. Encoding increases performance because there is less disk I/O during query execution. In addition, you can store more data in less space.

Compression allows a column store to occupy substantially less storage than a row store. In a column store, every value stored in a projection column has the same data type. This greatly facilitates compression, particularly in sorted columns. In a row store, each value of a row can have a different data type, resulting in a much less effective use of compression. The efficient storage methods that Vertica uses allow you to maintain more historical data in physical storage.

Projections

A *projection* consists of a set of columns with the same sort order, defined by a column to sort by or a sequence of columns by which to sort. Like an index or materialized view in a traditional database, a projection accelerates query processing. When you write queries in terms of the original tables, the query uses the projections to return query results. For more information, see [Projections](#).

Projections are distributed and replicated across nodes in your cluster, ensuring that if one node becomes unavailable, another copy of the data remains available. This redundancy is called *K-safety*.

Automatic data replication, failover, and recovery provide for active redundancy, which increases performance. Nodes recover automatically by querying the system.

Eon and Enterprise Modes

A Vertica database runs in one of two modes: Eon or Enterprise. Both modes can be deployed on-premises or in the cloud. In Eon Mode, compute and storage are separate; the database uses shared communal storage, and you can add or remove nodes or subclusters based on demand. In Enterprise Mode, each database node has a share of the data and queries are distributed to take advantage of data locality. Understanding the differences between these modes is key. See [Eon vs. Enterprise Mode](#).

In this section

- [Eon vs. Enterprise Mode](#)
- [Eon Mode concepts](#)
- [Enterprise Mode concepts](#)

Eon vs. Enterprise Mode

A Vertica database runs in one of two modes: Eon or Enterprise. Both modes can be deployed on-premises or in the cloud. Understanding the difference between these two modes is key. If you are deploying a Vertica database, you must decide which mode to run it in early in your deployment planning. If you are using an already-deployed Vertica database, you should understand how each mode affects loading and querying data.

Vertica databases running in Eon and Enterprise modes store their data differently:

- Eon Mode databases use communal storage for their data.
- Enterprise Mode databases store data locally in the file system of nodes that make up the database.

These different storage methods lead to a number of important differences between the two modes.

Storage overview

Eon Mode stores data in a shared object store called communal storage:

When deployed in a cloud environment, Vertica stores its data in a cloud-based storage container, such as an AWS S3 bucket. When deployed on-premises, Vertica stores data in a locally-deployed object store, such as a Pure Storage FlashBlade appliance. Separating the persistent data storage from the compute resources (the nodes that load data and process queries) provides flexibility.

Enterprise Mode stores data across the filesystems of the database nodes:

Enterprise Mode Vertica Cluster

Each node is responsible for storing and processing a portion of the data. The data is co-located on the nodes in both cloud-based and on-premises databases to provide resiliency in the event of node failure. Having the data located close to the computing power offers a different set of advantages. When a node is added to the cluster, or comes back online after being unavailable, it automatically queries other nodes to update its local data.

Key advantages of each mode

The different ways Eon Mode and Enterprise Mode store data give each mode an advantage in different environments. The following table summarizes these differences.

Chief advantages of...	Where database mode is...	
	Eon	Enterprise
Cloud	<ul style="list-style-type: none"> Easily scaled up or down to meet changing workloads and reduce costs. Workloads can be isolated to a subcluster of nodes. Virtually no limits on database size. Most cloud providers offer essentially unlimited data storage (for a price). 	Works in most cloud platforms. Eon Mode works in specific cloud providers.
On-premises	<ul style="list-style-type: none"> Workloads can be isolated to a subset of nodes called a subcluster. Can increase storage without adding nodes (and, if the object store supports hot plugging, without downtime). 	No additional hardware needed beyond the servers that make up the database cluster.

Note

You can migrate an Enterprise Mode database to Eon with the meta-function [MIGRATE_ENTERPRISE_TO_EON](#). For details on using this meta-function, see [Migrating an enterprise database to Eon Mode](#).

Performance

Eon Mode and Enterprise Mode databases have roughly the same performance in the same environment when properly configured.

An Eon Mode database typically enables caching data from communal storage on a node's [local depot](#), which the node uses to process queries. With depot caching enabled, query performance on an Eon Mode database is equivalent to an Enterprise Mode database, where each node stores a portion of the database locally. In both cases, nodes access locally-stored data to resolve queries.

To further improve performance, you can enable depot *warming* on an Eon Mode database. When depot warming is enabled, a node that is undergoing startup preemptively loads its depot with frequently queried and pinned data. When the node completes startup and begins to execute queries, its depot already contains much of the data it needs to process those queries. This reduces the need to fetch data from communal storage, and expedites query performance accordingly.

Query performance in an Eon Mode database is liable to decline if its depot is too small. A small depot increases the chance that a query will require data that is not in the depot. That results in nodes having to retrieve data from communal storage more frequently.

Note

When comparing a cloud-based Eon Mode database to an on-premises Enterprise Mode database, performance differences are typically due to the overall performance impact of a shared cloud-based virtual environment compared to on-premises dedicated hardware. An Enterprise Mode

database running in the same cloud would have the same performance as the Eon Mode, in most cases.

Installation

An Eon Mode database must have an object store to store its data communally. An Enterprise Mode database does not require any additional storage hardware beyond the storage installed on its nodes. Depending on the environment you've chosen for your Vertica database (especially if you are installing on-premises), the need to configure an object store may make your installation a bit more complex.

Because Enterprise Mode does not need additional hardware for data storage, it can be a bit simpler to install. An on-premises Eon Mode install needs additional hardware and additional configuration for the object store that provides the communal storage.

Enterprise Mode is especially useful for development environments because it does not require additional hardware beyond the nodes you use to run it. You can even create a single-node Enterprise Mode database, either on physical hardware or on a virtual machine. You can download a preconfigured single-node Enterprise Mode virtual machine that is ready to run. See [Vertica community edition \(CE\)](#) for more information.

Deploying an Eon Mode database in a cloud environment is usually simpler than an on-premises install. The cloud environments provide their own object store for you. For example, when you deploy an Eon Mode database in Amazon's AWS, you just need to create an S3 bucket for the communal data store. You then provide the S3 URL to Vertica when creating the database. There is no need to install and configure a separate data store.

Deploying an Enterprise Mode database in the cloud is similar to installing one on-premises. The virtual machines you create in the cloud must have enough local storage to store your database's data.

Workload isolation

You often want to prevent intensive workloads from interfering with other potentially time-sensitive workloads. For example, you may want to isolate ETL workloads from querying workloads. Groups of users that rely on real-time analytics can be isolated from groups that are running batched reports.

Eon Mode databases offer the best workload isolation option. It allows you to create groups of nodes called [subclusters](#) that isolate workloads. A query only runs on the nodes in a single subcluster. It does not affect nodes outside the subcluster. You can assign different groups of users to different subclusters.

In an Eon Mode database, subclusters and scalability work hand in hand. You often add, remove, stop, and start entire subclusters of nodes, rather than scaling nodes individually.

Enterprise Mode does not offer subclusters to isolate workloads. You can use features such as resource pools and other settings to give specific queries priority and access to more resources. However, these features do not truly isolate workloads as subclusters do. See [Managing workloads](#) for an explanation of managing workloads using these features.

Scalability

You can scale a Vertica database by adding or removing nodes to meet changing analytic needs. Scalability is usually more important in cloud environments where you are paying by the hour for each node in your database. If your database isn't busy, there is no reason to have underused nodes costing you money. You can reduce the number of nodes in your database during quiet times (weekends and holidays, for example) to save money.

Scalability is usually less important for on-premises installations. There are limited additional costs involved in having nodes running when they are not fully in use.

An Enterprise Mode database scales less efficiently than an Eon Mode one. When an Enterprise Mode database scales, it must re-segment (rebalance) its data to be spread among the new number of nodes.

Rebalancing is an expensive operation. When scaling the database up, Vertica must break up files and physically move a percentage of the data from the original nodes to the new nodes. When scaling down, Vertica must move the data off of the nodes that are being removed and distribute it among the remaining nodes. The database is not available during rebalancing. This process can take 12, 24, or even 36 hours to complete, depending on the size of the database. After scaling up an Enterprise Mode database, queries should run faster because each node is responsible for less data. Therefore, each node has less work to do to process each query. Scaling down an Enterprise Mode database usually has the opposite effect—queries will run slower. See [Elastic cluster](#) for more information on scaling an Enterprise Mode database.

Eon Mode databases scale more efficiently because data storage is separate from the computing resources.

When you scale up an Eon Mode database, the database's data does not need to be re-segmented. Instead, the additional nodes subscribe to preexisting segments (called shards) of data in communal storage. When expanding the cluster, Vertica rebalances the shards assigned to each node, rather than physically splitting the data storage and moving in between nodes. The new nodes prepare to process queries by retrieving data from the communal storage to fill their depots (a local cache of data from the communal storage). The database remains available while scaling and the process takes minutes rather than hours to complete.

Note

Node subscriptions are slightly more complicated than shown in the previous diagram. To ensure [K-safety](#), nodes actually subscribe to multiple shards to act as a backup in case the primary shard subscriber goes down. Eon Mode databases also group data into one or more namespaces, which each divide data into a set number of [shards](#). See [Namespaces and shards](#) for details.

If the number of shards is equal to or higher than the new number of nodes (as shown in the previous diagram), then query performance improves after expanding the cluster. Each node is responsible for processing less data, so the same queries will run faster after you scale the cluster up.

You can also scale your database up to improve query throughput. Query throughput improves the number of queries processed by your database in parallel. You usually care about query throughput when your workload contains many, shorter-running queries ("dashboard queries"). To improve throughput, add more nodes to your database in a new [subcluster](#). The subcluster isolates queries run by clients connected to it from the other nodes in the database. Subclusters work independently and in parallel. Isolating the workloads means that your database runs more queries simultaneously.

If a subcluster contains more nodes than the number of shards in a namespace, multiple nodes subscribe to the same shard. In this case, Vertica uses a feature called elastic crunch scaling to execute the query faster. Vertica divides the responsibility for the data in each shard between the subscribing nodes. Each node only needs to process a subset of the data in the shard it subscribes to. Having less data to process means that each node usually finishes its part of the query faster. This often translates into the query finishing its executing sooner.

Important

Always try to make the number of shards in a namespace a multiple of the number of nodes in your Eon Mode subclusters. Vertica recommends using shard counts that are multiples of twelve.

A mismatch between the number of shards and the number of nodes can impact performance. For example, suppose you have a twelve-shard namespace. If you expand a subcluster from six to eight nodes, some nodes would subscribe to two shards while others subscribe to only one shard. This means that some nodes have to do twice the work of the other nodes in the subcluster during queries. In this case, you see no benefit from adding the two new nodes because the nodes subscribing to two shards become a bottleneck.

Scaling down an Eon Mode database works similarly. Shutting down entire subclusters reduced your database's query throughput. If you remove nodes from a subcluster, the remaining nodes subscribe to any shards that do not have a subscriber. This process is fast, and the database remains running while it is happening.

Expandability

As you load more data into your database, you may eventually need to expand its data storage. Because Eon Mode databases separate compute from storage, you often expand its storage without changing the number of nodes.

In a cloud environment, you usually do not have a limit on storage. For example, an AWS S3 bucket can store as much data as you want. As long as you are willing to pay for additional storage charges, you do not have to worry about expanding your database's storage.

When you install Eon Mode on-premises, how you expand storage depends on the object store you are using. For example, Pure Storage FlashBlades support hot plugging new blades to add additional storage. This feature lets you expand the storage in your Eon Mode database with no downtime.

In most cases, you usually query a subset of the data in your database (called the working data set). Eon Mode's decoupling of compute and storage let you size your compute (the number of nodes in your database) to the working data set and your desired performance rather than to the entire data set.

For example, if you are performing time series analysis in which the active data set is usually the last 30 days, you can size your cluster to manage 30 days' worth of data. Data older than 30 days simply grows in communal storage. The only reason you need to add more nodes to your Eon Mode database is to meet additional workloads. On the other hand, if you want very high performance on a small data set, you can add as many nodes as you need to obtain the performance you want.

In an Enterprise Mode database, nodes are responsible for storage as well as compute. Because of the tight coupling between compute and storage, the best way to expand storage in an Enterprise Mode database is to add new nodes. As mentioned in the [Scalability](#) section, adding nodes to an Enterprise Mode database requires rebalancing the existing data in the database.

Due to the disruption rebalancing causes to the database, you usually expand the storage in an Enterprise Mode database infrequently. When you do expand its storage, you usually add significant amounts of storage to allow for future growth.

Adding nodes to increase storage has the downside that you may be adding compute power to your cluster that isn't really necessary. For example, suppose you are performing time-series analysis that focuses on recent data and your current cluster offers you enough query performance to meet your needs. However, you need to add additional storage to keep historical data. In this case, adding new nodes to your database for additional storage adds computing power you really don't need. Your queries may run a bit faster. However, the slight benefit of faster results probably does not justify the costs of adding more computing power.

Eon Mode concepts

Eon Mode separates the computational processes from the communal storage layer of your database. This separation gives you the ability to store your data in a single location (such as S3 on AWS or Pure Storage) and elastically vary the number of compute nodes connected to that location according to your computational needs. You can adjust the size of your cluster without interrupting analytic workloads, adding or removing nodes as the volume of work changes

The following topics explain how Eon Mode works.

In this section

- [Eon Mode architecture](#)
- [Namespaces and shards](#)
- [Subclusters](#)
- [Elasticity](#)
- [Data integrity and high availability in an Eon Mode database](#)
- [Stopping, starting, terminating, and reviving Eon Mode database clusters](#)

Eon Mode architecture

Eon Mode separates the computational resources from the storage layer of your database. This separation gives you the ability to store your data in a single location. You can elastically vary the number of nodes connected to that location according to your computational needs. Adjusting the size of your cluster does not interrupt analytic workloads.

You can create an Eon Mode database either in a cloud environment, or on-premises on your own systems.

Eon Mode Vertica Cluster

Eon Mode is suited to a range of needs and data volumes. Because compute and storage are separate, you can scale them separately.

Communal storage

Instead of storing data locally, Eon Mode uses a single communal storage location for all data and the catalog (metadata). Communal storage is the database's centralized storage location, shared among the database nodes. Communal storage is based on an object store, such as Amazon's S3 in the cloud or a PureStorage FlashBlade appliance in an on-premises deployment. In either case, Vertica relies on the object store to maintain the durable copy of the data.

Communal storage has the following properties:

- Communal storage in the cloud is more resilient and less susceptible to data loss due to storage failures than storage on disk on individual machines.
- Any data can be read by any node using the same path.
- Capacity is not limited by disk space on nodes.
- Because data is stored communally, you can elastically scale your cluster to meet changing demands. If the data were stored locally on the nodes, adding or removing nodes would require moving significant amounts of data between nodes to either move it off of nodes that are being removed, or onto newly-created nodes.

Communal storage locations are listed in the [STORAGE_LOCATIONS](#) system table with a SHARING_TYPE of COMMUNAL.

Within communal storage, the data is grouped into one or more [namespaces](#). Namespaces segment their associated data into a specific number of portions called [shards](#). Shards are how Vertica divides data among the nodes in the database. Nodes subscribe to particular shards, with subscriptions balanced among the nodes. When loading or querying data, each node is responsible for the data in the shards it subscribes to. See [Namespaces and shards](#) for more information.

Depot storage

A potential drawback of communal storage is its speed, especially in cloud environments. Accessing data from a shared cloud location is slower than reading it from local disk. Also, the connection to communal storage can become a bottleneck if many nodes are reading data from it at once. To improve data access speed, the nodes in an Eon Mode database maintain a local disk cache of data called the depot. When executing a query, the

nodes first check whether the data it needs is in the depot. If it is, then the node finishes the query using the local copy of the data. If the data is not in the depot, the node fetches the data from communal storage, and saves a copy in the depot.

The node stores newly-loaded data in the depot before sending it to communal storage. See [Loading Data](#) below for more details.

By default, Vertica sets the maximum size of the depot to be 60% of the total disk space of the filesystem that stores the depot. You can adjust the size of the depot if you wish. Vertica limits the size of the depot to a maximum of 80% of the filesystem that contains it. This upper limit ensures enough disk space for other uses, such as temporary files that Vertica creates during data loads.

Each node also stores a local copy of the database catalog.

Loading data

In Eon Mode, COPY statements usually write to read optimized store (ROS) files in a node's depot to improve performance. The COPY statement segments, sorts, and compresses for high optimization. Before the statement commits, Vertica ships the ROS files to communal storage.

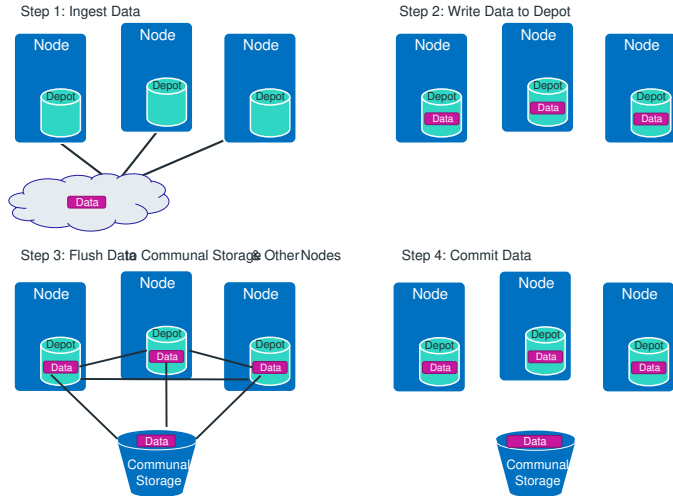

Because a load is buffered in the depot on the node executing the load, the size of your depot limits the amount of data you can load in a single operation. Unless you perform multiple loads in parallel sessions, you are unlikely to encounter this limit.

Note

If your data loads do overflow the amount of space in your database's depot, you can tell Vertica to bypass the depot and load data directly into communal storage. You enable direct writes to communal storage by setting the `UseDepotForWrites` configuration parameter to 0. See [Eon Mode parameters](#) for more information. Once you have completed your large data load, switch this parameter back to 1 to re-enable writing to the depot.

At load time, the participating nodes write files to the depot and synchronously send them to communal storage. The data is also sent to all nodes that subscribe to the shard into which the data is being loaded. This mechanism of sending data to peers at load time improves performance if a node goes down, because the cache of the peers who take over for the down node is already warm. The file compaction mechanism (mergeout) puts its output files into the cache and also uploads them to the communal storage.

The following diagram shows the flow of data during a COPY statement.

Querying data

Vertica uses a slightly different process to plan queries in Eon Mode to incorporate the sharding mechanism and remote storage. Instead of using a fixed-segmentation scheme to distribute data to each node, Vertica uses the sharding mechanism to segment the data in each namespace into a specific number of shards that at least one (and usually more) nodes subscribes to. When the optimizer selects a projection, the layout for the projection is determined by the participating subscriptions for the session. The optimizer generates query plans that are equivalent to those in Enterprise Mode. It selects one of the nodes that subscribes to each shard to participate in query execution.

Vertica first tries to use data in the depot to resolve a query. When the data in the depot cannot resolve the query, Vertica reads from the communal storage. You could see an impact on query performance when a substantial number of your queries read from the communal storage. If this is the case, then you should consider re-sizing your depot or use depot system tables to get a better idea of what is causing the issue. You can use [ALTER LOCATION SIZE](#) to change depot size.

Workload isolation and scaling

Eon Mode lets you define subclusters that divide up your nodes to isolate workloads from one another. You can also use subclusters to ensure that scaling down your cluster does not result in Vertica going into read-only mode to maintain data integrity. See [Subclusters](#) for more information.

Namespaces and shards

In Eon Mode, Vertica stores data communally in a shared data storage location, such as in S3 when running on AWS. All nodes are capable of accessing all of the data in the communal storage location. In order for nodes to divide the work of processing queries, Vertica must divide the data between them in some way. It breaks the data in communal storage into segments called shards. Each node in your database subscribes to a subset of the shards in the communal storage location. The shards in your communal storage location are similar to a collection of segmented projections in an Enterprise Mode database.

The number of shards that data is segmented into depends on the namespace to which the data belongs. Namespaces are a collection of schemas and tables in your database that are grouped under a common name and segmented into the number of shards defined by that namespace. In Eon Mode databases, namespaces represent the top-level data structure in the Vertica object hierarchy. Every table and schema in the database belongs to a namespace. By default, the database contains a single default namespace, `default_namespace`, which is created on database creation with the shard count specified during setup. For details about creating and managing additional namespaces, see [Managing namespaces](#).

When you create a table or schema, you can specify the namespace under which the object is created. If no namespace is specified, the table or schema is created under the default namespace.

Note

A replica shard is a special type of shard that stores metadata for unsegmented projections. Each namespace has one replica shard, which exists on all nodes.

Eon Mode Vertica Shard Subscriptions for default_namespace

The recommended shard count for a namespace depends primarily on the size of the tables it will store and the expected complexity of its query workload. Generally, the database performs best when large tables with complex analytic workloads are segmented with a larger shard count, and small tables with simpler query workloads are segmented with a smaller shard count. Aligning table size and query complexity to shard count also minimizes catalog overhead. If your database contains namespaces with a range of shard counts, you can create tables and schemas under the namespace that best fits these basic sizing guidelines, or those of your particular use case. For a more detailed exploration of shard count and various use cases, see [Configuring your Vertica cluster for Eon Mode](#).

For the best performance, the number of shards you choose for a namespace should be no greater than twice the number of nodes. At most, you should limit the shard:node ratio to no greater than 3:1. MC warns you to take all aspects of shard count into consideration. The number of shards should always be a multiple (or an even divisor) of the number of nodes in your database. See [Choosing shard and initial node counts](#) for more information.

For efficiency, Vertica transfers metadata about shards directly between database nodes. This peer-to-peer transfer applies only to metadata; the actual data that is stored on each node gets copied from communal storage to the node's depot as needed.

Shard subscriptions and k-safety

When [k-safety](#) is 1 or higher (high availability), each shard has more than one node subscribing to it in each subcluster. One of the subscribers is responsible for executing queries involving the shard. The other subscribers act as backups. If the main subscriber shuts down or is stopped, then another subscriber takes its place. See [Data integrity and high availability in an Eon Mode database](#) for more information.

Each shard in a namespace has a primary subscriber. This subscriber is a [primary node](#) that maintains the data in the shard by planning [Tuple Mover](#) operations on it. This node can delegate executing these actions to another node in the database cluster. See [Tuple mover](#) for more information about these operations. If the primary subscriber node is stopped or goes down, Vertica chooses another primary node that subscribes to the shard

as the shard's primary subscriber. If all of the primary nodes that subscribe to a shard go down or are stopped, your database goes into read-only mode to maintain data integrity. Any primary node that is the sole subscriber to a shard is a [critical node](#).

Subclusters

Because Eon Mode separates compute and storage, you can create subclusters within your cluster to isolate work. For example, you might want to dedicate some nodes to loading data and others to executing queries. Or you might want to create subclusters for dedicated groups of users (who might have different priorities). You can also use subclusters to organize nodes into groups for easily scaling your cluster up and down.

Every node in your Eon Mode database must belong to a subcluster. This requirement means your database must always have at least one subcluster. When you create a new Eon Mode database, Vertica creates a subcluster named `default_subcluster` that contains the nodes you create on database creation. If you add nodes to your database without assigning them to a subcluster, Vertica adds them to the default subcluster. You can choose to designate another subcluster as the default subcluster, or rename `default_subcluster` to something more descriptive. See [Altering subcluster settings](#) for more information.

Using subclusters for work isolation

Database administrators are often concerned about workload management. Intense analytics queries can consume so many resources that they interfere with other important database tasks, such as data loading. Subclusters help you prevent resource issues by isolating workloads from one another.

In Eon Mode, by default, queries only run on nodes in the subcluster that contains the initiator node. For example, consider the two subclusters shown in the following diagram. If you are connected to Node 4, your queries would run on nodes 4 through 9.

Similarly, queries started on Node 1 only run on nodes 1 through 3.

This isolation lets you configure your database cluster to prevent workloads from interfering with each other. You can assign subclusters to specific tasks such as loading data, performing in-depth analytics, and short-running dashboard queries. You can also create subclusters for different groups in your organization, so their workloads do not interfere with one another. You can tune the settings of each subcluster (resource pools, for example) to match their specific workloads.

Subcluster types

There are two types of subclusters: primary and secondary.

Primary subclusters form the core of your Vertica database. They are responsible for planning the maintenance of the data in the communal storage. Your primary subclusters must always be running. If all of your primary subclusters shut down, your database shuts down because it cannot maintain the data in communal storage without a primary subcluster.

Usually, you have just a single primary subcluster in your database. You can choose to have multiple primary subclusters. Additional primary subclusters can make your database more resilient to having primary nodes fail. However, additional primary subclusters make your database less scalable. You usually do not dynamically add or remove nodes from primary subclusters or shut them down to scale your database. In most cases, a single primary subcluster is enough.

Secondary subclusters are designed for dynamic scaling: you add and remove or start and stop these subclusters based on your analytic needs. They are not essential for maintaining your database's data. So, you can easily add, remove, and scale up or down secondary subclusters without impacting the database's ability to run normally.

The nodes in the subcluster inherit their primary or secondary status from the subcluster that contains them; primary subclusters contain primary nodes and secondary subclusters contain secondary nodes.

Subcluster types and elastic scaling

The most important difference between primary and secondary subclusters is their impact on how Vertica determines whether the database is [K-Safe](#) and has a [quorum](#). Vertica only considers the nodes in primary subclusters when determining whether all of the shards in the database have a subscribing node. It also only considers primary nodes when determining whether more than half the nodes in the database are running (also known as having a quorum of primary nodes). If either of these conditions is not met, the database goes into read-only mode to prevent data corruption. See [Data integrity and high availability in an Eon Mode database](#) for more information about how Vertica maintains data integrity.

Vertica does not consider the secondary nodes when determining whether the database has shard coverage or a quorum of nodes. This fact makes secondary subclusters perfect for managing groups of nodes that you plan to expand and reduce dynamically. You can stop or remove an entire subcluster of secondary nodes without forcing the database into read-only mode.

Minimum subcluster size for K-safe databases

In a [K-safe](#) database, subclusters must have at least three nodes in order to operate. Each subcluster tries to maintain subscriptions to all shards in the database. If a subcluster has less than three nodes, it cannot maintain redundant shard coverage where each shard has at least two subscribers in the subcluster. Without redundant coverage, the subcluster cannot continue processing queries if it loses a node. Vertica returns an error if you attempt to rebalance shards in a subcluster with less than three nodes in a K-safe database.

Elasticity

Elasticity refers to the ability for you adjust your database to changing workload demands by adding or removing nodes. When your database experiences high demand, you can add new nodes or start stopped nodes to increase the amount of compute available. When your database experiences lower demands (such as during holidays or weekends) you can stop or terminate nodes to save money. You can also gradually add nodes over time as your database demands grow.

All nodes in an Eon Mode database belong to a subcluster. By choosing which subclusters get new nodes, you can affect how the new nodes impact your database. There are two goals you can achieve when adding nodes to your database:

- Improve query throughput: higher throughput means your database processes more queries simultaneously. You often want to improve throughput when you have a workload of "dashboard queries": many relatively short-running queries. In this case, speeding up the processing of individual queries is not as important as having more queries run in parallel.
- Improve query performance: higher query performance means that your complex in-depth analytic queries complete faster.

Scaling for query throughput

To scale for query throughput, add additional nodes to your database in one or more new [subclusters](#). Subclusters independently process queries: a query only runs on the nodes in the subcluster containing the initiator node. By adding one or more subclusters, your database can process more queries at the same time. For the best performance, add the same number of nodes to each new subcluster as there are shards in the database. For example, if you have 6 shards in your database, add 6 nodes to each new subcluster you create.

To take advantage of the improved throughput offered by the new subclusters, clients must connect to them. The best way to ensure your users take advantage of the subclusters you have added for throughput scaling is to create connection load balancing policies that spread client connections across the all nodes in all of these subclusters. See [Connection load balancing policies](#) for more information.

Subclusters also organize nodes into groups that can easily be stopped or started together. This feature makes expanding and shrinking your database easier. See [Starting and stopping subclusters](#) for details.

Scaling for query performance

To improve the performance of individual queries in a subcluster, add more nodes to it. Queries perform faster when there is more computing power available to process them.

Adding nodes is especially effective if your subcluster has less nodes than there are shards in the database. In this case, nodes are responsible for processing data in multiple shards. When you add more nodes, the newly-added nodes take over responsibility for some of the shards. With less data to process, each node finishes their part of the query faster, resulting in better overall performance. For the best performance, make the number of nodes in the subcluster an even divisor of (or equal to) the number of shards in the database. For example, in a 12-shard database, make the number of nodes in the subcluster 3, 6, or 12.

You can further improve query performance by adding more nodes than there are shards in the database. When nodes outnumber shards, multiple nodes in the subcluster subscribe to the same shard. In this case, when processing a query, Vertica uses a feature called elastic crunch scaling (ECS) to have all of the nodes in the subcluster take part in the query. ECS assigns a subset of the data in each shard to the shard's subscribers. For example, in six-node subcluster in a a three-shard database, each shard has two subscribers. ECS assigns each of the subscribers half of the data in the shard to process during queries. In most cases, with less data to process, the nodes finish executing the query faster. When adding more nodes than shards to a subcluster, make the number of nodes a multiple of the number of shards to ensure an even distribution. For example, in a three-shard database, make the number of nodes in the subcluster 6, 9, 12, and so on.

Using different subclusters for different query types

You do not have to choose one form of elasticity over the other in your database. You can create a group of subclusters to improve query throughput and one or more subclusters that improve query performance. The difference between the two subcluster types is mainly the number of subclusters you create and the number of nodes they contain. To improve throughput, add a multiple subclusters that contain a number of nodes that is equal to or less than the number of shards in the database. The more subclusters you add, the greater the throughput you achieve. To improve query performance, add one or more subclusters where the number of nodes is a multiple of the number of shards in the database.

Once you have created your set of subclusters, you must have clients connect to the correct subcluster for the types of queries they will run. For clients executing frequent, simple dashboard queries, create a connection load balancing policy that connects them to nodes in the throughput scaling subclusters. For clients running more complex analytic queries, create another load balancing policy that connects them to nodes in the performance scaling subcluster.

For details on scaling your Eon Mode database, see [Scaling your Eon Mode database](#).

Data integrity and high availability in an Eon Mode database

The nodes in your Eon Mode database's [primary subclusters](#) are responsible for maintaining the data in your database. These nodes (collectively called the database's [primary nodes](#)) plan the [Tuple Mover mergeout](#) operations that manage the data in the shards. They can also execute these operations if they are the best candidate to do so (see [The Tuple Mover in Eon Mode Databases](#)).

The primary nodes can be spread across multiple primary subclusters—they all work together to maintain the data in the shards. The health of the primary nodes is key for your database to continue running normally.

The nodes in [secondary subclusters](#) do not plan Tuple Mover operations. They can execute Tuple Mover mergeout operations if a primary node assigns it to them. Your database cluster can lose all of its secondary nodes and still maintain the data in the shards.

Maintaining data integrity is the top goal of your database. If your database loses too many primary nodes, it cannot safely process data. In this case, it goes into read-only mode to prevent data inconsistency or corruption.

High availability (having the database continue running even if individual nodes are lost) is another goal of Vertica. It has several redundancy features to help it prevent downtime. With these features enabled, your database continues to run even if it loses one or more primary nodes.

There are two requirements for the database to continue normal operations: maintaining quorum, and maintaining shard coverage.

Maintaining quorum

The basic requirement for the primary nodes in your Eon Mode database is maintaining a [quorum](#) of primary nodes running at all times. To maintain quorum, more than half of the primary nodes (50% plus 1) must be up. For example, in a database with 6 primary nodes, at least 4 of them must be up. If half or more of the primary nodes are down, your database goes into read-only mode to prevent potential data integrity issues. In a database with 6 primary nodes, the database goes into read-only if it loses 3 or more of them. See [Read-Only Mode](#) below.

Vertica only counts the primary nodes that are currently part of the database when determining whether the database has quorum. Removing primary nodes cannot result in a loss of quorum. During the removal process, Vertica adjusts the node count to prevent the loss of quorum.

At a minimum, your Eon Mode database must have at least one primary node to function. In most cases, it needs more than one. See [Minimum Node Requirements for Eon Mode Database Operation](#) below.

Maintaining shard coverage

In order to continue to process data, your database must be able to maintain the data in its shards. To maintain the data, each shard must have a subscribing primary node that is responsible for running the Tuple Mover on it. This requirement is called having shard coverage. If one or more shards do not have a primary node maintaining its data, your database loses shard coverage and goes into read-only mode ([explained below](#)) to prevent possible data integrity issues.

The measure of how resilient your Eon Mode database is to losing a primary node is called its [K-safety](#) level. The value K is the number of redundant shard subscriptions your Eon Mode database cluster maintains. It also represents the number of primary nodes in your database that can fail and still be able to run safely. In many cases, your database can lose more than K nodes and still continue to run normally, as long as it maintains shard coverage.

Vertica recommends that your database always have a K-safety value of 1 (K=1). In a K=1 database, each shard has two subscribers: a primary subscriber that is responsible for the shard, and a secondary subscriber that can fill in if the primary subscriber is lost. The primary subscriber is responsible for running the Tuple Mover on the data in the shard. The secondary subscriber maintains a copy of the shard's catalog metadata, so it can fill in if the primary subscriber is lost.

If a shard's primary subscriber fails, the secondary subscriber fills in for it. Because it does not maintain a separate depot for its secondary subscription, the secondary subscriber always directly accesses the shard's data in communal storage. This direct access impacts your database's performance while a secondary subscriber fills in for a primary subscriber. For this reason, always restart or replace a down primary node as soon as possible.

With primary and secondary subscribers in a $K=1$ database, the loss of a single primary node does not affect the database's ability to process and maintain data. However, if the secondary subscriber fails while standing in for the primary subscriber, your database would lose shard coverage, and be forced to go into read-only mode.

Elastic K-safety

Vertica uses a feature called elastic K-safety to help limit the possibility of shard coverage loss. By default, if either the primary or secondary subscriber to a shard fails, Vertica subscribes an additional primary node to the shard. This subscription takes time to be established, as the newly-subscribed node must get a copy of the shard's metadata. If the shard's sole subscriber fails while the new subscriber is getting the shard's metadata, the database loses shard coverage and can shut down. Once the newly-subscribed node gets a copy of the metadata, it is able to take over maintenance of the shard in case the other subscriber fails. At this point, your database once again has two subscribers for the shard.

Once the down nodes recover and rejoin the subcluster, Vertica removes the subscriptions it added for elastic K-safety. Once all of the nodes rejoin the cluster, the shard subscriptions are the same as they were before the node loss.

With elastic K-safety, your database could manage to maintain shard coverage through the gradual loss of primary nodes, up to the point that it loses quorum. As long as there is enough time for newly-subscribed nodes to gather the shard's metadata, your database is able to maintain shard coverage. However, your database could still be forced into read-only mode due to loss of shard coverage if it lost the primary and secondary subscribers to a shard before a new primary node could complete the process of subscribing to the shard.

Note

Vertica stops adding new subscriptions when your database gets close to losing quorum. It continues to add new subscriptions if your cluster has more than $N \div 2 + K + 1$ primary nodes up, where N is the total number of primary nodes in the database. For example, if you have 10 primary nodes in your $K=1$ database, Vertica adds new subscriptions as long as the number of primary nodes that are up is greater than 7 ($10 \div 2 + 1 + 1$). If the number of up primary nodes falls to 6 in this database, adding an additional subscription does not make sense. Losing another primary node would force the database to shut down due to a loss of quorum.

Database read-only mode

If your database loses either quorum or primary shard coverage, it goes into read-only mode. This mode prevents potential data corruption that could result when too many nodes are down or unable to reach other nodes in the database. Read-only mode prevents changes being made to the database that require updates to the global catalog.

DML and DDL in read-only mode

In read-only mode, statements that change the global catalog (such as most DML and DDL statements) fail with an error message. For example, executing DDL statements such as [CREATE TABLE](#) while the database is in read-only mode results in the following error:

```
=> CREATE TABLE t (a INTEGER, b VARCHAR);
ERROR 10428: Transaction commit aborted since the database is currently in read-only mode
HINT: Commits will be restored when the database restores the quorum
```

DML statements such as [COPY](#) return a different error. Vertica stops them from executing before they perform any work:

```
=> COPY warehouse_dimension from stdin;
ERROR 10422: Running DML statements is not possible in read-only mode
HINT: Running DMLs will be restored when the database restores the quorum
```

By returning the error early, Vertica avoids performing all of the work required to load data, only to fail when it tries to commit the transaction.

DDL and DML statements that do not affect the global catalog still work. For example, you can create a local temporary table and load data into it while the database is in read-only mode.

Queries in read-only mode

Queries can run on any subcluster that has shard coverage. For example, suppose you have an Eon Mode database with a 3-node primary and a 3-node secondary subcluster. If two of the primary nodes go down, the database loses quorum and goes into read-only mode. The primary subcluster also loses shard coverage, because two of its nodes are down. The remaining node does not have a subscription to at least some of the shards. In this case, queries on the remaining primary node (except for some system table queries) always fail:

```
=> SELECT * FROM warehouse_dimension;
ERROR 9099: Cannot find participating nodes to run the query
```

The secondary subcluster still has shard coverage so you can execute queries on it.

Monitoring read-only mode

Besides noticing DML and DDL statements returning errors, you can determine whether the database has gone into read-only mode by monitoring system tables:

- The [NODES](#) system table has a column named `is_readonly` that becomes true for all nodes when the database is in read-only mode.

```
=> SELECT node_name, node_state, is_primary, is_readonly, subcluster_name FROM nodes;
```

node_name	node_state	is_primary	is_readonly	subcluster_name
v_verticadb_node0001	UP	t	t	default_subcluster
v_verticadb_node0002	DOWN	t	t	default_subcluster
v_verticadb_node0003	DOWN	t	t	default_subcluster
v_verticadb_node0004	UP	f	t	analytics
v_verticadb_node0005	UP	f	t	analytics
v_verticadb_node0006	UP	f	t	analytics

(6 rows)

- When the database goes into read-only mode, every node that is still up in the database records a Cluster Read-only event (event code 20). You can find these events by querying the event monitoring system tables such as [ACTIVE_EVENTS](#):

```
=> \x
```

Expanded display is on.

```
=> SELECT * FROM ACTIVE_EVENTS WHERE event_code = 20;
```

```

See [Monitoring events](#).

Recover from read-only mode

To recover from read-only mode, restart the down nodes. Restarting the nodes resolves loss of quorum or loss of primary shard coverage that caused the database to go into read-only mode.

Once the down nodes restart and rejoin the database, Vertica restarts on the nodes that were in read-only mode. This step is necessary to allow the nodes to resubscribe to their shards. During this restart, client connections to these nodes will drop. For example, users connected via vsql to one of the nodes where Vertica is restarting see the message:

```
server closed the connection unexpectedly
  This probably means the server terminated abnormally
  before or while processing the request.
The connection to the server was lost. Attempting reset: Succeeded.
```

Users using vsql to connect to nodes as Vertica restarts see the message:

```
vsq!l: FATAL 4149: Node startup/recovery in progress. Not yet ready
to accept connections
```

Once Vertica restarts on the nodes, the database resumes normal operation.

When Vertica sets the K-safety value in an Eon Mode database

When you have three or more primary nodes in your database, Vertica automatically sets the database's K-safety to 1 (K=1). It also automatically configures shard subscriptions so that each node can act as a backup for another node, as described in [Maintaining Shard Coverage](#).

This behavior is different than an Enterprise Mode database, where you must design your database's physical schema to meet several criteria before you can have Vertica mark the database as K-safe. See [Difference Between Enterprise Mode and Eon Mode K-safe Designs](#) below for details.

Note

Databases with less than three primary nodes have no data redundancy (K=0). Vertica recommends you only use a database with less than three primary nodes for testing.

Minimum node requirements for Eon Mode database operation

The K-safety level of your database determines the minimum number of primary nodes it must have:

- When K=0, your database must have at least 1 primary node. Setting K to 0 allows you to have a single-node Eon Mode database. Note that in a K=0 database, the loss of a primary node will result in the database going into read-only mode.
- When K=1 (the most common case), your database must have at least three primary nodes. This number of primary nodes allows Vertica to maintain data integrity if a primary node goes down.
- If you want to manually set the K-safe value to 2 (see [Difference Between Enterprise Mode and Eon Mode K-safe Designs](#) below) you must have at least 5 primary nodes.

Vertica prevents you from removing primary nodes if your cluster would fall below the lower limit for your database's K-safety setting. If you want to remove nodes in a database at this lower limit, you must lower the K-safety level using the [MARK_DESIGN_KSAFE](#) function and then call [REBALANCE_SHARDS](#).

Critical nodes and subclusters

Vertica designates any node or subcluster in the database whose loss would cause the database to go into read-only mode as critical. For example, in an Eon Mode database, when a primary node goes down, nodes with secondary subscriptions to its shards take over maintaining the shards' data. These nodes become critical. Their loss would cause the database to lose shard coverage and be forced to go into read-only mode.

Note

When elastic K-safety is enabled (which is the default) Vertica subscribes additional primary nodes to a down primary node's shards. After these nodes finish subscribing by getting a copy of the shard's metadata, they are ready to fill in if the secondary subscriber also goes down. When this happens, the node filling in for the down node is no longer considered critical.

Vertica maintains a list of critical nodes and subclusters in two system tables: [CRITICAL_NODES](#) and [CRITICAL_SUBCLUSTERS](#). Before stopping nodes or subclusters, check these tables to ensure the node or subcluster you intend to stop is not critical.

Difference between Enterprise Mode and Eon Mode K-safe designs

In an Enterprise Mode database, you use the [MARK_DESIGN_KSAFE](#) function to enable high availability in your database. You call this function after you have designed your database's physical schema to meet all the requirements for K-safe design (often, by running the database designer). If you attempt to mark your database as K-safe when the physical schema does not support the level K-safety you pass to [MARK_DESIGN_KSAFE](#), it returns an error. See [Designing segmented projections for K-safety](#) for more information.

In Eon Mode, you do not need to use the `MARK_DESIGN_KSAFE` because Vertica automatically makes the database K-safe when you have three or more primary nodes. You can use this function to change the K-safety level of your database. In an Eon Mode database, this function changes how Vertica configures shard subscriptions. You can call `MARK_DESIGN_KSAFE` with any level of K-safety you want. It only has an effect when you call [REBALANCE_SHARDS](#) to update the shard subscriptions for the nodes in your database.

Note

Usually, you do not use a K-safety value of greater than 1 in a cloud-based Eon Mode database. Adding replacement nodes to a cluster is easy in a cloud environment.

Stopping, starting, terminating, and reviving Eon Mode database clusters

If you do not need your Eon Mode database for a period of time, you can choose to stop or terminate its cluster. Stopping or terminating the cluster saves you money when running in cloud environments.

Stopping and starting a database cluster

When you stop your database cluster, you shut down the nodes in the cluster. Shutting down the cluster is an additional step beyond just shutting down the database. When you shut down the cluster in cloud environments, the node's instances no longer run but are still defined in the cloud platform. You can quickly restart the cluster and database when you need to use it again.

Stopping the database cluster is the best option to use when you will not need it for a short to medium time frame. For example, if no one accesses your database on weekends or holidays, you may consider stopping the cluster.

You save money when you shut down your database cluster in cloud environments. Stopped clusters do not consume expensive CPU resources. Stopped clusters can still cost you money, however. If you configured your nodes with persistent local storage, your cloud provider usually still charges a small amount to maintain that storage space.

Terminating and reviving a database cluster

Terminating a database cluster frees up the resources used by the database cluster's nodes.

On a cloud platform, terminating the database cluster deletes the node's virtual machine instances. The database's data and catalog remain stored in communal storage. You can restart the database by reviving it. When you revive a database, you provision a new database cluster and configure it to use the database's data and metadata stored in communal storage.

Note

You cannot revive sandboxed subclusters. If you call the `revive_db` admintools command on a cluster with both sandboxed and unsandboxed subclusters, the nodes in the unsandboxed subclusters start as expected, but the nodes in the sandboxed subclusters remain down. Attempting to revive only a sandboxed subcluster returns an error.

In an on-premises Eon Mode database, terminating the database cluster usually means shutting down the database and then repurposing the hardware that the nodes ran on.

Terminating the database cluster is the best option for when you will not need the database for an extended period (or if you are unsure whether you will ever need the database again). As long as you do not delete the communal storage location, you can get your database running again by reviving it.

To revive a database, you create a new Vertica Eon Mode cluster and configure it to use the database's communal storage location. The easiest way to revive a database in the cloud is to use the Management Console. It provisions a new Eon Mode cluster for you, and then revives the database onto it.

Reviving a database takes longer than starting a stopped database. Even if you use the MC to automate the process, provisioning a new set of nodes takes much longer than just restarting stopped nodes. When the new nodes start for the first time, they must load data from communal storage from scratch.

Terminating the database cluster can save you more money over simply stopping the database when the database's nodes have persistent local storage. Cloud providers usually charge you a small recurring fee for the space consumed by persistent local storage on the nodes.

- [Altering subcluster settings](#)

Enterprise Mode concepts

In an Enterprise Mode Vertica database, the physical architecture is designed to move data as close as possible to computing resources. This architecture differs from a cluster running in Eon Mode which is described in [Eon Mode concepts](#).

The data in an Enterprise Mode database is spread among the nodes in the database. Ideally, the data is evenly distributed to ensure that each node has an equal amount of the analytic workload.

Enterprise Mode Vertica Cluster

Hybrid data store

When running in Enterprise Mode, Vertica stores data on the database in read optimized store (ROS) containers. ROS data is segmented, sorted, and compressed for high optimization. To avoid fragmentation of data among many small ROS containers, Vertica periodically executes a [mergeout](#) operation, which consolidates ROS data into fewer and larger containers.

Data redundancy

In Enterprise Mode, each node of the Vertica database stores and operates on data locally. Without some form of redundancy, the loss of a node would force your database to shut down, as some of its data would be unavailable to service queries.

You usually choose to have your Enterprise Mode database store data redundantly to prevent data loss and service interruptions should a node shut down. See [K-safety in an Enterprise Mode database](#) for details.

In this section

- [K-safety in an Enterprise Mode database](#)
- [High availability with projections](#)
- [High availability with fault groups](#)

K-safety in an Enterprise Mode database

K-safety sets the fault tolerance in your Enterprise Mode database cluster. The value K represents the number of times the data in the database cluster is replicated. These replicas allow other nodes to take over query processing for any failed nodes.

Note

K-safety works in a similar manner in an Eon Mode database, with several important differences. See [Data integrity and high availability in an Eon Mode database](#) for details.

In Vertica, the value of K can be zero (0), one (1), or two (2). If a database with a K-safety of one (K=1) loses a node, the database continues to run normally. Potentially, the database could continue running if additional nodes fail, as long as at least one other node in the cluster has a copy of the failed node's data. Increasing K-safety to 2 ensures that Vertica can run normally if any two nodes fail. When the failed node or nodes return and successfully recover, they can participate in database operations again.

Note

If the number of failed nodes exceeds the K value, some the data may become unavailable. In this case, the database is considered unsafe and automatically shuts down. However, if every data segment is available on at least one functioning cluster node Vertica continues to run safely.

Potentially, up to half the nodes in a database with a K-safety of 1 could fail without causing the database to shut down. As long as the data on each failed node is available from another active node, the database continues to run.

Note

If half or more of the nodes in the database cluster fail, the database automatically shuts down even if all of the data in the database is available from replicas. This behavior prevents issues due to network partitioning.

Note

The physical schema design must meet certain requirements. To create designs that are K-safe, Vertica recommends using the [Database Designer](#).

Buddy projections

In order to determine the value of K-safety, Vertica creates [buddy projections](#), which are copies of segmented projections distributed across database nodes. (See [Segmented projections](#) and [Unsegmented projections](#).) Vertica distributes segments that contain the same data to different nodes. This ensures that if a node goes down, all the data is available on the remaining nodes.

K-Safety example

This diagram above shows a 5-node cluster with a K-safety level of 1. Each node contains buddy projections for the data stored in the next higher node (node 1 has buddy projections for node 2, node 2 has buddy projections for node 3, and so on). If any of the nodes fail, the database continues to run. The database will have lower performance because one of the nodes must handle its own workload and the workload of the failed node.

The diagram below shows a failure of Node 2. In this case, Node 1 handles processing for Node 2 since it contains a replica of node 2's data. Node 1 also continues to perform its own processing. The fault tolerance of the database falls from 1 to 0, since a single node failure could cause the database to become unsafe. In this example, if either Node 1 or Node 3 fails, the database becomes unsafe because not all of its data is available. If Node 1 fails, Node 2's data is no longer be available. If Node 3 fails, its data is no longer available, because node 2 is down and could not use the buddy projection. In this case, nodes 1 and 3 are considered critical nodes. In a database with a K-safety level of 1, the node that contains the buddy projection of a failed node, and the node whose buddy projections are on the failed node, always become critical nodes.

With Node 2 down, either node 4 or 5 could fail and the database still has all of its data available. The diagram below shows that if node 4 fails, node 3 can use its buddy projections to fill in for it. In this case, any further loss of nodes results in a database shutdown, since all the nodes in the cluster are now critical nodes. In addition, if one more node were to fail, half or more of the nodes would be down, requiring Vertica to automatically shut down, no matter if all of the data were available or not.

In a database with a K-safety level of 2, Node 2 and any other node in the cluster could fail and the database continues running. The diagram below shows that each node in the cluster contains buddy projections for both of its neighbors (for example, Node 1 contains buddy projections for Node 5 and Node 2). In this case, nodes 2 and 3 could fail and the database continues running. Node 1 could fill in for Node 2 and Node 4 could fill in for Node 3. Due to the requirement that half or more nodes in the cluster be available in order for the database to continue running, the cluster could not continue running if node 5 failed, even though nodes 1 and 4 both have buddy projections for its data.

Note

Vertica requires that more than half of all nodes in a cluster must always be available; otherwise, it views the database as being in an unsafe state and shuts it down. Thus, in the previous example, the cluster cannot continue running if Node 5 fails, even though nodes 1 and 4 have buddy projections for its data.

Monitoring K-safety

You can access System Tables to monitor and log various aspects of Vertica operation. Use the [SYSTEM](#) table to monitor information related to K-safety, such as:

- **NODE_COUNT** : Number of nodes in the cluster
- **NODE_DOWN_COUNT** : Number of nodes in the cluster that are currently down
- **CURRENT_FAULT_TOLERANCE** : The K-safety level

High availability with projections

To ensure high availability and recovery for database clusters of three or more nodes, Vertica:

- Replicates small, unsegmented projections
- Creates buddy projections for large, segmented projections.

Replication (unsegmented projections)

When it creates projections, Database Designer replicates them, creating and storing duplicates of these projections on all nodes in the database.

Replication ensures:

- Distributed query execution across multiple nodes.

- High availability and recovery. In a K-safe database, replicated projections serve as buddy projections. This means that you can use a replicated projection on any node for recovery.

Note

We recommend you use Database Designer to create your physical schema. If you choose not to, be sure to segment all large tables across all database nodes, and replicate small, unsegmented table projections on all database nodes.

The following illustration shows two projections, B and C, replicated across a three node cluster.

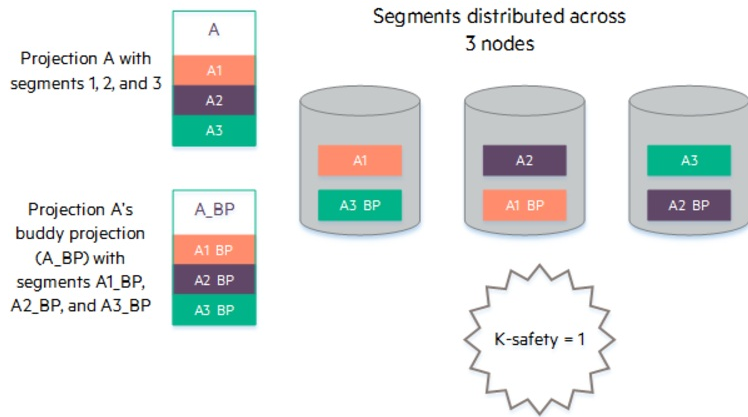

Buddy projections (segmented projections)

Vertica creates *buddy projections* which are copies of segmented projections that are distributed across database nodes (see [Segmented projections.](#)) Vertica distributes segments that contain the same data to different nodes. This ensures that if a node goes down, all the data is available on the remaining nodes. Vertica distributes segments to different nodes by using offsets. For example, segments that comprise the first buddy projection (A_BP1) are offset from projection A by one node, and segments from the second buddy projection (A_BP2) are offset from projection A by two nodes.

The following diagram shows the segmentation for a projection called A and its buddy projections, A_BP1 and A_BP2, for a three node cluster.

The following diagram shows how Vertica uses offsets to ensure that every node has a full set of data for the projection.

How result sets are stored

Vertica duplicates table columns on all nodes in the cluster to ensure high availability and recovery. Thus, if one node goes down in a [K-Safe](#) environment, the database continues to operate using duplicate data on the remaining nodes. Once the failed node resumes its normal operation, it automatically recovers its lost objects and data by querying other nodes.

Vertica compresses and encodes data to greatly reduce the storage space. It also operates on the encoded data whenever possible to avoid the cost of decoding. This combination of compression and encoding optimizes disk space while maximizing query performance.

Vertica stores table columns as projections. This enables you to optimize the stored data for specific queries and query sets. Vertica provides two methods for storing data:

- Projection segmentation is recommended for large tables (fact and large dimension tables)
- Replication is recommended for the rest of the tables.

High availability with fault groups

Use fault groups to reduce the risk of correlated failures inherent in your physical environment. Correlated failures occur when two or more nodes fail as a result of a single failure. For example, such failures can occur due to problems with shared resources such as power loss, networking issues, or storage.

Vertica minimizes the risk of correlated failures by letting you define fault groups on your cluster. Vertica then uses the fault groups to distribute data segments across the cluster, so the database continues running if a single failure event occurs.

Note

If your cluster layout is managed by a single network switch, a switch failure can be a single point of failure. Fault groups cannot help with single-point failures.

Vertica supports complex, hierarchical fault groups of different shapes and sizes. You can integrate fault groups with [elastic cluster](#) and [large cluster](#) arrangements to add cluster flexibility and reliability.

Making Vertica aware of cluster topology with fault groups

You can also use fault groups to make Vertica aware of the topology of the cluster on which your Vertica database is running. Making Vertica aware of your cluster's topology is required when using [terrace routing](#), which can significantly reduce message buffering on a large cluster database.

Automatic fault groups

When you configure a cluster of 120 nodes or more, Vertica automatically creates fault groups around control nodes. *Control nodes* are a subset of cluster nodes that manage [spread](#) (control messaging). Vertica places nodes that share a control node in the same fault group. See [Large cluster](#) for details.

User-defined fault groups

Define your own default groups if:

- Your cluster layout has the potential for correlated failures.
- You want to influence which cluster hosts manage control messaging.

Example cluster topology

The following diagram provides an example of hierarchical fault groups configured on a single cluster:

- Fault group **FG-A** contains nodes only.
- Fault group **FG-B** (parent) contains child fault groups **FG-C** and **FG-D**. Each child fault group also contains nodes.
- Fault group **FG-E** (parent) contains child fault groups **FG-F** and **FG-G**. The parent fault group **FG-E** also contains nodes.

How to create fault groups

Before you define fault groups, you must have a thorough knowledge of your physical cluster layout. Fault groups require careful planning.

To define fault groups, create an input file of your cluster arrangement. Then, pass the file to a script supplied by Vertica, and the script returns the SQL statements you need to run. See [Fault Groups](#) for details.

Setup

You can create Eon Mode and Enterprise Mode Vertica clusters in cloud and on-premises environments:

- On the cloud: Deploy Vertica clusters running on Amazon Web Services, Microsoft Azure, or Google Cloud Platform. For setup instructions for each cloud provider, see [Set up Vertica on the cloud](#).
- On-premises: Manually install Vertica on your host hardware. For detailed instructions on the manual install process, see [Set up Vertica on-premises](#).

In this section

- [Plan your setup](#)
- [Set up Vertica on the cloud](#)
- [Set up Vertica on-premises](#)
- [Upgrading Vertica](#)
- [Uninstall Vertica](#)

Plan your setup

Before you get started with Vertica, consider your business needs and available resources. Vertica is built to run in a variety of environments depending on your requirements:

- Infrastructure: [Cloud Environment](#) or [On-Premises Environment](#).
- Database Mode: [Eon or Enterprise](#).
- Setup Method (Cloud only): [Install Vertica Manually](#) or [Deploy Vertica Automatically or Manually](#).

Choosing an on-premises or cloud environment

You can choose to run Vertica on physical host hardware, or deploy Vertica on the cloud.

Cloud environment

Vertica can run on Amazon Web Services (AWS), Google Cloud Platform (GCP), and Microsoft Azure. You might consider running Vertica on cloud resources for any of the following benefits:

- You plan to quickly scale your cluster size up and down to accommodate varying analytic workload. You will provision more computing resources during peak work loads without incurring the same resource costs during low-demand periods. The Vertica database's [Eon Mode](#) is designed for this use case.
- You prefer to pay over time (OpEx) for ongoing cloud deployment, rather than the higher up-front cost of buying hardware for on-premises deployment.
- You need to reduce the costs, labor, and expertise involved in maintaining physical on-premises hardware (such as accommodating for server purchases, hardware depreciation, software maintenance, power consumption, floor space, and backup infrastructure).
- You prefer simpler, faster deployment. Deploying on the cloud eliminates the need for more specific hardware expertise during setup. In addition, on cloud platforms such as AWS and GCP, Vertica offers templates that allow you to deploy a pre-configured set of resources on which Vertica and Management Console are already installed, in just a few steps.
- You have very variable workloads and you do not want to pay for idle equipment in a data center when you can simply rent infrastructure when you need it.
- You are a start-up and don't want to build out a data center until your product or service is proven and growing.

If you plan to deploy Vertica on the cloud, see [Set up Vertica on the cloud](#).

On-premises environment

An on-premises environment can provide benefits in cases like the following:

- Your business requirements demand keeping sensitive data on-premises.
- You prefer to pay a higher up-front cost (CapEx) of buying hardware for on-premises deployment, rather than potentially paying a higher long-term total cost of a cloud deployment.
- You cannot rely on continuous access to the internet.
- You prefer end-to-end control over your environment, rather than depending on a third-party cloud provider to store your data.
- You may have already invested in a data center and suitable hardware for Vertica that you want to capitalize on.

If you plan to install Vertica in an on-premises environment, see [Set up Vertica on-premises](#).

Choosing a database mode

You can create a Vertica database in one of two modes: Eon Mode or Enterprise Mode. The mode determines the database's underlying architecture, how the database cluster scales, and how data is loaded. Eon Mode uses communal storage to separate storage from compute and allows you to easily scale compute up or down to meet changing workloads. Enterprise Mode is a share-nothing architecture that's particularly optimized for data local to each node. Database mode does not affect the way you run queries and other everyday tasks while using the database.

For an in-depth explanation of Enterprise Mode and Eon Mode, see [Eon vs. Enterprise Mode](#).

If you choose to create an Eon Mode database in an on-premises environment, see [Communal storage for on-premises Eon Mode databases](#) to estimate the amount of storage needed.

Choosing an installation method

After you have decided how you will run Vertica, you can choose which setup method works for your needs.

Install Vertica manually

Manually installing Vertica through the command line works on all platforms. You will first set up a cluster of nodes, then install Vertica.

Manual installation might be right for you if your cluster will have many specific configuration requirements, and you have a database administrator with the expertise to set up the cluster manually on your chosen platform. Manual installation takes more time, but you can configure your cluster to your system's exact needs.

For an on-premises environment, you must install Vertica manually. See [Set up Vertica on-premises](#) to get started.

For Amazon AWS, Google Cloud Platform, and Microsoft Azure, you have the option to deploy automatically or install manually. See [Set up Vertica on the cloud](#) for information on manual installation on each cloud platform.

Note

If you manually install Vertica in a cloud environment, you cannot access the Management Console.

Deploy Vertica automatically or manually

Automatic deployment is available on AWS, GCP, and Microsoft Azure. Manual deployment is only available on AWS through Vertica Amazon Machine Images (AMI), which include the Vertica software and the recommended configuration.

Automatic deployment creates a pre-configured environment consisting of cloud resources on which your cluster can run, with Vertica and Management Console already installed. You can enter a few parameters into a template on your chosen platform and be up and running with Vertica.

For cloud-specific deployment information, see [Set up Vertica on the cloud](#).

Set up Vertica on the cloud

This section explains how you can deploy Vertica clusters running on Amazon Web Services (AWS), Microsoft Azure, or Google Cloud Platform (GCP). It assumes that you are familiar with the cloud environment on which you will create your Vertica cluster.

Vertica offers simple, automatic deployment on all three platforms. By setting a few parameters, you can launch a fully functional environment with Vertica and Management Console already installed.

If launching a pre-configured environment doesn't work for your specific needs, you can instead set up your nodes in the cloud and manually install Vertica in order to have more control over your setup. AWS also supports manually deploying a Vertica Amazon Machine Image (AMI) that has Vertica pre-installed and allows for greater control over your environment configuration.

After you set up your environment, you can create a database in either Enterprise Mode or Eon Mode.

Automatic deployment (all cloud platforms)

Vertica offers automatic configuration of resources and quick deployment on the cloud.

AWS

Vertica provides CloudFormation Templates (CFTs) in the AWS Marketplace. You can use a CFT to automatically launch preconfigured AWS resources in minutes, with Vertica and Management Console automatically installed.

Each CFT includes the in-browser Vertica Management Console. When you install Vertica using one of the CFTs, Management Console provides AWS-specific cluster management options, including the ability to quickly create a new cluster and Vertica database.

To deploy Vertica on AWS automatically, see [Deploy Vertica using CloudFormation templates](#).

After deployment, you can create an [Eon Mode](#) or [Enterprise Mode](#) cluster and database using Management Console.

For more information about the AWS environment, see the official [Amazon Web Services documentation](#).

Google Cloud Platform

For GCP, Vertica provides an automated installer that is available from the Google Cloud Marketplace.

Input a few parameters, and the Google Cloud Launcher will deploy the Vertica solution, including your new database. You can create up to a 16-node cluster. The solution includes the Vertica Management Console as the primary UI to get started.

To deploy Vertica on GCP automatically, see [Deploy Vertica from the Google cloud marketplace](#).

For more information about the GCP environment, see the official [Google Cloud Platform documentation](#).

Microsoft Azure

Vertica offers a fully automated cluster deployment from the Microsoft Azure Marketplace. This solution will automatically deploy a Vertica cluster and create an initial database, allowing you to log in to the Vertica Management Console and start using it after deployment has finished.

To deploy Vertica on Azure automatically, see [Deploy Vertica from the Azure Marketplace](#).

For more information about the Azure environment, see the official [Microsoft Azure documentation](#).

Manual installation and deployment (GCP, azure)

Manual installation might be the right option for you if you have many specific configuration requirements, and have an administrator who is familiar with setting up and maintaining cloud resources in the environment of your choice. Setup and maintenance may take longer and requires more expertise, but you will have more control over how your cluster is configured.

The process of installing Vertica manually on cloud resources is very similar to doing so with on-premises hardware.

If you manually install the Vertica server on cloud hosts, you cannot access Management Console.

Vertica offers cloud-specific manual installation instructions for GCP and Azure. If you want more control over your AWS cluster configuration, see [Manual Deployment](#). Before you install, make sure to refer to the documentation of the platform you are using in order to set up your cloud resources correctly.

Google Cloud Platform

To install Vertica on GCP manually, see the GCP section of the Vertica documentation: [Vertica on Google Cloud Platform](#).

Refer to the official [Google Cloud Platform documentation](#) for more detail on setting up your GCP resources.

Microsoft Azure

To install Vertica on Azure manually, see the Azure section of the Vertica documentation: [Vertica on Microsoft Azure](#).

Refer to the official [Microsoft Azure documentation](#) for more detail on setting up your Azure resources.

Manual deployment (AWS)

Manual deployment is only available on AWS, which supports Amazon Machine Images (AMI) that include the Vertica software and the recommended configuration. The Vertica AMI acts as a template, requiring fewer configuration steps than a manual installation but still allowing control over your configuration. Vertica provides AMIs for both Management Console and cluster hosts.

For more information about the manual deployment process, see [Manually deploy Vertica on AWS](#).

In this section

- [Vertica on Amazon Web Services](#)
- [Vertica on Microsoft Azure](#)
- [Vertica on Google Cloud Platform](#)

Vertica on Amazon Web Services

Vertica clusters on AWS can operate on EC2 instances automatically provisioned using a CloudFormation Template (CFT), or manually deployed using Amazon Machine Images (AMIs). For information about these deployment methods, see [Deploy Vertica using CloudFormation templates](#) and [Manually deploy Vertica on AWS](#).

You can deploy a Vertica database on AWS running in either Enterprise Mode or Eon Mode. The differences between these two modes lay in their architecture, deployment, and scalability:

- **Enterprise Mode** stores data locally on the nodes in the database.

- **Eon Mode** stores its data in an S3 bucket.

Eon Mode separates the computational processes from the communal storage layer of your database. This separation lets you elastically vary the number of nodes in your database cluster to adjust to varying workloads.

Vertica also supports the following AWS features:

- **Enhanced Networking** : Vertica recommends that you use the AWS enhanced networking for optimal performance. For more information, see [Enabling Enhanced Networking on Linux Instances in a VPC](#) in the AWS documentation.
- **Command Line Interface** : Use the Amazon command-line Interface (CLI) with your Vertica AMIs. For more information, see [What Is the AWS Command Line Interface?](#).
- **Elastic Load Balancing** : Use elastic load balancing (ELB) for queries up to one hour. When enabling ELB, configure the timer to 3600 seconds. For more information see [Elastic Load Balancing](#) in the AWS documentation.

For more information about Amazon cluster instances and their limitations, see the [Amazon documentation](#).

In this section

In this section

- [Supported AWS instance types](#)
- [AWS authentication](#)
- [Deploy Vertica using CloudFormation templates](#)
- [Manually deploy Vertica on AWS](#)

Supported AWS instance types

Vertica supports a range of Amazon Web Services instance types, each optimized for different purposes. Choose the instance type that best matches your requirements. The two tables below list the AWS instance types that Vertica supports for Vertica cluster hosts, and for use in MC. For more information, see the [Amazon Web Services documentation on instance types and volumes](#).

Important

If you plan to use an Amazon Machine Image (AMI) on multiple AWS accounts, make sure to subscribe to the image on all your accounts. This allows you to access an image even when it is delisted from the AWS Marketplace.

Instance types for Vertica cluster hosts

Each Amazon EC2 Instance type natively provides one of the following storage options:

- Elastic Block Store (EBS) provides durable storage: Data files stored on instance persist after instance is stopped.

- Instance Store provides temporary storage: Data files stored on instance are lost when instance is stopped.

Vertica AMIs can use either the Instance Metadata Service Version 1 (IMDSv1) or the Instance Metadata Service Version 2 (IMDSv2) to authenticate to AWS services, including S3.

For more information about storage configuration in AWS, see [Configure storage](#).

Note

Instance types that support EBS volumes support encrypting.

Optimization	Instance Types Using <i>Only</i> EBS Volumes (Durable)	Instance Types Using Instance Store Volumes (Temporary)
General purpose	m4.4xlarge m4.10xlarge m5.4xlarge m5.8xlarge m5.12xlarge	m5d.4xlarge m5d.8xlarge m5d.12xlarge
Compute	c4.4xlarge c4.8xlarge c5.4xlarge c5.9xlarge c6i.4xlarge c6i.8xlarge c6i.12xlarge c6i.16xlarge c6i.24xlarge c6i.32xlarge	c3.4xlarge c3.8xlarge c5d.4xlarge c5d.9xlarge
Memory	r4.4xlarge r4.8xlarge r4.16xlarge r5.4xlarge r5.8xlarge r5.12xlarge r6i.4xlarge r6i.8xlarge r6i.12xlarge r6i.16xlarge r6i.24xlarge r6i.32xlarge	r3.4xlarge r3.8xlarge r5d.4xlarge r5d.8xlarge r5d.12xlarge

Storage	d2.4xlarge d2.8xlarge i3.4xlarge i3.8xlarge i3.16xlarge i3en.3xlarge i3en.6xlarge i3en.12xlarge i4i.4xlarge i4i.8xlarge i4i.16xlarge
---------	--

Note

By default, the c4.8xlarge, d2.8xlarge, and m4.10xlarge instances have their processor C-states set to a value of 1 in the Vertica AMI. This measure is meant to improve performance by limiting the sleep states that an instance running Vertica uses.

For more information about sleep states, visit the [AWS Documentation](#).

Instance types available for MC hosts

Optimization	Type	Supports EBS Storage (Durable)	Supports Ephemeral Storage (Temporary)
Computing	c4.large	Yes	No
	c4.xlarge	Yes	No
	c5.large	Yes	No
	c5.xlarge	Yes	No

Choosing AWS Eon Mode instance types

When running an Eon Mode database in AWS, choose instance types that support ephemeral instance storage or EBS volumes for your depot, depending on cost and availability. Vertica recommends either r4 or i3 instances for production clusters. It is not mandatory to have an EBS-backed depot, because in Eon Mode, a copy of the data is safely stored in communal storage. However, you must have an EBS-backed catalog for Eon Mode databases.

The following table provides information to help you make a decision on how to pick instances with ephemeral instance storage or EBS only storage. Check with [Amazon Web Services](#) for the latest cost per hour.

Important

If you select instances that use instance store, if you then terminate those instances there is the potential for data loss. For Eon mode, MC displays an alert to inform the user of the potential data loss when terminating instances that support instance store.

Storage Type	Instance Type	Pros/Cons
Instance storage	i3.8xlarge	Instance storage offers better performance than EBS attached storage through multiple EBS volumes. Instance storage can be striped (RAIDed) together to increase throughput and load balance I/O. Data stored in instance-store volumes is not persistent through instance stops, terminations, or hardware failures.

EBS-only storage	r4.xlarge with 600 GB EBS volume attached	Newer instance types from AWS have only the EBS option. In most AWS regions, it's easier to provision a large number of instances. You can terminate an instance but leave the EBS volume around for faster revive. Preserving the EBS will preserve the depot. While some of the cached files might have become stale, they will be ignored and evicted. Much of the cached data will not be stale. It will save time when the node revives and warms its depot. Take advantage of full-volume encryption.
------------------	--	---

More information

For more information about Amazon cluster instances and their limitations, see [Manage Clusters](#) in the Amazon Web Services documentation.

AWS authentication

Amazon defines two ways to control access to AWS resources such as S3: IAM roles and the combination of id, secrets, and (optionally) session tokens. For long-term access to non-communal storage buckets, you should use IAM roles for access control centralization. You do not need to change your application's configuration if you want to change its access settings. You just alter the IAM role applied to your EC2 instances.

However, for one-time tasks like [backing up and restoring the database](#) or loading data to and from non-communal storage buckets, you should use an [AWS access key](#).

Vertica uses both of these authentication methods to support different features and use cases:

- An Eon Mode database's access to S3 for communal and catalog storage must always use IAM role authentication. IAM roles are the default access control method for AWS resources. Vertica uses this method if you do not configure the legacy access control session parameters.
- Individual users can read data from S3 storage locations other than the ones Vertica uses for communal storage. For example, users can use COPY to load data into Vertica from an S3 bucket or query an external table stored on S3. If the IAM role assigned to the Vertica nodes does not have access to this external S3 data, the user must set an id, secret, and optionally an access token in session variables to authorize access to it. These session variables override the IAM role set on the server. See [S3 parameters](#) for a list of these session parameters.
- Individual users can export data to S3 using [file export](#). File export cannot use IAM authorization. Users who want to export data to S3 must set id, secret, and optionally access token values in session variables.

Important

If the database is running in Eon Mode, using id and secret authentication is more complex. In addition to having access to the external S3 data, any id that a user sets must be authorized to read from and write to the S3 storage locations that Vertica uses to store communal and catalog data. The queries that the user executes uses this id for all storage requests, not just those for accessing external S3 data. If the id does not have access to the catalog and communal storage, the user cannot execute queries.

Configuring an IAM role

To configure an IAM role to grant Vertica to access AWS resources you must:

1. Create an IAM role to allow EC2 instances to access the specific resources.
2. Grant that role permission to access your resources.
3. Attach this IAM role to each EC2 instance in the Vertica cluster.

To see an example of IAM roles for a Vertica cluster, look at the roles defined in one of the Cloud Formation Templates provided by Vertica. You can download these templates from any of the [Vertica entries in the Amazon Marketplace](#). Under each entry's Usage Information section, click the View CloudFormation Template link, then click Download CloudFormation Template.

For more information about IAM roles, see [IAM Roles for Amazon EC2](#) in the AWS documentation.

Deploy Vertica using CloudFormation templates

Vertica provides CloudFormation Templates (CFTs) on the AWS Marketplace that allow you to get a cluster up and running quickly. Using the template allows you to automatically provision your AWS resources and launch a Vertica cluster and Management Console, with minimal configuration required.

If you prefer to deploy a VPC, instances, and related resources manually, see [Manually deploy Vertica on AWS](#).

For details about creating an Eon Mode or Enterprise Mode database after you create a cluster with CFTs, see [Amazon Web Services in MC](#).

In this section

- [CloudFormation template \(CFT\) overview](#)

- [Creating a Virtual Private Cloud](#)
- [Deploy MC and AWS resources with a CloudFormation template](#)
- [Access Management Console](#)

CloudFormation template (CFT) overview

With Vertica on AWS, use CloudFormation Templates (CFTs) to easily manage provisioning the AWS resources with a running Vertica system. After you provide a few parameters to the template, you can create a stack to automatically provision the AWS resources for your Vertica system.

To access Vertica CFTs, go to the [AWS Marketplace](#).

CFT licensing models

Licensing models for CFTs are:

- **Bring Your Own License (BYOL)** : By default, free CE license is installed with 3 nodes and 1 TB. To extend nodes or size, you can purchase the Vertica BYOL license.
 - Outside of the BYOL license on CFTs, you can also access the Community Edition without a license file:
 - If you are using Management Console, simply leave the license field blank.
 - If you are using a command line (see [Install Vertica with the installation script](#)), specify CE in the `--license` parameter during installation.
- **By the Hour** : A pay-as-you-go model where you pay for only the number of hours you use for each node. One advantage of using the Paid Listing is that all charges appear on your Amazon AWS bill. This offers an alternative to purchasing a full Vertica license. This eliminates the need to compute potential storage needs in advance.

CFT prerequisites

Before you can deploy Vertica on AWS using CloudFormation Templates (CFTs), verify that you have:

- AWS account with permissions to create a VPC, subnet, security group, EC2 instances, and IAM roles (For more information about AWS accounts, see the [AWS documentation](#))
- Amazon key pair for SSH access to an EC2 instance. (See the [AWS documentation for key pairs](#).)

Supported CFTs and Vertica offerings

Available Vertica CFTs are:

- **Management Console with 3 Vertica nodes** : The easiest way to deploy Vertica. This CFT deploys an Eon Mode database by default. However, this environment can also be used to create an Enterprise Mode database. For more information, see [Creating a database](#).
- **Deploy Management Console into new VPC** : This CFT deploys all required AWS resources and installs the Vertica Management Console (MC). After stack creation completes, log in to the MC to provision a Vertica database cluster.
- **Deploy Management Console into existing VPC** : This CFT deploys the Vertica Management Console (MC) in an already-existing VPC and subnet. After stack creation completes, the MC is available. Log in to MC to provision either a Vertica database cluster or an Eon Mode database cluster. For this CFT, you must first set up the VPC, subnet, and related network resources. For more information about the correct configuration of these resources for Vertica, see the following topics in the AWS documentation:
 - [Creating a Virtual Private Cloud](#)
 - [Configure the network](#)

Using the license models and supported CFTs, you can deploy the following Vertica products:

- Vertica BYOL, Red Hat
- Vertica by the Hour, Red Hat

See [Deploy MC and AWS resources with a CloudFormation template](#) for information on deploying these products.

Creating a Virtual Private Cloud

A Vertica cluster on AWS must be logically located in the same network. This is similar to placing the nodes of an on-premises cluster within the same network. Create a virtual private cloud (VPC) to ensure the nodes in your cluster will be able to communicate with each other within AWS.

Create a single public subnet VPC with the following configurations:

- Assign a Network Access Control List (ACL) that is appropriate to your situation. [The default ACL](#) does not provide a high level of security.
- Enable DNS resolution and enable DNS hostname support for instances launched in this VPC.
- Add the required [network inbound and outbound rules to the Network ACL associated to the VPC](#).

Note

A Vertica cluster must be operated within a single availability zone.

For more information about VPCs, including how to create one, see the [AWS documentation](#).

Deploy MC and AWS resources with a CloudFormation template

You can deploy [Management Console](#) (MC) and its associated AWS resources using CloudFormation templates (CFTs) that are available through the AWS Marketplace. For a list of available CFTs, see [CloudFormation template \(CFT\) overview](#).

Complete the following to deploy the Vertica MC and related resources in AWS:

1. Log in to the [AWS Marketplace](#) with an AWS account (see the **Prerequisites** section above).
2. Search for "Vertica" in the AWS Marketplace.
3. Select a Vertica CFT. Each CFT leads you to a product overview page, with pricing estimates. (Also see [CloudFormation template \(CFT\) overview](#) for an overview of available templates and products).
4. Click Continue to Subscribe.
5. On the next page, select your launch settings based on your requirements for deployment.
6. If you have not agreed to Vertica EULA terms on the AWS Marketplace before, click Accept Software Terms to subscribe.
7. Click **Launch with CloudFormation Console**. The CloudFormation Console opens.
8. The CloudFormation Console automatically supplies the URL in the **Specify an Amazon S3 template URL field**. Click **Next**.
9. Follow the CloudFormation workflow and enter the parameters (collectively called a stack).

Note

Important: Take note of the username and password you set for Management Console during this step. You cannot recover or reset these credentials after you create the stack.

10. After confirming the details you have provided for your new stack, click **Create**. The AWS console brings you to the Stacks page, where you can view the progress of the creation process. The process takes several minutes.
11. The **Outputs** tab displays information about accessing your environment after the process completes.

Next, access the Management Console (MC) to deploy your cluster instances and create a database, as described in [Access Management Console](#).

Access Management Console

Complete the following steps to access Management Console on your deployed AWS resources:

1. On the AWS CloudFormation Stacks page, select your new stack and view the **Outputs** tab. This tab provides information about accessing your environment, as well as documentation and licensing resources.
2. In the **ManagementConsole** row, select the URL in the Value column to open the MC login page.
3. To log in, enter the MC username and password that you created using the CloudFormation Console.
After login, MC displays the home page, with options to provision a new cluster or database or import existing ones. If you chose a CFT that also creates a database, your new database is also displayed on the home page.
This page also provides a Resources section with links to online training, blogs, community, and help resources.

You have successfully launched and connected to Management Console on AWS resources.

If you have not yet provisioned a Vertica cluster and database, complete the steps in one of the following:

- [Creating an Eon Mode database in AWS with MC](#)
- [Creating an Enterprise Mode database in AWS with MC](#)

Manually deploy Vertica on AWS

Vertica provides tested and pre-configured Amazon Machine Images (AMIs) to deploy cluster hosts or MC hosts on AWS. When you create an EC2 instance on AWS using a Vertica AMI, the instance includes the Vertica software and the recommended configuration. The Vertica AMI acts as a template, requiring fewer configuration steps.

This section will guide you through configuring your network settings on AWS, launching and preparing EC2 instances using the Vertica AMI, and creating a Vertica cluster on those EC2 instances.

Choose this method of installation if you are familiar with configuring AWS and have many specific AWS configuration needs. To automatically deploy AWS resources and a Vertica cluster instead, see [Deploy Vertica using CloudFormation templates](#).

In this section

- [Configure your network](#)
- [Deploy AWS instances for your Vertica database cluster](#)

Configure your network

Before you deploy your cluster, you must configure the network on which Vertica will run. Vertica requires a number of specific network configurations to operate on AWS. You may also have specific network configuration needs beyond the default Vertica settings.

Important

You can create a Vertica database that uses IPv6 for internal communications running on AWS. However, if you do so, you must identify the hosts in your cluster using IP addresses rather than host names. The AWS DNS resolution service is incompatible with IPv6.

The following sections explain which Amazon EC2 features you need to configure for instance creation.

In this section

- [Create a placement group, key pair, and VPC](#)
- [Network ACL settings](#)
- [Configure TCP keepalive with AWS network load balancer](#)
- [Create and assign an internet gateway](#)
- [Assign an elastic IP address](#)
- [Create a security group](#)

Create a placement group, key pair, and VPC

Part of configuring your network for AWS is to create the following:

- [Placement Group](#)
- [Key Pair](#)
- [Virtual Private Cloud \(VPC\)](#)

Create a placement group

A placement group is a logical grouping of instances in a single [Availability Zone](#). Placement Groups are required for clusters and all Vertica nodes must be in the same Placement Group.

Vertica recommends placement groups for applications that benefit from low network latency, high network throughput, or both. To provide the lowest latency, and the highest packet-per-second network performance for your Placement Group, choose an [instance type](#) that supports enhanced networking.

For information on creating placement groups, see [Placement Groups](#) in the AWS documentation.

Create a key pair

You need a key pair to access your instances using SSH. Create the key pair using the AWS interface and store a copy of your key (*.pem) file on your local machine. When you access an instance, you need to know the local path of your key.

Use a key pair to:

- Authenticate your connection as dbadmin to your instances from outside your cluster.
- Install and configure Vertica on your AWS instances.

for information on creating a key pair, see [Amazon EC2 Key Pairs](#) in the AWS documentation.

Create a virtual private cloud (VPC)

You create a Virtual Private Cloud (VPC) on Amazon so that you can create a network of your EC2 instances. Your instances in the VPC all share the same network and security settings.

A Vertica cluster on AWS must be logically located in the same network. Create a VPC to ensure the nodes in you cluster can communicate with each other in AWS.

Create a single public subnet VPC with the following configurations:

- Assign a Network Access Control List (ACL) that is appropriate to your situation.
- Enable DNS resolution and enable DNS hostname support for instances launched in this VPC.
- Add the required [network inbound and outbound rules to the Network ACL associated to the VPC](#).

Note

A Vertica cluster must be operated in a single availability zone.

For information on creating a VPC, see [Create a Virtual Private Cloud \(VPC\)](#) in the AWS documentation.

Network ACL settings

Vertica requires the following basic network access control list (ACL) settings on an AWS instance running the Vertica AMI. Vertica recommends that you secure your network with additional ACL settings that are appropriate to your situation.

Inbound Rules

Type	Protocol	Port Range	Use	Source	Allow/Deny
SSH	TCP (6)	22	SSH (Optional—for access to your cluster from outside your VPC)	User Specific	Allow
Custom TCP Rule	TCP (6)	5450	MC (Optional—for MC running outside of your VPC)	User Specific	Allow
Custom TCP Rule	TCP (6)	5433	SQL Clients (Optional—for access to your cluster from SQL clients)	User Specific	Allow
Custom TCP Rule	TCP (6)	50000	Rsync (Optional—for backup outside of your VPC)	User Specific	Allow
Custom TCP Rule	TCP (6)	1024-65535	Ephemeral Ports (Needed if you use any of the above)	User Specific	Allow
ALL Traffic	ALL	ALL	N/A	0.0.0.0/0	Deny

Outbound Rules

Type	Protocol	Port Range	Use	Source	Allow/Deny
Custom TCP Rule	TCP (6)	0-65535	Ephemeral Ports	0.0.0.0/0	Allow

You can use the entire port range specified in the previous table, or find your specific ephemeral ports by entering the following command:

```
$ cat /proc/sys/net/ipv4/ip_local_port_range
```

More information

For detailed information on network ACLs within AWS, refer to [Network ACLs](#) in the Amazon documentation.

For detailed information on ephemeral ports within AWS, refer to [Ephemeral Ports](#) in the Amazon documentation.

Configure TCP keepalive with AWS network load balancer

AWS supports three types of elastic load balancers (ELBs):

- [Classic Load Balancers](#)
- [Application Load Balancers](#)
- [Network Load Balancers](#)

Vertica strongly recommends the AWS Network Load Balancer (NLB), which provides the best performance with your Vertica database. The Network Load Balancer acts as a proxy between clients (such as JDBC) and Vertica servers. The Classic and Application Load Balancers do not work with Vertica, in Enterprise Mode or Eon Mode.

To avoid timeouts and hangs when connecting to Vertica through the NLB, it is important to understand how AWS NLB handles idle timeouts for connections. For the NLB, AWS sets the idle timeout value to 350 seconds and you cannot change this value. The timeout applies to both connection points.

For a long-running query, if either the client or the server fails to send a timely keepalive, that side of the connection is terminated. This can lead to situations where a JDBC client hangs waiting for results that would never be returned because the server fails to send a keepalive within 350 seconds.

To identify an idle timeout/keepalive issue, run a query like this via a client such as JDBC:

```
=> SELECT SLEEP(355);
```

If there's a problem, one of the following situations occurs:

- The client connection terminates before 355 seconds. In this case, lower the JDBC keepalive setting so that keepalives are sent less than 350 seconds apart.
- The client connection doesn't return a result after 355 seconds. In this case, you need to adjust the server keepalive settings (`tcp_keepalive_time` and `tcp_keepalive_intvl`) so that keepalives are sent less than 350 seconds apart. You can adjust the keepalive settings on the server, or you can [adjust them in Vertica](#).

For detailed information about AWS Network Load Balancers, see the [AWS documentation](#).

Create and assign an internet gateway

When you create a VPC, an Internet gateway is automatically assigned to it. You can use that gateway, or you can assign your own. If you are using the default Internet gateway, continue with the procedure described in [Create a security group](#).

Otherwise, create an Internet gateway specific to your needs. Associate that internet gateway with your VPC and subnet.

For information about how to create an Internet Gateway, see [Internet Gateways](#) in the AWS documentation.

Assign an elastic IP address

An elastic IP address is an unchanging IP address that you can use to connect to your cluster externally. Vertica recommends you assign a single elastic IP to a node in your cluster. You can then connect to other nodes in your cluster from your primary node using their internal IP addresses dictated by your VPC settings.

Create an elastic IP address. For information, see [Elastic IP Addresses](#) in the AWS documentation.

Create a security group

The Vertica AMI has specific security group requirements. When you create a Virtual Private Cloud (VPC), AWS automatically creates a default security group and assigns it to the VPC. You can use the default security group, or you can name and assign your own.

Create and name your own security group using the following basic security group settings. You may make additional modifications based on your specific needs.

Inbound

Type	Use	Protocol	Port Range	IP
SSH		TCP	22	The CIDR address range of administrative systems that require SSH access to the Vertica nodes. Make this range as restrictive as possible. You can add multiple rules for separate network ranges, if necessary.
DNS (UDP)		UDP	53	Your private subnet address range (for example, 10.0.0.0/24).
Custom UDP	Spread	UDP	4803 and 4804	Your private subnet address range (for example, 10.0.0.0/24).
Custom TCP	Spread	TCP	4803	Your private subnet address range (for example, 10.0.0.0/24).
Custom TCP	VSQL/SQL	TCP	5433	The CIDR address range of client systems that require access to the Vertica nodes. This range should be as restrictive as possible. You can add multiple rules for separate network ranges, if necessary.
Custom TCP	Inter-node Communication	TCP	5434	Your private subnet address range (for example, 10.0.0.0/24).

Custom TCP		TCP	5444	Your private subnet address range (for example, 10.0.0.0/24).
Custom TCP	MC	TCP	5450	The CIDR address of client systems that require access to the management console. This range should be as restrictive as possible. You can add multiple rules for separate network ranges, if necessary.
Custom TCP	Rsync	TCP	50000	Your private subnet address range (for example, 10.0.0.0/24).
ICMP	Installer	Echo Reply	N/A	Your private subnet address range (for example, 10.0.0.0/24).
ICMP	Installer	Traceroute	N/A	Your private subnet address range (for example, 10.0.0.0/24).

Note

In Management Console (MC), the Java IANA discovery process uses port 7 once to detect if an IP address is reachable before the database import operation. Vertica tries port 7 first. If port 7 is blocked, Vertica switches to port 22.

Outbound

Type	Protocol	Port Range	Destination	IP
All TCP	TCP	0-65535	Anywhere	0.0.0.0/0
All ICMP	ICMP	0-65535	Anywhere	0.0.0.0/0
All UDP	UDP	0-65535	Anywhere	0.0.0.0/0

For information about what a security group is, as well as how to create one, see [Amazon EC2 Security Groups for Linux Instances](#) in the AWS documentation.

Deploy AWS instances for your Vertica database cluster

After you [Configure your network](#), you can create AWS instances and deploy Vertica. Follow these procedures to deploy and run Vertica on AWS.

In this section

- [Configure and launch an instance](#)
- [Connect to an instance](#)
- [Prepare instances for cluster formation](#)
- [Change instances on AWS](#)
- [Configure storage](#)
- [Create a cluster](#)
- [Management Console on AWS](#)

Configure and launch an instance

After you configure your network settings on AWS, configure and launch the instances where you will install Vertica. An Elastic Compute Cloud (EC2) instance without a Vertica AMI is similar to a traditional host. Just like with an on-premises cluster, you must prepare and configure your cluster and network at the hardware level before you can install Vertica.

When you create an EC2 instance on AWS using a Vertica AMI, the instance includes the Vertica software and the recommended configuration. Vertica recommends that you use the Vertica AMI unmodified. The Vertica AMI acts as a template, requiring fewer configuration steps:

1. [Choose a Vertica AMI Operating Systems](#)
2. [Configure EC2 instances.](#)
3. [Add storage to instances.](#)
4. Optionally, [configure EBS volumes as a RAID array.](#)
5. [Set the security group and S3 access.](#)
6. Launch instances and verify they are running.

OpenText provides Vertica and Management Console AMIs on the Red Hat Enterprise Linux 8 operating system.

You can use the AMI to deploy MC hosts or cluster hosts. For more information, see the [AWS Marketplace](#).

Configure EC2 instances in AWS

1. Select a Vertica AMI from the AWS marketplace. For instance type recommendations for Eon Mode databases, see [Choosing AWS Eon Mode Instance Types](#).
2. Select the desired fulfillment method.
3. Configure the following:
 - [Supported instance type](#)
 - Number of instances to launch. A Vertica cluster usually uses identically configured instances of the same type.
 - VPC [placement group](#)

Add storage to instances

Consider the following issues when you add storage to your instances:

- Add a number of drives equal to the number of physical cores in your instance—for example, for a c3.8xlarge instance, 16 drives; for an r3.4xlarge, 8 drives.
- Do not store your information on the root volume.
- Amazon EBS provides durable, block-level storage volumes that you can attach to running instances. For guidance on selecting and configuring an Amazon EBS volume type, see [Amazon EBS Volume Types](#).

Configure EBS volumes as a RAID array

You can configure your EBS volumes into a RAID 0 array to improve disk performance. Before doing so, use the [vioperf](#) utility to determine whether the performance of the EBS volumes is fast enough without using them in a RAID array. Pass vioperf the path to a mount point for an EBS volume. In this example, an EBS volume is mounted on a directory named /vertica/data:

```
[dbadmin@ip-10-11-12-13 ~]$ /opt/vertica/bin/vioperf /vertica/data
```

The minimum required I/O is 20 MB/s read and write per physical processor core on each node, in full duplex i.e. reading and writing at this rate simultaneously, concurrently on all nodes of the cluster. The recommended I/O is 40 MB/s per physical core on each node. For example, the I/O rate for a server node with 2 hyper-threaded six-core CPUs is 240 MB/s required minimum, 480 MB/s recommended.

Using direct io (buffer size=1048576, alignment=512) for directory "/vertica/data"

test	directory	counter name	counter	counter	counter	counter	thread	%CPU	%IO Wait	elapsed	remaining
		value	value (10	value/core	value/core	count		time (s)	time (s)		
		sec avg)		(10 sec avg)							
Write	/vertica/data	MB/s	259	259	32.375	32.375	8	4	11	10	65
Write	/vertica/data	MB/s	248	232	31	29	8	4	11	20	55
Write	/vertica/data	MB/s	240	234	30	29.25	8	4	11	30	45

SkipRead	/vertica/data	seeks/s	21272	21142	2659	2642.75	8	0	6	75	0

If the EBS volume read and write performance (the entries with Read and Write in column 1 of the output) is greater than 20MB/s per physical processor core (columns 6 and 7), you do not need to configure the EBS volumes as a RAID array to meet the minimum requirements to run Vertica. You may still consider configuring your EBS volumes as a RAID array if the performance is less than the optimal 40MB/s per physical core (as is the case in this example).

Note

If your EC2 instance has hyper-threading enabled, vioperf may incorrectly count the number of cores in your system. The 20MB/s throughput per core requirement only applies to physical cores, rather than virtual cores. If your EC2 instance has hyper-threading enabled, divide the counter value (column 4 in the output) by the number of physical cores. See CPU Cores and Threads Per CPU Core Per Instance Type section in the AWS documentation topic [Optimizing CPU Options](#) for a list of physical cores in each instance type.

If you determine you need to configure your EBS volumes as a RAID 0 array, see the AWS documentation topic [RAID Configuration on Linux](#) the steps you need to take.

Security group and access

1. Choose between your previously configured security group or the default security group.
2. Configure S3 access for your nodes by creating and assigning an IAM role to your EC2 instance. See [AWS authentication](#) for more information.

Connect to an instance

Using your private key, take these steps to connect to your cluster through the instance to which you attached an elastic IP address:

1. As the dbadmin user, type the following command, substituting your ssh key:

```
$ ssh --ssh-identity <ssh key> dbadmin@elasticipaddress
```

2. Select **Instances** from the Navigation panel.
3. Select the instance that is attached to the Elastic IP.
4. Click **Connect**.
5. On **Connect to Your Instance**, choose one of the following options:
 - **A Java SSH Client directly from my browser** —Add the path to your private key in the field **Private key path**, and click **Launch SSH Client**.
 - **Connect with a standalone SSH client** **—**Follow the steps required by your standalone SSH client.

Connect to an instance from windows using putty

If you connect to the instance from the Windows operating system, and plan to use Putty:

1. Convert your key file using PuTTYgen.
2. Connect with Putty or WinSCP (connect via the elastic IP), using your converted key (i.e., the *.ppk file).
3. Move your key file (the *.pem file) to the root dir using Putty or WinSCP.

Prepare instances for cluster formation

After you create your instances, you need to prepare them for cluster formation. Prepare your instances by adding your AWS *.pem key and your Vertica license.

By default, each AMI includes a Community Edition license. Once Vertica is installed, you can find the license at this location:

```
/opt/vertica/config/licensing/vertica_community_edition.license.key
```

1. As the dbadmin user, copy your *.pem file (from where you saved it locally) onto your primary instance.
Depending upon the procedure you use to copy the file, the permissions on the file may change. If permissions change, the `install_vertica` script fails with a message similar to the following:

```
FATAL (19): Failed Login Validation 10.0.3.158, cannot resolve or connect to host as root.
```

If you receive a failure message, enter the following command to correct permissions on your *.pem file:

```
$ chmod 600 /<name-of-pem>.pem
```

2. Copy your Vertica license over to your primary instance, placing it in your home directory or other known location.

Change instances on AWS

You can change instance types on AWS. For example, you can downgrade a c3.8xlarge instance to c3.4xlarge. See [Supported AWS instance types](#) for a list of valid AWS instances.

When you change AWS instances you may need to:

- Reconfigure memory settings
- Reset memory size in a resource pool
- Reset number of CPUs in a resource pool

Reconfigure memory settings

If you change to an AWS instance type that requires a different amount of memory, you may need to recompute the following and then reset the values:

- [min_free_kbytes setting](#)
- [max_map_count](#)

Note

You may need root user permissions to reset these values.

Reset memory size in a resource pool

If you used absolute memory in a resource pool, you may need to reconfigure the memory using the MEMORYSIZE parameter in [ALTER RESOURCE POOL](#).

Note

If you set memory size as a percentage when you created the original resource pool, you do not need to change it here.

Reset number of CPUs in a resource pool

If your new instance requires a different number of CPUs, you may need to reset the CPUAFFINITYSET parameter in [ALTER RESOURCE POOL](#).

Configure storage

Vertica recommends that you store information — especially your data and catalog directories — on dedicated [Amazon EBS volumes](#) formatted with a supported file system. The `/opt/vertica/sbin/configure_software_raid.sh` script automates the storage configuration process.

Caution

Do not store information on the root volume because it might result in data loss.

Vertica performance tests Eon Mode with a per-node EBS volume of up to 2TB. For best performance, combine multiple EBS volumes into a RAID 0 array.

For more information about RAID 0 arrays and EBS volumes, see [RAID configuration on Linux](#).

Determining volume names

Because the storage configuration script requires the volume names that you want to configure, you must identify the volumes on your machine. The following command lists the contents of the `/dev` directory. Search for the volumes that begin with `xvd`:

```
$ ls /dev
```

Important

Ignore the root volume. Do not include any of your root volumes in the RAID creation process.

Combining volumes for storage

The `configure_software_raid.sh` shell script combines your EBS volumes into a RAID 0 array.

Caution

Run `configure_software_raid.sh` in the default setting only if you have a fresh configuration with no existing RAID settings.

If you have existing RAID settings, open the script in a text editor and manually edit the `raid_dev` value to reflect your current RAID settings. If you have existing RAID settings and you do not edit the script, the script deletes important operating system device files.

Alternately, use the Management Console (MC) console to add storage nodes without unwanted changes to operating system device files. For more information, see [Managing database clusters](#).

The following steps combine your EBS volumes into RAID 0 with the `configure_software_raid.sh` script:

1. Edit the `/opt/vertica/sbin/configure_software_raid.sh` shell file as follows:
 1. Comment out the safety `exit` command at the beginning.
 2. Change the sample volume names to your own volume names, which you noted previously. Add more volumes, if necessary.
2. Run the `/opt/vertica/sbin/configure_software_raid.sh` shell file. Running this file creates a RAID 0 volume and mounts it to `/vertica/data`.
3. Change the owner of the newly created volume to `dbadmin` with `chown`.

4. Repeat steps 1-3 for each node on your cluster.

Create a cluster

On AWS, use the [install_vertica](#) script to combine instances and create a cluster. Check your **My Instances** page on AWS for a list of current instances and their associated IP addresses. You need these IP addresses when you run [install_vertica](#) .

Create a cluster as follows:

1. While connected to your primary instance, enter the following command to combine your instances into a cluster. Substitute the IP addresses for your instances and include your root *.pem file name.

```
$ sudo /opt/vertica/sbin/install_vertica --hosts 10.0.11.164,10.0.11.165,10.0.11.166 \  
--dba-user-password-disabled --point-to-point --data-dir /vertica/data \  
--ssh-identity ~/name-of-pem.pem --license license.file
```

Note

- If you are using Vertica Community Edition, which limits you to three instances, you can specify **-L CE** with no license file.
- When you issue `install_vertica` or `update_vertica` on a Vertica AMI script, `--point-to-point` is the default. This parameter configures [Spread](#) to use direct point-to-point communication between all Vertica nodes, which is a requirement for clusters on AWS.
- If you are using IPv6 network addresses to identify the hosts in your cluster, use the `--ipv6` flag in your `install_vertica` command. You must also use IP addresses instead of host names, as the AWS DNS server cannot resolve host names to IPv6 addresses.

2. After combining your instances, Vertica recommends deleting your *.pem key from your cluster to reduce security risks. The example below uses the `shred` command to delete the file:

```
$ shred name-of-pem.pem
```

3. After creating one or more clusters, [create your database](#) or connect to [Management Console on AWS](#) .

For complete information on the `install_vertica` script and its parameters, see [Install Vertica with the installation script](#) .

Important

Stopping or rebooting an instance or cluster without first shutting down the database down, may result in disk or database corruption. To safely shut down and restart your cluster, see [Operating the database](#) .

Check open ports manually using the netcat utility

Once your cluster is up and running, you can check ports manually through the command line using the netcat (nc) utility. What follows is an example using the utility to check ports.

Before performing the procedure, choose the private IP addresses of two nodes in your cluster.

The examples given below use nodes with the private IPs:

```
10.0.11.60 10.0.11.61
```

Install the nc utility on your nodes. Once installed, you can issue commands to check the ports on one node from another node.

To check a TCP port:

1. Put one node in listen mode and specify the port. The following sample shows how to put IP **10.0.11.60** into listen mode for port **480**

```
[root@ip-10-0-11-60 ~]# nc -l 4804
```

2. From the other node, run `nc` specifying the IP address of the node you just put in listen mode, and the same port number.

```
[root@ip-10-0-11-61 ~]# nc 10.0.11.60 4804
```

3. Enter sample text from either node and it should show up on the other node. To cancel after you have checked a port, enter **Ctrl+C** .

Note

To check a UDP port, use the same `nc` commands with the `-u` option.

```
[root@ip-10-0-11-60 ~]# nc -u -l 4804
[root@ip-10-0-11-61 ~]# nc -u 10.0.11.60 4804
```

Management Console on AWS

Management Console (MC) is a database management tool that allows you to view and manage aspects of your cluster. Vertica provides an MC AMI, which you can use with AWS. The MC AMI allows you to create an instance, dedicated to running MC, that you can attach to a new or existing Vertica cluster on AWS. You can create and attach an MC instance to your Vertica on AWS cluster at any time.

After you launch your MC instance and configure your security group settings, you can log in to your database. To do so, use the elastic IP you specified during instance creation.

From this elastic IP, you can manage your Vertica database on AWS using standard MC procedures.

Considerations when using MC on AWS

- Because MC is already installed on the MC AMI, the MC installation process does not apply.
- To uninstall MC on AWS, follow the procedures provided in [Uninstalling Management Console](#) before terminating the MC Instance.

- [Network ACL settings](#)

Vertica on Microsoft Azure

Vertica supports automatic deployment on Azure through the Microsoft Azure Marketplace, or manual installation and deployment on Azure VMs.

You can deploy a Vertica database on the Microsoft Azure Cloud running in either [Enterprise Mode](#) or [Eon Mode](#). In Eon Mode, Vertica stores its data communally using Azure block blob storage.

This section explains how to deploy a Vertica database to Microsoft Azure.

For more information about Azure, see the [Azure documentation](#).

In this section

- [Recommended Azure VM types and operating systems](#)
- [Eon Mode on Azure prerequisites](#)
- [Deploy Vertica from the Azure Marketplace](#)
- [Manually deploy Vertica on Microsoft Azure](#)

Recommended Azure VM types and operating systems

Recommended Azure VM types

Vertica supports a range of Microsoft Azure virtual machine (VM) types, each optimized for different purposes. Choose the VM type that best matches your performance and price needs as a user.

Note

The GS VMs are not available in all regions, or from the Azure Marketplace.

You can use them by following the manual deployment steps described in [Manually deploy Vertica on Microsoft Azure](#).

For the best performance in most common scenarios, use one of the following VMs:

Virtual Machine Types	Virtual Machine Size
-----------------------	----------------------

Memory optimized	DS13_v2 DS14_v2 DS15_v2 D8s_v3 D16s_v3 D32s_v3
High memory and I/O throughput	GS3 GS4 GS5 E8s_v3 E16s_v3 E32s_v3 L8s L16s L32s

Recommended Azure operating systems

For best performance, use one of the following operating systems when deploying Vertica on Azure:

- Red Hat 7.3 or later
- CentOS 7.3 or later. The Azure Marketplace solution as of this writing (June 2017) is based on CentOS 7.3.1611.

For more information, see [Supported platforms](#).

Eon Mode on Azure prerequisites

Before you can create an Eon Mode database on Azure, you must have a database cluster and an Azure blob storage container to store your database's data.

You can create an [Eon Mode](#) database on a cluster that is hosted on Azure. In this configuration, your database stores its data communally in Azure Blob storage. See [Eon Mode](#) to learn more about this database mode.

Note

If you have an existing Enterprise Mode database, you can migrate it to an Eon Mode database running on Azure. See [Migrating an enterprise database to Eon Mode](#).

Cluster requirements

Before you can create an Eon Mode database on Azure, you must provision a cluster to host it. See [Configuring your Vertica cluster for Eon Mode](#) for suggestions on choosing VM configurations and the number of nodes your cluster should start with.

Storage requirements

An Eon Mode database on Azure stores its data communally in Azure blob storage. Vertica only supports block blob storage for communal data storage, not append or page blob storage.

You must create a storage path for Vertica to use exclusively. This path can be a blob container or a folder within a blob container. This path must not contain any files. If you attempt to create an Eon Mode database with a container or folder that contains files, admintools returns an error.

You pass Vertica a URI for the storage path using the `azb://` schema. See [Azure Blob Storage object store](#) for the format of this URI.

You must also configure the storage container so Vertica is authorized to access it. Depending on authentication method you use, you may need to supply Vertica with credentials to access the container. Vertica can use one of following methods to authenticate with the blob storage container:

- Using Azure managed identities. This authentication method is transparent—you do not need to add any authentication configuration information to Vertica. Vertica automatically uses the managed identity bound to the VMs it runs on to authenticate with the blob storage container. See the [Azure AD-managed identities for Azure resources documentation](#) page in the Azure documentation for more information. If you provide credentials for either of the other two supported authentication methods, Vertica uses them instead of authenticating using a managed identity bound to your VM.

Note

If your Azure VMs have more than one managed identity bound to them, you must tell Vertica which identity to use when authenticating with the blob storage container. Vertica gets the identity to use from a tag set on the VMs that it is running on.

On your VMs, create a tag with its key named `VerticaManagedIdentityClientId` and its value to the name of a managed identity bound to your VMs. See the [Use tags to organize your Azure resources and management hierarchy](#) page in the Azure documentation for more information.

- Using an account name and access key credentials for a service account that has full access to the blob storage container. In this case, you provide Vertica with the credentials when you create the Eon Mode database. See [Creating an Authentication File](#) for details.
- Using a shared access signature (SAS) that grants Vertica access to the storage container. See [Grant limited access to Azure Storage resources using shared access signatures \(SAS\)](#) in the Azure documentation. See [Creating an Authentication File](#) for details.

For details on how Vertica accesses Azure blob storage, see [Azure Blob Storage object store](#).

Azure Blob Storage encryption

Eon Mode databases on Azure support some of the encryption features built into Azure Storage. You can use its encryption at rest feature transparently—you do not need to configure Vertica to take advantage of it. You can use Microsoft-managed or customer-managed keys for storage encryption. Vertica does not support Azure Storage's client-side encryption and encryption using customer-provided keys. See the [Azure Data Encryption at rest page](#) in the Azure documentation for more information about the encryption at rest features in Azure Storage.

Deploy Vertica from the Azure Marketplace

Deploy Vertica in the Microsoft Azure Cloud using the [Vertica Data Warehouse](#) entry in the Azure Marketplace. Vertica provides the following deployment options:

- **Eon Mode**: Deploy a Management Console (MC) instance, and then provision and create an Eon Mode database from the MC. For cluster and storage requirements, see [Eon Mode on Azure prerequisites](#).
- **Enterprise Mode**: Deploy a four-node Enterprise Mode database comprised of one MC instance and three database nodes. This requires an [Azure subscription](#) with a minimum of 12 cores for the Vertica Marketplace solution.

The Enterprise Mode deployment uses the MC primarily as a monitoring tool. For example, you cannot provision and create a database with an Enterprise Mode MC. For information about creating and managing an Enterprise Mode database, see [Create a database using administration tools](#).

Create a deployment

Eon Mode and Enterprise Mode require much of the same information for deployment. Any information that is not required for both deployment types is clearly marked.

1. Select the deployment type

1. Sign in to your Microsoft Azure account. From the **Home** screen, select **Create a resource** under **Azure services**.
2. Search for **Vertica Data Warehouse** and select it from the search results.
3. On the **Vertica Data Warehouse** page, select one of the following:
 - To deploy an MC instance that can manage an Eon Mode database, select Vertica **Data Warehouse, Eon BYOL**.
 - To deploy an Enterprise Mode database, select Vertica **Data Warehouse, Enterprise BYOL**.
4. On the next screen, select **Create**.

After you select your deployment type, the **Basics** tab on the **Create Vertica Data Warehouse** page displays.

2. Add project and instance details on the basics tab

Provide the following information in the **Project details** and **Instance details** sections:

1. **Subscription**: Azure bills this subscription for the cluster resources.
2. **Resource group**: The location to save all of the Azure resources. Create a new resource group or choose an existing one from the dropdown list.

3. **Region** : The location where the virtual machine running your MC instance is deployed.
4. VerticaManagement Console **User** : Eon Mode only. The administrator username for the MC.
5. **SSH public key for OS Access** : Provide the SSH public key associated with the Vertica **User** , for command line access to the virtual machine.
6. **Password for MC Access** : Enter a password to log in to Management Console. Note that Management Console requires that you change your password after the initial login.
7. **Confirm password** : Reenter the value you entered in **Password for MC Access** .
8. Select **Next: Virtual Machine Settings >** .

3. Select virtual machine settings

Provide the following information on the **Virtual Machine Settings** tab:

1. Management Console **VM size** : Select Change size to customize the VM settings or select the default. For a list of VM types recommended by use case, see [Recommended Azure VM types and operating systems](#) .
2. **Storage account of Eon DB** : Eon Mode only. The storage account associated with the database deployment.
3. **Number of Vertica Cluster nodes** : Enterprise Mode only. The number of nodes to deploy in the cluster, in addition to the MC instance. The Community Edition (CE) license is automatically applied to the cluster. This license is limited to 1 TB of RAW data 3 Vertica nodes. If you select more than 3 nodes with a CE license, the initial database is created on the first 3 nodes. For information about upgrading your license, see [Managing licenses](#) .
4. Vertica **Node VM size** : Enterprise Mode only. Select the VM type to deploy in your cluster. Use the default or select **Change size** to customize the VM settings. For a list of VM types recommended by use case, see [Recommended Azure VM types and operating systems](#) .
5. **Total RAW storage per node** : Enterprise Mode only. Select the amount of storage per node from the dropdown list. Each VM has a set of premium data disks that are configured and presented as a single storage location.
6. Select **Next: Network Settings >** .

4. Select network settings

Provide the following information on the **Network Settings** tab:

1. **Virtual Network** : The virtual network that hosts the Vertica cluster. Create a new virtual network or select an existing one from the dropdown list.
If you select an existing virtual network, Vertica recommends that you already created a subnet to use for the deployment.
2. **First subnet** : The subnet for the associated **Virtual Network** . Create a new subnet or select an existing one from the dropdown list.
3. **Public IP Address Resource Name** : Each VM is configured with a publicly accessible IP address. This field allows you to specify the resource name for those IP addresses, and whether they are static or dynamic. The first public IP address resource is created exactly as entered, and associated with the VerticaManagement Console. Azure appends a number from 1 to 16 to the resource name for each additional Vertica cluster node created. This number associates each VM with a resource.
4. **Domain Name Label for Management Console**: Because each VM has a public IP address, each node requires a DNS name. Enter a prefix for the name. The first DNS name is created exactly as entered, and associated with the VerticaManagement Console. Azure appends a number from 1 to 16 to the DNS name for each Vertica cluster node created. That number associates each VM with a resource. Azure adds the remaining part of the fully qualified domain name based on the location where you created the cluster.
5. Select **Next: Review + create >** .

5. Verify on review + create

As the **Review + create** page loads, Azure validates your settings. After it passes validation, review your settings. When you are satisfied with your selections, select **Create** .

Access the MC after deployment

After your resources are successfully deployed, you are brought to the **Overview** page on **Home > resources-name > Deployments** . You must retrieve your Management Console IP address and username to log in.

1. From the **Overview** page, select **Outputs** in the left navigation.
2. Copy the **Vertica Management Console URL** and *Vertica Management Console user name **.
3. Paste the **Vertica Management Console URL** in the browser address bar and press **Enter** .
4. Depending on your browser, you might receive a warning of a security risk. If you receive the warning, select the **Advanced** button and follow the browser's instructions to proceed to the Management Console.
5. On the VerticaManagement Console log in page, paste the **Vertica Management Console user name** , and enter the **Password for MC Access** that you entered on **Basics > Project details** when you were deploying your MC instance.

Delete a resource group

For details about the Azure Resource Manager and deleting a resource group, see the [Azure documentation](#) .

Manually deploy Vertica on Microsoft Azure

Manually creating a database cluster for your Vertica deployment lets you customize your VMs to meet your specific needs. You often want to manually configure your VMs when deploying a Vertica cluster to host an Eon Mode database.

To start creating your Vertica cluster in Azure using manual steps, you first need to create a VM. During the VM creation process, you create and configure the other resources required for your cluster, which are then available for any additional VMs that you create.

In this section

- [Configure and launch a new instance](#)
- [Connect to a virtual machine](#)
- [Prepare the virtual machines](#)
- [Configure storage](#)
- [Form a cluster and install Vertica](#)

Configure and launch a new instance

An Azure VM is similar to a traditional host. Just as with an on-premises cluster, you must prepare and configure the hardware settings for your cluster and network before you install Vertica.

The first steps are:

1. From the Azure marketplace, select an operating system that Vertica supports.
2. Select a VM type. See [Recommended Azure VM types and operating systems](#).
3. Choose a deployment model. For best results, choose the resource manager deployment model.

Configure network security group

Vertica has specific network security group requirements, as described in [Create a security group](#).

Create and name your own network security group, following these guidelines.

You must configure SSH as:

- Protocol: TCP
- Source port range: Any
- Destination port range: 22
- Source: Any
- Destination: Any

You can make additional modifications, based on your specific requirements.

Add disk containers

Create an Azure storage account, which later contains your cluster storage disk containers.

For optimal throughput, select Premium storage and align the storage to your chosen VM type.

For more information about what a storage account is, and how to create one, refer to [About Azure storage accounts](#).

For an Enterprise Mode database deployment, provision enough space

Configure credentials

Create a password or assign an SSH key pair to use with Vertica.

For information about how to use key pairs in Azure, see [How to create and use an SSH public and private key pair for Linux VMs in Azure](#).

Assign a public IP address

A public IP is an IP address that you can use to connect to your cluster externally. For best results, assign a single static public IP to a node in your cluster. You can then connect to other nodes in your cluster from your primary node using the internal IP addresses that Azure generated when you specified your virtual network settings.

By default, a public IP address is dynamic; it changes every time you shut down the server. You can choose a static IP address, but doing so can add cost to your deployment.

During a VM installation, you cannot set a DNS name. If you use dynamic public IPs, set the DNS name in the public IP resource for each VM after deployment.

For information about public IP addresses, refer to [IP address types and allocation methods in Azure](#).

Create additional VMs

If needed, to create additional VMs, repeat the previous instructions in this document.

Connect to a virtual machine

Before you can connect to any of the VMs you created, you must first make your virtual network externally accessible. To do so, you must attach the public IP address you created during network configuration to one of your VMs.

Connect to your VM

To connect to your VM, complete the following tasks:

1. Connect to your VM using SSH with the public IP address you created in the configuration steps.
2. Authenticate using the credentials and authentication method you specified during the VM creation process.

Connect to other VMs

Connect to other virtual machines in your virtual network by first using SSH to connect to your publicly connected VM. Then, use SSH again from that VM to connect through the private IP addresses of your other VMs.

If you are using private key authentication, you may need to move your key file to the root directory of your publicly connected VM. Then, use PuTTY or WinSCP to connect to other VMs in your virtual network.

Prepare the virtual machines

After you create your VMs, you need to prepare them for cluster formation.

Add the Vertica license and private key

Prepare your nodes by adding your private key (if you are using one) to each node and to your Vertica license. These steps assume that the initial user you configured is the DBADMIN user.

1. As the dbadmin user, copy your private key file from where you saved it locally onto your primary node.
Depending upon the procedure you use to copy the file, the permissions on the file may change. If permissions change, the `install_vertica` script fails with a message similar to the following:

```
Failed Login Validation 10.0.2.158, cannot resolve or connect to host as root.
```

If you receive a failure message, enter the following command to correct permissions on your private key file:

```
$ chmod 600 /<name-of-key>.pem
```

2. Copy your Vertica license to your primary VM. Save it in your home directory or other known location.

Install software dependencies for Vertica on Azure

In addition to the Vertica standard [Package dependencies](#), as the root user, you must install the following packages before you install Vertica on Azure:

- `pstack`
- `mcelog`
- `sysstat`
- `dialog`

Configure storage

Use a dedicated Azure storage account for node storage.

Caution

Caution: Do *not* store your information on the `root` volume, especially your `data` and `catalog` directories. Storing information on the `root` volume may result in data loss.

When configuring your storage, make sure to use a supported file system. For details, see [File system](#).

Attach disk containers to virtual machines (VMs)

Using your previously created storage account, attach disk containers to your VMs that are appropriate to your needs.

For best performance, combine multiple storage volumes into RAID-0. For most RAID-0 implementations, attach 6 storage disk containers per VM.

Combine disk containers for storage

If you are using RAID, follow these steps to create a RAID-0 drive on your VMs. The following example shows how you can create a RAID-0 volume named `md10` from 6 individual volumes named:

- `sd`
- `sdd`
- `sde`
- `sdf`
- `sdg`
- `sdh`

1. Form a RAID-0 volume using the `mdadm` utility:

```
$ mdadm --create /dev/md10 --level 0 --raid-devices=6 \  
/dev/sdc /dev/sdd /dev/sde /dev/sdf /dev/sdg /dev/sdh
```

2. Format the file system to be one that Vertica supports:

```
$ mkfs.ext4 /dev/md10
```

3. Find the UUID on the newly-formed RAID volume using the `blkid` command. In the output, look for the device you assigned to the RAID volume:

```
$ blkid  
...  
/dev/md10 : UUID="e7510a6f-2922-4413-b5fa-9dcd725967fd" TYPE="ext4" PARTUUID="fb9b7449-08c3-4231-9ee5-086f7b0c9001"  
...
```

4. The RAID device can be renamed after a reboot. To ensure the filesystem is mounted in a predictable location on your VM, create a directory to use as the mount point to mount the filesystem. For example, you can choose to create a mount point named `/data` that you will use to store your database's catalog and data (or depot, if you are running Vertica in Eon Mode).

```
$ mkdir /data
```

5. Using a text editor, add an entry to the `/etc/fstab` file for the UUID of the filesystem and your mount point so it is mounted when the system boots:

```
UUID=RAID_UUID mountpoint ext4 defaults,nofail,nobarrier 0 2
```

For example, if you have the UUID shown in the previous example and the mount point `/data`, add the following line to the `/etc/fstab` file:

```
UUID=e7510a6f-2922-4413-b5fa-9dcd725967fd /data ext4 defaults,nofail,nobarrier 0 2
```

6. Mount the RAID filesystem you added to the `fstab` file. For example, to mount a mount point named `/data` use the command:

```
$ mount /data
```

7. Create folders for your Vertica data and catalog under your mount point.

```
$ mkdir /data/vertica  
$ mkdir /data/vertica/data
```

If you are planning to run Vertica in Eon Mode, create a directory for the depot instead of data:

```
$ mkdir /data/vertica/depot
```

Create a swap file

In addition to storage volumes to store your data, Vertica requires a swap volume or swap file to operate.

Create a swap file or swap volume of at least 2 GB. The following steps show how to create a swap file within Vertica on Azure:

1. Install `devnull` and `swapfile`:

```
$ install -o root -g root -m 0600 /dev/null /swapfile
```

2. Create the swap file:

```
$ dd if=/dev/zero of=/swapfile bs=1024 count=2048k
```

3. Prepare the swap file using `mkswap` :

```
$ mkswap /swapfile
```

4. Use `swapon` to instruct Linux to swap on the swap file:

```
$ swapon /swapfile
```

5. Persist the swapfile in `FSTAB`:

```
$ echo "/swapfile swap swap auto 0 0" >> /etc/fstab
```

Repeat the volume attachment, combination, and swap file creation procedures for each VM in your cluster.

For more information

- [About Azure storage accounts](#)
- [Prepare disk storage locations](#)
- [Storage Requirements](#)

Form a cluster and install Vertica

Use the `install_vertica` script to combine two or more individual VMs to form a cluster and install the Vertica database.

Download Vertica

To download the Vertica server appropriate for your operating system and license type, go to www.vertica.com/download/vertica.

Run the rpm to extract the files.

After you complete the download and extraction, the next section describes how to use the `install_vertica` script to form a cluster and install the Vertica database software.

Before you start

Before you run the `install_vertica` script:

- Check the **Virtual Network** page for a list of current VMs and their associated private IP addresses.
- Identify your storage location. The installer assumes that you have mounted your storage to `/vertica/data`. To specify another location, use the `--data-dir` argument.
- Identify your storage location. To create your database's `data` directory on mounted RAID drive, when you run the `install_vertica` script, provide `/vertica/data` as the value of the `--data-dir` option.

Caution

Caution: Do *not* store your data on the root drive.

Combine virtual machines (VMs)

The following example shows how to combine VMs using the `install_vertica` script.

1. While connected to your primary node, construct the following command to combine your nodes into a cluster.

```
$ sudo /opt/vertica/sbin/install_vertica --hosts 10.2.0.164,10.2.0.165,10.2.0.166 --dba-user-password-disabled --point-to-point --data-dir /vertica/data --ssh-identity ~/<name-of-private-key>.pem --license <license.file>
```

2. Substitute the IP addresses for your VMs and include your root key file name, if applicable.
3. Include the `--point-to-point` parameter to configure spread to use direct point-to-point communication between all Vertica nodes, as required for clusters on Azure when installing or updating Vertica.
4. If you are using Vertica Community Edition, which limits you to three nodes, specify `-L CE` with no license file.
5. After you combine your nodes, to reduce security risks, keep your key file in a secure place—separate from your cluster—and delete your on-cluster key with the `shred` command:

```
$ shred examplekey.pem
```

Important

You need your key file to perform future Vertica updates.

6. Reboot your cluster to complete the cluster formation and Vertica installation.

For complete information on the `install_vertica` script and its parameters, see [Install Vertica with the installation script](#).

After your cluster is up and running

Now that your cluster is configured and running, take these steps:

1. Log into one of the database nodes using the database administrator account (named `dbadmin` by default).
2. Create and start a database:
 - To create an [Enterprise Mode](#) database, see [Create a database using administration tools](#).
 - To create an [Eon Mode](#) database, see [Manually create an Eon Mode database on Azure](#).
3. Configure your database. See [Configuring the database](#).

Vertica on Google Cloud Platform

Vertica supports automatic deployment on Google Cloud Platform (GCP) through the [Google Cloud Launcher](#), or manual installation and deployment on GCP machines.

You can deploy a Vertica database on GCP running in either [Enterprise Mode](#) or [Eon Mode](#). In Eon Mode, Vertica stores its data communally using Google Cloud Storage (GCS).

This section explains how to deploy a Vertica database to GCP.

For more information about GCP, see the [Google Cloud documentation](#).

In this section

- [Supported GCP machine types](#)
- [Deploy Vertica from the Google cloud marketplace](#)
- [Manually deploy an Enterprise Mode database on GCP](#)

Supported GCP machine types

Vertica Analytic Database supports a range of machine types, each optimized for different workloads. When you deploy your Vertica Analytic Database cluster to the Google Cloud Platform (GCP), different machine types are available depending on how you provision your database.

Note

Some machine types are not available across all regions.

The sections below list the GCP machine types that Vertica supports for Vertica cluster hosts, and for use in Management Console. For details on the configuration of the machine type options, see the Google Cloud documentation's [Machine types](#) page.

Machine types available for MC hosts

Vertica supports all N1, N2, E2, M1, M2, and C2 machine types to deploy an instance for running the Vertica Management Console.

Tip

In most cases, 8 vCPUs are sufficient when selecting a machine type for running the Management Console.

Machine types available for Vertica database cluster hosts

Vertica supports all N1, N2, E2, M1, M2, and C2 machine types to deploy cluster hosts.

Machine types for Vertica database cluster hosts provisioned from MC

The table below lists the GCP machine types that Vertica supports when you provision your cluster from Management Console.

Machine Type	Machine Name
N1 standard	n1-standard-16
	n1-standard-32
	n1-standard-64
N1 high-memory	n1-highmem-16
	n1-highmem-32
	n1-highmem-64

N2 standard	n2-standard-16 n2-standard-32 n2-standard-48 n2-standard-64
N2 high-memory	n2-highmem-16 n2-highmem-32 n2-highmem-48 n2-highmem-64

Deploy Vertica from the Google cloud marketplace

The Vertica entries in the Google Cloud Launcher Marketplace let you quickly deploy a Vertica cluster in the Google Cloud Platform (GCP). Currently, three entries let you select the database mode and the license you want to use:

- The Enterprise Mode launcher deploys a Vertica database with 3 or more nodes, plus an additional VM running the [Management Console \(MC\)](#). See [Deploy an Enterprise Mode database in GCP from the marketplace](#) for more information.
- The Eon Mode BYOL (bring your own license) launcher deploys a single instance running the MC. You use this MC instance to deploy a Vertica database running on Eon Mode. This database has a community license applied to it initially. You can later upgrade it to a license you have obtained from Vertica. See [Deploy an MC instance in GCP for Eon Mode](#) for more information.
- The Eon Mode BTH (by the hour) launcher also deploys a single instance running the MC that you use to deploy a database. This database has a by-the-hour license applied to it. Instead of paying for a license up front, you pay an hourly fee that covers both Vertica and running your instances. The BTH license is automatically applied to all clusters you create using a BTH MC instance. See [Deploy an MC instance in GCP for Eon Mode](#) for more information. If you choose, you can upgrade this hourly license to a longer-term license you purchase from Vertica. To move a BTH cluster to a BYOL license, follow the instructions in [Moving a cloud installation from by the hour \(BTH\) to bring your own license \(BYOL\)](#).

Note

Vertica clusters that use IPv6 to identify hosts have not been tested on GCP. Vertica recommends you use IPv4 addresses to identify the hosts in your cluster on GCP.

In this section

- [Eon Mode on GCP prerequisites](#)
- [Deploy an Enterprise Mode database in GCP from the marketplace](#)
- [Deploy an MC instance in GCP for Eon Mode](#)

Eon Mode on GCP prerequisites

Before deploying an Eon Mode database on GCP, you must take several steps:

- Review the default service account's permissions for your GCP project.
- Create an HMAC key to use when creating your cluster.
- Create a communal storage location.

Service account permissions

Service accounts allow automated processes to authenticate with GCP. The Eon Mode database deployment process uses the project's service account for your GCP project to deploy instances. When you create a new project, GCP automatically creates a default service account (identified by `project_number-compute@developer.gserviceaccount.com`) for the project and grants it the IAM role Editor. See the Google Cloud documentation's [Understanding roles](#) for details about this and other IAM roles.

The Editor role lets the service account create resources from the Marketplace. When you create an instance of the Management Console (MC), the MC uses the account to deploy further resources, such as provisioning instances for a database.

For details, see the Google Cloud documentation's [Understanding service accounts](#) page.

Permissions and roles

To deploy Vertica on GCP, your user account must have the:

- **Editor** role.
- `runtimeconfig.waiters.getIamPolicy` permission.

Creating an HMAC key

Vertica uses a hash-based message authentication code (HMAC) key to authenticate requests to access the communal storage location. This key has two parts: an access ID and a secret. When you create an Eon Mode database in GCP, you provide both parts of an HMAC key for the nodes to use to access communal storage.

To create an HMAC key:

1. Log in to your Google Cloud account.
2. If the name of the project you will use to create your database does not appear in the top banner, click the dropdown and select the correct project.
3. In the navigation menu in the upper-left corner, under the Storage heading, click **Storage** and select **Settings**.
4. In the Settings page, click **Interoperability**.
5. Scroll to the bottom of the page and find the User account HMAC heading.
6. Unless you have already set a default project, you will see the message stating you haven't set a default project for your user account yet. Click the **Set project-id as default project** button to choose the current project as your default for interoperability.

User account HMAC

You can authenticate yourself when making requests to Cloud Storage using access keys tied to your user account instead of your organization's service accounts. With this option, members of your organization maintain their own access keys and set their own default projects.

Default project for interoperable access

The Interoperability API uses your default project for all create bucket and list bucket requests made from your user account.

 You haven't set a default project for your user account yet

Set **myproject-1338** as default project

Note

The project ID appears in the button label, not the project name.

7. Under Access keys for your user account, click **Create a key**.
8. Your new access key and secret appear in the HMAC key list. You will need them when you create your Eon Mode database. You can copy them to a handy location (such as a text editor) or leave a browser tab open to this page while you use another tab or window to create your database. These keys remain available on this page, so you do not need to worry about saving them elsewhere.

Caution

It is vital that you protect the security of your HMAC key. It can grant others access to your Eon Mode database's communal storage location. This means they could access all of the data in your database. Do not write the HMAC key anywhere where it may be exposed, such as email, shared folders, or similar insecure locations.

Creating a communal storage location

Your Eon Mode database needs a storage location for its communal storage. Eon Mode databases running on GCP use Google Cloud Storage (GCS) for their communal storage location. When you create your new Eon Mode database, you will supply the MC's wizard with a GCS URL for the storage location.

This location needs to meet the following criteria:

- The URL must include at least a bucket name. You can use one or more levels of folders, as well. For example, the following GCS URLs are valid:
 - `gs://verticabucket/mydatabase`
 - `gs://verticabucket/databases/mydatabase`
 - `gs://verticabucket`

Multiple databases can share the same bucket, as long as each has its own folder.

- If provided, the lowest-level folder in the URL must not already exist. For example, in the GCS URL <gs://verticabucket/databases/mydatabase>, the bucket named [verticabucket](#) and the directory named [databases](#) must exist. The subdirectory named [mydatabase](#) must not exist. The Vertica install process expects to create the final folder itself. If the folder already exists, the installation process fails.

Note

If you have a communal storage location that already contains data from a previous Eon Mode database that you want to access, use the revive process, rather than installing a new database. See [Stopping, starting, terminating, and reviving Eon Mode database clusters](#) for details.

- The permissions on the bucket must be set to allow the service account read, write, and delete privileges on the bucket. The best role to assign to the user to gain these permissions is [Storage Object Admin](#).
- To prevent performance issues, the bucket must be in the same region as all of the nodes running the Eon Mode database.
- If you create the database through the admintools UI, you must set [gcsauth](#) as a bootstrap parameter in [admintools.conf](#). For more information on this and other GCP parameters, see [Google Cloud Storage parameters](#).

```
[BootstrapParameters]
```

```
gcsauth = ID:secret
```

Deploy an Enterprise Mode database in GCP from the marketplace

The Vertica Cloud Launcher solution creates a Vertica Enterprise Mode database. The solution includes the Vertica Management Console (MC) as the primary UI for you to get started.

The launcher automatically creates a database named vdb using the Community Edition (CE) license. The CE license is limited to a maximum of 3 nodes. You can tell the launcher to add more than 3 nodes to your deployment. In this case, it uses the first three nodes in the cluster to create the database. The remaining nodes are not part of the database, but are added to your cluster. To add these nodes to your database, you must replace the Community Edition license with a license key you receive from the Software Entitlement support site. See [Managing licenses](#) for more information.

After the launcher creates the initial database, it configures the MC to attach to that database automatically.

Configure the Vertica cloud launcher solution

To get started with a deployment of Vertica from the [Google Cloud Launcher](#), search for the Vertica Data Warehouse, Enterprise Mode entry.

Follow these steps:

1. Verify that your user account has the **Editor** role and the [runtimeconfig.waiters.getIamPolicy](#) permission.
2. From the listing page, click **LAUNCH**.
3. On the New Vertica Analytics Platform deployment page, enter the following information:
 - **Deployment name**: Each deployment must have a unique name. That name is used as the prefix for the names of all VMs created during the deployment. The deployment name can only contain lowercase characters, numbers, and dashes. The name must start with a lowercase letter and cannot end with a dash.
 - **Zone**: GCP breaks its cloud data centers into regions and zones. *Regions* are a collection of zones in the same geographical location. *Zones* are collections of compute resources, which vary from zone to zone. For best results, pick the zone in your designated region that supports the latest Intel CPUs. For a complete listing of regions and zones, including supported processors, see [Regions and Zones](#).
 - **Service Account**: Service accounts allow automated processes to authenticate with GCP. Select the default service account, identified by [project_number-compute@developer.gserviceaccount.com](#).
 - Under **Vertica Management Console**, choose the configuration for the virtual machine that will run the Management Console. The Vertica Analytics Platform in Cloud Launcher always deploys the Vertica Management Console (MC) as part of the solution. The default machine type for MC is sufficient for most deployments. You can choose another machine type that better suits any additional purposes, such as serving as a target node for backups, data transformation, or additional management tools.
 - **Node count for Vertica Cluster**: The total number of VMs you want to deploy in the Vertica Cluster. The default is 3.

Note

As mentioned above, the Cloud Launcher automatically deploys the Vertica Community Edition license, which limits the database to 3 nodes and up to 1 TB in raw data. Any additional nodes will be part of your database cluster, but will not be part of your database.

If you intend to use the Community Edition license for your database, leave the setting at 3. Otherwise, you would add nodes that will sit idle and cost you money without being part of your database.

- **Machine type for Vertica Cluster nodes** : The Cloud Launcher builds each node in the cluster using the same machine type. Modify the machine type for your nodes based on the workloads you expect your database to handle. See [Supported GCP machine types](#) for more information.
- **Data disk type** : GCP offers two types of persistent disk storage: Standard and SSD. The costs associated with Standard are less, but the performance of SSD storage is much better. Vertica recommends you use SSD storage. For more information on Standard and SSD persistent disks, see [Storage Options](#).
- **Disk size in GB** : Disk performance is directly tied to the disk size in GCP. The default value of 2000 GBs (2 TB) is the minimum disk size for SSD persistent disks that allows maximum throughput. If you select a smaller disk size, the throughput performance decreases. If you select a large disk size, the performance remains the same as the 2 TB option.
- **Network** : VMs in GCP must exist on a virtual private cloud (VPC). When you created your GCP account, a default VPC was created. Create additional VPCs to isolate solutions or projects from one another. The Vertica Analytics Platform creates all the nodes in the same VPC.
- **Subnetwork** : Just as a GCP account may have multiple VPCs, each VPC may also have multiple subnets. Use additional subnets to group or isolate solutions within the same VPC.
- **Firewall** : If you want your MC to be accessible via the internet, check the Allow access to the Management Console from the Internet box. Vertica recommends you protect your MC using a firewall that restricts access to just the IP addresses of users that need to access it. You can enter one or more comma-separated CIDR address ranges.

After you have entered all the required information, click **Deploy** to begin the deployment process.

Monitor the deployment

After the deployment begins, Google Cloud Launcher automatically opens the Deployment Manager page that displays the status of the deployment. Items that are still being processed have a spinning circle to the left of them and the text is a light gray color. Items that have been created are dark gray in color, with an icon designating that resource type on the left.

After the deployment completes, a green check mark appears next to the deployment name in the upper left-hand section of the screen.

Accessing the cluster after deployment

After the deployment completes, the right-hand section of the screen displays the following information:

- dbadmin password: A randomly generated password for the dbadmin account on the nodes. For security reasons, change the dbadmin password when you first log in to one of the Vertica cluster nodes.
- mcadmin password: A randomly generated password for the mcadmin account for accessing the Management Console. For security reasons, change the mcadmin password after you first log in to the MC.
- Vertica Node 1 IP address: The external IP address for the first node in the Vertica cluster is exposed here so that you can connect to the VM using a standard SSH client. To access the MC, press the **Access Vertica MC** button in the **Get Started** section of the dialog box. Copy the mcadmin password and paste it when asked.

For more information on using the MC, see [Management Console](#).

Access the cluster nodes

There are two ways to access the cluster nodes directly:

- Use GCP's integrated SSH shell by selecting the SSH button in the **Get Started** section. This shell opens a pop-up in your browser that runs GCP's web-based SSH client. You are automatically logged on as the user you authenticated as in the GCP environment. After you have access to the first Vertica cluster node, execute the `su dbadmin` command, and authenticate using the dbadmin password.
- In addition, use other standard SSH clients to connect directly to the first Vertica cluster node. Use the Vertica Node 1 IP address listed on the screen as the dbadmin user, and authenticate with the dbadmin password. Follow the on-screen directions to log in using the mcadmin account and accept the EULA. After you've been authenticated, access the initial database by clicking the vdb icon (looks like a green cylinder) in the **Recent Databases** section.

Using a custom service account

In general, you should use the default service account created by the GCP deployment (`project_number-compute@developer.gserviceaccount.com`), but if you want to use a custom service account:

- The custom service account must have the **Editor** role.
- Individual user accounts must have the **Service Account User** role on the custom service account.

Deploy an MC instance in GCP for Eon Mode

To deploy an Eon Mode database to GCP using Google Cloud Platform Launcher, you must deploy a Management Console (MC) instance. You then use the MC instance to provision and deploy an Eon Mode database.

Once you have taken the steps listed in [Eon Mode on GCP prerequisites](#), you are ready to deploy an Eon Mode database in GCP. To deploy an MC instance that is able to deploy Eon Mode databases to GCP:

1. Log into your GCP account, if you are not currently logged in.
2. Verify that your user account has the **Editor** role and the `runtimeconfig.waiters.getIamPolicy` permission.
3. Verify that the name of the GCP project you want to use for the deployment appears in the top banner. If it does not, click the down arrow next to the project name and select the correct project.
4. Click the navigation menu icon in the top left of the page and select **Marketplace**.
5. In the **Search for solutions** box, type Vertica Eon Mode and press enter.
6. Click the search result for Vertica **Data Warehouse**, Eon Mode. There are two license options: by the hour (BTH) and bring your own license (BYOL). See [Deploy Vertica from the Google cloud marketplace](#) for more information on this license choice.
7. Click **Launch** on the license option you prefer.
8. On the following page, fill in the fields to configure your MC instance:
 - **Deployment name** identifies your MC deployment in the GCP Deployments page.
 - **Zone** is the location where the virtual machine running your MC instance will be deployed. Make this the same location where your communal storage bucket is located.
 - **Service Account** : Service accounts allow automated processes to authenticate with GCP. Select the default service account, identified by `project_number-compute@developer.gserviceaccount.com`.
 - **Machine Type** is the virtual hardware configuration of the instance that will run the MC. The default values here are "middle of the road" settings which are sufficient for most use cases. If you are doing a small proof-of-concept deployment, you can choose a less powerful instance to save some money. If you are planning on deploying multiple large databases, consider increasing the count of virtual CPUs and RAM.
For details about Vertica's default volume configurations, see [Eon Mode volume configuration defaults for GCP](#).
 - **User Name for Access to MC** is the administrator username for the MC. You can customize this if you want.
 - **Network** and **Subnetwork** are the virtual private cloud (VPC) network and subnet within that network you want your MC instance and your Vertica nodes to use. This setting does not affect your MC's external network address. If you want to isolate your Vertica cluster from other GCP instances in your project, create a custom VPC network and optionally a subnet in your GCP project and select them in these fields. See the Google Cloud documentation's [VPC network overview](#) page for more information.
 - **Firewall** enables access to the MC from the internet by opening port 5450 in the firewall. You can choose to not open this port by clearing the **I accept opening a port in the firewall (5450) for Vertica** box. However, if you do not open the port in the firewall, your MC instance will only be accessible from within the VPC network. Not opening the port will make accessing your MC instance much harder.
 - **Source IP ranges for MC traffic** : If you choose to open the MC for external access, add one or more or more CIDR address ranges to this box for network addresses that you want to be able to access to the MC.

Caution

Make the address ranges as limited as possible to reduce the chances of unauthorized access to your MC instance.

9. Click the **Deploy** button to start the deployment of your MC instance.

The deployment process will take several minutes.

Using a custom service account

In general, you should use the default service account created by the GCP deployment (`project_number-compute@developer.gserviceaccount.com`), but if you want to use a custom service account:

- The custom service account must have the **Editor** role.
- Individual user accounts must have the **Service Account User** role on the custom service account.

Connect and log into the MC instance

After the deployment process is finished, the Deployment Manager page for your MC instance contains links to connect to the MC via your browser or ssh.

To connect to the MC instance:

1. The MC administrator user has a randomly-generated password that you need to log into the MC. Copy the password in the **MC Admin Password** field to the clipboard.
2. Click **Access Management Console**.
3. A new browser tab or window opens, showing you a page titled Redirection Notice. Click the link for the MC URL to continue to the MC login page.
4. Your browser will likely show you a security warning. The MC instance uses a self-signed security certificate. Most browsers treat these certificates as a security hazard because they cannot verify their origin. You can safely ignore this warning and continue. In most browsers, click the **Advanced** button on the warning page, and select the option to proceed. In Chrome, this is a link titled **Proceed to xxx.xxx.xxx.xxx (unsafe)**. In

Firefox, it is a button labeled **Accept the Risk and Continue** .

5. At the login screen, enter the MC administrator user name into the **Username** box. This user name is mcadmin, unless you changed the user name in the MC deployment form.
6. Paste the automatically-generated password you copied from the MC Admin Password field earlier into the **Password** box.
7. Click **Log In** .

Once you have logged into the MC, change the MC administrator account's password.

Caution

The automatically-generated password appears on the MC instance's deployment page and can be revealed in several locations in the deployment logs. Failure to change this password can lead to unauthorized access to your MC instance.

To change the password:

1. On the home page of the MC, under the MC Tools section, click **MC Settings**.
2. In the left-hand menu, click **User Management** .
3. Select the entry for the MC administrator account and click **Edit** .
4. Click either the **Generate new** or **Edit password** button to change the password. If you click the **Generate new** button, be sure to save the automatically-generated password in a safe location. If you click **Edit password** , you are prompted to enter a new password twice.
5. Click **Save** to update the password.

Now that you have created your MC instance, you are ready to deploy a Vertica Eon Mode cluster. See [Provision an Eon Mode cluster and database on GCP in MC](#).

Manually deploy an Enterprise Mode database on GCP

Before you create your Vertica cluster in Google Cloud Platform (GCP) using manual steps, you must create a virtual machine (VM) instance from the Compute Engine section of GCP.

Configure and launch a new instance

All VM instances that you create should be launched in the same virtual public cloud (VPC).

To configure and launch a new VM instance, follow these instructions:

1. From within the Compute Engine section of GCP, from the menu on the left-hand side of the screen, select **VM Instances** .
GCP displays all the VM instances that you have created so far.
2. Click **CREATE INSTANCE** .
3. Enter a name for the new instance.
4. Select the zone where you plan to deploy the instance.
GCP breaks its cloud data centers down by regions and zones. *Regions* are a collection of zones that are all in the same geographical location. Zones are collections of compute resources, which vary from zone to zone. Always pick the zone in your designated region that supports the latest Intel CPUs.
For a complete listing of regions and zones, including supported processors, see [Regions and Zones](#) .
5. Select a machine type.
GCE offers many different types of VM instances. For best results, only deploy Vertica on VM instances with 8 vCPUs or more and at least 30 GB of RAM.
6. Select the boot disk (image).
You create VM instances from a public or custom image. If you are starting with Vertica in GCP for the first time, select either the CentOS 7 or RHEL 7 public image. Those images have been tested thoroughly with Vertica.
For more information about deploying a VM instance, see [Creating and Starting an Instance](#) .

After you have configured the VM instance to be used as a Vertica cluster node, GCP allows you to convert that instance into a custom image. Doing so allows you to deploy multiple versions of that VM instance; each VM instance is identical except for the node name and IP address.

For more information about creating a custom image, see [Creating, Deleting, and Deprecating Custom Images](#) .

Connect to a virtual machine

Before you can connect to any of the VMs you created, you must first identify the external IP address. The VM instance section of GCP contains a list of all currently deployed VMs and their associated external IP addresses.

Connect to your VM

To connect to your VM, complete the following tasks:

1. Connect to your VM using SSH with the external IP address you created in the configuration steps.
2. Authenticate using the credentials and SSH key that you provided to your GCP account upon creation.

Connect to other VMs

To connect to other virtual machines in your virtual network:

1. Use SSH to connect to your publicly connected VM.
2. Use SSH again from that VM to connect through the private IP addresses of your other VMs.

Because GCP forces the use of private key authentication, you may need to move your key file to the `root` directory of your publicly connected VM. Then, use SSH to connect to other VMs in your virtual network.

Prepare the virtual machines

After you create your VMs, you need to prepare them for cluster formation.

Add the Vertica license and private key

Prepare your nodes by adding your private key (if you are using one) to each node and to your Vertica license. The following steps assume that the initial user you configured is the DBADMIN user:

1. As the DBADMIN user, copy your private key file from where you saved it locally onto your primary node. Depending upon the procedure you use to copy the file, the permissions on the file may change. If permissions change, the `install_vertica` script fails with a message similar to the following:

```
Failed Login Validation 10.0.2.158, cannot resolve or connect to host as root.
```

If you see the previous failure message, enter the following command to correct permissions on your private key file:

```
$ chmod 600 /<name-of-key>.pem
```

2. Copy your Vertica license to your primary VM. Save it in your home directory or other known location.

Install software dependencies for Vertica on GCP

In addition to the Vertica standard [Package dependencies](#), as the root user, you must install the following packages before you install Vertica:

- `pstack`
- `mcelog`
- `sysstat`
- `dialog`

Configure storage

For best disk performance in GCP, Vertica recommends customers use SSD persistent storage, configured to at least 2TB (2000 GB) in size. Disk performance is directly tied to the disk size in GCP. 2000 GBs (2TB) is the minimum disk size for SSD persistent disks that allows maximum throughput.

Caution

Do not store your information on the `root` volume, especially in your data and catalog directories. Storing information on the root volume may result in data loss.

When configuring your storage, make sure to use a supported file system. See for details.

Create a swap file

In addition to storage volumes to store your data, Vertica requires a swap volume or swap file for the setup script to complete.

Create a swap file or swap volume of at least 2 GB. The following steps show how to create a swap file within Vertica on GCP:

1. Install the `devnull` and `swapfile` files:

```
$ install -o root -g root -m 0600 /dev/null /swapfile
```

2. Create the swap file:

```
$ dd if=/dev/zero of=/swapfile bs=1024 count=2048k
```

3. Prepare the swap file using `mkswap` :

```
$ mkswap /swapfile
```

4. Use `swapon` to instruct Linux to swap on the swap file:

```
$ swapon /swapfile
```

5. Persist the swapfile in FSTAB:

```
$ echo "/swapfile swap swap auto 0 0" >> /etc/fstab
```

6. Repeat the volume attachment, combination, and swap file creation procedures for each VM in your cluster.

Download Vertica

To download the Vertica server appropriate for your operating system and license type, follow the steps in described in [Download and install the Vertica server package](#).

After you complete the download and extraction, use the `install_vertica` script to form a cluster and install the Vertica database software, as described in the next section.

Form a cluster and install Vertica

Use the `install_vertica` script to combine two or more individual VMs to form a cluster and install your Vertica database.

Before you run the `install_vertica` script, follow these steps:

1. Check the **VM Instances** page of the Compute Engine section on GCP to locate a list of current VMs and their associated internal IP addresses.
2. Identify your storage location on your VMs. The installer assumes that you have mounted your storage to `/home/dbadmin`. To specify another location, use the `--data-dir` argument.

Caution

Do not store your data on the root drive.

The following steps show how to combine virtual machines (VMs) into a cluster using the `install_vertica` script:

1. While connected to your primary node, construct the following command to combine your nodes into a cluster.

```
$ sudo /opt/vertica/sbin/install_vertica --hosts 10.2.0.164,10.2.0.165,10.2.0.166 --dba-user-password-disabled --point-to-point --data-dir /vertica/data --ssh-identity ~/.pem --license
```

2. Substitute the IP addresses for your VMs, and include your root key file name, if applicable.
3. Include the `--point-to-point` parameter to configure spread to use direct point-to-point communication among all Vertica nodes, as required for clusters on GCP when installing or updating Vertica.
4. If you are using Vertica Community Edition, which limits you to three nodes, specify `-L CE` with no license file.
5. After you combine your nodes, to reduce security risks, keep your key file in a secure place—separate from your cluster—and delete your on-cluster key with the `shred` command:

```
$ shred examplekey.pem
```

Important

You need your key file to perform future Vertica updates.

For complete information about the `install_vertica` script and its parameters, see [Install Vertica with the installation script](#).

After your cluster is up and running

Now that your cluster is configured and running, and Vertica is running, take these steps:

1. Create a database. See [Creating a database](#) for details.
2. When you installed Vertica, a database administrator user was created with the [DBADMIN](#) role (usually named `dbadmin`). Use this account to create and start a database.
3. See [Configuring the database](#) for important database configuration steps.

Set up Vertica on-premises

This section discusses the procedure for installing Vertica manually in an on-premises environment.

In this section

- [Installation overview and checklist](#)
- [Before you install Vertica](#)
- [Install Vertica using the command line](#)
- [After you install Vertica](#)

Installation overview and checklist

Carefully review and complete the installation tasks in all sections of this topic.

Important notes

- Vertica supports only one running database per cluster.
- Vertica supports installation on one, two, or multiple nodes. The steps for [Installing Vertica](#) are the same, no matter how many nodes are in the cluster.
- Prerequisites listed in [Before You Install Vertica](#) are required for all Vertica configurations.
- Only one instance of Vertica can be running on a host at any time.
- To run the `install_vertica` script, as well as adding, updating, or deleting nodes, you must be logged in as root, or sudo as a user with all privileges. You must run the script for all installations, including upgrades and single-node installations.

Installation scenarios

The three main scenarios for installing Vertica on hosts are:

- A single node install, where Vertica is installed on a single host as a *localhost* process. This form of install cannot be expanded to more hosts later on and is typically used for development or evaluation purposes.
- Installing to a cluster of physical host hardware. This is the most common scenario when deploying Vertica in a testing or production environment.
- Installing to a local cluster of virtual host hardware. This is similar to installing on physical hosts, but with network configuration differences.

Before you install

[Before You Install Vertica](#) describes how to construct a hardware platform and prepare Linux for Vertica installation.

These preliminary steps are broken into two categories:

- Configuring Hardware and Installing Linux
- Configuring the Network

Install or upgrade Vertica

Once you have completed the steps in the [Before You Install Vertica](#) section, you are ready to run the install script.

[Installing Vertica](#) describes how to:

- Back up any existing databases.
- Download and install the Vertica RPM package.
- Install a [cluster](#) using the `install_vertica` script.
- [Optional] [Create a properties file](#) that lets you install Vertica silently.

Post-installation tasks

[After You Install Vertica](#) describes subsequent steps to take after you've run the installation script. Some of the steps can be skipped based on your needs:

- Install the license key.
- Verify that kernel and user parameters are correctly set.
- Install the vsql client application on non-cluster hosts.
- Resolve any SLES 11.3 issues during spread configuration.
- Use the Vertica documentation online, or download and install Vertica documentation. Find the online documentation and documentation packages to download at <https://docs.vertica.com/latest>.
- Install client drivers.
- Extend your installation with Vertica packages.
- [Install](#) or [upgrade](#) the Management Console.

Before you install Vertica

Complete all of the tasks in this section before you install Vertica. When you have completed this section, proceed to [Install Vertica using the command line](#).

In this section

- [Platform and hardware requirements and recommendations](#)
- [Communal storage for on-premises Eon Mode databases](#)
- [Configure the network](#)
- [Operating system configuration overview](#)
- [Automatically configured operating system settings](#)

- [Manually configured operating system settings](#)
- [System user configuration](#)

Platform and hardware requirements and recommendations

Hardware recommendations

The Vertica Analytics Platform is based on a massively parallel processing (MPP), shared-nothing architecture, in which the query processing workload is divided among all nodes of the Vertica database. OpenText highly recommends using a homogeneous hardware configuration for your Vertica cluster; that is, each node of the cluster should be similar in CPU, clock speed, number of cores, memory, and operating system version.

Note that OpenText has not tested Vertica on clusters made up of nodes with disparate hardware specifications. While it is expected that a Vertica database would functionally work in a mixed hardware configuration, performance will be limited to that of the slowest node in the cluster.

Vertica performs best on processors with higher clock frequency. When possible, choose a faster processor with fewer cores as opposed to a slower processor with more cores.

Tests performed both internally and by customers have shown performance differences between processor architectures even when accounting for differences in core count and clock frequency. When possible, compare platforms by installing Vertica and running experiments using your data and workloads. Consider testing on cloud platforms that offer VMs running on different processor architectures, even if you intend to deploy your Vertica database on premises.

Detailed hardware recommendations are available in [Recommendations for Sizing Vertica Nodes and Clusters](#).

Platform requirements and recommendations

You must verify that your servers meet the platform requirements described in [Supported Platforms](#). The Supported Platforms topics detail supported versions for the following:

- OS for Server and Management Console (MC)
- Supported Browsers for MC
- Supported File Systems

Important

Deploy Vertica as the only active process on each host—other than Linux processes or software explicitly approved by Vertica. Vertica cannot be co-located with other software. Remove or disable all non-essential applications from cluster hosts.

Install the latest vendor-specific system software

Install the latest vendor drivers for your hardware.

Data storage recommendations

- All internal drives connect to a single RAID controller.
- The RAID array should form one hardware RAID device as a contiguous /data volume.

Install Perl

Before you perform the cluster installation, install Perl 5 on all the target hosts. Perl is available for download from www.perl.org.

Validation utilities

Vertica provides several validation utilities that validate the performance on prospective hosts. The utilities are installed when you install the Vertica RPM, but you can use them before you run the `install_vertica` script. See [Validation scripts](#) for more details on running the utilities and verifying that your hosts meet the recommended requirements.

Verify sudo

Vertica uses the sudo command during installation and some administrative tasks. Ensure that sudo is available on all hosts with the following command:

```
# which sudo
/usr/bin/sudo
```

If sudo is not installed, on all hosts, follow the instructions in [How to Enable sudo on Red Hat Enterprise Linux](#).

When you use sudo to install Vertica, the user that performs the installation must have privileges on all nodes in the cluster.

Configuring sudo with privileges for the individual commands can be a tedious and error-prone process; thus, the Vertica documentation does not include every possible sudo command that you can include in the sudoers file. Instead, Vertica recommends that you temporarily elevate the sudo user to have all privileges for the duration of the install.

Note

See the `sudoers` and `visudo` man pages for the details on how to write/modify a `sudoers` file.

To allow root sudo access on all commands as any user on any machine, use `visudo` as root to edit the `/etc/sudoers` file and add this line:

```
## Allow root to run any commands anywhere
root ALL=(ALL) ALL
```

After the installation completes, remove (or reset) sudo privileges to the pre-installation settings.

BASH shell requirements

All shell scripts included in Vertica must run under the BASH shell. If you are on a Debian system, then the default shell can be DASH. DASH is not supported. Change the shell for root and for the `dbadmin` user to BASH with the `chsh` command.

For example:

```
# getent passwd | grep root
root:x:0:0:root:/root:/bin/dash

# chsh
Changing shell for root.
New shell [/bin/dash]: /bin/bash
Shell changed.
```

Then, as root, change the symbolic link for `/bin/sh` from `/bin/dash` to `/bin/bash` :

```
# rm /bin/sh
# ln -s /bin/bash /bin/sh
```

Log out and back in for the change to take effect.

Communal storage for on-premises Eon Mode databases

If you create an Eon Mode database, you must plan for your use of communal storage to store your database's data. Communal storage is based on a shared storage, such as AWS S3 or Pure Storage FlashBlade servers.

Whatever communal storage platform you use, you must ensure that it is durable (protected against data loss). The data in your Eon Mode database is only as safe as the communal storage that contains it. Most cloud provider's object stores come with a guaranteed redundancy to prevent data loss. When you install an Eon Mode database on-premises, you may have to take additional steps to prevent data loss.

Planning communal storage capacity for on-premises databases

Most cloud providers do not limit the amount of data you can store in their object stores. The only real limit is your budget; storing more data costs more money.

When you create an Eon Mode database on-premises, your storage is limited to the size of your communal storage. Unlike the cloud, you must plan ahead for the amount of storage you will need. For example, if you have a Pure Admin FlashBlade installation with three 8TB blades, then in theory, your database can grow up to 24TB. In practice, you need to account other uses of your object store, as well as factors such as data compression, and space consumed by unrepaid ROS containers (storage containers no longer used by Vertica but not yet deleted by the object store).

The following calculator helps you determine the size for your communal storage needs, based on your estimated data size and additional uses of your communal storage. The values with white backgrounds in the Value column are editable. Change them to reflect your environment.

Note

The calculator currently does not work in mobile browsers. Please use a desktop browser to view the calculator.

Configure the network

This group of steps involve configuring the network. These steps differ depending on your installation scenario. A single node installation requires little network configuration, because the single instance of the Vertica server does not need to communication with other nodes in a cluster. For cluster install scenarios, you must make several decisions regarding your configuration.

Vertica supports server configuration with multiple network interfaces. For example, you might want to use one as a private network interface for internal communication among cluster hosts (the ones supplied via the `--hosts` option to `install_vertica`) and a separate one for client connections.

Important
Vertica performs best when all nodes are on the same subnet and have the same broadcast address for one or more interfaces. A cluster that has nodes on more than one subnet can experience lower performance due to the network latency associated with a multi-subnet system at high network utilization levels.

Important notes

- Network configuration is exactly the same for single nodes as for multi-node clusters, with one special exception. If you install Vertica on a single host machine that is to remain a permanent single-node configuration (such as for development or Proof of Concept), you can install Vertica using `localhost` or the loopback IP (typically 127.0.0.1) as the value for `--hosts`. Do not use the hostname `localhost` in a node definition if you are likely to add nodes to the configuration later.
- If you are using a host with multiple network interfaces, configure Vertica to use the address which is assigned to the NIC that is connected to the other cluster hosts.
- Use a dedicated gigabit switch. If you do not performance could be severely affected.
- Do not use DHCP dynamically-assigned IP addresses for the private network. Use only static addresses or permanently-leased DHCP addresses.

Choose IPv4 or IPv6 addresses for host identification and communications

Vertica supports using either IPv4 or IPv6 IP addresses for identifying the hosts in a database cluster. Vertica uses a single address to identify a host in the database cluster. All the IP addresses used to identify hosts in the cluster must use the same IP family.

The hosts in your database cluster can have both IPv4 and IPv6 network addresses assigned to them. Only one of these addresses is used to identify the node within the cluster. You can use the other addresses to handle client connections or connections to other systems.

You tell Vertica which address family to use when you install it. By default, Vertica uses IPv4 addresses for hosts. If you want the nodes in your database to use IPv6 addresses, add the `--ipv6` option to the arguments you pass to the `install_vertica` script.

Note

You cannot change the address family a database cluster uses after you create it. For example, suppose you created a Vertica database using IPv4 addresses to identify the hosts in your cluster. Then you cannot later change the hosts to use an IPv6 address for internal communications.

In most cases, the address family you select does not impact how your database functions. However, there are a few exceptions:

- Use IPv4 addresses to identify the nodes in your cluster if you want to use the Management Console to manage your database. Currently, the MC does not support databases that use IPv6 addresses.
- If you select IPv6 addressing for your cluster, it automatically uses point-to-point networking mode.
- Currently, AWS is the only cloud platform on which Vertica supports IPv6 addressing. To use IPv6 on AWS, you must identify cluster hosts using IP addresses instead of host names. The AWS DNS does not support resolving host names to IPv6.
- If you only assign IPv6 addresses to the hosts in your database cluster, you may have problems interfacing to other systems that do not support IPv6.

Part of the information you pass to the install script is the list of hosts it will use to form the Vertica cluster. If you use host names in this list instead of IP addresses, ensure that the host names resolve to the IP address family you want to use for your cluster. For example, if you want your cluster to use IPv6 addresses, ensure your DNS or `/etc/hosts` file resolves the host names to IPv6 addresses.

You can configure DNS to return both IPv4 and IPv6 addresses for a host name. In this case, the installer uses the IPv4 address unless you supply the `-ipv6` argument. If you use `/etc/hosts` for host name resolution (which is the best practice), host names cannot resolve to both IPv4 and IPv6 addresses.

Optionally run spread on a separate control network

If your query workloads are network intensive, you can use the `--control-network` parameter with the `install_vertica` script (see [Install Vertica with the installation script](#)) to allow spread communications to be configured on a subnet that is different from other Vertica data communications.

The `--control-network` parameter accepts either the `default` value or a broadcast network IP address (for example, `192.168.10.255`).

Configure SSH

- Verify that root can use Secure Shell (SSH) to log in (`ssh`) to all hosts that are included in the cluster. SSH (SSH client) is a program for logging into a remote machine and for running commands on a remote machine.
- If you do not already have SSH installed on all hosts, log in as root on each host and install it before installing Vertica. You can download a free version of the SSH connectivity tools from [OpenSSH](#).

- Make sure that `/dev/pts` is mounted. Installing Vertica on a host that is missing the mount point `/dev/pts` could result in the following error when you create a database:

```
TIMEOUT ERROR: Could not login with SSH. Here is what SSH said:Last login: Sat Dec 15 18:05:35 2007 from v_vmart_node0001
```

Allow passwordless SSH access for the dbadmin user

The dbadmin user must be authorized for passwordless ssh. In typical installs, you won't need to change anything; however, if you set up your system to disallow passwordless login, you'll need to enable it for the dbadmin user. See [Enable secure shell \(SSH\) logins](#).

In this section

- [Reserved ports](#)
- [Firewall considerations](#)

Reserved ports

The `install_vertica` script checks that required ports are open and available to Vertica. The installer reports any issues with identifier `N0020`.

You can also verify that ports required by Vertica are not in use by running the following command as the root user and comparing it with the ports required, as shown below:

```
$ ss -atupn
```

Firewall requirements

Vertica requires several ports to be open on the local network. Vertica does not recommend placing a firewall between nodes (all nodes should be behind a firewall), but if you must use a firewall between nodes, ensure the following ports are available:

Port	Protocol	Service	Notes
22	TCP	sshd	Required by Administration tools and the Management Console Cluster Installation wizard.
4803	TCP	Spread	Client connections
4803	UDP	Spread	Daemon-to-daemon connections
4804	UDP	Spread	Daemon-to-daemon connections
5433	TCP	Vertica	Vertica clients (vsq, ODBC, JDBC, etc)
5433	UDP	Vertica	Vertica Spread monitoring and MC cluster import
5434	TCP	Vertica	Intra- and inter-cluster communication. Vertica opens the Vertica client port +1 (5434 by default) for intra-cluster communication, such as during a plan. If the port +1 from the default client port is not available, then Vertica opens a random port for intra-cluster communication.
5444	TCP	Vertica Management Console	MC-to-node and node-to-node (agent) communications port. See Changing MC or agent ports .
5450	TCP	Vertica Management Console	Port used to connect to MC from a web browser and allows communication from nodes to the MC application/web server. See Connecting to Management Console .
5554	TCP	Node Management Agent	Node Management Agent
6543	UDP	Spread	Monitor-to-daemon connection
8443	TCP	HTTPS	HTTPS service. To change the port, use HTTPServerPortOffset .

Firewall considerations

Vertica requires multiple ports be open between nodes. You may use a firewall (IP Tables) on Redhat/CentOS and Ubuntu/Debian based systems. Note that firewall use is not supported on SuSE systems and that SuSE systems must disable the firewall. The installer reports issues found with your IP tables configuration with the identifiers **N0010** for (systems that use IP Tables) and **N011** (for SuSE systems).

The installer checks the IP tables configuration and issues a warning if there are any configured rules or chains. The installer does not detect if the configuration may conflict with Vertica. It is your responsibility to verify that your firewall allows traffic for Vertica as described in [Reserved ports](#).

Note

The installer does not check NAT entries in iptables.

You can modify your firewall to allow for Vertica network traffic, or you can disable the firewall if your network is secure. Note that firewalls are not supported for Vertica systems running on SuSE.

Important

You may encounter the **N0010** issue even when the firewall is disabled. If this occurs, you can workaroud this issue and install Vertica by ignoring installer WARN messages. To do this, install (or update) with a failure threshold of FAIL. For example, `/opt/vertica/sbin/install_vertica --failure-threshold FAIL <other install options...>`.

Red Hat and CentOS systems:

To disable the system firewall, run the following command as root or sudo:

```
# systemctl mask firewalld
# systemctl disable firewalld
# systemctl stop firewalld
```

Ubuntu and Debian systems

For details on how to configure iptables and allow specific ports to be open, see the platform-specific documentation for your platform:

- Debian: <https://wiki.debian.org/iptables>
- Ubuntu: <https://help.ubuntu.com/12.04/serverguide/firewall.html>.

Note

Ubuntu uses the ufw program to manage iptables.

To disable iptables on Debian, run the following command as root or sudo:

```
$ /etc/init.d/iptables stop
$ update-rc.d -f iptables remove
```

To disable iptables on Ubuntu, run the following command:

```
$ sudo ufw disable
```

SuSE systems

The firewall must be disabled on SUSE systems. To disable the firewall on SuSE systems, run the following command:

```
# /sbin/SuSEfirewall2 off
```

Operating system configuration overview

This topic provides a high-level overview of the OS settings required for Vertica. Each item provides a link to additional details about the setting and detailed steps on making the configuration change. The installer tests for all of these settings and provides hints, warnings, and failures if the current configuration does not meet Vertica requirements.

Before you install the operating system

The below sections detail system settings that must be configured when you install the operating system. These settings cannot be easily changed after the operating system is installed.

Configuration	Description
Supported Platforms	<p>Verify that your servers meet the platform requirements described in Supported Platforms. Unsupported operating systems are detected by the installer.</p> <p>The installer generates one of the following issue identifiers if it detects an unsupported operating system:</p> <ul style="list-style-type: none"> • [S0320] - Fedora OS is not supported. • [S0321] - The version of Red Hat/CentOS is not supported. • [S0322] - The version of Ubuntu/Debian is not supported. • [S0323] - The operating system could not be determined. The unknown operating system is not supported because it does not match the list of supported operating systems. • [S0324] - The version of Red Hat is not supported.
LVM	<p>Vertica Analytic Database supports Linux Volume Manager (LVM) on all supported operating systems. For information on LVM requirements and restrictions, see the section, Vertica Support for LVM.</p>
File system	<p>Choose the storage format type based on deployment requirements. Vertica recommends the following storage format types where applicable:</p> <ul style="list-style-type: none"> • ext3 • ext4 • NFS for backup • XFS • Amazon S3 Standard, Azure Blob Storage, or Google Cloud Storage for communal storage and related backup tasks when running in Eon Mode <div data-bbox="248 930 1557 1073" style="background-color: #e6f2ff; padding: 10px;"> <p>Note For the Vertica I/O profile, the ext4 file system is considerably faster than ext3.</p> </div> <p>The storage format type at your backup and temporary directory locations must support <code>fcntl lockf</code> (POSIX) file locking.</p>
Swap Space	<p>A 2GB swap partition is required, regardless of the amount of RAM installed on your system. Larger swap space is acceptable, but unnecessary. Partition the remaining disk space in a single partition under <code>/</code>. If you do not have the required 2GB swap partition, the installer reports this issue with identifier S0180.</p> <p>You typically define the swap partition when you install Linux. See your platform's documentation for details on configuring the swap partition.</p> <div data-bbox="248 1413 1557 1589" style="background-color: #e6f2ff; padding: 10px;"> <p>Note Do not place a swap file on a disk containing the Vertica data files. If a host has only two disks (boot and data), put the swap file on the boot disk.</p> </div>
Disk Block Size	<p>The disk block size for the Vertica data and catalog directories should be 4096 bytes, the default on ext4 and XFS file systems. You set the disk block size when you format your file system. If you change the block size, you will need to reformat the disk.</p>

Memory	<p>Vertica requires that your hosts have a minimum of 1GB of RAM per logical processor. If your hosts do not meet this requirement, the installer reports this issue with the identifier S0190 . For performance reasons, you typically require more RAM than the minimum.</p> <p>In addition to the individual host RAM requirement, the installer also reports a hint if the hosts in your cluster do not have identical amounts of RAM. Ensuring your host have the same amount of RAM helps prevent performance issues if one or more nodes has less RAM than the other nodes in your database.</p> <div style="background-color: #e6f2ff; padding: 10px; border: 1px solid #cfe2f3;"> <p>Note In an Eon Mode database, after you create the initial cluster, you can configure subclusters that have different hardware specifications (including RAM) than the initial primary subcluster the installer creates.</p> </div> <p>For more information on sizing your hardware, see the Vertica Knowledge Base Hardware documents .</p>
--------	--

Automatically configured operating system settings

These general OS settings are automatically made by the installer if they do not meet Vertica requirements. You can prevent the installer from automatically making these configuration changes by using the `--no-system-configuration` parameter for the `install_vertica` script.

For more information on each configuration setting, see [Automatically configured operating system settings](#) .

Configuration	Description
Nice Limits	The database administration user must be able to <i>nice</i> processes back to the default level of 0.
min_free_kbytes	The <code>vm.min_free_kbytes</code> setting in <code>/etc/sysctl.conf</code> must be configured sufficiently high. The specific value depends on your hardware configuration.
User Open Files Limit	The open file limit for the dbadmin user should be at least 1 file open per MB of RAM, 65536, or the amount of RAM in MB; whichever is greater.
System Open File Limits	The maximum number of files open on the system must not be less than at least the amount of memory in MB, but not less than 65536.
Pam Limits	<p><code>/etc/pam.d/su</code> must contain the line: <code>session required pam_limits.so</code></p> <p>This allows for the conveying of limits to commands run with the <code>su</code> - command.</p>
Address Space Limits	The address space limits (<code>as</code> setting) defined in <code>/etc/security/limits.conf</code> must be unlimited for the database administrator.
File Size Limits	The file sizelimits (<code>fsize</code> setting) defined in <code>/etc/security/limits.conf</code> must be unlimited for the database administrator.
User Process Limits	The <code>nproc</code> setting defined in <code>/etc/security/limits.conf</code> must be 1024 or the amount of memory in MB, whichever is greater.
Maximum Memory Maps	The <code>vm.max_map_count</code> in <code>/etc/sysctl.conf</code> must be 65536 or the amount of memory in KB / 16, whichever is greater.

Manually configured operating system settings

For more information on each configuration setting, see [Manually configured operating system settings](#) .

Configuration	Description
Disk Readahead	This disk readahead must be at least 2048, with a high of 8192. Set this high limit only with the help of Vertica support. The specific value depends on your hardware configuration.

NTP Services	The NTP daemon must be enabled and running, with the exception of Red Hat and CentOS systems.
SELinux	SELinux must be disabled or run in permissive mode.
CPU Frequency Scaling	Vertica recommends that you disable CPU Frequency Scaling. Important Your systems may use significantly more energy when CPU frequency scaling is disabled.
Transparent Hugepages	For Red Hat and CentOS, Transparent Hugepages must be set to always . For all other operating systems, Transparent Hugepages must be disabled or set to advise .
I/O Scheduler	The I/O Scheduler for disks used by Vertica must be set to <i>deadline</i> or <i>noop</i> .
Support Tools	Several optional packages can be installed to assist Vertica support when troubleshooting your system.

System user requirements

The following tasks pertain to the configuration of the system user required by Vertica.

For more information on each configuration setting, see [System user configuration](#).

Configuration	Required Setting(s)
System User Requirements	The installer automatically creates a user with the correct settings. If you specify a user with --dba-user r , then the user must conform to the requirements for the Vertica system user.
LANG Environment Settings	The LANG environment variable must be set and valid for the database administration user.
TZ Environment Settings	The TZ environment variable must be set and valid for the database administration user.

Automatically configured operating system settings

These general Operating System settings are automatically made by the installer. You can prevent the installer from automatically making these configuration changes by using the **--no-system-configuration** parameter for the **install_vertica** script.

In this section

- [Sysctl](#)
- [Nice limits configuration](#)
- [min_free_kbytes setting](#)
- [User max open files limit](#)
- [System max open files limit](#)
- [Pam limits](#)
- [pid_max setting](#)
- [User address space limits](#)
- [User file size limit](#)
- [User process limit](#)
- [Maximum memory maps configuration](#)

Sysctl

During installation, Vertica attempts to automatically change various OS level settings. The installer may not change values on your system if they exceed the threshold required by the installer. You can prevent the installer from automatically making these configuration changes by using the **--no-system-configuration** parameter for the **install_vertica** script.

To permanently edit certain settings and prevent them from reverting on reboot, use `sysctl`.

The `sysctl` settings relevant to the installation of Vertica include:

- [min_free_kbytes](#)
- [fs.file_max](#)
- [vm.max_map_count](#)

Permanently changing settings with `sysctl`:

1. As the root user, open the `/etc/sysctl.conf` file:

```
# vi /etc/sysctl.conf
```

2. Enter a parameter and value:

```
parameter = value
```

For example, to set the parameter and value for `fs.file-max` to meet Vertica requirements, enter:

```
fs.file-max = 65536
```

3. Save your changes, and close the `/etc/sysctl.conf` file.

4. As the root user, reload the config file:

```
# sysctl -p
```

Identifying settings added by the installer

You can see whether the installer has added a setting by opening the `/etc/sysctl.conf` file:

```
# vi /etc/sysctl.conf
```

If the installer has added a setting, the following line appears:

```
# The following 1 line added by Vertica tools. 2015-02-23 13:20:29  
parameter = value
```

Nice limits configuration

The Vertica system user (`dbadmin` by default) must be able to raise and lower the priority of Vertica processes. To do this, the `nice` option in the `/etc/security/limits.conf` file must include an entry for the `dbadmin` user. The installer reports this issue with the identifier: **S0010**.

The installer automatically configures the correct setting if the default value does not meet system requirements. If an issue occurs when setting this value, or you use the `--no-system-configuration` argument to the installer and the current setting is incorrect, then the installer reports this as an issue.

Note

Vertica never raises priority above the default level of 0. However, Vertica does lower the priority of certain Vertica threads and needs to be able to raise the priority of these threads back up to the default level. This setting allows Vertica to raise the priorities back to the default level.

All systems

To set the Nice Limit configuration for the `dbadmin` user, edit `/etc/security/limits.conf` and add the following line. Replace `dbadmin` with the name of your system user.

```
dbadmin - nice 0
```

`min_free_kbytes` setting

This topic details how to update the `min_free_kbytes` setting so that it is within the range supported by Vertica. The installer reports this issue with the identifier: **S0050** if the setting is too low, or **S0051** if the setting is too high.

The `vm.min_free_kbytes` setting configures the page reclaim thresholds. When this number is increased the system starts reclaiming memory earlier, when its lowered it starts reclaiming memory later. The default `min_free_kbytes` is calculated at boot time based on the number of pages of physical RAM available on the system.

The setting must be whichever value is the greatest from the following options:

- The default value configured by the system
- 4096

- The result of running the commands:

```
$ memtot=`grep MemTotal /proc/meminfo | awk '{printf "%.0f", $2}`  
$ echo "scale=0;sqrt ($memtot*16)" | bc
```

The installer automatically configures the correct setting if the default value does not meet system requirements. If an issue occurs when setting this value, or you use the `--no-system-configuration` argument to the installer and the current setting is incorrect, then the installer reports this as an issue.

All systems

To manually set `min_free_kbytes`:

1. Determine the current/default setting with the following command:

```
$ sysctl vm.min_free_kbytes
```

2. If the result of the previous command is `No such file or directory` or the default value is less than 4096, then run these commands to determine the correct value:

```
$ memtot=`grep MemTotal /proc/meminfo | awk '{printf "%.0f", $2}`  
$ echo "scale=0;sqrt ($memtot*16)" | bc
```

3. Edit or add the current value of `vm.min_free_kbytes` in `/etc/sysctl.conf` with the value from the output of the previous command.

```
# The min_free_kbytes setting  
vm.min_free_kbytes=16132
```

4. Run `sysctl -p` to apply the changes in `sysctl.conf` immediately.

Note

These steps must be repeated for each node in the cluster.

User max open files limit

This topic details how to change the user max open-files limit setting to meet Vertica requirements. The installer reports this issue with the identifier S0060.

The installer automatically configures the correct setting if the default value does not meet system requirements. If an issue occurs when setting this value, or you use the `--no-system-configuration` argument to the installer and the current setting is incorrect, then the installer reports this as an issue.

Vertica requires that the `dbadmin` user not be limited when opening files. The open file limit per user is calculated as follows:

user max open files = greater of { ≥ 65536 | $\leq RAM-MBs$ }

As a `dbadmin` user, you can determine the open file limit by running `ulimit -n`. For example:

```
$ ulimit -n  
65536
```

To manually set the limit, edit `/etc/security/limits.conf` and edit/add the `nofile` setting for the user who is configured as the database administrator—by default, `dbadmin`. For example:

```
dbadmin - nofile 65536
```

The setting must be no less than 65536 MB, but not greater than the system value of `fs.nr_open`. For example, the default value of `fs.nr_open` value on [Red Hat Enterprise Linux 9](#) is 1048576 MB.

Note

The system also has a [limit on open files](#).

System max open files limit

This topic details how to modify the limit for the number of open files on your system so that it meets Vertica requirements. The installer reports this issue with the identifier: **S0120**.

Vertica opens many files. Some platforms have global limits on the number of open files. The open file limit must be set sufficiently high so as not to interfere with database operations.

The recommended value is at least the amount of memory in MB, but not less than 65536.

The installer automatically configures the correct setting if the default value does not meet system requirements. If an issue occurs when setting this value, or you use the `--no-system-configuration` argument to the installer and the current setting is incorrect, then the installer reports this as an issue.

All systems

To manually set the open file limit:

1. Run `/sbin/sysctl fs.file-max` to determine the current limit.
2. If the limit is not **65536** or the amount of system memory in MB (whichever is higher), then edit or add `fs.file-max= max number of files` to `/etc/sysctl.conf`.

```
# Controls the maximum number of open files
fs.file-max=65536
```

3. Run `sysctl -p` to apply the changes in `sysctl.conf` immediately.

Note

These steps will need to be replicated for each node in the cluster.

Pam limits

This topic details how to enable the "su" `pam_limits.so` module required by Vertica. The installer reports issues with the setting with the identifier: **S0070**.

On some systems the pam module called `pam_limits.so` is not set in the file `/etc/pam.d/su`. When it is not set, it prevents the conveying of limits (such as open file descriptors) to any command started with `su -`.

In particular, the Vertica init script would fail to start Vertica because it calls the Administration Tools to start a database with the `su -` command. This problem was first noticed on Debian systems, but the configuration could be missing on other Linux distributions. See the [pam_limits](#) man page for more details.

The installer automatically configures the correct setting if the default value does not meet system requirements. If an issue occurs when setting this value, or you use the `--no-system-configuration` argument to the installer and the current setting is incorrect, then the installer reports this as an issue.

All systems

To manually configure this setting, append the following line to the `/etc/pam.d/su` file:

```
session required pam_limits.so
```

See the `pam_limits` man page for more details: `man pam_limits`.

pid_max setting

This topic explains how to change `pid_max` to a supported value. The value of `pid_max` should be

```
pid_max = num-user-proc + 2**15 = num-user-proc + 32768
```

where `num-user-proc` is the size of memory in megabytes.

The minimum value for `pid_max` is 524288.

If your `pid_max` value is too low, the installer reports this problem and indicates the minimum value.

The installer automatically configures the correct setting if the default value does not meet system requirements. If an issue occurs when setting this value, or you use the `--no-system-configuration` argument to the installer and the current setting is incorrect, then the installer reports this as an issue.

All systems

To change the `pid_max` value:

```
# sysctl -w kernel.pid_max=524288
```

User address space limits

This topic details how to modify the Linux address space limit for the dbadmin user so that it meets Vertica requirements. The address space setting controls the maximum number of threads and processes for each user. If this setting does not meet the requirements then the installer reports this issue with the identifier: **S0090**.

The installer automatically configures the correct setting if the default value does not meet system requirements. If an issue occurs when setting this value, or you use the `--no-system-configuration` argument to the installer and the current setting is incorrect, then the installer reports this as an issue.

The address space available to the dbadmin user must not be reduced via user limits and must be set to **unlimited**.

All systems

To manually set the address space limit:

1. Run `ulimit -v` as the dbadmin user to determine the current limit.
2. If the limit is not **unlimited**, then add the following line to `/etc/security/limits.conf`. Replace `dbadmin` with your database admin user

```
dbadmin - as unlimited
```

User file size limit

This topic details how to modify the file size limit for files on your system so that it meets Vertica requirements. The installer reports this issue with the identifier: **S0100**.

The installer automatically configures the correct setting if the default value does not meet system requirements. If an issue occurs when setting this value, or you use the `--no-system-configuration` argument to the installer and the current setting is incorrect, then the installer reports this as an issue.

The file size limit for the dbadmin user must not be reduced via user limits and must be set to **unlimited**.

All systems

To manually set the file size limit:

1. Run `ulimit -f` as the dbadmin user to determine the current limit.
2. If the limit is not **unlimited**, then edit/add the following line to `/etc/security/limits.conf`. Replace `dbadmin` with your database admin user.

```
dbadmin - fsize unlimited
```

User process limit

This topic details how to change the user process limit so that it meets Vertica requirements. The installer reports this issue with the identifier: **S0110**.

The installer automatically configures the correct setting if the default value does not meet system requirements. If an issue occurs when setting this value, or you use the `--no-system-configuration` argument to the installer and the current setting is incorrect, then the installer reports this as an issue.

The user process limit must be high enough to allow for the many threads opened by Vertica. The recommended limit is the amount of RAM in MB and must be at least 1024.

All systems

To manually set the user process limit:

1. Run `ulimit -u` as the dbadmin user to determine the current limit.
2. If the limit is not the amount of memory in MB on the server, then edit/add the following line to `/etc/security/limits.conf`. Replace `4096` with the amount of system memory, in MB, on the server.

```
dbadmin - nproc 4096
```

Maximum memory maps configuration

This topic details how to modify the limit for the number memory maps a process can have on your system so that it meets Vertica requirements. The installer reports this issue with the identifier: **S0130**.

The installer automatically configures the correct setting if the default value does not meet system requirements. If an issue occurs when setting this value, or you use the `--no-system-configuration` argument to the installer and the current setting is incorrect, then the installer reports this as an issue.

Vertica uses a lot of memory while processing and can approach the default limit for memory maps per process.

The recommended value is at least the amount of memory on the system in KB / 16, but not less than 65536.

All systems

To manually set the memory map limit:

1. Run `/sbin/sysctl vm.max_map_count` to determine the current limit.
2. If the limit is not **65536** or the amount of system memory in KB / 16 (whichever is higher), then edit/add the following line to `/etc/sysctl.conf` .
Replace `65536` with the value for your system.

```
# The following 1 line added by Vertica tools. 2014-03-07 13:20:31
```

```
vm.max_map_count=65536
```

3. Run `sysctl -p` to apply the changes in `sysctl.conf` immediately.

Note

These steps will need to be replicated for each node in the cluster.

Manually configured operating system settings

The topics in this section detail general Operating System settings that must be set manually.

Persisting operating system settings

To prevent manually set Operating System settings from reverting on reboot, you should configure some of these settings in the `/etc/rc.local` script. This script contains commands and scripts that run each time the system is booted.

Important

On reboot, SUSE systems use the `/etc/init.d/after.local` file rather than `/etc/rc.local` .

Vertica uses settings in `/etc/rc.local` to set the following functionality:

- [Disk readahead](#)
- [I/O scheduling](#)
- [Enabling or disabling transparent hugepages](#)

Editing `/etc/rc.local`

1. As the root user, open `/etc/rc.local` :

```
# vi /etc/rc.local
```

2. Enter a script or command. For example, to configure [transparent hugepages](#) to meet Vertica requirements, enter the following:

```
echo never > /sys/kernel/mm/redhat_transparent_hugepage/enabled
```

Important

On some Ubuntu/Debian systems, the last line in `/etc/rc.local` must be `exit 0` . All additions to `/etc/rc.local` must precede this line.

3. Save your changes, and close `/etc/rc.local` .
4. If you use Red Hat 7.0 or CentOS 7.0 or higher, run the following command as root or sudo:

```
$ chmod +x /etc/rc.d/rc.local
```

On reboot, the command runs during startup. You can also run the command manually as the root user, if you want it to take effect immediately.

Disabling tuning system service

If you use Red Hat 7.0 or CentOS 7.0 or higher, make sure the tuning system service does not start on when Vertica reboots. Turning off tuning prevents monitoring of your OS and any tuning of your OS based on this monitoring. Tuning also enables THP silently, which can cause issues in other areas such as read ahead.

Run the following command as sudo or root:

```
$ chkconfig tuned off
```

In this section

- [SUSE control groups configuration](#)
- [Cron required for scheduled jobs](#)
- [Disk readahead](#)
- [I/O scheduling](#)
- [Enabling or disabling transparent hugepages](#)
- [Check for swappiness](#)
- [Enabling network time protocol \(NTP\)](#)
- [Enabling chrony or ntpd for Red Hat and CentOS systems](#)
- [SELinux configuration](#)
- [CPU frequency scaling](#)
- [Enabling or disabling defrag](#)
- [Support tools](#)

SUSE control groups configuration

On SuSE 12, the installer checks the control group (cgroup) setting for the cgroups that Vertica may run under:

- `verticad`
- `vertica_agent`
- `sshd`

The installer verifies that the `pid.max` resource is large enough for all the threads that Vertica creates. We check the contents of:

- `/sys/fs/cgroup/pids/system.slice/verticad.service/pids.max`
- `/sys/fs/cgroup/pids/system.slice/vertica_agent.service/pids.max`
- `/sys/fs/cgroup/pids/system.slice/sshd.service/pids.max`

If these files exist and they fail to include the value `max`, the installation stops and the installer returns a failure message (code S0340).

If these files do not exist, they are created automatically when the `systemd` runs the `verticad` and `vertica_agent` startup scripts. However, the site's cgroup configuration process managed their default values. Vertica does not change the defaults.

Pre-installation configuration

Before installing Vertica, configure your system as follows:

```
# Create the following directories:
sudo mkdir /sys/fs/cgroup/pids/system.slice/verticad.service/
sudo mkdir /sys/fs/cgroup/pids/system.slice/vertica_agent.service/
# sshd service dir should already exist, so don't need to create it

# Set pids.max values:
sudo sh -c 'echo "max" > /sys/fs/cgroup/pids/system.slice/verticad.service/pids.max'
sudo sh -c 'echo "max" > /sys/fs/cgroup/pids/system.slice/vertica_agent.service/pids.max'
sudo sh -c 'echo "max" > /sys/fs/cgroup/pids/system.slice/sshd.service/pids.max'
```

Persisting configuration for restart

After installation, you can configure control groups for subsequent reboots of the Vertica database. You do so by editing configuration file `/etc/init.d/after.local` and adding the commands shown earlier.

Note

Because `after.local` is executed as root, it can omit `sudo` commands.

Cron required for scheduled jobs

Admintools uses the Linux `cron` package to schedule jobs that regularly rotate the database logs. Without this package installed, the database logs will never be rotated. The lack of rotation can lead to a significant consumption of storage for logs. On busy clusters, Vertica can produce hundreds of gigabytes of logs per day.

`cron` is installed by default on most Linux distributions, but it may not be present on some SUSE 12 systems.

To install `cron` , run this command:

```
$ sudo zypper install cron
```

Disk readahead

Vertica requires that [Disk Readahead](#) be set to at least 2048. The installer reports this issue with the identifier: **S0020** .

Note

- These commands must be executed with root privileges and assumes the blockdev program is in `/sbin` .
- The blockdev program operates on whole devices, and not individual partitions. You cannot set the readahead value to different settings on the same device. If you run blockdev against a partition, for example: `/dev/sda1`, then the setting is still applied to the entire `/dev/sda` device. For instance, running `/sbin/blockdev --setra 2048 /dev/sda1` also causes `/dev/sda2 through /dev/sda N` to use a readahead value of 2048.

RedHat/CentOS and SuSE based systems

For each drive in the Vertica system, Vertica recommends that you set the readahead value to at least 2048 for most deployments. The command immediately changes the readahead value for the specified disk. The second line adds the command to `/etc/rc.local` so that the setting is applied each time the system is booted. Note that some deployments may require a higher value and the setting can be set as high as 8192, under guidance of support.

Note

For systems that do not support `/etc/rc.local` , use the equivalent startup script that is run after the destination runlevel has been reached. For example SUSE uses `/etc/init.d/after.local` .

The following example sets the readahead value of the drive `sda` to 2048:

```
$ /sbin/blockdev --setra 2048 /dev/sda  
$ echo '/sbin/blockdev --setra 2048 /dev/sda' >> /etc/rc.local
```

If you are using Red Hat 7.0 or CentOS 7.0 or higher, run the following command as root or sudo:

```
$ chmod +x /etc/rc.d/rc.local
```

Ubuntu and debian systems

For each drive in the Vertica system, set the readahead value to 2048. Run the command once in your shell, then add the command to `/etc/rc.local` so that the setting is applied each time the system is booted. Note that on Ubuntu systems, the last line in `rc.local` must be " `exit 0` ". So you must manually add the following line to `etc/rc.local` before the last line with `exit 0` .

Note

For systems that do not support `/etc/rc.local` , use the equivalent startup script that is run after the destination runlevel has been reached. For example SuSE uses `/etc/init.d/after.local` .

```
/sbin/blockdev --setra 2048 /dev/sda
```

I/O scheduling

Vertica requires that [I/O Scheduling](#) be set to `deadline` or `noop`. The installer checks what scheduler the system is using, reporting an unsupported scheduler issue with identifier: **S0150** . If the installer cannot detect the type of scheduler in use (typically if your system is using a RAID array), it reports that issue with identifier: **S0151** .

If your system is not using a RAID array, then complete the following steps to change your system to a supported I/O Scheduler. If you are using a RAID array, then consult your RAID vendor documentation for the best performing scheduler for your hardware.

Configure the I/O scheduler

The Linux kernel can use several different I/O schedulers to prioritize disk input and output. Most Linux distributions use the Completely Fair Queuing (CFQ) scheme by default, which gives input and output requests equal priority. This scheduler is efficient on systems running multiple tasks that need equal access to I/O resources. However, it can create a bottleneck when used on Vertica drives containing the catalog and data directories, because it gives write requests equal priority to read requests, and its per-process I/O queues can penalize processes making more requests than other processes.

Instead of the CFQ scheduler, configure your hosts to use either the Deadline or NOOP I/O scheduler for the drives containing the catalog and data directories:

- The Deadline scheduler gives priority to read requests over write requests. It also imposes a deadline on all requests. After reaching the deadline, such requests gain priority over all other requests. This scheduling method helps prevent processes from becoming starved for I/O access. The Deadline scheduler is best used on physical media drives (disks using spinning platters), since it attempts to group requests for adjacent sectors on a disk, lowering the time the drive spends seeking.
- The NOOP scheduler uses a simple FIFO approach, placing all input and output requests into a single queue. This scheduler is best used on solid state drives (SSDs). Because SSDs do not have a physical read head, no performance penalty exists when accessing non-adjacent sectors.

Failure to use one of these schedulers for the Vertica drives containing the catalog and data directories can result in slower database performance. Other drives on the system (such as the drive containing swap space, log files, or the Linux system files) can still use the default CFQ scheduler (although you should always use the NOOP scheduler for SSDs).

You can set your disk device scheduler by writing the name of the scheduler to a file in the `/sys` directory or using a kernel boot parameter.

Changing the scheduler through the `/sys` directory

You can view and change the scheduler Linux uses for I/O requests to a single drive using a virtual file under the `/sys` directory. The name of the file that controls the scheduler a block device uses is:

```
/sys/block/deviceName/queue/scheduler
```

Where `deviceName` is the name of the disk device, such as `sda` or `cciss\lc0d1` (the first disk on an OpenText RAID array). Viewing the contents of this file shows you all of the possible settings for the scheduler. The currently-selected scheduler is surrounded by square brackets:

```
# cat /sys/block/sda/queue/scheduler
noop deadline [cfq]
```

To change the scheduler, write the name of the scheduler you want the device to use to its scheduler file. You must have root privileges to write to this file. For example, to set the `sda` drive to use the deadline scheduler, run the following command as root:

```
# echo deadline > /sys/block/sda/queue/scheduler
# cat /sys/block/sda/queue/scheduler
noop [deadline] cfq
```

Changing the scheduler immediately affects the I/O requests for the device. The Linux kernel starts using the new scheduler for all of the drive's input and output requests.

Note

While tests show that changing the scheduler settings while Vertica is running does not cause problems, Vertica recommends shutting down. Before changing the I/O schedule, or making any other changes to the system configuration, consider shutting down any running database.

Changes to the I/O scheduler made through the `/sys` directory only last until the system is rebooted, so you need to add the commands that change the I/O scheduler to a startup script (such as those stored in `/etc/init.d`, or though a command in `/etc/rc.local`). You also need to use a separate command for each drive on the system whose scheduler you want to change.

For example, to make the configuration take effect immediately and add it to `rc.local` so it is used on subsequent reboots.

Note

For systems that do not support `/etc/rc.local`, use the equivalent startup script that is run after the destination runlevel has been reached. For example SuSE uses `/etc/init.d/after.local`.

```
echo deadline > /sys/block/sda/queue/scheduler
echo 'echo deadline > /sys/block/sda/queue/scheduler' >> /etc/rc.local
```

Note

On some Ubuntu/Debian systems, the last line in `rc.local` must be `" exit 0 "`. So you must manually add the following line to `etc/rc.local` before the last line with `exit 0`.

You may prefer to use this method of setting the I/O scheduler over using a boot parameter if your system has a mix of solid-state and physical media drives, or has many drives that do not store Vertica catalog and data directories.

If you are using Red Hat 7.0 or CentOS 7.0 or higher, run the following command as root or sudo:

```
$ chmod +x /etc/rc.d/rc.local
```

Changing the scheduler with a boot parameter

Use the `elevator` kernel boot parameter to change the default scheduler used by all disks on your system. This is the best method to use if most or all of the drives on your hosts are of the same type (physical media or SSD) and will contain catalog or data files. You can also use the boot parameter to change the default to the scheduler the majority of the drives on the system need, then use the `/sys` files to change individual drives to another I/O scheduler. The format of the elevator boot parameter is:

```
elevator=schedulerName
```

Where `schedulerName` is `deadline`, `noop`, or `cfq`. You set the boot parameter using your bootloader (grub or grub2 on most recent Linux distributions). See your distribution's documentation for details on how to add a kernel boot parameter.

Enabling or disabling transparent hugepages

You can modify transparent hugepages to meet Vertica configuration requirements:

- For Red Hat/CentOS and SUSE 15.1, Vertica provides recommended settings to optimize your system performance by workload.
- For all other systems, you must disable transparent hugepages or set them to `madvise`. The installer reports this issue with the identifier: **S0310**.

Recommended settings by workload for Red Hat/CentOS and SUSE 15.1

Vertica recommends transparent hugepages settings to optimize performance by workload. The following table contains recommendations for systems that primarily run concurrent queries (such as short-running dashboard queries), or sequential SELECT or load (COPY) queries:

Operating System	Concurrent	Sequential	Important Notes
Red Hat and CentOS	Disable	Enable	
SUSE 15.1	Disable	Enable	Additionally, Vertica recommends the following <code>khugepaged</code> settings to optimize for each workload: Concurrent Workloads: Disable <code>khugepaged</code> with the following command: <code>echo 0 > /sys/kernel/mm/transparent_hugepage/khugepaged/defrag</code> Sequential Workloads: Enable <code>khugepaged</code> with the following command: <code>echo 1 > /sys/kernel/mm/transparent_hugepage/khugepaged/defrag</code>

See [Enabling or disabling defrag](#) for additional settings that optimize your system performance by workload.

Enabling transparent hugepages on Red Hat/CentOS and SUSE 15.1

Determine if transparent hugepages is enabled. To do so, run the following command.

```
cat /sys/kernel/mm/transparent_hugepage/enabled
[always] madvise never
```

The setting returned in brackets is your current setting.

For systems that do not support `/etc/rc.local`, use the equivalent startup script that is run after the destination runlevel has been reached. For example SuSE uses `/etc/init.d/after.local`.

You can enable transparent hugepages by editing `/etc/rc.local` and adding the following script:

```
if test -f /sys/kernel/mm/transparent_hugepage/enabled; then
    echo always > /sys/kernel/mm/transparent_hugepage/enabled
fi
```

You must reboot your system for the setting to take effect, or, as root, run the following echo line to proceed with the install without rebooting:

```
# echo always > /sys/kernel/mm/transparent_hugepage/enabled
```

If you are using Red Hat or CentOS or higher, run the following command as root or sudo:

```
$ chmod +x /etc/rc.d/rc.local
```

Disabling transparent hugepages on other systems

Note

SUSE did not offer transparent hugepage support in its initial 11.0 release. However, subsequent SUSE service packs do include support for transparent hugepages.

To determine if transparent hugepages is enabled, run the following command.

```
cat /sys/kernel/mm/transparent_hugepage/enabled
[always] madvise never
```

The setting returned in brackets is your current setting. Depending on your platform OS, the `madvise` setting may not be displayed.

You can disable transparent hugepages one of two ways:

- Edit your boot loader (for example `/etc/grub.conf`). Typically, you add the following to the end of the kernel line. However, consult the documentation for your system before editing your bootloader configuration.

```
transparent_hugepage=never
```

- Edit `/etc/rc.local` (on systems that support `rc.local`) and add the following script.

```
if test -f /sys/kernel/mm/transparent_hugepage/enabled; then
    echo never > /sys/kernel/mm/transparent_hugepage/enabled
fi
```

For systems that do not support `/etc/rc.local`, use the equivalent startup script that is run after the destination runlevel has been reached. For example SuSE uses `/etc/init.d/after.local`.

Regardless of which approach you choose, you must reboot your system for the setting to take effect, or run the following two echo lines to proceed with the install without rebooting:

```
echo never > /sys/kernel/mm/transparent_hugepage/enabled
```

Check for swappiness

The swappiness kernel parameter defines the amount, and how often, the kernel copies RAM contents to a swap space. Vertica recommends a value of 0. The installer reports any swappiness issues with identifier **S0112**.

You can check the swappiness value by running the following command:

```
$ cat /proc/sys/vm/swappiness
```

To set the swappiness value add or update the following line in `/etc/sysctl.conf`:

```
vm.swappiness = 0
```

This also ensures that the value persists after a reboot.

If necessary, you change the swappiness value at runtime by logging in as root and running the following:

```
$ echo 0 > /proc/sys/vm/swappiness
```

Enabling network time protocol (NTP)

Important
Data damage and performance issues might occur if you change host NTP settings while the database is running. Before you change the NTP settings, stop the database. If you cannot stop the database, stop the Vertica process of each host and change the NTP settings one host at a time.

For details, see [Stopping Vertica on host](#).

The network time protocol (NTP) daemon must be running on all of the hosts in the cluster so that their clocks are synchronized. The spread daemon relies on all of the nodes to have their clocks synchronized for timing purposes. If your nodes do not have NTP running, the installation can fail with a spread configuration error or other errors.

Note

Different Linux distributions refer to the NTP daemon in different ways. For example, SUSE and Debian/Ubuntu refer to it as `ntp`, while CentOS and Red Hat refer to it as `ntpd`. If the following commands produce errors, try using the other NTP daemon reference name.

Verify that NTP is running

To verify that your hosts are configured to run the NTP daemon on startup, enter the following command:

```
$ chkconfig --list ntpd
```

Debian and Ubuntu do not support `chkconfig`, but they do offer an optional package. You can install this package with the command `sudo apt-get install sysv-rc-conf`. To verify that your hosts are configured to run the NTP daemon on startup with the `sysv-rc-conf` utility, enter the following command:

```
$ sysv-rc-conf --list ntpd
```

The `chkconfig` command can produce an error similar to `ntpd: unknown service`. If you get this error, verify that your Linux distribution refers to the NTP daemon as `ntpd` rather than `ntp`. If it does not, you need to install the NTP daemon package before you can configure it. Consult your Linux documentation for instructions on how to locate and install packages.

If the NTP daemon is installed, your output should resemble the following:

```
ntp 0:off 1:off 2:on 3:on 4:off 5:on 6:off
```

The output indicates the runlevels where the daemon runs. Verify that the current runlevel of the system (usually 3 or 5) has the NTP daemon set to `on`. If you do not know the current runlevel, you can find it using the `runlevel` command:

```
$ runlevel  
N 3
```

Configure NTP for red hat 6/CentOS 6 and SLES

If your system is based on Red Hat 6/CentOS 6 or SUSE Linux Enterprise Server, use the `service` and `chkconfig` utilities to start NTP and have it start at startup.

```
$ /sbin/service ntpd restart  
$ /sbin/chkconfig ntpd on
```

- **Red Hat 6/CentOS 6** —NTP uses the default time servers at `ntp.org`. You can change the default NTP servers by editing `/etc/ntp.conf`.
- **SLES** —By default, no time servers are configured. You must edit `/etc/ntp.conf` after the install completes and add time servers.

Configure NTP for ubuntu and debian

By default, the [NTP daemon](#) is not installed on some Ubuntu and Debian systems. First, install NTP, and then start the NTP process. You can change the default NTP servers by editing `/etc/ntp.conf` as shown:

```
$ sudo apt-get install ntp
$ sudo /etc/init.d/ntp reload
```

Verify that NTP is operating correctly

To verify that the Network Time Protocol Daemon (NTPD) is operating correctly, issue the following command on all nodes in the cluster.

For Red Hat 6/CentOS 6 and SLES:

```
$/usr/sbin/ntpq -c rv | grep stratum
```

For Ubuntu and Debian:

```
$ ntpq -c rv | grep stratum
```

A stratum level of 16 indicates that NTP is not synchronizing correctly.

If a stratum level of 16 is detected, wait 15 minutes and issue the command again. It may take this long for the NTP server to stabilize.

If NTP continues to detect a stratum level of 16, verify that the NTP port (UDP Port 123) is open on all firewalls between the cluster and the remote machine to which you are attempting to synchronize.

Red hat documentation related to NTP

The preceding links were current as of the last publication of the Vertica documentation and could change between releases.

- <http://kbase.redhat.com/faq/docs/DOC-6731>
- <http://kbase.redhat.com/faq/docs/DOC-6902>
- <http://kbase.redhat.com/faq/docs/DOC-6991>

Enabling chrony or ntpd for Red Hat and CentOS systems

Before you can install Vertica, you must enable one of the following on your system for clock synchronization:

- chrony
- NTPD

You must enable and activate the Network Time Protocol (NTP) before installation. Otherwise, the installer reports this issue with the identifier **S0030**.

For information on installing and using chrony, see the information below. For information on NTPD see [Enabling network time protocol \(NTP\)](#). For more information about chrony, see [Using chrony](#) in the Red Hat documentation.

Install chrony

The chrony suite consists of:

- chronyd - the daemon for clock synchronization.
- chronyc - the command-line utility for configuring chronyd.

chrony is installed by default on some versions of Red Hat/CentOS 7. However, if chrony is not installed on your system, you must download it. To download chrony, run the following command as sudo or root:

```
# dnf install chrony
```

Verify that chrony is running

To view the status of the chronyd daemon, run the following command:

```
$ systemctl status chronyd
```

If chrony is running, an output similar to the following appears:

```
chronyd.service - NTP client/server
  Loaded: loaded (/usr/lib/systemd/system/chronyd.service; enabled)
  Active: active (running) since Mon 2015-07-06 16:29:54 EDT; 15s ago
Main PID: 2530 (chronyd)
  CGroup: /system.slice/chronyd.service
          └─2530 /usr/sbin/chronyd -u chrony
```

If chrony is not running, execute the following command as sudo or root. This command also causes chrony to run at boot time:

```
# systemctl enable chronyd
```

Verify that chrony is operating correctly

To verify that the chrony daemon is operating correctly, issue the following command on all nodes in the cluster:

```
$ chronyc tracking
```

An output similar to the following appears:

```
Reference ID   : 198.247.63.98 (time01.website.org)
Stratum       : 3
Ref time (UTC) : Thu Jul 9 14:58:01 2015
System time   : 0.000035685 seconds slow of NTP time
Last offset   : -0.000151098 seconds
RMS offset    : 0.000279871 seconds
Frequency     : 2.085 ppm slow
Residual freq : -0.013 ppm
Skew          : 0.185 ppm
Root delay    : 0.042370 seconds
Root dispersion : 0.022658 seconds
Update interval : 1031.0 seconds
Leap status   : Normal
```

A stratum level of 16 indicates that chrony is not synchronizing correctly. If chrony continues to detect a stratum level of 16, verify that the UDP port 323 is open. This port must be open on all firewalls between the cluster and the remote machine to which you are attempting to synchronize.

SELinux configuration

Vertica does not support SELinux except when SELinux is running in permissive mode. If it detects that SELinux is installed and the mode cannot be determined the installer reports this issue with the identifier: **S0080** . If the mode can be determined, and the mode is not permissive, then the issue is reported with the identifier: **S0081** .

Red hat and SUSE systems

You can either disable SELinux or change it to use permissive mode.

To disable SELinux:

1. Edit `/etc/selinux/config` and change setting for SELinux to disabled (`SELINUX=disabled`). This disables SELinux at boot time.
2. As root/sudo, type `setenforce 0` to disable SELinux immediately.

To change SELinux to use permissive mode:

1. Edit `/etc/selinux/config` and change setting for SELINUX to permissive (`SELINUX=Permissive`).
2. As root/sudo, type `setenforce Permissive` to switch to permissive mode immediately.

Ubuntu and debian systems

You can either disable SELinux or change it to use permissive mode.

To disable SELinux:

1. Edit `/selinux/config` and change setting for SELinux to disabled (`SELINUX=disabled`). This disables SELinux at boot time.
2. As root/sudo, type `setenforce 0` to disable SELinux immediately.

To change SELinux to use permissive mode:

1. Edit `/selinux/config` and change setting for SELinux to permissive (`SELINUX=Permissive`).
2. As root/sudo, type `setenforce Permissive` to switch to permissive mode immediately.

CPU frequency scaling

This topic details the various CPU frequency scaling methods supported by Vertica. In general, if you do not require CPU frequency scaling, then disable it so as not to impact system performance.

Important

Your systems may use significantly more energy when frequency scaling is disabled.

The installer allows CPU frequency scaling to be enabled when the cpufreq scaling governor is set to **performance** . If the cpu scaling governor is set to *ondemand* , and `ignore_nice_load` is 1 (true), then the installer **fails** with the error **S0140** . If the cpu scaling governor is set to *ondemand* and `ignore_nice_load` is 0 (false), then the installer **warns** with the identifier **S0141** .

CPU frequency scaling is a hardware and software feature that helps computers conserve energy by slowing the processor when the system load is low, and speeding it up again when the system load increases. This feature can impact system performance, since raising the CPU frequency in response to higher system load does not occur instantly. Always disable this feature on the Vertica database hosts to prevent it from interfering with performance.

You disable CPU scaling in your host's system BIOS. There may be multiple settings in your host's BIOS that you need to adjust in order to completely disable CPU frequency scaling. Consult your host hardware's documentation for details on entering the system BIOS and disabling CPU frequency scaling.

If you cannot disable CPU scaling through the system BIOS, you can limit the impact of CPU scaling by disabling the scaling through the Linux kernel or setting the CPU frequency governor to always run the CPU at full speed.

Caution

This method is not reliable, as some hardware platforms may ignore the kernel settings. For more information, see [Vertica Hardware Guide](#).

The method you use to disable frequency depends on the CPU scaling method being used in the Linux kernel. See your Linux distribution's documentation for instructions on disabling scaling in the kernel or changing the CPU governor.

Enabling or disabling defrag

You can modify the defrag utility to meet Vertica configuration requirements, or to optimize your system performance by workload.

On all Red Hat/CentOS systems, you must disable the defrag utility to meet Vertica configuration requirements.

For SUSE 15.1, Vertica recommends that you enable defrag for optimized performance.

Recommended settings by workload for Red Hat/CentOS and SUSE 15.1

Vertica recommends defrag settings to optimize performance by workload. The following table contains recommendations for systems that primarily run concurrent queries (such as short-running dashboard queries), or sequential SELECT or load (COPY) queries:

Operating System	Concurrent	Sequential
Red Hat/CentOS	Disable	Disable
SUSE 15.1	Enable	Enable

See [Enabling or disabling transparent hugepages](#) for additional settings that optimize your system performance by workload.

Disabling defrag on Red Hat/CentOS and SUSE 15.1

1. Determine if defrag is enabled by running the following command:

```
cat /sys/kernel/mm/transparent_hugepage/defrag  
[always] madvise never
```

The setting returned in brackets is your current setting. If you are not using **madvise** or **never** as your defrag setting, then you must disable defrag.

2. Edit `/etc/rc.local`, and add the following script:

```
if test -f /sys/kernel/mm/transparent_hugepage/enabled; then  
    echo never > /sys/kernel/mm/transparent_hugepage/defrag  
fi
```

You must reboot your system for the setting to take effect, or run the following echo line to proceed with the install without rebooting:

```
# echo never > /sys/kernel/mm/transparent_hugepage/defrag
```

3. If you are using Red Hat or CentOS, run the following command as root or sudo:

```
$ chmod +x /etc/rc.d/rc.local
```

Enabling defrag on Red Hat/CentOS and SUSE 15.1

1. Determine if defrag is enabled by running the following command:

```
cat /sys/kernel/mm/transparent_hugepage/defrag
[never] madvise never
```

The setting returned in brackets is your current setting. If you are not using `madvise` or `always` as your defrag setting, then you must enable defrag.

2. Edit `/etc/rc.local`, and add the following script:

```
if test -f /sys/kernel/mm/transparent_hugepage/enabled; then
    echo always > /sys/kernel/mm/transparent_hugepage/defrag
fi
```

You must reboot your system for the setting to take effect, or run the following echo line to proceed with the install without rebooting:

```
# echo always > /sys/kernel/mm/transparent_hugepage/defrag
```

3. If you are using Red Hat or CentOS, run the following command as root or sudo:

```
$ chmod +x /etc/rc.d/rc.local
```

Support tools

Vertica suggests that the following tools are installed so support can assist in troubleshooting your system if any issues arise:

- `pstack` (or `gstack`) package. Identified by issue **S0040** when not installed.
- `mcelog` package. Identified by issue **S0041** when not installed.
- `sysstat` package. Identified by issue **S0045** when not installed.

Red Hat and CentOS systems

To install the required tools on Red Hat and CentOS systems, run the following commands as sudo or root:

```
# dnf install gdb
# dnf install mcelog
# dnf install sysstat
```

Ubuntu and Debian systems

To install the required tools on Ubuntu and Debian systems, run the following commands as sudo or root:

```
$ apt-get install pstack
$ apt-get install mcelog
$ apt-get install sysstat
```

Important

For Ubuntu versions 18.04 and higher, run `apt-get install rasdaemon` instead of `apt-get install mcelog` .

SuSE systems

To install the required tools on SuSE systems, run the following commands as sudo or root.

```
# zypper install sysstat
# zypper install mcelog
```

There is no individual SuSE package for `pstack/gstack`. However, the `gdb` package contains `gstack`, so you could optionally install `gdb` instead, or build `pstack/gstack` from source. To install the `gdb` package:

```
# zypper install gdb
```

System user configuration

The following tasks pertain to the configuration of the system user required by Vertica.

In this section

- [System user requirements](#)
- [TZ environment variable](#)
- [LANG environment variable settings](#)
- [Package dependencies](#)

System user requirements

Vertica has specific requirements for the system user that runs and manages Vertica. If you specify a user during install, but the user does not exist, then the installer reports this issue with the identifier: **S0200** .

System user requirement details

Vertica requires a system user to own database files and run database processes and administration scripts. By default, the install script automatically configures and creates this user for you with the username `dbadmin` . See [Linux users created by Vertica](#) for details on the default user created by the install script. If you decide to manually create your own system user, then you must create the user **before** you run the install script. If you manually create the user:

Note

Instances of `dbadmin` and `verticadba` are placeholders for the names you choose if you do not use the default values.

- the user must have the same username and password on all nodes
- the user must use the BASH shell as the user's default shell. If not, then the installer reports this issue with identifier **[S0240]** .
- the user must be in the `verticadba` group (for example: `usermod -a -G verticadba userNameHere`). If not, the installer reports this issue with identifier **[S0220]** .

Note

You must create a `verticadba` group on all nodes. If you do not, then the installer reports the issue with identifier **[S0210]** .

- the user's login group must be either `verticadba` or a group with the same name as the user (for example, the home group for `dbadmin` is `dbadmin`). You can check the groups for a user with the `id` command. For example: `id dbadmin` . The "gid" group is the user's primary group. If this is not configured correctly then the installer reports this issue with the identifier **[S0230]** . Vertica recommends that you use `verticadba` as the user's primary login group. For example: `usermod -g verticadba userNameHere` . If the user's primary group is not `verticadba` as suggested, then the installer reports this with HINT **[S0231]** .
- the user must have a home directory. If not, then the installer reports this issue with identifier **[S0260]** .
- the user's home directory must be owned by the user. If not, then the installer reports the issue with identifier **[S0270]** .
- the system must be aware of the user's home directory (you can set it with the `usermod` command: `usermod -m -d /path/to/new/home/dir userNameHere`). If this is not configured correctly then the installer reports the issue with **[S0250]** .
- the user's home directory must be owned by the `dbadmin`'s primary group (use the `chown` and `chgrp` commands if necessary). If this is not configured correctly, then the installer reports the issue with identifier **[S0280]** .
- the user's home directory *should* have secure permissions. Specifically, it should not be writable by anyone or by the group. Ideally the permissions should be, when viewing with `ls` , " --- " (nothing), or " r-x " (read and execute). If this is not configured as suggested then the installer reports this with HINT **[S0290]** .

TZ environment variable

This topic details how to set or change the TZ environment variable and update your `tzdata` package. If this variable is not set, then the installer reports this issue with the identifier: **S0305** .

Before installing Vertica, update the `tzdata` package for your system and set the default time zone for your database administrator account by specifying the TZ environmental variable. If your database administrator is being created by the `install_vertica` script, then set the TZ variable after you have installed Vertica.

Update tzdata package

The `tzdata` package is a public-domain time zone database that is pre-installed on most Linux systems. The `tzdata` package is updated periodically for time-zone changes across the world. You should update to the latest `tzdata` package before installing or updating Vertica.

Update your `tzdata` package with the following command:

- RedHat based systems: `yum update tzdata`
- Debian and Ubuntu systems: `apt-get install tzdata`

Setting the default time zone

When a client receives the result set of a SQL query, all rows contain data adjusted, if necessary, to the same time zone. That time zone is the default time zone of the initiator node unless the client explicitly overrides it using the SQL `SET TIME ZONE` command described in the SQL Reference Manual. The default time zone of any node is controlled by the TZ environment variable. If TZ is undefined, the operating system time zone.

Important

The **TZ** variable must be set to the same value on all nodes in the cluster.

If your operating system timezone is not set to the desired timezone of the database then make sure that the Linux environment variable **TZ** is set to the desired value on all cluster hosts.

The installer returns a warning if the **TZ** variable is not set. If your operating system timezone is appropriate for your database, then the operating system timezone is used and the warning can be safely ignored.

Setting the time zone on a host

Important

If you explicitly set the **TZ** environment variable at a command line before you start the [Administration tools](#), the current setting will not take effect. The Administration Tools uses SSH to start copies on the other nodes, so each time SSH is used, the **TZ** variable for the startup command is reset. **TZ** must be set in the `.profile` or `.bashrc` files on all nodes in the cluster to take affect properly.

You can set the time zone several different ways, depending on the Linux distribution or the system administrator's preferences.

- To set the system time zone on Red Hat and SUSE Linux systems, edit:

```
/etc/sysconfig/clock
```

- To set the **TZ** variable, edit, `/etc/profile`, or `/home/dbadmin/.bashrc` or `/home/dbadmin/.bash_profile` and add the following line (for example, for the US Eastern Time Zone):

```
export TZ="America/New_York"
```

For details on which timezone names are recognized by Vertica, see the appendix: [Using time zones with Vertica](#).

LANG environment variable settings

This topic details how to set or change the **LANG** environment variable. The **LANG** environment variable controls the locale of the host. If this variable is not set, then the installer reports this issue with the identifier: **S0300**. If this variable is not set to a valid value, then the installer reports this issue with the identifier: **S0301**.

Set the host locale

Each host has a system setting for the Linux environment variable **LANG**. **LANG** determines the locale category for native language, local customs, and coded character set in the absence of the **LC_ALL** and other **LC_** environment variables. **LANG** can be used by applications to determine which language to use for error messages and instructions, collating sequences, date formats, and so forth.

To change the **LANG** setting for the database administrator, edit, `/etc/profile`, or `/dbadmin/.bashrc` or `/home/dbadmin/.bash_profile` on all cluster hosts and set the environment variable; for example:

```
export LANG=en_US.UTF-8
```

The **LANG** setting controls the following in Vertica:

- OS-level errors and warnings, for example, "file not found" during [COPY](#) operations.
- Some formatting functions, such as [TO_CHAR](#) and [TO_NUMBER](#). See also [Template patterns for numeric formatting](#).

The **LANG** setting does not control the following:

- Vertica specific error and warning messages. These are always in English at this time.
- Collation of results returned by SQL issued to Vertica. This must be done using a database parameter instead. See [Implement locales for international data sets](#) section for details.

Note

If the **LC_ALL** environment variable is set, it supersedes the setting of **LANG**.

Package dependencies

For successful Vertica installation, you must first install three packages on all nodes in your cluster before installing the database platform.

The required packages are:

- openssh—Required for [Administration tools](#) connectivity between nodes.
- which—Required for Vertica operating system integration and for validating installations.
- dialog—Required for interactivity with Administration Tools.

Installing the required packages

The procedure you follow to install the required packages depends on the operating system on which your node or cluster is running. See your operating system's documentation for detailed information on installing packages.

- **For CentOS/Red Hat Systems** —Typically, you manage packages on Red Hat and CentOS systems using the yum utility.

Run the following yum commands to install each of the package dependencies. The yum utility guides you through the installation:

```
# yum install openssh
# yum install which
# yum install dialog
```

- **For Debian/Ubuntu Systems** —Typically, you use the apt-get utility to manage packages on Debian and Ubuntu systems.

Run the following apt-get commands to install each of the package dependencies. The apt-get utility guides you through the installation:

```
# apt-get install openssh
# apt-get install which
# apt-get install dialog
```

Install Vertica using the command line

This section describes how to install the Vertica software on a cluster of nodes. It assumes that you have already performed the tasks in [Before You Install Vertica](#), and that you have a Vertica license key.

To install Vertica, complete the following tasks:

1. [Download and install the Vertica server package](#)
2. [Install Vertica with the installation script](#)

Special notes

- Downgrade installations are not supported.
- Be sure that you download the RPM for the correct operating system and architecture.
- Vertica supports two-node clusters with zero fault tolerance (K=0 safety). This means that you can [add a node](#) to a single-node cluster, as long as the installation node (the node upon which you build) is not the loopback node (`localhost/127.0.0.1`).
- The installer performs platform verification tests that prevent the install from continuing if the platform requirements are not met. These tests ensure that your platform meets the hardware and software requirements for Vertica. You can simply run the installer and view a list of the failures and warnings to determine which configuration changes you must make.

In this section

- [Download and install the Vertica server package](#)
- [Linux users created by Vertica](#)
- [Validation scripts](#)
- [Install Vertica with the installation script](#)
- [Install Vertica silently](#)
- [Enable secure shell \(SSH\) logins](#)

Download and install the Vertica server package

To download and install the Vertica server package:

1. Use a Web browser to go to the [Vertica website](#).
2. Click the **Support** tab and select **Customer Downloads**.
3. Log into the portal to download the install package.
Be sure the package you download matches the operating system and the machine architecture on which you intend to install it.
4. Transfer the installation package to the [Administration host](#).
5. If you installed a previous version of Vertica on any of the hosts in the cluster, use the [Administration tools](#) to shut down any running database. The database must stop normally; you cannot upgrade a database that requires recovery.
6. If you are using sudo, skip to the next step. If you are root, log in to the Administration Host as root (or log in as another user and switch to root).

```
$ su - root
password: root-password
#
```

Caution

When installing Vertica using an existing user as the dba, you must exit all UNIX terminal sessions for that user after setup completes and log in again to ensure that group privileges are applied correctly.

After Vertica is installed, you no longer need root privileges. To verify sudo, see [Platform and hardware requirements and recommendations](#).

7. Use one of the following commands to run the RPM package installer:

- If you are root and installing an RPM:

```
# rpm -Uvh pathname
```

Note

When installing a Vertica RPM, you might see an unexpected warning about a SHA256 signature. This warning indicates that you need to import a GPG key. Only necessary for versions after 10.0, keys can be downloaded under the Security section of your chosen release from the [Vertica Client Drivers page](#). After downloading the key, you can import it with the following command:

```
# rpm --import RPM-GPG-KEY-VERTICA
```

- If you are using sudo and installing an RPM:

```
$ sudo rpm -Uvh pathname
```

- If you are using Debian:

```
$ sudo dpkg -i pathname
```

where *pathname* is the Vertica package file you downloaded.

Note

If the package installer reports multiple dependency problems, or you receive the error *"ERROR: You're attempting to install the wrong RPM for this operating system"*, then you are trying to install the wrong Vertica server package.

After you install the Vertica RPM, you can use several [Validation scripts](#) to help determine if your hosts and network can properly handle the processing and network traffic required by Vertica.

Linux users created by Vertica

This topic describes the Linux accounts that the installer creates and configures so Vertica can run. When you install Vertica, the installation script optionally creates the following Linux user and group:

- dbadmin—Administrative user
- verticadba—Group for DBA users

dbadmin and verticadba are the default names. If you want to change what these Linux accounts are called, you can do so using the installation script. See [Install Vertica with the installation script](#) for details.

Dbadmin privileges

The Linux dbadmin user owns the database catalog and data storage on disk. When you run the install script, Vertica creates this user on each node in the database cluster. It also adds dbadmin to the Linux dbadmin and verticadba groups, and configures the account as follows:

- Configures and authorizes dbadmin for passwordless SSH between all cluster nodes. SSH must be installed and configured to allow passwordless logins. See [Enable secure shell \(SSH\) logins](#).
- Sets the dbadmin user's BASH shell to `/bin/bash`, required to run scripts, such as `install_vertica` and the [Administration tools](#).
- Provides read-write-execute permissions on the following directories:
 - `/opt/vertica/*`
 - `/home/dbadmin` —the default directory for database data and catalog files (configurable through the install script)

Note

The Vertica installation script also creates a Vertica database superuser named dbadmin. They share the same name, but they are not the same; one is a Linux user and the other is a Vertica user. See [Database administration user](#) for information about the database superuser.

After you install Vertica

Root or sudo privileges are not required to start or run Vertica after the installation process completes.

The dbadmin user can log in and perform Vertica tasks, such as creating a database, installing/changing the license key, or installing drivers. If dbadmin wants database directories in a location that differs from the default, the root user (or a user with sudo privileges) must create the requested directories and change ownership to the dbadmin user.

Vertica prevents administration from users other than the dbadmin user (or the user name you specified during the installation process if not dbadmin). Only this user can run Administration Tools.

- [Installation overview and checklist](#)
- [Before you install Vertica](#)
- [Platform and hardware requirements and recommendations](#)
- [Enable secure shell \(SSH\) logins](#)

Validation scripts

Vertica provides several validation utilities that can be used prior to deploying Vertica to help determine if your hosts and network can properly handle the processing and network traffic required by Vertica. These utilities can also be used if you are encountering performance issues and need to troubleshoot the issue.

After you install the Vertica RPM, you have access to the following scripts in `/opt/vertica/bin` :

- [Vcpuperf](#) - a CPU performance test used to verify your CPU performance.
- [Vioperf](#) - an Input/Output test used to verify the speed and consistency of your hard drives.
- [Vnetperf](#) - a Network test used to test the latency and throughput of your network between hosts.

These utilities can be run at any time, but are well suited to use before running the `install_vertica` script.

In this section

- [Vcpuperf](#)
- [Vioperf](#)
- [Vnetperf](#)

Vcpuperf

The `vcpuperf` utility measures your server's CPU processing speed and compares it against benchmarks for common server CPUs. The utility performs a CPU test and measures the time it takes to complete the test. The lower the number scored on the test, the better the performance of the CPU.

The `vcpuperf` utility also checks the high and low load times to determine if CPU throttling is enabled. If a server's low-load computation time is significantly longer than the high-load computation time, CPU throttling may be enabled. CPU throttling is a power-saving feature. However, CPU throttling can reduce the performance of your server. Vertica recommends disabling CPU throttling to enhance server performance.

Syntax

```
vcpuperf [-q]
```

Options

-q

Run in quiet mode. Quiet mode displays only the CPU Time, Real Time, and high and low load times.

Returns

- CPU Time: the amount of time it took the CPU to run the test.
- Real Time: the total time for the test to execute.
- High load time: The amount of time to run the load test while simulating a high CPU load.
- Low load time: The amount of time to run the load test while simulating a low CPU load.

Example

The following example shows a CPU that is running slightly slower than the expected time on a Xeon 5670 CPU that has CPU throttling enabled.

```
[root@node1 bin]# /opt/vertica/bin/vcpuperf
Compiled with: 4.1.2 20080704 (Red Hat 4.1.2-52) Expected time on Core 2, 2.53GHz: ~9.5s
Expected time on Nehalem, 2.67GHz: ~9.0s
Expected time on Xeon 5670, 2.93GHz: ~8.0s
```

This machine's time:
CPU Time: 8.540000s
Real Time:8.710000s

Some machines automatically throttle the CPU to save power.
This test can be done in <100 microseconds (60-70 on Xeon 5670, 2.93GHz).
Low load times much larger than 100-200us or much larger than the corresponding high load time indicate low-load throttling, which can adversely affect small query / concurrent performance.

This machine's high load time: 67 microseconds.
This machine's low load time: 208 microseconds.

Vioperf

The **vioperf** utility quickly tests the performance of your host's input and output subsystem. The utility performs the following tests:

- sequential write
- sequential rewrite
- sequential read
- skip read (read non-contiguous data blocks)

The utility verifies that the host reads the same bytes that it wrote and prints its output to STDOUT. The utility also logs the output to a JSON formatted file.

For data in HDFS, the utility tests reads but not writes.

Syntax

```
vioperf [--help] [--duration=<INTERVAL>] [--log-interval=<INTERVAL>]
[--log-file=<FILE>] [--condense-log] [--thread-count=<N>] [--max-buffer-size=<SIZE>]
[--preserve-files] [--disable-crc] [--disable-direct-io] [--debug]
[<DIR>*]
```

Minimum and recommended I/O performance

- The minimum required I/O is 20 MB/s read/write per physical processor core on each node, in full duplex (reading and writing) simultaneously, concurrently on all nodes of the cluster.

Note

Vertica supports some AWS instance types that do not meet these minimum I/O requirements. However, all supported AWS instances types, regardless of **vioperf** performance, can be used as Vertica cluster hosts. See [Supported AWS instance types](#) for a list of all supported AWS instance types.

- The recommended I/O is 40 MB/s per physical core on each node.
- The minimum required I/O rate for a node with 2 hyper-threaded six-core CPUs (12 physical cores) is 240 MB/s. Vertica recommends 480 MB/s.

For example, the I/O rate for a node with 2 hyper-threaded six-core CPUs (12 physical cores) is 240 MB/s required minimum, 480 MB/s recommended.

Disk space vioperf needs

vioperf requires about 4.5 GB to run.

Options

--help

Prints a help message and exits.

--duration

The length of time **vioprobe** runs performance tests. The default is 5 minutes. Specify the interval in seconds, minutes, or hours with any of these suffixes:

- Seconds: **s** , **sec** , **secs** , **second** , **seconds** . Example: `--duration=60sec`
- Minutes: **m** , **min** , **mins** , **minute** , **minutes** . Example: `--duration=10min`
- Hours: **h** , **hr** , **hrs** , **hour** , **hours** . Example: `--duration=1hrs`

--log-interval

The interval at which the log file reports summary information. The default interval is 10 seconds. This option uses the same interval notation as `--duration` .

--log-file

The path and name where log file contents are written, in JSON. If not specified, then `vioperf` creates a file named `results date-time .JSON` in the current directory.

--condense-log

Directs `vioperf` to write the log file contents in condensed format, one JSON entry per line, rather than as indented JSON syntax.

--thread-count=<N>

The number of execution threads to use. By default, `vioperf` uses all threads available on the host machine.

--max-buffer-size=<SIZE>

The maximum size of the in-memory buffer to use for reads or writes. Specify the units with any of these suffixes:

- Bytes: **b** , **byte** , **bytes** .
- Kilobytes: **k** , **kb** , **kilobyte** , **kilobytes** .
- Megabytes: **m** , **mb** , **megabyte** , **megabytes** .
- Gigabytes: **g** , **gb** , **gigabyte** , **gigabytes** .

--preserve-files

Directs `vioperf` to keep the files it writes. This parameter is ignored for HDFS tests, which are read-only. Inspecting the files can help diagnose write-related failures.

--disable-crc

Directs `vioperf` to ignore CRC checksums when validating writes. Verifying checksums can add overhead, particularly when running `vioperf` on slower processors. This parameter is ignored for HDFS tests.

--disable-direct-io

When reading from or writing to a local file system, `vioperf` goes directly to disk by default, bypassing the operating system's page cache. Using direct I/O allows `vioperf` to measure performance quickly without having to fill the cache.

Disabling this behavior can produce more realistic performance results but slows down the operation of `vioperf` .

--debug

Directs `vioperf` to report verbose error messages.

<DIR>

Zero or more directories to test. If you do not specify a directory, `vioperf` tests the current directory. To test the performance of each disk, specify different directories mounted on different disks.

To test reads from a directory on HDFS:

- Use a URL in the `hdfs` scheme that points to a single directory (not a path) containing files at least 10MB in size. For best results, use 10GB files and verify that there is at least one file per `vioperf` thread.
- If you do not specify a host and port, set the `HADOOP_CONF_DIR` environment variable to a path including the Hadoop configuration files. This value is the same value that you use for the `HadoopConfDir` configuration parameter in Vertica. For more information see [Configuring HDFS access](#) .
- If the HDFS cluster uses Kerberos, set the `HADOOP_USER_NAME` environment variable to a Kerberos principal.

Returns

The utility returns the following information:

test

The test being run (Write, ReWrite, Read, or Skip Read)

directory

The directory in which the test is being run.

counter name

The counter type of the test being run. Can be either MB/s or Seeks per second.

counter value

The value of the counter in MB/s or Seeks per second across all threads. This measurement represents the bandwidth at the exact time of measurement. Contrast with counter value (avg).

counter value (10 sec avg)

The average amount of data in MB/s, or the average number of Seeks per second, for the test being run in the duration specified with `--log-interval`. The default interval is 10 seconds. The `counter value (avg)` is the average bandwidth since the last log message, across all threads.

counter value/core

The `counter value` divided by the number of cores.

counter value/core (10 sec avg)

The `counter value (10 sec avg)` divided by the number of cores.

thread count

The number of threads used to run the test.

%CPU

The available CPU percentage used during this test.

%IO Wait

The CPU percentage in I/O Wait state during this test. I/O wait state is the time working processes are blocked while waiting for I/O operations to complete.

elapsed time

The amount of time taken for a particular test. If you run the test multiple times, elapsed time increases the next time the test is run.

remaining time

The time remaining until the next test. Based on the `--duration` option, each of the tests is run at least once. If the test set is run multiple times, then `remaining time` is how much longer the test will run. The `remaining time` value is cumulative. Its total is added to elapsed time each time the same test is run again.

Example

Invoking `vioperf` from a terminal outputs the following message and sample results:

```
[dbadmin@v_vmart_node0001 ~]$ /opt/vertica/bin/vioperf --duration=60s
The minimum required I/O is 20 MB/s read and write per physical processor core on each node, in full duplex
i.e. reading and writing at this rate simultaneously, concurrently on all nodes of the cluster.
The recommended I/O is 40 MB/s per physical core on each node.
For example, the I/O rate for a server node with 2 hyper-threaded six-core CPUs is 240 MB/s required minimum, 480 MB/s recommended.

Using direct io (buffer size=1048576, alignment=512) for directory "/home/dbadmin"

test | directory | counter name | counter value | counter value (10 sec avg) | counter value/core | counter value/core (10 sec avg) | thread count |
%CPU | %IO Wait | elapsed time (s)| remaining time (s)
-----
Write | /home/dbadmin | MB/s | 420 | 420 | 210 | 210 | 2 | 89 | 10 | 10 | 5
Write | /home/dbadmin | MB/s | 412 | 396 | 206 | 198 | 2 | 89 | 9 | 15 | 0
ReWrite | /home/dbadmin | (MB-read+MB-write)/s | 150+150 | 150+150 | 75+75 | 75+75 | 2 | 58 | 40 | 5
10 | 5
ReWrite | /home/dbadmin | (MB-read+MB-write)/s | 158+158 | 172+172 | 79+79 | 86+86 | 2 | 64 | 33 | 15
| 0
Read | /home/dbadmin | MB/s | 194 | 194 | 97 | 97 | 2 | 69 | 26 | 10 | 5
Read | /home/dbadmin | MB/s | 192 | 190 | 96 | 95 | 2 | 71 | 27 | 15 | 0
SkipRead | /home/dbadmin | seeks/s | 659 | 659 | 329.5 | 329.5 | 2 | 2 | 85 | 10 | 5
SkipRead | /home/dbadmin | seeks/s | 677 | 714 | 338.5 | 357 | 2 | 2 | 59 | 15 | 0
```

Note

When evaluating performance for minimum and recommended I/O, include the Write and Read values in your evaluation. ReWrite and SkipRead values are not relevant to determining minimum and recommended I/O.

Vnetperf

The `vnetperf` utility measures network performance of database hosts, as well as network latency and throughput for TCP and UDP protocols.

Caution

This utility incurs high network load, which degrades database performance. Do not use this utility on a Vertica production database.

This utility helps identify the following issues:

- Low throughput for all hosts or one
- High latency for all hosts or one
- Bottlenecks between one or more hosts or subnets
- Too-low limit on the number of TCP connections that can be established simultaneously
- High rates of network packet loss

Syntax

```
vnetperf [[options](#Options)] [[tests](#Tests)]
```

Options

--condense

Condenses the log into one JSON entry per line, instead of indented JSON syntax.

--collect-logs

Collects test log files from each host.

--datarate *rate*

Limits throughput to this rate in MB/s. A rate of 0 loops the tests through several different rates.

Default: 0

--duration *seconds*

Time limit for each test to run in seconds.

Default: 1

--hosts *host-name* [...]

Comma-separated list of host names or IP addresses on which to run the tests. The list must not contain embedded spaces.

--hosts *file*

File that specifies the hosts on which to run the tests. If you omit this option, then the vnetperf tries to access admintools to identify cluster hosts.

--identity-file *file*

If using passwordless SSH/SCP access between hosts, then specify the key file used to gain access to the hosts.

--ignore-bad-hosts

If set, runs tests on reachable hosts even if some hosts are not reachable. If you omit this option and a host is unreachable, then no tests are run on any hosts.

--log-dir *directory*

If **--collect-logs** is set, specifies the directory in which to place the collected logs.

Default: logs.netperf. *<timestamp>*

--log-level *level*

Log level to use, one of the following:

- INFO
- ERROR
- DEBUG
- WARN

Default: WARN

--list-tests

Lists the [tests](#) that vnetperf can run.

--output-file *file*

The file to which JSON results are written.

Default: results. *<timestamp>*.json

--ports port#[,...]

Comma-delimited list of port numbers to use. If only one port number is specified, then the next two numbers in sequence are also used.

Default: 14159,14160,14161

--scp-options ' scp-args '

Specifies one or more standard SCP command line arguments. SCP is used to copy test binaries over to the target hosts.

--ssh-options ' ssh-args '

Specifies one or more standard SSH command line arguments. SSH is used to issue test commands on the target hosts.

--tmp-dir *directory*

Specifies the temporary directory for vnetperf, where *directory* must have execute permission on all hosts, and does not include the unsupported characters " , "`, or ' .

Default: /tmp (execute permission required)

--vertica-install *directory*

Indicates that Vertica is installed on each of the hosts, so vnetperf uses test binaries on the target system rather than copying them over with SCP.

Tests

vnetperf can specify one or more of the following tests. If no test is specified, vnetperf runs all tests. Test results are printed for each host.

Test	Description	Results
<i>latency</i>	Measures latency from the host that is running the script to other hosts. Hosts with unusually high latency should be investigated further.	<ul style="list-style-type: none"> Round trip time latency for each host in milliseconds. Clock skew—the difference in time shown by the clock on the target host relative to the host running the utility.
<i>tcp-throughput</i>	Tests TCP throughput among hosts.	<ul style="list-style-type: none"> Date/time and test name Rate limit in MB/s Tested node Sent and received data in MB/s and bytes Duration of the test in seconds
<i>udp-throughput</i>	Tests UDP throughput among hosts	

Recommended network performance

- Maximum recommended RTT (round-trip time) latency is 1000 microseconds. Ideal RTT latency is 200 microseconds or less. Vertica recommends that clock skew be less than 1 second.
- Minimum recommended throughput is 100 MB/s. Ideal throughput is 800 MB/s or more.

Note

UDP throughput can be lower; multiple network switches can adversely affect performance.

Example

\$ vnetperf latency tcp-throughput

The maximum recommended rtt latency is 2 milliseconds. The ideal rtt latency is 200 microseconds or less. It is recommended that clock skew be kept to under 1 second.

test	date	node	index	rtt latency (us)	clock skew (us)
latency	2022-03-29_10:23:55,739	10.20.100.247	0	49	3
latency	2022-03-29_10:23:55,739	10.20.100.248	1	272	-702
latency	2022-03-29_10:23:55,739	10.20.100.249	2	245	1037

The minimum recommended throughput is 100 MB/s. Ideal throughput is 800 MB/s or more. Note: UDP numbers may be lower, multiple network switches may reduce performance results.

date	test	rate limit (MB/s)	node	MB/s (sent)	MB/s (rec)	bytes (sent)	bytes (rec)	duration (s)

Install Vertica with the installation script

You can run the installation script after you install the Vertica package. The installation script runs on a single node, using a Bash shell. The script copies the Vertica package to all other hosts (identified by the `--hosts` argument) in your planned cluster.

Tip

To speed up the installation, you can provide a local copy of the RPM to each node in the cluster before running the install script. This allows the

installer to bypass the time-consuming process of copying the RPM to the nodes. For details, see [--no-rpm-copy](#).

The installation script runs several tests on each of the target hosts to verify that the hosts meet system and performance requirements for a Vertica node. The installation script modifies some operating system configuration settings to meet these requirements. Other settings cannot be modified by the installation script and must be manually reconfigured. For details on operating system configuration settings, see [Manually configured operating system settings](#) and [Automatically configured operating system settings](#).

Note

The installation script sets up passwordless ssh for the admin user across all hosts. If passwordless ssh is already set up, the installation script verifies that it functions correctly.

In this section

- [Install on a FIPS 140-2 enabled machine](#)
- [Specifying disk storage location during installation](#)
- [Perform a basic install](#)
- [install_vertica options](#)

Install on a FIPS 140-2 enabled machine

Vertica supports the implementation of the Federal Information Processing Standard 140-2 (FIPS). You enable FIPS mode in the operating system.

Note

Enabling FIPS on the operating system occurs outside of Vertica.

During installation, the `install_vertica` script detects whether the host is operating in FIPS mode. The installer searches for the file `/proc/sys/crypto/fips_enabled` and examines its content. If the file exists and contains a '1' in the filename, the host is operating in FIPS mode and the following message appears:

```
/proc/sys/crypto/fips_enabled exists and contains '1', this is a FIPS system
```

Important

On certain systems where the `libssl` and `libcrypto` libraries do not have versioning information, when starting Vertica, you may see the message

No version information available

This message is benign and you can ignore it.

To implement FIPS 140-2 on your Vertica Analytic Database, you need to configure both the server and the client you are using. To see the detailed configuration steps, go to [Implementing FIPS 140-2](#).

Symbolic links for OpenSSL

On some non-FIPS systems, versioning anomalies can occur when you install a new version of OpenSSL. Sometimes, the default OpenSSL build procedure produces libraries with versions named 1.0.0. For Vertica to recognize that a library has a higher version number, the library name with a higher version number must be provided. As part of the Vertica installation, symbolic links are created to the appropriate OpenSSL files. The steps are as follows:

1. The RPM installer places two OpenSSL library files in `/opt/vertica/lib`:
 - `libssl.so.1.1`
 - `libcrypto.so.1.1`
2. The `install_vertica` script creates two symbolic links in `/opt/vertica/lib`:
 - `libssl.so`
 - `libcrypto.so`
3. The symbolic links point to `libssl.so.1.1` and `libcrypto.so.1.1`, which the RPM installer placed in `/opt/vertica/lib`.

Specifying disk storage location during installation

You can specify the disk storage location when you:

- Install Vertica (see below).
- [Create a database using the Administration Tools.](#)
- [Installing Management Console](#)

Specifying disk storage location when you install

When you install Vertica, the `--data-dir` parameter in the [install_vertica_script](#) lets you specify a directory to contain database data and catalog files. The script defaults to the database administrator's default home directory `/home/dbadmin`.

Important

Replace *this default* with a directory that has adequate space to hold your data and catalog files.

Requirements

- The data and catalog directory must exist on each node in the cluster.
- The directory on each node must be owned by the database administrator
- Catalog and data path names must contain only alphanumeric characters and cannot have leading space characters. Failure to comply with these restrictions will result in database creation failure.
- Vertica refuses to overwrite a directory if it appears to be in use by another database. Therefore, if you created a database for evaluation purposes, dropped the database, and want to reuse the database name, make sure that the disk storage location previously used has been completely cleaned up. See [Managing storage locations](#) for details.

Perform a basic install

For all installation options, see [install_vertica_options](#).

1. As root (or sudo) run the install script. The script must be run by a BASH shell as root or as a user with sudo privileges. You can configure many options when running the install script. See [Basic Installation Parameters](#) for the required options.

If the installer fails due to any requirements not being met, you can correct the issue and then rerun the installer with the same command line options.

To perform a basic installation:

- As root:

```
# /opt/vertica/sbin/install_vertica --hosts host_list --rpm package_name \
  --dba-user dba_username --parallel-no-prompts
```

- Using sudo:

```
$ sudo /opt/vertica/sbin/install_vertica --hosts host_list --rpm package_name \
  --dba-user dba_username --parallel-no-prompts
```

Important

If you place `install_vertica` in a location other than `/opt/vertica`, create a symlink from that location to `/opt/vertica`. Create this symlink on all cluster nodes, otherwise the database will not start.

2. When prompted for a password to log into the other nodes, provide the requested password. Doing so allows the installation of the package and system configuration on the other cluster nodes.
 - If you are root, this is the root password.
 - If you are using sudo, this is the sudo user password.

The password does not echo on the command line. For example:

```
Vertica Database 24.2.x Installation Tool
Please enter password for root@host01:password
```

3. If the dbadmin user, or the user specified in the argument `--dba-user`, does not exist, then the install script prompts for the password for the user. Provide the password. For example:

```
Enter password for new UNIX user dbadmin:password
Retype new UNIX password for user dbadmin:password
```

4. Carefully examine any warnings or failures returned by `install_vertica` and correct the problems. For example, insufficient RAM, insufficient network throughput, and too high readahead settings on the file system could cause performance problems later on. Additionally, LANG warnings, if not resolved, can cause database startup to fail and issues with VSQL. The system LANG attributes must be UTF-8 compatible. After you fix the problems, rerun the install script.
5. When installation is successful, disconnect from the [Administration host](#), as instructed by the script. Then, complete the required post-installation steps. At this point, root privileges are no longer needed and the database administrator can perform any remaining steps.

install_vertica options

The following tables describe `install_vertica` script options. Most options have long and short forms—for example, `--hosts` and `-s`.

Required

`install_vertica` requires the following options:

- `--hosts / -s`
- `--rpm / -r | --deb | --no-rpm-copy`
- `--dba-user username | -u username`

Required only if installing using root or upgrading versions.

For example:

```
# /opt/vertica/sbin/install_vertica --hosts node0001,node0002,node0003 --rpm /tmp/vertica-version.RHEL8.x86_64.rpm
```

`--hosts hostlist -s hostlist`

Comma-separated list of host names or IP addresses to include in the cluster. The list must not include embedded spaces. For example:

- `--hosts node01,node02,node03`
- `--hosts 192.168.233.101,192.168.233.102,192.168.233.103`
- `--hosts fd95:ff5d:5549:bdb0::1,fd95:ff5d:5549:bdb0::2,fd95:ff5d:5549:bdb0::3`

The following requirements apply:

- If upgrading an existing installation of Vertica, use the same host names used previously.
- IP addresses or hostnames must be for unique hosts. Do not list the same host using multiple IP addresses/hostnames.

Note

Vertica stores only IP addresses in its configuration files. If you provide host names, they are converted to IP addresses when the script runs.

`--rpm package-name -r package-name -deb package-name`

Path and name of the Vertica RPM or Debian package. For example:

```
--rpm /tmp/vertica-version.RHEL8.x86_64.rpm
```

For Debian and Ubuntu installs, provide the name of the Debian package:

```
--deb /tmp/vertica_10.1_amd64.deb
```

The install package must be provided if you install or upgrade the Vertica server package on multiple nodes where the nodes do not have the latest server package installed, or if you are adding a new node. You do not need to provide the server package if you have a local copy of the RPM on each node and call the install script with the `no-rpm-copy` option. Unless you provide the `--no-rpm-copy` option, the `install_vertica` and `update_vertica` scripts serially copy the server package to the other nodes and install the package.

Tip

If installing or upgrading a large number of nodes, consider manually installing the package on all nodes before running the install/upgrade script. The script runs faster if it does not need to serially upload and install the package on each node.

`--no-rpm-copy`

Installer does not copy the RPM to the nodes in the cluster. The RPM must be present on each node specified by `--hosts`, and you must provide the path to the local RPM files with the `--rpm-path` option (defaults to `/tmp/dbRPM.rpm`). If you specify this option, you do not need to provide the `--rpm` option.

`--dba-user username -u username`

Name of the database superuser account to create. Only this account can run the Administration Tools. If you omit this parameter, then the default administrator account name is `dbadmin`.

This parameter is optional for new installations done as root; they must be specified when upgrading or when installing using sudo. If upgrading, use this parameter to specify the same account name that you used previously. If installing using sudo, `username` must already exist. If you manually create the user, modify the user's `.bashrc` file to include the line: `PATH=/opt/vertica/bin:$PATH` so Vertica tools such as `vsqj` and `admintools` can be easily started by this user.

For details on a minimal installation procedure, see [Perform a basic install](#).

Optional

The following `install_vertica` options are not required. Many of them enable greater control over the installation process.

--help

Display help for this script.

--accept-eula -Y

Silently accepts the EULA agreement. On multi-node installations, this option is propagated across the cluster at the end of the installation, at the same time as the Administration Tools metadata.

Combine this option with `--license (-L)` to activate your license.

--add-hosts *hostlist* -A *hostlist*

Comma-separated list of hosts to add to an existing Vertica cluster.

`--add-hosts` modifies an existing installation of Vertica by adding a host to the database cluster and then reconfiguring [spread](#). This is useful for improving system performance, or making the database K-safe.

If `spread` is configured in your installation to use [point-to-point](#) communication within the existing cluster, you must also use it when you add a new host; otherwise, the new host automatically uses UDP broadcast traffic, resulting in cluster communication problems that prevent Vertica from running properly. For example:

```
--add-hosts host01
--add-hosts 192.168.233.101
```

You can also use this option with the `update_vertica` script. For details, see [Adding nodes](#).

--broadcast -U

Configures [spread](#) to use UDP broadcast traffic between nodes on the subnet. This is the default setting. Up to 80 spread daemons are supported by broadcast traffic. You can exceed the 80-node limit by using [large cluster](#) mode, which does not install a spread daemon on each node.

Do not combine this option with `--point-to-point`.

Important

When changing the configuration from `--point-to-point` to `--broadcast`, you must also specify `--control-network`.

--clean

Forcibly cleans previously stored configuration files. Use this option if you need to change the hosts that are included in your cluster. Only use this option when no database is defined.

This option is not supported by the `update_vertica` script.

--config-file *file* -z *file*

Use the properties file created earlier with `[--record-config](#record-config)`. This properties file contains key/value settings that map to `install_vertica` option.

--control-network { *IPaddress* | default } -S { *IPaddress* | default }

Set to one of the following arguments:

- *IPaddress*: A broadcast network IP address that enables configuration of spread communications on a subnet different from other Vertica data communications.

- *default*

Important

IPaddress must match the subnet for at least some database nodes. If the address does not match the subnet of any database node, then the installer displays an error and stops. If the provided address matches some, but not all of the node's subnets, the installer displays a warning, but installation continues.

Optimally, the value for `--control-network` matches all node subnets.

You can also use this option to force a cluster-wide spread reconfiguration when changing spread-related options.

--data-dir *directory* -d *directory*

Directory for database data and catalog files. For details, see [Specifying disk storage location during installation](#) and [Managing storage locations](#)

Caution

Do not use a shared directory over more than one host for this setting. Data and catalog directories must be distinct for each node. Multiple nodes must not be allowed to write to the same data or catalog directory.

Default: `/home/dbadmin`

--dba-group *group* -g *group*

UNIX group for DBA users.

Default: `verticadba`

--dba-user-home *directory* -l *directory*

Home directory for the database administrator.

Default: `/home/dbadmin`

--dba-user-password *password* -p *password*

Password for the database administrator account. If omitted, the script prompts for a password and does not echo the input.

--dba-use-password-disabled

Disables the password for `--dba-user`. This argument stops the installer from prompting for a password for `--dba-user`. You can assign a password later using standard user management tools such as `passwd`.

--failure-threshold [*threshold-arg*]

Stops the installation when the specified failure threshold is encountered, where *threshold-arg* is one of the following:

- **HINT** : Stop the install if a HINT or greater issue is encountered during the installation tests. HINT configurations are settings you should make, but the database runs with no significant negative consequences if you omit the setting.
- **WARN** : Stop the installation if a WARN or greater issue is encountered. WARN issues might affect database performance. However, for environments where high-level performance is not a priority—for example, testing—WARN issues can be ignored.
- **FAIL** : Stop the installation if a FAIL or greater issue is encountered. FAIL issues can have severely negative performance consequences and possible later processing issues if not addressed. However, Vertica can start even if FAIL issues are ignored.
- **HALT** : Stop the installation if a HALT or greater issue is encountered. The database might be unable to start if you choose this option. This option is not supported in production environments.
- **NONE** : Do not stop the installation. The database might be unable to start if you choose this option. This option is not supported in production environments.

Default: `WARN`

--ipv4

Hosts in the cluster are identified by IPv4 network addresses. This is the default behavior.

--ipv6

Hosts in the cluster are identified by IPv6 network addresses, required if the `--hosts` list specifies Pv6 addresses. This option automatically enables the `--point-to-point` option.

--large-cluster [*num-control-nodes* | `default`]

Enables the [large cluster](#) feature, where a subset of nodes called [control nodes](#) connect to [spread](#) to send and receive broadcast messages. Consider using this option for a cluster with more than 50 nodes in Enterprise Mode. Vertica automatically enables this feature if you install onto 120 or more nodes in Enterprise Mode, or 16 or more nodes in Eon Mode.

Supply this option with one of the following arguments:

- ***num-control-nodes*** : Sets the number of control nodes in the new database to the smaller of this value or the value of `--hosts`. This value is applied differently in Enterprise Mode and Eon Mode:
 - Enterprise Mode: Sets the number of control nodes in the entire cluster.
 - Eon Mode: Sets the number of control nodes in the initial default subcluster. This value must be between 1 to 120, inclusive.
- **`default`** : Vertica sets the number of control nodes to the square root of the total number of cluster nodes listed in `--hosts` (`-s`).

For details, see [Enable Large Cluster When Installing Vertica](#).

Default: `default`

--license { *license-file* | `CE` } -L { *hostlist* | `CE` }

Silently and automatically deploys the license key to `/opt/vertica/config/share` . On multi-node installations, the `--license` option also applies the license to all nodes declared by `--hosts` . To activate your license, combined this option with `--accept-eula` option. If you do not use the `--accept-eula` option, you are asked to accept the EULA when you connect to your database. After you accept the EULA, your license is activated.

If specified with `CE` , this option automatically deploys the Community Edition license key, which is included in your download.

---no-system-configuration

Installer makes no changes to system properties. By default, the installer makes system configuration changes that meet server requirements.

If you use this option, the installer posts warnings or failures for configuration settings that do not meet requirements that it otherwise configures automatically.

This option has no effect on creating or updating user accounts.

--parallel-no-prompts

Installs the server binary package (`.rpm` or `.deb`) on the hosts in parallel without prompting for confirmation. This option reduces the installation time, especially on large clusters. If omitted, the install script installs the package on one host at a time. .

This option requires that the installer use passwordless ssh to connect to the hosts. It has no effect if the installer is not using passwordless ssh.

--point-to-point -T

Configures spread to use direct point-to-point communication between all Vertica nodes. Use this option if nodes are not located on the same subnet. Also use this option for all virtual environment installations, whether or not virtual servers are on the same subnet.

Up to 80 spread daemons are supported by point-to-point communication. You can exceed the 80-node limit by using [large cluster](#) mode, which does not install a spread daemon on each node.

Do not combine this option with `--broadcast` .

This option is automatically enabled by the `--ipv6` option.

Important

When changing the configuration from `--broadcast` to `--point-to-point` , you must also specify `--control-network` .

--record-config *filename* -B *filename*

File name used with command line options to create a properties file that can be used with `[--config-file](#record-config)` . This option creates the properties file and exits; it does not affect installation.

--remove-hosts *hostlist* -R *hostlist*

Comma-separated list of hosts to remove from an existing Vertica cluster. After removing the specified hosts, spread is reconfigured on the cluster.

This option is useful for removing an obsolete or over-provisioned system.

If you use `--point-to-point` (`-T`) to configure spread to use direct point-to-point communication within the existing cluster, you must also use it when you remove a host; otherwise, the hosts automatically use UDP broadcast traffic, resulting in cluster communication problems that prevents Vertica from running properly.

The `update_vertica` script (see [Removing hosts from a cluster](#)) calls `install_vertica` to update the installation. You can use either script with this option.

--rpm-path *rpm-filepath*

Only used in conjunction with `--no-rpm-copy` , identifies the path to the local copy of the RPM on all nodes specified by `--hosts` .

Default: `/tmp/dbRPM.rpm`

--spread-logging -w

Configures spread to output logging to `/opt/vertica/log/spread_ hostname .log` . This option does not apply to upgrades.

Note

Enable spread logging only if requested by Vertica technical support.

--ssh-identity *file* -i *file*

The root private-key *file* to use if passwordless ssh was already configured between the hosts. Before using this option, verify that normal SSH works without a password . The file can be private key file—for example, `id_rsa` —or PEM file. Do not use with the `--ssh-password` (`-P`) option.

Vertica accepts the following:

- By providing an SSH private key which is not password protected. You cannot run the `install_vertica` script with the `sudo` command when using this method.
- By providing a password-protected private key and using an SSH-Agent. Note that `sudo` typically resets environment variables when it is invoked. Specifically, the `SSH_AUTHSOCK` variable required by the SSH-Agent may be reset. Therefore, configure your system to maintain `SSH_AUTHSOCK` or invoke `install_vertica` using a method similar to the following:

```
sudo SSH_AUTHSOCK=$SSH_AUTHSOCK /opt/vertica/sbin/install_vertica ...
```

`--ssh-password` *password* `-P` *password*

The password to use by default for each cluster host. If you omit this option and also omit `--ssh-identity` (`-i`), then the script prompts for the password as necessary and does not echo input.

Do not use this option together with `--ssh-identity` (`-i`).

Important

If you run the `install_vertica` script as root, specify the root password:

```
# /opt/vertica/sbin/install_vertica -P root-passwd
```

If you run the `install_vertica` script with the `sudo` command, specify the password of the user who runs `install_vertica`, not the root password. For example if the `dbadmin` user runs `install_vertica` with `sudo` and has the password `dbapasswd`, then specify the password as `dbapasswd`:

```
$ sudo /opt/vertica/sbin/install_vertica -P dbapasswd
```

`--temp-dir` *directory*

Temporary directory used for administrative purposes. If it is a directory within `/opt/vertica`, then it is created by the installer. Otherwise, the directory should already exist on all nodes in the cluster. The location should allow `dbadmin` write privileges.

Note

This is not a temporary data location for the database.

Default: `/tmp`

Install Vertica silently

This section describes how to create a properties file that lets you install and deploy Vertica-based applications quickly and without much manual intervention.

Note

The procedure assumes that you have already performed the tasks in [Before you install Vertica](#).

Install the properties file:

1. Download and install the Vertica install package, as described in [Download and install the Vertica server package](#).
2. Create the properties file that enables non-interactive setup by supplying the parameters you want Vertica to use. For example:

The following command assumes a multi-node setup:

```
# /opt/vertica/sbin/install_vertica --record-config file_name --license /tmp/license.txt --accept-eula \  
# --dba-user-password password --ssh-password password --hosts host_list --rpm package_name
```

The following command assumes a single-node setup:

```
# /opt/vertica/sbin/install_vertica --record-config file_name --license /tmp/license.txt --accept-eula \  
# --dba-user-password password
```

Option	Description
--------	-------------

<code>--record-file</code> <i>file_name</i>	[Required] Accepts a file name, which when used in conjunction with command line options, creates a properties file that can be used with the <code>--config-file</code> option during setup. This flag creates the properties file and exits; it has no impact on installation.
<code>--license {</code> <i>license_file</i> CE }	Silently and automatically deploys the license key to <code>/opt/vertica/config/share</code> . On multi-node installations, the <code>--license</code> option also applies the license to all nodes declared in the <code>--hosts host_list</code> . If specified with CE, automatically deploys the Community Edition license key, which is included in your download. You do not need to specify a license file.
<code>--accept-eula</code>	Silently accepts the EULA agreement during setup.
<code>--dba-user-</code> <code>password</code> <i>password</i>	The password for the Database Superuser account; if not supplied, the script prompts for the password and does not echo the input.
<code>--ssh-password</code> <i>password</i>	The root password to use by default for each cluster host; if not supplied, the script prompts for the password if and when necessary and does not echo the input.
<code>--hosts</code> <i>host_list</i>	A comma-separated list of hostnames or IP addresses to include in the cluster; do not include space characters in the list. Examples: <pre>--hosts host01,host02,host03 --hosts 192.168.233.101,192.168.233.102,192.168.233.103</pre>
<code>--rpm</code> <i>package_name</i> -- deb <i>package_name</i>	The name of the RPM or Debian package that contained this script. For example: <pre>--rpm vertica-version.RHEL8.x86_64.rpm</pre> This parameter is required on multi-node installations if the RPM or DEB package is not already installed on the other hosts.

See [install_vertica options](#) for the complete set of installation parameters.

Tip

Supply the parameters to the properties file once only. You can then install Vertica using just the `--config-file` parameter, as described below.

- Use one of the following commands to run the installation script.

- If you are root:

```
/opt/vertica/sbin/install_vertica --config-file file_name
```

- If you are using sudo:

```
$ sudo /opt/vertica/sbin/install_vertica --config-file file_name
```

`--config-file file_name` accepts an existing properties file created by `--record-config file_name`. This properties file contains key/value parameters that map to values in the `install_vertica` script, many with boolean arguments that default to false

The command for a single-node install might look like this:

```
# /opt/vertica/sbin/install_vertica --config-file /tmp/vertica-inst.prp
```

- If you did not supply a `--ssh-password` password parameter to the properties file, you are prompted to provide the requested password to allow installation of the RPM/DEB and system configuration of the other cluster nodes. If you are root, this is the root password. If you are using sudo, this is the sudo user password. The password does not echo on the command line.

Note

If you are root on a single-node installation, you are not prompted for a password.

- If you did not supply a `--dba-user-password` password parameter to the properties file, you are prompted to provide the database administrator account password.
The installation script creates a new Linux user account (dbadmin by default) with the password that you provide.
- Carefully examine any warnings produced by `install_vertica` and correct the problems if possible. For example, insufficient RAM, insufficient Network throughput and too high readahead settings on file system could cause performance problems later on.

Note

You can redirect any warning outputs to a separate file, instead of having them display on the system. Use your platforms standard redirected mechanisms. For example: `install_vertica [options] > /tmp/file 1>&2`.

- Optionally** perform the following steps:
 - [Install the ODBC and JDBC driver](#).
 - [Install vsql Client Application on Non-Cluster Hosts](#).
- Disconnect from the Administration Host as instructed by the script. This is required to:
 - Set certain system parameters correctly.
 - Function as the Vertica database administrator.

At this point, Linux root privileges are no longer needed. The database administrator can perform the remaining steps.

Note

When creating a new database, the database administrator might want to use different data or catalog locations than those created by the installation script. In that case, a Linux administrator might need to create those directories and change their ownership to the database administrator.

If you supplied the `--license` and `--accept-eula` parameters to the properties file, then proceed to [Getting started](#) and then see [Configuring the database](#).

Otherwise:

- Log in to the [Database Superuser](#) account on the administration host.
- Accept the End User License Agreement and install the license key you downloaded previously as described in [Install the License Key](#).
- Proceed to [Getting started](#) and then see [Configuring the database](#).

Notes

- Downgrade installations are not supported.
- The following is an example of the contents of the configuration properties file:

```
accept_eula = True
license_file = /tmp/license.txt
record_to = file_name
root_password = password
vertica_dba_group = verticadba
vertica_dba_user = dbadmin
vertica_dba_user_password = password
```

Enable secure shell (SSH) logins

The administrative account must be able to use Secure Shell (SSH) to log in (ssh) to all hosts without specifying a password. The shell script `install_vertica` does this automatically. This section describes how to do it manually if necessary.

- If you do not already have SSH installed on all hosts, log in as root on each host and install it now. You can download a free version of the SSH connectivity tools from [OpenSSH](#).
- Log in to the Vertica administrator account (dbadmin in this example).
- Make your home directory (~) writable only by yourself. Choose one of:

```
$ chmod 700 ~
```

or

```
$ chmod 755 ~
```

where:

700 includes	755 includes
400 read by owner	400 read by owner
200 write by owner	200 write by owner
100 execute by owner	100 execute by owner
	040 read by group
	010 execute by group
	004 read by anybody (other)
	001 execute by anybody

4. Change to your home directory:

```
$ cd ~
```

5. Generate a private key/ public key pair:

```
$ ssh-keygen -t rsa
Generating public/private rsa key pair.
Enter file in which to save the key (/home/dbadmin/.ssh/id_rsa):
Created directory '/home/dbadmin/.ssh'.
Enter passphrase (empty for no passphrase):
Enter same passphrase again:
Your identification has been saved in /home/dbadmin/.ssh/id_rsa.
Your public key has been saved in /home/dbadmin/.ssh/id_rsa.pub.
```

6. Make your .ssh directory readable and writable only by yourself:

```
$ chmod 700 ~/.ssh
```

7. Change to the .ssh directory:

```
$ cd ~/.ssh
```

8. Copy the file `id_rsa.pub` onto the file `authorized_keys2`.

```
$ cp id_rsa.pub authorized_keys2
```

9. Make the files in your .ssh directory readable and writable only by yourself:

```
$ chmod 600 ~/.ssh/*
```

10. For each cluster host:

```
$ scp -r ~/.ssh <host>.
```

11. Connect to each cluster host. The first time you ssh to a new remote machine, you could get a message similar to the following:

```
$ ssh dev0 Warning: Permanently added 'dev0,192.168.1.92' (RSA) to the list of known hosts.
```

This message appears only the first time you ssh to a particular remote host.

- [OpenSSH](#)

After you install Vertica

The tasks described in this section are optional and are provided for your convenience. When you have completed this section, proceed to one of the following:

- [Getting started](#)
- [Configuring the database](#)

Install client drivers

After you install Vertica, install drivers on the client systems from which you plan to access your databases. Vertica supplies drivers for ADO.NET, JDBC, ODBC, OLE DB, Perl, and Python. For instructions on installing these drivers, see [Client drivers](#).

Install the license key

If you did not supply the `-L` parameter during setup, or if you did not bypass the `-L` parameter for a [silent install](#), the first time you log in as the [Database Superuser](#) and run the Vertica [Administration tools](#) or Management Console, Vertica requires you to install a license key.

Follow the instructions in [Managing licenses](#) in the Administrator's Guide.

Create a database

To get started using Vertica immediately after installation, create a database. You can use either the Administration Tools or the Management Console. To create a database using MC, refer to [Creating a database using MC](#). For instructions on creating a database with admintools, see [Creating a database](#).

Install vsql client application on non-cluster hosts

You can use the Vertica vsql executable image on a non-cluster Linux host to connect to a Vertica database.

- On Red Hat, CentOS, and SUSE systems, you can install the client driver RPM, which includes the vsql executable. See [Installing the vsql client](#) for details.
- If the non-cluster host is running the same version of Linux as the cluster, copy the image file to the remote system. For example:

```
$ scp host01:/opt/vertica/bin/vsql .$.vsql
```

- If the non-cluster host is running a different distribution or version of Linux than your cluster hosts, you must install the Vertica server RPM in order to get vsql:
 1. Download the appropriate RPM package by browsing to [Vertica website](#). On the **Support** tab, select **Customer Downloads**.
 2. If the system you used to download the RPM is not the non-cluster host, transfer the file to the non-cluster host.
 3. Log into the non-cluster host as root and install the RPM package using the command:

```
# rpm -Uvh filename
```

Where *filename* is the package you downloaded. Note that you do not have to run the `install_vertica` script on the non-cluster host to use vsql.

Notes

- Use the same [Command-line options](#) that you would on a cluster host.
- You cannot run vsql on a Cygwin bash shell (Windows). Use ssh to connect to a cluster host, then run vsql.

vsql is also available for additional platforms. See [Installing the vsql client](#).

Upgrading Vertica

Upgrading your database with a new Vertica version includes the following steps:

1. [Complete upgrade prerequisites](#)
2. [Upgrade Vertica](#)
3. [Perform post-upgrade tasks](#)

You can upgrade your database from its current Vertica version to any higher version. Before upgrading, make sure that you have performed a [full database backup](#) and have tested the new version in an environment that closely resembles your production database.

Tip

If you want to test out a new version of Vertica for an Eon Mode database without spinning up a new cluster, you can [sandbox a secondary subcluster](#) and then upgrade the subcluster within the sandbox. By sandboxing the subcluster, you can try out the new version of Vertica stress-free and continue to use your main cluster as usual. After confirming that the upgrade works and performs as expected, you can downgrade the sandboxed subcluster, [remove the sandbox](#), and proceed to upgrade the main cluster.

Be sure to read the Release Notes and New Features for the Vertica version to which you intend to upgrade. Documentation and release notes for the current Vertica version are available in the RPM and at <https://docs.vertica.com/latest>, which also provides access to documentation for earlier versions.

For guidance on upgrading from unsupported versions, contact [Vertica Technical Support](#).

In this section

- [Before you upgrade](#)
- [Upgrade Vertica](#)
- [After you upgrade](#)

Before you upgrade

Before you upgrade the Vertica database, perform the following steps:

- Verify that you have enough RAM available to run the upgrade. The upgrade requires approximately three times the amount of memory your database catalog uses.

You can calculate catalog memory usage on all nodes by querying system table [RESOURCE_POOL_STATUS](#) :

```
=> SELECT node_name, pool_name, memory_size_kb FROM resource_pool_status WHERE pool_name = 'metadata';
```

- [Perform a full database backup](#). This precautionary measure allows you to restore the current version if the upgrade is unsuccessful.
- [Perform a backup of your grants](#).
- [Verify platform requirements](#) for the new version.
- Determine whether you are using any third-party user-defined extension libraries (UDxs). UDx libraries that are compiled (such as those developed using C++ or Java) may need to be recompiled with a new version of the Vertica SDK libraries to be compatible with the new version of Vertica. See [UDx library compatibility with new server versions](#).
- [Check catalog storage space](#).
- Note that any user or role with the same name as a [predefined role](#) is renamed to `OLD_n_name`, where *n* is an integer that increments from zero until the resulting name is unique and *name* is the previous name of the user or role.
- If you're upgrading from Vertica 9.2.x and have set the `PasswordMinCharChange` or `PasswordMinLifeTime` system-level [security parameters](#), take note of their current values. You will have to set these parameters again, this time at the PROFILE-level, to reproduce your configuration. To view the current values for these parameters, run the following query:

```
=> SELECT parameter_name,current_value from CONFIGURATION_PARAMETERS  
WHERE parameter_name IN ('PasswordMinCharChange', 'PasswordMinLifeTime');
```

After you complete these tasks, [shut down the database gracefully](#).

In this section

- [Verifying platform requirements](#)
- [Checking catalog storage space](#)
- [Verify license compliance for ORC and Parquet data](#)
- [Backing up and restoring grants](#)
- [Nonsequential FIPS database upgrades](#)

Verifying platform requirements

The Vertica installer checks the target platform as it runs, and stops whenever it determines the platform fails to meet an installation requirement. Before you update the server package on your systems, manually verify that your platform meets all hardware and software requirements (see [Platform and hardware requirements and recommendations](#)).

By default, the installer stops on all warnings. You can configure the level where the installer stops installation, through the installation parameter `--failure-threshold`. If you set the failure threshold to `FAIL`, the installer ignores warnings and stops only on failures.

Caution

Changing the failure threshold lets you immediately upgrade and bring up the Vertica database. However, Vertica cannot fully optimize performance until you correct all warnings.

Checking catalog storage space

Use the commands documented here to determine how much catalog space is available before upgrading. This helps you determine how much space the updated catalog may take up.

Compare how much space the catalog currently uses against space that is available in the same directory:

1. Use the `du` command to determine how much space the catalog directory currently uses:

```
$ du -s -BG v_vmart_node0001_catalog  
2G   v_vmart_node0001_catalog
```

2. Determine how much space is available in the same directory:

```
$ df -BG v_vmart_node0001_catalog  
Filesystem 1G-blocks Used Available Use% Mounted on  
/dev/sda2  48G 19G   26G 43% /
```

Verify license compliance for ORC and Parquet data

If you are upgrading from a version before 9.1.0 and:

- Your database has external tables based on ORC or Parquet files (whether stored locally on the Vertica cluster or on a Hadoop cluster)
- Your Vertica license has a raw data allowance

follow the steps in this topic before upgrading.

Background

Vertica licenses can include a raw data allowance. Since 2016, Vertica licenses have allowed you to use ORC and Parquet data in external tables. This data has always counted against any raw data allowance in your license. Previously, the audit of data in ORC and Parquet format was handled manually. Because this audit was not automated, the total amount of data in your native tables and external tables could exceed your licensed allowance for some time before being spotted.

Starting in version 9.1.0, Vertica automatically audits ORC and Parquet data in external tables. This auditing begins soon after you install or upgrade to version 9.1.0. If your Vertica license includes a raw data allowance and you have data in external tables based on Parquet or ORC files, review your license compliance before upgrading to Vertica 9.1.x. Verifying your database is compliant with your license terms avoids having your database become non-compliant soon after you upgrade.

Verifying your ORC and Parquet usage complies with your license terms

To verify your data usage is compliant with your license, run the following query as the database administrator:

```
SELECT (database_size_bytes + file_size_bytes) <= license_size_bytes
"license_compliant?"
FROM (SELECT database_size_bytes,
            license_size_bytes FROM license_audits
        WHERE audited_data='Total'
        ORDER BY audit_end_timestamp DESC LIMIT 1) dbs,
(SELECT sum(total_file_size_bytes) file_size_bytes
 FROM external_table_details
 WHERE source_format IN ('ORC', 'PARQUET')) ets;
```

This query returns one of three values:

- If you do not have any external data in ORC or Parquet format, the query returns 0 rows:

```
license_compliant?
-----
(0 rows)
```

In this case, you can proceed with your upgrade.

- If you have data in external tables based on ORC or Parquet format, and that data does not cause your database to exceed your raw data allowance, the query returns t:

```
license_compliant?
-----
t
(1 row)
```

In this case, you can proceed with your upgrade.

- If the data in your external tables based on ORC and Parquet causes your database to exceed your raw data allowance, the query returns f:

```
license_compliant?
-----
f
(1 row)
```

In this case, resolve the compliance issue before you upgrade. See below for more information.

Resolving non-compliance

If query in the previous section indicates that your database is not in compliance with your license, you should resolve this issue before upgrading. There are two ways you can bring your database into compliance:

- Contact Vertica to upgrade your license to a larger data size allowance. See [Obtaining a license key file](#).

- Delete data (either from ORC and Parquet-based external tables or Vertica native tables) to bring your data size into compliance with your license. You should always backup any data you are about to delete from Vertica. Dropping external tables is a less disruptive way to reduce the size of your database, as the data is not lost—it is still in the files that your external table is based on.

Note

You can still choose to upgrade your database if it is not compliant. However, soon after you upgrade, you will begin getting warnings that your database is out of compliance. See [Managing license warnings and limits](#) for more information.

Backing up and restoring grants

After an upgrade, if the prototypes of UDX libraries change, Vertica will drop the grants on those libraries since they aren't technically the same function anymore. To resolve these types of issues, it's best practice to back up the grants on these libraries so you can restore them after the upgrade.

1. Save the following SQL to a file named `user_ddl.sql`. It creates a view named `user_ddl` which contains the grants on all objects in the database.

```
CREATE OR REPLACE VIEW user_ddl AS
(
SELECT 0 as grant_order,
      name principal_name,
      'CREATE ROLE "' || name || '" AS sql,
      'NONE' AS object_type,
      'NONE' AS object_name
FROM v_internal.vs_roles vr
WHERE NOT vr.predefined_role -- Exclude system roles
      AND ldapdn = '' -- Limit to NON-LDAP created roles
)
UNION ALL
(
SELECT 1, -- CREATE USERS
      user_name,
      'CREATE USER "' || user_name || '"
      DECODE(is_locked, TRUE, ' ACCOUNT LOCK', '') ||
      DECODE(grace_period, 'undefined', '', ' GRACEPERIOD "' || grace_period || '"') ||
      DECODE(idle_session_timeout, 'unlimited', '', ' IDLESESSIONTIMEOUT "' || idle_session_timeout || '"') ||
      DECODE(max_connections, 'unlimited', '', ' MAXCONNECTIONS ' || max_connections || ' ON ' || connection_limit_mode) ||
      DECODE(memory_cap_kb, 'unlimited', '', ' MEMORYCAP "' || memory_cap_kb || 'K') ||
      DECODE(profile_name, 'default', '', ' PROFILE ' || profile_name) ||
      DECODE(resource_pool, 'general', '', ' RESOURCE POOL ' || resource_pool) ||
      DECODE(run_time_cap, 'unlimited', '', ' RUNTIMECAP "' || run_time_cap || '"') ||
      DECODE(search_path, '', ' SEARCH_PATH ' || search_path) ||
      DECODE(temp_space_cap_kb, 'unlimited', '', ' TEMPSPACECAP "' || temp_space_cap_kb || 'K') || ';' AS sql,
      'NONE' AS object_type,
      'NONE' AS object_name
FROM v_catalog.users
WHERE NOT is_super_user -- Exclude database superuser
      AND ldap_dn = '' -- Limit to NON-LDAP created users
)
UNION ALL
(
SELECT 2, -- GRANTS
      grantee,
      'GRANT ' || REPLACE(TRIM(BOTH ' ' FROM words), '**', '') ||
      CASE
        WHEN object_type = 'RESOURCEPOOL' THEN ' ON RESOURCE POOL '
        WHEN object_type = 'STORAGELOCATION' THEN ' ON LOCATION '
        WHEN object_type = 'CLIENTAUTHENTICATION' THEN ' AUTHENTICATION '
        WHEN object_type IN ('DATABASE', 'LIBRARY', 'MODEL', 'SEQUENCE', 'SCHEMA') THEN ' ON ' || object_type || ' '
        WHEN object_type = 'PROCEDURE' THEN (SELECT ' ON ' || CASE REPLACE(procedure_type, 'User Defined', '')
          WHEN 'Transform' THEN ' TRANSFORM FUNCTION '
          WHEN 'Aggregate' THEN ' AGGREGATE FUNCTION '

```

```

                WHEN Aggregate THEN AGGREGATE FUNCTION
                WHEN 'Analytic' THEN 'ANALYTIC FUNCTION '
                ELSE UPPER(REPLACE(procedure_type, 'User Defined ', '')) || ''
            END
        FROM vs_procedures
        WHERE proc_oid = object_id)
    WHEN object_type = 'ROLE' THEN "
    ELSE ' ON '
END ||
    NVL2(object_schema, object_schema || '.', '') || CASE WHEN object_type = 'STORAGELOCATION' THEN (SELECT "" || location_path || "" ON ' ||
node_name FROM storage_locations WHERE location_id = object_id) ELSE object_name END ||
CASE
    WHEN object_type = 'PROCEDURE' THEN (SELECT CASE WHEN procedure_argument_types = " OR procedure_argument_types = 'Any' THEN
'()' ELSE '(' || procedure_argument_types || ')' END
        FROM vs_procedures
        WHERE proc_oid = object_id)
    ELSE "
END ||
' TO ' || grantee ||
CASE WHEN INSTR(words, '**') > 0 THEN ' WITH GRANT OPTION' ELSE " END
|| ';',
object_type,
object_name
FROM (SELECT grantee, object_type, object_schema, object_name, object_id,
    v_txtindex.StringTokenizerDelim(DECODE(privileges_description, ',', ', ', privileges_description), ',')
    OVER (PARTITION BY grantee, object_type, object_schema, object_name, object_id)
    FROM v_catalog.grants) foo
ORDER BY CASE REPLACE(TRIM(BOTH '' FROM words), '**', '') WHEN 'USAGE' THEN 1 ELSE 2 END
)
UNION ALL
(
SELECT 3, -- Default ROLES
    user_name,
    'ALTER USER "" || user_name || "" ||
    DECODE(default_roles, ", ", ', ' DEFAULT ROLE ' || REPLACE(default_roles, '**', '')) || ';',
    'NONE' AS object_type,
    'NONE' AS object_name
FROM v_catalog.users
WHERE default_roles <> "
)
UNION ALL -- GRANTS WITH ADMIN OPTION
(
SELECT 4, user_name, 'GRANT ' || REPLACE(TRIM(BOTH '' FROM words), '**', '') || ' TO ' || user_name || ' WITH ADMIN OPTION;',
    'NONE' AS object_type ,
    'NONE' AS object_name
FROM (SELECT user_name, v_txtindex.StringTokenizerDelim(DECODE(all_roles, ", ', ', all_roles), ',') OVER (PARTITION BY user_name)
    FROM v_catalog.users
    WHERE all_roles <> ") foo
WHERE INSTR(words, '**') > 0
)
UNION ALL
(
SELECT 5, 'public', 'ALTER SCHEMA ' || name || ' DEFAULT ' || CASE WHEN defaultinheritprivileges THEN 'INCLUDE PRIVILEGES;' ELSE 'EXCLUDE
PRIVILEGES;' END, 'SCHEMA', name
FROM v_internal.vs_schemata
WHERE NOT issys -- Exclude system schemas
)
UNION ALL
(
SELECT 6, 'public', 'ALTER DATABASE ' || database_name || ' SET disableinheritedprivileges = ' || current_value || ';',
    'DATABASE', database_name
FROM v_internal.vs_configuration_parameters

```

```

FROM v_internal.vs_configuration_parameters
CROSS JOIN v_catalog.databases
WHERE parameter_name = 'DisableInheritedPrivileges'
)
UNION ALL -- TABLE PRIV INHERITENCE
(
SELECT 7, 'public', 'ALTER TABLE ' || table_schema || '.' || table_name ||
CASE WHEN inheritprivileges THEN ' INCLUDE PRIVILEGES;' ELSE ' EXCLUDE PRIVILEGES;' END,
'TABLE' AS object_type,
table_schema || '.' || table_name AS object_name
FROM v_internal.vs_tables
JOIN v_catalog.tables ON (table_id = oid)
)
UNION ALL -- VIEW PRIV INHERITENCE
(
SELECT 8, 'public', 'ALTER VIEW ' || table_schema || '.' || table_name || CASE WHEN inherit_privileges THEN ' INCLUDE PRIVILEGES;' ELSE '
EXCLUDE PRIVILEGES;' END,
'TABLE' AS object_type, table_schema || '.' || table_name AS object_name
FROM v_catalog.views
)
UNION ALL
(
SELECT 9, owner_name, 'ALTER TABLE ' || table_schema || '.' || table_name || ' OWNER TO ' || owner_name || ';',
'TABLE', table_schema || '.' || table_name
FROM v_catalog.tables
)
UNION ALL
(
SELECT 10, owner_name, 'ALTER VIEW ' || table_schema || '.' || table_name || ' OWNER TO ' || owner_name || ';', 'TABLE',
table_schema || '.' || table_name
FROM v_catalog.views
);

```

- From the Linux command line, run the script in the [user_ddl.sql](#) file:

```

$ vsql -f user_ddl.sql
CREATE VIEW

```

- Connect to Vertica using vsql.
- Export the content of the user_ddl's sql column ordered on the grant_order column to a file:

```

=> \o pre-upgrade.txt
=> SELECT sql FROM user_ddl ORDER BY grant_order ASC;
=> \o

```

- [Upgrade Vertica](#).
- Select and save to a different file the view's SQL column with the same command.

```

=> \o post-upgrade.txt
=> SELECT sql FROM user_ddl ORDER BY grant_order ASC;
=> \o

```

- Create a diff between [pre-upgrade.txt](#) and [post-upgrade.txt](#) . This collects the missing grants into [grants-list.txt](#) .

```

$ diff pre-upgrade.txt post-upgrade.txt > grants-list.txt

```

- To restore any missing grants, run the remaining grants in [grants-list.txt](#) , if any:

```

=> \i 'grants-list.txt'

```

Note

Attempting to restore grants to users with the ANY keyword triggers the following error:

```

ERROR 4856: Syntax error at or near "Any" at character

```

To avoid this error, use () instead of (ANY) as shown in the following example:

```
=> GRANT EXECUTE ON FUNCTION public.MapLookup() TO public;  
GRANT PRIVILEGE
```

Nonsequential FIPS database upgrades

As of Vertica 10.1.1, FIPS support has been reinstated. Prior to this, the last version to support FIPS was Vertica 9.2.x. If you are upgrading from 9.2.x and want to maintain your FIPS certification, you must first perform a direct upgrade from 9.2.x to 10.1.1 before performing further upgrades.

The following procedure performs a direct upgrade from Vertica 9.2.x running on RHEL 6.x to Vertica 10.1.1 on RHEL 8.1.

Important

If you have any questions or want additional guidance for performing this upgrade, contact [Vertica Support](#).

1. [Create a full backup](#) of your Vertica 9.2.x database. This example uses the configuration file [fullRestore.ini](#).

```
$ vbr --config-file=/tmp/fullRestore.ini -t init  
$ vbr --config-file=/tmp/fullRestore.ini -t backup
```

```
[Transmission]  
concurrency_backup = 1  
port_rsync = 50000  
encrypt = False  
serviceAccessPass = rsyncpw  
hardLinkLocal = False  
checksum = False  
total_bwlimit_restore = 0  
serviceAccessUser = rsyncuser  
total_bwlimit_backup = 0  
concurrency_restore = 1
```

```
[Misc]  
snapshotName = full_restore  
restorePointLimit = 1  
retryDelay = 1  
objects =  
retryCount = 0  
tempDir = /tmp/vbr
```

```
[Mapping]  
v_fips_db_node0001 = 198.51.100.0:/home/release/backup/  
v_fips_db_node0002 = 198.51.100.1:/home/release/backup/  
v_fips_db_node0003 = 198.51.100.2:/home/release/backup/
```

```
[Database]  
dbPort = 5433  
dbPromptForPassword = False  
dbUser =  
dbPassword =  
dbName = fips_db
```

2. [Shut down the database gracefully](#). Do not start the database until instructed.
3. Acquire a RHEL 8.1 cluster with one of the following methods:
 1. Upgrade in place
 2. Reimage your machines
 3. Use a completely different RHEL 8.1 cluster
4. Enable FIPS on your RHEL 8.1 machines and reboot.

```
$ fips-mode-setup --enable
```

5. Install Vertica 10.1.1 on the RHEL 8.1 cluster.

```
$ install_vertica --hosts node0001, node0002, node0003 \  
--rpm /tmp/vertica-10.1.1.x86_64.RHEL8.rpm
```

6. If you acquired your RHEL 8.1 cluster by reimaging or using a different cluster, you must [restore your database](#).

```
$ vbr -c /tmp/fullRestore.ini -t restore
```

If you encounter the following warning, you can safely ignore it.

```
Warning: Vertica versions do not match: v9.2.1-xx -> v10.1.1-xxxxxxx. This operation may not be supported.
```

7. Start the Vertica 10.1.1 database to trigger the upgrade. This should be the first time you've started your database since shutting it down in step 2.

```
$ admintools -t start_db -d fips_db
```

Upgrade Vertica

Important

Before running the upgrade script, be sure to review the tasks described in [Before you upgrade](#).

To upgrade your database to a new Vertica version, complete the following steps:

1. Perform a [full backup](#) of your existing database. This precautionary measure lets you restore from the backup, if the upgrade is unsuccessful. If the upgrade fails, you can reinstall the previous version of Vertica and [restore your database](#) to that version.
2. Use admintools to [stop the database](#).
3. On each host where an additional package is installed, such as the [R language pack](#), uninstall it. For example:

```
rpm -e vertica-R-lang
```

Important

If you omit this step and do not uninstall additional packages, the Vertica server package fails to install in the next step.

4. Make sure you are logged in as root or sudo and use one of the following commands to run the RPM package installer:

- If you are root and installing an RPM:

```
# rpm -Uvh pathname
```

- If you are using sudo and installing an RPM:

```
$ sudo rpm -Uvh pathname
```

- If you are using Debian:

```
$ sudo dpkg -i pathname
```

5. On the same node on which you just installed the RPM, run [update_vertica](#) as root or sudo. This installs the RPM on all the hosts in the cluster. For example:

- Red Hat or CentOS:

```
# /opt/vertica/sbin/update_vertica --rpm /home/dbadmin/vertica-version.RHEL8.x86_64.rpm --dba-user mydba
```

- Debian:

```
# /opt/vertica/sbin/update_vertica --deb /home/dbadmin/vertica-version_amd64.deb --dba-user mydba
```

Note

You can upgrade the Vertica server running on AWS instances created from a Vertica AMI. To upgrade the Vertica server on these AWS instances, you need to add the `--dba-user-password-disabled` and `--point-to-point` arguments to the upgrade script.

The following requirements and restrictions apply:

- The DBADMIN user must be able to read the RPM or DEB file when upgrading. Some upgrade scripts are run as the DBADMIN user, and that user must be able to read the RPM or DEB file.
- Use the same options that you used when you last installed or upgraded the database. You can find these options in `/opt/vertica/config/admintools.conf`, on the `install_opts` line. For details on all options, see [Install Vertica with the installation script](#).

Caution

If you omit any previous options, their default settings are restored. If you do so, or if you change any options, the upgrade script uses the new settings to reconfigure the cluster. This can cause issues with the upgraded database.

- Omit the `--hosts/-s host-list` parameter. The upgrade script automatically identifies cluster hosts.
 - If the root user is not in `/etc/sudoers`, an error appears. The installer reports this issue with **S0311**. See the [Sudoers Manual](#) for more information.
6. [Start the database](#). The start-up scripts analyze the database and perform necessary data and catalog updates for the new version. If Vertica issues a warning stating that one or more packages cannot be installed, run the `admintools --force-reinstall` option to force reinstallation of the packages. For details, see [Reinstalling packages](#).
When the upgrade completes, the database automatically restarts.

Note

Any user or role with the same name as a [predefined role](#) is renamed to `OLD_n_name`, where *n* is an integer that increments from zero until the resulting name is unique and *name* is the previous name of the user or role.

7. Manually restart any nodes that fail to start.
8. Perform another database backup.

Upgrade duration

Duration depends on average in-memory size of catalogs across all cluster nodes. For every 20GB, you can expect the upgrade to last between one and two hours.

You can calculate catalog memory usage on all nodes by querying system table [RESOURCE_POOL_STATUS](#):

```
=> SELECT node_name, pool_name, memory_size_kb FROM resource_pool_status WHERE pool_name = 'metadata';
```

Post-upgrade tasks

After you complete the upgrade, review post-upgrade tasks in [After you upgrade](#).

After you upgrade

After you finish upgrading the Vertica server package on your cluster, a number of tasks remain.

Required tasks

- If you created projections in earlier releases with [pre-aggregated data](#) (for example, LAPs and TopK projections) and the projections were partitioned with a GROUP BY clause, you must [rebuild these projections](#).
- Verify on each node that the upgrade [reduced database catalog memory usage](#).
- Verify your database retained the grants from before you upgraded. See [Backing up and restoring grants](#) for more information.
- [Reinstall packages](#) such as the R language pack that you uninstalled before upgrading. For each package, see its install/upgrade instructions.

Note

Vertica Place is automatically reinstalled with the Vertica server package.

- If the upgrade was unable to install one or more packages, [reinstall them with admintools](#).
- [Upgrade the Management Console](#).
- If your Vertica installation is integrated with Hadoop, [upgrade the HCatalog connector](#).

Optional tasks

- Import directed queries that you exported from the previous version. For details, see [Batch query plan export](#) and [Managing directed queries](#).
- If you're upgrading from Vertica 9.2.x and have set the `PasswordMinCharChange` or `PasswordMinLifeTime` system-level [security parameters](#), set them again at the [PROFILE-level](#).

In this section

- [Rebuilding partitioned projections with pre-aggregated data](#)
- [Verifying catalog memory consumption](#)
- [Reinstalling packages](#)
- [Writing bundle metadata to the catalog](#)
- [Upgrading the streaming data scheduler utility](#)

Rebuilding partitioned projections with pre-aggregated data

If you created projections in earlier (pre-10.0.x) releases with [pre-aggregated data](#) (for example, LAPs and TopK projections) and the anchor tables were partitioned with a GROUP BY clause, their ROS containers are liable to be corrupted from various DML and ILM operations. In this case, you must rebuild the projections:

1. Run the meta-function [REFRESH](#) on the database. If REFRESH detects problematic projections, it returns with failure messages. For example:

```
=> SELECT REFRESH();
```

```
REFRESH
```

```
-----  
Refresh completed with the following outcomes:
```

```
Projection Name: [Anchor Table] [Status] [ Refresh Method] [Error Count]
```

```
"public"."store_sales_udt_sum": [store_sales] [failed: Drop and recreate projection] [] [1]
```

```
"public"."product_sales_largest": [store_sales] [failed: Drop and recreate projection] [] [1]
```

```
"public"."store_sales_recent": [store_sales] [failed: Drop and recreate projection] [] [1]
```

```
(1 row)
```

Vertica also logs messages to [vertica.log](#) :

```
2020-07-07 11:28:41.618 Init Session:ox7fabbbfff700-ao000000oosbs [Txnl <INFO> Be in Txn: aooooo00005b5 'Refresh: Evaluating which projection to refresh'
```

```
2020-07-07 11:28:41.640 Init Session:ex7fabbbfff70e-ao000000oosbs [Refresh] <INFO> Storage issues detected, unable to refresh projection 'store_sales_recent'. Drop and recreate this projection, then refresh.
```

```
2020-07-07 11:28:41.641 Init Session:Ox7fabbbfff700-ao000000oosbs [Refresh] <INFO> Storage issues detected, unable to refresh projection 'product_sales_largest'. Drop and recreate this projection, then refresh.
```

```
2020-07-07 11:28:41.641 Init Session:Ox7fabbbfff700-ae000000oosbs [Refresh] <INFO> Storage issues detected, unable to refresh projection 'store_sales_udt_sum'. Drop and recreate this projection, then refresh.
```

2. Export the DDL of these projections with [EXPORT_OBJECTS](#) or [EXPORT_TABLES](#).
3. [Drop](#) the projections, then recreate them as defined in the exported DDL.
4. Run REFRESH. Vertica rebuilds the projections with new storage containers.

Verifying catalog memory consumption

Vertica versions ≥ 9.2 significantly reduce how much memory database catalogs consume. After you upgrade, check catalog memory consumption on each node to verify that the upgrade refactored catalogs correctly. If memory consumption for a given catalog is as large as or larger than it was in the earlier database, restart the host node.

Known issues

Certain operations might significantly inflate catalog memory consumption. For example:

- You created a backup on a 9.1.1 database and restored objects from the backup to a new database of version ≥ 9.2 .
- You [replicated objects](#) from a 9.1.1 database to a database of version ≥ 9.2 .

To refactor database catalogs and reduce their memory footprint, restart the database.

Reinstalling packages

In most cases, Vertica automatically reinstalls all default packages when you restart your database for the first time after running the upgrade script. Occasionally, however, one or more packages might fail to reinstall correctly.

To verify that Vertica succeeded in reinstalling all packages:

1. Restart the database after upgrading.
2. Enter a correct password.

If any packages failed to reinstall, Vertica issues a message that specifies the uninstalled packages. You can manually reinstall the packages with [admintools](#) or the [HTTPS service](#):

- To reinstall with admintools, run the `install_package` command with the option `--force-reinstall` :

```
admintools -t install_package -d db-name -p password -P pkg-spec --force-reinstall
```

- To reinstall with the HTTPS service, make a POST request to the `/v1/packages` endpoint on any node in the cluster:

Important

Only the [dbadmin](#) can access the HTTPS service.

```
$ curl -X POST -k -w "%n" --user dbadmin:password "https://ip-address:8443/v1/packages?force-install=true"
```

The **-w** flag prints information to the console after the command succeeds.

admintools options

Option	Function
-d <i>db-name</i> --dbname= * <i>db-name</i>	Database name
-p <i>password</i> --password= <i>password</i>	Database administrator password
-P <i>pkg</i> --package= <i>pkg-spec</i>	Specifies which packages to install, where <i>pkg</i> is one of the following: <ul style="list-style-type: none">• The name of a package—for example, flextable• all : All available packages• default : All default packages that are currently installed
--force-reinstall	Force installation of a package even if it is already installed.

Examples

Force reinstallation of default packages:

```
$ admintools -t install_package -d VMart -p 'password' -P default --force-reinstall
```

Force reinstallation of one package, **flextable** :

```
$ admintools -t install_package -d VMart -p 'password' -P flextable --force-reinstall
```

Writing bundle metadata to the catalog

Vertica internally stores physical table data in bundles together with metadata on the bundle contents. The query optimizer uses bundle metadata to look up and fetch the data it needs for a given query.

Vertica stores bundle metadata in the database catalog. This is especially beneficial in Eon mode: instead of fetching this metadata from remote (S3) storage, the optimizer can find it in the local catalog. This minimizes S3 reads, and facilitates faster query planning and overall execution.

Vertica writes bundle metadata to the catalog on two events:

- Any DML operation that changes table content, such as **INSERT** , **UPDATE** , or **COPY** . Vertica writes bundle metadata to the catalog on the new or changed table data. DML operations have no effect on bundle metadata for existing table data.
- Invocations of function **UPDATE_STORAGE_CATALOG** , as an argument to Vertica meta-function **DO_TM_TASK** , on existing data. You can narrow the scope of the catalog update operation to a specific projection or table. If no scope is specified, the operation is applied to the entire database.

Important

After upgrading to any Vertica version $\geq 9.2.1$, you only need to call **UPDATE_STORAGE_CATALOG** once on existing data. Bundle metadata on all new or updated data is always written automatically to the catalog.

For example, the following **DO_TM_TASK** call writes bundle metadata on all projections in table **store.store_sales_fact** :

```
=> SELECT DO_TM_TASK ('update_storage_catalog', 'store.store_sales_fact');
      do_tm_task
```

```
-----
Task: update_storage_catalog
(Table: store.store_sales_fact) (Projection: store.store_sales_fact_b0)
(Table: store.store_sales_fact) (Projection: store.store_sales_fact_b1)
(1 row)
```

Validating bundle metadata

You can query system table [STORAGE_BUNDLE_INFO_STATISTICS](#) to determine which projections have invalid bundle metadata in the database catalog. For example, results from the following query show that the database catalog has invalid metadata for projections [inventory_fact_b0](#) and [inventory_fact_b1](#) :

```
=> SELECT node_name, projection_name, total_ros_count, ros_without_bundle_info_count
FROM v_monitor.storage_bundle_info_statistics where ros_without_bundle_info_count > 0
ORDER BY projection_name, node_name;
node_name | projection_name | total_ros_count | ros_without_bundle_info_count
-----+-----+-----+-----
v_vmart_node0001 | inventory_fact_b0 | 1 | 1
v_vmart_node0002 | inventory_fact_b0 | 1 | 1
v_vmart_node0003 | inventory_fact_b0 | 1 | 1
v_vmart_node0001 | inventory_fact_b1 | 1 | 1
v_vmart_node0002 | inventory_fact_b1 | 1 | 1
v_vmart_node0003 | inventory_fact_b1 | 1 | 1
(6 rows)
```

Best practices

Updating the database catalog with [UPDATE_STORAGE_CATALOG](#) is recommended only for Eon users. Enterprise users are unlikely to see measurable performance improvements from this update.

Calls to [UPDATE_STORAGE_CATALOG](#) can incur considerable overhead, as the update process typically requires numerous and expensive S3 reads. Vertica advises against running this operation on the entire database. Instead, consider an incremental approach:

- Call [UPDATE_STORAGE_CATALOG](#) on a single large fact table. You can use performance metrics to estimate how much time updating other files will require.
- Identify which tables are subject to frequent queries and prioritize catalog updates accordingly.

Upgrading the streaming data scheduler utility

If you have integrated Vertica with a streaming data application, such as Apache Kafka, you must update the streaming data scheduler utility after you update Vertica.

From a command prompt, enter the following command:

```
/opt/vertica/packages/kafka/bin/vkconfig scheduler --upgrade --upgrade-to-schema schema_name
```

Running the upgrade task more than once has no effect.

For more information on the Scheduler utility, refer to [Scheduler tool options](#).

Uninstall Vertica

To uninstall Vertica, perform the following steps for each host in the cluster:

1. Choose a host machine and log in as root (or log in as another user and switch to root).

```
$ su - root
password: root-password
```

2. Find the name of the package that is installed:

```
RPM:
# rpm -qa | grep vertica
```

```
DEB:
# dpkg -l | grep vertica
```

3. Remove the package:

```
RPM:
# rpm -e package
```

```
DEB:
# dpkg -r package
```

Note

If you want to delete the configuration file used with your installation, you can choose to delete the `/opt/vertica/` directory and all subdirectories using this command: `# rm -rf /opt/vertica/`

Perform the following steps for each client system:

1. Delete the JDBC driver jar file.
2. Delete ODBC driver data source names.
3. Delete the ODBC driver software:
 1. In Windows, go to **Start > Control Panel > Add or Remove Programs** .
 2. Locate Vertica.
 3. Click **Remove** .

Eon Mode

You can operate your Vertica database in Eon Mode instead of in Enterprise Mode. The two modes differ primarily in how they store data:

- Eon Mode databases use communal storage for their data.
- Enterprise Mode databases store data locally in the file system of nodes that make up the database.

These different storage methods lead to a number of important differences between the two modes. In Enterprise Mode, each database node stores a portion of the data and performs a portion of the computation. In Eon Mode, computational processes are separated from a communal (shared) storage layer, which enables rapid scaling of computational resources as demand changes.

For more on how these two modes compare, see [Architecture](#) .

Create a database in Eon Mode

Create an Eon Mode database in a cloud environment

The easiest way to create an Eon Mode database in the cloud is to use the MC. The MC can create your database and provision the nodes to run the database at the same time. For specific instructions for your cloud environment, see:

- Amazon Web Services (AWS): [Amazon Web Services in MC](#)
- Google Cloud Platform (GCP): [Google Cloud Platform in MC](#)
- Microsoft Azure: [Microsoft Azure in MC](#)

On AWS and Azure, you can also create an Eon Mode database using admintools. For specific instructions for your cloud environment, see:

- AWS: [Create an Eon Mode Database](#)
- Azure: [Manually create an Eon Mode database on Azure](#)

Create an on-premises Eon Mode database

If you have an on-premises install, you can create an Eon Mode database using admintools. See [Eon on-premises storage](#) for a list of object stores that Vertica supports for communal storage. The following topics detail installation instructions for each on-premises communal storage option:

- [Create an Eon Mode database on-premises with FlashBlade](#)
- [Create an Eon Mode database on-premises with MinIO](#)
- [Create an Eon Mode database on-premises with HDFS](#)

In this section

- [Create an Eon Mode database on-premises with FlashBlade](#)
- [Create an Eon Mode database on-premises with HDFS](#)
- [Create an Eon Mode database on-premises with MinIO](#)
- [Manually create an Eon Mode database on Azure](#)

Create an Eon Mode database on-premises with FlashBlade

You have two options on how to create an Eon Mode database on premises with Pure Storage FlashBlade as your S3-compatible communal storage:

- **Using the admintools Command Line:** Use the Vertica admintools command line, and complete all the steps in this topic.
- **Using Management Console :** Execute the steps in [Creating an Eon Mode database on premises with FlashBlade in MC](#).

Step 1: create a bucket and credentials on the Pure Storage FlashBlade

To use a Pure Storage FlashBlade appliance as a communal storage location for an Eon Mode database you must have:

- The IP address of the FlashBlade appliance. You must also have the connection port number if your FlashBlade is not using the standard port 80 or 443 to access the bucket. All of the nodes in your Vertica cluster must be able to access this IP address. Make sure any firewalls between the FlashBlade appliance and the nodes are configured to allow access.
- The name of the bucket on the FlashBlade to use for communal storage.
- An access key and secret key for a user account that has read and write access to the bucket.

See the [Pure Storage support site](#) for instructions on how to create the bucket and the access keys needed for a communal storage location.

Step 2: install Vertica on your cluster

To install Vertica:

1. Ensure your nodes are configured properly by reviewing all of the content in the [Before you install Vertica](#) section.
2. Use the `install_vertica` script to verify that your nodes are correctly configured and to install the Vertica binaries on all of your nodes. Follow the steps under [Install Vertica using the command line](#) to install Vertica.

Note

These installation steps are the same ones you follow to install Vertica in Enterprise Mode. The difference between Eon Mode and Enterprise Mode on-premises databases is how you create the database, not how you install the Vertica software.

Step 3: create an authorization file

Before you create your Eon Mode on-premises database, you must create an authorization file that admintools will use to authenticate with the FlashBlade storage.

1. On the Vertica node where you will run admintools to create your database, use a text editor to create a file. You can name this file anything you wish. In these steps, it is named `auth_params.conf`. The location of this file isn't important, as long as it is readable by the Linux user you use to create the database (usually, `dbadmin`).

Important

The `auth_params.conf` file contains the secret key to access the bucket containing your Eon Mode database's data. This information is sensitive, and can be used to access the raw data in your database. Be sure this file is not readable by unauthorized users. After you have created your database, you can delete this file.

2. Add the following lines to the file:

```
awsauth = FlashBlade_Access_Key:FlashBlade_Secret_Key
awsendpoint = FlashBladeIp:FlashBladePort
```

Note

You do not need to supply a port number in the `awsendpoint` setting if you are using the default port for the connection between Vertica and the FlashBlade (80 for an unencrypted connection or 443 for an encrypted connection).

3. If you are not using TLS encryption for the connection between Vertica and the FlashBlade, add the following line to the file:

```
awsenablehttps = 0
```

4. Save the file and exit the editor.

This example `auth_params.conf` file is for an unencrypted connection between the Vertica cluster and a FlashBlade appliance at IP address 10.10.20.30 using the standard port 80.

```
awsauth = PIWHSNDGSHVRPIQ:339068001+e904816E02E5fe9103f8MQOEAEHFFVPKBAAL
awsendpoint = 10.10.20.30
awsenablehttps = 0
```

Step 4: choose a depot path on all nodes

Choose or create a directory on each node for the depot storage path. The directory you supply for the depot storage path parameter must:

- Have the same path on all nodes in the cluster (i.e. `/home/dbadmin/depot`).
- Be readable and writable by the dbadmin user.
- Have sufficient storage. By default, Vertica uses 60% of the filesystem space containing the directory for depot storage. You can limit the size of the depot by using the `--depot-size` argument in the `create_db` command. See [Configuring your Vertica cluster for Eon Mode](#) for guidelines on choosing a size for your depot.

The admintools `create_db` tool will attempt to create the depot path for you if it doesn't exist.

Step 5: create the Eon on-premises database

Use the admintools `create_db` tool to create the database. You must pass this tool the following arguments:

Argument	Description
<code>-x</code>	The path to the <code>auth_params.conf</code> file.
<code>--communal-storage-location</code>	The S3 URL for the bucket on the FlashBlade appliance (usually, this is <code>s3:// bucketname</code>).
<code>--depot-path</code>	The absolute path to store the depot on the nodes in the cluster.
<code>--shard-count</code>	The number of shards for the database. This is an integer number that is usually either a multiple of the number of nodes in your cluster, or an even divider. See Planning for Scaling Your Cluster for more information.
<code>-s</code>	A comma-separated list of the nodes in your database.
<code>-d</code>	The name for your database.

Some common optional arguments include:

Argument	Description
<code>-l</code>	The absolute path to the Vertica license file to apply to the new database.
<code>-p</code>	The password for the new database.
<code>--depot-size</code>	<p>The maximum size for the depot. Defaults to 60% of the filesystem containing the depot path.</p> <p>You can specify the size in two ways:</p> <ul style="list-style-type: none">• <code>integer%</code> : Percentage of filesystem's disk space to allocate.• <code>integer {K M G T}</code> : Amount of disk space to allocate for the depot in kilobytes, megabytes, gigabytes, or terabytes. <p>However you specify this value, the depot size cannot be more than 80 percent of disk space of the file system where the depot is stored.</p>

To view all arguments for the create_db tool, run the command:

```
admintools -t create_db --help
```

The following example demonstrates creating a three-node database named verticadb, specifying the depot will be stored in the home directory of the dbadmin user.

```
$ admintools -t create_db -x auth_params.conf \  
--communal-storage-location=s3://verticadbbucket \  
--depot-path=/home/dbadmin/depot --shard-count=6 \  
-s vnode01,vnode02,vnode03 -d verticadb -p 'YourPasswordHere'
```

Step 6: disable streaming limitations

After creating the database, disable the `AWSSStreamingConnectionPercentage` configuration parameter. This setting is unnecessary for an Eon Mode on-premises install with communal storage on FlashBlade or MinIO. This configuration parameter controls the number of connections to the object store that Vertica uses for streaming reads. In a cloud environment, this setting helps avoid having streaming data from the object store use up all of the available file handles. It leaves some file handles available for other object store operations. Due to the low latency of on-premises object stores, this option is unnecessary. Set it to 0 to disable it.

The following example shows how to disable this parameter using [ALTER DATABASE...SET PARAMETER](#) :

```
=> ALTER DATABASE DEFAULT SET PARAMETER AWSSStreamingConnectionPercentage = 0;  
ALTER DATABASE
```

Deciding whether to disable the depot

The FlashBlade object store's performance is fast enough that you may consider disabling the depot in your Vertica database. If you disable the depot, you can get by with less local storage on your nodes. However, there is always a performance impact of disabling the depot. The exact impact depends mainly on the types of workloads you run on your database. The performance impact can range from a 30% to 4000% decrease in query performance. Only consider disabling the depot if you will see a significant benefit from reducing the storage requirements of your nodes. Before disabling the depot on a production database, always run a proof of concept test that executes the same workloads as your production database.

To disable the depot, set the `UseDepotForReads` configuration parameter to 0. The following example demonstrates disabling this parameter using [ALTER DATABASE...SET PARAMETER](#) :

```
=> ALTER DATABASE DEFAULT SET PARAMETER UseDepotForReads = 0;  
ALTER DATABASE
```

Create an Eon Mode database on-premises with HDFS

Step 1: satisfy HDFS environment prerequisites

To use HDFS as a communal storage location for an Eon Mode database you must:

- Run the WebHDFS service.
- If using Kerberos, create a Kerberos principal for the Vertica (system) user as described in [Kerberos authentication](#), and grant it read and write access to the location in HDFS where you will place your communal storage. Vertica always uses this system principal to access communal storage.
- If using High Availability Name Node or `swebhdfs`, distribute the HDFS configuration files to all Vertica nodes as described in [Configuring HDFS access](#). This step is necessary even though you do not use the `hdfs` scheme for communal storage.
- If using `swebhdfs` (wire encryption) instead of `webhdfs`, configure the HDFS cluster with certificates trusted by the Vertica hosts and set `dfs.encrypt.data.transfer` in `hdfs-site.xml`.
- Vertica has no additional requirements for encryption at rest. Consult the documentation for your Hadoop distribution for information on how to configure encryption at rest for WebHDFS.

Note

Hadoop currently does not support IPv6 network addresses. Your cluster must use IPv4 addresses to access HDFS. If you choose to use IPv6 network addresses for the hosts in your database cluster, make sure they can access IPv4 addresses. One way to enable this access is to assign your Vertica hosts an IPv4 address in addition to an IPv6 address.

Step 2: install Vertica on your cluster

To install Vertica:

1. Ensure your nodes are configured properly by reviewing all of the content in the [Before you install Vertica](#) section.

- Use the `install_vertica` script to verify that your nodes are correctly configured and to install the Vertica binaries on all of your nodes. Follow the steps under [Install Vertica using the command line](#) to install Vertica.

Note

These installation steps are the same ones you follow to install Vertica in Enterprise Mode. The difference between Eon Mode and Enterprise Mode on-premises databases is how you create the database, not how you install the Vertica software.

Step 3: create a bootstrapping file

Before you create your Eon Mode on-premises database, you must create a bootstrapping file to specify parameters that are required for database creation. This step applies if you are using Kerberos, High Availability Name Node, or TLS (wire encryption).

- On the Vertica node where you will run admintools to create your database, use a text editor to create a file. You can name this file anything you wish. In these steps, it is named `bootstrap_params.conf`. The location of this file isn't important, as long as it is readable by the Linux user you use to create the database (usually, dbadmin).
- Add the following lines to the file. HadoopConfDir is typically set to `/etc/hadoop/conf`; KerberosServiceName is usually set to `vertica`.

```
HadoopConfDir = config-path
KerberosServiceName = principal-name
KerberosRealm = realm-name
KerberosKeytabFile = keytab-path
```

If you are not using HA Name Node, for example in a test environment, you can omit HadoopConfDir and use an explicit Name Node host and port when specifying the location of the communal storage.

- Save the file and exit the editor.

Step 4: choose a depot path on all nodes

Choose or create a directory on each node for the depot storage path. The directory you supply for the depot storage path parameter must:

- Have the same path on all nodes in the cluster (i.e. `/home/dbadmin/depot`).
- Be readable and writable by the dbadmin user.
- Have sufficient storage. By default, Vertica uses 60% of the filesystem space containing the directory for depot storage. You can limit the size of the depot by using the `--depot-size` argument in the `create_db` command. See [Configuring your Vertica cluster for Eon Mode](#) for guidelines on choosing a size for your depot.

The admintools `create_db` tool will attempt to create the depot path for you if it doesn't exist.

Step 5: create the Eon on-premises database

Use the admintools `create_db` tool to create the database. You must pass this tool the following arguments:

Argument	Description
<code>-x</code>	The path to the bootstrap configuration file (<code>bootstrap_params.conf</code> in the examples in this section).
<code>--communal-storage-location</code>	The webhdfs or swabhdfs URL for the HDFS location. You cannot use the hdfs scheme.
<code>--depot-path</code>	The absolute path to store the depot on the nodes in the cluster.
<code>--shard-count</code>	The number of shards for the database. This is an integer number that is usually either a multiple of the number of nodes in your cluster, or an even divider. See Planning for Scaling Your Cluster for more information.
<code>-s</code>	A comma-separated list of the nodes in your database.
<code>-d</code>	The name for your database.

Some common optional arguments include:

Argument	Description
----------	-------------

<code>-l</code>	The absolute path to the Vertica license file to apply to the new database.
<code>-p</code>	The password for the new database.
<code>--depot-size</code>	<p>The maximum size for the depot. Defaults to 60% of the filesystem containing the depot path.</p> <p>You can specify the size in two ways:</p> <ul style="list-style-type: none"> • <code>integer%</code> : Percentage of filesystem's disk space to allocate. • <code>integer{K M G T}</code> : Amount of disk space to allocate for the depot in kilobytes, megabytes, gigabytes, or terabytes. <p>However you specify this value, the depot size cannot be more than 80 percent of disk space of the file system where the depot is stored.</p>

To view all arguments for the `create_db` tool, run the command:

```
admintools -t create_db --help
```

The following example demonstrates creating a three-node database named `verticadb`, specifying the depot will be stored in the home directory of the `dbadmin` user.

```
$ admintools -t create_db -x bootstrap_params.conf \
--communal-storage-location=webhdfs://mycluster/verticadb \
--depot-path=/home/dbadmin/depot --shard-count=6 \
-s vnode01,vnode02,vnode03 -d verticadb -p 'YourPasswordHere'
```

If you are not using HA Name Node, for example in a test environment, you can use an explicit Name Node host and port for `--communal-storage-location` as in the following example.

```
$ admintools -t create_db -x bootstrap_params.conf \
--communal-storage-location=webhdfs://namenode.hadoop.example.com:50070/verticadb \
--depot-path=/home/dbadmin/depot --shard-count=6 \
-s vnode01,vnode02,vnode03 -d verticadb -p 'YourPasswordHere'
```

Create an Eon Mode database on-premises with MinIO

Step 1: create a bucket and credentials on MinIO

To use MinIO as a communal storage location for an Eon Mode database, you must have:

- The IP address and port number of the MinIO cluster. MinIO's default port number is 9000. A Vertica database running in Eon Mode defaults to using port 80 for unencrypted connections and port 443 for TLS encrypted connection. All of the nodes in your Vertica cluster must be able to access the MinIO cluster's IP address. Make sure any firewalls between the MinIO cluster and the nodes are configured to allow access.
- The name of the bucket on the MinIO cluster to use for communal storage.
- An access key and secret key for a user account that has read and write access to the bucket.

See the [MinIO documentation](#) for instructions on how to create the bucket and the access keys needed for a communal storage location.

Step 2: install Vertica on your cluster

To install Vertica:

1. Ensure your nodes are configured properly by reviewing all of the content in the [Before you install Vertica](#) section.
2. Use the `install_vertica` script to verify that your nodes are correctly configured and to install the Vertica binaries on all of your nodes. Follow the steps under [Install Vertica using the command line](#) to install Vertica.

Note

These installation steps are the same ones you follow to install Vertica in Enterprise Mode. The difference between Eon Mode and Enterprise Mode on-premises databases is how you create the database, not how you install the Vertica software.

Step 3: create an authorization file

Before you create your Eon Mode on-premises database, you must create an authorization file that `admintools` will use to authenticate with the MinIO storage cluster.

1. On the Vertica node where you will run admintools to create your database, use a text editor to create a file. You can name this file anything you wish. In these steps, it is named `auth_params.conf`. The location of this file isn't important, as long as it is readable by the Linux user you use to create the database (usually, `dbadmin`).

Important

The `auth_params.conf` file contains the secret key to access the bucket containing your Eon Mode database's data. This information is sensitive, and can be used to access the raw data in your database. Be sure this file is not readable by unauthorized users. After you have created your database, you can delete this file.

2. Add the following lines to the file:

```
awsauth = MinIO_Access_Key:MinIO_Secret_Key
awsendpoint = MinIOIp:MinIOPort
```

Note

You do not need to supply a port number in the `awsendpoint` setting if you configured your MinIO cluster to use the default HTTP ports (80 for an unencrypted connection or 443 for an encrypted connection). MinIO uses port 9000 by default.

3. If you are not using TLS encryption for the connection between Vertica and MinIO, add the following line to the file:

```
awsenablehttps = 0
```

4. Save the file and exit the editor.

This example `auth_params.conf` file is for an unencrypted connection between the Vertica cluster and a MinIO cluster at IP address 10.20.30.40 using port 9000 (which is the default for MinIO).

```
awsauth = PIWHSNDGSHVRPIQ:339068001+e904816E02E5fe9103f8MQOEAHEFFVPKBAAL
awsendpoint = 10.20.30.40:9000
awsenablehttps = 0
```

Step 4: choose a depot path on all nodes

Choose or create a directory on each node for the depot storage path. The directory you supply for the depot storage path parameter must:

- Have the same path on all nodes in the cluster (i.e. `/home/dbadmin/depot`).
- Be readable and writable by the `dbadmin` user.
- Have sufficient storage. By default, Vertica uses 60% of the filesystem space containing the directory for depot storage. You can limit the size of the depot by using the `--depot-size` argument in the `create_db` command. See [Configuring your Vertica cluster for Eon Mode](#) for guidelines on choosing a size for your depot.

The admintools `create_db` tool will attempt to create the depot path for you if it doesn't exist.

Step 5: create the Eon on-premises database

Use the admintools `create_db` tool to create the database. You must pass this tool the following arguments:

Argument	Description
<code>-x</code>	The path to the <code>auth_params.conf</code> file.
<code>--communal-storage-location</code>	The S3 URL for the bucket on the MinIO cluster (usually, this is <code>s3://bucketname</code>).
<code>--depot-path</code>	The absolute path to store the depot on the nodes in the cluster.
<code>--shard-count</code>	The number of shards for the database. This is an integer number that is usually either a multiple of the number of nodes in your cluster, or an even divider. See Planning for Scaling Your Cluster for more information.
<code>-s</code>	A comma-separated list of the nodes in your database.
<code>-d</code>	The name for your database.

Some common optional arguments include:

Argument	Description
<code>-l</code>	The absolute path to the Vertica license file to apply to the new database.
<code>-p</code>	The password for the new database.
<code>--depot-size</code>	<p>The maximum size for the depot. Defaults to 60% of the filesystem containing the depot path.</p> <p>You can specify the size in two ways:</p> <ul style="list-style-type: none">• <code>integer%</code> : Percentage of filesystem's disk space to allocate.• <code>integer {K M G T}</code> : Amount of disk space to allocate for the depot in kilobytes, megabytes, gigabytes, or terabytes. <p>However you specify this value, the depot size cannot be more than 80 percent of disk space of the file system where the depot is stored.</p>

To view all arguments for the `create_db` tool, run the command:

```
admintools -t create_db --help
```

The following example demonstrates creating a three-node database named `verticadb`, specifying the depot will be stored in the home directory of the `dbadmin` user.

```
$ admintools -t create_db -x auth_params.conf \  
--communal-storage-location=s3://verticadbbucket \  
--depot-path=/home/dbadmin/depot --shard-count=6 \  
-s vnode01,vnode02,vnode03 -d verticadb -p 'YourPasswordHere'
```

Step 6: disable streaming limitations

After creating the database, disable the `AWSSStreamingConnectionPercentage` configuration parameter. This setting is unnecessary for an Eon Mode on-premises install with communal storage on FlashBlade or MinIO. This configuration parameter controls the number of connections to the object store that Vertica uses for streaming reads. In a cloud environment, this setting helps avoid having streaming data from the object store use up all of the available file handles. It leaves some file handles available for other object store operations. Due to the low latency of on-premises object stores, this option is unnecessary. Set it to 0 to disable it.

The following example shows how to disable this parameter using [ALTER DATABASE...SET PARAMETER](#) :

```
=> ALTER DATABASE DEFAULT SET PARAMETER AWSSStreamingConnectionPercentage = 0;  
ALTER DATABASE
```

Manually create an Eon Mode database on Azure

Once you have met the cluster and storage requirements for using an Eon Mode database on Azure, you are ready to create an Eon Mode database. Use the `admintools create_db` tool to create your Eon Mode database.

Creating an authentication file

If your database will use a managed identity to authenticate with the Azure storage container, you do not need to supply any additional configuration information to the `create_db` tool.

If your database will not use a managed identity, you must supply `create_db` with authentication information in a configuration file. It must contain at least the `AzureStorageCredentials` parameter that defines one or more account names and keys Vertica will use to access blob storage. It can also contain an `AzureStorageEndpointConfig` parameter that defines an alternate endpoint to use instead of the the default Azure host name. This option is useful if you are creating a test environment using an Azure storage emulator such as Azurite.

Important

Vertica does not officially support Azure storage emulators as a communal storage location.

The following table defines the values that can be set in these two parameters.

AzureStorageCredentials

Collection of JSON objects, each of which specifies connection credentials for one endpoint. This parameter takes precedence over Azure

managed identities.

The collection must contain at least one object and may contain more. Each object must specify at least one of `accountName` or `blobEndpoint`, and at least one of `accountKey` or `sharedAccessSignature`.

- `accountName`: If not specified, uses the label of `blobEndpoint`.
- `blobEndpoint`: Host name with optional port (`host:port`). If not specified, uses `account.blob.core.windows.net`.
- `accountKey`: Access key for the account or endpoint.
- `sharedAccessSignature`: Access token for finer-grained access control, if being used by the Azure endpoint.

AzureStorageEndpointConfig

Collection of JSON objects, each of which specifies configuration elements for one endpoint. Each object must specify at least one of `accountName` or `blobEndpoint`.

- `accountName`: If not specified, uses the label of `blobEndpoint`.
- `blobEndpoint`: Host name with optional port (`host:port`). If not specified, uses `account.blob.core.windows.net`.
- `protocol`: HTTPS (default) or HTTP.
- `isMultiAccountEndpoint`: true if the endpoint supports multiple accounts, false otherwise (default is false). To use multiple-account access, you must include the account name in the URI. If a URI path contains an account, this value is assumed to be true unless explicitly set to false.

The authentication configuration file is a text file containing the configuration parameter names and their values. The values are in a JSON format. The name of this file is not important. The following examples use the file name `auth_params.conf`.

The following example is a configuration file for a storage account hosted on Azure. The storage account name is `mystore`, and the key value is a placeholder. In your own configuration file, you must provide the storage account's access key. You can find this value by right-clicking the storage account in the Azure Storage Explorer and selecting **Copy Primary Key**.

```
AzureStorageCredentials={"accountName": "mystore", "accountKey": "access-key"}
```

The following example shows a configuration file that defines an account for a storage container hosted on the local system using the Azurite storage system. The user account and key are the "well-known" account provided by Azurite by default. Because this configuration uses an alternate storage endpoint, it also defines the `AzureStorageEndpointConfig` parameter. In addition to reiterating the account name and endpoint definition, this example sets the protocol to the non-encrypted HTTP.

Important

This example wraps the contents of the JSON values for clarity. In an actual configuration file, you **cannot wrap these values**. They must be on a single line.

```
AzureStorageCredentials={"accountName": "devstoreaccount1", "blobEndpoint": "127.0.0.1:10000 ",
    "accountKey":
    "Eby8vdM02xNOcqFlqUwJPLimEtlCDXJ1OUzFT50uSRZ6IFsuFq2UVErCz4I6tq/K1SZFPTOtr/KBHBeksoGMGw=="
    }
```

```
AzureStorageEndpointConfig={"accountName": "devstoreaccount1",
    "blobEndpoint": "127.0.0.1:10000", "protocol": "http"}
```

Creating the Eon Mode database

Use the admintools `create_db` tool to create your Eon Mode database. The required arguments you pass to this tool are:

Argument	Description
-- communal-storage-location	The URI for the storage container Vertica will use for communal storage. This URI must use the <code>azb://</code> schema. See Azure Blob Storage object store for the format of this URI.
-x	The path to the file containing the authentication parameters Vertica needs to access the communal storage location. This argument is only required if your database will use a storage account name and key to authenticate with the storage container. If it is using a managed identity, you do not need to specify this argument.

<code>--depot-path</code>	The absolute path to store the depot on the nodes in the cluster.
<code>--shard-count</code>	The number of shards for the database. This is an integer number that is usually either a multiple of the number of nodes in your cluster, or an even divisor. See Planning for Scaling Your Cluster for more information.
<code>-s</code>	A comma-separated list of the nodes in your database.
<code>-d</code>	The name for your database.

Some other common optional arguments for `create_db` are:

Argument	Description
<code>-l</code>	The absolute path to the Vertica license file to apply to the new database.
<code>-p</code>	The password for the new database.
<code>--depot-size</code>	<p>The maximum size for the depot. Defaults to 60% of the filesystem containing the depot path.</p> <p>You can specify the size in two ways:</p> <ul style="list-style-type: none"> <code>integer%</code> : Percentage of filesystem's disk space to allocate. <code>integer {K M G T}</code> : Amount of disk space to allocate for the depot in kilobytes, megabytes, gigabytes, or terabytes. <p>However you specify this value, the depot size cannot be more than 80 percent of disk space of the file system where the depot is stored.</p>

To view all arguments for the `create_db` tool, run the command:

```
admintools -t create_db --help
```

The following example demonstrates creating an Eon Mode database with the following settings:

- Vertica will use a storage account named `mystore`.
- The communal data will be stored in a directory named `verticadb` located in a storage container named `db_blobs`.
- The authentication information Vertica needs to access the storage container is in the file named `auth_params.conf` in the current directory. The contents of this file are shown in the first example under [Creating an Authentication File](#).
- The hostnames of the nodes in the cluster are `node01` through `node03`.

```
$ admintools -t create_db \
  --communal-storage-location=azb://mystore/db_blobs/verticadb \
  -x auth_params.conf -s node01,node02,node03 \
  -d verticadb --depot-path /vertica/depot --shard-count 3 \
  -p 'mypassword'
```

Configuring your Vertica cluster for Eon Mode

Running Vertica in Eon Mode decouples the cluster size from the data volume and lets you configure for your compute needs independently from your storage needs. There are a number of factors you must consider when deciding what sorts of instances to use and how large your Eon Mode cluster will be.

Before you begin

Vertica Eon Mode works both in the cloud and on-premises. As a Vertica administrator setting up your production cluster running in Eon Mode, you must make decisions about the virtual or physical hardware you will use to meet your needs. This topic provides guidelines and best practices for selecting server types and cluster sizes for a Vertica database running in Eon Mode. It assumes that you have a basic understanding of the Eon Mode architecture and concepts such as [communal storage](#), [depot](#), [namespaces](#), and [shards](#). If you need to refresh your understanding, see [Eon Mode architecture](#) and [Namespaces and shards](#).

Cluster size overview

Because Eon Mode separates data storage from the computing power of your nodes, choosing a cluster size is more complex than for an Enterprise Mode database. Usually, you choose a base number of nodes that will form one or more [primary subclusters](#). These subclusters contain nodes that are always running in your database. You usually use them for workloads such as data loading and executing DDL statements. You rarely alter the size of these subclusters dynamically. As you need additional compute resources to execute queries, you add one or more subclusters (usually [secondary subclusters](#)) of nodes to your database.

When choosing your instances and sizing your cluster for Eon Mode, consider the working data size that your database will be dealing with. This is the amount of data that most of your queries operate on. For example, suppose your database stores sales data. If most of the queries running on your database analyze the last month or two of sales to create reports on sales trends, then your working data size is the amount of data you typically load over a few months.

Choosing instances or physical hardware

Depending on the complexity of your workload and expected concurrency, choose physical or virtual hardware that has sufficient CPU and memory. For production clusters Vertica recommends the following minimum configuration for either virtual or physical nodes in an Eon Mode database:

- 16 cores
- 128 GB RAM
- 2 TB of local storage

Note

The above specifications are just a minimum recommendation. You should consider increasing these specifications based on your workloads and the amount of data you are processing.

You must have a minimum of 3 nodes in the an Eon Mode database cluster.

For specific recommendations of instances for cloud-based Eon Mode database, see:

- [Choosing AWS Eon Mode Instance Types](#)
- [GCP Eon Mode instance recommendations](#)

Determining local storage requirements

For both virtual and physical hardware, you must decide how much local storage your nodes need. In Eon Mode, the definitive copy of your database's data resides in the communal storage. This storage is provided by either a cloud-based object store such as AWS S3, or by an on-premises object store, such as a Pure Storage FlashBlade appliance.

Even though your database's data is stored in communal storage, your nodes still need some local storage. A node in an Eon Mode database uses local storage for three purposes:

- **Depot storage** : To get the fastest response time for frequently executed queries, provision a depot large enough to hold your working data set after data compression. Divide the working data size by the number of nodes you will have in your subcluster to estimate the size of the depot you need for each node in a subcluster. See [Choosing the Number of Shards and the Initial Node Count](#) below to get an idea of how many nodes you want in your initial database subcluster. In cases where you expect to dynamically scale your cluster up, estimate the depot size based on the minimum number of nodes you anticipate having in the subcluster.
Also consider how much data you will load at once when sizing your depot. When loading data, Vertica defaults to writing uncommitted ROS files into the depot before uploading the files to communal storage. If the free space in the depot is not sufficient, Vertica evicts files from the depot to make space for new files.
Your data load fails if the amount of data you try to load in a single transaction is larger the total sizes of all the depots in the subcluster. To load more data than there is space in the subcluster's combined depots, set [UseDepotForWrites](#) to 0. This configuration parameter tells Vertica to load the data directly into communal storage.
- **Data storage** : The data storage location holds files that belong to temporary tables and temporary data from sort operators that spill to disk. When loading data into Vertica, the sort operator may spill to disk. Depending on the size of the load, Vertica may perform the sort in multiple merge phases. The amount of data concurrently loaded into Vertica cannot be larger than the sum of temporary storage location sizes across all nodes divided by 2.
- **Catalog storage** . The catalog size depends on the number of database objects per shard and the number of shard subscriptions per node.

Vertica recommends a minimum local storage capacity of 2 TB per node, out of which 60% is reserved for the depot and the other 40% is shared between the catalog and data location. If you determine that you need a depot larger than 1.2TB per node (which is 60% of 2TB) then add more storage than this minimum recommendation. You can calculate the space you need using this equation:

$$\text{Disk Space Per Node} = \frac{\text{Compressed Working Data Size}}{\text{\# of Nodes in Subcluster}} \times 1.67$$

For example, suppose you have a compressed working data size of 24TB, and you want to have a initial primary subcluster of 3 nodes. Using these values in the equation results in 13.33TB:

$$\frac{24\text{TB}}{3 \text{ Nodes}} \times 1.67 = 13.33\text{TB}$$

Choosing the initial node and shard counts

Shards are how Vertica divides the responsibility for the data in communal storage among nodes. The number of shards that data is segmented into depends on the shard count of the namespace to which the data belongs. Each node in a subcluster subscribes to at least one shard in communal storage. During queries, data loads, and other database tasks, each node is responsible for the data in the shards it subscribes to. See [Namespaces and shards](#) for more information.

The relation between shards and nodes means that when selecting the number of shards for a namespace, you must consider the number of nodes you will have in your database.

You set the initial shard count of the `default_namespace` when you create your database. The shard count of non-default namespaces is set with the `CREATE NAMESPACE` statement. The initial node count is the number of nodes you will have in your core primary subcluster. The number of shards in a namespace should always be a multiple or divisor of the node count. This ensures that the shards are evenly divided between the nodes. For example, in a six-shard namespace, you should have subclusters that contain two, three, six, or a multiple of six nodes. If the number of shards is not a divisor or multiple of the node count, the shard subscriptions are not spread evenly across the nodes. This leads to some nodes being more heavily loaded than others.

Note

In a database where the number of nodes is a multiple of the number of shards in a namespace, the subcluster uses Elastic Crunch Scaling (ECS) to evenly divide shard coverage among two or more nodes. For more information, see [Using elastic crunch scaling to improve query performance](#).

The following table shows the recommended initial node count based on the working data size:

Cluster Type	Working Data Size	Initial Node Count
Small	Up to 24 TB	3
Medium	Up to 48 TB	6
Large	Up to 96 TB	12
Extra large	Up to 192 TB	24

Scaling your cluster

There are two strategies you can use when adding nodes to your database. Each of these strategies lets you improve different types of database performance:

- To increase the performance of complex, long-running queries, add nodes to an existing subcluster. These additional nodes improve the overall performance of these complex queries by splitting the load across more compute nodes. You can add more nodes to a subcluster than you have shards in a namespace. In this case, nodes in the subcluster that subscribe to the same shard will split up the data in the shard when performing a query. See [Elasticity](#) for more information.
- To increase the throughput of multiple short-term queries (often called "dashboard queries"), improve your cluster's parallelism by adding additional [subclusters](#). Subclusters work independently and in parallel on these shorter queries. See [Subclusters](#) for more information.

Complex analytic queries perform better on subclusters with more nodes, which means that 6 nodes with 6 shards perform better than 3 nodes and 6 shards. Having more nodes than shards can increase performance further, but the performance gain is not linear. For example, a subcluster containing 12 nodes in a 6-shard namespace is not as efficient as a 12-node subcluster in a 12-shard namespace. Dashboard-type queries operating on smaller data sets may not see much difference between a 3-node subcluster in a 6-shard namespace and 6-node subcluster in a 6-shard namespace.

Use cases

Let's look at some use cases to learn how to size your Eon Mode cluster to meet your own particular requirements.

Use case 1: save compute by provisioning when needed, rather than for peak times

This use case highlights increasing query throughput in Eon Mode by scaling a cluster from 6 to 18 nodes with 3 subclusters of 6 nodes each. In this use case, you need to support a high concurrent, short query workload on a 24 TB or less working data set. You create an initial database with 6 nodes and `default_namespace` of 6 shards. You scale your database for concurrent throughput on demand by adding one or more subclusters during certain days of the week or for specific date ranges when you are expecting a peak load. You can then shut down or terminate the additional subclusters when your database experiences lower demand. With Vertica in Eon Mode, you save money by provisioning on demand, rather than provisioning for the peak times.

Use case 2: complex analytic workload requires more compute nodes

This use case showcases the idea that complex analytic workloads on large working data sets benefit from high shard count and node count. You create an initial subcluster with 24 nodes and `default_namespace` of 24 shards. As needed, you can add an additional 24 nodes to your initial subcluster. These additional nodes enable the subcluster to use elastic crunch scaling to reduce the time it takes to complete complex analytic queries.

If you use multiple namespaces, you can separate the large working data set and any smaller data sets into different namespaces. For details, see [Managing namespaces](#).

Use case 3: workload isolation

This use case showcases the idea of having separate subclusters to isolate ETL and report workloads. You create an initial [primary subcluster](#) with 6 nodes and a `default_namespace` of 6 shards for servicing ETL workloads. Then add another 6-node [secondary subcluster](#) for executing query workloads. To separate the two workloads, you can configure a network load balancer or create [connection load balancing policies](#) in Vertica to direct clients to the correct subcluster based on the type of workloads they need to execute.

Migrating an enterprise database to Eon Mode

The [MIGRATE_ENTERPRISE_TO_EON](#) function migrates an Enterprise database to Eon Mode. The migration process includes the following stages:

1. [Check migration prerequisites](#)
2. [Verify compliance](#)
3. [Execute the migration](#)
4. [Check migration results](#)
5. [Activate the Eon database](#)

Tip

When planning how to provision the target Eon database, consider that `MIGRATE_ENTERPRISE_TO_EON` creates the same number of nodes as on the original Enterprise database, and an equal number of segmented shards. Choose the appropriate instance type accordingly.

Migration prerequisites

The following conditions must be true; otherwise, `MIGRATE_ENTERPRISE_TO_EON` returns with an error:

- The source Enterprise database version must be ≥ 10.0 .
- All nodes in the source database must be in an UP state and of type PERMANENT or EPHEMERAL. Verify by querying the [NODES](#) system table:

```
=> SELECT node_name, node_type, node_state FROM nodes;
 node_name | node_type | node_state
-----+-----+-----
v_vmart_node0001 | PERMANENT | UP
v_vmart_node0002 | PERMANENT | UP
v_vmart_node0003 | PERMANENT | UP
(3 rows)
```

- The source database must be configured as an [elastic cluster](#). By default, any database created since Vertica release 9.2.1 is configured as an elastic cluster. To verify whether an Enterprise database is configured as an elastic cluster, query the [ELASTIC_CLUSTER](#) system table:

```
=> SELECT is_enabled FROM elastic_cluster;
 is_enabled
-----
t
(1 row)
```

If the query returns false, call the [ENABLE_ELASTIC_CLUSTER](#) function on the Enterprise database.

- The source Enterprise database must configure Eon parameters as required by the target Eon object store (see [Configuration Requirements](#) below).

- The database must not contain [projections that are unsupported by Eon](#).

Unsupported projections

Eon databases do not support four types of projections, as described below. If MIGRATE_ENTERPRISE_TO_EON finds any of these projection types in the Enterprise database, it rolls back the migration and reports the offending projections or their anchor tables in the migration error log. For example:

The following projections are inconsistent with cluster segmentation. Rebalance them with REBALANCE_CLUSTER() or REBALANCE_TABLE():
 Projection(Anchor Table): public.incon1_p1_b0(public.incon1)

Why projection is invalid	Notes	Resolution
Inconsistent with cluster segmentation.	For example, nodes were added to the cluster, so current distribution of projection data is inconsistent with new cluster segmentation requirements.	Rebalance cluster or table. The error log file lists the names of all tables with problematic projections. You can use these names as arguments to meta-function REBALANCE_TABLE . You can also rebalance all projections by calling REBALANCE_CLUSTER .
Does not support elastic segmentation.	Projection was created with the NODES option, or in a database where elastic segmentation was disabled.	Drop projection , recreate with ALL NODES.
Defined with a GROUPED clause .	Consolidates multiple columns in a single ROS container.	Drop projection , recreate without GROUPED clause.
Data stored in unbundled storage containers.	Found only in Vertica databases that were created before storage container bundling was introduced in version 7.2.	Bundle storage containers in database with meta-function COMPACT_STORAGE . The error log names all tables with projections that store data in unbundled storage containers. You can use these names as arguments to meta-function COMPACT_STORAGE .

Configuration requirements

Before migration, you must set certain configuration parameters in the source database. The specific parameters depend on the environment of the Eon database.

Important

All parameters must be set at the database level.

S3: AWS, Pure Storage, MinIO

The following requirements apply to all supported cloud and non-cloud (on-premises) S3 environments: AWS, Pure Storage, and MinIO. One exception applies: migration from an Enterprise Mode database on AWS.

- [AWSEndpoint](#) (Pure Storage, MinIO only)
- [AWSRegion](#) (AWS only)
- [AWSAuth / IAM role](#)
- [AWSEnableHttps](#)

Important

If migrating to on-premises communal storage with Pure Storage and MinIO, set AWSEnableHttps to be compatible with the database TLS encryption setup: AWSEnableHttps=1 if using TLS, otherwise 0. If settings are incompatible, the migration returns with an error.

Azure

- You must use an [azb://](#) schema URI to set the Azure Blob Storage location for communal data storage. See [Azure Blob Storage object store](#) for the format of this URI.

- Select one of the following authentication methods to grant Vertica access to the storage location:
 - Configure managed identities to grant your Azure VMs access to the storage location. This option does not require any configuration within Vertica.
 - Set the [AzureStorageCredentials](#) and [AzureStorageEndpointConfig](#) configuration parameters at the database level to have Vertica authenticate with the storage location.

See [Azure Blob Storage object store](#) for more about the two authentication methods.

GCP

- [GCSEndpoint](#)
- [GCSAuth](#)
- [GCSEnableHttp](#)

HDFS

- The source database must be [configured to access HDFS](#), including (as applicable) [high-availability](#) (HA) and [Kerberos authentication](#) settings.
- Set [HadoopConfDir](#) at the database level (not required for non-HA environments).

Tip

If using Kerberos authentication, record settings for the following [Kerberos configuration parameters](#). You will need to apply these settings to the migrated Eon database:

- KerberosServiceName
- KerberosRealm
- KerberosKeytabFile

Important

The following restrictions apply to Kerberos authentication:

- Migration only supports [Vertica authentication](#). User authentication through [delegation tokens or proxy users](#) is not supported.
- Migration does not support authentication of [multiple Kerberos realms](#).

Compliance verification

Before running migration, check whether the Enterprise source database complies with all [migration requirements](#). You do so by setting the last Boolean argument of [MIGRATE_ENTERPRISE_TO_EON](#) to true to indicate that this is a dry run and not an actual migration:

```
=> SELECT migrate_enterprise_to_eon('s3://dbbucket', 'vertica/depot', true);
```

If the function encounters any compliance issues, it writes these to the migration error log, [migrate_enterprise_to_eon_error.log](#), in the database directory.

Migration execution

[MIGRATE_ENTERPRISE_TO_EON](#) migrates an Enterprise database to an Eon Mode database. For example:

```
=> SELECT migrate_enterprise_to_eon('s3://dbbucket', 'vertica/depot', false);
```

If the last argument is omitted or false, the function executes the migration. [MIGRATE_ENTERPRISE_TO_EON](#) runs in the foreground, and until it returns—either with success or an error—it blocks all operations in the same session on the source Enterprise database. If successful, [MIGRATE_ENTERPRISE_TO_EON](#) returns with a list of nodes in the migrated database. You can then proceed to [revive the migrated Eon database](#).

Handling interrupted migration

If migration is interrupted before the function returns—for example, the client disconnects, or a network outage occurs—the migration errors out. In this case, call [MIGRATE_ENTERPRISE_TO_EON](#) to restart migration.

Communal storage of the target database retains data that was already copied before the error occurred. When you call [MIGRATE_ENTERPRISE_TO_EON](#) to resume migration, the function first checks the data on communal storage and only copies unprocessed data from the source database.

Important

When migrating to an Eon database with HDFS communal storage, migration interruptions can leave files in an incomplete state that is visible to users. When you call [MIGRATE_ENTERPRISE_TO_EON](#) to resume migration, the function first compares source and target file sizes. If it finds

inconsistent sizes for a given file, it truncates the target cluster file and repeats the entire transfer.

Repeating migration

You can repeat migration multiple times to the same communal storage location. This can be useful for backfilling changes that occurred in the source database during the previous migration.

The following constraints apply:

- You can migrate from only one database to the same communal storage location.
- After [reviving the newly migrated Eon database](#), you cannot migrate again to its communal storage, unless you first drop the database and then clean up storage.

Monitoring migration

The `DATABASE_MIGRATION_STATUS` system table displays the progress of a migration in real time, and also stores data from previous migrations. The following example shows data of a migration that is in progress:

```
=> SELECT node_name, phase, status, bytes_to_transfer, bytes_transferred, communal_storage_location FROM database_migration_status ORDER BY node_name, start_time;
```

node_name	phase	status	bytes_to_transfer	bytes_transferred	communal_storage_location
v_vmart_node0001	Catalog Conversion	COMPLETED	0	0	s3://verticadbbucket/
v_vmart_node0001	Data Transfer	COMPLETED	1134	1134	s3://verticadbbucket/
v_vmart_node0001	Catalog Transfer	COMPLETED	3765	3765	s3://verticadbbucket/
v_vmart_node0002	Catalog Conversion	COMPLETED	0	0	s3://verticadbbucket/
v_vmart_node0002	Data Transfer	COMPLETED	1140	1140	s3://verticadbbucket/
v_vmart_node0002	Catalog Transfer	COMPLETED	3766	3766	s3://verticadbbucket/
v_vmart_node0003	Catalog Conversion	COMPLETED	0	0	s3://verticadbbucket/
v_vmart_node0003	Data Transfer	RUNNING	5272616	183955	s3://verticadbbucket/

Error logging

MIGRATE_ENTERPRISE_TO_EON logs migration-related warnings, errors, and hints in `migrate_enterprise_to_eon_error.log` in the database directory. During execution, the function also prints messages to standard output, together with the error log's pathname.

Conversion results

Visible objects in the source database are handled as follows:

- Global catalog objects: synced to communal storage.
- Multiple segmented projections in identical buddy projection group: one projection in the group is migrated.
- Unsegmented projection replicated on only one node: distributed across all nodes.
- Number of nodes: same number of nodes, and an equal number of segmented shards. You might want to alter the number of shards to better align with the number of nodes in your subclusters. For details, see [RESHARD_DATABASE](#).
- USER and TEMP storage locations: migrated. Consider evaluating all migrated storage locations for their relevance in an Eon Mode database. For details, see [S3 Storage of Temporary Data](#).
- DATA and TEMP,DATA storage locations: not migrated. New default DATA and TEMP,DATA locations are on the same path as the depot.
- Fault groups and storage policies: not migrated.
- External procedures: not migrated.
- Catalog objects related to network settings (load balance groups, network addresses, routing rules, subnets, etc.): not migrated.

The depot location is specified in MIGRATE_ENTERPRISE_TO_EON. Default depot size is set to 80% of local file system after revive.

Eon database activation

HDFS prerequisites

If migrating to an Eon database with HDFS communal storage, create a bootstrapping file to use when you revive the new Eon database. The bootstrapping file must be on the same node where the revive operation is launched, and readable by the user who launches the revive operation.

A bootstrapping file is required only if the new Eon database uses one or both of the following:

- High Availability (HA) NameNodes: Set `HadoopConfDir` to the location of the `hdfs-site.xml` configuration file—typically, `/etc/hadoop/conf`. This file defines the `hdfs.nameservices` parameter and individual NameNodes, and must be distributed across all cluster nodes. For details, see [Configuring HDFS access](#).
- Kerberos authentication: Set the following [Kerberos configuration parameters](#):
 - KerberosServiceName

- KerberosRealm
- KerberosKeytabFile

For example, the bootstrapping file for an Eon database with HA and Kerberos authentication must have the following settings:

```
HadoopConfDir = config-path
KerberosServiceName = principal-name
KerberosRealm = realm-name
KerberosKeytabFile = keytab-path
```

All migrations

After migration is complete and the Eon database is ready for use, perform these steps:

1. Revive the database using one of the following methods:
 - From communal storage on [S3](#) or [GCP](#) with Management Console.
 - From communal storage on Azure, S3, GCP, or HDFS with [admintools](#).

In the following example, the `admintools revive_db` command revives a three-node database that uses S3 communal storage:

```
admintools -t revive_db
-x auth_params.conf \
--communal-storage-location=s3://verticadbbucket \
-d VMart \
-s 172.16.116.27,172.16.116.28,172.16.116.29 \
--force
```

In the next example, `revive_db` revives a three-node database that uses HDFS communal storage:

```
admintools -t revive_db
-x bootstrap_params.conf \
--communal-storage-location=webhdfs://mycluster/verticadb \
-d verticadb \
-s vnode01,vnode02,vnode03
```

2. Check the `controlmode` setting in `/opt/vertica/config/admintools.conf`. This setting must be compatible with the network messaging requirements of your Eon implementation. For example, S3/AWS (Amazon Cloud) relies on unicast messaging, which is compatible with a `controlmode` setting of `point-to-point` (pt2pt). If the source database `controlmode` setting was `broadcast` and you migrate to S3/AWS communal storage, you must change `controlmode` with `admintools`:

```
$ admintools -t re_ip -d dbname -T
```

Important

If `controlmode` is set incorrectly, attempts to start the migrated Eon database will fail.

3. Start the Eon Mode database.
4. Call [CLEAN_COMMUNAL_STORAGE](#) to remove unneeded data files that might be left over from the migration.
5. If migrating to S3 on-premises communal storage—Pure Storage or MinIO—set the [AWSStreamingConnectionPercentage](#) configuration parameter to 0 with [ALTER DATABASE...SET PARAMETER](#).
6. Review the depot storage location size and [adjust as needed](#).
7. Consider re-sharding the Eon Mode database if the number of shards is not optimal. See [Choosing the Number of Shards and the Initial Node Count](#) for more information. If needed, use [RESHARD_DATABASE](#) to change the number of shards.

Managing namespaces

Eon Mode databases group all schemas and tables in the database into one or more [namespaces](#). Namespaces represent the top level in the Vertica object hierarchy, where every schema—and its constituent tables—belong to a namespace. Each namespace has a distinct shard count that defines the segmentation of its member objects. By default, the database contains a single namespace, `default_namespace`, which is created on database creation with the shard count specified during setup.

You can create additional namespaces with the [CREATE NAMESPACE](#) statement. When you create a table or schema, you can specify the namespace under which to create the object. If no namespace is specified, the table or schema is created under the `default_namespace`. If you have not created any objects under non-default namespaces, you can ignore namespaces when operating your database because Vertica correctly assumes the namespace of all tables and schemas to be `default_namespace`.

If you upgrade a database using a Vertica version less than 24.1 to a version 24.1 or later, Vertica creates the `default_namespace` and assigns to it all schemata and tables in your database.

Create namespaces

To create a namespace, use [CREATE NAMESPACE](#), specifying its name and shard count:

```
=> CREATE NAMESPACE airport SHARD COUNT 12;  
CREATE NAMESPACE
```

If no shard count is provided, the namespace is created with the shard count of the [default_namespace](#). You can view all namespaces in your database by querying the [NAMESPACES](#) system table:

```
=> SELECT namespace_name, is_default, default_shard_count FROM NAMESPACES;  
namespace_name | is_default | default_shard_count  
-----  
default_namespace | t         | 6  
airport         | f         | 12  
(2 rows)
```

To drop namespaces, use [DROP NAMESPACE](#).

Create schemas and tables under namespaces

When creating schemas and tables, you can specify the namespace in which the object is created. The [CREATE TABLE](#) and [CREATE SCHEMA](#) statements accept a 3-part naming format, where the top level name identifies the namespace. For example, `n.s.t` refers to table `t` in schema `s` in namespace `n`. If no namespace is specified, the schema or table is created in the [default_namespace](#).

Schema names must be unique in the same namespace, but there can be schemas of the same name in different namespaces:

```
=> CREATE SCHEMA airline;  
CREATE SCHEMA  
  
=> CREATE SCHEMA airport.airline;  
CREATE SCHEMA  
  
=> SELECT schema_name, schema_namespace_name FROM SCHEMATA WHERE schema_name = 'airline' OR schema_name = 'airport.airline';  
schema_name | schema_namespace_name  
-----  
airline     | default_namespace  
airport.airline | airport  
(2 rows)
```

All tables created in a given schema exist in the same namespace as that schema. You can use the [ALTER TABLE](#) statement to change the schema of a table to another schema in the same namespace, but not to a schema in a different namespace.

Create a [flights](#) table in the [airline](#) schema under both the [airport](#) and default namespace:

```

=> CREATE TABLE airport.airline.flights(
  flight_number INT,
  leaving_from VARCHAR,
  arriving_at VARCHAR,
  expected_departure DATE,
  gate VARCHAR
);
CREATE TABLE
=> CREATE TABLE airline.flights(
  flight_number INT,
  leaving_from VARCHAR,
  arriving_at VARCHAR,
  expected_departure DATE,
  gate VARCHAR
);
CREATE TABLE
=> SELECT table_name, table_schema, table_namespace_name FROM TABLES WHERE table_name = 'flights';
table_name | table_schema | table_namespace_name
-----
flights    | airline      | default_namespace
flights    | airline      | airport
(2 rows)

```

Backing up, restoring, and replicating namespaces

The [vbr backup, restore, and replicate tasks](#) support namespaces. Full-database backup and restore operations work as expected and require no extra configurations for namespaces. However, object-level **vbr** tasks have the following requirements for databases using multiple namespaces:

- Specify the namespace of objects when identifying them in either the **vbr** configuration file or command line arguments. If you do not specify an object's namespace, it is assumed to be `default_namespace`.
 - For **vbr** tasks, namespaces are prefixed with a period. For example, `.n.s.t` refers to table `t` in schema `s` in namespace `n`.
 - Object-level restore and replicate **vbr** tasks let you specify a target namespace with the `--target-namespace` argument. This is the namespace to which the objects are restored or replicated.
- vbr** behaves differently depending on whether the target namespace exists:
- **Exists:** **vbr** attempts to restore or replicate the objects to the existing namespace, which must have the same shard count, shard boundaries, and node subscriptions as the source namespace. If these conditions are not met, the **vbr** task fails.
 - **Nonexistent:** **vbr** creates a namespace in the target database with the name specified in `--target-namespace` and the shard count of the source namespace, and then replicates or restores the objects to that namespace.

If no target namespace is specified, **vbr** attempts to restore or replicate objects to a namespace with the same name as the source namespace.

For details, see [Eon Mode database requirements](#).

[Server-based replication](#) also supports namespaces. The source and target namespaces of the replicated tables must have the same shard count and segmentation. The `REPLICATE` command accepts an optional target namespace parameter that specifies the namespace to which the tables are replicated in the target cluster. If you do not specify a target namespace, objects are replicated to a namespace with the same name as the source namespace. If no such namespace exists in the target cluster, it is created with the same name and shard count as the source namespace. For details, see [REPLICATE](#).

Namespace restrictions

Namespaces currently have the following restrictions:

- You can only use the `RESHARD_DATABASE` function to reshard the `default_namespace`. If your database has any non-default namespaces, running the function results in an error.
- You can only create, restore, and replicate flex tables to the `default_namespace`.
- Some third-party libraries do not support namespaces. If your workload relies on one of these libraries, Vertica recommends that you do not use non-default namespaces until the third-party library adds namespace support.

Managing subclusters

Subclusters help you organize the nodes in your clusters to isolate workloads and make elastic scaling easier. See [Subclusters](#) for an overview of how subclusters can help you.

In this section

- [Creating subclusters](#)
- [Duplicating a subcluster](#)
- [Adding and removing nodes from subclusters](#)
- [Managing workloads with subclusters](#)
- [Starting and stopping subclusters](#)
- [Altering subcluster settings](#)
- [Removing subclusters](#)

Creating subclusters

By default, new Eon Mode databases contain a single primary subcluster named `default_subcluster`. This subcluster contains all nodes that are part of the database when you create it. You will often want to create subclusters to separate and manage workloads. You have three options to add subclusters to the database:

- [Use the admintools command line to add a new subcluster from nodes in the database cluster](#)
- [Use admintools to create a duplicate of an existing subcluster](#)
- [Use the Management Console to provision and create a subcluster](#)

Create a subcluster using admintools

To create a subcluster, use the admintools `db_add_subcluster` tool:

```
$ admintools -t db_add_subcluster --help
Usage: db_add_subcluster [options]

Options:
-h, --help          show this help message and exit
-d DB, --database=DB Name of database to be modified
-s HOSTS, --hosts=HOSTS
                    Comma separated list of hosts to add to the subcluster
-p DBPASSWORD, --password=DBPASSWORD
                    Database password in single quotes
-c SCNAME, --subcluster=SCNAME
                    Name of the new subcluster for the new node
--is-primary        Create primary subcluster
--is-secondary      Create secondary subcluster
--control-set-size=CONTROLSETSIZE
                    Set the number of nodes that will run spread within
                    the subcluster
--like=CLONESUBCLUSTER
                    Name of an existing subcluster from which to clone
                    properties for the new subcluster
--timeout=NONINTERACTIVE_TIMEOUT
                    set a timeout (in seconds) to wait for actions to
                    complete ('never') will wait forever (implicitly sets
                    -i)
-i, --noprompts     do not stop and wait for user input(default false).
                    Setting this implies a timeout of 20 min.
```

The simplest command adds an empty subcluster. It requires the database name, password, and name for the new subcluster. This example adds a subcluster `analytics_cluster` to the `verticadb` database:

```
$ adminTools -t db_add_subcluster -d verticadb -p 'password' -c analytics_cluster
Creating new subcluster 'analytics_cluster'
Subcluster added to verticadb successfully.
```

By default, admintools creates the subcluster as a [secondary subcluster](#). You can have it create a [primary subcluster](#) instead by supplying the `--is-primary` argument.

Adding nodes while creating a subcluster

You can also specify one or more hosts for admintools to add to the subcluster as new nodes. These hosts must be part of the cluster but not already part of the database. For example, you can use hosts that you added to the cluster using the MC or admintools, or hosts that remain part of the cluster after you dropped nodes from the database. This example creates a subcluster `analytics_cluster` and uses the `-s` option to specify the available hosts in the cluster:

```
$ adminTools -t db_add_subcluster -c analytics_cluster -d verticadb -p 'password' -s 10.0.33.77,10.0.33.181,10.0.33.85
```

View the subscription status of all nodes in the database with the following query that joins the [V_CATALOG.NODES](#) and [V_CATALOG.NODE_SUBSCRIPTIONS](#) system tables:

```
=> SELECT subcluster_name, n.node_name, shard_name, subscription_state FROM
  v_catalog.nodes n LEFT JOIN v_catalog.node_subscriptions ns ON (n.node_name
  = ns.node_name) ORDER BY 1,2,3;
```

subcluster_name	node_name	shard_name	subscription_state
analytics_cluster	v_verticadb_node0004	replica	ACTIVE
analytics_cluster	v_verticadb_node0004	segment0001	ACTIVE
analytics_cluster	v_verticadb_node0004	segment0003	ACTIVE
analytics_cluster	v_verticadb_node0005	replica	ACTIVE
analytics_cluster	v_verticadb_node0005	segment0001	ACTIVE
analytics_cluster	v_verticadb_node0005	segment0002	ACTIVE
analytics_cluster	v_verticadb_node0006	replica	ACTIVE
analytics_cluster	v_verticadb_node0006	segment0002	ACTIVE
analytics_cluster	v_verticadb_node0006	segment0003	ACTIVE
default_subcluster	v_verticadb_node0001	replica	ACTIVE
default_subcluster	v_verticadb_node0001	segment0001	ACTIVE
default_subcluster	v_verticadb_node0001	segment0003	ACTIVE
default_subcluster	v_verticadb_node0002	replica	ACTIVE
default_subcluster	v_verticadb_node0002	segment0001	ACTIVE
default_subcluster	v_verticadb_node0002	segment0002	ACTIVE
default_subcluster	v_verticadb_node0003	replica	ACTIVE
default_subcluster	v_verticadb_node0003	segment0002	ACTIVE
default_subcluster	v_verticadb_node0003	segment0003	ACTIVE

(18 rows)

If you do not include hosts when you create the subcluster, you must manually rebalance the shards in the subcluster when you add nodes at a later time. For more information, see [Updating Shard Subscriptions After Adding Nodes](#).

Subclusters and large cluster

Vertica has a feature named large cluster that helps manage broadcast messages as the database cluster grows. It has several impacts on adding new subclusters:

- If you create a subcluster with 16 or more nodes, Vertica automatically enables the large cluster feature. It sets the number of [control nodes](#) to the square root of the number of nodes in the subcluster. See [Planning a large cluster](#).
- You can set the number of control nodes in a subcluster by using the `--control-set-size` option in the admintools command line.
- If the database cluster has 120 control nodes, Vertica returns an error if you try to add a new subcluster. Every subcluster must have at least one control node. The database cannot have more than 120 control nodes. When the database reaches this limit, you must reduce the number of control nodes in other subclusters before you can add a new subcluster. See [Changing the number of control nodes and realigning](#) for more information.
- If you attempt to create a subcluster with a number of control nodes that would exceed the 120 control node limit, Vertica warns you and creates the subcluster with fewer control nodes. It adds as many control nodes as it can to the subcluster, which is 120 minus the current count of control nodes in the cluster. For example, suppose you create a 16-node subcluster in a database cluster that already has 118 control nodes. In this case, Vertica warns you and creates the subcluster with just 2 control nodes rather than the default 4.

See [Large cluster](#) for more information about the large cluster feature.

Duplicating a subcluster

Subclusters have many settings you can tune to get them to work just the way you want. After you have tuned a subcluster, you may want additional subclusters that are configured the same way. For example, suppose you have a subcluster that you have tuned to perform analytics workloads. To improve query throughput, you can create several more subclusters configured exactly like it. Instead of creating the new subclusters and then manually configuring them from scratch, you can duplicate the existing subcluster (called the source subcluster) to a new subcluster (the target subcluster).

When you create a new subcluster based on another subcluster, Vertica copies most of the source subcluster's settings. See below for a list of the settings that Vertica copies. These settings are both on the node level and the subcluster level.

Note

After you duplicate a subcluster, the target is not connected to the source in any way. Any changes you make to the source subcluster's settings after duplication are not copied to the target. The subclusters are completely independent after duplication.

Requirements for the target subcluster

You must have a set of hosts in your database cluster that you will use as the target of the subcluster duplication. Vertica forms these hosts into a target subcluster that receives most of the settings of the source subcluster. The hosts for the target subcluster must meet the following requirements:

- They must be part of your database cluster but not part of your database. For example, you can use hosts you have dropped from a subcluster or whose subcluster you have removed. Vertica returns an error if you attempt to duplicate a subcluster onto one or more nodes that are currently participating in the database.

Tip

If you want to duplicate the settings of a subcluster to another subcluster, remove the target subcluster (see [Removing subclusters](#)). Then duplicate the source subcluster onto the hosts of the now-removed target subcluster.

- The number of nodes you supply for the target subcluster must equal the number of nodes in the source subcluster. When duplicating the subcluster, Vertica performs a 1:1 copy of some node-level settings from each node in the source subcluster to a corresponding node in the target.
- The RAM and disk allocation for the hosts in the target subcluster should be at least the same as the source nodes. Technically, your target nodes can have less RAM or disk space than the source nodes. However, you will usually see performance issues in the new subcluster because the settings of the original subcluster will not be tuned for the resources of the target subcluster.

You can duplicate a subcluster even if some of the nodes in the source subcluster or hosts in the target are down. If nodes in the target are down, they use the catalog Vertica copied from the source node when they recover.

Duplication of subcluster-level settings

The following table lists the subcluster-level settings that Vertica copies from the source subcluster to the target.

Setting Type	Setting Details
Basic subcluster settings	Whether the subcluster is a primary or secondary subcluster .
Large cluster settings	The number of control nodes in the subcluster.

Resource pool settings	<p>Vertica creates a new resource pool for every subcluster-specific resource pool in the source subcluster.</p> <div style="background-color: #e1f5fe; padding: 10px; border: 1px solid #cfe2f3;"> <p>Note Duplicating a subcluster can fail due to subcluster-specific resource pools. If creating the subcluster-specific resource pools leave less than 25% of the total memory free for the general pool, Vertica stops the duplication and reports an error.</p> </div> <p>Subcluster-specific resource pool cascade settings are copied from the source subcluster and are applied to the newly-created resource pool for the target subcluster.</p> <p>Subcluster-level overrides on global resource pools settings such as MEMORYSIZE. See Managing workload resources in an Eon Mode database for more information.</p> <p>Grants on resource pools are copied from the source subcluster.</p>
Connection load balancing settings	<p>If the source subcluster is part of a subcluster-based load balancing group (you created the load balancing group using CREATE LOAD BALANCE GROUP...WITH SUBCLUSTER) the new subcluster is added to the group. See Creating Connection Load Balance Groups.</p> <p>Important Vertica adds the new subcluster to the subcluster-based load balancing group. However, it does not create network addresses for the nodes in the target subcluster. Load balancing policies cannot direct connections to the new subcluster until you create network addresses for the nodes in the target subcluster. See Creating network addresses for the steps you must take.</p>
Storage policy settings	<p>Table and table partition pinning policies are copied from the source to the target subcluster. See Pinning Depot Objects for more information. Any existing storage policies on the target subcluster are dropped before the policies are copied from the source.</p>

Vertica **does not** copy the following subcluster settings:

Setting Type	Setting Details
Basic subcluster settings	<ul style="list-style-type: none"> Subcluster name (you must provide a new name for the target subcluster). If the source is the default subcluster, the setting is not copied to the target. Your Vertica database has a single default subcluster. If Vertica copied this value, the source subcluster could no longer be the default.
Connection load balancing settings	<p>Address-based load balancing groups are not duplicated for the target subcluster.</p> <p>For example, suppose you created a load balancing group for the source subcluster by adding the network addresses of all subcluster's nodes. In this case, Vertica does not create a load balancing group for the target subcluster because it does not duplicate the network addresses of the source nodes (see the next section). Because it does not copy the addresses, it cannot not create an address-based group.</p>

Duplication of node-level settings

When Vertica duplicates a subcluster, it maps each node in the source subcluster to a node in the destination subcluster. Then it copies relevant node-level settings from each individual source node to the corresponding target node.

For example, suppose you have a three-node subcluster consisting of nodes named node01, node02, and node03. The target subcluster has nodes named node04, node05, and node06. In this case, Vertica copies the settings from node01 to node04, from node02 to node05, and from node03 to node06.

The node-level settings that Vertica copies from the source nodes to the target nodes are:

Setting Type	Setting Details
--------------	-----------------

Configuration parameters	<p>Vertica copies the value of configuration parameters that you have set at the node level in the source node to the target node. For example, suppose you set <code>CompressCatalogOnDisk</code> on the source node using the statement:</p> <pre>ALTER NODE node01 SET CompressCatalogOnDisk = 0;</pre> <p>If you then duplicated the subcluster containing node01, the setting is copied to the target node.</p>
Eon Mode settings	<ul style="list-style-type: none"> • Shard subscriptions are copied from the source node to the target. • Whether the node is the participating primary node for the shard.
Storage location settings	<p>The DATA, TEMP, DEPOT, and USER storage location paths on the source node are duplicated on the target node. When duplicating node-specific paths (such as DATA or DEPOT) the path names are adjusted for the new node name. For example, suppose node 1 has a depot path of <code>/vertica/depot/vmart/v_vmart_node0001_depot</code> . If Vertica duplicates node 1 to node 4, it adjusts the path to <code>/vertica/depot/vmart/v_vmart_node0004_depot</code> .</p> <p>Important The directories for these storage locations on the target node must be empty. They must also have the correct file permissions to allow Vertica to read and write to them.</p> <p>Vertica does not duplicate a storage location if it cannot access its directory on the target node or if the directory is not empty. In this case, the target node will not have the location defined after the duplication process finishes. Admintools does not warn you if any locations were not duplicated.</p> <p>If you find that storage locations have not been duplicated on one or more target nodes, you must fix the issues with the directories on the target nodes. Then re-run the duplication command.</p>
Large cluster settings	<p>Control node assignments are copied from the source node to the target node:</p> <ul style="list-style-type: none"> • If the source node is a control node, then the target node is made into a control node. • If the source node depends on a control node, then the target node becomes a dependent of the corresponding control node in the new subcluster.

Vertica **does not** copy the following node-level settings:

Setting Type	Setting Details
Connection load balancing settings	Network Addresses are not copied. The destination node's network addresses do not depend on the settings of the source node. Therefore, Vertica cannot determine what the target node's addresses should be.
Depot settings	Depot-related configuration parameters that can be set on a node level (such as <code>FileDeletionServiceInterval</code>) are not copied from the source node to the target node.

Using admintools to duplicate a subcluster

To duplicate a subcluster, you use the same admintools `db_add_subcluster` tool that you use to create a new subcluster (see [Creating subclusters](#)). In addition to the required options to create a subcluster (the list of hosts, name for the new subcluster, database name, and so on), you also pass the `--like` option with the name of the source subcluster you want to duplicate.

Important

When you use the `--like` option, you cannot use the `--is-secondary` or `--control-set-size` options. Vertica determines whether the new subcluster is secondary and the number of control nodes it contains based on the source subcluster. If you supply these options along with the `--like` option, admintools returns an error.

The following examples demonstrate duplicating a three-node subcluster named `analytics_1`. The first example examines some of the settings in the `analytics_1` subcluster:

- An override of the global TM resource pool's memory size.
- Its own resource pool named analytics
- Its membership in a subcluster-based load balancing group named analytics

```
=> SELECT name, subcluster_name, memorysize FROM SUBCLUSTER_RESOURCE_POOL_OVERRIDES;
name | subcluster_name | memorysize
-----+-----+-----
tm | analytics_1 | 0%
(1 row)

=> SELECT name, subcluster_name, memorysize, plannedconcurrency
       FROM resource_pools WHERE subcluster_name IS NOT NULL;
name | subcluster_name | memorysize | plannedconcurrency
-----+-----+-----+-----
analytics_pool | analytics_1 | 70% | 8
(1 row)

=> SELECT * FROM LOAD_BALANCE_GROUPS;
name | policy | filter | type | object_name
-----+-----+-----+-----+-----
analytics | ROUNDROBIN | 0.0.0.0/0 | Subcluster | analytics_1
(1 row)
```

The following example calls admintool's `db_add_subcluster` tool to duplicate the `analytics_1` subcluster onto a set of three hosts to create a subcluster named `analytics_2`.

```
$ admintools -t db_add_subcluster -d verticadb \  
-s 10.11.12.13,10.11.12.14,10.11.12.15 \  
-p mypassword --like=analytics_1 -c analytics_2
```

Creating new subcluster 'analytics_2'

Adding new hosts to 'analytics_2'

Eon database detected, creating new depot locations for newly added nodes

Creating depot locations for 1 nodes

Warning when creating depot location for node: v_verticadb_node0007

WARNING: Target node v_verticadb_node0007 is down, so depot size has been estimated from depot location on initiator. As soon as the node comes up, its depot size might be altered depending on its disk size

Eon database detected, creating new depot locations for newly added nodes

Creating depot locations for 1 nodes

Warning when creating depot location for node: v_verticadb_node0008

WARNING: Target node v_verticadb_node0008 is down, so depot size has been estimated from depot location on initiator. As soon as the node comes up, its depot size might be altered depending on its disk size

Eon database detected, creating new depot locations for newly added nodes

Creating depot locations for 1 nodes

Warning when creating depot location for node: v_verticadb_node0009

WARNING: Target node v_verticadb_node0009 is down, so depot size has been estimated from depot location on initiator. As soon as the node comes up, its depot size might be altered depending on its disk size

Cloning subcluster properties

NOTICE: Nodes in subcluster analytics_1 have network addresses, you might need to configure network addresses for nodes in subcluster analytics_2 in order to get load balance groups to work correctly.

Replicating configuration to all nodes

Generating new configuration information and reloading spread

Starting nodes:

v_verticadb_node0007 (10.11.12.81)

v_verticadb_node0008 (10.11.12.209)

v_verticadb_node0009 (10.11.12.186)

Starting Vertica on all nodes. Please wait, databases with a large catalog may take a while to initialize.

Checking database state for newly added nodes

Node Status: v_verticadb_node0007: (DOWN) v_verticadb_node0008: (DOWN) v_verticadb_node0009: (DOWN)

Node Status: v_verticadb_node0007: (INITIALIZING) v_verticadb_node0008: (INITIALIZING) v_verticadb_node0009: (INITIALIZING)

Node Status: v_verticadb_node0007: (UP) v_verticadb_node0008: (UP) v_verticadb_node0009: (UP)

Syncing catalog on verticadb with 2000 attempts.

Multi-node DB add completed

Nodes added to subcluster analytics_2 successfully.

Subcluster added to verticadb successfully.

Re-running the queries in the first part of the example shows that the settings from analytics_1 have been duplicated in analytics_2:

```

=> SELECT name, subcluster_name, memorysize FROM SUBCLUSTER_RESOURCE_POOL_OVERRIDES;
name | subcluster_name | memorysize
-----+-----+-----
tm | analytics_1 | 0%
tm | analytics_2 | 0%
(2 rows)

=> SELECT name, subcluster_name, memorysize, plannedconcurrency
FROM resource_pools WHERE subcluster_name IS NOT NULL;
name | subcluster_name | memorysize | plannedconcurrency
-----+-----+-----+-----
analytics_pool | analytics_1 | 70% | 8
analytics_pool | analytics_2 | 70% | 8
(2 rows)

=> SELECT * FROM LOAD_BALANCE_GROUPS;
name | policy | filter | type | object_name
-----+-----+-----+-----+-----
analytics | ROUNDROBIN | 0.0.0.0/0 | Subcluster | analytics_2
analytics | ROUNDROBIN | 0.0.0.0/0 | Subcluster | analytics_1
(2 rows)

```

As noted earlier, even though analytics_2 subcluster is part of the analytics load balancing group, its nodes do not have network addresses defined for them. Until you define network addresses for the nodes, Vertica cannot redirect client connections to them.

Adding and removing nodes from subclusters

You will often want to add new nodes to and remove existing nodes from a subcluster. This ability lets you scale your database to respond to changing analytic needs. For more information on how adding nodes to a subcluster affects your database's performance, see [Scaling your Eon Mode database](#).

Adding new nodes to a subcluster

You can add nodes to a subcluster to meet additional workloads. The nodes that you add to the subcluster must already be part of your cluster. These can be:

- Nodes that you removed from other subclusters.
- Nodes you added following the steps in [Add nodes to a cluster in AWS using Management Console](#).
- Nodes you created using your cloud provider's interface, such as the AWS EC2 "Launch more like this" feature.

To add new nodes to a subcluster, use the `db_add_node` command of admintools:

```
$ adminTools -t db_add_node -h
```

```
Usage: db_add_node [options]
```

Options:

```
-h, --help          show this help message and exit
-d DB, --database=DB  Name of the database
-s HOSTS, --hosts=HOSTS
                    Comma separated list of hosts to add to database
-p DBPASSWORD, --password=DBPASSWORD
                    Database password in single quotes
-a AHOSTS, --add=AHOSTS
                    Comma separated list of hosts to add to database
-c SCNAME, --subcluster=SCNAME
                    Name of subcluster for the new node
--timeout=NONINTERACTIVE_TIMEOUT
                    set a timeout (in seconds) to wait for actions to
                    complete ('never') will wait forever (implicitly sets
                    -i)
-i, --noprompts     do not stop and wait for user input(default false).
                    Setting this implies a timeout of 20 min.
--compat21         (deprecated) Use Vertica 2.1 method using node names
                    instead of hostnames
```

If you do not use the `-c` option, Vertica adds new nodes to the [default subcluster](#) (set to `default_subcluster` in new databases). This example adds a new node without specifying the subcluster:

```
$ adminTools -t db_add_node -p 'password' -d verticadb -s 10.11.12.117
```

```
Subcluster not specified, validating default subcluster
```

```
Nodes will be added to subcluster 'default_subcluster'
```

```
    Verifying database connectivity...10.11.12.10
```

```
Eon database detected, creating new depot locations for newly added nodes
```

```
Creating depots for each node
```

```
    Generating new configuration information and reloading spread
```

```
    Replicating configuration to all nodes
```

```
    Starting nodes
```

```
    Starting nodes:
```

```
        v_verticadb_node0004 (10.11.12.117)
```

```
    Starting Vertica on all nodes. Please wait, databases with a

    Multi-node DB add completed
```

```
Nodes added to verticadb successfully.
```

```
You will need to redesign your schema to take advantage of the new nodes.
```

To add nodes to a specific existing subcluster, use the `db_add_node` tool's `-c` option:

```
$ adminTools -t db_add_node -s 10.11.12.178 -d verticadb -p 'password' \
-c analytics_subcluster
Subcluster 'analytics_subcluster' specified, validating
Nodes will be added to subcluster 'analytics_subcluster'
    Verifying database connectivity...10.11.12.10
Eon database detected, creating new depot locations for newly added nodes
Creating depots for each node
    Generating new configuration information and reloading spread
    Replicating configuration to all nodes
    Starting nodes
    Starting nodes:
        v_verticadb_node0007 (10.11.12.178)
    Starting Vertica on all nodes. Please wait, databases with a
        large catalog may take a while to initialize.
    Checking database state

    Node Status: v_verticadb_node0007: (DOWN)
    Node Status: v_verticadb_node0007: (DOWN)
    Node Status: v_verticadb_node0007: (DOWN)
    Node Status: v_verticadb_node0007: (UP)
Communal storage detected: syncing catalog

    Multi-node DB add completed
Nodes added to verticadb successfully.
You will need to redesign your schema to take advantage of the new nodes.
```

Updating shard subscriptions after adding nodes

After you add nodes to a subcluster they do not yet subscribe to shards. You can view the subscription status of all nodes in your database using the following query that joins the [V_CATALOG.NODES](#) and [V_CATALOG.NODE_SUBSCRIPTIONS](#) system tables:

```
=> SELECT subcluster_name, n.node_name, shard_name, subscription_state FROM
v_catalog.nodes n LEFT JOIN v_catalog.node_subscriptions ns ON (n.node_name
= ns.node_name) ORDER BY 1,2,3;
```

subcluster_name	node_name	shard_name	subscription_state
analytics_subcluster	v_verticadb_node0004		
analytics_subcluster	v_verticadb_node0005		
analytics_subcluster	v_verticadb_node0006		
default_subcluster	v_verticadb_node0001	replica	ACTIVE
default_subcluster	v_verticadb_node0001	segment0001	ACTIVE
default_subcluster	v_verticadb_node0001	segment0003	ACTIVE
default_subcluster	v_verticadb_node0002	replica	ACTIVE
default_subcluster	v_verticadb_node0002	segment0001	ACTIVE
default_subcluster	v_verticadb_node0002	segment0002	ACTIVE
default_subcluster	v_verticadb_node0003	replica	ACTIVE
default_subcluster	v_verticadb_node0003	segment0002	ACTIVE
default_subcluster	v_verticadb_node0003	segment0003	ACTIVE

(12 rows)

You can see that none of the nodes in the newly-added analytics_subcluster have subscriptions.

To update the subscriptions for new nodes, call the [REBALANCE_SHARDS](#) function. You can limit the rebalance to the subcluster containing the new nodes by passing its name to the REBALANCE_SHARDS function call. The following example runs rebalance shards to update the analytics_subcluster's subscriptions:

```
=> SELECT REBALANCE_SHARDS('analytics_subcluster');
REBALANCE_SHARDS
-----
REBALANCED SHARDS
(1 row)

=> SELECT subcluster_name, n.node_name, shard_name, subscription_state FROM
v_catalog.nodes n LEFT JOIN v_catalog.node_subscriptions ns ON (n.node_name
= ns.node_name) ORDER BY 1,2,3;

subcluster_name | node_name | shard_name | subscription_state
-----+-----+-----+-----
analytics_subcluster | v_verticadb_node0004 | replica | ACTIVE
analytics_subcluster | v_verticadb_node0004 | segment0001 | ACTIVE
analytics_subcluster | v_verticadb_node0004 | segment0003 | ACTIVE
analytics_subcluster | v_verticadb_node0005 | replica | ACTIVE
analytics_subcluster | v_verticadb_node0005 | segment0001 | ACTIVE
analytics_subcluster | v_verticadb_node0005 | segment0002 | ACTIVE
analytics_subcluster | v_verticadb_node0006 | replica | ACTIVE
analytics_subcluster | v_verticadb_node0006 | segment0002 | ACTIVE
analytics_subcluster | v_verticadb_node0006 | segment0003 | ACTIVE
default_subcluster | v_verticadb_node0001 | replica | ACTIVE
default_subcluster | v_verticadb_node0001 | segment0001 | ACTIVE
default_subcluster | v_verticadb_node0001 | segment0003 | ACTIVE
default_subcluster | v_verticadb_node0002 | replica | ACTIVE
default_subcluster | v_verticadb_node0002 | segment0001 | ACTIVE
default_subcluster | v_verticadb_node0002 | segment0002 | ACTIVE
default_subcluster | v_verticadb_node0003 | replica | ACTIVE
default_subcluster | v_verticadb_node0003 | segment0002 | ACTIVE
default_subcluster | v_verticadb_node0003 | segment0003 | ACTIVE
(18 rows)
```

Removing nodes

Your database must meet these requirements before you can remove a node from a subcluster:

- To remove a node from a [primary subcluster](#), all of the [primary nodes](#) in the subcluster must be up, and the database must be able to maintain quorum after the primary node is removed (see [Data integrity and high availability in an Eon Mode database](#)). These requirements are necessary because Vertica calls [REBALANCE_SHARDS](#) to redistribute shard subscriptions among the remaining nodes in the subcluster. If you attempt to remove a primary node when the database does not meet the requirements, the rebalance shards process waits until either the down nodes recover or a timeout elapses. While it waits, you periodically see a message "Rebalance shards polling iteration number [*nn*]" indicating that the rebalance process is waiting to complete.

You can remove nodes from a [secondary subcluster](#) even when nodes in the subcluster are down.

- If your database has the large cluster feature enabled, you cannot remove a node if it is the subcluster's last [control node](#) and there are nodes that depend on it. See [Large cluster](#) for more information.

If there are other control nodes in the subcluster, you can drop a control node. Vertica reassigns the nodes that depend on the node being dropped to other control nodes.

To remove one or more nodes, use admintools's [db_remove_node](#) tool:

```

$ adminTools -t db_remove_node -p 'password' -d verticadb -s 10.11.12.117
connecting to 10.11.12.10
Waiting for rebalance shards. We will wait for at most 36000 seconds.
Rebalance shards polling iteration number [0], started at [14:56:41], time out at [00:56:41]
Attempting to drop node v_verticadb_node0004 ( 10.11.12.117 )
  Shutting down node v_verticadb_node0004
  Sending node shutdown command to '['v_verticadb_node0004', '10.11.12.117', '/vertica/data', '/vertica/data']'
  Deleting catalog and data directories
  Update admintools metadata for v_verticadb_node0004
  Eon mode detected. The node v_verticadb_node0004 has been removed from host 10.11.12.117. To remove the
  node metadata completely, please clean up the files corresponding to this node, at the communal
  location: s3://eonbucket/metadata/verticadb/nodes/v_verticadb_node0004
  Reload spread configuration
  Replicating configuration to all nodes
  Checking database state
  Node Status: v_verticadb_node0001: (UP) v_verticadb_node0002: (UP) v_verticadb_node0003: (UP)
Communal storage detected: syncing catalog

```

When you remove one or more nodes from a subcluster, Vertica automatically rebalances shards in the subcluster. You do not need to manually rebalance shards after removing nodes.

Moving nodes between subclusters

To move a node from one subcluster to another:

1. Remove the node or nodes from the subcluster it is currently a part of.
2. Add the node to the subcluster you want to move it to.

Managing workloads with subclusters

By default, queries are limited to executing on the nodes in the subcluster that contains the initiator node (the node the client is connected to). This example demonstrates executing an explain plan for a query when connected to node 4 of a cluster. Node 4 is part of a subcluster containing nodes 4 through 6. You can see that only the nodes in the subcluster will participate in a query:

```

=> EXPLAIN SELECT customer_name, customer_state FROM customer_dimension LIMIT 10;

          QUERY PLAN
-----
QUERY PLAN DESCRIPTION:
-----
EXPLAIN SELECT customer_name, customer_state FROM customer_dimension LIMIT 10;

Access Path:
+-SELECT LIMIT 10 [Cost: 442, Rows: 10 (NO STATISTICS)] (PATH ID: 0)
| Output Only: 10 tuples
| Execute on: Query Initiator
| +----> STORAGE ACCESS for customer_dimension [Cost: 442, Rows: 10K (NO
| STATISTICS)] (PATH ID: 1)
|| Projection: public.customer_dimension_b0
|| Materialize: customer_dimension.customer_name,
|| customer_dimension.customer_state
|| Output Only: 10 tuples
|| Execute on: v_verticadb_node0004, v_verticadb_node0005,
|| v_verticadb_node0006
. . .

```

In Eon Mode, you can override the [MEMORYSIZE](#) , [MAXMEMORYSIZE](#) , and [MAXQUERYMEMORYSIZE](#) settings for built-in global resource pools to fine-tune workloads within a subcluster. See [Managing workload resources in an Eon Mode database](#) for more information.

What happens when a subcluster cannot run a query

In order to process queries, each subcluster's nodes must have full coverage of all shards in the database. If the nodes do not have full coverage (which can happen if nodes are down), the subcluster can no longer process queries. This state does not cause the subcluster to shut down. Instead, if you attempt to run a query on a subcluster in this state, you receive error messages telling you that not enough nodes are available to complete the query.

```
=> SELECT node_name, node_state FROM nodes
WHERE subcluster_name = 'analytics_cluster';
 node_name | node_state
-----+-----
v_verticadb_node0004 | DOWN
v_verticadb_node0005 | UP
v_verticadb_node0006 | DOWN
(3 rows)

=> SELECT * FROM online_sales.online_sales_fact;
ERROR 9099: Cannot find participating nodes to run the query
```

Once the down nodes have recovered and the subcluster has full shard coverage, it will be able to process queries.

Controlling where a query runs

You can control where specific types of queries run by controlling which subcluster the clients connect to. The best way to enforce restrictions is to create a set of connection load balancing policies to steer clients from specific IP address ranges to clients in the correct subcluster.

For example, suppose you have the following database with two subclusters: one for performing data loading, and one for performing analytics.

The data load tasks come from a set of ETL systems in the IP 10.20.0.0/16 address range. Analytics tasks can come from any other IP address. In this case, you can create set of connection load balance policies that ensure that the ETL systems connect to the data load subcluster, and all other connections go to the analytics subcluster.

```

=> SELECT node_name,node_address,node_address_family,subcluster_name
FROM v_catalog.nodes;
node_name | node_address | node_address_family | subcluster_name
-----+-----+-----+-----
v_verticadb_node0001 | 10.11.12.10 | ipv4 | load_subcluster
v_verticadb_node0002 | 10.11.12.20 | ipv4 | load_subcluster
v_verticadb_node0003 | 10.11.12.30 | ipv4 | load_subcluster
v_verticadb_node0004 | 10.11.12.40 | ipv4 | analytics_subcluster
v_verticadb_node0005 | 10.11.12.50 | ipv4 | analytics_subcluster
v_verticadb_node0006 | 10.11.12.60 | ipv4 | analytics_subcluster
(6 rows)

```

```

=> CREATE NETWORK ADDRESS node01 ON v_verticadb_node0001 WITH '10.11.12.10';
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS node02 ON v_verticadb_node0002 WITH '10.11.12.20';
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS node03 ON v_verticadb_node0003 WITH '10.11.12.30';
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS node04 ON v_verticadb_node0004 WITH '10.11.12.40';
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS node05 ON v_verticadb_node0005 WITH '10.11.12.50';
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS node06 ON v_verticadb_node0006 WITH '10.11.12.60';
CREATE NETWORK ADDRESS

=> CREATE LOAD BALANCE GROUP load_subcluster WITH SUBCLUSTER load_subcluster
FILTER '0.0.0.0/0';
CREATE LOAD BALANCE GROUP
=> CREATE LOAD BALANCE GROUP analytics_subcluster WITH SUBCLUSTER
analytics_subcluster FILTER '0.0.0.0/0';
CREATE LOAD BALANCE GROUP

```

```

=> CREATE ROUTING RULE etl_systems ROUTE '10.20.0.0/16' TO load_subcluster;
CREATE ROUTING RULE
=> CREATE ROUTING RULE analytic_clients ROUTE '0.0.0.0/0' TO analytics_subcluster;
CREATE ROUTING RULE

```

Once you have created the load balance policies, you can test them using the [DESCRIBE_LOAD_BALANCE_DECISION](#) function.

```
=> SELECT describe_load_balance_decision('192.168.1.1');

      describe_load_balance_decision
-----
Describing load balance decision for address [192.168.1.1]
Load balance cache internal version id (node-local): [1]
Considered rule [etl_systems] source ip filter [10.20.0.0/16]...
  input address does not match source ip filter for this rule.
Considered rule [analytic_clients] source ip filter [0.0.0.0/0]...
  input address matches this rule
Matched to load balance group [analytics_cluster] the group has
  policy [ROUNDROBIN] number of addresses [3]
(0) LB Address: [10.11.12.181]:5433
(1) LB Address: [10.11.12.205]:5433
(2) LB Address: [10.11.12.192]:5433
Chose address at position [1]
Routing table decision: Success. Load balance redirect to: [10.11.12.205]
  port [5433]

(1 row)
```

```
=> SELECT describe_load_balance_decision('10.20.1.1');

      describe_load_balance_decision
-----
Describing load balance decision for address [10.20.1.1]
Load balance cache internal version id (node-local): [1]
Considered rule [etl_systems] source ip filter [10.20.0.0/16]...
  input address matches this rule
Matched to load balance group [default_cluster] the group has policy
  [ROUNDROBIN] number of addresses [3]
(0) LB Address: [10.11.12.10]:5433
(1) LB Address: [10.11.12.20]:5433
(2) LB Address: [10.11.12.30]:5433
Chose address at position [1]
Routing table decision: Success. Load balance redirect to: [10.11.12.20]
  port [5433]

(1 row)
```

Normally, with these policies, all queries run by the ETL system will run on the load subcluster. All other queries will run on the analytics subcluster. There are some cases (especially if a subcluster is down or draining) where a client may connect to a node in another subcluster. For this reason, clients should always verify they are connected to the correct subcluster. See [Connection load balancing policies](#) for more information about load balancing policies.

Starting and stopping subclusters

Subclusters make it convenient to start and stop a group of nodes as needed. You start and stop them with admintools commands or Vertica functions. You can also [start and stop subclusters with Management Console](#).

Starting a subcluster

To start a subcluster, use the admintools command `restart_subcluster` :

```
$ adminTools -t restart_subcluster -h
```

```
Usage: restart_subcluster [options]
```

Options:

```
-h, --help          show this help message and exit
-d DB, --database=DB Name of database whose subcluster is to be restarted
-c SCNAME, --subcluster=SCNAME
                    Name of subcluster to be restarted
-p DBPASSWORD, --password=DBPASSWORD
                    Database password in single quotes
--timeout=NONINTERACTIVE_TIMEOUT
                    set a timeout (in seconds) to wait for actions to
                    complete ('never') will wait forever (implicitly sets
                    -i)
-i, --noprompts     do not stop and wait for user input(default false).
                    Setting this implies a timeout of 20 min.
-F, --force         Force the nodes in the subcluster to start and auto
                    recover if necessary
```

This example starts the subcluster [analytics_cluster](#) :

```
$ adminTools -t restart_subcluster -c analytics_cluster \
```

```
-d verticadb -p password
```

```
*** Restarting subcluster for database verticadb ***
```

```
Restarting host [10.11.12.192] with catalog [v_verticadb_node0006_catalog]
```

```
Restarting host [10.11.12.181] with catalog [v_verticadb_node0004_catalog]
```

```
Restarting host [10.11.12.205] with catalog [v_verticadb_node0005_catalog]
```

```
Issuing multi-node restart
```

```
Starting nodes:
```

```
    v_verticadb_node0004 (10.11.12.181)
```

```
    v_verticadb_node0005 (10.11.12.205)
```

```
    v_verticadb_node0006 (10.11.12.192)
```

```
Starting Vertica on all nodes. Please wait, databases with a large
catalog may take a while to initialize.
```

```

```

```
Communal storage detected: syncing catalog
```

```
Restart Subcluster result: 1
```

Stopping a subcluster

You can stop a subcluster [gracefully](#) with the function [SHUTDOWN_WITH_DRAIN](#), or [immediately](#) with [SHUTDOWN_SUBCLUSTER](#). You can also shut down subclusters with the admintools command [stop_subcluster](#).

Graceful shutdown

The [SHUTDOWN_WITH_DRAIN](#) function drains a subcluster's client connections before shutting it down. The function first marks all nodes in the specified subcluster as draining. Work from existing user sessions continues on draining nodes, but the nodes refuse new client connections and are excluded from load-balancing operations. A dbadmin user can still connect to draining nodes. For more information about client connection draining, see [Drain client connections](#).

To run the SHUTDOWN_WITH_DRAIN function, you must specify a timeout value. The function's behavior depends on the sign of the timeout value:

- Positive: The nodes drain until either all the existing connections close or the function reaches the runtime limit set by the timeout value. As soon as one of these conditions is met, the function sends a shutdown message to the subcluster and returns.

- Zero: The function immediately closes any active user sessions on the subcluster and then shuts down the subcluster and returns.
- Negative: The function marks the subcluster's nodes as draining and waits to shut down the subcluster until all active user sessions disconnect.

After all nodes in a draining subcluster are down, its nodes are automatically reset to a not draining status.

The following example demonstrates how you can use a positive timeout value to give active user sessions time to finish their work before shutting down the subcluster:

```
=> SELECT node_name, subcluster_name, is_draining, count_client_user_sessions, oldest_session_user FROM draining_status ORDER BY 1;
 node_name | subcluster_name | is_draining | count_client_user_sessions | oldest_session_user
-----+-----+-----+-----+-----
v_verticadb_node0001 | default_subcluster | f | 0 |
v_verticadb_node0002 | default_subcluster | f | 0 |
v_verticadb_node0003 | default_subcluster | f | 0 |
v_verticadb_node0004 | analytics | f | 1 | analyst
v_verticadb_node0005 | analytics | f | 0 |
v_verticadb_node0006 | analytics | f | 0 |
(6 rows)

=> SELECT SHUTDOWN_WITH_DRAIN('analytics', 300);
NOTICE 0: Draining has started on subcluster (analytics)
NOTICE 0: Begin shutdown of subcluster (analytics)
          SHUTDOWN_WITH_DRAIN
-----+-----+-----+-----+-----
Set subcluster (analytics) to draining state
Waited for 3 nodes to drain
Shutdown message sent to subcluster (analytics)
(1 row)
```

You can query the [NODES](#) system table to confirm that the subcluster shut down:

```
=> SELECT subcluster_name, node_name, node_state FROM nodes;
 subcluster_name | node_name | node_state
-----+-----+-----
default_subcluster | v_verticadb_node0001 | UP
default_subcluster | v_verticadb_node0002 | UP
default_subcluster | v_verticadb_node0003 | UP
analytics | v_verticadb_node0004 | DOWN
analytics | v_verticadb_node0005 | DOWN
analytics | v_verticadb_node0006 | DOWN
(6 rows)
```

If you want to see more information about the draining and shutdown events, such as whether all user sessions finished their work before the timeout, you can query the `dc_draining_events` table. In this case, the subcluster still had one active user session when the function reached timeout:

```
=> SELECT event_type, event_type_name, event_description, event_result, event_result_name FROM dc_draining_events;
 event_type | event_type_name | event_description | event_result | event_result_name
-----+-----+-----+-----+-----
0 | START_DRAIN_SUBCLUSTER | START_DRAIN for SHUTDOWN of subcluster (analytics) | 0 | SUCCESS
2 | START_WAIT_FOR_NODE_DRAIN | Wait timeout is 300 seconds | 4 | INFORMATIONAL
4 | INTERVAL_WAIT_FOR_NODE_DRAIN | 1 sessions remain after 0 seconds | 4 | INFORMATIONAL
4 | INTERVAL_WAIT_FOR_NODE_DRAIN | 1 sessions remain after 60 seconds | 4 | INFORMATIONAL
4 | INTERVAL_WAIT_FOR_NODE_DRAIN | 1 sessions remain after 120 seconds | 4 | INFORMATIONAL
4 | INTERVAL_WAIT_FOR_NODE_DRAIN | 1 sessions remain after 125 seconds | 4 | INFORMATIONAL
4 | INTERVAL_WAIT_FOR_NODE_DRAIN | 1 sessions remain after 180 seconds | 4 | INFORMATIONAL
4 | INTERVAL_WAIT_FOR_NODE_DRAIN | 1 sessions remain after 240 seconds | 4 | INFORMATIONAL
4 | INTERVAL_WAIT_FOR_NODE_DRAIN | 1 sessions remain after 250 seconds | 4 | INFORMATIONAL
4 | INTERVAL_WAIT_FOR_NODE_DRAIN | 1 sessions remain after 300 seconds | 4 | INFORMATIONAL
3 | END_WAIT_FOR_NODE_DRAIN | Wait for drain ended with 1 sessions remaining | 2 | TIMEOUT
5 | BEGIN_SHUTDOWN_AFTER_DRAIN | Staring shutdown of subcluster (analytics) following drain | 4 | INFORMATIONAL
(12 rows)
```

After you restart the subcluster, you can query the [DRAINING_STATUS](#) system table to confirm that the nodes have reset their draining statuses to not draining:

```
=> SELECT node_name, subcluster_name, is_draining, count_client_user_sessions, oldest_session_user FROM draining_status ORDER BY 1;
 node_name | subcluster_name | is_draining | count_client_user_sessions | oldest_session_user
-----+-----+-----+-----+-----
v_verticadb_node0001 | default_subcluster | f | 0 |
v_verticadb_node0002 | default_subcluster | f | 0 |
v_verticadb_node0003 | default_subcluster | f | 0 |
v_verticadb_node0004 | analytics | f | 0 |
v_verticadb_node0005 | analytics | f | 0 |
v_verticadb_node0006 | analytics | f | 0 |
(6 rows)
```

Immediate shutdown

To shut down a subcluster immediately, call [SHUTDOWN_SUBCLUSTER](#). The following example shuts down the [analytics](#) subcluster immediately, without checking for active client connections:

```
=> SELECT SHUTDOWN_SUBCLUSTER('analytics');
SHUTDOWN_SUBCLUSTER
-----
Subcluster shutdown
(1 row)
```

admintools

You can use the [stop_subcluster](#) tool to stop a subcluster:

```
$ adminTools -t stop_subcluster -h
Usage: stop_subcluster [options]

Options:
-h, --help          show this help message and exit
-d DB, --database=DB  Name of database whose subcluster is to be stopped
-c SCNAME, --subcluster=SCNAME
                    Name of subcluster to be stopped
-p DBPASSWORD, --password=DBPASSWORD
                    Database password in single quotes
-n DRAIN_SECONDS, --drain-seconds=DRAIN_SECONDS
                    Seconds to wait for user connections to close.
                    Default value is 60 seconds.
                    When the time expires, connections will be forcibly closed
                    and the db will shut down.
-F, --force         Force the subcluster to shutdown immediately,
                    even if users are connected.
--timeout=NONINTERACTIVE_TIMEOUT
                    set a timeout (in seconds) to wait for actions to
                    complete ('never') will wait forever (implicitly sets
                    -i)
-i, --noprompts     do not stop and wait for user input(default false).
                    Setting this implies a timeout of 20 min.
```

By default, [stop_subcluster](#) calls [SHUTDOWN_WITH_DRAIN](#) to [gracefully shut down](#) the target subcluster. The shutdown process drains client connections from the subcluster before shutting it down.

The `-n` (`--drain-seconds`) option, which has a default value of 60 seconds, allows you to specify the number of seconds to wait before forcefully closing client connections and shutting down the subcluster. If you set a negative `-n` value, the subcluster is marked as draining but is not shut down until all active user sessions disconnect.

In the following example, the subcluster named `analytics` initially has an active client session, but the session closes before the timeout limit is reached and the subcluster shuts down:

```
$ admintools -t stop_subcluster -d verticadb -c analytics --password password --drain-seconds 200
--- Subcluster shutdown ---
Verifying subcluster 'analytics'
Node 'v_verticadb_node0004' will shutdown
Node 'v_verticadb_node0005' will shutdown
Node 'v_verticadb_node0006' will shutdown
Connecting to database to begin shutdown of subcluster 'analytics'
Shutdown will use connection draining.
Shutdown will wait for all client sessions to complete, up to 200 seconds
Then it will force a shutdown.
Poller has been running for 0:00:00.000022 seconds since 2022-07-28 12:18:04.891781
```

```
-----
client_sessions |node_count |node_names
-----
0              |5          |v_verticadb_node0002,v_verticadb_node0004,v_verticadb_node0003,v_verticadb_node0...
1              |1          |v_verticadb_node0005

You can use the **-F** (or **--force**) option to shut down a subcluster immediately, without checking for active user sessions or draining the subcluster:

```
$ admintools -t stop_subcluster -d verticadb -c analytics --password password -F
--- Subcluster shutdown ---
Verifying subcluster 'analytics'
Node 'v_verticadb_node0004' will shutdown
Node 'v_verticadb_node0005' will shutdown
Node 'v_verticadb_node0006' will shutdown
Connecting to database to begin shutdown of subcluster 'analytics'
Running shutdown metafunction. Not using connection draining
STATUS: vertica.engine.api.db_client.module is still running on 1 host: 192.168.111.31 as of 2022-07-28 13:13:57. See /opt/vertica/log/adminTools.log for full details.
STATUS: vertica.engine.api.db_client.module is still running on 1 host: 192.168.111.31 as of 2022-07-28 13:14:07. See /opt/vertica/log/adminTools.log for full details.
SUCCESS running the shutdown metafunction
Not waiting for processes to completely exit
Shutdown operation was successful
```

If you want to shut down all subclusters in a database, see [Stopping an Eon Mode Database](#).

Altering subcluster settings

There are several settings you can alter on a subcluster using the [ALTER SUBCLUSTER](#) statement. You can also switch a subcluster from a primary to a secondary subcluster, or from a secondary to a primary.

Renaming a subcluster

To rename an existing subcluster, use the ALTER SUBCLUSTER statement's RENAME TO clause:

```
=> ALTER SUBCLUSTER default_subcluster RENAME TO load_subcluster;
ALTER SUBCLUSTER
```

```
=> SELECT DISTINCT subcluster_name FROM subclusters;
subcluster_name
-----
load_subcluster
analytics_cluster
(2 rows)
```

Changing the default subcluster

The default subcluster designates which subcluster Vertica adds nodes to if you do not explicitly specify a subcluster when adding nodes to the database. When you create a new database (or when a database is upgraded from a version prior to 9.3.0) the default_subcluster is the default. You can find the current default subcluster by querying the `is_default` column of the [SUBCLUSTERS](#) system table.

The following example demonstrates finding the default subcluster, and then changing it to the subcluster named `analytics_cluster`:

```
=> SELECT DISTINCT subcluster_name FROM SUBCLUSTERS WHERE is_default = true;
subcluster_name
-----
default_subcluster
(1 row)

=> ALTER SUBCLUSTER analytics_cluster SET DEFAULT;
ALTER SUBCLUSTER
=> SELECT DISTINCT subcluster_name FROM SUBCLUSTERS WHERE is_default = true;
subcluster_name
-----
analytics_cluster
(1 row)
```

Converting a subcluster from primary to secondary, or secondary to primary

You usually choose whether a subcluster is [primary](#) or [secondary](#) when creating it (see [Creating subclusters](#) for more information). However, you can switch a subcluster between the two settings after you have created it. You may want to change whether a subcluster is primary or secondary to impact the [K-safety](#) of your database. For example, if you have a single primary subcluster that has down nodes that you cannot easily replace, you can promote a secondary subcluster to primary to ensure losing another primary node will not cause your database to shut down. On the other hand, you may choose to convert a primary subcluster to a secondary before eventually shutting it down. This conversion can prevent the database from losing K-Safety if the subcluster you are shutting down contains half or more of the total number of primary nodes in the database.

Note

You cannot promote or demote a subcluster containing the [initiator node](#). You must be connected to a node in a subcluster other than the one you want to promote or demote.

To make a secondary subcluster into a primary subcluster, use the [PROMOTE_SUBCLUSTER_TO_PRIMARY](#) function:

```

=> SELECT DISTINCT subcluster_name, is_primary from subclusters;
subcluster_name | is_primary
-----+-----
analytics_cluster | f
load_subcluster | t
(2 rows)

=> SELECT PROMOTE_SUBCLUSTER_TO_PRIMARY('analytics_cluster');
PROMOTE_SUBCLUSTER_TO_PRIMARY
-----
PROMOTE SUBCLUSTER TO PRIMARY
(1 row)

=> SELECT DISTINCT subcluster_name, is_primary from subclusters;
subcluster_name | is_primary
-----+-----
analytics_cluster | t
load_subcluster | t
(2 rows)

```

Making a primary subcluster into a secondary subcluster is similar. Unlike converting a secondary subcluster to a primary, there are several issues that may prevent you from making a primary into a secondary. Vertica prevents you from making a primary into a secondary if any of the following is true:

- The subcluster contains a [critical node](#).
- The subcluster is the only primary subcluster in the database. You must have at least one primary subcluster.
- The [initiator node](#) is a member of the subcluster you are trying to demote. You must call `DEMOTE_SUBCLUSTER_TO_SECONDARY` from another subcluster.

To convert a primary subcluster to secondary, use the [DEMOTE_SUBCLUSTER_TO_SECONDARY](#) function:

```

=> SELECT DISTINCT subcluster_name, is_primary from subclusters;
subcluster_name | is_primary
-----+-----
analytics_cluster | t
load_subcluster | t
(2 rows)

=> SELECT DEMOTE_SUBCLUSTER_TO_SECONDARY('analytics_cluster');
DEMOTE_SUBCLUSTER_TO_SECONDARY
-----
DEMOTE SUBCLUSTER TO SECONDARY
(1 row)

=> SELECT DISTINCT subcluster_name, is_primary from subclusters;
subcluster_name | is_primary
-----+-----
analytics_cluster | f
load_subcluster | t
(2 rows)

```

Removing subclusters

Removing a subcluster from the database deletes the subcluster from the Vertica catalog. During the removal, Vertica removes any nodes in the subcluster from the database. These nodes are still part of the database cluster, but are no longer part of the database. If you view your cluster in the MC, you will see these nodes with the status `STANDBY`. They can be added back to the database by adding them to another subcluster. See [Creating subclusters](#) and [Adding New Nodes to a Subcluster](#).

Vertica places several restrictions on removing a subcluster:

- You cannot remove the [default subcluster](#). If you want to remove the subcluster that is set as the default, you must make another subcluster the default. See [Changing the Default Subcluster](#) for details.
- You cannot remove the last [primary subcluster](#) in the database. Your database must always have at least one primary subcluster.

Note

Removing a subcluster can fail if the database is repartitioning. If this happens, you will see the error message "Transaction commit aborted because session subscriptions do not match catalog." Wait until the repartitioning is done before removing a subcluster.

To remove a subcluster, use the admintools command line `db_remove_subcluster` tool:

```
$ adminTools -t db_remove_subcluster -h
Usage: db_remove_subcluster [options]

Options:
-h, --help          show this help message and exit
-d DB, --database=DB  Name of database to be modified
-c SCNAME, --subcluster=SCNAME
                    Name of subcluster to be removed
-p DBPASSWORD, --password=DBPASSWORD
                    Database password in single quotes
--timeout=NONINTERACTIVE_TIMEOUT
                    set a timeout (in seconds) to wait for actions to
                    complete ('never') will wait forever (implicitly sets
                    -i)
-i, --noprompts     do not stop and wait for user input(default false).
                    Setting this implies a timeout of 20 min.
--skip-directory-cleanup
                    Caution: this option will force you to do a manual
                    cleanup. This option skips directory deletion during
                    remove subcluster. This is best used in a cloud
                    environment where the hosts being removed will be
                    subsequently discarded.
```

This example removes the subcluster named `analytics_cluster`:

```
$ adminTools -t db_remove_subcluster -d verticadb -c analytics_cluster -p 'password'
Found node v_verticadb_node0004 in subcluster analytics_cluster
Found node v_verticadb_node0005 in subcluster analytics_cluster
Found node v_verticadb_node0006 in subcluster analytics_cluster
Found node v_verticadb_node0007 in subcluster analytics_cluster

```

Depot management

The nodes of an Eon Mode database fetch data from communal storage as needed to process queries, and cache that data locally on disk. The cached data of all nodes within a subcluster comprise that cluster's *depot*. Vertica uses depots to facilitate query execution: when processing a query, Vertica first checks the current depot for the required data. If the data is unavailable, Vertica fetches it from communal storage and saves a copy in the depot

to expedite future queries. Vertica also uses the depot for load operations, caching newly-loaded data in the depot before uploading it to communal storage.

In this section

- [Managing depot caching](#)
- [Resizing depot caching capacity](#)

Managing depot caching

You can control depot caching in several ways:

- [Configure gateway parameters](#) so a depot caches only queried data or loaded data.
- [Control fetching](#) of queried data from communal storage.
- [Manage eviction](#) of cached data.
- [Enable depot warming](#) on new and restarted nodes.

You can [monitor depot activity and settings](#) with several `V_MONITOR` system tables, or with the [Management Console](#).

Note

Depot caching is supported only on primary shard subscriber nodes.

Depot gateway parameters

Vertica depots can cache two types of data:

- Queried data: The depot facilitates query execution by fetching queried data from communal storage and caching it in the depot. The cached data remains available until it is evicted to make room for fresher data, or data that is fetched for more recent queries.
- Loaded data: The depot expedites load operations such as COPY by temporarily caching data until it is uploaded to communal storage.

By default, depots are configured to cache both types of data.

Two configuration parameters determine whether a depot caches queried or loaded data:

UseDepotForReads (BOOLEAN)

If `1` (default), search the depot for the queried data and if it is not found, fetch the data from communal storage. If `0`, bypass the depot and fetch queried data from communal storage.

UseDepotForWrites (BOOLEAN)

If `1` (default) write loaded data to the depot and then upload files to communal storage. If `0`, bypass the depot and write directly to communal storage.

Both parameters can be set at session, user and database levels.

If set at session or user levels, these parameters can be used to segregate read and write activity on the depots of different subclusters. For example, parameters `UseDepotForReads` and `UseDepotForWrites` might be set as follows for users `joe` and `rhonda`:

```
-> SHOW USER joe ALL;
  name      | setting
-----+-----
UseDepotForReads  | 1
UseDepotForWrites | 0
(2 rows)
-> SHOW USER rhonda ALL;
  name      | setting
-----+-----
UseDepotForReads  | 0
UseDepotForWrites | 1
(2 rows)
```

Given these user settings, when `joe` connects to a Vertica subcluster, his session only uses the current depot to process queries; all load operations are uploaded to communal storage. Conversely, `rhonda`'s sessions only use the depot to process load operations; all queries must fetch their data from communal storage.

Depot fetching

If a depot is enabled to cache queried data (`UseDepotForReads = 1`), you can configure how it fetches data from communal storage with configuration parameter `DepotOperationsForQuery`. This parameter has three settings:

- **ALL** (default): Fetch file data from communal storage, if necessary displace existing files by evicting them from the depot.
- **FETCHES** : Fetch file data from communal storage only if space is available; otherwise, read the queried data directly from communal storage.
- **NONE** : Do not fetch file data to the depot, read the queried data directly from communal storage.

You can set fetching behavior at four levels, in ascending levels of precedence:

- Database: [ALTER DATABASE...SET PARAMETER](#)
- Per user: [ALTER USER...SET PARAMETER](#)
- Per session: [ALTER SESSION...SET PARAMETER](#)
- Per query: `DEPOT_FETCH` hint

For example, you can set `DepotOperationsForQuery` at the database level as follows:

```
-> ALTER DATABASE default SET PARAMETER DepotOperationsForQuery = FETCHES;
ALTER DATABASE
```

This setting applies to all database depots unless overridden at other levels. For example, the following `ALTER USER` statement overrides database-level fetching behavior: file data is always fetched to the depot for all queries from user `joe` :

```
-> ALTER USER joe SET PARAMETER DepotOperationsForQuery = ALL;
ALTER USER
```

Finally, `joe` can override his own `DepotOperationsForQuery` setting by including the `DEPOT_FETCH` hint in individual queries:

```
-> SELECT /*+DEPOT_FETCH(NONE)*/ count(*) FROM bar;
```

Evicting depot data

In general, Vertica evicts data from the depot as needed to provide room for new data and expedite request processing. Before writing new data to the depot, Vertica evaluates it as follows:

- Data fetched from communal storage: Vertica sizes the download and evicts data from the depot accordingly.
- Data uploaded from a DML operation such as `COPY`: Vertica cannot estimate the total size of the upload before it is complete, so it sizes individual buffers and evicts data from the depot as needed.

In both cases, Vertica evicts objects from the depot in the following order, from highest eviction priority to lowest:

1. Least recently used objects with an [anti-pinning policy](#).
2. Objects with an anti-pinning policy.
3. Least recently used unpinned object evicted for any new object, [pinned](#) or unpinned.
4. Least recently used pinned object evicted for a new pinned object. Only pinned storage can evict other pinned storage.

Depot eviction policies

Vertica supports two policy types to manage precedence of object eviction from the depot:

- Apply [pinning policies](#) to objects so Vertica is less likely to evict them from the depot than other objects.
- Apply [anti-pinning policies](#) to objects so Vertica is more likely to evict them than other objects.

You can apply either type of policy on individual subclusters, or on the entire database. Policies can apply at different levels of granularity—table, projection, and partitions. Eviction policies that set on an individual subclusters have no effect on how other subclusters handle depot object eviction.

Pinning policies

You can set pinning policies on database objects to reduce their exposure to eviction from the depot. Pinning policies can be set on individual subclusters, or on the entire database, and at different levels of granularity—table, projection, and partitions:

- Tables: [SET_DEPOT_PIN_POLICY_TABLE](#)
- Projections: [SET_DEPOT_PIN_POLICY_PROJECTION](#)
- Partitions: [SET_DEPOT_PIN_POLICY_PARTITION](#)

By default, pinned objects are queued for download from communal storage as needed to execute a query or DML operation. `SET_DEPOT_PIN_POLICY` functions can specify to override this behavior and immediately queue newly pinned objects for download: set the last Boolean argument of the function to `true` . For example:

```
-> SELECT SET_DEPOT_PIN_POLICY_TABLE ('store.store_orders_fact', 'default_subcluster', true );
```

Tip

How soon Vertica downloads a pinned object from communal storage depends on a number of factors, including space availability and precedence of other pinned objects that are queued for download. You can force immediate download of queued objects by calling [FINISH_FETCHING_FILES](#).

Anti-pinning policies

Vertica complements pinning policies with anti-pinning policies. Among all depot-cached objects, Vertica chooses objects with an anti-pinning policy for eviction before all others. Like pinning policies, you can set anti-pinning policies on individual subclusters, or on the entire database, and at different levels of granularity—table, projection, and partitions:

- Tables: [SET_DEPOT_ANTI_PIN_POLICY_TABLE](#)
- Projections: [SET_DEPOT_ANTI_PIN_POLICY_PROJECTION](#)
- Partitions: [SET_DEPOT_ANTI_PIN_POLICY_PARTITION](#)

In some cases, object-specific anti-pinning might be preferable over [depot-wide exclusions](#), such as setting the depot to be read- or write-only, or [excluding specific users](#) from fetching objects to the depot. For example, you might want to set anti-pinning on an infrequently-used table to prevent it from displacing tables that are used more frequently.

Overlapping eviction policies

If you set multiple eviction policies on a table or projection, Vertica gives precedence to the most recent policy. For example, if you issue an anti-pinning policy on a table that already has a pinning policy, the Vertica favors the anti-pinning policy over the pinning policy.

If you issue partition-level eviction policies on the same partitioned table, and the key ranges of these policies overlap, Vertica acts as follows:

- If the overlapping policies are of the same type—that is, all are either anti-pinning or pinning partition policies—then Vertica collates the key ranges. For example, if you create two anti-pinning partition policies with key ranges of 1-3 and 2-10, Vertica combines them into a single anti-pinning partition policy with a key range of 1-10.
- If there are overlapping pinning and anti-pinning policies, Vertica favors the newer policy, either truncating or splitting the older policy. For example, if you create an anti-partition pinning policy and then a pinning policy with key ranges of 1-10 and 5-20, respectively, Vertica favors the newer pinning policy by truncating the earlier anti-pinning policy's key range:

policy_type	min_value	max_value
PIN	5	20
ANTI_PIN	1	4

If the new pinning policy's partition range falls inside the range of an older anti-pinning policy, Vertica splits the anti-pinning policy. So, given an existing partition anti-pinning policy with a key range from 1 through 20, a new partition pinning policy with a key range from 5 through 10 splits the anti-pinning policy:

policy_type	min_value	max_value
ANTI_PIN	1	4
PIN	5	10
ANTI_PIN	11	20

Eviction policy guidelines

Pinning and anti-pinning policies granularly control which objects consume depot space. When depot space is claimed by pinned objects, you guarantee that these objects and their operations take precedence over operations that involve unpinned objects or objects with an anti-pinning policy. However, if you do not create efficient pinning and anti-pinning policies, you might increase eviction frequency and adversely affect overall performance.

To minimize contention over depot usage, consider the following guidelines:

- Pin only those objects that are most active in DML operations and queries.
- Minimize the size of pinned data by setting policies at the smallest effective level. For example, pin only the data of a table's [active partition](#).
- Periodically review eviction policies across all database subclusters, and update as needed to optimize depot usage.

You can also use the configuration parameters `UseDepotForReads` or `UseDepotForWrites` to [optimize distribution of query and load activity](#) across database subcluster depots.

Clearing depot policies

You clear pinning and anti-pinning policies from objects with the following functions:

- Tables: [CLEAR_DEPOT_PIN_POLICY_TABLE](#), [CLEAR_DEPOT_ANTI_PIN_POLICY_TABLE](#)
- Projections: [CLEAR_DEPOT_PIN_POLICY_PROJECTION](#), [CLEAR_DEPOT_ANTI_PIN_POLICY_PROJECTION](#)
- Partitions: [CLEAR_DEPOT_PIN_POLICY_PARTITION](#), [CLEAR_DEPOT_ANTI_PIN_POLICY_PARTITION](#)

Depot warming

On startup, the depots of new nodes are empty, while the depots of restarted nodes often contain stale data that must be refreshed. When depot warming is enabled, a node that is undergoing startup preemptively loads its depot with frequently queried and pinned data. When the node completes startup and begins to execute queries, its depot already contains much of the data it needs to process those queries. This reduces the need to fetch data from communal storage, and expedites query performance accordingly.

Note

Fetching data to a warming depot can delay node startup.

By default, depot warming is disabled (`EnableDepotWarmingFromPeers = 0`). A node executes depot warming as follows:

1. The node checks configuration parameter `PreFetchPinnedObjectsToDepotAtStartup`. If enabled (set to 1), the node:
 - Gets from the database catalog a list of all objects pinned by the subcluster.
 - Queues the pinned objects for fetching and calculates their total size.
2. The node checks configuration parameter `EnableDepotWarmingFromPeers`. If enabled (set to 1), the node:
 - Identifies a peer node in the same subcluster whose depot contents it can copy.
 - After taking into account all pinned objects, calculates how much space remains available in the warming depot.
 - Gets from the peer node a list of the most recently used objects that can fit in the depot.
 - Queues the objects for fetching.
3. If `BackgroundDepotWarming` is enabled (set to 1, default), the node loads queued objects into its depot while it is warming, and continues to do so in the background after the node becomes active and starts executing queries. Otherwise (`BackgroundDepotWarming = 0`), node activation is deferred until the depot fetches and loads all queued objects.

Monitoring the depot

You can monitor depot activity and settings with several `V_MONITOR` system tables.

Tip

You can also use the Management Console to monitor depot activity. For details, see [Monitoring depot activity with MC](#)

- [DATA_READS](#): All storage locations that a query reads to obtain data.
- [DEPOT_EVICTIONS](#): Details about objects that were evicted from the depot.
- [DEPOT_FETCH_QUEUE](#): Pending depot requests for queried file data to fetch from communal storage.
- [DEPOT_FILES](#): Objects that are cached in database depots.
- [DEPOT_PIN_POLICIES](#): Objects —tables and table partitions—that have [depot eviction policies](#).
- [DEPOT_SIZES](#): Depot caching capacity per node.
- [DEPOT_UPLOADS](#): Details about depot uploads to communal storage.

Resizing depot caching capacity

Each node in an Eon database caches depot data in a predefined storage location. The storage location path depends on your Vertica installation's filesystem. By default, each node in a cluster can use up to 60 percent of disk space on the storage location's filesystem to cache depot data. You can change caching capacity with [ALTER_LOCATION_SIZE](#), by specifying to a fixed size or a percentage of total disk space. The function can specify a single node, a subcluster, or all nodes in the database cluster. You can increase depot caching capacity for each node up to 80 percent.

In the following example, [ALTER_LOCATION_SIZE](#) increases depot caching capacity to 80 percent of disk space on the storage location's filesystem. The function supplies an empty string as the second (*node-name*) argument, so the change applies to all nodes:

Important

By default, depot caching capacity cannot exceed 80 percent of disk space on the store location file system; attempts to set it to a higher value return

an error. Vertica requires at least 20 percent of disk space for the catalog, Data Collector tables, and temp files.

```
=> SELECT node_name, location_label, location_path, max_size, disk_percent FROM storage_locations WHERE location_usage = 'DEPOT' ORDER BY
node_name;
  node_name | location_label | location_path | max_size | disk_percent
-----+-----+-----+-----+-----
v_vmart_node0001 | auto-data-depot | /home/dbadmin/verticadb | 36060108800 | 70%
v_vmart_node0002 | auto-data-depot | /home/dbadmin/verticadb | 36059377664 | 70%
v_vmart_node0003 | auto-data-depot | /home/dbadmin/verticadb | 36060108800 | 70%
(3 rows)

=> SELECT alter_location_size('depot', ',80%');
alter_location_size
-----
depotSize changed.
(1 row)

=> SELECT node_name, location_label, location_path, max_size, disk_percent FROM storage_locations WHERE location_usage = 'DEPOT' ORDER BY
node_name;
  node_name | location_label | location_path | max_size | disk_percent
-----+-----+-----+-----+-----
v_vmart_node0001 | auto-data-depot | /home/dbadmin/verticadb | 41211552768 | 80%
v_vmart_node0002 | auto-data-depot | /home/dbadmin/verticadb | 41210717184 | 80%
v_vmart_node0003 | auto-data-depot | /home/dbadmin/verticadb | 41211552768 | 80%
(3 rows)
```

Rescaling depot capacity

When a database is revived on an instance with greater or lesser disk space than it had previously, Vertica evaluates the depot size settings that were previously in effect. If depot size was specified as a percentage of available disk space, Vertica proportionately rescales depot capacity. For example, if depot caching capacity for a given node was set to 70 percent, the revived node applies that setting to the new disk space and adjusts depot caching capacity accordingly. If depot capacity was set to a fixed size, Vertica applies that setting, unless doing so will consume more than 80 percent of available disk space. In that case, Vertica automatically adjusts depot size as needed.

Scaling your Eon Mode database

One of the strengths of an Eon Mode database is its ability to grow or shrink to meet your workload demands. You can add nodes to and remove nodes from your database to meet changing workload demands. For an overview of why you would scale your database and how it affects queries, see [Elasticity](#).

Scaling up your database by starting stopped nodes

The easiest way to scale up your database is to start any stopped nodes:

- To start individual nodes, see [Stopping and starting nodes on MC](#).
- To start an entire subcluster that has been stopped, see [Starting and stopping subclusters](#).

Scaling up your database by adding nodes

If you do not have stopped nodes in your database, or the stopped nodes are not in the subclusters where you want to add new nodes, then you can add new nodes to the database. In supported environments, you can use the MC to provision and add new nodes to your database in a single step. See [Viewing and managing your cluster](#) for more information.

You can also manually add new nodes:

- For databases running on AWS, see [Add nodes to a cluster in AWS using Management Console](#).
- For databases running on-premises, or in other environments:
 1. Provision the hardware for your new nodes. Be sure to follow the steps in [Before you install Vertica](#) to verify your hardware is configured correctly.
 2. Follow the steps in [Adding hosts to a cluster](#) to add the new nodes to the database cluster.
 3. Add the node to your database by following the steps in [Adding New Nodes to a Subcluster](#).

Controlling how Vertica uses your new nodes

New nodes can improve your database's performance in one of two ways:

- Increase the query throughput (the number of queries your database processes at the same time).
- Increase individual query performance (how fast each query runs).

See [Elasticity](#) for details on these performance improvements. You control how the new nodes improve your database's performance by choosing what subclusters you add them to. The following topics explain how to use scaling to improve throughput and query performance.

In this section

- [Reshard the default namespace](#)
- [Improving query throughput using subclusters](#)
- [Using elastic crunch scaling to improve query performance](#)
- [Manually choosing an ECS strategy](#)

Reshard the default namespace

Important

You can only change the number of shards in the `default_namespace` if it is the only namespace in your database. If your database contains any non-default namespaces, running `RESHARD_DATABASE` results in an error.

The initial number of shards for the `default_namespace` is set when you create a database. You might choose to change the number of shards in this namespace for the following reasons:

- Improve large subcluster performance. For example, if you have a 24-node subcluster and a namespace with 6 shards, the subcluster uses Elastic Crunch Scaling (ECS) to split the responsibility for processing the data in each shard among the nodes. Re-sharding the namespace to 24 shards avoids using ECS, which improves performance because ECS is not as efficient as having a 1:1 shard:node ratio. For more information, see [Using elastic crunch scaling to improve query performance](#).
- Reducing the number of shards in `default_namespace` reduces the catalog size.
- Improve performance after migrating from Enterprise Mode to Eon Mode. When you migrate your database from Enterprise Mode to Eon Mode, the number of shards in your `default_namespace` is initially set to the number of nodes that you had in your Enterprise database. This default number of shards might not be ideal. For details, see [Choosing the initial node and shard counts](#).
- Scale your database effectively. To evenly distribute work among nodes, the number of nodes in the database should be a multiple of the number of shards. You might re-shard the namespace if you plan to scale the subclusters to a size that is incompatible with this guidance. For example, a namespace with 7 shards works best with subclusters that have a multiple of 7 nodes. Choosing a shard count with more divisors, such as 8, gives you greater flexibility in choosing the number of nodes in a subcluster.

You should not re-shard your `default_namespace` every time you scale subclusters. While in progress, re-sharding might affect the database's performance. After re-sharding, the storage containers on the subcluster are not immediately aligned with the new shard subscription bounds. This misalignment adds overhead to query execution.

Re-sharding the default_namespace

To re-shard the `default_namespace`, call the `RESHARD_DATABASE` function with the new shard count as the argument. This function takes a global `catalog lock`, so avoid running it during busy periods or when performing heavy ETL loads. The runtime depends on the size of your catalog.

After `RESHARD_DATABASE` completes, the nodes in the cluster use the new catalog shard definitions. However, the re-sharding process does not immediately alter the storage containers in communal storage. The shards continue to point to the existing storage containers. For example, if you double the number of shards in the namespace, each storage container now has two associated shards. During queries, each node filters out the data in the storage containers that does not apply to its subscribed shard. This adds a small overhead to the query. Eventually, the Tuple Mover's background reflexive mergeout processes automatically update the storage containers so they align with the new shard definitions. You can call `DO_TM_TASK` to run a 'RESHARDMERGEOUT' task that has the Tuple Mover immediately realign the storage containers.

The following query returns the details of any storage containers that Tuple Mover has not yet realigned:

```
-> SELECT * FROM storage_containers WHERE original_segment_lower_bound IS NOT NULL AND original_segment_upper_bound IS NOT NULL;
```

Example

This example demonstrates the re-sharding process and how it affects shard assignments and storage containers. To illustrate the impact of re-sharding, the shard assignment and storage container details are compared before and after re-sharding. The following four queries return information about the namespace's shard count, shard bounds, node subscriptions, and storage container catalog objects:

```

=> SELECT * FROM NAMESPACES;
 namespace_oid | namespace_name | is_default | default_shard_count
-----
45035996273704988 | default_namespace | t | 4

=> SELECT shard_name, lower_hash_bound, upper_hash_bound FROM shards ORDER BY shard_name;

shard_name | lower_hash_bound | upper_hash_bound
-----
replica | |
segment0001 | 0 | 1073741825
segment0002 | 1073741826 | 2147483649
segment0003 | 2147483650 | 3221225473
segment0004 | 3221225474 | 4294967295
(5 rows)

=> SELECT node_name, shard_name, is_primary, is_resubscribing, is_participating_primary FROM node_subscriptions;

node_name | shard_name | is_primary | is_resubscribing | is_participating_primary
-----
initiator | replica | t | f | t
e0 | replica | f | f | t
e1 | replica | f | f | t
e2 | replica | f | f | t
e0 | segment0002 | t | f | t
e1 | segment0003 | t | f | t
e2 | segment0004 | t | f | t
initiator | segment0001 | t | f | t
(8 rows)

=> SELECT node_name, projection_name, storage_oid, sal_storage_id, total_row_count, deleted_row_count, segment_lower_bound, segment_upper_bound
FROM shards;

node_name | projection_name | storage_oid | sal_storage_id | total_row_count | deleted_row_count | segment_lower_bound | segment_upper_bound
-----
initiator | t_super | 45035996273842990 | 022e836b1f54b0aed318df2fe73b5afe00a0000000021b2d | 4 | 0 | 0 | 1073741825
e0 | t_super | 49539595901213486 | 024bbf043c1ca3f5c7a86a423fc7e1e300b0000000021b2d | 3 | 0 | 1073741826 | 2147483649
e1 | t_super | 54043195528583990 | 02dac7dc405a1620c92bae1a17c7bbad00c0000000021b35 | 8 | 0 | 2147483650 | 3221225473
e2 | t_super | 54043195528583992 | 02dac7dc405a1620c92bae1a17c7bbad00c0000000021b31 | 6 | 0 | 3221225474 | 4294967295
(4 rows)

```

The following call to [RESHARD_DATABASE](#) changes the shard count of `default_namespace` to eight:

```

=> SELECT RESHARD_DATABASE(8);

RESHARD_DATABASE
-----
The database has been re-sharded from 4 shards to 8 shards
(1 row)

```

To confirm that the reshard operation was successful, query the [NAMESPACES](#) system table:

```

=> SELECT * FROM NAMESPACES;
 namespace_oid | namespace_name | is_default | default_shard_count
-----
45035996273704988 | default_namespace | t | 8

```

You can use the following query to view the namespace's new shard definitions:

```
-> SELECT shard_name, lower_hash_bound, upper_hash_bound FROM shards ORDER BY shard_name;
```

```
shard_name | lower_hash_bound | upper_hash_bound
```

```
-----+-----+-----
replica    |          |
segment0001 |          0 | 536870913
segment0002 | 536870914 | 1073741825
segment0003 | 1073741826 | 1610612737
segment0004 | 1610612738 | 2147483649
segment0005 | 2147483650 | 2684354561
segment0006 | 2684354562 | 3221225473
segment0007 | 3221225474 | 3758096385
segment0008 | 3758096386 | 4294967295
(9 rows)
```

The namespace now has eight shards. Because re-sharding cut the boundary range of each shard in half, each shard is responsible for about half as much of the communal storage data.

The following query returns the namespace's new node subscriptions:

```
-> SELECT node_name, shard_name, is_primary, is_resubscribing, is_participating_primary FROM node_subscriptions;
```

```
node_name | shard_name | is_primary | is_resubscribing | is_participating_primary
```

```
-----+-----+-----+-----+-----
initiator | replica    | is_primary | is_resubscribing | is_participating_primary
-----+-----+-----+-----+-----
e0        | replica    | t          | f                 | t
e1        | replica    | f          | f                 | t
e2        | replica    | f          | f                 | t
initiator | segment0001 | t         | f                 | t
e0        | segment0002 | t         | f                 | t
e1        | segment0003 | t         | f                 | t
e2        | segment0004 | t         | f                 | t
initiator | segment0005 | t         | f                 | t
e0        | segment0006 | t         | f                 | t
e1        | segment0007 | t         | f                 | t
e2        | segment0008 | t         | f                 | t
(12 rows)
```

After re-sharding, each node now subscribes to two shards instead of one.

You can use the following query to see how re-sharding affected the database's storage container catalog objects:

```
-> SELECT node_name, projection_name, storage_oid, sal_storage_id, total_row_count, deleted_row_count, segment_lower_bound, segment_upper_bound
```

```
node_name | projection_name | storage_oid | sal_storage_id | total_row_count | deleted_row_count | segment_lower_bound | segment_upper_bound
```

```
-----+-----+-----+-----+-----+-----+-----+-----
initiator | t_super        | 45035996273843145 | 02dac7dc405a1620c92bae1a17c7bbad00c0000000021b35 | 8 | 0 | 2147483650 | 2684354561
initiator | t_super        | 45035996273843149 | 022e836bf54b0aed318df2fe73b5afe00a0000000021b2d | 4 | 0 | 0 | 1073741825
e0        | t_super        | 49539595901213641 | 02dac7dc405a1620c92bae1a17c7bbad00c0000000021b35 | 8 | 0 | 2147483650 | 2684354561
e0        | t_super        | 49539595901213645 | 022e836bf54b0aed318df2fe73b5afe00a0000000021b2d | 4 | 0 | 0 | 1073741825
e1        | t_super        | 54043195528584141 | 02dac7dc405a1620c92bae1a17c7bbad00c0000000021b31 | 6 | 0 | 3221225474 | 3758096385
e1        | t_super        | 54043195528584143 | 02dac7dc405a1620c92bae1a17c7bbad00c0000000021b31 | 6 | 0 | 1073741826 | 2147483649
e2        | t_super        | 54043195528584137 | 024bbf043c1ca3f5c7a86a423fc7e1e300b0000000021b2d | 3 | 0 | 3221225474 | 3758096385
e2        | t_super        | 54043195528584139 | 024bbf043c1ca3f5c7a86a423fc7e1e300b0000000021b2d | 3 | 0 | 1073741826 | 2147483649
(8 rows)
```

The shards point to storage files with the same `sal_storage_id` as before the re-shard. Eventually, the TM's mergeout processes will automatically update the storage containers.

You can query the `RESHARDING_EVENTS` system table for information about current and historical resharding operations, such as a node's previous shard subscription bounds and the current status of the resharding operation:

```

=> SELECT node_name, running_status, old_shard_name, old_shard_lower_bound, old_shard_upper_bound FROM RESHARDING_EVENTS;
node_name | running_status | old_shard_name | old_shard_lower_bound | old_shard_upper_bound
-----
e0 | Running | segment0001 | 0 | 1073741825
e0 | Running | segment0002 | 1073741826 | 2147483649
e0 | Running | segment0003 | 2147483650 | 3221225473
e0 | Running | segment0004 | 3221225474 | 4294967295
e1 | Running | segment0001 | 0 | 1073741825
e1 | Running | segment0002 | 1073741826 | 2147483649
e1 | Running | segment0003 | 2147483650 | 3221225473
e1 | Running | segment0004 | 3221225474 | 4294967295
initiator | Running | segment0001 | 0 | 1073741825
initiator | Running | segment0002 | 1073741826 | 2147483649
initiator | Running | segment0003 | 2147483650 | 3221225473
initiator | Running | segment0004 | 3221225474 | 4294967295
(12 rows)

```

After you re-shard the namespace, you can query the DC_ROSES_CREATED table to track the original ROS containers and DVMiniROSES from which the new storage containers were derived:

```

=> SELECT node_name, projection_name, storage_oid, old_storage_oid, is_dv FROM DC_ROSES_CREATED;
node_name | projection_name | storage_oid | old_storage_oid | is_dv
-----
initiator | t_super | 45035996273860625 | 45035996273843149 | f
initiator | t_super | 45035996273860632 | 0 | f
e0 | t_super | 45035996273843149 | 0 | f
(3 rows)

```

Improving query throughput using subclusters

Improving query throughput increases the number of queries your Eon Mode database processes at the same time. You are usually concerned about your database's throughput when your workload consists of many short-running queries. They are often referred to as "dashboard queries." This term describes type of workload you see when a large number of users have web-based dashboard pages open to monitor some sort of status. These dashboards tend to update frequently, using simpler, short-running queries instead of analytics-heavy long running queries.

The best way to improve your database's throughput is to add new subclusters to the database or start any stopped subclusters. Then distribute the client connections among these subclusters using connection load balancing policies. Subclusters independently process queries. By adding more subclusters, you improve your database's parallelism.

For the best performance, make the number of nodes in your subcluster the same as the number of shards in a namespace. If you choose to have less nodes than the number of shards, make the number of nodes an even divisor of the number of shards. When the number of shards is divisible by the number of nodes, the data in your namespace is equally divided among the nodes in the subcluster.

The easiest way of adding subclusters is to use the MC:

1. From the MC home page, click the database you want to add subclusters to.
2. Click **Manage**.
3. Click **Add Subcluster**.
4. Follow the steps in the wizard to add the subcluster. Normally, the only items you need to fill in are the subcluster name and the number of instances to add to it.

Note

The MC currently does not support creating instances on all platforms. For those platforms where the MC does not support instances, you can manually add subclusters. See [Creating subclusters](#) for more information.

Distributing clients among the throughput subclusters

To gain benefits from the added subclusters, you must have clients that will execute short-running queries connect to the nodes that the subclusters contain. Queries run only on the subcluster that contains the initiator node (the node that the client is connected to). Use connection load balancing policies to spread the connections across all of the subclusters you created to increase query throughput. See [Connection load balancing policies](#) for details.

The following example creates a load balancing policy that spreads client connections across two three-node subclusters named `query_pool_a` and `query_pool_b`. This example:

- Creates network addresses on the six nodes that are in the two subclusters.
- Creates a load balance group from all the nodes in the two subclusters.
- Creates the routing rule to redirect all incoming connections to the two subclusters.

```
=> CREATE NETWORK ADDRESS node04 ON v_verticadb_node0004 WITH '203.0.113.1';
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS node05 ON v_verticadb_node0005 WITH '203.0.113.2';
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS node06 ON v_verticadb_node0006 WITH '203.0.113.3';
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS node07 ON v_verticadb_node0007 WITH '203.0.113.4';
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS node08 ON v_verticadb_node0008 WITH '203.0.113.5';
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS node09 ON v_verticadb_node0009 WITH '203.0.113.6';
CREATE NETWORK ADDRESS

=> CREATE LOAD BALANCE GROUP query_subclusters WITH SUBCLUSTER query_pool_a,
  query_pool_b FILTER '0.0.0.0/0';
CREATE LOAD BALANCE GROUP
=> CREATE ROUTING RULE query_clients ROUTE '0.0.0.0/0' TO query_subclusters;
CREATE ROUTING RULE
```

Important

In cloud environments where clients will be connecting from outside the private network, use the external IP address for each node when creating the network addresses. Otherwise, external clients will not be able to connect to the nodes.

If you have a mix of internal and external clients, set up two network addresses for each node and add them to two separate load balancing groups: one for internal clients and another for external. Then create two routing rules one that routes the internal clients to the internal group, and another that routes the external clients to the external group. Make the routing rule for internal clients only apply to the virtual private networks where your internal clients will connect from (for example, 10.0.0.0/8). The routing rule for the external clients can use the 0.0.0.0/0 CIDR range (all IP addresses) as the incoming connection address range. The rules will work correctly together because the more-specific internal client routing rule takes precedence over the less-restrictive external client rule.

After creating the policy, any client that opts into load balancing is redirected to one of the nodes in the two subclusters. For example, when you connect to node 1 in the cluster (with the IP address 203.0.113.1) using `vsq` with the `-C` flag, you see output similar to this:

```
$ vsq -h 203.0.113.1 -U dbadmin -w mypassword -C
Welcome to vsq, the Vertica Analytic Database interactive terminal.

Type: \h or \? for help with vsq commands
      \g or terminate with semicolon to execute query
      \q to quit

SSL connection (cipher: ECDHE-RSA-AES256-GCM-SHA384, bits: 256, protocol: TLSv1.2)

INFO: Connected using a load-balanced connection.
INFO: Connected to 203.0.113.7 at port 5433.
=>
```

Connection load balancing policies take into account nodes that are stopped when picking a node to handle a client connection. If you shut down one or more subclusters to save money during low-demand periods, you do not need to adjust your load balancing policy as long as some of the nodes are still up.

Using elastic crunch scaling to improve query performance

You can choose to add nodes to your database to improve the performance of complex long-running analytic queries. Adding nodes helps these queries run faster.

When you have more nodes in a subcluster than you have shards in a namespace, multiple nodes subscribe to each shard. To involve all of the nodes in the subcluster in queries, the Vertica query optimizer automatically uses a feature called Elastic Crunch Scaling (ECS). This feature splits the responsibility for processing the data in each shard among the nodes that subscribe to it. During a query, each node has less data to process and usually finishes the query faster.

For example, suppose you have a six-node subcluster in a three-shard namespace. In this subcluster, two nodes subscribe to each shard of the namespace. When you execute a query, Vertica assigns each node roughly half of the data in the shard it subscribes to. Because all nodes in the subcluster participate in the query, the query usually finishes faster than if only half the nodes had participated.

ECS lets a subcluster that has more nodes than shards in a namespace act as if the shard count in the namespace were higher. In a three-shard namespace, a six-node subcluster acts as if the namespace has six shards by splitting each shard in half. However, using ECS isn't as efficient as having a higher shard count. In practice, you will see slightly slower query performance on a six-node subcluster in a three shard database than you would see from a six-node subcluster in a six-shard database.

If the only namespace in your database is `default_namespace`, you can call `RESHARD_DATABASE` to change the number of shards in the namespace. If the new number of shards is greater than or equal to the number of nodes in the subcluster, the subcluster no longer uses ECS. This will generally lead to faster query performance. However, re-sharding produces a larger catalog size and storage containers that are initially misaligned with the new shard definitions. Until the storage containers are realigned, queries must filter out the data in the storage containers that is outside the new shard bounds. This adds a small overhead to queries. For details, see [Reshard the default namespace](#).

You can determine when the optimizer will use ECS in a subcluster by querying the `V_CATALOG.SESSION_SUBSCRIPTIONS` system table and look for nodes whose `is_collaborating` column is TRUE. Subclusters whose node count is less than or equal to the number of shards in a namespace only have participating nodes. Subclusters that have more nodes than a namespace's shard count assign the "extra" nodes the role of collaborators. The differences between the two types of nodes are not important for when you are executing queries. The two types just relate to how Vertica organizes the nodes to execute ECS-enabled queries.

This example shows how to get the list of nodes that are participating or collaborating in resolving queries for the current session:

```
=> SELECT node_name, shard_name, is_collaborating, is_participating
      FROM V_CATALOG.SESSION_SUBSCRIPTIONS
      WHERE is_participating = TRUE OR is_collaborating = TRUE
      ORDER BY shard_name, node_name;
 node_name | shard_name | is_collaborating | is_participating
-----+-----+-----+-----
v_verticadb_node0004 | replica | f | t
v_verticadb_node0005 | replica | f | t
v_verticadb_node0006 | replica | t | f
v_verticadb_node0007 | replica | f | t
v_verticadb_node0008 | replica | t | f
v_verticadb_node0009 | replica | t | f
v_verticadb_node0007 | segment0001 | f | t
v_verticadb_node0008 | segment0001 | t | f
v_verticadb_node0005 | segment0002 | f | t
v_verticadb_node0009 | segment0002 | t | f
v_verticadb_node0004 | segment0003 | f | t
v_verticadb_node0006 | segment0003 | t | f
(12 rows)
```

You can see that nodes 4, 5, and 7 are participating, and nodes 6, 8, and 9 are collaborating.

You can also see that ECS is enabled by looking at an `EXPLAIN` plan for a query. At the top of the plan for an ECS-enabled query is the statement "this query involves non-participating nodes." These non-participating nodes are the collaborating nodes that are splitting the data in the shard with the participating nodes. The plan also lists the nodes taking part in the query.

This example shows an explain plan for an ECS-enabled query in a six-node subcluster in a three-shard namespace:

```
=> EXPLAIN SELECT sales_quantity, sales_dollar_amount, transaction_type, cc_name
FROM online_sales.online_sales_fact
INNER JOIN online_sales.call_center_dimension
ON (online_sales.online_sales_fact.call_center_key
    = online_sales.call_center_dimension.call_center_key
    AND sale_date_key = 156)
ORDER BY sales_dollar_amount DESC;
```

QUERY PLAN

QUERY PLAN DESCRIPTION:

The execution of this query involves non-participating nodes. Crunch scaling strategy preserves data segmentation

```
EXPLAIN SELECT sales_quantity, sales_dollar_amount, transaction_type, cc_name
FROM online_sales.online_sales_fact
INNER JOIN online_sales.call_center_dimension
ON (online_sales.online_sales_fact.call_center_key
    = online_sales.call_center_dimension.call_center_key
    AND sale_date_key = 156)
ORDER BY sales_dollar_amount DESC;
```

```

Taking advantage of ECS

To take advantage of ECS, create a secondary subcluster where the number of nodes is a multiple of the number of shards in a namespace. For example, in a 12-shard namespace, create a subcluster that contains a multiple of 12 nodes such as 24 or 36. The number of nodes must be a multiple of the number of shards to evenly distribute the data in the namespace across the nodes in the subcluster. See [Subclusters](#) for more information.

Note

Instead of creating a new subcluster, you can add more nodes to an existing secondary subcluster. If possible, make the number of nodes in the

subcluster a multiple of the shard count of the relevant namespace.

Once you have created the subcluster, have users connect to it and run their analytic queries. Vertica automatically enables ECS in the subcluster because it has more nodes than there are shards in a namespace.

How the optimizer assigns data responsibilities to nodes

The optimizer has two strategies to choose from when dividing the data in a shard among its subscribing nodes. One strategy is optimized for queries that use data segmentation. Queries that contain a JOIN or GROUP BY clause rely on data segmentation. The other strategy is for queries that do not need segmentation.

By default, the optimizer automatically chooses the strategy to use. For most queries, the automatically-chosen strategy results in faster query performance. For some queries, you may want to manually override the strategy using hints. In a small number of queries, ECS does not help performance. In these cases, you can disable ECS. See [Manually choosing an ECS strategy](#) for details.

Manually choosing an ECS strategy

When the number of nodes in a subcluster is greater than the number of database shards, the Vertica query optimizer uses [elastic crunch scaling](#) (ECS) to involve all nodes in processing queries. For each shard, the optimizer divides responsibility for processing shard data among its subscribing nodes, using one of the following strategies:

Strategy	Description
I/O-optimized	Optimizer divides the list of ROS containers in the shard among the subscribing nodes. Use this strategy when nodes must fetch the data for the query from communal storage , rather than the depot . Nodes only fetch the ROS containers they need to resolve the query from communal storage, reducing the amount of data each needs to transfer from communal storage. Due to the arbitrary division of data among the nodes, this strategy does not support query optimizations that rely on data segmentation.
Compute-optimized	Optimizer uses data segmentation to assign portions to each subscribing node. The nodes scan the entire shard, but use sub-segment filtering to find their assigned segments of the data. Use this strategy when most data for the query is in the depot, because nodes must scan the entire contents of the shard. Because this strategy uses data segmentation, it supports optimizations such as local joins that the I/O-optimized strategy cannot.

The optimizer automatically chooses a strategy based on whether the query can take advantage of data segmentation. You can tell which strategy the optimizer chooses for a query by using [EXPLAIN](#). The top of the plan explanation states whether ECS is preserving segmentation. For example, this simple query on a single table does not need to use segmentation, so it uses the I/O-optimized strategy:

```
=> EXPLAIN SELECT employee_last_name,  
       employee_first_name,employee_age  
       FROM employee_dimension  
       ORDER BY employee_age DESC;
```

QUERY PLAN

QUERY PLAN DESCRIPTION:

The execution of this query involves non-participating nodes.
Crunch scaling strategy does not preserve data segmentation

.....
...

A more complex query using a JOIN results in ECS preserving data segmentation by using the compute-optimized strategy. The query plan tells you that segmentation is preserved:

```
=> EXPLAIN SELECT sales_quantity, sales_dollar_amount, transaction_type, cc_name
FROM online_sales.online_sales_fact
INNER JOIN online_sales.call_center_dimension
ON (online_sales.online_sales_fact.call_center_key
= online_sales.call_center_dimension.call_center_key
AND sale_date_key = 156)
ORDER BY sales_dollar_amount DESC;
```

QUERY PLAN

QUERY PLAN DESCRIPTION:

The execution of this query involves non-participating nodes.

Crunch scaling strategy preserves data segmentation

...

In most cases, the optimizer chooses the best strategy to use to split the data among the nodes subscribing to the same shard. However, you might occasionally find that some queries perform poorly. In these cases, the query can embed the [ECSMODE](#) hint to specify which strategy to use, or even disable ECS.

Setting the ECS strategy for individual queries

You can use the [ECSMODE](#) hint in a query to force the optimizer to use a specific ECS strategy (or disable ECS entirely). The ECSMODE hint takes one of the following arguments:

- **AUTO** : The optimizer chooses the strategy to use, useful only if ECS mode is set at the session level (see [Setting the ECS Strategy for the Session or Database](#)).
- **IO_OPTIMIZED** : Use I/O-optimized strategy.
- **COMPUTE_OPTIMIZED** : Use compute-optimized strategy.
- **NONE** : Disable use of ECS for this query. Only participating nodes are involved in query execution; collaborating nodes are not.

The following example shows the query plan for a simple single-table query that is forced to use the compute-optimized strategy:

```
=> EXPLAIN SELECT /*+ECSMODE(COMPUTE_OPTIMIZED)*/ employee_last_name,
employee_first_name,employee_age
FROM employee_dimension
ORDER BY employee_age DESC;
```

QUERY PLAN

QUERY PLAN DESCRIPTION:

The execution of this query involves non-participating nodes.

Crunch scaling strategy preserves data segmentation

...

This example disable ECS in a six-node cluster in a three-shard database:

```
=> EXPLAIN SELECT /*+ECSMODE(NONE)*/ employee_last_name,  
employee_first_name,employee_age  
FROM employee_dimension  
ORDER BY employee_age DESC;
```

QUERY PLAN

QUERY PLAN DESCRIPTION:

```
EXPLAIN SELECT /*+ECSMODE(NONE)*/ employee_last_name,  
employee_first_name,employee_age  
FROM employee_dimension  
ORDER BY employee_age DESC;
```

Access Path:

```
+--SORT [Cost: 243, Rows: 10K] (PATH ID: 1)  
| Order: employee_dimension.employee_age DESC  
| Execute on: v_verticadb_node0007, v_verticadb_node0004, v_verticadb_node0005  
| +----> STORAGE ACCESS for employee_dimension [Cost: 71, Rows: 10K] (PATH ID: 2)  
|| Projection: public.employee_dimension_DBD_8_seg_vmart_b0  
|| Materialize: employee_dimension.employee_first_name,  
|| employee_dimension.employee_last_name, employee_dimension.employee_age  
|| Execute on: v_verticadb_node0007, v_verticadb_node0004,  
|| v_verticadb_node0005  
...  
...
```

Note that this query plan lacks the "this query involves non-participating nodes" statement, indicating that it does not use ECS. It also lists just three participating nodes. These nodes are marked as participating in the [V_CATALOG.SESSION_SUBSCRIPTIONS](#) system table.

Setting the ECS strategy for the session or database

You can use the [ECSMODE](#) configuration parameter to set the ECS strategy for the current session. This parameter accepts the same values as the ECSMODE hint except NONE, which is valid only for individual queries.

The following example demonstrates using the configuration parameter to force a simple query to use the COMPUTE_OPTIMIZED strategy. It then sets the parameter back to its default value of AUTO:

```
=> EXPLAIN SELECT employee_first_name,employee_age
FROM employee_dimension ORDER BY employee_age DESC;
```

QUERY PLAN

QUERY PLAN DESCRIPTION:

The execution of this query involves non-participating nodes.
Crunch scaling strategy does not preserve data segmentation

...

```
=> ALTER SESSION SET ECSSMode = 'COMPUTE_OPTIMIZED';
ALTER SESSION
```

```
=> EXPLAIN SELECT employee_first_name,employee_age
FROM employee_dimension ORDER BY employee_age DESC;
```

QUERY PLAN

QUERY PLAN DESCRIPTION:

The execution of this query involves non-participating nodes.
Crunch scaling strategy preserves data segmentation

...

```
=> ALTER SESSION SET ECSSMode = 'AUTO';
ALTER SESSION
```

Individual query hints override the session-level settings. This example sets the session default to use `COMPUTE_OPTIMIZED`, then restores the default behavior for a query by using the `ECSSMode` hint with the value `AUTO`:

```
=> ALTER SESSION SET ECSSMode = 'COMPUTE_OPTIMIZED';
ALTER SESSION
=> EXPLAIN SELECT /*+ECSSMode(AUTO)*/ employee_first_name,employee_age
FROM employee_dimension ORDER BY employee_age DESC;
```

QUERY PLAN

QUERY PLAN DESCRIPTION:

The execution of this query involves non-participating nodes.
Crunch scaling strategy does not preserve data segmentation

Note that setting the `ECSSMode` hint to `AUTO` let the optimizer pick the I/O-optimized strategy (which does not preserve segmentation) instead of using the compute-optimized strategy set at the session level.

You can also set the ECS strategy at the database level using [ALTER DATABASE](#). However, doing so overrides the Vertica optimizer's settings for all users in all subclusters that use ECS. Before setting the ECS strategy at the database level, verify that the majority of the queries run by all users of the ECS-enabled subclusters must have the optimizer's default behavior overridden. If not, then use the session or query-level settings to override the optimizer for just the queries that benefit from a specific strategy.

Subcluster sandboxing

Sandboxing enables you to spin-off secondary subclusters from an existing cluster, resulting in two or more mutually isolated clusters that share the same data but do not interfere with each other. Sandboxed clusters inherit the state of the catalog and data of the main cluster at the time of [sandbox creation](#). As soon as the sandbox is active, the catalog and data of the two clusters are independent and can diverge. Within each cluster, you can perform standard database operations and queries, such as creating new tables or loading libraries, without affecting the other cluster. For example, dropping a table in the sandboxed cluster does not drop the table in the main cluster, and vice versa.

Sandboxes support many use cases, including the following:

- Try out a version of Vertica without needing to spin-up a new cluster and reload data. After creating a sandbox, you can upgrade sandboxed subclusters and test out the new Vertica features. To rejoin sandboxed subclusters to the main cluster, you just need to downgrade the Vertica version and perform the necessary unsandboxing tasks.
- Experiment with new features without compromising the consistency of the main cluster. For instance, you could spin-off a sandbox and experiment with external tables using data stored by [Apache Iceberg](#).
- Share data with another team by giving them access to a sandboxed cluster. This gives the other team the necessary data access, but keeps the changes separate from the main cluster. Anything the other team changes in the sandbox, such as dropping tables, would not propagate back to the main cluster.

After [removing the sandbox](#) and performing necessary cleanup tasks, subclusters can rejoin the main cluster.

In this section

- [Creating sandboxes](#)
- [Removing sandboxes](#)

Creating sandboxes

In order to create a sandbox for a secondary subcluster, all nodes in the subcluster must have a status of UP and collectively provide full-subscription coverage for all shards.

To sandbox the first subcluster in a sandbox, use the `sandbox_subcluster` admintools command:

```
$ adminTools -t sandbox_subcluster -h
Usage: sandbox_subcluster [options]

Options:
-h, --help          show this help message and exit
-d DB, --database=DB Name of database to be modified
-p DBPASSWORD, --password=DBPASSWORD
                   Database password in single quotes
-c SCNAME, --subcluster=SCNAME
                   Name of subcluster to be sandboxed
-b SBNAME, --sandbox=SBNAME
                   Name of the sandbox
--timeout=NONINTERACTIVE_TIMEOUT
                   set a timeout (in seconds) to wait for actions to
                   complete ('never' will wait forever (implicitly sets
                   -i)
-i, --noprompts    do not stop and wait for user input(default false).
                   Setting this implies a timeout of 20 min.
```

At command runtime, under a global catalog lock (GCLX), the nodes in the specified subcluster create a checkpoint of the catalog. When these nodes auto-restart in the sandbox cluster, they form a primary subcluster that uses the data and catalog checkpoint from the main cluster. After the nodes successfully restart, the sandbox cluster and the main cluster are mutually isolated and can diverge.

While the nodes in the main cluster sync their metadata to `/path-to-communal-storage/metadata/db_name`, the nodes in the sandbox sync to `/path-to-communal-storage/metadata/sandbox_name`.

Note

Though the sandbox cluster and main cluster are mutually isolated, the nodes in both clusters remain in the same [Spread](#) ring. However, if the main cluster and sandbox cluster partition from each other—which can be caused by events like Spread communication problems—the two clusters are not affected.

You can perform standard database operations and queries, such as loading data or creating new tables, in either cluster without affecting the other cluster. For example, dropping a table in the sandbox cluster does not drop the table in the main cluster, and vice versa.

Because both clusters reference the same data files, neither cluster can delete files that existed at the time of sandbox creation. However, the sandbox can remove files that it creates after spin-off from the main cluster. Files in the main cluster are queued for removal, but they are not processed until all active sandboxes are removed.

You cannot nest sandboxes, remove a sandboxed subcluster from the database, or add or remove nodes to an existing sandbox, but you can have multiple individual sandboxes active at the same time.

Adding subclusters to existing sandboxes

You can add additional secondary subclusters to existing sandbox clusters using the [SANDBOX_SUBCLUSTER](#) function. Added subclusters must be [secondary](#), cannot be a member of any other sandbox cluster, and all member nodes must have a status of UP.

When sandboxing additional subclusters, you must first call the `SANDBOX_SUBCLUSTER` function in the sandbox cluster and then in the main cluster, providing the same sandbox cluster and subcluster names in both calls. This makes both clusters aware of the status of the sandboxed subcluster. After the function is called in both clusters, the subcluster automatically restarts, joins the sandbox cluster as a secondary subcluster, and subscribes to the sandbox cluster's shards.

Examples

The following command sandboxes the `sc01` secondary subcluster into a sandbox named `sand` :

```
$ admintools -t sandbox_subcluster -d verticadb -p password -c sc_01 -b sand
```

Validating sandboxing conditions

Sandboxing subcluster `sc_01` as `sand`...

Subcluster 'sc_01' has been sandboxed to 'sand'. It is going to auto-restart and re-form.

Checking for sandboxed nodes to be UP...

Node Status: v_verticadb_node0004: (DOWN) v_verticadb_node0005: (DOWN) v_verticadb_node0006: (DOWN)

Node Status: v_verticadb_node0004: (UP) v_verticadb_node0005: (UP) v_verticadb_node0006: (UP)

Sandboxing complete. Subcluster `sc_01` is ready for use

If you query the [NODES](#) system table from the main cluster, you can see that the `sc_01` nodes have a status of UNKNOWN and are listed as member of the `sand` sandbox:

```
=> SELECT node_name, subcluster_name, node_state, sandbox FROM NODES;
```

node_name	subcluster_name	node_state	sandbox
v_verticadb_node0001	default_subcluster	UP	
v_verticadb_node0002	default_subcluster	UP	
v_verticadb_node0003	default_subcluster	UP	
v_verticadb_node0004	sc_01	UNKNOWN	sand
v_verticadb_node0005	sc_01	UNKNOWN	sand
v_verticadb_node0006	sc_01	UNKNOWN	sand
v_verticadb_node0007	sc_02	UP	
v_verticadb_node0008	sc_02	UP	
v_verticadb_node0009	sc_02	UP	

(9 rows)

Note

If the sandboxed and main clusters are sufficiently incompatible or are Spread-partitioned from each other, the status of the sandboxed nodes might appear as DOWN in the above query.

When you issue the same query on one of the sandboxed nodes, the table shows that the sandboxed nodes are UP and the nodes from the main cluster are UNKNOWN, confirming that the cluster is successfully sandboxed and isolated from the main cluster:

```

=> SELECT node_name, subcluster_name, node_state, sandbox FROM NODES;
   node_name   | subcluster_name | node_state | sandbox
-----+-----+-----+-----
v_verticadb_node0001 | default_subcluster | UNKNOWN |
v_verticadb_node0002 | default_subcluster | UNKNOWN |
v_verticadb_node0003 | default_subcluster | UNKNOWN |
v_verticadb_node0004 | sc_01           | UP       | sand
v_verticadb_node0005 | sc_01           | UP       | sand
v_verticadb_node0006 | sc_01           | UP       | sand
v_verticadb_node0007 | sc_02           | UNKNOWN |
v_verticadb_node0008 | sc_02           | UNKNOWN |
v_verticadb_node0009 | sc_02           | UNKNOWN |
(9 rows)

```

You can now perform standard database operations in either cluster without impacting the other cluster. For instance, if you create a machine learning dataset named `train_data` in the sandboxed subcluster, the new table does not propagate to the main cluster:

```

--In the sandboxed subcluster
=> CREATE TABLE train_data(time timestamp, Temperature float);
CREATE TABLE

=> COPY train_data FROM LOCAL 'daily-min-temperatures.csv' DELIMITER ',';
Rows Loaded
-----
3650
(1 row)

=> SELECT * FROM train_data LIMIT 5;
   time           | Temperature
-----+-----
1981-01-27 00:00:00 |    19.4
1981-02-20 00:00:00 |    15.7
1981-02-27 00:00:00 |    17.5
1981-03-04 00:00:00 |     16
1981-04-24 00:00:00 |    11.5
(5 rows)

--In the main cluster
=> SELECT * FROM train_data LIMIT 5;
ERROR 4566: Relation "train_data" does not exist

```

Similarly, if you drop a table in the main cluster, the table is not subsequently dropped in the sandboxed cluster:

```
--In the main cluster
=> SELECT * FROM transaction_data LIMIT 5;
first_name | last_name | store | cost | fraud
-----+-----+-----+-----+-----
Adam      | Rice     | Gembucket | 8757.35 | FALSE
Alan      | Gordon   | Wrapsafe  | 3874.48 | FALSE
Albert    | Harvey   | Treeflex  | 1558.27 | FALSE
Andrea    | Bryant   | Greenlam  | 1148.2  | FALSE
Andrew    | Simmons  | Home Ing  | 8400.03 | FALSE
(5 rows)
```

```
=> DROP TABLE transaction_data;
DROP TABLE
```

```
--In the sandboxed subcluster
=> SELECT * FROM transaction_data LIMIT 5;
first_name | last_name | store | cost | fraud
-----+-----+-----+-----+-----
Adam      | Rice     | Gembucket | 8757.35 | FALSE
Alan      | Gordon   | Wrapsafe  | 3874.48 | FALSE
Albert    | Harvey   | Treeflex  | 1558.27 | FALSE
Andrea    | Bryant   | Greenlam  | 1148.2  | FALSE
Andrew    | Simmons  | Home Ing  | 8400.03 | FALSE
(5 rows)
```

To add an additional secondary subcluster to the sandbox cluster, call `SANDBOX_SUBCLUSTER` in the sandbox cluster and then in the main cluster:

```
--In the sandbox cluster
=> SELECT SANDBOX_SUBCLUSTER('sand', 'sc_02', '');
                sandbox_subcluster
```

```
-----
Subcluster 'sc_02' has been added to 'sand'. When the same command is executed in the main cluster, it can join the sandbox.
(1 row)
```

```
--In the main cluster
=> SELECT SANDBOX_SUBCLUSTER('sand', 'sc_02', '');
                sandbox_subcluster
```

```
-----
Subcluster 'sc_02' has been sandboxed to 'sand'. It is going to auto-restart and re-form.
(1 row)
```

```
--In the sandbox cluster
=> SELECT node_name, subcluster_name, node_state, sandbox FROM NODES;
node_name | subcluster_name | node_state | sandbox
```

```
-----+-----+-----+-----
v_verticadb_node0001 | default_subcluster | UNKNOWN |
v_verticadb_node0002 | default_subcluster | UNKNOWN |
v_verticadb_node0003 | default_subcluster | UNKNOWN |
v_verticadb_node0004 | sc_01              | UP      | sand
v_verticadb_node0005 | sc_01              | UP      | sand
v_verticadb_node0006 | sc_01              | UP      | sand
v_verticadb_node0007 | sc_02              | UP      | sand
v_verticadb_node0008 | sc_02              | UP      | sand
v_verticadb_node0009 | sc_02              | UP      | sand
(9 rows)
```

If you decide to upgrade your sandboxed cluster, you can confirm that the main cluster and sandboxed cluster are running two different Vertica versions by comparing their `build_info` values in the `NODES` system table:

```
=> SELECT node_name, subcluster_name, node_state, sandbox, build_info FROM NODES;
 node_name | subcluster_name | node_state | sandbox | build_info
-----+-----+-----+-----+-----
v_verticadb_node0001 | default_subcluster | UP | | v12.0.4-0
v_verticadb_node0002 | default_subcluster | UP | | v12.0.4-0
v_verticadb_node0003 | default_subcluster | UP | | v12.0.4-0
v_verticadb_node0004 | sc_01 | UNKNOWN | sand | v12.0.4-1
v_verticadb_node0005 | sc_01 | UNKNOWN | sand | v12.0.4-1
v_verticadb_node0006 | sc_01 | UNKNOWN | sand | v12.0.4-1
v_verticadb_node0007 | sc_02 | UNKNOWN | sand | v12.0.4-1

Removing sandboxes

To remove a sandbox's primary subcluster from the sandbox and return it to the main cluster, you can run the `unsandbox_subcluster` admintools command:

```
$ adminTools -t unsandbox_subcluster -h
Usage: unsandbox_subcluster [options]

Options:
-h, --help          show this help message and exit
-d DB, --database=DB Name of database to be modified
-p DBPASSWORD, --password=DBPASSWORD
                   Database password in single quotes
-c SCNAME, --subcluster=SCNAME
                   Name of subcluster to be un-sandboxed
--timeout=NONINTERACTIVE_TIMEOUT
                   set a timeout (in seconds) to wait for actions to
                   complete ('never') will wait forever (implicitly sets
                   -i)
-i, --noprompts    do not stop and wait for user input(default false).
                   Setting this implies a timeout of 20 min.
```

Note

If you upgraded the Vertica version of the sandboxed subcluster, you must downgrade the version of the subcluster before rejoining it to the main cluster.

The `unsandbox_subcluster` command stops the nodes in the sandboxed subcluster, changes the metadata in the main cluster that designates the specified subcluster as sandboxed, wipes the node's local catalogs, and then restarts the nodes. After the nodes restart, they rejoin the main cluster and inherit the current state of the main cluster's catalog. The nodes should then be back to their normal state and can be used as expected.

Because the sandbox synced its metadata to the same communal storage location as the main cluster, you must remove the metadata files that were created in the sandbox. Those files can be found by replacing the name of the database in the path to the metadata with the name of the sandbox—for instance, `/path-to-communal-storage/metadata/sandbox_name` instead of `/path-to-communal-storage/metadata/db_name`. Removing these files helps avoid problems that might arise from reusing the same sandbox name.

If there are no more active sandboxes, the main cluster can resume the processing of data queued for deletion. To remove any data created in the sandbox, you can run the `CLEAN_COMMUNAL_STORAGE` function.

You can also unsandbox a subcluster using the `UNSANDBOX_SUBCLUSTER` meta-function, but you must manually stop the nodes, wipe their catalog subdirectories, run the function, and restart the nodes.

Removing a sandbox's secondary subclusters

If your sandbox has additional secondary subclusters, you can remove them from the sandbox using the UNSANDBOX_SUBCLUSTER function. As with the `unsandbox_subcluster` admintools command, the function requires that the nodes in the specified subcluster are down. Any remaining subclusters in the sandbox cluster continue to operate as normal.

After you call the function in the main cluster and wipe the nodes' catalogs, you can restart the nodes to rejoin them to the main cluster. Vertica recommends that you also call the UNSANDBOX_SUBCLUSTER function in the sandbox cluster. This makes sure that both clusters are aware of the status of the subcluster and that relevant system tables accurately reflect the subcluster's state.

Examples

The following command unsandboxes the `sc02` secondary subcluster from the `sand` sandbox. The command stops the nodes in `sc02`, wipes the nodes catalogs, and then restarts the nodes. After the nodes restart, they should rejoin the main cluster and be ready for normal use:

```
$ admintools -t unsandbox_subcluster -d verticadb -p vertica -c analytics
Stopping subcluster nodes for unsandboxing...
Sending signal 'TERM' to ['192.168.111.34', '192.168.111.35', '192.168.111.36']

Node Status: v_verticadb_node0004: (DOWN) v_verticadb_node0005: (DOWN) v_verticadb_node0006: (DOWN)
Node Status: v_verticadb_node0004: (UP) v_verticadb_node0005: (UP) v_verticadb_node0006: (UP)
Syncing catalog on verticadb with 2000 attempts.

Unsandboxed nodes have restarted successfully and joined the main cluster and are ready to use
```

When the admintools command completes, you can query the [NODES](#) system table to confirm that the previously sandboxed nodes are UP and are no longer members of `sand` :

```
=> SELECT node_name, subcluster_name, node_state, sandbox FROM NODES;
 node_name | subcluster_name | node_state | sandbox
-----+-----+-----+-----
v_verticadb_node0001 | default_subcluster | UP | 
v_verticadb_node0002 | default_subcluster | UP | 
v_verticadb_node0003 | default_subcluster | UP | 
v_verticadb_node0004 | sc_02 | UP | 
v_verticadb_node0005 | sc_02 | UP | 
v_verticadb_node0006 | sc_02 | UP | 
(6 rows)
```

If there are no more active sandboxes, you can run the [CLEAN_COMMUNAL_STORAGE](#) function to remove any data created in the sandbox. You should also remove the sandbox's metadata from the shared communal storage location, which can be found at `/path-to-communal-storage/metadata/sandbox_name` . The following example removes the sandbox's metadata from an S3 bucket and then calls `CLEAN_COMMUNAL_STORAGE` to cleanup any data from the sandbox:

```
$ aws s3 rm /path-to-communal/metadata/sandbox_name
```

```
SELECT CLEAN_COMMUNAL_STORAGE('true');
      CLEAN_COMMUNAL_STORAGE
```

```
-----
CLEAN COMMUNAL STORAGE
Total leaked files: 143
Files have been queued for deletion.
Check communal_cleanup_records for more information.
```

```
(1 row)
```

Local caching of storage containers

The Vertica execution engine uses the `StorageMerge` operator to read data from storage containers in cases where it is important to read container data in its projection-specified sort order. This is particularly useful for operations that must preserve the sort order of the data that is read from multiple storage containers, before merging it into a single storage container. Common operations that enforce sort order include [mergeout](#) , and some queries with `ORDER BY` clauses—for example [CREATE TABLE...AS](#) , where the query includes an `ORDER BY` clause.

The execution engine typically allocates multiple threads to the `StorageMerge` operator. Each thread is assigned a single `Scan` operator to open and read container contents. If the number of containers to read is greater than the number of available threads, the execution engine is likely to assign individual `Scan` operators to multiple containers. In this case, `Scan` operators might need to switch among different containers and reopen them multiple times before all required data is fetched and assembled. Doing so is especially problematic when reading storage containers on remote filesystems such as S3. The extra overhead incurred by reopening and reading remote storage containers can significantly impact performance and usage costs.

You can configure your database so the execution engine caches on local disk the data of S3 storage containers that require multiple opens. The size of temp space allocated per query to the `StorageMerge` operator for caching is set by configuration parameter [StorageMergeMaxTempCacheMB](#) . By default, this configuration parameter is set to -1 (unlimited). If caching requests exceed temp space limits or available disk space, Vertica caches as much container data as it can, and then reads from S3.

Note

The actual temp space that is allocated is the lesser of these settings:

- [StorageMergeMaxTempCacheMB](#)
- A user's [TEMPSPACECAP](#) setting
- The session [TEMPSPACECAP](#) setting

To turn off caching, set `StorageMergeMaxTempCacheMB` to 0.

Managing an Eon Mode database in MC

Vertica Management Console (MC), a database health and activity monitoring tool, provides in-browser wizards you can follow to deploy Vertica cluster instances and create an Eon Mode database on them. You can also use MC to manage and monitor resources that are specific to Eon Mode:

- [Node and shard subscriptions](#)
- Depot [storage](#) and [activity](#)

See also

- [Management Console](#)

Stopping and starting an Eon Mode cluster

Stopping your Eon Mode database and cluster using the MC

When running an Eon Mode database in the cloud, you usually want to stop the nodes running your database when you stop the database. Stopping your nodes avoids wasting money. The nodes aren't needed while the database is down.

Note

Instead of shutting down your entire database, you can still save money by shutting down subclusters that aren't being used. This technique lets your database continue to run and load data, while reducing the hourly cost. See [Starting and stopping subclusters](#) for more information.

The easiest way to stop both your database and the nodes that run it is to use the MC:

1. From the MC home page, click **View Your Infrastructure**.
2. In row labeled Databases, click the database you want to stop.
3. In the popup, click **Stop**.
4. Click **OK** to confirm you want to stop the database.
5. Once your database has stopped, in the row labeled Clusters, click the entry for the cluster running the database you just stopped.
6. In the popup, click **Manage**.
7. In the ribbon at the top of the cluster view, click **Stop Cluster**.
8. In the dialog box, check the **I would like to stop all instances in the cluster** box and click **Stop Cluster**.

Manually stopping the database and cluster

To manually stop your database and cluster, first stop your database using one of the following methods:

- Use the `stop_db` admintools command to stop the database. See [Stopping the database](#).
- Use the [SHUTDOWN](#) or [SHUTDOWN_WITH_DRAIN](#) function to stop the database.

Once you have stopped the database, you can stop your nodes. If you are in a cloud environment, see your cloud provider's documentation for instruction on stopping nodes.

Starting your cluster and database using the MC

To start your database cluster and database:

1. From the MC home, click **View Infrastructure**.
2. In the Clusters row, click the cluster that runs the database you want to start.
3. In the pop-up, click **Manage**.
4. In the ribbon at the top of the cluster's page, click **Start Cluster**.
5. Check the **I would like to start all instances in the cluster** box and click **Start Cluster**.

Starting the cluster automatically starts the database.

Manually starting your cluster and database

To manually start your cluster and database:

1. Start the nodes in your database cluster. If you are running in the cloud, see your cloud provider's documentation on how to start instances.
2. Connect to one of the nodes in the cluster and use the admintools menus or command line to start your database. See [Starting the database](#) for

instructions.

Terminating an Eon Mode database cluster

When you terminate an Eon Mode database's cluster, you free its resources. In a cloud environment, terminating the cluster deletes the instances that ran the database's nodes. In an on-premises database, terminating the cluster usually means repurposing physical hardware for other uses. See [Stopping, starting, terminating, and reviving Eon Mode database clusters](#) for more information.

Terminating an Eon Mode database's cluster does not affect the data it stores. The data remains stored in the communal storage location. As long as you do not delete the communal storage location, you can revive the database onto a new Eon Mode cluster. See [Reviving an Eon Mode database cluster](#) for more information.

Important
Vertica persists catalog data in communal storage, updating it every few minutes. Nonetheless, before shutting down your database you should make sure your metadata is up to date on communal storage. To do so, see [Synchronizing metadata](#).

Terminating an Eon Mode cluster using Management Console

Management Console provides the easiest way to terminate an Eon Mode cluster. You must follow a two-step process: first stop the database, then terminate the cluster:

1. If you have not yet synchronized the database's catalog, follow the steps in [Synchronizing metadata](#).
2. From the Management Console home page, click **View Your Infrastructure**.
3. In the row labeled Databases, click the database whose cluster you want to terminate.
4. In the popup, click **Stop**.
5. Click **OK** to confirm you want to stop the database.
6. After the database stops, in the row labeled Clusters, click the entry for the cluster you want to terminate.
7. In the popup, click **Manage**.
8. In the ribbon at the top of the cluster view, click **Advanced** and then select **Terminate Cluster**.
9. In the dialog box:
 - Check **I understand that terminating a cluster will terminate all instances in the cluster**
 - Click **Terminate Cluster**.

Manually terminating an Eon Mode cluster

To manually terminate your Eon Mode cluster:

1. If you have not yet synchronized the database's catalog, follow the steps in [Synchronizing metadata](#).
2. Stop the database using one of the following methods:
 - [Use admintools](#).
 - Use the `SHUTDOWN` meta-function.
3. Terminate the database node instances. If you are in a cloud environment, see your cloud provider's documentation for instructions on terminating instances. For on-premises database clusters, you can repurpose the systems that were a part of the cluster.

- [Reviving an Eon Mode database cluster](#)
- [Stopping, starting, terminating, and reviving Eon Mode database clusters](#)
- [Eon Mode architecture](#)
- [Adding and removing nodes from subclusters](#)
- [Altering subcluster settings](#)

Reviving an Eon Mode database cluster

If you have terminated your Eon Mode database's cluster, but have not deleted the database's communal storage, you can revive your database. Reviving the database restores it to its pre-shutdown state. The revival process requires creating a new database cluster and configuring it to use the database's communal storage location. See [Stopping, starting, terminating, and reviving Eon Mode database clusters](#) for more information.

Note

You cannot revive sandboxed subclusters. If you call the `revive_db` admintools command on a cluster with both sandboxed and unsandboxed subclusters, the nodes in the unsandboxed subclusters start as expected, but the nodes in the sandboxed subclusters remain down. Attempting to revive only a sandboxed subcluster returns an error.

You can also use the revive process to restart a database when its nodes do not have persistent local storage. You may choose to configure your node's instances in your cloud-based Eon Mode cluster with non-persistent local storage to reduce cost. Cloud providers such as AWS and GCP charge less for instances when they are not required to retain data when you shut them down.

You revive a database using either the Management Console or admintools. The MC and admintools offer different revival methods:

- The MC always revives onto a newly-provision cluster that it creates itself. It cannot revive onto an existing cluster. Use the MC to revive a database when you do not have a cluster already provisioned for your database.
- admintools only revives onto an existing database cluster. You can manually create a cluster to revive your database. See [Set up Vertica on-premises](#).

You can also revive a database whose hosts use instance storage where data is not persistently stored between shutdowns. In this case, admintools treats the existing database cluster as a new cluster, because the hosts do not contain the database's catalog data.

- Currently, only admintools lets you revive just the [primary subclusters](#) in a database cluster. This option is useful if you want to revive the minimum number of nodes necessary to start your database. See [Reviving Only Primary Subclusters](#) below.

The MC always revives the entire database cluster.

Note

You cannot revive a database from a communal storage location that is currently running on another cluster. The revive process fails if it detects that there is a cluster already running the database. Having two instances of a database running on separate clusters using the same communal storage location leads to data corruption.

Reviving using the Management Console

You can use a wizard in the Management Console to provision a new cluster and revive a database onto it from a browser. For details, see:

- [Reviving an Eon Mode database on AWS in MC](#)
- [Reviving an Eon Mode database on GCP in MC](#)

Revive using admintools

You can use admintools to revive your Eon Mode database on an existing cluster.

Cluster requirements

This existing cluster must:

- Have the same version (or later version) of Vertica installed on it. You can repurpose an existing Vertica cluster whose database you have shut down. Another option is to create a cluster from scratch by manually installing Vertica (see [Set up Vertica on-premises](#)).
- Contain a number of hosts in the cluster that is equal to or greater than either:
 - The total number of nodes that the database cluster had when it shut down.
 - The total number of [primary nodes](#) the database cluster had when it shut down. When you supply a cluster that matches the number of primary nodes in the database, admintools revives just the primary nodes.

When reviving, you supply admintools with a list of the hosts in the cluster to revive the database onto. The number of hosts in this list must match either the total number of nodes or the number of primary nodes in the database when it shut down. If the number of nodes you supply does not match either of these values, admintools returns an error.

You do not need to use all of the hosts in the cluster to revive the database. You can revive a database onto a subset of the hosts in the cluster. But you must have at least enough hosts to revive all of the primary nodes.

For example, suppose you want to revive a database that had 16 nodes when it was shut down, with four of those nodes being primary nodes. In that case, you can revive:

- Just the primary nodes onto a cluster that contains at least four nodes.
- All of the 16 nodes onto a cluster that contains at least 16 nodes.

You may choose to revive your database onto a cluster with more nodes that is necessary in cases where you want to quickly add new nodes. You may also want to revive just the primary nodes in a database onto a larger cluster. In this case, you can use the extra nodes in the cluster to start one or more secondary subclusters.

Required database information

To revive the database, you must know:

- The name of the database to revive (note that the database name is case sensitive)
- The version of Vertica that created the database, so you can use the same or later version
- The total number of all nodes or the number of primary nodes in the database when it shut down

- The URL and credentials for the database's communal storage location
- The user name and password of the database administrator
- The IP addresses of all hosts in the cluster you want to revive onto

If you do not know what version of Vertica created the database or are unsure how many nodes it had, see [Getting Database Details From a Communal Storage Location](#) below.

Required database settings

Before starting the revive process, verify the following conditions are true for your Eon Mode environment:

Eon environment	Revived database requirements
All	<ul style="list-style-type: none"> • The uppermost directories of the <code>catalog</code> , <code>data</code> , and <code>depot</code> directories on all nodes exist and are owned by the database dbadmin • The cluster has no other database running on it
Azure	<p>If your database does not use Azure managed identities to authenticate with the communal storage blob container, the following values must be set:</p> <ul style="list-style-type: none"> • <code>AzureStorageCredentials</code> • <code>AzureStorageEndpointConfig</code> <p>See Azure Blob Storage object store for details.</p>
S3: AWS, on-premises	<p>The following configuration parameters are set:</p> <ul style="list-style-type: none"> • AWSEndpoint • AWSRegion (AWS only) • AWSAuth / IAM role • AWSEnableHttps <p>Important If migrating to an on-premises database, set configuration parameter <code>AWSEnableHttps</code> to be compatible with the database TLS setup: <code>AWSEnableHttps=1</code> if using TLS, otherwise 0. If settings are incompatible, the migration returns with an error.</p>
GCP	<p>The following configuration parameters are set:</p> <ul style="list-style-type: none"> • GCSEAuth • GCSEnableHttps (if not using the default value) • GCSEndpoint (if not using the default value)

Getting database details from a communal storage location

To revive a database, you must know:

- The version of Vertica that created it (so you can use the same or a later version)
- The total number of nodes (when reviving both primary and secondary nodes) or primary nodes (when just reviving the primary nodes) in the database's cluster when it shut down.

If you do not know these details, you can determine them based on the contents of the communal storage location.

If you are not sure which version of Vertica created the database stored in a communal storage location, examine the `cluster_config.json` file. This file is stored in the communal storage location in the folder named `metadata/ databasename` . For example, suppose you have a database named `mydb` stored in the communal storage location `s3://mybucket/mydb` . Then you can download and examine the file `s3://mybucket/mydb/metadata/mydb/cluster_config.json` .

In the `cluster_config.json` , the Vertica version that created the database is stored with the JSON key named `DatabaseVersion` near the top of the file:

```
{
  "CatalogTruncationVersion" : 804,
  "ClusterLeaseExpiration" : "2020-12-21 21:52:31.005936",
  "Database" : {
    "branch" : "",
    "name" : "verticadb"
  },
  "DatabaseVersion" : "v10.1.0",
  "GlobalSettings" : {
    "TupleMoverServices" : -33,
    "appliedUpgrades" : [
      ...
    ]
  }
}
```

In this example, you can revive the storage location using Vertica version 10.1.0 or later.

If you do not know how many nodes or primary nodes the cluster had when it shut down, use the `--display-only` option of the `admintools revive_db` tool. Adding this option prevents `admintools` from reviving the database. Instead, it validates the files in the communal storage and reports details about the nodes that made up the database cluster. Parts of this report show the total number of nodes in the cluster and the number of primary nodes:

```
$ admintools -t revive_db --display-only --communal-storage-location \
    s3://mybucket/verticadb -d verticadb
Attempting to retrieve file: [s3://mybucket/verticadb/metadata/verticadb/cluster_config.json]

Validated 6-node database verticadb defined at communal storage s3://mybucket/verticadb.

Expected layout of database after reviving from communal storage: s3://mybucket/verticadb

== Communal location details: ==
{
  "communal_storage_url": "s3://mybucket/verticadb",
  "num_shards": "3",
  "depot_path": "/vertica/data",
  ...
}

Number of primary nodes: 3
```

You can use `grep` to find just the relevant lines in the report:

```
$ admintools -t revive_db --display-only --communal-storage-location \
    s3://mybucket/verticadb -d verticadb | grep 'Validated\|primary nodes'
Validated 6-node database verticadb defined at communal storage s3://mybucket/verticadb.
Number of primary nodes: 3
```

Creating a parameter file

For Eon Mode deployments that are not on AWS, you must create a configuration file to pass the parameters listed in the table in the previous section to `admintools`. Traditionally this file is named `auth_params.conf` although you can choose any file name you want.

For on-premises Eon Mode databases, this parameter file is the same one you used when initially installing the database. See the following links for instructions on creating a parameter file for the communal storage solution you are using for your database:

- [Pure Storage FlashBlade](#)
- [HDFS](#)
- [MinIO](#)

For databases running on Microsoft Azure, the parameter file is only necessary if your database does not use managed identities. This file is the same format that you use to manually install an Eon Mode database. See [Manually create an Eon Mode database on Azure](#) for more information.

To revive an Eon Mode database on GCP manually, create a configuration file to hold the `GCSAuth` parameter and optionally, the `GCSEnableHttp` parameter.

You must supply the `GCSAuth` parameter to enable Vertica to read from the communal storage location stored in GCS. The value for this parameter is the HMAC access key and secret:

```
GCSAuth = HMAC_access_key:HMAC_secret_key
```

See [Creating an HMAC Key](#) for more information about HMAC keys.

If your Eon Mode database does not use encryption when accessing communal storage on GCS, then disable HTTPS access by adding the following line to `auth_params.conf` :

```
GCSEnableHttps = 0
```

Running the `revive_db` tool

Use the `admintools revive_db` tool to revive the database:

1. Use SSH to access a cluster host as an administrator.
2. Depending on your environment, run one of the following `admintools` commands:

- AWS:

```
$ admintools -t revive_db \  
--communal-storage-location=s3://communal_store_path \  
-s host1,... -d database_name
```

Important

If you revive an on-premises Eon Mode database to AWS, check the `controlmode` setting in `/opt/vertica/config/admintools.conf` . This setting must be compatible with the network messaging requirements of your Eon implementation. AWS relies on unicast messaging, which is compatible with a `controlmode` setting of `point-to-point` (pt2pt). If the source database `controlmode` setting was `broadcast` and you migrate to S3/AWS communal storage, you must change `controlmode` with `admintools`:

```
$ admintools -t re_ip -d dbname -T
```

- On-premises and other environments:

```
$ admintools -t revive_db -x auth_params.conf \  
--communal-storage-location=storage-schema://communal_store_path \  
-s host1_ip,... -d database_name
```

This example revives a six-node on-premises database:

```
$ admintools -t revive_db -x auth_params.conf \  
--communal-storage-location=s3://mybucket/mydir \  
-s 172.16.116.27,172.16.116.28,172.16.116.29,172.16.116.30,\  
172.16.116.31,172.16.116.32 -d VMart
```

The following example demonstrates reviving a three-node database hosted on GCP:

```
$ admintools -t revive_db -x auth_params.conf \  
--communal-storage-location gs://mybucket/verticadb \  
-s 10.142.0.35,10.142.0.38,10.142.0.39 -d VerticaDB
```

Attempting to retrieve file:

```
[gs://mybucket/verticadb/metadata/VerticaDB/cluster_config.json]
```

Validated 3-node database VerticaDB defined at communal storage

```
gs://mybucket/verticadb .
```

Cluster lease has expired.

Load Remote Catalog succeeded on all hosts

Database revived successfully.

Reviving only primary subclusters

You can revive just the primary subclusters in an Eon Mode database. Make the list of hosts you pass to the admintools `revive_db` tool's `--hosts` (or `-s`) argument match the number of primary nodes that were in the database when it shut down. For example, if you have a six-node Eon Mode database that had three primary nodes, you can revive just the primary nodes by supplying three hosts in the `--hosts` argument:

```
$ admintools -t revive_db --communal-storage-location=s3://verticadb -d verticadb \
-x auth_params.conf --hosts node01,node02,node03
Attempting to retrieve file: [s3://verticadb/metadata/verticadb/cluster_config.json]
Consider reviving to only primary nodes: communal storage indicates 6 nodes, while
3 nodes were specified

Validated 3-node database verticadb defined at communal storage s3://verticadb.
Cluster lease has expired.
Preparation succeeded all hosts

Calculated necessary addresses for all nodes.
Starting to bootstrap nodes. Please wait, databases with a large catalog may take a
while to initialize.
>>Calling bootstrap on node v_verticadb_node0002 (192.168.56.103)
>>Calling bootstrap on node v_verticadb_node0003 (192.168.56.104)
Load Remote Catalog succeeded on all hosts

Database revived successfully.
```

In a database where you have revived only the primary nodes, the secondary nodes are down. Their IP address is set to 0.0.0.0 so they are not part of the database. For example, querying the `NODES` system table in the database revived in the previous example shows the secondary nodes are all down:

```
=> SELECT node_name,node_state,node_address,subcluster_name FROM NODES;
 node_name | node_state | node_address | subcluster_name
-----+-----+-----+-----
v_verticadb_node0001 | UP | 192.168.56.102 | default_subcluster
v_verticadb_node0002 | UP | 192.168.56.103 | default_subcluster
v_verticadb_node0003 | UP | 192.168.56.104 | default_subcluster
v_verticadb_node0004 | DOWN | 0.0.0.0 | analytics
v_verticadb_node0005 | DOWN | 0.0.0.0 | analytics
v_verticadb_node0006 | DOWN | 0.0.0.0 | analytics
```

Note

Secondary nodes that have not been revived may cause error messages if your database has the large cluster feature enabled. (See [Large cluster](#) for more information about the large cluster feature.)

For example, adding a node to a secondary subcluster can fail if the new node would be assigned a control node that has not been revived. In this case, Vertica reports that adding the node failed because the control node has an invalid IP address.

If you encounter errors involving control nodes with invalid IP addresses, consider reviving the unrevived secondary subcluster, as explained below.

Because Vertica considers these unrevived nodes to be down, it may not allow you to remove them or remove their subcluster while they are in their unrevived state. The best way to remove the nodes or the secondary subcluster is to revive them first.

Reviving unrevived secondary subclusters

If you revived just the primary subclusters in your database, you can later choose to revive some or all of the secondary subclusters. Your cluster must have hosts that are not nodes in the database that Vertica can use to revive the unrevived nodes. If your cluster does not have enough of these non-node hosts, you can add more hosts. See [Adding hosts to a cluster](#).

You revive a secondary subcluster by using the admintools' `restart_subcluster` tool. You supply it with the list of hosts in the `--hosts` argument where the nodes will be revived. The number of hosts in this list must match the number of nodes in the subcluster. You must revive all nodes in the subcluster at the same time. If you pass `restart_subcluster` a list with fewer or more hosts than the number of nodes defined in the subcluster, it returns an error.

The follow example demonstrates reviving the secondary subcluster named analytics shown in the previous examples.

```
$ admintools -t restart_subcluster -d verticadb --hosts node04,node05,node06 \
    -p 'password' -c analytics
Updating hostnames of nodes in subcluster analytics.
Replicating configuration to all nodes
Generating new configuration information and reloading spread
Hostnames of nodes in subcluster analytics updated successfully.

Synchronizing metadata

An Eon Mode database maintains its catalog, which contains all database metadata, in communal storage. Vertica uses this metadata when it revives the database, so it is important that the catalog is always up to date. Vertica automatically synchronizes the catalog at regular intervals as specified by the configuration parameter [CatalogSyncInterval](#)—by default, set to five minutes.

In general, it is not necessary to monitor the synchronization process or change it. One exception applies: before shutting down a database that you intend to revive or replicate, it is good practice to verify that the catalog contains all recent changes, and if necessary synchronize it manually.

Verifying catalog status

You can verify the synchronization status of the database catalog in two ways, depending on whether the database is running.

If the database is running, query and compare these two system tables:

- [CATALOG_SYNC_STATE](#): Shows how recently each node synchronized its catalog to communal storage, and the version that it synchronized.
- [CATALOG_TRUNCATION_STATUS](#): Shows the latest synchronization status of the database catalog. Catalog synchronization is up to date when columns [TRUNCATION_CATALOG_VERSION](#) and [CURRENT_CATALOG_VERSION](#) are the same.

If the database is not currently running, check the following JSON file on communal storage:

```
/metadata/ database-name /cluster_config.json
```

The catalog truncation version and timestamp in this file indicate when Vertica last synchronized the database catalog.

Manually synchronizing the database datalog

If necessary, call [SYNC_CATALOG](#) to synchronize the catalog immediately with all nodes or a specific node:

```
=> SELECT sync_catalog();
```

Customizing synchronization intervals

By default, Vertica checks for catalog changes every five minutes. Occasionally, you might want to change this setting temporarily—for example, set it to a high value in order to take a snapshot of the current bucket contents:

```
=> ALTER DATABASE DEFAULT SET CatalogSyncInterval = 300;
```

Important

If you set CatalogSyncInterval to high value for a specific task, be sure to revert it to its default setting immediately after the task is complete:

```
=> ALTER DATABASE DEFAULT CLEAR PARAMETER CatalogSyncInterval;
```

Containerized Vertica

Vertica [Eon Mode](#) leverages [container technology](#) to meet the needs of modern application development and operations workflows that must deliver software quickly and efficiently across a variety of infrastructures. Containerized Vertica [supports Kubernetes](#) with [automation tools](#) to help maintain the state of your environment with minimal disruptions and manual intervention.

Containerized Vertica provides the following benefits:

- **Performance** : Eon Mode [separates compute from storage](#), which provides the optimal architecture for stateful, containerized applications. Eon Mode [subclusters](#) can target specific workloads and scale elastically according to the current computational needs.
- **High availability** : Vertica containers provide a consistent, repeatable environment that you can deploy quickly. If a database host or service fails, you can easily replace the resource.
- **Resource utilization** : A container is a runtime environment that packages an application and its dependencies in an isolated process. This isolation allows containerized applications to share hardware without interference, providing granular resource control and cost savings.
- **Flexibility** : Kubernetes is the de facto container orchestration platform. It is supported by a large ecosystem of public and private cloud providers.

Containerized Vertica ecosystem

Vertica provides various tools and artifacts for production and development environments. The containerized Vertica ecosystem includes the following:

- **Vertica Helm chart** : [Helm](#) is a Kubernetes package manager that bundles into a single package the YAML manifests that deploy Kubernetes objects. Download Vertica Helm charts from the [Vertica Helm Charts Repository](#).
- **Custom Resource Definition (CRD)** : A CRD is a shared global object that extends the Kubernetes API with your custom resource types. You can use a CRD to instantiate a custom resource (CR), a deployable object with a desired state. [Vertica provides CRDs](#) that deploy and support the Eon Mode architecture on Kubernetes.
- **VerticaDB Operator** : The operator is a custom controller that monitors the state of your CR and automates administrator tasks. If the current state differs from the declared state, the operator works to correct the current state.
- **Admission controller** : The admission controller uses a webhook that the operator queries to verify changes to mutable states in a CR.
- **VerticaDB vlogger** : The vlogger is a lightweight image used to deploy a sidecar utility container. The sidecar sends logs from `vertica.log` in the Vertica server container to standard output on the host node to simplify log aggregation.
- **Vertica Community Edition (CE) image** : The CE image is the containerized version of the limited Enterprise Mode [Vertica community edition \(CE\)](#) license. The CE image provides a test environment consisting of an example database and developer tools. In addition to the pre-built CE image, you can build a custom CE image with the tools provided in the Vertica [one-node-ce GitHub repository](#).
- **Communal Storage Options** : Vertica supports a variety of public and private cloud storage providers. For a list of supported storage providers, see [Containerized environments](#).
- **Kafka integration** : [Containerized Kafka Scheduler](#) provides a CRD and Helm chart to create and launch the [Vertica Kafka scheduler](#), a standalone Java application that automatically consumes data from one or more Kafka topics and then loads the structured data into Vertica.

Repositories

Vertica maintains the following open source projects on [GitHub](#) :

- **vertica-kubernetes** : Vertica on Kubernetes is an open source project that welcomes contributions from the Vertica community. The [vertica-kubernetes GitHub repository](#) contains all the source code for the Vertica on Kubernetes integration, and includes [contributing guidelines](#) and instructions on how to set up [development workflows](#).
- **vcluster** : [vcluster](#) is a Go library that uses a high-level REST interface to perform database operations with the [Node Management Agent \(NMA\)](#) and [HTTPS service](#). The [vclusterops](#) library replaces [Administration tools](#) (admintools), a traditional command-line interface that executes administrator commands through STDIN and required SSH keys for internal node communications. The [vclusterops](#) deployment is more efficient in containerized environments than the admintools deployment. vcluster is an open source project, so you can build custom implementations with the library. For details about migrating your existing admintools deployment to vcluster, see [Upgrading Vertica on Kubernetes](#).

- **vertica-containers** : [GitHub repository](#) that contains source code for the following container-based projects:
 - [one-node-ce](#) : Tools to build a single-node container that runs the [Vertica Community Edition \(CE\)](#), a limited license that allows up to 1TB of data.
 - [UDx-container](#) : Tools to build a container that packages the binaries, libraries, and compilers required to create C++ Vertica user-defined extensions. For additional details about extending Vertica in C++, see [C++ SDK](#).
 - [vertica-kafka-scheduler](#) : Tools to build and maintain a containerized [Vertica Kafka scheduler](#).

Containerized Vertica on Kubernetes

Kubernetes is an open-source container orchestration platform that automatically manages infrastructure resources and schedules tasks for containerized applications at scale. Kubernetes achieves automation with a declarative model that decouples the application from the infrastructure. The administrator provides Kubernetes the desired state of an application, and Kubernetes deploys the application and works to maintain that desired state. This frees the administrator to update the application as business needs evolve, without worrying about the implementation details.

An application consists of resources, which are stateful objects that you create from Kubernetes resource types. Kubernetes provides access to resource types through the Kubernetes API, an HTTP API that exposes resource types as endpoints. The most common way to create a resource is with a YAML-formatted manifest file that defines the desired state of the resource. You use the [kubectl command-line tool](#) to request a resource instance of that type from the Kubernetes API. In addition to the default resource types, you can extend the Kubernetes API and define your own resource types as a Custom Resource Definition (CRD).

To manage the infrastructure, Kubernetes uses a host to run the control plane, and designates one or more hosts as worker nodes. The control plane is a collection of services and controllers that maintain the desired state of Kubernetes objects and schedule tasks on worker nodes. Worker nodes complete tasks that the control plane assigns. Just as you can create a CRD to extend the Kubernetes API, you can create a custom controller that maintains the state of your custom resources (CR) created from the CRD.

Vertica custom resource definition and custom controller

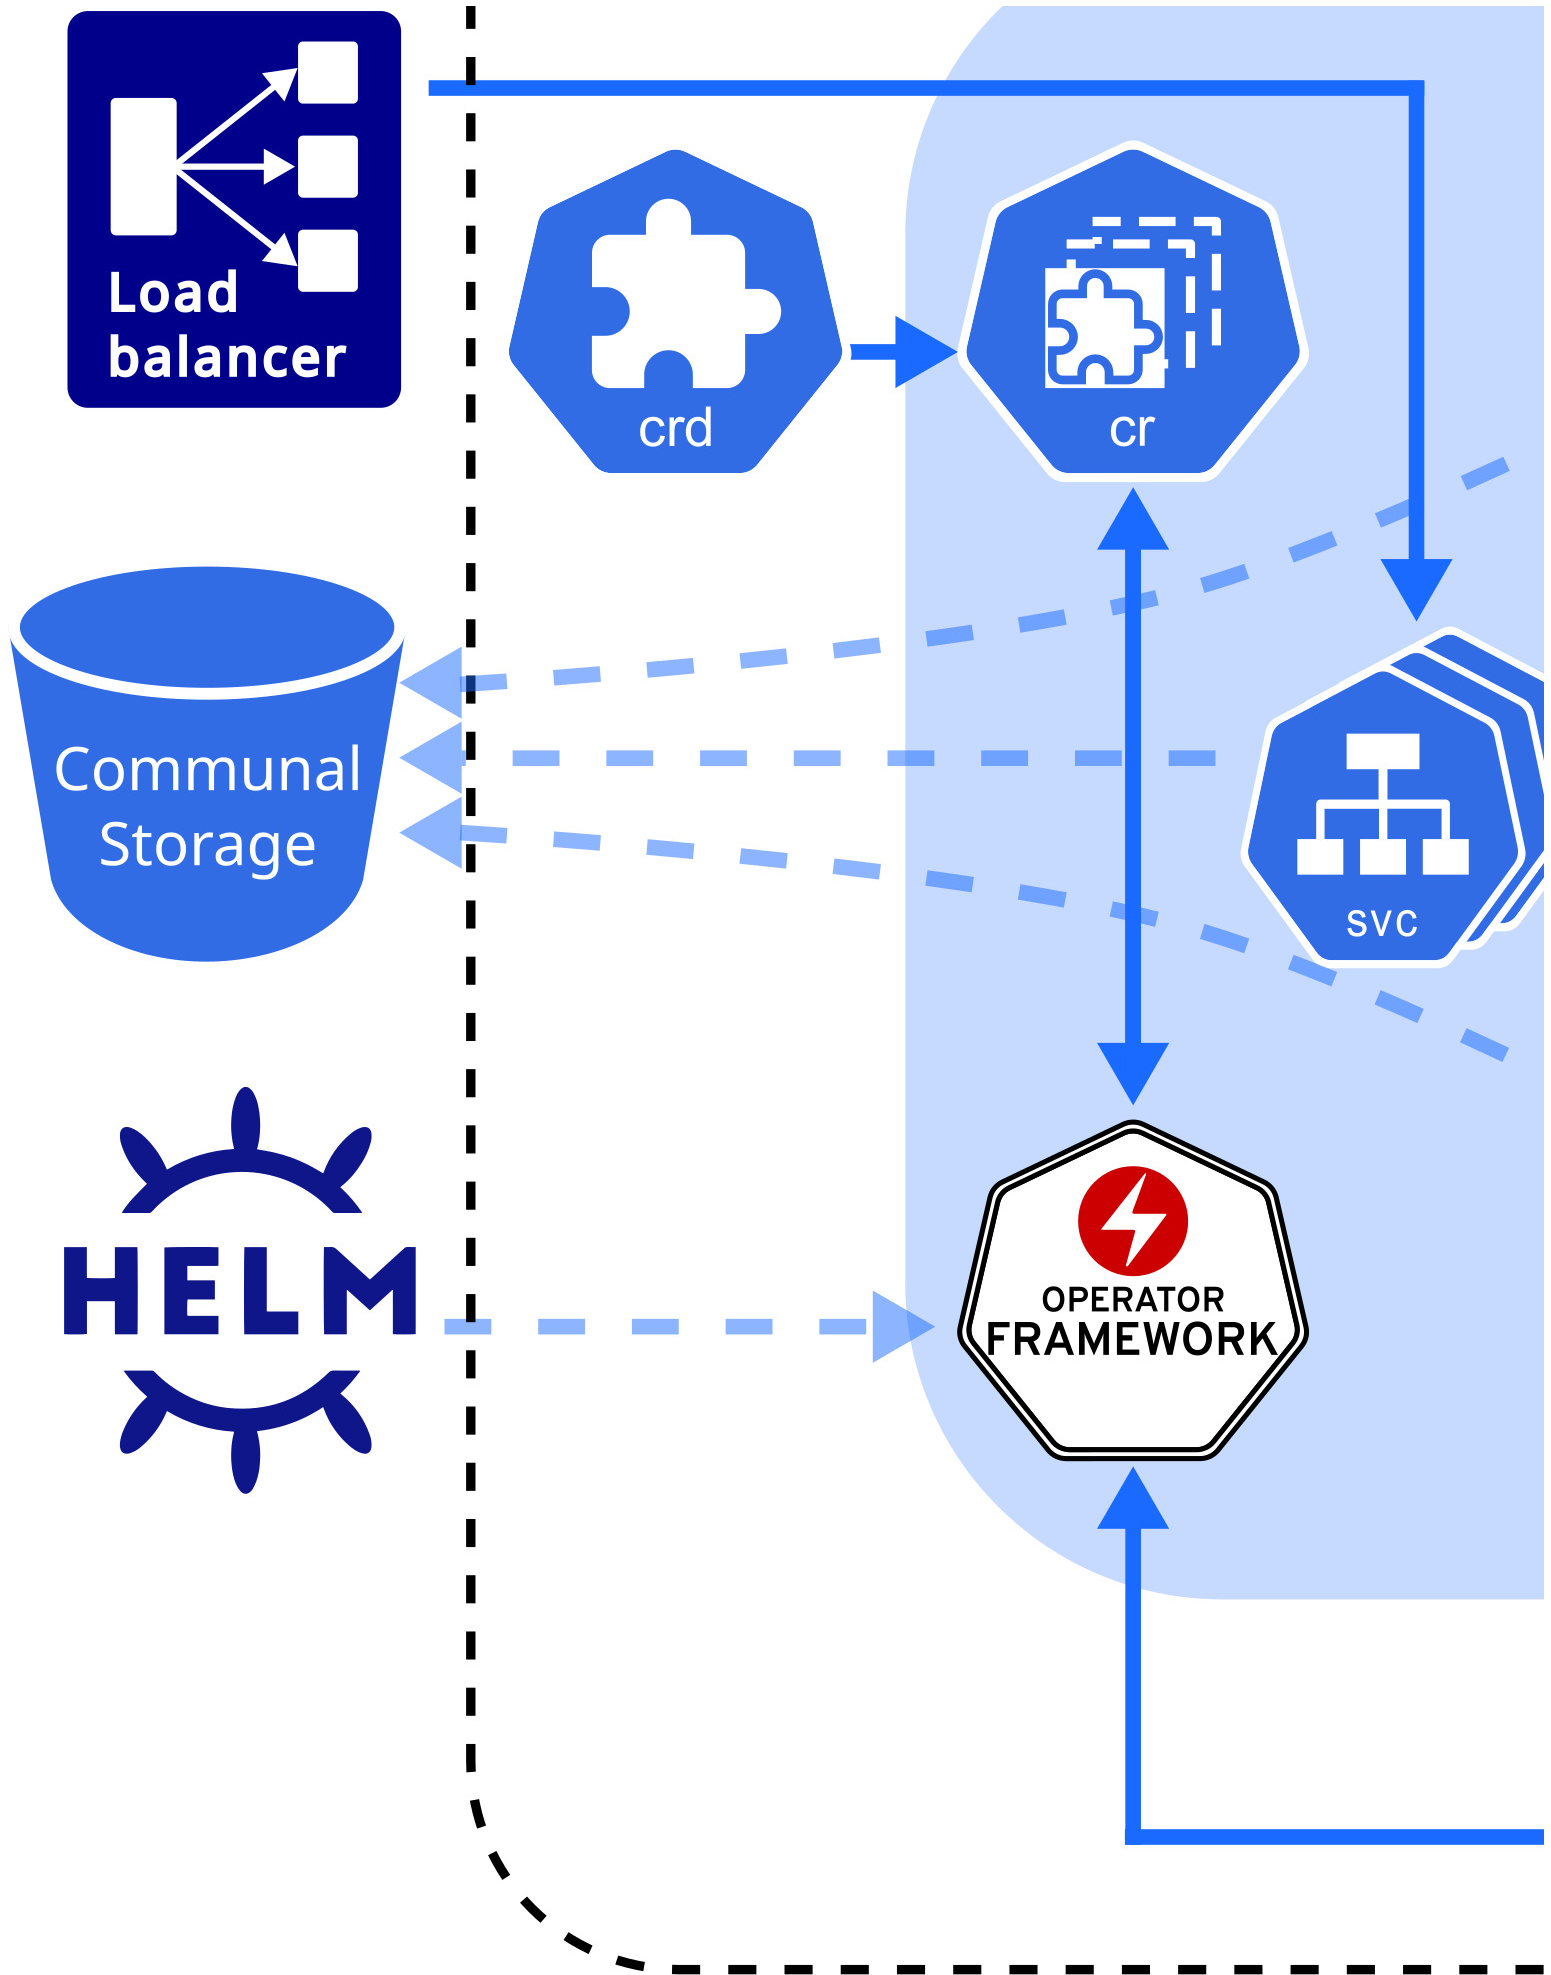

The [VerticaDB](#) CRD extends the Kubernetes API so that you can create custom resources that deploy an Eon Mode database as a [StatefulSet](#). In addition, Vertica provides the VerticaDB operator, a custom controller that maintains the desired state of your CR and automates lifecycle tasks. The result is a self-healing, highly-available, and scalable Eon Mode database that requires minimal manual intervention.

To simplify deployment, Vertica packages the CRD and the operator in Helm charts. A [Helm chart](#) bundles manifest files into a single package to create multiple resource type objects with a single command.

Custom resource definition architecture

The Vertica CRD creates a StatefulSet, a workload resource type that persists data with ephemeral Kubernetes objects. The following diagram describes the Vertica CRD architecture:

VerticaDB operator

The [VerticaDB operator](#) is a cluster-scoped custom controller that maintains the state of custom objects and automates administrator tasks across all namespaces in the cluster. The operator watches objects and compares their current state to the desired state declared in the [custom resource](#). When the current state does not match the desired state, the operator works to restore the objects to the desired state.

In addition to state maintenance, the operator:

- Installs Vertica
- Creates an Eon Mode database
- Upgrades Vertica
- Revives an existing Eon Mode database
- Restarts and reschedules DOWN pods
- Scales subclusters
- Manages services for pods
- Monitors pod health
- Handles load balancing for internal and external traffic

To validate changes to the custom resource, the operator queries the admission controller, a webhook that provides rules for mutable states in a custom resource.

Vertica makes the operator and admission controller available with [Helm charts](#), kubectl command-line tool, or through [OperatorHub.io](#). For details about installing the operator and the admission controller with both methods, see [Installing the VerticaDB operator](#).

Vertica pod

A pod is essentially a wrapper around one or more logically grouped containers. A Vertica pod in the default configuration consists of two containers: the Vertica server container that runs the main Vertica process, and the [Node Management Agent](#) (NMA) container.

The NMA runs in a [sidecar container](#), which is a container that contributes to the pod's main process, the Vertica server. The Vertica pod runs a single process per container to align each process lifetime with its container lifetime. This alignment provides the following benefits:

- Accurate health checks. A container can have only one health check, so performing a health check on a container with multiple running processes might return inaccurate results.
- Granular [Kubernetes probe](#) control. Kubernetes sets probes at the container level. If the Vertica container runs multiple processes, the NMA process might interfere with the probe that you set for the Vertica server process. This interference is not an issue with single-process containers.
- Simplified monitoring. A container with multiple processes has multiple states, which complicates monitoring. A container with a single process returns a single state.
- Easier troubleshooting. If a container runs multiple processes and crashes, it might be difficult to determine which failure caused the crash. Running one process per container makes it easier to pinpoint issues.

When a Vertica pod launches, the NMA process starts and prepares the configuration files for the Vertica server process. After the server container retrieves environment information from the NMA configuration files, the Vertica server process is ready.

All containers in the Vertica pod consume the host node resources in a shared execution environment. In addition to sharing resources, a pod extends the container to interact with Kubernetes services. For example, you can assign labels to associate pods to other objects, and you can implement affinity rules to schedule pods on specific host nodes.

DNS names provide continuity between pod lifecycles. Each pod is assigned an ordered and stable DNS name that is unique within its cluster. When a Vertica pod fails, the rescheduled pod uses the same DNS name as its predecessor. If a pod needs to persist data between lifecycles, you can [mount a custom volume](#) in its filesystem.

Rescheduled pods require information about the environment to become part of the cluster. This information is provided by the [Downward API](#). Environment information, such as the superuser password [Secret](#), is mounted in the `/etc/podinfo` directory.

NMA sidecar

The NMA sidecar exposes a REST API that the VerticaDB operator uses to administer your cluster. This container runs the same image as the Vertica server process, specified by the `spec.image` [parameter setting](#) in the [VerticaDB custom resource definition](#).

The NMA sidecar is designed to consume minimal resources, but because the database size determines the amount of resources consumed by some NMA operations, there are no default resource limits. This prevents failures that result from inadequate available resources.

Running the NMA in a sidecar enables idiomatic Kubernetes logging, which sends all logs to STDOUT and STDERR on the host node. In addition, the [kubectl logs command](#) accepts a container name, so you can specify a container name during log collection.

Sidecar logger

The Vertica server process [writes log messages](#) to a catalog file named `vertica.log`. However, idiomatic Kubernetes practices [send log messages](#) to

STDOUT and STDERR on the host node for log aggregation.

To align Vertica server logging with Kubernetes convention, Vertica provides the [vertica-logger sidecar image](#). You can run this image in a sidecar, and it retrieves logs from [vertica.log](#) and sends them to the container's STDOUT and STDERR stream. If your sidecar logger needs to persist data, you can mount a [custom volume](#) in the filesystem.

For implementation details, see [VerticaDB custom resource definition](#).

Persistent storage

A pod is an ephemeral, immutable object that requires access to external storage to persist data between lifecycles. To persist data, the operator uses the following API resource types:

- **StorageClass** : Represents an external storage provider. You must create a StorageClass object separately from your custom resource and set this value with the [local.storageClassName configuration parameter](#).
- **PersistentVolume (PV)** : A unit of storage that mounts in a pod to persist data. You dynamically or statically provision PVs. Each PV references a StorageClass.
- **PersistentVolumeClaim (PVC)** : The resource type that a pod uses to describe its StorageClass and storage requirements. When you delete a VerticaDB CR, its PVC is deleted.

A pod mounts a PV in its filesystem to persist data, but a PV is not associated with a pod by default. However, the pod is associated with a PVC that includes a StorageClass in its storage requirements. When a pod requests storage with a PVC, the operator observes this request and then searches for a PV that meets the storage requirements. If the operator locates a PV, it binds the PVC to the PV and mounts the PV as a volume in the pod. If the operator does not locate a PV, it must either dynamically provision one, or the administrator must manually provision one before the operator can bind it to a pod.

PVs persist data because they exist independently of the pod life cycle. When a pod fails or is rescheduled, it has no effect on the PV. When you delete a [VerticaDB](#), the VerticaDB operator automatically deletes any PVCs associated with that VerticaDB instance.

For additional details about StorageClass, PersistentVolume, and PersistentVolumeClaim, see the [Kubernetes documentation](#).

StorageClass requirements

The StorageClass affects how the Vertica server environment and operator function. For optimum performance, consider the following:

- If you do not set the [local.storageClassName configuration parameter](#), the operator uses the default storage class. If you use the default storage class, confirm that it meets storage requirements for a production workload.
- Select a StorageClass that uses a [recommended storage format type](#) as its `fsType`.
- Use [dynamic volume provisioning](#). The operator requires on-demand volume provisioning to create PVs as needed.

Local volume mounts

The operator mounts a single PVC in the `/home/dbadmin/local-data/` directory of each pod to persist data. Each of the following subdirectories is a [sub-path](#) into the volume that backs the PVC:

- `/catalog` : Optional subdirectory that you can create if your environment requires a catalog location that is separate from the local data. You can customize this path with the [local.catalogPath parameter](#).
By default, the catalog is stored in the `/data` subdirectory.
- `/data` : Stores any temporary files, and the catalog if [local.catalogPath](#) is not set. You can customize this path with the [local.dataPath parameter](#).
- `/depot` : Improves depot warming in a rescheduled pod. You can customize this path with the [local.depotPath parameter](#).

Note

You can change the volume type for the `/depot` with the [local.depotVolume parameter](#). By default, this parameter is set to `PersistentVolume`, and the operator creates the `/depot` sub-path. If [local.depotVolume](#) is not set to `PersistentVolume`, the operator does not create the sub-path.

- `/opt/vertica/config` : Persists the contents of the configuration directory between restarts.
- `/opt/vertica/log` : Persists log files between pod restarts.
- `/tmp/scrutinize` : Target location for the final scrutinize tar file and any additional files generated during scrutinize diagnostics collection.

Note

Kubernetes assigns each custom resource a unique identifier. The volume mount paths include the unique identifier between the mount point and the subdirectory. For example, the full path to the `/data` directory is `/home/dbadmin/local-data/ uid /data`.

By default, each path mounted in the `/local-data` directory is owned by the user or group specified by the operator. To customize the user or group, set the [podSecurityContext custom resource definition parameter](#).

Custom volume mounts

You might need to persist data between pod lifecycles in one of the following scenarios:

- An external process performs a task that requires long-term access to the Vertica server data.
- Your custom resource includes a [sidecar container](#) in the Vertica pod.

You can mount a custom volume in the Vertica pod or sidecar filesystem. To mount a custom volume in the Vertica pod, add the definition in the `spec` section of the CR. To mount the custom volume in the sidecar, add it in an element of the `sidecars` array.

The CR requires that you provide the volume type and a name for each custom volume. The CR accepts any Kubernetes volume type. The `volumeMounts.name` value identifies the volume within the CR, and has the following requirements and restrictions:

- It must match the `volumes.name` [parameter](#) setting.
- It must be unique among all volumes in the `/local-data`, `/podinfo`, or `/licensing` mounted directories.

For instructions on how to mount a custom volume in either the Vertica server container or in a sidecar, see [VerticaDB custom resource definition](#).

Service objects

Vertica on Kubernetes provides two service objects: a headless service that requires no configuration to maintain DNS records and ordered names for each pod, and a load balancing service that manages internal traffic and external client requests for the pods in your cluster.

Load balancing services

Each subcluster uses a single load balancing service object. You can manually assign a name to a load balancing service object with the `subclusters[].serviceName` parameter in the custom resource. Assigning a name is useful when you want to:

- Direct traffic from a single client to multiple subclusters.
- Scale subclusters by workload with more flexibility.
- Identify subclusters by a custom service object name.

To configure the type of service object, use the `subclusters[].serviceType` parameter in the custom resource to define a [Kubernetes service type](#).

Vertica supports the following service types:

- **ClusterIP** : The default service type. This service provides internal load balancing, and sets a stable IP and port that is accessible from within the subcluster only.
- **NodePort** : Provides external client access. You can specify a port number for each host node in the subcluster to open for client connections.
- **LoadBalancer** : Uses a cloud provider load balancer to create NodePort and ClusterIP services as needed. For details about implementation, see the [Kubernetes documentation](#) and your cloud provider documentation.

Important

To prevent performance issues during heavy network traffic, Vertica recommends that you set `--proxy-mode` to `iptables` for your Kubernetes cluster.

Because [native Vertica load balancing](#) interferes with the Kubernetes service object, Vertica recommends that you allow the Kubernetes services to manage load balancing for the subcluster. You can configure the native Vertica load balancer within the Kubernetes cluster, but you receive unexpected results. For example, if you set the Vertica load balancing policy to ROUNDROBIN, the load balancing appears random.

For additional details about Kubernetes services, see the [official Kubernetes documentation](#).

Security considerations

Vertica on Kubernetes supports both TLS and mTLS for communications between resource objects. You must manually configure TLS in your environment. For details, see [TLS protocol](#).

The VerticaDB operator manages changes to the certificates. If you update an existing certificate, the operator replaces the certificate in the Vertica server container. If you add or delete a certificate, the operator reschedules the pod with the new configuration.

The subsequent sections detail internal and external connections that require TLS for secure communications.

Admission controller webhook certificates

The VerticaDB operator Helm chart includes the admission controller, a webhook that communicates with the Kubernetes API server to validate changes to a resource object. Because the API server communicates over HTTPS only, you must configure TLS certificates to authenticate communications between the API server and the webhook.

The method you use to install the VerticaDB operator determines how you manage TLS certificates for the admission controller:

- Helm charts: In the default configuration, the operator generates self-signed certificates. You can add custom certificates with the [webhook.certSource Helm chart parameter](#).
- kubectl: The operator generates self-signed certificates.
- OperatorHub.io: Runs on the Operator Lifecycle Manager (OLM) and automatically creates and mounts a self-signed certificate for the webhook. This installation method does not require additional action.

For details about each installation method, see [Installing the VerticaDB operator](#).

Node Management Agent certificates

The [Node Management Agent](#) (NMA) exposes a REST API for cluster administration. By default, the NMA generates self-signed certificates that are safe for production environments, but you might require custom certificates. You can add these custom certificates with the [nmaTLSSecret custom resource parameter](#).

Communal storage certificates

[Supported storage locations](#) authenticate requests with a self-signed certificate authority (CA) bundle. For TLS configuration details for each provider, see [Configuring communal storage](#).

Client-server certificates

You might require multiple certificates to authenticate external client connections to the [load balancing service object](#). You can mount one or more custom certificates in the Vertica server container with the [certSecrets custom resource parameter](#). Each certificate is mounted in the container at `/certs/ cert-name / key`.

For details, see [VerticaDB custom resource definition](#).

Prometheus metrics certificates

Vertica integrates with [Prometheus](#) to scrape metrics about the VerticaDB operator and the server process. The operator and server export metrics independently from one another, and each set of metrics requires a different TLS configuration.

The operator SDK framework enforces role-based access control (RBAC) to the metrics with a proxy sidecar that uses self-signed certificates to authenticate requests for authorized service accounts. If you run Prometheus outside of Kubernetes, you cannot authenticate with a service account, so you must provide the proxy sidecar with custom TLS certificates.

The Vertica server exports metrics with the [HTTPS service](#). This service requires client, server, and CA certificates to configure [mutual mode TLS](#) for a secure connection.

For details about both the operator and server metrics, see [Prometheus integration](#).

System configuration

As a best practice, make system configurations on the host node so that pods inherit those settings from the host node. This strategy eliminates the need to provide each pod a [privileged security context](#) to make system configurations on the host.

To manually configure host nodes, refer to the following sections:

- [Automatically configured operating system settings](#)
- [Manually configured operating system settings](#)

The superuser account—historically, the dbadmin account—must use one of the authentication techniques described in [Dbadmin authentication access](#).

Vertica images

The following table describes Vertica server and automation tool images:

Image	Tags	Description
Minimal image	24.2.0-0-minimal latest	Optimized for Kubernetes. This image includes the following packages for UDx development : <ul style="list-style-type: none"> • C++ • Python

Full image	24.2.0-0	Optimized for Kubernetes, and includes the following packages for machine learning and UDx development : <ul style="list-style-type: none"> • TensorFlow • Java 8 • C++ • Python <p>Important</p> <p>The Apache Kafka and Apache Spark integrations require Java 8.</p>
Community Edition	24.2.0-0	A single-node Enterprise Mode image for test environments. For more information, see Vertica community edition (CE) .
VerticaDB operator	latest	This image includes the following packages for UDx development : <ul style="list-style-type: none"> • C++ • Python <p>The operator monitors the state of your custom resources and automates lifecycle tasks for Vertica on Kubernetes. For installation instructions, see Installing the VerticaDB operator .</p>
Vertica logger	1.0.1	Lightweight image for sidecar logging. The logger sends the contents of <code>vertica.log</code> to STDOUT on the host node. For implementation details, see VerticaDB custom resource definition .
Kafka Scheduler	24.2.0	Containerized version of the Vertica Kafka Scheduler , a mechanism that automatically loads data from Kafka into a Vertica database. For details, see Containerized Kafka Scheduler .

Creating a custom Vertica image

The [Creating a Vertica Image](#) tutorial in the [Vertica Integrator's Guide](#) provides a line-by-line description of the [Dockerfile](#) hosted on [GitHub](#) . You can add dependencies to replicate your development and production environments.

Python container UDx

The Vertica images with Python UDx development capabilities include the [vertica_sdk](#) package and the [Python Standard Library](#) .

If your UDx depends on a Python package that is not included in the image, you must make the package available to the Vertica process during runtime. You can either mount a volume that contains the package dependencies, or you can create a custom Vertica server image.

Important

When you load the UDx library with [CREATE LIBRARY](#) , the `DEPENDS` clause must specify the location of the Python package in the Vertica server container filesystem.

Use the [Python Package Index](#) to download Python package source distributions.

Mounting Python libraries as volumes

You can mount a Python package dependency as a volume in the Vertica server container filesystem. A Python UDx can access the contents of the volume at runtime.

1. Download the package source distribution to the host machine.
2. On the host machine, extract the tar file contents into a mountable volume:

```
$ tar -xvf lib-name.version.tar.gz -C /path/to/py-dependency-vol
```

3. Mount the volume that contains the extracted source distribution in the custom resource (CR). The following snippet mounts the `py-dependency-vol` volume in the Vertica server container:

```
spec:
  ..
  volumeMounts:
  - name: nfs
    mountPath: /path/to/py-dependency-vol
  volumes:
  - name: nfs
    nfs:
      path: /nfs
      server: nfs.example.com
  ..
```

For details about mounting custom volumes in a CR, see [VerticaDB custom resource definition](#).

Adding a Python library to a custom Vertica image

Create a custom image that includes any Python package dependencies in the Vertica server base image.

For a comprehensive guide about creating a custom Vertica image, see the [Creating a Vertica Image](#) tutorial in the [Vertica Integrator's Guide](#).

1. Download the package source distribution on the machine that builds the container.
2. Create a Dockerfile that includes the Python source distribution:

```
FROM vertica/vertica-k8s:latest
ADD lib-name.version.tar.gz /path/to/target-dir
..
```

In the preceding example, the **ADD** command automatically extracts the contents of the tar file into the **target-dir** directory.

3. Build the Dockerfile:

```
$ docker build -t image-name:tag
```

4. Push the image to a container registry so that you can add the image to a Vertica custom resource:

```
$ docker image push registry-host:port/registry-username/image-name:tag
```

VerticaDB operator

The Vertica operator automates error-prone and time-consuming tasks that a Vertica on Kubernetes administrator must otherwise perform manually. The operator:

- Installs Vertica
- Creates an Eon Mode database
- Upgrades Vertica
- Revives an existing Eon Mode database
- Restarts and reschedules DOWN pods
- Scales subclusters
- Manages services for pods
- Monitors pod health
- Handles load balancing for internal and external traffic

The Vertica operator is a Go binary that uses the [SDK operator framework](#). It runs in its own pod, and is cluster-scoped to manage any resource objects in any namespace across the cluster.

For details about installing and upgrading the operator, see [Installing the VerticaDB operator](#).

Monitoring desired state

Because the operator is cluster-scoped, each cluster is allowed one operator pod that acts as a custom controller and monitors the state of the [custom resource objects](#) within all namespaces across the cluster. The operator uses the [control loop](#) mechanism to reconcile state changes by investigating state change notifications from the custom resource instance, and periodically comparing the current state with the desired state.

If the operator detects a change in the desired state, it determines what change occurred and reconciles the current state with the new desired state. For example, if the user deletes a subcluster from the custom resource instance and successfully saves the changes, the operator deletes the corresponding subcluster objects in Kubernetes.

Validating state changes

All [VerticaDB operator installation options](#) include an admission controller, which uses a webhook to prevent invalid state changes to the custom resource. When you save a change to a custom resource, the admission controller webhook queries a REST endpoint that provides rules for mutable

states in a custom resource. If a change violates the state rules, the admission controller prevents the change and returns an error. For example, it returns an error if you try to save a change that violates [K-Safety](#).

Limitations

The operator has the following limitations:

- You must manually configure TLS. For details, see [Containerized Vertica on Kubernetes](#).
- Vertica recommends that you do not use the [Large cluster](#) feature. If a control node fails, it might cause more than half of the database nodes to fail. This results in the database losing quorum.
- [Importing and exporting](#) data between a cluster outside of Kubernetes requires that you expose the service with the [NodePort or LoadBalancer service type](#) and properly configure the network.

Important

When configuring the network to import or export data, you must assign each node a static IP export address. When pods are rescheduled to different nodes, you must update the static IP address to reflect the new node.

See [Configuring the Network to Import and Export Data](#) for more information.

The VerticaDB operator 2.0.0 does not use [Administration tools \(admintools\)](#) with API version `v1`. The following features require admintools commands, so they are not available with that operator version and API version configuration:

- [Hybrid Kubernetes clusters](#)
- [Backup and restore containerized Vertica \(vbr\)](#)

To use these features with operator 2.0.0, you must a lower server version.

In this section

- [Installing the VerticaDB operator](#)
- [Upgrading the VerticaDB operator](#)
- [Helm chart parameters](#)
- [Red Hat OpenShift integration](#)
- [Prometheus integration](#)
- [Secrets management](#)

Installing the VerticaDB operator

The VerticaDB operator is a custom controller that monitors CR instances to maintain the desired state of VerticaDB objects. The operator includes an admission controller, which is a webhook that queries a REST endpoint to verify changes to mutable states in a CR instance.

By default, the operator is cluster-scoped—you can deploy one operator per cluster to monitor objects across all namespaces in the cluster. For flexibility, Vertica also provides a Helm chart deployment option that installs the operator at the namespace level.

Installation options

Vertica provides the following options to install the VerticaDB operator and admission controller:

- [Helm charts](#). [Helm](#) is a package manager for Kubernetes. The Helm chart option is the most common installation method and lets you customize your TLS configuration and environment setup. For example, Helm chart installations include operator logging levels and log rotation policy. For details about additional options, see [Helm chart parameters](#).
Vertica also provides the [Quickstart](#) Helm chart option so that you can get started quickly with minimal requirements.
- [kubectl installation](#). Apply the Custom Resource Definitions (CRDs) and VerticaDB operator directly. You can use the `kubectl` tool to apply the latest CRD available on [vertica-kubernetes](#) GitHub repository.
- [OperatorHub.io](#). This is a registry that lets vendors share Kubernetes operators.

Note

Each installation option is mutually exclusive, with its own workflow that is incompatible with the other option. For example, you cannot install the VerticaDB operator with the Helm charts, and then deploy an operator in the same environment using OperatorHub.io.

Helm charts

Important

You must have cluster administrator privileges to install the operator Helm chart.

Vertica packages the VerticaDB operator and admission controller in a [Helm chart](#). The following sections detail different installation methods so that you can install the operator to meet your environment requirements. You can customize your operator during and after installation with [Helm chart parameters](#).

For additional details about Helm, see the [Helm documentation](#).

Prerequisites

- Kubernetes 1.21.1 and higher
- [Helm 3.5.0](#) and higher
- [kubectrl command-line tool](#)

Quickstart installation

The quickstart installation installs the VerticaDB Helm chart with minimal commands. This deployment installs the operator in the default configuration, which includes the following:

- Cluster-scoped webhook and controllers that monitor resources across all namespaces in the cluster. For namespace-scoped deployments, see [Namespace-scoped installation](#).
- Self-signed certificates to communicate with the Kubernetes API server. If your environment requires custom certificates, see [Custom certificate installation](#).

To quickly install the Helm chart, you must add the latest chart to your local repository and then install it in a namespace:

1. The **add** command downloads the chart to your local repository, and the **update** command gets the latest charts from the remote repository. When you add the Helm chart to your local chart repository, provide a descriptive name for future reference.

The following **add** command names the charts **vertica-charts** :

```
$ helm repo add vertica-charts https://vertica.github.io/charts
"vertica-charts" has been added to your repositories
$ helm repo update
Hang tight while we grab the latest from your chart repositories...
..Successfully got an update from the "vertica-charts" chart repository
Update Complete. ✨Happy Helming!*
```

2. Install the Helm chart to deploy the VerticaDB operator in your cluster. The following command names this chart instance **vdb-op** , and creates a default namespace for the operator if it does not already exist:

```
helm install vdb-op --namespace verticadb-operator --create-namespace vertica-charts/verticadb-operator
```

For **helm install** options, see the [Helm documentation](#).

Namespace-scoped installation

By default, the VerticaDB operator is cluster-scoped. However, Vertica provides an option to install a namespace-scoped operator for environments that require more granular control over which resources an operator watches for state changes.

The VerticaDB operator includes a webhook and controllers. The webhook is cluster-scoped and verifies state changes for resources across all namespaces in the cluster. The controllers—the control loops that reconcile the current and desired states for resources—do not have a cluster-scope requirement, so you can install them at the namespace level. The namespace-scoped operator installs the webhook once at the cluster level, and then installs the controllers in the specified namespace. You can install these namespaced controllers in multiple namespaces per cluster.

Important

Do not install a mix of cluster-scoped and namespace-scoped operators in the same cluster. For example, do not install an operator with [cluster-scoped controllers](#), and then install a namespace-scoped operator in the same cluster. This means that multiple operators serve the same CR, which results in unpredictable behavior.

To install a namespace-scoped operator, add the latest chart to your repository and issue separate commands to deploy the webhook and controllers:

1. The **add** command downloads the chart to your local repository, and the **update** command gets the latest charts from the remote repository. When you add the Helm chart to your local chart repository, provide a descriptive name for future reference.

The following **add** command names the charts **vertica-charts** :

```
$ helm repo add vertica-charts https://vertica.github.io/charts
"vertica-charts" has been added to your repositories
$ helm repo update
Hang tight while we grab the latest from your chart repositories...
...Successfully got an update from the "vertica-charts" chart repository
Update Complete. ✨Happy Helming!✨
```

2. Deploy the cluster-scoped webhook and install the required CRDs. To deploy the operator as a webhook without controllers, set `controllers.enable` to `false` . The following command deploys the webhook to the `vertica` namespace, which is the namespace for a Vertica cluster:

```
$ helm install webhook vertica-charts/verticadb-operator --namespace vertica --set controllers.enable=false
```

3. Deploy the namespace-scoped operator. To prevent a second webhook installation, set `webhook.enable` to `false` . To deploy only the controllers, set `controllers.scope` to `namespace` . The following command installs the operator in the `default` namespace:

```
$ helm install vdb-op vertica-charts/verticadb-operator --namespace default --set webhook.enable=false,controllers.scope=namespace
```

For details about the `controllers.*` parameter settings, see [Helm chart parameters](#) . For `helm install` options, see the [Helm documentation](#) .

Custom certificate installation

The admission controller uses a webhook that communicates with the Kubernetes API over HTTPS. By default, the Helm chart generates a self-signed certificate before installing the admission controller. A self-signed certificate might not be suitable for your environment—you might require custom certificates that are signed by a trusted third-party certificate authority (CA).

To add custom certificates for the webhook:

1. Set the TLS key's Subjective Alternative Name (SAN) to the admission controller's fully-qualified domain name (FQDN). Set the SAN in a configuration file using the following format:

```
[alt_names]
DNS.1 = verticadb-operator-webhook-service.operator-namespace.svc
DNS.2 = verticadb-operator-webhook-service.operator-namespace.svc.cluster.local
```

2. Create a [Secret](#) that contains the certificates. A Secret conceals your certificates when you pass them as command-line parameters. The following command creates a Secret named `tls-secret` . It stores the TLS key, TLS certificate, and CA certificate:

```
$ kubectl create secret generic tls-secret --from-file=tls.key=/path/to/tls.key --from-file=tls.crt=/path/to/tls.crt --from-file=ca.crt=/path/to/ca.crt
```

3. Install the Helm chart.

The `add` command downloads the chart to your local repository, and the `update` command gets the latest charts from the remote repository. When you add the Helm chart to your local chart repository, provide a descriptive name for future reference.

The following `add` command names the charts `vertica-charts` :

```
$ helm repo add vertica-charts https://vertica.github.io/charts
"vertica-charts" has been added to your repositories
$ helm repo update
Hang tight while we grab the latest from your chart repositories...
...Successfully got an update from the "vertica-charts" chart repository
Update Complete. ✨Happy Helming!✨
```

When you install the Helm chart with custom certificates for the admission controller, you have to use the `webhook.certSource` and `webhook.tlsSecret` [Helm chart parameters](#) :

- `webhook.certSource` indicates whether you want the admission controller to install user-provided certificates. To install with custom certificates, set this parameter to `secret` .
- `webhook.tlsSecret` accepts a [Secret](#) that contains your certificates.

The following command deploys the operator with the TLS certificates and creates `namespace` if it does not already exist:

```
$ helm install operator-name --namespace namespace --create-namespace vertica-charts/verticadb-operator \
--set webhook.certSource=secret \
--set webhook.tlsSecret=tls-secret
```

Granting user privileges

After the operator is deployed, the cluster administrator is the only user with privileges to create and modify [VerticaDB CRs](#) within the cluster. To grant other users the privileges required to work with custom resources, you can leverage namespaces and [Kubernetes RBAC](#) .

To grant these privileges, the cluster administrator creates a namespace for the user, then grants that user edit ClusterRole within that namespace. Next, the cluster administrator creates a Role with specific CR privileges, and binds that role to the user with a RoleBinding. The cluster administrator can repeat this process for each user that must create or modify VerticaDB CRs within the cluster.

To provide a user with privileges to create or modify a VerticaDB CR:

1. Create a namespace for the application developer:

```
$ kubectl create namespace user-namespace
namespace/user-namespace created
```

2. Grant the application developer [edit_role_privileges](#) in the namespace:

```
$ kubectl create --namespace user-namespace rolebinding edit-access --clusterrole=edit --user=username
rolebinding.rbac.authorization.k8s.io/edit-access created
```

3. Create the Role with privileges to create and modify any CRs in the namespace. Vertica provides the [verticadb-operator-cr-user-role.yaml](#) file that defines these rules:

```
$ kubectl --namespace user-namespace apply -f https://github.com/vertica/vertica-kubernetes/releases/latest/download/verticadb-operator-cr-user-role.yaml
role.rbac.authorization.k8s.io/vertica-cr-user-role created
```

Verify the changes with `kubectl get` :

```
$ kubectl get roles --namespace user-namespace
NAME                CREATED AT
vertica-cr-user-role 2023-11-30T19:37:24Z
```

4. Create a RoleBinding that associates this Role to the user. The following command creates a RoleBinding named `vdb-access` :

```
$ kubectl create --namespace user-namespace rolebinding vdb-access --role=vertica-cr-user-role --user=username
rolebinding.rbac.authorization.k8s.io/rolebinding created
```

Verify the changes with `kubectl get` :

```
$ kubectl get rolebinding --namespace user-namespace
NAME           ROLE           AGE
edit-access    ClusterRole/edit    16m
vdb-access     Role/vertica-cr-user-role 103s
```

Now, the user associated with `username` has access to create and modify VerticaDB CRs in the isolated `user-namespace` .

kubectl installation

You can install the VerticaDB operator from GitHub by applying the YAML manifests with the [kubectl command-line tool](#) :

1. Install all [Custom resource definitions](#) . Because the size of the CRD is too large for client-side operations, you must use the `server-side=true` and `--force-conflicts` options to apply the manifests:

```
kubectl apply --server-side=true --force-conflicts -f https://github.com/vertica/vertica-kubernetes/releases/latest/download/crds.yaml
```

For additional details about these commands, see [Server-Side Apply documentation](#) .

2. Install the VerticaDB operator:

```
$ kubectl apply -f https://github.com/vertica/vertica-kubernetes/releases/latest/download/operator.yaml
```

OperatorHub.io

[OperatorHub.io](#) is a registry that allows vendors to share Kubernetes operators. Each vendor must adhere to packaging guidelines to simplify user adoption.

To install the VerticaDB operator from OperatorHub.io, navigate to the [Vertica operator page](#) and follow the install instructions.

Upgrading the VerticaDB operator

Vertica supports two separate options to upgrade the VerticaDB operator:

- OperatorHub.io
- Helm Charts

Note

You must upgrade the operator with the same option that you selected for installation. For example, you cannot install the VerticaDB operator with Helm charts, and then upgrade the operator in the same environment using OperatorHub.io.

Prerequisites

- Complete [Installing the VerticaDB operator](#)

OperatorHub.io

Important

VerticaDB operator versions 1.x are namespace-scoped, and versions 2.x are cluster-scoped. To upgrade from version 1.x to 2.x, you must uninstall the operator in each namespace before you upgrade.

For detailed instructions about uninstalling your operator, see the [OLM documentation](#).

The Operator Lifecycle Manager (OLM) operator manages upgrades for OperatorHub.io installations. You can configure the OLM operator to upgrade the VerticaDB operator manually or automatically with the Subscription object's `spec.installPlanApproval` parameter.

Automatic upgrade

To configure automatic version upgrades, set `spec.installPlanApproval` to `Automatic`, or omit the setting entirely. When the OLM operator refreshes the catalog source, it installs the new VerticaDB operator automatically.

Manual upgrade

Upgrade the VerticaDB operator manually to approve version upgrades for specific install plans. To manually upgrade, set `spec.installPlanApproval` parameter to `Manual` and complete the following:

1. Verify if there is an install plan that requires approval to proceed with the upgrade:

```
$ kubectl get installplan
NAME CSV APPROVAL APPROVED
install-ftcj9 verticadb-operator.v1.7.0 Manual false
install-pw7ph verticadb-operator.v1.6.0 Manual true
```

The command output shows that the install plan `install-ftcj9` for VerticaDB operator version 1.7.0 is not approved.

2. Approve the install plan with a patch command:

```
$ kubectl patch installplan install-ftcj9 --type=merge --patch='{"spec": {"approved": true}}'
installplan.operators.coreos.com/install-ftcj9 patched
```

After you set the approval, the OLM operator silently upgrades the VerticaDB operator.

3. Optional. To monitor its progress, inspect the STATUS column of the Subscription object:

```
$ kubectl describe subscription subscription-object-name
```

Helm charts

You must have cluster administrator privileges to upgrade the VerticaDB operator with Helm charts.

The Helm chart includes the CRD, but the `helm install` command does not overwrite an existing CRD. To upgrade the operator, you must update the CRD with the manifest from the GitHub repository.

Additionally, you must upgrade all [custom resource definitions](#), even if you do deploy them in your environment. These CRDs are installed with the operator and maintained as separate YAML manifests. Upgrading all CRDs ensure that your operator is upgraded completely.

Important

VerticaDB operator versions 1.x are namespace-scoped, and versions 2.x are cluster-scoped. To upgrade from version 1.x to 2.x, you must uninstall the operator in each namespace before you upgrade.

You can uninstall the VerticaDB operator with the `helm uninstall` command:

```
$ helm uninstall vdb-op --namespace namespace
```

You can upgrade the CRDs and VerticaDB operator from GitHub by applying the YAML manifests with the [kubectl command-line tool](#):

1. Install all [Custom resource definitions](#). Because the size of the CRD is too large for client-side operations, you must use the `server-side=true` and `--force-conflicts` options to apply the manifests:

```
kubectl apply --server-side=true --force-conflicts -f https://github.com/vertica/vertica-kubernetes/releases/latest/download/crds.yaml
```

For additional details about these commands, see [Server-Side Apply documentation](#).

2. Upgrade the Helm chart:

```
$ helm upgrade operator-name --wait vertica-charts/verticadb-operator
```

Helm chart parameters

The following list describes the available settings for the VerticaDB operator and admission controller Helm chart:

affinity

Applies rules that constrain the VerticaDB operator to specific nodes. It is more expressive than `nodeSelector`. If this parameter is not set, then the operator uses no affinity setting.

controllers.enable

Determines whether controllers are enabled when running the operator. Controllers watch and act on custom resources within the cluster.

For namespace-scoped operators, set this to `false`. This deploys the cluster-scoped operator only as a webhook, and then you can set `webhook.enable` to `false` and deploy the controllers to an individual namespace. For details, see [Installing the VerticaDB operator](#).

Default: `true`

controllers.scope

Scope of the controllers in the VerticaDB operator. Controllers watch and act on custom resources within the cluster. This parameter accepts the following values:

- `cluster`: The controllers watch for changes to all resources across all namespaces in the cluster.
- `namespace`: The controllers watch for changes to resources only in the namespace specified during deployment. You must deploy the operator as a webhook for the cluster, then deploy the operator controllers in a namespace. You can deploy multiple namespace-scoped operators within the same cluster.

For details, see [Installing the VerticaDB operator](#).

Default: `cluster`

image.name

Name of the image that runs the operator.

Default: `vertica/verticadb-operator: version`

imagePullSecrets

List of Secrets that store credentials to authenticate to the private container repository specified by `image.repo` and `rbac_proxy_image`. For details, see [Specifying ImagePullSecrets](#) in the Kubernetes documentation.

image.repo

Server that hosts the repository that contains `image.name`. Use this parameter for deployments that require control over a private hosting server, such as an air-gapped operator.

Use this parameter with `rbac_proxy_image.name` and `rbac_proxy_image.repo`.

Default: `docker.io`

logging.filePath

Deprecated

This parameter is deprecated and will be removed in a future release.

Path to a log file in the VerticaDB operator filesystem. If this value is not specified, Vertica writes logs to standard output.

Default: Empty string (`'`) that indicates standard output.

logging.level

Minimum logging level. This parameter accepts the following values:

- `debug`
- `info`
- `warn`
- `error`

Default: `info`

logging.maxFileSize

Deprecated

This parameter is deprecated and will be removed in a future release.

When `logging.filePath` is set, the maximum size in MB of the logging file before log rotation occurs.

Default: 500

`logging.maxFileAge`

Deprecated

This parameter is deprecated and will be removed in a future release.

When `logging.filePath` is set, the maximum age in days of the logging file before log rotation deletes the file.

Default: 7

`logging.maxFileRotation`

Deprecated

This parameter is deprecated and will be removed in a future release.

When `logging.filePath` is set, the maximum number of files that are kept in rotation before the old ones are removed.

Default: 3

`nameOverride`

Sets the prefix for the name assigned to all objects that the Helm chart creates.

If this parameter is not set, each object name begins with the name of the Helm chart, `verticadb-operator`.

`nodeSelector`

Controls which nodes are used to schedule the operator pod. If this is not set, the node selector is omitted from the operator pod when it is created. To set this parameter, provide a list of key/value pairs.

The following example schedules the operator only on nodes that have the `region=us-east` label:

```
nodeSelector:  
  region: us-east
```

`priorityClassName`

[PriorityClass](#) name assigned to the operator pod. This affects where the pod is scheduled.

`prometheus.createProxyRBAC`

When set to true, creates role-based access control (RBAC) rules that authorize access to the operator's `/metrics` endpoint for the [Prometheus integration](#).

Default : true

`prometheus.createServiceMonitor`

Deprecated

This parameter is deprecated and will be removed in a future release.

When set to true, creates the ServiceMonitor custom resource for the Prometheus operator. You must install the Prometheus operator before you set this to true and install the Helm chart.

For details, see the [Prometheus operator GitHub repository](#).

Default : false

`prometheus.expose`

Configures the operator's `/metrics` endpoint for the [Prometheus integration](#). The following options are valid:

- `EnableWithAuthProxy`: Creates a new service object that exposes an HTTPS `/metrics` endpoint. The [RBAC proxy](#) controls access to the metrics.

- **EnableWithoutAuth**: Creates a new service object that exposes an HTTP `/metrics` endpoint that does not authorize connections. Any client with network access can read the metrics.
- **Disable**: Prometheus metrics are not exposed.

Default : Disable

prometheus.tlsSecret

Secret that contains the TLS certificates for the [Prometheus/metrics](#) endpoint. You must create this Secret in the same namespace that you deployed the Helm chart.

The Secret requires the following values:

- `tls.key`: TLS private key
- `tls.crt`: TLS certificate for the private key
- `ca.crt`: Certificate authority (CA) certificate

To ensure that the operator uses the certificates in this parameter, you must set `prometheus.expose` to [EnableWithAuthProxy](#) .

If `prometheus.expose` is not set to [EnableWithAuthProxy](#) , then this parameter is ignored, and the RBAC proxy sidecar generates its own self-signed certificate.

rbac_proxy_image.name

Name of the Kubernetes RBAC proxy image that performs authorization. Use this parameter for deployments that require authorization by a proxy server, such as an air-gapped operator.

Use this parameter with `image.repo` and `rbac_proxy_image.repo` .

Default: [kubebuilder/kube-rbac-proxy:v0.11.0](#)

rbac_proxy_image.repo

Server that hosts the repository that contains `rbac_proxy_image.name` . Use this parameter for deployments that perform authorization by a proxy server, such as an air-gapped operator.

Use this parameter with `image.repo` and `rbac_proxy_image.name` .

Default: [gcr.io](#)

reconcileConcurrency.verticaautoscaler

Number of concurrent reconciliation loops the operator runs for all [VerticaAutoscaler](#) CRs in the cluster.

reconcileConcurrency.verticadb

Number of concurrent reconciliation loops the operator runs for all [VerticaDB](#) CRs in the cluster.

reconcileConcurrency.verticaeventtrigger

Number of concurrent reconciliation loops the operator runs for all [EventTrigger](#) CRs in the cluster.

resources.limits and resources.requests

The resource requirements for the operator pod.

`resources.limits` is the maximum amount of CPU and memory that an operator pod can consume from its host node.

`resources.requests` is the maximum amount of CPU and memory that an operator pod can request from its host node.

Defaults :

```
resources:
  limits:
    cpu: 100m
    memory: 750Mi
  requests:
    cpu: 100m
    memory: 20Mi
```

serviceAccountAnnotations

Map of annotations that is added to the service account created for the operator.

serviceAccountNameOverride

Controls the name of the service account created for the operator.

tolerations

Any [taints and tolerations](#) that influence where the operator pod is scheduled.

webhook.certSource

How TLS certificates are provided for the admission controller webhook. This parameter accepts the following values:

- internal: The VerticaDB operator internally generates a self-signed, 10-year expiry certificate before starting the managing controller. When the certificate expires, you must manually restart the operator pod to create a new certificate.
- secret: You generate the custom certificates before you create the Helm chart and store them in a [Secret](#). This option requires that you set `webhook.tlsSecret`.

If `webhook.tlsSecret` is set, then this option is implicitly selected.

Default : internal

For details, see [Installing the VerticaDB operator](#).

webhook.enable

Determines whether the Helm chart installs the admission controller webhooks for the [custom resource definitions](#). The webhook is cluster-scoped, and you can install only one webhook per cluster.

If your environment uses namespace-scoped operators, you must install the webhook for the cluster, then disable the webhook for each namespace installation. For details, see [Installing the VerticaDB operator](#).

Caution

Webhooks prevent invalid state changes to the custom resource. Running Vertica on Kubernetes without webhook validations might result in invalid state transitions.

Default: true

webhook.tlsSecret

Secret that contains a PEM-encoded certificate authority (CA) bundle and its keys.

The CA bundle validates the webhook's server certificate. If this is not set, the webhook uses the system trust roots on the apiserver.

This Secret includes the following keys for the CA bundle:

- tls.key
- ca.crt
- tls.crt

Red Hat OpenShift integration

Red Hat OpenShift is a hybrid cloud platform that provides enhanced security features and greater control over the Kubernetes cluster. In addition, OpenShift provides the OperatorHub, a catalog of operators that meet OpenShift requirements.

For comprehensive instructions about the OpenShift platform, refer to the [Red Hat OpenShift documentation](#).

Note

If your Kubernetes cluster is in the cloud or on a managed service, each Vertica node must operate in the same availability zone.

Enhanced security with security context constraints

To enforce security measures, OpenShift requires that each deployment use a [security context constraint](#) (SCC). Vertica on Kubernetes supports the `restricted-v2` SCC, the most restrictive [default SCC](#) available.

The SCC lets administrators control the privileges of the pods in a cluster without manual configuration. For example, you can restrict namespace access for specific users in a multi-user environment.

Installing the operator

The VerticaDB operator is a community operator that is maintained by Vertica. Each operator available in the OperatorHub must adhere to requirements defined by the [Operator Lifecycle Manager](#) (OLM). To meet these requirements, vendors must provide a [cluster service version](#) (CSV) manifest for each operator. Vertica provides a CSV for each version of the VerticaDB operator available in the OpenShift OperatorHub.

The VerticaDB operator supports OpenShift versions 4.8 and higher.

You must have cluster-admin privileges on your OpenShift account to install the VerticaDB operator. For detailed installation instructions, refer to the [OpenShift documentation](#).

Deploying Vertica on OpenShift

After you installed the VerticaDB operator and added a supported SCC to your Vertica workloads service account, you can deploy Vertica on OpenShift.

For details about installing OpenShift in supported environments, see the [OpenShift Container Platform installation overview](#).

Before you deploy Vertica on OpenShift, create the required Secrets to store sensitive information. For details about Secrets and OpenShift, see the [OpenShift documentation](#). For guidance on deploying a Vertica custom resource, see [VerticaDB custom resource definition](#).

Prometheus integration

Vertica on Kubernetes integrates with [Prometheus](#) to scrape time series metrics about the VerticaDB operator and Vertica server process. These metrics create a detailed model of your application over time to provide valuable performance and troubleshooting insights as well as facilitate internal and external communications and service discovery in microservice and containerized architectures.

Prometheus requires that you set up targets—metrics that you want to monitor. Each target is exposed on an endpoint, and Prometheus periodically scrapes that endpoint to collect target data. Vertica exports metrics and provides access methods for both the VerticaDB operator and server process.

Server metrics

Vertica exports server metrics on port 8443 at the following endpoint:

```
https://host-address:8443/api-version/metrics
```

Only the [superuser](#) can authenticate to the HTTPS service, and the service accepts only [mutual TLS \(mTLS\)](#) authentication. The setup for both Vertica on Kubernetes and non-containerized Vertica environments is identical. For details, see [HTTPS service](#).

Vertica on Kubernetes lets you set a custom port for its HTTP service with the `subclusters[i].verticaHTTPNodePort` [custom resource parameter](#). This parameter sets a custom port for the HTTPS service for `NodePort` serviceTypes.

For request and response examples, see the [/metrics endpoint description](#). For a list of available metrics, see [Prometheus metrics](#).

Grafana dashboards

You can visualize Vertica server time series metrics with Grafana dashboards. Vertica dashboards that use a Prometheus data source are available at [Grafana Dashboards](#):

- [Vertica Overview \(Prometheus\)](#)
- [Vertica Queries \(Prometheus\)](#)
- [Vertica Resource Management \(Prometheus\)](#)
- [Vertica Depot \(Prometheus\)](#)

You can also download the source for each dashboard from the [vertica/grafana-dashboards repository](#).

Operator metrics

The VerticaDB operator supports the [Operator SDK framework](#), which requires that an authorization proxy impose role-based-access control (RBAC) to access operator metrics over HTTPS. To increase flexibility, Vertica provides the following options to access the Prometheus `/metrics` endpoint:

- HTTPS access: Meet operator SDK requirements and use a sidecar container as an RBAC proxy to authorize connections.
- HTTP access: Expose the `/metrics` endpoint to external connections without RBAC. Any client with network access can read from `/metrics`.
- Disable Prometheus entirely.

Vertica provides [Helm chart parameters](#) and YAML manifests to configure each option.

Note

If you installed the VerticaDB operator with [OperatorHub.io](#), you can use the Prometheus integration with the default Helm chart settings. OperatorHub.io installations cannot configure any Helm chart parameters.

Prerequisites

- Complete [Installing the VerticaDB operator](#).
- Install the [kubectl](#) command line tool.

HTTPS with RBAC

The operator SDK framework requires that operators use an authorization proxy for metrics access. Because the operator sends metrics to localhost only, Vertica meets these requirements with a sidecar container with localhost access that enforces RBAC.

RBAC rules are cluster-scoped, and the sidecar authorizes connections from clients associated with a service account that has the correct ClusterRole and ClusterRoleBindings. Vertica provides the following example manifests:

- [verticadb-operator-proxy-role-cr](#): ClusterRole that has TokenReviews and SubjectAccessReviews access so that the sidecar can verify privileges on connections.
- [verticadb-operator-proxy-rolebinding-crb](#): ClusterRoleBinding that associates the ClusterRole that verifies sidecar privileges to a service account.
- [verticadb-operator-metrics-reader-cr](#): ClusterRole that allows HTTP GET requests on the `/metrics` endpoint for non-Kubernetes resources.
- [verticadb-operator-metrics-reader-crb](#): ClusterRoleBinding that associates the metrics reader ClusterRole with a service account.

For additional details about ClusterRoles and ClusterRoleBindings, see the [Kubernetes documentation](#).

Create RBAC rules

Note

This section details how to create RBAC rules for environments that require that you set up ClusterRole and ClusterRoleBinding objects outside of the Helm chart installation.

The following steps create the ClusterRole and ClusterRoleBindings objects that grant access to the `/metrics` endpoint to a non-Kubernetes resource such as Prometheus. Because RBAC rules are cluster-scoped, you must create or add to an existing ClusterRoleBinding:

1. Create a ClusterRoleBinding that binds the role for the RBAC sidecar proxy with a service account:

- Create a ClusterRoleBinding:

```
$ kubectl create clusterrolebinding verticadb-operator-proxy-rolebinding \
  --clusterrole=verticadb-operator-proxy-role \
  --serviceaccount=namespace:serviceaccount
```

- Add a service account to an existing ClusterRoleBinding:

```
$ kubectl patch clusterrolebinding verticadb-operator-proxy-rolebinding \
  --type=json \
  -p=[{"op": "add", "path": "/subjects/-", "value": {"kind": "ServiceAccount", "name": "serviceaccount", "namespace": "namespace"} }]
```

2. Create a ClusterRoleBinding that binds the role for the non-Kubernetes object to the RBAC sidecar proxy service account:

- Create a ClusterRoleBinding:

```
$ kubectl create clusterrolebinding verticadb-operator-metrics-reader \
  --clusterrole=verticadb-operator-metrics-reader \
  --serviceaccount=namespace:serviceaccount \
  --group=system:authenticated
```

- Bind the service account to an existing ClusterRoleBinding:

```
$ kubectl patch clusterrolebinding verticadb-operator-metrics-reader \
  --type=json \
  -p=[{"op": "add", "path": "/subjects/-", "value": {"kind": "ServiceAccount", "name": "serviceaccount", "namespace": "namespace"}}, {"op": "add", "path": "/subjects/-", "value": {"kind": "ServiceAccount", "name": "serviceaccount", "namespace": "namespace"} }]
```

```
$ kubectl patch clusterrolebinding verticadb-operator-metrics-reader \
  --type=json \
  -p=[{"op": "add", "path": "/subjects/-", "value": {"kind": "ServiceAccount", "name": "serviceaccount", "namespace": "namespace"} }]
```

When you [install the Helm chart](#), the ClusterRole and ClusterRoleBindings are created automatically. By default, the `prometheus.expose` parameter is set to `EnableWithProxy`, which creates the service object and exposes the operator's `/metrics` endpoint.

For details about creating a sidecar container, see [VerticaDB custom resource definition](#).

Service object

Vertica provides a service object `verticadb-operator-metrics-service` to access the Prometheus `/metrics` endpoint. The VerticaDB operator does not manage this service object. By default, the service object uses the ClusterIP service type to support RBAC.

Connect to the `/metrics` endpoint at port 8443 with the following path:

```
https://verticadb-operator-metrics-service.namespace.svc.cluster.local:8443/metrics
```

Bearer token authentication

Kubernetes authenticates requests to the API server with service account credentials. Each pod is associated with a service account and has the following credentials stored in the filesystem of each container in the pod:

- Token at `/var/run/secrets/kubernetes.io/serviceaccount/token`
- Certificate authority (CA) bundle at `/var/run/secrets/kubernetes.io/serviceaccount/ca.crt`

Use these credentials to authenticate to the `/metrics` endpoint through the service object. You must use the credentials for the service account that you used to create the ClusterRoleBindings.

For example, the following cURL request accesses the `/metrics` endpoint. Include the `--insecure` option only if you do not want to verify the serving certificate:

```
$ curl --insecure --cacert /var/run/secrets/kubernetes.io/serviceaccount/ca.crt -H "Authorization: Bearer $(cat /var/run/secrets/kubernetes.io/serviceaccount/token)" https://verticadb-operator-metrics-service.namespace.svc.cluster.local:8443/metrics
```

For additional details about service account credentials, see the [Kubernetes documentation](#).

TLS client certificate authentication

Some environments might prevent you from authenticating to the `/metrics` endpoint with the service account token. For example, you might run Prometheus outside of Kubernetes. To allow external client connections to the `/metrics` endpoint, you have to supply the RBAC proxy sidecar with TLS certificates.

You must create a Secret that contains the certificates, and then use the `prometheus.tlsSecret` Helm chart parameter to pass the Secret to the RBAC proxy sidecar when you install the Helm chart. The following steps create the Secret and install the Helm chart:

1. Create a Secret that contains the certificates:

```
$ kubectl create secret generic metrics-tls --from-file=tls.key=/path/to/tls.key --from-file=tls.crt=/path/to/tls.crt --from-file=ca.crt=/path/to/ca.crt
```

2. Install the Helm chart with `prometheus.tlsSecret` set to the Secret that you just created:

```
$ helm install operator-name --namespace namespace --create-namespace vertica-charts/verticadb-operator \
--set prometheus.tlsSecret=metrics-tls
```

The `prometheus.tlsSecret` parameter forces the RBAC proxy to use the TLS certificates stored in the Secret. Otherwise, the RBAC proxy sidecar generates its own self-signed certificate.

After you install the Helm chart, you can authenticate to the `/metrics` endpoint with the certificates in the Secret. For example:

```
$ curl --key tls.key --cert tls.crt --cacert ca.crt https://verticadb-operator-metrics-service.namespace.svc:8443/metrics
```

HTTP access

You might have an environment that does not require privileged access to Prometheus metrics. For example, you might run Prometheus outside of Kubernetes.

To allow external access to the `/metrics` endpoint with HTTP, set `prometheus.expose` to `EnableWithoutAuth`. For example:

```
$ helm install operator-name --namespace namespace --create-namespace vertica-charts/verticadb-operator \
--set prometheus.expose=EnableWithoutAuth
```

Service object

Vertica provides a service object `verticadb-operator-metrics-service` to access the Prometheus `/metrics` endpoint. The VerticaDB operator does not manage this service object. By default, the service object uses the ClusterIP service type, so you must change the `serviceType` for external client access. The service object's fully-qualified domain name (FQDN) is as follows:

```
verticadb-operator-metrics-service.namespace.svc.cluster.local
```

Connect to the `/metrics` endpoint at port 8443 with the following path:

```
http://verticadb-operator-metrics-service.namespace.svc.cluster.local:8443/metrics
```

Prometheus operator integration (optional)

Vertica on Kubernetes integrates with the [Prometheus operator](#), which provides custom resources (CRs) that simplify targeting metrics. Vertica supports the ServiceMonitor CR that discovers the VerticaDB operator automatically, and authenticates requests with a [bearer token](#).

The ServiceMonitor CR is [available as a release artifact](#) in our [GitHub repository](#). See [Helm chart parameters](#) for details about the `prometheus.createServiceMonitor` parameter.

Disabling Prometheus

To disable Prometheus, set the prometheus.expose Helm chart parameter to **Disable** :

```
$ helm install operator-name --namespace namespace --create-namespace vertica-charts/verticadb-operator \
--set prometheus.expose=Disable
```

For details about Helm install commands, see [Installing the VerticaDB operator](#).

Metrics

The following table describes the available VerticaDB operator metrics:

Name	Type	Description
controller_runtime_active_workers	gauge	Number of currently used workers per controller.
controller_runtime_max_concurrent_reconciles	gauge	Maximum number of concurrent reconciles per controller.
controller_runtime_reconcile_errors_total	counter	Total number of reconciliation errors per controller.
controller_runtime_reconcile_time_seconds	histogram	Length of time per reconciliation per controller.
controller_runtime_reconcile_total	counter	Total number of reconciliations per controller.
controller_runtime_webhook_latency_seconds	histogram	Histogram of the latency of processing admission requests.
controller_runtime_webhook_requests_in_flight	gauge	Current number of admission requests being served.
controller_runtime_webhook_requests_total	counter	Total number of admission requests by HTTP status code.
go_gc_duration_seconds	summary	A summary of the pause duration of garbage collection cycles.
go_goroutines	gauge	Number of goroutines that currently exist.
go_info	gauge	Information about the Go environment.
go_memstats_alloc_bytes	gauge	Number of bytes allocated and still in use.
go_memstats_alloc_bytes_total	counter	Total number of bytes allocated, even if freed.
go_memstats_buck_hash_sys_bytes	gauge	Number of bytes used by the profiling bucket hash table.
go_memstats_frees_total	counter	Total number of frees.
go_memstats_gc_sys_bytes	gauge	Number of bytes used for garbage collection system metadata.
go_memstats_heap_alloc_bytes	gauge	Number of heap bytes allocated and still in use.
go_memstats_heap_idle_bytes	gauge	Number of heap bytes waiting to be used.
go_memstats_heap_inuse_bytes	gauge	Number of heap bytes that are in use.
go_memstats_heap_objects	gauge	Number of allocated objects.
go_memstats_heap_released_bytes	gauge	Number of heap bytes released to OS.
go_memstats_heap_sys_bytes	gauge	Number of heap bytes obtained from system.
go_memstats_last_gc_time_seconds	gauge	Number of seconds since 1970 of last garbage collection.

go_memstats_lookups_total	counter	Total number of pointer lookups.
go_memstats_mallocs_total	counter	Total number of mallocs.
go_memstats_mcache_inuse_bytes	gauge	Number of bytes in use by mcache structures.
go_memstats_mcache_sys_bytes	gauge	Number of bytes used for mcache structures obtained from system.
go_memstats_mspan_inuse_bytes	gauge	Number of bytes in use by mspan structures.
go_memstats_mspan_sys_bytes	gauge	Number of bytes used for mspan structures obtained from system.
go_memstats_next_gc_bytes	gauge	Number of heap bytes when next garbage collection will take place.
go_memstats_other_sys_bytes	gauge	Number of bytes used for other system allocations.
go_memstats_stack_inuse_bytes	gauge	Number of bytes in use by the stack allocator.
go_memstats_stack_sys_bytes	gauge	Number of bytes obtained from system for stack allocator.
go_memstats_sys_bytes	gauge	Number of bytes obtained from system.
go_threads	gauge	Number of OS threads created.
process_cpu_seconds_total	counter	Total user and system CPU time spent in seconds.
process_max_fds	gauge	Maximum number of open file descriptors.
process_open_fds	gauge	Number of open file descriptors.
process_resident_memory_bytes	gauge	Resident memory size in bytes.
process_start_time_seconds	gauge	Start time of the process since unix epoch in seconds.
process_virtual_memory_bytes	gauge	Virtual memory size in bytes.
process_virtual_memory_max_bytes	gauge	Maximum amount of virtual memory available in bytes.
vertica_cluster_restart_attempted_total	counter	The number of times we attempted a full cluster restart.
vertica_cluster_restart_failed_total	counter	The number of times we failed when attempting a full cluster restart.
vertica_cluster_restart_seconds	histogram	The number of seconds it took to do a full cluster restart.
vertica_nodes_restart_attempted_total	counter	The number of times we attempted to restart down nodes.
vertica_nodes_restart_failed_total	counter	The number of times we failed when trying to restart down nodes.
vertica_nodes_restart_seconds	histogram	The number of seconds it took to restart down nodes.
vertica_running_nodes_count	gauge	The number of nodes that have a running pod associated with it.
vertica_subclusters_count	gauge	The number of subclusters that exist.
vertica_total_nodes_count	gauge	The number of nodes that currently exist.
vertica_up_nodes_count	gauge	The number of nodes that have vertica running and can accept connections.

<code>vertica_upgrade_total</code>	counter	The number of times the operator performed an upgrade caused by an image change.
<code>workqueue_adds_total</code>	counter	Total number of adds handled by workqueue.
<code>workqueue_depth</code>	gauge	Current depth of workqueue.
<code>workqueue_longest_running_processor_seconds</code>	gauge	How many seconds has the longest running processor for workqueue been running.
<code>workqueue_queue_duration_seconds</code>	histogram	How long in seconds an item stays in workqueue before being requested.
<code>workqueue_retries_total</code>	counter	Total number of retries handled by workqueue.
<code>workqueue_unfinished_work_seconds</code>	gauge	How many seconds of work has been done that is in progress and hasn't been observed by <code>work_duration</code> . Large values indicate stuck threads. One can deduce the number of stuck threads by observing the rate at which this increases.
<code>workqueue_work_duration_seconds</code>	histogram	How long in seconds processing an item from workqueue takes.

Secrets management

The Kubernetes declarative model requires that you develop applications with manifest files or command line interactions with the Kubernetes API. These workflows expose your sensitive information in your application code and shell history, which compromises your application security.

To mitigate any security risks, Kubernetes uses the concept of a secret to store this sensitive information. A secret is an object with a plain text name and a value stored as a base64 encoded string. When you reference a secret by name, Kubernetes retrieves and decodes its value. This lets you openly reference confidential information in your application code and shell without compromising your data.

Kubernetes supports secret workflows with its native [Secret](#) object, and cloud providers offer solutions that store your confidential information in a centralized location for easy management. By default, Vertica on Kubernetes supports native Secrets objects, and it also supports [cloud solutions](#) so that you have options for storing your confidential data.

For best practices about handling confidential data in Kubernetes, see the [Kubernetes documentation](#).

Manually encode data

In some circumstances, you might need to manually base64 encode your secret value and add it to a [Secret manifest](#) or a [cloud service secret manager](#). You can base64 encode data with tools available in your shell. For example, pass the string value to the `echo` command, and pipe the output to the `base64` command to encode the value. In the `echo` command, include the `-n` option so that it does not append a newline character:

```
$ echo -n 'secret-value' | base64
c2VjcmV0LXZhbHVI
```

You can take the output of this command and add it to a [Secret manifest](#) or cloud service secret manager.

Kubernetes Secrets

A [Secret](#) is an Kubernetes object that you can reference by name that conceals confidential data in a base64 encoded string. For example, you can create a Secret named `su-password` that stores the database superuser password. In a manifest file, you can add `su-password` in place of the literal password value, and then you can safely store the manifest in a file system or pass it on the command line.

The idiomatic way to create a Secret in Kubernetes is with the [kubectl](#) command-line tool's `create secret` command, which provides options to create Secret object from various data sources. For example, the following command creates a Secret named `superuser-password` from a literal value passed on the command line:

```
$ kubectl create secret generic superuser-password \
  --from-literal=password=secret-value
secret/superuser-password created
```

Instead of creating a Kubernetes Secret with `kubectl`, you can [manually base64 encode a string on the command line](#), and then add the encoded output to a Secrets manifest.

Cloud providers

Cloud providers offer services that let you store sensitive information in a central location and reference it securely. Vertica on Kubernetes requires a specific format for secrets stored in cloud providers. In addition, each cloud provider requires unique configuration before you can add a secret to your [VerticaDB custom resource \(CR\)](#).

The following [VerticaDB CR parameters](#) accept secrets from cloud services:

- `communal.credentialSecret`
- `nmaTLSSecret`
- `passwordSecret`

Format requirements

Cloud provider secrets consist of a name and a secret value. To provide flexibility, cloud services let you store the value in a variety of formats. Vertica on Kubernetes requires that you format the secret value as a JSON document consisting of plain text string keys and base64 encoded values. For example, you might have a secret named `tlsSecrets` whose value is a JSON document in the following format:

```
{
  "ca.crt": "base64-encoded-ca.crt",
  "tls.crt": "base64-encoded-tls.crt",
  "tls.key": "base64-encoded-tls.key",
  "password": "base64-encoded-password"
}
```

Amazon Web Services

Amazon Web Services (AWS) provides the [AWS Secrets Manager](#), a storage system for your sensitive data. To access secrets from your AWS console, go to **Services > Security, Identity, & Compliance > Secrets Manager**.

IAM permissions

Before you can add a secret to a CR, you must grant the following permissions to the VerticaDB operator pod and the Vertica server pods so they can access AWS Secret Manager. You can grant these permissions to the worker node's IAM policy or the [IAM roles for service account \(IRSA\)](#):

- [secretsmanager:GetSecretValue](#)
- [secretsmanager:DescribeSecret](#)

For instructions about adding permissions to an AWS Secrets Manager secret, see the [AWS documentation](#). For details about Vertica on Kubernetes and AWS IRSA, see [Configuring communal storage](#).

Adding a secret to a CR

AWS stores secrets with metadata that describe and track changes to the secret. An important piece of metadata is the Amazon Resource Name (ARN), a unique identifier for the secret. The ARN uses the following format:

```
arn:aws:secretsmanager:region:accountId:secret:SecretName-randomChars
```

To use an AWS secret in a CR, you have to add the ARN to the applicable CR parameter and prefix it with `awssm://`. For example:

```
spec:
  ...
  passwordSecret: awssm://arn:aws:secretsmanager:region:account-id:secret:myPasswordSecret-randomChars
  nmaTLSSecret: awssm://arn:aws:secretsmanager:region:account-id:secret:myNmaTLSSecret-randomChars
  communal:
    credentialSecret: awssm://arn:aws:secretsmanager:region:account-id:secret:myCredentialSecret-randomChars
    path: s3://bucket-name/key-name
  ...
```

Google Cloud Platform

Google Cloud provides [Google Secret Manager](#), a storage system for your sensitive data. To access your secrets from your Google Cloud console, go to **Security > Secret Manager**.

When you pass a Google secret as a CRD parameter, use the secret's resource name. The resource name uses the following format:

```
projects/project-id/secrets/secret-name/versions/version-number
```

To use a Secret Manager secret in a CR, you have to add the resource name to the applicable CR parameter and prefix it with `gsm://`. For example:

```
spec:
  ...
  passwordSecret: gsm://projects/project-id/secrets/password-secret/versions/version-number
  ninaTLSSecret: gsm://projects/project-id/secrets/nina-certs-secret/versions/version-number
  communal:
    credentialSecret: gsm://projects/project-id/secrets/gcp-creds-secret/versions/version-number
    path: gs://bucket-name/path/to/database-name
  ...
```

Configuring communal storage

Vertica on Kubernetes supports a variety of communal storage providers to accommodate your storage requirements. Each storage provider uses authentication methods that conceal sensitive information so that you can declare that information in your [Custom Resource \(CR\)](#) without exposing any literal values.

Note

If your Kubernetes cluster is in the cloud or on a managed service, each Vertica node must operate in the same availability zone.

AWS S3 or S3-Compatible storage

Vertica on Kubernetes supports multiple authentication methods for Amazon Web Services (AWS) communal storage locations and private cloud S3 storage such as [MinIO](#).

For additional details about Vertica and AWS, see [Vertica on Amazon Web Services](#).

Secrets authentication

To connect to an S3-compatible storage location, create a [Secret](#) to store both your communal access and secret key credentials. Then, add the Secret, path, and S3 endpoint to the CR spec.

1. The following command stores both your S3-compatible communal access and secret key credentials in a Secret named **s3-creds** :

```
$ kubectl create secret generic s3-creds --from-literal=accesskey=accesskey --from-literal=secretkey=secretkey
```

2. Add the Secret to the **communal** section of the CR spec:

```
spec:
  ...
  communal:
    credentialSecret: s3-creds
    endpoint: https://path/to/s3-endpoint
    path: s3://bucket-name/key-name
  ...
```

For a detailed description of an S3-compatible storage implementation, see [VerticaDB custom resource definition](#).

IAM profile authentication

Identify and access management (IAM) profiles manage user identities and control which services and resources a user can access. IAM authentication to Vertica on Kubernetes reduces the number of manual updates when you rotate your access keys.

The IAM profile must have read and write access to the communal storage. The IAM profile is associated with the EC2 instances that run worker nodes.

1. Create an [EKS node group](#) using a [Node IAM role](#) with a policy that allows read and write access to the S3 bucket used for communal storage.
2. Deploy the VerticaDB operator in a namespace. For details, see [Installing the VerticaDB operator](#).
3. [Create a VerticaDB custom resource \(CR\)](#), and omit the **communal.credentialSecret** field:

```
spec:
  ...
  communal:
    endpoint: https://path/to/s3-endpoint
    path: s3://bucket-name/key-name
  ...
```

When the Vertica server accesses the communal storage location, it uses the policy associated to the EKS node.

For additional details about authenticating to Vertica with an IAM profile, see [AWS authentication](#).

IRSA profile authentication

Important

This authentication method requires an image running Vertica server version 12.0.3 or later.

You can use [IAM roles for service accounts \(IRSA\)](#) to associate an IAM role with a Kubernetes service account. You must set the IAM policies for the Kubernetes service account, and then pods running that service account have the IAM policies.

Before you begin, complete the following prerequisites:

- Configure the EKS cluster's control plane. For details, see the [Amazon documentation](#).
- Create a bucket policy that has access to the S3 communal storage bucket. For details, see the [Amazon documentation](#).

1. Create an [EKS node group](#) using a [Node IAM role](#) that does not have S3 access.
2. Use `eksctl` to create the IAM OpenID Connect (OIDC) provider for your EKS cluster:

```
$ eksctl utils associate-iam-oidc-provider --cluster cluster --approve
2022-10-07 08:31:37 [i] will create IAM Open ID Connect provider for cluster "cluster" in "us-east-1"
2022-10-07 08:31:38 [✓] created IAM Open ID Connect provider for cluster "cluster" in "us-east-1"
```

3. Create the Kubernetes namespace where you plan to create the `iamserviceaccount`. The following command creates the `vertica` namespace:

```
$ kubectl create ns vertica
namespace/vertica created
```

4. Use `eksctl` to create a Kubernetes service account in the `vertica` namespace. When you create a service account with `eksctl`, you can attach an IAM policy that allows S3 access:

```
$ eksctl create iamserviceaccount --name shared-service-account --namespace vertica --cluster cluster --attach-policy-arn arn:aws:iam::profile:policy/policy
2022-10-07 08:38:32 [i] iamserviceaccount (vertica/my-serviceaccount) was included (based on the include/exclude rules)
2022-10-07 08:38:32 [i] serviceaccounts that exist in Kubernetes will be excluded, use --override-existing-serviceaccounts to override
2022-10-07 08:38:32 [i] 1 task: {
  2 sequential sub-tasks: {
    create IAM role for serviceaccount "vertica/my-serviceaccount",
    create serviceaccount "vertica/my-serviceaccount",
  }
}
2022-10-07 08:38:32 [i] building iamserviceaccount stack "eksctl-cluster-addon-iamserviceaccount-vertica-my-serviceaccount"
2022-10-07 08:38:33 [i] deploying stack "eksctl-cluster-addon-iamserviceaccount-vertica-my-serviceaccount"
2022-10-07 08:38:33 [i] waiting for CloudFormation stack "eksctl-cluster-addon-iamserviceaccount-vertica-my-serviceaccount"
2022-10-07 08:39:03 [i] waiting for CloudFormation stack "eksctl-cluster-addon-iamserviceaccount-vertica-my-serviceaccount"
2022-10-07 08:39:04 [i] created serviceaccount "vertica/my-serviceaccount"
```

5. Create a [VerticaDB custom resource \(CR\)](#). Specify the service account with the `serviceAccountName` field, and omit the `communal.credentialSecret` field:

```
apiVersion: vertica.com/v1
kind: VerticaDB
metadata:
  name: irsadb
  annotations:
    vertica.com/run-nma-in-sidecar: "false"
spec:
  image: vertica/vertica-k8s:12.0.3-0
  serviceAccountName: shared-service-account
  communal:
    path: "s3://path/to/s3-endpoint"
    endpoint: https://s3.amazonaws.com
  subclusters:
    - name: sc
      size: 3
```

When pods are created, they use the service account that has a policy that provides access to the S3 communal storage.

Server-side encryption

Important

Vertica supports S3 server-side encryption in versions 12.0.1 and higher.

If your S3 communal storage uses server-side encryption (SSE), you must configure the encryption type when you create the CR. Vertica supports the following types of SSE:

- SSE-S3
- SSE-KMS
- SSE-C

For details about Vertica support for each encryption type, see [S3 object store](#).

The following tabs provide examples on how to implement each SSE type. For details about the parameters, see [Custom resource definition parameters](#).

[SSE-S3](#)

[SSE-KMS](#)

[SSE-C](#)

```
apiVersion: vertica.com/v1
kind: VerticaDB
metadata:
  name: verticadb
  annotations:

    path: "s3://bucket-name"
    s3ServerSideEncryption: SSE-S3
```

Google Cloud Storage

Authenticating to Google Cloud Storage (GCS) requires your hash-based message authentication code (HMAC) access and secret keys, and the path to your GCS bucket. For details about HMAC keys, see [Eon Mode on GCP prerequisites](#).

You have two authentication options: you can authenticate with [Kubernetes Secrets](#), or you can use the keys stored in Google [Secret Manager](#).

For additional details about Vertica and GCS, see [Vertica on Google Cloud Platform](#).

Kubernetes Secret authentication

To authenticate with a Kubernetes Secret, create the secret and add it to the CR manifest:

1. The following command stores your HMAC access and secret key in a Secret named **gcs-creds** :

```
$ kubectl create secret generic gcs-creds --from-literal=accesskey=accessKey --from-literal=secretkey=secretkey
```

2. Add the Secret and the path to the GCS bucket that contains your Vertica database to the **communal** section of the CR spec:

```
spec:
  communal:
    credentialSecret: gcs-creds
    path: gs://bucket-name/path/to/database-name
  ...
```

Azure Blob Storage

Microsoft Azure provides a variety of options to authenticate to Azure Blob Storage location. Depending on your environment, you can use one of the following combinations to store credentials in a [Secret](#) :

- accountName and accountKey
- accountName and shared access signature (SAS)

If you use an Azure storage emulator such as [Azurite](#) in a testing environment, you can authenticate with accountName and blobStorage values.

Important

Vertica does not officially support Azure storage emulators as a communal storage location.

1. The following command stores `accountName` and `accountKey` in a Secret named `azb-creds` :

```
$ kubectl create secret generic azb-creds --from-literal=accountKey=accessKey --from-literal=accountName=accountName
```

Alternately, you could store your `accountName` and your SAS credentials in `azb-creds` :

```
$ kubectl create secret generic azb-creds --from-literal=sharedAccessSignature=sharedAccessSignature --from-literal=accountName=accountName
```

2. Add the Secret and the path that contains your AZB storage bucket to the `communal` section of the CR spec:

```
spec:
  ...
  communal:
    credentialSecret: azb-creds
    path: azb://accountName/bucket-name/database-name
  ...
```

For details about Vertica and authenticating to Microsoft Azure, see [Eon Mode on GCP prerequisites](#).

Hadoop file storage

Connect to Hadoop Distributed Filesystem (HDFS) communal storage with the standard `webhdfs` scheme, or the `swebhdfs` scheme for wire encryption. In addition, you must add your HDFS configuration files in a [ConfigMap](#), a Kubernetes object that stores data in key-value pairs. You can optionally configure Kerberos to authenticate connections to your HDFS storage location.

The following example uses the `swebhdfs` wire encryption scheme that requires a certificate authority (CA) bundle in the CR spec.

1. The following command stores a PEM-encoded CA bundle in a [Secret](#) named `hadoop-cert` :

```
$ kubectl create secret generic hadoop-cert --from-file=ca-bundle.pem
```

2. HDFS configuration files are located in the `/etc/hadoop` directory. The following command creates a ConfigMap named `hadoop-conf` :

```
$ kubectl create configmap hadoop-conf --from-file=/etc/hadoop
```

3. Add the configuration values to the `communal` and `certSecrets` sections of the spec:

```
spec:
  ...
  hadoopConfig: hadoop-conf
  communal:
    path: "swebhdfs://path/to/database"

    caFile: /certs/hadoop-cert/ca-bundle.pem
  certSecrets:
    - name: hadoop-cert
  ...
```

The previous example defines the following:

- `hadoopConfig` : ConfigMap that stores the contents of the `/etc/hadoop` directory.
- `communal.path` : Path to the database, using the wire encryption scheme. Enclose the path in double quotes.
- `communal.caFile` : Mount path in the container filesystem containing the CA bundle used to create the `hadoop-cert` Secret.
- `certSecrets.name` : Secret containing the CA bundle.

For additional details about HDFS and Vertica, see [Apache Hadoop integration](#).

Kerberos authentication (optional)

Vertica authenticates connections to HDFS with Kerberos. The Kerberos configuration between Vertica on Kubernetes is the same as between a standard Eon Mode database and Kerberos, as described in [Kerberos authentication](#).

1. The following command stores the `krb5.conf` and `krb5.keytab` files in a [Secret](#) named `krb5-creds` :

```
$ kubectl create secret generic krb5-creds --from-file=kerberos-conf=/etc/krb5.conf --from-file=kerberos-keytab=/etc/krb5.keytab
```

Consider the following when managing the `krb5.conf` and `krb5.keytab` files in Vertica on Kubernetes:

- Each pod uses the same `krb5.keytab` file, so you must update the `krb5.keytab` file before you begin any scaling operation.
- When you update the contents of the `krb5.keytab` file, the operator updates the mounted files automatically, a process that does not require a pod restart.
- The `krb5.conf` file must include a `[domain_realm]` section that maps the Kubernetes cluster domain to the Kerberos realm. The following example maps the default `.cluster.local` domain to a Kerberos realm named `EXAMPLE.COM`:

```
[domain_realm]
.cluster.local = EXAMPLE.COM
```

2. Add the Secret and additional Kerberos configuration information to the CR:

```
spec:
  ...
  hadoopConfig: hadoop-conf
  communal:
    path: "swebhdfs://path/to/database"
  additionalConfig:
    kerberosServiceName: verticadb
    kerberosRealm: EXAMPLE.COM
    kerberosSecret: krb5-creds
  ...
```

The previous example defines the following:

- **hadoopConfig** : ConfigMap that stores the contents of the `/etc/hadoop` directory.
- **communal.path** : Path to the database, using the wire encryption scheme. Enclose the path in double quotes.
- **communal.additionalConfig.kerberosServiceName** : Service name for the Vertica principal.
- **communal.additionalConfig.kerberosRealm** : Realm portion of the principal.
- **kerberosSecret** : Secret containing the `krb5.conf` and `krb5.keytab` files.

For a complete definition of each of the previous values, see [Custom resource definition parameters](#).

Custom resource definitions

The custom resource definition (CRD) is a shared global object that extends the Kubernetes API beyond the standard resource types. The CRD serves as a blueprint for custom resource (CR) instances. You create CRs that specify the desired state of your environment, and the operator monitors the CR to maintain state for the objects within its namespace.

In this section

- [VerticaDB custom resource definition](#)
- [EventTrigger custom resource definition](#)
- [VerticaAutoscaler custom resource definition](#)
- [VerticaRestorePointsQuery custom resource definition](#)
- [VerticaScrutinize custom resource definition](#)

VerticaDB custom resource definition

Important

Beginning with version 24.1.0, the [VerticaDB operator version 2.0.0](#) manages deployments with `vclusterops`, a Go library that uses a high-level REST interface to leverage the [Node Management Agent](#) and [HTTPS service](#). The `vclusterops` library replaces [Administration tools \(admintools\)](#), so you cannot access a shell within a container and execute any `admintools` commands.

Version 24.1.0 also introduces API version `v1`. All examples in this section use API version `v1` and the `vcluster` deployment type. API version `v1beta1` is [deprecated](#), and Vertica recommends that you migrate to API version `v1`. For migration details, see [Upgrading Vertica on Kubernetes](#).

The Kubernetes API server stores only one format version of the custom resource. If you migrate to API version `v1` and then create a custom resource with API version `v1beta1`, then the conversion webhook converts the custom resource to API version `v1` automatically.

If you migrated to API version `v1`, you can view the `v1beta1` equivalent of your custom resource with the following command:

```
$ kubectl get verticadbs.v1beta1.vertica.com cr-name -o yaml
```

The VerticaDB custom resource definition (CRD) deploys an Eon Mode database. Each subcluster is a [StatefulSet](#), a workload resource type that persists data with ephemeral Kubernetes objects.

A VerticaDB custom resource (CR) requires a primary subcluster and a connection to a communal storage location to persist its data. The [VerticaDB operator](#) monitors the CR to maintain its desired state and validate state changes.

The following sections provide a YAML-formatted manifest that defines the minimum required fields to create a VerticaDB CR, and each subsequent section implements a production-ready recommendation or best practice using custom resource parameters. For a comprehensive list of all parameters and their definitions, see [custom resource parameters](#).

Prerequisites

- Complete [Installing the VerticaDB operator](#).
- Configure a [dynamic volume provisioner](#).
- Confirm that you have the resources to deploy objects you plan to create.
- Optionally, acquire a Vertica license. By default, the Helm chart deploys the free [Community Edition](#) license. This license limits you to a three-node cluster and 1TB data.
- Configure a [supported communal storage location](#) with an empty communal path bucket.
- Understand [Kubernetes Secrets](#) and how [Vertica manages Secrets](#). Secrets conceal sensitive information in your custom resource.

Minimal manifest

At minimum, a VerticaDB CR requires a connection to an empty communal storage bucket and a primary subcluster definition. The operator is namespace-scoped, so make sure that you apply the CR manifest in the same namespace as the operator.

The following VerticaDB CR connects to S3 communal storage and deploys a three-node primary subcluster on three nodes. This manifest serves as the starting point for all implementations detailed in the subsequent sections:

```
apiVersion: vertica.com/v1
kind: VerticaDB
metadata:
  name: cr-name
spec:
  licenseSecret: vertica-license
  passwordSecret: su-password
  communal:
    path: "s3://bucket-name/key-name"
    endpoint: "https://path/to/s3-endpoint"
    credentialSecret: s3-creds
    region: region
  subclusters:
    - name: primary
      size: 3
  shardCount: 6
```

The following sections detail the minimal manifest's CR parameters, and how to create the CR in the current namespace.

Required fields

Each VerticaDB manifest begins with required fields that describe the version, resource type, and metadata:

- **apiVersion** : The API group and Kubernetes API version in **api-group/version** format.
- **kind** : The resource type. **VerticaDB** is the name of the Vertica custom resource type.
- **metadata** : Data that identifies objects in the namespace.
- **metadata.name** : The name of this CR object. Provide a unique **metadata.name** value so that you can identify the CR and its resources in its namespace.

spec definition

The **spec** field defines the desired state of the CR. The operator control loop compares the **spec** definition to the current state and reconciles any differences.

Nest all fields that define your StatefulSet under the **spec** field.

Add a license

By default, the Helm chart pulls the free [Vertica Community Edition \(CE\) image](#). The CE image has a restricted license that limits you to a three-node cluster and 1TB of data.

To add your license so that you can deploy more nodes and use more data, store your license in a Secret and add it to the manifest:

1. Create a Secret from your Vertica license file:

```
$ kubectl create secret generic vertica-license --from-file=license.dat=/path/to/license-file.dat
```

2. Add the Secret to the `licenseSecret` field:

```
...
spec:
  licenseSecret: vertica-license
...
```

The `licenseSecret` value is mounted in the Vertica server container in the `/home/dbadmin/licensing/mnt` directory.

Add password authentication

The `passwordSecret` field enables password authentication for the database. You must define this field when you create the CR—you cannot define a password for an existing database.

To create a database password, conceal it in a Secret before you add it to the manifest:

1. Create a Secret from a literal string. You must use `password` as the key:

```
$ kubectl create secret generic su-passwd --from-literal=password=password-value
```

2. Add the Secret to the `passwordSecret` field:

```
...
spec:
  passwordSecret: su-passwd
...
```

Connect to communal storage

Vertica on Kubernetes supports multiple [communal storage locations](#). For implementation details for each communal storage location, see [Configuring communal storage](#).

This CR connects to an S3 communal storage location. Define your communal storage location with the `communal` field:

```
...
spec:
  communal:
    path: "s3://bucket-name/key-name"
    endpoint: "https://path/to/s3-endpoint"
    credentialSecret: s3-creds
    region: region
...
```

This manifest sets the following parameters:

- `credentialSecret` : The Secret that contains your communal access and secret key credentials.

The following command stores both your S3-compatible communal access and secret key credentials in a Secret named `s3-creds` :

```
$ kubectl create secret generic s3-creds --from-literal=accesskey=accesskey --from-literal=secretkey=secretkey
```

Note

Omit `credentialSecret` for environments that authenticate to S3 communal storage with Identity and Access Management (IAM) or IAM roles for service accounts (IRSA)—these methods do not require that you store your credentials in a Secret. For details, see [Configuring communal storage](#).

- `endpoint` : The S3 endpoint URL.
- `path` : The location of the S3 storage bucket, in S3 bucket notation. This bucket must exist before you create the custom resource. After you create the custom resource, you cannot change this value.
- `region` : The geographic location of the communal storage resources. This field is valid for AWS and GCP only. If you set the wrong region, you cannot connect to the communal storage location.

Define a primary subcluster

Each CR requires a primary subcluster or it returns an error. At minimum, you must define the name and size of the subcluster:

```
..
spec:
  ..
  subclusters:
  - name: primary
    size: 3
  ..
```

This manifest sets the following parameters:

- **name** : The name of the subcluster.
- **size** : The number of pods in the subcluster.

When you define a CR with a single subcluster, the operator designates it as the primary subcluster. If your manifest includes multiple subclusters, you must use the **type** parameter to identify the primary subcluster. For example:

```
spec:
  ..
  subclusters:
    name: primary
    size: 3
    type: primary
  - name: secondary
    size: 3
```

For additional details about primary and secondary subclusters, see [Subclusters](#).

Set the shard count

shardCount specifies the number of shards in the database, which determines how subcluster nodes subscribe to communal storage data. You cannot change this value after you instantiate the CR. When you change the number of pods in a subcluster or add or remove a subcluster, the operator [rebalances shards automatically](#).

Vertica recommends that the shard count equals double the number of nodes in the cluster. Because this manifest creates a three-node cluster with one Vertica server container per node, set **shardCount** to **6** :

```
..
spec:
  ..
  shardCount: 6
```

For guidance on selecting the shard count, see [Configuring your Vertica cluster for Eon Mode](#). For details about limiting each node to one Vertica server container, see [Node affinity](#).

Apply the manifest

After you define the minimal manifest in a YAML-formatted file, use **kubectl** to create the VerticaDB CR. The following command creates a CR in the current namespace:

```
$ kubectl apply -f minimal.yaml
verticadb.vertica.com/cr-name created
```

After you apply the manifest, the operator creates the primary subcluster, connects to the communal storage, and creates the database. You can use **kubectl wait** to see when the database is ready:

```
$ kubectl wait --for=condition=DBInitialized=True vdb/cr-name --timeout=10m
verticadb.vertica.com/cr-name condition met
```

Specify an image

Each time the operator launches a container, it pulls the image for the most recently released Vertica version from the OpenText Dockerhub repository. Vertica recommends that you explicitly set the image that the operator pulls for your CR. For a list of available Vertica images, see the [OpenText Dockerhub registry](#).

To run a specific image version, set the `image` parameter in `docker-registry-hostname/image-name:tag` format:

```
spec:
  ...
  image: vertica/vertica-k8s:version
```

When you specify an image other than the `latest`, the operator pulls the image only when it is not available locally. You can control when the operator pulls the image with the `imagePullPolicy` [custom resource parameter](#).

Communal storage authentication

Your communal storage validates HTTPS connections with a self-signed certificate authority (CA) bundle. You must make the CA bundle's root certificate available to each Vertica server container so that the communal storage can authenticate requests from your subcluster.

This authentication requires that you set the following parameters:

- `certSecrets`: Adds a Secret that contains the root certificate.
This parameter is a list of Secrets that encrypt internal and external communications for your CR. Each certificate is mounted in the Vertica server container filesystem in the `/certs/ Secret-name / cert-name` directory.
- `communal.caFile`: Makes the communal storage location aware of the mount path that stores the certificate Secret.

Complete the following to add these parameters to the manifest:

1. Create a Secret that contains the PEM-encoded root certificate. The following command creates a Secret named `aws-cert`:

```
$ kubectl create secret generic aws-cert --from-file=root-cert.pem
```

2. Add the `certSecrets` and `communal.caFile` parameters to the manifest:

```
spec:
  ...
  communal:
    ...
    caFile: /certs/aws-cert/root_cert.pem
  certSecrets:
    - name: aws-cert
```

Now, the communal storage authenticates requests with the `/certs/aws-cert/root_cert.pem` file, whose contents are stored in the `aws-cert` Secret.

External client connections

Each subcluster communicates with external clients and internal pods through a service object. To configure the service object to accept external client connections, set the following parameters:

- `serviceName`: Assigns a custom name to the service object. A custom name lets you identify it among multiple subclusters.
Service object names use the `metadata.name-serviceName` naming convention.
- `serviceType`: Defines the type of the subcluster service object.
By default, a subcluster uses the `ClusterIP` serviceType, which sets a stable IP and port that is accessible from within Kubernetes only. In many circumstances, external client applications need to connect to a subcluster that is fine-tuned for that specific workload. For external client access, set the `serviceType` to `NodePort` or `LoadBalancer`.

Note

The `LoadBalancer` service type is an external service type that is managed by your cloud provider. For implementation details, refer to the [Kubernetes documentation](#) and your cloud provider's documentation.

- `serviceAnnotations`: Assigns a custom annotation to the service object for implementation-specific services.

Add these external client connection parameters under the `subclusters` field:

```
spec:
  ...
  subclusters:
    ...
    serviceName: connections
    serviceType: LoadBalancer
    serviceAnnotations:
      service.beta.kubernetes.io/load-balancer-source-ranges: 10.0.0.0/24
```

This example creates a **LoadBalancer** service object named **verticadb-connections** . The **serviceAnnotations** parameter defines the CIDRs that can access the network load balancer (NLB). For additional details, see the [AWS Load Balancer Controller](#) documentation.

Note

If you run your CR on Amazon Elastic Kubernetes Service (EKS), Vertica recommends the [AWS Load Balancer Controller](#) . To use the AWS Load Balancer Controller, apply the following annotations:

```
serviceAnnotations:
  service.beta.kubernetes.io/aws-load-balancer-type: external
  service.beta.kubernetes.io/aws-load-balancer-nlb-target-type: ip
  service.beta.kubernetes.io/aws-load-balancer-scheme: internet-facing
```

For longer-running queries, you might need to [configure TCP keepalive](#) settings.

For additional details about Vertica and service objects, see [Containerized Vertica on Kubernetes](#) .

Authenticate clients

You might need to connect applications or command-line interface (CLI) tools to your VerticaDB CR. You can add TLS certificates that authenticate client requests with the **certSecrets** parameter:

1. Create a Secret that contains your TLS certificates. The following command creates a Secret named **mtls** :

```
$ kubectl create secret generic mtls --from-file=mtls=/path/to/mtls-cert
```

2. Add the Secret to the **certSecrets** parameter :

```
spec:
  ...
  certSecrets:
    ...
    - name: mtls
```

This mounts the TLS certificates in the **/certs/mtls/mtls-cert** directory.

Sidecar logger

A sidecar is a utility container that runs in the same pod as your main application container and performs a task for that main application's process. The VerticaDB CR uses a sidecar container to handle logs for the Vertica server container. You can use the [vertica-logger](#) image to add a sidecar that sends logs from **vertica.log** to standard output on the host node for log aggregation.

Add a sidecar with the **sidecars** parameter. This parameter accepts a list of sidecar definitions, where each element specifies the following:

- **name** : Name of the sidecar. **name** indicates the beginning of a sidecar element.
- **image** : Image for the sidecar container.

The following example adds a single sidecar container that shares a pod with each Vertica server container:

```
spec:
  ...
  sidecars:
    - name: sidecar-container
      image: sidecar-image:latest
```

This configuration persists logs only for the lifecycle of the container. To persist log data between pod lifecycles, you must [mount a custom volume](#) in the sidecar filesystem.

Persist logs with a volume

An external service that requires long-term access to Vertica server data should use a volume to persist that data between pod lifecycles. For details about volumes, see the [Kubernetes documentation](#).

The following parameters add a volume to your CR and mounts it in a sidecar container:

- **volumes** : Make a custom volume available to the CR so that you can mount it in a container filesystem. This parameter requires a **name** value and a volume type.
- **sidecars[j].volumeMounts** : Mounts one or more volumes in the sidecar container filesystem. This parameter requires a **name** value and a **mountPath** value that defines where the volume is mounted in the sidecar container.

Note

Vertica also provides a **spec.volumeMounts** parameter so you can mount volumes for other use cases. This parameter behaves like **sidecars[j].volumeMounts**, but it mounts volumes in the Vertica server container filesystem.

For details, see [Custom resource definition parameters](#).

The following example creates a volume of type **emptyDir**, and mounts it in the **sidecar-container** filesystem:

```
spec:
  ...
  volumes:
  - name: sidecar-vol
    emptyDir: {}
  ...
  sidecars:
  - name: sidecar-container
    image: sidecar-image:latest
    volumeMounts:
    - name: sidecar-vol
      mountPath: /path/to/sidecar-vol
```

Resource limits and requests

You should limit the amount of CPU and memory resources that each host node allocates for the Vertica server pod, and set the amount of resources each pod can request.

To control these values, set the following parameters under the **subclusters.resources** field:

- **limits.cpu** : Maximum number of CPUs that each server pod can consume.
- **limits.memory** : Maximum amount of memory that each server pod can consume.
- **requests.cpu** : Number CPUs that each pod requests from the host node.
- **requests.memory** : Amount of memory that each pod requests from a PV.

When you change resource settings, Kubernetes restarts each pod with the updated settings.

Note

Select resource settings that your host nodes can accommodate. When a pod is started or rescheduled, Kubernetes searches for host nodes with enough resources available to start the pod. If there is not a host node with enough resources, the pod **STATUS** stays in **Pending** until the resources become available.

For guidance on setting production limits and requests, see [Recommendations for Sizing Vertica Nodes and Clusters](#).

As a best practice, set **resource.limits.*** and **resource.requests.*** to equal values so that the pods are assigned to the [Guaranteed Quality of Service \(QoS\) class](#). Equal settings also provide the best safeguard against the Out Of Memory (OOM) Killer in constrained environments.

The following example allocates 32 CPUs and 96 gigabytes of memory on the host node, and limits the requests to the same values. Because the **limits.*** and **requests.*** values are equal, the pods are assigned the **Guaranteed** QoS class:

```
spec:
  ...
  subclusters:
  ...
  resources:
    limits:
      cpu: 32
      memory: 96Gi
    requests:
      cpu: 32
      memory: 96Gi
```

Node affinity

Kubernetes affinity and anti-affinity settings control which resources the operator uses to schedule pods. As a best practice, you should set **affinity** to ensure that a single node does not serve more than one Vertica pod.

The following example creates an anti-affinity rule that schedules only one Vertica server pod per node:

```
spec:
  ...
  subclusters:
  ...
  affinity:
    podAntiAffinity:
      requiredDuringSchedulingIgnoredDuringExecution:
      - labelSelector:
          matchExpressions:
          - key: app.kubernetes.io/name
            operator: In
            values:
            - vertica
        topologyKey: "kubernetes.io/hostname"
```

The following provides a detailed explanation about all settings in the previous example:

- **affinity** : Provides control over pod and host scheduling using labels.
- **podAntiAffinity** : Uses pod labels to prevent scheduling on certain resources.
- **requiredDuringSchedulingIgnoredDuringExecution** : The rules defined under this statement must be met before a pod is scheduled on a host node.
- **labelSelector** : Identifies the pods affected by this affinity rule.
- **matchExpressions** : A list of pod selector requirements that consists of a **key** , **operator** , and **values** definition. This **matchExpression** rule checks if the host node is running another pod that uses a **vertica** label.
- **topologyKey** : Defines the scope of the rule. Because this uses the **hostname** topology label, this applies the rule in terms of pods and host nodes.

For additional details, see the [Kubernetes documentation](#) .

EventTrigger custom resource definition

The EventTrigger custom resource definition (CRD) runs a task when the [condition](#) of a Kubernetes object changes to a specified status. EventTrigger extends the [Kubernetes Job](#) , a workload resource that creates pods, runs a task, then cleans up the pods after the task completes.

Prerequisites

- Deploy a [VerticaDB operator](#) .
- Confirm that you have the resources to deploy objects you plan to create.

Limitations

The EventTrigger CRD has the following limitations:

- It can monitor a condition status on only one VerticaDB custom resource (CR).
- You can match only one condition status.
- The EventTrigger and the object that it watches must exist within the same namespace.

Creating an EventTrigger

An EventTrigger resource defines the Kubernetes object that you want to watch, the status condition that triggers the Job, and a [pod template](#) that contains the Job logic and provides resources to complete the Job.

This example creates a YAML-formatted file named `eventtrigger.yaml`. When you apply `eventtrigger.yaml` to your VerticaDB CR, it creates a single-column database table when the VerticaDB CR's `DBInitialized` condition status changes to `True`:

```
$ kubectl describe vdb verticadb-name
Status:
...
Conditions:
...
  Last Transition Time: transition-time
  Status:             True
  Type:              DBInitialized
```

The following fields form the `spec`, which defines the desired state of the EventTrigger object:

- `references`: The Kubernetes object whose condition status you want to watch.
- `matches`: The condition and status that trigger the Job.
- `template`: Specification for the pods that run the Job after the condition status triggers an event.

The following steps create an EventTrigger CR:

1. Add the `apiVersion`, `kind`, and `metadata.name` [required fields](#):

```
apiVersion: vertica.com/v1beta1
kind: EventTrigger
metadata:
  name: eventtrigger-example
```

2. Begin the `spec` definition with the `references` field. The `object` field is an array whose values identify the VerticaDB CR object that you want to watch. You must provide the VerticaDB CR's `apiVersion`, `kind`, and `name`:

```
spec:
  references:
  - object:
    apiVersion: vertica.com/v1beta1
    kind: VerticaDB
    name: verticadb-example
```

3. Define the `matches` field that triggers the Job. `EventTrigger` can match only one condition:

```
spec:
...
  matches:
  - condition:
    type: DBInitialized
    status: "True"
```

The preceding example defines the following:

- `condition.type`: The condition that the operator watches for state change.
 - `condition.status`: The status that triggers the Job.
4. Add the `template` that defines the pod specifications that run the Job after `matches.condition` triggers an event.

A pod template requires its own `spec` definition, and it can optionally have its own metadata. The following example includes `metadata.generateName`, which instructs the operator to generate a unique, random name for any pods that it creates for the Job. The trailing dash (-) separates the user-provided portion from the generated portion:

```
spec:
  ...
  template:
    metadata:
      generateName: create-user-table-
    spec:
      template:
        spec:
          restartPolicy: OnFailure
        containers:
        - name: main
          image: "vertica/vertica-k8s:latest"
          command: ["/opt/vertica/bin/vsql", "-h", "verticadb-sample-defaultsubcluster", "-f", "CREATE TABLE T1 (C1 INT);"]
```

The remainder of the `spec` defines the following:

- `restartPolicy` : When to restart all containers in the pod.
- `containers` : The containers that run the Job.
 - `name` : The name of the container.
 - `image` : The image that the container runs.
 - `command` : An array that contains a command, where each element in the array combines to form a command. The final element creates the single-column SQL table.

Apply the manifest

After you create the EventTrigger, apply the manifest in the same namespace as the VerticaDB CR:

```
$ kubectl apply -f eventtrigger.yaml
eventtrigger.vertica.com/eventtrigger-example created
configmap/create-user-table-sql created
```

After you create the database, the operator runs a Job that creates a table. You can check the status with `kubectl get job` :

```
$ kubectl get job
NAME                COMPLETIONS  DURATION  AGE
create-user-table  1/1          4s       7s
```

Verify that the table was created in the logs:

```
$ kubectl logs create-user-table-guid
CREATE TABLE
```

Complete file reference

```

apiVersion: vertica.com/v1beta1
kind: EventTrigger
metadata:
  name: eventtrigger-example
spec:
  references:
  - object:
    apiVersion: vertica.com/v1beta1
    kind: VerticaDB
    name: verticadb-example
  matches:
  - condition:
    type: DBInitialized
    status: "True"
  template:
    metadata:
      generateName: create-user-table-
    spec:
      template:
        spec:
          restartPolicy: OnFailure
          containers:
          - name: main
            image: "vertica/vertica-k8s:latest"
            command: ["/opt/vertica/bin/vsqr", "-h", "verticadb-sample-defaultsubcluster", "-f", "CREATE TABLE T1 (C1 INT);"]

```

Monitoring an EventTrigger

The following table describes the status fields that help you monitor an EventTrigger CR:

Status Field	Description
<code>references[].apiVersion</code>	Kubernetes API version of the object that the EventTrigger CR watches.
<code>references[].kind</code>	Type of object that the EventTrigger CR watches.
<code>references[].name</code>	Name of the object that the EventTrigger CR watches.
<code>references[].namespace</code>	Namespace of the object that the EventTrigger CR watches. The EventTrigger and the object that it watches must exist within the same namespace.
<code>references[].uid</code>	Generated UID of the reference object. The operator generates this identifier when it locates the reference object.
<code>references[].resourceVersion</code>	Current resource version of the object that the EventTrigger watches.
<code>references[].jobNamespace</code>	If a Job was created for the object that the EventTrigger watches, the namespace of the Job.
<code>references[].jobName</code>	If a Job was created for the object that the EventTrigger watches, the name of the Job.

VerticaAutoscaler custom resource definition

The VerticaAutoscaler custom resource (CR) is a [HorizontalPodAutoscaler](#) that automatically scales resources for existing subclusters using one of the following strategies:

- Subcluster scaling for short-running dashboard queries.
- Pod scaling for long-running analytic queries.

The VerticaAutoscaler CR scales using [resource or custom metrics](#). Vertica manages subclusters by workload, which helps you pinpoint the best metrics to trigger a scaling event. To maintain data integrity, the operator does not scale down unless all connections to the pods are drained and sessions are closed.

For details about the algorithm that determines when the VerticaAutoscaler scales, see the [Kubernetes documentation](#).

Additionally, the VerticaAutoscaler provides a webhook to validate state changes. By default, this webhook is enabled. You can configure this webhook with the `webhook.enable` [Helm chart parameter](#).

Examples

The examples in this section use the following [VerticaDB](#) custom resource. Each example uses CPU to trigger scaling:

```
apiVersion: vertica.com/v1beta1
kind: VerticaDB
metadata:
  name: dbname
spec:
  communal:
    path: "path/to/communal-storage"
    endpoint: "path/to/communal-endpoint"
    credentialSecret: credentials-secret
  subclusters:
  - name: primary1
    size: 3
    isPrimary: true
    serviceName: primary1
  resources:
    limits:
      cpu: "8"
    requests:
      cpu: "4"
```

Prerequisites

- Complete [Installing the VerticaDB operator](#).
- Install the [kubectl](#) command line tool.
- Complete [VerticaDB custom resource definition](#).
- Confirm that you have the resources to scale.

Note

By default, the custom resource uses the free [Community Edition \(CE\)](#) license. This license allows you to deploy up to three nodes with a maximum of 1TB of data. To add resources beyond these limits, you must add your Vertica license to the custom resource as described in [VerticaDB custom resource definition](#).

- Set a value for the metric that triggers scaling. For example, if you want to scale by CPU utilization, you must set [CPU limits and requests](#).

Subcluster scaling

Automatically adjust the number of subclusters in your custom resource to fine-tune resources for short-running dashboard queries. For example, increase the number of subclusters to increase throughput. For more information, see [Improving query throughput using subclusters](#).

All subclusters share the same service object, so there are no required changes to external service objects. Pods in the new subcluster are load balanced by the existing service object.

The following example creates a VerticaAutoscaler custom resource that scales by subcluster when the VerticaDB uses 50% of the node's available CPU:

1. Define the VerticaAutoscaler custom resource in a YAML-formatted manifest:

```
apiVersion: vertica.com/v1beta1
kind: VerticaAutoscaler
metadata:
  name: autoscaler-name
spec:
  verticaDBName: dbname
  scalingGranularity: Subcluster
  serviceName: primary1
```

2. Create the VerticaAutoscaler with the `kubectl autoscale` command:

```
% kubectl autoscale verticaautoscaler autoscaler-name --cpu-percent=50 --min=3 --max=12
```

The previous command creates a HorizontalPodAutoscaler object that:

- Sets the target CPU utilization to 50%.
- Scales to a minimum of three pods in one subcluster, and 12 pods in four subclusters.

Pod scaling

For long-running, analytic queries, increase the pod count for a subcluster. For additional information about Vertica and analytic queries, see [Using elastic crunch scaling to improve query performance](#).

When you scale pods in an Eon Mode database, you must consider the impact on database shards. For details, see [Namespaces and shards](#).

The following example creates a VerticaAutoscaler custom resource that scales by pod when the VerticaDB uses 50% of the node's available CPU:

1. Define the VerticaAutoScaler custom resource in a YAML-formatted manifest:

```
apiVersion: vertica.com/v1beta1
kind: VerticaAutoscaler
metadata:
  name: autoscaler-name
spec:
  verticaDBName: dbname
  scalingGranularity: Pod
  serviceName: primary1
```

2. Create the autoscaler instance with the kubectl autoscale command:

```
$ kubectl autoscale verticaautoscaler autoscaler-name --cpu-percent=50 --min=3 --max=12
```

The previous command creates a HorizontalPodAutoscaler object that:

- Sets the target CPU utilization to 50%.
- Scales to a minimum of three pods in one subcluster, and 12 pods in four subclusters.

Event monitoring

To view the VerticaAutoscaler object, use the kubectl describe hpa command:

```
$ kubectl describe hpa autoscaler-name
Name: as
Namespace: vertica
Labels: <none>
Annotations: <none>
CreationTimestamp: Tue, 12 Apr 2022 15:11:28 -0300
Reference: VerticaAutoscaler/as
Metrics: ( current / target )
  resource cpu on pods (as a percentage of request): 0% (9m) / 50%
Min replicas: 3
Max replicas: 12
VerticaAutoscaler pods: 3 current / 3 desired
Conditions:
  Type           Status Reason
  ----           -
  AbleToScale    True   ReadyForNewScale recommended size matches current size
  ScalingActive  True   ValidMetricFound the HPA was able to successfully calculate a replica count from cpu resource utilization (percentage of request)
  ScalingLimited False  DesiredWithinRange the desired count is within the acceptable range
```

When a scaling event occurs, you can view the admintools commands to scale the cluster. Use kubectl to view the StatefulSets:

```
$ kubectl get statefulsets
NAME                                READY AGE
db-name-as-instance-name-0         0/3 71s
db-name-primary1                    3/3 39m
```

Use kubectl describe to view the executing commands:

```
$ kubectl describe vdb dbname | tail
Upgrade Status:
Events:
Type Reason Age From Message
----
Normal ReviveDBStart 41m verticadb-operator Calling 'admintools -t revive_db'
Normal ReviveDBSucceeded 40m verticadb-operator Successfully revived database. It took 25.255683916s
Normal ClusterRestartStarted 40m verticadb-operator Calling 'admintools -t start_db' to restart the cluster
Normal ClusterRestartSucceeded 39m verticadb-operator Successfully called 'admintools -t start_db' and it took 44.713787718s
Normal SubclusterAdded 10s verticadb-operator Added new subcluster 'as-0'
Normal AddNodeStart 9s verticadb-operator Calling 'admintools -t db_add_node' for pod(s) 'db-name-as-instance-name-0-0 db-name-as-instance-name-0-1'
```

VerticaRestorePointsQuery custom resource definition

Important

Beta Feature — For Test Environments Only

The VerticaRestorePointsQuery custom resource (CR) retrieves details about saved restore points that you can use to roll back your database to a previous state or restore specific objects in a [VerticaDB CR](#).

A VerticaRestorePointsQuery CR defines query parameters that the VerticaDB operator uses to retrieve restore points from an archive. A *restore point* is a snapshot of a database at a specific point in time that can consist of an entire database or a subset of database objects. Each restore point has a unique identifier and a timestamp. An *archive* is a collection of chronologically organized restore points.

You specify the archive and an optional period of time, and the operator queries the archive and retrieves details about restore points saved in the archive. You can use the query results to revive a [VerticaDB CR](#) with the data saved in the restore point.

Prerequisites

- Deploy a [VerticaDB CR](#)
- Deploy a [VerticaDB operator](#)

Save restore points

Important

This section contains the following SQL elements that are in Beta:

- **CREATE ARCHIVE** statement
- **SAVE RESTORE POINT TO ARCHIVE** statement
- **ARCHIVE_RESTORE_POINTS** system table

Before the VerticaDB operator can retrieve restore points, you must create an archive and save restore points to that archive. You can leverage [stored procedures](#) and [scheduled execution](#) to save restore points to an archive on a regular schedule. In the following sections, you schedule a stored procedure to save restore points to an archive every night at 9:00 PM.

Note

The following steps demonstrate how to retrieve restore points for a VerticaDB CR named `restorepoints`. Each `kubectl exec` command executes `vsq` statements in a running Vertica server container in `restorepoints`.

For details about `kubectl exec`, see the [Kubernetes documentation](#).

Create the archive and schedule restore points

Create an archive and then create a [stored procedure](#) that saves a restore point to that archive:

1. Create an archive with **CREATE ARCHIVE**. The following statement creates an archive named `nightly` because it will store restore points that are saved every night:

```
$ kubectl exec -it restorepoints-primary1-0 -c server -- vsq \
-w password \
-c "CREATE ARCHIVE nightly;"
CREATE ARCHIVE
```

2. Create a stored procedure that saves a restore point. The **SAVE RESTORE POINT TO ARCHIVE** statement creates a restore point and saves it to the **nightly** archive:

```
$ kubectl exec -it restorepoints-primary1-0 -c server -- vsql \  
-w password \  
-c "CREATE OR REPLACE PROCEDURE take_nightly()  
LANGUAGE PLvSQL AS $$  
BEGIN  
EXECUTE 'SAVE RESTORE POINT TO ARCHIVE nightly';  
END;  
$$;"  
CREATE PROCEDURE
```

3. To test the stored procedure, execute it with the **CALL** statement:

```
$ kubectl exec -it restorepoints-primary1-0 -c server -- vsql \  
-w password \  
-c "CALL take_nightly();"  
take_nightly  
-----  
0  
(1 row)
```

4. To verify that the stored procedure saved the restore point, query the **ARCHIVE_RESTORE_POINTS** system table to return the number of restore points in the specified archive:

```
$ kubectl exec -it restorepoints-primary1-0 -c server -- vsql \  
-w password \  
-c "SELECT COUNT(*) FROM ARCHIVE_RESTORE_POINTS  
WHERE ARCHIVE = 'nightly';"  
COUNT  
-----  
1  
(1 row)
```

Schedule the stored procedure

Schedule the stored procedure so that it saves a restore point to the **nightly** archive each night:

1. Schedule a time to execute the stored procedure with **CREATE SCHEDULE**. This function uses a **cron** expression to create a schedule at 9:00 PM each night:

```
$ kubectl exec -it restorepoints-primary1-0 -c server -- vsql \  
-w password \  
-c "CREATE SCHEDULE nightly_sched USING CRON '0 21 * * *';"  
CREATE SCHEDULE
```

2. Set **CREATE TRIGGER** to execute the **take_nightly** stored procedure with the **nightly_sched** schedule:

```
$ kubectl exec -it restorepoints-primary1-0 -c server -- vsql \  
-w password \  
-c "CREATE TRIGGER trigger_nightly_sched ON SCHEDULE nightly_sched  
EXECUTE PROCEDURE take_nightly() AS DEFINER;"  
CREATE TRIGGER
```

Verify the archive automation

After you create the stored procedure and configure its schedule, test that it executes and saves a stored procedure at the scheduled time:

1. Before the cron job is scheduled to run, verify the system time with the **date** shell built-in:

```
$ date -u  
Thu Feb 29 20:59:15 UTC 2024
```

2. Wait until the scheduled time elapses:

```
$ date -u  
Thu Feb 29 21:00:07 UTC 2024
```

3. To verify that the scheduled stored procedure executed on time, query **ARCHIVE_RESTORE_POINTS** system table for details about the **nightly** archive:

```
$ kubectl exec -it restorepoints-primary1-0 -c server -- vsql \
-w password \
-c "SELECT COUNT(*) FROM ARCHIVE_RESTORE_POINTS WHERE ARCHIVE = 'nightly';"
COUNT
-----
      2
(1 row)
```

COUNT is incremented by one, so the stored procedure saved the restore point on schedule.

Create a VerticaRestorePointsQuery

A VerticaRestorePointsQuery manifest specifies an archive and an optional time duration. The VerticaDB operator uses this information to retrieve details about the restore points that were saved to the archive.

Create and apply the manifest

The following manifest defines a VerticaRestorePointsQuery CR named **vrqp**. The **vrqp** CR instructs the operator to retrieve from the [nightly archive](#) all restore points saved on February 29, 2024:

1. Create a file named **vrpq.yaml** that contains the following manifest. This CR retrieves restore points :

```
apiVersion: vertica.com/v1beta1
kind: VerticaRestorePointsQuery
metadata:
  name: vrqp
spec:
  verticaDBName: restorepoints
  filterOptions:
    archiveName: "nightly"
    startTimestamp: 2024-02-29
    endTimestamp: 2024-02-29
```

The **spec** contains the following fields:

- **verticaDBName** : Name of the [VerticaDB](#) CR that you want to retrieve restore points for.
- **filterOptions.archiveName** : Archive that contains the restore points that you want to retrieve.
- **filterOptions.startTimestamp** : Retrieve restore points that were saved on or after this date.
- **filterOptions.endTimestamp** : Retrieve restore points that were saved on or before this date.

For additional details about these parameters, see [Custom resource definition parameters](#).

2. Apply the manifest in the current namespace with **kubectl** :

```
$ kubectl apply -f vrpq.yaml
verticarestorepointsquery.vertica.com/vrqp created
```

After you apply the manifest, the operator begins working to retrieve the restore points.

3. Verify that the query succeeded with **kubectl** :

```
$ kubectl get vrqp
NAME VERTICADB  STATE      AGE
vrqp  restorepoints  Query successful  10s
```

View retrieved restore points

After you apply the VerticaRestorePointsQuery CR, you can view the retrieved restore points with **kubectl describe**. **kubectl describe** returns a **Status** section, which describes the query activity and properties for each retrieved restore point:

```

$ kubectl describe vrpq
Name:          vrpq
...
Status:
Conditions:
  Last Transition Time: 2024-03-15T17:40:39Z
  Message:
  Reason:         Completed
  Status:         True
  Type:          QueryReady
  Last Transition Time: 2024-03-15T17:40:41Z
  Message:
  Reason:         Completed
  Status:         False
  Type:          Querying
  Last Transition Time: 2024-03-15T17:40:41Z
  Message:
  Reason:         Completed
  Status:         True
  Type:          QueryComplete
Restore Points:
  Archive:        nightly
  Id:             af8cd407-246a-4500-bc69-0b534e998ccc6
  Index:          1
  Timestamp:      2024-03-29 21:00:00.728787
  vertica_version: version
State:          Query successful

```

The **Status** section contains relevant restore points details in the **Conditions** and **Restore Points** fields.

Conditions

The **Conditions** field summarizes each stage of the restore points query and contains the following fields:

- **Last Transition Time** : Timestamp that indicates when the status condition last changed.
- **Message** : This field is not in use, you can safely ignore it.
- **Reason** : Indicates why the query stage is in its current **Status** .
- **Status** : Boolean, indicates whether the query stage is currently in process.
- **Type** : The query that the VerticaDB operator is executing in this stage.

The following table describes each **Conditions.Type** , and all possible value combinations for its **Reason** and **Status** field values:

Type	Description	Status	Reason
QueryReady	The operator verified that the query is executable in the environment.	True	Completed
		False	IncompatibleDB : CR specified by verticaDBName is not version 24.2 or later. AdmintoolsNotSupported : CR specified by verticaDBName does not use apiVersion v1 . For details, see VerticaDB custom resource definition .
Querying	The operator is running the query.	True	Started
		False	Failed Completed

QueryComplete	The query is complete and the restore points are available in the Restore Points array.	True	Completed
---------------	--	------	-----------

Restore Points

The **Restore Points** field lists each restore point that was retrieved from the archive and contains the following fields:

- **Archive** : The archive that contains this restore point.
- **Id** : Unique identifier for the restore point.
- **Index** : Restore point rank ordering in the archive, by descending timestamp. **1** is the most recent restore point.
- **Timestamp** : Time that indicates when the restore point was created.
- **vertica_version** : Database version when this restore point was saved to the archive.

Restore the database

After the operator retrieves the restore points, you can restore the database with the archive name and either the restore point **Index** or **Id** . In addition, you must set **initPolicy** to **Revive** :

1. Delete the existing CR:

```
$ kubectl delete -f restorepoints.yaml
verticadb.vertica.com "restorepoints" deleted
```

2. Update the CR. Change the **initPolicy** to **Revive** , and add the restore point information. You might have to set **ignore-cluster-lease** to **true** :

```
apiVersion: vertica.com/v1
kind: VerticaDB
metadata:
  name: restorepoints
  annotations:
    vertica.com/ignore-cluster-lease: "true"
spec:
  initPolicy: Revive
  restorePoint:
    archive: "nightly"
    index: 1
  ...
```

3. Apply the updated manifest:

```
$ kubectl apply -f restorepoints.yaml
verticadb.vertica.com/restorepoints created
```

VerticaScrutinize custom resource definition

The VerticaScrutinize custom resource (CR) runs [scrutinize](#) on a [VerticaDB CR](#) , which collects diagnostic information about the VerticaDB cluster and packages it in a tar file. This diagnostic information is commonly requested when resolving a case with [Vertica Support](#) .

When you create a VerticaScrutinize CR in your cluster, the VerticaDB operator creates a short-lived pod and runs scrutinize in two stages:

1. An [init container](#) runs scrutinize on the VerticaDB CR. This produces a tar file named **VerticaScrutinize.timestamp.tar** that contains the diagnostic information. Optionally, you can define one or more init containers that perform additional processing after scrutinize completes.
2. A main container persists the tar file in its file system in the **/tmp/scrutinize/** directory. This main container lives for 30 minutes.

When resolving a support case, Vertica Support might request that you upload the tar file to a secure location, such as [Vertica Advisor Report](#) .

Prerequisites

- Deploy a [VerticaDB CR](#) that uses [VerticaDB API version v1](#) with **vclusterops** .
- Deploy a [VerticaDB operator](#) version 2.0 and higher.

Create a VerticaScrutinize CR

A VerticaScrutinize CR **spec** requires only the name of the VerticaDB CR for which you want to collect diagnostic information. The following example defines the CR as a YAML-formatted file named **vscrutinize-example.yaml** :

```
apiVersion: vertica.com/v1beta1
kind: VerticaScrutinize
metadata:
  name: vscrutinize-example
spec:
  verticaDBName: verticadb-name
```

For a complete list of parameters that you can set for a VerticaScrutinize CR, see [Custom resource definition parameters](#).

Apply the manifest

After you create the VerticaScrutinize CR, apply the manifest in the same namespace as the CR specified by `verticaDBName`:

```
$ kubectl apply -f vscrutinize-example.yaml
verticascrutinize.vertica.com/vscrutinize-example created
```

The operator creates an init container that runs scrutinize:

```
$ kubectl get pods
NAME                                READY STATUS RESTARTS AGE
-
verticadb-operator-manager-68b7d45854-22c8p 1/1 Running 0 3d17h
vscrutinize-example                       0/1 Init:0/1 0 14s
```

After the init container completes, a new container is created, and the tar file is stored in its file system at `/tmp/scrutinize`. This container persists for 30 minutes:

```
$ kubectl get pods
NAME                                READY STATUS RESTARTS AGE
-
verticadb-operator-manager-68b7d45854-22c8p 1/1 Running 0 3d20h
vscrutinize-example                       1/1 Running 0 21s
```

Add init containers

When you apply a VerticaScrutinize CR, the VerticaDB operator creates an [init container](#) that prepares and runs the scrutinize command. You can add one or more init containers to perform additional steps after scrutinize creates a tar file and before the tar file is saved in the main container.

For example, you can define an init container that sends the tar file to another location, such as an S3 bucket. The following manifest defines an `initContainer` field that uploads the scrutinize tar file to an S3 bucket:

```
apiVersion: vertica.com/v1beta1
kind: VerticaScrutinize
metadata:
  name: vscrutinize-example-copy-to-s3
spec:
  verticaDBName: verticadb-name
  initContainers:
    - command:
      - bash
      - '-c'
      - 'aws s3 cp $(SCRUTINIZE_TARBALL) s3://k8test/scrutinize/'
      env:
        - name: AWS_REGION
          value: us-east-1
      image: 'amazon/aws-cli:2.2.24'
      name: copy-tarfile-to-s3
      securityContext:
        privileged: true
```

Note

Before you can send the tar file to an S3 bucket, make sure you can write to the S3 bucket. The scrutinize pod assumes the same service account as the Vertica pod.

In the previous example, `initContainers.command` executes a command that accesses the `SCRUTINIZE_TARBALL` environment variable. The operator sets this environment variable in the scrutinize pod, and it defines the location of the tar file in the main container.

Custom resource definition parameters

The following lists describes the available settings for Vertica [custom resource definitions](#) (CRDs).

VerticaDB

Parameters

annotations

Custom annotations added to all of the objects that the operator creates. Each annotation is encoded as an environment variable in the Vertica server container. Annotations accept the following characters:

- Letters
- Numbers
- Underscores

Invalid character values are converted to underscore characters. For example:

`vertica.com/git-ref: 1234abcd`

Is converted to:

`VERTICA_COM_GIT_REF=1234abcd`

Note

Enclose integer values in double quotes (""), or the admission controller returns an error.

autoRestartVertica

Whether the operator restarts the Vertica process when the process is not running.

Set this parameter to false when performing manual maintenance that requires a DOWN database. This prevents the operator from interfering with the database state.

Default: true

certSecrets

A list of Secrets for custom TLS certificates.

Each certificate is mounted in the container at `/certs/ cert-name / key`. For example, a PEM-encoded CA bundle named `root_cert.pem` and concealed in a Secret named `aws-cert` is mounted in `/certs/aws-cert/root_cert.pem`.

If you update the certificate after you add it to a custom resource, the operator updates the value automatically. If you add or delete a certificate, the operator reschedules the pod with the new configuration.

For implementation details, see [VerticaDB custom resource definition](#).

communal.additionalConfig

Sets one or more [configuration parameters](#) in the CR:

```
spec:
  communal:
    additionalConfig:
      config-param: "value"
      ...
  ...
```

Configuration parameters are set only when the database is initialized. After the database is initialized, changes to this parameter have no effect in the server.

Important

Configuration parameters in the CR have the following requirements and behaviors:

- If you set an invalid configuration parameter, the Vertica server process does not start. For example, the server does not start if you misspell a parameter name or if the configuration parameter is not supported by the Vertica server version.
- If `communal.additionalConfig` sets a configuration parameter that the operator sets with a CR parameter, the operator ignores the `communal.additionalConfig` setting. For example, the `communal.endpoint` parameter sets the [AWSEndpoint](#) S3 parameter. If you set `communal.endpoint` and also set `AWSEndpoint` with `communal.additionalConfig`, the operator enforces the `communal.endpoint` setting.

communal.caFile

The mount path in the container filesystem to a CA certificate file that validates HTTPS connections to a communal storage endpoint.

Typically, the certificate is stored in a Secret and included in `certSecrets`. For details, see [VerticaDB custom resource definition](#).

communal.credentialSecret

The name of the Secret that stores the credentials for the communal storage endpoint. This parameter is optional when you authenticate to an S3-compatible endpoint with an Identity and Access Management (IAM) profile.

You can store this value as a secret in [AWS Secrets Manager](#) or [Google Secret Manager](#). For implementation details, see [Secrets management](#). For implementation details for each [supported communal storage location](#), see [Configuring communal storage](#).

communal.endpoint

A communal storage endpoint URL. The endpoint must begin with either the `http://` or `https://` protocol. For example:

`https://path/to/endpoint`

You cannot change this value after you create the custom resource instance.

If you omit this setting, Vertica selects one of the following endpoints based on your communal storage provider:

- AWS: `https://s3.amazonaws.com`
- GCS: `https://storage.googleapis.com`

communal.s3ServerSideEncryption

Server-side encryption type used when reading from or writing to S3. The value depends on which type of encryption at rest is configured for S3.

This parameter accepts the following values:

- `SSE-S3`
- `SSE-KMS` : Requires that you pass the key identifier with the `communal.additionalConfig` parameter.
- `SSE-C` : Requires that you pass the client key with the `communal.s3SSECustomerKeySecret` parameter.

You cannot change this value after you create the custom resource instance.

For implementation examples of all encryption types, see [Configuring communal storage](#).

For details about each encryption type, see [S3 object store](#).

Default : Empty string (""), no encryption

communal.s3SSECustomerKeySecret

If `s3ServerSideEncryption` is set to `SSE-C`, a Secret containing the client key for S3 access with the following requirements:

- The Secret must be in the same namespace as the CR.
- You must set the client key contents with the `clientKey` field.

The client key must use one of the following formats:

- 32-character plaintext
- 44-character base64-encoded

For additional implementation details, see [Configuring communal storage](#).

communal.path

The path to the communal storage bucket. For example:

`s3://bucket-name/key-name`

You must create this bucket before you create the Vertica database.

The following `initPolicy` values determine how to set this value:

- **Create** : The path must be empty.
- **Revive** : The path cannot be empty.

You cannot change this value after you create the custom resource.

communal.region

The geographic location where the communal storage resources are located.

If you do not set the correct region, the configuration fails. You might experience a delay because Vertica retries several times before failing. This setting is valid for Amazon Web Services (AWS) and Google Cloud Platform (GCP) only. Vertica ignores this setting for other communal storage providers.

Default:

- AWS: us-east-1
- GCP: US-EAST1

dbName

The database name. When **initPolicy** is set to **Revive** or **ScheduleOnly** , this must match the name of the source database.

Default: vertdb

encryptSpreadComm

Sets the [EncryptSpreadComm](#) security parameter to configure Spread encryption for a new Vertica database. The VerticaDB operator ignores this parameter unless you set **initPolicy** to **Create**.

Spread encryption is enabled by default. This parameter accepts the following values:

- **vertica** or Empty string (""): Enables Spread encryption. Vertica generates the Spread encryption key for the database cluster.
- **disabled** : Clears encryption.

Default : Empty string ("")

Important

If you use the [deprecated v1beta1 API version](#) with server version 24.1.0, **encryptSpreadComm** behaves differently. Spread encryption is disabled by default and accepts the following values:

- **vertica** : Enables Spread encryption. Vertica generates the Spread encryption key for the database cluster.
- Empty string (""): Default setting. Clears encryption.

hadoopConfig

A ConfigMap that contains the contents of the `/etc/hadoop` directory.

This is mounted in the container to configure connections to a Hadoop Distributed File System (HDFS) communal path.

image

The image that defines the Vertica server container's runtime environment. If the container is hosted in a private container repository, this name must include the path to the repository.

When you update the image, the operator stops and restarts the cluster.

Default: vertica/vertica-k8s:latest

imagePullPolicy

How often Kubernetes pulls the image for an object. For details, see [Updating Images](#) in the Kubernetes documentation.

Default: If the image tag is **latest** , the default is **Always** . Otherwise, the default is **IfNotPresent** .

imagePullSecrets

List of Secrets that store credentials for authentication to a private container repository. For details, see [Specifying imagePullSecrets](#) in the Kubernetes documentation.

initPolicy

How to initialize the Vertica database in Kubernetes. This parameter accepts the following values:

- **Create** : Forces the creation of a new database for the custom resource.
- **CreateSkipPackageInstall** : Same as **Create** , but does not install any default packages to quickly create a database. To install default packages, see [Reinstalling packages](#) .

Note

`CreateSkipPackageInstall` is available in Vertica version 12.0.1 and later.

- **Revive** : Initializes an existing Eon Mode database as a StatefulSet with the `revive` command. For information about **Revive** , see [Generating a custom resource from an existing Eon Mode database](#) and [VerticaRestorePointsQuery custom resource definition](#) .
- **ScheduleOnly** : Schedules a subcluster for a [Hybrid Kubernetes cluster](#) .

kerberosSecret

The Secret that stores the following values for Kerberos authentication to Hadoop Distributed File System (HDFS):

- `krb5.conf`: Contains Kerberos configuration information.
- `krb5.keytab`: Contains credentials for the Vertica Kerberos principal. This file must be readable by the file owner that is running the process.

The default location for each of these files is the `/etc` directory.

labels

Custom labels added to all of the objects that the operator creates.

licenseSecret

The Secret that contains the contents of license files. The Secret must share a namespace with the custom resource (CR). Each of the keys in the Secret is mounted as a file in `/home/dbadmin/licensing/mnt` .

If this value is set when the CR is created, the operator installs one of the licenses automatically, choosing the first one alphabetically. If you update this value after you create the custom resource, you must manually install the Secret in each Vertica pod.

livenessProbeOverride

Overrides default **livenessProbe** settings that indicate whether the container is running. The VerticaDB operator sets or updates the liveness probe in the StatefulSet.

For example, the following object overrides the default `initialDelaySeconds` , `periodSeconds` , and `failureThreshold` settings:

```
spec:
...
livenessProbeOverride:
  initialDelaySeconds: 120
  periodSeconds: 15
  failureThreshold: 8
```

For a detailed list of the available probe settings, see the [Kubernetes documentation](#) .

local.catalogPath

Optional parameter that sets a custom path in the container filesystem for the catalog, if your environment requires that the catalog is stored in a location separate from the local data.

If `initPolicy` is set to **Revive** or **ScheduleOnly** , `local.catalogPath` for the new database must match `local.catalogPath` for the source database.

local.dataPath

The path in the container filesystem for the local data. If `local.catalogPath` is not set, the catalog is stored in this location.

If `initPolicy` is set to **Revive** or **ScheduleOnly** , the `dataPath` for the new database must match the `dataPath` for the source database.

Default: `/data`

local.depotPath

The path in the container filesystem that stores the depot.

If `initPolicy` is set to **Revive** or **ScheduleOnly** , the `depotPath` for the new database must match the `depotPath` for the source database.

Default: `/depot`

local.depotVolume

The type of volume to use for the depot. This parameter accepts the following values:

- **PersistentVolume** : A PersistentVolume is used to store the depot data. This volume type persists depot data between pod lifecycles.

- **EmptyDir** : A volume of type emptyDir is used to store the depot data. When the pod is removed from a node, the contents of the volume are deleted. If a container crashes, the depot data is unaffected.

Important

You cannot change the depot volume type on an existing database. If you want to change this setting, you must create a new custom resource.

For details about each volume type, see the [Kubernetes documentation](#).

Default : **PersistentVolume**

local.requestSize

The minimum size of the local data volume when selecting a PersistentVolume (PV).

If **local.storageClass** allows volume expansion, the operator automatically increases the size of the PV when you change this setting. It expands the size of the depot if the following conditions are met:

- **local.storageClass** is set to **PersistentVolume** .
- Depot storage is allocated using a percentage of the total disk space rather than a unit, such as a gigabyte.

If you decrease this value, the operator does not decrease the size of the PV or the depot.

Default: 500 Gi

local.storageClass

The [StorageClass](#) for the PersistentVolumes that persist local data between pod lifecycles. Select this value when defining the persistent volume claim (PVC).

By default, this parameter is not set. The PVC in the default configuration uses the default storage class set by Kubernetes.

nmaTLSSecret

Adds custom [Node Management Agent](#) (NMA) certificates to the CR. The value must include the tls.key, tls.crt, and ca.crt encoded in base64 format.

You can store this value as a secret in [AWS Secrets Manager](#) or [Google Secret Manager](#). For implementation details, see [Secrets management](#). If you omit this setting, the operator generates self-signed certificates for the NMA.

passwordSecret

The [Secret](#) that contains the database superuser password. Create this Secret before deployment.

If you do not create this Secret before deployment, there is no password authentication for the database.

The Secret must use a key named **password** :

```
$ kubectl create secret generic su-passwd --from-literal=password=secret-password
```

Add this Secret to the custom resource:

```
spec:
  passwordSecret: su-passwd
```

You can store this value as a secret in [AWS Secrets Manager](#) or [Google Secret Manager](#). For implementation details, see [Secrets management](#).

podSecurityContext

Overrides any pod-level security context. This setting is merged with the default context for the pods in the cluster.

vclusterops deployments can use this parameter to set a custom UID or GID:

```
...
spec:
  ...
  podSecurityContext:
    runAsUser: 3500
    runAsGroup: 3500
  ...
```

For details about the available settings for this parameter, see the [Kubernetes documentation](#).

readinessProbeOverride

Overrides default `readinessProbe` settings that indicate whether the Vertica pod is ready to accept traffic. The VerticaDB operator sets or updates the readiness probe in the StatefulSet.

For example, the following object overrides the default `timeoutSeconds` and `periodSeconds` settings:

```
spec:
...
readinessProbeOverride:
  initialDelaySeconds: 0
  periodSeconds: 10
  failureThreshold: 3
```

For a detailed list of the available probe settings, see the [Kubernetes documentation](#).

restorePoint.archive

Archive that contains the restore points that you want to use in a restore operation. When you revive a database with a restore point, this parameter is required.

restorePoint.id

Unique identifier for the restore point. When you revive a database with a restore point, you must provide either `restorePoint.id` or `restorePoint.index`.

restorePoint.index

Identifier that describes the restore point's chronological position in the archive. Restore points are ordered by descending timestamp, where the most recent index is `1`.

reviveOrder

The order of nodes during a revive operation. Each entry contains the subcluster index, and the number of pods to include from the subcluster.

For example, consider a database with the following setup:

```
- v_db_node0001: subcluster A
- v_db_node0002: subcluster A
- v_db_node0003: subcluster B
- v_db_node0004: subcluster A
- v_db_node0005: subcluster B
- v_db_node0006: subcluster B
```

If the `subclusters[]` list is defined as `{'A', 'B'}`, the revive order is as follows:

```
- {subclusterIndex:0, podCount:2} # 2 pods from subcluster A
- {subclusterIndex:1, podCount:1} # 1 pod from subcluster B
- {subclusterIndex:0, podCount:1} # 1 pod from subcluster A
- {subclusterIndex:1, podCount:2} # 2 pods from subcluster B
```

This parameter is used only when `initPolicy` is set to `Revive`.

securityContext

Sets any additional security context for the Vertica server container. This setting is merged with the security context value set for the VerticaDB Operator.

For example, if you need a core file for the Vertica server process, you can set the `privileged` property to `true` to elevate the server privileges on the host node:

```
spec:
...
securityContext:
  privileged: true
```

For additional information about generating a core file, see [Metrics gathering](#). For details about this parameter, see the [Kubernetes documentation](#).

serviceAccountName

Sets the name of the ServiceAccount. This lets you create a service account independently of an operator or VerticaDB instance so that you can add it to the CR as needed.

If you omit this setting, the operator uses the default service account. If you specify a service account that does not exist, the operator creates that service account and then uses it.

shardCount

The number of shards in the database. You cannot update this value after you create the custom resource.

For more information about database shards and Eon Mode, see [Configuring your Vertica cluster for Eon Mode](#).

sidecars[]

One or more optional utility containers that complete tasks for the Vertica server container. Each [sidecar](#) entry is a fully-formed container spec, similar to the container that you add to a Pod spec.

The following example adds a sidecar named `vlogger` to the custom resource:

```
spec:
...
sidecars:
- name: vlogger
  image: vertica/vertica-logger:1.0.0
  volumeMounts:
  - name: my-custom-vol
    mountPath: /path/to/custom-volume
```

`volumeMounts.name` is the name of a custom volume. This value must match `volumes.name` to mount the custom volume in the sidecar container filesystem. See [volumes](#) for additional details.

For implementation details, see [VerticaDB custom resource definition](#).

sidecars[i].volumeMounts

List of custom volumes and mount paths that persist sidecar container data. Each volume element requires a `name` value and a `mountPath`.

To mount a volume in the Vertica sidecar container filesystem, `volumeMounts.name` must match the `volumes.name` value for the corresponding sidecar definition, or the webhook returns an error.

For implementation details, see [VerticaDB custom resource definition](#).

startupProbeOverride

Overrides the default `startupProbe` settings that indicate whether the Vertica process is started in the container. The VerticaDB operator sets or updates the startup probe in the StatefulSet.

For example, the following object overrides the default `initialDelaySeconds`, `periodSeconds`, and `failureThreshold` settings:

```
spec:
...
startupProbeOverride:
  initialDelaySeconds: 30
  periodSeconds: 10
  failureThreshold: 117
  timeoutSeconds: 5
```

For a detailed list of the available probe settings, see the [Kubernetes documentation](#).

subclusters[i].affinity

Applies rules that constrain the Vertica server pod to specific nodes. It is more expressive than `nodeSelector`. If this parameter is not set, then the pods use no `affinity` setting.

In production settings, it is a best practice to configure affinity to run one server pod per host node. For configuration details, see [VerticaDB custom resource definition](#).

subclusters[i].externalIPs

Enables the service object to attach to a specified [external IP](#).

If not set, the external IP is empty in the service object.

subclusters[i].verticaHTTPNodePort

When `subclusters[i].serviceType` is set to `NodePort`, sets the port on each node that listens for external connections to the [HTTPS service](#). The port must be within the defined range allocated by the control plane (ports 30000-32767).

If you do not manually define a port number, Kubernetes chooses the port automatically.

subclusters[i].type

Indicates the subcluster type. Valid values include the following:

- `primary`
- `secondary`

The admission controller's webhook verifies that each database has at least one primary subcluster.

Default: `primary`

subclusters[i].loadBalancerIP

When `subcluster[i].serviceType` is set to `LoadBalancer`, assigns a static IP to the load balancing service.

Default: Empty string ("")

subclusters[i].name

The subcluster name. This is a required setting. If you change the name of an existing subcluster, the operator deletes the old subcluster and creates a new one with the new name.

Kubernetes derives names for the subcluster Statefulset, service object, and pod from the subcluster name. For additional details about Kubernetes and subcluster naming conventions, see [Subclusters on Kubernetes](#).

subclusters[i].clientNodePort

When `subclusters[i].serviceType` is set to `NodePort`, sets the port on each node that listens for external client connections. The port must be within the defined range allocated by the control plane (ports 30000-32767).

If you do not manually define a port number, Kubernetes chooses the port automatically.

subclusters[i].nodeSelector

List of `label` key/value pairs that restrict Vertica pod scheduling to nodes with matching labels. For details, see the [Kubernetes documentation](#). The following example schedules server pods only at nodes that have the `disktype=ssd` and `region=us-east` labels:

```
subclusters:
- name: defaultsubcluster
  nodeSelector:
    disktype: ssd
    region: us-east
```

subclusters[i].priorityClassName

The [PriorityClass](#) name assigned to pods in the StatefulSet. This affects where the pod gets scheduled. For details, see the [Kubernetes documentation](#).

subclusters[i].resources.limits

The [resource limits](#) for pods in the StatefulSet, which sets the maximum amount of CPU and memory that the server pod can consume from its host.

Vertica recommends that you set these values equal to [subclusters\[i\].resources.requests](#) to ensure that the pods are assigned to the [guaranteed QoS class](#). This reduces the possibility that pods are chosen by the out of memory (OOM) Killer.

For more information, see [Recommendations for Sizing Vertica Nodes and Clusters](#) in the Vertica Knowledge Base.

subclusters[i].resources.requests

The [resource requests](#) for pods in the StatefulSet, which sets the amount of CPU and memory that the server pod requests during [pod scheduling](#).

Vertica recommends that you set these values equal to [subclusters\[i\].resources.limits](#) to ensure that the pods are assigned to the [guaranteed QoS class](#). This reduces the possibility that pods are chosen by the out of memory (OOM) Killer.

For more information, see [Recommendations for Sizing Vertica Nodes and Clusters](#) in the Vertica Knowledge Base.

subclusters[i].serviceAnnotations

Custom annotations added to implementation-specific services. [Managed Kubernetes](#) use service annotations to configure services such as network load balancers, virtual private cloud (VPC) subnets, and loggers.

subclusters[i].serviceName

Identifies the service object that directs client traffic to the subcluster. Assign a single service object to multiple subclusters to process client data with one or more subclusters. For example:

```
spec:
...
subclusters:
- name: subcluster-1
  size: 3
  serviceName: connections
- name: subcluster-2
  size: 3
  serviceName: connections
```

The previous example creates a service object named [metadata.name -connections](#) that load balances client traffic among its assigned subclusters.

For implementation details, see [VerticaDB custom resource definition](#).

subclusters[i].serviceType

Identifies the [type of Kubernetes](#) service to use for external client connectivity. The default is type is ClusterIP, which sets a stable IP and port that is accessible only from within Kubernetes itself.

Depending on the service type, you might need to set [nodePort](#) or [externalIPs](#) in addition to this configuration parameter.

Default: ClusterIP

subclusters[i].size

The number of pods in the subcluster. This determines the number of Vertica nodes in the subcluster. Changing this number deletes or

schedules new pods.

The minimum size of a subcluster is 1. The subclusters `kSafety` setting determines the minimum and maximum size of the cluster.

Note

By default, the Vertica container uses the [Vertica community edition \(CE\)](#) license. The CE license limits subclusters to 3 Vertica nodes and a maximum of 1TB of data. Use the `licenseSecret` parameter to add your Vertica license.

For instructions about how to create the license Secret, see [VerticaDB custom resource definition](#).

`subclusters[i].tolerations`

Any [tolerations](#) and taints that aid in determining where to schedule a pod.

`temporarySubclusterRouting.names`

The existing subcluster that accepts traffic during an online upgrade. The operator routes traffic to the first subcluster that is online. For example:

```
spec:
  ...
  temporarySubclusterRouting:
    names:
      - subcluster-2
      - subcluster-1
```

In the previous example, the operator selects subcluster-2 during the upgrade, and then routes traffic to subcluster-1 when subcluster-2 is down. As a best practice, use secondary subclusters when rerouting traffic.

Note

By default, the operator selects an existing subcluster to receive rerouted client traffic even if you do not specify a subcluster with this parameter.

`temporarySubclusterRouting.template`

Instructs the operator create a new secondary subcluster during an Online upgrade. The operator creates the subcluster when the upgrade begins and deletes it when the upgrade completes.

To define a temporary subcluster, provide a name and size value. For example:

```
spec:
  ...
  temporarySubclusterRouting:
    template:
      name: transient
      size: 1
```

`upgradePolicy`

Determines how the operator upgrades Vertica server versions. Accepts the following values:

- Offline: The operator stops the cluster to prevent multiple versions from running simultaneously.
- Online: The cluster continues to operator during a rolling update. The data is in read-only mode while the operator upgrades the image for the primary subcluster.

The Online setting has the following restrictions:

- The cluster must currently run Vertica server version 11.1.0 or higher.

- If you have only one subcluster, you must configure [temporarySubclusterRouting.template](#) to create a new secondary subcluster during the Online upgrade. Otherwise, the operator performs an Offline upgrade, regardless of the setting.
- Auto: The operator selects either Offline or Online depending on the configuration. The operator selects Online if all of the following are true:
 - A license Secret exists.
 - [K-Safety](#) is 1.
 - The cluster is currently running Vertica version 11.1.0 or higher.

Default: Auto

volumeMounts

List of custom volumes and mount paths that persist Vertica server container data. Each volume element requires a [name](#) value and a [mountPath](#).

To mount a volume in the Vertica server container filesystem, [volumeMounts.name](#) must match the [volumes.name](#) value defined in the [spec](#) definition, or the webhook returns an error.

For implementation details, see [VerticaDB custom resource definition](#).

volumes

List of custom volumes that persist Vertica server container data. Each volume element requires a [name](#) value and a volume type. [volumes](#) accepts any Kubernetes volume type.

To mount a volume in a filesystem, [volumes.name](#) must match the [volumeMounts.name](#) value for the corresponding volume mount, or the webhook returns an error.

For implementation details, see [VerticaDB custom resource definition](#).

Annotations

Apply each of the following annotations to the [metadata.annotations](#) section in the CR:

vertica.com/https-tls-conf-generation

Determines whether the Vertica pod stores a plain text configuration file used to generate default certificates for the HTTPS service.

Set this to [false](#) to hide the configuration file when you are certain that the HTTPS service can start in its current configuration. For example:

- You [altered the TLS configuration](#) with custom certificates.
- The VerticaDB CR was created on server version 24.1.0 or later.

The presence of this configuration file does not interfere with either of these certificate configurations.

Default : true

vertica.com/ignore-cluster-lease

Ignore the cluster lease when starting or reviving the database.

Default: false

Caution

If another system is using the same communal storage, setting [ignore-cluster-lease](#) to [true](#) results in data corruption.

vertica.com/ignore-upgrade-path

When set to [false](#), the operator ensures that you do not downgrade to an earlier release.

Default : true

vertica.com/include-uid-in-path

When set to [true](#), the operator includes in the path the unique identifier (UID) that Kubernetes assigns to the VerticaDB object. Including the UID creates a unique database path so that you can reuse the communal path in the same endpoint.

Default: false

vertica.com/restart-timeout

When restarting pods, the number of seconds before the operation times out.

Default: 0. The operator uses a 20 minute default.

vertica.com/superuser-name

For **vclusterops** deployments, sets a custom superuser name. All admintools deployments use the default superuser name, **dbadmin** .

vertica.com/vcluster-ops

Determines whether the VerticaDB CR installs the **vclusterops** library to manage the cluster. When omitted, API version **v1** assumes this annotation is set to **true** , and the **v1beta1** annotation is set to **false** .

API version **v1** must install **vclusterops** . You can omit this setting to use the default empty string, or explicitly set this to **true** .

For deprecated API version **v1beta1** , you must set this to **true** for **vclusterops** deployments. For admintools deployments, you can omit this setting or set it to **false** .

Default : Empty string ("")

EventTrigger

For implementation details, see [EventTrigger custom resource definition](#) .

matches[].condition.status

The status portion of the status condition match. The operator watches the condition specified by **matches[].condition.type** on the EventTrigger reference object. When that condition changes to the status specified in this parameter, the operator runs the task defined in the EventTrigger.

matches[].condition.type

The condition portion of the status condition match. The operator watches this condition on the EventTrigger reference object. When this condition changes to the status specified with **matches[].condition.status** , the operator runs the task defined in the EventTrigger.

references[].object.apiVersion

Kubernetes API version of the object that the EventTrigger watches.

references[].object.kind

The type of object that the EventTrigger watches.

references[].object.name

The name of the object that the EventTrigger watches.

references[].object.namespace

Optional. The namespace of the object that the EventTrigger watches. The object and the EventTrigger CR must exist within the same namespace.

If omitted, the operator uses the same namespace as the EventTrigger.

template

Full **spec** for the **Job** that EventTrigger runs when **references[].condition.type** and **references[].condition.status** are found for a reference object.

For implementation details, see [EventTrigger custom resource definition](#) .

VerticaAutoScaler

verticaDBName

Required. Name of the VerticaDB CR that the VerticaAutoscaler CR scales resources for.

scalingGranularity

Required. The scaling strategy. This parameter accepts one of the following values:

- Subcluster: Create or delete entire subclusters. To create a new subcluster, the operator uses a template or an existing subcluster with the same serviceName.
- Pod: Increase or decrease the size of an existing subcluster.

Default : Subcluster

serviceName

Required. Refers to the [subclusters\[j\].serviceName](#) for the VerticaDB CR.

VerticaAutoscaler uses this value as a selector when scaling subclusters together.

template

When **scalingGranularity** is set to Subcluster, you can use this parameter to define how VerticaAutoscaler scales the new subcluster. The following is an example:

```
spec:
  verticaDBName: dbname
  scalingGranularity: Subcluster
  serviceName: service-name
  template:
    name: autoscaler-name
    size: 2
    serviceName: service-name
    isPrimary: false
```

If you set `template.size` to 0, VerticaAutoscaler selects as a template an existing subcluster that uses `service-name` . This setting is ignored when `scalingGranularity` is set to Pod.

VerticaRestorePointsQuery

Important

Beta Feature — For Test Environments Only

verticaDBName

The VerticaDB CR instance that you want to retrieve restore points for.

filterOptions.archive

The archive that contains the restore points that you want to retrieve. If omitted, the query returns all restore points from all archives.

filterOptions.startTimestamp

Limits the query results to restore points with a UTC timestamp that is equal to or later than this value. This parameter accepts the following UTC formats:

- `YYYY-MM-DD`
- `YYYY-MM-DD HH:MM:ss`
- `YYYY-MM-DD HH:MM:ss.SSSSSSSS`

filterOptions.endTimestamp

Limits the query results to restore points with a UTC timestamp that is equal to or earlier than this value. This parameter accepts the following UTC date and time formats:

- `YYYY-MM-DD` . When you use this format, the VerticaDB operator populates the time portion with `23:59:59.999999999` .
- `YYYY-MM-DD HH:MM:ss` .
- `YYYY-MM-DD HH:MM:ss.SSSSSSSS` .

VerticaScrutinize

affinity

Applies rules that constrain the VerticaScrutinize pod to specific nodes. It is more expressive than `nodeSelector` . If this parameter is not set, then the scrutinize pod uses no affinity setting.

For details, see the [Kubernetes documentation](#) .

annotations

Custom annotations added to all objects created to run scrutinize.

initContainers

A list of custom [init containers](#) to run after the init container collects diagnostic information with `scrutinize` . You can use an init container to perform additional processing on the scrutinize tar file, such as uploading it to an external storage location.

labels

Custom labels added to the scrutinize pod.

nodeSelector

List of `label` key/value pairs that restrict Vertica pod scheduling to nodes with matching labels. For details, see the [Kubernetes documentation](#) .

priorityClassName

The [PriorityClass](#) name assigned to the scrutinize pod. This affects where the pod gets scheduled.

For details, see the [Kubernetes documentation](#) .

resources.limits

The [resource limits](#) for the scrutinize pod, which sets the maximum amount of CPU and memory that the pod can consume from its host.

resources.requests

The [resource requests](#) for the scrutinize pod, which sets the amount of CPU and memory that the pod requests during [pod scheduling](#).

tolerations

Any [tolerations](#) and taints that aid in determining where to schedule a pod.

verticaDBName

Required. Name of the VerticaDB CR that the VerticaScrutinize CR collects diagnostic information for. The VerticaDB CR must exist in the same namespace as the VerticaScrutinize CR.

volume

Custom volume that stores the finalized scrutinize tar file and any intermediate files. The volume must have enough space to store the scrutinize data. The volume is mounted in `/tmp/scrutinize`.

If this setting is omitted, an emptyDir volume is created to store the scrutinize data.

Default : `emptyDir`

Subclusters on Kubernetes

Eon Mode uses [subclusters](#) for [workload isolation](#) and scaling. The [VerticaDB operator](#) provides tools to direct external client communications to specific subclusters, and automate scaling without stopping your database.

The [custom resource definition](#) (CRD) provides [parameters](#) that allow you to fine-tune each subcluster for specific workloads. For example, you can increase the subcluster `size` setting for increased throughput, or adjust the resource requests and limits to manage compute power. When you create a custom resource instance, the operator deploys each subcluster as a [StatefulSet](#). Each StatefulSet has a service object, which allows an external client to connect to a specific subcluster.

Naming conventions

Kubernetes derives names for the subcluster Statefulset, service object, and pod from the subcluster name. This naming convention tightly couples the subcluster objects to help Kubernetes manage the cluster effectively. If you want to rename a subcluster, you must delete it from the CRD and redefine it so that the operator can create new objects with a derived name.

Kubernetes forms an object's fully qualified domain name (FQDN) with its resource type name, so resource type names must follow [FQDN naming conventions](#). The underscore character (`"_"`) does not follow FQDN rules, but you can use it in the subcluster name. Vertica converts each underscore to a hyphen (`"-"`) in the FQDN for any object name derived from the subcluster name. For example, Vertica generates a default subcluster and names it `default_subcluster`, and then converts the corresponding portion of the derived object's FQDN to `default-subcluster`.

For additional naming guidelines, see the [Kubernetes documentation](#).

External client connections

External clients can target specific subclusters that are fine-tuned to handle their workload. Each subcluster has a service object that handles external connections. To target multiple subclusters with a single service object, assign each subcluster the same `spec.subclusters.serviceName` value in the custom resource (CR). For implementation details, see [VerticaDB custom resource definition](#).

The operator performs health monitoring that checks whether the Vertica daemon is running on each pod. If the daemon is running, then the operator allows the service object to route traffic to the pod.

By default, the service object derives its name from the custom resource name and the associated subcluster and uses the following format:

```
customResourceName-subclusterName
```

To override this default format, set the [subclusters\[j\].serviceName CR parameter](#), which changes the format to the following:

```
metadata.name-serviceName
```

Vertica supports the following service object types:

- **ClusterIP** : The default service type. This service provides internal load balancing, and sets a stable IP and port that is accessible from within the subcluster only.
- **NodePort** : Provides external client access. You can specify a port number for each host node in the subcluster to open for client connections.
- **LoadBalancer** : Uses a cloud provider load balancer to create NodePort and ClusterIP services as needed. For details about implementation, see the [Kubernetes documentation](#) and your cloud provider documentation.

For configuration details, see [VerticaDB custom resource definition](#).

Managing internal and external workloads

The Vertica StatefulSet is associated with an external service object. All external client requests are sent through this service object and load balanced among the pods in the cluster.

Import and export

[Importing and exporting](#) data between a cluster outside of Kubernetes requires that you expose the service with the **NodePort** or **LoadBalancer** service type and properly configure the network.

Important

When importing or exporting data, each node must have a static IP address. Rescheduled pods might be on different host nodes, so you must monitor and update the static IP addresses to reflect the new node.

For more information, see [Configuring the Network to Import and Export Data](#).

In this section

- [Scaling subclusters](#)

Scaling subclusters

The operator enables you to scale the number of subclusters and the number of pods per subcluster automatically. This utilizes or conserves resources depending on the immediate needs of your workload.

The following sections explain how to scale resources for new workloads. For details about scaling resources for existing workloads, see [VerticaAutoscaler custom resource definition](#).

Prerequisites

- Complete [Installing the VerticaDB operator](#).
- Install the [kubectl](#) command line tool.
- Complete [VerticaDB custom resource definition](#).
- Confirm that you have the resources to scale.

Note

By default, the custom resource uses the free [Community Edition \(CE\)](#) license. This license allows you to deploy up to three nodes with a maximum of 1TB of data. To add resources beyond these limits, you must add your Vertica license to the custom resource as described in [VerticaDB custom resource definition](#).

Scaling the number of subclusters

Adjust the number of subclusters in your custom resource to fine-tune resources for short-running dashboard queries. For example, increase the number of subclusters to increase throughput. For more information, see [Improving query throughput using subclusters](#).

1. Use `kubectl edit` to open your default text editor and update the YAML file for the specified custom resource. The following command opens a custom resource named `vdb` for editing:

```
% kubectl edit vdb
```

2. In the `spec` section of the custom resource, locate the `subclusters` subsection. Begin with the `type` field to define a new subcluster. The `type` field indicates the subcluster type. Because there is already a primary subcluster, enter `Secondary` :

```
spec:
  ...
  subclusters:
  ...
  - type: secondary
```

3. Follow the steps in [VerticaDB custom resource definition](#) to complete the subcluster definition. The following completed example adds a secondary subcluster for dashboard queries:

```
spec:
  ..
  subclusters:
  - type: primary
    name: primary-subcluster
  ...
  - type: secondary
    name: dashboard
    clientNodePort: 32001
  resources:
    limits:
      cpu: 32
      memory: 96Gi
    requests:
      cpu: 32
      memory: 96Gi
  serviceType: NodePort
  size: 3
```

4. Save and close the custom resource file. When the update completes, you receive a message similar to the following:

```
verticadb.vertica.com/vertica-db edited
```

5. Use the `kubectl wait` command to monitor when the new pods are ready:

```
$ kubectl wait --for=condition=Ready pod --selector app.kubernetes.io/name=verticadb --timeout 180s
pod/vdb-dashboard-0 condition met
pod/vdb-dashboard-1 condition met
pod/vdb-dashboard-2 condition met
```

Scaling the pods in a subcluster

For long-running, analytic queries, increase the pod count for a subcluster. See [Using elastic crunch scaling to improve query performance](#).

1. Use `kubectl edit` to open your default text editor and update the YAML file for the specified custom resource. The following command opens a custom resource named `verticadb` for editing:

```
$ kubectl edit verticadb
```

2. Update the `subclusters.size` value to 6:

```
spec:
  ..
  subclusters:
  ...
  - type: secondary
  ...
  size: 6
```

Shards are rebalanced automatically.

3. Save and close the custom resource file. You receive a message similar to the following when you successfully update the file:
verticadb.vertica.com/verticadb edited
4. Use the `kubectl wait` command to monitor when the new pods are ready:

```
$ kubectl wait --for=condition=Ready pod --selector app.kubernetes.io/name=verticadb --timeout 180s
pod/vdb-subcluster1-3 condition met
pod/vdb-subcluster1-4 condition met
pod/vdb-subcluster1-5 condition met
```

Removing a subcluster

Remove a subcluster when it is no longer needed, or to preserve resources.

Important

Because each custom resource instance requires a primary subcluster, you cannot remove all subclusters.

1. Use `kubectl edit` to open your default text editor and update the YAML file for the specified custom resource. The following command opens a custom resource named `verticadb` for editing:

- In the `subclusters` subsection nested under `spec`, locate the subcluster that you want to delete. Delete the element in the subcluster array represents the subcluster that you want to delete. Each element is identified by a hyphen (-).
- After you delete the subcluster and save, you receive a message similar to the following:

```
verticadb.vertica.com/verticadb edited
```

Upgrading Vertica on Kubernetes

The operator automates Vertica server version upgrades for a custom resource (CR). Use the [upgradePolicy setting](#) in the CR to determine whether your cluster remains online or is taken offline during the version upgrade.

Note

You cannot downgrade Vertica server versions. The VerticaDB operator validates the pre- and post-upgrade versions before it proceeds with any changes to the server version. Vertica uses semantic versioning for each release in the *major . minor . patch* format.

For a comprehensive list of containerized server versions, see the [Docker Hub repository](#).

Prerequisites

Before you begin, complete the following:

- Install the [VerticaDB operator](#).
- Create a [VerticaDB custom resource definition](#) manifest.

Setting the policy

The [upgradePolicy](#) CR parameter setting determines how the operator upgrades Vertica server versions. It provides the following options:

Setting	Description
Offline	<p>The operator shuts down the cluster to prevent multiple versions from running simultaneously.</p> <p>The operator performs all server version upgrades using the Offline setting in the following circumstances:</p> <ul style="list-style-type: none"> You have only one subcluster You are upgrading from a Vertica server version prior to version 11.1.0
Online	<p>The cluster continues to operate during an online upgrade. The data is in read-only mode while the operator upgrades the image for the primary subcluster.</p> <p>Important</p> <p>To perform an online upgrade, you must upgrade from Vertica server version 11.1.0 and higher.</p>
Auto	<p>The default setting. The operator selects either Offline or Online depending on the configuration. The operator performs an Online upgrade if all of the following are true:</p> <ul style="list-style-type: none"> A license Secret exists K-Safety is 1 The cluster is currently running a Vertica version 11.1.0 or higher <p>If the current configuration does not meet all of the previous requirements, the operator performs an Offline upgrade.</p>

Reconcile loop iteration time

During an upgrade, the operator runs the reconcile loop to compare the actual state of the objects to the desired state defined in the CR. The operator requeues any unfinished work, and the reconcile loop compares states with a set period of time between each reconcile iteration.

Routing client traffic during an online upgrade

During an online upgrade, the operator begins by upgrading the Vertica server version in the primary subcluster to form a cluster with the new version. When the operator restarts the primary nodes, it places the secondary subclusters in read-only mode. Next, the operator upgrades any secondary subclusters one at a time. During the upgrade for any subcluster, all client connections are drained, and traffic is rerouted to either an existing subcluster or a temporary subcluster.

Online upgrades require more than one subcluster so that the operator can reroute client traffic for the subcluster while it is upgrading. By default, the operator selects which subcluster receives the rerouted traffic using the following rules:

- When rerouting traffic for the primary subcluster, the operator selects the first secondary subcluster defined in the CR.
- When restarting the first secondary subcluster after the upgrade, the operator selects the first subcluster that is defined in the CR that is up.
- If no secondary subclusters exist, you cannot perform an online upgrade. The operator selects the first primary subcluster defined in the CR and performs an offline upgrade.

Route to an existing subcluster

You might want to control which subclusters handle rerouted client traffic due to subcluster capacity or licensing limitations. You can set the [temporarySubclusterRouting.names parameter](#) to specify an existing subcluster to receive the rerouted traffic:

```
spec:
  ...
  temporarySubclusterRouting:
    names:
      - subcluster-2
      - subcluster-1
```

In the previous example, **subcluster-2** accepts traffic when the other **subcluster-1** is offline. When **subcluster-2** is down, **subcluster-1** accepts its traffic.

Route to a temporary subcluster

To create a temporary subcluster that exists for the duration of the upgrade process, use the [temporarySubclusterRouting.template parameter](#) to provide a name and size for the temporary subcluster:

```
spec:
  ...
  temporarySubclusterRouting:
    template:
      name: transient
      size: 3
```

If you choose to upgrade with a temporary subcluster, ensure that you have the necessary resources.

Migrating deployment types

Beginning with Vertica server version 24.1.0, the operator manages deployments with **vclusterops**, a Go library that uses a high-level REST interface to perform database operations with the [Node Management Agent \(NMA\)](#) and [HTTPS service](#). The **vclusterops** library replaces [Administration tools](#) (admintools), a traditional command-line interface that executes administrator commands through STDIN and required SSH keys for internal node communications. The **vclusterops** deployment is more efficient in containerized environments than the admintools deployment.

Because version 24.1.0 does not include admintools, you must migrate to the vcluster deployment type when you upgrade from an earlier server version.

Migrate the VerticaDB CR

Before you can migrate deployment types, you must [upgrade the VerticaDB operator](#) to version 2.0.0.

Important

The following requirements and restrictions apply to deployment type migrations:

- You can only migrate a custom resource from admintools to vclusterops. You cannot migrate a vclusterops deployment to admintools.
- All migrations require that you use the [Offline upgrade policy](#). If you try to migrate deployments with an **Online** upgrade, the operator transitions to an **Offline** upgrade automatically.

To migrate deployment types, update the manifest and apply it:

1. Update the manifest to a vcluster deployment. The following sample manifest includes all fields that are required to migrate to a **vclusterops** deployment:

```

apiVersion: vertica.com/v1
kind: VerticaDB
metadata:
  name: cr-name
  annotations:
    vertica.com/vcluster-ops: "true"
    vertica.com/run-nma-in-sidecar: "false"
spec:
  image: "vertica/vertica-k8s:24.1.0-0"
  ...

```

This manifest sets the following parameters:

- **apiVersion** : By default, **v1** supports vcluster deployments. Deprecated API version **v1beta1** also supports vcluster, but Vertica recommends that you change to **v1** .
- **vertica.com/vcluster-ops** : Set to **true** . With API version **v1** , this field and setting are optional. If you use the deprecated **v1beta1** , this setting is required or the migration fails.
- **vertica.com/run-nma-in-sidecar** : You must set this to **false** for vcluster deployments. For additional details, see [VerticaDB custom resource definition](#) .
- **spec.image** : Set this to a 24.1.0 image version. For a list images, see [Vertica images](#) .

2. Apply the updated manifest to complete the migration:

```
$ kubectl apply -f migration.yaml
```

Upgrade the Vertica server version

Important

If you are upgrading to 24.1.0 from version 23.4.0 or earlier, you must [migrate deployment types](#) .

After you [select your upgrade policy](#) and optionally [configure temporary subcluster routing](#) , use the [kubectl command line tool](#) to perform the upgrade and monitor its progress. The following steps demonstrate an online upgrade:

1. Set the upgrade policy to **Online** :

```
$ kubectl patch verticadb cluster-name --type=merge --patch '{"spec": {"upgradePolicy": "Online"}}'
```

2. Update the image setting in the CR:

```
$ kubectl patch verticadb cluster-name --type=merge --patch '{"spec": {"image": "vertica/vertica-k8s:new-version"}}'
```

3. Use **kubectl wait** to wait until the operator leaves upgrade mode:

```
$ kubectl wait --for=condition=UpgradeInProgress=False vdb/cluster-name --timeout=800s
```

View the upgrade process

To view the current phase of the upgrade process, use **kubectl get** to inspect the **upgradeStatus** status field:

```
$ kubectl get vdb -n namespacesdatabase-name -o jsonpath='{.status.upgradeStatus}'{"\n"}
Restarting cluster with new image
```

To view the entire upgrade process, use **kubectl describe** to list the events the operator generated during the upgrade:

```

$ kubectl describe vdb cluster-name
...
Events:
  Type Reason          Age From          Message
  ----
Normal UpgradeStart      5m10s verticadb-operator Vertica server upgrade has started. New image is 'vertica-k8s:new-version'
Normal ClusterShutdownStarted 5m12s verticadb-operator Calling 'admintools -t stop_db'
Normal ClusterShutdownSucceeded 4m08s verticadb-operator Successfully called 'admintools -t stop_db' and it took 56.22132s
Normal ClusterRestartStarted 4m25s verticadb-operator Calling 'admintools -t start_db' to restart the cluster
Normal ClusterRestartSucceeded 25s verticadb-operator Successfully called 'admintools -t start_db' and it took 240s
Normal UpgradeSucceeded 5s verticadb-operator Vertica server upgrade has completed successfully

```

Hybrid Kubernetes clusters

Important

Image versions [24.1.0-0](#) and higher do not support any of the following features:

- Backup and restore with vbr
- Hybrid Kubernetes clusters

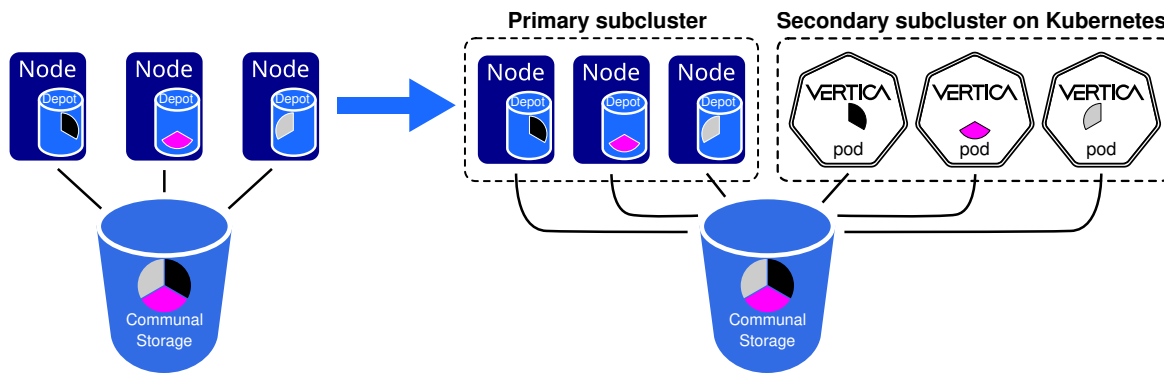

These operations require [Administration tools \(admintools\)](#), which is not included in the Vertica server image beginning with version [24.1.0-0](#). To perform these tasks, you must use image [version 23.4.0-0 or lower](#) with one of the following API version configurations:

- [v1beta1](#)
- [v1](#) and [vertica.com/vcluster-ops annotation](#) set to `false`

An Eon Mode database can run hosts separate from the database and within Kubernetes. This architecture is useful in the following scenarios:

- Leveraging Kubernetes tooling to quickly create a secondary subcluster for a database.
- Creating an isolated sandbox environment to run ad hoc queries on a communal dataset.
- Experimenting with the Vertica on Kubernetes performance overhead without migrating your primary subcluster into Kubernetes.

Define the Kubernetes portion of a hybrid architecture with a [custom resource \(CR\)](#). The custom resource has no knowledge of Vertica hosts that exist separately from the custom resource. This limits the operator's functionality and requires that you manually complete some tasks that the operator automates for a standard Vertica on Kubernetes custom resource.

Requirements and restrictions

The hybrid Kubernetes architecture has the following requirements and restrictions:

- Hybrid Kubernetes clusters require a tool that enables Border Gateway Protocol (BGP) so that pods are accessible to your on-premises subcluster for external communication. For example, you can use the [Calico CNI plugin to enable BGP](#).
- You cannot use network address translation (NAT) between the Kubernetes pods and the on-premises cluster.

Operator limitations

In a hybrid architecture, the operator has no visibility outside of the custom resource. This limited visibility means that the operator cannot interact with the Eon Mode database or the primary subcluster. Within the scope of the custom resource, the operator automates only the following:

- Schedules pods based on the manifest.
- Creates service objects for the subcluster.
- Creates a PersistentVolumeClaim (PVC) that persists data for each pod.
- Executes the [restart_node](#) administration tool command if the Vertica server process is not running. To override this default behavior, set the [autoRestartVertica custom resource parameter](#) to `false`.

Defining a hybrid cluster

To define a hybrid cluster, you must set up SSH communications between the Eon Mode nodes and containers, and then define the hybrid CR.

SSH between environments

In an Eon Mode database, nodes communicate through SSH. Vertica containers use SSH with a static key. Because the CR has no knowledge of any of the Eon Mode hosts, you must make the containers aware of the Eon Mode SSH keys.

You can create a [Secret](#) for the CR that stores SSH credentials for both the Eon Mode database and the Vertica container. The Secret must contain the following:

- `id_rsa`: private key shared among the pods.
- `id_rsa.pub`: public key shared among the pods.
- `authorized_keys`: file that contains the following keys:

- id_rsa.pub for pod-to-pod traffic.
- public key of on-premises root account.
- public key of on-prem dbadmin account.

The following command creates a Secret named `ssh-key` that stores these SSH credentials. The Secret persists between life cycles to allow secure connections between the on-premises nodes and the CR:

```
$ kubectl create secret generic ssh-keys --from-file=$HOME/.ssh
```

Hybrid CR definition

Create a custom resource to define a subcluster that runs outside your standard Eon Mode database:

```
apiVersion: vertica.com/v1beta1
kind: VerticaDB
metadata:
  name: hybrid-secondary-sc
spec:
  image: vertica/vertica-k8s:latest
  initPolicy: ScheduleOnly
  sshSecret: ssh-keys
  local:
    dataPath: /data
    depotPath: /depot
  dbName: vertdb
  subclusters:
    - name: sc1
      size: 3
    - name: sc2
      size: 3
```

Deprecated

The `v1beta1` API version is deprecated and will be removed in a future release. Vertica recommends that you upgrade to API version `v1`. For details, see [Upgrading Vertica on Kubernetes](#) and [VerticaDB custom resource definition](#).

In the previous example:

- `initPolicy`: Hybrid clusters require that you set this to `ScheduleOnly`.
- `sshSecret`: The Secret that contains SSH keys that authenticate connections to Vertica hosts outside the CR.
- `local`: Required. The values persist data to the PersistentVolume (PV). These values must match the directory locations in the Eon Mode database that is associated with the Kubernetes pods.
- `dbName`: This value must match the name of the standard Eon Mode database that is associated with this subcluster.
- `subclusters`: Definition for each subcluster.

Note

Hybrid custom resources ignore configuration parameters that control settings outside the scope of the hybrid subcluster, such as the `communal.*` and the `subclusters[i].isPrimary` parameters.

For complete implementation details, see [VerticaDB custom resource definition](#). For details about each setting, see [Custom resource definition parameters](#).

Maintaining quorum

If quorum is lost, you must manually restart the cluster with `admintools`:

```
$ /opt/vertica/bin/admintools -t restart_db --database database-name;
```

For details about maintaining quorum, see [Data integrity and high availability in an Eon Mode database](#).

Scaling the Kubernetes subcluster

When you scale a hybrid cluster, you add nodes from the primary subcluster to the secondary subcluster on Kubernetes.

HDFS with Kerberos authentication

If you are scaling a cluster that authenticates Hadoop file storage (HDFS) data with Kerberos, you must alter the [database configuration](#) before you scale.

In the default configuration, the Vertica server process running in the Kubernetes pods cannot access the HDFS data due to incorrect permissions on the keytab file mounted in the pod. This requires that you set the [KerberosEnableKeytabPermissionCheck](#) [Kerberos parameter](#):

1. Set the [KerberosEnableKeytabPermissionCheck](#) configuration parameter to 0 :

```
-> ALTER DATABASE DEFAULT SET KerberosEnableKeytabPermissionCheck = 0;
WARNING 4324: Parameter KerberosEnableKeytabPermissionCheck will not take effect until database restart
ALTER DATABASE
```

2. Restart the cluster with [admintools](#) so that the new setting takes effect:

```
$ /opt/vertica/bin/admintools -t restart_db --database database-name;
```

For additional details about Vertica on Kubernetes and HDFS, see [Configuring communal storage](#).

Scale the subcluster

When you add nodes from the primary subcluster to the secondary subcluster on Kubernetes, you must set up the configuration directory for the new nodes and change operator behavior during the scaling event:

1. Execute the [update_vertica](#) script to set up the configuration directory. Vertica on Kubernetes requires the following configuration options for [update_vertica](#) :

```
$ /opt/vertica/sbin/update_vertica \
--accept-eula \
--add-hosts host-list \
--dba-user-password dba-user-password \
--failure-threshold NONE \
--no-system-configuration \
--point-to-point \
--data-dir /data-dir \
--dba-user dbadmin \
--no-package-checks \
--no-ssh-key-install
```

2. Set [autoRestartVertica](#) to **false** so that the operator does not interfere with the scaling operation:

```
$ kubectl patch vdb database-name --type=merge --patch='{"spec":{"autoRestartVertica": false}}'
```

3. Add the new nodes with the [admintools db_add_node](#) option:

```
$ /opt/vertica/bin/admintools \
-t db_add_node \
--hosts host-list \
--database database-name \
--subcluster so-name \
--noprompt
```

For details, see [Adding and removing nodes from subclusters](#).

4. After the scaling operation, set [autoRestartVertica](#) back to **true** :

```
$ kubectl patch vdb database-name --type=merge --patch='{"spec":{"autoRestartVertica": true}}'
```

Generating a custom resource from an existing Eon Mode database

To simplify Vertica on Kubernetes adoption, Vertica provides the [vdb-gen](#) migration tool that revives an existing Eon Mode database as a StatefulSet in Kubernetes. [vdb-gen](#) generates a [custom resource](#) (CR) from an existing Eon Mode database by connecting to the database and writing to standard output.

The [vdb-gen](#) tool is available for [download as a release artifact](#) in the [vertica-kubernetes](#) GitHub repository.

Use the [-h](#) flag to view a full list of the available [vdb-gen](#) options, including options for debugging and working with environment variables. The following steps generate a CR using basic commands:

1. Execute [vdb-gen](#) and redirect the output to a YAML-formatted file:

```
$ vdb-gen --password secret --name mydb 10.20.30.40 vertdb > vdb.yaml
```

The previous command uses the following flags and values:

- password: The existing database superuser secret password.
- name: The name of the new custom resource object.
- 10.20.30.40: The IP address of the existing database
- vertdb: The name of the existing Eon Mode database.
- vdb.yaml: The YAML formatted file that contains the custom resource definition generated by the vdb-gen tool.

2. Use the [admintools stop_db command](#) to stop the existing database:

```
$ /opt/vertica/bin/admintools -f stop_db -d vertdb
```

Wait for the cluster lease to expire before continuing. For details, see [Reviving an Eon Mode database cluster](#).

3. Apply the YAML-formatted manifest that was generated by the vdb-gen tool:

```
$ kubectl apply -f vdb.yaml
verticadb.vertica.com/mydb created
```

Note

For performance purposes, do not apply the manifest to resources that already contain a Vertica on Kubernetes install.

4. The operator creates the StatefulSet, installs Vertica on each pod, and runs [revive](#). To view the events generated for the new database, use [kubectl describe](#) :

```
$ kubectl describe vdb mydb
```

Containerized Kafka Scheduler

The Vertica [Apache Kafka integration](#) includes a scheduler, a mechanism that you can configure to automatically consume data from Kafka and load that data into a Vertica database. The Vertica [Kafka Scheduler](#) is the containerized version of that scheduler that runs natively on Kubernetes. Both schedulers have identical functionality and accept the same configuration parameters.

This document provides quickstart instructions about how to create, configure, and launch the Vertica Kafka Scheduler on Kubernetes. It includes minimal details about each command. For in-depth documentation about scheduler behavior and advanced configuration, see [Automatically consume data from Kafka with a scheduler](#).

Prerequisites

- Kubernetes 1.21.1 and higher
- [Helm 3.5.0](#) and higher
- [kubectl command-line tool](#)
- [Kafka cluster](#)

Add the Helm charts

To simplify deployment, Vertica packages the Kafka Scheduler in a Helm chart. Add the charts to your local helm repository:

```
$ helm repo add vertica-charts https://vertica.github.io/charts
$ helm repo update
```

Launch a scheduler

When you launch a scheduler, you must update the scheduler configuration, create the scheduler, set up a Vertica database to consume data from the scheduler, and then launch the scheduler.

The Vertica Kafka scheduler has two modes:

- initializer: Configuration mode. Starts a container so that you can [exec](#) into it and configure it.
- launcher: Launch mode. Launches the scheduler. Starts a container that calls [vkconfig launch](#) automatically. Run this mode after you configure the container in [initializer](#) mode.

Use the [initializer](#) mode to configure all the scheduler settings. After you configure the scheduler, you upgrade the helm chart to launch it in [launcher](#) mode.

Install the scheduler

Install the scheduler Helm chart to start the scheduler in initializer mode. The following [helm install](#) command deploys a scheduler named [vkscheduler](#) in the [kafka](#) namespace:

```
$ helm install vkscheduler --namespace kafka vertica-charts/vertica-kafka-scheduler
NAME: vkscheduler
LAST DEPLOYED: Tue Apr 2 11:53:49 2024
NAMESPACE: kafka
STATUS: deployed
REVISION: 1
TEST SUITE: None
NOTES:
Vertica's Kafka Scheduler has been deployed.

The initializer pod is running. You can exec into it and run your vkconfig
commands with this command:

kubectl exec -n kafka -it vkscheduler-vertica-kafka-scheduler-initializer -- bash
```

The command output provides the `kubectl exec` command that you can use to access a shell in the initializer pod and configure the scheduler.

Verify that the scheduler's initializer pod is running:

```
$ kubectl get pods --namespace kafka
NAME                                READY STATUS RESTARTS AGE
vkscheduler-vertica-kafka-scheduler-initializer 1/1 Running 1 (12s ago) 77s
```

Create the target table

The target table is the Vertica database table that stores the data that the scheduler loads from Kafka. In this example, you create a [flex table](#) so that you can load data with an unknown or varying schema:

1. [Create a flex table](#) to store the data:

```
=> CREATE FLEX TABLE KafkaFlex();
CREATE TABLE
```

2. [Create a user](#) for the flex table:

```
=> CREATE USER KafkaUser;
CREATE USER
```

3. [Create a resource pool](#) for the scheduler. Vertica recommends that each scheduler have exclusive use of its own resource pool so that you can fine-tune the scheduler's impact on your Vertica cluster's performance:

```
=> CREATE RESOURCE POOL scheduler_pool PLANNEDCONCURRENCY 1;
CREATE RESOURCE POOL
```

For additional details, see [Managing scheduler resources and performance](#).

Override scheduler configuration

After you install the scheduler, you need to configure it for your environment. The scheduler configuration file is `vkconfig.conf`, and it is stored in the following location in the initializer pod:

```
/opt/vertica/packages/kafka/config/vkconfig.conf
```

By default, `vkconfig.conf` contains the following values:

```
config-schema=Scheduler
dbport=5433
enable-ssl=false
username=dbadmin
```

`vkconfig.conf` is read-only from within the filesystem, so you must upgrade the Helm chart to override the default settings. The following YAML-formatted file provides a template for scheduler overrides:

```
image:
  repository: opentext/kafka-scheduler
  pullPolicy: IfNotPresent
  tag: scheduler-version
launcherEnabled: false
replicaCount: 1
initializerEnabled: true
conf:
  generate: true
  content:
    config-schema: scheduler-name
    username: dbadmin
    dbport: "5433"
    enable-ssl: "false"
    dbhost: vertica-db-host-ip
fs:
  enabled: false
serviceAccount:
  create: true
```

This template requires that you update the following values:

- **image.tag** : Scheduler version. The scheduler version must match the version of the Vertica database that you used to [create the target table](#).
- **conf.content.config-schema** : Scheduler name. When you launch the scheduler, the Vertica database creates a schema that you can track with [data streaming tables](#).
- **conf.content.dbhost** : IP address for a host in your Vertica cluster.

For example, the **scheduler-overrides.yaml** file contains the following values:

```
image:
  repository: opentext/kafka-scheduler
  pullPolicy: IfNotPresent
  tag: 24.2.0
launcherEnabled: false
replicaCount: 1
initializerEnabled: true
conf:
  generate: true
  content:
    config-schema: scheduler-sample
    username: dbadmin
    dbport: "5433"
    enable-ssl: "false"
    dbhost: 10.20.30.40
fs:
  enabled: false
serviceAccount:
  create: true
```

After you define your overrides, use **helm upgrade** to apply the overrides to the scheduler initializer pod:

```
$ helm upgrade vkscheduler --namespace kafka vertica-charts/vertica-kafka-scheduler -f scheduler-overrides.yaml
Release "vkscheduler" has been upgraded. Happy Helming!
NAME: vkscheduler
LAST DEPLOYED: Tue Apr 2 11:54:35 2024
NAMESPACE: kafka
STATUS: deployed
REVISION: 2
TEST SUITE: None
NOTES:
Vertica's Kafka Scheduler has been deployed.

The initializer pod is running. You can exec into it and run your vkconfig
commands with this command:

kubectl exec -n kafka -it vkscheduler-vertica-kafka-scheduler-initializer -- bash
```

Configure the scheduler

After you update [vkconfig.conf](#), you need to configure the scheduler itself. A scheduler is a combination of multiple components that you must configure individually with the [vkconfig](#) command.

Note

The following steps do not provide detail about each component's configuration. For a detailed example, see [Setting up a scheduler](#). For details about all options for each component, see [vkconfig script options](#).

To configure the scheduler, you must access the scheduler initializer pod to execute the [vkconfig](#) commands:

1. Access a bash shell in the scheduler initializer pod:

```
$ kubectl exec -n kafka -it vkscheduler-vertica-kafka-scheduler-initializer -- bash
```

2. Define the scheduler. This command identifies the [Vertica user](#), [resource pool](#), and settings such as [frame duration](#):

```
bash-5.1$ vkconfig scheduler --conf /opt/vertica/packages/kafka/config/vkconfig.conf \
--frame-duration 00:00:10 \
--create --operator KafkaUser \
--eof-timeout-ms 2000 \
--config-refresh 00:01:00 \
--new-source-policy START \
--resource-pool scheduler_pool
```

3. Define the target, which is the [Vertica database table](#) that the loads data from the scheduler:

```
bash-5.1$ vkconfig target --add --conf /opt/vertica/packages/kafka/config/vkconfig.conf \
--target-schema public \
--target-table KafkaFlex
```

4. Define the load spec. This defines how Vertica parses the data from Kafka:

```
bash-5.1$ vkconfig load-spec --add --conf /opt/vertica/packages/kafka/config/vkconfig.conf \
--load-spec KafkaSpec \
--parser kfkajsonparser \
--load-method DIRECT \
--message-max-bytes 1000000
```

5. Define the cluster. This identifies your Kafka cluster:

```
bash-5.1$ vkconfig cluster --add --conf /opt/vertica/packages/kafka/config/vkconfig.conf \
--cluster KafkaCluster \
--hosts kafka01.example.com:9092,kafka03.example.com:9092
```

6. Define the source. The source is the Kafka topic and partitions that you want to load data from:

```
bash-5.1$ vkconfig source --add --conf /opt/vertica/packages/kafka/config/vkconfig.conf \
--cluster KafkaCluster \
--source KafkaTopic1 \
--partitions 1
```

7. Define the microbatch. The microbatch combines the components you created in the previous steps:

```
bash-5.1$ vkconfig microbatch --add --conf /opt/vertica/packages/kafka/config/vkconfig.conf \  
--microbatch KafkaBatch1 \  
--add-source KafkaTopic1 \  
--add-source-cluster KafkaCluster \  
--target-schema public \  
--target-table KafkaFlex \  
--rejection-schema public \  
--rejection-table KafkaFlex_rej \  
--load-spec KafkaSpec
```

After you configure the scheduler, exit the pod:

```
bash-5.1$ exit  
exit  
$
```

Launch the scheduler

After you configure the scheduler, you must launch it. To launch the scheduler, upgrade the Helm chart to change the `launcherEnabled` field to `true` :

```
$ helm upgrade --namespace kafka vkscheduler vertica-charts/vertica-kafka-scheduler \  
--set "launcherEnabled=true"
```

A new pod starts that runs the scheduler in launch mode:

```
$ kubectl get pods  
NAME                                READY STATUS RESTARTS AGE  
tester-vertica-kafka-scheduler-66d5c49dbf-nc86k 1/1 Running 0 14s  
tester-vertica-kafka-scheduler-initializer      1/1 Running 0 85m
```

Test your deployment

Now that you have a containerized Kafka cluster and VerticaDB CR running, you can test that the scheduler is automatically sending data from the Kafka producer to Vertica:

1. Open a shell that is running your Kafka producer and send sample JSON data:

```
=> {"a": 1}  
=> {"a": 1000}
```

2. Open a terminal with access to your Vertica cluster and `vsq!`. Query the `KafkaFlex` table to confirm that it contains the sample JSON data that you sent through the Kafka producer:

```
=> SELECT compute_flexible_keys_and_build_view('KafkaFlex');  
compute_flexible_keys_and_build_view  
-----  
Please see public.KafkaFlex_keys for updated keys  
The view public.KafkaFlex_view is ready for querying  
(1 row)  
  
=> SELECT a from KafkaFlex_view;  
a  
----  
1  
1000  
(2 rows)
```

Clean up

To delete the scheduler, you must use the `vkconfig` command with the `scheduler tool --drop` option and the scheduler schema. You must access a shell within the scheduler pod to run the commands:

```
$ kubectl exec -n kafka -it vkscheduler-vertica-kafka-scheduler-initializer -- bash  
bash-5.1$ /opt/vertica/packages/kafka/bin/vkconfig scheduler --drop --config-schema scheduler_sample
```

You can delete your Kubernetes resources with the `helm uninstall` command:

```
$ helm uninstall vkscheduler -n kafka
```

Kafka scheduler parameters

The following list describes the available settings for the Vertica Kafka Scheduler:

affinity

Applies [affinity rules](#) that constrain the scheduler to specific nodes.

conf.configMapName

Name of the [ConfigMap](#) to use and optionally generate. If omitted, the chart picks a suitable default.

conf.content

Set of key-value pairs in the generated ConfigMap. If **conf.generate** is **false**, this setting is ignored.

conf.generate

When set to **true**, the Helm chart controls the creation of the **vkconfig.conf** ConfigMap.

Default : **true**

fullNameOverride

Gives the Helm chart full control over the name of the objects that get created. This takes precedence over **nameOverride**.

initializerEnabled

When set to **true**, the initializer pod is created. This can be used to run any setup tasks needed.

Default : **true**

image.pullPolicy

How often Kubernetes pulls the image for an object. For details, see [Updating Images](#) in the Kubernetes documentation.

Default : **IfNotPresent**

image.repository

The image repository and name that contains the Vertica Kafka Scheduler.

Default : **opentext/kafka-scheduler**

image.tag

Version of the Vertica Kafka Scheduler. This setting must match the version of the Vertica server that the scheduler connects to.

For a list of available tags, see [opentext/kafka-scheduler](#).

Default : Helm chart's **appVersion**

imagePullSecrets

List of [Secrets](#) that contain the required credentials to pull the image.

launcherEnabled

When set to **true**, the Helm chart creates the launch deployment. Enable this setting after you configure the scheduler options in the container.

Default : **true**

jvmOpts

Values to assign to the **VKCONFIG_JVM_OPTS** environment variable in the pods.

Note

You can omit most truststore and keystore settings because they are set by **tls.*** parameters.

nameOverride

Controls the name of the objects that get created. This is combined with the Helm chart release to form the name.

nodeSelector

[nodeSelector](#) that controls where the pod is scheduled.

podAnnotations

[Annotations](#) that you want to attach to the pods.

podSecurityContext

[Security context](#) for the pods.

replicaCount

Number of launch pods that the chart deploys.

Default : 1

resources

Host resources to use for the pod.

securityContext

[Security context](#) for the container in the pod.

serviceAccount.annotations

Annotations to attach to the [ServiceAccount](#).

serviceAccount.create

When set to **true**, a [ServiceAccount](#) is created as part of the deployment.

Default : true

serviceAccount.name

Name of the [service account](#). If this parameter is not set and **serviceAccount.create** is set to **true**, a name is generated using the fullname template.

timezone

Manages the timezone of the logger. As logging employs log4j, ensure you use a Java-friendly timezone ID. For details, see this [Oracle documentation](#).

Default : UTC

tls.enabled

When set to **true**, the scheduler is set up for TLS authentication.

Default : false

tls.keyStoreMountPath

Directory name where the keystore is mounted in the pod. This setting controls the name of the keystore within the pod. The full path to the keystore is constructed by combining this parameter and **tls.keyStoreSecretKey**.

tls.keyStorePassword

Password that protects the keystore. If this setting is omitted, then no password is used.

tls.keyStoreSecretKey

Key within **tls.keyStoreSecretName** that is used as the keystore file name. This setting and **tls.keyStoreMountPath** form the full path to the key in the pod.

tls.keyStoreSecretName

Name of an existing [Secret](#) that contains the keystore. If this setting is omitted, no keystore information is included.

tls.trustStoreMountPath

Directory name where the truststore is mounted in the pod. This setting controls the name of the truststore within the pod. The full path to the truststore is constructed by combining this parameter with **tls.trustStoreSecretKey**.

tls.trustStorePassword

Password that protects the truststore. If this setting is omitted, then no password is used.

tls.trustStoreSecretKey

Key within **tls.trustStoreSecretName** that is used as the truststore file name. This is used with **tls.trustStoreMountPath** to form the full path to the key in the pod.

tls.trustStoreSecretName

Name of an existing [Secret](#) that contains the truststore. If this setting is omitted, then no truststore information is included.

Backup and restore containerized Vertica (vbr)

Important

Image versions **24.1.0-0** and higher do not support any of the following features:

- Backup and restore with vbr
- Hybrid Kubernetes clusters

These operations require [Administration tools \(admintools\)](#), which is not included in the Vertica server image beginning with version [24.1.0-0](#). To perform these tasks, you must use image [version 23.4.0-0 or lower](#) with one of the following API version configurations:

- [v1beta1](#)
- [v1](#) and [vertica.com/vcluster-ops annotation](#) set to `false`

Important

This section describes backup and restore operations with the `vbr` command-line utility.

Vertica provides the [VerticaRestorePoints custom resource definition \(CRD\)](#), a beta feature for in-database backup and restore operations in test environments. You can perform full database and object restore operations with only a VerticaRestorePoints custom resource and native SQL statements.

In Vertica on Kubernetes, backup and restore operations use the same components and tooling as non-containerized environments, including the following:

- [Configuration file](#) that specifies [environment details and custom options](#)
- Backup location that was prepared by an init script
- [vbr utility](#)

Containerized backup and restore operations require that you make these components and tools available to the Vertica server process running within a pod. The following sections describe strategies that back up and restore your [VerticaDB custom resource \(CR\)](#) with Kubernetes objects.

For comprehensive backup and restore documentation, see [Backing up and restoring the database](#).

Prerequisites

- Complete [Installing the VerticaDB operator](#)
- Create a [VerticaDB CR object](#)
- The `kubectl` command line tool
- Review [Setting up backup locations](#) and complete necessary steps

Sample configuration file

The `vbr` configuration file defines parameters that the `vbr` utility uses to execute backup and restore tasks. For details, see the following:

- [vbr configuration file reference](#)
- [Sample vbr configuration files](#)

To define a `vbr` configuration file in Kubernetes, you can create a [ConfigMap](#) whose `data` field defines `vbr` configuration values. After you create the ConfigMap object in your Kubernetes environment, you can run `vbr` commands from within a pod that has access to the ConfigMap.

The following [backup-configmap.yaml](#) manifest creates a configuration file named `backup.ini` that backs up to an S3 bucket:

```
apiVersion: v1
kind: ConfigMap
metadata:
  name: backup-configmap
data:
  backup-host: |
    backup-pod-dns
  backup.ini: |
    [CloudStorage]
    cloud_storage_backup_path = s3://backup-bucket/database-backup-path
    cloud_storage_backup_file_system_path = [backup-pod-dns]/opt/vertica/config/

    [Database]
    dbName = database-name

    [Misc]
    tempDir = /tmp/vbr
    restorePointLimit = 7
    objectRestoreMode = coexist
```

To create the ConfigMap object, apply the manifest to your Kubernetes environment:

```
$ kubectl apply -f backup-configmap.yaml
```

backup-host definition

In the [sample configuration file](#), *backup-pod-dns* is a portion of the pod's fully qualified domain name (FQDN). Vertica on Kubernetes creates a headless service object that constructs the FQDN for each object. The DNS format for each pod is as follows:

```
podName.headlessServiceName
```

Note

The headless service name always matches the VerticaDB CR name.

The *podName* portion of the DNS is itself constructed from Kubernetes object names. For example, the following is a complete pod DNS:

```
vdb-main-0.vdb
```

In the preceding example:

- **vdb** : VerticaDB CR name
- **main** : Subcluster name
- **0** : [StatefulSet ordinal index](#)
- **vdb** : Headless service name (always identical to the VerticaDB CR name)

To access a pod from outside the namespace, append the namespace to the pod DNS:

```
podName.headlessService.namespace
```

For additional details, see the [Kubernetes documentation](#).

Mount the configuration file

After you define a ConfigMap with vbr configuration information, you must make it available to the Vertica pods that can execute the vbr utility. You can mount the ConfigMap as a volume in a [VerticaDB CR](#) instance. For details about mounting volumes in the VerticaDB CR, see [Mounting custom volumes](#).

Cloud storage locations require access to information that you cannot provide in your [configuration file](#), such as [environment variables](#). You can set environment variables in your CR with [annotations](#).

The following [mounted-vbr-config.yaml](#) manifest mounts a [backup-config](#) ConfigMap object in the Vertica container's `/vbr` directory:

```
apiVersion: vertica.com/v1beta1
kind: VerticaDB
metadata:
  name: verticadb
spec:
  annotations:
    VBR_BACKUP_STORAGE_SECRET_ACCESS_KEY: "access-key"
    VBR_BACKUP_STORAGE_ACCESS_KEY_ID: "access-key-id"
    VBR_BACKUP_STORAGE_ENDPOINT_URL: "https://path/to/backup/storage"
    VBR_COMMUNAL_STORAGE_SECRET_ACCESS_KEY: "access-key"
    VBR_COMMUNAL_STORAGE_ACCESS_KEY_ID: "access-key-id"
    VBR_COMMUNAL_STORAGE_ENDPOINT_URL: "https://path/to/communal/storage"
  communal:
    endpoint: https://path/to/s3-endpoint
    path: "s3://bucket/database-path"
  image: vertica/vertica-k8s:version
  subclusters:
    - isPrimary: true
      name: main
  volumeMounts:
    - name: backup-configmap
      mountPath: /vbr
  volumes:
    - name: backup-configmap
      configMap:
        name: backup-configmap
```

Deprecated

The **v1beta1** API version is deprecated and will be removed in a future release. Vertica recommends that you upgrade to API version **v1**. For details, see [Upgrading Vertica on Kubernetes](#) and [VerticaDB custom resource definition](#).

To mount the ConfigMap, apply the manifest

```
$ kubectl apply -f mounted-vbr-config.yaml
```

After you apply the manifest, each Vertica pod restarts, and the new backup volume is mounted.

Prepare the backup location

Before you can run a backup, you must prepare the backup location with the [vbr init](#) command. This command initializes a directory on the backup host to receive and store Vertica backup data. You need to initialize a backup location only once. For details, see [Setting up backup locations](#).

The following [backup-init.yaml](#) manifest creates a pod to initialize the [backup-host](#) defined in the [sample configuration file](#):

```
apiVersion: v1
kind: Pod
metadata:
  name: backup-init
spec:
  restartPolicy: OnFailure
  containers:
  - name: main
    image: vertica/vertica-k8s:version
    command:
    - bash
    - -c
    - "ssh -o 'StrictHostKeyChecking no' -i /home/dbadmin/.ssh/id_rsa dbadmin@$BACKUP_HOST /opt/vertica/bin/vbr -t init --cloud-force-init --config-file /vbr/backup.conf"
  env:
  - name: BACKUP_HOST
    valueFrom:
      configMapKeyRef:
        key: backup-host
        name: backup-configmap
```

Apply the manifest to initialize the backup location:

```
$ kubectl create -f backup-init.yaml
```

Run a backup

Your organization might run backups as needed or on a schedule. The following sections use the [sample configuration file ConfigMap](#) to demonstrate both scenarios.

On-demand backups

In some circumstances, you might need to run backup operations as needed. You can create a [Kubernetes Job](#) to run an on-demand backup. The following [backup-on-demand.yaml](#) manifest creates a Job object that executes a backup:

```
apiVersion: batch/v1
kind: Job
metadata:
  generateName: vertica-backup-
spec:
  template:
    spec:
      restartPolicy: OnFailure
      containers:
      - name: main
        image: vertica/vertica-k8s:version
        command:
        - bash
        - -c
        - "ssh -o 'StrictHostKeyChecking no' -i /home/dbadmin/.ssh/id_rsa dbadmin@$BACKUP_HOST /opt/vertica/bin/vbr -t backup --config-file /vbr/backup.conf"
      env:
      - name: BACKUP_HOST
        valueFrom:
          configMapKeyRef:
            key: backup-host
            name: backup-configmap
```

Each time that you want to create a new backup, execute the following command:

```
$ kubectl create -f backup-on-demand.yaml
```

Scheduled backups

You might need to schedule a backup at a fixed time or interval. You can run the backup as a [Kubernetes CronJob object](#) that schedules a Kubernetes Job as specified in [Cron format](#).

The following `backup-cronjob.yaml` manifest runs a daily backup at 2:00 AM:

```
apiVersion: batch/v1
kind: CronJob
metadata:
  generateName: vertica-backup-
spec:
  schedule: "00 2 * * *"
  jobTemplate:
    spec:
      template:
        spec:
          restartPolicy: OnFailure
          containers:
            - name: main
              image: vertica/vertica-k8s:version
              command:
                - bash
                - -c
                - "ssh -o 'StrictHostKeyChecking no' -i /home/dbadmin/.ssh/id_rsa dbadmin@$BACKUP_HOST /opt/vertica/bin/vbr -t backup --config-file /vbr/backup.
          env:
            - name: BACKUP_HOST
              valueFrom:
                configMapKeyRef:
                  key: backup-host
                  name: backup-configmap
```

To schedule the backup, create the CronJob object:

```
$ kubectl create -f backup-cronjob.yaml
```

Restore from a backup

You can create a [Kubernetes Job](#) to restore database objects from a backup. For comprehensive documentation about the vbr restore task, see [Restoring backups](#).

The following `restore-on-demand-job.yaml` manifest creates a Job object that restores a database:

```
apiVersion: batch/v1
kind: Job
metadata:
  generateName: vertica-restore-
spec:
  template:
    spec:
      restartPolicy: OnFailure
      containers:
        - name: main
          image: vertica/vertica-k8s:version
          command:
            - bash
            - -c
            - "ssh -o 'StrictHostKeyChecking no' -i /home/dbadmin/.ssh/id_rsa dbadmin@$BACKUP_HOST /opt/vertica/bin/vbr -t restore --config-file /vbr/backup.
          env:
            - name: BACKUP_HOST
              valueFrom:
                configMapKeyRef:
                  key: backup-host
                  name: backup-configmap
```

The restore process requires that you stop the database, run the restore operation, and then restart the database. This workflow requires additional steps in a containerized environment because Kubernetes has components that monitor and maintain the desired state of the database. You must temporarily adjust some settings to provide time for the restore operation to complete. For details about the settings in this section, see [Custom resource definition parameters](#).

The following steps change the environment for the resource process and then restore the original values:

1. Update the CR to extend the [livenessProbe](#) timeout. This timeout triggers a container restart when it expires. The default livenessProbe timeout is about two and half minutes, which does not provide enough time to restore the database. The following `patch` command uses the `livenessProberOverride` parameter to set the timeout to about 20 minutes:

```
❯ kubectl patch vdb customResourceName --type=json --patch '[{"op": "add", "path": "/spec/livenessProbeOverride", "value": {"initialDelaySeconds": 60}}']
```

2. Delete the StatefulSet for each subcluster so that the pods are restarted with the new `livenessProberOverride` setting:

```
❯ kubectl delete statefulset customResourceName-subclusterName
```

3. Wait until the pods restart and the new pod IPs are present in `admintools.conf`:

```
❯ kubectl wait --for=condition=Ready=True pod --selector=app.kubernetes.io/instance=customResourceName --timeout=10m
```

4. Set `autoRestartVertica` to `false` so that the Vertica server process does not automatically restart when you stop the database:

```
❯ kubectl patch vdb customResourceName --type=merge --patch '{"spec": {"autoRestartVertica": false}}'
```

5. Access a shell in a host that is running a Vertica pod, and stop the database with [admintools](#):

```
❯ kubectl exec -it hostname -- admintools -f stop_db -d database-name
```

After you stop the database, wait for the cluster lease to expire.

Note

In some scenarios, estimating when the cluster lease expires is difficult. If the restore fails, it logs when the lease expires.

You can also experiment with the [restartPolicy](#) and [backoff failure policy](#) in the Job spec to control how many times to retry the restore.

6. Apply the manifest to run a Job that restores the backup:

```
❯ kubectl create -f restore-on-demand-job.yaml
```

7. After the Job completes, use `patch` to reset the livenessProbe timeout to its default setting:

```
❯ kubectl patch vdb customResourceName --type=json --patch '[{"op": "remove", "path": "/spec/livenessProbeOverride"}]'
```

8. Set `autoRestartVertica` back to `true` to reset the restart behavior to its state before the restore operation:

```
❯ kubectl patch vdb customResourceName --type=merge --patch '{"spec": {"autoRestartVertica": true}}'
```

9. To speed up the restart process, delete the StatefulSet for each subcluster. The restart speed was affected when you increased the `livenessProbeOverride` setting:

```
❯ kubectl delete statefulset customResourceName-subclusterName
```

10. Wait for the Vertica server to restart:

```
❯ kubectl wait --for=condition=Ready=True pod --selector=app.kubernetes.io/instance=customResourceName --timeout=10m
```

Troubleshooting your Kubernetes cluster

These tips can help you avoid issues related to your Vertica on Kubernetes deployment and troubleshoot any problems that occur.

Download the [kubectl command line tool](#) to debug your Kubernetes resources.

In this section

- [General cluster and database](#)
- [Helm charts](#)
- [Metrics gathering](#)
- [VerticaAutoscaler](#)

General cluster and database

Inspect objects to diagnose issues

When you deploy a [custom resource \(CR\)](#), you might encounter a variety of issues. To pinpoint an issue, use the following commands to inspect the objects that the CR creates:

`kubectl get` returns basic information about deployed objects:

```
$ kubectl get pods -n namespace
$ kubectl get statefulset -n namespace
$ kubectl get pvc -n namespace
$ kubectl get event
```

`kubectl describe` returns detailed information about deployed objects:

```
$ kubectl describe pod pod-name -n namespace
$ kubectl describe statefulset name -n namespace
$ kubectl describe custom-resource-name -n namespace
```

Verify updates to a custom resource

Because the operator takes time to perform tasks, updates to the custom resource are not effective immediately. Use the `kubectl` command line tool to verify that changes are applied.

You can use the `kubectl wait` command to wait for a specified condition. For example, the operator uses the `UpgradeInProgress` condition to provide an upgrade status. After you begin the [image version upgrade](#), wait until the operator acknowledges the upgrade and sets this condition to True:

```
$ kubectl wait --for=condition=UpgradeInProgress=True vdb/cluster-name --timeout=180s
```

After the upgrade begins, you can wait until the operator leaves upgrade mode and sets this condition to False:

```
$ kubectl wait --for=condition=UpgradeInProgress=False vdb/cluster-name --timeout=800s
```

For more information about `kubectl wait`, see the [kubectl reference documentation](#).

Pods are running but the database is not ready

When you check the pods in your cluster, the pods are running but the database is not ready:

```
$ kubectl get pods
NAME                                READY  STATUS   RESTARTS  AGE
vertica-crd-sc1-0                   0/1    Running  0          12m
vertica-crd-sc1-1                   0/1    Running  1          12m
vertica-crd-sc1-2                   0/1    Running  0          12m
verticadb-operator-controller-manager-5d9cdc9b8-kw9nv  2/2    Running  0          24m
```

To find the root cause of the issue, use `kubectl logs` to check the operator manager. The following example shows that the communal storage bucket does not exist:

```
$ kubectl logs -l app.kubernetes.io/name=verticadb-operator -c manager -f
2021-08-04T20:03:00.289Z      INFO    controllers.VerticaDB   ExecInPod entry ("verticadb": "default/vertica-crd", "pod": {"namespace": "default", "name": "ve
2021-08-04T20:03:00.369Z      INFO    controllers.VerticaDB   ExecInPod stream      ("verticadb": "default/vertica-crd", "pod": {"namespace": "default", "name
2021-08-04T20:03:00.369Z      INFO    controllers.VerticaDB   ExecInPod entry ("verticadb": "default/vertica-crd", "pod": {"namespace": "default", "name": "ve
2021-08-04T20:03:00.369Z      DEBUG   controller-runtime.manager.events   Normal {"object": {"kind": "VerticaDB", "namespace": "default", "name": "vertica-
2021-08-04T20:03:17.051Z      INFO    controllers.VerticaDB   ExecInPod stream      ("verticadb": "default/vertica-crd", "pod": {"namespace": "default", "name
2021-08-04T20:03:17.051Z      INFO    controllers.VerticaDB   aborting reconcile of VerticaDB ("verticadb": "default/vertica-crd", "result": {"Requeue": true, "Re
2021-08-04T20:03:17.051Z      DEBUG   controller-runtime.manager.events   Warning {"object": {"kind": "VerticaDB", "namespace": "default", "name": "vertica
```

Create an S3 bucket for the cluster:

```
$ S3_BUCKET=newbucket
$ S3_CLUSTER_IP=$(kubectl get svc | grep minio | head -1 | awk '{print $3}')
$ export AWS_ACCESS_KEY_ID=minio
$ export AWS_SECRET_ACCESS_KEY=minio123
$ aws s3 mb s3://$S3_BUCKET --endpoint-url http://$S3_CLUSTER_IP
make_bucket: newbucket
```

Use `kubectl get pods` to verify that the cluster uses the new S3 bucket and the database is ready:

```
$ kubectl get pods
NAME                                READY STATUS RESTARTS AGE
minio-ss-0-0                        1/1   Running 0       18m
minio-ss-0-1                        1/1   Running 0       18m
minio-ss-0-2                        1/1   Running 0       18m
minio-ss-0-3                        1/1   Running 0       18m
vertica-crd-sc1-0                   1/1   Running 0       20m
vertica-crd-sc1-1                   1/1   Running 0       20m
vertica-crd-sc1-2                   1/1   Running 0       20m
verticadb-operator-controller-manager-5d9cdc9b8-kw9nv 2/2   Running 0       63m
```

Database is not available

After you create a custom resource instance, the database is not available. The `kubectl get custom-resource` command does not display information:

```
$ kubectl get vdb
NAME      AGE SUBCLUSTERS INSTALLED DBADDED UP
vertica-crd 4s
```

Use `kubectl describe custom-resource` to check the events for the pods to identify any issues:

```
$ kubectl describe vdb
Name:      vertica-crd
Namespace: default
Labels:    <none>
Annotations: <none>
API Version: vertica.com/v1
Kind:      VerticaDB
Metadata:
  ...
  Superuser Password Secret: su-passwd
Events:
  Type      Reason              Age           From          Message
  ----      -
  Warning   SuperuserPasswordSecretNotFound 5s (x12 over 15s) verticadb-operator Secret for superuser password 'su-passwd' was not found
```

In this circumstance, the custom resource uses a Secret named `su-passwd` to store the `Superuser Password Secret`, but there is no such Secret available. Create a Secret named `su-passwd` to store the Secret:

```
$ kubectl create secret generic su-passwd --from-literal=password=sup3rs3cr3t
secret/su-passwd created
```

Note

For detailed steps about creating the Secret manifest and applying it to a namespace, see the [Kubernetes documentation](#).

For details about Vertica and secret credentials, see [Secrets management](#).

Use `kubectl get custom-resource` to verify the issue is resolved:

```
$ kubectl get vdb
NAME      AGE SUBCLUSTERS INSTALLED DBADDED UP
vertica-crd 89s 1         0         0         0
```

Image pull failure

You receive an `ImagePullBackOff` error when you deploy a Vertica cluster with Helm charts, but you do not pre-pull the Vertica image from the local registry server:

```
$ kubectl describe pod pod-name-0
...
Events:
  Type     Reason      Age           From          Message
  ---     -
  Warning  Failed      2m32s        kubelet       Failed to pull image "k8s-rhel7-01:5000/vertica-k8s:default-1": rpc error: code = Unknown desc = con
  Warning  Failed      2m32s        kubelet       Error: ErrImagePull
  Normal   BackOff     2m32s        kubelet       Back-off pulling image "k8s-rhel7-01:5000/vertica-k8s:default-1"
  Warning  Failed      2m32s        kubelet       Error: ImagePullBackOff
  Normal   Pulling     2m18s (x2 over 4m22s) kubelet       Pulling image "k8s-rhel7-01:5000/vertica-k8s:default-1"
```

This occurs because the Vertica image size is too big to pull from the registry while deploying the Vertica cluster. Execute the following command on a Kubernetes host:

```
$ docker image list | grep vertica-k8s
k8s-rhel7-01:5000/vertica-k8s default-1 2d6f5d3d90d6 9 days ago 1.55GB
```

To solve this issue, complete one of the following:

- Pull the Vertica images on each node before creating the Vertica StatefulSet:

```
$ NODES=$(kubectl get nodes | grep -v NAME | awk '{print $1}')
$ for node in $NODES; do ssh $node docker pull $DOCKER_REGISTRY-5000/vertica-k8s:$K8S_TAG; done
```

- Use the reduced-size [vertica/vertica-k8s:latest](#) image for the Vertica server.

Pending pods due to insufficient CPU

If your host nodes do not have enough resources to fulfill the resource request from a pod, the pod stays in pending status.

Note

As a best practice, do not request the maximum amount of resources available on a host node to leave resources for other processes on the host node.

In the following example, the pod requests 40 CPUs on the host node, and the pod stays in **Pending** :

```
$ kubectl describe pod cluster-vertica-defaultsubcluster-0
...
Status:      Pending
...
Containers:
  server:
    image:      docker.io/library/vertica-k8s:default-1
    ports:     5433/TCP, 5434/TCP, 22/TCP
    host ports: 0/TCP, 0/TCP, 0/TCP
    command:
      /opt/vertica/bin/docker-entrypoint.sh
      restart-vertica-node
    limits:
      memory: 200Gi
    requests:
      cpu: 40
      memory: 200Gi
...
Events:
  Type     Reason      Age           From          Message
  ---     -
  Warning  FailedScheduling 3h20m        default-scheduler  0/5 nodes are available: 5 insufficient cpu.
```

To confirm the resources available on the host node. The following command confirms that the host node has only 40 allocatable CPUs:

```

$ kubectl describe node host-node-1
.
Conditions:
  Type              Status  LastHeartbeatTime           LastTransitionTime          Reason                    Message

  hugepages-1Gi:     0
  hugepages-2Mi:     0
  memory:             263839236Ki
  pods:              110
--
Non-terminated Pods: (3 in total)
  Namespace           Name                               CPU Requests  CPU Limits  Memory Requests  Memory Limits  AGE
  -----
  default             cluster-vertica-defaultsubcluster-0  38 (95%)     0 (0%)     200Gi (79%)     200Gi (79%)   51m
  kube-system         kube-flannel-ds-8brv9              100m (0%)    100m (0%)   50Mi (0%)       50Mi (0%)     9h
  kube-system         kube-proxy-lqjhp                    0 (0%)       0 (0%)     0 (0%)          0 (0%)        9h

```

To correct this issue, reduce the [resource.requests](#) in the subcluster to values lower than the maximum allocatable CPUs. The following example uses a YAML-formatted file named [patch.yaml](#) to lower the resource requests for the pod:

```

$ cat patch.yaml
spec:
  subclusters:
  - name: defaultsubcluster
    resources:
      requests:
        memory: 238Gi
        cpu: "38"
      limits:
        memory: 238Gi
$ kubectl patch vdb cluster-vertica --type=merge --patch "$(cat patch.yaml)"
verticadb.vertica.com/cluster-vertica patched

```

Pending pod after node removed

When you remove a host node from your Kubernetes cluster, a Vertica pod might stay in pending status if the pod uses a PersistentVolume (PV) that has a node affinity rule that prevents the pod from running on another node.

To resolve this issue, you must verify that the pods are pending because of an affinity rule, and then use the [vdb-gen tool to revive](#) the entire cluster.

First, determine if the pod is pending because of a node affinity rule. This requires details about the pending pod, the PersistentVolumeClaim (PVC) associated with the pod, and the PersistentVolume (PV) associated with the PVC:

1. Use [kubectl describe](#) to return details about the pending pod:

```
$ kubectl describe pod pod-name
..
Events:
  Type      Reason      Age          From          Message
  ----      -
Warning    FailedScheduling 28s (x2 over 48s) default-scheduler 0/2 nodes are available: 1 node(s) had untolerated taint (node.kubernetes.io/unschedu
```

The **Message** column verifies that the pod was not scheduled due a **volume node affinity conflict** .

- 2. Get the name of the PVC associated with the pod:

```
$ kubectl get pod -o jsonpath={.spec.volumes[0].persistentVolumeClaim.claimName}{"\n"} pod-name
local-data-pod-name
```

- 3. Use the PVC to get the PV. PVs are associated with nodes:

```
$ kubectl get pvc -o jsonpath={.spec.volumeName}{"\n"} local-data-pod-name
pvc-1926ae96-574d-4433-99b4-ec9ab0e5e497
```

- 4. Use the PV to get the name of the node that has the affinity rule:

```
$ kubectl get pv -o jsonpath={.spec.nodeAffinity.required.nodeSelectorTerms[0].matchExpressions[0].values[0]}{"\n"} pvc-1926ae96-574d-4433-99b4-ec9ab0e5e497
p-10-20-30-40.ec2.internal
```

- 5. Verify that the node with the affinity rule is the node that was removed from the Kubernetes cluster.

Next, you must revive the entire cluster to get all pods running again. When you revive the cluster, you create new PVCs that restore the association between each pod and a PV to satisfy the node affinity rule.

While you have nodes running in the cluster, you can use the **vdb-gen** tool to generate a manifest and revive the database:

- 1. Download the **vdb-gen** tool from the [vertica-kubernetes](https://github.com/vertica/vertica-kubernetes) GitHub repository:

```
$ wget https://github.com/vertica/vertica-kubernetes/releases/latest/download/vdb-gen
```

- 2. Copy the tool into a pod that has a running Vertica process:

```
$ kubectl cp vdb-gen pod-name:/tmp/vdb-gen
```

- 3. The **vdb-gen** tool requires the database name, so retrieve it with the following command:

```
$ kubectl get vdb -o jsonpath={.spec.dbName}{"\n"} v
database-name
```

- 4. Run the **vdb-gen** tool with the database name. The following command runs the tool and pipes the output to a file named **revive.yaml** :

```
$ kubectl exec -i pod-name -- bash -c "chmod +x /tmp/vdb-gen && /tmp/vdb-gen --ignore-cluster-lease --name v localhost database-name | tee /tmp/revive.yaml"
```

- 5. Copy **revive.yaml** to your local machine so that you can use it after you remove the cluster:

```
$ kubectl cp pod-name:/tmp/revive.yaml revive.yaml
```

- 6. Save the current VerticaDB Custom Resource (CR). For example, the following command saves a CR named **vertdb** to a file named **orig.yaml** :

```
$ kubectl get vdb vertdb -o yaml > orig.yaml
```

- 7. Update **revive.yaml** with parts of **orig.yaml** that **vdb-gen** did not capture. For example, custom resource limits.

- 8. Delete the existing Vertica cluster:

```
$ kubectl delete vdb vertdb
verticadb.vertica.com "vertdb" deleted
```

- 9. Confirm that all PVCs that are associated with the deleted cluster were removed:

- 1. Retrieve the PVC names. A PVC name uses the **dbname - subcluster - podindex** format:

```
$ kubectl get pvc
NAME                STATUS  VOLUME                                     CAPACITY  ACCESS MODES  STORAGECLASS  AGE
local-data-vertdb-sc-0  Bound  pvc-e9834c18-b160-4a4b-a686-ba8f7b601230  1Gi       RWO           local-path    34m
local-data-vertdb-sc-1  Bound  pvc-1926ae96-574d-4433-99b4-ec9ab0e5e497  1Gi       RWO           local-path    34m
local-data-vertdb-sc-2  Bound  pvc-4541f7c9-3afc-47f0-8d04-67fac370ee88  1Gi       RWO           local-path    34m
```

- 2. Delete the PVCs:

```
kubectl delete pvc local-data-vertdb-sc-0 local-data-vertdb-sc-1 local-data-vertdb-sc-2
persistentvolumeclaim "local-data-vertdb-sc-0" deleted
persistentvolumeclaim "local-data-vertdb-sc-1" deleted
persistentvolumeclaim "local-data-vertdb-sc-2" deleted
```

10. Revive the database with `revive.yaml` :

```
kubectl apply -f revive.yaml
verticadb.vertica.com/vertdb created
```

After the revive completes, all Vertica pods are running, and PVCs are recreated on new nodes. Wait for the operator to start the database.

Deploying to Istio

Vertica does not officially support Istio because the Istio sidecar port requirement conflicts with the port that Vertica requires for internal node communication. However, you can deploy Vertica on Kubernetes to Istio with changes to the Istio [InboundInterceptionMode](#) setting. Vertica provides access to this setting with annotations on the VerticaDB CR.

REDIRECT mode

REDIRECT mode is the default `InboundInterceptionMode` setting, and it requires that you disable network address translation (NAT) on port 5434, the port that the pods use for internal communication. Disable NAT on this port with the `excludeInboundPorts` annotation:

```
apiVersion: vertica.com/v1
kind: VerticaDB
metadata:
  name: vdb
spec:
  annotations:
    traffic.sidecar.istio.io/excludeInboundPorts: "5434"
```

Helm charts

Custom certificate helm install error

If you use custom certificates when you install the operator with the Helm chart, the `helm install` or `kubectl apply` command might return an error similar to the following:

```
$ kubectl apply -f ../operatorcrd.yaml
Error from server (InternalError): error when creating "../operatorcrd.yaml": Internal error occurred: failed calling webhook "mverticadb.kb.io": Post "https://verticadb-operator-webhook-service.namespace.svc:443/mutate-vertica-com-v1-verticadb?timeout=10s": x509: certificate is valid for ip-10-0-21-169.ec2.internal, test-bastion, not verticadb-operator-webhook-service.default.svc
```

You receive this error when the TLS key's Domain Name System (DNS) or Subject Alternate Name (SAN) is incorrect. To correct this error, define the DNS and SAN in a configuration file in the following format:

```
commonName = verticadb-operator-webhook-service.namespace.svc
...
[alt_names]
DNS.1 = verticadb-operator-webhook-service.namespace.svc
DNS.2 = verticadb-operator-webhook-service.namespace.svc.cluster.local
```

For additional details, see [Installing the VerticaDB operator](#).

Metrics gathering

Adding and testing the vlogger sidecar

Vertica provides the [vlogger](#) image that sends logs from `vertica.log` to standard output on the host node for log aggregation.

To add the sidecar to the CR, add an element to the `spec.sidecars` definition:

```
spec:
  ...
  sidecars:
  - name: vlogger
    image: vertica/vertica-logger:1.0.0
```

To test the sidecar, run the following command and verify that it returns logs:

```
$ kubectl logs pod-name -c vlogger
2021-12-08 14:39:08.538 DistCall Dispatch:0x7f3599ffd700-c000000000997e [Txn

```

Generating core files

In some circumstances, you might need to examine a core file that contains information about the Vertica server container process.

Vertica server container process

The following steps generate a core file for the Vertica server process:

1. Use the `securityContext` value to set the `privileged` property to `true` :

```
apiVersion: vertica.com/v1
kind: VerticaDB
...
spec:
...
securityContext:
  privileged: true
```

2. On the host machine, verify that `/proc/sys/kernel/core_pattern` is set to `core` :

```
$ cat /proc/sys/kernel/core_pattern
core
```

The `/proc/sys/kernel/core_pattern` file is not namespaced, so setting this value affects all containers running on that host.

When Vertica generates a core, the machine writes a message to `vertica.log` that indicates where you can locate the core file.

OpenShift core files

If you want to generate a core file in OpenShift, you must add the `SYS_PTRACE` capability in the CR to collect vstacks:

1. Use the `securityContext` value to set the `capabilities.add` property to `["SYS_PTRACE"]` :

```
apiVersion: vertica.com/v1
kind: VerticaDB
...
spec:
...
securityContext:
  capabilities:
    add: ["SYS_PTRACE"]
```

2. Apply the changes:

```
$ kubectl apply -f core-file-manifest.yaml
```

3. Get a shell in the container and execute `vstack` as the superuser:

```
$ kubectl exec svc/subcluster-name -- sh -c "echo root | su root /opt/vertica/bin/vstack"
```

VerticaAutoscaler

Cannot find CPU metrics with VerticaAutoscaler

You might notice that your VerticaAutoScaler is not scaling correctly according to CPU utilization:

```
$ kubectl get hpa
NAME                REFERENCE                      TARGETS   MINPODS  MAXPODS  REPLICAS  AGE
autoscaler-name    VerticaAutoscaler/autoscaler-name  <unknown>/50%  3        12       0         19h

$ kubectl describe hpa
Warning: autoscaling/v2beta2 HorizontalPodAutoscaler is deprecated in v1.23+, unavailable in v1.26+; use autoscaling/v2 HorizontalPodAutoscaler
Name: autoscaler-name
Namespace: namespace
Labels: <none>
Annotations: <none>
CreationTimestamp: Thu, 12 May 2022 10:25:02 -0400
Reference: VerticaAutoscaler/autoscaler-name
Metrics: ( current / target )
resource cpu on pods (as a percentage of request): <unknown> / 50%
Min replicas: 3
Max replicas: 12
VerticaAutoscaler pods: 3 current / 0 desired
Conditions:
Type Status Reason Message
-----
AbleToScale True SucceededGetScale the HPA controller was able to get the target's current scale
ScalingActive False FailedGetResourceMetric the HPA was unable to compute the replica count: failed to get cpu utilization: unable to get metrics for resource
Events:
Type Reason Age From Message
-----
Warning FailedGetResourceMetric 7s horizontal-pod-autoscaler failed to get cpu utilization: unable to get metrics for resource cpu: unable to fetch metrics from
Warning FailedComputeMetricsReplicas 7s horizontal-pod-autoscaler invalid metrics (1 invalid out of 1), first error is: failed to get cpu utilization: unable to get
```

You receive this error because the metrics server is not installed:

```
$ kubectl top nodes
error: Metrics API not available
```

To install the metrics server:

1. Download the components.yaml file:

```
$ kubectl apply -f https://github.com/kubernetes-sigs/metrics-server/releases/latest/download/components.yaml
```

2. Optionally, disable TLS:

```
$ if ! grep kubelet-insecure-tls components.yaml; then
sed -i 's/- args:/- args:\n --kubelet-insecure-tls/' components.yaml;
```

3. Apply the YAML file:

```
$ kubectl apply -f components.yaml
```

4. Verify that the metrics server is running:

```
$ kubectl get svc metrics-server -n namespace
NAME                TYPE        CLUSTER-IP    EXTERNAL-IP  PORT(S)  AGE
metrics-server     ClusterIP   10.105.239.175 <none>       443/TCP  19h
```

CPU request error with VerticaAutoscaler

You might receive an error that states:

```
failed to get cpu utilization: missing request for cpu
```

You get this error because you must set resource limits on all containers, including sidecar containers. To correct this error:

1. Verify the error:

```
$ kubectl get hpa
NAME                REFERENCE                TARGETS   MINPODS  MAXPODS  REPLICAS  AGE
autoscaler-name     VerticaAutoscaler/autoscaler-name  <unknown>/50%  3       12       0         19h

$ kubectl describe hpa
Warning: autoscaling/v2beta2 HorizontalPodAutoscaler is deprecated in v1.23+, unavailable in v1.26+; use autoscaling/v2 HorizontalPodAutoscaler
Name: autoscaler-name
Namespace: namespace
Labels: <none>
Annotations: <none>
CreationTimestamp: Thu, 12 May 2022 15:58:31 -0400
Reference: VerticaAutoscaler/autoscaler-name
Metrics: ( current / target )
resource cpu on pods (as a percentage of request): <unknown> / 50%
Min replicas: 3
Max replicas: 12
VerticaAutoscaler pods: 3 current / 0 desired
Conditions:
Type Status Reason Message
-----
AbleToScale True SucceededGetScale the HPA controller was able to get the target's current scale
ScalingActive False FailedGetResourceMetric the HPA was unable to compute the replica count: failed to get cpu utilization: missing request for cpu
Events:

-----
Warning FailedGetResourceMetric 4s (x5 over 64s) horizontal-pod-autoscaler failed to get cpu utilization: missing request for cpu
Warning FailedComputeMetricsReplicas 4s (x5 over 64s) horizontal-pod-autoscaler invalid metrics (1 invalid out of 1), first error is: failed to get cpu utilization
```

2. Add resource limits to the CR:

```
$ cat /tmp/vdb.yaml
apiVersion: vertica.com/v1
kind: VerticaDB
metadata:
  name: vertica-vdb
spec:
  sidecars:
  - name: vlogger
    image: vertica/vertica-logger:latest
  resources:
    requests:
      memory: "100Mi"
      cpu: "100m"
    limits:
      memory: "100Mi"
      cpu: "100m"
  communal:
    credentialSecret: communal-creds
    endpoint: https://endpoint
    path: s3://bucket-location
  dbName: verticadb
  image: vertica/vertica-k8s:latest
  subclusters:
  - type: primary
    name: sc1
    resources:
      requests:
        memory: "4Gi"
        cpu: 2
      limits:
        memory: "4Gi"
        cpu: 2
    serviceType: ClusterIP
    serviceName: sc1
    size: 3
  upgradePolicy: Auto
```

3. Apply the update:

```
$ kubectl apply -f /tmp/vdb.yaml
verticadb.vertica.com/vertica-vdb created
```

When you set a new CPU resource limit, Kubernetes reschedules each pod in the StatefulSet in a rolling update until all pods have the updated CPU resource limit.

Data exploration

If the data you need to analyze is already well-specified in a schema, such as if it was exported from another database, then you can usually proceed to defining tables and [loading the data](#). Often, however, your initial data is less clear or is in a format that does not require a consistent schema, like JSON. Before you can define database tables for your data, you must explore that data in more detail and make decisions about how to represent it in tables.

During data exploration, you [develop a schema](#) and decide what [kind of table](#) to use in your production database. In some cases, you might choose to use external tables to describe data, and in other cases you might choose to load data into the database. Either way, over time, you might need to [make changes if the schema evolves](#). For example, new data might add columns or change the data type of existing columns. You should expect to revisit your data schema over time. When you do, use the techniques described in the following sections.

In this section

- [Develop a schema](#)
- [Table types](#)
- [Schema changes](#)

Develop a schema

Vertica provides two general approaches to developing a table definition during data exploration without resorting to inspecting data files by hand: inference and flex tables.

If your data is in Parquet, ORC, JSON, or Avro format, you can use a Vertica function to inspect a sample file and automatically generate a "first draft" of a table definition. The output indicates where the function could not make a decision, so that you can focus on those areas as you refine the definition. Using this approach, you iteratively test sample data, refine the table definition, and test more data until you arrive at a satisfactory table definition.

Alternatively, you can use flex tables, a special type of table designed for exploring data with an unknown or varying schema. You can use flex functions to explore this data and materialize individual columns in your table. When you have identified the columns that should consistently be part of your table, you can then define a regular (non-flex) table.

In this section

- [Inference](#)
- [Flex tables](#)

Inference

If your data is in Parquet, ORC, JSON, or Avro format, you can use a Vertica function to inspect a sample file and automatically generate a "first draft" of a table definition. You can then refine this definition, such as by specifying VARCHAR lengths, NUMERIC precision, and ARRAY bounds. If the data format supports it, you can ignore columns in the data that you do not need for your table.

When you have an initial table definition, you can load more data. New data might have different properties, so it's important to adjust your table definition in light of more data. Test the table definition with enough data to feel confident before putting it into production.

You might find it easier to do initial exploration with external tables, whose definitions are more easily modified.

Create first draft of table

The [INFER_TABLE_DDL](#) function inspects a data file and returns a CREATE TABLE or CREATE EXTERNAL TABLE statement based on its contents. The column definitions in the returned statement can be incomplete, and sometimes the function cannot determine a column's data type. The function also uses the column names as they appear in the data, even if they violate Vertica restrictions. For all of these reasons, you must review and adjust the proposed definition.

In the following example, the input path contains data for a product catalog. Note the warnings about data types:

```
-> SELECT INFER_TABLE_DDL('/data/products/products.parquet'
  USING PARAMETERS format = 'parquet', table_name = 'products');

WARNING 9311: This generated statement contains one or more varchar/varbinary columns which default to length 80

  INFER_TABLE_DDL

-----
create table "products"(
  "id" int,
  "msrp" numeric(6,2),
  "name" varchar,
  "description" varchar,
  "vendors" Array[Row(
    "name" varchar,
    "price" numeric(6,2)
  )]
);
(1 row)
```

The table definition contains several VARCHAR values with unspecified lengths. The Vertica default length for VARCHAR is 80, and for a native table, Vertica allocates memory based on the maximum length. If a value is unlikely to be that large, such as for a name, you can specify a smaller size to improve query performance. Conversely, if a value could be much longer, such as the description field here, you can specify a larger size so that Vertica does not truncate the value.

For numeric values, INFER_TABLE_DDL suggests precision and scale based on the data in the sample file. As with VARCHAR, values that are too high cause more memory to be allocated. In addition, computations could produce unexpected results by using the extra precision instead of rounding.

Arrays, by default, are unbounded, and Vertica allocates memory to accommodate the maximum binary size. To reduce this footprint, you can specify a maximum number of elements for an array or its maximum binary size. For more information about array bounds, see [Limits on Element Count and Collection Size](#) on the ARRAY reference page.

In this example, you might make the following changes:

- Shorten the product name and vendor name fields, for example VARCHAR(32).
- Lengthen the description field, for example VARCHAR(1000).
- Accept the suggested numeric precision and scale.
- Specify a maximum number of elements for the vendors array.

With these changes, the table definition becomes:

```
--> CREATE TABLE products(  
  id INT,  
  msrp NUMERIC(6,2),  
  name VARCHAR(),  
  description VARCHAR(),  
  vendors ARRAY[ROW(name VARCHAR(), price NUMERIC(6,2));]  
);
```

As a sanity check, start by loading the data file you used for INFER_TABLE_DDL. All rows should load successfully. The following query output has added carriage returns for readability:

```
--> COPY products FROM '/data/products/products.parquet' PARQUET;  
Rows Loaded  
-----  
      1  
(1 row)  
  
=> \x  
=> SELECT * FROM products;  
[ RECORD 1 ]-----  
id          | 1064  
msrp       | 329.99  
name       | 4k 48in TV  
description | something long goes here  
vendors    | [{"name":"Amazon","price":"299.99"}, {"name":"Best Buy","price":"289.99"}, {"name":"Bob's Hardware","price":"309.99"}]
```

Test with data

INFER_TABLE_DDL bases its recommendations on a small sample of your data. As you load more data you might find outliers. Before you use your new table in production, test it with more data.

In the following example, a data file contains values that do not satisfy the table definition:

```
=> COPY products FROM '/data/products/products2.parquet' PARQUET;
```

```
WARNING 9738: Some rows were rejected by the parquet parser
```

```
Rows Loaded
```

```
-----  
      2  
(1 row)  
  
=> \x  
=> SELECT * FROM products;  
[ RECORD 1 ]-----  
id          | 1064  
msrp       | 329.99  
name       | 4k 48in TV  
description | something long goes here  
vendors    | [{"name":"Amazon","price":"299.99"}, {"name":"Best Buy","price":"289.99"}, {"name":"Bob's Hardware","price":"309.99"}]  
[ RECORD 2 ]-----  
id          | 1271  
msrp       | 8999.99  
name       | professional kitchen appliance s  
description | product description goes here  
vendors    | [{"name":"Amazon","price":"8299.99"}, {"name":"Designer Solutions","price":"8999.99"}]
```

If you compare the query output to the previous query, one immediate difference is the width of the name column. The value in the second row uses the full VARCHAR(32) length and appears to be truncated.

By default, [COPY](#) truncates VARCHAR values that are too long instead of rejecting them. The warning from the COPY statement indicates that in addition to the name length, there is another problem that caused data not to be loaded.

COPY can [report rejected data to a \(different\) table](#). You can also direct COPY to [enforce VARCHAR lengths](#) instead of truncating:

```
=> COPY products FROM '/data/products/products2.parquet' PARQUET
```

```
Rows Loaded
```

```
-----  
      1  
(1 row)
```

Note that only one row of data is loaded this time instead of two, because ENFORCELENGTH rejects the too-long string.

You can query the rejections table for more information:

```
=> \x  
  
=> SELECT rejected_reason, rejected_data FROM products_rejected;  
[ RECORD 1 ]-----  
rejected_reason | The 34-byte value is too long for type varchar(32), column 3 (name)  
rejected_data   | professional kitchen appliance set  
[ RECORD 2 ]-----  
rejected_reason | In column 2: Value (11999.99) exceeds range of type NUMERIC(6,2)  
rejected_data   | 11999.99
```

The first rejection is caused by the long string. The second is caused by a price that exceeds the defined scale. You can increase both using ALTER TABLE:

```
=> ALTER TABLE products ALTER COLUMN name SET DATA TYPE VARCHAR(50);
```

```
=> ALTER TABLE products ALTER COLUMN msrp SET DATA TYPE NUMERIC(8,2);
```

With these changes, the data file now loads without errors:

```

=> TRUNCATE TABLE products;

=> DROP TABLE products_rejected;

=> COPY products FROM '/data/products/products2.parquet' PARQUET
ENFORCELENGTH REJECTED DATA AS TABLE products_rejected;

Rows Loaded
-----
      3
(1 row)

=> \x
=> SELECT * FROM products;
[ RECORD 1 ]-----
d      | 1064
msrp   | 329.99
name   | 4k 48in TV
description | something long goes here
vendors | [{"name":"Amazon","price":"299.99"},{"name":"Best Buy","price":"289.99"},{"name":"Bob's Hardware","price":"309.99"}]
[ RECORD 2 ]-----
d      | 1183
msrp   | 11999.99
name   | home theatre system
description | product description...
vendors | [{"name":"Amazon","price":"8949.99"},{"name":"Bob's Hardware","price":"9999.99"}]
[ RECORD 3 ]-----
d      | 1271
msrp   | 8999.99
name   | professional kitchen appliance set
description | product description goes here
vendors | [{"name":"Amazon","price":"8299.99"},{"name":"Designer Solutions","price":"8999.99"}]

=> SELECT rejected_reason, rejected_data FROM products_rejected;
(No rows)

```

Continue to load more data using the ENFORCELENGTH and REJECTED DATA options, adjusting your table definition as needed, until the rate of new problems drops to an acceptable level. Most data sets of any size contain some anomalies that will be rejected. You can use the [REJECTMAX](#) option to set a limit on rejections per data load; if the limit is exceeded, COPY aborts the load.

Data formats

INFER_TABLE_DDL supports data in Parquet, ORC, Avro, and JSON formats. The first three formats enforce a schema on each file, but JSON data can contain any mix of fields and data types. When inspecting JSON data, INFER_TABLE_DDL can [report multiple options](#). The iterative process of loading samples, examining the results, and adjusting the table definition is the same, but some details are different for JSON.

For data in other formats, including delimited text data, you cannot use INFER_TABLE_DDL. You can examine sample data and create your own initial table definition, and then test iteratively. Alternatively, you can [use a flex table to explore the data](#).

Flex tables

Flex tables are designed for data with an unknown or varying schema. While flex tables generally do not meet the performance needs of a production system, you can use them to explore data and develop a table definition. You can use flex tables with all data formats, including delimited (CSV).

A flex table has a special column, named `__raw__`, that contains all fields from data you load into it. Each row is independent and might have different fields in this column. You can use flex functions to explore this data and materialize individual columns in your table. When you have identified the columns that should consistently be part of your table, you can then define a regular (non-flex) table.

You can iterate by loading and exploring small amounts of data, as described in [Inference](#). However, flex tables allow you to load larger amounts of data without producing errors and rejections, so you might choose to start with a larger sample.

Column discovery

The simplest flex table does not specify any columns. In this example, the first thousand rows are pulled from a much larger data set:

```

-> CREATE FLEX TABLE reviews_flex();

-> COPY reviews_flex FROM '/home/data/reviews/sample_1000.json' PARSER FJSONPARSER();

Rows Loaded
-----
      1000
(1 row)

```

The [COMPUTE_FLEXTABLE_KEYS](#) function extrapolates field names and candidate data types from the raw data. The more data you have loaded the more work this function needs to do and the longer it takes to finish. If the function runs slowly for you, try a smaller sample size.

```

-> SELECT COMPUTE_FLEXTABLE_KEYS(reviews_flex);
      COMPUTE_FLEXTABLE_KEYS
-----
Please see public.reviews_flex_keys for updated keys
(1 row)

SELECT * FROM reviews_flex_keys;
 key_name | frequency | data_type_guess
-----
user_id   |    1000 | Varchar(44)
useful    |    1000 | Integer
text      |    1000 | Varchar(9878)
stars     |    1000 | Numeric(5,2)
review_id |    1000 | Varchar(44)
funny     |    1000 | Integer
date      |    1000 | Timestamp
cool      |    1000 | Integer
business_id |    1000 | Varchar(44)
(9 rows)

```

In this example, all 1000 rows have all of the fields. This suggests that the larger data set is probably consistent, particularly if the sample was taken from the middle. In this case, the data was exported from another database. Had the data been more varied, you would see different numbers of occurrences in the keys table.

COMPUTE_FLEXTABLE_KEYS, unlike INFER_TABLE_DDL, proposes lengths for VARCHAR values and precision and scale for NUMERIC values. The function uses the largest values found in the data in the table. Future data could exceed these limits, so make sure you are using representative data or a large-enough sample.

If you query a flex table using SELECT *, the results include the raw column. This column is in a binary format, so querying it is not especially useful. To see a sample of the data, query the fields explicitly, as if they were columns. The following example omits the text of the review, which COMPUTE_FLEXTABLE_KEYS reported as potentially quite large (VARCHAR(9878)):

```

=> \x
SELECT user_id, useful, stars, review_id, funny, date, cool, business_id
FROM reviews_flex ORDER BY date DESC LIMIT 3;
[ RECORD 1 ]-----
user_id   | mY8vqRndQ_jHel-kUZc-rw
useful    | 0
stars     | 5.0
review_id | viMRTXxVGZa_E0J5i3fD5A
funny     | 0
date      | 2021-01-28 01:25:04
cool      | 0
business_id | LsR1rENf9596Oo07QFjtaQ
[ RECORD 2 ]-----
user_id   | vLKy-xJoyeSAVhPbG8-Pfg
useful    | 0
stars     | 5.0
review_id | 8Bcq-HllpdDJ773AkNAUeg
funny     | 0
date      | 2021-01-27 16:08:53
cool      | 0
business_id | ljNN92X-WRVzhkHelgnlIA
[ RECORD 3 ]-----
user_id   | yixdPMh2UidS3qOquE1Yow
useful    | 0
stars     | 5.0
review_id | h_z6g8iOrvUgsLg-bkixVg
funny     | 0
date      | 2021-01-27 15:58:42
cool      | 0
business_id | WITPQwhKyEDogIXQfP0uYA

```

This sample shows several integer fields with values of 0. These fields (useful, funny, and cool) appear to be counters indicating how many people found the review to have those qualities. To see how often they are used, which might help you decide whether to include them in your table, you can use the COUNT function:

```

=> SELECT COUNT(useful) FROM reviews_flex WHERE useful > 0;
COUNT
-----
   548
(1 row)

=> SELECT COUNT(funny) FROM reviews_flex WHERE funny > 0;
COUNT
-----
   234
(1 row)

=> SELECT COUNT(cool) FROM reviews_flex WHERE cool > 0;
COUNT
-----
   296
(1 row)

```

All of the fields in this data except text are fairly small. How much of the review text you want to include depends on how you plan to use the data. If you plan to analyze the text, such as to perform sentiment analysis, you might set a larger size. If you don't plan to use the text, you might either ignore the text entirely or set a small size and allow the data to be truncated on load:

```

=> CREATE TABLE reviews(
  review_id VARCHAR(44), business_id VARCHAR(44), user_id VARCHAR(44),
  stars NUMERIC(5,2), date TIMESTAMP,
  useful INT, funny INT, cool INT);

=> COPY reviews FROM '/home/data/reviews/reviews_set1.json' PARSER FJSONPARSER() NO COMMIT;
WARNING 10596: Warning in UDX call in user-defined object [FJSONParser], code:
0, message: Data source contained keys which did not match table schema
HINT: SELECT key, sum(num_instances) FROM v_monitor.udx_events WHERE event_type
= 'UNMATCHED_KEY' GROUP BY key
Rows Loaded

-----
      10000
(1 row)

```

The JSON parser warns about keys found in the data that are not part of the table definition. Some other parsers require you to consume all of the fields. Consult the reference pages for specific parsers for more information about whether and how you can ignore fields.

To find out what unmatched fields appeared in the data, query the [UDX_EVENTS](#) system table:

```

=> SELECT key, SUM(num_instances) FROM UDX_EVENTS
WHERE event_type='UNMATCHED_KEY' AND transaction_id = CURRENT_TRANS_ID()
GROUP BY key;
key | SUM
-----+-----
text | 10000
(1 row)

```

The UDX_EVENTS table shows that the only unmatched field is the previously-seen text field. You can safely commit the load transaction. When you have tested with enough data to feel confident, you can suppress the parser warning as explained on [FJSONPARSER](#).

Complex types

Consider the following JSON data in a flex table:

```

=> CREATE FLEX TABLE products_flex();
COPY products_flex FROM '/home/data/products/sample.json' PARSER FJSONPARSER();
Rows Loaded

-----
      3
(1 row)

=> SELECT COMPUTE_FLEXTABLE_KEYS('products_flex');
          COMPUTE_FLEXTABLE_KEYS
-----+-----
Please see public.products_flex_j_keys for updated keys
(1 row)

=> SELECT * FROM products_flex_keys;
key_name | frequency | data_type_guess
-----+-----+-----
description |      3 | Varchar(58)
id          |      3 | Integer
msrp       |      3 | Numeric(10,3)
name       |      3 | Varchar(68)
vendors    |      3 | long varbinary(298)
(5 rows)

```

The vendors field has a type of LONG VARBINARY, but the name of the column implies a collection. You can use the [MAPTOSTRING](#) function to sample the data:

```
=> SELECT MAPTOSTRING(__raw__) FROM products_flex LIMIT 1;
```

MAPTOSTRING

```
{
  "description": "something long goes here",
  "id": "1064",
  "msrp": "329.99",
  "name": "4k 48in TV",
  "vendors": {
    "0.name": "Amazon",
    "0.price": "299.99",
    "1.name": "Best Buy",
    "1.price": "289.99",
    "2.name": "Bob's Hardware",
    "2.price": "309.99"
  }
}
(1 row)
```

By default, the JSON parser "flattens" JSON maps (key/value pairs). In this example, the value of the vendors field is presented as a set of six key/value pairs, but the key names (*number.name* and *number.price*) indicate that the data is more structured. Disabling this flattening makes the true structure of the JSON data more clear:

```
=> TRUNCATE TABLE products_flex;
```

```
=> COPY products_flex FROM '/home/data/products/sample.json'
```

```
PARSER FJSONPARSER();
```

```
Rows Loaded
```

```
-----
      3
(1 row)
```

```
=> SELECT MAPTOSTRING(__raw__) FROM products_flex LIMIT 1;
```

MAPTOSTRING

```
{
  "description": "something long goes here",
  "id": "1064",
  "msrp": "329.99",
  "name": "4k 48in TV",
  "vendors": {
    "0": {
      "name": "Amazon",
      "price": "299.99"
    },
    "1": {
      "name": "Best Buy",
      "price": "289.99"
    },
    "2": {
      "name": "Bob's Hardware",
      "price": "309.99"
    }
  }
}
(1 row)
```

This data indicates that the vendors field holds an array of structs with two fields, name and price. Using this information and the computed keys for the other fields in the data, you can define a table with strongly-typed columns:

```
-> CREATE TABLE products(
  id INT, name VARCHAR(100), msrp NUMERIC(8,2), description VARCHAR(1000),
  vendors );
```

After loading data, you can use an array function to confirm that the collection was loaded correctly:

```
-> COPY products FROM '/home/data/products/sample.json'
PARSER FJSONPARSER(flatten_maps=false);
Rows Loaded
-----
      3
(1 row)

-> SELECT EXPLODE(vendors) OVER() FROM products;
position |          value
-----|-----
      0 | [{"name":"Amazon","price":"299.99"}]
      1 | [{"name":"Best Buy","price":"289.99"}]
      2 | [{"name":"Bob's Hardware","price":"309.99"}]
      0 | [{"name":"Amazon","price":"8949.99"}]
      1 | [{"name":"Bob's Hardware","price":"9999.99"}]
      0 | [{"name":"Amazon","price":"8299.99"}]
      1 | [{"name":"Designer Solutions","price":"8999.99"}]
(7 rows)
```

Handling limitations of some file formats

The JSON format supports arrays, structs, and combinations of the two. Some formats are more limited. Delimited (CSV) data can represent arrays of scalar types, but not structs. Further, not all parsers that you can use with flex tables support complex types.

Consider the following delimited data:

```
id|msrp|name|vendors|prices
1064|329.99|4k 48in TV|[Amazon,Best Buy]|[299.99,289.99]
1183|11999.99|home theatre system|[Amazon,Bob's Hardware]|[8949.99,9999.99]
1271|8999.99|professional kitchen appliance set|[Amazon,Designer Solutions]|[829
9.99,8999.99]
```

You can load this data into a flex table using [FDELIMITEDPARSER](#), but the parser misinterprets the arrays:

```

-> CREATE FLEX TABLE catalog_flex();

-> COPY catalog_flex FROM '/home/data/catalog/sample.csv' PARSER FDELIMITEDPARSER();
Rows Loaded
-----
      3
(1 row)

-> SELECT MAPTOSTRING(__raw__) FROM catalog_flex LIMIT 1;
              MAPTOSTRING
-----
[
  "id": "1064",
  "msrp": "329.99",
  "name": "4k 48in TV",
  "prices": ,
  "vendors":
]
(1 row)

-> SELECT COMPUTE_FLEXTABLE_KEYS('catalog_flex');
              COMPUTE_FLEXTABLE_KEYS
-----
Please see public.catalog_flex_keys for updated keys
(1 row)

```

```

-> SELECT * FROM catalog_flex_keys;
key_name | frequency | data_type_guess
-----
id       |          3 | Integer
msrp     |          3 | Numeric(10,3)
name     |          3 | Varchar(68)
prices   |          3 |
vendors  |          3 |
(5 rows)

```

The parser has mistaken the arrays as strings, and COMPUTE_FLEXTABLE_KEYS has mistaken an array of numbers for an INTERVAL and an array of strings as a VARCHAR. These are limitations of flex tables used with certain file formats, not of Vertica in general. If you see unusual results, try adding real columns to the flex table:

```

-> CREATE FLEX TABLE catalog_flex(
  vendors ARRAY[VARCHAR(50), 10],
  prices ARRAY[Numeric(10,2), 10] );
WARNING 5727: Sort clause contains a Array attribute, catalog_flex.prices - data loads may be slowed significantly
HINT: Consider using a non-long type column for sorting or adding at least one such column to the table

```

For data exploration you need not be concerned with warnings such as this one. When you are ready to define a production table, heed any warnings you receive.

After loading the data, you can confirm that the arrays were loaded correctly:

```

-> SELECT EXPLODE(vendors, prices USING PARAMETERS explode_count=2) OVER()
AS (v_idx,vendor,p_idx,price)
FROM catalog_flex;
v_idx | vendor | p_idx | price
-----|-----|-----|-----
0 | Amazon | 0 | 299.99
0 | Amazon | 1 | 289.99
1 | Best Buy | 0 | 299.99
1 | Best Buy | 1 | 289.99
0 | Amazon | 0 | 8949.99
0 | Amazon | 1 | 9999.99
1 | Bob's Hardware | 0 | 8949.99
1 | Bob's Hardware | 1 | 9999.99
0 | Amazon | 0 | 8299.99
0 | Amazon | 1 | 8999.99
1 | Designer Solutions | 0 | 8299.99
1 | Designer Solutions | 1 | 8999.99
(12 rows)

```

Create table definition

You can continue to use flex tables to explore data, creating real columns for complex types as you encounter them. `FDELIMITEDPARSER` is specific to flex tables; for native tables (created with `CREATE TABLE`), `DELIMITED` is the default parser:

```

-> CREATE TABLE catalog(
  id INT, msrp NUMERIC(8,2), name VARCHAR(100),
  vendors ARRAY[VARCHAR(50), 10], prices ARRAY[NUMERIC(10,2), 10]);

-> COPY catalog FROM '/home/data/catalog/sample.csv';
Rows Loaded

-----
      3
(1 row)

-> SELECT * FROM catalog;
id | msrp | name | vendors | prices
-----|-----|-----|-----|-----
1064 | 329.99 | 4k 48in TV | ["Amazon","Best Buy"] | ["299.99","289.99"]
1183 | 11999.99 | home theatre system | ["Amazon","Bob's Hardware"] | ["8949.99","9999.99"]
1271 | 8999.99 | professional kitchen appliance set | ["Amazon","Designer Solutions"] | ["8299.99","8999.99"]
(3 rows)

```

Table types

Vertica has several types of tables. During initial exploration, your focus should be on whatever is most expedient for you; you will modify or replace the tables you build at this stage before you put them in production. As you get closer to production-ready definitions, pay more attention to the specific considerations for each table type.

Native (ROS) tables

Native tables store their data in ROS format in the database. After you have finalized table definitions, you can optimize the performance of your most important or frequent queries by creating projections.

If you are exploring data that is in multiple locations, using a native table for exploration can be easier than using external tables. With a native table, you can load data from many sources into the database. If multiple people are exploring the same data together, you do not need to grant additional permissions for an external file system or object store. You only need one person to have permission to read the files being loaded.

On the other hand, if you make a change to a native table definition that is not compatible with existing data, the change fails:

```

=> SELECT name FROM catalog;
      name
-----
4k 48in TV
home theatre system
professional kitchen appliance set
(3 rows)

=> ALTER TABLE catalog ALTER COLUMN name SET DATA TYPE VARCHAR(10);
ROLLBACK 2378: Cannot convert column "name" to type "varchar(10)"
HINT: Verify that the data in the column conforms to the new type

```

To make an incompatible change, you can create a new table and then use [INSERT](#) with SELECT to transform and copy existing data to the new table. For example, you can cast existing data to new types:

```

=> CREATE TABLE catalog2(
  id INT, msrp NUMERIC(8,2), name VARCHAR(10),
  vendors ARRAY[VARCHAR(50), 2],
  prices ARRAY[NUMERIC(10,2), 2] );

-- cannot directly insert:
=> INSERT INTO catalog2 SELECT * FROM catalog;
ERROR 4800: String of 19 octets is too long for type Varchar(10)

-- violating array bounds is also an error:
=> INSERT INTO catalog2
SELECT id, msrp, name::VARCHAR(10), vendors, prices FROM catalog;
ERROR 9227: Output array isn't big enough
DETAIL: Type limit is 2 elements, but value has 3 elements

-- cast to truncate:
=> INSERT INTO catalog2
SELECT id, msrp, name::VARCHAR(10),
       vendors::ARRAY[VARCHAR(50), 2],
       prices::ARRAY[NUMERIC(10,2), 2] FROM catalog;
OUTPUT
-----
 3
(1 row)

=> SELECT * FROM catalog2;
 id | msrp | name | vendors | prices
-----+-----+-----+-----+-----
1064 | 329.99 | 4k 48in TV | ["Amazon","Best Buy"] | ["299.99","289.99"]
1183 | 11999.99 | home theat | ["Amazon","Bob's Hardware"] | ["8949.99","9999.99"]
1271 | 8999.99 | profession | ["Amazon","Designer Solutions"] | ["8299.99","8999.99"]
(3 rows)

```

External tables

With an external table, Vertica reads data at query time instead of storing it in the database. External tables are a good choice when you do not need the performance of native tables, for example for older data or partitions that you query less frequently.

External tables are particularly useful when the external data is growing or changing, because you do not need to reload data yourself. However, this means you discover structural changes such as changed column types or new columns at query time rather than at load time.

You can drop an external table and recreate it to change its definition. Because the database does not store the data, replacing a table is not a destructive operation. During data exploration, you can treat external tables as lightweight and disposable.

Because the data is read at query time, you must ensure that your users have and retain permission to read the data in its original location. Depending on where the data is stored, you might need to take additional steps to manage access, such as creating AWS IAM roles on S3.

For more information, see [How external tables differ from native tables](#).

Flex tables

Flex tables are designed for data with an unknown or varying schema. They are a good choice for exploring data with varying fields or columns. JSON and delimited formats, in particular, do not embed a schema, so these formats are particularly prone to variation.

You can use flex tables as either native tables (`CREATE FLEX TABLE`) or external tables (`CREATE FLEX EXTERNAL TABLE`).

Flex tables trade flexibility for reduced performance and are not a good choice for production environments. You can [use flex tables to explore data](#) and then create standard (non-flex) native or external tables to deploy.

Schema changes

After you [develop a schema](#) for a table and continue to load data, you might find that some new data diverges from that schema. Sometimes new fields appear, and sometimes fields change data types or stop appearing. Depending on how volatile you expect your data to be, you might decide to load what you can and ignore the rest, or you might decide to update your table definition to handle the changes.

Typically, COPY rejects data that does not match the definition and loads the rest. You can monitor these rejections and adjust your table definition, as described in [Test with Data](#). Parsers for some formats have additional considerations:

- Parquet and ORC: by default, the table definition must include all columns. Alternatively, you can use loose schema matching to load only columns that are part of the table definition, ignoring others. Type mismatches that cannot be coerced are errors.
- JSON and Avro: the parser loads only the columns that are part of the table definition. If the data contains other columns, the parsers emit warnings. Type mismatches that cannot be coerced are errors.

Parquet and ORC

If you load Parquet or ORC data that contains extra columns, by default the load fails with an error:

```
-> CREATE TABLE orders_summary(orderid INT, accountid INT);
-> COPY orders_summary FROM '/data/orders.parquet' PARQUET;
ERROR 9135: Attempt to load 2 columns from a parquet source [/data/orders.parquet] that has 3 columns
```

If you do not know what the extra columns are, you can use [inference](#) to inspect a sample file. If the new columns are important, you can use [ALTER TABLE](#) to add them to the table definition and then load the data.

If the new columns are not important and you want to ignore them, you can use loose schema matching. Loose schema matching means that the parser loads columns whose names match the table definition and ignores any others. For the Parquet parser, loose schema matching also applies to struct fields.

Enable loose matching with the `do_soft_schema_match_by_name` parameter in the [PARQUET](#) or [ORC](#) parser:

```
-> COPY orders_summary FROM '/data/orders.parquet'
  PARQUET(do_soft_schema_match_by_name='true');
Rows Loaded
-----
      3
(1 row)
```

Loose schema matching allows you to ignore extra data. Missing data and mismatched data types are still errors. If loads fail with these errors, you can use inference to inspect the data and then alter your table definition.

JSON and Avro

By default, the [JSON](#) and [Avro](#) parsers skip fields in the data that are not part of the table definition and proceed with the rest of the load. This means that the JSON and Avro parsers are more flexible in the face of variability in the data, but also that you must monitor your loads more closely for new fields.

When creating tables that will use JSON or Avro data, a good first step is to [infer](#) a table definition from a sample file:

```

=> SELECT INFER_TABLE_DDL ('/data/rest1.json'
  USING PARAMETERS table_name='restaurants', format='json');
WARNING 9311: This generated statement contains one or more varchar/varbinary columns which default to length 80
--
=> CREATE TABLE restaurants(
  name VARCHAR(50),
  cuisine VARCHAR(25),
  location ARRAY[ROW(city VARCHAR(20), state VARCHAR(2)),50],
  hours ROW(open TIME, close TIME),
  menu ARRAY[ROW(item VARCHAR(50), price NUMERIC(8,2)),100]);
=> COPY restaurants FROM '/data/rest1.json' PARSER FJSONPARSER();
Rows Loaded
-----
      2
(1 row)

```

A second data file has some new fields. These parsers load what can be loaded and warn about the new data:

```

=> COPY restaurants FROM '/data/rest2.json' PARSER FJSONPARSER() NO COMMIT;
WARNING 10596: Warning in UDX call in user-defined object [FJSONParser], code: 0, message:
Data source contained keys which did not match table schema
HINT: SELECT key, sum(num_instances) FROM v_monitor.udx_events WHERE event_type = 'UNMATCHED_KEY' GROUP BY key
Rows Loaded
-----
      2
(1 row)

```

Loads that use the NO COMMIT option, as in this example, can recover from errors. Without NO COMMIT, COPY loads the data, skipping the new fields. If you change your table definition to handle the new fields and repeat the load, the table has two rows for each record, one with the new fields and one without. Use NO COMMIT to experiment, and use [ROLLBACK](#) to recover.

New fields are logged in the [UDX_EVENTS](#) system table:

```

-- from the HINT:
=> SELECT key, SUM(num_instances) FROM v_monitor.UDX_EVENTS
  WHERE event_type = 'UNMATCHED_KEY' AND transaction_id=CURRENT_TRANS_ID()
  GROUP BY key;
   key          | SUM
-----+-----
chain           | 1
menu.elements.calories | 7
(2 rows)

=> ROLLBACK;

```

The data file has two new fields, one at the top level and one in the existing menu complex-type column. To find out their data types, you can inspect the file or use [INFER_TABLE_DDL](#):

```
=> SELECT INFER_TABLE_DDL ('/data/rest2.json'
  USING PARAMETERS table_name='restaurants', format='json');
WARNING 9311: This generated statement contains one or more varchar/varbinary columns which default to length 80
          INFER_TABLE_DDL
```

Candidate matched 1 out of 1 total files:

```
create table "restaurants"(
  ;
  "cuisine" varchar,
  "hours" Row(
    "close" time,
    "open" time
  ),
  "location" Array[Row(
    "city" varchar,
    "state" varchar
  )],
  "menu" Array[Row(
    ;
    "item" varchar,
    "price" numeric(precision, scale)
  )],
  "name" varchar
);
(1 row)
```

You can use [ALTER TABLE](#) to add the new column and alter the menu column. With these changes, the data can be loaded without errors:

```
=> ALTER TABLE restaurants ADD COLUMN chain BOOLEAN;

=> ALTER TABLE restaurants ALTER COLUMN menu
SET DATA TYPE ARRAY[ROW(item VARCHAR(50), price NUMERIC(8,2), calories INT),100];

-- repeat the load:
COPY restaurants FROM '/data/rest2.json' PARSER FJSONPARSER();
Rows Loaded
-----
      2
(1 row)
```

ALTER TABLE affects future loads. Data already in the table has null values for the added column and field:

```
=> SELECT EXPLODE(name, chain, menu) OVER() FROM restaurants;
 name | chain | position | value
-----+-----+-----+-----
Pizza House | | 0 | {"item":"cheese pizza","price":"7.99","calories":null}
Pizza House | | 1 | {"item":"spinach pizza","price":"8.99","calories":null}
Pizza House | | 2 | {"item":"garlic bread","price":"4.99","calories":null}
Sushi World | | 0 | {"item":"maki platter","price":"21.95","calories":null}
Sushi World | | 1 | {"item":"tuna roll","price":"4.95","calories":null}
Greasy Spoon | f | 0 | {"item":"scrambled eggs","price":"3.99","calories":350}
Greasy Spoon | f | 1 | {"item":"grilled cheese","price":"3.95","calories":500}
Greasy Spoon | f | 2 | {"item":"tuna melt","price":"5.95","calories":600}
Greasy Spoon | f | 3 | {"item":"french fries","price":"1.99","calories":350}
Pasta World | t | 0 | {"item":"cheese pizza","price":"7.99","calories":1200}
Pasta World | t | 1 | {"item":"spinach pizza","price":"8.99","calories":900}
Pasta World | t | 2 | {"item":"garlic bread","price":"4.99","calories":250}
(12 rows)
```

If you are only interested in certain fields and don't care about new fields found in data loads, you can use the `suppress_warnings` parameter on the JSON or Avro parser to ignore them. If you suppress warnings, you can separately check for new fields from time to time with `INFER_TABLE_DDL` or by loading sample data with warnings and `NO COMMIT`.

Data load

Vertica provides many ways to read data. You can load data into the database from a variety of sources, optionally transforming it in various ways. You can read data in place in its original format using external tables. You can use streaming, and you can import data from other Vertica databases. See [Common use cases](#) for an introduction.

Most data-loading operations, including external tables, revolve around the `COPY` statement, which has many options. This book focuses on `COPY`-based reads (data load and external tables). Other data-loading options supported by Vertica are described elsewhere:

- [Apache Kafka integration](#)
- [Apache Spark integration](#)
- [Using the HCatalog Connector](#) (HCatalog is part of HDFS)
- [Database export and import](#)
- Clients: [Batch inserts using JDBC prepared statements](#), [Using batch inserts](#) (ODBC)
- Inserting individual rows and queried data into a table: [INSERT/INSERT...SELECT](#)

In this section

- [Working with external data](#)

Common use cases

Vertica supports a variety of use cases for reading data. Some of the most common are summarized here with links for more information. This is not a complete list of capabilities.

The `COPY` statement is central to loading data. See [Introduction to the COPY statement](#) for an overview of its use.

Loading data from files

You might have data, perhaps quite a bit of data, that you want to load into Vertica. These files might reside on shared storage, in the cloud, or on local nodes, and might be in a variety of formats.

For information about source locations, see [Specifying where to load data from](#). To handle data in different formats you specify a *parser*; for more information about the options, see [Data formats](#).

You are not limited to loading data "as-is"; you can also transform it during load. See [Transforming data during loads](#).

Automatically loading new files

You can create a data pipeline to automatically load new data. A data loader automatically loads new files from a location, so that you do not have to add them to Vertica manually. Automatically loading new data into ROS tables is an alternative to using external tables. External tables load selected data at query time, which can be convenient but also can incur API costs for object stores.

You execute a data loader explicitly. To run it periodically, you can put the execution in a scheduled stored procedure. See [Automatic load](#) for an example.

Loading data from other services

Apache Kafka is a platform for streaming data. Vertica supports streaming data to and from Kafka. See [Apache Kafka integration](#).

Apache Spark is a cluster-computing framework for distributed data. Vertica supports connecting to Spark for data. See [Apache Spark integration](#).

You can copy data directly from another Vertica cluster, instead of exporting to files and then loading those files. See [Database export and import](#).

Read data where it exists (don't import)

Instead of loading data into Vertica, you can read it in place using external tables. External tables can be advantageous in the following cases:

- If you want to explore data, such as in a data lake, before selecting data to load into Vertica.
- If you are one of several consumers sharing the same data, for example in a data lake, then reading it in place eliminates concerns about whether query results are up to date. There's only one copy, so all consumers see the same data.
- If your data changes rapidly but you do not want to stream it into Vertica, you can instead query the latest updates automatically.
- If you have lower-priority data in Vertica that you still want to be able to query.

When you query an external table, Vertica loads the data it needs from the external source. The Parquet and ORC columnar formats are optimized for this kind of load, so using external tables does not necessarily have a large effect on performance compared to loading data into Vertica native tables.

For more information about using external tables, see [Working with external data](#).

Complex types

Some data formats support complex types such as arrays and structs (sets of property-value pairs). You can use strong typing to define columns using the ARRAY and ROW types (including nesting) in native and external tables. See [Complex types](#). Alternatively, you can define tables using flexible (schemaless) complex types without fully specifying them. You can load flexible complex types in the Parquet, ORC, JSON, and Avro formats; see [Flexible complex types](#).

Unknown or evolving schema

Sometimes the schema for the data you want to load is unknown or changes over time, particularly with JSON data which does not embed a schema in data files. There are two primary ways to explore data with an unknown schema, explained in detail in [Data exploration](#):

- You can inspect sample data files and derive an initial table definition using the [INFER_TABLE_DDL](#) function. For tables with many or complex columns, using this function can save time and reduce manual effort.
- You can use [flex tables](#) to load schemaless data as blobs and inspect it using flex functions. Flex tables are best used for initial exploration of heterogeneous or poly-structured data, not in production databases, because the query-time extraction affects performance.

If your data changes over time, some parsers emit warnings about mismatches or new columns. You can use ALTER TABLE to modify the table definition as the data evolves. For more information and an example, see [Schema evolution](#).

Messy data

Sometimes data is not clean; values might not match the declared data types, or required values might be missing, or the parser might not be able to interpret a row for other reasons. You might still want to be able to load and explore this data. You can specify how error-tolerant to be and where to record information about rejected data using parameters to the COPY statement. For more information, see [Handling messy data](#).

Introduction to the COPY statement

Use the the [COPY](#) statement to load data. [COPY](#) is a large and versatile statement with many parameters; for all of the details, see the reference page. In its simplest form, [COPY](#) copies data from a source to a table, as follows:

```
=> COPY target-table FROM data-source;
```

You also use COPY when defining an external table:

```
=> CREATE EXTERNAL TABLE target-table (...) AS COPY FROM data-source;
```

Source data can be a data stream or a file path. For more about the FROM clause, see [Specifying where to load data from](#).

You can specify many details about a data load, including:

- [Global and column-specific options](#)
- [Data formats](#) and compression
- Which built-in parser to use, or which user-defined source, filters, or parser to use
- How to distribute the data load among database nodes ([Distributing a load](#))
- How to transform data during loading ([Transforming data during loads](#))
- What to do with data that could not be loaded ([Handling messy data](#))

For a complete list of parameters, see [Parameters](#).

Permissions

Generally, only a superuser can use the COPY statement to bulk-load data. Non-supersuers can use COPY in certain cases:

- To load from a stream on the host (such as STDIN) rather than a file (see [Streaming data via JDBC](#)).
- To load with the FROM LOCAL option.
- To load into a storage location where the user has been granted permission.
- To use a user-defined-load function for which the user has permission.

A non-superuser can also perform a [batch load with a JDBC prepared statement](#), which invokes COPY to load data as a background task.

Users must also have read permission to the source from which the data is to be loaded.

Global and column-specific options

You can specify some COPY options globally, for the entire COPY statement, or limit their scope to a column. For example, in the following COPY statement, the first column is delimited by '|' but the others are delimited by commas.

```
=> COPY employees(id DELIMITER '|', name, department) FROM ... DELIMITER ',';
```

You could specify a different default for null inputs for one column:

```
=> COPY employees(id, name, department NULL 'General Admin') FROM ... ;
```

Alternatively, you can use the COLUMN OPTION parameter to specify column-specific parameters instead of enumerating the columns:

```
=> COPY employees COLUMN OPTION (department NULL 'General Admin') FROM ... ;
```

Where both global and column-specific values are provided for the same parameter, the column-specific value governs those columns and the global one governs others.

All parameters can be used globally. The description of each parameter indicates whether it can be restricted to specific columns.

Specifying where to load data from

Each COPY statement requires either a FROM clause to indicate the location of the file or files being loaded or a SOURCE clause when using a user-defined source. For more about the SOURCE clause, see [Parameters](#). This section covers use of the FROM clause.

Loading from a specific path

Use the [path-to-data](#) argument to indicate the location of one or more files to load. You can load data from the following locations:

- The local file system.
- NFS, through a mount point on the local file system.
- [S3 object store](#), [Google Cloud Storage \(GCS\) object store](#), and [Azure Blob Storage object store](#). If a data file you want to read resides in an S3 bucket that uses server-side encryption, you might need to set [additional parameters](#).
- [HDFS file system](#). If a data file you want to read resides on an HDFS cluster that uses Kerberos authentication, Vertica uses the current user's principal, session [doAs](#) user, or session delegation token. See [Accessing kerberized HDFS data](#) for more information about these options.

If the path is a URL, you must use URL encoding for the '%' character. Otherwise, URL encoding ('%NN' where NN is a two-digit hexadecimal number) is permitted but not required.

When copying from the local file system, the COPY statement expects to find files in the same location on every node that participates in the query. If you are using NFS, then you can create an NFS mount point on each node. Doing so allows all database nodes to participate in the load for better performance without requiring files to be copied to all nodes.

Treat NFS mount points as local files in paths:

```
=> COPY sales FROM '/mount/sales.dat' ON ANY NODE;
```

You can specify more than one path in the same COPY statement, as in the following example.

```
=> COPY myTable FROM 'webhdfs:///data/sales/01/*.dat', 'webhdfs:///data/sales/02/*.dat',  
'webhdfs:///data/sales/historical.dat';
```

For files in HDFS, you can specify a name service ([hadoopNS](#)). In this example, the COPY statement is part of the definition of an external table:

```
=> CREATE EXTERNAL TABLE users (id INT, name VARCHAR(20))
AS COPY FROM 'webhdfs://hadoopNS/data/users.csv';
```

If [path-to-data](#) resolves to a storage location on a local file system, and the user invoking COPY is not a superuser, these permissions are required:

- The storage location must have been created with the USER option (see [CREATE LOCATION](#)).
- The user must already have been granted READ access to the storage location where the file or files exist, as described in [GRANT \(storage location\)](#).

Vertica prevents symbolic links from allowing unauthorized access.

Loading with wildcards (glob)

You can invoke COPY for a large number of files in a shared directory with a single statement such as:

```
=> COPY myTable FROM '/data/manyfiles/*.dat' ON ANY NODE;
```

The glob (*) must indicate a set of files, not directories. The following statement fails if [/data/manyfiles](#) contains any subdirectories:

```
=> COPY myTable FROM '/data/manyfiles/**' ON ANY NODE;
```

If [/data/manyfiles](#) contains subdirectories that contain files, you can use a glob in the path for the subdirectories:

```
=> COPY myTable FROM '/data/manyfiles/*/*' ON ANY NODE;
```

Sometimes a directory structure partitions the data, as in the following example:

```
path/created=2016-11-01/*
path/created=2016-11-02/*
path/created=2016-11-03/*
path/...
```

You still use a glob to read the data, but you can also read the partition values themselves (creation date, in this case) as table columns. See [Partitioned data](#).

Using a wildcard with the ON ANY NODE clause expands the file list on the initiator node. This command then distributes the individual files among all nodes, so that the COPY workload is evenly distributed across the entire cluster. ON ANY NODE is the default for all file systems other than Linux.

Loading from a Vertica client

Use COPY LOCAL to load files on a client system to the Vertica database. For example, to copy a GZIP file from your local client, use a command such as this:

```
=> COPY store.store_dimension FROM LOCAL '/usr/files/my_data/input_file' GZIP;
```

You can use a comma-separated list to load multiple files of the same compression type. COPY LOCAL then concatenates the files into a single file, so you cannot combine files with different compression types in the list. When listing multiple files, be sure to specify the type of every input file, such as BZIP, as shown:

```
=> COPY simple_table FROM LOCAL 'input_file.bz' BZIP, 'input_file.bz' BZIP;
```

You can load data from a local client from STDIN, as follows:

```
=> COPY simple_table FROM LOCAL STDIN;
```

Loading from Kafka or Spark

For information about streaming data from Kafka, see [Apache Kafka integration](#).

For information about using Vertica with Spark data, see [Apache Spark integration](#).

Loading data from an IDOL CFS client

The IDOL Connector Framework Server (CFS) VerticalIndexer feature lets CFS clients connect to your Vertica database using ODBC. After it is connected, CFS uses COPY...FROM LOCAL statements to load IDOL document metadata into an existing flex table. For more information, see the [Using flex tables for IDOL data](#) section in Using Flex Tables.

Partitioned data

Data files are sometimes partitioned in the file system using the directory structure. Partitioning allows you to move values out of the raw data, where they have to be included for each row, and into the directory structure. Partitioning can improve query performance by allowing entire directories to be skipped. Partitioning can also save disk space if partition values are not repeated in the data.

There are two important aspects to working with partitioned data:

- Telling COPY how to extract column values from paths.
- Enabling partition pruning, a performance optimization.

Partitions as directory structure

Partitioning is reflected in the directory structure of the data files. In Hive-style partitioning, each directory name contains the column name and the value:

```
/data/created=2016-11-01/*  
/data/created=2016-11-02/*  
/data/created=2016-11-03/*  
/data/...
```

The files in the globs do not contain a `created` column because this information is expressed through the file system. Vertica can read the partitioned values (dates, in this example) into a table column (`created` , in this example).

Data can be partitioned by more than one value:

```
/data/created=2016-11-01/region=northeast/*  
/data/created=2016-11-01/region=central/*  
/data/created=2016-11-01/region=southeast/*  
/data/created=2016-11-01/...  
/data/created=2016-11-02/region=northeast/*  
/data/created=2016-11-02/region=central/*  
/data/created=2016-11-02/region=southeast/*  
/data/created=2016-11-02/...  
/data/created=2016-11-03/...  
/data/...
```

Another way to partition data is to use the values directly, without the column names:

```
/data/2017/01*  
/data/2017/02*  
/data/2017/03*  
/data/...
```

In this case, you have to use an expression to tell COPY how to extract columns and values from the paths, for example to read the first level as a year and the second as a month.

The syntax for loading partitioned data differs for [Hive-style](#) and [other](#) partitioning schemes. For both schemes, list partition columns in the PARTITION COLUMNS clause. Doing so allows Vertica to improve query performance when predicates involve partition columns by eliminating irrelevant partitions from consideration.

COPY syntax for Hive-style partitions

Consider the following partition layout:

```
/data/created=2016-11-01/region=northeast/*  
/data/created=2016-11-01/region=central/*  
/data/created=2016-11-01/...  
/data/created=2016-11-02/region=northeast/*  
/data/created=2016-11-02/region=central/*  
/data/created=2016-11-02/...  
/data/...
```

To load values for the `created` and `region` columns, use wildcards (globs) in the COPY path and the PARTITION COLUMNS option:

```
-> CREATE EXTERNAL TABLE records (id int, name varchar(50), created date, region varchar(50))  
AS COPY FROM 'webhdfs:///data/*/*'  
PARTITION COLUMNS created, region;
```

The path includes one wildcard (*) for each level of directory partitioning and then one more for the files. The number of wildcards must be at least one more than the number of partitioned columns. Data files must include at least one real column; you cannot represent data entirely through directory structure.

The first part of each partition directory name must match the column name in the table definition. COPY parses the string after the = for the values. Empty values, for example a directory named `created=`, are treated as null values. For backward compatibility, a value of `__HIVE_DEFAULT_PARTITION__` also means null.

Values that cannot be coerced to the correct types are rejected in the same way that non-coercible values in data are rejected.

The PARTITION COLUMNS option specifies the partition columns in order.

If data is partitioned by more than one value, the partitions must appear in the same order in all directory paths in the glob even though the directory names contain the column name.

COPY syntax for other partition schemes

Consider the following partition layout:

```
/data/reviews/2023/07/*.json
/data/reviews/2023/08/*.json
/data/reviews/2023/09/*.json
/data/reviews/...
```

Suppose you want to load this data into the following table:

```
-> CREATE TABLE reviews(review_id VARCHAR, stars FLOAT, year INT, month INT);
```

You can use the [CURRENT_LOAD_SOURCE](#) function to read values out of the path. The function takes an integer argument, which is the position in a / - delimited path. For example, in the path `/data/reviews/2023/09/*.json`, `CURRENT_LOAD_SOURCE(3)` returns `2023`.

The following statement loads this data:

```
-> COPY reviews
  (review_id, stars,
   year AS CURRENT_LOAD_SOURCE(3)::INT,
   month AS CURRENT_LOAD_SOURCE(4)::INT)
FROM 'data/reviews/**/*.json' PARSER FJSONPARSER();
```

The same approach works for external tables. For external tables, use the PARTITION COLUMNS clause to tell Vertica which columns can benefit from partition pruning, a performance optimization:

```
-> CREATE EXTERNAL TABLE reviews
  (review_id VARCHAR, stars FLOAT, year INT, month INT)
  AS COPY (review_id, stars,
   year AS CURRENT_LOAD_SOURCE(3)::INT,
   month AS CURRENT_LOAD_SOURCE(4)::INT)
FROM 'data/reviews/**/*.json'
PARTITION COLUMNS year, month
PARSER FJSONPARSER();
```

Query execution

When executing queries with predicates, Vertica skips partitioned subdirectories that do not satisfy the predicate. This process is called *partition pruning* and it can significantly improve query performance. The following example reads only the partitions for the specified region, for all dates. Although the data is also partitioned by date, the query does not restrict the date.

```
-> SELECT * FROM records WHERE region='northeast';
```

To verify that Vertica is pruning partitions, look in the [QUERY_EVENTS](#) system table for the PARTITION_PATH_PRUNED event type. Alternatively, you can use the `vsq! \o meta-command` with `grep` to look in the explain plan, before running a query, for a message containing "unmatched partitions have been pruned":

```

=> \0 | grep -l pruned
=> EXPLAIN SELECT * FROM sales WHERE year = 2022;

3[label = "LoadStep: sales
(1 paths with unmatched partition have been pruned from DELIMITED source list)
(year = 2022)
Unc: Integer(8)
Unc: Integer(8)
Unc: Integer(8)", color = "brown", shape = "box"];

=> \0

```

Partitions on object stores

When reading partitioned data from a file system, COPY can prune unneeded directories at each level, skipping entire directories of files. Object stores (S3, GCS, and Azure) do not have directories, so COPY cannot prune paths in the same way.

By default, when querying data on an object store, COPY first fetches a list of all object names. It then prunes unneeded ones before fetching the objects themselves. This approach is called flat listing. Accessing object stores can have high latency, and flat listing maximizes the number of results returned per request. Flat listing retrieves more object names than are needed but does so in as few calls to the object store as possible. In most cases this strategy is an acceptable tradeoff.

If the number of partitions at each level is large, or if there are many layers of partitioning, fetching all of the object names can have a noticeable performance cost. In this situation, you can set the [ObjectStoreGlobStrategy](#) configuration parameter to have COPY use hierarchical listing instead of flat listing. With hierarchical listing, COPY fetches information about objects one level at a time, so that COPY can prune unproductive paths earlier.

Consider data that is partitioned by date and then by region:

```

/data/created=2016-11-01/region=northeast/*
/data/created=2016-11-01/region=central/*
/data/created=2016-11-01/region=southeast/*
/data/created=2016-11-01/...
/data/created=2016-11-02/region=northeast/*
/data/created=2016-11-02/region=central/*
/data/created=2016-11-02/region=southeast/*
/data/created=2016-11-02/...
/data/created=2016-11-03/...
/data/...

```

Suppose a query needs only `created=2016-11-02` and `region=central`. With the flat strategy, COPY retrieves the names of all objects in all dates and all regions before pruning most of them. With the hierarchical strategy, COPY first fetches the names of all of the `created` values, without expanding the paths further. In a second call, it then fetches the names of all of the `region` values below only that date, ignoring other paths. Finally, it fetches the names of the objects only below that path.

Creating partition structures

To create partitioned file structures, you can use Hive or the [file exporters](#). For information about using Hive, see [Hive primer for Vertica integration](#).

You can create partitions for columns of any simple data type. As a best practice, however, you should avoid partitioning columns with BOOLEAN, FLOAT, and NUMERIC types.

Data formats

COPY supports many data formats, detailed in the sections that follow. You specify a data format by specifying a parser.

By default, COPY uses the DELIMITED parser ([Delimited data](#)) to load raw data into the database. Raw input data must be in UTF-8, delimited text format. Other parsers support other data formats.

The syntax for specifying which parser to use varies. The description of each parser includes this information.

The same COPY statement cannot mix raw data types that require different parsers, such as NATIVE and FIXEDWIDTH. You can, however, load data of different formats, using different parsers, into the same table using separate COPY statements.

For information about verifying input data formats, see [Handling Non-UTF-8 input](#).

All parsers described in this section can be used with conventional tables (those created with CREATE TABLE or CREATE EXTERNAL TABLE). Some also support Flex tables (CREATE FLEX TABLE). For more information specific to Flex tables, see [Using flex table parsers](#).

All parsers support all primitive data types and several support one-dimensional arrays of primitive types. Some parsers support other complex types. See the documentation of individual parsers for information about supported types.

- [JSON data](#)
- [Avro data](#)
- [Matches from regular expressions](#)
- [Common event format \(CEF\) data](#)

Delimited data

If you do not specify another parser, Vertica defaults to the [DELIMITED parser](#). You can specify the delimiter, escape characters, how to handle null values, and other parameters in the COPY statement.

The following example shows the default behavior, in which the delimiter character is '|'

```
=> CREATE TABLE employees (id INT, name VARCHAR(50), department VARCHAR(50));
CREATE TABLE

=> COPY employees FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 42|Sheldon Cooper|Physics
>> 17|Howard Wolowitz|Astronomy
>> \.

=> SELECT * FROM employees;
id | name | department
-----+-----
17 | Howard Wolowitz | Astrophysics
42 | Sheldon Cooper | Physics
(2 rows)
```

By default, collection values are delimited by brackets and elements are delimited by commas. Collections must be one-dimensional arrays or sets of scalar types.

```
=> CREATE TABLE researchers (id INT, name VARCHAR, grants ARRAY[VARCHAR], values ARRAY[INT]);
CREATE TABLE

=> COPY researchers FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 42|Sheldon Cooper|[US-7376,DARPA-1567]|[65000,135000]
>> 17|Howard Wolowitz|[NASA-1683,NASA-7867,SPX-76]|[16700,85000,45000]
>> \.

=> SELECT * FROM researchers;
id | name | grants | values
-----+-----
17 | Howard Wolowitz | ["NASA-1683","NASA-7867","SPX-76"] | [16700,85000,45000]
42 | Sheldon Cooper | ["US-7376","DARPA-1567"] | [65000,135000]
(2 rows)
```

To use a special character as a literal, prefix it with an escape character. For example, to include a literal backslash () in the loaded data (such as when including a file path), use two backslashes (\). COPY removes the escape character from the input when it loads escaped characters.

When loading delimited data, two consecutive delimiters indicate a null value, unless the NULL parameter is set otherwise. The final delimiter is optional. For example, the following input is valid for the previous table:

```
=> COPY employees FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 45|Raj|
>> 21|Leonard||
>> \.

=> SELECT * FROM employees;
 id | name | department
-----+-----
 21 | Leonard |
 42 | Raj |
(2 rows)
```

By default, if the data has too few values, the load fails. You can use the TRAILING NULLCOLS option to accept any number of missing columns and treat their values as null.

Vertica assumes that data is in the UTF-8 encoding.

The options specific to the DELIMITED parser and their default values are:

Option	Default
DELIMITER	
ENCLOSED BY	"
ESCAPE	\
NULL	" (empty string)
COLLECTIONOPEN	[
COLLECTIONCLOSE]
COLLECTIONDELIMITER	,
COLLECTIONNULLELEMENT	null
COLLECTIONENCLOSE	" (double quote)
TRAILING NULLCOLS	(none)

To load delimited data into a Flex table, use the [FDELIMITEDPARSER](#) parser.

Changing the column separator (DELIMITER)

The default COPY delimiter is a vertical bar ('|'). The DELIMITER is a single ASCII character used to separate columns within each record of an input source. Between two delimiters, COPY interprets all string data in the input as characters. Do not enclose character strings in quotes, because quote characters are also treated as literals between delimiters.

You can define a different delimiter using any ASCII value in the range E'000' to E'177' inclusive. For instance, if you are loading CSV data files, and the files use a comma (',') character as a delimiter, you can change the default delimiter to a comma. You cannot use the same character for both the DELIMITER and NULL options.

If the delimiter character is among a string of data values, use the ESCAPE AS character (" by default) to indicate that the delimiter should be treated as a literal.

The COPY statement accepts empty values (two consecutive delimiters) as valid input data for CHAR and VARCHAR data types. COPY stores empty columns as an empty string (''). An empty string is not equivalent to a NULL string.

To indicate a non-printing delimiter character (such as a tab), specify the character in extended string syntax (E'...'). If your database has [StandardConformingStrings](#) enabled, use a Unicode string literal (U&'...'). For example, use either E't' or U'\0009' to specify tab as the delimiter.

The following example loads data from a comma-separated file:

```
=> COPY employees FROM ... DELIMITER ',';
```

In the following example, the first column has a column-specific delimiter:

```
=> COPY employees(id DELIMITER ':', name, department) FROM ... DELIMITER ',';
```

Changing collection delimiters (COLLECTIONDELIMITER, COLLECTIONOPEN, COLLECTIONCLOSE)

The DELIMITER option specifies the value that separates columns in the input. For a column with a collection type (ARRAY or SET), a delimiter is also needed between elements of the collection. In addition, the collection itself has start and end markers. By default, collections are enclosed in brackets and elements are delimited by commas, but you can change these values.

In the following example, collections are enclosed in braces and delimited by periods.

```
=> COPY researchers FROM STDIN COLLECTIONOPEN '{' COLLECTIONCLOSE '}' COLLECTIONDELIMITER '.';
```

Enter data to be copied followed by a newline.

End with a backslash and a period on a line by itself.

```
>> 19|Leonard|{"us-1672"."darpa-1963"}|{16200.16700}
```

```
>> \.
```

```
=> SELECT * FROM researchers;
```

```
id | name | grants | values
```

```
-----+-----+-----+-----  
17 | Howard Wolowitz | ["NASA-1683","NASA-7867","SPX-76"] | [16700,85000,45000]
```

```
42 | Sheldon Cooper | ["US-7376","DARPA-1567"] | [65000,135000]
```

```
19 | Leonard | ["us-1672","darpa-1963"] | [16200,16700]
```

```
(3 rows)
```

Changing the character enclosing column or collection values (ENCLOSED BY, COLLECTIONENCLOSE)

The ENCLOSED BY parameter lets you set an ASCII character to delimit characters to embed in string values. The enclosing character is not considered to be part of the data if and only if it is the first and last character of the input. You can use any ASCII value in the range E'\001' to E'\177' inclusive (any ASCII character except NULL: E'\000') for the ENCLOSED BY value. Using double quotation marks (") is common, as shown in the following example.

```
=> COPY employees FROM STDIN ENCLOSED BY '"';
```

Enter data to be copied followed by a newline.

End with a backslash and a period on a line by itself.

```
>> 21|Leonard|Physics
```

```
>> 42|"Sheldon"|"Physics"
```

```
>> 17|Rajesh "Raj" K|Astronomy
```

```
>> \.
```

```
=> SELECT * FROM employees;
```

```
id | name | department
```

```
-----+-----+-----  
17 | Rajesh "Raj" K | Astronomy
```

```
21 | Leonard | Physics
```

```
42 | Sheldon | Physics
```

```
(3 rows)
```

Notice that while ENCLOSED BY is a double quote, the embedded quotes in Rajesh's name are treated as part of the data because they are not the first and last characters in the column. The quotes that enclose "Sheldon" and "Physics" are dropped because of their positions.

Within a collection value, the COLLECTIONENCLOSE parameter is like ENCLOSED BY for individual elements of the collection.

Changing the null indicator (NULL)

By default, an empty string (') for a column value means NULL. You can specify a different ASCII value in the range E'\001' to E'\177' inclusive (any ASCII character except NULL: E'\000') as the NULL indicator. You cannot use the same character for both the DELIMITER and NULL options.

A column containing one or more whitespace characters is not NULL unless the sequence of whitespace exactly matches the NULL string.

A NULL is case-insensitive and must be the only value between the data field delimiters. For example, if the null string is NULL and the delimiter is the default vertical bar (|):

|NULL| indicates a null value.

| NULL | does not indicate a null value.

When you use the COPY statement in a script, you must substitute a double-backslash for each null string that includes a backslash. For example, the scripts used to load the example database contain:

```
COPY ... NULL E'\n' ...
```

Changing the null indicator for collection values (COLLECTIONNULLELEMENT)

The NULL option specifies the value to be treated as null for a column value. For a column with a collection type (ARRAY or SET), a separate option specifies how to interpret null *elements*. By default, "null" indicates a null value. An empty value, meaning two consecutive element delimiters, does *not* indicate null:

```
=> COPY researchers FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 17|Howard|["nasa-143",,"nasa-6262"]|[10000,1650,15367]
>> 19|Leonard|["us-177",null,"us-6327"]|[16200,64000,26500]
>> \.

=> SELECT * FROM researchers;
id | name | grants | values
-----+-----+-----
17 | Howard | ["nasa-143",,"nasa-6262"] | [10000,1650,15367]
19 | Leonard | ["us-177",null,"us-6327"] | [16200,64000,26500]
(2 rows)
```

Use COLLECTIONNULLELEMENT to specify a different value, as in the following example.

```
=> COPY researchers from STDIN COLLECTIONNULLELEMENT 'x';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 42|Sheldon|[x,"us-1672"]|[x,165000]
>> \.

=> SELECT * FROM researchers;
id | name | grants | values
-----+-----+-----
17 | Howard | ["nasa-143",,"nasa-6262"] | [10000,1650,15367]
19 | Leonard | ["us-177",null,"us-6327"] | [16200,64000,26500]
42 | Sheldon | [null, "us-1672"] | [null,165000]
(3 rows)
```

Filling missing columns (TRAILING NULLCOLS)

By default, COPY fails if the input does not contain enough columns. Use the TRAILING NULLCOLS option to instead insert NULL values for any columns that lack data. This option cannot be used with columns that have a NOT NULL constraint.

The following example demonstrates use of this option.

```
=> CREATE TABLE z (a INT, b INT, c INT );
```

```
--- insert with enough data:
```

```
=> INSERT INTO z VALUES (1, 2, 3);
```

```
=> SELECT * FROM z;
```

```
a | b | c
---+---+---
1 | 2 | 3
(1 row)
```

```
--- insert deficient data:
```

```
=> COPY z FROM STDIN TRAILING NULLCOLS;
```

Enter data to be copied followed by a newline.

End with a backslash and a period on a line by itself.

```
>> 4 | 5 | 6
```

```
>> 7 | 8
```

```
>> \.
```

```
=> SELECT * FROM z;
```

```
a | b | c
---+---+---
1 | 2 | 3
4 | 5 | 6
7 | 8 |
(3 rows)
```

Changing the escape character (ESCAPE AS, NO ESCAPE)

You can specify an escape character, which enables any special characters to be treated as part of the data. For example, if an element from a CSV file should contain a comma, you can indicate that by pre-pending the escape character to the comma in the data. The default escape character is a backslash ().

To change the default to a different character, use the ESCAPE AS option. You can set the escape character to be any ASCII value in the range `E'\001'` to `E'\177'` inclusive.

If you do not want any escape character and want to prevent any characters from being interpreted as escape sequences, use the NO ESCAPE option.

ESCAPE AS and NO ESCAPE can be set at both the column and global levels.

Changing the end-of-line character (RECORD TERMINATOR)

To specify the literal character string that indicates the end of a data file record, use the RECORD TERMINATOR parameter, followed by the string to use. If you do not specify a value, then Vertica attempts to determine the correct line ending, accepting either just a linefeed (`E'\n'`) common on UNIX systems, or a carriage return and linefeed (`E'\r\n'`) common on Windows platforms.

For example, if your file contains comma-separated values terminated by line feeds that you want to maintain, use the RECORD TERMINATOR option to specify an alternative value:

```
=> COPY mytable FROM STDIN DELIMITER ',' RECORD TERMINATOR E'\n';
```

To specify the RECORD TERMINATOR as non-printing characters, use either the extended string syntax or Unicode string literals. The following table lists some common record terminator characters. See [String Literals](#) for an explanation of the literal string formats.

Extended String Syntax	Unicode Literal String	Description	ASCII Decimal
<code>E'\b'</code>	<code>U&'\0008'</code>	Backspace	8
<code>E'\t'</code>	<code>U&'\0009'</code>	Horizontal tab	9
<code>E'\n'</code>	<code>U&'\000a'</code>	Linefeed	10
<code>E'\f'</code>	<code>U&'\000c'</code>	Formfeed	12

E\r'	U&'\000d'	Carriage return	13
E\'	U&'\005c'	Backslash	92

If you use the RECORD TERMINATOR option to specify a custom value, be sure the input file matches the value. Otherwise, you may get inconsistent data loads.

Note

The record terminator cannot be the same as DELIMITER , NULL , ESCAPE , or ENCLOSED BY .

If using JDBC, Vertica recommends that you use the following value for RECORD TERMINATOR :

```
System.getProperty("line.separator")
```

Binary (native) data

You can load binary data using the **NATIVE** parser option, except with **COPY LOCAL** , which does not support this option. Since binary-format data does not require the use and processing of delimiters, it precludes the need to convert integers, dates, and timestamps from text to their native storage format, and improves load performance over delimited data. All binary-format files must adhere to the formatting specifications described in [Appendix: creating native binary format files](#) .

Native binary format data files are typically larger than their delimited text format counterparts, so compress the data before loading it. The **NATIVE** parser does not support concatenated compressed binary files. You can load native (binary) format files when developing plug-ins to ETL applications.

There is no copy format to load binary data byte-for-byte because the column and record separators in the data would have to be escaped. Binary data type values are padded and translated on input, and also in the functions, operators, and casts supported.

Loading hexadecimal, octal, and bitstring data

You can use the formats hexadecimal, octal, and bitstring only to load binary columns. To specify these column formats, use the **COPY** statement's **FORMAT** options:

- Hexadecimal
- Octal
- Bitstring

The following examples illustrate how to use the **FORMAT** option.

1. Create a table:

```
=> CREATE TABLE t(oct VARBINARY(5),
  hex VARBINARY(5),
  bitstring VARBINARY(5) );
```

2. Create the projection:

```
=> CREATE PROJECTION t_p(oct, hex, bitstring) AS SELECT * FROM t;
```

3. Use a **COPY** statement with the **STDIN** clause, specifying each of the formats:

```
=> COPY t (oct FORMAT 'octal', hex FORMAT 'hex',
  bitstring FORMAT 'bitstring')
  FROM STDIN DELIMITER ',';
```

4. Enter the data to load, ending the statement with a backslash () and a period (.) on a separate line:

```
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 141142143144145,0x6162636465,0110000101100010011000110110010001100101
>> \.
```

5. Use a select query on table **t** to view the input values results:

```
=> SELECT * FROM t;
oct | hex | bitstring
-----+-----+-----
abcde | abcde | abcde
(1 row)
```

COPY uses the same default format to load binary data, as used to input binary data. Since the backslash character (`\`) is the default escape character, you must escape octal input values. For example, enter the byte `'\141'` as `'\\141'`.

Note
If you enter an escape character followed by an invalid octal digit or an escape character being escaped, **COPY** returns an error.

On input, **COPY** translates string data as follows:

- Uses the [HEX_TO_BINARY](#) function to translate from hexadecimal representation to binary.
- Uses the [BITSTRING_TO_BINARY](#) function to translate from bitstring representation to binary.

Both functions take a `VARCHAR` argument and return a `VARBINARY` value.

You can also use the escape character to represent the (decimal) byte 92 by escaping it twice; for example, `'\\'\\'`. Note that `vsq` inputs the escaped backslash as four backslashes. Equivalent inputs are hex value `'0x5c'` and octal value `'\134'` ($134 = 1 \times 8^2 + 3 \times 8^1 + 4 \times 8^0 = 92$).

You can load a delimiter value if you escape it with a backslash. For example, given delimiter `|`, `'\\001\\002'` is loaded as `{ 1,124,2 }`, which can also be represented in octal format as `'\\001\\174\\002'`.

If you insert a value with more bytes than fit into the target column, **COPY** returns an error. For example, if column `c1` is `VARBINARY(1)`:

```
=> INSERT INTO t (c1) values ('ab'); ERROR: 2-byte value too long for type Varbinary(1)
```

If you implicitly or explicitly cast a value with more bytes than fit the target data type, **COPY** silently truncates the data. For example:

```
=> SELECT 'abcd'::binary(2);
binary
-----
ab
(1 row)
```

Hexadecimal data

The optional `'0x'` prefix indicates that a value is hexadecimal, not decimal, although not all hexadecimal values use A-F; for example, 5396. **COPY** ignores the `0x` prefix when loading the input data.

If there are an odd number of characters in the hexadecimal value, the first character is treated as the low nibble of the first (furthest to the left) byte.

Octal data

Loading octal format data requires that each byte be represented by a three-digit octal code. The first digit must be in the range [0,3] and the second and third digits must both be in the range [0,7].

If the length of an octal value is not a multiple of three, or if one of the three digits is not in the proper range, the value is invalid and **COPY** rejects the row in which the value appears. If you supply an invalid octal value, **COPY** returns an error. For example:

```
=> SELECT '\\000\\387'::binary(8);
ERROR: invalid input syntax for type binary
```

Rows that contain binary values with invalid octal representations are also rejected. For example, **COPY** rejects `'\\008'` because `'\ 008'` is not a valid octal number.

BitString data

Loading bitstring data requires that each character must be zero (0) or one (1), in multiples of eight characters. If the bitstring value is not a multiple of eight characters, **COPY** treats the first n characters as the low bits of the first byte (furthest to the left), where n is the remainder of the value's length, divided by eight.

Examples

The following example shows `VARBINARY HEX_TO_BINARY(VARCHAR)` and `VARCHAR TO_HEX(VARBINARY)` usage.

1. Create table `t` and its projection with binary columns:

```
=> CREATE TABLE t (c BINARY(1));
=> CREATE PROJECTION t_p (c) AS SELECT c FROM t;
```

2. Insert minimum and maximum byte values, including an IP address represented as a character string:

```
=> INSERT INTO t values(HEX_TO_BINARY('0x00'));
=> INSERT INTO t values(HEX_TO_BINARY('0xFF'));
=> INSERT INTO t values (V6_ATON('2001:DB8::8:800:200C:417A'));
```

Use the `TO_HEX` function to format binary values in hexadecimal on output:

```
=> SELECT TO_HEX(c) FROM t;
to_hex
-----
00
ff
20
(3 rows)
```

- [ASCII](#)

Native varchar data

Use the `NATIVE VARCHAR` parser option when the raw data consists primarily of `CHAR` or `VARCHAR` data. `COPY` performs the conversion to the actual table data types on the database server. This parser option is not supported with `COPY LOCAL`.

Using `NATIVE VARCHAR` does not provide the same efficiency as `NATIVE`. However, `NATIVE VARCHAR` precludes the need to use delimiters or to escape special characters, such as quotes, which can make working with client applications easier.

Note

`NATIVE VARCHAR` does not support concatenated compressed files.

Batch data inserts performed through the Vertica ODBC and JDBC drivers automatically use the `NATIVE VARCHAR` format.

Fixed-width format data

Use the `FIXEDWIDTH` parser option to bulk load fixed-width data. You must specify the `COLSIZES` option values to specify the number of bytes for each column. The definition of the table you are loading (`COPY table f (x, y, z)`) determines the number of `COLSIZES` values to declare.

To load fixed-width data, use the `COLSIZES` option to specify the number of bytes for each input column. If any records do not have values, `COPY` inserts one or more null characters to equal the specified number of bytes. The last record in a fixed-width data file must include a record terminator to determine the end of the load data.

The following `COPY` options are not supported:

- `DELIMITER`
- `ENCLOSED BY`
- `ESCAPE AS`
- `TRAILING NULLCOLS`

Using nulls in fixed-width data

The default `NULL` string for a fixed-width load cannot be an empty string, and instead, consists of all spaces. The number of spaces depends on the column width declared with the `COLSIZES (integer, [...])` option.

For fixed-width loads, the `NULL` definition depends on whether you specify `NULL` at the column or statement level:

- *Statement level*: `NULL` must be defined as a single-character. The default (or custom) `NULL` character is repeated for the entire width of the column.
- *Column level*: `NULL` must be defined as a string whose length matches the column width.

For fixed-width loads, if the input data column has fewer values than the specified column size, **COPY** inserts NULL characters. The number of NULLs must match the declared column width. If you specify a NULL string at the column level, **COPY** matches the string with the column width.

Note

To turn off NULLs, use the **NULL AS** option and specify **NULL AS ''**.

Defining a null character (statement level)

1. Create a two-column table (**fw**):

```
=> CREATE TABLE fw(co int, ci int);
CREATE TABLE
```

2. Copy the table, specifying null as 'N', and enter some data:

```
=> COPY fw FROM STDIN FIXEDWIDTH colsizes(2,2) null AS 'N' NO COMMIT;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> NN12
>> 23NN
>> NNNN
>> nnnn
>> \.
```

3. Select all (*****) from the table:

```
=> SELECT * FROM fw;
co | ci
----+----
 | 12
23 |
(2 rows)
```

Defining a custom record terminator

To define a record terminator other than the **COPY** default when loading fixed-width data, take these steps:

1. Create table **fw** with two columns, **co** and **ci** :

```
=> CREATE TABLE fw(co int, ci int);
CREATE TABLE
```

2. Copy table **fw** , specifying two 2-byte column sizes, and specifying a comma (,) as the record terminator:

```
=> COPY fw FROM STDIN FIXEDWIDTH colsizes(2,2) RECORD TERMINATOR ',';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 1234,1444,6666
>> \.
```

3. Query all data in table **fw** :

```
=> SELECT * FROM fw;
co | ci
----+----
12 | 34
14 | 44
(2 rows)
```

The **SELECT** output indicates only two values. **COPY** rejected the third value (**6666**) because it was not followed by a comma (,) record terminator. Fixed-width data requires a trailing record terminator only if you explicitly specify a record terminator explicitly.

Copying fixed-width data

Use **COPY FIXEDWIDTH COLSIZES (n [...])** to load files into a Vertica database. By default, all spaces are NULLs. For example:

```

=> CREATE TABLE mytest(co int, ci int);
=> CREATE PROJECTION mytest_p1 AS SELECT * FROM mytest SEGMENTED BY HASH(co) ALL NODES;
=> COPY mytest(co,ci) FROM STDIN FIXEDWIDTH colsizes(6,4) NO COMMIT;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> \.
=> SELECT * FROM mytest ORDER BY co;
co | ci
----+----
(0 rows)

```

Skipping content in fixed-width data

The **COPY** statement has two options to skip input data. The **SKIP BYTES** option is only for fixed-width data loads:

SKIP BYTES <i>num-bytes</i>	Skips the specified number of bytes from the input data.
SKIP <i>num-records</i>	Skips the specified number of records.

The following example uses **SKIP BYTES** to skip 11 bytes when loading a fixed-width table with two columns (4 and 6 bytes):

1. Copy a table using **SKIP BYTES** :

```

=> COPY fw FROM STDIN FIXEDWIDTH colsizes (4,6) SKIP BYTES 11;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 2222666666
>> 1111999999
>> 1632641282
>> \.

```

2. Query all data in table **fw** :

```

=> SELECT * FROM fw ORDER BY co;
co | ci
----+-----
1111 | 999999
1632 | 641282
(2 rows)

```

The output confirms that **COPY** skipped the first 11 bytes of loaded data.

The following example uses **SKIP** when loading a fixed-width (4,6) table:

1. Copy a table, using **SKIP** to skip two records of input data:

```

=> COPY fw FROM STDIN FIXEDWIDTH colsizes (4,6) SKIP 2;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 2222666666
>> 1111999999
>> 1632641282
>> 3333888888
>> \.

```

2. Query all data in table **fw** :

```

=> SELECT * FROM fw ORDER BY co;
co | ci
----+-----
1632 | 641282
3333 | 888888
(2 rows)

```

The output confirms that **COPY** skipped the first two records of load data.

Trimming characters in fixed-width data loads

Use the **TRIM** option to trim a character. **TRIM** accepts a single-byte character, which is trimmed at the beginning and end of the data. For fixed-width data loads, when you specify a **TRIM** character, **COPY** first checks to see if the row is NULL. If the row is not null, **COPY** trims the character(s). The next example instructs **COPY** to trim the character A, and shows the results:

1. Copy table **fw** , specifying **TRIM** character **A** :

```
=> COPY fw FROM STDIN FIXEDWIDTH colsizes(4,6) TRIM 'A';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> A22A444444
>> A22AA44444A
>> \.
```

2. Query all data in table **fw** :

```
=> SELECT * FROM fw ORDER BY co;
co | ci
----+-----
22 | 4444
22 | 4444444
(2 rows)
```

Using padding in fixed-width data loads

By default, the padding character is ' ' (a single space). The padding behavior for fixed-width data loads is similar to how a space is treated in other formats, differing by data type as follows:

Data type	Padding
Integer	Leading and trailing spaces
Bool	Leading and trailing spaces
Float	Leading and trailing spaces
[var]Binary	None, all characters are significant.
[Var]Char	Trailing spaces if string is too large
DateInterval , Time , Timestamp , TimeTZ	None, all characters are significant. COPY uses an internal algorithm to parse these data types.
Date (formatted)	Use the COPY FORMAT option string to match the expected column length.
Numerics	Leading and trailing spaces

ORC data

The ORC (Optimized Row Columnar) format is a column-oriented file format. Vertica has a parser for this format that can take advantage of the columnar layout.

In the **COPY** statement, specify the parser as follows. Note that this is not the usual **PARSER parser-name** syntax; **COPY** supports ORC directly:

```
=> COPY tableName FROM path ORC[...];
```

The parser takes several optional parameters; see the [ORC](#) reference page.

Be aware that if you load from multiple files in the same **COPY** statement, and any of them is aborted, the entire load aborts. This behavior differs from that for delimited files, where the **COPY** statement loads what it can and ignores the rest.

Schema matching

By default, the ORC parser uses strong schema matching. This means that the load must consume all columns in the Parquet data in the order they occur in the data. You can, instead, use loose schema matching, which allows you to select the columns you want and ignore the rest. (You must specify all struct fields.) Loose schema matching depends on the names of the columns in the data rather than their order, so the names in your table

must match those in the data. Types must match or be coercible. For more information on how to use loose schema matching, see [Loose Schema Matching](#) on the [ORC](#) reference page.

Supported data types

Vertica can natively read columns of all Hive primitive data types. For a complete list, see [HIVE Data Types](#) (specifically the Numeric, Date/Time, String, and Misc lists). Vertica can also load UUIDs and [complex types](#) (arrays and structs in any combination).

The data types you specify for COPY or CREATE EXTERNAL TABLE AS COPY must exactly match the types in the data, though Vertica permits implicit casting among compatible numeric types.

Timestamps and time zones

To correctly report timestamps, Vertica must know what time zone the data was written in. Older versions of the ORC format do not record the time zone.

Hive version 1.2.0 and later records the writer time zone in the stripe footer. Vertica uses that time zone to make sure the timestamp values read into the database match the ones written in the source file. For ORC files that are missing this time zone information, Vertica assumes the values were written in the local time zone and logs an ORC_FILE_INFO event in the [QUERY_EVENTS](#) system table. Check for events of this type after your first query to verify that timestamps are being handled as you expected.

Parquet data

Parquet is a column-oriented file format. Vertica has a parser that can take advantage of the columnar layout.

In the [COPY](#) statement, specify the parser as follows. Note that this is not the usual `PARSER parser-name` syntax; COPY supports Parquet directly:

```
=> COPY tableName FROM path PARQUET[(...)];
```

The parser takes several optional parameters; see the [PARQUET](#) reference page.

Be aware that if you load from multiple files in the same COPY statement, and any of them is aborted, the entire load aborts. This behavior differs from that for delimited files, where the COPY statement loads what it can and ignores the rest.

Schema matching

By default, the Parquet parser uses strong schema matching. This means that the load must consume all columns in the Parquet data in the order they occur in the data. You can, instead, use loose schema matching, which allows you to select the columns and struct fields you want and ignore the rest. Loose schema matching depends on the names of the columns and fields in the data rather than their order, so the names in your table must match those in the data. Types must match or be coercible. For more information on how to use loose schema matching, see [Loose Schema Matching](#) on the [PARQUET](#) reference page.

Use the `do_soft_schema_match_by_name` parameter to specify loose schema matching. In the following example, the Parquet data contains more columns than those used in the table.

```
=> CREATE EXTERNAL TABLE restaurants(name VARCHAR, cuisine VARCHAR)
  AS COPY FROM '/data/rest*.parquet'
  PARQUET(do_soft_schema_match_by_name='True');
```

```
=> SELECT * from restaurant;
```

```
  name      | cuisine
-----+-----
Bob's pizzeria | Italian
Bakersfield Tacos | Mexican
(2 rows)
```

Metadata caching

Parquet files include metadata that Vertica uses when loading data. To avoid repeatedly fetching this data, particularly from remote sources or where API calls incur financial costs, Vertica caches this metadata on each participating node during the planning phase for use during the execution phase.

Vertica uses TEMP storage for the cache, and only if TEMP storage is on the local file system.

You can limit the size of the cache by setting the [ParquetMetadataCacheSizeMB](#) configuration parameter. The default is 4GB.

Supported data types

Vertica can natively read columns of all Hive primitive data types. For a complete list, see [HIVE Data Types](#) (specifically the Numeric, Date/Time, String, and Misc lists). Vertica can also load UUIDs and [complex types](#) (arrays and structs in any combination).

The data types you specify for COPY or CREATE EXTERNAL TABLE AS COPY must exactly match the types in the data, though Vertica permits implicit casting among compatible numeric types.

For the Parquet format only, you can use flexible complex types instead of fully specifying the schema for complex types. See [Flexible complex types](#).

Timestamps and time zones

To correctly report timestamps, Vertica must know what time zone the data was written in. Hive does not record the writer time zone. Vertica assumes timestamp values were written in the local time zone and reports a warning at query time.

Hive provides an option, when writing Parquet files, to record timestamps in the local time zone. If you are using Parquet files that record times in this way, set the UseLocalTzForParquetTimestampConversion configuration parameter to 0 to disable the conversion done by Vertica. (See [General parameters](#).)

JSON data

Use [FJSONPARSER](#) to load data in JSON format.

The schema for JSON data is the set of property names in the property/value pairs. When you load JSON data into a columnar table or materialized columns in a Flex table, the property names in the data must match the column names in the table. You do not need to load all of the columns in the data.

The JSON parser can load data into columns of any scalar type, [strongly-typed complex type](#), or [flexible complex type](#). A flexible complex type means you do not fully specify the schema for that column. You define these columns in the table as LONG VARBINARY, and you can use Flex functions to extract values from them.

In the COPY statement, use the PARSER parameter to specify the JSON parser as in the following example:

```
=> CREATE EXTERNAL TABLE customers(id INT, address VARCHAR, transactions ARRAY[INT,10])
  AS COPY FROM 'cust.json' PARSER FJSONPARSER();
```

This parser has several optional parameters, some of which are specific to use with Flex tables and flexible complex types.

Before loading JSON data, consider using a tool such as [JSONLint](#) to verify that the data is valid.

If you load JSON data into a Flex table, Vertica loads all data into the `__raw__` (VMap) column, including complex types found in the data. You can use [Flex functions](#) to extract values.

Strongly-typed complex types

JSON data can contain arrays, structs, and combinations of the two. You can load this data either as flexible (VMap) columns or with strong typing. Strong typing allows you to query values directly, without having to use functions to unpack a VMap column.

Use the [ARRAY](#) and [ROW](#) types in the table definition as usual:

```
=> CREATE EXTERNAL TABLE rest
  (name VARCHAR, cuisine VARCHAR,
  location_city ARRAY[VARCHAR(80),50],
  menu ARRAY[ ROW(item VARCHAR(80), price FLOAT), 100 ]
  )
  AS COPY FROM :restdata PARSER FJSONPARSER();

=> SELECT name, location_city, menu FROM rest;
```

name	location_city	menu
Bob's pizzeria	["Cambridge", "Pittsburgh"]	[{"item": "cheese pizza", "price": 8.25}, {"item": "spinach pizza", "price": 10.5}]
Bakersfield Tacos	["Pittsburgh"]	[{"item": "veggie taco", "price": 9.95}, {"item": "steak taco", "price": 10.95}]

(2 rows)

When loading JSON data into a table with strong typing for complex types, Vertica ignores the parser's `flatten_maps` and `flatten_arrays` parameters.

Strong and flexible complex types

An advantage of strong typing is the easier (and more efficient) access in queries. A disadvantage is that additional values found in the data but not included in the column definition are ignored. If the menu struct in this data includes more attributes, such as calories, they are not loaded because the definition of the column only specified item and price. The following example uses flexible complex types to reveal the extra attributes:

```

=> CREATE EXTERNAL TABLE rest
(name VARCHAR, cuisine VARCHAR,
 location_city LONG VARBINARY, menu LONG VARBINARY)
AS COPY FROM :restdata
PARSER FJSONPARSER(flatten_maps=false);

=> SELECT name, MAPTOSTRING(location_city) as location_city, MAPTOSTRING(menu) AS menu FROM rest;

```

name	location_city	menu
Bob's pizzeria	{ "0": "Cambridge", "1": "Pittsburgh"	{ "0": { "calories": "1200", "item": "cheese pizza", "price": "8.25" }, "1": { "calories": "900", "item": "spinach pizza", "price": "10.50" }
Bakersfield Tacos	{ "0": "Pittsburgh"	{ "0": { "item": "veggie taco", "price": "9.95", "vegetarian": "true" }, "1": { "item": "steak taco", "price": "10.95" }

(2 rows)

Unmatched fields

The JSON parser loads all fields from the data that are part of the table definition. If the data contains other fields, the parser produces a warning and logs the new fields in a system table. You can review the logged events and decide whether to modify your table definition. For details, see [Schema evolution](#).

Loading from a specific start point

You need not load an entire JSON file. You can use the `start_point` parameter to load data beginning at a specific key, rather than at the beginning of a file. Data is parsed from after the `start_point` key until the end of the file, or to the end of the first `start_point`'s value. The parser ignores any subsequent instance of the `start_point`, even if that key appears multiple times in the input file. If the input data contains only one copy of the `start_point` key, and that value is a list of JSON elements, the parser loads each element in the list as a row.

If a `start_point` value occurs more than once in your JSON data, you can use the `start_point_occurrence` integer parameter to specify the occurrence at which to start parsing.

This example uses the following JSON data, saved to a file named `alphanums.json`:

```

{ "A": { "B": { "C": [ { "d": 1, "e": 2, "f": 3 }, { "g": 4, "h": 5, "i": 6 },
{ "j": 7, "k": 8, "l": 9 } ] } } }

```

Loading this data into a flex table produces the following results:

```

=> CREATE FLEX TABLE start_json;
CREATE TABLE

=> COPY start_json FROM '/home/dbadmin/data/alphanums.json' PARSER FJSONPARSER();
Rows Loaded
-----
      1
(1 row)

=> SELECT maptostring(__raw__) FROM start_json;
      maptostring
-----
{
  "A.B.C" : {
    "0.d" : "1",
    "0.e" : "2",
    "0.f" : "3",
    "1.g" : "4",
    "1.h" : "5",
    "1.i" : "6",
    "2.j" : "7",
    "2.k" : "8",
    "2.l" : "9"
  }
}
(1 row)

```

The following load specifies a start point:

```

=> TRUNCATE TABLE start_json;
TRUNCATE TABLE

=> COPY start_json FROM '/home/dbadmin/data/alphanums.json' PARSER FJSONPARSER(start_point='B');
Rows Loaded
-----
      1
(1 row)

=> SELECT maptostring(__raw__) FROM start_json;
      maptostring
-----
{
  "C" : {
    "0.d" : "1",
    "0.e" : "2",
    "0.f" : "3",
    "1.g" : "4",
    "1.h" : "5",
    "1.i" : "6",
    "2.j" : "7",
    "2.k" : "8",
    "2.l" : "9"
  }
}
(1 row)

```

Dealing with invalid JSON records

If your JSON data contains syntax errors, your load can fail due to invalid records. You can use the `RECORD_TERMINATOR` option in the `COPY` statement to skip these invalid records if your JSON records are consistently delimited by a character like a line break. Setting a record terminator allows the parser to skip over invalid records and continue parsing the rest of the data.

If your records are not consistently marked by a character, you can use the `ERROR TOLERANCE` option. `ERROR TOLERANCE` skips entire source files with invalid JSON records, while `RECORD_TERMINATOR` skips individual malformed JSON records. You can use the two options together.

The following example uses invalid records:

```
=> => CREATE FLEX TABLE fruits();
CREATE TABLE

=> COPY fruits FROM STDIN PARSER FJSONPARSER(RECORD_TERMINATOR=E'\n');
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself
>> {"name": "orange", "type": "fruit", "color": "orange", "rating": 5 }
>> {"name": "apple", "type": "fruit", "color": "green" }
>> {"name": "blueberry", "type": "fruit", "color": "blue", "rating": 10 }
>> "type": "fruit", "rating": 7 }
>> {"name": "banana", "type": "fruit", "color": "yellow", "rating": 3 }
>> \.
```

View the flex table using `MAPTOSTRING` to confirm that the invalid record was skipped while the rest of the records were successfully loaded:

```
=> SELECT MAPTOSTRING(__raw__) FROM fruits;
maptostring
-----
{
"color" : "orange",
"name" : "orange",
"rating" : "5",
"type" : "fruit"
}
{
"color" : "green",
"name" : "apple",
"type" : "fruit"
}
{
"color" : "blue",
"name" : "blueberry",
"rating" : "10",
"type" : "fruit"
}
{
"color" : "yellow",
"name" : "banana",
"rating" : "3",
"type" : "fruit"
}
(4 rows)
```

Rejecting data on materialized column type errors

By default, if `FJSONPARSER` cannot coerce a data value to a type that matches the column definition, it sets the value to `NULL`. You can choose to instead reject these values using the `reject_on_materialized_type_error` parameter. If this parameter is true, `COPY` rejects such rows and reports an error.

If the column is a strongly-typed [complex type](#), as opposed to a [flexible complex type](#), then a type mismatch anywhere in the complex type causes the entire column to be treated as a mismatch. The parser does not partially load complex types; if any `ROW` field or `ARRAY` element cannot be coerced, it loads `NULL` for the column.

The following example attempts to load invalid data. Note that the invalid row is missing from the query results:

```

=> CREATE TABLE test(one VARCHAR, two INT);
CREATE TABLE

=> COPY test FROM stdin
  PARSER FJSONPARSER(reject_on_materialized_type_error=true);
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> {"one": 1, "two": 2}
>> {"one": "one", "two": "two"}
>> {"one": "one", "two": 2}
>> \.

=> SELECT one, two FROM test;
 one | two
-----+-----
  1  |  2
 one |  2
(2 rows)

```

Rejecting or omitting empty keys in flex tables

Valid JSON files can include empty key and value pairs. By default, for a Flex table, FJSONPARSER loads them, as in the following example:

```

=> CREATE FLEX TABLE fruits();
CREATE TABLE

=> COPY fruits FROM STDIN PARSER FJSONPARSER();
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> {"name": "orange", "rating": 5}
>> {"name": "apple", "rating" : 10}
>> {"": "banana", "rating" : 2}
>> \.

=> SELECT MAPTOSTRING(__raw__) FROM fruits;
      maptostring
-----
{
  "name": "orange",
  "rating": "5"
}
{
  "name": "apple",
  "rating": "10"
}
{
  "": "banana",
  "rating": "2"
}
(3 rows)

```

To omit fields with empty keys, use the [omit_empty_keys](#) parameter:

```
=> COPY fruits FROM STDIN PARSER FJSONPARSER(omit_empty_keys=true);
```

Enter data to be copied followed by a newline.

End with a backslash and a period on a line by itself.

```
>> {"name": "apple", "rating": 5}
```

```
>> {"": "missing", "rating" : 1}
```

```
>> {"name": "", "rating" : 3}
```

```
>> \.
```

```
=> SELECT MAPTOSTRING(__raw__) FROM fruits;
```

```
maptostring
```

```
-----  
{  
  "name": "apple",  
  "rating": "5"
```

```
}  
{  
  "rating": "1"
```

```
}  
{  
  "name": "",  
  "rating": "3"
```

```
}
```

```
(3 rows)
```

Note that the second value, with the missing name, still loads with the other (non-empty) field. To instead reject the row entirely, use the [reject_on_empty_key](#) parameter:

```
=> COPY fruits FROM STDIN PARSER FJSONPARSER(reject_on_empty_key=true);
```

Enter data to be copied followed by a newline.

End with a backslash and a period on a line by itself.

```
>> {"name": "apple", "rating" : 5}
```

```
>> {"": "missing", "rating" : 1}
```

```
>> {"name": "", "rating" : 3}
```

```
>> \.
```

```
=> SELECT MAPTOSTRING(__raw__) FROM fruits;
```

```
maptostring
```

```
-----  
{  
  "name": "apple",  
  "rating": "5"
```

```
}  
{  
  "name": "",  
  "rating": "3"
```

```
}
```

```
(2 rows)
```

Avro data

Use [FAVROPARSER](#) to load Avro data files. This parser supports both columnar and Flex tables.

A column can be of any scalar type, a [strongly-typed complex type](#), or a [flexible complex type](#). A flexible complex type means you do not fully specify the schema for that column. You define these columns in the table as LONG VARBINARY, and you can use Flex functions to extract values from them.

The following requirements apply:

- Avro files must be encoded in the Avro binary serialization encoding format, described in the [Apache Avro standard](#). The parser also supports Snappy and deflate compression.
- The Avro file must have its related schema in the file being loaded; FAVROPARSER does not support Avro files with separate schema files.

In the COPY statement, use the PARSER parameter to specify the Avro parser as in the following example:

```
=> COPY weather FROM '/home/dbadmin/data/weather.avro' PARSER FAVROPARSER()
```

This parser has several optional parameters, some of which are specific to use with Flex tables and flexible complex types.

Avro schemas and columnar tables

Avro includes the schema with the data. When you load Avro data into a columnar table, the column names in the schema in the data must match the column names in the table. You do not need to load all of the columns in the data.

For example, the following Avro schema uses the Avro record type to represent a user profile:

```
{
  "type": "record",
  "name": "Profile",
  "fields" : [
    {"name": "UserName", "type": "string"},
    {"name": "Email", "type": "string"},
    {"name": "Address", "type": "string"}
  ]
}
```

To successfully load the data into a columnar table with this schema, each target column name must match the "name" value in the schema. In the following example, the `profiles` table does not load values corresponding to the schema's `Email` field because the target column is named `EmailAddr`:

```
=> COPY profiles FROM '/home/dbadmin/data/user_profile.avro' PARSER FAVROPARSER();

=> SELECT * FROM profiles;
  UserName | EmailAddr | Address
-----+-----+-----
  dbadmin  |           | 123 Main St.
```

Strongly-typed complex types

Avro data can contain arrays, structs, and combinations of the two. You can read this data either as flexible (VMap) columns or with strong typing. Strong typing allows you to query values directly, without having to use functions to unpack a VMap column.

Use the [ARRAY](#) and [ROW](#) types in the table definition as usual:

```
=> CREATE EXTERNAL TABLE rest
(name VARCHAR, cuisine VARCHAR,
 location_city ARRAY[VARCHAR(80)],
 menu ARRAY[ ROW(item VARCHAR(80), price FLOAT) ]
)
AS COPY FROM :avro_file PARSER FAVROPARSER();
```

You can use strong typing in both external tables and native tables.

An alternative to strong typing for complex types is [flexible complex types](#).

Unmatched fields

The Avro parser loads all fields from the data that are part of the table definition. If the data contains other fields, the parser produces a warning and logs the new fields in a system table. You can review the logged events and decide whether to modify your table definition. For details, see [Schema evolution](#).

Rejecting data on materialized column type errors

By default, if FAVROPARSER cannot coerce a data value to a type that matches the column definition, it sets the value to NULL. You can choose to instead reject these values using the `reject_on_materialized_type_error` parameter. If this parameter is true, COPY rejects such rows and reports an error.

If the column is a strongly-typed [complex type](#), as opposed to a [flexible complex type](#), then a type mismatch anywhere in the complex type causes the entire column to be treated as a mismatch. The parser does not partially load complex types.

If a flex table has a materialized column, the data being loaded must be coercible to that column's type. For example, if a materialized column is declared as a FLOAT and you try to load a VARCHAR value for that key, FAVROPARSER rejects the data row.

Using external tables with fregexparser

By creating an external columnar table for your Vertica log file, querying the table will return updated log information. The following basic example illustrate this usage.

1. Create a columnar table, `vertica_log`, using the `AS COPY` clause and `fregexparser` to load matched results from the regular expression. For illustrative purposes, this regular expression has new line characters to split long text lines. Remove any line returns before testing with this expression:

```

=> CREATE EXTERNAL TABLE public.vertica_log
(
  "text" varchar(2322),
  thread_id varchar(28),
  thread_name varchar(44),
  "time" varchar(46),
  component varchar(30),
  level varchar(20),
  transaction_id varchar(32),
  elevel varchar(20),
  enode varchar(34)
)
AS COPY
FROM '/home/dbadmin/data/vertica.log'
PARSER FRegexParser(pattern=
'^(<time>\d\d\d\d-\d\d-\d\d \d\d:\d\d:\d\d\.\d+)
(<thread_name>[A-Za-z ]+):(<thread_id>(?:0x)?[0-9a-f]+)
-?(<transaction_id>[0-9a-f])?(?:[(<component>\w+)]
\(<level>\w+)\> )?(?:-<elevel>\w+\> @[(<enode>\w+)]?:)
?(<text>.*)'
);

```

2. Query from the external table to get updated results:

```
=> SELECT component, thread_id, time FROM vertica_log limit 10;
component | thread_id |      time
-----+-----+-----
Init      | 0x16321430 | 2014-04-02 04:02:02.613
Init      | 0x16321430 | 2014-04-02 04:02:02.613
Init      | 0x16321430 | 2014-04-02 04:02:02.613
Init      | 0x16321430 | 2014-04-02 04:02:02.613
Init      | 0x16321430 | 2014-04-02 04:02:02.613
Init      | 0x16321430 | 2014-04-02 04:02:02.613
Init      | 0x16321430 | 2014-04-02 04:02:02.613
          | 0x16321430 | 2014-04-02 04:02:02.614
          | 0x16321430 | 2014-04-02 04:02:02.614
          | 0x16321430 | 2014-04-02 04:02:02.614
(10 rows)
```

Common event format (CEF) data

Use the flex parser [fcefparser](#) to load OpenText ArcSight or other Common Event Format (CEF) log file data into columnar and flexible tables.

When you use the parser to load arbitrary CEF-format files, it interprets key names in the data as virtual columns in your flex table. After loading, you can query your CEF data directly, regardless of which set of keys exist in each row. You can also use the associated flex table data and map functions to manage CEF data access.

Create a flex table and load CEF data

This section uses a sample set of CEF data. All IP addresses have been purposely changed to be inaccurate, and Return characters added for illustration.

To use this sample data, copy the following text and remove all Return characters. Save the file as [CEF_sample.cef](#), which is the name used throughout these examples.

```
CEF:0|ArcSight|ArcSight|6.0.3.6664.0|agent:030|Agent [test] type [testalertng] started|Low|
eventId=1 mrt=1396328238973 categorySignificance=/Normal categoryBehavior=/Execute/Start

  "version" : "0"
}
(1 row)

```

Create a columnar table and load CEF data

This example lets you compare the flex table for CEF data with a columnar table. You do so by creating a new table and load the same [CEF_sample.cef](#) file used in the preceding flex table example.

1. Create a columnar table, `col_logs`, defining the prefix names that are hard coded in `fcefparser`:

```

=> CREATE TABLE col_logs(version INT,
  devicevendor VARCHAR,
  deviceproduct VARCHAR,
  deviceversion VARCHAR,
  signatureid VARCHAR,
  name VARCHAR,
  severity VARCHAR);
CREATE TABLE

```

2. Load the sample file into `col_logs`, as you did for the flex table:

```
=> COPY col_logs FROM '/home/dbadmin/data/CEF_sample.cef' PARSER fcefparser();
```

Rows Loaded

```
-----  
      1  
(1 row)
```

3. Query the table. You can find the identical information in the flex table output.

```
=> \x
```

Expanded display is on.

```
VMart=> SELECT * FROM col_logs;
```

```
-[ RECORD 1 ]-----  
version      | 0  
devicevendor | ArcSight  
deviceproduct | ArcSight  
deviceversion | 6.0.3.6664.0  
signatureid  | agent:030  
name         | Agent [test] type [testalertng] started  
severity     | Low
```

Compute keys and build a flex table view

In this example, you use a flex helper function to compute keys and build a view for the `logs` flex table.

1. Use the `compute_flexable_keys_and_build_view` function to compute keys and populate a view generated from the `logs` flex table:

```
=> SELECT compute_flexable_keys_and_build_view('logs');  
      compute_flexable_keys_and_build_view
```

```
-----  
Please see public.logs_keys for updated keys
```

```
The view public.logs_view is ready for querying
```

```
(1 row)
```

2. Query the `logs_keys` table to see what the function computed from the sample CEF data:

```

=> SELECT * FROM logs_keys;
  key_name | frequency | data_type_guess
-----+-----+-----
c6a4      |         1 | varchar(60)
c6a4label |         1 | varchar(36)
categoryobject |         1 | varchar(50)
categoryoutcome |         1 | varchar(20)
categorysignificance |         1 | varchar(20)
cs2       |         1 | varchar(84)
cs2label  |         1 | varchar(44)
deviceproduct |         1 | varchar(20)
deviceversion |         1 | varchar(24)
devicezoneuri |         1 | varchar(180)
dvchost   |         1 | varchar(20)
version   |         1 | varchar(20)
ahost     |         1 | varchar(20)
art       |         1 | varchar(26)
at        |         1 | varchar(22)
cat       |         1 | varchar(28)
catdt     |         1 | varchar(36)
devicevendor |         1 | varchar(20)
dtz       |         1 | varchar(32)
dvc       |         1 | varchar(24)
filetype  |         1 | varchar(20)
mrt       |         1 | varchar(26)
_cefver   |         1 | varchar(20)
agentzoneuri |         1 | varchar(180)
agt       |         1 | varchar(24)
aid       |         1 | varchar(50)
atz       |         1 | varchar(32)
av        |         1 | varchar(24)
categorybehavior |         1 | varchar(28)
categorydevicegroup |         1 | varchar(24)
deviceseverity |         1 | varchar(20)
eventid   |         1 | varchar(20)
name      |         1 | varchar(78)
rt        |         1 | varchar(26)
severity  |         1 | varchar(20)
signatureid |         1 | varchar(20)
(36 rows)

```

3. Query several columns from the `logs_view` :

```

=> \x
Expanded display is on.
VMart=> select version, devicevendor, deviceversion, name, severity, signatureid
  from logs_view;
-[ RECORD 1 ]+-----
version   | 0
devicevendor | ArcSight
deviceversion | 6.0.3.6664.0
name      | Agent [test] type [testalertng] started
severity  | Low
signatureid | agent:030

```

Use the `cefparser delimiter` parameter

In this example, you use the `cefparser delimiter` parameter to query events located in California, New Mexico, and Arizona.

1. Create a new columnar table, `CEFData3` :

```

=> CREATE TABLE CEFData3(eventId INT, location VARCHAR(20));
CREATE TABLE

```

2. Using the `delimiter=','` parameter, load some CEF data into the table:

```
=> COPY CEFDData3 FROM stdin PARSER fcefparser(delimiter=',');
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> eventId=1,location=California
>> eventId=2,location=New Mexico
>> eventId=3,location=Arizona
>> \.
```

3. Query the table:

```
=> SELECT eventId, location FROM CEFDData3;
eventId | location
-----+-----
 1 | California
 2 | New Mexico
 3 | Arizona
(3 rows)
```

Complex types

Tables can have columns of complex types, including nested complex types. You can use the [ROW](#) (struct), [ARRAY](#), and [SET](#) types in native and external tables, including flex tables. Sets are limited to one-dimensional collections of scalar types. A limited [MAP](#) type is available for external tables, but you can use `ARRAY` and `ROW` to express a map instead. Selected parsers support loading data with complex types.

You can define a column for heterogeneous combinations of the `ARRAY` and `ROW` types: a struct containing array fields or an array of structs. These types can be nested up to the maximum nesting depth of 100.

Restrictions for native tables

Complex types used in native tables have some restrictions, in addition to the restrictions for individual types listed on their reference pages:

- A native table must have at least one column that is a primitive type or a native array (one-dimensional array of a primitive type). If a flex table has real columns, it must also have at least one column satisfying this restriction.
- Complex type columns cannot be used in `ORDER BY` or `PARTITION BY` clauses nor as `FILLER` columns.
- Complex type columns cannot have [constraints](#).
- Complex type columns cannot use `DEFAULT` or `SET USING`.
- Expressions returning complex types cannot be used as projection columns, and projections cannot be segmented or ordered by columns of complex types.

See [CREATE TABLE](#) and [ALTER TABLE](#) for additional restrictions.

Deriving a table definition from the data

You can use the [INFER_TABLE_DDL](#) function to inspect Parquet, ORC, JSON, or Avro data and produce a starting point for a table definition. This function returns a `CREATE TABLE` statement, which might require further editing. For columns where the function could not infer the data type, the function labels the type as `unknown` and emits a warning. For `VARCHAR` and `VARBINARY` columns, you might need to adjust the length. Always review the statement the function returns, but especially for tables with many columns, using this function can save time and effort.

Parquet, ORC, and Avro files include schema information, but JSON files do not. For JSON, the function inspects the raw data to produce one or more candidate table definitions. In the following example, two input files differ in the structure of the `menu` column:

```
=> SELECT INFER_TABLE_DDL ('/data/*.json'
  USING PARAMETERS table_name='restaurants', format='json',
max_files=3, max_candidates=3);
WARNING 0: This generated statement contains one or more float types which might lose precision
WARNING 0: This generated statement contains one or more varchar/varbinary types which default to length 80
```

INFER_TABLE_DDL

Candidate matched 1 out of 2 total files:

```
create table "restaurants"(
  "cuisine" varchar,
  "location_city" Array[varchar],
  "menu" Array[Row(
    "item" varchar,
    "price" float
  )],
  "name" varchar
);
```

Candidate matched 1 out of 2 total files:

```
create table "restaurants"(
  "cuisine" varchar,
  "location_city" Array[varchar],
  "menu" Array[Row(
    "items" Array[Row(
      "item" varchar,
      "price" numeric
    )],
    "time" varchar
  )],
  "name" varchar
);
```

(1 row)

Alternative to strong typing

Though you can fully specify a column representing any combination of ROW and ARRAY types, there might be cases where you prefer a more flexible approach. If the data contains a struct with hundreds of fields, only a few of which you need, you might prefer to extract just those few at query time instead of defining all of the fields. Similarly, if the data structure is likely to change, you might prefer to defer fully specifying the complex types. You can use flexible columns as an alternative to fully specifying the structure of a complex column. This is the same approach used for flex tables, where all data is initially loaded into a single binary column and materialized from there as needed. See [Flexible complex types](#) for more information about using this approach.

In this section

- [Structs](#)
- [Arrays](#)
- [Flexible complex types](#)
- [System tables for complex types](#)

Structs

Columns can contain structs, which store property-value pairs. For example, a struct representing an address could have strings for the street address and city/state and an integer for the postal code:

```
{ "street": "150 Cambridgepark Dr.",
  "city": "Cambridge MA",
  "postalcode": 02140 }
```

Struct fields can be primitive types or other complex types.

Use the [ROW](#) expression to define a struct column. In the following example, the data has columns for customer name, address, and account number, and the address is a struct in the data. The types you declare in Vertica must be compatible with the types in the data you load into them.

```
=> CREATE TABLE customers (  
  name VARCHAR,  
  address ROW(street VARCHAR, city VARCHAR, zipcode INT),  
  accountID INT);
```

Within the ROW, you specify the fields and their data types using the same syntax as for columns. Vertica treats the ROW as a single column for purposes of queries.

Structs can contain other structs. In the following example, employees have various personal information, including an address which is itself a struct.

```
=> CREATE TABLE employees(  
  employeeID INT,  
  personal ROW(  
    name VARCHAR,  
    address ROW(street VARCHAR, city VARCHAR, zipcode INT),  
    taxID INT),  
  department VARCHAR);
```

Structs can contain arrays of primitive types, arrays, or structs.

```
=> CREATE TABLE customers(  
  name VARCHAR,  
  contact ROW(  
    street VARCHAR,  
    city VARCHAR,  
    zipcode INT,  
    email ARRAY[VARCHAR]  
  ),  
  accountid INT);
```

When defining an external table with Parquet or ORC data, Vertica requires the definition of the table to match the schema of the data. For example, with the data used in the previous employees example, the following definition is an error:

```
=> CREATE EXTERNAL TABLE employees(  
  employeeID INT,  
  personal ROW(  
    name VARCHAR,  
    address ROW(street VARCHAR, city VARCHAR),  
    zipcode INT,  
    taxID INT),  
  department VARCHAR)  
AS COPY FROM '...' PARQUET;  
ERROR 9151: Datatype mismatch [...]
```

The data contains an address struct with three fields (street, city, zipcode), so the external table must also use a ROW with three fields. Changing the ROW to have two fields and promoting one of the fields to the parent ROW is a mismatch. Each ROW must match and, if structs are nested in the data, the complete structure must match.

For native tables, you can specify which columns to load from the data, so you do not need to account for all of them. For the columns you load, the definition of the table must match the schema in the data file. Some parsers report fields found in that data that are not part of the table definition.

Handling nulls

If a struct exists but a field value is null, Vertica assigns NULL as its value in the ROW. A struct where all fields are null is treated as a ROW with null fields. If the struct itself is null, Vertica reads the ROW as NULL.

Queries

See [Rows \(structs\)](#).

Restrictions

ROW columns have several restrictions:

- Maximum nesting depth is 100.
- Vertica tables support up to 9800 columns and fields. The ROW itself is not counted, only its fields.
- ROW columns cannot use any constraints (such as NOT NULL) or defaults.

- ROW fields cannot be auto_increment or setof.
- ROW definition must include at least one field.
- Row is a reserved keyword within a ROW definition, but is permitted as the name of a table or column.
- Tables containing ROW columns cannot also contain IDENTITY, default, SET USING, or named sequence columns.

Arrays

Columns can contain arrays, which store ordered lists of elements of the same type. For example, an address column could use an array of strings to store multiple addresses that an individual might have, such as [668 SW New Lane', '518 Main Ave', '7040 Campfire Dr'] .

There are two types of arrays:

- Native array: a one-dimensional array of a primitive type.
- Non-native array: all other supported arrays, including arrays that contain other arrays (multi-dimensional arrays) or structs (ROWS). Non-native arrays have some [usage restrictions](#).

Use the [ARRAY](#) type to define an array column, specifying the type of its elements (a primitive type, a [ROW](#) (struct), or an array):

```
=> CREATE TABLE orders
(orderkey INT,
 custkey INT,
 prodkey ARRAY[VARCHAR(10)],
 orderprices ARRAY[DECIMAL(12,2)],
 orderdate DATE
);
```

If an array is multi-dimensional, represent it as an array containing an array:

```
ARRAY[ARRAY[FLOAT]]
```

Queries

See [Arrays and sets \(collections\)](#).

Restrictions

- Native arrays support only data of primitive types, for example, int, UUID, and so on.
- Array dimensionality is enforced. A column cannot contain arrays of varying dimensions. For example, a column that contains a three-dimensional array can only contain other three-dimensional arrays; it cannot simultaneously include a one-dimensional array. However, the arrays in a column can vary in size, where one array can contain four elements while another contains ten.
- Array bounds, if specified, are enforced for all operations that load or alter data. Unbounded arrays may have as many elements as will fit in the allotted binary size.
- An array has a maximum binary size. If this size is not set when the array is defined, a default value is used.
- Arrays do not support LONG types (like LONG VARBINARY or LONG VARCHAR) or user-defined types (like Geometry).

Flexible complex types

When defining tables, you can use strongly-typed complex types to fully describe any combination of structs and arrays. However, there are times when you might prefer not to:

- If the data contains a struct with a very large number of fields, and in your queries you will need only a few of them, you can avoid having to enumerate the rest in the table DDL. Further, a deeply-nested set of structs could exceed the nesting limit for the table if fully specified.
- If the data schema is still evolving, you can delay finalizing strongly-typed DDL.
- If you anticipate the introduction of new fields in the data, you can use flexible types to discover them. A table with strong typing, on the other hand, would silently ignore those values. For an example of using flexible types to discover new fields, see [Strong and Flexible Typing](#).

Flexible types are a way to store complex or unstructured data as a binary blob in one column, in a way that allows access to individual elements of that data. This is the same approach that Vertica uses with [flex tables](#), which support loading unstructured or semi-structured data. In a flex table, all data from a source is loaded into a single VMap column named `__raw__`. From this column you can materialize other columns, such as a specific field in JSON data, or use special lookup functions in queries to read values directly out of the `__raw__` column.

Vertica uses a similar approach with complex types. You can describe the types fully using the [ROW](#) and [ARRAY](#) types in your table definition, or you can instead treat a complex type as a flexible type and not fully describe it. Each complex type that you choose to treat this way becomes its own flex-style column. You are not limited to a single column containing all data as in flex tables; instead, you can treat any complex type column, no matter how deeply it nests other types, as one flex-like column.

Defining flexible columns

To use a flexible complex type, declare the column as `LONG VARBINARY`. You might also need to set other parameters in the parser, as described in the parser documentation.

Consider a Parquet file with a `restaurants` table and the following columns:

- `name`: `varchar`
- `cuisine type`: `varchar`
- `location (cities)`: `array[varchar]`
- `menu`: array of structs, each struct having an item name and a price

This data contains two complex columns, `location` (an array) and `menu` (an array of structs). The following example defines both columns as flexible columns by using `LONG VARBINARY`:

```
=> CREATE EXTERNAL TABLE restaurants(name VARCHAR, cuisine VARCHAR,
    location_city LONG VARBINARY, menu LONG VARBINARY)
AS COPY FROM '/data/rest*.parquet'
PARQUET(allow_long_varbinary_match_complex_type='True');
```

The `allow_long_varbinary_match_complex_type` parameter is specific to the Parquet parser. It is required if you define any column as a flexible type. Without this parameter, Vertica tries to match the `LONG VARBINARY` declaration in the table to a `VARBINARY` column in the Parquet file, finds a complex type instead, and reports a data-type mismatch.

You need not treat all complex columns as flexible types. The following definition is also valid:

```
=> CREATE EXTERNAL TABLE restaurants(
    name VARCHAR, cuisine VARCHAR,
    location_city ARRAY[VARCHAR,50],
    menu LONG VARBINARY)
AS COPY FROM '/data/rest*.parquet'
PARQUET(allow_long_varbinary_match_complex_type='True');
```

For many common data formats, you can use the [INFER_TABLE_DDL](#) function to derive a table definition from a data file. This function uses strong typing for complex types in almost all cases.

Querying flexible columns

Flexible columns are stored as `LONG VARBINARY`, so selecting them directly produces unhelpful results. Instead, use the flex mapping functions to extract values from these columns. The [MAPTOSTRING](#) function translates the complex type to JSON, as shown in the following example:

```
=> SELECT name, location_city, MAPTOSTRING(menu) AS menu FROM restaurants;
```

name	location_city	menu
Bob's pizzeria	["Cambridge","Pittsburgh"]	{ "0": { "item": "cheese pizza", "price": "\$8.25" }, "1": { "item": "spinach pizza", "price": "\$10.50" } }
Bakersfield Tacos	["Pittsburgh"]	{ "0": { "item": "veggie taco", "price": "\$9.95" }, "1": { "item": "steak taco", "price": "\$10.95" } }

(2 rows)

The menu column is an array of structs. Notice that the output is a set of key/value pairs, with the key being the array index. Bob's Pizzeria has two items on its menu, and each value is a struct. The first item ("0") is a struct with an "item" value of "cheese pizza" and a "price" of "\$8.25".

You can use keys to access specific values. The following example selects the first menu item from each restaurant. Note that all keys are strings, even array indexes:

```
=> SELECT name, location_city, menu[0]['item'] AS item, menu[0]['price'] AS price FROM restaurants;
```

name	location_city	item	price
Bob's pizzeria	["Cambridge", "Pittsburgh"]	cheese pizza	\$8.25
Bakersfield Tacos	["Pittsburgh"]	veggie taco	\$9.95

(2 rows)

Instead of accessing specific indexes, you can use the [MAPITEMS](#) function in a subquery to explode a flexible type, as in the following example:

```
=> SELECT name, location_city, menu_items['item'], menu_items['price']  
FROM (SELECT mapitems(menu, name, location_city) OVER(PARTITION BEST)  
AS (indexes, menu_items, name, location_city)  
FROM restaurants) explode_menu;
```

name	location_city	menu_items	menu_items
Bob's pizzeria	["Cambridge", "Pittsburgh"]	cheese pizza	\$8.25
Bob's pizzeria	["Cambridge", "Pittsburgh"]	spinach pizza	\$10.50
Bakersfield Tacos	["Pittsburgh"]	veggie taco	\$9.95
Bakersfield Tacos	["Pittsburgh"]	steak taco	\$10.95

(4 rows)

For a complete list of flex mapping functions, see [Flex data functions](#).

JSON and Avro flexible types

The parsers for [JSON](#) and [Avro](#) support both flexible and strong types for complex types. When using flexible complex types or loading into a flex table, use the [flatten_maps](#) and [flatten_arrays](#) parameters to control how the parser handles complex data. These parsers ignore these parameters for strongly-typed complex types.

The following example demonstrates the use of flexible complex types. Consider a JSON file containing the following data:

```
{  
  "name": "Bob's pizzeria",  
  "cuisine": "Italian",  
  "location_city": ["Cambridge", "Pittsburgh"],  
  "menu": [{"item": "cheese pizza", "price": "$8.25"},  
           {"item": "spinach pizza", "price": "$10.50"}]  
}  
  
{  
  "name": "Bakersfield Tacos",  
  "cuisine": "Mexican",  
  "location_city": ["Pittsburgh"],  
  "menu": [{"item": "veggie taco", "price": "$9.95"},  
           {"item": "steak taco", "price": "$10.95"}]  
}
```

Create a table, using LONG VARBINARY for the flexible complex types, and load data specifying these parameters:

```
=> CREATE TABLE restaurant(name VARCHAR, cuisine VARCHAR,  
  location_city LONG VARBINARY, menu LONG VARBINARY);  
  
=> COPY restaurant FROM '/data/restaurant.json'  
  PARSER FJSONPARSER(flatten_maps=false, flatten_arrays=false);
```

You can use Flex functions and direct access (through indexes) to return readable values:

```

=> SELECT MAPTOSTRING(location_city), MAPTOSTRING(menu) FROM restaurant;
      maptostring      |      maptostring
-----+-----
{
  "0": "Cambridge",
  "1": "Pittsburgh"
} | {
  "0": {
    "item": "cheese pizza",
    "price": "$8.25"
  },
  "1": {
    "item": "spinach pizza",
    "price": "$10.50"
  }
}
{
  "0": "Pittsburgh"
} | {
  "0": {
    "item": "veggie taco",
    "price": "$9.95"
  },
  "1": {
    "item": "steak taco",
    "price": "$10.95"
  }
}
(2 rows)

```

```

=> SELECT menu['0']['item'] FROM restaurant;
      menu
-----
cheese pizza
veggie taco
(2 rows)

```

The COPY statement shown in this example sets `flatten_maps` to false. Without that change, the keys for the complex columns would not work as expected, because record and array keys would be "flattened" at the top level. Querying `menu['0']['item']` would produce no results. Instead, query flattened values as in the following example:

```

=> SELECT menu['0.item'] FROM restaurant;
      menu
-----
veggie taco
cheese pizza
(2 rows)

```

Flattening directives apply to the entire COPY statement. You cannot flatten some columns and not others, or prevent flattening values in a complex column that is itself within a flattened flex table. Because flexible complex types and strongly-typed complex types require different values for flattening, you cannot combine strong and flexible complex types in the same load operation.

System tables for complex types

Information about all complex types is recorded in the [COMPLEX_TYPES](#) system table. You must have read permission for the external table that uses a type to see its entries in this system table. Complex types are not shown in the [TYPES](#) system table.

For [ROW](#) types, each row in `COMPLEX_TYPES` represents one field of one ROW. The field name is the name used in the table definition if present, or a generated name beginning with `_field` otherwise. Each row also includes the (generated) name of its containing type, a string beginning with `_ct_`. ("CT" stands for "complex type".)

The following example defines one external table and then shows the types in `COMPLEX_TYPES`:

```
=> CREATE EXTERNAL TABLE warehouse(
  name VARCHAR, id_map MAP<INT, VARCHAR>,
  data row(record INT, total FLOAT, description VARCHAR(100)),
  prices ARRAY[INT], comment VARCHAR(200), sales_total FLOAT, storeID INT)
AS COPY FROM ... PARQUET;
```

```
=> SELECT type_id, type_kind, type_name, field_id, field_name, field_type_name, field_position
FROM COMPLEX_TYPES ORDER BY type_id, field_name;
```

type_id	type_kind	type_name	field_id	field_name	field_type_name	field_position
45035996274278280	Map	_ct_45035996274278280	6	key	int	0
45035996274278280	Map	_ct_45035996274278280	9	value	varchar(80)	1
45035996274278282	Row	_ct_45035996274278282	9	description	varchar(80)	2
45035996274278282	Row	_ct_45035996274278282	6	record	int	0
45035996274278282	Row	_ct_45035996274278282	7	total	float	1
45035996274278284	Array	_ct_45035996274278284	6		int	0

(6 rows)

This table shows the fields for the two ROW types defined in the table. When a ROW contains another ROW, as is the case here with the nested address field, the field_type_name column uses the generated name of the contained ROW. The same number, minus the leading " ct ", serves as the field_id.

Schema evolution

When you load data, Vertica must be able to match the columns or fields in the data to the columns defined in the table. Typically, you use strong typing to specify the table columns and parsers reject data that does not match the table definition. Some parsers cause the entire load to fail if the data does not match, and some load what they can and produce warnings about unhandled data.

For long-lived databases or more volatile domains, new columns and fields can appear in data, disrupting existing ETL pipelines. Some parsers provide ways to handle differences between the data and the table definition.

Parquet and ORC

By default, the Parquet and ORC parsers use strong schema matching. This means that all columns in the data must be loaded in the same order as in the data. Unmatched columns produce load errors:

```
=> CREATE TABLE orders_summary(orderid INT, accountid INT);
=> COPY orders_summary FROM '/data/orders.parquet' PARQUET;
ERROR 9135: Attempt to load 2 columns from a parquet source [/data/orders.parquet] that has 3 columns
```

You can pick out only the specific columns you want using loose schema matching. Use the [do_soft_schema_match_by_name](#) parameter in the [PARQUET](#) or [ORC](#) parser. With loose schema matching, columns in the data are matched to columns in the table by their names. Columns in the data that are not part of the table definition are ignored:

```
=> COPY orders_summary FROM '/data/orders.parquet'
PARQUET(do_soft_schema_match_by_name=true);
Rows Loaded
-----
3
(1 row)
```

Alternatively, you can use [ALTER TABLE](#) to add new columns to the table definition and continue to use strong schema matching.

JSON and Avro

By default, the [JSON](#) and [Avro](#) parsers skip fields in the data that are not part of the table definition and proceed with the rest of the load. This behavior is in contrast to the Parquet and ORC parsers, which by default require that a table consume all of the columns in the data. This means that the JSON and Avro parsers are more flexible in the face of variability in the data, but also that you must monitor your loads more closely for new fields.

When creating tables that will use JSON or Avro data, a good first step is to infer a table definition from a sample data file using [INFER_TABLE_DDL](#). You can use the results to define a table. If later data files add more fields, the parser emits a warning and logs information about the new fields in the [UDX_EVENTS](#) system table. You can use this information to decide whether to alter the table definition or ignore the new fields.

If you are only interested in certain fields and don't care about new fields found in data loads, you can use the `suppress_warnings` parameter on the JSON or Avro parser to ignore them. If you suppress warnings, you can separately check for new fields from time to time with `INFER_TABLE_DDL` or by loading sample data with warnings enabled and without committing (`COPY...NO COMMIT`).

For a detailed discussion of this workflow, see [Schema changes](#) in [Data exploration](#).

Handling Non-UTF-8 input

Vertica supports loading data files in the Unicode UTF-8 format. You can load ASCII data, which is UTF-8 compatible. Character sets like ISO 8859-1 (Latin1) are incompatible with UTF-8 and are not directly supported.

If you have data that does not meet the UTF-8 standard, you can modify the data during the load or you can transform the data files before loading.

Checking data format

Before loading data from text files, you can use several Linux tools to ensure that your data is in UTF-8 format. The `file` command reports the encoding of any text files. For example:

```
$ file Date_Dimension.tbl
Date_Dimension.tbl: ASCII text
```

The `file` command could indicate ASCII text even though the file contains multibyte characters.

To check for multibyte characters in an ASCII file, use the `wc` command. For example:

```
$ wc Date_Dimension.tbl
1828 5484 221822 Date_Dimension.tbl
```

If the `wc` command returns an error such as `Invalid or incomplete multibyte or wide character`, the data file is using an incompatible character set.

This example shows two files that are not UTF-8 data files:

```
$ file data*
data1.txt: Little-endian UTF-16 Unicode text
data2.txt: ISO-8859 text
```

The results indicate that neither of the files is in UTF-8 format.

Converting data while loading

You can remove or replace non-UTF-8 characters in text data during the load. The `MAKEUTF8` function removes such characters by default, or you can specify a replacement string.

The following example shows how to use this function during a load. The original data is loaded into the `orig_name` column, and the transformed data is loaded into the `name` column. Typically you would use a FILLER column for the original value instead of adding the column to the table definition; this example adds the column to show the differences side by side.

```

=> CREATE TABLE people (orig_name VARCHAR, name VARCHAR);
CREATE TABLE

=> COPY people (orig_name, name AS MAKEUTF8(orig_name)) FROM ...;
Rows Loaded
-----
      8
(1 row)

=> SELECT * FROM people;
orig_name | name
-----+-----
Dáithí   | Dith
Fiona    | Fona
Móirín   | Mirn
Róisín   | Risn
Séamus   | Samus
Séan     | San
Tiarnán  | Tiarnn
Áine     | ine
(8 rows)

```

For general information about transforming data, see [Transforming data during loads](#).

Converting files before loading data

To convert files before loading them into Vertica, use the `iconv` UNIX command. For example, to convert the `data2.txt` file from the previous example, use the `iconv` command as follows:

```
$ iconv -f ISO88599 -t utf-8 data2.txt > data2-utf8.txt
```

See the man pages for `file` and `iconv` for more information.

Checking UTF-8 compliance after loading data

After loading data, use the `ISUTF8` function to verify that all of the string-based data in the table is in UTF-8 format. For example, if you loaded data into a table named `people` that has a `VARCHAR` column named `name`, you can use this statement to verify that all of the strings are UTF-8 encoded:

```
=> SELECT name FROM people WHERE NOT ISUTF8(name);
```

If all of the strings are in UTF-8 format, the query should not return any rows.

Transforming data during loads

To promote a consistent database and reduce the need for scripts to transform data at the source, you can transform data with an expression as part of loading. Transforming data while loading lets you compute values to insert into a target column, either from other columns or from values in the data that you load as `FILLER` columns (see [Deriving Table Columns From Data File Columns](#)). You can transform data to be loaded into columns of scalar types and native arrays, but not other [complex types](#).

For example, you might have text data that is not compatible with UTF-8, the encoding that Vertica expects. You can use the `MAKEUTF8` function during load to remove or replace non-UTF-8 characters, as illustrated in [Converting Data While Loading](#). Or you might want to extract fields for day, month, and year from a single input date.

When transforming data during a load, you load the data into a column normally, and then use that column in an expression to populate another column. The `COPY` statement must always contain at least one parsed column, which can be a `FILLER` column. You can intersperse parsed and computed columns in a `COPY` statement.

The following example extracts day, month, and year columns from a single input date column:

```

-> CREATE TABLE purchases
  (id INT, year VARCHAR(10), month VARCHAR(10), day VARCHAR(10), ts TIMESTAMP);

-> COPY purchases (id, year AS TO_CHAR(ts,'YYYY'),
  month AS TO_CHAR(ts,'MM'), day AS TO_CHAR(ts,'DD'),
  ts FORMAT 'YYYY-MM-DD') FROM STDIN;

Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 1943|2021-03-29
>> 1256|2021-03-30
>> 1512|2021-03-31
>> \.

-> SELECT * FROM purchases;
 id | year | month | day |      ts
-----+-----+-----+-----+-----
1256 | 2021 | 03   | 30 | 2021-03-30 00:00:00
1512 | 2021 | 03   | 31 | 2021-03-31 00:00:00
1943 | 2021 | 03   | 29 | 2021-03-29 00:00:00
(3 rows)

```

The input data has two columns, `id` and `ts` (timestamp). The COPY statement specifies the format of the timestamp column using the `FORMAT` option. The `TO_CHAR` function uses that format information to extract the `year`, `month`, and `day` columns.

Using expressions in COPY statements

The expression in a COPY statement can be as simple as a single column, or more complex, such as a case statement for multiple columns. An expression can specify multiple columns, and multiple expressions can refer to the same parsed column. You can use expressions for columns of all supported data types.

COPY expressions can use many SQL functions, operators, constants, NULLs, and comments, including these functions:

- [Date/time](#)
- [Formatting functions](#)
- [String](#)
- [Null-handling](#)
- [System information](#)

Requirements and restrictions:

- COPY expressions cannot use SQL meta-functions, [analytic](#) functions, [aggregate](#) functions, or computed columns.
- For computed columns, you must list all parsed columns in the COPY statement expression. Do not specify `FORMAT` or `RAW` in the source data for a computed column.
- The return data type of the expression must be coercible to that of the target column. Parsed column parameters are also coerced to match the expression.

Handling expression errors

Errors in expressions within your COPY statement are SQL errors. As such, they are handled differently from parse errors. When a parse error occurs, COPY rejects the row and adds it to the rejected data file or table. COPY also adds the reason for a rejected row to the exceptions file or the rejected data table. For example, COPY parsing does not implicitly cast data types. If a type mismatch occurs between the data being loaded and a column type (such as attempting to load a text value into a FLOAT column), COPY rejects the row and continues processing.

If an error occurs in an expression in your COPY statement, then by default the entire load fails. For example, if your COPY statement uses a function expression, and a syntax error exists in that expression, the entire load is rolled back. All SQL errors, including ones caused by rolling back the COPY, are stored in the Vertica log file. However, unlike parse rejections and exception messages, SQL expression errors are brief and may require further research.

You can have COPY treat errors in transformation expressions like parse errors. Rejected rows are added to the same file or table, and exceptions are added to the same exceptions file or table. To enable this behavior, set the `CopyFaultTolerantExpressions` configuration parameter to 1. (See [General parameters](#).)

Loading data with expression rejections is potentially slower than loading with the same number of parse rejections. Enable expression rejections if your data has a few bad rows, to allow the rest of the data to be loaded. If you are concerned about the time it takes to complete a load with many bad rows, use the `REJECTMAX` parameter to set a limit. If COPY finds more than `REJECTMAX` bad rows, it aborts and rolls back the load.

See [Handling messy data](#) for more information about managing rejected data.

Deriving table columns from data file columns

Your source data might contain one or more columns that do not exist in the target table, or you might want to use columns in the source to compute values for different columns in the table. In both cases, use the FILLER option with the source column.

In the following example, the table has columns for first name, last name, and full name, but the data being loaded contains columns for first, middle, and last names. The COPY statement reads all of the source data but only loads the source columns for first and last names. It constructs the data for the full name by concatenating each of the source data columns, including the middle name. The middle name is read as a FILLER column so it can be used in the concatenation, but is ignored otherwise. (There is no table column for middle name.)

```
--> CREATE TABLE names(first VARCHAR(20), last VARCHAR(20), full VARCHAR(60));
CREATE TABLE
--> COPY names(first,
              middle FILLER VARCHAR(20),
              last,
              full AS first||' '||middle||' '||last)
FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
--> Marc|Gregory|Smith
--> Sue|Lucia|Temp
--> Jon|Pete|Hamilton
--> \.
--> SELECT * from names;
first | last | full
-----+-----+-----
Jon | Hamilton | Jon Pete Hamilton
Marc | Smith | Marc Gregory Smith
Sue | Temp | Sue Lucia Temp
(3 rows)
```

If the name of the filler column is the same as the name of a column in the target table, you must disambiguate references elsewhere in the COPY statement. To refer to an ambiguous filler column, prefix the name with **"*FILLER*"**.

In the following example, JSON data contains an unencrypted password. The JSON data and the table definition use the same name for the field. Instead of loading the value directly, the COPY statement uses a filler column and a (hypothetical) function to encrypt the value. Both the table column (`users.password`) and the filler column (`"*FILLER*".password`) are fully qualified:

```
--> CREATE TABLE users(user VARCHAR(32), password VARCHAR(32));
--> COPY users(user, password FILLER VARCHAR(32),
              users.password AS encrypt("*FILLER".password))
FROM ... PARSER FJSONPARSER();
```

Distributing a load

Vertica can divide the work of loading data among multiple database nodes, taking advantage of parallelism to speed up the operation. How this is done depends on where the data is and what types of parallelism the parsers support.

Vertica can be most effective in distributing a load when the data to be loaded is found in shared storage available to all nodes. Sometimes, however, data is available only on specific nodes, which you must specify.

Types of load parallelism

Vertica supports several types of parallelism. All built-in parsers support distributed load, and some parsers support apportioned load and cooperative parse. The reference pages for individual parsers include the kinds of load parallelism they support.

Load parallelism is enabled by default but can be disabled. The configuration parameters named in this section are described in [General parameters](#).

Distributed load

Vertica distributes files in a multi-file load to several nodes to load in parallel, instead of loading all of them on a single node. Vertica automatically distributes a load if the files are accessible to all nodes and you do not restrict participating nodes.

Apportioned load and cooperative parse both require an input that can be divided at record boundaries. The difference is that cooperative parse does a sequential scan to find record boundaries, while apportioned load first jumps (seeks) to a given position and then scans. Some formats, like generic XML, do not support seeking.

Apportioned load

In an apportioned load, Vertica divides a single large file or other single source into segments (portions), which it assigns to several nodes to load in parallel. Apportioned load divides the load at planning time, based on available nodes and cores on each node.

To use apportioned load, you must ensure that the source is reachable by all participating database nodes. You typically use apportioned load with distributed file systems.

Apportioned load is enabled by default for parsers that support it. To disable it, set the `EnableApportionLoad` configuration parameter to 0.

Cooperative parse

By default, Vertica parses a data source in a single thread on one database node. If a parser supports cooperative parse, the node instead uses multiple threads to parallelize the parse. Cooperative parse divides a load at execution time, based on how threads are scheduled.

Cooperative parse is enabled by default for parsers that support it. To disable it, set the `EnableCooperativeParse` configuration parameter to 0.

Loading on specific nodes

You can indicate which node or nodes should parse an input path by using any of the following:

- A node name: `ON node`
- A set of nodes: `ON nodeset` (see [Specifying Distributed File Loads](#))
- `ON ANY NODE` (default for HDFS and cloud paths)
- `ON EACH NODE`

Using the `ON ANY NODE` clause indicates that the source path is available on all of the nodes. If you specify this clause, COPY parses the files from any node in the cluster. If the path contains a glob, COPY expands the glob on the initiator node. `ON ANY NODE` is the default for all file systems except Linux.

Using the `ON nodeset` clause indicates that the source file is on all named nodes. If you specify this clause, COPY opens the file and parses it from any node in the set. Be sure that the source file you specify is available and accessible on each applicable cluster node.

`ON node` and `ON ANY NODE` load each file once, choosing one node to perform the load. If, instead, you have different data on each node and you want to load all of it, and the path is the same, use `ON EACH NODE` :

```
=> COPY myTable FROM '/local_export/*.dat' ON EACH NODE;
```

If the path is not valid on all nodes, COPY loads the valid paths and produces a warning. If the path is a shared location, COPY loads it only once as for `ON ANY NODE` .

Use `ON EACH NODE` when you want to load from the same path on every node and the files are different. For example, if you have machine-specific data, such as system event logs, or if an operation wrote data on each node individually, you can use this clause to load all of it.

If the data to be loaded is on a client, use `COPY FROM LOCAL` instead of specifying nodes. All local files are loaded and parsed serially with each COPY statement, so you cannot perform parallel loads with the `LOCAL` option.

Specifying distributed file loads

You can direct individual files in a multi-file load to specific nodes:

```
=> COPY t FROM '/data/file1.dat' ON v_vmart_node0001, '/data/file2.dat' ON v_vmart_node0002;
```

You can use globbing (wildcard expansion) to specify a group of files with the `ON ANY NODE` option:

```
=> COPY t FROM '/data/*.dat' ON ANY NODE;
```

You can limit the nodes that participate in an apportioned load. Doing so is useful if you need to balance several concurrent loads. Vertica apportions each load individually; it does not account for other loads that might be in progress on those nodes. You can, therefore, potentially speed up your loads by managing apportioning yourself:

```
=> COPY t FROM '/data/big1.dat' ON (v_vmart_node0001, v_vmart_node0002, v_vmart_node0003),  
      '/data/big2.dat' ON (v_vmart_node0004, v_vmart_node0005);
```

You can specify a compression type for each path. However, because file compression is a filter, you cannot use apportioned load for a compressed file.

Specifying distributed loads with sources

You can also apportion loads using `COPY WITH SOURCE`. You can create sources and parsers with the user-defined load (UDL) API. If both the source and parser support apportioned load, and `EnableApportionLoad` is set, then Vertica attempts to divide the load among nodes.

The following example shows a load that you could apportion:

```
=> COPY t WITH SOURCE MySource() PARSER MyParser();
```

The built-in delimited parser supports apportioning, so you can use it with a user-defined source:

```
=> COPY t WITH SOURCE MySource();
```

Number of load streams

Although the number of files you can load is not restricted, the optimal number of load streams depends on several factors, including:

- Number of nodes
- Physical and logical schemas
- Host processors
- Memory
- Disk space

Using too many load streams can deplete or reduce system memory required for optimal query processing. See [Best practices for managing workload resources](#) for advice on configuring load streams.

Using transactions to stage a load

By default, `COPY` automatically commits itself and other current transactions except when loading temporary tables or querying external tables. You can override this behavior by qualifying the `COPY` statement with the `NO COMMIT` option. When you specify `NO COMMIT`, Vertica does not commit the transaction until you explicitly issue a `COMMIT` statement.

You can use `COPY...NO COMMIT` in two ways:

- Execute multiple `COPY` commands as a single transaction.
- Check data for constraint violations before committing the load.

Combine multiple `COPY` statements in the same transaction

When you combine multiple `COPY...NO COMMIT` statements in the same transaction, Vertica can consolidate the data for all operations into fewer [ROS](#) containers, and thereby perform more efficiently.

For example, the following set of `COPY...NO COMMIT` statements performs several copy statements sequentially, and then commits them all. In this way, all of the copied data is either committed or rolled back as a single transaction.

```
COPY... NO COMMIT;  
COPY... NO COMMIT;  
COPY... NO COMMIT;  
COPY X FROM LOCAL NO COMMIT;  
COMMIT;
```

Tip

Be sure to commit or roll back any previous DML operations before you use `COPY...NO COMMIT`. Otherwise, `COPY...NO COMMIT` is liable to include earlier operations that are still in progress, such as `INSERT`, in its own transaction. In this case, the previous operation and copy operation are combined as a single transaction and committed together.

Check constraint violations

If constraints are not enforced in the target table, `COPY` does not check for constraint violations when it loads data. To troubleshoot loaded data for constraint violations, use `COPY...NO COMMIT` with [ANALYZE CONSTRAINTS](#). Doing so enables you detect constraint violations before you commit the load operation and, if necessary, roll back the operation. For details, see [Detecting constraint violations](#).

Handling messy data

Loading data with COPY has two main phases, parsing and loading. During parsing, if COPY encounters errors it rejects the faulty data and continues loading data. Rejected data is created whenever COPY cannot parse a row of data. Following are some parser errors that can cause a rejected row:

- Unsupported parser options
- Incorrect data types for the table into which data is being loaded, including incorrect data types for members of collections
- Malformed context for the parser in use
- Missing delimiters

Optionally, COPY can reject data and continue loading when transforming data during the load phase. This behavior is controlled by a configuration parameter. By default, COPY aborts a load if it encounters errors during the loading phase.

Several optional parameters let you determine how strictly COPY handles rejections. For example, you can have COPY fail when it rejects a single row, or allow a specific number of rejections before the load fails. This section presents the parameters to determine how COPY handles rejected data.

Save rejected rows (REJECTED DATA and EXCEPTIONS)

The COPY statement automatically saves a copy of each rejected row in a rejections file. COPY also saves a corresponding explanation of what caused the rejection in an exceptions file. By default, Vertica saves both files in a database catalog subdirectory, called `CopyErrorLogs`, as shown in this example:

```
v_mart_node003_catalog\CopyErrorLogs\trans-STDIN-copy-from-rejected-data.1
v_mart_node003_catalog\CopyErrorLogs\trans-STDIN-copy-from-exceptions.1
```

You can optionally save COPY rejections and exceptions in one of two other ways:

- Use the REJECTED DATA and EXCEPTIONS options to save both outputs to locations of your choice. REJECTED DATA records rejected rows, while EXCEPTIONS records a description of why each row was rejected. If a path value is an existing directory or ends in '/', or the load includes multiple sources, files are written in that directory. (COPY creates the directory if it does not exist.) If a path value is a file, COPY uses it as a file prefix if multiple files are written.
- Use the REJECTED DATA AS TABLE option. This option writes both the rejected data and the exception descriptions to the same table. For more information, see [Saving rejected data to a table](#).

Note

Vertica recommends saving rejected data to a table. However, saving to a table excludes saving to a default or specific rejected data file.

If you save rejected data to a table, the table files are stored in the data subdirectory. For example, in a VMart database installation, rejected data table records are stored in the `RejectionTableData` directory as follows:

```
=> cd v_mart_node003_data\RejectionTableData\
=> ls
TABLE_REJECTED_RECORDS_"bg"_mytest01.example.-25441:0x6361_45035996273805099_1.1
TABLE_REJECTED_RECORDS_"bg"_mytest01.example.-25441:0x6361_45035996273805113_2.2
.
.
.
TABLE_REJECTED_RECORDS_"delimr"_mytest01.example.-5958:0x3d47_45035996273815749_1.1
TABLE_REJECTED_RECORDS_"delimr"_mytest01.example.-5958:0x3d47_45035996273815749_1.2
```

COPY LOCAL rejected data

For COPY LOCAL operations, if you use REJECTED DATA or EXCEPTIONS with a file path, the files are written on the client. If you want rejections to be available on all nodes, use REJECTED DATA AS TABLE instead of REJECTED DATA .

Enforce truncating or rejecting rows (ENFORCELENGTH)

When parsing CHAR, VARCHAR, BINARY, or VARBINARY data, rows may exceed the target table length. By default, COPY truncates such rows without rejecting them. Use the ENFORCELENGTH option to instead reject rows that exceed the target table.

For example, loading 'abc' into a table column specified as VARCHAR(2) results in COPY truncating the value to 'ab' and loading it. Loading the same row with the ENFORCELENGTH option causes COPY to reject the row.

Note

Vertica supports NATIVE and NATIVE VARCHAR values up to 65K. If any value exceeds this limit, COPY rejects the row, even when ENFORCELENGTH is not in use.

Specify a maximum number of rejections (REJECTMAX)

The REJECTMAX option specifies the maximum number of logical records that can be rejected before a load fails. A rejected row consists of the data that could not be parsed (or optionally transformed) into the corresponding data type during a bulk load. Rejected data does not indicate referential constraints. For information about using constraints, and the option of enforcing constraints during bulk loading, see [Constraints](#).

When the number of rejected records becomes equal to the REJECTMAX value, the load fails. If you do not specify a value for REJECTMAX, or if the value is 0, COPY allows an unlimited number of exceptions to occur.

If you allow COPY to reject rows and proceed when it encounters transformation errors, consider using REJECTMAX to limit the impact. See [Handling Transformation Errors](#).

Handling transformation errors

By default, COPY aborts a load if it encounters errors when performing transformations. This is the default because rejecting transformation errors is potentially more expensive than rejecting parse errors. Sometimes, however, you would prefer to load the data anyway and reject the problematic rows, the way it does for parse errors.

To have COPY treat errors in transformation expressions like parse errors, set the CopyFaultTolerantExpressions configuration parameter to 1. (See [General parameters](#).) Rows that are rejected during transformation, in the expression-evaluation phase of a data load, are written to the same destination as rows rejected during parsing. Use REJECTED DATA or REJECTED DATA AS TABLE to specify the output location.

You might want to enable transformation rejections if your data contains a few bad rows. By enabling these rejections, you can load the majority of your data and proceed. Vertica recommends using REJECTMAX when enabling transformation rejections.

If your data contains many bad values, then the performance for loading the good rows could be worse than with parser errors.

Abort data loads for any error (ABORT ON ERROR)

Using the ABORT ON ERROR option is the most restrictive way to load data, because no exceptions or rejections are allowed. A COPY operation stops if any row is rejected. No data is loaded and Vertica rolls back the command.

If you use ABORT ON ERROR as part of a CREATE EXTERNAL TABLE statement, the option is used whenever a query references the external table. The offending error is saved in the COPY exceptions or rejected data file.

Understanding row rejections and rollback errors

Depending on the type of error that COPY encounters, Vertica does one of the following:

- Rejects the offending row and loads other rows into a table
- Rolls back the entire COPY statement without loading any data

Note

If you specify ABORT ON ERROR with the COPY statement, the load automatically rolls back if COPY cannot parse any row.

COPY cannot parse rows that contain any of the following:

- Incompatible data types
- Missing fields
- Missing delimiters

COPY rolls back a load if it encounters any of these conditions:

- Server-side errors, such as lack of memory
- Primary key or foreign key constraint violations
- Loading NULL data into a NOT NULL column
- Transformation errors (by default)

This example illustrates what happens when Vertica cannot coerce a row to the requested data type. For example, in the following COPY statement, "a::INT + b::INT" is a SQL expression in which a and b are derived values:

```
=> CREATE TABLE t (i INT);
=> COPY t (a FILLER VARCHAR, b FILLER VARCHAR, i AS a::INT + b::INT)
  FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> cat|dog
>> \.
```

Vertica cannot parse the row to the requested data type and rejects the row:

```
ERROR 2827: Could not convert "cat" from column "**FILLER**".a to an int8
```

If **a** resolved to 'cat' and **b** to 'dog', the next expression 'cat'::INT + 'dog'::INT would return an expression evaluator error:

```
=> SELECT 'cat'::INT + 'dog'::INT;
ERROR 3681: Invalid input syntax for integer: "cat"
```

The following COPY statement would also roll back because Vertica cannot parse the row to the requested data type:

```
=> COPY t (a FILLER VARCHAR, i AS a::INT) FROM STDIN;
```

In the following COPY statement, Vertica rejects only the offending row without rolling back the statement. Instead of evaluating the 'cat' row as a VARCHAR type, COPY parses 'cat' directly as an INTEGER.

```
=> COPY t (a FILLER INT, i AS a) FROM STDIN;
```

In the following example, transformation errors are rejected instead of aborting the load.

```
=> ALTER DATABASE DEFAULT SET CopyFaultTolerantExpressions = 1;
ALTER DATABASE

=> CREATE TABLE sales (price INTEGER);
CREATE TABLE

=> COPY sales (f FILLER VARCHAR, price AS f::INT)
  FROM STDIN REJECTED DATA AS TABLE sales_rej;

=> COPY sales FROM STDIN REJECTED DATA AS TABLE sales_rej;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>>1
>>2a
>>3
>>\.

=> SELECT * FROM sales;
price
-----
 1
 3
(2 rows)

=> SELECT rejected_data, rejected_reason FROM sales_rej;
rejected_data |          rejected_reason
-----+-----
 Tuple (2a)  | ERROR 2827: Could not convert "2a" from column "**FILLER**".f to an int8
(1 row)
```

Saving load rejections (REJECTED DATA)

Load rejections are data rows that **COPY** did not load due to a parser exception or, optionally, transformation error. By default Vertica saves information about rejections in files on database nodes. A better approach is to [save rejections to a table](#).

By default, if you do not specify a rejected data file, **COPY** saves rejected data files to this location:

```
catalog_dir/CopyErrorLogs/target_table-source-copy-from-rejected-data.sequence-number
```

catalog_dir

The database catalog files directory, for example `/home/dbadmin/VMart/v_vmart_node0001_catalog`.

target_table

The table into which data was loaded.

source

The source of the load data, which can be STDIN or a file name, such as `baseball.csv`.

copy-from-rejected-data. sequence-number

The default name for a rejected data file, followed by a numeric suffix, indicating the number of files, such as `.1`, `.2`, `.3`. For example, this default file name indicates file 3 after loading from STDIN: `fw-STDIN-copy-from-rejected-data.3`.

Saving rejected data to the default location, or to a location of your choice, lets you review the file contents, resolve problems, and reload the data from the rejected data files. Saving rejected data to a table lets you query the table to see rejected data rows and the reasons (exceptions) why the rows could not be parsed. Vertica recommends saving rejected data to a table.

Multiple rejected data files

Unless a load is very small (< 10MB), **COPY** creates more than one file to hold rejected rows. Several factors determine how many files **COPY** creates for rejected data, including:

- Number of sources being loaded
- Total number of rejected rows
- Size of the source file (or files)
- Cooperative parsing and number of threads being used
- UDLs that support apportioned loads
- For your own parser, the number of objects returned from `prepareUDSources()`

Naming conventions for rejected files

You can specify one or more files for rejected data using the **REJECTED DATA** clause. If you do so, and **COPY** requires multiple files for rejected data, **COPY** uses the rejected data file names you supply as a prefix and appends numeric suffixes. For example, if you specify **REJECTED DATA my_rejects**, and the file you are loading is large enough (> 10MB), rejections are written to several files named `my_rejects-1`, `my_rejects-2`, and so on.

By default **COPY** uses cooperative parsing, which means a node uses multiple threads to load portions in parallel. Depending on the file or portion size, each thread generates at least one rejected data file per source file or portion, and returns load results to the initiator node. The file suffix is a thread index when **COPY** uses multiple threads (`.1`, `.2`, `.3`, and so on).

If you use **COPY** with a UDL that supports apportioned load, the file suffix is an offset value. UDLs that support apportioned loading render cooperative parsing unnecessary. For apportioned loads, **COPY** creates at least one rejected file per data portion, and more files depending on the size of the load and number of rejected rows.

For all data loads except **COPY LOCAL**, **COPY** behaves as follows:

If no rejected data file is specified:

- For a single data file or **STDIN**, **COPY** stores one or more rejected data files in the default location.
- For multiple source files, **COPY** stores all rejected data in separate files in the default directory, using the source file as a filename prefix.
- Rejected data files are returned to the initiator node.

If a rejected data file is specified:

- For one data file, **COPY** interprets the rejected data path as a file, and stores all rejected data at the location. If more than one file is required from parallel processing, **COPY** appends a numeric suffix. If the path is not a file, **COPY** returns an error.
- For multiple source files, **COPY** interprets the rejected path as a directory. **COPY** stores all information in separate files, one for each source. If the path is not a directory, **COPY** returns an error.
COPY accepts only one path per node. For example, if you specify the rejected data path as `my_rejected_data`, **COPY** creates a directory of that name on each node. If you provide more than one rejected data path, **COPY** returns an error.
- Rejected data files are not shipped to the initiator node.

Maximum length of file names

Loading multiple input files in one statement requires specifying full path names for each file. Keep in mind that long input file names, combined with rejected data file names, can exceed the operating system's maximum length (typically 255 characters). To work around file names that exceed the maximum length, use a path for the rejected data file that differs from the default path—for example, `/tmp/<shorter-file-name>`.

Saving rejected data to a table

Use the **REJECTED DATA AS TABLE** option to collect rejected data, including exceptions, in a table that can be queried. **REJECTED DATA AS TABLE** is incompatible with rejection or exception paths.

When you use **REJECTED DATA AS TABLE**, Vertica creates a new table if one does not exist, or appends to an existing table from a previous load. Vertica always creates the table if it does not already exist, even if the load produces no rejections. You cannot create the table directly.

Load rejection tables do not support DML and DDL operations and are not **K-safe**. You can query and drop them.

To make the data in a rejected table K-safe, you can copy it to another table using **CREATE TABLE AS**:

```
-> CREATE TABLE save_rejections AS SELECT * FROM rejected_data_table;
```

Alternatively, you can copy data to another table using **INSERT SELECT**.

Location of rejected data table records

When you save rejected records to a table, the data for the table is saved in a database data subdirectory, **RejectionTableData**. For example, a VMart database uses a path like `/home/dbadmin/VMart/v_vmart_node0001_data/RejectionTableData`.

If you need to make rejected data available from outside of Vertica, you can export the rejections table to a shared file system.

Vertica suggests that you periodically drop any rejected data tables that you no longer require.

Using COPY NO COMMIT

If the **COPY** statement includes the **NO COMMIT** option, and the rejections table does not already exist, Vertica saves the rejected data table as a LOCAL TEMP table.

Rejected-data tables are useful for Extract-Load-Transform workflows, where you will likely use temporary tables more frequently. The rejected-data tables let you quickly load data and identify which records failed to load. If you load data into a temporary table that you created using the **ON COMMIT DELETE** clause, the **COPY** operation will not commit.

Querying a rejected data table

After a load, you can query the corresponding rejections table for information about failures. For example, consider the following table definition and **COPY** statement:

```
-> CREATE TABLE loader(x INT)
CREATE TABLE
-> COPY loader FROM STDIN REJECTED DATA AS TABLE loader_rejects:
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 1
>> 2
>> 3
>> a
>> \.
```

Three rows were successfully loaded:

```

=> SELECT * FROM loader;
x
_
1
2
3
(3 rows)

```

The `loader_rejects` table records the failed row. The data that was rejected is in the `rejected_data` column and the reason for the rejection is in `rejected_reason` :

```

=> SELECT * FROM loader_rejects;
[ RECORD 1 ]-----+-----
node_name      | v_vmart_node0001
file_name      | STDIN
session_id     | v_vmart_node0001.example.-24016:0x3439
transaction_id | 45035996274080923
statement_id   | 1
batch_number   | 0
row_number     | 4
rejected_data  | a
rejected_data_orig_length | 1
rejected_reason | Invalid integer format 'a' for column 1 (x)

```

The rejected data table has the following columns:

Column	Data Type	Description
<code>node_name</code>	<code>VARCHAR</code>	The name of the Vertica node on which the input load file was located.
<code>file_name</code>	<code>VARCHAR</code>	The name of the file being loaded, which applies if you loaded a file (as opposed to using STDIN).
<code>session_id</code>	<code>VARCHAR</code>	The session ID number in which the COPY statement occurred.
<code>transaction_id</code>	<code>INTEGER</code>	Identifier for the transaction within the session, if any; otherwise NULL.
<code>statement_id</code>	<code>INTEGER</code>	The unique identification number of the statement within the transaction that included the rejected data. <div style="background-color: #e6e6fa; padding: 10px; border: 1px solid #d1c4e9;"> <p>Tip You can use the <code>session_id</code> , <code>transaction_id</code> , and <code>statement_id</code> columns to create joins with many system tables. For example, if you join against the <code>QUERY_REQUESTS</code> table using those three columns, the <code>QUERY_REQUESTS.REQUEST</code> column contains the actual <code>COPY</code> statement (as a string) used to load this data.</p> </div>
<code>batch_number</code>	<code>INTEGER</code>	INTERNAL USE. Represents which batch (chunk) the data comes from.
<code>row_number</code>	<code>INTEGER</code>	The rejected row number from the input file, or -1 if it could not be determined. The value can be -1 when using cooperative parse. Each parse operation resets the row number, so in an apportioned load, there can be several entries with the same row number but different rows.
<code>rejected_data</code>	<code>LONG VARCHAR</code>	The data that was not loaded.

<code>rejected_data_orig_length</code>	INTEGER	The length of the rejected data.
<code>rejected_reason</code>	VARCHAR	The error that caused the rejected row. This column returns the same message that exists in a load exceptions file when you do not save to a table.

Correcting rejected data

If a load rejects data, you can save the rejected data in a file, correct the errors, and reload the updated file. First, direct `vsqll` to show only tuples and set the output format:

```
-> !t
Showing only tuples.
-> !a
Output format is unaligned.
```

Then query the rejections table and direct output to a file:

```
-> !o rejected.txt
-> SELECT rejected_data FROM loader_rejects;
-> !o
```

The saved file has the following output:

```
-> !l cat rejected.txt
1
```

You can edit the file to correct the errors and then use `COPY` to load the updated file.

Saving load exceptions (EXCEPTIONS)

`COPY` exceptions consist of informational messages describing why a row of data could not be parsed. The `EXCEPTIONS` option lets you specify a file to which `COPY` writes exceptions. If you omit this option, `COPY` saves exception files to the following path: `catalog-dir/CopyErrorLogs/ tablename - sourcefilename -copy-from-exceptions` , where:

- `catalog-dir` is the directory holding the database catalog files
- `table` is the name of the table being loaded into
- `sourcefile` is the name of the file being loaded

Note

`REJECTED DATA AS TABLE` is mutually exclusive with `EXCEPTIONS` .

The file produced by the `EXCEPTIONS` option indicates the line number and the reason for each exception.

If copying from `STDIN`, the source file name is `STDIN` .

You can specify rejected data and exceptions files for individual files in a data load. Separate rejected data and exception file names with commas in the `COPY` statement.

You must specify a filename in the path to load multiple input files. Keep in mind that long table names combined with long data file names can exceed the operating system's maximum length (typically 255 characters). To work around file names exceeding the maximum length, use a path for the exceptions file that differs from the default path; for example, `/tmp/<shorter-file-name>` .

If you specify an `EXCEPTIONS` path:

- For one data file, the path must be a file, and `COPY` stores all information in this file.
- For multiple data files, the path must be a directory. `COPY` creates one file in this directory for each data file.
- Exceptions files are not stored on the initiator node.
- You can specify only one path per node.

If you do not specify the `EXCEPTIONS` path, `COPY` stores exception files in the default directory.

`COPY` rejected data and exception files

When executing a **COPY** statement, and parallel processing is ON (the default setting), COPY creates separate threads to process load files. Typically, the number of threads depends on the number of node cores in the system. Each node processes part of the load data. If the load succeeds overall, any parser rejections that occur during load processing are written to that node's specific rejected data and exceptions files. If the load fails, the rejected data file contents can be incomplete, or empty. If you do not specify a file name explicitly, COPY uses a default name and location for rejected data files. See the next topic for specifying your own rejected data and exception files.

Both rejected data and exceptions files are saved and stored on a per-node basis. This example uses multiple files as **COPY** inputs. Since the statement does not include either the **REJECTED DATA** or **EXCEPTIONS** parameters, rejected data and exceptions files are written to the default location, the database catalog subdirectory, **CopyErrorLogs**, on each node:

```
\set dir `pwd`/data/ \set remote_dir /vertica/test_dev/tmp_ms/
\set file1 ""':dir'C1_large_tbl.dat""
\set file2 ""':dir'C2_large_tbl.dat""
\set file3 ""':remote_dir'C3_large_tbl.dat""
\set file4 ""':remote_dir'C4_large_tbl.dat""
=>COPY large_tbl FROM :file1 ON site01, :file2 ON site01,
      :file3 ON site02,
      :file4 ON site02
      DELIMITER '|';
```

Specifying rejected data and exceptions files

The optional **COPY REJECTED DATA** and **EXCEPTIONS** parameters **'path'** element lets you specify a non-default path in which to store the files.

If **path** resolves to a storage location, and the user invoking COPY is not a superuser, these are the required permissions:

- The storage location must have been created (or altered) with the **USER** option (see [CREATE LOCATION](#) and [ALTER LOCATION USE](#))
- The user must already have been granted **READ** access to the storage location where the file(s) exist, as described in [GRANT \(storage location\)](#)

Both parameters also have an optional **ON nodename** clause that uses the specified path:

```
...[ EXCEPTIONS 'path' [ ON nodename ] [, ...] ]...[ REJECTED DATA 'path' [ ON nodename ] [, ...] ]
```

While **'path'** specifies the location of the rejected data and exceptions files (with their corresponding parameters), the optional **ON nodename** clause moves any existing rejected data and exception files on the node to the specified path on the same node.

Saving rejected data and exceptions files to a single server

The **COPY** statement does not have a facility to merge exception and rejected data files after **COPY** processing is complete. To see the contents of exception and rejected data files requires accessing each node's specific files.

Note

To save all exceptions and rejected data files on a network host, be sure to give each node's files unique names, so that different cluster nodes do not overwrite other nodes' files. For instance, if you set up a server with two directories (**/vertica/exceptions** and **/vertica/rejections**), specify file names for each Vertica cluster node to identify each node, such as **node01_exceptions.txt** and **node02_exceptions.txt**. This way, each cluster node's files are easily distinguishable in the exceptions and rejections directories.

Using VSQL variables for rejected data and exceptions files

This example uses **vsql** variables to specify the path and file names to use with the **exceptions** and **rejected data** parameters (**except_s1** and **reject_s1**). The **COPY** statement specifies a single input file (**large_tbl**) on the initiator node:

```
\set dir `pwd`/data/ \set file1 ""':dir'C1_large_tbl.dat""
\set except_s1 ""':dir'exceptions""
\set reject_s1 ""':dir'rejections""

COPY large_tbl FROM :file1 ON site01 DELIMITER '|'
REJECTED DATA :reject_s1 ON site01
EXCEPTIONS :except_s1 ON site01;
```

This example uses variables to specify exception and rejected data files (**except_s2** and **reject_s2**) on a remote node. The **COPY** statement consists of a single input file on a remote node (**site02**):

```
\set remote_dir /vertica/test_dev/tmp_ms/\set except_s2 ""':remote_dir'exceptions""
\set reject_s2 ""':remote_dir'rejections""
```

```
COPY large_tbl FROM :file1 ON site02 DELIMITER '|'
REJECTED DATA :reject_s2 ON site02
EXCEPTIONS :except_s2 ON site02;
```

This example uses variables to specify that the exception and rejected data files are on a remote node (indicated by `:remote_dir`). The inputs to the COPY statement consist of multiple data files on two nodes (`site01` and `site02`). The `exceptions` and `rejected data` options use the `ON nodename` clause with the variables to indicate where the files reside (`site01` and `site02`):

```
\set dir `pwd`/data/ \set remote_dir /vertica/test_dev/tmp_ms/
\set except_s1 ""':dir'""
\set reject_s1 ""':dir'""
\set except_s2 ""':remote_dir'""
\set reject_s2 ""':remote_dir'""
COPY large_tbl FROM :file1 ON site01,
    :file2 ON site01,
    :file3 ON site02,
    :file4 ON site02
    DELIMITER '|'
    REJECTED DATA :reject_s1 ON site01, :reject_s2 ON site02
    EXCEPTIONS :except_s1 ON site01, :except_s2 ON site02;
```

COPY LOCAL rejection and exception files

Invoking COPY LOCAL (or COPY LOCAL FROM STDIN) does not automatically create rejected data and exceptions files. This behavior differs from using COPY, which saves both files automatically, regardless of whether you use the optional `REJECTED DATA` and `EXCEPTIONS` parameters to specify either file explicitly.

Use the `REJECTED DATA` and `EXCEPTIONS` parameters with COPY LOCAL and COPY LOCAL FROM STDIN to save the corresponding output files on the client. If you do *not* use these options, rejected data parsing events (and the exceptions that describe them) are not retained, even if they occur.

You can load multiple input files using COPY LOCAL (or COPY LOCAL FROM STDIN). If you also use the `REJECTED DATA` and `EXCEPTIONS` options, the statement writes rejected rows and exceptions and to separate files. The respective files contain all rejected rows and corresponding exceptions, respectively, regardless of how many input files were loaded.

If COPY LOCAL does not reject any rows, it does not create either file.

Note

Because COPY LOCAL (and COPY LOCAL FROM STDIN) must write any rejected rows and exceptions to the client, you cannot use the `[ON nodename]` clause with either the `rejected data` or `exceptions` options.

Specifying rejected data and exceptions files

To save any rejected data and their exceptions to files:

1. In the COPY LOCAL (and COPY LOCAL FROM STDIN) statement, use the `REJECTED DATA 'path'` and the `EXCEPTIONS 'path'` parameters, respectively.
2. Specify two different file names for the two options. You cannot use one file for both the `REJECTED DATA` and the `EXCEPTIONS`.
3. When you invoke COPY LOCAL or COPY LOCAL FROM STDIN, the files you specify need not pre-exist. If they do, COPY LOCAL must be able to overwrite them.

You can specify the path and file names with vsql variables:

```
\set rejected ../except_reject/copyLocal.rejected
\set exceptions ../except_reject/copyLocal.exceptions
```

Note

Using `COPY LOCAL` does not support storing rejected data in a table, as you can when using the `COPY` statement.

When you use the COPY LOCAL or COPY LOCAL FROM STDIN statement, specify the variable names for the files with their corresponding parameters:

```
=> COPY large_tbl FROM LOCAL rejected_data :rejected_exceptions :exceptions;
=> COPY large_tbl FROM LOCAL STDIN rejected_data :rejected_exceptions :exceptions;
```

Monitoring COPY loads and metrics

You can check COPY loads using:

- Vertica functions
- LOAD_STREAMS system table
- LOAD_SOURCES system table

More generally, the [EXECUTION_ENGINE_PROFILES](#) system table records information about query events, including loads.

Using Vertica functions

Two meta-functions return COPY metrics for the number of accepted or rejected rows from the most recent COPY statement run in the current session:

1. To get the number of accepted rows, use the [GET_NUM_ACCEPTED_ROWS](#) function:

```
=> select get_num_accepted_rows();
get_num_accepted_rows
-----
                11
(1 row)
```

2. To check the number of rejected rows, use the [GET_NUM_REJECTED_ROWS](#) function:

```
=> select get_num_rejected_rows();
get_num_rejected_rows
-----
                0
(1 row)
```

Note

GET_NUM_ACCEPTED_ROWS and GET_NUM_REJECTED_ROWS support loads from STDIN, COPY LOCAL from a Vertica client, or a single file on the initiator. You cannot use these functions for multi-node loads.

Using the CURRENT_LOAD_SOURCE function

You can include the [CURRENT_LOAD_SOURCE](#) function as a part of the COPY statement. Doing so allows you to insert into a column the input file name or value computed by this function.

To insert the file names into a column from multiple source files:

```
=> COPY t (c1, c2, c3 as CURRENT_LOAD_SOURCE()) FROM '/home/load_file_1' ON exampledb_node02,
'/home/load_file_2' ON exampledb_node03 DELIMITER ';;';
```

Using the LOAD_STREAMS system table

Vertica includes a set of system tables that include monitoring information. The [LOAD_STREAMS](#) system table includes information about load stream metrics from [COPY](#) and [COPY FROM VERTICA](#) statements. Thus, you can query table values to get COPY metrics.

Vertica maintains system table metrics until they reach a designated size quota (in kilobytes). This quota is set through internal processes, which you cannot set or view directly.

Labeling copy streams

COPY can include the STREAM NAME parameter to label its load stream so it is easy to identify in the LOAD_STREAMS system table. For example:

```
=> COPY mytable FROM myfile DELIMITER '|' STREAM NAME 'My stream name';
```

Load stream metrics

The following [LOAD_STREAMS](#) columns show on the status of a load as it progresses:

Column name	Value...
<code>ACCEPTED_ROW_COUNT</code>	Increases during parsing, up to the maximum number of rows in the input file.
<code>PARSE_COMPLETE_PERCENT</code>	Remains zero (0) until all named pipes return an EOF. While COPY awaits an EOF from multiple pipes, it can appear to be hung. However, before canceling the COPY statement, check your system CPU and disk accesses to determine if any activity is in progress. In a typical load, the <code>PARSE_COMPLETE_PERCENT</code> value can either increase slowly or jump quickly to 100%, if you are loading from named pipes or STDIN.
<code>SORT_COMPLETE_PERCENT</code>	Remains at 0 when loading from named pipes or STDIN. After <code>PARSE_COMPLETE_PERCENT</code> reaches 100 percent, <code>SORT_COMPLETE_PERCENT</code> increases to 100 percent.

Depending on the data sizes, a significant lag can occur between the time `PARSE_COMPLETE_PERCENT` reaches 100 percent and the time `SORT_COMPLETE_PERCENT` begins to increase.

This example queries load stream data from the `LOAD_STREAMS` system table:

```
=> \pset expanded
Expanded display is on.
=> SELECT stream_name, table_name, load_start, accepted_row_count,
  rejected_row_count, read_bytes, unsorted_row_count, sorted_row_count,
  sort_complete_percent FROM load_streams;
-[ RECORD 1 ]-----+-----
stream_name      | fact-13
table_name       | fact
load_start       | 2010-12-28 15:07:41.132053
accepted_row_count | 900
rejected_row_count | 100
read_bytes       | 11975
input_file_size_bytes | 0
parse_complete_percent | 0
unsorted_row_count | 3600
sorted_row_count  | 3600
sort_complete_percent | 100
```

Using the `LOAD_SOURCES` system table

The `LOAD_STREAMS` table shows the total number of rows that were loaded or rejected. Grouping this information by source can help you determine from where data is coming. The `LOAD_SOURCES` system table includes some of the same data as `LOAD_STREAMS` does but adds this source-specific information. If apportioning is enabled, `LOAD_SOURCES` also provides information about how loads are apportioned among nodes.

You can use this table to identify causes of differing query results. For example, you can use the following statement to create an external table based on globs:

```
=> CREATE EXTERNAL TABLE tt AS COPY WITH SOURCE AWS(dir = 'foo', file = '*');
```

If you select from this table, Vertica loads data from every file in the `foo` directory and creates one row in the `LOAD_SOURCES` table for each file. Suppose you later repeat the query and see different results. You could look at the `LOAD_SOURCES` table and discover that—between the two queries—somebody added another file to the `foo` directory. Because each file is recorded in `LOAD_SOURCES`, you can see the new file that explains the changed query results.

If you are using many data sources, you might prefer to disable this reporting. To disable reporting, set the `LoadSourceStatisticsLimit` configuration parameter to 0. This parameter sets the upper bound on the number of sources profiled by `LOAD_SOURCES` per load. The default value is 256.

Automatic load

A data loader automatically loads new files from a location so that you do not have to add them to Vertica manually. Automatically loading new data into ROS tables is an alternative to using external tables. External tables load selected data at query time, which can be convenient but also can incur API costs for object stores.

A data loader is tied to a path for data and a target table. When executed, the loader attempts to load files that it has not previously loaded. A loader has a retry limit to prevent malformed files from being tried over and over. Data loaders record monitoring information in the [DATA_LOADER_EVENTS](#) system table.

You can execute a data loader in the following ways:

- Use EXECUTE DATA LOADER to load new data on demand.
- Use a scheduled stored procedure to load new data periodically.
- Use an AWS SQS queue to load data automatically in response to notifications.

Data pipelines

Automatic load enables data pipelines. The usual workflow is:

1. Stage files for loading, adding new files over time.
2. Run the data loader automatically, either periodically as a scheduled task or (for AWS) using SQS triggers.
3. Remove loaded files from the staging path.

Data loaders do not detect if files have been edited or deleted. When a data loader runs, it attempts to load all files that it has not yet loaded (up to the retry limit).

Records in the monitoring table are eventually purged. If previously-loaded files are still in the source path, future executions of the data loader will load them again. To avoid duplicate loads, you can set the purge interval to a value that is higher than your retention time for source files.

Creating loaders

A data loader connects a table in Vertica to a source path. The loader definition includes a COPY statement. The FROM clause includes the source path with globbing.

Use [CREATE DATA LOADER](#) to create the loader:

```
--> CREATE TABLE sales(...);  
--> CREATE DATA LOADER sales_dl AS COPY sales FROM 's3://MyBucket/sales/2023/*.dat';
```

The source path can be any shared file system or object store that all database nodes can access. To use an HDFS or Linux file system safely, you must prevent the loader from reading a partially-written file. One way to achieve this is to only execute the loader when files are not being written to the loader's path. Another way to achieve this is to write new files in a temporary location and move them to the loader's path only when they are complete.

Executing loaders

[EXECUTE DATA LOADER](#) executes the loader:

```
--> EXECUTE DATA LOADER sales_dl;  
Rows Loaded  
-----  
5  
(1 row)
```

By default, Vertica retries a failed file load three times. You can change this value using the RETRY LIMIT argument.

Vertica groups input files into batches to distribute the load for better performance. You can override this behavior if needed.

EXECUTE DATA LOADER runs the loader once. Create a scheduled task to run it periodically:

```
--> CREATE SCHEDULE daily_load USING CRON '0 13 * * *';  
-- statement must be quoted:  
--> CREATE PROCEDURE dl_runner() as $$ begin EXECUTE 'EXECUTE DATA LOADER sales_dl'; end; $$;  
--> CREATE TRIGGER t_load ON SCHEDULE daily_load EXECUTE PROCEDURE dl_runner() AS DEFINER;
```

If the files to be loaded are in an AWS S3 bucket, you can use an SQS (Simple Queue Service) queue on AWS to notify Vertica to load new files as they are added to the bucket. You define a [trigger](#) as part of the data loader, and Vertica automatically runs EXECUTE DATA LOADER in response to events in the queue.

Monitoring loads

The [DATA_LOADERS](#) system table shows all defined loaders, and the [DATA_LOADER_EVENTS](#) system table records load events for all data loaders. You must own or have any privilege on a data loader to see its events in DATA_LOADER_EVENTS.

Records in the events table are purged periodically. You can set the purge frequency for individual data loaders in CREATE DATA LOADER or change it using ALTER DATA LOADER. The default is 14 days.

Using load scripts

You can write and run a load script for the [COPY](#) statement using a simple text-delimited file format. For information about other load formats see [Data formats](#). Vertica recommends that you load the smaller tables before the largest tables. To check data formats before loading, see [Handling Non-UTF-8 input](#).

To define a data pipeline to automatically load new files, see [Automatic load](#).

Using absolute paths in a load script

Unless you are using the [COPY FROM LOCAL](#) statement, using [COPY](#) on a remote client requires an absolute path for a data file. You cannot use relative paths on a remote client. For a load script, you can use vsql variables to specify the locations of data files relative to your Linux working directory.

To use vsql variables to specify data file locations:

1. Create a vsql variable containing your Linux current directory.

```
\set t_pwd `pwd`
```

2. Create another vsql variable that uses a path relative to the Linux current directory variable for a specific data file.

```
\set input_file "${t_pwd}/Date_Dimension.tbl"
```

3. Use the second variable in the COPY statement:

```
=> COPY Date_Dimension FROM :input_file DELIMITER '|';
```

4. Repeat steps 2 and 3 to load all data files.

Note

[COPY FROM LOCAL](#) does not require an absolute path for data files. You can use paths that are relative to the client's directory system.

Running a load script

You can run a load script on any host, as long as the data files are on that host.

1. Change your Linux working directory to the location of the data files.

```
$ cd /opt/vertica/doc/retail_example_database
```

2. Run the Administration Tools.

```
$/opt/vertica/bin/admintools
```

3. Connect to the database.

4. Run the load script.

Troubleshooting data loads

You might encounter the following issues when loading data. For issues specific to external tables, see [Troubleshooting external tables](#).

Cannot load data because all columns are complex types

A native table must contain at least one column that is either a scalar type or a native array (one-dimensional array of scalar types). If the data you wish to load consists entirely of complex types, you must add a scalar column to the table before loading the data. You do not need to populate the scalar column.

First, create a native table with the columns in the data plus one scalar column, and then load the data into that table as shown in the following example:

```
-- Native table with extra scalar column:
=> CREATE TABLE customers(person ROW(name VARCHAR, card VARCHAR), tempval int);
CREATE TABLE

-- Load complex data, ignoring scalar column:
=> COPY customers(person) FROM :custdata PARQUET;
Rows Loaded
-----
      3
(1 row)
```

Load fails because of disk quota

COPY can fail if the volume of data being loaded causes a table or schema to exceed a disk quota:

```
ERROR 0: Disk Quota for the Table Level Exceeded
HINT: Delete data and PURGE or increase disk quota at the table level
```

By default, Vertica tables and schemas do not have a disk quota; they are limited only by the capacity of your hardware and license. However, a superuser can set quotas, as described in [Disk quotas](#).

If you encounter a failure due to quota, you cannot simply use [DELETE](#) to reduce consumption. DELETE does not free space, because deleted data is still preserved in the storage containers. To reclaim space you must purge deleted data; see [Removing table data](#).

Reads from Parquet files report unexpected data-type mismatches

If a Parquet file contains a column of type STRING but the column in Vertica is of a different type, such as INTEGER, you might see an unclear error message. In this case Vertica reports the column in the Parquet file as BYTE_ARRAY, as shown in the following example:

```
ERROR 7247: Datatype mismatch: column 2 in the parquet_cpp source
[/tmp/nation.0.parquet] has type BYTE_ARRAY, expected int
```

This behavior is specific to Parquet files; with an ORC file the type is correctly reported as STRING. The problem occurs because Parquet does not natively support the STRING type and uses BYTE_ARRAY for strings instead. Because the Parquet file reports its type as BYTE_ARRAY, Vertica has no way to determine if the type is actually a BYTE_ARRAY or a STRING.

Error 7087: wrong number of columns

When loading ORC or Parquet data, you might see an error stating that you have the wrong number of columns:

```
=> CREATE TABLE nation (nationkey bigint, name varchar(500),
      regionkey bigint, comment varchar(500));
CREATE TABLE

=> COPY nation from :orc_dir ORC;
ERROR 7087: Attempt to load 4 columns from an orc source
[/tmp/orc_glob/test.orc] that has 9 columns
```

When you load data from ORC or Parquet files, your table must consume all of the data in the file, or this error results. To avoid this problem, add the missing columns to your table definition.

For Parquet data, time zones in timestamp values are not correct

Reading timestamps from a Parquet file in Vertica might result in different values, based on the local time zone. This issue occurs because the Parquet format does not support the SQL TIMESTAMP data type. If you define the column in your table with the TIMESTAMP data type, Vertica interprets timestamps read from Parquet files as values in the local time zone. This same behavior occurs in Hive. When this situation occurs, Vertica produces a warning at query time such as the following:

```
WARNING 0: SQL TIMESTAMPTZ is more appropriate for Parquet TIMESTAMP
because values are stored in UTC
```

When creating the table in Vertica, you can avoid this issue by using the TIMESTAMPTZ data type instead of TIMESTAMP.

Time zones can also be incorrect in ORC data, but the reason is different.

For ORC data, time zones in timestamp values are not correct

Vertica and Hive both use the Apache ORC library to interact with ORC data. The behavior of this library changed with Hive version 1.2.0, so timestamp representation depends on what version was used to write the data.

When writing timestamps, the ORC library now records the time zone in the stripe footer. Vertica looks for this value and applies it when loading timestamps. If the file was written with an older version of the library, the time zone is missing from the file.

If the file does not contain a time zone, Vertica uses the local time zone and logs an ORC_FILE_INFO event in the [QUERY_EVENTS](#) system table.

The first time you query a new ORC data source, you should query this table to look for missing time zone information:

```
=> SELECT event_category, event_type, event_description, operator_name, event_details, COUNT(event_type)
  AS COUNT FROM QUERY_EVENTS WHERE event_type ILIKE 'ORC_FILE_INFO'
  GROUP BY event_category, event_type, event_description, operator_name, event_details
  ORDER BY event_details;
event_category | event_type | event_description | operator_name | event_details | count
-----+-----+-----+-----+-----+-----
EXECUTION | ORC_FILE_INFO | ORC file does not have writer timezone information | OrcParser | Timestamp values in the ORC source
[data/sales_stats.orc] will be computed using local timezone | 2

(1 row)
```

Time zones can also be incorrect in Parquet data, but the reason is different.

Some date and timestamp values are wrong by several days

When Hive writes ORC or Parquet files, it converts dates before 1583 from the Gregorian calendar to the Julian calendar. Vertica does not perform this conversion. If your file contains dates before this time, values in Hive and the corresponding values in Vertica can differ by up to ten days. This difference applies to both DATE and TIMESTAMP values.

Working with external data

An alternative to importing data into Vertica is to query it in place. Querying external data instead of importing it can be advantageous in some cases:

- If you want to explore data, such as in a data lake, before selecting data to load into Vertica.
- If you are one of several consumers sharing the same data, for example in a data lake, then reading it in place eliminates concerns about whether query results are up to date. There's only one copy, so all consumers see the same data.
- If your data changes rapidly but you do not want to stream it into Vertica, you can instead query the latest updates automatically.
- If you have a very large volume of data and do not want to increase your license capacity.
- If you have lower-priority data in Vertica that you still want to be able to query.

To query external data, you must describe your data as an *external table*. Like native tables, external tables have table definitions and can be queried. Unlike native tables, external tables have no catalog and Vertica loads selected data from the external source as needed. For some formats, the query planner can take advantage of partitions and sorting in the data, so querying an external table does not mean you load all of the data at query time. (For more information about native tables, see [Working with native tables](#).)

There is one special type of external data not covered in this section. If you are reading data from Hadoop, and specifically from a Hive data warehouse, then instead of defining your own external tables you can read the schema information from Hive. For more information, see [Using the HCatalog Connector](#).

In this section

- [How external tables differ from native tables](#)
- [Creating external tables](#)
- [Querying external tables](#)
- [Monitoring external tables](#)
- [Troubleshooting external tables](#)

How external tables differ from native tables

You can use external tables in the same ways you use Vertica native tables. Because the data is external to the database, however, there are some differences in how external tables operate.

Data

The data for an external table can reside anywhere, so long as all database nodes can access it. S3, HDFS, and NFS mount points are common places to find external data. Naturally, querying external data can incur some latency compared to querying locally-stored ROS data, but Vertica has optimizations that can reduce the impact. For example, Vertica can take advantage of node and rack locality for HDFS data.

Because the data is external, Vertica loads external data each time you query it. Vertica is optimized to reduce the volume of read data, including predicate pushdown and partition pruning for formats that support partitioning. The ORC and Parquet formats support these optimizations.

Because the data is read at query time, you must ensure that your users have and retain permission to read the data in its original location. Depending on where the data is stored, you might need to take additional steps to manage access, such as creating AWS IAM roles on S3.

Because the data is not stored in Vertica, external tables do not use superprojections and buddy projections.

Resource consumption

External tables add very little to the Vertica catalog, which reduces the resources that queries consume. Because the data is not stored in Vertica, external tables are not affected by the Tuple Mover and do not cause ROS pushback. Vertica uses a small amount of memory when reading external table data, because the table contents are not part of your database and are parsed each time the external table is used.

Backup and restore

Because the data in external tables is managed outside of Vertica, only the external table definitions, not the data files, are included in database backups. Arrange for a separate backup process for your external table data.

DML support

External tables allow you to read external data. They do not allow you to modify it. Some DML operations are therefore not available for external tables, including:

- DELETE FROM
- INSERT INTO
- SELECT...FOR UPDATE

Sequences and IDENTITY columns

The COPY statement definition for external tables can include IDENTITY columns and sequences. Whenever a select statement queries the external table, sequences and IDENTITY columns are re-evaluated. This results in changing the external table column values, even if the underlying external table data remains the same.

Creating external tables

To create an external table, combine a table definition with a copy statement using the [CREATE EXTERNAL TABLE AS COPY](#) statement. CREATE EXTERNAL TABLE AS COPY uses a subset of parameters from CREATE TABLE and COPY.

You define your table columns as you would for a Vertica native table using [CREATE TABLE](#). You also specify a [COPY FROM](#) clause to describe how to read the data, as you would for loading data. How you specify the FROM path depends on where the file is located and the data format. See [Specifying where to load data from](#) and [Data formats](#).

As with native tables, you can use the [INFER_TABLE_DDL](#) function to derive column definitions from data files in supported formats.

The following example defines an external table for delimited data stored in HDFS:

```
=> CREATE EXTERNAL TABLE sales (itemID INT, date DATE, price FLOAT)
  AS COPY FROM 'hdfs:///data/ext1.csv' DELIMITER ',';
```

The following example uses data in the [ORC](#) format that is stored in S3. The data has two partition columns. For more information about partitions, see [Partitioned data](#).

```
=> CREATE EXTERNAL TABLE records (id int, name varchar(50), created date, region varchar(50))
  AS COPY FROM 's3://datalake/sales/*/*/*'
  PARTITION COLUMNS created, region;
```

The following example shows how you can read from all [Parquet](#) files in a local directory, with no partitions and no globs:

```
=> CREATE EXTERNAL TABLE sales (itemID INT, date DATE, price FLOAT)
  AS COPY FROM '/data/sales/*.parquet' PARQUET;
```

When you create an external table, data is not added to the database and no projections are created. Instead, Vertica performs a syntactic check of the CREATE EXTERNAL TABLE AS COPY statement and stores the table name and COPY statement definition in the catalog. Each time a SELECT query references an external table, Vertica parses and executes the stored COPY statement to obtain the referenced data. Any problems in the table definition, such as incorrect column types, can be discovered only by querying the table.

Successfully returning data from an external table requires that the COPY definition be correct, and that other dependencies, such as files, nodes, and other resources are accessible and available at query time. If the table definition uses globs (wildcards), and files are added or deleted, the data in the external table can change between queries.

Iceberg format

You can create an external table for data stored by [Apache Iceberg](#) using [CREATE EXTERNAL TABLE ICEBERG](#). An Iceberg table consists of data files and metadata describing the schema. Unlike other external tables, an Iceberg external table need not specify column definitions (DDL). The information is read from Iceberg metadata at query time. For certain data types you can adjust column definitions when creating the table, for example to specify VARCHAR sizes.

Special considerations for external tables

If the maximum length of a column is smaller than the actual data, such as a VARCHAR that is too short, Vertica truncates the data and logs the event.

You can see unexpected query results if constraints on columns cause values to be rejected:

- If you specify a NOT NULL column constraint and the data contains null values, those rows are rejected.
- If you use ENFORCELENGTH, values that are too long are rejected rather than being truncated.
- When reading ORC data, if you declare a scalar precision and some data does not fit, that row is rejected. For example, if you specify a column as Decimal(6,5), a value of 123.456 is rejected.

One way to know if column constraints have caused data to be rejected is if COUNT on a column returns a different value than COUNT(*).

The [JSON](#) and [Avro](#) parsers produce warnings when the data contains columns or fields that are not part of the table definition. External tables load data at query time, so these warnings appear for each query. You can use the parser's [suppress_warnings](#) parameter to prevent these warnings in external tables. See the parser reference pages for an example.

When using the [COPY parameter](#) ON ANY NODE, confirm that the source file definition is identical on all nodes. Specifying different external files can produce inconsistent results.

You can take advantage of partitioning to limit the amount of data that Vertica reads. For more information about using partitioned data, see [Partitioned data](#).

Canceling a CREATE EXTERNAL TABLE AS COPY statement can cause unpredictable results. If you realize after beginning the operation that your table definition is incorrect (for example, you inadvertently specify the wrong external location), wait for the query to complete. When the external table exists, use [DROP TABLE](#) to remove its definition.

Tip

When working with a new external data source, consider setting REJECTMAX to 1 to make problems in the data apparent. Testing in this way allows you to discover problems in the data before running production queries against it.

After you create an external table, analyze its row count to improve query performance. See [Improving Query Performance for External Tables](#).

Required permissions

In addition to having permission in Vertica, users must have read access to the external data.

- For data on the local disk this access is governed by local file permissions.
- For data in HDFS, access might be governed by Kerberos authentication. See [Accessing kerberized HDFS data](#).
- For data on S3, you need access through an AWS IAM role. See [S3 object store](#).

For data in GCS, you must enable S3 compatibility before reading data. See [Google Cloud Storage \(GCS\) object store](#).

By default, you must also be a database superuser to access external tables through a SELECT statement.

In most cases, to allow users without superuser access to query external tables, an administrator must create a USER storage location and grant those users read access to the location. See [CREATE LOCATION](#) and [GRANT \(storage location\)](#). This location must be a parent of the path used in the COPY statement when creating the external table. This requirement does not apply to external tables stored in HDFS. The following example shows granting access to a user named Bob to any external table whose data is located under /tmp (including in subdirectories to any depth):

```
=> CREATE LOCATION '/tmp' ALL NODES USAGE 'user';  
=> GRANT ALL ON LOCATION '/tmp' to Bob;
```

Organizing external table data

If the data you store in external tables changes regularly (for instance, each month in the case of storing recent historical data), you can use partitioning in combination with wildcards (globs) to make parsing the stored COPY statement definition more dynamic. For instance, if you store

monthly data on an NFS mount, you could organize monthly files within a top-level directory for a calendar year, such as:

```
/year=2018/month=01/
```

You can then read the year and month values from the directory names in the COPY statement:

```
=> CREATE EXTERNAL TABLE archive (...) AS COPY FROM '/nfs_name/*/*/*' PARTITION COLUMNS year, month;
```

Whenever a Vertica query references the external table `archive`, and Vertica parses the COPY statement, all stored data in the top-level `monthly` directory is accessible to the query. If the query filters by year or month, such as in a WHERE clause, Vertica skips irrelevant directories when evaluating the glob. See [Partitioned data](#) for more information.

Validating table definitions

When you create an external table, Vertica validates the syntax of the CREATE EXTERNAL TABLE AS COPY FROM statement. For example, if you omit a required keyword in the statement, creating the external table fails:

```
=> CREATE EXTERNAL TABLE ext (ts timestamp, d varchar)
  AS COPY '/home/dbadmin/designer.log';
ERROR 2778: COPY requires a data source; either a FROM clause or a WITH SOURCE for a user-defined source
```

Checking other components of the COPY definition, such as path statements and node availability, does not occur until a SELECT query references the external table.

To validate an external table definition, run a SELECT query that references the external table. Check that the returned query data is what you expect. If the query does not return data correctly, check the COPY exception and rejected data log files.

Because the COPY definition determines what occurs when you query an external table, COPY statement errors can reveal underlying problems. For more information about COPY exceptions and rejections, see [Handling messy data](#).

Viewing external table definitions

When you create an external table, Vertica stores the COPY definition statement in the `table_definition` column of the [TABLES](#) system table.

To list all tables, use a SELECT * query, as shown:

```
=> SELECT * FROM TABLES WHERE table_definition <> '';
```

Use a query such as the following to list the external table definitions:

```
=> SELECT table_name, table_definition FROM TABLES;
table_name |          table_definition
-----+-----
t1         | COPY FROM 'TMPDIR/external_table.dat' DELIMITER ','
t1_copy    | COPY FROM 'TMPDIR/external_table.dat' DELIMITER ','
t2         | COPY FROM 'TMPDIR/external_table2.dat' DELIMITER ','
(3 rows)
```

Querying external tables

After you create an external table, you can query it as you would query any other table. Suppose you have created the following external tables:

```
=> CREATE EXTERNAL TABLE catalog (id INT, description VARCHAR, category VARCHAR)
  AS COPY FROM 'hdfs:///dat/catalog.csv' DELIMITER ',';
CREATE TABLE
=> CREATE EXTERNAL TABLE inventory(storeID INT, prodID INT, quantity INT)
  AS COPY FROM 'hdfs:///dat/inventory.csv' DELIMITER ',';
CREATE TABLE
```

You can now write queries against these tables, such as the following:

```
=> SELECT * FROM catalog;
id | description | category
-----+-----+-----
10 | 24in monitor | computers
11 | 27in monitor | computers
12 | 24in IPS monitor | computers
20 | 1TB USB drive | computers
21 | 2TB USB drive | computers
22 | 32GB USB thumb drive | computers
30 | 40in LED TV | electronics
31 | 50in LED TV | electronics
32 | 60in plasma TV | electronics
(9 rows)
```

```
=> SELECT * FROM inventory;
storeID | prodID | quantity
-----+-----+-----
502 | 10 | 17
502 | 11 | 2
517 | 10 | 1
517 | 12 | 2
517 | 12 | 4
542 | 10 | 3
542 | 11 | 11
542 | 12 | 1
(8 rows)
```

```
=> SELECT inventory.storeID,catalog.description,inventory.quantity
FROM inventory JOIN catalog ON inventory.prodID = catalog.id;
storeID | description | quantity
-----+-----+-----
502 | 24in monitor | 17
517 | 24in monitor | 1
542 | 24in monitor | 3
502 | 27in monitor | 2
542 | 27in monitor | 11
517 | 24in IPS monitor | 2
517 | 24in IPS monitor | 4
542 | 24in IPS monitor | 1
(8 rows)
```

One important difference between external tables and Vertica native tables is that querying an external table reads the external data every time. (See [How external tables differ from native tables](#).) Specifically, each time a select query references the external table, Vertica parses the COPY statement definition again to access the data. Certain errors in either your table definition or your data do not become apparent until you run a query, so test your external tables before deploying them in a production environment.

Handling errors

Querying external table data with an incorrect COPY FROM statement definition can potentially result in many rejected rows. To limit the number of rejections, Vertica sets the maximum number of retained rejections with the `ExternalTablesExceptionsLimit` configuration parameter. The default value is 100. Setting the `ExternalTablesExceptionsLimit` to `-1` removes the limit, but is not recommended.

If COPY errors reach the maximum number of rejections, the external table query continues, but COPY generates a warning in the `vertica.log` file and does not report subsequent rejected rows.

Using the `ExternalTablesExceptionsLimit` configuration parameter differs from using the COPY statement `REJECTMAX` parameter to set a low rejection threshold. The `REJECTMAX` value controls how many rejected rows to permit before causing the load to fail. If COPY encounters a number of rejected rows equal to or greater than `REJECTMAX`, COPY aborts execution instead of logging a warning in `vertica.log`.

Improving query performance for external tables

Queries that include joins perform better if the smaller table is the inner one. For native tables, the query optimizer uses cardinality to choose the inner table. For external tables, the query optimizer uses the row count if available.

After you create an external table, use [ANALYZE_EXTERNAL_ROW_COUNT](#) to collect this information. Calling this function is potentially expensive because it has to materialize one column of the table to be able to count the rows, so do this analysis when your database is not busy with critical queries. (This is why Vertica does not perform this operation automatically when you create the table.)

The query optimizer uses the results of your most-recent call to this function when planning queries. If the volume of data changes significantly, therefore, you should run it again to provide updated statistics. A difference of a few percent does not matter, but if your data volume grows by 20% or more, you should repeat this operation when able.

If your data is partitioned, Vertica automatically prunes partitions that cannot affect query results, causing less data to be loaded.

For ORC and Parquet data written with Hive version 0.14 and later, Vertica automatically uses predicate pushdown to further improve query performance. Predicate pushdown moves parts of the query execution closer to the data, reducing the amount of data that must be read from disk or across the network. ORC files written with earlier versions of Hive might not contain the statistics required to perform this optimization. When executing a query against a file that lacks these statistics, Vertica logs an `EXTERNAL_PREDICATE_PUSHDOWN_NOT_SUPPORTED` event in the [QUERY_EVENTS](#) system table. If you are seeing performance problems with your queries, check this table for these events.

Using external tables with user-defined load (UDL) functions

You can use external tables in conjunction with UDL functions that you create. For more information about using UDLs, see [User Defined Load \(UDL\)](#).

Monitoring external tables

Vertica records information about external tables in system tables. You can use these tables to track your external data and queries against it.

The [TABLES](#) system table contains data about all tables, both native and external. The `TABLE_DEFINITION` column is specific to external tables. You can query this column to see all external data sources currently in use, as in the following example:

```
=> SELECT table_name, create_time, table_definition FROM tables WHERE table_definition != "";
```

table_name	create_time	table_definition
customers_orc	2018-03-21 11:07:30.159442-04	COPY from '/home/dbadmin/sample_orc_files/0*' ORC
miscprod	2018-06-26 17:40:04.012121-04	copy from '/home/dbadmin/data/prod.csv'
students	2018-06-26 17:46:50.695024-04	copy from '/home/dbadmin/students.csv'
numbers	2018-06-26 17:53:52.407441-04	copy from '/home/dbadmin/tt.dat'
catalog	2018-06-26 18:12:28.598519-04	copy from '/home/dbadmin/data/prod.csv' delimiter ','
inventory	2018-06-26 18:13:06.951802-04	copy from '/home/dbadmin/data/stores.csv' delimiter ','
test	2018-06-27 16:31:39.170866-04	copy from '/home/dbadmin/data/stores.csv' delimiter ','

(7 rows)

The [EXTERNAL_TABLE_DETAILS](#) table provides more details, including file sizes. Vertica computes the values in this table at query time, which is potentially expensive, so consider restricting the query by schema or table.

```
=> SELECT table_name, source_format, total_file_size_bytes FROM external_table_details;
```

table_name	source_format	total_file_size_bytes
customers_orc	ORC	619080883
miscprod	DELIMITED	254
students	DELIMITED	763
numbers	DELIMITED	30
catalog	DELIMITED	254
inventory	DELIMITED	74
test	DELIMITED	74

(7 rows)

If the size of an external table changes significantly over time, you should rerun `ANALYZE_EXTERNAL_ROW_COUNT()` to gather updated statistics. See [Improving Query Performance for External Tables](#).

The [LOAD_SOURCES](#) table shows information for loads currently in progress. This table does not record information about loads of ORC or Parquet data.

Troubleshooting external tables

You might encounter the following issues when creating or querying external tables. For general data-load troubleshooting, see [Troubleshooting data loads](#).

File not found or permission denied

If a query against an external table produces a file or permission error, ensure that the user executing the query has the necessary permissions in both Vertica and the file system. See the permissions section in [Creating external tables](#).

Error 7226: cannot find partition column

When querying external tables backed by partitioned data, you might see an error message stating that a partition column is missing:

```
ERROR 7226: Cannot find partition column [region] in parquet source
[/data/table_int/int_original/000000_0]
```

If you create an external table and then change the partition structure, for example by renaming a column, you must then re-create the external table. If you see this error, update your table to match the partitioning on disk.

For more information about partition structure, see [Partitioned data](#)).

Error 6766: is a directory

When querying data, you might see an error message stating that an input file is a directory:

```
ERROR 6766: Error reading from orc parser input stream
[/tmp/orc_glob/more_nations]: Is a directory
```

This error occurs if the glob in the table's COPY FROM clause matches an empty directory. This error occurs only for files in the Linux file system; empty directories in HDFS are ignored.

To correct the error, make the glob more specific. Instead of *, for example, use *.orc.

Data analysis

This guide explains how to query and analyze data in your Vertica database.

In this section

- [Queries](#)
- [Query optimization](#)

- [Data aggregation](#)

Queries

Queries are database operations that retrieve data from one or more tables or views. In Vertica, the top-level **SELECT** statement is the query, and a query nested within another SQL statement is called a subquery.

Vertica is designed to run the same SQL standard queries that run on other databases. However, there are some differences between Vertica queries and queries used in other relational database management systems.

The Vertica [transaction model](#) is different from the SQL standard in a way that has a profound effect on query performance. You can:

- Run a query on a static backup of the database from any specific date and time. Doing so avoids holding locks or blocking other database operations.
- Use a subset of the standard SQL isolation levels and access modes (read/write or read-only) for a user [session](#).

In Vertica, the primary structure of a SQL query is its statement. Each statement ends with a semicolon, and you can write multiple queries separated by semicolons; for example:

```
=> CREATE TABLE t1( ..., date_col date NOT NULL, ...);
=> CREATE TABLE t2( ..., state VARCHAR NOT NULL, ...);
```

In this section

- [Historical queries](#)
- [Temporary tables](#)
- [SQL queries](#)

- [Arrays and sets \(collections\)](#)
- [Rows \(structs\)](#)
- [Subqueries](#)
- [Joins](#)

Historical queries

Vertica can execute historical queries, which execute on a snapshot of the database taken at a specific timestamp or epoch. Historical queries can be used to evaluate and possibly recover data that was deleted but has not yet been [purged](#).

You specify a historical query by qualifying the [SELECT](#) statement with an *AT epoch* clause, where *epoch* is one of the following:

- EPOCH LATEST : Return data up to but not including the current epoch. The result set includes data from the latest committed DML transaction.
- EPOCH *integer* : Return data up to and including the *integer*-specified epoch.
- TIME ' *timestamp* ' : Return data from the *timestamp*-specified epoch.

Note

These options are ignored if used to query temporary or external tables.

See [Epochs](#) for additional information about how Vertica uses epochs.

Historical queries return data only from the specified epoch. Because they do not return the latest data, historical queries hold no locks or blocking write operations.

Query results are private to the transaction and valid only for the length of the transaction. Query execution is the same regardless of the transaction isolation level.

Restrictions

- The specified epoch, or epoch of the specified timestamp, cannot be less than the [Ancient History Mark](#) epoch.
- Vertica does not support running historical queries on temporary tables.

Important

Any changes to a table schema are reflected across all epochs. For example, if you add a column to a table and specify a default value for it, all historical queries on that table display the new column and its default value.

Temporary tables

You can use the [CREATE TEMPORARY TABLE](#) statement to implement certain queries using multiple steps:

1. Create one or more temporary tables.
2. Execute queries and store the result sets in the temporary tables.
3. Execute the main query using the temporary tables as if they were a normal part of the [logical schema](#).

See [CREATE TEMPORARY TABLE](#) in the SQL Reference Manual for details.

SQL queries

All DML (Data Manipulation Language) statements can contain queries. This section introduces some of the query types in Vertica, with additional details in later sections.

Note

Many of the examples in this chapter use the [VMart schema](#).

Simple queries

Simple queries contain a query against one table. Minimal effort is required to process the following query, which looks for product keys and SKU numbers in the product table:

```
=> SELECT product_key, sku_number FROM public.product_dimension;
```

```
product_key | sku_number
```

```
-----+-----  
43          | SKU-#129  
87          | SKU-#250  
42          | SKU-#125  
49          | SKU-#154  
37          | SKU-#107  
36          | SKU-#106  
86          | SKU-#248  
41          | SKU-#121  
88          | SKU-#257  
40          | SKU-#120
```

```
(10 rows)
```

Tables can contain arrays. You can select the entire array column, an index into it, or the results of a function applied to the array. For more information, see [Arrays and sets \(collections\)](#).

Joins

Joins use a relational operator that combines information from two or more tables. The query's **ON** clause specifies how tables are combined, such as by matching foreign keys to primary keys. In the following example, the query requests the names of stores with transactions greater than 70 by joining the store key ID from the store schema's sales fact and sales tables:

```
=> SELECT store_name, COUNT(*) FROM store.store_sales_fact
```

```
JOIN store.store_dimension ON store.store_sales_fact.store_key = store.store_dimension.store_key
```

```
GROUP BY store_name HAVING COUNT(*) > 70 ORDER BY store_name;
```

```
store_name | count
```

```
-----+-----  
Store49    | 72  
Store83    | 78
```

```
(2 rows)
```

For more detailed information, see [Joins](#). See also the Multicolumn subqueries section in [Subquery examples](#).

Cross joins

Also known as the Cartesian product, a cross join is the result of joining every record in one table with every record in another table. A cross join occurs when there is no join key between tables to restrict records. The following query, for example, returns all instances of vendor and store names in the vendor and store tables:

```
=> SELECT vendor_name, store_name FROM public.vendor_dimension
      CROSS JOIN store.store_dimension;
vendor_name | store_name
-----+-----
Deal Warehouse | Store41
Deal Warehouse | Store12
Deal Warehouse | Store46
Deal Warehouse | Store50
Deal Warehouse | Store15
Deal Warehouse | Store48
Deal Warehouse | Store39
Sundry Wholesale | Store41
Sundry Wholesale | Store12
Sundry Wholesale | Store46
Sundry Wholesale | Store50
Sundry Wholesale | Store15
Sundry Wholesale | Store48
Sundry Wholesale | Store39
Market Discounters | Store41
Market Discounters | Store12
Market Discounters | Store46
Market Discounters | Store50
Market Discounters | Store15
Market Discounters | Store48
Market Discounters | Store39
Market Suppliers | Store41
Market Suppliers | Store12
Market Suppliers | Store46
Market Suppliers | Store50
Market Suppliers | Store15
Market Suppliers | Store48
Market Suppliers | Store39
... | ...
(4000 rows)
```

This example's output is truncated because this particular cross join returned several thousand rows. See also [Cross joins](#).

Subqueries

A subquery is a query nested within another query. In the following example, we want a list of all products containing the highest fat content. The inner query (subquery) returns the product containing the highest fat content among all food products to the outer query block (containing query). The outer query then uses that information to return the names of the products containing the highest fat content.

```
=> SELECT product_description, fat_content FROM public.product_dimension
      WHERE fat_content IN
      (SELECT MAX(fat_content) FROM public.product_dimension
        WHERE category_description = 'Food' AND department_description = 'Bakery')
      LIMIT 10;
product_description | fat_content
-----+-----
Brand #59110 hotdog buns | 90
Brand #58107 english muffins | 90
Brand #57135 english muffins | 90
Brand #54870 cinnamon buns | 90
Brand #53690 english muffins | 90
Brand #53096 bagels | 90
Brand #50678 chocolate chip cookies | 90
Brand #49269 wheat bread | 90
Brand #47156 coffee cake | 90
Brand #43844 corn muffins | 90
(10 rows)
```

For more information, see [Subqueries](#).

Sorting queries

Use the **ORDER BY** clause to order the rows that a query returns.

Special note about query results

You could get different results running certain queries on one machine or another for the following reasons:

- [Partitioning](#) on a **FLOAT** type could return nondeterministic results because of the precision, especially when the numbers are close to one another, such as results from the **RADIANS()** function, which has a very small range of output. To get deterministic results, use **NUMERIC** if you must partition by data that is not an **INTEGER** type.
- Most analytics (with analytic aggregations, such as **MIN()/MAX()/SUM()/COUNT()/AVG()** as exceptions) rely on a unique order of input data to get deterministic result. If the analytic [window-order](#) clause cannot resolve ties in the data, results could be different each time you run the query. For example, in the following query, the analytic **ORDER BY** does not include the first column in the query, **promotion_key**. So for a tie of **AVG(RADIANS(cost_dollar_amount))**, **product_version**, the same **promotion_key** could have different positions within the analytic partition, resulting in a different **NTILE()** number. Thus, **DISTINCT** could also have a different result:

```
=> SELECT COUNT(*) FROM
  (SELECT DISTINCT SIN(FLOOR(MAX(store.store_sales_fact.promotion_key))),
   NTILE(79) OVER(PARTITION BY AVG (RADIANS
    (store.store_sales_fact.cost_dollar_amount ))
   ORDER BY store.store_sales_fact.product_version)
  FROM store.store_sales_fact
  GROUP BY store.store_sales_fact.product_version,
           store.store_sales_fact.sales_dollar_amount ) AS store;
count
-----
1425
(1 row)
```

If you add **MAX(promotion_key)** to analytic **ORDER BY**, the results are the same on any machine:

```
=> SELECT COUNT(*) FROM (SELECT DISTINCT MAX(store.store_sales_fact.promotion_key),
  NTILE(79) OVER(PARTITION BY MAX(store.store_sales_fact.cost_dollar_amount)
  ORDER BY store.store_sales_fact.product_version,
  MAX(store.store_sales_fact.promotion_key))
  FROM store.store_sales_fact
  GROUP BY store.store_sales_fact.product_version,
           store.store_sales_fact.sales_dollar_amount) AS store;
```

Arrays and sets (collections)

Tables can include collections (arrays or sets). An [ARRAY](#) is an ordered collection of elements that allows duplicate values, and a [SET](#) is an unordered collection of unique values.

Consider an orders table with columns for product keys, customer keys, order prices, and order date, with some containing arrays. A basic query in Vertica results in the following:

```
=> SELECT * FROM orders LIMIT 5;
orderkey | custkey |   prodkey   |   orderprices   | orderdate
-----+-----+-----+-----+-----
19626 | 91 | ["P1262","P68","P101"] | ["192.59","49.99","137.49"] | 2021-03-14
25646 | 716 | ["P997","P31","P101"] | ["91.39","29.99","147.49"] | 2021-03-14
25647 | 716 | ["P12"] | ["8.99"] | 2021-03-14
19743 | 161 | ["P68","P101"] | ["49.99","137.49"] | 2021-03-15
19888 | 241 | ["P1262","P101"] | ["197.59","142.49"] | 2021-03-15
(5 rows)
```

As shown in this example, array values are returned in [JSON format](#). Set values are also returned in JSON array format.

You can access elements of nested arrays (multi-dimensional arrays) with multiple indexes:

```
=> SELECT host, pingtimes FROM network_tests;
host |          pingtimes
-----+-----
eng1 | [[24.24,25.27,27.16,24.97], [23.97,25.01,28.12,29.50]]
eng2 | [[27.12,27.91,28.11,26.95], [29.01,28.99,30.11,31.56]]
qa1  | [[23.15,25.11,24.63,23.91], [22.85,22.86,23.91,31.52]]
(3 rows)
```

```
=> SELECT pingtimes[0] FROM network_tests;
          pingtimes
-----
[24.24,25.27,27.16,24.97]
[27.12,27.91,28.11,26.95]
[23.15,25.11,24.63,23.91]
(3 rows)
```

```
=> SELECT pingtimes[0][0] FROM network_tests;
          pingtimes
-----
24.24
27.12
23.15
(3 rows)
```

Vertica supports several [functions](#) to manipulate arrays and sets.

Consider the orders table, which has an array of product keys for all items purchased in a single order. You can use the `APPLY_COUNT_ELEMENTS` function to find out how many items each order contains (excluding null values):

```
=> SELECT APPLY_COUNT_ELEMENTS(prodkey) FROM orders LIMIT 5;
          apply_count_elements
-----
3
2
2
3
1
(5 rows)
```

Vertica also supports aggregate functions for collections. Consider a column with an array of prices for items purchased in a single order. You can use the `APPLY_SUM` function to find the total amount spent for each order:

```
=> SELECT APPLY_SUM(orderprices) FROM orders LIMIT 5;
          apply_sum
-----
380.07
187.48
340.08
268.87
8.99
(5 rows)
```

Most of the array functions operate only on one-dimensional arrays. To use them with multi-dimensional arrays, first dereference one dimension:

```
=> SELECT APPLY_MAX(pingtimes[0]) FROM network_tests;
          apply_max
-----
27.16
28.11
25.11
(3 rows)
```

See [Collection functions](#) for a comprehensive list of functions.

You can include both column names and literal values in queries. The following example returns the product keys for orders where the number of items in each order is three or more:

```
=> SELECT prodkey FROM orders WHERE APPLY_COUNT_ELEMENTS(prodkey)>2;
prodkey
-----
["P1262","P68","P101"]
["P997","P31","P101"]
(2 rows)
```

You can use aggregate functions in a WHERE clause:

```
=> SELECT custkey, cust_custname, cust_email, orderkey, prodkey, orderprices FROM orders
JOIN cust ON custkey = cust_custkey
WHERE APPLY_SUM(orderprices)>150 ;
custkey| cust_custname | cust_email | orderkey | prodkey | orderprices
-----+-----+-----+-----+-----+-----
342799 | "Ananya Patel" | "ananyapatel98@gmail.com" | "113-341987" | ["MG-7190","VA-4028","EH-1247","MS-7018"] | [60.00,67.00,22.00,14.99]
342845 | "Molly Benton" | "molly_benton@gmail.com" | "111-952000" | ["ID-2586","IC-9010","MH-2401","JC-1905"] | [22.00,35.00,90.00,12.00]
342989 | "Natasha Abbasi" | "natsabbasi@live.com" | "111-685238" | ["HP-4024"] | [650.00]
342176 | "Jose Martinez" | "jmartinez@hotmail.com" | "113-672238" | ["HP-4768","IC-9010"] | [899.00,60.00]
342845 | "Molly Benton" | "molly_benton@gmail.com" | "113-864153" | ["AE-7064","VA-4028","GW-1808"] | [72.00,99.00,185.00]
(5 rows)
```

Element data types

Collections support elements of any scalar type, arrays, or structs (ROW). In the following version of the orders table, an array of ROW elements contains information about all shipments for an order:

```
=> CREATE TABLE orders(
orderid INT,
accountid INT,
shipments ARRAY[
ROW(
shipid INT,
address ROW(
street VARCHAR,
city VARCHAR,
zip INT
),
shipdate DATE
)
];
```

Some orders consist of more than one shipment. Line breaks have been inserted into the following output for legibility:

```
=> SELECT * FROM orders;
orderid | accountid | shipments
-----+-----+-----
99123 | 17 | [{"shipid":1,"address":{"street":"911 San Marcos St","city":"Austin","zip":73344},"shipdate":"2020-11-05"},
{"shipid":2,"address":{"street":"100 main St Apt 4B","city":"Pasadena","zip":91001},"shipdate":"2020-11-06"}]
99149 | 139 | [{"shipid":3,"address":{"street":"100 main St Apt 4B","city":"Pasadena","zip":91001},"shipdate":"2020-11-06"}]
99162 | 139 | [{"shipid":4,"address":{"street":"100 main St Apt 4B","city":"Pasadena","zip":91001},"shipdate":"2020-11-04"},
{"shipid":5,"address":{"street":"100 Main St Apt 4A","city":"Pasadena","zip":91001},"shipdate":"2020-11-11"}]
(3 rows)
```

You can use array indexing and ROW field selection together in queries:

```
=> SELECT orderid, shipments[0].shipdate AS ship1, shipments[1].shipdate AS ship2 FROM orders;
orderid | ship1 | ship2
-----+-----+-----
 99123 | 2020-11-05 | 2020-11-06
 99149 | 2020-11-06 |
 99162 | 2020-11-04 | 2020-11-11
(3 rows)
```

This example selects specific array indices. To access all entries, use [EXPLODE](#). To search or filter elements, see [Searching and Filtering](#).

Some data formats have a map type, which is a set of key/value pairs. Vertica does not directly support querying maps, but you can define a map column as an array of structs and query that. In the following example, the `prods` column in the data is a map:

```
=> CREATE EXTERNAL TABLE orders
(orderkey INT,
 custkey INT,
 prods ARRAY[ROW(key VARCHAR(10), value DECIMAL(12,2))],
 orderdate DATE
) AS COPY FROM '...' PARQUET;

=> SELECT orderkey, prods FROM orders;
orderkey |
-----+-----
 19626 | [{"key":"P68","value":"49.99"},{"key":"P1262","value":"192.59"},{"key":"P101","value":"137.49"}]
 25646 | [{"key":"P997","value":"91.39"},{"key":"P101","value":"147.49"},{"key":"P31","value":"29.99"}]
 25647 | [{"key":"P12","value":"8.99"}]
 19743 | [{"key":"P68","value":"49.99"},{"key":"P101","value":"137.49"}]
 19888 | [{"key":"P1262","value":"197.59"},{"key":"P101","value":"142.49"}]
(5 rows)
```

You cannot use complex columns in [CREATE TABLE AS SELECT](#) (CTAS). This restriction applies for the entire column or for field selection within it.

Ordering and grouping

You can use [Comparison operators](#) with collections of scalar values. Null collections are ordered last. Otherwise, collections are compared element by element until there is a mismatch, and then they are ordered based on the non-matching elements. If all elements are equal up to the length of the shorter one, then the shorter one is ordered first.

You can use collections in the ORDER BY and GROUP BY clauses of queries. The following example shows ordering query results by an array column:

```
=> SELECT * FROM employees
ORDER BY grant_values;
id | department | grants | grant_values
-----+-----+-----+-----
 36 | Astronomy | ["US-7376","DARPA-1567"] | [5000,4000]
 36 | Physics | ["US-7376","DARPA-1567"] | [10000,25000]
 33 | Physics | ["US-7376"] | [30000]
 42 | Physics | ["US-7376","DARPA-1567"] | [65000,135000]
(4 rows)
```

The following example queries the same table using GROUP BY :

```
=> SELECT department, grants, SUM(apply_sum(grant_values))
FROM employees
GROUP BY grants, department;
department | grants | SUM
-----+-----+-----
Physics | ["US-7376","DARPA-1567"] | 235000
Astronomy | ["US-7376","DARPA-1567"] | 9000
Physics | ["US-7376"] | 30000
(3 rows)
```

See the "Functions and Operators" section on the [ARRAY](#) reference page for information on how Vertica orders collections. (The same information is also on the [SET](#) reference page.)

Null semantics

Null semantics for collections are consistent with normal columns in most regards. See [NULL sort order](#) for more information on null-handling.

The null-safe equality operator (`<=>`) behaves differently from equality (`=`) when the collection is null rather than empty. Comparing a collection to NULL strictly returns null:

```
=> SELECT ARRAY[1,3] = NULL;
```

```
?column?
```

```
-----
```

```
(1 row)
```

```
=> SELECT ARRAY[1,3] <=> NULL;
```

```
?column?
```

```
-----
```

```
f
```

```
(1 row)
```

In the following example, the grants column in the table is null for employee 99:

```
=> SELECT grants = NULL FROM employees WHERE id=99;
```

```
?column?
```

```
-----
```

```
(1 row)
```

```
=> SELECT grants <=> NULL FROM employees WHERE id=99;
```

```
?column?
```

```
-----
```

```
t
```

```
(1 row)
```

Empty collections are not null and behave as expected:

```
=> SELECT ARRAY[]::ARRAY[INT] = ARRAY[]::ARRAY[INT];
```

```
?column?
```

```
-----
```

```
t
```

```
(1 row)
```

Collections are compared element by element. If a comparison depends on a null element, the result is unknown (null), not false. For example, `ARRAY[1,2,null]=ARRAY[1,2,null]` and `ARRAY[1,2,null]=ARRAY[1,2,3]` both return null, but `ARRAY[1,2,null]=ARRAY[1,4,null]` returns false because the second elements do not match.

Out-of-bound indexes into collections return NULL:

```
=> SELECT prodkey[2] FROM orders LIMIT 4;
```

```
prodkey
```

```
-----
```

```
"EH-1247"
```

```
"MH-2401"
```

```
(4 rows)
```

The results of the query return NULL for two out of four rows, the first and the fourth, because the specified index is greater than the size of those arrays.

Casting

When the data type of an expression value is unambiguous, it is implicitly coerced to match the expected data type. However, there can be ambiguity about the data type of an expression. Write an explicit cast to avoid the default:

```
=> SELECT APPLY_SUM(ARRAY['1','2','3']);
ERROR 5595: Invalid argument type VarcharArray1D in function apply_sum
```

```
=> SELECT APPLY_SUM(ARRAY['1','2','3']::ARRAY[INT]);
apply_sum
-----
      6
(1 row)
```

You can cast arrays or sets of one scalar type to arrays or sets of other (compatible) types, following the same rules as for casting scalar values. Casting a collection casts each element of that collection. Casting an array to a set also removes any duplicates.

You can cast arrays (but not sets) with elements that are arrays or structs (or combinations):

```
=> SELECT shipments::ARRAY[ROW(id INT,addr ROW(VARCHAR,VARCHAR,INT),shipped DATE)]
FROM orders;
      shipments
-----
[{"id":1,"addr":{"street":"911 San Marcos St","city":"Austin","zip":73344},"shipped":"2020-11-05"},
 {"id":2,"addr":{"street":"100 main St Apt 4B","city":"Pasadena","zip":91001},"shipped":"2020-11-06"}]
[{"id":3,"addr":{"street":"100 main St Apt 4B","city":"Pasadena","zip":91001},"shipped":"2020-11-06"}]
[{"id":4,"addr":{"street":"100 main St Apt 4B","city":"Pasadena","zip":91001},"shipped":"2020-11-04"},
 {"id":5,"addr":{"street":"100 Main St Apt 4A","city":"Pasadena","zip":91001},"shipped":"2020-11-11"}]
(3 rows)
```

You can change the bound of an array or set by casting. When casting to a bounded native array, inputs that are too long are truncated. When casting to a multi-dimensional array, if the new bounds are too small for the data the cast fails:

```
=> SELECT ARRAY[1,2,3]::ARRAY[VARCHAR,2];
array
-----
["1","2"]
(1 row)

=> SELECT ARRAY[ARRAY[1,2,3],ARRAY[4,5,6]]::ARRAY[ARRAY[VARCHAR,2],2];
ERROR 9227: Output array isn't big enough
DETAIL:  Type limit is 4 elements, but value has 6 elements
```

If you cast to a bounded multi-dimensional array, you must specify the bounds at all levels.

An array or set with a single null element must be explicitly cast because no type can be inferred.

See [Data type coercion](#) for more information on casting for data types.

Exploding and imploding array columns

To simplify access to elements, you can use the [EXPLODE](#) and [UNNEST](#) functions. These functions take one or more array columns from a table and expand them, producing one row per element. You can use EXPLODE and UNNEST when you need to perform aggregate operations across all elements of all arrays. You can also use EXPLODE when you need to operate on individual elements. See [Manipulating Elements](#).

EXPLODE and UNNEST differ in their output:

- EXPLODE returns two columns for each array, one for the element index and one for the value at that position. If the function explodes a single array, these columns are named **position** and **value** by default. If the function explodes two or more arrays, the columns for each array are named **pos_ column-name** and **val_ column-name**.
- UNNEST returns only the values. For a single array, the output column is named **value**. For multiple arrays, each output column is named **val_ column-name**.

EXPLODE and UNNEST also differ in their inputs. UNNEST accepts only array arguments and expands all of them. EXPLODE can accept other arguments and passes them through, expanding only as many arrays as requested (default 1).

Consider an orders table with the following contents:

```
=> SELECT orderkey, custkey, prodkey, orderprices, email_addrs
       FROM orders LIMIT 5;
orderkey | custkey |          prodkey          |          orderprices          |          email_addrs
-----+-----+-----+-----+-----
113-341987 | 342799 | ["MG-7190 ", "VA-4028 ", "EH-1247 ", "MS-7018 "] | ["60.00", "67.00", "22.00", "14.99"] | ["bob@example.com", "robert.jones@example.com"]
111-952000 | 342845 | ["ID-2586 ", "IC-9010 ", "MH-2401 ", "JC-1905 "] | ["22.00", "35.00", null, "12.00"] | ["br92@cs.example.edu"]
111-345634 | 342536 | ["RS-0731 ", "SJ-2021 "] | ["50.00", null] | [null]
113-965086 | 342176 | ["GW-1808 "] | ["108.00"] | ["joe.smith@example.com"]
111-335121 | 342321 | ["TF-3556 "] | ["50.00"] | ["789123@example-isp.com", "alexjohnson@example.com", "monica@eng.example.com", "sara@johnson.example.name", null]
(5 rows)
```

The following query explodes the order prices for a single customer. The other two columns are passed through and are repeated for each returned row:

```
=> SELECT EXPLODE(orderprices, custkey, email_addrs
                  USING PARAMETERS skip_partitioning=true)
       AS (position, orderprices, custkey, email_addrs)
       FROM orders WHERE custkey='342845' ORDER BY orderprices;
position | orderprices | custkey |          email_addrs
-----+-----+-----+-----
2 |          | 342845 | ["br92@cs.example.edu", null]
3 |    12.00 | 342845 | ["br92@cs.example.edu", null]
0 |    22.00 | 342845 | ["br92@cs.example.edu", null]
1 |    35.00 | 342845 | ["br92@cs.example.edu", null]
(4 rows)
```

The previous example uses the `skip_partitioning` parameter. Instead of setting it for each call to `EXPLODE`, you can set it as a session parameter. `EXPLODE` is part of the `ComplexTypesLib` UDX library. The following example returns the same results:

```
=> ALTER SESSION SET UDPARAMETER FOR ComplexTypesLib skip_partitioning=true;

=> SELECT EXPLODE(orderprices, custkey, email_addrs)
       AS (position, orderprices, custkey, email_addrs)
       FROM orders WHERE custkey='342845' ORDER BY orderprices;
```

You can explode more than one column by specifying the `explode_count` parameter:

```
=> SELECT EXPLODE(orderkey, prodkey, orderprices
      USING PARAMETERS explode_count=2, skip_partitioning=true)
      AS (orderkey,pk_idx,pk_val,ord_idx,ord_val)
FROM orders
WHERE orderkey='113-341987';
orderkey | pk_idx | pk_val | ord_idx | ord_val
-----+-----+-----+-----+-----
113-341987 | 0 | MG-7190 | 0 | 60.00
113-341987 | 0 | MG-7190 | 1 | 67.00
113-341987 | 0 | MG-7190 | 2 | 22.00
113-341987 | 0 | MG-7190 | 3 | 14.99
113-341987 | 1 | VA-4028 | 0 | 60.00
113-341987 | 1 | VA-4028 | 1 | 67.00
113-341987 | 1 | VA-4028 | 2 | 22.00
113-341987 | 1 | VA-4028 | 3 | 14.99
113-341987 | 2 | EH-1247 | 0 | 60.00
113-341987 | 2 | EH-1247 | 1 | 67.00
113-341987 | 2 | EH-1247 | 2 | 22.00
113-341987 | 2 | EH-1247 | 3 | 14.99
113-341987 | 3 | MS-7018 | 0 | 60.00
113-341987 | 3 | MS-7018 | 1 | 67.00
113-341987 | 3 | MS-7018 | 2 | 22.00
113-341987 | 3 | MS-7018 | 3 | 14.99
(16 rows)
```

If you do not need the element positions, you can use UNNEST:

```
=> SELECT orderkey, UNNEST(prodkey, orderprices)
FROM orders WHERE orderkey='113-341987';
orderkey | val_prodkey | val_orderprices
-----+-----+-----
113-341987 | MG-7190 | 60.00
113-341987 | MG-7190 | 67.00
113-341987 | MG-7190 | 22.00
113-341987 | MG-7190 | 14.99
113-341987 | VA-4028 | 60.00
113-341987 | VA-4028 | 67.00
113-341987 | VA-4028 | 22.00
113-341987 | VA-4028 | 14.99
113-341987 | EH-1247 | 60.00
113-341987 | EH-1247 | 67.00
113-341987 | EH-1247 | 22.00
113-341987 | EH-1247 | 14.99
113-341987 | MS-7018 | 60.00
113-341987 | MS-7018 | 67.00
113-341987 | MS-7018 | 22.00
113-341987 | MS-7018 | 14.99
(16 rows)
```

The following example uses a multi-dimensional array:

```
=> SELECT name, pingtimes FROM network_tests;
name |          pingtimes
-----+-----
eng1 | [[24.24,25.27,27.16,24.97],[23.97,25.01,28.12,29.5]]
eng2 | [[27.12,27.91,28.11,26.95],[29.01,28.99,30.11,31.56]]
qa1  | [[23.15,25.11,24.63,23.91],[22.85,22.86,23.91,31.52]]
(3 rows)
```

```
=> SELECT EXPLODE(name, pingtimes USING PARAMETERS explode_count=1) OVER()
FROM network_tests;
name | position | value
-----+-----
eng1 | 0 | [24.24,25.27,27.16,24.97]
eng1 | 1 | [23.97,25.01,28.12,29.5]
eng2 | 0 | [27.12,27.91,28.11,26.95]
eng2 | 1 | [29.01,28.99,30.11,31.56]
qa1  | 0 | [23.15,25.11,24.63,23.91]
qa1  | 1 | [22.85,22.86,23.91,31.52]
(6 rows)
```

You can rewrite the previous query as follows to produce the same results:

```
=> SELECT name, EXPLODE(pingtimes USING PARAMETERS skip_partitioning=true)
FROM network_tests;
```

The [IMPLODE](#) function is the inverse of EXPLODE and UNNEST: it takes a column and produces an array containing the column's values. You can use WITHIN GROUP ORDER BY to control the order of elements in the imploded array. Combined with GROUP BY, IMPLODE can be used to reverse an EXPLODE operation.

If the output array would be too large for the column, IMPLODE returns an error. To avoid this, you can set the [allow_truncate](#) parameter to omit some elements from the results. Truncation never applies to individual elements; for example, the function does not shorten strings.

Searching and filtering

You can search array elements without having to first explode the array using the following functions:

- [CONTAINS](#): tests whether an array contains an element
- [ARRAY_FIND](#): returns the position of the first matching element
- [FILTER](#): returns an array containing only matching elements from an input array

You can use CONTAINS and ARRAY_FIND to search for specific elements:

```
=> SELECT CONTAINS(email, 'frank@example.com') FROM people;
CONTAINS
-----
f
t
f
f
(4 rows)
```

Suppose, instead of finding a particular address, you want to find all of the people who use an [example.com](#) email address. Instead of specifying a literal value, you can supply a [lambda function](#) to test elements. A lambda function has the following syntax:

```
argument -> expression
```

The lambda function takes the place of the second argument:

```
=> SELECT CONTAINS(email, e -> REGEXP_LIKE(e,'example.com','i')) FROM people;
CONTAINS
-----
f
t
f
t
(4 rows)
```

The FILTER function tests array elements, like ARRAY_FIND and CONTAINS, but then returns an array containing only the elements that match the filter:

```
=> SELECT name, email FROM people;
name | email
-----+-----
Elaine Jackson | ["ejackson@somewhere.org","elaine@jackson.com"]
Frank Adams | ["frank@example.com"]
Lee Jones | ["lee.jones@somewhere.org"]
M Smith | ["msmith@EXAMPLE.COM","ms@MSMITH.COM"]
(4 rows)

=> SELECT name, FILTER(email, e -> NOT REGEXP_LIKE(e,'example.com','i')) AS 'real_email'
FROM people;
name | real_email
-----+-----
Elaine Jackson | ["ejackson@somewhere.org","elaine@jackson.com"]
Frank Adams | []
Lee Jones | ["lee.jones@somewhere.org"]
M Smith | ["ms@MSMITH.COM"]
(4 rows)
```

To filter out entire rows without real email addresses, test the array length after applying the filter:

```
=> SELECT name, FILTER(email, e -> NOT REGEXP_LIKE(e,'example.com','i')) AS 'real_email'
FROM people
WHERE ARRAY_LENGTH(real_email) > 0;
name | real_email
-----+-----
Elaine Jackson | ["ejackson@somewhere.org","elaine@jackson.com"]
Lee Jones | ["lee.jones@somewhere.org"]
M Smith | ["ms@MSMITH.COM"]
(3 rows)
```

The lambda function has an optional second argument, which is the element index. For an example that uses the index argument, see [Lambda functions](#).

Manipulating elements

You can filter array elements using the FILTER function as explained in [Searching and Filtering](#). Filtering does not allow for operations on the filtered elements. For this case, you can use FILTER, EXPLODE, and IMPLODE together.

Consider a table of people, where each row has a person's name and an array of email addresses, some invalid:

```
=> SELECT * FROM people;
id | name | email
-----+-----
56 | Elaine Jackson | ["ejackson@somewhere.org","elaine@jackson.com"]
61 | Frank Adams | ["frank@example.com"]
87 | Lee Jones | ["lee.jones@somewhere.org"]
91 | M Smith | ["msmith@EXAMPLE.COM","ms@MSMITH.COM"]
(4 rows)
```

Email addresses are case-insensitive but VARCHAR values are not. The following example filters out invalid email addresses and normalizes the remaining ones by converting them to lowercase. The order of operations for each row is:

1. Filter each array to remove addresses using `example.com` , partitioning by name.
2. Explode the filtered array.
3. Convert each element to lowercase.
4. Implode the lowercase elements, grouping by name.

```
=> WITH exploded AS
(SELECT EXPLODE(FILTER(email, e -> NOT REGEXP_LIKE(e, 'example.com', 'i')), name)
  OVER (PARTITION BEST) AS (pos, addr, name)
 FROM people)
SELECT name, IMPLODE(LOWER(addr)) AS email
FROM exploded GROUP BY name;
name | email
-----+-----
Elaine Jackson | ["ejackson@somewhere.org","elaine@jackson.com"]
Lee Jones | ["lee.jones@somewhere.org"]
M Smith | ["ms@msmith.com"]
(3 rows)
```

Because the second row in the original table did not have any remaining email addresses after the filter step, there was nothing to partition by. Therefore, the row does not appear in the results at all.

Rows (structs)

Tables can include columns of the [ROW](#) data type. A ROW, sometimes called a struct, is a set of typed property-value pairs.

Consider a table of customers with columns for name, address, and an ID. The address is a ROW with fields for the elements of an address (street, city, and postal code). As shown in this example, ROW values are returned in [JSON format](#) :

```
=> SELECT * FROM customers ORDER BY accountID;
name | address | accountID
-----+-----+-----
Missy Cooper | {"street":"911 San Marcos St","city":"Austin","zipcode":73344} | 17
Sheldon Cooper | {"street":"100 Main St Apt 4B","city":"Pasadena","zipcode":91001} | 139
Leonard Hofstadter | {"street":"100 Main St Apt 4A","city":"Pasadena","zipcode":91001} | 142
Leslie Winkle | {"street":"23 Fifth Ave Apt 8C","city":"Pasadena","zipcode":91001} | 198
Raj Koothrappali | {"street":null,"city":"Pasadena","zipcode":91001} | 294
Stuart Bloom | | 482
(6 rows)
```

Most values are cast to UTF-8 strings, as shown for street and city here. Integers and booleans are cast to JSON Numerics and thus not quoted.

Use dot notation (`column . field`) to access individual fields:

```
=> SELECT address.city FROM customers;
city
-----
Pasadena
Pasadena
Pasadena
Pasadena
Austin
(6 rows)
```

In the following example, the contact information in the customers table has an email field, which is an array of addresses:

```
=> SELECT name, contact.email FROM customers;
```

name	email
Missy Cooper	["missy@mit.edu", "mcooper@cern.gov"]
Sheldon Cooper	["shelly@meemaw.name", "cooper@caltech.edu"]
Leonard Hofstadter	["hofstadter@caltech.edu"]
Leslie Winkle	[]
Raj Koothrappali	["raj@available.com"]
Stuart Bloom	

(6 rows)

You can use ROW columns or specific fields to restrict queries, as in the following example:

```
=> SELECT address FROM customers WHERE address.city ='Pasadena';
```

address
{"street": "100 Main St Apt 4B", "city": "Pasadena", "zipcode": "91001"}
{"street": "100 Main St Apt 4A", "city": "Pasadena", "zipcode": "91001"}
{"street": "23 Fifth Ave Apt 8C", "city": "Pasadena", "zipcode": "91001"}
{"street": null, "city": "Pasadena", "zipcode": "91001"}

(4 rows)

You can use the ROW syntax to specify literal values, such as the address in the WHERE clause in the following example:

```
=> SELECT name, address FROM customers
```

```
WHERE address = ROW('100 Main St Apt 4A', 'Pasadena', 91001);
```

name	address
Leonard Hofstadter	{"street": "100 Main St Apt 4A", "city": "Pasadena", "zipcode": "91001"}

(1 row)

You can join on field values as you would from any other column:

```
=> SELECT accountID, department from customers JOIN employees
```

```
ON customers.name=employees.personal.name;
```

```
accountID | department
```

accountID	department
139	Physics
142	Physics
294	Astronomy

You can join on full structs. The following example joins the addresses in the employees and customers tables:

```
=> SELECT employees.personal.name, customers.accountID FROM employees
```

```
JOIN customers ON employees.personal.address=customers.address;
```

name	accountID
Sheldon Cooper	139
Leonard Hofstadter	142

(2 rows)

You can cast structs, optionally specifying new field names:

```
=> SELECT contact::ROW(str VARCHAR, city VARCHAR, zip VARCHAR, email ARRAY[VARCHAR, 20]) FROM customers;
```

contact

```
-----  
-----  
{"str":"911 San Marcos St","city":"Austin","zip":"73344","email":["missy@mit.edu", "mcooper@cern.gov"]}  
{"str":"100 Main St Apt 4B","city":"Pasadena","zip":"91001","email":["shelly@emaw.name", "cooper@caltech.edu"]}  
{"str":"100 Main St Apt 4A","city":"Pasadena","zip":"91001","email":["hofstadter@caltech.edu"]}

```

(6 rows)

You can use structs in views and in subqueries, as in the following example:

```
=> CREATE VIEW neighbors (num_neighbors, area(city, zipcode))
```

```
AS SELECT count(*), ROW(address.city, address.zipcode)  
FROM customers GROUP BY address.city, address.zipcode;  
CREATE VIEW
```

```
=> SELECT employees.personal.name, neighbors.area FROM neighbors, employees  
WHERE employees.personal.address.zipcode=neighbors.area.zipcode AND neighbors.num_neighbors > 1;
```

```
name | area
```

```
-----+-----  
Sheldon Cooper | {"city":"Pasadena","zipcode":91001}  
Leonard Hofstadter | {"city":"Pasadena","zipcode":91001}
```

(2 rows)

If a reference is ambiguous, Vertica prefers column names over field names.

You can use many operators and predicates with ROW columns, including JOIN, GROUP BY, ORDER BY, IS [NOT] NULL, and comparison operations in nullable filters. Some operators do not logically apply to structured data and are not supported. See the [ROW](#) reference page for a complete list.

Subqueries

A subquery is a SELECT statement embedded within another SELECT statement. The embedded subquery is often referenced as the query's inner statement, while the containing query is typically referenced as the query's statement, or outer query block. A subquery returns data that the outer query uses as a condition to determine what data to retrieve. There is no limit to the number of nested subqueries you can create.

Like any query, a subquery returns records from a table that might consist of a single column and record, a single column with multiple records, or multiple columns and records. Subqueries can be [noncorrelated or correlated](#). You can also use them to [update or delete](#) table records, based on values in other database tables.

In this section

- [Subqueries used in search conditions](#)
- [Subqueries in the SELECT list](#)
- [Noncorrelated and correlated subqueries](#)
- [Flattening FROM clause subqueries](#)
- [Subqueries in UPDATE and DELETE statements](#)
- [Subquery examples](#)
- [Subquery restrictions](#)

Subqueries used in search conditions

Subqueries are used as search conditions in order to filter results. They specify the conditions for the rows returned from the containing query's select-list, a query expression, or the subquery itself. The operation evaluates to TRUE, FALSE, or UNKNOWN (NULL).

Syntax

```

search-condition {
  [ { AND | OR | NOT } { predicate | ( search-condition ) } ]
  [... ]
}
predicate
{ expression comparison-operator expression
  | string-expression [ NOT ] { LIKE | ILIKE | LIKEB | ILIKEB } string-expression
  | expression IS [ NOT ] NULL
  | expression [ NOT ] IN ( subquery | expression[,... ] )
  | expression comparison-operator [ ANY | SOME ] ( subquery )
  | expression comparison-operator ALL ( subquery )
  | expression OR ( subquery )
  | [ NOT ] EXISTS ( subquery )
  | [ NOT ] IN ( subquery )
}

```

Arguments

<p><i>search-condition</i></p>	<p>Specifies the search conditions for the rows returned from one of the following:</p> <ul style="list-style-type: none"> • Containing query's select-list • Query expression • Subquery <p>If the subquery is used with an UPDATE or DELETE statement, UPDATE specifies the rows to update and DELETE specifies the rows to delete.</p>
<p>{ AND OR NOT }</p>	<p>Logical operators:</p> <ul style="list-style-type: none"> • AND : Combines two conditions and evaluates to TRUE when both of the conditions are TRUE. • OR : Combines two conditions and evaluates to TRUE when either condition is TRUE. • NOT : Negates the Boolean expression specified by the predicate.
<p><i>predicate</i></p>	<p>An expression that returns TRUE, FALSE, or UNKNOWN (NULL).</p>
<p><i>expression</i></p>	<p>A column name, constant, function, or scalar subquery, or combination of column names, constants, and functions connected by operators or subqueries.</p>
<p><i>comparison-operator</i></p>	<p>An operator that tests conditions between two expressions, one of the following:</p> <ul style="list-style-type: none"> • < : less than • > : greater than • <= : less than or equal • >= : greater than or equal • = : equal; returns UNKNOWN if either expression does • <=> : Like the = operator, but returns TRUE (instead of UNKNOWN) if both expressions evaluate to UNKNOWN, and FALSE (instead of UNKNOWN) if one expression evaluates to UNKNOWN. • <> : not equal • != : not equal
<p><i>string-expression</i></p>	<p>A character string with optional wildcard (*) characters.</p>
<p>[NOT] { LIKE ILIKE LIKEB ILIKEB }</p>	<p>Indicates that the character string following the predicate is to be used (or not used) for pattern matching.</p>

IS [NOT] NULL	Searches for values that are null or are not null.
ALL	Used with a comparison operator and a subquery. Returns TRUE for the left-hand predicate if all values returned by the subquery satisfy the comparison operation, or FALSE if not all values satisfy the comparison or if the subquery returns no rows to the outer query block.
ANY SOME	ANY and SOME are synonyms and are used with a comparison operator and a subquery. Either returns TRUE for the left-hand predicate if any value returned by the subquery satisfies the comparison operation, or FALSE if no values in the subquery satisfy the comparison or if the subquery returns no rows to the outer query block. Otherwise, the expression is UNKNOWN.
[NOT] EXISTS	Used with a subquery to test for the existence of records that the subquery returns.
[NOT] IN	Searches for an expression on the basis of an expression's exclusion or inclusion from a list. The list of values is enclosed in parentheses and can be a subquery or a set of constants.

Expressions as subqueries

Subqueries that return a single value (unlike a list of values returned by IN subqueries) can generally be used anywhere an expression is allowed in SQL: a column name, constant, function, scalar subquery, or a combination of column names, constants, and functions connected by operators or subqueries.

For example:

```
=> SELECT c1 FROM t1 WHERE c1 = ANY (SELECT c1 FROM t2) ORDER BY c1;
=> SELECT c1 FROM t1 WHERE COALESCE((t1.c1 > ANY (SELECT c1 FROM t2)), TRUE);
=> SELECT c1 FROM t1 GROUP BY c1 HAVING
    COALESCE((t1.c1 <> ALL (SELECT c1 FROM t2)), TRUE);
```

Multi-column expressions are also supported:

```
=> SELECT c1 FROM t1 WHERE (t1.c1, t1.c2) = ALL (SELECT c1, c2 FROM t2);
=> SELECT c1 FROM t1 WHERE (t1.c1, t1.c2) <> ANY (SELECT c1, c2 FROM t2);
```

Vertica returns an error on queries where more than one row would be returned by any subquery used as an expression:

```
=> SELECT c1 FROM t1 WHERE c1 = (SELECT c1 FROM t2) ORDER BY c1;
ERROR: more than one row returned by a subquery used as an expression
```

See also

- [Subquery restrictions](#)

Subqueries in the SELECT list

Subqueries can occur in the select list of the containing query. The results from the following statement are ordered by the first column (customer_name). You could also write **ORDER BY 2** and specify that the results be ordered by the select-list subquery.

```
=> SELECT c.customer_name, (SELECT AVG(annual_income) FROM customer_dimension
  WHERE deal_size = c.deal_size) AVG_SAL_DEAL FROM customer_dimension c
  ORDER BY 1;
customer_name | AVG_SAL_DEAL
```

...
```

Notes

- Scalar subqueries in the select-list return a single row/column value. These subqueries use Boolean comparison operators: =, >, <, <>, <=, >=. If the query is correlated, it returns NULL if the correlation results in 0 rows. If the query returns more than one row, the query errors out at run time and Vertica displays an error message that the scalar subquery must only return 1 row.
- Subquery expressions such as [NOT] IN, [NOT] EXISTS, ANY/SOME, or ALL always return a single Boolean value that evaluates to TRUE, FALSE, or UNKNOWN; the subquery itself can have many rows. Most of these queries can be correlated or noncorrelated.

Note

ALL subqueries cannot be correlated.

- Subqueries in the ORDER BY and GROUP BY clauses are supported; for example, the following statement says to order by the first column, which is the select-list subquery:

```
=> SELECT (SELECT MAX(x) FROM t2 WHERE y=t1.b) FROM t1 ORDER BY 1;
```

See also

- [Subquery restrictions](#)

Noncorrelated and correlated subqueries

Subqueries can be categorized into two types:

- A *noncorrelated* subquery obtains its results independently of its containing (outer) statement.
- A *correlated* subquery requires values from its outer query in order to execute.

Noncorrelated subqueries

A noncorrelated subquery executes independently of the outer query. The subquery executes first, and then passes its results to the outer query. For example:

```
=> SELECT name, street, city, state FROM addresses WHERE state IN (SELECT state FROM states);
```

Vertica executes this query as follows:

1. Executes the subquery **SELECT state FROM states** (in bold).
2. Passes the subquery results to the outer query.

A query's **WHERE** and **HAVING** clauses can specify noncorrelated subqueries if the subquery resolves to a single row, as shown below:

In WHERE clause

```
=> SELECT COUNT(*) FROM SubQ1 WHERE SubQ1.a = (SELECT y from SubQ2);
```

In HAVING clause

```
=> SELECT COUNT(*) FROM SubQ1 GROUP BY SubQ1.a HAVING SubQ1.a = (SubQ1.a & (SELECT y from SubQ2))
```

Correlated subqueries

A correlated subquery typically obtains values from its outer query before it executes. When the subquery returns, it passes its results to the outer query. Correlated subqueries generally conform to the following format:

```
SELECT outer-column[...] FROM t1 outer
WHERE outer-column comparison-operator
(SELECT sq-column[...] FROM t2 sq
WHERE sq.expr = outer.expr);
```

Note

You can use an outer join to obtain the same effect as a correlated subquery.

In the following example, the subquery needs values from the `addresses.state` column in the outer query:

```
=> SELECT name, street, city, state FROM addresses
WHERE EXISTS (SELECT * FROM states WHERE states.state = addresses.state);
```

Vertica executes this query as follows:

1. Extracts and evaluates each `addresses.state` value in the outer subquery records.
2. Using the EXISTS predicate, checks addresses in the inner (correlated) subquery.
3. Stops processing when it finds the first match.

When Vertica executes this query, it translates the full query into a JOIN WITH SIPS.

Flattening FROM clause subqueries

[FROM clause](#) subqueries are always evaluated before their containing query. In some cases, the optimizer *flattens* FROM clause subqueries so the query can execute more efficiently.

For example, in order to create a query plan for the following statement, the Vertica query optimizer evaluates all records in table `t1` before it evaluates the records in table `t0`:

```
=> SELECT * FROM (SELECT a, MAX(a) AS max FROM (SELECT * FROM t1) AS t0 GROUP BY a);
```

Given the previous query, the optimizer can internally flatten it as follows:

```
=> SELECT * FROM (SELECT a, MAX(a) FROM t1 GROUP BY a) AS t0;
```

Both queries return the same results, but the flattened query runs more quickly.

Flattening views

When a query's FROM clause specifies a [view](#), the optimizer expands the view by replacing it with the query that the view encapsulates. If the view contains subqueries that are eligible for flattening, the optimizer produces a query plan that flattens those subqueries.

Flattening restrictions

The optimizer cannot create a flattened query plan if a subquery or view contains one of the following elements:

- Aggregate function
- Analytic function
- Outer join (left, right or full)
- GROUP BY , ORDER BY , or HAVING clause
- DISTINCT keyword
- LIMIT or OFFSET clause
- UNION , EXCEPT , or INTERSECT clause
- EXISTS subquery

Examples

If a predicate applies to a view or subquery, the flattening operation can allow for optimizations by evaluating the predicates before the flattening takes place. Two examples follow.

View flattening

In this example, view `v1` is defined as follows:

```
=> CREATE VIEW v1 AS SELECT * FROM a;
```

The following query specifies this view:

```
=> SELECT * FROM v1 JOIN b ON x=y WHERE x > 10;
```

Without flattening, the optimizer evaluates the query as follows:

1. Evaluates the subquery.
2. Applies the predicate **WHERE x > 10** .

In contrast, the optimizer can create a flattened query plan by applying the predicate before evaluating the subquery. This reduces the optimizer's work because it returns only the records **WHERE x > 10** to the containing query.

Vertica internally transforms the previous query as follows:

```
=> SELECT * FROM (SELECT * FROM a) AS t1 JOIN b ON x=y WHERE x > 10;
```

The optimizer then flattens the query:

```
=> SELECT * FROM a JOIN b ON x=y WHERE x > 10;
```

Subquery flattening

The following example shows how Vertica transforms **FROM** clause subqueries within a **WHERE** clause **IN** subquery. Given the following query:

```
=> SELECT * FROM a  
WHERE b IN (SELECT b FROM (SELECT * FROM t2)) AS D WHERE x=1;
```

The optimizer flattens it as follows:

```
=> SELECT * FROM a  
WHERE b IN (SELECT b FROM t2) AS D WHERE x=1;
```

[Subquery restrictions](#)

Subqueries in UPDATE and DELETE statements

You can nest subqueries within [UPDATE](#) and [DELETE](#) statements.

UPDATE subqueries

You can update records in one table according to values in others, by nesting a subquery within an **UPDATE** statement. The example below illustrates this through a couple of [noncorrelated subqueries](#). You can reproduce this example with the following tables:

```

=> CREATE TABLE addresses(cust_id INTEGER, address VARCHAR(2000));
CREATE TABLE
dbadmin=> INSERT INTO addresses VALUES(20,'Lincoln Street'),(30,'Booth Hill Road'),(30,'Beach Avenue'),(40,'Mt. Vernon Street'),(50,'Hillside Avenue');
OUTPUT
-----
      5
(1 row)

=> CREATE TABLE new_addresses(new_cust_id integer, new_address Boolean DEFAULT 'T');
CREATE TABLE
dbadmin=> INSERT INTO new_addresses VALUES (20),(30),(80);
OUTPUT
-----
      3
(1 row)

=> INSERT INTO new_addresses VALUES (60,'F');
OUTPUT
-----
      1

=> COMMIT;
COMMIT

```

Queries on these tables return the following results:

```

=> SELECT * FROM addresses;
cust_id | address
-----+-----
      20 | Lincoln Street
      30 | Beach Avenue
      30 | Booth Hill Road
      40 | Mt. Vernon Street
      50 | Hillside Avenue
(5 rows)

=> SELECT * FROM new_addresses;
new_cust_id | new_address
-----+-----
          20 | t
          30 | t
          80 | t
          60 | f
(4 rows)

```

1. The following UPDATE statement uses a [noncorrelated subquery](#) to join `new_addresses` and `addresses` records on customer IDs. UPDATE sets the value 'New Address' in the joined `addresses` records. The statement output indicates that three rows were updated:

```

=> UPDATE addresses SET address='New Address'
WHERE cust_id IN (SELECT new_cust_id FROM new_addresses WHERE new_address='T');
OUTPUT
-----
      3
(1 row)

```

2. Query the `addresses` table to see the changes for matching customer ID 20 and 30. Addresses for customer ID 40 and 50 are not updated:

```

=> SELECT * FROM addresses;
cust_id | address
-----+-----
      40 | Mt. Vernon Street
      50 | Hillside Avenue
      20 | New Address
      30 | New Address
      30 | New Address
(5 rows)

=> COMMIT;
COMMIT

```

DELETE subqueries

You can delete records in one table based according to values in others by nesting a subquery within a [DELETE](#) statement.

For example, you want to remove records from `new_addresses` that were used earlier to update records in `addresses`. The following DELETE statement uses a [noncorrelated subquery](#) to join `new_addresses` and `addresses` records on customer IDs. It then deletes the joined records from table `new_addresses`:

```

=> DELETE FROM new_addresses
WHERE new_cust_id IN (SELECT cust_id FROM addresses WHERE address='New Address');
OUTPUT
-----
      2
(1 row)
=> COMMIT;
COMMIT

```

Querying `new_addresses` confirms that the records were deleted:

```

=> SELECT * FROM new_addresses;
new_cust_id | new_address
-----+-----
      60 | f
      80 | t
(2 rows)

```

Subquery examples

This topic illustrates some of the subqueries you can write. The examples use the [VMart](#) example database.

Single-row subqueries

Single-row subqueries are used with single-row comparison operators (`=`, `>=`, `<=`, `<>`, and `<=>`) and return exactly one row.

For example, the following query retrieves the name and hire date of the oldest employee in the Vmart database:

```

=> SELECT employee_key, employee_first_name, employee_last_name, hire_date
FROM employee_dimension
WHERE hire_date = (SELECT MIN(hire_date) FROM employee_dimension);
employee_key | employee_first_name | employee_last_name | hire_date
-----+-----+-----+-----
      2292 | Mary | Bauer | 1956-01-11
(1 row)

```

Multiple-row subqueries

Multiple-row subqueries return multiple records.

For example, the following IN clause subquery returns the names of the employees making the highest salary in each of the six regions:

```
=> SELECT employee_first_name, employee_last_name, annual_salary, employee_region
      FROM employee_dimension WHERE annual_salary IN
      (SELECT MAX(annual_salary) FROM employee_dimension GROUP BY employee_region)
      ORDER BY annual_salary DESC;
employee_first_name | employee_last_name | annual_salary | employee_region
```

```
-----+-----+-----+-----
Alexandra | Sanchez | 992363 | West
Mark | Vogel | 983634 | South
Tiffany | Vu | 977716 | SouthWest
Barbara | Lewis | 957949 | MidWest
Sally | Gauthier | 927335 | East
Wendy | Nielson | 777037 | NorthWest
(6 rows)
```

Multicolumn subqueries

Multicolumn subqueries return one or more columns. Sometimes a subquery's result set is evaluated in the containing query in column-to-column and row-to-row comparisons.

Note

Multicolumn subqueries can use the <>, !=, and = operators but not the <, >, <=, >= operators.

You can substitute some multicolumn subqueries with a join, with the reverse being true as well. For example, the following two queries ask for the sales transactions of all products sold online to customers located in Massachusetts and return the same result set. The only difference is the first query is written as a join and the second is written as a subquery.

Join query:

```
=> SELECT *
      FROM online_sales.online_sales_fact
      INNER JOIN public.customer_dimension
      USING (customer_key)
      WHERE customer_state = 'MA';
```

Subquery:

```
=> SELECT *
      FROM online_sales.online_sales_fact
      WHERE customer_key IN
      (SELECT customer_key
       FROM public.customer_dimension
       WHERE customer_state = 'MA');
```

The following query returns all employees in each region whose salary is above the average:

```
=> SELECT e.employee_first_name, e.employee_last_name, e.annual_salary,
       e.employee_region, s.average
FROM employee_dimension e,
     (SELECT employee_region, AVG(annual_salary) AS average
      FROM employee_dimension GROUP BY employee_region) AS s
WHERE e.employee_region = s.employee_region AND e.annual_salary > s.average
ORDER BY annual_salary DESC;
```

employee_first_name	employee_last_name	annual_salary	employee_region	average
Doug	Overstreet	995533	East	61192.786013986
Matt	Gauthier	988807	South	57337.8638902996
Lauren	Nguyen	968625	West	56848.4274914089
Jack	Campbell	963914	West	56848.4274914089
William	Martin	943477	NorthWest	58928.2276119403
Luigi	Campbell	939255	MidWest	59614.9170454545
Sarah	Brown	901619	South	57337.8638902996
Craig	Goldberg	895836	East	61192.786013986
Sam	Vu	889841	MidWest	59614.9170454545
Luigi	Sanchez	885078	MidWest	59614.9170454545
Michael	Weaver	882685	South	57337.8638902996
Doug	Pavlov	881443	SouthWest	57187.2510548523
Ruth	McNulty	874897	East	61192.786013986
Luigi	Dobisz	868213	West	56848.4274914089
Laura	Lang	865829	East	61192.786013986
...				

You can also use the [EXCEPT](#), [INTERSECT](#), and [UNION](#) [ALL] keywords in FROM, WHERE, and HAVING clauses.

The following subquery returns information about all Connecticut-based customers who bought items through either stores or online sales channel and whose purchases amounted to more than 500 dollars:

```
=> SELECT DISTINCT customer_key, customer_name FROM public.customer_dimension
WHERE customer_key IN (SELECT customer_key FROM store.store_sales_fact
WHERE sales_dollar_amount > 500
UNION ALL
SELECT customer_key FROM online_sales.online_sales_fact
WHERE sales_dollar_amount > 500)
AND customer_state = 'CT';
```

customer_key	customer_name
200	Carla Y. Kramer
733	Mary Z. Vogel
931	Lauren X. Roy
1533	James C. Vu
2948	Infocare
4909	Matt Z. Winkler
5311	John Z. Goldberg
5520	Laura M. Martin
5623	Daniel R. Kramer
6759	Daniel Q. Nguyen
...	

HAVING clause subqueries

A HAVING clause is used in conjunction with the GROUP BY clause to filter the select-list records that a GROUP BY returns. HAVING clause subqueries must use Boolean comparison operators: =, >, <, <>, <=, >= and take the following form:

```

SELECT <column, ...>
FROM <table>
GROUP BY <expression>
HAVING <expression>
(SELECT <column, ...>
 FROM <table>
 HAVING <expression>);

```

For example, the following statement uses the [VMart](#) database and returns the number of customers who purchased lowfat products. Note that the GROUP BY clause is required because the query uses an aggregate (COUNT).

```

=> SELECT s.product_key, COUNT(s.customer_key) FROM store.store_sales_fact s
   GROUP BY s.product_key HAVING s.product_key IN
   (SELECT product_key FROM product_dimension WHERE diet_type = 'Low Fat');

```

The subquery first returns the product keys for all low-fat products, and the outer query then counts the total number of customers who purchased those products.

```

product_key | count
-----+-----
      15 | 2
      41 | 1
      66 | 1
     106 | 1
     118 | 1
     169 | 1
     181 | 2
     184 | 2
     186 | 2
     211 | 1
     229 | 1
     267 | 1
     289 | 1
     334 | 2
     336 | 1
(15 rows)

```

Subquery restrictions

The following restrictions apply to Vertica subqueries:

- Subqueries are not allowed in the defining query of a [CREATE PROJECTION](#) statement.
- Subqueries can be used in the **SELECT** list, but **GROUP BY** or aggregate functions are not allowed in the query if the subquery is not part of the **GROUP BY** clause in the containing query. For example, the following two statement returns an error message:

```

=> SELECT y, (SELECT MAX(a) FROM t1) FROM t2 GROUP BY y;
ERROR: subqueries in the SELECT or ORDER BY are not supported if the
subquery is not part of the GROUP BY
=> SELECT MAX(y), (SELECT MAX(a) FROM t1) FROM t2;
ERROR: subqueries in the SELECT or ORDER BY are not supported if the
query has aggregates and the subquery is not part of the GROUP BY

```

- Subqueries are supported within **UPDATE** statements with the following exceptions:
 - You cannot use **SET column = { expression }** to specify a subquery.
 - The table specified in the **UPDATE** list cannot also appear in the **FROM** clause (no self joins).
- **FROM** clause subqueries require an alias but tables do not. If the table has no alias, the query must refer its columns as *table-name . column-name*. However, column names that are unique among all tables in the query do not need to be qualified by their table name.
- If the **ORDER BY** clause is inside a **FROM** clause subquery, rather than in the containing query, the query is liable to return unexpected sort results. This occurs because Vertica data comes from multiple nodes, so sort order cannot be guaranteed unless the outer query block specifies an **ORDER BY** clause. This behavior complies with the SQL standard, but it might differ from other databases.
- Multicolumn subqueries cannot use the **<**, **>**, **<=**, **>=** comparison operators. They can use **<>**, **!=**, and **=** operators.
- **WHERE** and **HAVING** clause subqueries must use Boolean comparison operators: **=**, **>**, **<**, **<>**, **<=**, **>=**. Those subqueries can be noncorrelated and correlated.

- **[NOT] IN** and **ANY** subqueries nested in another expression are not supported if any of the column values are NULL. In the following statement, for example, if column x from either table **t1** or **t2** contains a NULL value, Vertica returns a run-time error:

```
=> SELECT * FROM t1 WHERE (x IN (SELECT x FROM t2)) IS FALSE;
ERROR: NULL value found in a column used by a subquery
```

- Vertica returns an error message during subquery run time on scalar subqueries that return more than one row.
- Aggregates and GROUP BY clauses are allowed in subqueries, as long as those subqueries are not correlated.
- Correlated expressions under **ALL** and **[NOT] IN** are not supported.
- Correlated expressions under **OR** are not supported.
- Multiple correlations are allowed only for subqueries that are joined with an equality (=) predicate. However, **IN / NOT IN**, **EXISTS / NOT EXISTS** predicates within correlated subqueries are not allowed:

```
=> SELECT t2.x, t2.y, t2.z FROM t2 WHERE t2.z NOT IN
      (SELECT t1.z FROM t1 WHERE t1.x = t2.x);
ERROR: Correlated subquery with NOT IN is not supported
```

- Up to one level of correlated subqueries is allowed in the **WHERE** clause if the subquery references columns in the immediate outer query block. For example, the following query is not supported because the **t2.x = t3.x** subquery can only refer to table **t1** in the outer query, making it a correlated expression because **t3.x** is two levels out:

```
=> SELECT t3.x, t3.y, t3.z FROM t3 WHERE t3.z IN (
      SELECT t1.z FROM t1 WHERE EXISTS (
        SELECT 'x' FROM t2 WHERE t2.x = t3.x) AND t1.x = t3.x);
ERROR: More than one level correlated subqueries are not supported
```

The query is supported if it is rewritten as follows:

```
=> SELECT t3.x, t3.y, t3.z FROM t3 WHERE t3.z IN
      (SELECT t1.z FROM t1 WHERE EXISTS
        (SELECT 'x' FROM t2 WHERE t2.x = t1.x)
      AND t1.x = t3.x);
```

Joins

Queries can combine records from multiple tables, or multiple instances of the same table. A query that combines records from one or more tables is called a join. Joins are allowed in **SELECT** statements and subqueries.

Supported join types

Vertica supports the following join types:

- Inner (including natural, cross) joins
- Left, right, and full outer joins
- Optimizations for equality and range joins predicates

Vertica does not support nested loop joins.

Join algorithms

Vertica's query optimizer implements joins with either the hash join or merge join algorithm. For details, see [Hash joins versus merge joins](#).

In this section

- [Join syntax](#)
- [Join conditions vs. filter conditions](#)
- [Inner joins](#)
- [Outer joins](#)
- [Controlling join inputs](#)
- [Range joins](#)
- [Event series joins](#)

Join syntax

Vertica supports the ANSI SQL-92 standard for joining tables, as follows:

```
table-reference [join-type] JOIN table-reference [ ON join-predicate ]
```

where *join-type* can be one of the following:

- [INNER](#) (default)
- [LEFT \[OUTER \]](#)
- [RIGHT \[OUTER \]](#)
- [FULL \[OUTER \]](#)
- [NATURAL](#)
- [CROSS](#)

For example:

```
=> SELECT * FROM T1 INNER JOIN T2 ON T1.id = T2.id;
```

Note

The [ON join-predicate](#) clause is invalid for NATURAL and CROSS joins, required for all other join types.

Alternative syntax options

Vertica also supports two older join syntax conventions:

Join specified by WHERE clause join predicate

INNER JOIN is equivalent to a query that specifies its join predicate in a WHERE clause. For example, this example and the previous one return equivalent results. They both specify an inner join between tables [T1](#) and [T2](#) on columns [T1.id](#) and [T2.id](#) , respectively.

```
=> SELECT * FROM T1, T2 WHERE T1.id = T2.id;
```

JOIN USING clause

You can join two tables on identically named columns with a JOIN USING clause. For example:

```
=> SELECT * FROM T1 JOIN T2 USING(id);
```

By default, a join that is specified by JOIN USING is always an inner join.

Note

JOIN USING joins the two tables by combining the two join columns into one. Therefore, the two join column data types must be the same or compatible—for example, FLOAT and INTEGER—regardless of the actual data in the joined columns.

Benefits of SQL-92 join syntax

Vertica recommends that you use SQL-92 join syntax for several reasons:

- SQL-92 outer join syntax is portable across databases; the older syntax was not consistent between databases.
- SQL-92 syntax provides greater control over whether predicates are evaluated during or after outer joins. This was also not consistent between databases when using the older syntax.
- SQL-92 syntax eliminates ambiguity in the order of evaluating the joins, in cases where more than two tables are joined with outer joins.

Join conditions vs. filter conditions

If you do not use the SQL-92 syntax, join conditions (predicates that are evaluated during the join) are difficult to distinguish from filter conditions (predicates that are evaluated after the join), and in some cases cannot be expressed at all. With SQL-92, join conditions and filter conditions are separated into two different clauses, the [ON](#) clause and the [WHERE](#) clause, respectively, making queries easier to understand.

- **The ON clause** contains relational operators (for example, <, <=, >, >=, <>, =, <=>) or other predicates that specify which records from the left and right input relations to combine, such as by matching foreign keys to primary keys. [ON](#) can be used with inner, left outer, right outer, and full outer joins. Cross joins and union joins do not use an [ON](#) clause. Inner joins return all pairings of rows from the left and right relations for which the [ON](#) clause evaluates to TRUE. In a left join, all rows from the left relation in the join are present in the result; any row of the left relation that does not match any rows in the right relation is still present in the result but with nulls in any columns taken from the right relation. Similarly, a right join preserves all rows from the right relation, and a full join retains all rows from both relations.
- **The WHERE clause** is evaluated after the join is performed. It filters records returned by the [FROM](#) clause, eliminating any records that do not satisfy the [WHERE](#) clause condition.

Vertica automatically converts outer joins to inner joins in cases where it is correct to do so, allowing the optimizer to choose among a wider set of query plans and leading to better performance.

Inner joins

An inner join combines records from two tables based on a join predicate and requires that each record in the first table has a matching record in the second table. Thus, inner joins return only records from both joined tables that satisfy the join condition. Records that contain no matches are excluded from the result set.

Inner joins take the following form:

```
SELECT column-list FROM left-join-table  
[INNER] JOIN right-join-table ON join-predicate
```

If you omit the **INNER** keyword, Vertica assumes an inner join. Inner joins are commutative and associative. You can specify tables in any order without changing the results.

Example

The following example specifies an inner join between tables `store.store_dimension` and `public.employee_dimension` whose records have matching values in columns `store_region` and `employee_region`, respectively:

```
=> SELECT s.store_region, SUM(e.vacation_days) TotalVacationDays  
FROM public.employee_dimension e  
JOIN store.store_dimension s ON s.store_region=e.employee_region  
GROUP BY s.store_region ORDER BY TotalVacationDays;
```

This join can also be expressed as follows:

```
=> SELECT s.store_region, SUM(e.vacation_days) TotalVacationDays  
FROM public.employee_dimension e, store.store_dimension s  
WHERE s.store_region=e.employee_region  
GROUP BY s.store_region ORDER BY TotalVacationDays;
```

Both queries return the same result set:

store_region	TotalVacationDays
NorthWest	23280
SouthWest	367250
MidWest	925938
South	1280468
East	1952854
West	2849976

(6 rows)

If the join's inner table `store.store_dimension` has any rows with `store_region` values that do not match `employee_region` values in table `public.employee_dimension`, those rows are excluded from the result set. To include that row, you can specify an [outer join](#).

In this section

- [Equi-joins and non equi-joins](#)
- [Natural joins](#)
- [Cross joins](#)

Equi-joins and non equi-joins

Vertica supports any arbitrary join expression with both matching and non-matching column values. For example:

```
SELECT * FROM fact JOIN dim ON fact.x = dim.x;  
SELECT * FROM fact JOIN dim ON fact.x > dim.y;  
SELECT * FROM fact JOIN dim ON fact.x <= dim.y;  
SELECT * FROM fact JOIN dim ON fact.x <> dim.y;  
SELECT * FROM fact JOIN dim ON fact.x <=> dim.y;
```

Operators = and <=> generally run the fastest.

Equi-joins are based on equality (matching column values). This equality is indicated with an equal sign (=), which functions as the comparison operator in the **ON** clause using SQL-92 syntax or the **WHERE** clause using older join syntax.

The first example below uses SQL-92 syntax and the **ON** clause to join the online sales table with the call center table using the call center key; the query then returns the sale date key that equals the value 156:

```
=> SELECT sale_date_key, cc_open_date FROM online_sales.online_sales_fact
  INNER JOIN online_sales.call_center_dimension
  ON (online_sales.online_sales_fact.call_center_key =
  online_sales.call_center_dimension.call_center_key
  AND sale_date_key = 156);
sale_date_key | cc_open_date
-----+-----
          156 | 2005-08-12
(1 row)
```

The second example uses older join syntax and the **WHERE** clause to join the same tables to get the same results:

```
=> SELECT sale_date_key, cc_open_date
  FROM online_sales.online_sales_fact, online_sales.call_center_dimension
  WHERE online_sales.online_sales_fact.call_center_key =
  online_sales.call_center_dimension.call_center_key
  AND sale_date_key = 156;
sale_date_key | cc_open_date
-----+-----
          156 | 2005-08-12
(1 row)
```

Vertica also permits tables with compound (multiple-column) primary and foreign keys. For example, to create a pair of tables with multi-column keys:

```
=> CREATE TABLE dimension(pk1 INTEGER NOT NULL, pk2 INTEGER NOT NULL);=> ALTER TABLE dimension ADD PRIMARY KEY (pk1, pk2);
=> CREATE TABLE fact (fk1 INTEGER NOT NULL, fk2 INTEGER NOT NULL);
=> ALTER TABLE fact ADD FOREIGN KEY (fk1, fk2) REFERENCES dimension (pk1, pk2);
```

To join tables using compound keys, you must connect two [join predicates](#) with a Boolean **AND** operator. For example:

```
=> SELECT * FROM fact f JOIN dimension d ON f.fk1 = d.pk1 AND f.fk2 = d.pk2;
```

You can write queries with expressions that contain the <=> operator for **NULL=NULL** joins.

```
=> SELECT * FROM fact JOIN dim ON fact.x <=> dim.y;
```

The <=> operator performs an equality comparison like the = operator, but it returns true, instead of **NULL**, if both operands are **NULL**, and false, instead of **NULL**, if one operand is **NULL**.

```
=> SELECT 1 <=> 1, NULL <=> NULL, 1 <=> NULL;
?column? | ?column? | ?column?
-----+-----+-----
t       | t       | f
(1 row)
```

Compare the <=> operator to the = operator:

```
=> SELECT 1 = 1, NULL = NULL, 1 = NULL;
?column? | ?column? | ?column?
-----+-----+-----
t       |         |
(1 row)
```

Note

Writing `NULL=NULL` joins on primary key/foreign key combinations is not an optimal choice because PK/FK columns are usually defined as `NOT NULL`.

When composing joins, it helps to know in advance which columns contain null values. An employee's hire date, for example, would not be a good choice because it is unlikely hire date would be omitted. An hourly rate column, however, might work if some employees are paid hourly and some are salaried. If you are unsure about the value of columns in a given table and want to check, type the command:

```
=> SELECT COUNT(*) FROM tablename WHERE columnname IS NULL;
```

Natural joins

A natural join is just a join with an implicit join predicate. Natural joins can be inner, left outer, right outer, or full outer joins and take the following form:

```
SELECT column-list FROM left-join-table  
NATURAL [ INNER | LEFT OUTER | RIGHT OUTER | FULL OUTER ] JOIN right-join-table
```

Natural joins are, by default, natural inner joins; however, there can also be natural left/right/full outer joins. The primary difference between an inner and natural join is that inner joins have an explicit join condition, whereas the natural join's conditions are formed by matching all pairs of columns in the tables that have the same name and compatible data types, making natural joins equi-joins because join conditions are equal between common columns. (If the data types are incompatible, Vertica returns an error.)

Note

The [Data type coercion chart](#) lists the data types that can be cast to other data types. If one data type can be cast to the other, those two data types are compatible.

The following query is a simple natural join between tables T1 and T2 when the T2 column `val` is greater than 5:

```
=> SELECT * FROM T1 NATURAL JOIN T2 WHERE T2.val > 5;
```

The `store_sales_fact` table and the `product_dimension` table have two columns that share the same name and data type: `product_key` and `product_version`. The following example creates a natural join between those two tables at their shared columns:

```
=> SELECT product_description, sales_quantity FROM store.store_sales_fact  
NATURAL JOIN public.product_dimension;
```

The following three queries return the same result expressed as a basic query, an inner join, and a natural join. At the table expressions are equivalent only if the common attribute in the `store_sales_fact` table and the `store_dimension` table is `store_key`. If both tables have a column named `store_key`, then the natural join would also have a `store_sales_fact.store_key = store_dimension.store_key` join condition. Since the results are the same in all three instances, they are shown in the first (basic) query only:

```
=> SELECT store_name FROM store.store_sales_fact, store.store_dimension  
WHERE store.store_sales_fact.store_key = store.store_dimension.store_key  
AND store.store_dimension.store_state = 'MA' ORDER BY store_name;  
store_name  
-----  
Store11  
Store128  
Store178  
Store66  
Store8  
Store90  
(6 rows)
```

The query written as an inner join:

```
=> SELECT store_name FROM store.store_sales_fact  
INNER JOIN store.store_dimension  
ON (store.store_sales_fact.store_key = store.store_dimension.store_key)  
WHERE store.store_dimension.store_state = 'MA' ORDER BY store_name;
```

In the case of the natural join, the join predicate appears implicitly by comparing all of the columns in both tables that are joined by the same column name. The result set contains only one column representing the pair of equally-named columns.

```
=> SELECT store_name FROM store.store_sales_fact
NATURAL JOIN store.store_dimension
WHERE store.store_dimension.store_state = 'MA' ORDER BY store_name;
```

Cross joins

Cross joins are the simplest joins to write, but they are not usually the fastest to run because they consist of all possible combinations of two tables' records. Cross joins contain no join condition and return what is known as a Cartesian product, where the number of rows in the result set is equal to the number of rows in the first table multiplied by the number of rows in the second table.

The following query returns all possible combinations from the promotion table and the store sales table:

```
=> SELECT * FROM promotion_dimension CROSS JOIN store.store_sales_fact;
```

Because this example returns over 600 million records, many cross join results can be extremely large and difficult to manage. Cross joins can be useful, however, such as when you want to return a single-row result set.

Tip

Filter out unwanted records in a cross with **WHERE** clause join predicates:

```
=> SELECT * FROM promotion_dimension p CROSS JOIN store.store_sales_fact f
WHERE p.promotion_key LIKE f.promotion_key;
```

Implicit versus explicit joins

Vertica recommends that you do not write implicit cross joins (comma-separated tables in the **FROM** clause). These queries can imply accidental omission of a join predicate.

The following query implicitly cross joins tables **promotion_dimension** and **store.store_sales_fact** :

```
=> SELECT * FROM promotion_dimension, store.store_sales_fact;
```

It is better practice to express this cross join explicitly, as follows:

```
=> SELECT * FROM promotion_dimension CROSS JOIN store.store_sales_fact;
```

Examples

The following example creates two small tables and their superprojections and then runs a cross join on the tables:

```
=> CREATE TABLE employee(employee_id INT, employee_fname VARCHAR(50));
=> CREATE TABLE department(dept_id INT, dept_name VARCHAR(50));
=> INSERT INTO employee VALUES (1, 'Andrew');
=> INSERT INTO employee VALUES (2, 'Priya');
=> INSERT INTO employee VALUES (3, 'Michelle');
=> INSERT INTO department VALUES (1, 'Engineering');
=> INSERT INTO department VALUES (2, 'QA');
=> SELECT * FROM employee CROSS JOIN department;
```

In the result set, the cross join retrieves records from the first table and then creates a new row for every row in the 2nd table. It then does the same for the next record in the first table, and so on.

```
employee_id | employee_name | dept_id | dept_name
-----+-----+-----+-----
1 | Andrew      | 1 | Engineering
2 | Priya       | 1 | Engineering
3 | Michelle    | 1 | Engineering
1 | Andrew      | 2 | QA
2 | Priya       | 2 | QA
3 | Michelle    | 2 | QA
```

(6 rows)

Outer joins

Outer joins extend the functionality of inner joins by letting you preserve rows of one or both tables that do not have matching rows in the non-preserved table. Outer joins take the following form:

```
SELECT column-list FROM left-join-table  
[ LEFT | RIGHT | FULL ] OUTER JOIN right-join-table ON join-predicate
```

Note

Omitting the keyword **OUTER** from your statements does not affect results of left and right joins. **LEFT OUTER JOIN** and **LEFT JOIN** perform the same operation and return the same results.

Left outer joins

A left outer join returns a complete set of records from the left-joined (preserved) table **T1**, with matched records, where available, in the right-joined (non-preserved) table **T2**. Where Vertica finds no match, it extends the right side column (**T2**) with null values.

```
=> SELECT * FROM T1 LEFT OUTER JOIN T2 ON T1.x = T2.x;
```

To exclude the non-matched values from T2, write the same left outer join, but filter out the records you don't want from the right side by using a **WHERE** clause:

```
=> SELECT * FROM T1 LEFT OUTER JOIN T2  
ON T1.x = T2.x WHERE T2.x IS NOT NULL;
```

The following example uses a left outer join to enrich telephone call detail records with an incomplete numbers dimension. It then filters out results that are known not to be from Massachusetts:

```
=> SELECT COUNT(*) FROM calls LEFT OUTER JOIN numbers  
ON calls.to_phone = numbers.phone WHERE NVL(numbers.state, "") <> 'MA';
```

Right outer joins

A right outer join returns a complete set of records from the right-joined (preserved) table, as well as matched values from the left-joined (non-preserved) table. If Vertica finds no matching records from the left-joined table (**T1**), **NULL** values appears in the **T1** column for any records with no matching values in **T1**. A right join is, therefore, similar to a left join, except that the treatment of the tables is reversed.

```
=> SELECT * FROM T1 RIGHT OUTER JOIN T2 ON T1.x = T2.x;
```

The above query is equivalent to the following query, where **T1 RIGHT OUTER JOIN T2 = T2 LEFT OUTER JOIN T1**.

```
=> SELECT * FROM T2 LEFT OUTER JOIN T1 ON T2.x = T1.x;
```

The following example identifies customers who have *not* placed an order:

```
=> SELECT customers.customer_id FROM orders RIGHT OUTER JOIN customers  
ON orders.customer_id = customers.customer_id  
GROUP BY customers.customer_id HAVING COUNT(orders.customer_id) = 0;
```

Full outer joins

A full outer join returns results for both left and right outer joins. The joined table contains all records from both tables, including nulls (missing matches) from either side of the join. This is useful if you want to see, for example, each employee who is assigned to a particular department and each department that has an employee, but you also want to see all the employees who are not assigned to a particular department, as well as any department that has no employees:

```
=> SELECT employee_last_name, hire_date FROM employee_dimension emp  
FULL OUTER JOIN department dept ON emp.employee_key = dept.department_key;
```

Notes

Vertica also supports joins where the outer (preserved) table or subquery is replicated on more than one node and the inner (non-preserved) table or subquery is segmented across more than one node. For example, in the following query, the fact table, which is almost always segmented, appears on the non-preserved side of the join, and it is allowed:

```
=> SELECT sales_dollar_amount, transaction_type, customer_name
       FROM store.store_sales_fact f RIGHT JOIN customer_dimension d
       ON f.customer_key = d.customer_key;
sales_dollar_amount | transaction_type | customer_name
```

```
-----+-----+-----
252 | purchase | Inistar
363 | purchase | Inistar
510 | purchase | Inistar
-276 | return   | Foodcorp
252 | purchase | Foodcorp
195 | purchase | Foodcorp
290 | purchase | Foodcorp
222 | purchase | Foodcorp
    |         | Foodgen
    |         | Goldcare
```

(10 rows)

Controlling join inputs

By default, the optimizer uses its own internal logic to determine whether to join one table to another as an inner or outer input. Occasionally, the optimizer might choose the larger table as the inner input to a join. Doing so can incur performance and concurrency issues.

If the configuration parameter `EnableForceOuter` is set to 1, you can control join inputs for specific tables through [ALTER TABLE..FORCE OUTER](#). The `FORCE OUTER` option modifies a table's `force_outer` setting in the system table `TABLES`. When implementing a join, Vertica compares the `force_outer` settings of the participating tables:

- If table settings are unequal, Vertica uses them to set the join inputs:
 - A table with a low `force_outer` setting relative to other tables is joined to them as an inner input.
 - A table with a high `force_outer` setting relative to other tables is joined to them as an outer input.
- If all table settings are equal, Vertica ignores them and assembles the join on its own.

The `force_outer` column is initially set to 5 for all newly-defined tables. You can use [ALTER TABLE..FORCE OUTER](#) to reset `force_outer` to a value equal to or greater than 0. For example, you might change the `force_outer` settings of tables `abc` and `xyz` to 3 and 8, respectively:

```
=> ALTER TABLE abc FORCE OUTER 3;
=> ALTER TABLE xyz FORCE OUTER 8;
```

Given these settings, the optimizer joins `abc` as the inner input to any table with a `force_outer` value greater than 3. The optimizer joins `xyz` as the outer input to any table with a `force_outer` value less than 8.

Projection inheritance

When you query a projection directly, it inherits the `force_outer` setting of its anchor table. The query then uses this setting when joined to another projection.

Enabling forced join inputs

The configuration parameter `EnableForceOuter` determines whether Vertica uses a table's `force_outer` value to implement a join. By default, this parameter is set to 0, and forced join inputs are disabled. You can enable forced join inputs at session and database scopes, through [ALTER SESSION](#) and [ALTER DATABASE](#), respectively:

```
=> ALTER SESSION SET EnableForceOuter = { 0 | 1 };
=> ALTER DATABASE db-name SET EnableForceOuter = { 0 | 1 };
```

If `EnableForceOuter` is set to 0, [ALTER TABLE..FORCE OUTER](#) statements return with this warning:

Note

WARNING 0: Set configuration parameter `EnableForceOuter` for the current session or the database in order to use `force_outer` value

Viewing forced join inputs

EXPLAIN -generated query plans indicate whether the configuration parameter **EnableForceOuter** is on. A join query might include tables whose **force_outer** settings are less or greater than the default value of 5. In this case, the query plan includes a **Force outer level** field for the relevant join inputs.

For example, the following query joins tables **store.store_sales** and **public.products**, where both tables have the same **force_outer** setting (5). **EnableForceOuter** is on, as indicated in the generated query plan:

```
=> EXPLAIN SELECT s.store_key, p.product_description, s.sales_quantity, s.sale_date
FROM store.store_sales s JOIN public.products p ON s.product_key=p.product_key
WHERE s.sale_date='2014-12-01' ORDER BY s.store_key, s.sale_date;
```

EnableForceOuter is on
Access Path:
+-SORT [Cost: 7K, Rows: 100K (NO STATISTICS)] (PATH ID: 1)
| Order: sales.store_key ASC, sales.sale_date ASC
| Execute on: All Nodes
| +---> JOIN HASH [Cost: 5K, Rows: 100K (NO STATISTICS)] (PATH ID: 2) Outer (BROADCAST)(LOCAL ROUND ROBIN)
|| Join Cond: (sales.product_key = products.product_key)
|| Execute on: All Nodes
|| +-- Outer -> STORAGE ACCESS for sales [Cost: 2K, Rows: 100K (NO STATISTICS)] (PATH ID: 3)
||| Projection: store.store_sales_b0
||| Materialize: sales.sale_date, sales.store_key, sales.product_key, sales.sales_quantity
||| Filter: (sales.sale_date = '2014-12-01'::date)
||| Execute on: All Nodes
|| +-- Inner -> STORAGE ACCESS for products [Cost: 177, Rows: 60K (NO STATISTICS)] (PATH ID: 4)
||| Projection: public.products_b0
||| Materialize: products.product_key, products.product_description
||| Execute on: All Nodes

The following **ALTER TABLE** statement resets the **force_outer** setting of **public.products** to 1:

```
=> ALTER TABLE public.products FORCE OUTER 1;
ALTER TABLE
```

The regenerated query plan for the same join now includes a **Force outer level** field and specifies **public.products** as the inner input:

```
=> EXPLAIN SELECT s.store_key, p.product_description, s.sales_quantity, s.sale_date
FROM store.store_sales s JOIN public.products p ON s.product_key=p.product_key
WHERE s.sale_date='2014-12-01' ORDER BY s.store_key, s.sale_date;
```

EnableForceOuter is on
Access Path:
+-SORT [Cost: 7K, Rows: 100K (NO STATISTICS)] (PATH ID: 1)
| Order: sales.store_key ASC, sales.sale_date ASC
| Execute on: All Nodes
| +---> JOIN HASH [Cost: 5K, Rows: 100K (NO STATISTICS)] (PATH ID: 2) Outer (BROADCAST)(LOCAL ROUND ROBIN)
|| Join Cond: (sales.product_key = products.product_key)
|| Execute on: All Nodes
|| +-- Outer -> STORAGE ACCESS for sales [Cost: 2K, Rows: 100K (NO STATISTICS)] (PATH ID: 3)
||| Projection: store.store_sales_b0
||| Materialize: sales.sale_date, sales.store_key, sales.product_key, sales.sales_quantity
||| Filter: (sales.sale_date = '2014-12-01'::date)
||| Execute on: All Nodes
|| +-- **Inner -> STORAGE ACCESS for products** [Cost: 177, Rows: 60K (NO STATISTICS)] (PATH ID: 4)
||| **Projection: public.products_b0**
||| Force outer level: 1
||| Materialize: products.product_key, products.product_description
||| Execute on: All Nodes

If you change the **force_outer** setting of **public.products** to 8, Vertica creates a different query plan that specifies **public.products** as the outer input:

```
=> ALTER TABLE public.products FORCE OUTER 8;
ALTER TABLE
```

```
=> EXPLAIN SELECT s.store_key, p.product_description, s.sales_quantity, s.sale_date
FROM store.store_sales s JOIN public.products p ON s.product_key=p.product_key
WHERE s.sale_date='2014-12-01' ORDER BY s.store_key, s.sale_date;
```

EnableForceOuter is on

Access Path:

```
+--SORT [Cost: 7K, Rows: 100K (NO STATISTICS)] (PATH ID: 1)
| Order: sales.store_key ASC, sales.sale_date ASC
| Execute on: All Nodes
| +---> JOIN HASH [Cost: 5K, Rows: 100K (NO STATISTICS)] (PATH ID: 2) Inner (BROADCAST)
||   Join Cond: (sales.product_key = products.product_key)
||   Materialize at Output: products.product_description
||   Execute on: All Nodes
|| +-- Outer -> STORAGE ACCESS for products [Cost: 20, Rows: 60K (NO STATISTICS)] (PATH ID: 3)
|||   Projection: public.products_b0
|||   Force outer level: 8
|||   Materialize: products.product_key
|||   Execute on: All Nodes
|||   Runtime Filter: (SIP1(HashJoin): products.product_key)
|| +-- Inner -> STORAGE ACCESS for sales [Cost: 2K, Rows: 100K (NO STATISTICS)] (PATH ID: 4)
|||   Projection: store.store_sales_b0
|||   Materialize: sales.sale_date, sales.store_key, sales.product_key, sales.sales_quantity
|||   Filter: (sales.sale_date = '2014-12-01'::date)
|||   Execute on: All Nodes
```

Restrictions

Vertica ignores `force_outer` settings when it performs the following operations:

- Outer joins: Vertica generally respects **OUTER JOIN** clauses regardless of the `force_outer` settings of the joined tables.
- **MERGE** statement joins.
- Queries that include the **SYNTACTIC_JOIN** hint.
- Half-join queries such as **SEMI JOIN**.
- Joins to subqueries, where the subquery is always processed as having a `force_outer` setting of 5 regardless of the `force_outer` settings of the tables that are joined in the subquery. This setting determines a subquery's designation as inner or outer input relative to other join inputs. If two subqueries are joined, the optimizer determines which one is the inner input, and which one the outer.

Range joins

Vertica provides performance optimizations for `<`, `<=`, `>`, `>=`, and **BETWEEN** predicates in join **ON** clauses. These optimizations are particularly useful when a column from one table is restricted to be in a range specified by two columns of another table.

Key ranges

Multiple, consecutive key values can map to the same dimension values. Consider, for example, a table of IPv4 addresses and their owners. Because large subnets (ranges) of IP addresses can belong to the same owner, this dimension can be represented as:

```
=> CREATE TABLE ip_owners(
  ip_start INTEGER,
  ip_end INTEGER,
  owner_id INTEGER);
=> CREATE TABLE clicks(
  ip_owners INTEGER,
  dest_ip INTEGER);
```

A query that associates a click stream with its destination can use a join similar to the following, which takes advantage of range optimization:

```
=> SELECT owner_id, COUNT(*) FROM clicks JOIN ip_owners
ON clicks.dest_ip BETWEEN ip_start AND ip_end
GROUP BY owner_id;
```

Requirements

Operators `<`, `<=`, `>`, `>=`, or **BETWEEN** must appear as top-level conjunctive predicates for range join optimization to be effective, as shown in the following examples:

``BETWEEN`` as the only predicate:

```
...
=> SELECT COUNT(*) FROM fact JOIN dim
     ON fact.point BETWEEN dim.start AND dim.end;
...
```

Comparison operators as top-level predicates (within ``AND``):

```
...
=> SELECT COUNT(*) FROM fact JOIN dim
     ON fact.point > dim.start AND fact.point < dim.end;
...
```

``BETWEEN`` as a top-level predicate (within ``AND``):

```
...
=> SELECT COUNT(*) FROM fact JOIN dim
     ON (fact.point BETWEEN dim.start AND dim.end) AND fact.c <> dim.c;
...
```

Query not optimized because ``OR`` is top-level predicate (disjunctive):

```
...
=> SELECT COUNT(*) FROM fact JOIN dim
     ON (fact.point BETWEEN dim.start AND dim.end) OR dim.end IS NULL;
...
```

Notes

- Expressions are optimized in range join queries in many cases.
- If range columns can have **NULL** values indicating that they are open-ended, it is possible to use range join optimizations by replacing nulls with very large or very small values:

```
=> SELECT COUNT(*) FROM fact JOIN dim
     ON fact.point BETWEEN NVL(dim.start, -1) AND NVL(dim.end, 1000000000000);
```

- If there is more than one set of ranging predicates in the same **ON** clause, the order in which the predicates are specified might impact the effectiveness of the optimization:

```
=> SELECT COUNT(*) FROM fact JOIN dim ON fact.point1 BETWEEN dim.start1 AND dim.end1
     AND fact.point2 BETWEEN dim.start2 AND dim.end2;
```

The optimizer chooses the first range to optimize, so write your queries so that the range you most want optimized appears first in the statement.

- The use of the range join optimization is not directly affected by any characteristics of the physical schema; no schema tuning is required to benefit from the optimization.
- The range join optimization can be applied to joins without any other predicates, and to **HASH** or **MERGE** joins.
- To determine if an optimization is in use, search for **RANGE** in the **EXPLAIN** plan.

Event series joins

An [event series](#) join is a Vertica SQL extension that enables the analysis of two series when their measurement intervals don't align precisely, such as with mismatched timestamps. You can compare values from the two series directly, rather than having to normalize the series to the same measurement interval.

Event series joins are an extension of [Outer joins](#), but instead of padding the non-preserved side with NULL values when there is no match, the event series join pads the non-preserved side values that it interpolates from either the previous or next value, whichever is specified in the query.

The difference in how you write a regular join versus an event series join is the INTERPOLATE predicate, which is used in the ON clause. For example, the following two statements show the differences, which are shown in greater detail in [Writing event series joins](#).

Examples

Regular full outer join

```
SELECT * FROM hTicks h FULL OUTER JOIN aTicks a
ON (h.time = a.time);
```

Event series join

```
SELECT * FROM hTicks h FULL OUTER JOIN aTicks a
ON (h.time INTERPOLATE PREVIOUS VALUE a.time);
```

Similar to regular joins, an event series join has inner and outer join modes, which are described in the topics that follow.

For full syntax, including notes and restrictions, see [INTERPOLATE](#)

In this section

- [Sample schema for event series joins examples](#)
- [Writing event series joins](#)

Sample schema for event series joins examples

If you don't plan to run the queries and just want to look at the examples, you can skip this topic and move straight to [Writing event series joins](#).

Schema of hTicks and aTicks tables

The examples that follow use the following hTicks and aTicks tables schemas:

```
CREATE TABLE hTicks (
  stock VARCHAR(20),
  time TIME,
  price NUMERIC(8,2)
);
CREATE TABLE aTicks (
  stock VARCHAR(20),
  time TIME,
  price NUMERIC(8,2)
);
```

Although TIMESTAMP is more commonly used for the event series column, the examples in this topic use TIME to keep the output simple.

```
INSERT INTO hTicks VALUES ('HPQ', '12:00', 50.00);
INSERT INTO hTicks VALUES ('HPQ', '12:01', 51.00);
INSERT INTO hTicks VALUES ('HPQ', '12:05', 51.00);
INSERT INTO hTicks VALUES ('HPQ', '12:06', 52.00);
INSERT INTO aTicks VALUES ('ACME', '12:00', 340.00);
INSERT INTO aTicks VALUES ('ACME', '12:03', 340.10);
INSERT INTO aTicks VALUES ('ACME', '12:05', 340.20);
INSERT INTO aTicks VALUES ('ACME', '12:05', 333.80);
COMMIT;
```

Output of the two tables:

hTicks	aTicks
--------	--------

=> SELECT * FROM hTicks;

There are no entry records between 12:02–12:04:

stock	time	price
HPQ	12:00:00	50.00
HPQ	12:01:00	51.00
HPQ	12:05:00	51.00
HPQ	12:06:00	52.00

(4 rows)

=> SELECT * FROM aTicks;

There are no entry records at 12:01, 12:02 and at 12:04:

stock	time	price
ACME	12:00:00	340.00
ACME	12:03:00	340.10
ACME	12:05:00	340.20
ACME	12:05:00	333.80

(4 rows)

Example query showing gaps

A full outer join shows the gaps in the timestamps:

=> SELECT * FROM hTicks h FULL OUTER JOIN aTicks a ON h.time = a.time;

stock	time	price	stock	time	price
HPQ	12:00:00	50.00	ACME	12:00:00	340.00
HPQ	12:01:00	51.00			
HPQ	12:05:00	51.00	ACME	12:05:00	333.80
HPQ	12:05:00	51.00	ACME	12:05:00	340.20
HPQ	12:06:00	52.00			
			ACME	12:03:00	340.10

(6 rows)

Schema of bid and asks tables

The examples that follow use the following hTicks and aTicks tables.

```
CREATE TABLE bid(stock VARCHAR(20), time TIME, price NUMERIC(8,2));
CREATE TABLE ask(stock VARCHAR(20), time TIME, price NUMERIC(8,2));
INSERT INTO bid VALUES ('HPQ', '12:00', 100.10);
INSERT INTO bid VALUES ('HPQ', '12:01', 100.00);
INSERT INTO bid VALUES ('ACME', '12:00', 80.00);
INSERT INTO bid VALUES ('ACME', '12:03', 79.80);
INSERT INTO bid VALUES ('ACME', '12:05', 79.90);
INSERT INTO ask VALUES ('HPQ', '12:01', 101.00);
INSERT INTO ask VALUES ('ACME', '12:00', 80.00);
INSERT INTO ask VALUES ('ACME', '12:02', 75.00);
COMMIT;
```

Output of the two tables:

bid

ask

=> SELECT * FROM bid;

There are no entry records for stocks HPQ and ACME at 12:02 and at 12:04:

stock	time	price
HPQ	12:00:00	100.10
HPQ	12:01:00	100.00
ACME	12:00:00	80.00
ACME	12:03:00	79.80
ACME	12:05:00	79.90

(5 rows)

=> SELECT * FROM ask;

There are no entry records for stock HPQ at 12:00 and none for ACME at 12:01:

stock	time	price
HPQ	12:01:00	101.00
ACME	12:00:00	80.00
ACME	12:02:00	75.00

(3 rows)

Example query showing gaps

A full outer join shows the gaps in the timestamps:

=> SELECT * FROM bid b FULL OUTER JOIN ask a ON b.time = a.time;

stock	time	price	stock	time	price
HPQ	12:00:00	100.10	ACME	12:00:00	80.00
HPQ	12:01:00	100.00	HPQ	12:01:00	101.00
ACME	12:00:00	80.00	ACME	12:00:00	80.00
ACME	12:03:00	79.80			
ACME	12:05:00	79.90			
			ACME	12:02:00	75.00

(6 rows)

Writing event series joins

The examples in this topic contains mismatches between timestamps—just as you'd find in real life situations; for example, there could be a period of inactivity on stocks where no trade occurs, which can present challenges when you want to compare two stocks whose timestamps don't match.

The hTicks and aTicks tables

As described in the [example ticks schema](#), tables, hTicks is missing input rows for 12:02, 12:03, and 12:04, and aTicks is missing inputs at 12:01, 12:02, and 12:04.

hTicks

=> SELECT * FROM hTicks;

stock	time	price
HPQ	12:00:00	50.00
HPQ	12:01:00	51.00
HPQ	12:05:00	51.00
HPQ	12:06:00	52.00

(4 rows)

aTicks

=> SELECT * FROM aTicks;

stock	time	price
ACME	12:00:00	340.00
ACME	12:03:00	340.10
ACME	12:05:00	340.20
ACME	12:05:00	333.80

(4 rows)

Querying event series data with full outer joins

Using a traditional full outer join, this query finds a match between tables hTicks and aTicks at 12:00 and 12:05 and pads the missing data points with NULL values.

```
=> SELECT * FROM hTicks h FULL OUTER JOIN aTicks a ON (h.time = a.time);
```

stock	time	price	stock	time	price
HPQ	12:00:00	50.00	ACME	12:00:00	340.00
HPQ	12:01:00	51.00			
HPQ	12:05:00	51.00	ACME	12:05:00	333.80
HPQ	12:05:00	51.00	ACME	12:05:00	340.20
HPQ	12:06:00	52.00			
			ACME	12:03:00	340.10

(6 rows)

To replace the gaps with interpolated values for those missing data points, use the [INTERPOLATE](#) predicate to create an [event series](#) join. The join condition is restricted to the ON clause, which evaluates the equality predicate on the timestamp columns from the two input tables. In other words, for each row in outer table hTicks, the ON clause predicates are evaluated for each combination of each row in the inner table aTicks.

Simply rewrite the full outer join query to use the INTERPOLATE predicate with either the required PREVIOUS VALUE or NEXT VALUE keywords. Note that a full outer join on event series data is the most common scenario for event series data, where you keep all rows from both tables.

```
=> SELECT * FROM hTicks h FULL OUTER JOIN aTicks a
  ON (h.time INTERPOLATE PREVIOUS VALUE a.time);
```

Vertica interpolates the missing values (which appear as NULL in the full outer join) using that table's previous or next value, whichever is specified. This example shows INTERPOLATE PREVIOUS. Notice how in the second row, blank cells have been filled using values interpolated from the previous row:

```
=> SELECT * FROM hTicks h FULL OUTER JOIN aTicks a ON (h.time = a.time);
```

stock	time	price	stock	time	price
HPQ	12:00:00	50.00	ACME	12:00:00	340.00
HPQ	12:01:00	51.00	ACME	12:00:00	340.00
HPQ	12:01:00	51.00	ACME	12:03:00	340.10
HPQ	12:05:00	51.00	ACME	12:05:00	333.80
HPQ	12:05:00	52.00	ACME	12:05:00	340.20
HPQ	12:06:00	52.00	ACME	12:05:00	340.20

(6 rows)

Note

The output ordering above is different from the regular full outer join because in the event series join, interpolation occurs independently for each stock (hTicks and aTicks), where the data is partitioned and sorted based on the equality predicate. This means that interpolation occurs within, not across, partitions.

If you review the regular full outer join output, you can see that both tables have a match in the time column at 12:00 and 12:05, but at 12:01, there is no entry record for ACME. So the operation interpolates a value for ACME (**ACME,12:00,340**) based on the previous value in the aTicks table.

Querying event series data with left outer joins

You can also use left and right outer joins. You might, for example, decide you want to preserve only hTicks values. So you'd write a left outer join:

```
=> SELECT * FROM hTicks h LEFT OUTER JOIN aTicks a
  ON (h.time INTERPOLATE PREVIOUS VALUE a.time);
```

stock	time	price	stock	time	price
HPQ	12:00:00	50.00	ACME	12:00:00	340.00
HPQ	12:01:00	51.00	ACME	12:00:00	340.00
HPQ	12:05:00	51.00	ACME	12:05:00	333.80
HPQ	12:05:00	51.00	ACME	12:05:00	340.20
HPQ	12:06:00	52.00	ACME	12:05:00	340.20

(5 rows)

Here's what the same data looks like using a traditional left outer join:

```
=> SELECT * FROM hTicks h LEFT OUTER JOIN aTicks a ON h.time = a.time;
stock | time | price | stock | time | price
-----+-----+-----+-----+-----+-----
HPQ | 12:00:00 | 50.00 | ACME | 12:00:00 | 340.00
HPQ | 12:01:00 | 51.00 | | | 
HPQ | 12:05:00 | 51.00 | ACME | 12:05:00 | 333.80
HPQ | 12:05:00 | 51.00 | ACME | 12:05:00 | 340.20
HPQ | 12:06:00 | 52.00 | | | 
(5 rows)
```

Note that a right outer join has the same behavior with the preserved table reversed.

Querying event series data with inner joins

Note that INNER event series joins behave the same way as normal ANSI SQL-99 joins, where all gaps are omitted. Thus, there is nothing to interpolate, and the following two queries are equivalent and return the same result set:

A regular inner join:

```
=> SELECT * FROM HTicks h JOIN aTicks a
  ON (h.time INTERPOLATE PREVIOUS VALUE a.time);
stock | time | price | stock | time | price
-----+-----+-----+-----+-----+-----
HPQ | 12:00:00 | 50.00 | ACME | 12:00:00 | 340.00
HPQ | 12:05:00 | 51.00 | ACME | 12:05:00 | 333.80
HPQ | 12:05:00 | 51.00 | ACME | 12:05:00 | 340.20
(3 rows)
```

An event series inner join:

```
=> SELECT * FROM hTicks h INNER JOIN aTicks a ON (h.time = a.time);
stock | time | price | stock | time | price
-----+-----+-----+-----+-----+-----
HPQ | 12:00:00 | 50.00 | ACME | 12:00:00 | 340.00
HPQ | 12:05:00 | 51.00 | ACME | 12:05:00 | 333.80
HPQ | 12:05:00 | 51.00 | ACME | 12:05:00 | 340.20
(3 rows)
```

The bid and ask tables

Using the [example schema](#) for the `bid` and `ask` tables, write a full outer join to interpolate the missing data points:

```
=> SELECT * FROM bid b FULL OUTER JOIN ask a
  ON (b.stock = a.stock AND b.time INTERPOLATE PREVIOUS VALUE a.time);
```

In the below output, the first row for stock HPQ shows nulls because there is no entry record for HPQ before 12:01.

```
stock | time | price | stock | time | price
-----+-----+-----+-----+-----+-----
ACME | 12:00:00 | 80.00 | ACME | 12:00:00 | 80.00
ACME | 12:00:00 | 80.00 | ACME | 12:02:00 | 75.00
ACME | 12:03:00 | 79.80 | ACME | 12:02:00 | 75.00
ACME | 12:05:00 | 79.90 | ACME | 12:02:00 | 75.00
HPQ | 12:00:00 | 100.10 | | | 
HPQ | 12:01:00 | 100.00 | HPQ | 12:01:00 | 101.00
(6 rows)
```

Note also that the same row (`ACME,12:02,75`) from the `ask` table appears three times. The first appearance is because no matching rows are present in the `bid` table for the row in `ask` , so Vertica interpolates the missing value using the ACME value at 12:02 (75.00). The second appearance occurs because the row in `bid` (`ACME,12:05,79.9`) has no matches in `ask` . The row from `ask` that contains (`ACME,12:02,75`) is the closest row; thus, it is used to interpolate the values.

If you write a regular full outer join, you can see where the mismatched timestamps occur:

```
=> SELECT * FROM bid b FULL OUTER JOIN ask a ON (b.time = a.time);
```

stock	time	price	stock	time	price
ACME	12:00:00	80.00	ACME	12:00:00	80.00
ACME	12:03:00	79.80			
ACME	12:05:00	79.90			
HPQ	12:00:00	100.10	ACME	12:00:00	80.00
HPQ	12:01:00	100.00	HPQ	12:01:00	101.00
			ACME	12:02:00	75.00

(6 rows)

Query optimization

When you submit a query to Vertica for processing, the Vertica query optimizer automatically chooses a set of operations to compute the requested result. These operations together are called a *query plan*. The choice of operations can significantly affect how many resources are needed to compute query results, and overall run-time performance. Optimal performance depends in great part on the projections that are available for a given query.

This section describes the different operations that the optimizer uses and how you can facilitate optimizer performance.

Note

Database response time depends on many factors. These include type and size of the application query, database design, data size and data types stored, available computational power, and network bandwidth. Adding nodes to a database cluster does not necessarily improve the system response time for every query, especially if response times are already short, or are not hardware bound.

In this section

- [Initial process for improving query performance](#)
- [Column encoding](#)
- [Projections for queries with predicates](#)
- [GROUP BY queries](#)
- [DISTINCT in a SELECT query list](#)

- [Data collector table queries](#)

Initial process for improving query performance

To optimize query performance, begin by performing the following tasks:

1. [Run Database Designer.](#)
2. [Check query events proactively.](#)
3. [Review the query plan.](#)

Run Database Designer

Database Designer creates a physical schema for your database that provides optimal query performance. The first time you run Database Designer, you should create a comprehensive design that includes relevant sample queries and data on which to base the design. If you develop performance issues later, consider loading additional queries that you run frequently and then rerunning Database Designer to create an incremental design.

When you run Database Designer, choose the option, Update Statistics. The Vertica query optimizer uses statistics about the data to create a query plan. Statistics help the optimizer determine:

- Multiple eligible projections to answer the query
- The best order in which to perform joins
- Data distribution algorithms, such as broadcast and resegmentation

If your statistics become out of date, run the Vertica function [ANALYZE_STATISTICS](#) function to update statistics for a schema, table, or columns. For more information, see [Collecting database statistics](#).

Check query events proactively

The [QUERY_EVENTS](#) system table returns information on query planning, optimization, and execution events.

The [EVENT_TYPE](#) column provides various event types:

- Some event types are [informational](#).
- Others you should [review for possible corrective action](#).
- Several are [most important to address](#).

Review the query plan

A *query plan* is a sequence of step-like [paths](#) that the Vertica query optimizer selects to access or alter information in your Vertica database. There are two ways to get information about the query plan:

- Run the [EXPLAIN](#) command. Each step (path) represents a single operation that the optimizer uses for its execution strategy.
- Query the [QUERY_PLAN_PROFILES](#) system table. This table provides detailed execution status for currently running queries. Output from the [QUERY_PLAN_PROFILES](#) table shows the real-time flow of data and the time and resources consumed for each path in each query plan.

- [QUERY_EVENTS](#)

Column encoding

You can potentially make queries faster by changing column encoding. Encoding reduces the on-disk size of your data so the amount of I/O required for queries is reduced, resulting in faster execution times. Make sure all columns and projections included in the query use the correct data encoding. To do this, take the following steps:

1. Run Database Designer to create an incremental design. Database Designer implements the optimum encoding and projection design.
2. After creating the incremental design, update statistics using the [ANALYZE_STATISTICS](#) function.
3. Run [EXPLAIN](#) with one or more of the queries you submitted to the design to make sure it is using the new projections.

Alternatively, run [DESIGNER_DESIGN_PROJECTION_ENCODINGS](#) to re-evaluate the current encoding and update it if necessary.

In this section

- [Improving column compression](#)
- [Using run length encoding](#)

Improving column compression

If you see slow performance or a large storage footprint with your [FLOAT](#) data, evaluate the data and your business needs to see if it can be contained in a [NUMERIC](#) column with a precision of 18 digits or less. Converting a [FLOAT](#) column to a [NUMERIC](#) column can improve data compression, reduce the on-disk size of your database, and improve performance of queries on that column.

When you define a [NUMERIC](#) data type, you specify the precision and the scale; [NUMERIC](#) data are exact representations of data. [FLOAT](#) data types represent variable precision and approximate values; they take up more space in the database.

Converting [FLOAT](#) columns to [NUMERIC](#) columns is most effective when:

- [NUMERIC](#) precision is 18 digits or less. Performance of [NUMERIC](#) data is fine-tuned for the common case of 18 digits of precision. Vertica recommends converting [FLOAT](#) columns to [NUMERIC](#) columns only if they require precision of 18 digits or less.
- [FLOAT](#) precision is bounded, and the values will all fall within a specified precision for a [NUMERIC](#) column. One example is monetary values like product prices or financial transaction amounts. For example, a column defined as [NUMERIC](#)(11,2) can accommodate prices from 0 to a few million dollars and can store cents, and compresses more efficiently than a [FLOAT](#) column.

If you try to load a value into a [NUMERIC](#) column that exceeds the specified precision, Vertica returns an error and does not load the data. If you assign a value with more decimal digits than the specified scale, the value is rounded to match the specified scale and stored in that column.

[Numeric data types](#)

Using run length encoding

When you run Database Designer, you can choose to optimize for loads, which minimizes database footprint. In this case, Database Designer applies encodings to columns to maximize query performance. [Encoding options](#) include run length encoding (RLE), which replaces sequences (runs) of identical values in a column with a set of pairs, where each pair represents the number of contiguous occurrences for a given value: (*occurrences* , *value*).

RLE is generally applicable to a column with low-cardinality, and where identical values are contiguous—typically, because table data is sorted on that column. For example, a customer profile table typically includes a gender column that contains values of F and M only. Sorting on gender ensures runs of F or M values that can be expressed as a set of two pairs: (*occurrences* , F) and (*occurrences* , M). So, given 8,147 occurrences of F and 7,956 occurrences of M, and a projection that is sorted primarily on gender, Vertica can apply RLE and store these values as a single set of two pairs: (8147, F) and (7956, M). Doing so reduces this projection's footprint and improves query performance.

Projections for queries with predicates

If your query contains one or more predicates, you can modify the projections to improve the query's performance, as described in the following two examples.

Queries that use date ranges

This example shows how to encode data using RLE and change the projection sort order to improve the performance of a query that retrieves all data within a given date range.

Suppose you have a query that looks like this:

```
=> SELECT * FROM trades
WHERE trade_date BETWEEN '2016-11-01' AND '2016-12-01';
```

To optimize this query, determine whether all of the projections can perform the SELECT operation in a timely manner. Run SELECT COUNT(*) statement for each projection, specifying the date range, and note the response time. For example:

```
=> SELECT COUNT(*) FROM [ projection_name ]
WHERE trade_date BETWEEN '2016-11-01' AND '2016-12-01';
```

If one or more of the queries is slow, check the uniqueness of the `trade_date` column and determine if it needs to be in the projection's ORDER BY clause and/or can be encoded using RLE. RLE replaces sequences of the same data values within a column by a pair that represents the value and a count. For best results, order the columns in the projection from lowest cardinality to highest cardinality, and use RLE to encode the data in low-cardinality columns.

Note

For an example of using sorting and RLE, see [Choosing sort order: best practices](#).

If the number of unique columns is unsorted, or if the average number of repeated rows is less than 10, `trade_date` is too close to being unique and cannot be encoded using RLE. In this case, add a new column to minimize the search scope.

The following example adds a new column `trade_year` :

1. Determine if the new column `trade_year` returns a manageable result set. The following query returns the data grouped by `trade_year` :

```
=> SELECT DATE_TRUNC('trade_year', trade_date), COUNT(*)
FROM trades
GROUP BY DATE_TRUNC('trade_year', trade_date);
```

2. Assuming that `trade_year = 2007` is near 8k, add a column for `trade_year` to the `trades` table. The `SELECT` statement then becomes:

```
=> SELECT * FROM trades
WHERE trade_year = 2007
AND trade_date BETWEEN '2016-11-01' AND '2016-12-01';
```

As a result, you have a projection that is sorted on `trade_year` , which can be encoded using RLE.

Queries for tables with a high-cardinality primary key

This example demonstrates how you can modify the projection to improve the performance of queries that select data from a table with a high-cardinality primary key.

Suppose you have the following query:

```
=> SELECT FROM [table]
WHERE pk IN (12345, 12346, 12347,...);
```

Because the primary key is a high-cardinality column, Vertica has to search a large amount of data.

To optimize the schema for this query, create a new column named `buckets` and assign it the value of the primary key divided by 10000. In this example, `buckets=(int) pk/10000`. Use the `buckets` column to limit the search scope as follows:

```
=> SELECT FROM [table]
WHERE buckets IN (1,...)
AND pk IN (12345, 12346, 12347,...);
```

Creating a lower cardinality column and adding it to the query limits the search scope and improves the query performance. In addition, if you create a projection where `buckets` is first in the sort order, the query may run even faster.

GROUP BY queries

The following sections include several examples that show how you can design your projections to optimize the performance of your `GROUP BY` queries.

In this section

- [GROUP BY implementation options](#)
- [Avoiding resegmentation during GROUP BY optimization with projection design](#)

GROUP BY implementation options

Vertica implements a query `GROUP BY` clause with one of these algorithms: `GROUPBY PIPELINED` or `GROUPBY HASH`. Both algorithms return the same results. Performance of both is generally similar for queries that return a small number of distinct groups—typically a thousand per node.

You can use [EXPLAIN](#) to determine which algorithm the query optimizer chooses for a given query. The following conditions generally determine which algorithm is chosen:

- `GROUPBY PIPELINED` requires all `GROUP BY` data to be specified in the projection's `ORDER BY` clause. For details, see [GROUPBY PIPELINED Requirements](#) below. Because `GROUPBY PIPELINED` only needs to retain in memory the current group data, this algorithm generally requires less memory and executes faster than `GROUPBY HASH`. Performance improvements are especially notable for queries that aggregate large numbers of distinct groups.
- `GROUPBY HASH` is used for any query that does not comply with `GROUPBY PIPELINED` sort order requirements. In this case, Vertica must build a hash table on `GROUP BY` columns before it can start grouping the data.

GROUPBY PIPELINED requirements

You can enable use of the `GROUPBY PIPELINED` algorithm by ensuring that the query and one of its projections comply with `GROUPBY PIPELINED` requirements. The following conditions apply to `GROUPBY PIPELINED`. If none of them is true for the query, then Vertica uses `GROUPBY HASH`.

All examples that follow assume this schema:

```
CREATE TABLE sortopt (
  a INT NOT NULL,
  b INT NOT NULL,
  c INT,
  d INT
);
CREATE PROJECTION sortopt_p (
  a_proj,
  b_proj,
  c_proj,
  d_proj )
AS SELECT * FROM sortopt
ORDER BY a,b,c
UNSEGMENTED ALL NODES;
INSERT INTO sortopt VALUES(5,2,13,84);
INSERT INTO sortopt VALUES(14,22,8,115);
INSERT INTO sortopt VALUES(79,9,401,33);
```

Condition 1

All `GROUP BY` columns are also included in the projection `ORDER BY` clause. For example:

GROUP BY columns	GROUPBY algorithm	Reason chosen
------------------	-------------------	---------------

a a,b b,a a,b,c c,a,b	GROUPBY PIPELINED	Columns a , b , and c are included in the projection sort columns.
a,b,c,d	GROUPBY HASH	Column d is not part of the projection sort columns.

Condition 2

If the query's GROUP BY clause has fewer columns than the projection's ORDER BY clause, the GROUP BY columns must:

- Be a subset of ORDER BY columns that are contiguous.
- Include the first ORDER BY column.

For example:

GROUP BY columns	GROUPBY algorithm	Reason chosen
a a,b b,a	GROUPBY PIPELINED	All GROUP BY columns are a subset of contiguous columns in the projection's ORDER BY clause {a,b,c} , and include column a .
a,c	GROUPBY HASH	GROUP BY columns {a,c} are not contiguous in the projection ORDER BY clause {a,b,c} .
b,c	GROUPBY HASH	GROUP BY columns {b,c} do not include the projection's first ORDER BY column a .

Condition 3

If a query's GROUP BY columns do not appear first in the projection's ORDER BY clause, then any early-appearing projection sort columns that are missing in the query's GROUP BY clause must be present as single-column constant equality predicates in the query's WHERE clause.

For example:

Query	GROUPBY algorithm	Reason chosen
SELECT SUM(a) FROM sortopt WHERE a = 10 GROUP BY b	GROUPBY PIPELINED	All columns preceding b in the projection sort order appear as constant equality predicates.
SELECT SUM(a) FROM sortopt WHERE a = 10 GROUP BY a, b	GROUPBY PIPELINED	Grouping column a is redundant but has no effect on algorithm selection.
SELECT SUM(a) FROM sortopt WHERE a = 10 GROUP BY b, c	GROUPBY PIPELINED	All columns preceding b and c in the projection sort order appear as constant equality predicates.
SELECT SUM(a) FROM sortopt WHERE a = 10 GROUP BY c, b	GROUPBY PIPELINED	All columns preceding b and c in the projection sort order appear as constant equality predicates.

<pre>SELECT SUM(a) FROM sortopt WHERE a = 10 GROUP BY c</pre>	GROUPBY HASH	All columns preceding c in the projection sort order do not appear as constant equality predicates.
---	--------------	--

Controlling GROUPBY algorithm choice

It is generally best to allow Vertica to determine which GROUP BY algorithm is best suited for a given query. Occasionally, you might want to use one algorithm over another. In such cases, you can qualify the GROUP BY clause with a [GBYTYPE](#) hint:

```
GROUP BY /*+ GBYTYPE( HASH | PIPE ) */
```

For example, given the following query, the query optimizer uses the GROUPBY PIPELINED algorithm:

```
=> EXPLAIN SELECT SUM(a) FROM sortopt GROUP BY a,b;
-----
QUERY PLAN DESCRIPTION:
-----

EXPLAIN SELECT SUM(a) FROM sortopt GROUP BY a,b;

Access Path:
+-GROUPBY PIPELINED [Cost: 11, Rows: 3 (NO STATISTICS)] (PATH ID: 1)
| Aggregates: sum(sortopt.a)
| Group By: sortopt.a, sortopt.b

...
```

You can use the GBYTYPE hint to force the query optimizer to use the GROUPBY HASH algorithm instead:

```
=> EXPLAIN SELECT SUM(a) FROM sortopt GROUP BY /*+GBYTYPE(HASH) */ a,b;
-----
QUERY PLAN DESCRIPTION:
-----

EXPLAIN SELECT SUM(a) FROM sortopt GROUP BY /*+GBYTYPE(HASH) */ a,b;

Access Path:
+-GROUPBY HASH (LOCAL RESEGMENT GROUPS) [Cost: 11, Rows: 3 (NO STATISTICS)] (PATH ID: 1)
| Aggregates: sum(sortopt.a)
| Group By: sortopt.a, sortopt.b

...
```

The GBYTYPE hint can specify a PIPE (GROUPBY PIPELINED algorithm) argument only if the query and one of its projections comply with GROUPBY PIPELINED [requirements](#). Otherwise, Vertica issues a warning and uses GROUPBY HASH.

For example, the following query cannot use the GROUPBY PIPELINED algorithm, as the GROUP BY columns {**b,c** } do not include the projection's first ORDER BY column **a** :

```
=> SELECT SUM(a) FROM sortopt GROUP BY /*+GBYTYPE(PIPE) */ b,c;
WARNING 7765: Cannot apply Group By Pipe algorithm. Proceeding with Group By Hash and hint will be ignored
SUM
-----
 79
 14
  5
(3 rows)
```

Avoiding resegmentation during GROUP BY optimization with projection design

To compute the correct result of a query that contains a **GROUP BY** clause, Vertica must ensure that all rows with the same value in the **GROUP BY** expressions end up at the same node for final computation. If the projection design already guarantees the data is segmented by the **GROUP BY** columns, no resegmentation is required at run time.

To avoid resegmentation, the **GROUP BY** clause must contain all the segmentation columns of the projection, but it can also contain other columns.

When your query includes a **GROUP BY** clause and joins, if the join depends on the results of the **GROUP BY**, as in the following example, Vertica performs the **GROUP BY** first:

```
=> EXPLAIN SELECT * FROM (SELECT b from foo GROUP BY b) AS F, foo WHERE foo.a = F.b;
Access Path:
+-JOIN MERGEJOIN(inputs presorted) [Cost: 649, Rows: 10K (NO STATISTICS)] (PATH ID: 1)
| Join Cond: (foo.a = F.b)
| Materialize at Output: foo.b
| Execute on: All Nodes
| +- Outer -> STORAGE ACCESS for foo [Cost: 202, Rows: 10K (NO STATISTICS)] (PATH ID: 2)
| | Projection: public.foo_super
| | Materialize: foo.a
| | Execute on: All Nodes
| | Runtime Filter: (SIP1(MergeJoin): foo.a)
| +- Inner -> SELECT [Cost: 245, Rows: 10K (NO STATISTICS)] (PATH ID: 3)
| | Execute on: All Nodes
| | +---> GROUPBY HASH (SORT OUTPUT) (GLOBAL RESEGMENT GROUPS) (LOCAL RESEGMENT GROUPS) [Cost: 245, Rows: 10K (NO STATISTICS)] (PATH ID: 4)
| | | Group By: foo.b
| | | Execute on: All Nodes
| | | +---> STORAGE ACCESS for foo [Cost: 202, Rows: 10K (NO STATISTICS)] (PATH ID: 5)
| | | | Projection: public.foo_super
| | | | Materialize: foo.b
| | | | Execute on: All Nodes
```

If the result of the join operation is the input to the **GROUP BY** clause, Vertica performs the join first, as in the following example. The segmentation of those intermediate results may not be consistent with the **GROUP BY** clause in your query, resulted in resegmentation at run time.

```
=> EXPLAIN SELECT * FROM foo AS F, foo WHERE foo.a = F.b GROUP BY 1,2,3,4;
Access Path:
+-GROUPBY HASH (LOCAL RESEGMENT GROUPS) [Cost: 869, Rows: 10K (NO STATISTICS)] (PATH ID: 1)
| Group By: F.a, F.b, foo.a, foo.b
| Execute on: All Nodes
| +---> JOIN HASH [Cost: 853, Rows: 10K (NO STATISTICS)] (PATH ID: 2) Outer (RESEGMENT)(LOCAL ROUND ROBIN)
| | Join Cond: (foo.a = F.b)
| | Execute on: All Nodes
| +- Outer -> STORAGE ACCESS for F [Cost: 403, Rows: 10K (NO STATISTICS)] (PUSHED GROUPING) (PATH ID: 3)
| | Projection: public.foo_super
| | Materialize: F.a, F.b
| | Execute on: All Nodes
| +- Inner -> STORAGE ACCESS for foo [Cost: 403, Rows: 10K (NO STATISTICS)] (PATH ID: 4)
| | Projection: public.foo_super
| | Materialize: foo.a, foo.b
| | Execute on: All Nodes
```

If your query does not include joins, the **GROUP BY** clauses are processed using the existing database projections.

Examples

Assume the following projection:

```
CREATE PROJECTION ... SEGMENTED BY HASH(a,b) ALL NODES
```

The following table explains whether or not resegmentation occurs at run time and why.

GROUP BY a

Requires resegmentation at run time. The query does not contain all the projection segmentation columns.

GROUP BY a, b	Does not require resegmentation at run time. The GROUP BY clause contains all the projection segmentation columns.
GROUP BY a, b, c	Does not require resegmentation at run time. The GROUP BY clause contains all the projection segmentation columns.
GROUP BY a+1, b	Requires resegmentation at run time because of the expression on column a .

To determine if resegmentation will occur during your **GROUP BY** query, look at the [EXPLAIN](#)-generated query plan.

For example, the following plan uses **GROUPBY PIPELINED** sort optimization and requires resegmentation to perform the **GROUP BY** calculation:

```
+GROUPBY PIPELINED (RESEGMENT GROUPS) [Cost: 194, Rows: 10K (NO STATISTICS)] (PATH ID: 1)
```

The following plan uses **GROUPBY PIPELINED** sort optimization, but does not require resegmentation:

```
+GROUPBY PIPELINED [Cost: 459, Rows: 10K (NO STATISTICS)] (PATH ID: 1)
```

DISTINCT in a SELECT query list

This section describes how to optimize queries that have the **DISTINCT** keyword in their **SELECT** list. The techniques for optimizing **DISTINCT** queries are similar to the techniques for optimizing **GROUP BY** queries because when processing queries that use **DISTINCT**, the Vertica optimizer rewrites the query as a **GROUP BY** query.

The following sections below this page describe specific situations:

- [Query has no aggregates in SELECT list](#)
- [COUNT \(DISTINCT\) and other DISTINCT aggregates](#)
- [Approximate count distinct functions](#)
- [Single DISTINCT aggregates](#)
- [Multiple DISTINCT aggregates](#)

Examples in these sections use the following table:

```
=> CREATE TABLE table1 (
  a INT,
  b INT,
  c INT
);
```

In this section

- [Query has no aggregates in SELECT list](#)
- [COUNT \(DISTINCT\) and other DISTINCT aggregates](#)
- [Approximate count distinct functions](#)
- [Single DISTINCT aggregates](#)
- [Multiple DISTINCT aggregates](#)

Query has no aggregates in SELECT list

If your query has no aggregates in the **SELECT** list, internally, Vertica treats the query as if it uses **GROUP BY** instead.

For example, you can rewrite the following query:

```
SELECT DISTINCT a, b, c FROM table1;
```

as:

```
SELECT a, b, c FROM table1 GROUP BY a, b, c;
```

For fastest execution, apply the optimization techniques for **GROUP BY** queries described in [GROUP BY queries](#).

COUNT (DISTINCT) and other DISTINCT aggregates

Computing a **DISTINCT** aggregate generally requires more work than other aggregates. Also, a query that uses a single **DISTINCT** aggregate consumes fewer resources than a query with multiple **DISTINCT** aggregates.

Tip

Vertica executes queries with multiple distinct aggregates more efficiently when all distinct aggregate columns have a similar number of distinct values.

Examples

The following query returns the number of distinct values in a column:

```
=> SELECT COUNT (DISTINCT date_key) FROM date_dimension;
```

```
COUNT
-----
1826
(1 row)
```

This example returns the number of distinct return values from an expression:

```
=> SELECT COUNT (DISTINCT date_key + product_key) FROM inventory_fact;
```

```
COUNT
-----
21560
(1 row)
```

You can create an equivalent query using the LIMIT keyword to restrict the number of rows returned:

```
=> SELECT COUNT(date_key + product_key) FROM inventory_fact GROUP BY date_key LIMIT 10;
```

```
COUNT
-----
173
31
321
113
286
84
244
238
145
202
(10 rows)
```

The following query uses GROUP BY to count distinct values within groups:

```
=> SELECT product_key, COUNT (DISTINCT date_key) FROM inventory_fact
GROUP BY product_key LIMIT 10;
```

```
product_key | count
-----+-----
1 | 12
2 | 18
3 | 13
4 | 17
5 | 11
6 | 14
7 | 13
8 | 17
9 | 15
10 | 12
(10 rows)
```

The following query returns the number of distinct products and the total inventory within each date key:

```
=> SELECT date_key, COUNT (DISTINCT product_key), SUM(qty_in_stock) FROM inventory_fact
GROUP BY date_key LIMIT 10;
```

```
date_key | count | sum
```

```
-----+-----+-----
1 | 173 | 88953
2 | 31 | 16315
3 | 318 | 156003
4 | 113 | 53341
5 | 285 | 148380
6 | 84 | 42421
7 | 241 | 119315
8 | 238 | 122380
9 | 142 | 70151
10 | 202 | 95274
```

```
(10 rows)
```

This query selects each distinct `product_key` value and then counts the number of distinct `date_key` values for all records with the specific `product_key` value. It also counts the number of distinct `warehouse_key` values in all records with the specific `product_key` value:

```
=> SELECT product_key, COUNT (DISTINCT date_key), COUNT (DISTINCT warehouse_key) FROM inventory_fact
GROUP BY product_key LIMIT 15;
```

```
product_key | count | count
```

```
-----+-----+-----
1 | 12 | 12
2 | 18 | 18
3 | 13 | 12
4 | 17 | 18
5 | 11 | 9
6 | 14 | 13
7 | 13 | 13
8 | 17 | 15
9 | 15 | 14
10 | 12 | 12
11 | 11 | 11
12 | 13 | 12
13 | 9 | 7
14 | 13 | 13
15 | 18 | 17
```

```
(15 rows)
```

This query selects each distinct `product_key` value, counts the number of distinct `date_key` and `warehouse_key` values for all records with the specific `product_key` value, and then sums all `qty_in_stock` values in records with the specific `product_key` value. It then returns the number of `product_version` values in records with the specific `product_key` value:

```
=> SELECT product_key, COUNT (DISTINCT date_key),
      COUNT (DISTINCT warehouse_key),
      SUM (qty_in_stock),
      COUNT (product_version)
      FROM inventory_fact GROUP BY product_key LIMIT 15;
```

```
product_key | count | count | sum | count
```

```
-----+-----+-----+-----+-----
 1 | 12 | 12 | 5530 | 12
 2 | 18 | 18 | 9605 | 18
 3 | 13 | 12 | 8404 | 13
 4 | 17 | 18 | 10006 | 18
 5 | 11 | 9 | 4794 | 11
 6 | 14 | 13 | 7359 | 14
 7 | 13 | 13 | 7828 | 13
 8 | 17 | 15 | 9074 | 17
 9 | 15 | 14 | 7032 | 15
10 | 12 | 12 | 5359 | 12
11 | 11 | 11 | 6049 | 11
12 | 13 | 12 | 6075 | 13
13 | 9 | 7 | 3470 | 9
14 | 13 | 13 | 5125 | 13
15 | 18 | 17 | 9277 | 18
```

```
(15 rows)
```

Approximate count distinct functions

The aggregate function [COUNT\(DISTINCT\)](#) computes the exact number of distinct values in a data set. COUNT(DISTINCT) performs well when it executes with the [GROUPBY PIPELINED](#) algorithm.

An aggregate [COUNT](#) operation performs well on a data set when the following conditions are true:

- One of the target table's projections has an ORDER BY clause that facilitates sorted aggregation.
- The number of distinct values is fairly small.
- Hashed aggregation is required to execute the query.

Alternatively, consider using the [APPROXIMATE_COUNT_DISTINCT](#) function instead of COUNT(DISTINCT) when the following conditions are true:

- You have a large data set and you do not require an exact count of distinct values.
- The performance of COUNT(DISTINCT) on a given data set is insufficient.
- You calculate several distinct counts in the same query.
- The plan for COUNT(DISTINCT) uses hashed aggregation.

The expected value that APPROXIMATE_COUNT_DISTINCT returns is equal to COUNT(DISTINCT), with an error that is lognormally distributed with standard deviation s . You can control the standard deviation by setting the function's optional error tolerance argument—by default, 1.25 percent.

Other APPROXIMATE_COUNT_DISTINCT functions

Vertica supports two other functions that you can use together, instead of APPROXIMATE_COUNT_DISTINCT:

[APPROXIMATE_COUNT_DISTINCT_SYNOPSIS](#) and [APPROXIMATE_COUNT_DISTINCT_OF_SYNOPSIS](#). Use these functions when the following conditions are true:

- You have a large data set and you don't require an exact count of distinct values.
- The performance of COUNT(DISTINCT) on a given data set is insufficient.
- You want to pre-compute the distinct counts and later combine them in different ways.

Use the two functions together as follows:

1. Pass APPROXIMATE_COUNT_DISTINCT_SYNOPSIS the data set and a normally distributed confidence interval. The function returns a subset of the data, as a binary *synopsis* object*.*
2. Pass the synopsis to the APPROXIMATE_COUNT_DISTINCT_OF_SYNOPSIS function, which then performs an approximate count distinct on the synopsis.

You also use [APPROXIMATE_COUNT_DISTINCT_SYNOPSIS_MERGE](#), which merges multiple synopses into one synopsis. With this function, you can continually update a "master" synopsis by merging in one or more synopses that cover more recent, shorter periods of time.

Example

The following example shows how to use APPROXIMATE_COUNT_DISTINCT functions to keep an approximate running count of users who click on a given web page within a given time span.

1. Create the `pviews` table to store data about website visits—time of visit, web page visited, and visitor:

```
=> CREATE TABLE pviews(  
visit_time TIMESTAMP NOT NULL,  
page_id INTEGER NOT NULL,  
user_id INTEGER NOT NULL)  
ORDER BY page_id, visit_time  
SEGMENTED BY HASH(user_id) ALL NODES KSAFE  
PARTITION BY visit_time::DATE GROUP BY CALENDAR_HIERARCHY_DAY(visit_time::DATE, 2, 2);
```

`pviews` is segmented by hashing `user_id` data, so all visits by a given user are stored on the same segment, on the same node. This prevents inefficient cross-node transfer of data, when later we do a COUNT (DISTINCT user_id).

The table also uses [hierarchical partitioning](#) on time of visit to optimize the ROS storage. Doing so improves performance when filtering data by time.

2. Load data into `pviews` :

```
=> INSERT INTO pviews VALUES
('2022-02-01 10:00:02',1002,1),
('2022-02-01 10:00:03',1002,2),
('2022-02-01 10:00:04',1002,1),
('2022-02-01 10:00:05',1002,3),
('2022-02-01 10:00:06',1000,1),
('2022-02-01 10:00:07',1002,3),
('2022-02-01 10:00:08',1002,1),
('2022-02-01 10:00:09',1002,3),
('2022-02-01 10:00:12',1002,2),
('2022-02-02 10:00:01',1000,1),
('2022-02-02 10:00:02',1002,4),
('2022-02-02 10:00:03',1002,2),
('2022-02-02 10:00:04',1002,1),
('2022-02-02 10:00:05',1002,3),
('2022-02-02 10:00:06',1002,4),
('2022-02-02 10:00:07',1002,3),
('2022-02-02 10:00:08',1002,4),
('2022-02-02 10:00:09',1002,3),
('2022-02-02 10:00:12',1002,2),
('2022-03-02 10:00:01',1000,1),
('2022-03-02 10:00:02',1002,1),
('2022-03-02 10:00:03',1002,2),
('2022-03-02 10:00:04',1002,1),
('2022-03-02 10:00:05',1002,3),
('2022-03-02 10:00:06',1002,4),
('2022-03-02 10:00:07',1002,3),
('2022-03-02 10:00:08',1002,6),
('2022-03-02 10:00:09',1002,5),
('2022-03-02 10:00:12',1002,2),
('2022-03-02 11:00:01',1000,5),
('2022-03-02 11:00:02',1002,6),
('2022-03-02 11:00:03',1002,7),
('2022-03-02 11:00:04',1002,4),
('2022-03-02 11:00:05',1002,1),
('2022-03-02 11:00:06',1002,6),
('2022-03-02 11:00:07',1002,8),
('2022-03-02 11:00:08',1002,6),
('2022-03-02 11:00:09',1002,7),
('2022-03-02 11:00:12',1002,1),
('2022-03-03 10:00:01',1000,1),
('2022-03-03 10:00:02',1002,2),
('2022-03-03 10:00:03',1002,4),
('2022-03-03 10:00:04',1002,1),
('2022-03-03 10:00:05',1002,2),
('2022-03-03 10:00:06',1002,6),
('2022-03-03 10:00:07',1002,9),
('2022-03-03 10:00:08',1002,10),
('2022-03-03 10:00:09',1002,7),
('2022-03-03 10:00:12',1002,1);
```

OUTPUT

```
-----
 50
(1 row)
```

```
=> COMMIT;
COMMIT
```

3. Create the `pview_summary` table by querying `pviews` with `CREATE TABLE...AS SELECT`. Each row of this table summarizes data selected from `pviews` for a given date:

- `partial_visit_count` stores the number of rows (website visits) in `pviews` with that date.
- `daily_users_acdp` uses `APPROXIMATE_COUNT_DISTINCT_SYNOPSIS` to construct a synopsis that approximates the number of distinct users (`user_id`) who visited that website on that date.

```
=> CREATE TABLE pview_summary AS SELECT
  visit_time::DATE "date",
  COUNT(*) partial_visit_count,
  APPROXIMATE_COUNT_DISTINCT_SYNOPSIS(user_id) AS daily_users_acdp
FROM pviews GROUP BY 1;
CREATE TABLE
=> ALTER TABLE pview_summary ALTER COLUMN "date" SET NOT NULL;
```

4. Update the `pview_summary` table so it is partitioned like `pviews`. The `REORGANIZE` keyword forces immediate repartitioning of the table data:

```
=> ALTER TABLE pview_summary
  PARTITION BY "date"
  GROUP BY CALENDAR_HIERARCHY_DAY("date", 2, 2) REORGANIZE;
vsq!:/home/ale/acd_ex4.sql:93: NOTICE 8364: The new partitioning scheme will produce partitions in 2 physical storage containers per projection
vsq!:/home/ale/acd_ex4.sql:93: NOTICE 4785: Started background repartition table task
ALTER TABLE
```

5. Use `CREATE TABLE..LIKE` to create two ETL tables, `pviews_etl` and `pview_summary_etl` with the same DDL as `pviews` and `pview_summary`, respectively. These tables serve to process incoming data:

```
=> CREATE TABLE pviews_etl LIKE pviews INCLUDING PROJECTIONS;
CREATE TABLE
=> CREATE TABLE pview_summary_etl LIKE pview_summary INCLUDING PROJECTIONS;
CREATE TABLE
```

6. Load new data into `pviews_etl`:

```
=> INSERT INTO pviews_etl VALUES
  ('2022-03-03 11:00:01',1000,8),
  ('2022-03-03 11:00:02',1002,9),
  ('2022-03-03 11:00:03',1002,1),
  ('2022-03-03 11:00:04',1002,11),
  ('2022-03-03 11:00:05',1002,10),
  ('2022-03-03 11:00:06',1002,12),
  ('2022-03-03 11:00:07',1002,3),
  ('2022-03-03 11:00:08',1002,10),
  ('2022-03-03 11:00:09',1002,1),
  ('2022-03-03 11:00:12',1002,1);
OUTPUT
-----
  10
(1 row)

=> COMMIT;
COMMIT
```

7. Summarize the new data in `pview_summary_etl`:

```
=> INSERT INTO pview_summary_etl SELECT
  visit_time::DATE visit_date,
  COUNT(*) partial_visit_count,
  APPROXIMATE_COUNT_DISTINCT_SYNOPSIS(user_id) AS daily_users_acdp
FROM pviews_etl GROUP BY visit_date;
OUTPUT
-----
  1
(1 row)
```

8. Append the `pviews_etl` data to `pviews` with `COPY_PARTITIONS_TO_TABLE`:

```
=> SELECT COPY_PARTITIONS_TO_TABLE('pviews_etl', '01-01-0000'::DATE, '01-01-9999'::DATE, 'pviews');
COPY_PARTITIONS_TO_TABLE
```

1 distinct partition values copied at epoch 1403.

(1 row)

```
=> SELECT COPY_PARTITIONS_TO_TABLE('pview_summary_etl', '01-01-0000'::DATE, '01-01-9999'::DATE, 'pview_summary');
COPY_PARTITIONS_TO_TABLE
```

1 distinct partition values copied at epoch 1404.

(1 row)

9. Create views and distinct (approximate) views by day for all data, including the partition that was just copied from [pviews_etl](#) :

```
=> SELECT
  "date" visit_date,
  SUM(partial_visit_count) visit_count,
  APPROXIMATE_COUNT_DISTINCT_OF_SYNOPSIS(daily_users_acdp) AS daily_users_acd
FROM pview_summary GROUP BY visit_date ORDER BY visit_date;
visit_date | visit_count | daily_users_acd
```

visit_date	visit_count	daily_users_acd
2022-02-01	10	3
2022-02-02	10	4
2022-03-02	20	8
2022-03-03	20	11

(4 rows)

10. Create views and distinct (approximate) views by month:

```
=> SELECT
  DATE_TRUNC('MONTH', "date")::DATE "month",
  SUM(partial_visit_count) visit_count,
  APPROXIMATE_COUNT_DISTINCT_OF_SYNOPSIS(daily_users_acdp) AS monthly_users_acd
FROM pview_summary GROUP BY month ORDER BY month;
month | visit_count | monthly_users_acd
```

month	visit_count	monthly_users_acd
2022-02-01	20	4
2022-03-01	40	12

(2 rows)

11. Merge daily synopses into monthly synopses:

```
=> CREATE TABLE pview_monthly_summary AS SELECT
  DATE_TRUNC('MONTH', "date")::DATE "month",
  SUM(partial_visit_count) partial_visit_count,
  APPROXIMATE_COUNT_DISTINCT_SYNOPSIS_MERGE(daily_users_acdp) AS monthly_users_acdp
FROM pview_summary GROUP BY month ORDER BY month;
CREATE TABLE
```

12. Create views and distinct views by month, generated from the merged synopses:

```
=> SELECT
  month,
  SUM(partial_visit_count) monthly_visit_count,
  APPROXIMATE_COUNT_DISTINCT_OF_SYNOPSIS(monthly_users_acdp) AS monthly_users_acd
FROM pview_monthly_summary GROUP BY month ORDER BY month;
month | monthly_visit_count | monthly_users_acd
```

month	monthly_visit_count	monthly_users_acd
2019-02-01	20	4
2019-03-01	40	12

(2 rows)

13. You can use the monthly summary to produce a yearly summary. This approach is likely to be faster than using a daily summary if a lot of data needs to be processed:

```
=> SELECT
  DATE_TRUNC('YEAR', "month")::DATE "year",
  SUM(partial_visit_count) yearly_visit_count,
  APPROXIMATE_COUNT_DISTINCT_OF_SYNOPSIS(monthly_users_acdp) AS yearly_users_acd
FROM pview_monthly_summary GROUP BY year ORDER BY year;
year | yearly_visit_count | yearly_users_acd
-----+-----+-----
2022-01-01 | 60 | 12
(1 row)
```

14. Drop the ETL tables:

```
=> DROP TABLE IF EXISTS pviews_etl, pview_summary_etl;
DROP TABLE
```

Single DISTINCT aggregates

Vertica computes a **DISTINCT** aggregate by first removing all duplicate values of the aggregate's argument to find the distinct values. Then it computes the aggregate.

For example, you can rewrite the following query:

```
SELECT a, b, COUNT(DISTINCT c) AS dcnt FROM table1 GROUP BY a, b;
```

as:

```
SELECT a, b, COUNT(dcnt) FROM
  (SELECT a, b, c AS dcnt FROM table1 GROUP BY a, b, c)
GROUP BY a, b;
```

For fastest execution, apply the optimization techniques for GROUP BY queries.

Multiple DISTINCT aggregates

If your query has multiple **DISTINCT** aggregates, there is no straightforward SQL rewrite that can compute them. The following query cannot easily be rewritten for improved performance:

```
SELECT a, COUNT(DISTINCT b), COUNT(DISTINCT c) AS dcnt FROM table1 GROUP BY a;
```

For a query with multiple **DISTINCT** aggregates, there is no projection design that can avoid using **GROUPBY HASH** and resegmenting the data. To improve performance of this query, make sure that it has large amounts of memory available. For more information about memory allocation for queries, see [Resource manager](#).

JOIN queries

In general, you can optimize execution of queries that join multiple tables in several ways:

- [Create projections for the joined tables that are sorted on join predicate columns](#). This facilitates use of the merge join algorithm, which generally joins tables more efficiently than the hash join algorithm.
- [Create projections that are identically segmented on the join keys](#).

Other best practices

Vertica also executes joins more efficiently if the following conditions are true:

- Query construction enables the query optimizer to create a plan where the larger table is defined as the outer input.
- The columns on each side of the equality predicate are from the same table. For example in the following query, the left and right sides of the equality predicate include only columns from tables T and X, respectively:

```
=> SELECT * FROM T JOIN X ON T.a + T.b = X.x1 - X.x2;
```

Conversely, the following query incurs more work to process, because the right side of the predicate includes columns from both tables T and X:

```
=> SELECT * FROM T JOIN X WHERE T.a = X.x1 + T.b
```

In this section

- [Hash joins versus merge joins](#)
- [Identical segmentation](#)
- [Joining variable length string data](#)

Hash joins versus merge joins

The Vertica optimizer implements a join with one of the following algorithms:

- **Merge join** is used when projections of the joined tables are sorted on the join columns. Merge joins are faster and uses less memory than hash joins.
- **Hash join** is used when projections of the joined tables are not already sorted on the join columns. In this case, the optimizer builds an in-memory hash table on the inner table's join column. The optimizer then scans the outer table for matches to the hash table, and joins data from the two tables accordingly. The cost of performing a hash join is low if the entire hash table can fit in memory. Cost rises significantly if the hash table must be written to disk.

The optimizer automatically chooses the most appropriate algorithm to execute a query, given the projections that are available.

Facilitating merge joins

To facilitate a merge join, create projections for the joined tables that are sorted on the join predicate columns. The join predicate columns should be the first columns in the **ORDER BY** clause.

For example, tables **first** and **second** are defined as follows, with projections **first_p1** and **second_p1**, respectively. The projections are sorted on **data_first** and **data_second**:

```
CREATE TABLE first ( id INT, data_first INT );
CREATE PROJECTION first_p1 AS SELECT * FROM first ORDER BY data_first;

CREATE TABLE second ( id INT, data_second INT );
CREATE PROJECTION second_p1 AS SELECT * FROM second ORDER BY data_second;
```

When you join these tables on unsorted columns **first.id** and **second.id**, Vertica uses the hash join algorithm:

```
EXPLAIN SELECT first.data_first, second.data_second FROM first JOIN second ON first.id = second.id;
```

Access Path:

```
+--JOIN HASH [Cost: 752, Rows: 300K] (PATH ID: 1) Inner (BROADCAST)
```

You can facilitate execution of this query with the merge join algorithm by creating projections **first_p2** and **second_p2**, which are sorted on join columns **first_p2.id** and **second_p2.id**, respectively:

```
CREATE PROJECTION first_p2 AS SELECT id, data_first FROM first ORDER BY id SEGMENTED BY hash(id, data_first) ALL NODES;
CREATE PROJECTION second_p2 AS SELECT id, data_second FROM second ORDER BY id SEGMENTED BY hash(id, data_second) ALL NODES;
```

If the query joins significant amounts of data, the query optimizer uses the merge algorithm:

```
EXPLAIN SELECT first.data_first, second.data_second FROM first JOIN second ON first.id = second.id;
```

Access Path:

```
+--JOIN MERGEJOIN(inputs presorted) [Cost: 731, Rows: 300K] (PATH ID: 1) Inner (BROADCAST)
```

You can also facilitate a merge join by using subqueries to pre-sort the join predicate columns. For example:

```
SELECT first.id, first.data_first, second.data_second FROM
  (SELECT * FROM first ORDER BY id ) first JOIN (SELECT * FROM second ORDER BY id) second ON first.id = second.id;
```

Identical segmentation

To improve query performance when you join multiple tables, create projections that are identically segmented on the join keys. Identically-segmented projections allow the joins to occur locally on each node, thereby helping to reduce data movement across the network during query processing.

To determine if projections are identically-segmented on the query join keys, create a query plan with **EXPLAIN** . If the query plan contains **RESEGMENT** or **BROADCAST** , the projections are not identically segmented.

The Vertica optimizer chooses a projection to supply rows for each table in a query. If the projections to be joined are segmented, the optimizer evaluates their segmentation against the query join expressions. It thereby determines whether the rows are placed on each node so it can join them without fetching data from another node.

Join conditions for identically segmented projections

A projection **p** is segmented on join columns if all column references in **p**'s segmentation expression are a subset of the columns in the join expression.

The following conditions must be true for two segmented projections **p1** of table **t1** and **p2** of table **t2** to participate in a join of **t1** to **t2** :

- The join condition must have the following form:

```
t1.j1 = t2.j1 AND t1.j2 = t2.j2 AND ... t1.jN = t2.jN
```

- The join columns must share the same base data type. For example:
 - If **t1.j1** is an INTEGER, **t2.j1** can be an INTEGER but it cannot be a FLOAT.
 - If **t1.j1** is a CHAR(10), **t2.j1** can be any CHAR or VARCHAR (for example, CHAR(10), VARCHAR(10), VARCHAR(20)), but **t2.j1** cannot be an INTEGER.
- If **p1** is segmented by an expression on columns { **t1.s1**, **t1.s2**, ... **t1.sN** }, each segmentation column **t1.sX** must be in the join column set { **t1.jX** }.
- If **p2** is segmented by an expression on columns { **t2.s1**, **t2.s2**, ... **t2.sN** }, each segmentation column **t2.sX** must be in the join column set { **t2.jX** }.
- The segmentation expressions of **p1** and **p2** must be structurally equivalent. For example:
 - If **p1** is **SEGMENTED BY hash(t1.x)** and **p2** is **SEGMENTED BY hash(t2.x)** , **p1** and **p2** are identically segmented.
 - If **p1** is **SEGMENTED BY hash(t1.x)** and **p2** is **SEGMENTED BY hash(t2.x + 1)** , **p1** and **p2** are not identically segmented.
- **p1** and **p2** must have the same segment count.
- The assignment of segments to nodes must match. For example, if **p1** and **p2** use an **OFFSET** clause, their offsets must match.
- If Vertica finds projections for **t1** and **t2** that are not identically segmented, the data is redistributed across the network during query run time, as necessary.

Tip

If you create custom designs, try to use segmented projections for joins whenever possible.

Examples

The following statements create two tables and specify to create identical segments:

```
=> CREATE TABLE t1 (id INT, x1 INT, y1 INT) SEGMENTED BY HASH(id, x1) ALL NODES;
=> CREATE TABLE t2 (id INT, x1 INT, y1 INT) SEGMENTED BY HASH(id, x1) ALL NODES;
```

Given this design, the join conditions in the following queries can leverage identical segmentation:

```
=> SELECT * FROM t1 JOIN t2 ON t1.id = t2.id;
=> SELECT * FROM t1 JOIN t2 ON t1.id = t2.id AND t1.x1 = t2.x1;
```

Conversely, the join conditions in the following queries require resegmentation:

```
=> SELECT * FROM t1 JOIN t2 ON t1.x1 = t2.x1;
=> SELECT * FROM t1 JOIN t2 ON t1.id = t2.x1;
```

Joining variable length string data

When you join tables on VARCHAR columns, Vertica calculates how much storage space it requires to buffer join column data. It does so by formatting the column data in one of two ways:

- Uses the join column metadata to size column data to a fixed length and buffer accordingly. For example, given a column that is defined as **VARCHAR(1000)** , Vertica always buffers 1000 characters.
- Uses the actual length of join column data, so buffer size varies for each join. For example, given a join on strings Xi, John, and Amrita, Vertica buffers only as much storage as it needs for each join—in this case, 2, 4, and 6 bytes, respectively.

The second approach can improve join query performance. It can also reduce memory consumption, which helps prevent join spills and minimize how often memory is borrowed from the resource manager. In general, these benefits are especially marked in cases where the defined size of a join column significantly exceeds the average length of its data.

Setting and verifying variable length formatting

You can control how Vertica implements joins at the session or database levels, through configuration parameter [JoinDefaultTupleFormat](#), or for individual queries, through the [JFMT](#) hint. Vertica supports variable length formatting for all joins except [merge](#) and [event series](#) joins.

Use [EXPLAIN VERBOSE](#) to verify whether a given query uses variable character formatting, by checking for these flags:

- JF_EE_VARIABLE_FORMAT
- JF_EE_FIXED_FORMAT

ORDER BY queries

You can improve the performance of queries that contain only **ORDER BY** clauses if the columns in a projection's **ORDER BY** clause are the same as the columns in the query.

If you define the projection sort order in the **CREATE PROJECTION** statement, the Vertica query optimizer does not have to sort projection data before performing certain **ORDER BY** queries.

The following table, `sortopt`, contains the columns `a`, `b`, `c`, and `d`. Projection `sortopt_p` specifies to order on columns `a`, `b`, and `c`.

```
CREATE TABLE sortopt (  
  a INT NOT NULL,  
  b INT NOT NULL,  
  c INT,  
  d INT  
);  
CREATE PROJECTION sortopt_p (  
  a_proj,  
  b_proj,  
  c_proj,  
  d_proj )  
AS SELECT * FROM sortopt  
ORDER BY a,b,c  
UNSEGMENTED ALL NODES;  
INSERT INTO sortopt VALUES(5,2,13,84);  
INSERT INTO sortopt VALUES(14,22,8,115);  
INSERT INTO sortopt VALUES(79,9,401,33);
```

Based on this sort order, if a `SELECT * FROM sortopt` query contains one of the following **ORDER BY** clauses, the query does not have to resort the projection:

- **ORDER BY a**
- **ORDER BY a, b**
- **ORDER BY a, b, c**

For example, Vertica does not have to resort the projection in the following query because the sort order includes columns specified in the **CREATE PROJECTION..ORDER BY a, b, c** clause, which mirrors the query's **ORDER BY a, b, c** clause:

```
=> SELECT * FROM sortopt ORDER BY a, b, c;  
a | b | c | d  
-----+-----+-----+-----  
5 | 2 | 13 | 84  
14 | 22 | 8 | 115  
79 | 9 | 401 | 33  
(3 rows)
```

If you include column `d` in the query, Vertica must re-sort the projection data because column `d` was not defined in the **CREATE PROJECTION..ORDER BY** clause. Therefore, the **ORDER BY d** query won't benefit from any sort optimization.

You cannot specify an ASC or DESC clause in the CREATE PROJECTION statement's ORDER BY clause. Vertica always uses an ascending sort order in physical storage, so if your query specifies descending order for any of its columns, the query still causes Vertica to re-sort the projection data. For example, the following query requires Vertica to sort the results:

```
=> SELECT * FROM sortopt ORDER BY a DESC, b, c;
a | b | c | d
-----+-----+-----+-----
79 | 9 | 401 | 33
14 | 22 | 8 | 115
5 | 2 | 13 | 84
(3 rows)
```

Analytic functions

The following sections describe how to optimize SQL-99 analytic functions that Vertica supports.

In this section

- [Empty OVER clauses](#)
- [NULL sort order](#)
- [Runtime sorting of NULL values in analytic functions](#)

Empty OVER clauses

The **OVER()** clause does not require a windowing clause. If your query uses an analytic function like **SUM(x)** and you specify an empty **OVER()** clause, the analytic function is used as a reporting function, where the entire input is treated as a single partition; the aggregate returns the same aggregated value for each row of the result set. The query executes on a single node, potentially resulting in poor performance.

If you add a **PARTITION BY** clause to the **OVER()** clause, the query executes on multiple nodes, improving its performance.

NULL sort order

By default, projection column values are stored in ascending order, but placement of NULL values depends on a column's data type.

NULL placement differences with ORDER BY clauses

The analytic **OVER()** ([window-order-clause](#)) and the SQL **ORDER BY** clause have slightly different semantics:

OVER(ORDER BY ...)

The analytic window order clause uses the **ASC** or **DESC** sort order to determine **NULLS FIRST** or **NULLS LAST** placement for analytic function results. NULL values are placed as follows:

- **ASC , NULLS LAST** — NULL values appear at the end of the sorted result.
- **DESC , NULLS FIRST** — NULL values appear at the beginning of the sorted result.

(SQL) ORDER BY

The SQL and Vertica **ORDER BY** clauses produce different results. The SQL **ORDER BY** clause specifies only ascending or descending sort order. The Vertica **ORDER BY** clause determines NULL placement based on the column data type:

- NUMERIC, INTEGER, DATE, TIME, TIMESTAMP, and INTERVAL columns: **NULLS FIRST** (NULL values appear at the beginning of a sorted projection.)
- FLOAT, STRING, and BOOLEAN columns: **NULLS LAST** (NULL values appear at the end of a sorted projection.)

NULL sort options

If you do not care about NULL placement in queries that involve analytic computations, or if you know that columns do not contain any NULL values, specify **NULLS AUTO** —irrespective of data type. Vertica chooses the placement that gives the fastest performance, as in the following query.

Otherwise, specify **NULLS FIRST** or **NULLS LAST** .

```
=> SELECT x, RANK() OVER (ORDER BY x NULLS AUTO) FROM t;
```

You can carefully formulate queries so Vertica can avoid sorting the data and increase query performance, as illustrated by the following example. Vertica sorts inputs from table **t** on column **x** , as specified in the **OVER(ORDER BY)** clause, and then evaluates **RANK()** :

```
=> CREATE TABLE t (  
  x FLOAT,  
  y FLOAT );  
=> CREATE PROJECTION t_p (x, y) AS SELECT * FROM t  
  ORDER BY x, y UNSEGMENTED ALL NODES;  
=> SELECT x, RANK() OVER (ORDER BY x) FROM t;
```

In the preceding **SELECT** statement, Vertica eliminates the **ORDER BY** clause and executes the query quickly because column **x** is a **FLOAT** data type. As a result, the projection sort order matches the analytic default ordering (**ASC + NULLS LAST**). Vertica can also avoid having to sort the data when the underlying projection is already sorted.

However, if column **x** is an **INTEGER** data type, Vertica must sort the data because the projection sort order for **INTEGER** data types (**ASC + NULLS FIRST**) does not match the default analytic ordering (**ASC + NULLS LAST**). To help Vertica eliminate the sort, specify the placement of **NULLS** to match the default ordering:

```
=> SELECT x, RANK() OVER (ORDER BY x NULLS FIRST) FROM t;
```

If column **x** is a **STRING**, the following query eliminates the sort:

```
=> SELECT x, RANK() OVER (ORDER BY x NULLS LAST) FROM t;
```

If you omit **NULLS LAST** in the preceding query, Vertica eliminates the sort because **ASC + NULLS LAST** is the default sort specification for both the analytic **ORDER BY** clause and for string-related columns in Vertica.

See also

- [Runtime sorting of NULL values in analytic functions](#)
- [SQL analytics](#)

Runtime sorting of NULL values in analytic functions

By carefully writing queries or creating your design (or both), you can help the Vertica query optimizer skip sorting all columns in a table when performing an analytic function, which can improve query performance.

To minimize Vertica's need to sort projections during query execution, redefine the **employee** table and specify that **NULL** values are not allowed in the sort fields:

```
=> DROP TABLE employee CASCADE;  
=> CREATE TABLE employee  
  (empno INT,  
   deptno INT NOT NULL,  
   sal INT NOT NULL);  
CREATE TABLE  
=> CREATE PROJECTION employee_p AS  
  SELECT * FROM employee  
  ORDER BY deptno, sal;  
CREATE PROJECTION  
=> INSERT INTO employee VALUES(101,10,50000);  
=> INSERT INTO employee VALUES(103,10,43000);  
=> INSERT INTO employee VALUES(104,10,45000);  
=> INSERT INTO employee VALUES(105,20,97000);  
=> INSERT INTO employee VALUES(108,20,33000);  
=> INSERT INTO employee VALUES(109,20,51000);  
=> COMMIT;  
COMMIT
```

```
=> SELECT * FROM employee;
```

```
empno | deptno | sal
```

```
-----+-----+-----  
101 | 10 | 50000  
103 | 10 | 43000  
104 | 10 | 45000  
105 | 20 | 97000  
108 | 20 | 33000  
109 | 20 | 51000
```

(6 rows)

```
=> SELECT deptno, sal, empno, RANK() OVER  
      (PARTITION BY deptno ORDER BY sal)  
FROM employee;
```

```
deptno | sal | empno | ?column?
```

```
-----+-----+-----+-----  
10 | 43000 | 103 | 1  
10 | 45000 | 104 | 2  
10 | 50000 | 101 | 3  
20 | 33000 | 108 | 1  
20 | 51000 | 109 | 2  
20 | 97000 | 105 | 3
```

(6 rows)

Tip

If you do not care about NULL placement in queries that involve analytic computations, or if you know that columns contain no NULL values, specify **NULLS AUTO** in your queries. Vertica attempts to choose the placement that gives the fastest performance. Otherwise, specify **NULLS FIRST** or **NULLS LAST**.

LIMIT queries

A query can include a LIMIT clause to limit its result set in two ways:

- Return a subset of rows from the entire result set.
- Set window partitions on the result set and limit the number of rows in each window.

Limiting the query result set

Queries that use the [LIMIT clause](#) with **ORDER BY** return a specific subset of rows from the queried dataset. Vertica processes these queries efficiently using *Top-K optimization*, which is a database query ranking process. Top-K optimization avoids sorting (and potentially writing to disk) an entire data set to find a small number of rows. This can significantly improve query performance.

For example, the following query returns the first 20 rows of data in table `customer_dimension`, as ordered by `number_of_employees`:

```
=> SELECT store_region, store_city||', '||store_state location, store_name, number_of_employees
       FROM store.store_dimension ORDER BY number_of_employees DESC LIMIT 20;
store_region | location | store_name | number_of_employees
-----+-----+-----+-----
East | Nashville, TN | Store141 | 50
East | Manchester, NH | Store225 | 50
East | Portsmouth, VA | Store169 | 50
SouthWest | Fort Collins, CO | Store116 | 50
SouthWest | Phoenix, AZ | Store232 | 50
South | Savannah, GA | Store201 | 50
South | Carrollton, TX | Store8 | 50
West | Rancho Cucamonga, CA | Store102 | 50
MidWest | Lansing, MI | Store105 | 50
West | Provo, UT | Store73 | 50
East | Washington, DC | Store180 | 49
MidWest | Sioux Falls, SD | Store45 | 49
NorthWest | Seattle, WA | Store241 | 49
SouthWest | Las Vegas, NV | Store104 | 49
West | El Monte, CA | Store100 | 49
SouthWest | Fort Collins, CO | Store20 | 49
East | Lowell, MA | Store57 | 48
SouthWest | Arvada, CO | Store188 | 48
MidWest | Joliet, IL | Store82 | 48
West | Berkeley, CA | Store248 | 48
(20 rows)
```

Important

If a LIMIT clause omits **ORDER BY**, results can be nondeterministic.

Limiting window partitioning results

You can use LIMIT to set window partitioning on query results, and limit the number of rows that are returned in each window:

```
SELECT ... FROM dataset LIMIT num-rows OVER ( PARTITION BY column-expr-x, ORDER BY column-expr-y [ASC | DESC] )
```

where querying *dataset* returns *num-rows* rows in each *column-expr-x* partition with the highest or lowest values of *column-expr-y*.

For example, the following statement queries table `store.store_dimension` and includes a LIMIT clause that specifies window partitioning. In this case, Vertica partitions the result set by `store_region`, where each partition window displays for one region the two stores with the fewest employees:

```
=> SELECT store_region, store_city||', '||store_state location, store_name, number_of_employees FROM store.store_dimension
       LIMIT 2 OVER (PARTITION BY store_region ORDER BY number_of_employees ASC);
store_region | location | store_name | number_of_employees
-----+-----+-----+-----
West | Norwalk, CA | Store43 | 10
West | Lancaster, CA | Store95 | 11
East | Stamford, CT | Store219 | 12
East | New York, NY | Store122 | 12
SouthWest | North Las Vegas, NV | Store170 | 10
SouthWest | Phoenix, AZ | Store228 | 11
NorthWest | Bellevue, WA | Store200 | 19
NorthWest | Portland, OR | Store39 | 22
MidWest | South Bend, IN | Store134 | 10
MidWest | Evansville, IN | Store30 | 11
South | Mesquite, TX | Store124 | 10
South | Beaumont, TX | Store226 | 11
(12 rows)
```

INSERT-SELECT operations

An INSERT-SELECT query selects values from a source and inserts them into a target, as in the following example:

```
=> INSERT /*+direct*/ INTO destination SELECT * FROM source;
```

You can optimize an INSERT-SELECT query by matching sort orders or using identical segmentation.

Matching sort orders

To prevent the INSERT operation from sorting the SELECT output, make sure that the sort order for the SELECT query matches the projection sort order of the target table.

For example, on a single-node database:

```
=> CREATE TABLE source (col1 INT, col2 INT, col3 INT);

=> CREATE PROJECTION source_p (col1, col2, col3)
  AS SELECT col1, col2, col3 FROM source
  ORDER BY col1, col2, col3
  SEGMENTED BY HASH(col3)
  ALL NODES;

=> CREATE TABLE destination (col1 INT, col2 INT, col3 INT);

=> CREATE PROJECTION destination_p (col1, col2, col3)
  AS SELECT col1, col2, col3 FROM destination
  ORDER BY col1, col2, col3
  SEGMENTED BY HASH(col3)
  ALL NODES;
```

The following INSERT operation does not require a sort because the query result has the column order of the projection:

```
=> INSERT /*+direct*/ INTO destination SELECT * FROM source;
```

In the following example, the INSERT operation does require a sort because the column order does not match the projection order:

```
=> INSERT /*+direct*/ INTO destination SELECT col1, col3, col2 FROM source;
```

The following INSERT does not require a sort. The order of the columns does not match, but the explicit ORDER BY clause causes the output to be sorted by **col1**, **col3**, and **col2**:

```
=> INSERT /*+direct*/ INTO destination SELECT col1, col3, col2 FROM source
  GROUP BY col1, col3, col2
  ORDER BY col1, col2, col3 ;
```

Identical segmentation

When selecting from a segmented source table and inserting into a segmented destination table, segment both projections on the same column to avoid resegmenting the data, as in the following example:

```
=> CREATE TABLE source (col1 INT, col2 INT, col3 INT);

=> CREATE PROJECTION source_p (col1, col2, col3) AS
  SELECT col1, col2, col3 FROM source
  SEGMENTED BY HASH(col3) ALL NODES;

=> CREATE TABLE destination (col1 INT, col2 INT, col3 INT);

=> CREATE PROJECTION destination_p (col1, col2, col3) AS
  SELECT col1, col2, col3 FROM destination
  SEGMENTED BY HASH(col3) ALL NODES;

=> INSERT /*+direct*/ INTO destination SELECT * FROM source;
```

DELETE and UPDATE queries

Vertica is optimized for query-intensive workloads, so DELETE and UPDATE queries might not achieve the same level of performance as other queries. DELETE and UPDATE operations must update all projections, so these operations can be no faster than the slowest projection. For details, see [Optimizing DELETE and UPDATE](#).

Data collector table queries

The Vertica Data Collector extends system table functionality by gathering and retaining information about your database cluster. The Data Collector makes this information available in system tables.

Vertica Analytic Database stores Data Collection data in the Data Collector directory under the Vertica or catalog path. Use Data Collector information to query the past state of system tables and extract aggregate information.

In general, queries on Data Collector tables are more efficient when they include only the columns that contain the desired data. Queries are also more efficient when they:

- [Avoid resegmentation](#)
- [Use time predicates](#)

Avoiding resegmentation

You can avoid resegmentation when you join the following DC tables on `session_id` or `transaction_id`, because all data is local:

- `dc_session_starts`
- `dc_session_ends`
- `dc_requests_issued`
- `dc_requests_completed`

Resegmentation is not required when a query includes the `node_name` column. For example:

```
=> SELECT dri.transaction_id, dri.request, drc.processed_row_count
FROM dc_requests_issued dri
JOIN dc_requests_completed drc
USING (node_name, session_id, request_id)
WHERE dri.time between 'April 7,2015'::timestampz and 'April 8,2015'::timestampz
AND drc.time between 'April 7,2015'::timestampz and 'April 8,2015'::timestampz;
```

This query runs efficiently because:

- The [initiator node](#) writes only to `dc_requests_issued` and `dc_requests_completed`.
- Columns `session_id` and `node_name` are correlated.

Using time predicates

Use non-volatile functions and [TIMESTAMP](#) for the time range predicates. Vertica Analytic Database optimizes SQL performance for DC tables that use the time predicate.

Each DC table has a `time` column. Use this column to enter the time range as the query predicate.

For example, this query returns data for dates between September 1 and September 10: `select * from dc_foo where time > 'Sept 1, 2015'::timestampz and time < 'Sept 10 2015':: timestampz`; You can change the minimum and maximum time values to adjust the time for which you want to retrieve data.

You must use non-volatile functions as time predicates. [Volatile functions](#) cause queries to run inefficiently. This example returns all queries that started and ended on April 7, 2015. However, the query runs at less than optimal performance because `trunc` and `timestamp` are volatile:

```
=> SELECT dri.transaction_id, dri.request, drc.processed_row_count
FROM dc_requests_issued dri
LEFT JOIN dc_requests_completed drc
USING (session_id, request_id)
WHERE trunc(dri.time, 'DDD') > 'April 7,2015'::timestamp
AND trunc(drc.time, 'DDD') < 'April 8,2015'::timestamp;
```

Views

A view is a stored query that encapsulates one or more SELECT statements. Views dynamically access and compute data from the database at execution time. A view is read-only, and can reference any combination of tables, temporary tables, and other views.

You can use views to achieve the following goals:

- Hide the complexity of SELECT statements from users for support or security purposes. For example, you can create a view that exposes only the data users need from various tables, while withholding sensitive data from the same tables.

- Encapsulate details about table structures, which might change over time, behind a consistent user interface.

Unlike projections, views are not materialized—that is, they do not store data on disk. Thus, the following restrictions apply:

- Vertica does not need to refresh view data when the underlying table data changes. However, a view does incur overhead to access and compute data.
- Views do not support inserts, deletes, or updates.

In this section

- [Creating views](#)
- [Using views](#)
- [View execution](#)
- [Managing views](#)

Creating views

You can create two types of views:

- [CREATE VIEW](#) creates a view that persists across all sessions until it is explicitly dropped with [DROP VIEW](#)
- [CREATE LOCAL TEMPORARY VIEW](#) creates a view that is accessible only during the current Vertica session, and only to its creator. The view is automatically dropped when the current session ends.

After you create a view, you cannot change its definition. You can replace it with another view of the same name; or you can delete and redefine it.

Permissions

To create a view, a non-superuser must have the following privileges:

Privilege	Objects
CREATE	Schema where the view is created
DROP	The view (only required if you specify an existing view in CREATE OR REPLACE VIEW)
SELECT	Tables and views referenced by the view query
USAGE	All schemas that contain tables and views referenced by the view query

For information about enabling users to access views, see [View Access Permissions](#).

Using views

Views can be used in the **FROM** clause of any SQL query or subquery. At execution, Vertica internally substitutes the name of the view used in the query with the actual query used in the view definition.

CREATE VIEW example

The following [CREATE VIEW](#) statement creates the view `myview`, which sums all individual incomes of customers listed in the `store.store_sales_fact` table, and groups results by state:

```
=> CREATE VIEW myview AS
SELECT SUM(annual_income), customer_state FROM public.customer_dimension
WHERE customer_key IN (SELECT customer_key FROM store.store_sales_fact)
GROUP BY customer_state
ORDER BY customer_state ASC;
```

You can use this view to find all combined salaries greater than \$2 billion:

```
=> SELECT * FROM myview where sum > 2000000000 ORDER BY sum DESC;
SUM | customer_state
-----+-----
29253817091 | CA
14215397659 | TX
5225333668 | MI
4907216137 | CO
4581840709 | IL
3769455689 | CT
3330524215 | FL
3310667307 | IN
2832710696 | TN
2806150503 | PA
2793284639 | MA
2723441590 | AZ
2642551509 | UT
2128169759 | NV
(14 rows)
```

Enabling view access

You can query any view that you create. To enable other non-superusers to access a view, you must:

- Have SELECT...WITH GRANT OPTION privileges on the view's base table
- Grant users USAGE privileges on the view schema
- Grant users SELECT privileges to the view itself

The following example grants `user2` access to view `schema1.view1` :

```
=> GRANT USAGE ON schema schema1 TO user2;
=> GRANT SELECT ON schema1.view1 TO user2;
```

Important

If the view references an external table, you must also grant USAGE privileges to the external table's schema. So, if `schema1.view1` references external table `schema2.extTable1` , you must also grant `user2` USAGE privileges to `schema2` :

```
=> GRANT USAGE on schema schema2 to user2;
```

For more information see [GRANT \(view\)](#).

View execution

When Vertica processes a query that contains a view, it treats the view as a subquery. Vertica executes the query by expanding it to include the query in the view definition. For example, Vertica expands the query on the view `myview` shown in [Using Views](#), to include the query that the view encapsulates, as follows:

```
=> SELECT * FROM
(SELECT SUM(annual_income), customer_state FROM public.customer_dimension
WHERE customer_key IN
(SELECT customer_key FROM store.store_sales_fact)
GROUP BY customer_state
ORDER BY customer_state ASC)
AS ship where sum > 2000000000;
```

View optimization

If you query a view and your query only includes columns from a subset of the tables that are joined in that view, Vertica executes that query by expanding it to include only those tables. This optimization requires one of the following conditions to be true:

- Join columns are foreign and primary keys.
- The join is a left or right outer join on columns with unique values.

View sort order

When processing a query on a view, Vertica considers the **ORDER BY** clause only in the outermost query. If the view definition includes an **ORDER BY** clause, Vertica ignores it. Thus, in order to sort the results returned by a view, you must specify the **ORDER BY** clause in the outermost query:

```
=> SELECT * FROM view-name ORDER BY view-column;
```

Note

One exception applies: Vertica sorts view data when the view includes a **LIMIT** clause. In this case, Vertica must sort the data before it can process the **LIMIT** clause.

For example, the following view definition contains an **ORDER BY** clause inside a **FROM** subquery:

```
=> CREATE VIEW myview AS SELECT SUM(annual_income), customer_state FROM public.customer_dimension
WHERE customer_key IN
(SELECT customer_key FROM store.store_sales_fact)
GROUP BY customer_state
ORDER BY customer_state ASC;
```

When you query the view, Vertica does not sort the data:

```
=> SELECT * FROM myview WHERE SUM > 2000000000;
SUM | customer_state
-----+-----
5225333668 | MI
2832710696 | TN
14215397659 | TX
4907216137 | CO
2793284639 | MA
3769455689 | CT
3310667307 | IN
2723441590 | AZ
2642551509 | UT
3330524215 | FL
2128169759 | NV
29253817091 | CA
4581840709 | IL
2806150503 | PA
(14 rows)
```

To return sorted results, the outer query must include an **ORDER BY** clause:

```
=> SELECT * FROM myview WHERE SUM > 2000000000 ORDER BY customer_state ASC;
SUM | customer_state
-----+-----
2723441590 | AZ
29253817091 | CA
4907216137 | CO
3769455689 | CT
3330524215 | FL
4581840709 | IL
3310667307 | IN
2793284639 | MA
5225333668 | MI
2128169759 | NV
2806150503 | PA
2832710696 | TN
14215397659 | TX
2642551509 | UT
(14 rows)
```

If Vertica does not have to evaluate an expression that would generate a run-time error in order to answer a query, the run-time error might not occur.

For example, the following query returns an error, because `TO_DATE` cannot convert the string `F` to the specified date format:

```
=> SELECT TO_DATE('F','dd mm yyyy') FROM customer_dimension;
ERROR: Invalid input for DD: "F"
```

Now create a view using the same query:

```
=> CREATE VIEW temp AS SELECT TO_DATE('F','dd mm yyyy')
FROM customer_dimension;
CREATE VIEW
```

In many cases, this view generates the same error message. For example:

```
=> SELECT * FROM temp;
ERROR: Invalid input for DD: "F"
```

However, if you query that view with the `COUNT` function, Vertica returns with the desired results:

```
=> SELECT COUNT(*) FROM temp;
COUNT
-----
  100
(1 row)
```

This behavior works as intended. You can create views that contain subqueries, where not every row is intended to pass the predicate.

Managing views

Obtaining view information

You can query system tables [VIEWS](#) and [VIEW_COLUMNS](#) to obtain information about existing views—for example, a view's definition and the attributes of columns that comprise that view. You can also query system table [VIEW_TABLES](#) to examine view-related dependencies—for example, to determine how many views reference a table before you drop it.

Renaming a view

Use [ALTER VIEW](#) to rename a view.

Dropping a view

Use [DROP VIEW](#) to drop a view. Only the specified view is dropped. Vertica does not support `CASCADE` functionality for views, and does not check for dependencies. Dropping a view causes any view that references it to fail.

Disabling and re-enabling views

If you drop a table that is referenced by a view, Vertica does not drop the view. However, attempts to use that view or access information about it from system table [VIEW_COLUMNS](#) return an error that the referenced table does not exist. If you restore that table, Vertica also re-enables usage of the view.

Flattened tables

Highly normalized database design often uses a star or snowflake schema model, comprising multiple large fact tables and many smaller dimension tables. Queries typically involve joins between a large fact table and multiple dimension tables. Depending on the number of tables and quantity of data that are joined, these queries can incur significant overhead.

To avoid this problem, some users create wide tables that combine all fact and dimension table columns that their queries require. These tables can dramatically speed up query execution. However, maintaining redundant sets of normalized and denormalized data has its own administrative costs.

Denormalized, or *flattened*, tables, can minimize these problems. Flattened tables can include columns that get their values by querying other tables. Operations on the source tables and flattened table are decoupled; changes in one are not automatically propagated to the other. This minimizes the overhead that is otherwise typical of denormalized tables.

A flattened table defines derived columns with one or both of the following column constraint clauses:

- `DEFAULT query-expression` sets the column value when the column is created with `CREATE TABLE` or `ALTER TABLE...ADD COLUMN`.
- `SET USING query-expression` sets the column value when the function [REFRESH_COLUMNS](#) is invoked.

In both cases, *query-expression* must return only one row and column value, or none. If the query returns no rows, the column value is set to NULL.

Like other tables defined in Vertica, you can add and remove DEFAULT and SET USING columns from a flattened table at any time. Vertica enforces dependencies between a flattened table and the tables that it queries. For details, see [Modifying SET USING and DEFAULT columns](#).

In this section

- [Flattened table example](#)
- [Creating flattened tables](#)
- [Required privileges](#)
- [DEFAULT versus SET USING](#)
- [Modifying SET USING and DEFAULT columns](#)
- [Rewriting SET USING queries](#)
- [Impact of SET USING columns on license limits](#)

Flattened table example

In the following example, columns `orderFact.cust_name` and `orderFact.cust_gender` are defined as SET USING and DEFAULT columns, respectively. Both columns obtain their values by querying table `custDim` :

```
=> CREATE TABLE public.custDim(  
    cid int PRIMARY KEY NOT NULL,  
    name varchar(20),  
    age int,  
    gender varchar(1)  
);  
  
=> CREATE TABLE public.orderFact(  
    order_id int PRIMARY KEY NOT NULL,  
    order_date timestamp DEFAULT CURRENT_TIMESTAMP NOT NULL,  
    cid int REFERENCES public.custDim(cid),  
    cust_name varchar(20) SET USING (SELECT name FROM public.custDim WHERE (custDim.cid = orderFact.cid)),  
    cust_gender varchar(1) DEFAULT (SELECT gender FROM public.custDim WHERE (custDim.cid = orderFact.cid)),  
    amount numeric(12,2)  
)  
PARTITION BY order_date::DATE GROUP BY CALENDAR_HIERARCHY_DAY(order_date::DATE, 2, 2);
```

The following INSERT commands load data into both tables:

```
=> INSERT INTO custDim VALUES(1, 'Alice', 25, 'F');  
=> INSERT INTO custDim VALUES(2, 'Boz', 30, 'M');  
=> INSERT INTO custDim VALUES(3, 'Eva', 32, 'F');  
=>  
=> INSERT INTO orderFact (order_id, cid, amount) VALUES(100, 1, 15);  
=> INSERT INTO orderFact (order_id, cid, amount) VALUES(200, 1, 1000);  
=> INSERT INTO orderFact (order_id, cid, amount) VALUES(300, 2, -50);  
=> INSERT INTO orderFact (order_id, cid, amount) VALUES(400, 3, 100);  
=> INSERT INTO orderFact (order_id, cid, amount) VALUES(500, 2, 200);  
=> COMMIT;
```

When you query the tables, Vertica returns the following result sets:

```
=> SELECT * FROM custDim;
```

```
cid | name | age | gender
```

```
-----+-----+-----+-----  
 1 | Alice | 25 | F  
 2 | Boz  | 30 | M  
 3 | Eva  | 32 | F
```

```
(3 rows)
```

```
=> SELECT order_id, order_date::date, cid, cust_name, cust_gender, amount FROM orderFact ORDER BY cid;
```

```
order_id | order_date | cid | cust_name | cust_gender | amount
```

```
-----+-----+-----+-----+-----+-----  
 100 | 2018-12-31 | 1 |      | F      | 15.00  
 200 | 2018-12-31 | 1 |      | F      | 1000.00  
 300 | 2018-12-31 | 2 |      | M      | -50.00  
 500 | 2018-12-31 | 2 |      | M      | 200.00  
 400 | 2018-12-31 | 3 |      | F      | 100.00
```

```
(5 rows)
```

Vertica automatically populates the DEFAULT column `orderFact.cust_gender`, but the SET USING column `orderFact.cust_name` remains NULL. You can automatically populate this column by calling the function [REFRESH_COLUMNS](#) on flattened table `orderFact`. This function invokes the SET USING query for column `orderFact.cust_name` and populates the column from the result set:

```
=> SELECT REFRESH_COLUMNS('orderFact', 'cust_name', 'REBUILD');
```

```
REFRESH_COLUMNS
```

```
refresh_columns completed
```

```
(1 row)
```

```
=> SELECT order_id, order_date::date, cid, cust_name, cust_gender, amount FROM orderFact ORDER BY cid;
```

```
order_id | order_date | cid | cust_name | cust_gender | amount
```

```
-----+-----+-----+-----+-----+-----  
 100 | 2018-12-31 | 1 | Alice | F      | 15.00  
 200 | 2018-12-31 | 1 | Alice | F      | 1000.00  
 300 | 2018-12-31 | 2 | Boz   | M      | -50.00  
 500 | 2018-12-31 | 2 | Boz   | M      | 200.00  
 400 | 2018-12-31 | 3 | Eva   | F      | 100.00
```

```
(5 rows)
```

Creating flattened tables

A flattened table is typically a fact table where one or more columns query other tables for their values, through DEFAULT or SET USING constraints. DEFAULT and SET USING constraints can be used for columns of all data types. Like other columns, you can set these constraints when you create the flattened table, or any time thereafter by modifying the table DDL:

- [CREATE TABLE ...](#) (*column-name data-type* { DEFAULT | SET USING } *expression*)
- [ALTER TABLE...ADD COLUMN](#) *column-name* { DEFAULT | SET USING } *expression*
- [ALTER TABLE...ALTER COLUMN](#) *column-name* { SET DEFAULT | SET USING } *expression*

In all cases, the expressions that you set for these constraints are stored in the system table [COLUMNS](#), in columns COLUMN_DEFAULT and COLUMN_SET_USING.

Supported expressions

DEFAULT and SET USING generally support the same expressions. These include:

- Queries
- Other columns in the same table
- [Literals](#) (constants)
- All [operators](#) supported by Vertica
- The following categories of functions:
 - [Null-handling](#)
 - [User-defined scalar](#)

- [System information](#)
- [String](#)
- [Mathematical](#)
- [Formatting](#)

For more information about DEFAULT and SET USING expressions, including restrictions, see [Defining column values](#).

Required privileges

The following operations on flattened table require privileges as shown:

Operation	Object	Privileges
Retrieve data from a flattened table.	Schema	USAGE
	Flattened table	SELECT
Add SET USING or DEFAULT columns to a table.	Schemas (queried/flattened tables)	USAGE
	Queried tables	SELECT
	Target table	CREATE
INSERT data on a flattened table with SET USING and/or DEFAULT columns.	Schemas (queried/flattened tables)	USAGE
	Queried tables	SELECT
	Flattened table	INSERT
Run REFRESH_COLUMNS on a flattened table.	Schemas (queried/flattened tables)	USAGE
	Queried tables	SELECT
	Flattened table	SELECT, UPDATE

DEFAULT versus SET USING

Columns in a flattened table can query other tables with constraints DEFAULT and SET USING. In both cases, changes in the queried tables are not automatically propagated to the flattened table. The two constraints differ as follows:

DEFAULT columns

Vertica typically executes DEFAULT queries on new rows when they are added to the flattened table, through load operations such as INSERT and COPY, or when you create or alter a table with a new column that specifies a DEFAULT expression. In all cases, values in existing rows, including other columns with DEFAULT expressions, remain unchanged.

To refresh a column's default values, you must explicitly call [UPDATE](#) on that column as follows:

```
=> UPDATE table-name SET column-name=DEFAULT;
```

SET USING columns

Vertica executes SET USING queries only when you invoke the function [REFRESH_COLUMNS](#). Load operations set SET USING columns in new rows to NULL. After the load, you must call REFRESH_COLUMNS to populate these columns from the queried tables. This can be useful in two ways: you can defer the overhead of updating the flattened table to any time that is convenient; and you can repeatedly query source tables for new data.

SET USING is especially useful for large flattened tables that reference data from multiple dimension tables. Often, only a small subset of SET USING columns are subject to change, and queries on the flattened table do not always require up-to-the-minute data. Given this scenario, you can refresh table content at regular intervals, or only during off-peak hours. One or both of these strategies can minimize overhead, and facilitate performance when querying large data sets.

You can control the scope of the refresh operation by calling REFRESH_COLUMNS in one of two modes:

- UPDATE : Marks original rows as deleted and replaces them with new rows. In order to save these updates, you must issue a COMMIT statement.
- REBUILD: Replaces all data in the specified columns. The rebuild operation is auto-committed.

If a flattened table is partitioned, you can reduce the overhead of calling `REFRESH_COLUMNS` in `REBUILD` mode by specifying one or more partition keys. Doing so limits the rebuild operation to the specified partitions. For details, see [Partition-based REBUILD Operations](#).

Examples

Note

Examples use the `custDim` and `orderFact` tables described in [Flattened table example](#).

The following `UPDATE` statement updates the `custDim` table:

```
=> UPDATE custDim SET name='Roz', gender='F' WHERE cid=2;
OUTPUT
-----
 1
(1 row)

=> COMMIT;
COMMIT
```

Changes are not propagated to flattened table `orderFact`, which includes `SET USING` and `DEFAULT` columns `cust_name` and `cust_gender`, respectively:

```
=> SELECT * FROM custDim ORDER BY cid;
cid | name | age | gender
-----+-----+-----+-----
 1 | Alice | 25 | F
 2 | Roz  | 30 | F
 3 | Eva  | 32 | F
(3 rows)

=> SELECT order_id, order_date::date, cid, cust_name, cust_gender, amount FROM orderFact ORDER BY cid;
order_id | order_date | cid | cust_name | cust_gender | amount
-----+-----+-----+-----+-----+-----
 100 | 2018-12-31 | 1 | Alice  | F      | 15.00
 200 | 2018-12-31 | 1 | Alice  | F      | 1000.00
 300 | 2018-12-31 | 2 | Boz    | M      | -50.00
 500 | 2018-12-31 | 2 | Boz    | M      | 200.00
 400 | 2018-12-31 | 3 | Eva    | F      | 100.00
(5 rows)
```

The following `INSERT` statement invokes the `cust_gender` column's `DEFAULT` query and sets that column to `F`. The load operation does not invoke the `cust_name` column's `SET USING` query, so `cust_name` is set to null:

```
=> INSERT INTO orderFact(order_id, cid, amount) VALUES(500, 3, 750);
```

```
OUTPUT
```

```
-----  
1  
(1 row)
```

```
=> COMMIT;
```

```
COMMIT
```

```
=> SELECT order_id, order_date::date, cid, cust_name, cust_gender, amount FROM orderFact ORDER BY cid;  
order_id | order_date | cid | cust_name | cust_gender | amount
```

```
-----+-----+-----+-----+-----  
100 | 2018-12-31 | 1 | Alice | F | 15.00  
200 | 2018-12-31 | 1 | Alice | F | 1000.00  
300 | 2018-12-31 | 2 | Boz | M | -50.00  
500 | 2018-12-31 | 2 | Boz | M | 200.00  
400 | 2018-12-31 | 3 | Eva | F | 100.00  
500 | 2018-12-31 | 3 | | F | 750.00
```

```
(6 rows)
```

To update the values in `cust_name` , invoke its SET USING query by calling REFRESH_COLUMNS. REFRESH_COLUMNS executes `cust_name` 's SET USING query: it queries the `name` column in table `custDim` and updates `cust_name` with the following values:

- Sets `cust_name` in the new row to `Eva` .
- Returns updated values for `cid=2` , and changes `Boz` to `Roz` .

```
=> SELECT REFRESH_COLUMNS ('orderFact,');
```

```
REFRESH_COLUMNS
```

```
-----  
refresh_columns completed
```

```
(1 row)
```

```
=> COMMIT;
```

```
COMMIT
```

```
=> SELECT order_id, order_date::date, cid, cust_name, cust_gender, amount FROM orderFact ORDER BY cid;  
order_id | order_date | cid | cust_name | cust_gender | amount
```

```
-----+-----+-----+-----+-----  
100 | 2018-12-31 | 1 | Alice | F | 15.00  
200 | 2018-12-31 | 1 | Alice | F | 1000.00  
300 | 2018-12-31 | 2 | Roz | M | -50.00  
500 | 2018-12-31 | 2 | Roz | M | 200.00  
400 | 2018-12-31 | 3 | Eva | F | 100.00  
500 | 2018-12-31 | 3 | Eva | F | 750.00
```

```
(6 rows)
```

REFRESH_COLUMNS only affects the values in column `cust_name` . Values in column `gender` are unchanged, so settings for rows where `cid=2` (`Roz`) remain set to `M` . To repopulate `orderFact.cust_gender` with default values from `custDim.gender` , call UPDATE on `orderFact` :

```
=> UPDATE orderFact SET cust_gender=DEFAULT WHERE cust_name='Roz';
```

```
OUTPUT
```

```
-----  
  2  
(1 row)
```

```
=> COMMIT;
```

```
COMMIT
```

```
=> SELECT order_id, order_date::date, cid, cust_name, cust_gender, amount FROM orderFact ORDER BY cid;

Modifying SET USING and DEFAULT columns

Note

Examples use the `custDim` and `orderFact` tables described in [Flattened table example](#).

Modifying a SET USING and DEFAULT expression

[ALTER TABLE...ALTER COLUMN](#) can set an existing column to SET USING or DEFAULT, or change the query expression of an existing SET USING or DEFAULT column. In both cases, existing values remain unchanged. Vertica refreshes column values in the following cases:

- DEFAULT column: Refreshed only when you load new rows, or when you invoke UPDATE to set column values to **DEFAULT**.
- SET USING column: Refreshed only when you call [REFRESH_COLUMNS](#) on the table.

For example, you might set an entire column to NULL as follows:

```
=> ALTER TABLE orderFact ALTER COLUMN cust_name SET USING NULL;
```

```
ALTER TABLE
```

```
=> SELECT REFRESH_COLUMNS('orderFact', 'cust_name', 'REBUILD');
```

```
REFRESH_COLUMNS
```

```
-----  
refresh_columns completed
```

```
(1 row)
```

```
=> SELECT order_id, order_date::date, cid, cust_name, cust_gender, amount FROM orderFact ORDER BY cid;
```

```
order_id | order_date | cid | cust_name | cust_gender | amount
```

```
-----+-----+-----+-----+-----  
 100 | 2018-12-31 | 1 | | F | 15.00  
 200 | 2018-12-31 | 1 | | F | 1000.00  
 300 | 2018-12-31 | 2 | | M | -50.00  
 500 | 2018-12-31 | 2 | | M | 200.00  
 400 | 2018-12-31 | 3 | | F | 100.00
```

```
(5 rows)
```

For details, see [Defining column values](#)

Removing SET USING and DEFAULT constraints

You remove a column's **SET USING** or **DEFAULT** constraint with [ALTER TABLE...ALTER COLUMN](#), as follows:

```
ALTER TABLE table-name ALTER COLUMN column-name DROP { SET USING | DEFAULT };
```

Vertica removes the constraint from the specified column, but the column and its data are otherwise unaffected. For example:

```
=> ALTER TABLE orderFact ALTER COLUMN cust_name DROP SET USING;
ALTER TABLE
```

Dropping columns queried by SET USING or DEFAULT

Vertica enforces dependencies between a flattened table and the tables that it queries. Attempts to drop a queried column or its table return an error unless the drop operation also includes the **CASCADE** option. Vertica implements **CASCADE** by removing the SET USING or DEFAULT constraint from the flattened table. The table column and its data are otherwise unaffected.

For example, attempts to drop column **name** in table **custDim** returns a rollback error, as this column is referenced by SET USING column **orderFact.cust_gender** :

```
=> ALTER TABLE custDim DROP COLUMN gender;
ROLLBACK 7301: Cannot drop column "gender" since it is referenced in the default expression of table "public.orderFact", column "cust_gender"
```

To drop this column, use the **CASCADE** option:

```
=> ALTER TABLE custDim DROP COLUMN gender CASCADE;
ALTER TABLE
```

Vertica removes the DEFAULT constraint from **orderFact.cust_gender** as part of the drop operation. However, **cust_gender** retains the data that it previously queried from the dropped column **custDim.gender** :

```
=> SELECT EXPORT_TABLES('', 'orderFact');
          EXPORT_TABLES
-----
CREATE TABLE public.orderFact
(
  order_id int NOT NULL,
  order_date timestamp NOT NULL DEFAULT (now())::timestampz(6),
  cid int,
  cust_name varchar(20),
  cust_gender varchar(1) SET USING NULL,
  amount numeric(12,2),
  CONSTRAINT C_PRIMARY PRIMARY KEY (order_id) DISABLED
)
PARTITION BY ((orderFact.order_date)::date) GROUP BY (CASE WHEN ("datediff"('year', (orderFact.order_date)::date, ((now())::timestampz(6))::date) >=
2) THEN (date_trunc('year', (orderFact.order_date)::date))::date WHEN ("datediff"('month', (orderFact.order_date)::date, ((now())::timestampz(6))::date) >= 2)
THEN (date_trunc('month', (orderFact.order_date)::date))::date ELSE (orderFact.order_date)::date END);
ALTER TABLE public.orderFact ADD CONSTRAINT C_FOREIGN FOREIGN KEY (cid) references public.custDim (cid);

(1 row)

=> SELECT * FROM orderFact;
order_id |   order_date   | cid | cust_name | cust_gender | amount
-----+-----+-----+-----+-----+-----
  400 | 2021-01-05 13:27:56.026115 | 3 |      | F      | 100.00
  300 | 2021-01-05 13:27:56.026115 | 2 |      | F      | -50.00
  200 | 2021-01-05 13:27:56.026115 | 1 |      | F      | 1000.00

(6 rows)
```

Rewriting SET USING queries

When you call **REFRESH_COLUMNS** on a **flattened table**'s **SET USING** (or **DEFAULT USING**) column, it executes the SET USING query by joining the target and source tables. By default, the source table is always the inner table of the join. In most cases, cardinality of the source table is less than the target table, so **REFRESH_COLUMNS** executes the join efficiently.

Occasionally—notably, when you call **REFRESH_COLUMNS** on a partitioned table—the source table can be larger than the target table. In this case, performance of the join operation can be suboptimal.

You can address this issue by enabling configuration parameter [RewriteQueryForLargeDim](#). When enabled (1), Vertica rewrites the query, by reversing the inner and outer join between the target and source tables.

Important
Enable this parameter only if the SET USING source data is in a table that is larger than the target table. If the source data is in a table smaller than the target table, then enabling RewriteQueryForLargeDim can adversely affect refresh performance.

Impact of SET USING columns on license limits

Vertica does not count the data in denormalized columns towards your raw data license limit. SET USING columns obtain their data by querying columns in other tables. Only data from the source tables counts against your raw data license limit.

For a list of SET USING restrictions, see [Defining column values](#).

You can remove a SET USING column so it counts toward your license limit with the following command:

```
=> ALTER TABLE table1 ALTER COLUMN column1 DROP SET USING;
```

SQL analytics

Vertica analytics are SQL functions based on the ANSI 99 standard. These functions handle complex analysis and reporting tasks—for example:

- Rank the longest-standing customers in a particular state.
- Calculate the moving average of retail volume over a specified time.
- Find the highest score among all students in the same grade.
- Compare the current sales bonus that salespersons received against their previous bonus.

Analytic functions return aggregate results but they do not group the result set. They return the group value multiple times, once per record. You can sort group values, or partitions, using a window **ORDER BY** clause, but the order affects only the function result set, not the entire query result set.

For details about supported functions, see [Analytic functions](#).

In this section

- [Invoking analytic functions](#)
- [Analytic functions versus aggregate functions](#)
- [Window partitioning](#)
- [Window ordering](#)
- [Window framing](#)
- [Named windows](#)
- [Analytic query examples](#)
- [Event-based windows](#)
- [Sessionization with event-based windows](#)

Invoking analytic functions

You invoke analytic functions as follows:

```
analytic-function(arguments) OVER(  
  [ window-partition-clause ]  
  [ window-order-clause [ window-frame-clause ] ]  
)
```

An analytic function's **OVER** clause contains up to three sub-clauses, which specify how to partition and sort function input, and how to frame input with respect to the current row. Function input is the result set that the query returns after it evaluates **FROM**, **WHERE**, **GROUP BY**, and **HAVING** clauses.

Note

Each function has its own **OVER** clause requirements. For example, some analytic functions do not support window order and window frame clauses.

For syntax details, see [Analytic functions](#).

Function execution

An analytic function executes as follows:

1. Takes the input rows that the query returns after it performs all joins, and evaluates **FROM** , **WHERE** , **GROUP BY** , and **HAVING** clauses.
2. Groups input rows according to the window partition (**PARTITION BY**) clause. If this clause is omitted, all input rows are treated as a single partition.
3. Sorts rows within each partition according to window order (**ORDER BY**) clause.
4. If the **OVER** clause includes a window order clause, the function checks for a window frame clause and executes it as it processes each input row. If the **OVER** clause omits a window frame clause, the function treats the entire partition as a window frame.

Restrictions

- Analytic functions are allowed only in a query's **SELECT** and **ORDER BY** clauses.
- Analytic functions cannot be nested. For example, the following query throws an error:

```
=> SELECT MEDIAN(RANK() OVER(ORDER BY sal) OVER());
```

Analytic functions versus aggregate functions

Like aggregate functions, analytic functions return aggregate results, but analytics do not group the result set. Instead, they return the group value multiple times with each record, allowing further analysis.

Analytic queries generally run faster and use fewer resources than aggregate queries.

Aggregate functions	Analytic functions
Return a single summary value.	Return the same number of rows as the input.
Define the groups of rows on which they operate through the SQL GROUP BY clause.	Define the groups of rows on which they operate through window partition and window frame clauses.

Examples

The examples below contrast the aggregate function [COUNT](#) with its analytic counterpart [COUNT](#). The examples use the **employees** table as defined below:

```
CREATE TABLE employees(emp_no INT, dept_no INT);
INSERT INTO employees VALUES(1, 10);
INSERT INTO employees VALUES(2, 30);
INSERT INTO employees VALUES(3, 30);
INSERT INTO employees VALUES(4, 10);
INSERT INTO employees VALUES(5, 30);
INSERT INTO employees VALUES(6, 20);
INSERT INTO employees VALUES(7, 20);
INSERT INTO employees VALUES(8, 20);
INSERT INTO employees VALUES(9, 20);
INSERT INTO employees VALUES(10, 20);
INSERT INTO employees VALUES(11, 20);
COMMIT;
```

When you query this table, the following result set returns:

```
=> SELECT * FROM employees ORDER BY emp_no;
```

```
emp_no | dept_no
```

```
+-----+-----+
 1 | 10
 2 | 30
 3 | 30
 4 | 10
 5 | 30
 6 | 20
 7 | 20
 8 | 20
 9 | 20
10 | 20
11 | 20
```

(11 rows)

Below, two queries use the **COUNT** function to count the number of employees in each department. The query on the left uses aggregate function **COUNT**; the query on the right uses analytic function **COUNT**:

Aggregate COUNT

```
=> SELECT dept_no, COUNT(*) AS emp_count
FROM employees
GROUP BY dept_no ORDER BY dept_no;
```

```
dept_no | emp_count
```

```
+-----+-----+
 10 | 2
 20 | 6
 30 | 3
```

(3 rows)

Aggregate function **COUNT** returns one row per department for the number of employees in that department.

Analytics COUNT

```
=> SELECT emp_no, dept_no, COUNT(*) OVER(
PARTITION BY dept_no
ORDER BY emp_no) AS emp_count
FROM employees;
```

```
emp_no | dept_no | emp_count
```

```
+-----+-----+-----+
 1 | 10 | 1
 4 | 10 | 2
-----+-----+-----+
 6 | 20 | 1
 7 | 20 | 2
 8 | 20 | 3
 9 | 20 | 4
10 | 20 | 5
11 | 20 | 6
```

```
+-----+-----+-----+
 2 | 30 | 1
 3 | 30 | 2
 5 | 30 | 3
```

(11 rows)

Within each **dept_no** partition analytic function **COUNT** returns a cumulative count of employees. The count is ordered by **emp_no**, as specified by the **ORDER BY** clause.

See also

- [Analytic query examples](#)

Window partitioning

Optionally specified in a function's **OVER** clause, a partition (**PARTITION BY**) clause groups input rows before the function processes them. Window partitioning using **PARTITION NODES** or **PARTITION BEST** is similar to an aggregate function's **GROUP BY** clause, except it returns exactly one result row per input row. Window partitioning using **PARTITION ROW** allows you to provide single-row partitions of input, allowing you to use window partitioning on 1:N transform functions. If you omit the window partition clause, the function treats all input rows as a single partition.

Specifying window partitioning

You specify window partitioning in the function's **OVER** clause, as follows:

```
{ PARTITION BY expression[,...]
| PARTITION BEST
| PARTITION NODES
| PARTITION ROW
| PARTITION LEFT JOIN }
```

For syntax details, see [Window partition clause](#).

Examples

The examples in this topic use the `allsales` schema defined in [Invoking analytic functions](#).

```
CREATE TABLE allsales(state VARCHAR(20), name VARCHAR(20), sales INT);
INSERT INTO allsales VALUES('MA', 'A', 60);
INSERT INTO allsales VALUES('NY', 'B', 20);
INSERT INTO allsales VALUES('NY', 'C', 15);
INSERT INTO allsales VALUES('MA', 'D', 20);
INSERT INTO allsales VALUES('MA', 'E', 50);
INSERT INTO allsales VALUES('NY', 'F', 40);
INSERT INTO allsales VALUES('MA', 'G', 10);
COMMIT;
```

The following query calculates the median of sales within each state. The analytic function is computed per partition and starts over again at the beginning of the next partition.

```
=> SELECT state, name, sales, MEDIAN(sales)
      OVER (PARTITION BY state) AS median from allsales;
```

The results are grouped into partitions for MA (35) and NY (20) under the median column.

```
state | name | sales | median
-----+-----+-----+-----
NY   | C   | 15   | 20
NY   | B   | 20   | 20
NY   | F   | 40   | 20
-----+-----+-----+-----
MA   | G   | 10   | 35
MA   | D   | 20   | 35
MA   | E   | 50   | 35
MA   | A   | 60   | 35
(7 rows)
```

The following query calculates the median of total sales among states. When you use `OVER()` with no parameters, there is one partition—the entire input:

```
=> SELECT state, sum(sales), median(SUM(sales))
      OVER () AS median FROM allsales GROUP BY state;
state | sum | median
-----+-----+-----
NY   | 75 | 107.5
MA   | 140 | 107.5
(2 rows)
```

Sales larger than median (evaluation order)

Analytic functions are evaluated *after* all other clauses except the query's final SQL `ORDER BY` clause. So a query that asks for all rows with sales larger than the median returns an error because the `WHERE` clause is applied before the analytic function and column `m` does not yet exist:

```
=> SELECT name, sales, MEDIAN(sales) OVER () AS m
      FROM allsales WHERE sales > m;
ERROR 2624: Column "m" does not exist
```

You can work around this by placing in a subquery the predicate `WHERE sales > m` :

```
=> SELECT * FROM
  (SELECT name, sales, MEDIAN(sales) OVER () AS m FROM allsales) sq
  WHERE sales > m;
name | sales | m
-----+-----+----
F   |   40 | 20
E   |   50 | 20
A   |   60 | 20
(3 rows)
```

For more examples, see [Analytic query examples](#).

Window ordering

Window ordering specifies how to sort rows that are supplied to the function. You specify window ordering through an **ORDER BY** clause in the function's **OVER** clause, as shown below. If the **OVER** clause includes a [window partition clause](#), rows are sorted within each partition. A window order clause also creates a default [window frame](#) if none is explicitly specified.

The window order clause only specifies order within a window result set. The query can have its own [ORDER BY](#) clause outside the **OVER** clause. This has precedence over the window order clause and orders the final result set.

Specifying window order

You specify a window frame in the analytic function's **OVER** clause, as shown below:

```
ORDER BY { expression [ ASC | DESC [ NULLS { FIRST | LAST | AUTO } ] ]
}[,...]
```

For syntax details, see [Window order clause](#).

Analytic function usage

Analytic aggregation functions such as [SUM](#) support window order clauses.

Required Usage

The following functions require a window order clause:

- [RANK](#)
- [DENSE_RANK](#)
- [LEAD](#)
- [LAG](#)
- [PERCENT_RANK](#)
- [CUME_DIST](#)
- [NTILE](#)

Invalid Usage

You cannot use a window order clause with the following functions:

- [PERCENTILE_CONT](#)
- [PERCENTILE_DISC](#)
- [MEDIAN](#)

Examples

The examples below use the [allsales](#) table schema:

```
CREATE TABLE allsales(state VARCHAR(20), name VARCHAR(20), sales INT);
INSERT INTO allsales VALUES('MA', 'A', 60);
INSERT INTO allsales VALUES('NY', 'B', 20);
INSERT INTO allsales VALUES('NY', 'C', 15);
INSERT INTO allsales VALUES('MA', 'D', 20);
INSERT INTO allsales VALUES('MA', 'E', 50);
INSERT INTO allsales VALUES('NY', 'F', 40);
INSERT INTO allsales VALUES('MA', 'G', 10);
COMMIT;
```

Example 1

The following query orders sales inside each state partition:

```
=> SELECT state, sales, name, RANK() OVER(
PARTITION BY state ORDER BY sales) AS RANK
FROM allsales;
state | sales | name | RANK
-----+-----+-----+-----
MA | 10 | G | 1
MA | 20 | D | 2
MA | 50 | E | 3
MA | 60 | A | 4
-----+-----+-----+-----
NY | 15 | C | 1
NY | 20 | B | 2
NY | 40 | F | 3
(7 rows)
```

Example 2

The following query's final **ORDER BY** clause sorts results by name:

```
=> SELECT state, sales, name, RANK() OVER(
PARTITION BY state ORDER BY sales) AS RANK
FROM allsales ORDER BY name;
state | sales | name | RANK
-----+-----+-----+-----
MA | 60 | A | 4
NY | 20 | B | 2
NY | 15 | C | 1
MA | 20 | D | 2
MA | 50 | E | 3
NY | 40 | F | 3
MA | 10 | G | 1
(7 rows)
```

Window framing

The window frame of an analytic function comprises a set of rows relative to the row that is currently being evaluated by the function. After the analytic function processes that row and its window frame, Vertica advances the current row and adjusts the frame boundaries accordingly. If the OVER clause also specifies a [partition](#), Vertica also checks that frame boundaries do not cross partition boundaries. This process repeats until the function evaluates the last row of the last partition.

Specifying a window frame

You specify a window frame in the analytic function's OVER clause, as follows:

```
{ ROWS | RANGE } { BETWEEN start-point AND end-point } | start-point
start-point | end-point:
{ UNBOUNDED {PRECEDING | FOLLOWING}
| CURRENT ROW
| constant-value {PRECEDING | FOLLOWING}}
```

start-point and *end-point* specify the window frame's offset from the current row. Keywords [ROWS](#) and [RANGE](#) specify whether the offset is physical or logical. If you specify only a start point, Vertica creates a window from that point to the current row.

For syntax details, see [Window frame clause](#).

Requirements

In order to specify a window frame, the OVER must also specify a [window order](#) (ORDER BY) clause. If the OVER clause includes a window order clause but omits specifying a window frame, the function creates a default frame that extends from the first row in the current partition to the current row. This is equivalent to the following clause:

```
RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW
```

Window aggregate functions

Analytic functions that support window frames are called window aggregates. They return information such as moving averages and cumulative results. To use the following functions as window (analytic) aggregates, instead of basic aggregates, the `OVER` clause must specify a [window order](#) clause and, optionally, a window frame clause. If the `OVER` clause omits specifying a window frame, the function creates a default window frame as described earlier.

The following analytic functions support window frames:

- [AVG](#)
- [COUNT](#)
- [MAX / MIN](#)
- [SUM](#)
- [STDDEV / STDDEV_POP / STDDEV_SAMP](#)
- [VARIANCE / VAR_POP / VAR_SAMP](#)

Note

Functions [FIRST_VALUE](#) and [LAST_VALUE](#) also support window frames, but they are only analytic functions with no aggregate counterpart. [EXPONENTIAL_MOVING_AVERAGE](#), [LAG](#), and [LEAD](#) analytic functions do not support window frames.

A window aggregate with an empty `OVER` clause creates no window frame. The function is used as a reporting function, where all input is treated as a single partition.

In this section

- [Windows with a physical offset \(ROWS\)](#)
- [Windows with a logical offset \(RANGE\)](#)
- [Reporting aggregates](#)

Windows with a physical offset (ROWS)

The keyword `ROWS` in a window frame clause specifies window dimensions as the number of rows relative to the current row. The value can be `INTEGER` data type only.

Note

The value returned by an analytic function with a physical offset is liable to produce nondeterministic results unless the ordering expression results in a unique ordering. To achieve unique ordering, the [window order clause](#) might need to specify multiple columns.

Examples

The examples on this page use the `emp` table schema:

```
CREATE TABLE emp(deptno INT, sal INT, empno INT);
INSERT INTO emp VALUES(10,101,1);
INSERT INTO emp VALUES(10,104,4);
INSERT INTO emp VALUES(20,100,11);
INSERT INTO emp VALUES(20,109,7);
INSERT INTO emp VALUES(20,109,6);
INSERT INTO emp VALUES(20,109,8);
INSERT INTO emp VALUES(20,110,10);
INSERT INTO emp VALUES(20,110,9);
INSERT INTO emp VALUES(30,102,2);
INSERT INTO emp VALUES(30,103,3);
INSERT INTO emp VALUES(30,105,5);
COMMIT;
```

The following query invokes `COUNT` to count the current row and the rows preceding it, up to two rows:

```
SELECT deptno, sal, empno, COUNT(*) OVER
  (PARTITION BY deptno ORDER BY sal ROWS BETWEEN 2 PRECEDING AND CURRENT ROW)
  AS count FROM emp;
```

The **OVER** clause contains three components:

- Window partition clause **PARTITION BY deptno**
- Order by clause **ORDER BY sal**
- Window frame clause **ROWS BETWEEN 2 PRECEDING AND CURRENT ROW** . This clause defines window dimensions as extending from the current row through the two rows that precede it.

The query returns results that are divided into three partitions, indicated below as red lines. Within the second partition (**deptno=20**), **COUNT** processes the window frame clause as follows:

1. Creates the first window (green box). This window comprises a single row, as the current row (blue box) is also the the partition's first row. Thus, the value in the **count** column shows the number of rows in the current window, which is 1:

deptno	sal	empno	count
10	101	1	1
10	104	4	2
20	100	11	1
20	109	7	
20	109	6	
20	109	8	
20	110	10	
20	110	9	
30	102	2	1
30	103	3	2
30	105	5	3

2. After **COUNT** processes the partition's first row, it resets the current row to the partition's second row. The window now spans the current row and the row above it, so **COUNT** returns a value of 2:

deptno	sal	empno	count
10	101	1	1
10	104	4	2
20	100	11	1
20	109	7	2
20	109	6	
20	109	8	
20	110	10	
20	110	9	
30	102	2	1
30	103	3	2
30	105	5	3

3. After **COUNT** processes the partition's second row, it resets the current row to the partition's third row. The window now spans the current row and the two rows above it, so **COUNT** returns a value of 3:

deptno	sal	empno	count
10	101	1	1
10	104	4	2
20	100	11	1
20	109	7	2
20	109	6	3
20	109	8	
20	110	10	
20	110	9	
30	102	2	1
30	103	3	2
30	105	5	3

4. Thereafter, **COUNT** continues to process the remaining partition rows and moves the window accordingly, but the window dimensions (**ROWS BETWEEN 2 PRECEDING AND CURRENT ROW**) remain unchanged as three rows. Accordingly, the value in the **count** column also remains unchanged (3):

deptno	sal	empno	count
10	101	1	1
10	104	4	2
20	100	11	1
20	109	7	2
20	109	6	3
20	109	8	3
20	110	10	1
20	110	9	1
30	102	2	1
30	103	3	2
30	105	5	3

deptno	sal	empno	count
10	101	1	1
10	104	4	2
20	100	11	1
20	109	7	2
20	109	6	3
20	109	8	3
20	110	10	3
20	110	9	1
30	102	2	1
30	103	3	2
30	105	5	3

deptno	sal	empno	count
10	101	1	1
10	104	4	2
20	100	11	1
20	109	7	2
20	109	6	3
20	109	8	3
20	110	10	3
20	110	9	3
30	102	2	1
30	103	3	2
30	105	5	3

Windows with a logical offset (RANGE)

The **RANGE** keyword defines an analytic window frame as a logical offset from the current row.

Note

The value returned by an analytic function with a logical offset is always deterministic.

For each row, an analytic function uses the [window order clause](#) (**ORDER_BY**) column or expression to calculate window frame dimensions as follows:

1. Within the current partition, evaluates the **ORDER_BY** value of the current row against the **ORDER_BY** values of contiguous rows.
2. Determines which of these rows satisfy the specified range requirements relative to the current row.
3. Creates a window frame that includes only those rows.
4. Executes on the current window.

Example

This example uses the table **property_sales**, which contains data about neighborhood home sales:

```
=> SELECT property_key, neighborhood, sell_price FROM property_sales ORDER BY neighborhood, sell_price;
```

```
property_key | neighborhood | sell_price
```

```
+-----+-----+-----+
10918 | Jamaica Plain | 353000
10921 | Jamaica Plain | 450000
10927 | Jamaica Plain | 450000

10939 | West Roxbury | 720000
```

(23 rows)

The analytic function [AVG](#) can obtain the average of proximate selling prices within each neighborhood. The following query calculates for each home the average sale for all other neighborhood homes whose selling price was \$50k higher or lower:

```
=> SELECT property_key, neighborhood, sell_price, AVG(sell_price) OVER(
PARTITION BY neighborhood ORDER BY sell_price
RANGE BETWEEN 50000 PRECEDING and 50000 FOLLOWING)::int AS comp_sales
FROM property_sales ORDER BY neighborhood;
property_key | neighborhood | sell_price | comp_sales
```

```

10935 | West Roxbury | 598000 | 577400
10936 | West Roxbury | 615000 | 595667
10939 | West Roxbury | 720000 | 720000
```

(23 rows)

AVG processes this query as follows:

1. **AVG** evaluates row 1 of the first partition (Jamaica Plain), but finds no sales within \$50k of this row's **sell_price** , (\$353k). **AVG** creates a window that includes this row only, and returns an average of 353k for row 1:

property_key	neighborhood	sell_price	comp_sales
10918	Jamaica Plain	353000	353000
10927	Jamaica Plain	450000	458000
10921	Jamaica Plain	450000	458000
10922	Jamaica Plain	474000	472250

2. **AVG** evaluates row 2 and finds three **sell_price** values within \$50k of the current row. **AVG** creates a window that includes these three rows, and returns an average of 458k for row 2:

property_key	neighborhood	sell_price	comp_sales
10918	Jamaica Plain	353000	353000
10927	Jamaica Plain	450000	458000
10921	Jamaica Plain	450000	458000
10922	Jamaica Plain	474000	472250

3. **AVG** evaluates row 3 and finds the same three **sell_price** values within \$50k of the current row. **AVG** creates a window identical to the one before, and returns the same average of 458k for row 3:

property_key	neighborhood	sell_price	comp_sales
10918	Jamaica Plain	353000	353000
10927	Jamaica Plain	450000	458000
10921	Jamaica Plain	450000	458000
10922	Jamaica Plain	474000	472250

4. **AVG** evaluates row 4 and finds four **sell_price** values within \$50k of the current row. **AVG** expands its window to include rows 2 through 5, and returns an average of \$472.25k for row 4:

property_key	neighborhood	sell_price	comp_sales
10918	Jamaica Plain	353000	353000
10927	Jamaica Plain	450000	458000
10921	Jamaica Plain	450000	458000
10922	Jamaica Plain	474000	472250
10919	Jamaica Plain	515000	494500
10917	Jamaica Plain	675000	691250

5. In similar fashion, **AVG** evaluates the remaining rows in this partition. When the function evaluates the first row of the second partition (Roslindale), it resets the window as follows:

property_key	neighborhood	sell_price	comp_sales
10918	Jamaica Plain	353000	353000
10927	Jamaica Plain	450000	458000
10921	Jamaica Plain	450000	458000
10922	Jamaica Plain	474000	472250
10919	Jamaica Plain	515000	494500
10917	Jamaica Plain	675000	691250
10924	Jamaica Plain	675000	691250
10920	Jamaica Plain	705000	691250
10923	Jamaica Plain	710000	691250
10926	Jamaica Plain	875000	887500
10925	Jamaica Plain	900000	887500
10930	Roslindale	300000	300000
10928	Roslindale	422000	436000

Restrictions

If **RANGE** specifies a constant value, that value's data type and the window's **ORDER BY** data type must be the same. The following exceptions apply:

- **RANGE** can specify **INTERVAL Year to Month** if the window order clause data type is one of following: **TIMESTAMP** , **TIMESTAMP WITH TIMEZONE** , or **DATE** . **TIME** and **TIME WITH TIMEZONE** are not supported.
- **RANGE** can specify **INTERVAL Day to Second** if the window order clause data is one of following: **TIMESTAMP** , **TIMESTAMP WITH TIMEZONE** , **DATE** , **TIME** , or **TIME WITH TIMEZONE** .

The window order clause must specify one of the following data types: **NUMERIC** , **DATE/TIME** , **FLOAT** or **INTEGER** . This requirement is ignored if the window specifies one of following frames:

- **RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW**
- **RANGE BETWEEN CURRENT ROW AND UNBOUNDED FOLLOWING**
- **RANGE BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING**

Reporting aggregates

Some of the analytic functions that take the window-frame-clause are the reporting aggregates. These functions let you compare a partition's aggregate values with detail rows, taking the place of correlated subqueries or joins.

- [AVG\(\)](#)
- [COUNT\(\)](#)
- [MAX\(\)](#) and [MIN\(\)](#)
- [SUM\(\)](#)
- [STDDEV\(\)](#), [STDDEV_POP\(\)](#), and [STDDEV_SAMP\(\)](#)
- [VARIANCE\(\)](#), [VAR_POP\(\)](#), and [VAR_SAMP\(\)](#)

If you use a window aggregate with an empty `OVER()` clause, the analytic function is used as a reporting function, where the entire input is treated as a single partition.

About standard deviation and variance functions

With standard deviation functions, a low standard deviation indicates that the data points tend to be very close to the mean, whereas high standard deviation indicates that the data points are spread out over a large range of values.

Standard deviation is often graphed and a distributed standard deviation creates the classic bell curve.

Variance functions measure how far a set of numbers is spread out.

Examples

Think of the window for reporting aggregates as a window defined as `UNBOUNDED PRECEDING` and `UNBOUNDED FOLLOWING`. The omission of a window-order-clause makes all rows in the partition also the window (reporting aggregates).

```
=> SELECT deptno, sal, empno, COUNT(sal)
      OVER (PARTITION BY deptno) AS COUNT FROM emp;
```

```
deptno | sal | empno | count
```

```
-----+-----+-----+-----
 10 | 101 | 1 | 2
 10 | 104 | 4 | 2
-----+-----+-----+-----
 20 | 110 | 10 | 6
 20 | 110 | 9 | 6
 20 | 109 | 7 | 6
 20 | 109 | 6 | 6
 20 | 109 | 8 | 6
 20 | 100 | 11 | 6
-----+-----+-----+-----
 30 | 105 | 5 | 3
 30 | 103 | 3 | 3
 30 | 102 | 2 | 3
(11 rows)
```

If the `OVER()` clause in the above query contained a [window-order-clause](#) (for example, `ORDER BY sal`), it would become a moving window (window aggregate) query with a default window of `RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW`:

```
=> SELECT deptno, sal, empno, COUNT(sal) OVER (PARTITION BY deptno ORDER BY sal) AS COUNT FROM emp;
```

```
deptno | sal | empno | count
```

deptno	sal	empno	count
10	101	1	1
10	104	4	2
20	100	11	1
20	109	7	4
20	109	6	4
20	109	8	4
20	110	10	6
20	110	9	6
30	102	2	1
30	103	3	2
30	105	5	3

(11 rows)

What about LAST_VALUE?

You might wonder why you couldn't just use the LAST_VALUE() analytic function.

For example, for each employee, get the highest salary in the department:

```
=> SELECT deptno, sal, empno, LAST_VALUE(empno) OVER (PARTITION BY deptno ORDER BY sal) AS lv FROM emp;
```

Due to default window semantics, LAST_VALUE does not always return the last value of a partition. If you omit the window-frame-clause from the analytic clause, LAST_VALUE operates on this default window. Results, therefore, can seem non-intuitive because the function does not return the bottom of the current partition. It returns the bottom of the window, which continues to change along with the current input row being processed.

Remember the default window:

```
OVER (PARTITION BY deptno ORDER BY sal)
```

is the same as:

```
OVER(PARTITION BY deptno ORDER BY sal ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW)
```

deptno	sal	empno	lv

20	109	7	7
20	109	6	6
20	109	8	8
20	110	10	10
20	110	9	9
30	102	2	2
30	103	3	3
30	105	5	5

deptno	sal	empno	lv
10	101	1	1
10	104	4	4
20	100	11	11
20	109	7	7
20	109	6	7
20	109	8	7
20	110	10	10
20	110	9	10
30	102	2	2
30	103	3	3
30	105	5	5

deptno	sal	empno	lv
10	101	1	1
10	104	4	4
20	100	11	11
20	109	7	7
20	109	6	7
20	109	8	7
20	110	10	10
20	110	9	10
30	102	2	2
30	103	3	3
30	105	5	5

If you want to return the last value of a partition, use UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING.

```
=> SELECT deptno, sal, empno, LAST_VALUE(empno)
OVER (PARTITION BY deptno ORDER BY sal
ROWS BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING) AS lv
FROM emp;
```

Vertica recommends that you use LAST_VALUE with the window-order-clause to produce deterministic results.

In the following example, empno 6, 7, and 8 have the same salary, so they are in adjacent rows. empno 8 appears first in this case but the order is not guaranteed.

deptno	sal	empno	lv
10	101	1	4
10	104	4	4
20	100	11	7
20	109	8	7
20	109	6	7
20	109	7	7
30	102	2	5
30	103	3	5
30	105	5	5

Notice in the output above, the last value is 7, which is the last row from the partition deptno = 20. If the rows have a different order, then the function returns a different value:

deptno	sal	empno	lv
10	101	1	4
10	104	4	4
20	100	11	6
20	109	8	6
20	109	7	6
20	109	6	6
30	102	2	5
30	103	3	5
30	105	5	5

Now the last value is 6, which is the last row from the partition deptno = 20. The solution is to add a unique key to the sort order. Even if the order of the query changes, the result will always be the same, and so deterministic.

```
=> SELECT deptno, sal, empno, LAST_VALUE(empno)
OVER (PARTITION BY deptno ORDER BY sal, empno
ROWS BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING) as lv
FROM emp;
```

deptno	sal	empno	lv
10	101	1	4
10	104	4	4
20	100	11	8
20	109	6	8
20	109	7	8
20	109	8	8
30	102	2	5
30	103	3	5
30	105	5	5

Notice how the rows are now ordered by **empno**, the last value stays at 8, and it does not matter the order of the query.

Named windows

An analytic function's **OVER** clause can reference a named window, which encapsulates one or more window clauses: a window partition (**PARTITION BY**) clause and (optionally) a window order (**ORDER BY**) clause. Named windows can be useful when you write queries that invoke multiple analytic functions with similar **OVER** clause syntax—for example, they use the same partition clauses.

A query names a window as follows:

```
WINDOW window-name AS ( window-partition-clause [window-order-clause] );
```

The same query can name and reference multiple windows. All window names must be unique within the same query.

Examples

The following query invokes two analytic functions, **RANK** and **DENSE_RANK**. Because the two functions use the same partition and order clauses, the query names a window **w** that specifies both clauses. The two functions reference this window as follows:

```
=> SELECT employee_region region, employee_key, annual_salary,
       RANK() OVER w Rank,
       DENSE_RANK() OVER w "Dense Rank"
       FROM employee_dimension WINDOW w AS (PARTITION BY employee_region ORDER BY annual_salary);
       region      | employee_key | annual_salary | Rank | Dense Rank
```

region	employee_key	annual_salary	Rank	Dense Rank
West	5248	1200	1	1
West	6880	1204	2	2
West	5700	1214	3	3
West	9857	1218	4	4
West	6014	1218	4	4
West	9221	1220	6	5
West	7646	1222	7	6
West	6621	1222	7	6
West	6488	1224	9	7
West	7659	1226	10	8
West	7432	1226	10	8
West	9905	1226	10	8
West	9021	1228	13	9
West	7855	1228	13	9
West	7119	1230	15	10
...				

If the named window omits an order clause, the query's **OVER** clauses can specify their own order clauses. For example, you can modify the previous query so each function uses a different order clause. The named window is defined so it includes only a partition clause:

```
=> SELECT employee_region region, employee_key, annual_salary,
       RANK() OVER (w ORDER BY annual_salary DESC) Rank,
       DENSE_RANK() OVER (w ORDER BY annual_salary ASC) "Dense Rank"
FROM employee_dimension WINDOW w AS (PARTITION BY employee_region);
       region      | employee_key | annual_salary | Rank | Dense Rank
-----+-----+-----+-----+-----
West              |      5248   |      1200 | 2795 |      1
West              |      6880   |      1204 | 2794 |      2
West              |      5700   |      1214 | 2793 |      3
West              |      6014   |      1218 | 2791 |      4
West              |      9857   |      1218 | 2791 |      4
West              |      9221   |      1220 | 2790 |      5
West              |      6621   |      1222 | 2788 |      6
West              |      7646   |      1222 | 2788 |      6
West              |      6488   |      1224 | 2787 |      7
West              |      7432   |      1226 | 2784 |      8
West              |      9905   |      1226 | 2784 |      8
West              |      7659   |      1226 | 2784 |      8
West              |      7855   |      1228 | 2782 |      9
West              |      9021   |      1228 | 2782 |      9
West              |      7119   |      1230 | 2781 |     10
...
```

Similarly, an **OVER** clause specifies a named window can also specify a [window frame clause](#), provided the named window includes an order clause. This can be useful inasmuch as you cannot define a named windows to include a window frame clause.

For example, the following query defines a window that encapsulates partitioning and order clauses. The **OVER** clause invokes this window and also includes a window frame clause:

```
=> SELECT deptno, sal, empno, COUNT(*) OVER (w ROWS BETWEEN 2 PRECEDING AND CURRENT ROW) AS count
FROM emp WINDOW w AS (PARTITION BY deptno ORDER BY sal);
deptno | sal | empno | count
-----+-----+-----+-----
10 | 101 | 1 | 1
10 | 104 | 4 | 2
20 | 100 | 11 | 1
20 | 109 | 8 | 2
20 | 109 | 6 | 3
20 | 109 | 7 | 3
20 | 110 | 10 | 3
20 | 110 | 9 | 3
30 | 102 | 2 | 1
30 | 103 | 3 | 2
30 | 105 | 5 | 3
(11 rows)
```

Recursive window references

A **WINDOW** clause can reference another window that is already named. For example, because named window **w1** is defined before **w2**, the **WINDOW** clause that defines **w2** can reference **w1**:

```
=> SELECT RANK() OVER(w1 ORDER BY sal DESC), RANK() OVER w2
FROM EMP WINDOW w1 AS (PARTITION BY deptno), w2 AS (w1 ORDER BY sal);
```

Restrictions

- An **OVER** clause can reference only one named window.
- Each **WINDOW** clause within the same query must have a unique name.

Analytic query examples

The topics in this section show how to use analytic queries for calculations.

In this section

- [Calculating a median value](#)
- [Getting price differential for two stocks](#)
- [Calculating the moving average](#)
- [Getting latest bid and ask results](#)

Calculating a median value

A median is a numerical value that separates the higher half of a sample from the lower half. For example, you can retrieve the median of a finite list of numbers by arranging all observations from lowest value to highest value and then picking the middle one.

If the number of observations is even, then there is no single middle value; the median is the mean (average) of the two middle values.

The following example uses this table:

```
CREATE TABLE allsales(state VARCHAR(20), name VARCHAR(20), sales INT);
INSERT INTO allsales VALUES('MA', 'A', 60);
INSERT INTO allsales VALUES('NY', 'B', 20);
INSERT INTO allsales VALUES('NY', 'C', 15);
INSERT INTO allsales VALUES('MA', 'D', 20);
INSERT INTO allsales VALUES('MA', 'E', 50);
INSERT INTO allsales VALUES('NY', 'F', 40);
INSERT INTO allsales VALUES('MA', 'G', 10);
COMMIT;
```

You can use the analytic function [MEDIAN](#) to calculate the median of all sales in this table. In the following query, the function's **OVER** clause is empty, so the query returns the same aggregated value for each row of the result set:

```
=> SELECT name, sales, MEDIAN(sales) OVER() AS median FROM allsales;
name | sales | median
-----+-----+-----
G | 10 | 20
C | 15 | 20
D | 20 | 20
B | 20 | 20
F | 40 | 20
E | 50 | 20
A | 60 | 20
(7 rows)
```

You can modify this query to group sales by state and obtain the median for each one. To do so, include a window partition clause in the **OVER** clause:

```
=> SELECT state, name, sales, MEDIAN(sales) OVER(partition by state) AS median FROM allsales;
state | name | sales | median
-----+-----+-----
MA | G | 10 | 35
MA | D | 20 | 35
MA | E | 50 | 35
MA | A | 60 | 35
NY | C | 15 | 20
NY | B | 20 | 20
NY | F | 40 | 20
(7 rows)
```

Getting price differential for two stocks

The following subquery selects out two stocks of interest. The outer query uses the `LAST_VALUE()` and `OVER()` components of analytics, with `IGNORE NULLS`.

Schema

```
DROP TABLE Ticks CASCADE;
```

```
CREATE TABLE Ticks (ts TIMESTAMP, Stock varchar(10), Bid float);  
INSERT INTO Ticks VALUES('2011-07-12 10:23:54', 'abc', 10.12);  
INSERT INTO Ticks VALUES('2011-07-12 10:23:58', 'abc', 10.34);  
INSERT INTO Ticks VALUES('2011-07-12 10:23:59', 'abc', 10.75);  
INSERT INTO Ticks VALUES('2011-07-12 10:25:15', 'abc', 11.98);  
INSERT INTO Ticks VALUES('2011-07-12 10:25:16', 'abc');  
INSERT INTO Ticks VALUES('2011-07-12 10:25:22', 'xyz', 45.16);  
INSERT INTO Ticks VALUES('2011-07-12 10:25:27', 'xyz', 49.33);  
INSERT INTO Ticks VALUES('2011-07-12 10:31:12', 'xyz', 65.25);  
INSERT INTO Ticks VALUES('2011-07-12 10:31:15', 'xyz');  
  
COMMIT;
```

Ticks table

```
=> SELECT * FROM ticks;
```

ts	stock	bid
2011-07-12 10:23:59	abc	10.75
2011-07-12 10:25:22	xyz	45.16
2011-07-12 10:23:58	abc	10.34
2011-07-12 10:25:27	xyz	49.33
2011-07-12 10:23:54	abc	10.12
2011-07-12 10:31:15	xyz	
2011-07-12 10:25:15	abc	11.98
2011-07-12 10:25:16	abc	
2011-07-12 10:31:12	xyz	65.25

(9 rows)

Query

```
=> SELECT ts, stock, bid, last_value(price1 IGNORE NULLS)  
OVER(ORDER BY ts) - last_value(price2 IGNORE NULLS)  
OVER(ORDER BY ts) as price_diff  
FROM  
(SELECT ts, stock, bid,  
CASE WHEN stock = 'abc' THEN bid ELSE NULL END AS price1,  
CASE WHEN stock = 'xyz' then bid ELSE NULL END AS price2  
FROM ticks  
WHERE stock IN ('abc','xyz')  
) v1  
ORDER BY ts;
```

ts	stock	bid	price_diff
2011-07-12 10:23:54	abc	10.12	
2011-07-12 10:23:58	abc	10.34	
2011-07-12 10:23:59	abc	10.75	
2011-07-12 10:25:15	abc	11.98	
2011-07-12 10:25:16	abc		
2011-07-12 10:25:22	xyz	45.16	-33.18
2011-07-12 10:25:27	xyz	49.33	-37.35
2011-07-12 10:31:12	xyz	65.25	-53.27
2011-07-12 10:31:15	xyz		-53.27

(9 rows)

Calculating the moving average

Calculating the moving average is useful to get an estimate about the trends in a data set. The moving average is the average of any subset of numbers over a period of time. For example, if you have retail data that spans over ten years, you could calculate a three year moving average, a four year moving average, and so on. This example calculates a 40-second moving average of bids for one stock. This examples uses the [ticks](#) table schema.

Query

```
=> SELECT ts, bid, AVG(bid)
      OVER(ORDER BY ts
           RANGE BETWEEN INTERVAL '40 seconds'
           PRECEDING AND CURRENT ROW)
FROM ticks
WHERE stock = 'abc'
GROUP BY bid, ts
ORDER BY ts;
```

ts	bid	?column?
2011-07-12 10:23:54	10.12	10.12
2011-07-12 10:23:58	10.34	10.23
2011-07-12 10:23:59	10.75	10.403333333333333
2011-07-12 10:25:15	11.98	11.98
2011-07-12 10:25:16		11.98

(5 rows)

```
DROP TABLE Ticks CASCADE;
```

```
CREATE TABLE Ticks (ts TIMESTAMP, Stock varchar(10), Bid float);
INSERT INTO Ticks VALUES('2011-07-12 10:23:54', 'abc', 10.12);
INSERT INTO Ticks VALUES('2011-07-12 10:23:58', 'abc', 10.34);
INSERT INTO Ticks VALUES('2011-07-12 10:23:59', 'abc', 10.75);
INSERT INTO Ticks VALUES('2011-07-12 10:25:15', 'abc', 11.98);
INSERT INTO Ticks VALUES('2011-07-12 10:25:16', 'abc');
INSERT INTO Ticks VALUES('2011-07-12 10:25:22', 'xyz', 45.16);
INSERT INTO Ticks VALUES('2011-07-12 10:25:27', 'xyz', 49.33);
INSERT INTO Ticks VALUES('2011-07-12 10:31:12', 'xyz', 65.25);
INSERT INTO Ticks VALUES('2011-07-12 10:31:15', 'xyz');

COMMIT;
```

Getting latest bid and ask results

The following query fills in missing NULL values to create a full book order showing latest bid and ask price and size, by vendor id. Original rows have values for (typically) one price and one size, so use last_value with "ignore nulls" to find the most recent non-null value for the other pair each time there is an entry for the ID. Sequenceno provides a unique total ordering.

Schema:

```
=> CREATE TABLE bookorders(
  vendorid VARCHAR(100),
  date TIMESTAMP,
  sequenceno INT,
  askprice FLOAT,
  asksize INT,
  bidprice FLOAT,
  bidsize INT);
=> INSERT INTO bookorders VALUES('3325XPK','2011-07-12 10:23:54', 1, 10.12, 55, 10.23, 59);
=> INSERT INTO bookorders VALUES('3345XPZ','2011-07-12 10:23:55', 2, 10.55, 58, 10.75, 57);
=> INSERT INTO bookorders VALUES('445XPKF','2011-07-12 10:23:56', 3, 10.22, 43, 54);
=> INSERT INTO bookorders VALUES('445XPKF','2011-07-12 10:23:57', 3, 10.22, 59, 10.25, 61);
=> INSERT INTO bookorders VALUES('3425XPY','2011-07-12 10:23:58', 4, 11.87, 66, 11.90, 66);
=> INSERT INTO bookorders VALUES('3727XVK','2011-07-12 10:23:59', 5, 11.66, 51, 11.67, 62);
=> INSERT INTO bookorders VALUES('5325XYZ','2011-07-12 10:24:01', 6, 15.05, 44, 15.10, 59);
=> INSERT INTO bookorders VALUES('3675XVS','2011-07-12 10:24:05', 7, 15.43, 47, 58);
=> INSERT INTO bookorders VALUES('8972VUG','2011-07-12 10:25:15', 8, 14.95, 52, 15.11, 57);

COMMIT;
```

Query:

```
=> SELECT
  sequenceno Seq,
  date "Time",
  vendorid ID,
  LAST_VALUE (bidprice IGNORE NULLS)
  OVER (PARTITION BY vendorid ORDER BY sequenceno
        ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW)
  AS "Bid Price",
  LAST_VALUE (bidsize IGNORE NULLS)
  OVER (PARTITION BY vendorid ORDER BY sequenceno
        ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW)
  AS "Bid Size",
  LAST_VALUE (askprice IGNORE NULLS)
  OVER (PARTITION BY vendorid ORDER BY sequenceno
        ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW)
  AS "Ask Price",
  LAST_VALUE (asksize IGNORE NULLS)
  OVER (PARTITION BY vendorid order by sequenceno
        ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW )
  AS "Ask Size"
FROM bookorders
ORDER BY sequenceno;
Seq |   Time   | ID | Bid Price | Bid Size | Ask Price | Ask Size
-----+-----+-----+-----+-----+-----+-----
1 | 2011-07-12 10:23:54 | 3325XPK | 10.23 | 59 | 10.12 | 55
2 | 2011-07-12 10:23:55 | 3345XPZ | 10.75 | 57 | 10.55 | 58

```

Event-based windows

Event-based windows let you break time series data into windows that border on significant events within the data. This is especially relevant in financial data where analysis often focuses on specific events as triggers to other activity.

Vertica provides two event-based window functions that are not part of the SQL-99 standard:

- [CONDITIONAL_CHANGE_EVENT](#) assigns an event window number to each row, starting from 0, and increments by 1 when the result of evaluating the argument expression on the current row differs from that on the previous row. This function is similar to the analytic function [ROW_NUMBER](#), which assigns a unique number, sequentially, starting from 1, to each row within a partition.
- [CONDITIONAL_TRUE_EVENT](#) assigns an event window number to each row, starting from 0, and increments the number by 1 when the result of the boolean argument expression evaluates true.

Both functions are described in greater detail below.

Note

[CONDITIONAL_CHANGE_EVENT](#) and [CONDITIONAL_TRUE_EVENT](#) do not support [window framing](#).

Example schema

The examples on this page use the following schema:

```
CREATE TABLE TickStore3 (ts TIMESTAMP, symbol VARCHAR(8), bid FLOAT);
CREATE PROJECTION TickStore3_p (ts, symbol, bid) AS SELECT * FROM TickStore3 ORDER BY ts, symbol, bid UNSEGMENTED ALL NODES;
INSERT INTO TickStore3 VALUES ('2009-01-01 03:00:00', 'XYZ', 10.0);
INSERT INTO TickStore3 VALUES ('2009-01-01 03:00:03', 'XYZ', 11.0);
INSERT INTO TickStore3 VALUES ('2009-01-01 03:00:06', 'XYZ', 10.5);
INSERT INTO TickStore3 VALUES ('2009-01-01 03:00:09', 'XYZ', 11.0);
COMMIT;
```

Using `CONDITIONAL_CHANGE_EVENT`

The analytical function `CONDITIONAL_CHANGE_EVENT` returns a sequence of integers indicating event window numbers, starting from 0. The function increments the event window number when the result of evaluating the function expression on the current row differs from the previous value.

In the following example, the first query returns all records from the `TickStore3` table. The second query uses the `CONDITIONAL_CHANGE_EVENT` function on the `bid` column. Since each `bid` row value is different from the previous value, the function increments the window ID from 0 to 3:

<pre>SELECT ts, symbol, bid FROM Tickstore3 ORDER BY ts;</pre>	<pre>==></pre>	<pre>SELECT CONDITIONAL_CHANGE_EVENT(bid) OVER(ORDER BY ts) FROM Tickstore3;</pre>																																			
<table border="1"> <thead> <tr> <th>ts</th> <th>symbol</th> <th>bid</th> </tr> </thead> <tbody> <tr><td>2009-01-01 03:00:00</td><td>XYZ</td><td>10</td></tr> <tr><td>2009-01-01 03:00:03</td><td>XYZ</td><td>11</td></tr> <tr><td>2009-01-01 03:00:06</td><td>XYZ</td><td>10.5</td></tr> <tr><td>2009-01-01 03:00:09</td><td>XYZ</td><td>11</td></tr> </tbody> </table> <p>(4 rows)</p>	ts	symbol	bid	2009-01-01 03:00:00	XYZ	10	2009-01-01 03:00:03	XYZ	11	2009-01-01 03:00:06	XYZ	10.5	2009-01-01 03:00:09	XYZ	11		<table border="1"> <thead> <tr> <th>ts</th> <th>symbol</th> <th>bid</th> <th>cce</th> </tr> </thead> <tbody> <tr><td>2009-01-01 03:00:00</td><td>XYZ</td><td>10</td><td>0</td></tr> <tr><td>2009-01-01 03:00:03</td><td>XYZ</td><td>11</td><td>1</td></tr> <tr><td>2009-01-01 03:00:06</td><td>XYZ</td><td>10.5</td><td>2</td></tr> <tr><td>2009-01-01 03:00:09</td><td>XYZ</td><td>11</td><td>3</td></tr> </tbody> </table> <p>(4 rows)</p>	ts	symbol	bid	cce	2009-01-01 03:00:00	XYZ	10	0	2009-01-01 03:00:03	XYZ	11	1	2009-01-01 03:00:06	XYZ	10.5	2	2009-01-01 03:00:09	XYZ	11	3
ts	symbol	bid																																			
2009-01-01 03:00:00	XYZ	10																																			
2009-01-01 03:00:03	XYZ	11																																			
2009-01-01 03:00:06	XYZ	10.5																																			
2009-01-01 03:00:09	XYZ	11																																			
ts	symbol	bid	cce																																		
2009-01-01 03:00:00	XYZ	10	0																																		
2009-01-01 03:00:03	XYZ	11	1																																		
2009-01-01 03:00:06	XYZ	10.5	2																																		
2009-01-01 03:00:09	XYZ	11	3																																		

The following figure is a graphical illustration of the change in the bid price. Each value is different from its previous one, so the window ID increments for each time slice:

So the window ID starts at 0 and increments at every change in from the previous value.

In this example, the bid price changes from \$10 to \$11 in the second row, but then stays the same. `CONDITIONAL_CHANGE_EVENT` increments the event window ID in row 2, but not subsequently:

<pre>SELECT ts, symbol, bid FROM Tickstore3 ORDER BY ts;</pre>	<pre>==></pre>	<pre>SELECT CONDITIONAL_CHANGE_EVENT(bid) OVER(ORDER BY ts) FROM Tickstore3;</pre>																																			
<table border="1"> <thead> <tr> <th>ts</th> <th>symbol</th> <th>bid</th> </tr> </thead> <tbody> <tr><td>2009-01-01 03:00:00</td><td>XYZ</td><td>10</td></tr> <tr><td>2009-01-01 03:00:03</td><td>XYZ</td><td>11</td></tr> <tr><td>2009-01-01 03:00:06</td><td>XYZ</td><td>11</td></tr> <tr><td>2009-01-01 03:00:09</td><td>XYZ</td><td>11</td></tr> </tbody> </table>	ts	symbol	bid	2009-01-01 03:00:00	XYZ	10	2009-01-01 03:00:03	XYZ	11	2009-01-01 03:00:06	XYZ	11	2009-01-01 03:00:09	XYZ	11		<table border="1"> <thead> <tr> <th>ts</th> <th>symbol</th> <th>bid</th> <th>cce</th> </tr> </thead> <tbody> <tr><td>2009-01-01 03:00:00</td><td>XYZ</td><td>10</td><td>0</td></tr> <tr><td>2009-01-01 03:00:03</td><td>XYZ</td><td>11</td><td>1</td></tr> <tr><td>2009-01-01 03:00:06</td><td>XYZ</td><td>11</td><td>1</td></tr> <tr><td>2009-01-01 03:00:09</td><td>XYZ</td><td>11</td><td>1</td></tr> </tbody> </table>	ts	symbol	bid	cce	2009-01-01 03:00:00	XYZ	10	0	2009-01-01 03:00:03	XYZ	11	1	2009-01-01 03:00:06	XYZ	11	1	2009-01-01 03:00:09	XYZ	11	1
ts	symbol	bid																																			
2009-01-01 03:00:00	XYZ	10																																			
2009-01-01 03:00:03	XYZ	11																																			
2009-01-01 03:00:06	XYZ	11																																			
2009-01-01 03:00:09	XYZ	11																																			
ts	symbol	bid	cce																																		
2009-01-01 03:00:00	XYZ	10	0																																		
2009-01-01 03:00:03	XYZ	11	1																																		
2009-01-01 03:00:06	XYZ	11	1																																		
2009-01-01 03:00:09	XYZ	11	1																																		

The following figure is a graphical illustration of the change in the bid price at 3:00:03 only. The price stays the same at 3:00:06 and 3:00:09, so the window ID remains at 1 for each time slice after the change:

![[CCE 2]](/images/cce2.png)

Using CONDITIONAL_TRUE_EVENT

Like `CONDITIONAL_CHANGE_EVENT`, the analytic function `CONDITIONAL_TRUE_EVENT` also returns a sequence of integers indicating event window numbers, starting from 0. The two functions differ as follows:

- `CONDITIONAL_TRUE_EVENT` increments the window ID each time its expression evaluates to true.
- `CONDITIONAL_CHANGE_EVENT` increments on a comparison expression with the previous value.

In the following example, the first query returns all records from the TickStore3 table. The second query uses `CONDITIONAL_TRUE_EVENT` to test whether the current bid is greater than a given value (10.6). Each time the expression tests true, the function increments the window ID. The first time the function increments the window ID is on row 2, when the value is 11. The expression tests false for the next row (value is not greater than 10.6), so the function does not increment the event window ID. In the final row, the expression is true for the given condition, and the function increments the window:

<pre>SELECT ts, symbol, bid FROM Tickstore3 ORDER BY ts;</pre>	<pre>SELECT CONDITIONAL_TRUE_EVENT(bid > 10.6) OVER(ORDER BY ts) FROM Tickstore3;</pre>															
<table border="1"> <thead> <tr> <th>ts</th> <th>symbol</th> <th>bid</th> </tr> </thead> <tbody> <tr> <td>2009-01-01 03:00:00</td> <td>XYZ</td> <td>10</td> </tr> <tr> <td>2009-01-01 03:00:03</td> <td>XYZ</td> <td>11</td> </tr> <tr> <td>2009-01-01 03:00:06</td> <td>XYZ</td> <td>10.5</td> </tr> <tr> <td>2009-01-01 03:00:09</td> <td>XYZ</td> <td>11</td> </tr> </tbody> </table>	ts	symbol	bid	2009-01-01 03:00:00	XYZ	10	2009-01-01 03:00:03	XYZ	11	2009-01-01 03:00:06	XYZ	10.5	2009-01-01 03:00:09	XYZ	11	<pre>ts symbol bid cte-----+-----+-----+----- 2009-01-01 03:00:00 XYZ 10 0 2009-01-01 03:00:03 XYZ 11 1 2009-01-01 03:00:06 XYZ 10.5 1 2009-01-01 03:00:09 XYZ 11 2</pre>
ts	symbol	bid														
2009-01-01 03:00:00	XYZ	10														
2009-01-01 03:00:03	XYZ	11														
2009-01-01 03:00:06	XYZ	10.5														
2009-01-01 03:00:09	XYZ	11														

The following figure is a graphical illustration that shows the bid values and window ID changes. Because the bid value is greater than \$10.6 on only the second and fourth time slices (3:00:03 and 3:00:09), the window ID returns <0, 1, 1, 2>:

In the following example, the first query returns all records from the TickStore3 table, ordered by the tickstore values (ts). The second query uses `CONDITIONAL_TRUE_EVENT` to increment the window ID each time the bid value is greater than 10.6. The first time the function increments the event window ID is on row 2, where the value is 11. The window ID then increments each time after that, because the expression (bid > 10.6) tests true for each time slice:

<pre>SELECT ts, symbol, bid FROM Tickstore3 ORDER BY ts;</pre>	<pre>SELECT CONDITIONAL_TRUE_EVENT(bid > 10.6) OVER(ORDER BY ts) FROM Tickstore3;</pre>															
<table border="1"> <thead> <tr> <th>ts</th> <th>symbol</th> <th>bid</th> </tr> </thead> <tbody> <tr> <td>2009-01-01 03:00:00</td> <td>XYZ</td> <td>10</td> </tr> <tr> <td>2009-01-01 03:00:03</td> <td>XYZ</td> <td>11</td> </tr> <tr> <td>2009-01-01 03:00:06</td> <td>XYZ</td> <td>11</td> </tr> <tr> <td>2009-01-01 03:00:09</td> <td>XYZ</td> <td>11</td> </tr> </tbody> </table>	ts	symbol	bid	2009-01-01 03:00:00	XYZ	10	2009-01-01 03:00:03	XYZ	11	2009-01-01 03:00:06	XYZ	11	2009-01-01 03:00:09	XYZ	11	<pre>ts symbol bid cte-----+-----+-----+----- 2009-01-01 03:00:00 XYZ 10 0 2009-01-01 03:00:03 XYZ 11 1 2009-01-01 03:00:06 XYZ 11 2 2009-01-01 03:00:09 XYZ 11 3</pre>
ts	symbol	bid														
2009-01-01 03:00:00	XYZ	10														
2009-01-01 03:00:03	XYZ	11														
2009-01-01 03:00:06	XYZ	11														
2009-01-01 03:00:09	XYZ	11														

The following figure is a graphical illustration that shows the bid values and window ID changes. The bid value is greater than 10.6 on the second time slice (3:00:03) and remains for the remaining two time slices. The function increments the event window ID each time because the expression tests true:

Advanced use of event-based windows

In event-based window functions, the condition expression accesses values from the current row only. To access a previous value, you can use a more powerful event-based window that allows the window event condition to include previous data points. For example, analytic function [LAG\(x, n\)](#) retrieves the value of column *x* in the *n*th to last input record. In this case, [LAG](#) shares the [OVER](#) specifications of the [CONDITIONAL_CHANGE_EVENT](#) or [CONDITIONAL_TRUE_EVENT](#) function expression.

In the following example, the first query returns all records from the TickStore3 table. The second query uses [CONDITIONAL_TRUE_EVENT](#) with the [LAG](#) function in its boolean expression. In this case, [CONDITIONAL_TRUE_EVENT](#) increments the event window ID each time the bid value on the current row is less than the previous value. The first time [CONDITIONAL_TRUE_EVENT](#) increments the window ID starts on the third time slice, when the expression tests true. The current value (10.5) is less than the previous value. The window ID is not incremented in the last row because the final value is greater than the previous row:

```
SELECT ts, symbol, bid FROM Tickstore3 ORDER BY ts;
```

ts	symbol	bid
2009-01-01 03:00:00	XYZ	10
2009-01-01 03:00:03	XYZ	11
2009-01-01 03:00:06	XYZ	10.5
2009-01-01 03:00:09	XYZ	11

```
SELECT CONDITIONAL_TRUE_EVENT(bid < LAG(bid))
OVER(ORDER BY ts) FROM Tickstore3;
```

ts	symbol	bid	cte
2009-01-01 03:00:00	XYZ	10	0
2009-01-01 03:00:03	XYZ	11	0
2009-01-01 03:00:06	XYZ	10.5	1
2009-01-01 03:00:09	XYZ	11	1

The following figure illustrates the second query above. When the bid price is less than the previous value, the window ID gets incremented, which occurs only in the third time slice (3:00:06):

Sessionization with event-based windows

Sessionization, a special case of event-based windows, is a feature often used to analyze click streams, such as identifying web browsing sessions from recorded web clicks.

In Vertica, given an input clickstream table, where each row records a Web page click made by a particular user (or IP address), the sessionization computation attempts to identify Web browsing sessions from the recorded clicks by grouping the clicks from each user based on the time-intervals between the clicks. If two clicks from the same user are made too far apart in time, as defined by a time-out threshold, the clicks are treated as though they are from two different browsing sessions.

Example Schema The examples in this topic use the following WebClicks schema to represent a simple clickstream table:

```
CREATE TABLE WebClicks(userId INT, timestamp TIMESTAMP);
INSERT INTO WebClicks VALUES (1, '2009-12-08 3:00:00 pm');
INSERT INTO WebClicks VALUES (1, '2009-12-08 3:00:25 pm');
INSERT INTO WebClicks VALUES (1, '2009-12-08 3:00:45 pm');
INSERT INTO WebClicks VALUES (1, '2009-12-08 3:01:45 pm');
INSERT INTO WebClicks VALUES (2, '2009-12-08 3:02:45 pm');
INSERT INTO WebClicks VALUES (2, '2009-12-08 3:02:55 pm');
INSERT INTO WebClicks VALUES (2, '2009-12-08 3:03:55 pm');
COMMIT;
```

The input table `WebClicks` contains the following rows:

```
=> SELECT * FROM WebClicks;
```

userId	timestamp
1	2009-12-08 15:00:00
1	2009-12-08 15:00:25
1	2009-12-08 15:00:45
1	2009-12-08 15:01:45
2	2009-12-08 15:02:45
2	2009-12-08 15:02:55
2	2009-12-08 15:03:55

(7 rows)

In the following query, sessionization performs computation on the SELECT list columns, showing the difference between the current and previous timestamp value using `LAG()`. It evaluates to true and increments the window ID when the difference is greater than 30 seconds.

```
=> SELECT userId, timestamp,
CONDITIONAL_TRUE_EVENT(timestamp - LAG(timestamp) > '30 seconds')
OVER(PARTITION BY userId ORDER BY timestamp) AS session FROM WebClicks;
```

userId	timestamp	session
1	2009-12-08 15:00:00	0
1	2009-12-08 15:00:25	0
1	2009-12-08 15:00:45	0
1	2009-12-08 15:01:45	1
2	2009-12-08 15:02:45	0
2	2009-12-08 15:02:55	0
2	2009-12-08 15:03:55	1

(7 rows)

In the output, the session column contains the window ID from the `CONDITIONAL_TRUE_EVENT` function. The window ID evaluates to true on row 4 (timestamp 15:01:45), and the ID that follows row 4 is zero because it is the start of a new partition (for user ID 2), and that row does not evaluate to true until the last line in the output.

You might want to give users different time-out thresholds. For example, one user might have a slower network connection or be multi-tasking, while another user might have a faster connection and be focused on a single Web site, doing a single task.

To compute an adaptive time-out threshold based on the last 2 clicks, use `CONDITIONAL_TRUE_EVENT` with `LAG` to return the average time between the last 2 clicks with a grace period of 3 seconds:

```
=> SELECT userId, timestamp, CONDITIONAL_TRUE_EVENT(timestamp - LAG(timestamp) >
(LAG(timestamp, 1) - LAG(timestamp, 3)) / 2 + '3 seconds')
OVER(PARTITION BY userId ORDER BY timestamp) AS session
FROM WebClicks;
userId | timestamp | session
-----+-----+-----
 2 | 2009-12-08 15:02:45 | 0
 2 | 2009-12-08 15:02:55 | 0
 2 | 2009-12-08 15:03:55 | 0
 1 | 2009-12-08 15:00:00 | 0
 1 | 2009-12-08 15:00:25 | 0
 1 | 2009-12-08 15:00:45 | 0
 1 | 2009-12-08 15:01:45 | 1
(7 rows)
```

Note

You cannot define a moving window in time series data. For example, if the query is evaluating the first row and there's no data, it will be the current row. If you have a lag of 2, no results are returned until the third row.

Machine learning for predictive analytics

Vertica provides a number of machine learning functions for performing in-database analysis. These functions perform data preparation, model training, model management, and predictive tasks. Vertica supports the following in-database machine learning algorithms:

- [Regression algorithms](#): Linear regression, PLS regression, random forest, SVM, XGBoost
- [Classification algorithms](#): Logistic regression, naive Bayes, random forest, SVM, XGBoost
- [Clustering algorithms](#): K-means, bisecting k-means
- [Time series forecasting](#): Autoregression, moving-average, ARIMA

For a scikit-like machine learning library that integrates directly with the data in your Vertica database, see [VerticaPy](#).

For more information about specific machine learning functions, see [Machine learning functions](#).

In this section

- [Download the machine learning example data](#)
- [Data preparation](#)
- [Regression algorithms](#)
- [Classification algorithms](#)
- [Clustering algorithms](#)
- [Time series forecasting](#)
- [Model management](#)
- [Using external models with Vertica](#)

Download the machine learning example data

You need several data sets to run the machine learning examples. You can download these data sets from the Vertica GitHub repository.

Important

The GitHub examples are based on the latest Vertica version. If you note differences, please upgrade to the latest version.

You can download the example data in either of two ways:

- Download the ZIP file. Extract the contents of the file into a directory.
- Clone the Vertica Machine Learning GitHub repository. Using a terminal window, run the following command:

```
$ git clone https://github.com/vertica/Machine-Learning-Examples
```

Loading the example data

You can load the example data by doing one of the following. Note that models are not automatically dropped. You must either rerun the [load_ml_data.sql](#) script to drop models or manually drop them.

- Copying and pasting the DDL and DML operations in [load_ml_data.sql](#) in a vsql prompt or another Vertica client.
- Running the following command from a terminal window within the data folder in the Machine-Learning-Examples directory:

```
$ /opt/vertica/bin/vsql -d <name of your database> -f load_ml_data.sql
```

You must also load the [naive_bayes_data_preparation.sql](#) script in the Machine-Learning-Examples directory:

```
$ /opt/vertica/bin/vsql -d <name of your database> -f ./naive_bayes/naive_bayes_data_preparation.sql
```

Example data descriptions

The repository contains the following data sets.

Name	Description
agar_dish	Synthetic data set meant to represent clustering of bacteria on an agar dish. Contains the following columns: id, x-coordinate, and y-coordinate.
agar_dish_2	125 rows sampled randomly from the original 500 rows of the agar_dish data set.
agar_dish_1	375 rows sampled randomly from the original 500 rows of the agar_dish data set.
baseball	Contains statistics from a fictional baseball league. The statistics included are: first name, last name, date of birth, team name, homeruns, hits, batting average, and salary.
daily-min-temperatures	Contains data on the daily minimum temperature in Melbourne, Australia from 1981 through 1990.
dem_votes	Contains data on the number of yes and no votes by Democrat members of U.S. Congress for each of the 16 votes in the house84 data set. The table must be populated by running the naive_bayes_data_preparation.sql script. Contains the following columns: vote, yes, no.
faithful	Wait times between eruptions and the duration of the eruption for the Old Faithful geyser in Yellowstone National Park, Wyoming, USA. Reference Härdle, W. (1991) <i>Smoothing Techniques with Implementation in S</i> . New York: Springer. Azzalini, A. and Bowman, A. W. (1990). A look at some data on the Old Faithful geyser. <i>Applied Statistics</i> 39, 357–365.
faithful_testing	Roughly 60% of the original 272 rows of the faithful data set.
faithful_training	Roughly 40% of the original 272 rows of the faithful data set.
house84	The house84 data set includes votes for each of the U.S. House of Representatives Congress members on 16 votes. Contains the following columns: id, party, vote1, vote2, vote3, vote4, vote5, vote6, vote7, vote8, vote9, vote10, vote11, vote12, vote13, vote14, vote15, vote16. Reference Congressional Quarterly Almanac, 98th Congress, 2nd session 1984, Volume XL: Congressional Quarterly Inc. Washington, D.C., 1985.

iris	<p>The iris data set gives the measurements in centimeters of the variables sepal length and width and petal length and width, respectively, for 50 flowers from each of 3 species of iris. The species are Iris setosa, versicolor, and virginica.</p> <p>Reference</p> <p>Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) <i>The New S Language</i> . Wadsworth & Brooks/Cole.</p>
iris1	90 rows sampled randomly from the original 150 rows in the iris data set.
iris2	60 rows sampled randomly from the original 150 rows in the iris data set.
mtcars	<p>The data was extracted from the 1974 Motor Trend US magazine, and comprises fuel consumption and 10 aspects of automobile design and performance for 32 automobiles (1973–74 models).</p> <p>Reference</p> <p>Henderson and Velleman (1981), Building multiple regression models interactively. <i>Biometrics</i> , 37, 391–411.</p>
rep_votes	Contains data on the number of yes and no votes by Republican members of U.S. Congress for each of the 16 votes in the house84 data set. The table must be populated by running the naive_bayes_data_preparation.sql script. Contains the following columns: vote, yes, no.
salary_data	Contains fictional employee data. The data included are: employee id, first name, last name, years worked, and current salary.
transaction_data	Contains fictional credit card transactions with a BOOLEAN column indicating whether there was fraud associated with the transaction. The data included are: first name, last name, store, cost, and fraud.
titanic_testing	Contains passenger information from the Titanic ship including sex, age, passenger class, and whether or not they survived.
titanic_training	Contains passenger information from the Titanic ship including sex, age, passenger class, and whether or not they survived.
world	Contains country-specific information about human development using HDI, GDP, and CO2 emissions.

Data preparation

Before you can analyze your data, you must prepare it. You can do the following data preparation tasks in Vertica:

In this section

- [Balancing imbalanced data](#)
- [Detect outliers](#)
- [Encoding categorical columns](#)
- [Imputing missing values](#)
- [Normalizing data](#)
- [PCA \(principal component analysis\)](#)
- [Sampling data](#)
- [SVD \(singular value decomposition\)](#)

Balancing imbalanced data

Imbalanced data occurs when an uneven distribution of classes occurs in the data. Building a predictive model on the imbalanced data set would cause a model that appears to yield high accuracy but does not generalize well to the new data in the minority class. To prevent creating models with false levels of accuracy, you should rebalance your imbalanced data before creating a predictive model.

Before you begin the example, [load the Machine Learning sample data](#).

You see imbalanced data a lot in financial transaction data where the majority of the transactions are not fraudulent and a small number of the transactions are fraudulent, as shown in the following example.

1. View the distribution of the classes.

```
=> SELECT fraud, COUNT(fraud) FROM transaction_data GROUP BY fraud;
fraud | COUNT
-----+-----
TRUE  | 19
FALSE | 981
(2 rows)
```

2. Use the BALANCE function to create a more balanced data set.

```
=> SELECT BALANCE('balance_fin_data', 'transaction_data', 'fraud', 'under_sampling'
      USING PARAMETERS sampling_ratio = 0.2);
      BALANCE
-----
Finished in 1 iteration

(1 row)
```

3. View the new distribution of the classifiers.

```
=> SELECT fraud, COUNT(fraud) FROM balance_fin_data GROUP BY fraud;
fraud | COUNT
-----+-----
t     | 19
f     | 236
(2 rows)
```

See also

- [BALANCE](#)

Detect outliers

Outliers are data points that greatly differ from other data points in a dataset. You can use outlier detection for applications such as fraud detection and system health monitoring, or you can detect outliers to then remove them from your data. If you leave outliers in your data when training a machine learning model, your resultant model is at risk for bias and skewed predictions. Vertica supports two methods for detecting outliers: the [DETECT_OUTLIERS](#) function and the [IFOREST](#) algorithm.

Note

The examples below use the baseball dataset from the machine learning example data. If you haven't already, [Download the machine learning example data](#).

Isolation forest

Isolation forest (iForest) is an unsupervised algorithm that operates on the assumption that outliers are few and different. This assumption makes outliers susceptible to a separation mechanism called isolation. Instead of comparing data instances to a constructed normal distribution of each data feature, isolation focuses on outliers themselves.

To isolate outliers directly, iForest builds binary tree structures named isolation trees (iTrees) to model the feature space. These iTrees randomly and recursively split the feature space so that each node of the tree represents a feature subspace. For instance, the first split divides the whole feature space into two subspaces, which are represented by the two child nodes of the root node. A data instance is considered isolated when it is the only member of a feature subspace. Because outliers are assumed to be few and different, outliers are likely to be isolated sooner than normal data instances.

In order to improve the robustness of the algorithm, iForest builds an ensemble of iTrees, which each separate the feature space differently. The algorithm calculates the average path length needed to isolate a data instance across all iTrees. This average path length helps determine the [anomaly_score](#) for each data instance in a dataset. The data instances with an [anomaly_score](#) above a given threshold are considered outliers.

You do not need a large dataset to train an iForest, and even a small sample should suffice to train an accurate model. The data can have columns of types CHAR, VARCHAR, BOOL, INT, or FLOAT.

After you have a trained an iForest model, you can use the [APPLY_IFOREST](#) function to detect outliers in any new data added to the dataset.

The following example demonstrates how to train an iForest model and detect outliers on the baseball dataset.

To build and train an iForest model, call [IFOREST](#):

```
=> SELECT IFOREST('baseball_outliers','baseball','hr, hits, salary' USING PARAMETERS max_depth=30, nbins=100);
IFOREST
-----
Finished
(1 row)
```

You can view a summary of the trained model using [GET_MODEL_SUMMARY](#):

```
=> SELECT GET_MODEL_SUMMARY(USING PARAMETERS model_name='baseball_outliers');
GET_MODEL_SUMMARY
-----
=====
call_string
=====
SELECT iforest('public.baseball_outliers', 'baseball', 'hr, hits, salary' USING PARAMETERS exclude_columns="", ntree=100, sampling_size=0.632,
col_sample_by_tree=1, max_depth=30, nbins=100);

=====
details
=====
predictor|  type
-----+-----
  hr |   int
  hits |   int
  salary |float or numeric

=====
Additional Info
=====
  Name      |Value
-----+-----
tree_count   | 100
rejected_row_count| 0
accepted_row_count|1000

(1 row)
```

You can apply the trained iForest model to the baseball dataset with [APPLY_IFOREST](#). To view only the data instances that are identified as outliers, you can run the following query:

```
=> SELECT * FROM (SELECT first_name, last_name, APPLY_IFOREST(hr, hits, salary USING PARAMETERS model_name='baseball_outliers',
threshold=0.6)
  AS predictions FROM baseball) AS outliers WHERE predictions.is_anomaly IS true;
first_name | last_name |           predictions
-----+-----+-----
Jacqueline | Richards | {"anomaly_score":0.8572338674053986,"is_anomaly":true}
Debra      | Hall     | {"anomaly_score":0.6007846156043213,"is_anomaly":true}
Gerald     | Fuller   | {"anomaly_score":0.6813650107767862,"is_anomaly":true}

(3 rows)
```

Instead of specifying a **threshold** value for `APPLY_IFOREST`, you can set the **contamination** parameter. This parameter sets a threshold so that the ratio of training data points labeled as outliers is approximately equal to the value of **contamination**:

```
=> SELECT * FROM (SELECT first_name, last_name, APPLY_IFOREST(team, hr, hits, avg, salary USING PARAMETERS
model_name='baseball_anomalies',
contamination = 0.1) AS predictions FROM baseball) AS outliers WHERE predictions.is_anomaly IS true;
first_name | last_name | predictions
-----+-----+-----
Marie | Fields | {"anomaly_score":0.5307715717521868,"is_anomaly":true}
Jacqueline | Richards | {"anomaly_score":0.777757463074347,"is_anomaly":true}
Debra | Hall | {"anomaly_score":0.5714649698133808,"is_anomaly":true}
Gerald | Fuller | {"anomaly_score":0.5980549926114661,"is_anomaly":true}
(4 rows)
```

DETECT_OUTLIERS

The [DETECT_OUTLIERS](#) function assumes a normal distribution for each data dimension, and then identifies data instances that differ strongly from the normal profile of any dimension. The function uses the robust z-score detection method to normalize each input column. If a data instance contains a normalized value greater than a specified threshold, it is identified as an outlier. The function outputs a table that contains all the outliers.

The function accepts data with only numeric input columns, treats each column independently, and assumes a Gaussian distribution on each column. If you want to detect outliers in new data added to the dataset, you must rerun [DETECT_OUTLIERS](#).

The following example demonstrates how you can detect the outliers in the baseball dataset based on the hr, hits, and salary columns. The [DETECT_OUTLIERS](#) function creates a table containing the outliers with the input and key columns:

```
=> SELECT DETECT_OUTLIERS('baseball_hr_hits_salary_outliers', 'baseball', 'hr, hits, salary', 'robust_zscore'
USING PARAMETERS outlier_threshold=3.0);
DETECT_OUTLIERS
-----
Detected 5 outliers
(1 row)
```

To view the outliers, query the output table containing the outliers:

```
=> SELECT * FROM baseball_hr_hits_salary_outliers;
id | first_name | last_name | dob | team | hr | hits | avg | salary
-----+-----+-----+-----+-----+-----+-----+-----+-----
73 | Marie | Fields | 1985-11-23 | Mauv | 8888 | 34 | 0.283 | 9.99999999341471e+16
89 | Jacqueline | Richards | 1975-10-06 | Pink | 273333 | 4490260 | 0.324 | 4.4444444444828e+17
87 | Jose | Stephens | 1991-07-20 | Green | 80 | 64253 | 0.69 | 16032567.12
222 | Gerald | Fuller | 1991-02-13 | Goldenrod | 3200000 | 216 | 0.299 | 37008899.76
147 | Debra | Hall | 1980-12-31 | Maroon | 1100037 | 230 | 0.431 | 9000101403
(5 rows)
```

You can create a view omitting the outliers from the table:

```
=> CREATE VIEW clean_baseball AS
SELECT * FROM baseball WHERE id NOT IN (SELECT id FROM baseball_hr_hits_salary_outliers);
CREATE VIEW
```

Encoding categorical columns

Many machine learning algorithms cannot work with categorical data. To accommodate such algorithms, categorical data must be converted to numerical data before training. Directly mapping the categorical values into indices is not enough. For example, if your categorical feature has three distinct values "red", "green" and "blue", replacing them with 1, 2 and 3 may have a negative impact on the training process because algorithms usually rely on some kind of numerical distances between values to discriminate between them. In this case, the Euclidean distance from 1 to 3 is twice the distance from 1 to 2, which means the training process will think that "red" is much more different than "blue", while it is more similar to

"green". Alternatively, one hot encoding maps each categorical value to a binary vector to avoid this problem. For example, "red" can be mapped to [1,0,0], "green" to [0,1,0] and "blue" to [0,0,1]. Now, the pair-wise distances between the three categories are all the same. One hot encoding allows you to convert categorical variables to binary values so that you can use different machine learning algorithms to evaluate your data.

The following example shows how you can apply one hot encoding to the Titanic data set. If you would like to read more about this data set, see the [Kaggle site](#).

Suppose you want to use a logistic regression classifier to predict which passengers survived the sinking of the Titanic. You cannot use categorical features for logistic regression without one hot encoding. This data set has two categorical features that you can use. The "sex" feature can be either male or female. The "embarkation_point" feature can be one of the following:

- S for Southampton
- Q for Queenstown
- C for Cherbourg

Before you begin the example, [load the Machine Learning sample data](#).

1. Run the [ONE_HOT_ENCODER_FIT](#) function on the training data:

```
=> SELECT ONE_HOT_ENCODER_FIT('titanic_encoder', 'titanic_training', 'sex, embarkation_point');
ONE_HOT_ENCODER_FIT
-----
Success
```

(1 row)

2. View a summary of the titanic_encoder model:

```
=> SELECT GET_MODEL_SUMMARY(USING PARAMETERS model_name='titanic_encoder');
GET_MODEL_SUMMARY
-----
=====
call_string
=====
SELECT one_hot_encoder_fit('public.titanic_encoder','titanic_training','sex, embarkation_point'
USING PARAMETERS exclude_columns="", output_view="", extra_levels='{}');
=====
varchar_categories
=====
category_name |category_level|category_level_index
-----+-----+-----
embarkation_point| C | 0
embarkation_point| Q | 1
embarkation_point| S | 2
embarkation_point| | 3
sex | female | 0
sex | male | 1
(1 row)
```

3. Run the [GET_MODEL_ATTRIBUTE](#) function. This function returns the categorical levels in their native data types, so they can be compared easily with the original table:

```
=> SELECT * FROM (SELECT GET_MODEL_ATTRIBUTE(USING PARAMETERS model_name='titanic_encoder',
attr_name='varchar_categories')) AS attrs INNER JOIN (SELECT passenger_id, name, sex, age,
embarkation_point FROM titanic_training) AS original_data ON attrs.category_level
ILIKE original_data.embarkation_point ORDER BY original_data.passenger_id LIMIT 10;
category_name | category_level | category_level_index | passenger_id | name
| sex | age | embarkation_point
-----+-----+-----+-----+-----
embarkation_point | S | 2 | 1 | Braund, Mr. Owen Harris
| male | 22 | S
embarkation_point | C | 0 | 2 | Cumings, Mrs. John Bradley
(Florence Briggs Thayer | female | 38 | C
embarkation_point | S | 2 | 3 | Heikkinen, Miss. Laina
| female | 26 | S
embarkation_point | S | 2 | 4 | Futrelle, Mrs. Jacques Heath
(Lily May Peel) | female | 35 | S
embarkation_point | S | 2 | 5 | Allen, Mr. William Henry
| male | 35 | S
embarkation_point | Q | 1 | 6 | Moran, Mr. James
| male | | Q
embarkation_point | S | 2 | 7 | McCarthy, Mr. Timothy J
| male | 54 | S
embarkation_point | S | 2 | 8 | Palsson, Master. Gosta Leonard
| male | 2 | S
embarkation_point | S | 2 | 9 | Johnson, Mrs. Oscar W
(Elisabeth Vilhelmina Berg) | female | 27 | S
embarkation_point | C | 0 | 10 | Nasser, Mrs. Nicholas
(Adele Achem) | female | 14 | C
(10 rows)
```

4. Run the APPLY_ONE_HOT_ENCODER function on both the training and testing data:

```
=> CREATE VIEW titanic_training_encoded AS SELECT passenger_id, survived, pclass, sex_1, age,
sibling_and_spouse_count, parent_and_child_count, fare, embarkation_point_1, embarkation_point_2
FROM (SELECT APPLY_ONE_HOT_ENCODER(* USING PARAMETERS model_name='titanic_encoder')
FROM titanic_training) AS sq;

CREATE VIEW

=> CREATE VIEW titanic_testing_encoded AS SELECT passenger_id, name, pclass, sex_1, age,
sibling_and_spouse_count, parent_and_child_count, fare, embarkation_point_1, embarkation_point_2
FROM (SELECT APPLY_ONE_HOT_ENCODER(* USING PARAMETERS model_name='titanic_encoder')
FROM titanic_testing) AS sq;

CREATE VIEW
```

5. Then, train a logistic regression classifier on the training data, and execute the model on the testing data:

```
=> SELECT LOGISTIC_REG('titanic_log_reg', 'titanic_training_encoded', 'survived', '**'
USING PARAMETERS exclude_columns='passenger_id, survived');
LOGISTIC_REG
```

Finished in 5 iterations
(1 row)

```
=> SELECT passenger_id, name, PREDICT_LOGISTIC_REG(pclass, sex_1, age, sibling_and_spouse_count,
parent_and_child_count, fare, embarkation_point_1, embarkation_point_2 USING PARAMETERS
model_name='titanic_log_reg') FROM titanic_testing_encoded ORDER BY passenger_id LIMIT 10;
passenger_id | name | PREDICT_LOGISTIC_REG
```

passenger_id	name	PREDICT_LOGISTIC_REG
893	Wilkes, Mrs. James (Ellen Needs)	0
894	Myles, Mr. Thomas Francis	0
895	Wirz, Mr. Albert	0
896	Hirvonen, Mrs. Alexander (Helga E Lindqvist)	1
897	Svensson, Mr. Johan Cervin	0
898	Connolly, Miss. Kate	1
899	Caldwell, Mr. Albert Francis	0
900	Abraham, Mrs. Joseph (Sophie Halaut Easu)	1
901	Davies, Mr. John Samuel	0
902	Ilieff, Mr. Ylio	

(10 rows)

Imputing missing values

You can use the [IMPUTE](#) function to replace missing data with the most frequent value or with the average value in the same column. This impute example uses the [small_input_impute](#) table. Using the function, you can specify either the mean or mode method.

These examples show how you can use the IMPUTE function on the [small_input_impute](#) table.

Before you begin the example, [load the Machine Learning sample data](#).

First, query the table so you can see the missing values:

```
=> SELECT * FROM small_input_impute;
pid | pclass | gender | x1 | x2 | x3 | x4 | x5 | x6
```

pid	pclass	gender	x1	x2	x3	x4	x5	x6
5	0	1	-2.590837	-2.892819	-2.70296	2	t	C
7	1	1	3.829239	3.08765	Infinity		f	C
13	0	0	-9.060605	-9.390844	-9.559848	6	t	C

16	0	1	-2.264599	-2.615146	-2.10729	11	f	A
19	1	1		3.841606	3.754375	20	t	
1	0	0	-9.445818	-9.740541	-9.786974	3	t	A
1	0	0	-9.445818	-9.740541	-9.786974	3	t	A
2	0	0	-9.618292	-9.308881	-9.562255	4	t	A
3	0	0	-9.060605	-9.390844	-9.559848	6	t	B
4	0	0	-2.264599	-2.615146	-2.10729	15	t	B
6	0	1	-2.264599	-2.615146	-2.10729	11	t	C
8	1	1	3.273592		3.477332	18	f	B
10	1	1		3.841606	3.754375	20	t	A
18	1	1	3.273592		3.477332	18	t	B
20	1	1		3.841606	3.754375	20		C
9	1	1		3.841606	3.754375	20	f	B
11	0	0	-9.445818	-9.740541	-9.786974	3	t	B
12	0	0	-9.618292	-9.308881	-9.562255	4	t	C
14	0	0	-2.264599	-2.615146	-2.10729	15	f	A
17	1	1	3.829239	3.08765	Infinity		f	B

(21 rows)

Specify the mean method

Execute the IMPUTE function, specifying the mean method:

```
=> SELECT IMPUTE('output_view','small_input_impute', 'pid, x1,x2,x3,x4','mean'
                USING PARAMETERS exclude_columns='pid');
```

IMPUTE

Finished in 1 iteration

(1 row)

View [output_view](#) to see the imputed values:

```
=> SELECT * FROM output_view;
```

pid	pclass	gender	x1	x2	x3	x4	x5	x6
5	0	1	-2.590837	-2.892819	-2.70296	2	t	C

[IMPUTE](#)

Normalizing data

The purpose of normalization is, primarily, to scale numeric data from different columns down to an equivalent scale. For example, suppose you execute the [LINEAR_REG](#) function on a data set with two feature columns, [current_salary](#) and [years_worked](#) . The output value you are trying to predict is a worker's future salary. The values in the [current_salary](#) column are likely to have a far wider range, and much larger values, than the values in the [years_worked](#) column. Therefore, the values in the [current_salary](#) column can overshadow the values in the [years_worked](#) column, thus skewing your model.

Vertica offers the following data preparation methods which use normalization. These methods are:

- **MinMax**
Using the MinMax normalization method, you can normalize the values in both of these columns to be within a distribution of values between 0 and 1. Doing so allows you to compare values on very different scales to one another by reducing the dominance of one column over the other.
- **Z-score**
Using the Z-score normalization method, you can normalize the values in both of these columns to be the number of standard deviations an observation is from the mean of each column. This allows you to compare your data to a normally distributed random variable.
- **Robust Z-score**
Using the Robust Z-score normalization method, you can lessen the influence of outliers on Z-score calculations. Robust Z-score normalization uses the median value as opposed to the mean value used in Z-score. By using the median instead of the mean, it helps remove some of the influence of outliers in the data.

Normalizing data results in the creation of a view where the normalized data is saved. The [output_view](#) option in the [NORMALIZE](#) function determines name of the view .

Normalizing salary data using MinMax

The following example shows how you can normalize the [salary_data](#) table using the MinMax normalization method.

Before you begin the example, [load the Machine Learning sample data](#) .

```
=> SELECT NORMALIZE('normalized_salary_data', 'salary_data', 'current_salary, years_worked', 'minmax');
NORMALIZE
```

```
-----
Finished in 1 iteration
```

```
(1 row)
```

```
=> SELECT * FROM normalized_salary_data;
```

```
employee_id | first_name | last_name | years_worked | current_salary
```

```

PCA (principal component analysis)

Principal Component Analysis (PCA) is a technique that reduces the dimensionality of data while retaining the variation present in the data. In essence, a new coordinate system is constructed so that data variation is strongest along the first axis, less strong along the second axis, and so on. Then, the data points are transformed into this new coordinate system. The directions of the axes are called principal components.

If the input data is a table with p columns, there could be maximum p principal components. However, it's usually the case that the data variation along the direction of some k -th principal component becomes almost negligible, which allows us to keep only the first k components. As a result, the new coordinate system has fewer axes. Hence, the transformed data table has only k columns instead of p . It is important to remember that the k output columns are not simply a subset of p input columns. Instead, each of the k output columns is a combination of all p input columns.

You can use the following functions to train and apply the PCA model:

- [APPLY_INVERSE_PCA](#)
- [APPLY_PCA](#)
- [PCA](#)

For a complete example, see [Dimension reduction using PCA](#).

In this section

- [Dimension reduction using PCA](#)

Dimension reduction using PCA

This PCA example uses a data set with a large number of columns named world. The example shows how you can apply PCA to all columns in the data set (except HDI) and reduce them into two dimensions.

Before you begin the example, [load the Machine Learning sample data](#).

1. Create the PCA model, named `pcamodel`.

```
=> SELECT PCA ('pcamodel', 'world', 'country, HDI, em1970, em1971, em1972, em1973, em1974, em1975, em1976, em1977, em1978, em1979, em1980, em1981, em1982, em1983, em1984, em1985, em1986, em1987, em1988, em1989, em1990, em1991, em1992, em1993, em1994, em1995, em1996, em1997, em1998, em1999, em2000, em2001, em2002, em2003, em2004, em2005, em2006, em2007, em2008, em2009, em2010, gdp1970, gdp1971, gdp1972, gdp1973, gdp1974, gdp1975, gdp1976, gdp1977, gdp1978, gdp1979, gdp1980, gdp1981, gdp1982, gdp1983, gdp1984, gdp1985, gdp1986, gdp1987, gdp1988, gdp1989, gdp1990, gdp1991, gdp1992, gdp1993, gdp1994, gdp1995, gdp1996, gdp1997, gdp1998, gdp1999, gdp2000, gdp2001, gdp2002, gdp2003, gdp2004, gdp2005, gdp2006, gdp2007, gdp2008, gdp2009, gdp2010' USING PARAMETERS exclude_columns='HDI, country');
```

PCA

Finished in 1 iterations.

Accepted Rows: 96 Rejected Rows: 0

(1 row)

2. View the summary output of `pcamodel`.

```
=> SELECT GET_MODEL_SUMMARY(USING PARAMETERS model_name='pcamodel');  
GET_MODEL_SUMMARY
```

3. Next, apply PCA to a select few columns, with the exception of HDI and country.

```
=> SELECT APPLY_PCA (HDI, country, em1970, em2010, gdp1970, gdp2010 USING PARAMETERS model_name='pcamodel',  
exclude_columns='HDI, country', key_columns='HDI, country', cutoff=.3) OVER () FROM world;
```

```
HDI | country | col1
```

Sampling data

The goal of data sampling is to take a smaller, more manageable sample of a much larger data set. With a sample data set, you can produce predictive models or use it to help you tune your database. The following example shows how you can use the **TABLESAMPLE** clause to create a sample of your data.

Sampling data from a table

Before you begin the example, [load the Machine Learning sample data](#).

Using the **baseball** table, create a new table named **baseball_sample** containing a 25% sample of **baseball**. Remember, **TABLESAMPLE** does not guarantee that the exact percentage of records defined in the clause are returned.

```

=> CREATE TABLE baseball_sample AS SELECT * FROM baseball TABLESAMPLE(25);
CREATE TABLE
=> SELECT * FROM baseball_sample;
id | first_name | last_name | dob | team | hr | hits | avg | salary
-----+-----+-----+-----+-----+-----+-----+-----+-----
 4 | Amanda | Turner | 1997-12-22 | Maroon | 58 | 177 | 0.187 | 8047721
20 | Jesse | Cooper | 1983-04-13 | Yellow | 97 | 39 | 0.523 | 4252837
22 | Randy | Peterson | 1980-05-28 | Orange | 14 | 16 | 0.141 | 11827728.1

SVD (singular value decomposition)

Singular Value Decomposition (SVD) is a matrix decomposition method that allows you to approximate matrix X with dimensions n-by-p as a product of 3 matrices: $X(n\text{-by-}p) = U(n\text{-by-}k).S(k\text{-by-}k).V^T(k\text{-by-}p)$ where k is an integer from 1 to p, and S is a diagonal matrix. Its diagonal has non-negative values, called singular values, sorted from the largest, at the top left, to the smallest, at the bottom right. All other elements of S are zero.

In practice, the matrix $V(p\text{-by-}k)$, which is the transposed version of V^T , is more preferred.

If k (an input parameter to the decomposition algorithm, also known as the number of components to keep in the output) is equal to p , the decomposition is exact. If k is less than p , the decomposition becomes an approximation.

An application of SVD is lossy data compression. For example, storing X required $n \cdot p$ elements, while storing the three matrices U , S , and V^T requires storing $n \cdot k + k + k \cdot p$ elements. If $n=1000$, $p=10$, and $k=2$, storing X would require 10,000 elements while storing the approximation would require $2,000+4+20 = 2,024$ elements. A smaller value of k increases the savings in storage space, while a larger value of k gives a more accurate approximation.

Depending on your data, the singular values may decrease rapidly, which allows you to choose a value of k that is much smaller than the value of p .

Another common application of SVD is to perform the principal component analysis.

You can use the following functions to train and apply the SVD model:

- [APPLY_INVERSE_SVD](#)
- [APPLY_SVD](#)
- [SVD](#)

For a complete example, see [Computing SVD](#).

In this section

- [Computing SVD](#)

Computing SVD

This SVD example uses a small data set named `small_svd`. The example shows you how to compute SVD using the given data set. The table is a matrix of numbers. The singular value decomposition is computed using the SVD function. This example computes the SVD of the table matrix and assigns it to a new object, which contains one vector, and two matrices, U and V . The vector contains the singular values. The first matrix, U contains the left singular vectors and V contains the right singular vectors.

Before you begin the example, [load the Machine Learning sample data](#).

1. Create the SVD model, named `svdmodel`.

```
=> SELECT SVD ('svdmodel', 'small_svd', 'x1,x2,x3,x4');
SVD
-----
Finished in 1 iterations.

SELECT SVD('public.svdmodel', 'small_svd', 'x1,x2,x3,x4');  
(1 row)
```

3. Create a new table, named **Umat** to obtain the values for U.

```
=> CREATE TABLE Umat AS SELECT APPLY_SVD(id, x1, x2, x3, x4 USING PARAMETERS model_name='svdmodel',  
exclude_columns='id', key_columns='id') OVER() FROM small_svd;  
CREATE TABLE
```

4. View the results in the **Umat** table. This table transforms the matrix into a new coordinates system.

```
=> SELECT * FROM Umat ORDER BY id;
```

id	col1	col2	col3	col4
1	-0.494871802886819	-0.161721379259287	0.0712816417153664	-0.473145877877408
2	-0.17652411036246	0.0753183783382909	-0.678196192333598	0.0567124770173372
3	-0.150974762654569	-0.589561842046029	0.00392654610109522	0.360011163271921
4	-0.44849499240202	0.347260956311326	0.186958376368345	0.378561270493651
5	-0.494871802886819	-0.161721379259287	0.0712816417153664	-0.473145877877408
6	-0.17652411036246	0.0753183783382909	-0.678196192333598	0.0567124770173372
7	-0.150974762654569	-0.589561842046029	0.00392654610109522	0.360011163271921
8	-0.44849499240202	0.347260956311326	0.186958376368345	0.378561270493651

(8 rows)

5. Then, we can optionally transform the data back by converting it from Umat to Xmat. First, we must create the Xmat table and then apply the `APPLY_INVERSE_SVD` function to the table:

```
=> CREATE TABLE Xmat AS SELECT APPLY_INVERSE_SVD(* USING PARAMETERS model_name='svdmodel',
exclude_columns='id', key_columns='id') OVER() FROM Umat;
CREATE TABLE
```

6. Then view the data from the Xmat table that was created:

```
=> SELECT id, x1::NUMERIC(5,1), x2::NUMERIC(5,1), x3::NUMERIC(5,1), x4::NUMERIC(5,1) FROM Xmat
ORDER BY id;
```

id	x1	x2	x3	x4
1	7.0	3.0	8.0	2.0

Regression algorithms

Regression is an important and popular machine learning tool that makes predictions from data by learning the relationship between some features of the data and an observed value response. Regression is used to make predictions about profits, sales, temperature, stocks, and more. For example, you could use regression to predict the price of a house based on the location, the square footage, the size of the lot, and so on. In this example, the house's value is the response, and the other factors, such as location, are the features.

The optimal set of coefficients found for the regression's equation is known as the model. The relationship between the outcome and the features is summarized in the model, which can then be applied to different data sets, where the outcome value is unknown.

In this section

- [Autoregression](#)
- [Linear regression](#)
- [PLS regression](#)
- [Poisson regression](#)
- [Random forest for regression](#)
- [SVM \(support vector machine\) for regression](#)
- [XGBoost for regression](#)

Autoregression

See the [autoregressive model example](#) under time series models.

Linear regression

Using linear regression, you can model the linear relationship between independent variables, or features, and a dependent variable, or outcome. You can build linear regression models to:

- Fit a predictive model to a training data set of independent variables and some dependent variable. Doing so allows you to use feature variable values to make predictions on outcomes. For example, you can predict the amount of rain that will fall on a particular day of the year.
- Determine the strength of the relationship between an independent variable and some outcome variable. For example, suppose you want to determine the importance of various weather variables on the outcome of how much rain will fall. You can build a linear regression model based on observations of weather patterns and rainfall to find the answer.

Unlike [Logistic regression](#), which you use to determine a binary classification outcome, linear regression is primarily used to predict continuous numerical outcomes in linear relationships.

You can use the following functions to build a linear regression model, view the model, and use the model to make predictions on a set of test data:

- [LINEAR_REG](#)
- [PREDICT_LINEAR_REG](#)
- [GET_MODEL_SUMMARY](#)

For a complete example of how to use linear regression on a table in Vertica, see [Building a linear regression model](#).

In this section

- [Building a linear regression model](#)

Building a linear regression model

This linear regression example uses a small data set named `faithful`. The data set contains the intervals between eruptions and the duration of eruptions for the Old Faithful geyser in Yellowstone National Park. The duration of each eruption can be between 1.5 and 5 minutes. The length of intervals between eruptions and of each eruption varies. However, you can estimate the time of the next eruption based on the duration of the previous eruption. The example shows how you can build a model to predict the value of `eruptions`, given the value of the `waiting` feature.

Before you begin the example, [load the Machine Learning sample data](#).

1. Create the linear regression model, named `linear_reg_faithful`, using the `faithful_training` training data:

```
=> SELECT LINEAR_REG('linear_reg_faithful', 'faithful_training', 'eruptions', 'waiting'  
      USING PARAMETERS optimizer='BFGS');  
      LINEAR_REG  
-----  
Finished in 6 iterations  
  
(1 row)
```

2. View the summary output of `linear_reg_faithful`:

```
=> SELECT GET_MODEL_SUMMARY(USING PARAMETERS model_name='linear_reg_faithful');
```

```
=====
details
=====
predictor|coefficient|std_err |t_value |p_value

rejected_row_count| 0
accepted_row_count| 162
(1 row)
```

3. Create a table that contains the response values from running the `PREDICT_LINEAR_REG` function on your test data. Name this table `pred_faithful_results`. View the results in the `pred_faithful_results` table:

```
=> CREATE TABLE pred_faithful_results AS
  (SELECT id, eruptions, PREDICT_LINEAR_REG(waiting USING PARAMETERS model_name='linear_reg_faithful')
  AS pred FROM faithful_testing);
CREATE TABLE

=> SELECT * FROM pred_faithful_results ORDER BY id;
id | eruptions |    pred
-----+-----
 4 |    2.283 | 2.8151271587036
 5 |    4.533 | 4.62659045686076
 8 |    3.6   | 4.62659045686076
 9 |    1.95 | 1.94877514654148
11 |    1.833 | 2.18505296804024
12 |    3.917 | 4.54783118302784
14 |    1.75 | 1.6337380512098
20 |    4.25 | 4.15403481386324
22 |    1.75 | 1.6337380512098
.
.
.
(110 rows)
```

Calculating the mean squared error (MSE)

You can calculate how well your model fits the data using the MSE function. MSE returns the average of the squared differences between actual value and predicted values.

```
=> SELECT MSE (eruptions::float, pred::float) OVER() FROM
(SELECT eruptions, pred FROM pred_faithful_results) AS prediction_output;
mse      |      Comments
-----+-----
0.252925741352641 | Of 110 rows, 110 were used and 0 were ignored
(1 row)
```

PLS regression

Combining aspects of [PCA \(principal component analysis\)](#) and [linear regression](#), the PLS regression algorithm extracts a set of latent components that explain as much covariance as possible between the predictor and response variables, and then performs a regression that predicts response values using the extracted components.

This technique is particularly useful when the number of predictor variables is greater than the number of observations or the predictor variables are highly collinear. If either of these conditions is true of the input relation, ordinary linear regression fails to converge to an accurate model.

Use the following functions to train and make predictions with PLS regression models:

- [PLS_REG](#): Creates and trains a PLS regression model
- [PREDICT_PLS_REG](#): Applies a trained PLS model to an input relation and returns predicted values

The [PLS_REG](#) function supports PLS regression with only one response column, often referred to as PLS1. PLS regression with multiple response columns, known as PLS2, is not currently supported.

Example

This example uses a [Monarch butterfly population dataset](#), which includes columns such as:

- [Log_N](#) (dependent variable): natural log of the western monarch population in the overwintering habitat for the respective year
- [Log_PrevN](#): natural log of the western monarch population in the overwintering habitat for the previous year
- [Coast_Dev](#): estimated proportion of developed lands in the overwintering habitat in coastal California
- [Br_Temp](#): average monthly maximum temperature in degrees Celsius from June to August in the breeding habitat
- [Gly_Ag](#): summed amount of glyphosate, in pounds, applied for agricultural purposes in California
- [Coast_T](#): minimum monthly temperature in degrees Celsius averaged across the overwintering habitat in coastal California from December to February

As reported in [Crone et al. \(2019\)](#), the predictor variables in this dataset are highly collinear. Unlike ordinary linear regression techniques, which cannot disambiguate linearly dependent variables, the PLS regression algorithm is designed to handle collinearity.

After you have downloaded the Monarch data locally, you can load the data into Vertica with the following statements:

```
=> CREATE TABLE monarch_data (Year INTEGER, Log_N FLOAT, Log_PrevN FLOAT, CoastDev FLOAT, Br_PDSI FLOAT, Br_Temp FLOAT,
Gly_Ag FLOAT, Gly_NonAg FLOAT, NN_Ag FLOAT, NN_NonAg FLOAT, Coast_P FLOAT, Coast_T FLOAT);
=> COPY monarch_data FROM LOCAL 'path-to-data' DELIMITER ',';
```

You can then split the data into a training and test set:

```
=> CREATE TABLE monarch_train AS (SELECT * FROM monarch_data WHERE Year < 2010);
=> CREATE TABLE monarch_test AS (SELECT Log_PrevN, CoastDev, Br_PDSI, Br_Temp, Gly_Ag, Gly_NonAg, NN_Ag, NN_NonAg, Coast_P, Coast_T FROM monarch_data WHERE Year >= 2010);
```

To train a PLS regression model on the training data, use the [PLS_REG](#) function. In this example, two models are trained, one with the default [num_components](#) of 2 and the other with [num_components](#) set to 3:

```
=> SELECT PLS_REG ('monarch_pls', 'monarch_train', 'Log_N', '') USING PARAMETERS exclude_columns='Log_N, Year';  
      PLS_REG
```

Number of components 2.

Accepted Rows: 28 Rejected Rows: 0

(1 row)

```
=> SELECT PLS_REG ('monarch_pls_3', 'monarch_train', 'Log_N', '' USING PARAMETERS exclude_columns='Log_N, Year',  
      num_components=3);
```

PLS_REG

Number of components 3.

Accepted Rows: 28 Rejected Rows: 0

(1 row)

You can use the [GET_MODEL_SUMMARY](#) function to view a summary of the model, including coefficient and parameter values:

```
=> SELECT GET_MODEL_SUMMARY(USING PARAMETERS model_name='monarch_pls'),
        GET_MODEL_SUMMARY
-----
=====
details
=====

-----+-----
  is_scaled    | 1
  n_components  | 2
rejected_row_count| 0
accepted_row_count| 28

(1 row)
```

After you train the PLS models, use the [PREDICT_PLS_REG](#) function to make predictions on an input relation, in this case the `monarch_test` data:

```
-2 component model
-> SELECT PREDICT_PLS_REG (* USING PARAMETERS model_name='monarch_pls') FROM monarch_test;
PREDICT_PLS_REG
-----
2.88462577469318
2.86535009598611
2.84138719904564
 2.7222022770597
3.96163608455087
3.30690898656628
2.99904802221049
(7 rows)
```

```
-3 component model
-> SELECT PREDICT_PLS_REG (* USING PARAMETERS model_name='monarch_pls_3') FROM monarch_test;
PREDICT_PLS_REG
-----
3.02572904832937
3.68777887527724
3.21578610703037
3.51114625472752
4.81912351259015
4.18201014233219
3.69428768763682
(7 rows)
```

Query the `monarch_data` table to view the actual measured monarch population from the years for which values were predicted:

```
-> SELECT Year, Log_N FROM monarch_data WHERE YEAR >= 2010;
Year | Log_N
-----+-----
2010 | 3.721
2011 | 4.231
2012 | 3.742
2013 | 3.515
2014 | 3.807
2015 | 4.032
2016 | 3.528373
(7 rows)

(7 rows)
```

To compute the mean squared error (MSE) of the models' predictions, use the [MSE](#) function:

```
--2 component model
-> SELECT MSE(obs, prediction) OVER()
  FROM (SELECT Log_N AS obs,
  PREDICT_PLS_REG (Log_PrevN, CoastDev, Br_PDSI, Br_Temp, Gly_Ag, Gly_NonAg, NN_Ag, NN_NonAg, Coast_P, Coast_T USING PARAMETERS r
  FROM monarch_test WHERE Year >= 2010) AS prediction_output;
  mse      |      Comments
-----|-----
0.678821911958195 | Of 7 rows, 7 were used and 0 were ignored
(1 row)

--3 component model
-> SELECT MSE(obs, prediction) OVER()
  FROM (SELECT Log_N AS obs,
  PREDICT_PLS_REG (Log_PrevN, CoastDev, Br_PDSI, Br_Temp, Gly_Ag, Gly_NonAg, NN_Ag, NN_NonAg, Coast_P, Coast_T USING PARAMETERS r
  FROM monarch_test WHERE Year >= 2010) AS prediction_output;
  mse      |      Comments
-----|-----
0.368195839329685 | Of 7 rows, 7 were used and 0 were ignored
(1 row)
```

Comparing the MSE of the models' predictions, the PLS model trained with 3 components performs better than the model with only 2 components.

- [PLS_REG](#)
- [GET_MODEL_SUMMARY](#)

Poisson regression

Using Poisson regression, you can model count data. Poisson regression offers an alternative to linear regression or logistic regression and is useful when the target variable describes event frequency (event count in a fixed interval of time). [Linear regression](#) is preferable if you aim to predict continuous numerical outcomes in linear relationships, while [logistic regression](#) is used for predicting a binary classification.

You can use the following functions to build a Poisson regression model, view the model, and use the model to make predictions on a set of test data:

- [POISSON_REG](#)
- [PREDICT_POISSON_REG](#)
- [GET_MODEL_SUMMARY](#)

Random forest for regression

The Random Forest for regression algorithm creates an ensemble model of regression trees. Each tree is trained on a randomly selected subset of the training data. The algorithm predicts the value that is the mean prediction of the individual trees.

You can use the following functions to train the Random Forest model, and use the model to make predictions on a set of test data:

- [GET_MODEL_SUMMARY](#)
- [PREDICT_RF_REGRESSOR](#)
- [RF_REGRESSOR](#)

For a complete example of how to use the Random Forest for regression algorithm in Vertica, see [Building a random forest regression model](#).

In this section

- [Building a random forest regression model](#)

Building a random forest regression model

This example uses the "mtcars" dataset to create a random forest model to predict the value of **carb** (the number of carburetors).

Before you begin the example, [load the Machine Learning sample data](#).

1. Use [RF_REGRESSOR](#) to create the random forest model `myRFRegressorModel` using the `mtcars` training data. View the summary output of the model with [GET_MODEL_SUMMARY](#):

```

=> SELECT RF_REGRESSOR ('myRFRegressorModel', 'mtcars', 'carb', 'mpg, cyl, hp, drat, wt' USING PARAMETERS
ntree=100, sampling_size=0.3);
RF_REGRESSOR

SVM (support vector machine) for regression

Support Vector Machine (SVM) for regression predicts continuous ordered variables based on the training data.

Unlike [Logistic regression](#), which you use to determine a binary classification outcome, SVM for regression is primarily used to predict continuous numerical outcomes.

You can use the following functions to build an SVM for regression model, view the model, and use the model to make predictions on a set of test data:

- [SVM_REGRESSOR](#)
- [PREDICT_SVM_REGRESSOR](#)
- [GET_MODEL_SUMMARY](#)

For a complete example of how to use the SVM algorithm in Vertica, see [Building an SVM for regression model](#).

In this section

- [Building an SVM for regression model](#)

Building an SVM for regression model

This SVM for regression example uses a small data set named `faithful`, based on the Old Faithful geyser in Yellowstone National Park. The data set contains values about the waiting time between eruptions and the duration of eruptions of the geyser. The example shows how you can build a model to predict the value of `eruptions`, given the value of the `waiting` feature.

Before you begin the example, [load the Machine Learning sample data](#).

1. Create the SVM model, named `svm_faithful`, using the `faithful_training` training data:

```
=> SELECT SVM_REGRESSOR('svm_faithful', 'faithful_training', 'eruptions', 'waiting'
      USING PARAMETERS error_tolerance=0.1, max_iterations=100);
      SVM_REGRESSOR
-----
Finished in 5 iterations
Accepted Rows: 162  Rejected Rows: 0
(1 row)
```

2. View the summary output of `svm_faithful`:

```
=> SELECT GET_MODEL_SUMMARY(USING PARAMETERS model_name='svm_faithful');
-----
=====
details
=====
-----
Predictors and Coefficients
=====
      |Coefficients
-----+-----

XGBoost for regression

[XGBoost](#) (eXtreme Gradient Boosting) is a popular supervised-learning algorithm used for regression and classification on large datasets. It uses sequentially-built shallow decision trees to provide accurate results and a highly-scalable training method that avoids overfitting.

The following XGBoost functions create and perform predictions with a regression model:

- [XGB_REGRESSOR](#)
- [PREDICT_XGB_REGRESSOR](#)

Example

This example uses a small data set named "mtcars", which contains design and performance data for 32 automobiles from 1973-1974, and creates an XGBoost regression model to predict the value of the variable `carb` (the number of carburetors).

Before you begin the example, [load the Machine Learning sample data](#).

1. Use [XGB_REGRESSOR](#) to create the XGBoost regression model `xgb_cars` from the `mtcars` dataset:

```

=> SELECT XGB_REGRESSOR ('xgb_cars', 'mtcars', 'carb', 'mpg, cyl, hp, drat, wt'
      USING PARAMETERS learning_rate=0.5);
XGB_REGRESSOR
-----
Finished
(1 row)

```

You can then view a summary of the model with [GET_MODEL_SUMMARY](#):

```

=> SELECT GET_MODEL_SUMMARY(USING PARAMETERS model_name='xgb_cars');
      GET_MODEL_SUMMARY
-----
=====
call_string
=====
xgb_regressor('public.xgb_cars', 'mtcars', '"carb"', 'mpg, cyl, hp, drat, wt'
USING PARAMETERS exclude_columns="", max_ntree=10, max_depth=5, nbins=32, objective=squarederror,
split_proposal_method=global, epsilon=0.001, learning_rate=0.5, min_split_loss=0, weight_reg=0, sampling_size=1)

Classification algorithms

Classification is an important and popular machine learning tool that assigns items in a data set to different categories. Classification is used to predict risk over time, in fraud detection, text categorization, and more. Classification functions begin with a data set where the different categories are known. For example, suppose you want to classify students based on how likely they are to get into graduate school. In addition to factors like admission score exams and grades, you could also track work experience.

Binary classification means the outcome, in this case, admission, only has two possible values: admit or do not admit. Multiclass outcomes have more than two values. For example, low, medium, or high chance of admission. During the training process, classification algorithms find the relationship between the outcome and the features. This relationship is summarized in the model, which can then be applied to different data sets, where the categories are unknown.

In this section

- [Logistic regression](#)
- [Naive bayes](#)
- [Random forest for classification](#)
- [SVM \(support vector machine\) for classification](#)
- [XGBoost for classification](#)

Logistic regression

Using logistic regression, you can model the relationship between independent variables, or features, and some dependent variable, or outcome. The outcome of logistic regression is always a binary value.

You can build logistic regression models to:

- Fit a predictive model to a training data set of independent variables and some binary dependent variable. Doing so allows you to make predictions on outcomes, such as whether a piece of email is spam mail or not.
- Determine the strength of the relationship between an independent variable and some binary outcome variable. For example, suppose you want to determine whether an email is spam or not. You can build a logistic regression model, based on observations of the properties of email messages. Then, you can determine the importance of various properties of an email message on that outcome.

You can use the following functions to build a logistic regression model, view the model, and use the model to make predictions on a set of test data:

- [LOGISTIC_REG](#)
- [PREDICT_LOGISTIC_REG](#)
- [GET_MODEL_SUMMARY](#)

For a complete programming example of how to use logistic regression on a table in Vertica, see [Building a logistic regression model](#).

In this section

- [Building a logistic regression model](#)

Building a logistic regression model

This logistic regression example uses a small data set named `mtcars`. The example shows how to build a model that predicts the value of `am`, which indicates whether the car has an automatic or a manual transmission. It uses the given values of all the other features in the data set.

In this example, roughly 60% of the data is used as training data to create a model. The remaining 40% is used as testing data against which you can test your logistic regression model.

Before you begin the example, [load the Machine Learning sample data](#).

1. Create the logistic regression model, named `logistic_reg_mtcars`, using the `mtcars_train` training data.

```
=> SELECT LOGISTIC_REG('logistic_reg_mtcars', 'mtcars_train', 'am', 'cyl, wt'  
      USING PARAMETERS exclude_columns='hp');  
      LOGISTIC_REG  
-----  
Finished in 15 iterations  
  
(1 row)
```

2. View the summary output of `logistic_reg_mtcars`.

```

=> SELECT GET_MODEL_SUMMARY(USING PARAMETERS model_name='logistic_reg_mtcars');
-----

Porsche 914-2 | 1 | 1
Valiant | 0 | 0
```

```
(12 rows)
```

4. Evaluate the accuracy of the [PREDICT_LOGISTIC_REG](#) function, using the [CONFUSION_MATRIX](#) evaluation function.

```
=> SELECT CONFUSION_MATRIX(obs::int, pred::int USING PARAMETERS num_classes=2) OVER()
FROM (SELECT am AS obs, Prediction AS pred FROM mtcars_predict_results) AS prediction_output;
```

```
class | 0 | 1 | comment
```

```
-----+-----+-----
0 | 6 | 1 |
1 | 1 | 4 | Of 12 rows, 12 were used and 0 were ignored
```

```
(2 rows)
```

In this case, [PREDICT_LOGISTIC_REG](#) correctly predicted that four out of five cars with a value of **1** in the **am** column have a value of **1**. Out of the seven cars which had a value of **0** in the **am** column, six were correctly predicted to have the value **0**. One car was incorrectly classified as having the value **1**.

Naive bayes

You can use the Naive Bayes algorithm to classify your data when features can be assumed independent. The algorithm uses independent features to calculate the probability of a specific class. For example, you might want to predict the probability that an email is spam. In that case, you would use a corpus of words associated with spam to calculate the probability the email's content is spam.

You can use the following functions to build a Naive Bayes model, view the model, and use the model to make predictions on a set of test data:

- [NAIVE_BAYES](#)
- [PREDICT_NAIVE_BAYES](#)
- [PREDICT_NAIVE_BAYES_CLASSES](#)
- [GET_MODEL_SUMMARY](#)

For a complete example of how to use the Naive Bayes algorithm in Vertica, see [Classifying data using naive bayes](#).

In this section

- [Classifying data using naive bayes](#)

Classifying data using naive bayes

This Naive Bayes example uses the HouseVotes84 data set to show you how to build a model. With this model, you can predict which party the member of the United States Congress is affiliated based on their voting record. To aid in classifying the data it has been cleaned, and any missed votes have been replaced. The cleaned data replaces missed votes with the voter's party majority vote. For example, suppose a member of the Democrats had a missing value for vote1 and majority of the Democrats voted in favor. This example replaces all missing Democrats' votes for vote1 with a vote in favor.

In this example, approximately 75% of the cleaned HouseVotes84 data is randomly selected and copied to a training table. The remaining cleaned HouseVotes84 data is used as a testing table.

Before you begin the example, [load the Machine Learning sample data](#).

You must also load the [naive_bayes_data_preparation.sql](#) script:

```
$ /opt/vertica/bin/vsql -d <name of your database> -f naive_bayes_data_preparation.sql
```

1. Create the Naive Bayes model, named `naive_house84_model`, using the `house84_train` training data.

```
=> SELECT NAIVE_BAYES('naive_house84_model', 'house84_train', 'party',
    *** USING PARAMETERS exclude_columns='party, id');
    NAIVE_BAYES
```

```
-----
Finished. Accepted Rows: 315 Rejected Rows: 0
(1 row)
```

2. Create a new table, named `predicted_party_naive`. Populate this table with the prediction outputs you obtain from the `PREDICT_NAIVE_BAYES` function on your test data.

```
=> CREATE TABLE predicted_party_naive
AS SELECT party,
    PREDICT_NAIVE_BAYES (vote1, vote2, vote3, vote4, vote5,
        vote6, vote7, vote8, vote9, vote10,
        vote11, vote12, vote13, vote14,
        vote15, vote16
        USING PARAMETERS model_name = 'naive_house84_model',
            type = 'response') AS Predicted_Party
FROM house84_test;
CREATE TABLE
```

3. Calculate the accuracy of the model's predictions.

```
=> SELECT (Predictions.Num_Correct_Predictions / Count.Total_Count) AS Percent_Accuracy
FROM ( SELECT COUNT(Predicted_Party) AS Num_Correct_Predictions
    FROM predicted_party_naive
    WHERE party = Predicted_Party
    ) AS Predictions,
    ( SELECT COUNT(party) AS Total_Count
    FROM predicted_party_naive
    ) AS Count;
Percent_Accuracy
```

```
-----
0.93333333333333333333333333333333
(1 row)
```

The model correctly predicted the party of the members of Congress based on their voting patterns with 93% accuracy.

Viewing the probability of each class

You can also view the probability of each class. Use `PREDICT_NAIVE_BAYES_CLASSES` to see the probability of each class.

```

=> SELECT PREDICT_NAIVE_BAYES_CLASSES (id, vote1, vote2, vote3, vote4, vote5,
    vote6, vote7, vote8, vote9, vote10,
    vote11, vote12, vote13, vote14,
    vote15, vote16
    USING PARAMETERS model_name = 'naive_house84_model',
    key_columns = 'id', exclude_columns = 'id',
    classes = 'democrat, republican')
    OVER() FROM house84_test;

SVM (support vector machine) for classification

Support Vector Machine (SVM) is a classification algorithm that assigns data to one category or the other based on the training data. This algorithm implements linear SVM, which is highly scalable.

You can use the following functions to train the SVM model, and use the model to make predictions on a set of test data:

- [SVM_CLASSIFIER](#)
- [PREDICT_SVM_CLASSIFIER](#)
- [GET_MODEL_SUMMARY](#)

You can also use the following evaluation functions to gain further insights:

- [CONFUSION_MATRIX](#)
- [DETECT_OUTLIERS](#)
- [ERROR_RATE](#)

- [ROC](#)

For a complete example of how to use the SVM algorithm in Vertica, see [Classifying data using SVM \(support vector machine\)](#).

The implementation of the SVM algorithm in Vertica is based on the paper [Distributed Newton Methods for Regularized Logistic Regression](#).

In this section

- [Classifying data using SVM \(support vector machine\)](#)

Classifying data using SVM (support vector machine)

This SVM example uses a small data set named `mtcars`. The example shows how you can use the `SVM_CLASSIFIER` function to train the model to predict the value of `am` (the transmission type, where 0 = automatic and 1 = manual) using the `PREDICT_SVM_CLASSIFIER` function.

Before you begin the example, [load the Machine Learning sample data](#).

1. Create the SVM model, named `svm_class`, using the `mtcars_train` training data.

```
=> SELECT SVM_CLASSIFIER('svm_class', 'mtcars_train', 'am', 'cyl, mpg, wt, hp, gear'
      USING PARAMETERS exclude_columns='gear');
SVM_CLASSIFIER
-----
Finished in 12 iterations.
Accepted Rows: 20 Rejected Rows: 0
(1 row)
```

2. View the summary output of ``svm_class``.

```
=> SELECT GET_MODEL_SUMMARY(USING PARAMETERS model_name='svm_class');
-----
=====
details
=====
predictor|coefficient
-----+-----
Intercept| -0.02006
cyl      |  0.15367
mpg      |  0.15698
wt       | -1.78157
hp       |  0.00957

=====
call_string
=====
SELECT svm_classifier('public.svm_class', 'mtcars_train', "'am'", 'cyl, mpg, wt, hp, gear'
USING PARAMETERS exclude_columns='gear', C=1, max_iterations=100, epsilon=0.001);

=====
Additional Info
=====
Name      |Value
-----+-----
accepted_row_count| 20
rejected_row_count|  0
iteration_count  | 12
(1 row)
```

3. Create a new table, named `svm_mtcars_predict`. Populate this table with the prediction outputs you obtain from running the `PREDICT_SVM_CLASSIFIER` function on your test data.

```
=> CREATE TABLE svm_mtcars_predict AS
  (SELECT car_model, am, PREDICT_SVM_CLASSIFIER(cyl, mpg, wt, hp
        USING PARAMETERS model_name='svm_class')
        AS Prediction FROM mtcars_test);
CREATE TABLE
```

4. View the results in the `svm_mtcars_predict` table.

```
=> SELECT * FROM svm_mtcars_predict;
car_model | am | Prediction
-----+-----+-----
Toyota Corona | 0 | 1
Camaro Z28 | 0 | 0
Datsun 710 | 1 | 1
Valiant | 0 | 0
Volvo 142E | 1 | 1
AMC Javelin | 0 | 0
Honda Civic | 1 | 1
Hornet 4 Drive | 0 | 0
Maserati Bora | 1 | 1
Merc 280 | 0 | 0
Merc 450SL | 0 | 0
Porsche 914-2 | 1 | 1
(12 rows)
```

5. Evaluate the accuracy of the `PREDICT_SVM_CLASSIFIER` function, using the `CONFUSION_MATRIX` evaluation function.

```
=> SELECT CONFUSION_MATRIX(obs::int, pred::int USING PARAMETERS num_classes=2) OVER()
  FROM (SELECT am AS obs, Prediction AS pred FROM svm_mtcars_predict) AS prediction_output;
class | 0 | 1 |
-----+-----+-----
0 | 6 | 1 |
1 | 0 | 5 | Of 12 rows, 12 were used and 0 were ignored
(2 rows)
```

In this case, `PREDICT_SVM_CLASSIFIER` correctly predicted that the cars with a value of `1` in the `am` column have a value of `1`. No cars were incorrectly classified. Out of the seven cars which had a value of `0` in the `am` column, six were correctly predicted to have the value `0`. One car was incorrectly classified as having the value `1`.

XGBoost for classification

[XGBoost](#) (eXtreme Gradient Boosting) is a popular supervised-learning algorithm used for regression and classification on large datasets. It uses sequentially-built shallow decision trees to provide accurate results and a highly-scalable training method that avoids overfitting.

The following XGBoost functions create and perform predictions with a classification model:

- [XGB_CLASSIFIER](#)
- [PREDICT_XGB_CLASSIFIER](#)
- [PREDICT_XGB_CLASSIFIER_CLASSES](#)

Example

This example uses the "iris" dataset, which contains measurements for various parts of a flower, and can be used to predict its species and creates an XGBoost classifier model to classify the species of each flower.

Before you begin the example, [load the Machine Learning sample data](#).

1. Use [XGB_CLASSIFIER](#) to create the XGBoost classifier model `xgb_iris` using the `iris` dataset:

```
=> SELECT XGB_CLASSIFIER ('xgb_iris', 'iris', 'Species', 'Sepal_Length, Sepal_Width, Petal_Length, Petal_Width'
    USING PARAMETERS max_ntree=10, max_depth=5, weight_reg=0.1, learning_rate=1);
XGB_CLASSIFIER
```

```
-----
Finished
(1 row)
```

You can then view a summary of the model with [GET_MODEL_SUMMARY](#):

```
=> SELECT GET_MODEL_SUMMARY(USING PARAMETERS model_name='xgb_iris');
                                                                GET_MODEL_SUMMARY

Clustering algorithms

Clustering is an important and popular machine learning tool used to find clusters of items in a data set that are similar to one another. The goal of clustering is to create clusters with a high number of objects that are similar. Similar to classification, clustering segments the data. However, in clustering, the categorical groups are not defined.

Clustering data into related groupings has many useful applications. If you already know how many clusters your data contains, the [K-means](#) algorithm may be sufficient to train your model and use that model to predict cluster membership for new data points.

However, in the more common case, you do not know before analyzing the data how many clusters it contains. In these cases, the [Bisecting k-means](#) algorithm is much more effective at finding the correct clusters in your data.

Both k-means and bisecting k-means predict the clusters for a given data set. A model trained using either algorithm can then be used to predict the cluster to which new data points are assigned.

Clustering can be used to find anomalies in data and find natural groups of data. For example, you can use clustering to analyze a geographical region and determine which areas of that region are most likely to be hit by an earthquake. For a complete example, see [Earthquake Cluster Analysis Using the KMeans Approach](#).

In Vertica, clustering is computed based on Euclidean distance. Through this computation, data points are assigned to the cluster with the nearest center.

In this section

- [K-means](#)
- [K-prototypes](#)
- [Bisecting k-means](#)

K-means

You can use the *k-means* clustering algorithm to cluster data points into *k* different groups based on similarities between the data points.

k-means partitions *n* observations into *k* clusters. Through this partitioning, *k-means* assigns each observation to the cluster with the nearest mean, or *cluster center*.

For a complete example of how to use *k-means* on a table in Vertica, see [Clustering data using k-means](#).

In this section

- [Clustering data using k-means](#)

Clustering data using k-means

This *k-means* example uses two small data sets: `agar_dish_1` and `agar_dish_2`. Using the numeric data in the `agar_dish_1` data set, you can cluster the data into *k* clusters. Then, using the created *k-means* model, you can run [APPLY_KMEANS](#) on `agar_dish_2` and assign them to the clusters created in your original model.

Before you begin the example, [load the Machine Learning sample data](#).

Clustering training data into *k* clusters

1. Create the *k-means* model, named `agar_dish_kmeans` using the `agar_dish_1` table data.

```
=> SELECT KMEANS('agar_dish_kmeans', 'agar_dish_1', '*', 5
      USING PARAMETERS exclude_columns='id', max_iterations=20, output_view='agar_1_view',
      key_columns='id');
      KMEANS
-----
Finished in 7 iterations
(1 row)
```

The example creates a model named `agar_dish_kmeans` and a view containing the results of the model named `agar_1_view`. You might get different results when you run the clustering algorithm. This is because `KMEANS` randomly picks initial centers by default.

2. View the output of `agar_1_view`.

```
=> SELECT * FROM agar_1_view;
id | cluster_id
-----+-----
 2 |         4
 5 |         4
 7 |         4
 9 |         4
13 |         4
.
.
.
(375 rows)
```

3. Because you specified the number of clusters as 5, verify that the function created five clusters. Count the number of data points within each cluster.

```
=> SELECT cluster_id, COUNT(cluster_id) as Total_count
      FROM agar_1_view
      GROUP BY cluster_id;
cluster_id | Total_count
-----+-----
         0 |          76
         2 |          80
         1 |          74
         3 |          73
         4 |          72
(5 rows)
```

From the output, you can see that five clusters were created: 0, 1, 2, 3, and 4.

You have now successfully clustered the data from `agar_dish_1.csv` into five distinct clusters.

Summarizing your model

```

Clustering data using a k-means model

Using `agar_dish_kmeans`, the k-means model you just created, you can assign the points in `agar_dish_2` to cluster centers.

Create a table named `kmeans_results`, using the `agar_dish_2` table as your input table and the `agar_dish_kmeans` model for your initial cluster centers.

Add only the relevant feature columns to the arguments in the `APPLY_KMEANS` function.

```
=> CREATE TABLE kmeans_results AS
  (SELECT id,
    APPLY_KMEANS(x, y
      USING PARAMETERS
        model_name='agar_dish_kmeans') AS cluster_id
  FROM agar_dish_2);
```

The `kmeans_results` table shows that the `agar_dish_kmeans` model correctly clustered the `agar_dish_2` data.

K-prototypes

You can use the *k-prototypes* clustering algorithm to cluster mixed data into different groups based on similarities between the data points. The *k-prototypes* algorithm extends the functionality of [k-means](#) clustering, which is limited to numerical data, by combining it with *k-modes* clustering, a clustering algorithm for categorical data.

See the [syntax for k-prototypes here](#).

Bisecting k-means

The *bisecting k-means* clustering algorithm combines *k-means* clustering with divisive hierarchy clustering. With bisecting *k-means*, you get not only the clusters but also the hierarchical structure of the clusters of data points.

This hierarchy is more informative than the unstructured set of flat clusters returned by [K-means](#). The hierarchy shows how the clustering results would look at every step of the process of bisecting clusters to find new clusters. The hierarchy of clusters makes it easier to decide the number of clusters in the data set.

Given a hierarchy of *k* clusters produced by bisecting *k-means*, you can easily calculate any prediction of the form: Assume the data contain only *k'* clusters, where *k'* is a number that is smaller than or equal to the *k* used to train the model.

For a complete example of how to use bisecting *k-means* to analyze a table in Vertica, see [Clustering data hierarchically using bisecting k-means](#).

In this section

- [Clustering data hierarchically using bisecting k-means](#)

Clustering data hierarchically using bisecting k-means

This bisecting *k-means* example uses two small data sets named `agar_dish_training` and `agar_dish_testing`. Using the numeric data in the `agar_dish_training` data set, you can cluster the data into *k* clusters. Then, using the resulting bisecting *k-means* model, you can run `APPLY_BISECTING_KMEANS` on `agar_dish_testing` and assign the data to the clusters created in your trained model. Unlike regular *k-means* (also provided in Vertica), bisecting *k-means* allows you to predict with any number of clusters less than or equal to *k*. So if you train the model with *k*=5 but later decide to predict with *k*=2, you do not have to retrain the model; just run `APPLY_BISECTING_KMEANS` with *k*=2.

Before you begin the example, [load the Machine Learning sample data](#). For this example, we load `agar_dish_training.csv` and `agar_dish_testing.csv`.

Clustering training data into *k* clusters to train the model

1. Create the bisecting *k-means* model, named `agar_dish_bkmeans`, using the `agar_dish_training` table data.

```
=> SELECT BISECTING_KMEANS('agar_dish_bkmeans', 'agar_dish_training', '*', 5 USING PARAMETERS exclude_columns='id', key_columns='id',
output_view='agar_1_view');
BISECTING_KMEANS
-----
Finished.
(1 row)
```

This example creates a model named `agar_dish_bkmeans` and a view containing the results of the model named `agar_1_view`. You might get slightly different results when you run the clustering algorithm. This is because `BISECTING_KMEANS` uses random numbers to generate the best clusters.

2. View the output of `agar_1_view`.

```
=> SELECT * FROM agar_1_view;
```

```
id | cluster_id
```

```
-----+-----
```

```
2 | 4
```

```
5 | 4
```

```
7 | 4
```

```
9 | 4
```

```
...
```

Here we can see the id of each point in the agar_dish_training table and which cluster it has been assigned to.

3. Because we specified the number of clusters as 5, verify that the function created five clusters by counting the number of data points within each cluster.

```
=> SELECT cluster_id, COUNT(cluster_id) as Total_count FROM agar_1_view GROUP BY cluster_id;
```

```
cluster_id | Total_count
```

```
-----+-----
```

```
5 | 76
```

```
7 | 73
```

```
8 | 74
```

```
4 | 72
```

```
6 | 80
```

```
(5 rows)
```

You may wonder why the cluster_ids do not start at 0 or 1. The reason is that the bisecting k-means algorithm generates many more clusters than k-means, and then outputs the ones that are needed for the designated value of k . We will see later why this is useful.

You have now successfully clustered the data from [agar_dish_training.csv](#) into five distinct clusters.

Summarizing your model

View the summary output of agar_dish_bkmeans using the GET_MODEL_SUMMARY function.

...

```
=> SELECT GET_MODEL_SUMMARY(USING PARAMETERS model_name='agar_dish_bkmeans');
```

...

Here we can see the details of all the intermediate clusters created by bisecting k-means during training, some metrics for evaluating the quality of the clustering (the lower the sum of squares, the better), the specific parameters with which the algorithm was trained, and some general information about the data algorithm.

Clustering testing data using a bisecting k-means model

Using `agar_dish_bkmeans`, the bisecting k-means model you just created, you can assign the points in `agar_dish_testing` to cluster centers.

1. Create a table named `bkmeans_results`, using the `agar_dish_testing` table as your input table and the `agar_dish_bkmeans` model for your cluster centers. Add only the relevant feature columns to the arguments in the `APPLY_BISECTING_KMEANS` function.

```
=> CREATE TABLE bkmeans_results_k5 AS
  (SELECT id,
    APPLY_BISECTING_KMEANS(x, y
      USING PARAMETERS
        model_name='agar_dish_bkmeans', number_clusters=5) AS cluster_id
    FROM agar_dish_testing);
=> SELECT cluster_id, COUNT(cluster_id) as Total_count FROM bkmeans_results_k5 GROUP BY cluster_id;
cluster_id | Total_count
-----+-----
5 | 24
4 | 28
6 | 20
8 | 26
7 | 27
(5 rows)
```

The `bkmeans_results_k5` table shows that the `agar_dish_bkmeans` model correctly clustered the `agar_dish_testing` data.

2. The real advantage of using bisecting k-means is that the model it creates can cluster data into any number of clusters less than or equal to the k with which it was trained. Now you could cluster the above testing data into 3 clusters instead of 5, without retraining the model:

```
=> CREATE TABLE bkmeans_results_k3 AS
  (SELECT id,
    APPLY_BISECTING_KMEANS(x, y
      USING PARAMETERS
        model_name='agar_dish_bkmeans', number_clusters=3) AS cluster_id
    FROM agar_dish_testing);
=> SELECT cluster_id, COUNT(cluster_id) as Total_count FROM bkmeans_results_k3 GROUP BY cluster_id;
cluster_id | Total_count
-----+-----
4 | 28
3 | 53
1 | 44
(3 rows)
```

Prediction using the trained bisecting k-means model

To cluster data using a trained model, the bisecting k-means algorithm starts by comparing the incoming data point with the child cluster centers of the root cluster node. The algorithm finds which of those centers the data point is closest to. Then the data point is compared with the child cluster centers of the closest child of the root. The prediction process continues to iterate until it reaches a leaf cluster node. Finally, the point is assigned to the closest leaf cluster. The following picture gives a simple illustration of the training process and prediction process of the bisecting k-means algorithm. An advantage of using bisecting k-means is that you can predict using any value of k from 2 to the largest k value the model was trained on.

The model in the picture below was trained on $k=5$. The middle picture shows using the model to predict with $k=5$, in other words, match the incoming data point to the center with the closest value, in the level of the hierarchy where there are 5 leaf clusters. The picture on the right shows using the model to predict *as if* $k=2$, in other words, first compare the incoming data point to the leaf clusters at the level where there were only two clusters, then match the data point to the closer of those two cluster centers. This approach is faster than predicting with k-means.

Train: $K=5$

Predict: $K'=5$

Predict: $K'=2$ (pretend as if we have only 2 clusters)

Time series forecasting

Time series models are trained on stationary time series (that is, time series where the mean doesn't change over time) of stochastic processes with consistent time steps. These algorithms forecast future values by taking into account the influence of values at some number of preceding timesteps (lags).

Examples of applicable datasets include those for temperature, stock prices, earthquakes, product sales, etc.

To normalize datasets with inconsistent timesteps, see [Gap filling and interpolation \(GFI\)](#).

In this section

- [Autoregression algorithms](#)
- [ARIMA model example](#)
- [Moving-average model example](#)

Autoregression algorithms

Autoregressive models use past time series values to predict future values. These models assume that a future value in a time series is dependent on its past values, and attempt to capture this relationship in a set of coefficient values.

Vertica supports both autoregression (AR) and vector autoregression (VAR) models:

- AR is a univariate autoregressive time series algorithm that predicts a variable's future values based on its preceding values. The user specifies the number of lagged timesteps taken into account during computation, and the model then predicts future values as a linear combination of the values at each lag.
- VAR is a multivariate autoregressive time series algorithm that captures the relationship between multiple time series variables over time. Unlike AR, which only considers a single variable, VAR models incorporate feedback between different variables in the model, enabling the model to analyze how variables interact across lagged time steps. For example, with two variables—atmospheric pressure and rain accumulation—a VAR model could determine whether a drop in pressure tends to result in rain at a future date.

The [AUTOREGRESSOR](#) function automatically executes the algorithm that fits your input data:

- One value column: the function executes autoregression and returns a trained AR model.
- Multiple value columns: the function executes vector autoregression and returns a trained VAR model.

In this section

- [Autoregressive model example](#)
- [VAR model example](#)

Autoregressive model example

Autoregressive models predict future values of a time series based on the preceding values. More specifically, the user-specified *lag* determines how many previous timesteps it takes into account during computation, and predicted values are linear combinations of the values at each lag.

Use the following functions when training and predicting with autoregressive models. Note that these functions require datasets with consistent timesteps.

- [AUTOREGRESSOR](#): trains an autoregressive model
- [PREDICT_AUTOREGRESSOR](#): applies the model to a dataset to make predictions

To normalize datasets with inconsistent timesteps, see [Gap filling and interpolation \(GFI\)](#).

Example

1. Load the datasets from the [Machine-Learning-Examples](#) repository.

This example uses the daily-min-temperatures dataset, which contains data on the daily minimum temperature in Melbourne, Australia from 1981 through 1990:

```
=> SELECT * FROM temp_data;
  time      | Temperature
-----+-----
1981-01-01 00:00:00 | 20.7
1981-01-02 00:00:00 | 17.9
1981-01-03 00:00:00 | 18.8
1981-01-04 00:00:00 | 14.6
1981-01-05 00:00:00 | 15.8
...
1990-12-27 00:00:00 | 14
1990-12-28 00:00:00 | 13.6
1990-12-29 00:00:00 | 13.5
1990-12-30 00:00:00 | 15.7
1990-12-31 00:00:00 | 13
(3650 rows)
```

2. Use [AUTOREGRESSOR](#) to create the autoregressive model `AR_temperature` from the `temp_data` dataset. In this case, the model is trained with a lag of `p = 3`, taking the previous 3 entries into account for each estimation:

```
=> SELECT AUTOREGRESSOR('AR_temperature', 'temp_data', 'Temperature', 'time' USING PARAMETERS p=3);
      AUTOREGRESSOR
-----
Finished. 3650 elements accepted, 0 elements rejected.
(1 row)
```

You can view a summary of the model with [GET_MODEL_SUMMARY](#):

```

=> SELECT GET_MODEL_SUMMARY(USING PARAMETERS model_name='AR_temperature');

GET_MODEL_SUMMARY

VAR model example

The following example trains a vector autoregression (VAR) model on an electricity usage dataset, and then makes predictions with that model.

[Download and load the data](#)

You can download the data from [Mendeley Data](#). The dataset consists of metrics related to daily electricity load forecasting in Panama, including columns such as the following:

- **datetime** : hourly datetime index corresponding to Panama time-zone (UTC-05:00)
- **nat_demand** : national electricity load in Panama, measured in megawatt hours
- **T2M_toc** : temperature at 2 meters in Tocumen, Panama City
- **QV2M_toc** : relative humidity at 2 meters in Tocumen, Panama City
- **TQL_toc** : liquid precipitation in Tocumen, Panama City
- **W2M_toc** : wind speed at 2 meters in Tocumen, Panama City

The dataset also includes temperature, humidity, precipitation, and wind speed columns for two other cities in Panama: Santiago City and David City.

Unlike the AR algorithm, which can only model a single variable over time, the VAR algorithm captures the relationship between time series variables across lagged time steps. For example, when trained on the above dataset, the VAR algorithm could model whether a rise in temperature tends to lead to an increase in electricity demand hours later.

After you have downloaded the data locally, you can load the data into Vertica with the following statements:

```
-> CREATE TABLE electric_data(ts timestamp, nat_demand float, T2M_toc float, QV2M_toc float,
    TQL_toc float, W2M_toc float, T2M_san float, QV2M_san float, TQL_san float, W2M_san float, T2M_dav
    float, QV2M_dav float, TQL_dav float, W2M_dav float, Holiday_ID int, holiday bool, school bool);

-> COPY electric_data (ts,nat_demand,T2M_toc,QV2M_toc,TQL_toc,W2M_toc,T2M_san,QV2M_san,TQL_san,W2M_san,
    T2M_dav,QV2M_dav,TQL_dav,W2M_dav,Holiday_ID,holiday,school) FROM LOCAL 'path-to-data'
DELIMITER ',';
```

The dataset includes some categorical columns, which need to be dropped before training a VAR model:

```
-> ALTER TABLE electric_data DROP column Holiday_ID;
-> ALTER TABLE electric_data DROP column holiday;
-> ALTER TABLE electric_data DROP column school;
```

Query the **electric_data** table to view a sample of the data that will be used to train the model:

```
-> SELECT * FROM electric_data LIMIT 3;

   ts           | nat_demand | T2M_toc | QV2M_toc | TQL_toc | W2M_toc | T2M_san | QV2M_san | TQL_san | W2M_san |
-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
2015-01-03 01:00:00 | 970.345 | 25.8652587890625 | 0.018576382 | 0.016174316 | 21.8505458178752 | 23.4824462890625 | 0.017271755 | 0.001855373

Train the model

To train a VAR model, use the [AUTOREGRESSOR](#) function. In this example, the model is trained with a lag of 3, meaning 3 previous timesteps are taken into account during computation:

```
-> SELECT AUTOREGRESSOR ('var_electric', 'electric_data', 'nat_demand, T2M_toc, QV2M_toc, TQL_toc, W2M_toc, T2M_san, QV2M_san,
    TQL_san, W2M_san, T2M_dav, QV2M_dav, TQL_dav, W2M_dav', 'ts' USING PARAMETERS P=3, compute_mse=True);
WARNING 0: Only the Yule Walker method is currently supported for Vector Autoregression, setting method to Yule Walker
      AUTOREGRESSOR
-----
Finished. 48048 elements accepted, 0 elements rejected.
(1 row)
```

Use the [GET_MODEL_SUMMARY](#) function to view a summary of the model, including its coefficient and parameter values:

```
-> SELECT GET_MODEL_SUMMARY( USING PARAMETERS model_name='var_electric');
      GET_MODEL_SUMMARY
-----
=====

=====
predictor | nat_demand | t2m_toc | qv2m_toc | tql_toc | w2m_toc | t2m_san | qv2m_san | tql_san | w2m_san | t2m_dav | qv2m_dav | tql_dav | w2m_dav
```

```

lag_order | 3
num_predictors | 13
lambda | 1.00000
rejected_row_count| 0
accepted_row_count| 48048

(1 row)

```

Make predictions

After you have trained the model, use [PREDICT_AUTOREGRESSOR](#) to make predictions. The following query makes predictions for 10 timesteps after the end of the training data:

```

-> SELECT PREDICT_AUTOREGRESSOR (nat_demand, T2M_toc, QV2M_toc, TQL_toc, W2M_toc, T2M_san, QV2M_san, TQL_san, W2M_san, T2M_dav,
  QV2M_dav, TQL_dav, W2M_dav USING PARAMETERS model_name='var_electric', npredictions=10) OVER (ORDER BY ts) FROM electric_data;

```

index	nat_demand	T2M_toc	QV2M_toc	TQL_toc	W2M_toc	T2M_san	QV2M_san	TQL_san	W2M

ARIMA model example

Autoregressive integrated moving average (ARIMA) models combine the abilities of [AUTOREGRESSOR](#) and [MOVING_AVERAGE](#) models by making predictions based on both preceding time series values and errors of previous predictions. ARIMA models also provide the option to apply a differencing operation to the input data, which can turn a non-stationary time series into a stationary time series. At model training time, you specify the differencing order and the number of preceding values and previous prediction errors that the model uses to calculate predictions.

You can use the following functions to train and make predictions with ARIMA models:

- [ARIMA](#): Creates and trains an ARIMA model
- [PREDICT_ARIMA](#): Applies a trained ARIMA model to an input relation or makes predictions using the in-sample data

These functions require time series data with consistent timesteps. To normalize a time series with inconsistent timesteps, see [Gap filling and interpolation \(GFI\)](#).

The following example trains three ARIMA models, two that use differencing and one that does not, and then makes predictions using the models.

Load the training data

Before you begin the example, [load the Machine Learning sample data](#).

This example uses the following data:

- [daily-min-temperatures](#): provided in the machine learning sample data, this dataset contains data on the daily minimum temperature in Melbourne, Australia from 1981 through 1990. After you load the sample datasets, this data is available in the [temp_data](#) table.
- [db_size](#): a table that tracks the size of a database over consecutive months.

```

=> SELECT * FROM temp_data;
   time      | Temperature
-----+-----
1981-01-01 00:00:00 | 20.7

7 | 110
8 | 145
9 | 185
10 | 230
(10 rows)

```

Train the ARIMA models

After you load the [daily-min-temperatures](#) data, you can use the [ARIMA](#) function to create and train an ARIMA model. For this example, the model is trained with lags of $p=3$ and $q=3$, taking the value and prediction error of three previous time steps into account for each prediction. Because the input time series is stationary, you don't need to apply differencing to the data:

```

=> SELECT ARIMA('arima_temp', 'temp_data', 'temperature', 'time' USING PARAMETERS p=3, d=0, q=3);
ARIMA
-----
Finished in 20 iterations.
3650 elements accepted, 0 elements rejected.
(1 row)

```

You can view a summary of the model with the [GET_MODEL_SUMMARY](#) function:

```

=> SELECT GET_MODEL_SUMMARY(USING PARAMETERS model_name='arima_temp');
      GET_MODEL_SUMMARY
-----

(1 row)

```

Examining the `db_size` table, it is clear that there is an upward trend to the database size over time. Each month the database size increases five more gigabytes than the increase in the previous month. This trend indicates the time series is non-stationary.

To account for this in the ARIMA model, you must difference the data by setting a non-zero **d** parameter value. For comparison, two ARIMA models are trained on this data, the first with a **d** value of one and the second with a **d** value of two:

```
=> SELECT ARIMA('arima_d1', 'db_size', 'GB', 'month' USING PARAMETERS p=2, d=1, q=2);
-----
ARIMA
-----
Finished in 9 iterations.
10 elements accepted, 0 elements rejected.

(1 row)

=> SELECT ARIMA('arima_d2', 'db_size', 'GB', 'month' USING PARAMETERS p=2, d=2, q=2);
-----
ARIMA
-----
Finished in 0 iterations.
10 elements accepted, 0 elements rejected.

(1 row)
```

Make predictions

After you train the ARIMA models, you can call the [PREDICT_ARIMA](#) function to predict future time series values. This function supports making predictions using the in-sample data that the models were trained on or applying the model to an input relation.

Using in-sample data

The following `PREDICT_ARIMA` call makes temperature predictions using the in-sample data that the `arima_temp` model was trained on. The model begins prediction at the end of the `temp_data` table and returns predicted values for ten timesteps:

```
=> SELECT PREDICT_ARIMA(USING PARAMETERS model_name='arima_temp', start=0, npredictions=10) OVER();
-----
index | prediction
-----+-----
 1 | 12.9745063293842
 2 | 13.4389080858551
 3 | 13.3955791360528
 4 | 13.3551146487462
 5 | 13.3149336514747
 6 | 13.2750516811057
 7 | 13.2354710353376
 8 | 13.1961939790513
 9 | 13.1572226788109
10 | 13.1185592045127
(10 rows)
```

For both prediction methods, if you want the function to return the standard error of each prediction, you can set `output_standard_errors` to true:

```
=> SELECT PREDICT_ARIMA(USING PARAMETERS model_name='arima_temp', start=0, npredictions=10, output_standard_errors=true) OVER();
-----
index | prediction | std_err
-----+-----+-----
 1 | 12.9745063293842 | 1.00621890780865
 2 | 13.4389080858551 | 1.45340836833232
 3 | 13.3955791360528 | 1.61041524562932
 4 | 13.3551146487462 | 1.76368421116143
 5 | 13.3149336514747 | 1.91223938476627
 6 | 13.2750516811057 | 2.05618464609977
 7 | 13.2354710353376 | 2.19561771498385
 8 | 13.1961939790513 | 2.33063553781651
 9 | 13.1572226788109 | 2.46133422924445
10 | 13.1185592045127 | 2.58780904243988
(10 rows)
```

To make predictions with the two models trained on the `db_size` table, you only need to change the specified `model_name` in the above calls:

```
=> SELECT PREDICT_ARIMA(USING PARAMETERS model_name='arima_d1', start=0, npredictions=10) OVER();
```

index	prediction
1	279.882778508943
2	334.398317856829
3	393.204492820962
4	455.909453114272
5	522.076165355683
6	591.227478668175
7	662.851655189833
8	736.408301395412
9	811.334631481162
10	887.051990217688

(10 rows)

```
=> SELECT PREDICT_ARIMA(USING PARAMETERS model_name='arima_d2', start=0, npredictions=10) OVER();
```

index	prediction
1	280
2	335
3	395
4	460
5	530
6	605
7	685
8	770
9	860
10	955

(10 rows)

Comparing the outputs from the two models, you can see that the model trained with a **d** value of two correctly captures the trend in the data. Each month the rate of database growth increases by five gigabytes.

Applying to an input relation

You can also apply the model to an input relation. The following example makes predictions by applying the **arima_temp** model to the **temp_data** training set:

```
=> SELECT PREDICT_ARIMA(temperature USING PARAMETERS model_name='arima_temp', start=3651, npredictions=10, output_standard_errors=true) OVER();
```

index	prediction	std_err
1	12.9745063293842	1.00621890780865
2	13.4389080858551	1.45340836833232
3	13.3955791360528	1.61041524562932
4	13.3551146487462	1.76368421116143
5	13.3149336514747	1.91223938476627
6	13.2750516811057	2.05618464609977
7	13.2354710353376	2.19561771498385
8	13.1961939790513	2.33063553781651
9	13.1572226788109	2.46133422924445
10	13.1185592045127	2.58780904243988

(10 rows)

Because the same data and relative start index were provided to both prediction methods, the **arima_temp** model predictions for each method are identical.

When applying a model to an input relation, you can set **add_mean** to false so that the function returns the predicted difference from the mean instead of the sum of the model mean and the predicted difference:

```
=> SELECT PREDICT_ARIMA(temperature USING PARAMETERS model_name='arima_temp', start=3680, npredictions=10, add_mean=false) OVER(ORDER BY index)
index | prediction
-----+-----
1 | 1.2026877112171
2 | 1.17114068517961
3 | 1.13992534953432
4 | 1.10904183333367
5 | 1.07849019986692
6 | 1.04827044781798
7 | 1.01838251238116
8 | 0.98882626641461
9 | 0.959601521551628
10 | 0.93070802931751
(10 rows)
```

Moving-average model example

Moving average models use the errors of previous predictions to make future predictions. More specifically, the user-specified *lag* determines how many previous predictions and errors it takes into account during computation.

Use the following functions when training and predicting with moving-average models. Note that these functions require datasets with consistent timesteps.

- [MOVING_AVERAGE](#): trains a moving-average model
- [PREDICT_MOVING_AVERAGE](#): applies the model to a dataset to make predictions

To normalize datasets with inconsistent timesteps, see [Gap filling and interpolation \(GFI\)](#).

Example

1. Load the datasets from the [Machine-Learning-Examples](#) repository.

This example uses the daily-min-temperatures dataset, which contains data on the daily minimum temperature in Melbourne, Australia from 1981 through 1990:

```
=> SELECT * FROM temp_data;
time | Temperature
-----+-----
1981-01-01 00:00:00 | 20.7
1981-01-02 00:00:00 | 17.9
1981-01-03 00:00:00 | 18.8
1981-01-04 00:00:00 | 14.6
1981-01-05 00:00:00 | 15.8
..
1990-12-27 00:00:00 | 14
1990-12-28 00:00:00 | 13.6
1990-12-29 00:00:00 | 13.5
1990-12-30 00:00:00 | 15.7
1990-12-31 00:00:00 | 13
(3650 rows)
```

2. Use [MOVING_AVERAGE](#) to create the moving-average model `MA_temperature` from the `temp_data` dataset. In this case, the model is trained with a lag of $p=3$, taking the error of 3 previous predictions into account for each estimation:

```
=> SELECT MOVING_AVERAGE('MA_temperature', 'temp_data', 'temperature', 'time' USING PARAMETERS q=3, missing='linear_interpolation', regularity='regular') AS MOVING_AVERAGE
Finished. 3650 elements accepted, 0 elements rejected.
(1 row)
```

You can view a summary of the model with [GET_MODEL_SUMMARY](#):

```
=> SELECT GET_MODEL_SUMMARY(USING PARAMETERS model_name='MA_temperature');

GET_MODEL_SUMMARY

Model management

Vertica provides a number of tools to manage existing models. You can view model summaries and attributes, alter model characteristics like name and privileges, drop models, and version models.

In this section

- [Model versioning](#)
- [Altering models](#)
- [Dropping models](#)
- [Managing model security](#)
- [Viewing model attributes](#)
- [Summarizing models](#)
- [Viewing models](#)

Model versioning

Model versioning provides an infrastructure to track and manage the status of registered models in a database. The versioning infrastructure supports a collaborative environment where multiple users can submit candidate models for individual applications, which are identified by their *registered_name*. Models in Vertica are by default unregistered, but any user with sufficient privileges can register a model to an application and add it to the versioning environment.

Register models

When a candidate model is ready to be submitted to an application, the model owner or any user with sufficient privileges, including any user with the DBADMIN or [MLSUPERVISOR](#) role, can register the model using the [REGISTER_MODEL](#) function. The registered model is assigned an initial status of 'under_review' and is visible in the [REGISTERED_MODELS](#) system table to users with USAGE privileges.

All registered models under a given *registered_name* are considered different versions of the same model, regardless of trainer, algorithm type, or production status. If a model is the first to be registered to a given *registered_name*, the model is assigned a *registered_version* of one. Otherwise, newly registered models are assigned an incremented *registered_version* of $n + 1$, where n is the number of models already registered to the given *registered_name*. Each registered model can be uniquely identified by the combination of *registered_name* and *registered_version*.

Change model status

After a model is registered, the model owner is automatically changed to superuser and the previous owner is given USAGE privileges. The MLSUPERVISOR role has full privileges over all registered models, as does dbadmin. Only users with these two roles can call the [CHANGE_MODEL_STATUS](#) function to change the status of registered models. There are six possible statuses for registered models:

- **under_review**: Status assigned to newly registered models.
- **staging**: Model is targeted for A/B testing against the model currently in production.
- **production**: Model is in production for its specified application. Only one model can be in production for a given *registered_name* at one time.
- **archived**: Status of models that were previously in production. Archived models can be returned to production at any time.
- **declined**: Model is no longer in consideration for production.
- **unregistered**: Model is removed from the versioning environment. The model does not appear in the REGISTERED_MODELS system table.

The following diagram depicts the valid status transitions:

Note

If you change the status of a model to 'production' and there is already a model in production under the given *registered_name*, the status of the new model is set to 'production' and that of the old model to 'archived'.

You can view the status history of registered models with the [MODEL_STATUS_HISTORY](#) system table, which includes models that have been unregistered or dropped. Only superusers or users to whom they have granted sufficient privileges can query the table. Vertica recommends granting access on the table to the MLSUPERVISOR role.

Only users with the `MLSUPERVISOR` role, or those granted equivalent privileges, can drop or alter registered models. As with unregistered models, you can drop and alter registered models with the [DROP MODEL](#) and [ALTER MODEL](#) commands. Dropped models no longer appear in the [REGISTERED_MODELS](#) system table.

To make predictions with a registered model, you must use the [*schema_name.*] *model_name* and `predict` function for the appropriate model type. You can find all necessary information in the [REGISTERED_MODELS](#) system table.

Model registration does not effect the process of exporting models. However, model registration information, such as *registered_version*, is not captured in exported models. All imported models are initially unregistered, but each category of imported model—native Vertica, PMML, and TensorFlow—is compatible with model versioning.

Examples

The following example demonstrates a possible model versioning workflow. This workflow begins with registering multiple models to an application, continues with an `MLSUPERVISOR` managing and changing the status of those models, and concludes with one of the models in production.

First, the models must be registered to an application. In this case, the models, *native_linear_reg* and *linear_reg_spark1*, are registered as the *linear_reg_app* application:

```
=> SELECT REGISTER_MODEL('native_linear_reg', 'linear_reg_app');
      REGISTER_MODEL
-----
Model [native_linear_reg] is registered as [linear_reg_app], version [2]
(1 row)

=> SELECT REGISTER_MODEL('linear_reg_spark1', 'linear_reg_app');
      REGISTER_MODEL
-----
Model [linear_reg_spark1] is registered as [linear_reg_app], version [3]
(1 row)
```

You can query the [REGISTERED_MODELS](#) system table to view details about the newly registered models, such as the version number and model status:

```
=> SELECT * FROM REGISTERED_MODELS;
registered_name | registered_version | status | registered_time | model_id | schema_name | model_name | model_type |
category
-----+-----+-----+-----+-----+-----+-----+-----
linear_reg_app | 3 | UNDER_REVIEW | 2023-01-26 09:52:00.082166-04 | 45035996273714020 | public | linear_reg_spark1 |
PMML_REGRESSION_MODEL | PMML
linear_reg_app | 2 | UNDER_REVIEW | 2023-01-26 09:51:04.553102-05 | 45035996273850350 | public | native_linear_reg |
LINEAR_REGRESSION | VERTICA_MODELS
linear_reg_app | 1 | PRODUCTION | 2023-01-24 05:29:25.990626-02 | 45035996273853740 | public | linear_reg_newton |
LINEAR_REGRESSION | VERTICA_MODELS
logistic_reg_app | 1 | PRODUCTION | 2023-01-23 08:49:25.990626-02 | 45035996273853740 | public | log_reg_cgd |
LOGISTIC_REGRESSION | VERTICA_MODELS
(4 rows)
```

If you query the [MODELS](#) system table, you can see that the model owner has automatically been changed to superuser, `dbadmin` in this case:

```
=> SELECT model_name, owner_name FROM MODELS WHERE model_name IN ('native_linear_reg', 'linear_reg_spark1');
 model_name | owner_name
-----+-----
native_linear_reg | dbadmin
linear_reg_spark1 | dbadmin
(2 rows)
```

As a user with the `MLSUPERVISOR` role enabled, you can then change the status of both models to 'staging' with the [CHANGE_MODEL_STATUS](#) function, which accepts a *registered_name* and *registered_version* :

```
=> SELECT CHANGE_MODEL_STATUS('linear_reg_app', 2, 'staging');
CHANGE_MODEL_STATUS
```

The status of model [linear_reg_app] - version [2] is changed to [staging]
(1 row)

```
=> SELECT CHANGE_MODEL_STATUS('linear_reg_app', 3, 'staging');
CHANGE_MODEL_STATUS
```

The status of model [linear_reg_app] - version [3] is changed to [staging]
(1 row)

After comparing the evaluation metrics of the two staged models against the model currently in production, you can put the better performing model into production. In this case, the [linear_reg_spark1](#) model is moved into production and the [linear_reg_spark1](#) model is declined:

```
=> SELECT CHANGE_MODEL_STATUS('linear_reg_app', 2, 'declined');
CHANGE_MODEL_STATUS
```

The status of model [linear_reg_app] - version [2] is changed to [declined]
(1 row)

```
=> SELECT CHANGE_MODEL_STATUS('linear_reg_app', 3, 'production');
CHANGE_MODEL_STATUS
```

The status of model [linear_reg_app] - version [3] is changed to [production]
(1 row)

You can then query the [REGISTERED_MODELS](#) system table to confirm that the [linear_reg_spark1](#) model is now in 'production', the [native_linear_reg](#) model has been set to 'declined', and the previously in production [linear_reg_spark1](#) model has been automatically moved to 'archived':

```
=> SELECT * FROM REGISTERED_MODELS;
```

registered_name	registered_version	status	registered_time	model_id	schema_name	model_name	model_type	category
-----------------	--------------------	--------	-----------------	----------	-------------	------------	------------	----------

linear_reg_app	3	PRODUCTION	2023-01-26 09:52:00.082166-04	45035996273714020	public	linear_reg_spark1

logistic_reg_app	1	PRODUCTION	2023-01-23 08:49:25.990626-02	45035996273853740	public	log_reg_cgd		
LOGISTIC_REGRESSION							VERTICA_MODELS	

(4 rows)

To remove the declined [native_linear_reg](#) model from the versioning environment, you can set the status to 'unregistered':

```
=> SELECT CHANGE_MODEL_STATUS('linear_reg_app', 2, 'unregistered');
CHANGE_MODEL_STATUS
```

The status of model [linear_reg_app] - version [2] is changed to [unregistered]

(1 row)

```
=> SELECT * FROM REGISTERED_MODELS;
```

```
registered_name | registered_version | status | registered_time | model_id | schema_name | model_name | model_type |
category
```

```
linear_reg_app | 3 | PRODUCTION | 2023-01-26 09:52:00.082166-04 | 45035996273714020 | public | linear_reg_spark1 |
PMML_REGRESSION_MODEL | PMML
```

```
linear_reg_app | 1 | ARCHIVED | 2023-01-24 05:29:25.990626-02 | 45035996273853740 | public | linear_reg_newton |
LINEAR_REGRESSION | VERTICA_MODELS
```

```
logistic_reg_app | 1 | PRODUCTION | 2023-01-23 08:49:25.990626-02 | 45035996273853740 | public | log_reg_cgd |
LOGISTIC_REGRESSION | VERTICA_MODELS
```

(3 rows)

You can see that the [native_linear_reg](#) model no longer appears in the REGISTERED_MODELS system table. However, you can still query the [MODEL_STATUS_HISTORY](#) system table to view the status history of [native_linear_reg](#) :

```
=> SELECT * FROM MODEL_STATUS_HISTORY WHERE model_id=45035996273850350;
```

```
registered_name | registered_version | new_status | old_status | status_change_time | operator_id | operator_name | model_id |

Altering models

You can modify a model using [ALTER MODEL](#), in response to your model's needs. You can alter a model by renaming the model, changing the owner, and changing the schema.

You can drop or alter any model that you create.

In this section

- [Changing model ownership](#)
- [Moving models to another schema](#)
- [Renaming a model](#)

Changing model ownership

As a superuser or model owner, you can reassign model ownership with [ALTER MODEL](#) as follows:

```
ALTER MODEL model-name OWNER TO owner-name
```

Changing model ownership is useful when a model owner leaves or changes responsibilities. Because you can change the owner, the models do not need to be rewritten.

Example

The following example shows how you can use ALTER_MODEL to change the model owner:

1. Find the model you want to alter. As the dbadmin, you own the model.

```
=> SELECT * FROM V_CATALOG.MODELS WHERE model_name='mykmeansmodel';
-[ RECORD 1 ]--+-----
model_id   | 45035996273816618
model_name | mykmeansmodel
schema_id  | 45035996273704978
schema_name | public
owner_id   | 45035996273704962
owner_name | dbadmin
category   | VERTICA_MODELS
model_type  | kmeans
is_complete | t
create_time | 2017-03-02 11:16:04.990626-05
size       | 964
```

2. Change the model owner from dbadmin to user1.

```
=> ALTER MODEL mykmeansmodel OWNER TO user1;
ALTER MODEL
```

3. Review [V_CATALOG.MODELS](#) to verify that the owner was changed.

```
=> SELECT * FROM V_CATALOG.MODELS WHERE model_name='mykmeansmodel';

-[ RECORD 1 ]--+-----
model_id   | 45035996273816618
model_name | mykmeansmodel
schema_id  | 45035996273704978
schema_name | public
owner_id   | 45035996273704962
owner_name | user1
category   | VERTICA_MODELS
model_type  | kmeans
is_complete | t
create_time | 2017-03-02 11:16:04.990626-05
size       | 964
```

Moving models to another schema

You can move a model from one schema to another with [ALTER MODEL](#). You can move the model as a superuser or user with [USAGE](#) privileges on the current schema and [CREATE](#) privileges on the destination schema.

Example

The following example shows how you can use [ALTER MODEL](#) to change the model schema:

1. Find the model you want to alter.

```
=> SELECT * FROM V_CATALOG.MODELS WHERE model_name='mykmeansmodel';
-[ RECORD 1 ]--+-----
model_id   | 45035996273816618
model_name | mykmeansmodel
schema_id  | 45035996273704978
schema_name | public
owner_id   | 45035996273704962
owner_name | dbadmin
category   | VERTICA_MODELS
model_type  | kmeans
is_complete | t
create_time | 2017-03-02 11:16:04.990626-05
size       | 964
```

2. Change the model schema.

```
=> ALTER MODEL mykmeansmodel SET SCHEMA test;
ALTER MODEL
```

3. Review [V_CATALOG.MODELS](#) to verify that the owner was changed.

```
=> SELECT * FROM V_CATALOG.MODELS WHERE model_name='mykmeansmodel';
```

```
-[ RECORD 1 ]--+-+-----
model_id    | 45035996273816618
model_name  | mykmeansmodel
schema_id   | 45035996273704978
schema_name | test
owner_id    | 45035996273704962
owner_name  | dbadmin
category    | VERTICA_MODELS
model_type  | kmeans
is_complete | t
create_time | 2017-03-02 11:16:04.990626-05
size        | 964
```

Renaming a model

[ALTER MODEL](#) lets you rename models. For example:

1. Find the model you want to alter.

```
=> SELECT * FROM V_CATALOG.MODELS WHERE model_name='mymodel';
```

```
-[ RECORD 1 ]--+-+-----
model_id    | 45035996273816618
model_name  | mymodel
schema_id   | 45035996273704978
schema_name | public
owner_id    | 45035996273704962
owner_name  | dbadmin
category    | VERTICA_MODELS
model_type  | kmeans
is_complete | t
create_time | 2017-03-02 11:16:04.990626-05
size        | 964
```

2. Rename the model.

```
=> ALTER MODEL mymodel RENAME TO mykmeansmodel;
ALTER MODEL
```

3. Review [V_CATALOG.MODELS](#) to verify that the model name was changed.

```
=> SELECT * FROM V_CATALOG.MODELS WHERE model_name='mykmeansmodel';
```

```
-[ RECORD 1 ]--+-+-----
model_id    | 45035996273816618
model_name  | mykmeansmodel
schema_id   | 45035996273704978
schema_name | public
owner_id    | 45035996273704962
owner_name  | dbadmin
category    | VERTICA_MODELS
model_type  | kmeans
is_complete | t
create_time | 2017-03-02 11:16:04.990626-05
size        | 964
```

Dropping models

[DROP MODEL](#) removes one or more models from the database. For example:

1. Find the model you want to drop.

```
=> SELECT * FROM V_CATALOG.MODELS WHERE model_name='mySvmClassModel';
-[ RECORD 1 ]-----
model_id   | 45035996273765414
model_name | mySvmClassModel
schema_id  | 45035996273704978
schema_name | public
owner_id   | 45035996273704962
owner_name | dbadmin
category   | VERTICA_MODELS
model_type  | SVM_CLASSIFIER
is_complete | t
create_time | 2017-02-14 10:30:44.903946-05
size       | 525
```

2. Drop the model.

```
=> DROP MODEL mySvmClassModel;
DROP MODEL
```

3. Review `V_CATALOG.MODELS` to verify that the model was dropped.

```
=> SELECT * FROM V_CATALOG.MODELS WHERE model_name='mySvmClassModel';
(0 rows)
```

Managing model security

You can manage the security privileges on your models by using the GRANT and REVOKE statements. The following examples show how you can change privileges on user1 and user2 using the `faithful` table and the `linearReg` model.

- In the following example, the dbadmin grants the SELECT privilege to user1:

```
=> GRANT SELECT ON TABLE faithful TO user1;
GRANT PRIVILEGE
```

- Then, the dbadmin grants the CREATE privilege on the public schema to user1:

```
=> GRANT CREATE ON SCHEMA public TO user1;
GRANT PRIVILEGE
```

- Connect to the database as user1:

```
=> \c - user1
```

- As user1, build the `linearReg` model:

```
=> SELECT LINEAR_REG('linearReg', 'faithful', 'waiting', 'eruptions');
LINEAR_REG
-----
Finished in 1 iterations
(1 row)
```

- As user1, grant USAGE privileges to user2:

```
=> GRANT USAGE ON MODEL linearReg TO user2;
GRANT PRIVILEGE
```

- Connect to the database as user2:

```
=> \c - user2
```

- To confirm privileges were granted to user2, run the `GET_MODEL_SUMMARY` function. A user with the USAGE privilege on a model can run `GET_MODEL_SUMMARY` on that model:

```
=> SELECT GET_MODEL_SUMMARY(USING PARAMETERS model_name='linearReg');
```

```
=====
```

```
details
```

```

Using external models with Vertica

To give you the utmost in machine learning flexibility and scalability, Vertica supports importing, exporting, and predicting with PMML and TensorFlow models.

The machine learning configuration parameter [MaxModelSizeKB](#) sets the maximum size of a model that can be imported into Vertica.

Support for PMML models

Vertica supports the import and export of machine learning models in Predictive Model Markup Language (PMML) format. Support for this platform-independent model format allows you to use models trained on other platforms to predict on data stored in your Vertica database. You can also use Vertica as your model repository. Vertica supports [PMML version 4.4.1](#).

With the [PREDICT_PMML](#) function, you can use a PMML model archived in Vertica to run prediction on data stored in the Vertica database. For more information, see [Using PMML models](#).

For details on the PMML models, tags, and attributes that Vertica supports, see [PMML features and attributes](#).

Support for TensorFlow models

Vertica now supports importing trained TensorFlow models, and using those models to do prediction in Vertica on data stored in the Vertica database. Vertica supports TensorFlow models trained in TensorFlow version 1.15.

The [PREDICT_TENSORFLOW](#) and [PREDICT_TENSORFLOW_SCALAR](#) functions let you predict on data in Vertica with TensorFlow models.

For additional information, see [TensorFlow models](#).

Additional external model support

The following functions support both PMML and TensorFlow models:

- [IMPORT_MODELS](#)
- [EXPORT_MODELS](#)
- [GET_MODEL_ATTRIBUTE](#)
- [GET_MODEL_SUMMARY](#)

In this section

- [TensorFlow models](#)
- [Using PMML models](#)

TensorFlow models

[Tensorflow](#) is a framework for creating neural networks. It implements basic linear algebra and multi-variable calculus operations in a scalable fashion, and allows users to easily chain these operations into a computation graph.

Vertica supports importing, exporting, and making predictions with [TensorFlow](#) 1.x and 2.x models trained outside of Vertica.

In-database TensorFlow integration with Vertica offers several advantages:

- Your models live inside your database, so you never have to move your data to make predictions.
- The volume of data you can handle is limited only by the size of your Vertica database, which makes Vertica particularly well-suited for machine learning on Big Data.
- Vertica offers in-database model management, so you can store as many models as you want.
- Imported models are portable and can be exported for use elsewhere.

When you run a TensorFlow model to predict on data in the database, Vertica calls a TensorFlow process to run the model. This allows Vertica to support any model you can create and train using TensorFlow. Vertica just provides the inputs - your data in the Vertica database - and stores the outputs.

In this section

- [TensorFlow integration and directory structure](#)
- [TensorFlow example](#)
- [tf_model_desc.json overview](#)

TensorFlow integration and directory structure

This page covers importing Tensorflow models into Vertica, making predictions on data in the Vertica database, and exporting the model for use on another Vertica cluster or a third-party platform.

For a start-to-finish example through each operation, see [TensorFlow example](#).

Vertica supports models created with either TensorFlow 1.x and 2.x, but 2.x is strongly recommended.

To use TensorFlow with Vertica, install the TFIntegration UDX package on any node. You only need to do this once:

```
$ /opt/vertica/bin/admintools -t install_package -d database_name -p 'password' --package TFIntegration
```

Directory and file structure for TensorFlow models

Before importing your models, you should have a separate directory for each model that contains each of the following files. Note that Vertica uses the directory name as the model name when you import it:

- *model_name.pb* : a trained model in frozen graph format
- *tf_model_desc.json* : a description of the model

For example, a *tf_models* directory that contains two models, *tf_mnist_estimator* and *tf_mnist_keras* , has the following layout:

```
tf_models/
├── tf_mnist_estimator
│   ├── mnist_estimator.pb
│   └── tf_model_desc.json
└── tf_mnist_keras
    ├── mnist_keras.pb
    └── tf_model_desc.json
```

You can generate both of these files for a given TensorFlow 2 (TF2) model with the [freeze_tf2_model.py](#) script included in the [Machine-Learning-Examples](#) GitHub repository and in the `opt/vertica/packages/TFIntegration/examples` directory in the Vertica database. The script accepts three arguments:

model-path

Path to a saved TF2 model directory.

folder-name

(Optional) Name of the folder to which the frozen model is saved; by default, `frozen_tfmodel`.

column-type

(Optional) Integer, either 0 or 1, that signifies whether the input and output columns for the model are primitive or complex types. Use a value of 0 (default) for primitive types, or 1 for complex.

For example, the following call outputs the frozen `tf_autoencoder` model, which accepts complex input/output columns, into the `frozen_autoencoder` folder:

```
$ python3 ./freeze_tf2_model.py path/to/tf_autoencoder frozen_autoencoder 1
```

`tf_model_desc.json`

The `tf_model_desc.json` file forms the bridge between TensorFlow and Vertica. It describes the structure of the model so that Vertica can correctly match up its inputs and outputs to input/output tables.

Notice that the `freeze_tf2_model.py` script automatically generates this file for your TensorFlow 2 model, and this generated file can often be used as-is. For more complex models or use cases, you might have to edit this file. For a detailed breakdown of each field, see [tf_model_desc.json overview](#).

Importing TensorFlow models into Vertica

To import TensorFlow models, use `IMPORT_MODELS` with the category `'TensorFlow'`.

Import a single model. Keep in mind that the Vertica database uses the directory name as the model name:

```
select IMPORT_MODELS ('/path/tf_models/tf_mnist_keras' USING PARAMETERS category='TensorFlow');
import_models
-----
Success
(1 row)
```

Import all models in the directory (where each model has its own directory) with a wildcard (*):

```
select IMPORT_MODELS ('/path/tf_models/*' USING PARAMETERS category='TensorFlow');
import_models
-----
Success
(1 row)
```

Make predictions with an imported TensorFlow model

After importing your TensorFlow model, you can use the model to predict on data in a Vertica table. Vertica provides two functions for making predictions with imported TensorFlow models: `PREDICT_TENSORFLOW` and `PREDICT_TENSORFLOW_SCALAR`.

The function you choose depends on whether you specified a `column-type` of 0 or 1 when calling the `freeze_tf2_model.py` script. If `column-type` was 0, meaning the model accepts primitive input and output types, use `PREDICT_TENSORFLOW` to make predictions; otherwise, use `PREDICT_TENSORFLOW_SCALAR`, as your model should accept complex input and output types.

Using `PREDICT_TENSORFLOW`

The `PREDICT_TENSORFLOW` function is different from the other predict functions in that it does not accept any parameters that affect the input columns such as `exclude_columns` or `id_column`; rather, the function always predicts on all the input columns provided. However, it does accept a `num_passthru_cols` parameter which allows the user to "skip" some number of input columns, as shown below.

The `OVER(PARTITION BEST)` clause tells Vertica to parallelize the operation across multiple nodes. See [Window partition clause](#) for details:

```
=> select PREDICT_TENSORFLOW (*
      USING PARAMETERS model_name='tf_mnist_keras', num_passthru_cols=1)
      OVER(PARTITION BEST) FROM tf_mnist_test_images;
```

--example output, the skipped columns are displayed as the first columns of the output

```
ID | col0 | col1 | col2 | col3 | col4 | col5 | col6 | col7 | col8 | col9
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----
 1 |  0 |  0 |  1 |  0 |  0 |  0 |  0 |  0 |  0 |  0
 3 |  1 |  0 |  0 |  0 |  0 |  0 |  0 |  0 |  0 |  0
 6 |  0 |  0 |  0 |  0 |  1 |  0 |  0 |  0 |  0 |  0
...
```

Using `PREDICT_TENSORFLOW_SCALAR`

The `PREDICT_TENSORFLOW_SCALAR` function accepts one input column of type [ROW](#), where each field corresponds to an input tensor. It returns one output column of type `ROW`, where each field corresponds to an output tensor. This complex type support can simplify the process for making predictions on data with many input features.

For instance, the [MNIST handwritten digit classification dataset](#) contains 784 input features for each input row, one feature for each pixel in the images of handwritten digits. The `PREDICT_TENSORFLOW` function requires that each of these input features are contained in a separate input column. By encapsulating these features into a single `ARRAY`, the `PREDICT_TENSORFLOW_SCALAR` function only needs a single input column of type `ROW`, where the pixel values are the array elements for an input field:

```
--Each array for the "image" field has 784 elements.
```

```
=> SELECT * FROM mnist_train;
id |          inputs
---+-----
 1 | {"image":[0, 0, 0, ..., 244, 222, 210, ...]}
 2 | {"image":[0, 0, 0, ..., 185, 84, 223, ...]}
 3 | {"image":[0, 0, 0, ..., 133, 254, 78, ...]}
 ...
```

In this case, the function output consists of a single operation with one tensor. The value of this field is an array of ten elements, which are all zero except for the element whose index is the predicted digit:

```
=> SELECT id, PREDICT_TENSORFLOW_SCALAR(inputs USING PARAMETERS model_name='tf_mnist_ct') FROM mnist_test;
id |          PREDICT_TENSORFLOW_SCALAR
---+-----
 1 | {"prediction:0":["0", "0", "0", "0", "1", "0", "0", "0", "0", "0"]}
 2 | {"prediction:0":["0", "1", "0", "0", "0", "0", "0", "0", "0", "0"]}
 3 | {"prediction:0":["0", "0", "0", "0", "0", "0", "0", "1", "0", "0"]}
 ...
```

Exporting TensorFlow models

Vertica exports the model as a frozen graph, which can then be re-imported at any time. Keep in mind that models that are saved as a frozen graph cannot be trained further.

Use [EXPORT_MODELS](#) to export TensorFlow models. For example, to export the `tf_mnist_keras` model to the `/path/to/export/to` directory:

```
=> SELECT EXPORT_MODELS ('/path/to/export/to', 'tf_mnist_keras');
export_models
-----
Success
(1 row)
```

When you export a TensorFlow model, the Vertica database creates and uses the specified directory to store files that describe the model:

```
$ ls tf_mnist_keras/
crc.json metadata.json mnist_keras.pb model.json tf_model_desc.json
```

The `.pb` and `tf_model_desc.json` files describe the model, and the rest are organizational files created by the Vertica database.

File Name	Purpose
<code>model_name.pb</code>	Frozen graph of the model.
<code>tf_model_desc.json</code>	Describes the model.
<code>crc.json</code>	Keeps track of files in this directory and their sizes. It is used for importing models.
<code>metadata.json</code>	Contains Vertica version, model type, and other information.
<code>model.json</code>	More verbose version of <code>tf_model_desc.json</code> .

TensorFlow example

Vertica uses the TFIntegration UDX package to integrate with TensorFlow. You can train your models outside of your Vertica database, then import them to Vertica and make predictions on your data.

TensorFlow scripts and datasets are included in the GitHub repository under [Machine-Learning-Examples/TensorFlow](#).

The example below creates a Keras (a TensorFlow API) neural network model trained on the [MNIST handwritten digit classification dataset](#), the layers of which are shown below.

The data is fed through each layer from top to bottom, and each layer modifies the input before returning a score. In this example, the data passed in is a set of images of handwritten Arabic numerals and the output would be the probability of the input image being a particular digit:

```
inputs = keras.Input(shape=(28, 28, 1), name="image")
x = layers.Conv2D(32, 5, activation="relu")(inputs)
x = layers.MaxPooling2D(2)(x)
x = layers.Conv2D(64, 5, activation="relu")(x)
x = layers.MaxPooling2D(2)(x)
x = layers.Flatten()(x)
x = layers.Dense(10, activation='softmax', name='OUTPUT')(x)
tfmodel = keras.Model(inputs, x)
```

For more information on how TensorFlow interacts with your Vertica database and how to import more complex models, see [TensorFlow integration and directory structure](#).

Prepare a TensorFlow model for Vertica

The following procedures take place outside of Vertica.

Train and save a TensorFlow model

1. [Install TensorFlow 2](#).
2. Train your model. For this particular example, you can run [train_simple_model.py](#) to train and save the model. Otherwise, [and more generally, you can manually train your model in Python](#) and then [save it](#):

```
$ mymodel.save('my_saved_model_dir')
```

3. Run the [freeze_tf2_model.py](#) script included in the [Machine-Learning-Examples repository](#) or in `opt/vertica/packages/TFIntegration/examples`, specifying your model, an output directory (optional, defaults to `frozen_tfmodel`), and the input and output column type (0 for primitive, 1 for complex).

This script transforms your saved model into the Vertica-compatible frozen graph format and creates the `tf_model_desc.json` file, which describes how Vertica should translate its tables to TensorFlow tensors:

```
$ ./freeze_tf2_model.py path/to/tf/model frozen_model_dir 0
```

Import TensorFlow models and make predictions in Vertica

1. If you haven't already, as `dbadmin`, install the TFIntegration UDX package on any node. You only need to do this once.

```
$ /opt/vertica/bin/admintools -t install_package -d database_name -p 'password' --package TFIntegration
```

2. Copy the `directory` to any node in your Vertica cluster and import the model:

```
=> SELECT IMPORT_MODELS('path/to/frozen_model_dir' USING PARAMETERS category='TENSORFLOW');
```

3. Import the dataset you want to make a prediction on. For this example:

1. Copy the [Machine-Learning-Examples/TensorFlow/data](#) directory to any node on your Vertica cluster.
2. From that `data` directory, run the SQL script [load_tf_data.sql](#) to load the MNIST dataset:

```
$ vsql -f load_tf_data.sql
```

4. Make a prediction with your model on your dataset with [PREDICT_TENSORFLOW](#). In this example, the model is used to classify the images of handwritten numbers in the MNIST dataset:

```
=> SELECT PREDICT_TENSORFLOW (*
      USING PARAMETERS model_name='tf_mnist_keras', num_passthru_cols=1)
      OVER(PARTITION BEST) FROM tf_mnist_test_images;
```

--example output, the skipped columns are displayed as the first columns of the output

```
ID | col0 | col1 | col2 | col3 | col4 | col5 | col6 | col7 | col8 | col9
```

```
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----
1 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0
3 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0
6 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 0
...
```

Note

Because a *column-type* of 0 was used when calling the `freeze_tf2_model.py` script, the `PREDICT_TENSORFLOW` function must be used to make predictions. If *column-type* was 1, meaning the model accepts complex input and output types, predictions must be made with the `PREDICT_TENSORFLOW_SCALAR` function.

5. To export the model with `EXPORT_MODELS`:

```
=> SELECT EXPORT_MODELS('/path/to/export/to', 'tf_mnist_keras');
EXPORT_MODELS
```

```
-----
Success
(1 row)
```

Note

While you cannot continue training a TensorFlow model after you export it from Vertica, you can use it to predict on data in another Vertica cluster, or outside Vertica on another platform.

TensorFlow 1 (deprecated)

1. [Install TensorFlow 1.15](#) with Python 3.7 or below.
2. Run `train_save_model.py` in [Machine-Learning-Examples/TensorFlow/tf1](#) to train and save the model in TensorFlow and frozen graph formats.

Note

Vertica does not supply a script to save and freeze TensorFlow 1 models that use complex column types.

- [TensorFlow models](#)
- [User-defined extensions](#)

tf_model_desc.json overview

Before importing your externally trained TensorFlow models, you must:

- save the model in frozen graph (`.pb`) format
- create `tf_model_desc.json`, which describes to your Vertica database how to map its inputs and outputs to input/output tables

Conveniently, the script `freeze_tf2_model.py` included in the `TensorFlow` directory of the [Machine-Learning-Examples](#) repository (and in `opt/vertica/packages/TFIntegration/examples`) will do both of these automatically. In most cases, the generated `tf_model_desc.json` can be used as-is, but for more complex datasets and use cases, you might need to edit it.

The contents of the `tf_model_desc.json` file depend on whether you provide a *column-type* of 0 or 1 when calling the `freeze_tf2_model.py` script. If *column-type* is 0, the imported model accepts primitive input and output columns. If it is 1, the model accepts complex input and output columns.

Models that accept primitive types

The following `tf_model_desc.json` is generated from the MNIST handwriting dataset used by the [TensorFlow example](#).

```
{
  "frozen_graph": "mnist_keras.pb",
  "input_desc": [
    {
      "op_name": "image_input",
      "tensor_map": [
        {
          "idx": 0,
          "dim": [
            1,
            28,
            28,
            1
          ],
          "col_start": 0
        }
      ]
    }
  ],
  "output_desc": [
    {
      "op_name": "OUTPUT/Softmax",
      "tensor_map": [
        {
          "idx": 0,
          "dim": [
            1,
            10
          ],
          "col_start": 0
        }
      ]
    }
  ]
}
```

This file describes the structure of the model's inputs and outputs. It must contain a `frozen_graph` field that matches the filename of the .pb model, an `input_desc` field, and an `output_desc` field.

- `input_desc` and `output_desc` : the descriptions of the input and output nodes in the TensorFlow graph. Each of these include the following fields:
 - `op_name` : the name of the operation node which is set when creating and training the model. You can typically retrieve the names of these parameters from `tfmodel.inputs` and `tfmodel.outputs` . For example:

```
$ print({t.name:t for t in tfmodel.inputs})
{'image_input:0': <tf.Tensor 'image_input:0' shape=(?, 28, 28, 1) dtype=float32>}
```

```
$ print({t.name:t for t in tfmodel.outputs})
{'OUTPUT/Softmax:0': <tf.Tensor 'OUTPUT/Softmax:0' shape=(?, 10) dtype=float32>}
```

In this case, the respective values for `op_name` would be the following.

- `input_desc` : `image_input`
- `output_desc` : `OUTPUT/Softmax`

For a more detailed example of this process, review the code for `freeze_tf2_model.py` .

- `tensor_map` : how to map the tensor to Vertica columns, which can be specified with the following:
 - `idx` : the index of the output tensor under the given operation (should be 0 for the first output, 1 for the second output, etc.).
 - `dim` : the vector holding the dimensions of the tensor; it provides the number of columns.
 - `col_start` (only used if `col_idx` is not specified): the starting column index. When used with `dim` , it specifies a range of indices of Vertica columns starting at `col_start` and ending at `col_start + flattened_tensor_dimension` . Vertica starts at the column specified by the index `col_start` and gets the next `flattened_tensor_dimension` columns.

- **col_idx** : the indices in the Vertica columns corresponding to the flattened tensors. This allows you explicitly specify the indices of the Vertica columns that couldn't otherwise be specified as a simple range with **col_start** and **dim** (e.g. 1, 3, 5, 7).
- **data_type** (not shown): the data type of the input or output, one of the following:
 - TF_FLOAT (default)
 - TF_DOUBLE
 - TF_INT8
 - TF_INT16
 - TF_INT32
 - TF_INT64

Below is a more complex example that includes multiple inputs and outputs:

```
{
  "input_desc": [
    {
      "op_name": "input1",
      "tensor_map": [
        {
          "idx": 0,
          "dim": [
            4
          ],
          "col_idx": [
            0,
            1,
            2,
            3
          ]
        }
      ],
      {
        "idx": 1,
        "dim": [
          2,
          2
        ],
        "col_start": 4
      }
    ]
  },
  {
    "op_name": "input2",
    "tensor_map": [
      {
        "idx": 0,
        "dim": [],
        "col_idx": [
          8
        ]
      },
      {
        "idx": 1,
        "dim": [
          2
        ],
        "col_start": 9
      }
    ]
  }
],
  "output_desc": [
    {
      "op_name": "output"
```

```

    op_name : output ,
    "tensor_map": [
      {
        "idx": 0,
        "dim": [
          2
        ],
        "col_start": 0
      }
    ]
  }
}
]
}

```

Models that accept complex types

The following `tf_model_desc.json` is generated from a model that inputs and outputs complex type columns:

```

{
  "column_type": "complex",
  "frozen_graph": "frozen_graph.pb",
  "input_tensors": [
    {
      "name": "x:0",
      "data_type": "int32",
      "dims": [
        -1,
        1
      ]
    },
    {
      "name": "x_1:0",
      "data_type": "int32",
      "dims": [
        -1,
        2
      ]
    }
  ],
  "output_tensors": [
    {
      "name": "Identity:0",
      "data_type": "float32",
      "dims": [
        -1,
        1
      ]
    },
    {
      "name": "Identity_1:0",
      "data_type": "float32",
      "dims": [
        -1,
        2
      ]
    }
  ]
}

```

As with models that accept primitive types, this file describes the structure of the model's inputs and outputs and contains a `frozen_graph` field that matches the filename of the `.pb` model. However, instead of an `input_desc` field and an `output_desc` field, models with complex types have an `input_tensors` field and an `output_tensors` field, as well as a `column_type` field.

- **column_type** : specifies that the model accepts input and output columns of complex types. When imported into Vertica, the model must make predictions using the [PREDICT_TENSORFLOW_SCALAR](#) function.
- **input_tensors** and **output_tensors** : the descriptions of the input and output tensors in the TensorFlow graph. Each of these fields include the following sub-fields:
 - **name** : the name of the tensor for which information is listed. The name is in the format of *operation:tensor-number* , where *operation* is the operation that contains the tensor and *tensor-number* is the index of the tensor under the given operation.
 - **data_type** : the data type of the elements in the input or output tensor, one of the following:
 - TF_FLOAT (default)
 - TF_DOUBLE
 - TF_INT8
 - TF_INT16
 - TF_INT32
 - TF_INT64
 - **dims** : the dimensions of the tensor. Each input/output tensor is contained in a 1D [ARRAY](#) in the input/output [ROW](#) column.

Using PMML models

Vertica can import, export, and make predictions with PMML models of [version 4.4](#) and below.

In this section

- [Exporting Vertica models in PMML format](#)
- [Importing and predicting with PMML models](#)
- [PMML features and attributes](#)

Exporting Vertica models in PMML format

You can take advantage of the built-in distributed algorithms in Vertica to train machine learning models. There might be cases in which you want to use these models for prediction outside Vertica, for example on an edge node. You can export certain Vertica models in PMML format and use them for prediction using a library or platform that supports reading and evaluating PMML models. Vertica supports the export of the following Vertica model types into PMML format: KMEANS, LINEAR_REGRESSION, LOGISTIC_REGRESSION, RF_CLASSIFIER, RF_REGRESSOR, XGB_CLASSIFIER, and XGB_REGRESSOR.

Here is an example for training a model in Vertica and then exporting it in PMML format. The following diagram shows the workflow of the example. We use vsql to run this example.

Let's assume that you want to train a logistic regression model on the data in a relation named 'patients' in order to predict the second attack of patients given their treatment and trait anxiety.

After training, the model is shown in a system table named V_CATALOG.MODELS which lists the archived ML models in Vertica.

```

=> -- Training a logistic regression model on a training_data
=> SELECT logistic_reg('myModel', 'patients', 'second_attack', 'treatment, trait_anxiety');
      logistic_reg
-----
Finished in 5 iterations

(1 row)

=> -- Looking at the models table
=> SELECT model_name, schema_name, category, model_type, create_time, size FROM models;
model_name | schema_name | category | model_type | create_time | size
-----+-----+-----+-----+-----+-----
myModel | public | VERTICA_MODELS | LOGISTIC_REGRESSION | 2020-07-28 00:05:18.441958-04 | 1845
(1 row)

```

You can look at the summary of the model using the [GET_MODEL_SUMMARY](#) function.

```

=> -- Looking at the summary of the model
=> \t
Showing only tuples.

Importing and predicting with PMML models

As a Vertica user, you can train ML models in other platforms, convert them to standard PMML format, and then import them into Vertica for in-database prediction on data stored in Vertica relations.

Here is an example of how to import a PMML model trained in Spark. The following diagram shows the workflow of the example.

You can use the [IMPORT_MODELS](#) function in a simple statement to import the PMML model. The imported model then appears in a system table named `V_CATALOG.MODELS` which lists the archived ML models in Vertica.

```
=> -- importing the PMML model trained and generated in Spark
=> SELECT import_models('/data/username/temp/spark_logistic_reg' USING PARAMETERS category='PMML');
import_models
-----
Success
(1 row)

=> -- Looking at the models table=> SELECT model_name, schema_name, category, model_type, create_time, size FROM models;

PMML features and attributes

To be compatible with Vertica, PMML models must conform to the following:

- The PMML model does not have a data preprocessing step.
- The encoded PMML model type is [ClusteringModel](#), [GeneralRegressionModel](#), [MiningModel](#), [RegressionModel](#), or [TreeModel](#).

Supported PMML tags and attributes

Geospatial analytics

Vertica provides functions that allows you to manipulate complex two- and three-dimensional spatial objects. These functions follow the Open Geospatial Consortium (OGC) standards. Vertica also provides data types and SQL functions that allow you to specify and store spatial objects in a database according to OGC standards.

Convert well-known text (WKT) and well-known binary (WKB)

Convert WKT and WKB.

Optimized spatial joins

Perform fast spatial joins using `ST_Intersects` and `STV_Intersects`.

Load and export spatial data from shapefiles

Easily load and export shapefiles.

Store and retrieve objects

Determine if:

- An object contains self-intersection or self-tangency points.
- One object is entirely within another object, such as a point within a polygon.

Test the relationships between objects

For example, if they intersect or touch:

- Identify the boundary of an object.
- Identify vertices of an object.

Calculate

- Shortest distance between two objects.
- Size of an object (length, area).
- Centroid for one or more objects.
- Buffer around one or more objects.

In this section

- [Best practices for geospatial analytics](#)
- [Spatial objects](#)
- [Working with spatial objects in tables](#)
- [Working with spatial objects from client applications](#)
- [OGC spatial definitions](#)
- [Spatial data type support limitations](#)

Best practices for geospatial analytics

Vertica recommends the following best practices when performing geospatial analytics in Vertica.

Performance optimization

Recommendation	Details
Use the minimum column size for spatial data.	Performance degrades as column widths increase. When creating columns for your spatial data, use the smallest size column that can accommodate your data. For example, use <code>GEOMETRY(85)</code> for point data.
Use <code>GEOMETRY</code> types where possible.	Performance of functions on <code>GEOGRAPHY</code> types is slower than functions that support <code>GEOMETRY</code> types. Use <code>GEOMETRY</code> types where possible.
To improve the performance of the following functions, sort projections on spatial columns: <ul style="list-style-type: none">• <code>STV_Intersect</code> scalar function• <code>ST_Distance</code>• <code>ST_Area</code>• <code>ST_Length</code>	You may improve the pruning efficiency of these functions by sorting the projection on the <code>GEOMETRY</code> column. However, sorting on a large <code>GEOMETRY</code> column may slow down data load.

Spatial joins with points and polygons

Vertica provides two ways to identify whether a set of points intersect with a set of polygons. Depending on the size of your data set, choose the approach that gives the best performance.

For a detailed example of best practices with spatial joins, see [Best practices for spatial joins](#).

Recommendation	Details
Use <code>ST_Intersects</code> to intersect a constant geometry with a set of geometries.	<p>When you intersect a set of geometries with a geometry, use the <code>ST_Intersects</code> function. Express the constant geometry argument as a WKT or WKB. For example:</p> <pre>ST_Intersects(geom,ST_GeomFromText('POLYGON((43.1 50.1,43.1 59.0, 48.9 59.0,43.1 50.1))'))</pre> <p>For more information, see Performing spatial joins with ST_Intersects.</p>
Create a spatial index only when performing spatial joins with <code>STV_Intersect</code> .	Spatial indexes should only be used with <code>STV_Intersect</code> . Creating a spatial index and then performing spatial joins with <code>ST_Intersects</code> will not improve performance.
Use the <code>STV_Intersect</code> function when you intersect a set of points with a set of polygons.	<p>Determine if a set of points intersects with a set of polygons in a medium to large data set. First, create a spatial index using <code>STV_Create_Index</code>. Then, use one of the <code>STV_Intersect</code> functions to return the set of pairs that intersect.</p> <p>Spatial indexes provide the best performance for accessing a large number of polygons.</p>
When using the <code>STV_Intersect</code> transform function, partition the data and use an <code>OVER(PARTITION BEST)</code> clause.	The STV_Intersect transform function does not require that you partition the data. However, you may improve performance by partitioning the data and using an <code>OVER(PARTITION BEST)</code> clause.

Spatial indexes

The `STV_Create_Index` function can consume large amounts of processing time and memory. When you index new data for the first time, monitor memory usage to be sure it stays within safe limits. Memory usage depends on:

- Number of polygons
- Number of vertices
- Amount of overlap among polygons

Recommendation	Details
Segment polygon data when a table contains a large number of polygons.	Segmenting the data allows the index creation process to run in parallel. This is advantageous because sometimes <code>STV_Create_Index</code> tasks cannot be completed when large tables that are not segmented prior to index creation.
Adjust <code>STV_Create_Index</code> parameters as needed for memory allocation and CPU usage.	<p>The <code>max_mem_mb</code> parameter can affect the resource usage of <code>STV_Create_Index</code>. <code>max_mem_mb</code> assigns a limit to the amount of memory that <code>STV_Create_Index</code> can allocate.</p> <p>Default: 256</p> <p>Valid values: Any value less than or equal to the amount of memory in the GENERAL resource pool. Assigning a higher value results in an error.</p>
Make changes if <code>STV_Create_Index</code> cannot allocate 300 MB memory.	<p>Before <code>STV_Create_Index</code> starts creating the index, it tries to allocate about 300 MB of memory. If that much memory is not available, the function fails. If you get a failure message, try these solutions:</p> <ul style="list-style-type: none"> • Create the index at a time of less load on the system. • Avoid concurrent index creation. • Add more memory to your system.
Create misplaced indexes again, if needed.	When you back up your Vertica database, spatial index files are not included. If you misplace an index, use <code>STV_Create_Index</code> to re-create it.
Use <code>STV_Refresh_Index</code> to add new or updated polygons to an existing index.	Instead of rebuilding your spatial index each time you add new or updated polygons to a table, you can use <code>STV_Refresh_Index</code> to append the polygons to your existing spatial index.

Checking polygon validity

Recommendation	Details
Run <code>ST_IsValid</code> to check if polygons are valid.	<p>Many spatial functions do not check the validity of polygons.</p> <ul style="list-style-type: none">• Run ST_IsValid on all polygons to determine if they are valid.• If your object is not valid, run STV_IsValidReason to get information about the location of the invalid polygon. <p>For more information, see Ensuring polygon validity before creating or refreshing an index.</p>

Spatial objects

Vertica implements several data types for storing spatial objects, Well-Known Text (WKT) strings, and Well-Known Binary (WKB) representations. These data types include:

- [Supported spatial objects](#)
- [Spatial reference identifiers \(SRIDs\)](#)

In this section

- [Supported spatial objects](#)
- [Spatial reference identifiers \(SRIDs\)](#)

Supported spatial objects

Vertica supports two spatial data types. These data types store two- and three-dimensional spatial objects in a table column:

- **GEOMETRY**: Spatial object with coordinates expressed as (x, y) pairs, defined in the Cartesian plane. All calculations use Cartesian coordinates.
- **GEOGRAPHY**: Spatial object defined as on the surface of a perfect sphere, or a spatial object in the WGS84 coordinate system. Coordinates are expressed in longitude/latitude angular values, measured in degrees. All calculations are in meters. For perfect sphere calculations, the sphere has a radius of 6371 kilometers, which approximates the shape of the earth.

Note

Some spatial programs use an ellipsoid to model the earth, resulting in slightly different data.

The maximum size of a **GEOMETRY** or **GEOGRAPHY** data type is 10,000,000 bytes (10 MB). You cannot use either data type as a table's primary key.

Spatial reference identifiers (SRIDs)

A *spatial reference identifier* (SRID) is an integer value that represents a method for projecting coordinates on the plane. A SRID is metadata that indicates the coordinate system in which a spatial object is defined.

Geospatial functions using Geometry arguments must contain the same SRID. If the functions do not contain the same SRID, then the query returns an error.

For example, in this query the two points have different SRIDs. As a result the query returns an error:

```
=> SELECT ST_Distance(ST_GeomFromText('POINT(34 9)',2749), ST_GeomFromText('POINT(70 12)', 3359));  
ERROR 5861: Error calling processBlock() in User Function ST_Distance at [src/Distance.cpp:65],  
error code: 0, message: Geometries with different SRIDs found: 2749, 3359
```

Supported SRIDs

Vertica supports SRIDs derived from the EPSG standards. Geospatial functions using Geometry arguments must use supported SRIDs when performing calculations. SRID values of 0 to $2^{32}-1$ are valid. Queries with SRID values outside of this range will return an error.

Working with spatial objects in tables

- [Defining table columns for spatial data](#)
- [Exporting spatial data from a table](#)
- [Identifying null spatial objects](#)

- [Loading spatial data from shapefiles](#)
- [Loading spatial data into tables using COPY](#)
- [Retrieving spatial data from a table as well-known text \(WKT\)](#)

In this section

- [Defining table columns for spatial data](#)
- [Exporting spatial data from a table](#)
- [Identifying null spatial objects](#)
- [Loading spatial data from shapefiles](#)
- [Loading spatial data into tables using COPY](#)
- [Retrieving spatial data from a table as well-known text \(WKT\)](#)
- [Working with GeoHash data](#)
- [Spatial joins with ST_Intersects and STV_Intersect](#)

Defining table columns for spatial data

To define columns to contain GEOMETRY and GEOGRAPHY data, use this command:

```
=> CREATE TABLE [[db-name.]schema.]table-name (
  column-name GEOMETRY[(length)],
  column-name GEOGRAPHY[(length)];
```

If you omit the length specification, the default column size is 1 MB. The maximum column size is 10 MB. The upper limit is not enforced, but the geospatial functions can only accept or return spatial data up to 10 MB.

You cannot modify the size or data type of a GEOMETRY or GEOGRAPHY column after creation. If the column size you created is not sufficient, create a new column with the desired size. Then copy the data from the old column, and drop the old column from the table.

You cannot import data to or export data from tables that contain spatial data from another Vertica database.

Important

A column width that is too large could impact performance. Use a column width that fits the data without being excessively large. See [STV_MemSize](#).

Exporting spatial data from a table

You can export spatial data from a table in your Vertica database to a shapefile.

To export spatial data from a table to a shapefile:

1. As the [superuser](#), set the shapefile export directory.

```
=> SELECT STV_SetExportShapefileDirectory(USING PARAMETERS path = '/home/geo/temp');
      STV_SetExportShapefileDirectory
-----
SUCCESS. Set shapefile export directory: [/home/geo/temp]
(1 row)
```

2. Export your spatial data to a shapefile.

```
=> SELECT STV_Export2Shapefile(*
      USING PARAMETERS shapefile = 'visualizations/city-data.shp',
      shape = 'Polygon') OVER() FROM spatial_data;
Rows Exported |          File Path
-----+-----
185873 | v_geo-db_node0001: /home/geo/temp/visualizations/city-data.shp
(1 row)
```

- The value asterisk (*) is the equivalent to listing all columns in the FROM clause.
 - You can specify sub-directories when exporting your shapefile.
 - Your shapefile must end with the file extension .shp.
3. Verify that three files now appear in the shapefile export directory.

```
$ ls
city-data.dbf city-data.shp city-data.shx
```

Identifying null spatial objects

You can identify null GEOMETRY and GEOGRAPHY objects using the Vertica IS NULL and IS NOT NULL constructs.

This example uses the following table, where the row with `id =2` has a null value in the `geog` field.

```
=> SELECT id, ST_AsText(geom), ST_AsText(geog) FROM locations
ORDER BY 1 ASC;
id |      ST_AsText      |      ST_AsText
+-----+-----+-----+
1 | POINT (2 3)         | POINT (-85 15)
2 | POINT (4 5)         |
3 | POLYGON ((-1 2, 0 3, 1 2, -1 2)) | POLYGON ((-24 12, -15 23, -20 27, -24 12))
4 | LINESTRING (-1 2, 1 5) | LINESTRING (-42.74 23.98, -62.19 23.78)
(4 rows)
```

Identify all the rows that have a null `geog` value:

```
=> SELECT id, ST_AsText(geom), (ST_AsText(geog) IS NULL) FROM locations
ORDER BY 1 ASC;
id |      ST_AsText      | ?column?
+-----+-----+-----+
1 | POINT (2 3)         | f
2 | POINT (4 5)         | t
3 | POLYGON ((-1 2, 0 3, 1 2, -1 2)) | f
4 | LINESTRING (-1 2, 1 5) | f
(4 rows)
```

Identify the rows where the `geog` value is not null:

```
=> SELECT id, ST_AsText(geom), (ST_AsText(geog) IS NOT NULL) FROM locations
ORDER BY 1 ASC;
id |      st_astext      | ?column?
+-----+-----+-----+
1 | POINT (2 3)         | t
2 | POINT (4 5)         | f
3 | LINESTRING (-1 2, 1 5) | t
4 | POLYGON ((-1 2, 0 3, 1 2, -1 2)) | t
(4 rows)
```

Loading spatial data from shapefiles

Vertica provides the capability to load and parse spatial data that is stored in shapefiles. Shapefiles describe points, lines, and polygons. A shapefile is made up of three required files; all three files must be present and in the same directory to define the geometries:

- `.shp`—Contains the geometry data.
- `.shx`—Contains the positional index of the geometry.
- `.dbf`—Contains the attributes for each geometry.

To load spatial data from a shapefile:

1. Use `STV_ShpCreateTable` to generate a `CREATE TABLE` statement.

```
=> SELECT STV_ShpCreateTable ( USING PARAMETERS file = '/home/geo/temp/shp-files/spatial_data.shp')
OVER() AS spatial_data;
spatial_data
+-----+
CREATE TABLE spatial_data(
gid IDENTITY(64) PRIMARY KEY,
uniq_id INT8,
geom GEOMETRY(85)
);
(5 rows)
```

2. Create the table.

```
=> CREATE TABLE spatial_data(  
gid IDENTITY(64) PRIMARY KEY,  
uniq_id INT8,  
geom GEOMETRY(85));
```

3. Load the shapefile.

```
=> COPY spatial_data WITH SOURCE STV_ShpSource(file='/home/geo/temp/shp-files/spatial_data.shp')  
PARSER STV_ShpParser();  
Rows Loaded  
-----  
10  
(1 row)
```

Supported shapefile shape types

The following table lists the shapefile shape types that Vertica supports.

Shapefile Shape Type	Supported
Null shape	Yes
Point	Yes
Polyline	Yes
Polygon	Yes
MultiPoint	Yes
PointZ	No
PolylineZ	No
PolygonZ	No
MultiPointZ	No
PointM	No
PolylineM	No
PolygonM	No
MultiPointM	No
MultiPatch	No

Loading spatial data into tables using COPY

You can load spatial data into a table in Vertica using a COPY statement.

To load data into Vertica using a COPY statement:

1. Create a table.

```
=> CREATE TABLE spatial_data (id INTEGER, geom GEOMETRY(200));  
CREATE TABLE
```

2. Create a text file named `spatial.dat` with the following data.

```
1|POINT(2 3)  
2|LINESTRING(-1 2, 1 5)  
3|POLYGON((-1 2, 0 3, 1 2, -1 2))
```

3. Use COPY to load the data into the table.

```
=> COPY spatial_data (id, gx FILLER LONG VARCHAR(605), geom AS ST_GeomFromText(gx)) FROM LOCAL 'spatial.dat';
Rows Loaded
-----
      3
(1 row)
```

The statement specifies a LONG VARCHAR(32000000) filler, which is the maximum size of WKT. You must specify a filler value large enough to hold the largest WKT you want to insert into the table.

Retrieving spatial data from a table as well-known text (WKT)

GEOMETRY and GEOGRAPHY data is stored in Vertica tables as LONG VARBINARY, which isn't human readable. You can use [ST_AsText](#) to return the spatial data as Well-Known Text (WKT).

To return spatial data as WKT:

```
=> SELECT id, ST_AsText(geom) AS WKT FROM spatial_data;
id |          WKT
-----+-----
 1 | POINT (2 3)
 2 | LINESTRING (-1 2, 1 5)
 3 | POLYGON ((-1 2, 0 3, 1 2, -1 2))
(3 rows)
```

Working with GeoHash data

Vertica supports [GeoHashes](#). A GeoHash is a geocoding system for hierarchically encoding increasingly granular spatial references. Each additional character in a GeoHash drills down to a smaller section of a map.

You can use Vertica to generate spatial data from GeoHashes and GeoHashes from spatial data. Vertica supports the following functions for use with GeoHashes:

- [ST_GeoHash](#) - Returns a GeoHash in the shape of the specified geometry.
- [ST_GeomFromGeoHash](#) - Returns a polygon in the shape of the specified GeoHash.
- [ST_PointFromGeoHash](#) - Returns the center point of the specified GeoHash.

For example, to generate a full precision and partial precision GeoHash from a single point.

```
=> SELECT ST_GeoHash(ST_GeographyFromText('POINT(3.14 -1.34)'), LENGTH(ST_GeoHash(ST_GeographyFromText('POINT(3.14 -1.34)'))),
          ST_GeoHash(ST_GeographyFromText('POINT(3.14 -1.34)') USING PARAMETERS numchars=5) partial_hash;
ST_GeoHash | LENGTH | partial_hash
-----+-----+-----
kpf0rkn3zmcswks75010 |    20 | kpf0r
(1 row)
```

This example shows how to generate a GeoHash from a multipoint point object. The returned polygon is a geometry object of the smallest tile that encloses that GeoHash.

```
=> SELECT ST_AsText(ST_GeomFromGeoHash(ST_GeoHash(ST_GeomFromText('MULTIPOINT(0 0, 0.0002 0.0001)')))) AS region_1,
          ST_AsText(ST_GeomFromGeoHash(ST_GeoHash(ST_GeomFromText('MULTIPOINT(0.0001 0.0001, 0.0003 0.0002)')))) AS region_2;
-[ RECORD 1 ]-----
region_1 | POLYGON ((0 0, 0.00137329101562 0, 0.00137329101562 0.00137329101562, 0 0.00137329101562, 0 0))
region_2 | POLYGON ((0 0, 0.010986328125 0, 0.010986328125 0.0054931640625, 0 0.0054931640625, 0 0))
```

Spatial joins with ST_Intersects and STV_Intersect

Spatial joins allow you to identify spatial relationships between two sets of spatial data. For example, you can use spatial joins to:

- Calculate the density of mobile calls in various regions to determine the location of a new cell phone tower.
- Identify homes that fall within the impact zone of a hurricane.
- Calculate the number of users who live within a certain ZIP code.
- Calculate the number of customers in a retail store at any given time.

In this section

- [Best practices for spatial joins](#)
- [Ensuring polygon validity before creating or refreshing an index](#)
- [STV_Intersect: scalar function vs. transform function](#)
- [Performing spatial joins with STV_Intersect functions](#)
- [When to use ST_Intersects vs. STV_Intersect](#)

Best practices for spatial joins

Use these best practices to improve overall performance and optimize your spatial queries.

Best practices for using spatial joins in Vertica include:

- Table segmentation to speed up index creation
- Adequately sizing a geometry column to store point data
- Loading Well-Known Text (WKT) directly into a Geometry column, using STV_GeometryPoint in a COPY statement
- Using OVER (PARTITION BEST) with STV_Intersect transform queries

Best practices example

Note

The following example was originally published in a Vertica blog post about using spatial data in museums. To read the entire blog, see [Using Location Data with Vertica Place](#)

Before performing the steps in the following example, download [place_output.csv.zip](#) from the Vertica Place GitHub repository (<https://github.com/vertica/Vertica-Geospatial>). You need to use the data set from this repository.

1. Create the table for the polygons. Use a GEOMETRY column width that fits your data without being excessively large. A good column-width fit improves performance. In addition, segmenting the table by HASH provides the advantages of parallel computation.

```
=> CREATE TABLE artworks (gid int, g GEOMETRY(700)) SEGMENTED BY HASH(gid) ALL NODES;
```

2. Use a copy statement with ST_Buffer to create and load the polygons on which to run the intersect. By using ST_Buffer in your copy statement, you can use that function to create the polygons.

```
=> COPY artworks(gid, gx FILLER LONG VARCHAR, g AS ST_Buffer(ST_GeomFromText(gx),8)) FROM STDIN DELIMITER ',';
>> 1, POINT(10 45)
>> 2, POINT(25 45)
>> 3, POINT(35 45)
>> 4, POINT(35 15)
>> 5, POINT(30 5)
>> 6, POINT(15 5)
>> \.
```

3. Create a table for the location data, represented by points. You can store point data in a GEOMETRY column of 100 bytes. Avoid over-fitting your GEOMETRY column. Doing so can significantly degrade spatial intersection performance. Also, segment this table by HASH, to take advantage of parallel computation.

```
=> CREATE TABLE usr_data (gid identity, usr_id int, date_time timestamp, g GEOMETRY(100))
SEGMENTED BY HASH(gid) ALL NODES;
```

4. During the copy statement, transform the raw location data to GEOMETRY data. You must perform this transformation because your location data needs to use the GEOMETRY data type. Use the function STV_GeometryPoint to transform the x and y columns of the source table.

```
=> COPY usr_data (usr_id, date_time, x FILLER LONG VARCHAR,
                y FILLER LONG VARCHAR, g AS STV_GeometryPoint(x, y))
FROM LOCAL 'place_output.csv' DELIMITER ',' ENCLOSED BY '";
```

5. Create the spatial index for the polygons. This index helps you speed up intersection calculations.

```
=> SELECT STV_Create_Index(gid, g USING PARAMETERS index='art_index', overwrite=true) OVER() FROM artworks;
```

6. Write an analytic query that returns the number of intersections per polygon. Specify that Vertica ignore any `usr_id` that intersects less than 20 times with a given polygon.

```

=> SELECT pol_gid,
       COUNT(DISTINCT(usr_id)) AS count_user_visit
FROM
  (SELECT pol_gid,
         usr_id,
         COUNT(usr_id) AS user_points_in
FROM
  (SELECT STV_Intersect(usr_id, g USING PARAMETERS INDEX='art_index') OVER(PARTITION BEST) AS (usr_id,
                                                pol_gid)
FROM usr_data
WHERE date_time BETWEEN '2014-07-02 09:30:20' AND '2014-07-02 17:05:00') AS c
GROUP BY pol_gid,
usr_id HAVING COUNT(usr_id) > 20) AS real_visits
GROUP BY pol_gid
ORDER BY count_user_visit DESC;

```

Optimizations in the example query

This query has the following optimizations:

- The time predicated appears in the subquery.
- Using the location data table avoids the need for an expensive join.
- The query uses OVER (PARTITION BEST), to improve performance by partitioning the data.
- The `user_points_in` provides an estimate of the combined time spent intersecting with the artwork by all visitors.

Ensuring polygon validity before creating or refreshing an index

When Vertica creates or updates a spatial index it does not check polygon validity. To prevent getting invalid results when you query your spatial index, you should check the validity of your polygons prior to creating or updating your spatial index.

The following example shows you how to check the validity of polygons.

1. Create a table and load spatial data.

```

=> CREATE TABLE polygon_validity_test (gid INT, geom GEOMETRY);
CREATE TABLE
=> COPY polygon_validity_test (gid, gx FILLER LONG VARCHAR, geom AS St_GeomFromText(gx)) FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 2|POLYGON((-31 74,8 70,8 50,-36 53,-31 74))
>> 3|POLYGON((-38 50,4 13,11 45,0 65,-38 50))
>> 4|POLYGON((-12 42,-12 42,27 48,14 26,-12 42))
>> 5|POLYGON((0 0,1 1,0 0,2 1,1 1,0 0))
>> 6|POLYGON((3 3,2 2,2 1,2 3,3 3))
>> \.

```

2. Use ST_IsValid and STV_IsValidReason to find any invalid polygons.

```

=> SELECT gid, ST_IsValid(geom), STV_IsValidReason(geom) FROM polygon_validity_test;
gid | ST_IsValid |          STV_IsValidReason
-----+-----+-----
4 | t          |
6 | f          | Self-intersection at or near POINT (2 1)
2 | t          |
3 | t          |
5 | f          | Self-intersection at or near POINT (0 0)
(5 rows)

```

Now that we have identified the invalid polygons in our table, there are a couple different ways you can handle the invalid polygons when creating or refreshing a spatial index.

Filtering invalid polygons using a WHERE clause

This method is slower than filtering before creating an index because it checks the validity of each polygon at execution time.

The following example shows you how to exclude invalid polygons using a WHERE clause.

```

'''
=> SELECT STV_Create_Index(gid, geom USING PARAMETERS index = 'valid_polygons') OVER()
   FROM polygon_validity_test
   WHERE ST_IsValid(geom) = 't';
'''

```

Filtering invalid polygons before creating or refreshing an index

This method is faster than filtering using a WHERE clause because you incur the performance cost prior to building the index.

The following example shows you how to exclude invalid polygons by creating a new table excluding invalid polygons.

```

'''
=> CREATE TABLE polygon_validity_clean AS
   SELECT *
   FROM polygon_validity_test
   WHERE ST_IsValid(geom) = 't';
CREATE TABLE
=> SELECT STV_Create_Index(gid, geom USING PARAMETERS index = 'valid_polygons') OVER()
   FROM polygon_validity_clean;
'''

```

STV_Intersect: scalar function vs. transform function

The **STV_Intersect** functions are similar in purpose, but you use them differently.

STV_Intersect Function Type	Description	Performance
Scalar	Matches a point to a polygon. If several polygons contain the point, this function returns a gid value. The result is a polygon gid or, if no polygon contains the point, the result is NULL.	Eliminates points that do not intersect with any indexed polygons, avoiding unnecessary comparisons.
Transform	Matches a point to all the polygons that contain it. When a point does not intersect with any polygon in the index, the function returns no rows.	Processes all input points regardless of whether or not they intersect with the indexed polygons.

In the following example, the **STV_Intersect** scalar function compares the points in the **points** table to the polygons in a spatial index named **my_polygons**. **STV_Intersect** returns all points and polygons that match exactly:

```

=> SELECT gid AS pt_gid
   STV_Intersect(geom USING PARAMETERS index='my_polygons') AS pol_gid
   FROM points ORDER BY pt_gid;
pt_gid | pol_gid
-----+-----
 100 |    2
 101 |
 102 |    2
 103 |
 104 |
 105 |    3
 106 |
 107 |
(8 rows)

```

The following example shows how to use the **STV_Intersect** transform function to return information about the three point-polygon pairs that match and each of the polygons they match:

```
=> SELECT STV_Intersect(gid, geom
  USING PARAMETERS index='my_polygons')
  OVER (PARTITION BEST) AS (pt_gid, pol_id)
  FROM points;
pt_gid | pol_id
-----+-----
  100 |    1
  100 |    2
  100 |    3
  102 |    2
  105 |    3
(3 rows)
```

- [STV_Intersect transform function](#)

Performing spatial joins with STV_Intersect functions

Suppose you want to process a medium-to-large spatial data set and determine which points intersect with which polygons. In that case, first create a spatial index using [STV_Create_Index](#) . A spatial index provides efficient access to the set of polygons.

Then, use the [STV_Intersect](#) scalar or transform function to identify which point-polygon pairs match.

In this section

- [Spatial indexes and STV_Intersect](#)

Spatial indexes and STV_Intersect

Before performing a spatial join using one of the [STV_Intersect](#) functions, you must first run [STV_Create_Index](#) to create a database object that contains information about polygons. This object is called a *spatial index* of the set of polygons. The spatial index improves the time it takes for the [STV_Intersect](#) functions to access the polygon data.

Vertica creates spatial indexes in a global space. Thus, any user with access to the [STV_*_Index](#) functions can describe, rename, or drop indexes created by any other user.

Vertica provides functions that work with spatial indexes:

- [STV_Create_Index](#)—Stores information about polygons in an index to improve performance.
- [STV_Describe_Index](#)—Retrieves information about an index.
- [STV_Drop_Index](#)—Deletes a spatial index.
- [STV_Refresh_Index](#)—Refreshes a spatial index.
- [STV_Rename_Index](#)—Renames a spatial index.

When to use ST_Intersects vs. STV_Intersect

Vertica provides two capabilities to identify whether a set of points intersect with a set of polygons. Depending on the size of your data set, choose the approach that gives the best performance:

- When comparing a set of geometries to a single geometry to see if they intersect, use the [ST_Intersects](#) function.
- To determine if a set of points intersects with a set of polygons in a medium-to-large data set, first create a spatial index using [STV_Create_Index](#) . Then, use one of the [STV_Intersect](#) functions to return the set of pairs that intersect.

Note

You can only perform spatial joins on GEOMETRY data.

In this section

- [Performing spatial joins with ST_Intersects](#)

Performing spatial joins with ST_Intersects

The ST_Intersects function determines if two GEOMETRY objects intersect or touch at a single point.

Use ST_Intersects when you want to identify if a small set of geometries in a column intersect with a given geometry.

Example

The following example uses ST_Intersects to compare a column of point geometries to a single polygon. The table that contains the points has 1 million rows.

ST_Intersects returns only the points that intersect with the polygon. Those points represent about 0.01% of the points in the table:

```
=> CREATE TABLE points_1m(gid IDENTITY, g GEOMETRY(100)) ORDER BY gid;
=> COPY points_1m(wkt FILLER LONG VARCHAR(100), g AS ST_GeomFromText(wkt))
  FROM LOCAL 'data/points.dat';
Rows Loaded
-----
 1000000
(1 row)
=> SELECT ST_AsText(g) FROM points_1m WHERE
  ST_Intersects
  (
  g,
  ST_GeomFromText('POLYGON((-71 42, -70.9 42, -70.9 42.1, -71 42.1, -71 42))')
  );
  st_astext
-----
POINT (-70.97532 42.03538)
POINT (-70.97421 42.0376)
POINT (-70.99004 42.07538)
POINT (-70.99477 42.08454)
POINT (-70.99088 42.08177)
POINT (-70.98643 42.07593)
POINT (-70.98032 42.07982)
POINT (-70.95921 42.00982)
POINT (-70.95115 42.02177)
...
(116 rows)
```

Vertica recommends that you test the intersections of two columns of geometries by creating a spatial index. Use one of the STV_Intersect functions as described in [STV_Intersect: scalar function vs. transform function](#).

Working with spatial objects from client applications

The Vertica client driver libraries provide interfaces for connecting your client applications to your Vertica database. The drivers simplify exchanging data for loading, report generation, and other common database tasks.

There are three separate client drivers:

- Open Database Connectivity (ODBC)—The most commonly-used interface for third-party applications and clients written in C, Python, PHP, Perl, and most other languages.
- Java Database Connectivity (JDBC)—Used by clients written in the Java programming language.
- ActiveX Data Objects for .NET (ADO.NET)—Used by clients developed using Microsoft's .NET Framework and written in C#, Visual Basic .NET, and other .NET languages.

Vertica Place supports the following new data types:

- LONG VARCHAR
- LONG VARBINARY
- GEOMETRY
- GEOGRAPHY

The client driver libraries support these data types; the following sections describe that support and provide examples.

In this section

- [Using LONG VARCHAR and LONG VARBINARY data types with ODBC](#)
- [Using LONG VARCHAR and LONG VARBINARY data types with JDBC](#)
- [Using GEOMETRY and GEOGRAPHY data types in ODBC](#)
- [Using GEOMETRY and GEOGRAPHY data types in JDBC](#)
- [Using GEOMETRY and GEOGRAPHY data types in ADO.NET](#)

Using LONG VARCHAR and LONG VARBINARY data types with ODBC

The ODBC drivers support the LONG VARCHAR and LONG VARBINARY data types similarly to VARCHAR and VARBINARY data types. When binding input or output parameters to a LONG VARCHAR or LONG VARBINARY column in a query, use the SQL_LONGVARCHAR and SQL_LONGVARBINARY constants to set the column's data type. For example, to bind an input parameter to a LONG VARCHAR column, you would use a statement that looks like this:

```
c = SQLBindParameter(hdStmt, 1, SQL_PARAM_INPUT, SQL_C_CHAR, SQL_LONGVARCHAR,
                    80000, 0, (SQLPOINTER)myLongString, sizeof(myLongString), NULL);
```

Note

Do not use inefficient encoding formats for LONG VARBINARY and LONG VARCHAR values. Vertica cannot load encoded values larger than 32MB, even if the decoded value is less than 32 MB in size. For example, Vertica returns an error if you attempt to load a 32MB LONG VARBINARY value encoded in octal format, since the octal encoding quadruples the size of the value (each byte is converted into a backslash followed by three digits).

Using LONG VARCHAR and LONG VARBINARY data types with JDBC

Using LONG VARCHAR and LONG VARBINARY data types in a JDBC client application is similar to using VARCHAR and VARBINARY data types. The JDBC driver transparently handles the conversion (for example, between a Java [String](#) object and a LONG VARCHAR).

The following example code demonstrates inserting and retrieving a LONG VARCHAR string. It uses the JDBC Types class to determine the data type of the string returned by Vertica, although it does not actually need to know whether the database column is a LONG VARCHAR or just a VARCHAR in order to retrieve the value.

```
import java.sql.*;
import java.util.Properties;

public class LongVarcharExample {
    public static void main(String[] args) {
        try {
            Class.forName("com.vertica.jdbc.Driver");
        } catch (ClassNotFoundException e) {
            System.err.println("Could not find the JDBC driver class.");
            e.printStackTrace();
            return;
        }
        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser");
        myProp.put("password", "password123");
        Connection conn;
        try {
            conn = DriverManager.getConnection(
                "jdbc:vertica://VerticaHost:5433/ExampleDB",
                myProp);
            // establish connection and make a table for the data.
            Statement stmt = conn.createStatement();

            // How long we want the example string to be. This is
            // larger than can fit into a traditional VARCHAR (which is limited
            // to 65000.
            int length = 100000;

            // Create a table with a LONG VARCHAR column that can store
            // strings up to 100,000 characters long.
```

Note

Do not use inefficient encoding formats for LONG VARBINARY and LONG VARCHAR values. Vertica cannot load encoded values larger than 32MB, even if the decoded value is less than 32 MB in size. For example, Vertica returns an error if you attempt to load a 32MB LONG VARBINARY value encoded in octal format, since the octal encoding quadruples the size of the value (each byte is converted into a backslash followed by three digits).

Using GEOMETRY and GEOGRAPHY data types in ODBC

Vertica GEOMETRY and GEOGRAPHY data types are backed by LONG VARBINARY native types and ODBC client applications treat them as binary data. However, these data types have a format that is unique to Vertica. To manipulate this data in your C++ application, you must use the functions in Vertica that convert them to a recognized format.

To convert a WKT or WKB to the GEOMETRY or GEOGRAPHY format, use one of the following SQL functions:

- [ST_GeographyFromText](#)—Converts a WKT to a GEOGRAPHY type.
- [ST_GeographyFromWKB](#)—Converts a WKB to a GEOGRAPHY type.
- [ST_GeomFromText](#)—Converts a WKT to a GEOMETRY type.
- [ST_GeomFromWKB](#)—Converts a WKB to GEOMETRY type.

To convert a GEOMETRY or GEOGRAPHY object to its corresponding WKT or WKB, use one of the following SQL functions:

- [ST_AsText](#)—Converts a GEOMETRY or GEOGRAPHY object to a WKT, returns a LONGVARCHAR.
- [ST_AsBinary](#)—Converts a GEOMETRY or GEOGRAPHY object to a WKB, returns a LONG VARBINARY.

The following code example converts WKT data into GEOMETRY data using [ST_GeomFromText](#) and stores it in a table. Later, this example retrieves the GEOMETRY data from the table and converts it to WKT and WKB format using [ST_AsText](#) and [ST_AsBinary](#).

```
// Compile on Linux using:
// g++ -g -I/opt/vertica/include -L/opt/vertica/lib64 -lodbc -o SpatialData SpatialData.cpp
// Some standard headers
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <assert.h>
#include <sstream>
// Only needed for Windows clients
// #include <windows.h>
// Standard ODBC headers
#include <sql.h>
#include <sqltypes.h>
#include <sqlext.h>
// Helper function to print SQL error messages.
template <typename HandleT>
void reportError(int handleTypeEnum, HandleT hdl)
{
    // Get the status records.
    SQLSMALLINT i, MsgLen;
    SQLRETURN ret2;
    SQLCHAR SqlState[6], Msg[SQL_MAX_MESSAGE_LENGTH];
    SQLINTEGER NativeError;
    i = 1;
    printf("\n");
    while ((ret2 = SQLGetDiagRec(handleTypeEnum, hdl, i, SqlState, &NativeError,
        Msg, sizeof(Msg), &MsgLen)) != SQL_NO_DATA) {
        printf("error record %d\n", i);
        printf("sqlstate: %s\n", SqlState);
        printf("detailed msg: %s\n", Msg);
        printf("native error code: %d\n\n", NativeError);
        i++;
    }
}
```

```

    i++;
}
exit(EXIT_FAILURE); // bad form... but Ok for this demo
}
int main()
{
    // Set up the ODBC environment
    SQLRETURN ret;
    SQLHENV hdlEnv;
    ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hdlEnv);
    assert(SQL_SUCCEEDED(ret));
    // Tell ODBC that the application uses ODBC 3.
    ret = SQLSetEnvAttr(hdlEnv, SQL_ATTR_ODBC_VERSION,
        (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_UINTEGER);
    assert(SQL_SUCCEEDED(ret));
    // Allocate a database handle.
    SQLHDBC hdlDbc;
    ret = SQLAllocHandle(SQL_HANDLE_DBC, hdlEnv, &hdlDbc);
    assert(SQL_SUCCEEDED(ret));
    // Connect to the database
    printf("Connecting to database.\n");
    const char *dsnName = "ExampleDB";
    const char* userID = "dbadmin";
    const char* passwd = "password123";
    ret = SQLConnect(hdlDbc, (SQLCHAR*)dsnName,
        SQL_NTS, (SQLCHAR*)userID, SQL_NTS,
        (SQLCHAR*)passwd, SQL_NTS);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not connect to database.\n");
        reportError<SQLHDBC>(SQL_HANDLE_DBC, hdlDbc);
    }
    else {
        printf("Connected to database.\n");
    }

    // Disable AUTOCOMMIT
    ret = SQLSetConnectAttr(hdlDbc, SQL_ATTR_AUTOCOMMIT, SQL_AUTOCOMMIT_OFF,

```
        // The WKB format geometry data
```

- [ST_GeomFromText](#)—Converts a WKT to a GEOMETRY type.
- [ST_GeomFromWKB](#)—Converts a WKB to GEOMETRY type.

To convert a GEOMETRY or GEOGRAPHY object to its corresponding WKT or WKB, use one of the following SQL functions:

- [ST_AsText](#)—Converts a GEOMETRY or GEOGRAPHY object to a WKT, returns a LONGVARCHAR.
- [ST_AsBinary](#)—Converts a GEOMETRY or GEOGRAPHY object to a WKB, returns a LONG VARBINARY.

The following code example converts WKT and WKB data into GEOMETRY data using [ST_GeomFromText](#) and [ST_GeomFromWKB](#) and stores it in a table. Later, this example retrieves the GEOMETRY data from the table and converts it to WKT and WKB format using [ST_AsText](#) and [ST_AsBinary](#).

                            ST_Contains(ST_GeomFromText(?, poly)");
pstmt.setString(1, "polygon((1 1, 1 2, 2 2, 2 1, 1 1))");
rs = pstmt.executeQuery();
while(rs.next())
{
    int pk = rs.getInt(1);
    //process the results as necessary
}
rs.close();

conn.close();
}
}

```

Using GEOMETRY and GEOGRAPHY data types in ADO.NET

Vertica GEOMETRY and GEOGRAPHY data types are backed by LONG VARBINARY native types and ADO.NET client applications treat them as binary data. However, these data types have a format that is unique to Vertica. To manipulate this data in your C# application, you must use the functions in Vertica that convert them to a recognized format.

To convert a WKT or WKB to the GEOMETRY or GEOGRAPHY format, use one of the following SQL functions:

- [ST_GeographyFromText](#)—Converts a WKT to a GEOGRAPHY type.
- [ST_GeographyFromWKB](#)—Converts a WKB to a GEOGRAPHY type.
- [ST_GeomFromText](#)—Converts a WKT to a GEOMETRY type.
- [ST_GeomFromWKB](#)—Converts a WKB to GEOMETRY type.

To convert a GEOMETRY or GEOGRAPHY object to its corresponding WKT or WKB, use one of the following SQL functions:

- [ST_AsText](#)—Converts a GEOMETRY or GEOGRAPHY object to a WKT, returns a LONGVARCHAR.
- [ST_AsBinary](#)—Converts a GEOMETRY or GEOGRAPHY object to a WKB, returns a LONG VARBINARY.

The following C# code example converts WKT data into GEOMETRY data using `ST_GeomFromText` and stores it in a table. Later, this example retrieves the GEOMETRY data from the table and converts it to WKT and WKB format using `ST_AsText` and `ST_AsBinary`.

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            VerticaConnectionStringBuilder builder =
                new VerticaConnectionStringBuilder();
            builder.Host = "VerticaHost";
            builder.Database = "VMart";
            builder.User = "ExampleUser";
            builder.Password = "password123";
            VerticaConnection _conn = new
                VerticaConnection(builder.ToString());
            _conn.Open();

            VerticaCommand command = _conn.CreateCommand();
            command.CommandText = "DROP TABLE IF EXISTS polygons";
            command.ExecuteNonQuery();
            command.CommandText =
                "CREATE TABLE polygons (id INTEGER PRIMARY KEY, poly GEOMETRY)";
            command.ExecuteNonQuery();
            // Prepare to insert a polygon using a prepared statement. Use the
            // ST_GeomFromText SQL function to convert from WKT to GEOMETRY.
            VerticaTransaction txn = _conn.BeginTransaction();
            command.CommandText =
                "INSERT into polygons VALUES(@id, ST_GeomFromText(@polygon))";
            command.Parameters.Add(new
                VerticaParameter("id", VerticaType.BigInt));
            command.Parameters.Add(new
                VerticaParameter("polygon", VerticaType.VarChar));
            command.Prepare();
            // Set the values for the parameters
            command.Parameters["id"].Value = 0;
            //
            command.Parameters["polygon"].Value =
                "polygon((1 1, 1 2, 2 2, 2 1, 1 1))";
            // Execute the query to insert the value
            command.ExecuteNonQuery();

            // Now query the table
            VerticaCommand query = _conn.CreateCommand();
            query.CommandText =
                "SELECT id, ST_AsText(poly), ST_AsBinary(poly) FROM polygons;";
            VerticaDataReader dr = query.ExecuteReader();
            while (dr.Read())
            {
                Console.WriteLine("ID: " + dr[0]);
                Console.WriteLine("Polygon WKT format data type: "
                    + dr.GetDataTypeName(1) +
                    " Value: " + dr[1]);
                // Get the WKB format of the polygon and print it out as hex.
            }
        }
    }
}
```

```
Console.WriteLine("Polygon WKB format data type: "
    + dr.GetDataTypeName(2));
Console.WriteLine(" Value: "
    + BitConverter.ToString((byte[])dr[2]));
}
_conn.Close();
}
}
```

The example code prints the following on the system console:

```
ID: 0
Polygon WKT format data type: LONG VARCHAR Value: POLYGON ((1 1, 1 2,
2 2, 2 1,1 1))
Polygon WKB format data type: LONG VARBINARY Value: 01-03-00-00-00-01
-00-00-00-05-00-00-00-00-00-00-00-00-00-F0-3F-00-00-00-00-00-00-F0-3F
-00-00-00-00-00-00-F0-3F-00-00-00-00-00-00-40-00-00-00-00-00-00-00

-F0-3F-00-00-00-00-00-00-F0-3F-00-00-00-00-00-00-F0-3F
```

OGC spatial definitions

Using Vertica requires an understanding of the Open Geospatial Consortium (OGC) concepts and capabilities. For more information, see the [OGC Simple Feature Access Part 1 - Common Architecture](#) specification.

In this section

- [Spatial classes](#)
- [Spatial object representations](#)
- [Spatial definitions](#)

Spatial classes

Vertica supports several classes of objects, as defined in the OGC standards.

In this section

- [Point](#)
- [Multipoint](#)
- [Linestring](#)
- [Multilinestring](#)
- [Polygon](#)
- [Multipolygon](#)

Point

A location in two-dimensional space that is identified by one of the following:

- X and Y coordinates
- Longitude and latitude values

A point has dimension 0 and no boundary.

Examples

The following example uses a GEOMETRY point:

```

=> CREATE TABLE point_geo (gid int, geom GEOMETRY(100));
CREATE TABLE
=> COPY point_geo(gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin delimiter ';';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>>1, POINT(3 5)
>>\.
=> SELECT gid, ST_AsText(geom) FROM point_geo;
gid | ST_AsText
-----+-----
  1 | POINT (3 5)
(1 row)

```

The following example uses a GEOGRAPHY point:

```

=> CREATE TABLE point_geog (gid int, geog GEOGRAPHY(100));
CREATE TABLE
=> COPY point_geog(gid, gx filler LONG VARCHAR, geog AS ST_GeographyFromText(gx)) FROM stdin delimiter ';';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>>1, POINT(42 71)
>>\.
=> SELECT gid, ST_AsText(geog) FROM point_geog;
gid | ST_AsText
-----+-----
  1 | POINT (42 71)
(1 row)

```

Multipoint

A set of one or more points. A multipoint object has dimension 0 and no boundary.

Examples

The following example uses a GEOMETRY multipoint:

```

=> CREATE TABLE mpoint_geo (gid int, geom GEOMETRY(1000));
CREATE TABLE
=> COPY mpoint_geo(gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>>1|MULTIPOINT(4 7, 8 10)
>>\.
=> SELECT gid, ST_AsText(geom) FROM mpoint_geo;
gid | st_astext
-----+-----
  1 | MULTIPOINT (7 8, 6 9)
(1 row)

```

The following example uses a GEOGRAPHY multipoint:

```

=> CREATE TABLE mpoint_geog (gid int, geog GEOGRAPHY(1000));
CREATE TABLE
=> COPY mpoint_geog(gid, gx filler LONG VARCHAR, geog AS ST_GeographyFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>>1|MULTIPOINT(42 71, 41.4 70)
>>\.
=> SELECT gid, ST_AsText(geom) FROM mpoint_geog;
gid | st_astext
-----+-----
  1 | MULTIPOINT (42 71, 41.4 70)
(1 row)

```

Linestring

One or more connected lines, identified by pairs of consecutive points. A linestring has dimension 1. The boundary of a linestring is a multipoint object containing its start and end points.

The following are examples of linestrings:

Examples

The following example uses the GEOMETRY type to create a table, use copy to load a linestring to the table, and then queries the table to view the linestring:

```
=> CREATE TABLE linestring_geom (gid int, geom GEOMETRY(1000));
CREATE TABLE
=> COPY linestring_geom(gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>>1|LINESTRING(0 0, 1 1, 2 2, 3 4, 2 4, 1 5)
>>\.
=> SELECT gid, ST_AsText(geom) FROM linestring_geom;
gid |          ST_AsText
-----+-----
  1 | LINESTRING (0 0, 1 1, 2 2, 3 4, 2 4, 1 5)
(1 row)
```

The following example uses the GEOGRAPHY type to create a table, use copy to load a linestring to the table, and then queries the table to view the linestring:

```
=> CREATE TABLE linestring_geog (gid int, geog GEOGRAPHY(1000));
CREATE TABLE
=> COPY linestring_geog(gid, gx filler LONG VARCHAR, geog AS ST_GeographyFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>>1|LINESTRING(42.1 71, 41.4 70, 41.3 72.9, 42.99 71.46, 44.47 73.21)
>>\.
=> SELECT gid, ST_AsText(geog) FROM linestring_geog;
gid |          ST_AsText
-----+-----
  1 | LINESTRING (42.1 71, 41.4 70, 41.3 72.9, 42.99 71.46, 44.47 73.21)
(1 row)
```

Multilinestring

A collection of zero or more linestrings. A multilinestring has no dimension. The boundary of a multilinestring is a multipoint object containing the start and end points of all the linestrings.

The following are examples of multilinestrings:

Examples

The following example uses the GEOMETRY type to create a table, use copy to load a multilinestring to the table, and then queries the table to view the multilinestring:

```
=> CREATE TABLE multilinestring_geom (gid int, geom GEOMETRY(1000));
CREATE TABLE
=> COPY multilinestring_geom(gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>>1|MULTILINESTRING((1 5, 2 4, 5 3, 6 6),(3 5, 3 7))
>>\.
=> SELECT gid, ST_AsText(geom) FROM multilinestring_geom;
gid |          ST_AsText
-----+-----
  1 | MULTILINESTRING ((1 5, 2 4, 5 3, 6 6), (3 5, 3 7))
(1 row)
```

The following example uses the GEOGRAPHY type to create a table, use copy to load a multilinestring to the table, and then queries the table to view the multilinestring:

```
=> CREATE TABLE multilinestring_geog (gid int, geog GEOGRAPHY(1000));
CREATE TABLE
=> COPY multilinestring_geog(gid, gx filler LONG VARCHAR, geog AS ST_GeographyFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>>1|MULTILINESTRING((42.1 71, 41.4 70, 41.3 72.9), (42.99 71.46, 44.47 73.21))
>>\.
=> SELECT gid, ST_AsText(geog) FROM multilinestring_geog;
gid |          ST_AsText
-----+-----
  1 | MULTILINESTRING((42.1 71, 41.4 70, 41.3 72.9), (42.99 71.46, 44.47 73.21))
(1 row)
```

Polygon

An object identified by a set of closed linestrings. A polygon can have one or more holes, as defined by interior boundaries, but all points must be connected. Two examples of polygons are:

Inclusive and exclusive polygons

Polygons that include their points in clockwise order include all space inside the perimeter of the polygon and exclude all space outside that perimeter. Polygons that include their points in counterclockwise order exclude all space inside the perimeter and include all space outside that perimeter.

Examples

The following example uses the GEOMETRY type to create a table, use copy to load a polygon into the table, and then queries the table to view the polygon:

```
=> CREATE TABLE polygon_geom (gid int, geom GEOMETRY(1000));
CREATE TABLE
=> COPY polygon_geom(gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>>1|POLYGON(( 2 6, 2 9, 6 9, 7 7, 4 6, 2 6))
>>\.
=> SELECT gid, ST_AsText(geom) FROM polygon_geom;
gid |          ST_AsText
-----+-----
  1 | POLYGON((2 6, 2 9, 6 9, 7 7, 4 6, 2 6))
(1 row)
```

The following example uses the GEOGRAPHY type to create a table, use copy to load a polygon into the table, and then queries the table to view the polygon:

```
=> CREATE TABLE polygon_geog (gid int, geog GEOGRAPHY(1000));
CREATE TABLE
=> COPY polygon_geog(gid, gx filler LONG VARCHAR, geog AS ST_GeographyFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>>1|POLYGON((42.1 71, 41.4 70, 41.3 72.9, 44.47 73.21, 42.99 71.46, 42.1 71))
>>\.
=> SELECT gid, ST_AsText(geog) FROM polygon_geog;
gid |          ST_AsText
-----+-----
  1 | POLYGON((42.1 71, 41.4 70, 41.3 72.9, 44.47 73.21, 42.99 71.46, 42.1 71))
(1 row)
```

Multipolygon

A collection of zero or more polygons that do not overlap.

Examples

The following example uses the GEOMETRY type to create a table, use copy to load a multipolygon into the table, and then queries the table to view the polygon:

```

=> CREATE TABLE multipolygon_geom (gid int, geom GEOMETRY(1000));
CREATE TABLE
=> COPY multipolygon_geom(gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>>9|MULTIPOLYGON(((2 6, 2 9, 6 9, 7 7, 4 6, 2 6)),((0 0, 0 5, 1 0, 0 0)),((0 2, 2 5, 4 5, 0 2)))
>>\.
=> SELECT gid, ST_AsText(geom) FROM polygon_geom;
gid |                ST_AsText
-----+-----
  9 | MULTIPOLYGON(((2 6, 2 9, 6 9, 7 7, 4 6, 2 6)),((0 0, 0 5, 1 0, 0 0)),((0 2, 2 5, 4 5, 0 2)))
(1 row)

```

The following example uses the GEOGRAPHY type to create a table, use copy to load a multipolygon into the table, and then queries the table to view the polygon:

```

=> CREATE TABLE multipolygon_geog (gid int, geog GEOGRAPHY(1000));
CREATE TABLE
=> COPY polygon_geog(gid, gx filler LONG VARCHAR, geog AS ST_GeographyFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>>1|POLYGON((42.1 71, 41.4 70, 41.3 72.9, 44.47 73.21, 42.99 71.46, 42.1 71))
>>\.
=> SELECT gid, ST_AsText(geog) FROM polygon_geog;
gid |                ST_AsText
-----+-----
  1 | POLYGON(((42.1 71, 41.4 70, 41.3 72.9, 42.1 71)),((44.47 73.21, 42.99 71.46, 42.1 71, 44.47 73.21)))
(1 row)

```

Spatial object representations

The OGC defines two ways to represent spatial objects:

- [Well-known text \(WKT\)](#)
- [Well-known binary \(WKB\)](#)

In this section

- [Well-known text \(WKT\)](#)
- [Well-known binary \(WKB\)](#)

Well-known text (WKT)

Well-Known Text (WKT) is an ASCII representation of a spatial object.

WKTs are not case sensitive; Vertica recognizes any combination of lowercase and uppercase letters.

Some examples of valid WKTs are:

WKT Example	Description
POINT(1 2)	The point (1,2)
MULTIPOINT(0 0,1 1)	A set made up of the points (0,0) and (1,1)
LINESTRING(1.5 2.45,3.21 4)	The line from the point (1.5,2.45) to the point (3.21,4)
MULTILINESTRING((0 0,-1 -2,-3 -4),(2 3,3 4,6 7))	Two linestrings, one that passes through (0,0), (-1,-2), and (-3,-4), and one that passes through (2,3), (3,4), and (6,7).
POLYGON((1 2,1 4,3 4,3 2,1 2))	The rectangle whose four corners are indicated by (1,2), (1,4), (3,4), and (3,2). A polygon must be closed, so the first and last points in the WKT must match.

POLYGON((0.5 0.5,5 0.5,5 0.5,0 0.5), (1.5 1,4 3,4 1,1.5 1))	A polygon (0.5 0.5,5 0.5,5 0.5,0 0.5) with a hole in it (1.5 1,4 3,4 1,1.5 1).
MULTIPOLYGON(((0 1,3 0,4 3,0 4,0 1)), ((3 4,6 3,5 5,3 4)), ((0 0,-1 -2,-3 -2,-2 -1,0 0)))	A set of three polygons
GEOMETRYCOLLECTION(POINT(5 8), LINESTRING(-1 3,1 4))	A set containing the point (5,8) and the line from (-1,3) to (1,4)
POINT EMPTY MULTIPOINT EMPTY LINESTRING EMPTY MULTILINESTRING EMPTY MULTILINESTRING(EMPTY) POLYGON EMPTY POLYGON(EMPTY) MULTIPOLYGON EMPTY MULTIPOLYGON(EMPTY)	Empty spatial objects; empty objects have no points.

Invalid WKTs are:

- POINT(1 NAN), POINT(1 INF)—Coordinates must be numbers.
- POLYGON((1 2, 1 4, 3 4, 3 2))—A polygon must be closed.
- POLYGON((1 4, 2 4))—A linestring is not a valid polygon.

Well-known binary (WKB)

Well-Known Binary (WKB) is a binary representation of a spatial object. This format is primarily used to port spatial data between applications.

Spatial definitions

The OGC defines properties that describe

- Characteristics of spatial objects
- Spatial relationships that can exist among objects

Vertica provides functions that test for and analyze the following properties and relationships.

In this section

- [Boundary](#)
- [Buffer](#)
- [Contains](#)
- [Convex hull](#)
- [Crosses](#)
- [Disjoint](#)
- [Envelope](#)
- [Equals](#)
- [Exterior](#)
- [GeometryCollection](#)
- [Interior](#)
- [Intersection](#)
- [Overlaps](#)
- [Relates](#)
- [Simple](#)
- [Symmetric difference](#)
- [Union](#)

- [Validity](#)
- [Within](#)

Boundary

The set of points that define the limit of a spatial object:

- Points, multipoints, and geometrycollections do not have boundaries.
- The boundary of a linestring is a multipoint object. This object contains its start and end points.
- The boundary of a multilinestring is a multipoint object. This object contains the start and end points of all the linestrings that make up the multilinestring.
- The boundary of a polygon is a linestring that begins and ends at the same point. If the polygon has one or more holes, the boundary is a multilinestring that contains the boundaries of the exterior polygon and any interior polygons.
- The boundary of a multipolygon is a multilinestring that contains the boundaries of all the polygons that make up the multipolygon.

Buffer

The set of all points that are within or equal to a specified distance from the boundary of a spatial object. The distance can be positive or negative.

Positive buffer:

Negative buffer:

Contains

One spatial object contains another spatial object if its interior includes all points of the other object. If an object such as a point or linestring only exists along a polygon's boundary, the polygon does not contain it. If a point is on a linestring, the linestring contains it; the interior of a linestring is all the points on the linestring *except* the start and end points.

Contains(a, b) is spatially equivalent to within(b, a).

Convex hull

The smallest convex polygon that contains one or more spatial objects.

In the following figure, the dotted lines represent the convex hull for a linestring and a triangle.

Crosses

Two spatial objects cross if both of the following are true:

- The two objects have some but not all interior points in common.
- The dimension of the result of their intersection is less than the maximum dimension of the two objects.

Disjoint

Two spatial objects have no points in common; they do not intersect or touch.

Envelope

The minimum bounding rectangle that contains a spatial object.

The envelope for the following polygon is represented by the dotted lines in the following figure.

Equals

Two spatial objects are equal when their coordinates match exactly. Synonymous with *spatially equivalent*.

The order of the points do not matter in determining spatial equivalence:

- `LINSTRING(1 2, 4 3)` equals `LINSTRING(4 3, 1 2)`.
- `POLYGON((0 0, 1 1, 1 2, 2 2, 2 1, 3 0, 1.5 -1.5, 0 0))` equals `POLYGON((1 1, 1 2, 2 2, 2 1, 3 0, 1.5 -1.5, 0 0, 1 1))`.
- `MULTILINESTRING((1 2, 4 3),(0 0, -1 -4))` equals `MULTILINESTRING((0 0, -1 -4),(1 2, 4 3))`.

Exterior

The set of points not contained within a spatial object nor on its boundary.

GeometryCollection

A set of zero or more objects from any of the supported classes of spatial objects.

Interior

The set of points contained in a spatial object, excluding its boundary.

Intersection

The set of points that two or more spatial objects have in common.

Overlaps

If a spatial object shares space with another object, but is not contained within that object, the objects overlap. The objects must overlap at their interiors; if two objects touch at a single point or intersect only along a boundary, they do not overlap.

Relates

When a spatial object is spatially related to another object as defined by a DE-9IM pattern matrix string.

A DE-9IM pattern matrix string identifies how two spatial objects are spatially related to each other. For more information about the DE-9IM standard, see [Understanding Spatial Relations](#).

Simple

For points, multipoints, linestrings, or multilinestrings, a spatial object is simple if it does not intersect itself or has no self-tangency points.

Polygons, multipolygons, and geometrycollections are always simple.

Symmetric difference

The set of all points of a pair of spatial objects where the objects do not intersect. This difference is spatially equivalent to the union of the two objects less their intersection. The symmetric difference contains the boundaries of the intersections.

In the following figure, the shaded areas represent the symmetric difference of the two rectangles.

The following figure shows the symmetric difference of two overlapping linestrings.

Union

For two or more spatial objects, the set of all points in all the objects.

Validity

For a polygon or multipolygon, when all of the following are true:

- It is closed; its start point is the same as its end point.
- Its boundary is a set of linestrings.
- No two linestrings in the boundary cross. The linestrings in the boundary may touch at a point but they cannot cross.
- Any polygons in the interior must be completely contained; they cannot touch the boundary of the exterior polygon *except* at a vertex.

Valid polygons:

Invalid polygon:

Within

A spatial object is considered within another spatial object when all its points are inside the other object's interior. Thus, if a point or linestring only exists along a polygon's boundary, it is not considered within the polygon. The polygon boundary is not part of its interior.

If a point is on a linestring, it is considered within the linestring. The interior of a linestring is all the points along the linestring, except the start and end points.

Within(a, b) is spatially equivalent to contains(b, a).

Spatial data type support limitations

Vertica does not support all types of GEOMETRY and GEOGRAPHY objects. See the respective function page for a list of objects that function supports. Spherical geometry is generally more complex than Euclidean geometry. Thus, there are fewer spatial functions that support the GEOGRAPHY data type.

Limitations of spatial data type support:

- A non-WGS84 GEOGRAPHY object is a spatial object defined on the surface of a perfect sphere of radius 6371 kilometers. This sphere approximates the shape of the earth. Other spatial programs may use an ellipsoid to model the earth, resulting in slightly different data.
- You cannot modify the size or data type of a GEOMETRY or GEOGRAPHY column after creation.
- You cannot import data to or export data from tables that contain spatial data from another Vertica database.
- You can only use the STV_Intersect functions with points and polygons.
- GEOGRAPHY objects of type GEOMETRYCOLLECTION are not supported.
- Values for longitude must be between -180 and +180 degrees. Values for latitude must be between -90 and +90 degrees. The Vertica geospatial functions do not validate these values.
- GEOMETRYCOLLECTION objects cannot contain empty objects. For example, you cannot specify `GEOMETRYCOLLECTION (LINESTRING(1 2, 3 4), POINT(5 6), POINT EMPTY)`.
- If you pass a spatial function a NULL geometry, the function returns NULL, unless otherwise specified. A result of NULL has no value.
- Polymorphic functions, such as `NVL` and `GREATEST`, do not accept GEOMETRY and GEOGRAPHY arguments.

Time series analytics

Time series analytics evaluate the values of a given set of variables over time and group those values into a window (based on a time interval) for analysis and aggregation. Common scenarios for using time series analytics include: stock market trades and portfolio performance changes over time, and charting trend lines over data.

Since both time and the state of data within a time series are continuous, it can be challenging to evaluate SQL queries over time. Input records often occur at non-uniform intervals, which can create gaps. To solve this problem Vertica provides:

- Gap-filling functionality, which fills in missing data points
- Interpolation scheme, which constructs new data points within the range of a discrete set of known data points.

Vertica interpolates the non-time series columns in the data (such as analytic function results computed over time slices) and adds the missing data points to the output. This section describes gap filling and interpolation in detail.

You can use [event-based windows](#) to break time series data into windows that border on significant events within the data. This is especially relevant in financial data, where analysis might focus on specific events as triggers to other activity.

[Sessionization](#) is a special case of event-based windows that is frequently used to analyze click streams, such as identifying web browsing sessions from recorded web clicks.

Vertica provides additional support for time series analytics with the following SQL extensions:

- [TIMESERIES clause](#) in a SELECT statement supports gap-filling and interpolation (GFI) computation.
- [TS_FIRST_VALUE](#) and [TS_LAST_VALUE](#) are time series aggregate functions that return the value at the start or end of a time slice, respectively, which is determined by the interpolation scheme.
- [TIME_SLICE](#) is a (SQL extension) date/time function that aggregates data by different fixed-time intervals and returns a rounded-up input TIMESTAMP value to a value that corresponds with the start or end of the time slice interval.

See also

- [Sessionization with event-based windows](#)

In this section

- [Gap filling and interpolation \(GFI\)](#)
- [Null values in time series data](#)

Gap filling and interpolation (GFI)

The examples and graphics that explain the concepts in this topic use the following simple schema:

```
CREATE TABLE TickStore (ts TIMESTAMP, symbol VARCHAR(8), bid FLOAT);
INSERT INTO TickStore VALUES ('2009-01-01 03:00:00', 'XYZ', 10.0);
INSERT INTO TickStore VALUES ('2009-01-01 03:00:05', 'XYZ', 10.5);
COMMIT;
```

In Vertica, time series data is represented by a sequence of rows that conforms to a particular table schema, where one of the columns stores the time information.

Both time and the state of data within a time series are continuous. Thus, evaluating SQL queries over time can be challenging because input records usually occur at non-uniform intervals and can contain gaps.

For example, the following table contains two input rows five seconds apart: 3:00:00 and 3:00:05.

```
=> SELECT * FROM TickStore;
   ts      | symbol | bid
-----+-----+-----
2009-01-01 03:00:00 | XYZ   | 10
2009-01-01 03:00:05 | XYZ   | 10.5
(2 rows)
```

Given those two inputs, how can you determine a bid price that falls between the two points, such as at 3:00:03 PM? The [TIME_SLICE](#) function normalizes timestamps into corresponding time slices; however, [TIME_SLICE](#) does not solve the problem of missing inputs (time slices) in the data. Instead, Vertica provides gap-filling and interpolation (GFI) functionality, which fills in missing data points and adds new (missing) data points within a range of known data points to the output. It accomplishes these tasks with the time series aggregate functions ([TS_FIRST_VALUE](#) and [TS_LAST_VALUE](#)) and the SQL [TIMESERIES clause](#) . But first, we'll illustrate the components that make up gap filling and interpolation in Vertica, starting with [Constant interpolation](#) . The images in the following topics use the following legend:

- The x-axis represents the timestamp ([ts](#)) column
- The y-axis represents the bid column.
- The vertical blue lines delimit the time slices.
- The red dots represent the input records in the table, \$10.0 and \$10.5.
- The blue stars represent the output values, including interpolated values.

In this section

- [Constant interpolation](#)
- [TIMESERIES clause and aggregates](#)
- [Time series rounding](#)
- [Linear interpolation](#)
- [GFI examples](#)

Constant interpolation

Given known input timestamps at 03:00:00 and 03:00:05 in the [sample TickStore schema](#) , how might you determine the bid price at 03:00:03?

A common interpolation scheme used on financial data is to set the bid price to *the last seen value so far* . This scheme is referred to as **constant interpolation** , in which Vertica computes a new value based on the previous input records.

Note

Constant is Vertica's default interpolation scheme. Another interpolation scheme, [linear](#) , is discussed in an upcoming topic.

Returning to the problem query, here is the table output, which shows a 5-second lag between bids at 03:00:00 and 03:00:05:

```
=> SELECT * FROM TickStore;
      ts      | symbol | bid
-----+-----+-----
2009-01-01 03:00:00 | XYZ   | 10
2009-01-01 03:00:05 | XYZ   | 10.5
(2 rows)
```

Using constant interpolation, the interpolated bid price of XYZ remains at \$10.0 at 3:00:03, which falls between the two known data inputs (3:00:00 PM and 3:00:05). At 3:00:05, the value changes to \$10.5. The known data points are represented by a red dot, and the interpolated value at 3:00:03 is represented by the blue star.

In order to write a query that makes the input rows more uniform, you first need to understand the [TIMESERIES clause and time series aggregate functions](#).

TIMESERIES clause and aggregates

The SELECT..TIMESERIES clause and time series aggregates help solve the problem of gaps in input records by normalizing the data into 3-second time slices and interpolating the bid price when it finds gaps.

TIMESERIES clause

The [TIMESERIES clause](#) is an important component of time series analytics computation. It performs gap filling and interpolation (GFI) to generate time slices missing from the input records. The clause applies to the timestamp columns/expressions in the data, and takes the following form:

```
TIMESERIES slice_time AS 'length_and_time_unit_expression'
OVER ( ... [ window-partition-clause[ , ... ] ]
... ORDER BY time_expression )
... [ ORDER BY table_column [ , ... ] ]
```

Note

The TIMESERIES clause requires an ORDER BY operation on the timestamp column.

Time series aggregate functions

The Timeseries Aggregate (TSA) functions [TS_FIRST_VALUE](#) and [TS_LAST_VALUE](#) evaluate the values of a given set of variables over time and group those values into a window for analysis and aggregation.

TSA functions process the data that belongs to each time slice. One output row is produced per time slice or per partition per time slice if a partition expression is present.

The following table shows 3-second time slices where:

- The first two rows fall within the first time slice, which runs from 3:00:00 to 3:00:02. These are the input rows for the TSA function's output for the time slice starting at 3:00:00.
- The second two rows fall within the second time slice, which runs from 3:00:03 to 3:00:05. These are the input rows for the TSA function's output for the time slice starting at 3:00:03.

The result is the start of each time slice.

ts	symbol	bid	ts	symbol	bid
3:00:00	XYZ	10.0	3:00:00	XYZ	10.0
3:00:01	XYZ	10.1	3:00:03	XYZ	10.1
3:00:04	XYZ	10.3			
3:00:05	XYZ	10.5			

Examples

The following examples compare the values returned with and without the `TS_FIRST_VALUE` TSA function.

This example shows the `TIMESERIES` clause without the `TS_FIRST_VALUE` TSA function.

```
=> SELECT slice_time, bid FROM TickStore TIMESERIES slice_time AS '3 seconds' OVER(PARTITION by TickStore.bid ORDER BY ts);
```

This example shows both the `TIMESERIES` clause and the `TS_FIRST_VALUE` TSA function. The query returns the values of the `bid` column, as determined by the specified constant interpolation scheme.

```
=> SELECT slice_time, TS_FIRST_VALUE(bid, 'CONST') bid FROM TickStore  
TIMESERIES slice_time AS '3 seconds' OVER(PARTITION by symbol ORDER BY ts);
```

Vertica interpolates the last known value and fills in the missing datapoint, returning 10 at 3:00:03:

First query		Interpolated value
<pre>slice_time bid -----+----- 2009-01-01 03:00:00 10 2009-01-01 03:00:03 10.5 (2 rows)</pre>	=>	<pre>slice_time bid -----+----- 2009-01-01 03:00:00 10 2009-01-01 03:00:03 10 (2 rows)</pre>

Time series rounding

Vertica calculates all time series as equal intervals relative to the timestamp `2000-01-01 00:00:00`. Vertica rounds time series timestamps as needed, to conform with this baseline. Start times are also rounded down to the nearest whole unit for the specified interval.

Given this logic, the `TIMESERIES` clause generates series of timestamps as described in the following sections.

Minutes

Time series of minutes are rounded down to full minutes. For example, the following statement specifies a time span of `00:00:03 - 00:05:50`:

```
=> SELECT ts FROM (  
  SELECT '2015-01-04 00:00:03'::TIMESTAMP AS tm  
  UNION  
  SELECT '2015-01-04 00:05:50'::TIMESTAMP AS tm  
) t  
TIMESERIES ts AS '1 minute' OVER (ORDER BY tm);
```

Vertica rounds down the time series start and end times to full minutes, `00:00:00` and `00:05:00`, respectively:

ts

2015-01-04 00:00:00
2015-01-04 00:01:00
2015-01-04 00:02:00
2015-01-04 00:03:00
2015-01-04 00:04:00
2015-01-04 00:05:00
(6 rows)

Weeks

Because the baseline timestamp `2000-01-01 00:00:00` is a Saturday, all time series of weeks start on Saturday. Vertica rounds down the series start and end timestamps accordingly. For example, the following statement specifies a time span of `12/10/99 - 01/10/00`:

```
=> SELECT ts FROM (
  SELECT '1999-12-10 00:00:00'::TIMESTAMP AS tm
  UNION
  SELECT '2000-01-10 23:59:59'::TIMESTAMP AS tm
) t
TIMESERIES ts AS '1 week' OVER (ORDER BY tm);
```

The specified time span starts on Friday (12/10/99), so Vertica starts the time series on the preceding Saturday, 12/04/99. The time series ends on the last Saturday within the time span, 01/08/00:

```
ts
-----
1999-12-04 00:00:00
1999-12-11 00:00:00
1999-12-18 00:00:00
1999-12-25 00:00:00
2000-01-01 00:00:00
2000-01-08 00:00:00
(6 rows)
```

Months

Time series of months are divided into equal 30-day intervals, relative to the baseline timestamp `2000-01-01 00:00:00`. For example, the following statement specifies a time span of 09/01/99 - 12/31/00:

```
=> SELECT ts FROM (
  SELECT '1999-09-01 00:00:00'::TIMESTAMP AS tm
  UNION
  SELECT '2000-12-31 23:59:59'::TIMESTAMP AS tm
) t
TIMESERIES ts AS '1 month' OVER (ORDER BY tm);
```

Vertica generates a series of 30-day intervals, where each timestamp is rounded up or down, relative to the baseline timestamp:

```
ts
-----
1999-08-04 00:00:00
1999-09-03 00:00:00
1999-10-03 00:00:00
1999-11-02 00:00:00
1999-12-02 00:00:00
2000-01-01 00:00:00
2000-01-31 00:00:00
2000-03-01 00:00:00
2000-03-31 00:00:00
2000-04-30 00:00:00
2000-05-30 00:00:00
2000-06-29 00:00:00
2000-07-29 00:00:00
2000-08-28 00:00:00
2000-09-27 00:00:00
2000-10-27 00:00:00
2000-11-26 00:00:00
2000-12-26 00:00:00
(18 rows)
```

Years

Time series of years are divided into equal 365-day intervals. If a time span overlaps leap years since or before the baseline timestamp `2000-01-01 00:00:00`, Vertica rounds the series timestamps accordingly.

For example, the following statement specifies a time span of 01/01/95 - 05/08/09, which overlaps four leap years, including the baseline timestamp:

```
=> SELECT ts FROM (
  SELECT '1995-01-01 00:00:00'::TIMESTAMP AS tm
  UNION
  SELECT '2009-05-08'::TIMESTAMP AS tm
) t timeseries ts AS '1 year' over (ORDER BY tm);
```

Vertica generates a series of timestamps that are rounded up or down, relative to the baseline timestamp:

```
ts
-----
1994-01-02 00:00:00
1995-01-02 00:00:00
1996-01-02 00:00:00
1997-01-01 00:00:00
1998-01-01 00:00:00
1999-01-01 00:00:00
2000-01-01 00:00:00
2000-12-31 00:00:00
2001-12-31 00:00:00
2002-12-31 00:00:00
2003-12-31 00:00:00
2004-12-30 00:00:00
2005-12-30 00:00:00
2006-12-30 00:00:00
2007-12-30 00:00:00
2008-12-29 00:00:00
(16 rows)
```

Linear interpolation

Instead of interpolating data points based on the last seen value ([Constant interpolation](#)), linear interpolation is where Vertica interpolates values in a linear slope based on the specified time slice.

The query that follows uses linear interpolation to place the input records in 2-second time slices and return the first bid value for each symbol/time slice combination (the value at the start of the time slice):

```
=> SELECT slice_time, TS_FIRST_VALUE(bid, 'LINEAR') bid FROM Tickstore
  TIMESERIES slice_time AS '2 seconds' OVER(PARTITION BY symbol ORDER BY ts);
 slice_time | bid
-----+-----
2009-01-01 03:00:00 | 10
2009-01-01 03:00:02 | 10.2
2009-01-01 03:00:04 | 10.4
(3 rows)
```

The following figure illustrates the previous query results, showing the 2-second time gaps (3:00:02 and 3:00:04) in which no input record occurs. Note that the interpolated bid price of XYZ changes to 10.2 at 3:00:02 and 10.3 at 3:00:03 and 10.4 at 3:00:04, all of which fall between the two known data inputs (3:00:00 and 3:00:05). At 3:00:05, the value would change to 10.5.

Note

The known data points above are represented by a red dot, and the interpolated values are represented by blue stars.

The following is a side-by-side comparison of constant and linear interpolation schemes.

GFI examples

This topic illustrates some of the queries you can write using the constant and linear interpolation schemes.

Constant interpolation

The first query uses [TS_FIRST_VALUE\(\)](#) and the [TIMESERIES clause](#) to place the input records in 3-second time slices and return the first bid value for each symbol/time slice combination (the value at the start of the time slice).

Note

The [TIMESERIES](#) clause requires an [ORDER BY](#) operation on the [TIMESTAMP](#) column.

```
=> SELECT slice_time, symbol, TS_FIRST_VALUE(bid) AS first_bid FROM TickStore
TIMESERIES slice_time AS '3 seconds' OVER (PARTITION BY symbol ORDER BY ts);
```

Because the bid price of stock **XYZ** is 10.0 at 3:00:03, the **first_bid** value of the second time slice, which starts at 3:00:03 is till 10.0 (instead of 10.5) because the input value of 10.5 does not occur until 3:00:05. In this case, the interpolated value is inferred from the last value seen on stock **XYZ** for time 3:00:03:

slice_time	symbol	first_bid
2009-01-01 03:00:00	XYZ	10
2009-01-01 03:00:03	XYZ	10

(2 rows)

The next example places the input records in 2-second time slices to return the first bid value for each symbol/time slice combination:

```
=> SELECT slice_time, symbol, TS_FIRST_VALUE(bid) AS first_bid FROM TickStore
TIMESERIES slice_time AS '2 seconds' OVER (PARTITION BY symbol ORDER BY ts);
```

The result now contains three records in 2-second increments, all of which occur between the first input row at 03:00:00 and the second input row at 3:00:05. Note that the second and third output record correspond to a time slice where there is no input record:

slice_time	symbol	first_bid
2009-01-01 03:00:00	XYZ	10
2009-01-01 03:00:02	XYZ	10
2009-01-01 03:00:04	XYZ	10

(3 rows)

Using the same table schema, the next query uses [TS_LAST_VALUE\(\)](#), with the [TIMESERIES](#) clause to return the last values of each time slice (the values at the end of the time slices).

Note

Time series aggregate functions process the data that belongs to each time slice. One output row is produced per time slice or per partition per time slice if a partition expression is present.

```
=> SELECT slice_time, symbol, TS_LAST_VALUE(bid) AS last_bid FROM TickStore
TIMESERIES slice_time AS '2 seconds' OVER (PARTITION BY symbol ORDER BY ts);
```

Notice that the last value output row is 10.5 because the value 10.5 at time 3:00:05 was the last point inside the 2-second time slice that started at 3:00:04:

slice_time	symbol	last_bid
2009-01-01 03:00:00	XYZ	10
2009-01-01 03:00:02	XYZ	10
2009-01-01 03:00:04	XYZ	10.5

(3 rows)

Remember that because constant interpolation is the default, the same results are returned if you write the query using the CONST parameter as follows:

```
=> SELECT slice_time, symbol, TS_LAST_VALUE(bid, 'CONST') AS last_bid FROM TickStore
TIMESERIES slice_time AS '2 seconds' OVER (PARTITION BY symbol ORDER BY ts);
```

Linear interpolation

Based on the same input records described in the constant interpolation examples, which specify 2-second time slices, the result of TS_LAST_VALUE with linear interpolation is as follows:

```
=> SELECT slice_time, symbol, TS_LAST_VALUE(bid, 'linear') AS last_bid FROM TickStore
TIMESERIES slice_time AS '2 seconds' OVER (PARTITION BY symbol ORDER BY ts);
```

In the results, no last_bid value is returned for the last row because the query specified TS_LAST_VALUE, and there is no data point after the 3:00:04 time slice to interpolate.

slice_time	symbol	last_bid
2009-01-01 03:00:00	XYZ	10.2
2009-01-01 03:00:02	XYZ	10.4
2009-01-01 03:00:04	XYZ	

(3 rows)

Using multiple time series aggregate functions

Multiple time series aggregate functions can exist in the same query. They share the same *gap-filling* policy as defined in the TIMESERIES clause; however, each time series aggregate function can specify its own interpolation policy. In the following example, there are two constant and one linear interpolation schemes, but all three functions use a three-second time slice:

```
=> SELECT slice_time, symbol,
    TS_FIRST_VALUE(bid, 'const') fv_c,
    TS_FIRST_VALUE(bid, 'linear') fv_l,
    TS_LAST_VALUE(bid, 'const') lv_c
FROM TickStore
TIMESERIES slice_time AS '3 seconds' OVER(PARTITION BY symbol ORDER BY ts);
```

In the following output, the original output is compared to output returned by multiple time series aggregate functions.

ts	symbol	bid
03:00:00	XYZ	10
03:00:05	XYZ	10.5

(2 rows)

==>

slice_time	symbol	fv_c	fv_l	lv_c
2009-01-01 03:00:00	XYZ	10	10	10
2009-01-01 03:00:03	XYZ	10	10.3	10.5

(2 rows)

Using the analytic LAST_VALUE function

Here's an example using LAST_VALUE(), so you can see the difference between it and the GFI syntax.

```
=> SELECT *, LAST_VALUE(bid) OVER(PARTITION by symbol ORDER BY ts)
AS "last bid" FROM TickStore;
```

There is no gap filling and interpolation to the output values.

ts	symbol	bid	last bid
2009-01-01 03:00:00	XYZ	10	10
2009-01-01 03:00:05	XYZ	10.5	10.5

(2 rows)

Using slice_time

In a TIMESERIES query, you cannot use the column `slice_time` in the WHERE clause because the WHERE clause is evaluated before the TIMESERIES clause, and the `slice_time` column is not generated until the TIMESERIES clause is evaluated. For example, Vertica does not support the following query:

```
=> SELECT symbol, slice_time, TS_FIRST_VALUE(bid IGNORE NULLS) AS fv
FROM TickStore
WHERE slice_time = '2009-01-01 03:00:00'
TIMESERIES slice_time as '2 seconds' OVER (PARTITION BY symbol ORDER BY ts);
ERROR: Time Series timestamp alias/Time Series Aggregate Functions not allowed in WHERE clause
```

Instead, you could write a subquery and put the predicate on `slice_time` in the outer query:

```
=> SELECT * FROM (
SELECT symbol, slice_time,
TS_FIRST_VALUE(bid IGNORE NULLS) AS fv
FROM TickStore
TIMESERIES slice_time AS '2 seconds'
OVER (PARTITION BY symbol ORDER BY ts) ) sq
WHERE slice_time = '2009-01-01 03:00:00';
symbol | slice_time | fv
-----+-----+----
XYZ | 2009-01-01 03:00:00 | 10
(1 row)
```

Creating a dense time series

The TIMESERIES clause provides a convenient way to create a dense time series for use in an outer join with fact data. The results represent every time point, rather than just the time points for which data exists.

The examples that follow use the same TickStore schema described in [Gap filling and interpolation \(GFI\)](#), along with the addition of a new inner table for the purpose of creating a join:

```
=> CREATE TABLE inner_table (
ts TIMESTAMP,
bid FLOAT
);
=> CREATE PROJECTION inner_p (ts, bid) as SELECT * FROM inner_table
ORDER BY ts, bid UNSEGMENTED ALL NODES;
=> INSERT INTO inner_table VALUES ('2009-01-01 03:00:02', 1);
=> INSERT INTO inner_table VALUES ('2009-01-01 03:00:04', 2);
=> COMMIT;
```

You can create a simple union between the start and end range of the timeframe of interest in order to return every time point. This example uses a 1-second time slice:

```
=> SELECT ts FROM (
  SELECT '2009-01-01 03:00:00'::TIMESTAMP AS time FROM TickStore
  UNION
  SELECT '2009-01-01 03:00:05'::TIMESTAMP FROM TickStore) t
TIMESERIES ts AS '1 seconds' OVER(ORDER BY time);
ts
-----
2009-01-01 03:00:00
2009-01-01 03:00:01
2009-01-01 03:00:02
2009-01-01 03:00:03
2009-01-01 03:00:04
2009-01-01 03:00:05
(6 rows)
```

The next query creates a union between the start and end range of the timeframe using 500-millisecond time slices:

```
=> SELECT ts FROM (
  SELECT '2009-01-01 03:00:00'::TIMESTAMP AS time
  FROM TickStore
  UNION
  SELECT '2009-01-01 03:00:05'::TIMESTAMP FROM TickStore) t
TIMESERIES ts AS '500 milliseconds' OVER(ORDER BY time);
ts
-----
2009-01-01 03:00:00
2009-01-01 03:00:00.5
2009-01-01 03:00:01
2009-01-01 03:00:01.5
2009-01-01 03:00:02
2009-01-01 03:00:02.5
2009-01-01 03:00:03
2009-01-01 03:00:03.5
2009-01-01 03:00:04
2009-01-01 03:00:04.5
2009-01-01 03:00:05
(11 rows)
```

The following query creates a union between the start- and end-range of the timeframe of interest using 1-second time slices:

```
=> SELECT * FROM (
  SELECT ts FROM (
    SELECT '2009-01-01 03:00:00'::timestamp AS time FROM TickStore
    UNION
    SELECT '2009-01-01 03:00:05'::timestamp FROM TickStore) t
  TIMESERIES ts AS '1 seconds' OVER(ORDER BY time) ) AS outer_table
LEFT OUTER JOIN inner_table ON outer_table.ts = inner_table.ts;
```

The union returns a complete set of records from the left-joined table with the matched records in the right-joined table. Where the query found no match, it extends the right side column with null values:

ts	ts	bid
2009-01-01 03:00:00		
2009-01-01 03:00:01		
2009-01-01 03:00:02	2009-01-01 03:00:02	1
2009-01-01 03:00:03		
2009-01-01 03:00:04	2009-01-01 03:00:04	2
2009-01-01 03:00:05		

(6 rows)

Null values in time series data

Null values are uncommon inputs for gap-filling and interpolation (GFI) computation. When null values exist, you can use time series aggregate (TSA) functions [TS_FIRST_VALUE](#) and [TS_LAST_VALUE](#) with [IGNORE NULLS](#) to affect output of the interpolated values. TSA functions are treated like their analytic counterparts [FIRST_VALUE](#) and [LAST_VALUE](#): if the timestamp itself is null, Vertica filters out those rows before gap filling and interpolation occurs.

Constant interpolation with null values

Figure 1 illustrates a default (constant) interpolation result on four input rows where none of the inputs contains a NULL value:

Figure 2 shows the same input rows with the addition of another input record whose bid value is NULL, and whose timestamp (ts) value is 3:00:03:

For constant interpolation, the bid value starting at 3:00:03 is null until the next non-null bid value appears in time. In Figure 2, the presence of the null row makes the interpolated bid value null in the time interval denoted by the shaded region. If [TS_FIRST_VALUE\(bid\)](#) is evaluated with constant interpolation on the time slice that begins at 3:00:02, its output is non-null. However, [TS_FIRST_VALUE\(bid\)](#) on the next time slice produces null. If the last value of the 3:00:02 time slice is null, the first value for the next time slice (3:00:04) is null. However, if you use a TSA function with [IGNORE NULLS](#), then the value at 3:00:04 is the same value as it was at 3:00:02.

To illustrate, insert a new row into the TickStore table at 03:00:03 with a null bid value, Vertica outputs a row for the 03:00:02 record with a null value but no row for the 03:00:03 input:

```
=> INSERT INTO tickstore VALUES('2009-01-01 03:00:03', 'XYZ', NULL);
=> SELECT slice_time, symbol, TS_LAST_VALUE(bid) AS last_bid FROM TickStore
-> TIMESERIES slice_time AS '2 seconds' OVER (PARTITION BY symbol ORDER BY ts);
 slice_time | symbol | last_bid
-----+-----+-----
2009-01-01 03:00:00 | XYZ | 10
2009-01-01 03:00:02 | XYZ |
2009-01-01 03:00:04 | XYZ | 10.5
(3 rows)
```

If you specify [IGNORE NULLS](#), Vertica fills in the missing data point using a constant interpolation scheme. Here, the bid price at 03:00:02 is interpolated to the last known input record for bid, which was \$10 at 03:00:00:

```
=> SELECT slice_time, symbol, TS_LAST_VALUE(bid IGNORE NULLS) AS last_bid FROM TickStore
TIMESERIES slice_time AS '2 seconds' OVER (PARTITION BY symbol ORDER BY ts);
 slice_time | symbol | last_bid
-----+-----+-----
2009-01-01 03:00:00 | XYZ | 10
2009-01-01 03:00:02 | XYZ | 10
2009-01-01 03:00:04 | XYZ | 10.5
(3 rows)
```

Now, if you insert a row where the timestamp column contains a null value, Vertica filters out that row before gap filling and interpolation occurred.

```
=> INSERT INTO tickstore VALUES(NULL, 'XYZ', 11.2);
=> SELECT slice_time, symbol, TS_LAST_VALUE(bid) AS last_bid FROM TickStore
    TIMESERIES slice_time AS '2 seconds' OVER (PARTITION BY symbol ORDER BY ts);
```

Notice there is no output for the 11.2 bid row:

slice_time	symbol	last_bid
2009-01-01 03:00:00	XYZ	10
2009-01-01 03:00:02	XYZ	
2009-01-01 03:00:04	XYZ	10.5

(3 rows)

Linear interpolation with null values

For linear interpolation, the interpolated bid value becomes null in the time interval, represented by the shaded region in Figure 3:

In the presence of an input null value at 3:00:03, Vertica cannot linearly interpolate the bid value around that time point.

Vertica takes the closest non null value on either side of the time slice and uses that value. For example, if you use a linear interpolation scheme and do not specify **IGNORE NULLS**, and your data has one real value and one null, the result is null. If the value on either side is null, the result is null.

Therefore, to evaluate **TS_FIRST_VALUE(bid)** with linear interpolation on the time slice that begins at 3:00:02, its output is null.

TS_FIRST_VALUE(bid) on the next time slice remains null.

```
=> SELECT slice_time, symbol, TS_FIRST_VALUE(bid, 'linear') AS fv_l FROM TickStore
    TIMESERIES slice_time AS '2 seconds' OVER (PARTITION BY symbol ORDER BY ts);
slice_time | symbol | fv_l
```

slice_time	symbol	fv_l
2009-01-01 03:00:00	XYZ	10
2009-01-01 03:00:02	XYZ	
2009-01-01 03:00:04	XYZ	

(3 rows)

Data aggregation

You can use functions such as [SUM](#) and [COUNT](#) to aggregate the results of **GROUP BY** queries at one or more levels.

In this section

- [Single-level aggregation](#)
- [Multi-level aggregation](#)
- [Aggregates and functions for multilevel grouping](#)
- [Aggregate expressions for GROUP BY](#)
- [Pre-aggregating data in projections](#)

Single-level aggregation

The simplest **GROUP BY** queries aggregate data at a single level. For example, a table might contain the following information about family expenses:

- Category
- Amount spent on that category during the year
- Year

Table data might look like this:

```
=> SELECT * FROM expenses ORDER BY Category;
```

Year	Category	Amount
2005	Books	39.98
2007	Books	29.99
2008	Books	29.99
2006	Electrical	109.99
2005	Electrical	109.99
2007	Electrical	229.98

You can use aggregate functions to get the total expenses per category or per year:

```
=> SELECT SUM(Amount), Category FROM expenses GROUP BY Category;
```

SUM	Category
99.96	Books
449.96	Electrical

```
=> SELECT SUM(Amount), Year FROM expenses GROUP BY Year;
```

SUM	Year
149.97	2005
109.99	2006
29.99	2008
259.97	2007

Multi-level aggregation

Over time, tables that are updated frequently can contain large amounts of data. Using the simple table shown earlier, suppose you want a multilevel query, like the number of expenses per category per year.

The following query uses the **ROLLUP** aggregation with the SUM function to calculate the total expenses by category and the overall expenses total. The NULL fields indicate subtotal values in the aggregation.

- When only the **Year** column is **NULL**, the subtotal is for all the **Category** values.
- When both the **Year** and **Category** columns are **NULL**, the subtotal is for all **Amount** values for both columns.

Using the **ORDER BY** clause orders the results by expense category, the year the expenses took place, and the **GROUP BY** level that the **GROUPING_ID** function creates:

```
=> SELECT Category, Year, SUM(Amount) FROM expenses  
GROUP BY ROLLUP(Category, Year) ORDER BY Category, Year, GROUPING_ID();
```

Category	Year	SUM
Books	2005	39.98
Books	2007	29.99
Books	2008	29.99
Books		99.96
Electrical	2005	109.99
Electrical	2006	109.99
Electrical	2007	229.98
Electrical		449.96
		549.92

Similarly, the following query calculates the total sales by year and the overall sales total and then uses the **ORDER BY** clause to sort the results:

```
=> SELECT Category, Year, SUM(Amount) FROM expenses
      GROUP BY ROLLUP(Year, Category) ORDER BY 2, 1, GROUPING_ID();
Category | Year | SUM
-----+-----+-----
Books    | 2005 | 39.98
Electrical | 2005 | 109.99
          | 2005 | 149.97
Electrical | 2006 | 109.99
          | 2006 | 109.99
Books    | 2007 | 29.99
Electrical | 2007 | 229.98
          | 2007 | 259.97
Books    | 2008 | 29.99
          | 2008 | 29.99
          |      | 549.92
(11 rows)
```

You can use the **CUBE** aggregate to perform all possible groupings of the category and year expenses. The following query returns all possible groupings, ordered by grouping:

```
=> SELECT Category, Year, SUM(Amount) FROM expenses
      GROUP BY CUBE(Category, Year) ORDER BY 1, 2, GROUPING_ID();
Category | Year | SUM
-----+-----+-----
Books    | 2005 | 39.98
Books    | 2007 | 29.99
Books    | 2008 | 29.99
Books    |      | 99.96
Electrical | 2005 | 109.99
Electrical | 2006 | 109.99
Electrical | 2007 | 229.98
Electrical |      | 449.96
          | 2005 | 149.97
          | 2006 | 109.99
          | 2007 | 259.97
          | 2008 | 29.99
          |      | 549.92
```

The results include subtotals for each category and each year and a total (\$549.92) for all transactions, regardless of year or category.

ROLLUP, **CUBE**, and **GROUPING SETS** generate **NULL** values in grouping columns to identify subtotals. If table data includes **NULL** values, differentiating these from **NULL** values in subtotals can sometimes be challenging.

In the preceding output, the **NULL** values in the **Year** column indicate that the row was grouped on the **Category** column, rather than on both columns. In this case, **ROLLUP** added the **NULL** value to indicate the subtotal row.

Aggregates and functions for multilevel grouping

Vertica provides several aggregates and functions that group the results of a **GROUP BY** query at multiple levels.

Aggregates for multilevel grouping

Use the following aggregates for multilevel grouping:

- **ROLLUP** automatically performs subtotal aggregations. **ROLLUP** performs one or more aggregations across multiple dimensions, at different levels.
- **CUBE** performs the aggregation for all permutations of the **CUBE** expression that you specify.
- **GROUPING SETS** let you specify which groupings of aggregations you need.

You can use **CUBE** or **ROLLUP** expressions inside **GROUPING SETS** expressions. Otherwise, you cannot nest multilevel aggregate expressions.

Grouping functions

You use one of the following three grouping functions with **ROLLUP**, **CUBE**, and **GROUPING SETS**:

- [GROUP_ID](#) returns one or more numbers, starting with zero (0), to uniquely identify duplicate sets.
- [GROUPING_ID](#) produces a unique ID for each grouping combination.
- [GROUPING](#) identifies for each grouping combination whether a column is a part of this grouping. This function also differentiates NULL values in the data from NULL grouping subtotals.

These functions are typically used with multilevel aggregates.

Aggregate expressions for GROUP BY

You can include CUBE and ROLLUP aggregates within a GROUPING SETS aggregate. Be aware that the CUBE and ROLLUP aggregates can result in a large amount of output. However, you can avoid large outputs by using GROUPING SETS to return only specified results.

```
...GROUP BY a,b,c,d,ROLLUP(a,b)...
...GROUP BY a,b,c,d,CUBE((a,b),c,d)...
```

You cannot include any aggregates in a CUBE or ROLLUP aggregate expression.

You can append multiple GROUPING SETS, CUBE, or ROLLUP aggregates in the same query.

```
...GROUP BY a,b,c,d,CUBE(a,b),ROLLUP (c,d)...
...GROUP BY a,b,c,d,GROUPING SETS ((a,d),(b,c),CUBE(a,b));...
...GROUP BY a,b,c,d,GROUPING SETS ((a,d),(b,c),(a,b),(a),(b),())...
```

Pre-aggregating data in projections

Queries that use aggregate functions such as [SUM](#) and [COUNT](#) can perform more efficiently when they use projections that already contain the aggregated data. This improved efficiency is especially true for queries on large quantities of data.

For example, a power grid company reads 30 million smart meters that provide data at five-minute intervals. The company records each reading in a database table. Over a given year, three trillion records are added to this table.

The power grid company can analyze these records with queries that include aggregate functions to perform the following tasks:

- Establish usage patterns.
- Detect fraud.
- Measure correlation to external events such as weather patterns or pricing changes.

To optimize query response time, you can create an aggregate projection, which stores the data is stored after it is aggregated.

Aggregate projections

Vertica provides several types of projections for storing data that is returned from aggregate functions or expressions:

- [Live aggregate projection](#): Projection that contains columns with values that are aggregated from columns in its anchor table. You can also define live aggregate projections that include [user-defined transform functions](#).
- [Top-K projection](#): Type of live aggregate projection that returns the top *k* rows from a partition of selected rows. Create a Top-K projection that satisfies the criteria for a Top-K query.
- [Projection that pre-aggregates UDTF results](#): Live aggregate projection that invokes user-defined transform functions (UDTFs). To minimize overhead when you query those projections of this type, Vertica processes the UDTF functions in the background and stores their results on disk.
- [Projection that contains expressions](#): Projection with columns whose values are calculated from anchor table columns.

Recommended use

- Aggregate projections are most useful for queries against large sets of data.
- For optimal query performance, the size of LAP projections should be a small subset of the anchor table—ideally, between 1 and 10 percent of the anchor table, or smaller, if possible.

Restrictions

- MERGE operations must be [optimized](#) if they are performed on target tables that have live aggregate projections.
- You cannot update or delete data in temporary tables with live aggregate projections.

Requirements

In the event of manual recovery from an unclean database shutdown, live aggregate projections might require some time to refresh.

In this section

- [Live aggregate projections](#)
- [Top-k projections](#)

- [Pre-aggregating UDTF results](#)
- [Aggregating data through expressions](#)
- [Aggregation information in system tables](#)

Live aggregate projections

A live aggregate projection contains columns with values that are aggregated from columns in its anchor table. When you load data into the table, Vertica aggregates the data before loading it into the live aggregate projection. On subsequent loads—for example, through [INSERT](#) or [COPY](#)—Vertica recalculates aggregations with the new data and updates the projection.

In this section

- [Functions supported for live aggregate projections](#)
- [Creating live aggregate projections](#)
- [Live aggregate projection example](#)

Functions supported for live aggregate projections

Vertica can aggregate results in live aggregate projections from the following aggregate functions:

- [SUM](#)
- [MAX](#)
- [MIN](#)
- [COUNT](#)

Aggregate functions with DISTINCT

Live aggregate projections can support queries that include aggregate functions qualified with the keyword **DISTINCT**. The following requirements apply:

- The aggregated expression must evaluate to a non-constant.
- The projection's **GROUP BY** clause must specify the aggregated expression.

For example, the following query uses **SUM(DISTINCT)** to calculate the total of all unique salaries in a given region:

```
SELECT customer_region, SUM(DISTINCT annual_income)::INT
FROM customer_dimension GROUP BY customer_region;
```

This query can use the following live aggregate projection, which specifies the aggregated column (**annual_income**) in its **GROUP BY** clause:

```
CREATE PROJECTION public.TotalRegionalIncome
(
  customer_region,
  annual_income,
  Count
)
AS
SELECT customer_dimension.customer_region,
       customer_dimension.annual_income,
       count(*) AS Count
FROM public.customer_dimension
GROUP BY customer_dimension.customer_region,
         customer_dimension.annual_income
;
```

Note

This projection includes the aggregate function **COUNT**, which here serves no logical objective; it is included only because live aggregate projections require at least one aggregate function.

Creating live aggregate projections

You define a live aggregate projection with the following syntax:

```
=> CREATE PROJECTION proj-name AS
  SELECT select-expression FROM table
  GROUP BY group-expression;
```

For full syntax options, see [CREATE PROJECTION](#).

For example:

```
=> CREATE PROJECTION clicks_agg AS
  SELECT page_id, click_time::DATE click_date, COUNT(*) num_clicks FROM clicks
  GROUP BY page_id, click_time::DATE KSAFE 1;
```

For an extended discussion, see [Live aggregate projection example](#).

Requirements

The following requirements apply to live aggregate projections:

- The projection cannot be unsegmented. Unless the CREATE PROJECTION statement or its anchor table DDL [specifies otherwise](#), all projections are segmented by default.
- [SELECT](#) and [GROUP BY](#) columns must be in the same order. GROUP BY expressions must be at the beginning of the SELECT list.

Restrictions

The following restrictions apply to live aggregate projections:

- MERGE operations must be [optimized](#) if they are performed on target tables that have live aggregate projections.
- Live aggregate projections can reference only one table.
- Live aggregate projections cannot use row access policies.
- Vertica does not regard live aggregate projections as superprojections, even those that include all table columns.
- You cannot [modify the anchor table metadata](#) of columns that are included in live aggregate projections—for example, a column's data type or default value. You also cannot [drop](#) these columns. To make these changes, first [drop](#) all live aggregate and Top-K projections that are associated with the table.

Note

One exception applies: You can set and drop NOT NULL on columns that are included in a live aggregate projection.

Live aggregate projection example

This example shows how you can track user clicks on a given web page using the following `clicks` table:

```
=> CREATE TABLE clicks(
  user_id INTEGER,
  page_id INTEGER,
  click_time TIMESTAMP NOT NULL);
```

You can aggregate user-specific activity with the following query:

```
=> SELECT page_id, click_time::DATE click_date, COUNT(*) num_clicks FROM clicks
  WHERE click_time::DATE = '2015-04-30'
  GROUP BY page_id, click_time::DATE ORDER BY num_clicks DESC;
```

To facilitate performance of this query, create a live aggregate projection that counts the number of clicks per user:

```
=> CREATE PROJECTION clicks_agg AS
  SELECT page_id, click_time::DATE click_date, COUNT(*) num_clicks FROM clicks
  GROUP BY page_id, click_time::DATE KSAFE 1;
```

When you query the `clicks` table on user clicks, Vertica typically directs the query to the live aggregate projection `clicks_agg`. As additional data is loaded into `clicks`, Vertica pre-aggregates the new data and updates `clicks_agg`, so queries always return with the latest data.

For example:

```
=> SELECT page_id, click_time::DATE click_date, COUNT(*) num_clicks FROM clicks
  WHERE click_time::DATE = '2015-04-30' GROUP BY page_id, click_time::DATE
  ORDER BY num_clicks DESC;
page_id | click_date | num_clicks
-----+-----+-----
 2002 | 2015-04-30 |      10
 3003 | 2015-04-30 |       3
 2003 | 2015-04-30 |       1
 2035 | 2015-04-30 |       1
12034 | 2015-04-30 |       1
(5 rows)
```

Top-k projections

A Top-K query returns the top *k* rows from partitions of selected rows. Top-K projections can significantly improve performance of Top-K queries. For example, you can define a table that stores gas meter readings with three columns: gas meter ID, time of meter reading, and the read value:

```
=> CREATE TABLE readings (
  meter_id INT,
  reading_date TIMESTAMP,
  reading_value FLOAT);
```

Given this table, the following Top-K query returns the five most recent meter readings for a given meter:

```
SELECT meter_id, reading_date, reading_value FROM readings
  LIMIT 5 OVER (PARTITION BY meter_id ORDER BY reading_date DESC);
```

To improve the performance of this query, you can create a Top-K projection, which is a special type of live aggregate projection:

```
=> CREATE PROJECTION readings_topk (meter_id, recent_date, recent_value)
  AS SELECT meter_id, reading_date, reading_value FROM readings
  LIMIT 5 OVER (PARTITION BY meter_id ORDER BY reading_date DESC);
```

After you create this Top-K projection and load its data (through [START_REFRESH](#) or [REFRESH](#)), Vertica typically redirects the query to the projection and returns with the pre-aggregated data.

In this section

- [Creating top-k projections](#)
- [Top-k projection examples](#)

Creating top-k projections

You define a Top-K projection with the following syntax:

```
CREATE PROJECTION proj-name [(proj-column-spec)]
  AS SELECT select-expression FROM table
  LIMIT num-rows OVER (PARTITION BY expression ORDER BY column-expr);
```

For full syntax options, see [CREATE PROJECTION](#).

For example:

```
=> CREATE PROJECTION readings_topk (meter_id, recent_date, recent_value)
  AS SELECT meter_id, reading_date, reading_value FROM readings
  LIMIT 5 OVER (PARTITION BY meter_id ORDER BY reading_date DESC);
```

For an extended discussion, see [Top-k projection examples](#).

Requirements

The following requirements apply to Top-K projections:

- The projection cannot be unsegmented.
- The [window partition clause](#) must use **PARTITION BY**.
- Columns in **PARTITION BY** and **ORDER BY** clauses must be the first columns specified in the **SELECT** list.
- You must use the **LIMIT** option to create a Top-K projection, instead of subqueries. For example, the following **SELECT** statements are equivalent:

```
=> SELECT symbol, trade_time last_trade, price last_price FROM (
  SELECT symbol, trade_time, price, ROW_NUMBER()
  OVER(PARTITION BY symbol ORDER BY trade_time DESC) rn FROM trades) trds WHERE rn <=1;

=> SELECT symbol, trade_time last_trade, price last_price FROM trades
LIMIT 1 OVER(PARTITION BY symbol ORDER BY trade_time DESC);
```

Both return the same results:

symbol	last_trade	last_price
AAPL	2011-11-10 10:10:20.5	108.4000
HPQ	2012-10-10 10:10:10.4	42.0500

(2 rows)

A Top-K projection that pre-aggregates data for use by both queries must include the **LIMIT** option:

```
=> CREATE PROJECTION trades_topk AS
  SELECT symbol, trade_time last_trade, price last_price FROM trades
  LIMIT 1 OVER(PARTITION BY symbol ORDER BY trade_time DESC);
```

Restrictions

The following restrictions apply to Top-K projections:

- Top-K projections can reference only one table.
- Vertica does not regard Top-K projections as superprojections, even those that include all table columns.
- You cannot [modify the anchor table metadata](#) of columns that are included in Top-K projections—for example, a column's data type or default value. You also cannot [drop](#) these columns. To make these changes, first [drop](#) all live aggregate and Top-K projections that are associated with the table.

Note

One exception applies: You can set and drop NOT NULL on columns that are included in a live aggregate projection.

Top-k projection examples

The following examples show how to query a table with two Top-K projections for the most-recent trade and last trade of the day for each stock symbol.

1. Create a table that contains information about individual stock trades:

- Stock symbol
- Timestamp
- Price per share
- Number of shares

```
=> CREATE TABLE trades(
  symbol CHAR(16) NOT NULL,
  trade_time TIMESTAMP NOT NULL,
  price NUMERIC(12,4),
  volume INT )
PARTITION BY (EXTRACT(year from trade_time) * 100 +
  EXTRACT(month from trade_time));
```

2. Load data into the table:

```

INSERT INTO trades VALUES('AAPL','2010-10-10 10:10:10'::TIMESTAMP,100.00,100);
INSERT INTO trades VALUES('AAPL','2010-10-10 10:10:10.3'::TIMESTAMP,101.00,100);
INSERT INTO trades VALUES ('AAPL','2011-10-10 10:10:10.5'::TIMESTAMP,106.1,1000);
INSERT INTO trades VALUES ('AAPL','2011-10-10 10:10:10.2'::TIMESTAMP,105.2,500);
INSERT INTO trades VALUES ('HPQ','2012-10-10 10:10:10.2'::TIMESTAMP,42.01,400);
INSERT INTO trades VALUES ('HPQ','2012-10-10 10:10:10.3'::TIMESTAMP,42.02,1000);
INSERT INTO trades VALUES ('HPQ','2012-10-10 10:10:10.4'::TIMESTAMP,42.05,100);
COMMIT;

```

3. Create two Top-K projections that obtain the following information from the `trades` table:

- [Return the most recent trades for each stock symbol.](#)
- [Return the last trade on each trading day.](#)

For each stock symbol, return the most recent trade.

```

=> CREATE PROJECTION trades_topk_a AS SELECT symbol, trade_time last_trade, price last_price
FROM trades LIMIT 1 OVER(PARTITION BY symbol ORDER BY trade_time DESC);

```

```

=> SELECT symbol, trade_time last_trade, price last_price FROM trades
LIMIT 1 OVER(PARTITION BY symbol ORDER BY trade_time DESC);

```

symbol	last_trade	last_price
HPQ	2012-10-10 10:10:10.4	42.0500
AAPL	2011-10-10 10:10:10.5	106.1000

(2 rows)

For each stock symbol, return the last trade on each trading day.

```

=> CREATE PROJECTION trades_topk_b
AS SELECT symbol, trade_time::DATE trade_date, trade_time, price close_price, volume
FROM trades LIMIT 1 OVER(PARTITION BY symbol, trade_time::DATE ORDER BY trade_time DESC);

```

```

=> SELECT symbol, trade_time::DATE trade_date, trade_time, price close_price, volume
FROM trades LIMIT 1 OVER(PARTITION BY symbol, trade_time::DATE ORDER BY trade_time DESC);

```

symbol	trade_date	trade_time	close_price	volume
HPQ	2012-10-10	2012-10-10 10:10:10.4	42.0500	100
AAPL	2011-10-10	2011-10-10 10:10:10.5	106.1000	1000
AAPL	2010-10-10	2010-10-10 10:10:10.3	101.0000	100

(3 rows)

In each scenario, Vertica redirects queries on the `trades` table to the appropriate Top-K projection and returns the aggregated data from them. As additional data is loaded into this table, Vertica pre-aggregates the new data and updates the Top-K projections, so queries always return with the latest data.

Pre-aggregating UDTF results

[CREATE PROJECTION](#) can define live aggregate projections that invoke user-defined transform functions (UDTFs). To minimize overhead when you query those projections, Vertica processes these functions in the background and stores their results on disk.

Important

Currently, live aggregate projections can only reference UDTFs that are developed in C++.

Defining projections with UDTFs

The projection definition characterizes UDTFs in one of two ways:

- Identifies the UDTF as a *pre-pass UDTF*, which transforms newly loaded data before it is stored in the projection ROS containers.
- Identifies the UDTF as a *batch UDTF*, which aggregates and stores projection data.

The projection definition identifies a UDTF as a pre-pass UDTF or batch UDTF in its [window partition clause](#), through the keywords **PREPASS** or **BATCH**. A projection can specify one pre-pass or batch UDTF or include both (see [UDTF Specification Options](#)).

In all cases, the projection is implicitly segmented and ordered on the PARTITION BY columns.

UDTF specification options

Projections can invoke batch and pre-pass UDTFs singly or in combination.

Single pre-pass UDTF

Vertica invokes the pre-pass UDTF when you load data into the projection's anchor table—for example through COPY or INSERT statements. A pre-pass UDTF transforms the new data and then stores the transformed data in the projection's ROS containers.

Use the following syntax:

```
CREATE PROJECTION [ IF NOT EXISTS ] [[database.]schema.]projection
[ (
  { projection-column | grouped-clause
  [ ENCODING encoding-type ]
  [ ACCESSRANK integer ] }[,...]]
) ]
AS SELECT { table-column | expr-with-table-columns }[,...], prepass-udtf(prepass-args)
  OVER (PARTITION PREPASS BY partition-column-expr[,...])
  [ AS (prepass-output-columns) ] FROM table [[AS] alias]
```

Single batch UDTF

When invoked singly, a batch UDTF transforms and aggregates projection data on mergeout, data load, and query operations. The UDTF stores aggregated results in the projection's ROS containers. Aggregation is cumulative across mergeout and load operations, and is completed (if necessary) on query execution.

Use the following syntax:

```
CREATE PROJECTION [ IF NOT EXISTS ] [[database.]schema.]projection
[ (
  { projection-column | grouped-clause
  [ ENCODING encoding-type ]
  [ ACCESSRANK integer ] }[,...]]
) ]
AS SELECT { table-column | expr-with-table-columns }[,...], batch-udtf(batch-args)
  OVER (PARTITION BATCH BY partition-column-expr[,...])
  [ AS (batch-output-columns) ] FROM table [ [AS] alias ]
```

Combined pre-pass and batch UDTFs

You can define a projection with a subquery that invokes a pre-pass UDTF. The pre-pass UDTF returns transformed data to the outer batch query. The batch UDTF then iteratively aggregates results across mergeout operations. It completes aggregation (if necessary) on query execution.

Use the following syntax:

```
CREATE PROJECTION [ IF NOT EXISTS ] [[database.]schema.]projection
[ (
  { projection-column | grouped-clause
  [ ENCODING encoding-type ]
  [ ACCESSRANK integer ] }[,...]]
) ]
AS SELECT { table-column | expr-with-table-columns }[,...], batch-udtf(batch-args)
  OVER (PARTITION BATCH BY partition-column-expr[,...]) [ AS (batch-output-columns) ] FROM (
  SELECT { table-column | expr-with-table-columns }[,...], prepass-udtf (prepass-args)
  OVER (PARTITION PREPASS BY partition-column-expr[,...]) [ AS (prepass-output-columns) ] FROM table ) sq-ref
```

Important

The outer batch UDTF arguments *batch-args* must exactly match the output columns returned by the pre-pass UDTF, in name and order.

Examples

Single pre-pass UDTF

The following example shows how to use the UDTF `text_index`, which extracts from a text document strings that occur more than once.

The following projection specifies to invoke `text_index` as a pre-pass UDTF:

```
=> CREATE TABLE documents ( doc_id INT PRIMARY KEY, text VARCHAR(140));
=> CREATE PROJECTION index_proj (doc_id, text)
  AS SELECT doc_id, text_index(doc_id, text)
  OVER (PARTITION PREPASS BY doc_id) FROM documents;
```

The UDTF is invoked whenever data is loaded into the anchor table `documents`. `text_index` transforms the newly loaded data, and Vertica stores the transformed data in the live aggregate projection ROS containers.

So, if you load the following data into `documents` :

```
=> INSERT INTO documents VALUES
(100, 'A SQL Query walks into a bar. In one corner of the bar are two tables.
The Query walks up to the tables and asks - Mind if I join you?');
OUTPUT
-----
 1
(1 row)
```

`text_index` transforms the newly loaded data and stores it in the projection ROS containers. When you query the projection, it returns with the following results:

doc_id	frequency	term
100	2	bar
100	2	Query
100	2	tables
100	2	the
100	2	walks

Combined Pre-Pass and Batch UDTFs

The following projection specifies pre-pass and batch UDTFs `stv_intersect` and `aggregate_classified_points`, respectively:

```
CREATE TABLE points( point_id INTEGER, point_type VARCHAR(10), coordinates GEOMETRY(100));
CREATE PROJECTION aggregated_proj
  AS SELECT point_type, aggregate_classified_points( sq.point_id, sq.polygon_id)
  OVER (PARTITION BATCH BY point_type) AS some_alias
  FROM
  (SELECT point_type, stv_intersect(
    point_id, coordinates USING PARAMETERS index='polygons' )
  OVER (PARTITION PREPASS BY point_type) AS (point_id, polygon_id) FROM points) sq;
```

The pre-pass query UDTF `stv_intersect` returns its results (a set of point and matching polygon IDs) to the outer batch query. The outer batch query then invokes the UDTF `aggregate_classified_points`. Vertica aggregates the result set that is returned by `aggregate_classified_points` whenever a mergeout operation consolidates projection data. Final aggregation (if necessary) occurs when the projection is queried.

The batch UDTF arguments must exactly match the output columns returned by the pre-pass UDTF `stv_intersect`, in name and order. In this example, the pre-pass subquery explicitly names the pre-pass UDTF output columns `point_id` and `polygon_id`. Accordingly, the batch UDTF arguments match them in name and order: `sq.point_id` and `sq.polygon_id`.

Aggregating data through expressions

You can create projections where one or more columns are defined by expressions. An expression can reference one or more anchor table columns. For example, the following table contains two integer columns, **a** and **b** :

```
=> CREATE TABLE values (a INT, b INT);
```

You can create a projection with an expression that calculates the value of column **c** as the product of **a** and **b** :

```
=> CREATE PROJECTION values_product (a, b, c)
AS SELECT a, b, a*b FROM values SEGMENTED BY HASH(a) ALL NODES KSAFE;
```

When you load data into this projection, Vertica resolves the expression **a*b** in column **c**. You can then query the projection instead of the anchor table. Vertica returns the pre-calculated data and avoids the overhead otherwise incurred by resource-intensive computations.

Using expressions in projections also lets you sort or segment data on the calculated results of an expression instead of sorting on single column values.

Note

If a projection with expressions also includes aggregate functions such as [SUM](#) or [COUNT](#), Vertica treats it like a [live aggregate projection](#).

Support for user-defined scalar functions

Important

Currently, support for pre-aggregating UDSF results is limited to C++.

Vertica treats user-defined scalar functions (UDSFs) like other expressions. On each load operation, the UDSF is invoked and returns its results. Vertica stores these results on disk, and returns them when you query the projection directly.

In the following example, the projection **points_p1** specifies the UDSF **zorder**, which is invoked whenever data is loaded in the anchor table **points**. When data is loaded into the projection, Vertica invokes this function and stores its results for fast access by future queries.

```
=> CREATE TABLE points(point_id INTEGER, lat NUMERIC(12,9), long NUMERIC(12,9));

=> CREATE PROJECTION points_p1
AS SELECT point_id, lat, long, zorder(lat, long) zorder FROM points
ORDER BY zorder(lat, long) SEGMENTED BY hash(point_id) ALL NODES;
```

Requirements

- Any **ORDER BY** expression must be in the **SELECT** list.
- All projection columns must be named.

Restrictions

- **MERGE** operations must be [optimized](#) if they are performed on target tables that have live aggregate projections.
- Unlike live aggregate projections, Vertica does not redirect queries with expressions to an equivalent existing projection.
- Projection expressions must be immutable—that is, they must always return the same result. For example, a projection cannot include expressions that use **TO CHAR** (depends on locale) or **RANDOM** (returns different value at each invocation).
- Projection expressions cannot include Vertica meta-functions such as **ADVANCE_EPOCH**, **ANALYZE_STATISTICS**, **EXPORT_TABLES**, or **START_REFRESH**.

In this section

- [Querying data through expressions example](#)

Querying data through expressions example

The following example uses a table that contains two integer columns, **a** and **b** :

```
=> CREATE TABLE values (a INT, b INT);
```

You can create a projection with an expression that calculates the value of column **c** as the product of **a** and **b** :

```

=> CREATE PROJECTION values_product (a, b, c)
  AS SELECT a, b, a*b FROM values SEGMENTED BY HASH(a) ALL NODES KSAFE;
=> COPY values FROM STDIN DELIMITER ',' DIRECT;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 3,11
>> 3,55
>> 8,9
>> 8,23
>> 16,41
>> 22,111
>> \.
=>

```

To query this projection, use the name that Vertica assigns to it or to its buddy projections. For example, the following queries target different instances of the projection defined earlier, and return the same results:

```

=> SELECT * FROM values_product_b0;
=> SELECT * FROM values_product_b1;

```

The following example queries the anchor table:

```

=> SELECT * FROM values;
a | b
----+-----
3 | 11
3 | 55
8 | 9
8 | 23
16 | 41
22 | 111

```

Given the projection created earlier, querying that projection returns the following values:

```

VMart=> SELECT * FROM values_product_b0;
a | b | product
----+-----+-----
3 | 11 | 33
3 | 55 | 165
8 | 9 | 72
8 | 23 | 184
16 | 41 | 656
22 | 111 | 2442

```

Aggregation information in system tables

You can query the following system table fields for information about live aggregate projections, Top-K projections, and projections with expressions:

Table	Fields
TABLES	TABLE_HAS_AGGREGATE_PROJECTION
PROJECTIONS	AGGREGATE_TYPE
	HAS_EXPRESSIONS
	AGGREGATE_TYPE
PROJECTION_COLUMNS	COLUMN_EXPRESSION
	IS_AGGREGATE

IS_EXPRESSION
ORDER_BY_POSITION
ORDER_BY_TYPE
PARTITION_BY_POSITION

Flex tables

Flex tables are a different kind of database table designed for loading and querying unstructured data, also called *semi-structured* data. Flex tables allow you to load data with different or evolving schemas into a single table. You can then explore this data and materialize real columns from it.

If you know some of the columns in the data, you can define them. A flex table that also has real columns is called a hybrid table. Both flex and hybrid tables are fully supported tables, stored as projections and with the same K-safety as your database.

After you create a flex table, you can quickly load data without specifying its schema. This allows you to load arbitrary JSON data, log files, and other semi-structured data and immediately begin querying it.

Creating flex tables is similar to creating other tables, except column definitions are optional. When you create flex tables, with or without column definitions, Vertica implicitly adds a real column to your table, called `__raw__`. This column stores loaded data. The `__raw__` column is a LONG VARBINARY column with a NOT NULL constraint. It contains the documented limits for its data type (see [Long data types](#)). The `__raw__` column's default maximum width is 130,000 bytes (with an absolute maximum of 32,000,000 bytes). You can change the default width with the `FlexTableRowSize` configuration parameter.

If you create a flex table without other column definitions, the table includes a second default column, `__identity__`, declared as an auto-incrementing `IDENTITY(1,1)` column. When no other columns are defined, flex tables use the `__identity__` column for segmentation and sort order.

Loading data into a flex table encodes the record into a VMap type and populates the `__raw__` column. The VMap is a standard dictionary type, pairing keys with string values as virtual columns.

Flex table terms

Flex tables have the following special vocabulary:

- VMap: An internal map data format.
- Virtual Columns: Key-value pairs contained in a flex table `__raw__` column.
- Real Columns: Explicit columns defined in addition to the flex (VMap) column.
- Promoted Columns: Virtual columns that have been materialized to real columns.
- Map Keys: Virtual column names within VMap data.

In this section

- [Computing flex table keys](#)
- [Materializing flex tables](#)
- [Updating flex table views](#)
- [Querying flex tables](#)
- [Querying nested data](#)
- [Querying flex views](#)
- [Listing flex tables](#)

Getting started

The following tutorial demonstrates the basics of creating, exploring, and using flex tables.

These examples use a data file named `mountains.json` with the following contents:

As this example demonstrates, querying `__raw__` directly is not generally helpful. Instead, you can use functions to extract values from it. Use the [MAPTOSTRING](#) function to see this column in a more readable JSON format:

```
=> SELECT MAPTOSTRING(__raw__) FROM mountains;
```

```
MAPTOSTRING
```

```
-----  
{  
  "height" : "29029",  
  "hike_safety" : "34.1",  
  "name" : "Everest",  
  "type" : "mountain"  
}  
  
{  
  "height" : "29029",  
  "hike_safety" : "15.4",  
  "name" : "Mt St Helens",  
  "type" : "volcano"  
}  
  
{  
  "height" : "17000",  
  "hike_safety" : "12.2",  
  "name" : "Denali",  
  "type" : "mountain"  
}  
  
{  
  "height" : "14000",  
  "name" : "Kilimanjaro",  
  "type" : "mountain"  
}  
  
{  
  "hike_safety" : "50.6",  
  "name" : "Mt Washington",  
  "type" : "mountain"  
}
```

You can use the [COMPUTE_FLEXTABLE_KEYS](#) function to extract information about the keys in the `__raw__` column into a new table. The new table shows the key names, frequencies, and inferred data types:

```
=> SELECT COMPUTE_FLEXTABLE_KEYS('mountains');
```

```
COMPUTE_FLEXTABLE_KEYS
```

```
-----  
Please see public.mountains_keys for updated keys
```

```
(1 row)
```

```
=> SELECT * FROM public.mountains_keys;
```

```
key_name | frequency | data_type_guess
```

```
-----+-----+-----  
height   |         4 | Integer  
hike_safety |         4 | Numeric(6,2)  
name     |         5 | Varchar(26)  
type     |         5 | Varchar(20)
```

```
(4 rows)
```

Vertica generates this table automatically when you create a flex table.

Review data types

Vertica infers data types from the raw data. You can adjust these types, either to be more specific or more general. The example that follows changes the NUMERIC value to FLOAT. Note also that VARCHAR sizes are based on the strings in the data and might not be large enough for future data. You should review and adjust data types before loading more data into a new flex table.

When you create a flex table, you can create a corresponding view. If you make changes in the data types in the keys table, regenerate the view. The following example demonstrates this process.

First, create the view:

```
=> SELECT BUILD_FLEXTABLE_VIEW('mountains');
        BUILD_FLEXTABLE_VIEW
```

```
-----
The view public.mountains_view is ready for querying
(1 row)
```

```
=> SELECT * FROM public.mountains_view;
 name | type | height | hike_safety
```

```
-----+-----+-----+-----
Everest | mountain | 29029 | 34.10
Mt St Helens | volcano | 29029 | 15.40
Denali | mountain | 17000 | 12.20
Kilimanjaro | mountain | 14000 |
Mt Washington | mountain | | 50.60
(5 rows)
```

Query the [VIEW_COLUMNS](#) system table to review the columns and data types:

```
=> SELECT column_name, data_type FROM VIEW_COLUMNS
       WHERE table_name = 'mountains_view';
column_name | data_type
```

```
-----+-----
name      | varchar(26)
type      | varchar(20)
height    | int
hike_safety | numeric(6,2)
(4 rows)
```

The view has the same data types as the keys table. Now update one of these data types in the keys table. After making the change, rebuild the view:

```
=> UPDATE mountains_keys SET data_type_guess = 'float' WHERE key_name = 'hike_safety';
OUTPUT
```

```
-----
1
(1 row)
```

```
=> COMMIT;
```

```
=> SELECT BUILD_FLEXTABLE_VIEW('mountains');
        BUILD_FLEXTABLE_VIEW
```

```
-----
The view public.mountains_view is ready for querying
(1 row)
```

Now, repeat the VIEW_COLUMNS query and note the changed type:

```
=> SELECT column_name, data_type FROM VIEW_COLUMNS WHERE table_name = 'mountains_view';
column_name | data_type
```

```
-----+-----
name      | varchar(26)
type      | varchar(20)
height    | int
hike_safety | float
(4 rows)
```

Create a hybrid flex table

If you already know that some of the data you load and query regularly needs full Vertica performance and support, you can create a hybrid flex table. A hybrid flex table has one or more real columns that you define, as well as the `__raw__` column that holds all of the data. Querying real columns is faster than querying the `__raw__` column. You can define default values for the columns.

When creating a hybrid flex table, specify real columns as you would for other tables:

```
=> CREATE FLEX TABLE mountains_hybrid(  
  name VARCHAR(41) DEFAULT name::VARCHAR(41),  
  hike_safety FLOAT DEFAULT hike_safety::float);  
  
=> COPY mountains_hybrid FROM '/home/dbadmin/Downloads/mountains.json'  
  PARSER FJSONPARSER();  
Rows Loaded  
-----  
      5  
(1 row)
```

You can compute keys and build the view in a single step:

```
=> SELECT COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW('mountains_hybrid');  
          COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW  
-----  
Please see public.mountains_hybrid_keys for updated keys  
The view public.mountains_hybrid_view is ready for querying  
(1 row)
```

The keys table shows the data types you declared for the real columns and inferred types for other fields:

```
=> SELECT * FROM mountains_hybrid_keys;  
key_name | frequency | data_type_guess  
-----+-----  
height   | 4 | Integer  
hike_safety | 4 | float  
name     | 5 | varchar(41)  
type    | 5 | Varchar(20)  
(4 rows)
```

If you create a basic flex table, you can later promote one or more virtual columns to real columns by using `ALTER TABLE`. See [Materializing flex tables](#).

Materialize virtual columns in a hybrid flex table

After you explore your flex table data, you can promote one or more virtual columns in your flex table to real columns. You do not need to create a separate columnar table.

The [MATERIALIZED_FLEXTABLE_COLUMNS](#) function creates real columns for a specified number of virtual columns, starting with the most-used:

```
=> SELECT MATERIALIZED_FLEXTABLE_COLUMNS('mountains_hybrid', 3);  
          MATERIALIZED_FLEXTABLE_COLUMNS  
-----  
The following columns were added to the table public.mountains_hybrid:  
  type  
  height  
For more details, run the following query:  
SELECT * FROM v_catalog.materialize_flextable_columns_results WHERE table_schema = 'public' and table_name = 'mountains_hybrid';  
(1 row)
```

The call specified three columns to materialize, but the table was created with two real columns, leaving only two more virtual columns. After materializing columns, you can check the results in the [MATERIALIZED_FLEXTABLE_COLUMNS_RESULTS](#) system table. The following output shows two columns with a status of `ADDED` and one with a status of `EXISTS`:

```
=> \x
Expanded display is on.
=> SELECT table_id, table_schema, table_name, key_name, status, message FROM MATERIALIZE_FLEXTABLE_COLUMNS_RESULTS
WHERE table_name = 'mountains_hybrid';
-[ RECORD 1 ]+-----
table_id   | 45035996273708192
table_schema | public
table_name | mountains_hybrid
key_name   | type
status     | ADDED
message    | Added successfully
-[ RECORD 2 ]+-----
table_id   | 45035996273708192
table_schema | public
table_name | mountains_hybrid
key_name   | height
status     | ADDED
message    | Added successfully
-[ RECORD 3 ]+-----
table_id   | 45035996273708192
table_schema | public
table_name | mountains_hybrid
key_name   | name
status     | EXISTS
message    | Column of same name already exists in table definition
```

View the definition of the hybrid table after these changes:

```

=> \d mountains_hybrid
List of Fields by Tables
-[ RECORD 1 ]-----
Schema   | public
Table    | mountains_hybrid
Column   | __raw__
Type     | long varbinary(130000)

```

Understanding flex tables

The term *unstructured data* (sometimes called *semi-structured* or *dark data*) does not indicate that the data you load into flex tables is entirely without structure. However, you may not know the data's composition or the inconsistencies of its design. In some cases, the data might not be relational.

Your data might have some structure (like JSON and delimited data). Data might be semi-structured or stringently structured, but in ways that you either do not know about or do not expect. The term *flexible data* encompasses these and other kinds of data. You can load your flexible data directly into a flex table and query its contents.

To summarize, you can load data first, without knowing its structure, and then query its content after a few simple transformations. In some cases, you already know the data structure, such as some keys in the data. If so, you can query these values explicitly as soon as you load the data.

Storing flex table data

While you can store unstructured data in a flex table `__raw__` column, that column is implemented as a real column.

Vertica compresses `__raw__` column data by about one half (1/2). While this factor is less than the compression rate for real columns, the reduction is significant for large amounts (more than 1TB) of unstructured data. After compression is complete, Vertica writes the data to disk. This approach maintains K-safety in your cluster and supports standard recovery processes should node failures occur. Flex tables are included in full backups (or, if you choose, in object-level backups).

What happens when you create flex tables?

Whenever you execute a CREATE FLEX TABLE statement, Vertica creates three objects, as follows:

- The flexible table (`flex_table`)
- An associated keys table (`flex_table_keys`)
- A default view for the main table (`flex_table_view`)

The `_keys` and `_view` objects are dependents of the parent, `flex_table`. Dropping the flex table also removes its dependents, although you can drop the `_keys` or `_view` objects independently.

You can create a flex table without specifying any column definitions. When you do so, Vertica automatically creates two tables, the named flex table (such as `darkdata`) and its associated keys table, `darkdata_keys`:

```
=> CREATE flex table darkdata();
CREATE TABLE
=> \dt dark*
      List of tables
Schema | Name      | Kind | Owner | Comment
-----+-----+-----+-----+-----
public | darkdata  | table | dbadmin |
public | darkdata_keys | table | dbadmin |
(2 rows)
```

Each flex table has two default columns, `__raw__` and `__identity__`. The `__raw__` column exists in every flex table to hold the data you load. The `__identity__` column is auto-incrementing. Vertica uses the `__identity__` column for segmentation and sort order when no other column definitions exist. The flex keys table has three columns:

```
=> SELECT * FROM darkdata_keys;
key_name | frequency | data_type_guess
-----+-----+-----
(0 rows)
```

If you define columns when creating a flex table, Vertica still creates the `__raw__` column. However, the table has no `__identity__` column because columns are specified for segmentation and sort order. Two tables are created automatically, as shown in the following example:

```
=> CREATE FLEX TABLE darkdata1 (name VARCHAR);
```

```
CREATE TABLE
```

```
=> SELECT * FROM darkdata1;
```

```
__raw__ | name
```

```
(0 rows)
```

```
=> \d darkdata1*
```

List of Fields by Tables

```
Schema | Table | Column | Type | Size | Default | Not Null | Primary Key | Foreign Key
```

```
public | darkdata1 | __raw__ | long varbinary(130000) | 130000 | | t | f |
```

```
public | darkdata1 | name | varchar(80) | 80 | | f | f |
```

```
(2 rows)
```

```
=> \dt darkdata1*
```

List of tables

```
Schema | Name | Kind | Owner | Comment
```

```
public | darkdata1 | table | dbadmin |
```

```
public | darkdata1_keys | table | dbadmin |
```

```
(2 rows)
```

For more examples, see [Creating flex tables](#).

Creating superprojections automatically

In addition to creating two tables for each flex table, Vertica creates superprojections for both the main flex table and its associated keys table. Using the `\dj` command, you can display the projections created automatically for the `darkdata` and `darkdata1` tables in this set of examples:

```
=> \dj darkdata*
```

List of projections

```
Schema | Name | Owner | Node | Comment
```

```
public | darkdata1_b0 | dbadmin | |
```

```
public | darkdata1_b1 | dbadmin | |
```

```
public | darkdata1_keys_super | dbadmin | v_vmart_node0001 |
```

```
public | darkdata1_keys_super | dbadmin | v_vmart_node0003 |
```

```
public | darkdata1_keys_super | dbadmin | v_vmart_node0004 |
```

```
public | darkdata_b0 | dbadmin | |
```

```
public | darkdata_b1 | dbadmin | |
```

```
public | darkdata_keys_super | dbadmin | v_vmart_node0001 |
```

```
public | darkdata_keys_super | dbadmin | v_vmart_node0003 |
```

```
public | darkdata_keys_super | dbadmin | v_vmart_node0004 |
```

```
(10 rows)
```

Default flex table view

When you create a flex table, you also create a default view. This default view uses the table name with a `_view` suffix. If you query the default view, you are prompted to use the [COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW](#) function. This view enables you to update the view after you load data so that it includes all keys and values:

```
=> \dv darkdata*
```

List of View Fields

```
Schema | View | Column | Type | Size
```

```
public | darkdata_view | status | varchar(124) | 124
```

```
public | darkdata1_view | status | varchar(124) | 124
```

```
(2 rows)
```

For more information, see [Updating flex table views](#).

Flex functions

Three sets of functions support flex tables and extracting data into VMaps:

- [Data \(helper\) functions](#)
- [Extractor functions](#)
- [Map functions](#)

Using clients with flex tables

You can use the Vertica-supported client drivers with flex tables as follows:

- To load data into a flex table, you can use the INSERT or COPY LOCAL statement with the appropriate flex parser.
- The driver metadata APIs return only real columns. For example, if you select * from a flex table with a single materialized column, the statement returns that column and the `__raw__`. However, it does not return virtual columns from within `__raw__`. To access virtual columns and their values, query the associated `_keys` table, just as you would in `vsq`.

Creating flex tables

You can create a flex table or an external flex table without column definitions or other parameters. You can use any CREATE TABLE statement parameters you prefer, as usual.

Note

If you have an Eon Mode database with multiple [namespaces](#), flex tables must be created under the `default_namespace`.

Creating basic flex tables

Here's how to create the table:

```
=> CREATE FLEX TABLE darkdata();  
CREATE TABLE
```

Selecting from the table before loading any data into it reveals its two real columns, `__identity__` and `__raw__`:

```
=> SELECT * FROM darkdata;  
__identity__ | __raw__  
-----+-----  
(0 rows)
```

Below is an example of creating a flex table with a column definition:

```
=> CREATE FLEX TABLE darkdata1(name VARCHAR);  
CREATE TABLE
```

When flex tables exist, you can add new columns (including those with default derived expressions), as described in [Materializing Flex Tables](#).

Materializing flex table virtual columns

After you create your flex table and load data, you compute keys from virtual columns. After completing those tasks, you can materialize some keys by promoting virtual columns to real table columns. By promoting virtual columns, you query real columns rather than the raw data.

You can promote one or more virtual columns — materializing those keys from within the `__raw__` data to real columns. Vertica recommends this approach to get the best query performance for all important keys. You don't need to create new columnar tables from your flex table.

Materializing flex table columns results in a hybrid table. Hybrid tables:

- Maintain the convenience of a flex table for loading unstructured data
- Improve query performance for any real columns

If you have only a few columns to materialize, try altering your flex table progressively, adding columns whenever necessary. You can use the `ALTER TABLE...ADD COLUMN` statement to do so, just as you would with a columnar table. See [Materializing flex tables](#) for ideas about adding columns.

If you want to materialize columns automatically, use the helper function [MATERIALIZER_FLEXTABLE_COLUMNS](#).

Creating columnar tables from flex tables

You can create a regular Vertica table from a flex table, but you cannot use one flex table to create another.

Typically, you create a columnar table from a flex table after loading data. Then, you specify the virtual column data you want in a regular table, casting virtual columns to regular data types.

To create a columnar table from a flex table, `darkdata`, select two virtual columns, (`user.lang` and `user.name`), for the new table. Use a command such as the following, which casts both columns to `varchar` for the new table:

```
=> CREATE TABLE darkdata_full AS SELECT "user.lang"::VARCHAR, "user.name"::VARCHAR FROM darkdata;
CREATE TABLE
=> SELECT * FROM darkdata_full;
user.lang | user.name
-----+-----
en      | Frederick Danjou
en      | The End
en      | Uptown gentleman.
en      | ~G A B R I E L A â¿
es      | Flu Beach
es      | I'm Toasterâ¿
it      | laughing at clouds.
tr      | seydo shi
      |
      |
      |
      |
(12 rows)
```

Creating temporary flex tables

Before you create temporary global and local flex tables, be aware of the following considerations:

- GLOBAL TEMP flex tables are supported. Creating a temporary global flex table results in the `flexible_keys` table and the `flexible_view` having temporary table restrictions for their content.
- LOCAL TEMP flex tables must include at least one column definition. The reason for this requirement is that local temp tables do not support automatically-incrementing data (such as the flex table default `__identity__` column). Creating a temporary local flex table results in the `flexible_keys` table and the `flexible_view` existing in the local temporary object scope.
- LOCAL TEMP views are supported for flex and columnar temporary tables.

For global or local temp flex tables to function correctly, you must also specify the `ON COMMIT PRESERVE ROWS` clause. You must use the `ON COMMIT` clause for the flex table helper functions, which rely on commits. Create a local temp table as follows:

```
=> CREATE FLEX LOCAL TEMP TABLE good(x int) ON COMMIT PRESERVE ROWS;
CREATE TABLE
```

After creating a local temporary flex table using this approach, you can then load data into the table, create table keys, and a flex table view:

```
=> COPY good FROM '/home/release/KData/bake.json' PARSER fjsonparser();
Rows Loaded
-----
      1
(1 row)

=> select compute_flexible_keys_and_build_view('good');
      compute_flexible_keys_and_build_view
-----
Please see v_temp_schema.good_keys for updated keys
The view good_view is ready for querying
(1 row)
```

Similarly, you can create global temp tables as follows:

```
=> CREATE FLEX GLOBAL TEMP TABLE good_global(x int) ON COMMIT PRESERVE ROWS;
```

After creating a global temporary flex table using this approach, you can then load data into the table, create table keys, and a flex table view:

```
=> COPY good_global FROM '/home/dbadmin/data/flex/bake_single.json' PARSER fjsonparser();
```

Rows Loaded

```
-----  
5  
(1 row)
```

```
=> SELECT compute_flexable_keys_and_build_view('good_global');  
           compute_flexable_keys_and_build_view
```

Please see v_temp_schema.good_keys for updated keys

The view good_view is ready for querying

```
(1 row)
```

Creating external flex tables

To create an external flex table:

```
=> CREATE flex external table mountains() AS COPY FROM 'home/release/KData/kmm_ountains.json' PARSER fjsonparser();
```

```
CREATE TABLE
```

As with other flex tables, creating an external flex table produces two regular tables: the named table and its associated [_keys](#) table. The keys table is not an external table:

```
=> \dt mountains
```

List of tables

Schema	Name	Kind	Owner	Comment
--------	------	------	-------	---------

public	mountains	table	release	
--------	-----------	-------	---------	--

```
-----
```

```
public | mountains | table | release |
```

```
(1 row)
```

You can use the helper function, [COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW](#), to compute keys and create a view for the external table:

```
=> SELECT compute_flexable_keys_and_build_view ('appLog');
```

```
           compute_flexable_keys_and_build_view
```

Please see public.appLog_keys for updated keys

The view public.appLog_view is ready for querying

```
(1 row)
```

Check the keys from the [_keys](#) table for the results of running the helper application:

```
=> SELECT * FROM appLog_keys;
```

key_name	frequency	data_type_guess
----------	-----------	-----------------

```
-----
```

contributors	8	varchar(20)
--------------	---	-------------

coordinates	8	varchar(20)
-------------	---	-------------

created_at	8	varchar(60)
------------	---	-------------

entities.hashtags	8	long varbinary(186)
-------------------	---	---------------------

```
.
```

```
.
```

```
.
```

retweeted_status.user.time_zone	1	varchar(20)
---------------------------------	---	-------------

retweeted_status.user.url	1	varchar(68)
---------------------------	---	-------------

retweeted_status.user.utc_offset	1	varchar(20)
----------------------------------	---	-------------

retweeted_status.user.verified	1	varchar(20)
--------------------------------	---	-------------

```
(125 rows)
```

You can query the view:

```
=> SELECT "user.lang" FROM appLog_view;
user.lang
-----
it
en
es
en
en
es
tr
en
(12 rows)
```

Note

External tables are fully supported for both flex and columnar tables. However, using external flex (or columnar) tables is less efficient than using flex tables whose data is stored in the Vertica database. Data that is maintained externally requires reloading each time you query.

Creating a flex table from query results

You can use the CREATE FLEX TABLE AS statement to create a flex table from the results of a query.

You can use this statement to create three types of flex tables:

- Flex table with no materialized columns
- Flex table with some materialized columns
- Flex table with all materialized columns

When a flex `__raw__` column is present in the CTAS query, the entire source VMap is carried to the flex table. If the query has matching column names, the key values are overridden.

Note

ORDER BY and segmentation clauses are only passed to the new flex table if the relevant columns are materialized.

Examples

Creating a flex table with no materialized columns from a regular table causes the results of the query to be stored in the `__raw__` column as a VMap.

1. Create a regular table named `pets` with two columns:

```
=> CREATE TABLE pets(age INT, name VARCHAR);
CREATE TABLE
```

2. Create a flex table named `family_pets` by using the CTAS statement to copy the columns `age` and `name` from the `pets` :

```
=> CREATE FLEX TABLE family_pets() AS SELECT age, name FROM pets;
CREATE TABLE
```

3. View the new flex table to confirm the operation has been successful and that the columns `age` and `name` have not been materialized.

```
=> \d family_pets;
List of Fields by Tables
Schema | Table | Column | Type | Size | Default | Not Null | Primary Key | Foreign Key
-----+-----+-----+-----+-----+-----+-----+-----+-----
public | family_pets | __identity__ | int | 8 | | t | f |
public | family_pets | __raw__ | long varbinary(130000) | 130000 | | t | f |
(2 rows)
```

You can create a flex table with no materialized columns from the results of a query of another flex table. This inserts all the VMaps from the source flex table into the target. This creates a flex table segmented and ordered by the `__identity__` column.

4. Create a flex table named `city_pets` by using the CTAS statement to copy the `age` and `__raw__` columns from `family_pets` :

```
=> CREATE FLEX TABLE city_pets() AS SELECT age, __raw__ FROM family_pets;
CREATE TABLE
```

5. View the new flex table to confirm that the operation has been successful and the columns `age` and `__raw__` have not been materialized.

```
=> SELECT * FROM city_pets;
List of Fields by Tables
Schema | Table | Column | Type | Size | Default | Not Null | Primary Key | Foreign Key
-----+-----+-----+-----+-----+-----+-----+-----+-----
public | city_pets | __identity__ | int | 8 | | t | f |
public | city_pets | __raw__ | long varbinary(130000) | 130000 | | t | f |
(2 rows)
```

You can create a flex table with some materialized columns. This uses a syntax similar to the syntax for creating columnar tables with some materialized columns. Unlike columnar tables, however, you need to match the number of columns with the columns that are returned by the query. In the following example, our query returns three columns (`amount` , `type` , and `available`), but Vertica only materializes the first two.

6. Create a table named `animals` with three columns, `amount` , `type` , and `available` :

```
=> CREATE TABLE animals(amount INT, type VARCHAR, available DATE);
```

7. Create a flex table named `inventory` with columns `animal_amount` and `animal_type` using the CTAS statement to copy columns `amount` , `type` , and `available` from `animals` .

```
=> CREATE FLEX TABLE inventory(animal_amount, animal_type) AS SELECT amount, type, available FROM animals;
CREATE TABLE
```

8. View the table data to confirm that columns `amount` and `type` have been materialized under the column names `animal_amount` and `animal_type` . Column `available` from `animals` has also been copied over but was not materialized:

```
=> \d inventory
List of Fields by Tables
Schema | Table | Column | Type | Size | Default | Not Null | Primary Key | Foreign Key
-----+-----+-----+-----+-----+-----+-----+-----+-----
public | flex3 | __raw__ | long varbinary(130000) | 130000 | | t | f |
public | flex3 | animal_amount | int | 8 | | f | f |
public | flex3 | animal_type | varchar(80) | 80 | | f | f |
(3 rows)
```

Notice that including empty parentheses in the statement results in a flex table with no materialized columns:

9. Create a flex table named `animals_for_sale` using the CTAS statement with empty parentheses to copy columns `amount` , `type` , and `available` from `animals` into a pure flex table:

```
=> CREATE FLEX TABLE animals__for_sale() AS SELECT amount, type, available FROM animals;
CREATE TABLE
```

10. View the table data to confirm that no columns were materialized:

```
=> \d animals_for_sale;
List of Fields by Tables
Schema | Table | Column | Type | Size | Default | Not Null | Primary Key | Foreign Key
-----+-----+-----+-----+-----+-----+-----+-----+-----
public | animals_for_sale | __identity__ | int | 8 | | t | f |
public | animals_for_sale | __raw__ | long varbinary(130000) | 130000 | | t | f |
(2 rows)
```

Omitting any parentheses in the statement causes all columns to be materialized:

11. Create a flex table named `animals_sold` using the CTAS statement without parentheses. This copies columns `amount` , `type` , and `available` from `animals` and materialize all columns:

```
=> CREATE FLEX TABLE animals_sold AS SELECT amount, type, available FROM animals;
CREATE TABLE
```

12. View the table data to confirm that all columns were materialized:

```
=> \d animals_sold;
List of Fields by Tables
Schema | Table | Column | Type | Size | Default | Not Null | Primary Key | Foreign Key
-----+-----+-----+-----+-----+-----+-----+-----+-----
public | animals_sold | __raw__ | long varbinary(130000) | 130000 | | t | f |
public | animals_sold | amount | int | 8 | | f | f |
public | animals_sold | type | varchar(80) | 80 | | f | f |
public | animals_sold | available | date | 8 | | f | f |
(4 rows)
```

Bulk loading data into flex tables

You bulk load data into a flex table with a COPY statement, specifying one of the flex parsers:

- FAVROPARSER
- FCEFPARSER
- FCSVPARSER
- FDELIMITEDPAIRPARSER
- FDELIMITEDPARSER
- FJSONPARSER
- FREGEXPARSER

All flex parsers store the data as a single-value VMap. They reside in the VARBINARY `__raw__` column, which is a real column with a NOT NULL constraint. The VMap is encoded into a single binary value for storage in the `__raw__` column. The encoding places the value strings in a contiguous block, followed by the key strings. Vertica supports null values within the VMap for keys with NULL -specified columns. The key and value strings represent the virtual columns and their values in your flex table.

If a flex table data row is too large to fit in the `__raw__` column, it is rejected. By default, the rejected data and exceptions files are stored in the standard [CopyErrorLogs](#) location, a subdirectory of the catalog directory:

```
v_mart_node003_catalog/CopyErrorLogs/trans-STDIN-copy-from-exceptions.1
v_mart_node003_catalog/CopyErrorLogs/trans-STDIN-copy-rejections.1
```

Flex tables do not copy any rejected data, due to disk space considerations. The rejected data file exists, but it contains only a new line character for every rejected record. The corresponding exceptions file lists the reason why each record was rejected.

You can specify a different path and file for the rejected data and exceptions files. To do so, use the COPY options REJECTED DATA and EXCEPTIONS , respectively. You can also save rejections and exceptions in a table. For more information, see [Data load](#) .

Basic flex table load and query

Loading data into a flex table is similar to loading data into a regular columnar table. The difference is that you must use the PARSE option with one of the flex parsers:

```
=> COPY darkdata FROM '/home/dbadmin/data/tweets_12.json' PARSER fjsonparser();
Rows Loaded
-----
12
(1 row)
```

Note

You can use many additional COPY parameters as required but not all are supported.

Loading data into flex table real columns

If you create a hybrid flex table with one or more real column definitions, COPY evaluates each virtual column key name during data load and automatically populates real columns with the values from their virtual column counterparts. For columns of scalar types, COPY also loads the keys and values as part of the VMap data in the `__raw__` column. For columns of [complex types](#) , COPY does not add the values to the `__raw__` column.

Note

Over time, storing values in both column types can impact your licensed data limits. For more information about Vertica licenses, see [Managing licenses](#) .

For example, continuing with the JSON example:

1. Create a flex table with a column definition of one of the keys in the data you will load:

```
=> CREATE FLEX TABLE darkdata1 ("user.lang" VARCHAR);  
CREATE TABLE
```

2. Load data into the table:

```
=> COPY darkdata1 FROM '/test/vertica/flextable/DATA/tweets_12.json' PARSER fjsonparser();  
Rows Loaded  
-----  
      12  
(1 row)
```

3. Query the real column directly:

```
=> SELECT "user.lang" FROM darkdata1;  
user.lang  
-----  
es  
es  
tr  
it  
en  
en  
en  
en  
(12 rows)
```

Empty column rows indicate NULL values. For more information about how NULLs are handled in flex tables, see [NULL value](#).

4. You can query for other virtual columns with similar results:

```
=> SELECT "user.name" FROM darkdata1;  
user.name  
-----  
I'm Toasterâ¥  
Flu Beach  
seydo shi  
The End  
Uptown gentleman.  
~G A B R I E L A â¿  
Frederick Danjou  
laughing at clouds.  
(12 rows)
```

Note

While the results for these two queries are similar, the difference in accessing the keys and their values is significant. Data for `user.lang` has been materialized into a real table column, while `user.name` remains a virtual column. For production-level data usage (rather than test data sets), materializing flex table data improves query performance significantly.

Handling default values during loading

You can create a flex table with a real column, named for a virtual column that exists in your incoming data. For example, if the data you load has a `user.lang` virtual column, define the flex table with that column. You can also specify a default column value when creating the flex table with real columns. The next example shows how to define a real column (`user.lang`), which has a default value from a virtual column (`user.name`):

```
=> CREATE FLEX TABLE darkdata1 ("user.lang" LONG VARCHAR default "user.name");
```

When you load data into a flex table, COPY uses values from the flex table data, ignoring the default column definition. Loading data into a flex table requires [MAPLOOKUP](#) to find keys that match any real column names. A match exists when the incoming data has a virtual column with the same name as a real column. When COPY detects a match, it populates the column with values. COPY returns either a value or NULL for each row, so real columns always have values.

For example, after creating the flex table described in the previous example, load data with COPY :

```
=> COPY darkdata1 FROM '/test/vertica/flextable/DATA/tweets_12.json' PARSER fjsonparser();
Rows Loaded
-----
      12
(1 row)
```

If you query the table after loading, the data shows that the values for the `user.lang` column were extracted:

- From the data being loaded — values for the `user.lang` virtual column
- With NULL — rows without values

In this case, the table column default value for `user.lang` was ignored:

```
=> SELECT "user.lang" FROM darkdata1;
user.lang
-----
it
en
es
en
en
es
tr
en
(12 rows)
```

Using COPY to specify default column values

You can add an expression to a COPY statement to specify default column values when loading data. For flex tables, specifying any column information requires that you list the `__raw__` column explicitly. The following example shows how to use an expression for the default column value. In this case, loading populates the defined `user.lang` column with data from the input data `user.name` values:

```
=> COPY darkdata1(__raw__, "user.lang" as "user.name"::VARCHAR)
FROM '/test/vertica/flextable/DATA/tweets_12.json' PARSER fjsonparser();
Rows Loaded
-----
      12
(1 row)
=> SELECT "user.lang" FROM darkdata1;
user.lang
-----
laughing at clouds.
Avita Desai
I'm Toasterâ
Uptown gentleman.
~G A B R I E L A â
Flu Beach
seydo shi
The End
(12 rows)
```

You can specify default values when adding columns, as described in [Altering Flex Tables](#) . When you do so, a different behavior results. For more information about using COPY, its expressions and parameters, see [Getting Data into Vertica](#) and the [COPY](#) reference page.

Inserting data into flex tables

You can load data into a Vertica flex table using a standard INSERT statement, specifying data for one or more columns. When you use INSERT, Vertica populates any materialized columns and stores the VMap data in the `__raw__` column.

Vertica provides two ways to use INSERT with flex tables:

- INSERT ... VALUES
- INSERT ... SELECT

Inserting values into flex tables

To insert data values into a flex table, use an INSERT ... VALUES statement. If you do not specify any columns in your INSERT ... VALUES statement, Vertica positionally assigns values to the real columns of the flex table.

This example shows two ways to insert values into a simple flex table. For both statements, Vertica assigns the values 1 and 'x' to columns a and b, respectively. This example inserts values into the two real columns defined in the flex table:

```
=> CREATE FLEX TABLE flex0 (a INT, b VARCHAR);
CREATE TABLE
=> INSERT INTO flex0 VALUES (1, 'x');
OUTPUT
-----
  1
(1 row)
```

This example inserts values into a flex table without any real columns:

```
=> CREATE FLEX TABLE flex1();
CREATE TABLE
=> INSERT INTO flex1(a,b) VALUES (1, 'x');
OUTPUT
-----
  1
(1 row)
```

For the preceding example, the __row__ column contains the inserted data:

```
=> SELECT MapToString(__row__) FROM flex1;
      MapToString
-----
{
"a": "1",
"b": "x"
}
(1 row)
```

Using INSERT ... SELECT with flex tables

Using an INSERT ... SELECT statement with a flex table is similar to using INSERT ... SELECT with a regular table. The SELECT statement returns the data to insert into the target table.

However, Vertica does *not* require that you balance the number of columns and values. If you do not specify a value for a column, Vertica inserts NULL.

In the next example, Vertica copies the a and b values from the flex1 table, and creates columns c, d, e, and f. Because the statement does not specify a value for f, Vertica assigns it a NULL.

```

=> CREATE FLEX TABLE flex2();
CREATE TABLE
=> INSERT INTO flex2(a,b) SELECT a,b, '2016-08-10 11:10' c, 'Hello' d, 3.1415 e, f from flex1;
OUTPUT
-----
 1
(1 row)
=> SELECT MapToString(__raw__) FROM flex2;
      MapToString
-----
{
"a": "1",
"b": "x",
"c": "2016-08-10 11:10",
"d": "Hello",
"e": "3.1415",
"f": null
}
(1 row)

```

Inserting __raw__ columns into a flex table

Inserting a __raw__ column into a flex table inserts the entire source VMap into the target table. Vertica does not assign the __raw__ column to any target column. Its position in the SELECT statement does not matter.

The following two INSERT statements are equivalent.

```

=> INSERT INTO flex4(a,b) SELECT a, __raw__, b FROM flex3;
=> INSERT INTO flex4(a,b) SELECT a, b, __raw__ FROM flex3;

```

Error handling

Type coercion errors occur only with real columns. The insert operation fails as follows:

```

=> CREATE FLEX TABLE my_table(a INT, b VARCHAR);
CREATE TABLE
=> INSERT INTO my_table(a, b) VALUES ('xyz', '5');
ERROR: Invalid input syntax for integer: "xyz"

```

If you try to insert values into the __raw__ column, the insert fails as follows:

```

=> CREATE FLEX TABLE my_table(a INT, b VARCHAR);
CREATE TABLE
=> INSERT INTO my_table(a,b,__raw__) VALUES (1,'x','abcdef');
ERROR 7372: Cannot assign value to "__raw__" column

```

Using flex tables for IDOL data

You can create flex tables to use with the IDOL Connector Framework Server (CFS) and an ODBC client. The CFS VerticalIndexer module uses the connector to retrieve data. CFS then indexes the data into your Vertica database.

CFS supports many connectors for interfacing to different unstructured file types stored in repositories. Examples of repositories include Microsoft Exchange (email), file systems (including Word documents, images, and videos), Microsoft SharePoint, and Twitter (containing Tweets).

Connectors retrieve and aggregate data from repositories. CFS indexes the data, sending it to IDOL, IDOL OnDemand, or Vertica. The following figure illustrates a basic setup with a repository and a connector.

After you configure CFS and connect it to your Vertica database, the connector monitors the repository for changes and deletions to loaded documents, and for new files not previously added to the server. CFS then updates its server destinations automatically.

To achieve the best query results with ongoing CFS updates and deletes, Vertica recommends using live aggregate projections and top-K projections. For more information about how these projections work, and for examples of using them, see [Projections](#).

ODBC connection string for CFS

There are several steps to setting up the CFS VerticalIndexer to load IDOL metadata into your database.

One of the first steps is to add information to the CFS configuration file. To do so, add an **Indexing** section to the configuration file that specifies the ODBC ConnectionString details.

Successfully loading data requires a valid database user with write permissions to the destination table. Two ODBC connection parameters (**UID** and **PWD**) specify the Vertica user and password. The following example shows a sample CFS **Indexing** section. The section includes a **ConnectionString** with the basic parameters, including a sample user (**UID=fjones**) and password (**PWD=fjones_password**):

```
[Indexing]
IndexerSections=vertica
IndexTimeInterval=30
[vertica]
IndexerType = Library
ConnectionString=Driver=Vertica;Server=123.456.478.900;Database=myDB;UID=fjones;PWD=fjones_password
TableName = marcomm.myFlexTable
LibraryDirectory = ./shared_library_indexers
LibraryName = verticalIndexer
```

For more information about ODBC connection parameters, see [ODBC Configuration Parameters.]([http://vertica.com/docs/7.1.x/HTML/index.htm#Authoring/ConnectingToVertica/ClientODBC/DSNParameters.htm?TocPath=Connecting to HP Vertica|Client Libraries|Creating an ODBC Data Source Name \(DSN\)|____4](http://vertica.com/docs/7.1.x/HTML/index.htm#Authoring/ConnectingToVertica/ClientODBC/DSNParameters.htm?TocPath=Connecting%20to%20HP%20Vertica|Client%20Libraries|Creating%20an%20ODBC%20Data%20Source%20Name%20(DSN)|____4))

CFS COPY LOCAL statement

CFS first indexes and processes metadata from a document repository to add to your database. Then, CFS uses the Indexing information you added to the configuration file to create an ODBC connection. After establishing a connection, CFS generates a standard **COPY LOCAL** statement, specifying the **fjsonparser** . CFS loads data directly into your pre-existing flex table with a statement such as the following:

```
=> COPY myFlexTable FROM LOCAL path_to_compressed_temporary_json_file PARSER fjsonparser();
```

```
=> SELECT * FROM myavro;
__identity__ | __raw__
-----+-----
(0 rows)
```

When your IDOL metadata appears in a flex table, you can optionally add new table columns, or materialize other data, as described in [Altering Flex Tables](#).

Using flex table parsers

You can load flex tables with one of several parsers, using the options that these parsers support.

In addition to the parsers listed in this section, the following parsers described in [Data formats](#) in [Data load](#) support flex tables:

- [JSON data](#)
- [Avro data](#)
- [Matches from regular expressions](#)

- [Common event format \(CEF\) data](#)

In this section

- [Loading columnar tables with flex parsers](#)
- [Loading CSV data](#)
- [Loading delimited data](#)

Loading columnar tables with flex parsers

You can use any of the flex parsers to load data into columnar tables. Using the flex table parsers to load columnar tables gives you the capability to mix data loads in one table. For example, you can load JSON data in one session and delimited data in another.

Note

For Avro data, you can load only data into a columnar table, not the schema. For flex tables, Avro schema information is required to be embedded in the data.

The following basic examples illustrate how you can use flex parsers with columnar tables.

1. Create a columnar table, `super`, with two columns, `age` and `name` :

```
=> CREATE TABLE super(age INT, name VARCHAR);
CREATE TABLE
```

2. Enter JSON values from STDIN, using the `fjsonparser()` :

```
=> COPY super FROM stdin PARSER fjsonparser();
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> {"age": 5, "name": "Tim"}
>> {"age": 3}
>> {"name": "Fred"}
>> {"name": "Bob", "age": 10}
>> \.
```

3. Query the table to see the values you entered:

```
=> SELECT * FROM super;
age | name
-----+-----
   | Fred
 10 | Bob
   | 5 | Tim
   | 3 |
(4 rows)
```

4. Enter some delimited values from STDIN, using the `fdelimitedparser()` :

```
=> COPY super FROM stdin PARSER fdelimitedparser();
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> name |age
>> Tim|50
>> |30
>> Fred|
>> Bob|100
>> \.
```

5. Query the flex table. Both JSON and delimited data are saved in the same columnar table, `super` .

```

=> SELECT * FROM super;
age | name
-----+-----
50 | Tim
30 |
3 |
5 | Tim
100 | Bob
| Fred
10 | Bob
| Fred
(8 rows)

```

Use the `reject_on_materialized_type_error` parameter to avoid loading data with type mismatch. If `reject_on_materialized_type_error` is set to `false`, the flex parser will accept the data with type mismatch. Consider the following example:

Assume that the CSV file to be loaded has the following sample contents:

```

$ cat json.dat
{"created_by":"system","site_source":"flipkart_india_kol","updated_by":"system1","invoice_id":"INVDPKOL100",
"vendor_id":"VEN15731","total_quantity":12,"created_at":"2012-01-09 23:15:52.0"}
{"created_by":"system","site_source":"flipkart_india_kol","updated_by":"system2","invoice_id":"INVDPKOL101",
"vendor_id":"VEN15732","total_quantity":14,"created_at":"hello"}

```

1. Create a columnar table.

```

=> CREATE TABLE hdfs_test (
site_source VARCHAR(200),
total_quantity int ,
vendor_id varchar(200),
invoice_id varchar(200),
updated_by varchar(200),
created_by varchar(200),
created_at timestamp
);

```

2. Load JSON data.

```

=> COPY hdfs_test FROM '/home/dbadmin/json.dat' PARSER fjsonparser() ABORT ON ERROR;
Rows Loaded
-----
2
(1 row)

```

3. View the contents.

```

=> SELECT * FROM hdfs_test;
site_source | total_quantity | vendor_id | invoice_id | updated_by | created_by | created_at
-----+-----+-----+-----+-----+-----+-----
flipkart_india_kol | 12 | VEN15731 | INVDPKOL100 | system1 | system | 2012-01-09 23:15:52
flipkart_india_kol | 14 | VEN15732 | INVDPKOL101 | system2 | system |
(2 rows)

```

4. If `reject_on_materialized_type_error` parameter is set to `true`, you will receive errors when loading the sample JSON data.

```

=> COPY hdfs_test FROM '/home/dbadmin/data/flex/json.dat' PARSER fjsonparser(reject_on_materialized_type_error=true) ABORT ON ERROR;
ERROR 2035: COPY: Input record 2 has been rejected (Rejected by user-defined parser)

```

Loading CSV data

Use the `fcsvparser` to load data in CSV format (comma-separated values). Because no formal CSV standard exists, Vertica supports the [RFC 4180](#) standard as the default behavior for `fcsvparser`. Other parser parameters simplify various combinations of CSV options into columnar or flex tables. Using `fcsvparser` parses the following CSV data formats:

- **RFC 4180:** The RFC4180 CSV format parser for Vertica flex tables. The parameters for this format are fixed and cannot be changed.
- **Traditional:** The traditional CSV parser lets you specify the parameter values such as delimiter or record terminator. For a detailed list of parameters, see [FCVSPARSER](#).

Using default parser settings

These fixed parameter settings apply to the RFC4180 format.

You may use the same value for `enclosed_by` and `escape` . Other values must be unique.

Parameter	Data Type	Fixed Value (RFC4180)	Default Value (Traditional)
<code>delimiter</code>	CHAR	,	,
<code>enclosed_by</code>	CHAR	"	"
<code>escape</code>	CHAR	"	\
<code>record_terminator</code>	CHAR	\n or \r\n	\n or \r\n

Use the `type` parameter to indicate either an RFC 4180-compliant file or a traditional-compliant file. You can specify `type` as `RFC4180` . However, you must first verify that the data is compatible with the preceding fixed values for parameters of the RFC4180 format. The default value of the `type` parameter is `RFC4180`.

Loading CSV data (RFC4180)

This example shows how you can use `fcsvparser` to load a flex table, build a view, and then query that view.

1. Create a flex table for CSV data:

```
=> CREATE FLEX TABLE rfc();  
CREATE TABLE
```

2. Use `fcsvparser` to load the data from STDIN. Specify that no header exists, and enter some data as shown:

```
=> COPY rfc FROM stdin PARSER fcsvparser(header='false');  
Enter data to be copied followed by a newline.  
End with a backslash and a period on a line by itself.  
>> 10,10,20  
>> 10,"10",30  
>> 10,"20""5",90  
>> \
```

3. Run the `compute_flexible_keys_and_build_view` function, and query the `rfc_view` . Notice that the default `enclosed_by` character permits an escape character (`"`) within a field (`"20""5"`). Thus, the resulting value was parsed correctly. Since no header existed in the input data, the function added `ucol n` for each column:

```
=> SELECT compute_flexible_keys_and_build_view('rfc');  
compute_flexible_keys_and_build_view  
-----  
Please see public.rfc_keys for updated keys  
The view public.rfc_view is ready for querying  
(1 row)  
  
=> SELECT * FROM rfc_view;  
ucol0 | ucol1 | ucol2  
-----  
10 | 10 | 20  
10 | 10 | 30  
10 | 20"5 | 90  
(3 rows)
```

Loading CSV data (traditional)

Follow these steps to use `fcsvparser` to load data in traditional CSV data format using `fcsvparser` .

In this example, the CSV file uses `$` as a `delimiter` and `#` as a `record_terminator` . The sample CSV file to load has the following contents:

```
$ more /home/dbadmin/flex/flexData1.csv
sno$name$age$gender#
1$John$14$male#
2$Mary$23$female#
3$Mark$35$male#
```

1. Create a flex table:

```
=> CREATE FLEX TABLE csv_basic();
CREATE TABLE
```

2. Load the data in flex table using `fscvparser` with parameters `type='traditional'`, `delimiter='$'` and `record_terminator='#'`:

```
=> COPY csv_basic FROM '/home/dbadmin/flex/flexData2.csv' PARSER fscvparser(type='traditional',
delimiter='$', record_terminator='#');
Rows Loaded
-----
3
(1 row)
```

3. View the data loaded in the flex table:

```
=> SELECT maptostring(__row__) FROM csv_basic;
maptostring
-----
{"age": "14",
"gender": "male",
"name": "John",
"sno": "1"}
{"age": "23",
"gender": "female",
"name": "Mary",
"sno": "2"}
{"age": "35",
"gender": "male",
"name": "Mark",
"sno": "3"}
(3 rows)
```

Rejecting duplicate values

You can reject duplicate values using the `reject_on_duplicate=true` option with the `fscvparser`. The load continues after it rejects a duplicate value. The next example shows how to use this parameter and then displays the specified exception and rejected data files. Saving rejected data to a table, rather than a file, includes both the data and its exception.

```

=> CREATE FLEX TABLE csv_basic();
CREATE TABLE
=> COPY csv_basic FROM stdin PARSER fcsvparser(reject_on_duplicate=true)
exceptions /home/dbadmin/load_errors/except.out' rejected data '/home/dbadmin/load_errors/reject.out';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> A|A
>> 1|2
>> \.
=> \! cat /home/dbadmin/load_errors/reject.out
A|A
=> \! cat /home/dbadmin/load_errors/except.out
COPY: input record 1 has been rejected (Processed a header row with duplicate keys with
reject_on_duplicate specified; rejecting.). Please see /home/dbadmin/load_errors/reject.out,
record 1 for the rejected record.
COPY: Loaded 0 rows, rejected 1 rows.

```

Rejecting data on materialized column type errors

The `fcsvparser` parser has a Boolean parameter, `reject_on_materialized_type_error`. Setting this parameter to `true` causes rows to be rejected if *both* the following conditions exist in the input data:

- Includes keys matching an existing materialized column
- Has a key value that cannot be coerced into the materialized column's data type

The following examples illustrate setting this parameter.

1. Create a table, `reject_true_false`, with two real columns:

```

=> CREATE FLEX TABLE reject_true_false(one int, two int);
CREATE TABLE

```

2. Load CSV data into the table (from STDIN), using the `fcsvparser` with `reject_on_materialized_type_error=false`. While `false` is the default value, you can specify it explicitly, as shown. Additionally, set the parameter `header=true` to specify the columns for input values:

```

=> COPY reject_true_false FROM stdin PARSER fcsvparser(reject_on_materialized_type_error=false,header=true);
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> one,two
>> 1,2
>> "3","four"
>> "five",6
>> 7,8
>> \.

```

3. Invoke `maptostring` to display the table values after loading data:

```

=> SELECT maptostring(__raw__), one, two FROM reject_true_false;
maptostring      | one | two
-----+-----+-----
{"one": "1",
 "two": "2"}
1 | 2
{"one": "3",
 "two": "four"}
3 |
{"one": "five",
 "two": "6"}
 | 6
{"one": "7",
 "two": "8"}
7 | 8
(4 rows)

```

4. Truncate the table to empty the data stored in the table:

```

=> TRUNCATE TABLE reject_true_false;
TRUNCATE TABLE

```

5. Reload the same data again, but this time, set `reject_on_materialized_type_error=true` :

```

=> COPY reject_true_false FROM stdin PARSER fcsvparser(reject_on_materialized_type_error=true,header=true);
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> one,two
>> 1,2
>> "3","four"
>> "five",6
>> 7,8
>> \.

```

6. Call `maptostring` to display the table contents. Only two rows are currently loaded, whereas the previous results had four rows. The rows having input values with incorrect data type have been rejected:

```

=> SELECT maptostring(__raw__), one, two FROM reject_true_false;
maptostring      | one | two
-----+-----+-----
{"one": "1",
 "two": "2"}
1 | 2
{"one": "7",
 "two": "8"}
7 | 8
(2 rows)

```

Note

The parser `fcsvparser` uses `null` values if there is a type mismatch and you set the `reject_on_materialized_type_error` parameter to `false` .

Rejecting or omitting empty rows

Valid CSV files can include empty key and value pairs. Such rows are invalid for SQL. You can control the behavior for empty rows by either rejecting or omitting them, using two boolean **FCSVPARSER** parameters:

- **reject_on_empty_key**
- **omit_empty_keys**

The following example illustrates how to set these parameters:

1. Create a flex table:

```
=> CREATE FLEX TABLE csv_basic();
CREATE TABLE
```

2. Load CSV data into the table (from STDIN), using the **fcsvparser** with **reject_on_empty_key=false** . While **false** is the default value, you can specify it explicitly, as shown. Additionally, set the parameter **header=true** to specify the columns for input values:

```
=> COPY csv_basic FROM stdin PARSER fcsvparser(reject_on_empty_key=false,header=true);
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> ,num
>> 1,2
>> \.
```

3. Invoke **maptostring** to display the table values after loading data:

```
=>SELECT maptostring(__row__) FROM csv_basic;
maptostring
-----
{"": "1",
"num": "2"}
(1 row)
```

4. Truncate the table to empty the data stored in the table:

```
=> TRUNCATE TABLE csv_basic;
TRUNCATE TABLE
```

5. Reload the same data again, but this time, set **reject_on_empty_key=true** :

```
=> COPY csv_basic FROM stdin PARSER fcsvparser(reject_on_empty_key=true,header=true);
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> ,num
>> 1,2
>> \.
```

6. Call **maptostring** to display the table contents. No rows are loaded because one of the keys is empty:

```
=> SELECT maptostring(__row__) FROM csv_basic;
maptostring
-----
(0 rows)
```

7. Truncate the table to empty the data stored in the table:

```
=> TRUNCATE TABLE csv_basic;
TRUNCATE TABLE
```

8. Reload the same data again, but this time, set **omit_empty_keys=true** :

```
=> COPY csv_basic FROM stdin PARSER fcsvparser(omit_empty_keys=true,header=true);
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> ,num
>> 1,2
>> \.
```

9. Call `maptostring` to display the table contents. One row is now loaded, and the rows with empty keys are omitted:

```
=> SELECT maptostring(__row__) FROM csv_basic;
maptostring
-----
|
|
| "num" : "2"
|
|
(1 row)
```

Note

If no header names exist, `fcsvparser` uses a default header of `ucol n`, where `n` is the column offset number. If a table header name and key name match, the parser loads the column with values associated with the matching key name.

Using the NULL parameter

Use the COPY NULL metadata parameter with `fcsvparser` to load NULL values into a flex table.

The next example uses this parameter:

1. Create a flex table:

```
=> CREATE FLEX TABLE fcsv(c1 int);
CREATE TABLE
```

2. Load CSV data in the flex table using STDIN and the NULL parameter:

```
=> COPY fcsv FROM STDIN PARSER fcsvparser() NULL 'NULL';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> a,b,c1
>> 10,20,NULL
>> 20,30,50
>> 20,30,40
>> \.
```

3. Use the `compute_flexible_keys_and_build_view` function to compute keys and build the flex view:

```
=> SELECT compute_flexible_keys_and_build_view('fcsv');
compute_flexible_keys_and_build_view
-----
Please see public.fcsv_keys for updated keys
The view public.fcsv_view is ready for querying
(1 row)
```

4. View the flex view and replace the NULL values:

```
=> SELECT * FROM public.fcsv_view;
a | b | c1
---+---+---
20 | 30 | 50
10 | 20 |
20 | 30 | 40
(3 rows)
=> SELECT a,b, ISNULL(c1,-1) from public.fcsv_view;
a | b | ISNULL
---+---+---
20 | 30 | 50
10 | 20 | -1
20 | 30 | 40
(3 rows)
```

Handling column headings

The `fcsvparser` lets you specify your own column headings with the `HEADER_NAMES=` parameter. This parameter entirely replaces column names in the CSV source header row.

For example, to use these six column headings for a CSV file you are loading, use the `fcsvparser` parameter as follows:

```
HEADER_NAMES='FIRST, LAST, SOCIAL_SECURITY, TOWN, STATE, COUNTRY'
```

Supplying fewer header names than existing data columns causes `fcsvparser` to use default names after those you supply. Default header names consist of `ucol n`, where `n` is the column offset number, starting at 0 for the first column. For example, if you supply four header names for a 6-column table, `fcsvparser` supplies the default names `ucol4` and `ucol5`, following the fourth header name you provide.

If you supply more headings than the existing table columns, any additional headings remain unused.

Loading delimited data

You can load flex tables with one of two delimited parsers, `fdelimitedparser` or `fdelimitedpairparser`.

- Use `fdelimitedpairparser` when the data specifies column names with the data in each row.
- Use `fdelimitedparser` when the data does not specify column names or has a header row for column names.

This section describes using some options that `fdelimitedpairparser` and `fdelimitedparser` support.

Rejecting duplicate values

You can reject duplicate values using the `reject_on_duplicate=true` option with the `fdelimitedparser`. The load continues after it rejects a duplicate value. The next example shows how to use this parameter and then displays the specified exception and rejected data files. Saving rejected data to a table, rather than a file, includes both the data and its exception.

```
=> CREATE FLEX TABLE delim_dupes();
CREATE TABLE
=> COPY delim_dupes FROM stdin PARSER fdelimitedparser(reject_on_duplicate=true)
exceptions '/home/dbadmin/load_errors/except.out' rejected data '/home/dbadmin/load_errors/reject.out';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> A|A
>> 1|2
>> \.
=> \! cat /home/dbadmin/load_errors/reject.out
A|A
=> \! cat /home/dbadmin/load_errors/except.out
COPY: Input record 1 has been rejected (Processed a header row with duplicate keys with
reject_on_duplicate specified; rejecting.). Please see /home/dbadmin/load_errors/reject.out,
record 1 for the rejected record.
COPY: Loaded 0 rows, rejected 1 rows.
```

Rejecting materialized column type errors

Both the `fjsonparser` and `fdelimitedparser` parsers have a boolean parameter, `reject_on_materialized_type_error`. Setting this parameter to `true` causes rows to be rejected if *both* the following conditions exist in the input data:

- Includes keys matching an existing materialized column
- Has a value that cannot be coerced into the materialized column's data type

Suppose the flex table has a materialized column, `OwnerPercent`, declared as a `FLOAT`. Trying to load a row with an `OwnerPercent` key that has a `VARCHAR` value causes `fdelimitedparser` to reject the data row.

The following examples illustrate setting this parameter.

1. Create a table, `reject_true_false`, with two real columns:

```
=> CREATE FLEX TABLE reject_true_false(one VARCHAR, two INT);
CREATE TABLE
```

2. Load JSON data into the table (from `STDIN`), using the `fjsonparser` with `reject_on_materialized_type_error=false`. While `false` is the default value, the following example specifies it explicitly for illustration:

```
=> COPY reject_true_false FROM stdin PARSE fjsonparser(reject_on_materialized_type_error=false);
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> {"one": 1, "two": 2}
>> {"one": "one", "two": "two"}
>> {"one": "one", "two": 2}
>> \.
```

3. Invoke `maptostring` to display the table values after loading data:

```
=> SELECT maptostring(__raw__), one, two FROM reject_true_false;
      maptostring      | one | two
-----+-----+-----
{
  "one": "one",
  "two": "2"
}
| one | 2
{
  "one": "1",
  "two": "2"
}
| 1 | 2
{
  "one": "one",
  "two": "two"
}
| one |
(3 rows)
```

4. Truncate the table:

```
=> TRUNCATE TABLE reject_true_false;
```

5. Reload the same data again, but this time, set `reject_on_materialized_type_error=true` :

```
=> COPY reject_true_false FROM stdin PARSE fjsonparser(reject_on_materialized_type_error=true);
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> {"one": 1, "two": 2}
>> {"one": "one", "two": "two"}
>> {"one": "one", "two": 2}
>> \.
```

6. Call `maptostring` to display the table contents. Only two rows were loaded, whereas the previous results had three rows:

```
=> SELECT maptostring(__raw__), one, two FROM reject_true_false;
      maptostring      | one | two
-----+-----+-----
{
  "one": "1",
  "two": "2"
}
| 1 | 2
{
  "one": "one",
  "two": "2"
}
| one | 2
(2 rows)
```

Computing flex table keys

After loading data into a flex table, you can determine the set of keys that exist in the `__raw__` column (the map data). Two helper functions compute keys from flex table map data:

- [COMPUTE_FLEXTABLE_KEYS](#) determines which keys exist as virtual columns in the flex map.
- [COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW](#) performs the same functionality as [COMPUTE_FLEXTABLE_KEYS](#), additionally building a new view. See [Updating Flex Table Views](#).

Using [COMPUTE_FLEXTABLE_KEYS](#)

During execution, this function calculates the following information for the flex keys table columns:

Column	Description
KEY_NAME	The name of the virtual column (key). Keys larger than 65,000 bytes are truncated.
FREQUENCY	The number of times the key occurs in the VMap.
DATA_TYPE_GUESS	Estimate of the data type for the key based on the non-null values found in the VMap. The function determines the type of each non-string value, depending on the length of the key, and whether the key includes nested maps. If the EnableBetterFlexTypeGuessing configuration parameter is 0 (OFF), this function instead treats all flex table keys as string types ([LONG] VARCHAR or [LONG] VARBINARY).

[COMPUTE_FLEXTABLE_KEYS](#) sets the column width for keys to the length of the largest value for each key multiplied by the [FlexTableDataTypeGuessMultiplier](#) factor.

Assigning flex key data types

When the [EnableBetterFlexTypeGuessing](#) configuration parameter is ON (the default), [COMPUTE_FLEXTABLE_KEYS](#) produces more specific results.

Use the sample CSV data in this section to compare the results of using or not using the parameter:

```
Year,Quarter,Region,Species,Grade,Pond Value,Number of Quotes,Available
2015,1,2 - Northwest Oregon & Willamette,Douglas-fir,1P,$615.12 ,12,No
2015,1,2 - Northwest Oregon & Willamette,Douglas-fir,SM,$610.78 ,12,Yes
2015,1,2 - Northwest Oregon & Willamette,Douglas-fir,2S,$596.00 ,20,Yes
2015,1,2 - Northwest Oregon & Willamette,Hemlock,P,$520.00 ,6,Yes
2015,1,2 - Northwest Oregon & Willamette,Hemlock,SM,$510.00 ,6,No
2015,1,2 - Northwest Oregon & Willamette,Hemlock,2S,$490.00 ,14,No
```

Create a flex table and load this data:

```
=> CREATE FLEX TABLE trees();
=> COPY trees FROM '/home/dbadmin/tempdat/trees.csv' PARSER fcsvparser();
```

Compute keys and check the results with the default setting:

```
=> SELECT COMPUTE_FLEXTABLE_KEYS('trees');
      COMPUTE_FLEXTABLE_KEYS
```

```
-----
Please see public.trees_keys for updated keys
(1 row)
```

```
=> SELECT * FROM trees_keys;
  key_name  | frequency | data_type_guess
```

```
-----+-----
Year       |         6 | Integer
Quarter    |         6 | Integer
Region     |         6 | Varchar(66)
Available  |         6 | Boolean
Number of Quotes |         6 | Integer
Grade      |         6 | Varchar(20)
Species    |         6 | Varchar(22)
Pond Value |         6 | Numeric(8,3)
(8 rows)
```

Set [EnableBetterFlexTypeGuessing](#) to 0 (OFF), compute keys again, and compare the results:

```
=> SELECT * FROM trees_keys;
  key_name | frequency | data_type_guess
-----+-----+-----
Year      |          6 | varchar(20)
Quarter   |          6 | varchar(20)
Region    |          6 | varchar(66)
Available |          6 | varchar(20)
Grade     |          6 | varchar(20)
Number of Quotes |          6 | varchar(20)
Pond Value |          6 | varchar(20)
Species   |          6 | varchar(22)
(8 rows)
```

Materializing flex tables

After creating flex tables, you can change the table structure to promote virtual columns to materialized (real) columns. If your table is already a hybrid table, you can change existing real columns and promote other important virtual columns. This section describes some key aspects of promoting columns, adding columns, specifying constraints, and declaring default values. It also presents some differences when loading flex or hybrid tables, compared with columnar tables.

Materializing virtual columns by promoting them to real columns can significantly improve query performance. Vertica recommends that you materialize important virtual columns before running large and complex queries. Promoted columns cause a small decrease in load performance.

Adding columns

You can add a real column to a flex table using `ALTER TABLE ADD COLUMN`. By default, data already in the table remains in the `__raw__` column and only new data is added to the real column:

```
=> CREATE FLEX TABLE mtns();

=> COPY mtns FROM STDIN PARSER FJSONPARSER();
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
-> {"name": "Everest"}
-> {"name": "Mt St Helens"}
-> {"name": "Denali"}
-> {"name": "Kilimanjaro"}
-> {"name": "Mt Washington"}
-> \.

=> ALTER TABLE mtns ADD COLUMN name VARCHAR;

=> INSERT INTO mtns(name) VALUES('Fuji');
OUTPUT
-----
   1
(1 row)

-- Querying the real column shows only the inserted value:
SELECT name FROM mtns;
name
-----

Fuji
(6 rows)
```

To instead add the real column and import values from the `__raw__` column, use the DEFAULT option with the [MAPLOOKUP](#) function to find the value in the flex data:

```
=> ALTER TABLE mtns ADD COLUMN name VARCHAR
DEFAULT (MapLookup(mtns.__raw__, 'name'))::VARCHAR;

-- column now has all values:
=> SELECT name FROM mtns;
  name
-----
Fuji
Everest
Mt St Helens
Denali
Kilimanjaro
Mt Washington
(6 rows)
```

Changing the `__raw__` column size

You can change the default size of the `__raw__` column for flex tables you plan to create, the current size of an existing flex table, or both.

To change the default size for the `__raw__` column in new flex tables, set the [FlexTableRawSize](#) configuration parameter:

```
=> ALTER DATABASE DEFAULT SET FlexTableRawSize = 120000;
```

Changing the configuration parameter affects all flex tables you create after making this change.

To change the size of the `__raw__` column in an existing flex table, use the [ALTER TABLE](#) statement to change the definition of the `__raw__` column:

```
=> ALTER TABLE tester ALTER COLUMN __raw__ SET DATA TYPE LONG VARBINARY(120000);
ALTER TABLE
```

Note

An error occurs if you try to reduce the `__raw__` column size to a value smaller than any data the column contains.

Changing flex table real columns

You can make the following changes to the flex table real columns (`__raw__` and `__identity__`), but not to any virtual columns:

Actions	raw	identity
Change NOT NULL constraints (default)	Yes	Yes
Add primary key and foreign key (PK/FK) constraints	No	Yes
Create projections	No	Yes
Segment	No	Yes
Partition	No	Yes
Specify a user-defined scalar function (UDSF) as a default column expression in <code>ALTER TABLE x ADD COLUMN y</code> statement	No	No

Note

While segmenting and partitioning the `__raw__` column is permitted, it is not recommended due to its long data type. By default, if you not define any real columns, flex tables are segmented on the `__identity__` column.

Dropping flex table columns

There are two considerations about dropping columns:

- You cannot drop the last column in your flex table's sort order.
- If you have not created a flex table with any real columns, or materialized any columns, you cannot drop the `__identity__` column.

Updating flex table views

Adding new columns to a flex table that has an associated view does not update the view's result set, even if the view uses a wildcard (*) to represent all table columns. To incorporate new columns, you must [re-create the view](#).

Updating flex table views

Creating a flex table also creates a default view to accompany the table. The view has the name of the flex table with an underscore (`_view`) suffix.

When you perform a SELECT query from the default view, Vertica prompts you to call the helper function

COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW:

```
=> \dv dark*
      List of View Fields
Schema | View | Column | Type | Size
-----+-----+-----+-----+-----
public | darkdata_view | status | varchar(124) | 124
public | darkdata1_view | status | varchar(124) | 124
(2 rows)

=> SELECT * FROM darkdata_view;
      status
-----
Please run compute_flexable_keys_and_build_view() to update this view to reflect real and
virtual columns in the flex table
(1 row)
```

There are two helper functions that create views:

- [BUILD_FLEXTABLE_VIEW](#): Creates or re-creates a view for a default or user-defined keys table, ignoring any empty keys.
- [COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW](#): Computes virtual columns (keys) from the VMap data of a flex table and constructs a view (see also [Using COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW](#)).

Using BUILD_FLEXTABLE_VIEW

After computing keys for a flex table ([Computing flex table keys](#)), call this function with one or more arguments. The records under the `key_name` column of the `table_name_keys` table are used as view columns, along with any values for the key. If no values exist, the column value is NULL.

Regardless of the number of arguments, calling this function replaces the contents of the existing view as follows:

- [BUILD_FLEXTABLE_VIEW \(' table '\)](#): Changes the table's existing view with the current contents of the `table_keys` table.
- [BUILD_FLEXTABLE_VIEW \(' table ', ' view_name '\)](#): Changes the named view with the current contents of the `table_keys` table.
- [BUILD_FLEXTABLE_VIEW \(' table ', ' view_name ', ' table_keys '\)](#): Changes the named view using the named keys table. Use this option if you created a custom keys table from the flex table map data, rather than from the default keys table.

If you do not specify a view name, the default name is the flex table name with a `_view` suffix. For example, if you specify the table `darkdata` as the sole argument to this function, the default view is called `darkdata_view`.

You cannot specify a custom view name with the same name as the default view (`table_name_view`), unless you first drop the default-named view and then create your own view of the same name.

Creating a view stores a definition of the column structure at the time of creation. Thus, if you create a flex table view and then promote virtual columns to real columns, you must rebuild the view. Querying a rebuilt flex table view that has newly promoted real columns produces two results. These results reflect values from both virtual columns in the map data and real columns.

Handling JSON duplicate key names in views

SQL is a case-insensitive language, so the names `TEST`, `test`, and `TeSt` are identical. JSON data is case sensitive, so that it can validly contain key names of different cases with separate values.

When you build a flex table view, the function generates a warning if it detects same-name keys with different cases in the `table_keys` table. For example, calling `BUILD_FLEXTABLE_VIEW` or `COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW` on a flex table with duplicate key names results in these warnings:

```
=> SELECT COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW('dupe');
WARNING 5821: Detected keys sharing the same case-insensitive key name
WARNING 5909: Found and ignored keys with names longer than the maximum column-name length limit

      compute_flextable_keys_and_build_view
-----
Please see public.dupe_keys for updated keys
The view public.dupe_view is ready for querying
(1 row)
```

While a keys table can include duplicate key names with different cases, a view cannot. Creating a flex table view with either of the helper functions consolidates any duplicate key names to one column name, consisting of all lowercase characters. All duplicate key values for that column are saved. For example, if a flex table contains keys named `test`, `Test`, and `tEst`, the view includes a virtual column `test` with values from all three keys.

The following examples include added line breaks for readability.

Consider the following query, showing the duplicate `test` key names:

```
=> \x
Expanded display is on.
dbt=> select * from dupe_keys;
-[ RECORD 1 ]---+-----
key_name      | TesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttest
TesttestTesttestTesttestTesttest
frequency     | 2
data_type_guess | varchar(20)
-[ RECORD 2 ]---+-----
key_name      | TesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttest
TesttestTesttestTesttestTest12345
frequency     | 2
data_type_guess | varchar(20)
-[ RECORD 3 ]---+-----
key_name      | test
frequency     | 8
data_type_guess | varchar(20)
-[ RECORD 4 ]---+-----
key_name      | TEst
frequency     | 8
data_type_guess | varchar(20)
-[ RECORD 5 ]---+-----
key_name      | TEST
frequency     | 8
data_type_guess | varchar(20)
```

The following query displays the `dupe` flex table (`dupe_view`). It shows the consolidated virtual columns, with all values in the `test` column:

```

=> SELECT * FROM dupe_view;
  test | testtesttesttesttesttesttesttesttesttesttesttesttesttesttesttesttesttest
testtesttesttesttesttesttest
-----+-----
upper2 |
half4  |
lower1 |
upper1 |
half1  |
half4  |
      |
lower1 |
half1  |
upper2 |
      |
lower2 |
lower3 |
upper1 |
lower2 |
lower3 |
(16 rows)

```

Creating a flex table view

The following example shows how to create and query a view for a flex table that contains JSON data:

```

=> CREATE VIEW dd_view AS SELECT "user.lang"::VARCHAR, "user.name"::VARCHAR FROM darkdata;
CREATE VIEW

=> SELECT * FROM dd_view;
user.lang | user.name
-----+-----
en      | Uptown gentleman.
en      | The End
it      | laughing at clouds.
es      | I'm Toasterâ
      |
en      | ~G A B R I E L A â¸
      |
en      | Avita Desai
tr      | seydo shi
      |
      |
es      | Flu Beach
(12 rows)

```

This example shows how to call `BUILD_FLEXTABLE_VIEW` with the original table and the view you previously created:

```

=> SELECT BUILD_FLEXTABLE_VIEW ('darkdata', 'dd_view');
      build_flextable_view
-----+-----
The view public.dd_view is ready for querying
(1 row)

```

Query the view again. You can see that the function populated the view with the contents of the `darkdata_keys` table. Next, review a snippet from the results, with the key columns and their values:

```

=> \x
Expanded display is on.

=> SELECT * FROM dd_view;
.
.
.
user.following          |
user.friends_count     | 791
user.geo_enabled       | F
user.id                 | 164464905
user.id_str            | 164464905
user.is_translator     | F
user.lang              | en
user.listed_count      | 4
user.location          | Uptown..
user.name              | Uptown gentleman.
.
.
.

```

When building views, be aware that creating a view stores a definition of the column structure at the time the view is created. If you promote virtual columns to real columns after building a view, the existing view definition is not changed. Querying this view with a select statement such as the following, returns values from only the `__raw__` column:

```

=> SELECT * FROM myflextable_view;

```

Also understand that rebuilding the view after promoting virtual columns changes the resulting value. Future queries return values from both virtual columns in the map data and from real columns.

Using `COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW`

Call this function with a flex table to compute Flex table keys (see [Computing flex table keys](#)) and create a view in one step.

Querying flex tables

After you create your flex table (with or without additional columns) and load data, you can use `SELECT`, `COPY`, `TRUNCATE`, and `DELETE` as with other tables. You can use `SELECT` queries for virtual columns that exist in the `__raw__` column and other real columns in your flex tables. Field names in the `__raw__` column are case-insensitive, as are the names of real columns.

Unsupported DDL and DML statements

You cannot use the following DDL and DML statements with flex tables:

- `CREATE TABLE...AS...`
- `CREATE TABLE...LIKE...`
- `SELECT INTO`
- `UPDATE`
- `MERGE`

Determining flex table data contents

If you do not know what your flex table contains, two helper functions explore the VMap data to determine its contents. Use these functions to compute the keys in the flex table `__raw__` column and, optionally, build a view based on those keys:

- [COMPUTE_FLEXTABLE_KEYS](#)
- [COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW](#)

For more information about these and other helper functions, see [Flex data functions](#).

To determine what key value pairs exist as virtual columns:

1. Call the function as follows:

```
=> SELECT compute_flexible_keys('darkdata');
compute_flexible_keys
```

Please see public.darkdata_keys for updated keys(1 row)

2. View the key names by querying the `darkdata_keys` table:

```
=> SELECT * FROM darkdata_keys;
```

key_name	frequency	data_type_guess
contributors	8	varchar(20)
coordinates	8	varchar(20)
created_at	8	varchar(60)
entities.hashtags	8	long varbinary(186)
.		
.		
retweeted_status.user.time_zone	1	varchar(20)
retweeted_status.user.url	1	varchar(68)
retweeted_status.user.utc_offset	1	varchar(20)
retweeted_status.user.verified	1	varchar(20)

(125 rows)

Querying virtual columns

Continuing with the JSON data example, use a SELECT statement query to explore content from the virtual columns. Then, analyze what is most important to you in case you want to materialize any virtual columns. This example shows how to query some common virtual columns in the VMap data:

```
=> SELECT "user.name", "user.lang", "user.geo_enabled" FROM darkdata1;
```

user.name	user.lang	user.geo_enabled
laughing at clouds.	it	T
Avita Desai	en	F
I'm Toasterâ€	es	T
Uptown gentleman.	en	F
~G A B R I E L A â¿	en	F
Flu Beach	es	F
seydo shi	tr	T
The End	en	F

(12 rows)

Querying flex table keys

If you reference an undefined column (`'which_column'`) in a flex table query, Vertica converts the query to a call to the MAPLOOKUP function as follows:

```
MAPLOOKUP(__raw__, 'which_column')
```

The MAPLOOKUP function searches the VMap data for the requested key and returns the following information:

- String values associated with the key for a row.
- `NULL` if the key is not found.

For more information about handling NULL values, see [MAPCONTAINSKEY\(\)](#).

Using functions and casting in flex table queries

You can cast the virtual columns as required and use functions in your SELECT statement queries. The next example uses a SELECT statement to query the `created_at` and `retweet_count` virtual columns, and to cast their values in the process:

```
=> SELECT "created_at"::TIMESTAMP, "retweet_count"::INT FROM darkdata1 ORDER BY 1 DESC;
```

created_at	retweet_count
2012-10-15 14:41:05	0
2012-10-15 14:41:05	0
2012-10-15 14:41:05	0
2012-10-15 14:41:05	0
2012-10-15 14:41:05	0
2012-10-15 14:41:05	0
2012-10-15 14:41:05	0
2012-10-15 14:41:04	1

(12 rows)

The following query uses the COUNT and AVG functions to determine the average length of text in different languages:

```
=> SELECT "user.lang", count (*), avg(length("text"))::int  
FROM darkdata1 GROUP BY 1 ORDER BY 2 DESC;
```

user.lang	count	avg
en	4	42
es	2	96
it	1	50

Casting data types in a query

The following query requests the values of the `created_at` virtual column, without casting to a specific data type:

```
=> SELECT "created_at" FROM darkdata1;
```

created_at
Mon Oct 15 18:41:04 +0000 2012
Mon Oct 15 18:41:05 +0000 2012
Mon Oct 15 18:41:05 +0000 2012
Mon Oct 15 18:41:05 +0000 2012
Mon Oct 15 18:41:05 +0000 2012
Mon Oct 15 18:41:05 +0000 2012
Mon Oct 15 18:41:05 +0000 2012
Mon Oct 15 18:41:05 +0000 2012

(12 rows)

The next example queries the same virtual column, casting `created_at` to a `TIMESTAMP`. Casting results in different output and the regional time:

```
=> SELECT "created_at"::TIMESTAMP FROM darkdata1 ORDER BY 1 DESC;
```

created_at
2012-10-15 14:41:05

Accessing an epoch key

The term `EPOCH` (all uppercase letters) is reserved in Vertica for internal use.

If your JSON data includes a virtual column called `epoch`, you can query it within your flex table. However, use the `MAPLOOKUP` function to do so.

Querying nested data

If you load JSON or Avro data with `flatten_arrays=FALSE` (the default), VMap data in the `__raw__` column can contain multiple nested structures. In fact, any VMap JSON or Avro data can contain nested structures. This section describes how best to query such data.

Query VMap nested values

To query a nested structure, you can use multiple `maplookup()` functions, one for each level. However, the most efficient method is to use bracket (`[]`) operators.

When parsing or extracting VMap data, the default behavior is to flatten data. Flattened VMap data concatenates key names into one long name, delimiting elements with either the default delimiter (`.`), or a user-defined delimiter character.

To use bracket operators for nested structures in your VMap data, the data must not be flattened. Further, you cannot use bracket operators on any existing, flattened VMap data.

To load or extract VMap data correctly, specify `flatten_maps=FALSE` for `fjsonparser`, `favroparser`, and the `mapjsonextractor()` function.

Note

While bracket operator values look similar to array element specifications, they are strings, not integers. You must enter each nested structure as a string, even if the value is an integer. For example, if the value is 2, specify it as `[2]`, not `[2]`.

Bracket operators for nested JSON

This example uses the following JSON data as an example of nested data. Save this data as `restaurant.json`:

```
{
  "restaurant": {
    "_name_": "Bob's pizzeria",
    "cuisine": "Italian",
    "location": {"city": "Cambridge", "zip": "02140"},
    "menu": [{"item": "cheese pizza", "price": "$8.25"},
             {"item": "chicken pizza", "price": "$11.99"},
             {"item": "spinach pizza", "price": "$10.50"}]
  }
}
```

Create a flex table, `rests`, and load it with the `restaurant.json` file:

```
=> COPY rests FROM '/home/dbadmin/tempdat/restaurant.json' PARSER fjsonparser (flatten_maps=false);
```

Rows Loaded

1

(1 row)

After loading your data into a flex table, there are two ways to access nested data using brackets:

- Beginning with the `__raw__` column, followed by the character values in brackets
- Starting with the name of the top-most element, followed by the character values in brackets

Both methods are equally efficient. Here are examples of both:

```

=> SELECT __raw__['restaurant']['location']['city'] FROM rests;
__raw__
-----
Cambridge
(1 row)
=> SELECT restaurant['location']['city'] from rests;
restaurant
-----
Cambridge
(1 row)

```

Bracket operators for twitter data

This example shows how to extract some basic information from Twitter data.

After creating a flex table, `tweets`, and loading in some data, the flex table has a block of tweets.

In the following `SELECT` statement, notice how to specify the `__raw__` column of table `tweets`, followed by the bracket operators to define the virtual columns of interest (`['delete']['status']['user_id']`). This query uses the `COUNT()` function to calculate the number of deleted tweets and outputs 10 results:

```

=> SELECT __raw__['delete']['status']['user_id'] as UserId, COUNT(*) as TweetsDelete from tweets
-> WHERE mapcontainskey(__raw__, 'delete')
-> GROUP BY __raw__['delete']['status']['user_id']
-> ORDER BY TweetsDelete DESC, UserID ASC LIMIT 10;
  UserId | TweetsDelete
-----+-----
106079547 |          4
403474369 |          4
181188657 |          3
223136123 |          3
770139481 |          3
154602299 |          2
192127653 |          2
215011332 |          2
23321883  |          2
242173898 |          2
(10 rows)

```

Querying flex views

Flex tables offer the ability of dynamic schema through the application of query rewriting. Use flex views to support restricted access to flex tables. As with flex tables, each time you use a `select` query on a flex table view, internally, Vertica invokes the `maplookup()` function, to return information on all virtual columns. This query behavior occurs for any flex or columnar table that includes a `__raw__` column.

This example illustrates querying a flex view:

1. Create a flex table.

```

=> CREATE FLEX TABLE twitter();

```

2. Load JSON data into flex table using `fjsonparser`.

```

=> COPY twitter FROM '/home/dbadmin/data/flex/tweets_10000.json' PARSER fjsonparser();
Rows Loaded
-----
10000
(1 row)

```

3. Create a flex view on top of flex table `twitter` with constraint `retweet_count>0`.

```

=> CREATE VIEW flex_view AS SELECT __raw__ FROM twitter WHERE retweet_count::int > 0;
CREATE VIEW

```

4. Query the view. First 5 rows are displayed.

```
=> SELECT retweeted,retweet_count,source FROM (select __raw__ from flex_view) t1 limit 5;
retweeted | retweet_count | source
-----+-----+-----
F      | 1      | <a href="http://blackberry.com/twitter" rel="nofollow">Twitter for BlackBerry@</a>
F      | 1      | web
F      | 1      | <a href="http://twitter.com/download/iphone" rel="nofollow">Twitter for iPhone</a>
F      | 23     | <a href="http://twitter.com/download/android" rel="nofollow">Twitter for Android</a>
F      | 7      | <a href="http://twitter.com/download/iphone" rel="nofollow">Twitter for iPhone</a>
(5 rows)
```

Listing flex tables

You can determine which tables in your database are flex tables by querying the `is_flexitable` column of the `v_catalog.tables` system table. For example, use a query such as the following to see all tables with a true (`t`) value in the `is_flexitable` column:

```
=> SELECT table_name, table_schema, is_flexitable FROM v_catalog.tables;
table_name | table_schema | is_flexitable
-----+-----+-----
bake1      | public      | t
bake1_keys | public      | f
del        | public      | t
del_keys   | public      | f
delicious  | public      | t
delicious_keys | public      | f
bake       | public      | t
bake_keys  | public      | f
appLog     | public      | t
appLog_keys | public      | f
darkdata   | public      | t
darkdata_keys | public      | f
(12 rows)
```

Data export and replication

Vertica supports transferring data by exporting or replicating it. These two methods differ slightly:

Exporting data

Transforms the data into a new format. You can export data to files to use with other tools or as Vertica external tables. You can also export data to another Vertica database using the `COPY FROM VERTICA` or `EXPORT TO VERTICA` statements.

Replicating data

Copies data in the Vertica native format. Replicating data is more efficient than exporting because Vertica does not need to decompress, sort, and recompress the data. However, unlike exporting, replication only copies data between Vertica databases running in the same mode (Eon or Enterprise).

Data export

Reasons you might want to export data from Vertica include:

- To use the data in external tables; see [Working with external data](#).
- To share data with other clients or consumers in an ecosystem.
- To copy data to another Vertica cluster.

Vertica provides two ways to export data:

- Export data to files using data exporters. You can export the results of a `SELECT` query to files in Parquet, ORC, or delimited format. You can use partitioning in the export to reduce the file size and improve performance when reading the data in external tables. For more information, see [File export](#).
- Export data directly between Vertica clusters. Direct export lets you copy data between databases without having to save it to an intermediate file. You can perform the operation as either an import from another database or an export to another database; aside from the direction of data travel, these two operations are equal. Direct export lets you copy data between Vertica databases which have different configurations, such as clusters running in different modes or have a different number of nodes or shards. For more information, see [Database export and import](#).

Data replication

Replication transfers data between Vertica databases in native format. Vertica supports two types of replication:

- **vbr** -based replication uses the Vertica backup script to copy ROS containers from one database to another. This type of replication supports both Eon Mode and Enterprise Mode databases. However, the two databases must be running in the same mode and have the same number of nodes (for Enterprise Mode databases) or primary nodes (for Eon Mode databases). See [Replicating objects to another database cluster](#) for more information about this replication method.
- Server-based replication is an Eon Mode-only method that copies data directly from the communal store of one database to another. Both databases must have the same shard segmentation layout and run compatible versions of the Vertica server. The replication feature is backwards compatible on the target side of the replication. The target database can run a later version of the database than the source database.

In this section

- [File export](#)
- [Database export and import](#)
- [Replication](#)

File export

You might want to export a table or other query results from Vertica, either to share it with other applications or to move lower-priority data from ROS to less-expensive storage. Vertica supports several EXPORT TO statements for different file formats: [EXPORT TO PARQUET](#), [EXPORT TO ORC](#), [EXPORT TO JSON](#), and [EXPORT TO DELIMITED](#).

You can export data to HDFS, S3, Google Cloud Storage (GCS), Azure Blob Storage, or the Linux file system. Be careful to avoid concurrent exports to the same output destination. Doing so is an error on any file system and can produce incorrect results.

Not all exporters support all complex types. See the Data Types section on individual reference pages.

You can export ROS data or data that is readable through external tables. After exporting ROS data, you can drop affected ROS partitions to reclaim storage space.

After exporting data, you can define external tables to read that data in Vertica. Parquet and ORC are columnar formats that Vertica can take advantage of in query optimization, so consider using one of those formats for external tables. See [Working with external data](#).

In this section

- [Syntax](#)
- [Partitioning and sorting data](#)
- [Exporting to object stores](#)
- [Exporting to the Linux file system](#)
- [Monitoring exports](#)

Syntax

Note

[EXPORT TO PARQUET](#), [EXPORT TO ORC](#), [EXPORT TO JSON](#), and [EXPORT TO DELIMITED](#) have the same general syntax. This documentation refers to them collectively as EXPORT statements, not to be confused with [EXPORT TO VERTICA](#).

Use the EXPORT statements to export data specified by a SELECT statement, as in the following example:

```
=> EXPORT TO PARQUET(directory='webhdfs:///data/sales_data')
AS SELECT * FROM public.sales;
Rows Exported
-----
      14336
(1 row)
```

The **directory** parameter specifies where to write the files and is required. You must have permission to write to the output directory. You can use the **ifDirExists** parameter to specify what to do if the directory already exists:

- **fail** (default)
- **overwrite** : replace the entire directory
- **append** : export new files into the existing directory

You can export to HDFS, S3, GCS, Azure, or the Linux file system. For additional considerations specific to object stores, see [Exporting to object stores](#). If you export to the local Linux file system (not a shared NFS mount) you must take some additional steps; see [Exporting to the Linux file system](#).

You can use EXPORT statements to write queries across multiple tables in Vertica and export the results. With this approach you can take advantage of powerful, fast query execution in Vertica while making the results available to other clients:

```
=> EXPORT TO ORC(directory='webhdfs:///data/sales_by_region')
AS SELECT sale.price, sale.date, store.region
FROM public.sales sale
JOIN public.vendor store ON sale.distribID = store.ID;
Rows Exported
-----
      23301
(1 row)
```

Restrictions

- If you perform more than one concurrent export to the same directory, only one succeeds. If you perform concurrent exports with `ifDirExists=overwrite`, the results will be incorrect.
- Exports cannot be run in fenced mode. If the `ForceUDxFencedMode` configuration parameter is set to true to support other UDxs, you can set it to false at the session level before performing the export.

Data types

All exporters can export scalar types. All except EXPORT TO DELIMITED also support [primitive arrays](#). The JSON and Parquet exporters also support the [ARRAY](#) and [ROW](#) types in any combination:

```
=> SELECT * FROM restaurants;
 name | cuisine | location_city | menu
-----+-----+-----+-----
Bob's pizzeria | Italian | ["Cambridge", "Pittsburgh"] | [{"item":"cheese pizza","price":null}, {"item":"spinach pizza","price":10.5}]
Bakersfield Tacos | Mexican | ["Pittsburgh"] | [{"item":"veggie taco","price":9.95}, {"item":"steak taco","price":10.95}]
(2 rows)

=> EXPORT TO JSON (directory='/output/json') AS SELECT * FROM restaurants;
Rows Exported
-----
      2
(1 row)

=> \! cat /output/json/*.json
{"name":"Bob's pizzeria","cuisine":"Italian","location_city":["Cambridge","Pittsburgh"],"menu":[{"item":"cheese pizza","price":null}, {"item":"spinach pizza","price":10.5}]}
{"name":"Bakersfield Tacos","cuisine":"Mexican","location_city":["Pittsburgh"],"menu":[{"item":"veggie taco","price":9.95}, {"item":"steak taco","price":10.95}]}
```

Query

EXPORT statements rewrite the query you specify, because the export is done by a user-defined transform function (UDTF). Because of this rewrite, there are some restrictions on the query you supply.

The query can contain only a single outer SELECT statement. For example, you cannot use UNION:

```
=> EXPORT TO PARQUET(directory = '/mnt/shared_nfs/accounts/rm')
OVER(PARTITION BY hash)
AS
SELECT 1 as account_id, '{}' as json, 0 hash
UNION ALL
SELECT 2 as account_id, '{}' as json, 1 hash;
ERROR 8975: Only a single outer SELECT statement is supported
HINT: Please use a subquery for multiple outer SELECT statements
```

Instead, rewrite the query to use a subquery:

```

=> EXPORT TO PARQUET(directory = '/mnt/shared_nfs/accounts/rm')
  OVER(PARTITION BY hash)
  AS
  SELECT
    account_id,
    json
  FROM
  (
    SELECT 1 as account_id, '{}' as json, 0 hash
  UNION ALL
    SELECT 2 as account_id, '{}' as json, 1 hash
  ) a;
Rows Exported
-----
      2
(1 row)

```

To use composite statements such as UNION, INTERSECT, and EXCEPT, rewrite them as subqueries.

When exporting data you can use an OVER() clause to partition and sort the data as described in [Partitioning and sorting data](#). Partitioning and sorting can improve query performance. If you partition the data, you cannot specify schema and table names in the SELECT statement. In this case, specify only the column name.

All exporters have a required **directory** parameter. All allow you to specify a compression type, and each exporter has format-specific parameters. See the parameter descriptions on the individual reference pages: [EXPORT TO PARQUET](#), [EXPORT TO ORC](#), [EXPORT TO JSON](#), and [EXPORT TO DELIMITED](#).

Partitioning and sorting data

When exporting, you can use the optional OVER clause in the SELECT statement to specify how to partition and/or sort the exported data. Partitioning reduces the sizes of the output data files and can improve performance when Vertica queries external tables containing this data. (See [Partitioned data](#).) If you do not specify how to partition the data, Vertica optimizes the export for maximum parallelism.

To specify partition columns, use PARTITION BY in the OVER clause as in the following example:

```

=> EXPORT TO PARQUET(directory = 'webhdfs:///data/export')
  OVER(PARTITION BY date) AS SELECT transactionID, price FROM public.sales;
Rows Exported
-----
    28337
(1 row)

```

You can both partition by a column and include that column in the SELECT clause. Including the column allows you to sort it. Vertica still takes advantage of the partitioning during query execution.

You can sort values within a partition for a further performance improvement. Sort table columns based on the likelihood of their occurrence in query predicates; columns that most frequently occur in comparison or range predicates should be sorted first. You can sort values within each partition using ORDER BY in the OVER clause:

```

=> EXPORT TO PARQUET(directory = 'webhdfs:///data/export')
  OVER(PARTITION BY date ORDER BY price) AS SELECT date, price FROM public.sales;
Rows Exported
-----
    28337
(1 row)

```

You can use ORDER BY even without partitioning. Storing data in sorted order can improve data access and predicate evaluation performance.

Targets in the OVER clause must be column references; they cannot be expressions. For more information about OVER, see [SQL analytics](#).

If you are exporting data to a local file system, you might want to force a single node to write all of the files. To do so, use an empty OVER clause.

Exporting to object stores

Object-store file systems (S3, Google Cloud Storage, and Azure Blob Storage) have some differences from other file systems that affect data export. You must set some additional configuration parameters for authentication and region, and there are some restrictions on the output.

URI formats and configuration parameters are described on the following reference pages:

- [S3 object store](#)
- [Google Cloud Storage \(GCS\) object store](#)
- [Azure Blob Storage object store](#)

Configuration parameters affect all access to the corresponding object stores, both reads and writes. Instead of setting them globally, you can limit the effects of your settings by setting them at the session level before exporting data.

Overwrites

By default, exports fail if the target directory already exists. You can use the `ifDirExists` parameter to instead append or overwrite. If you specify `overwrite` for an export to an object store, the existing directory is deleted recursively at the beginning of the operation and is not restored if the operation fails. Be careful not to export to a directory containing data you want to keep.

Output restrictions

Object-store file systems do not support renaming files in place; they implement a rename as a copy followed by a delete. On other file systems, the exporters support atomicity by writing output into a temporary directory and renaming it when complete. Such an approach is impractical for object stores, so the exporters write directly to the destination path. It is therefore possible to begin reading the exported data before the export has finished, which could lead to errors. Be careful to wait for the export to finish before using the data.

Vertica does not support simultaneous exports to the same path in object stores. The results are undefined.

S3 limits buckets to 5TB. You might need to divide very large exports.

Exporting to the Linux file system

Exports to the local file system can be to an NFS mount (shared) or to the Linux file system on each node (non-shared). If you export to an NFS mount on the Linux file system, the exporters behave the same way as for any other shared location: all of the exported files are written to the same (shared) destination.

If you export to the local Linux file system, each Vertica node writes its portion of the export to its local (non-shared) file system. Exports to non-shared local file systems have the following restrictions:

- The output directory must not exist on any node.
- You must have a USER storage location or superuser privileges.
- You cannot override the permissions mode of 700 for directories and 600 for files.

To define an external table to read data exported to a non-shared local file system, use `COPY...ON EACH NODE`, as in the following example:

```
=> CREATE EXTERNAL TABLE sales (...)  
AS COPY FROM '/data/sales/*.parquet' ON EACH NODE PARQUET;
```

The path is the same path that you specified in the export statement and is the same on all nodes.

If you omit the `ON` clause and just specify a path, `COPY` only loads the data it finds on the initiator node.

Monitoring exports

You can review information about exports, including numbers of row groups, file sizes, and file names.

The export statements are UDxs. The `UDX_EVENTS` system table records events logged during UDX execution, including timestamps, node names, and session IDs. This table contains a column (`__RAW__`), which holds a VMap of whatever additional data an individual UDX logged. The export statements log details about the exported files in this table. While you can work with this table directly and materialize values from the VMap column, you might prefer to define a view to simplify your access.

The following statement defines a view showing only the events from `EXPORT TO PARQUET`, materializing the VMap values.

```

=> CREATE VIEW parquet_export_events AS
SELECT
  report_time,
  node_name,
  session_id,
  user_id,
  user_name,
  transaction_id,
  statement_id,
  request_id,
  udx_name,
  event_type,
  file,
  created,
  closed,
  rows,
  row_groups,
  size_mb,
  row_group_file,
  row_group_n,
  row_group_rows,
  row_group_bytes,
  row_group_expected_size_mb,
  row_groups_exceeding_target
FROM
  v_monitor.udx_events
WHERE
  udx_name ilike 'ParquetExport%';

```

The exporters report the following UDX-specific columns:

Column Name	Data Type	Description
EVENT_TYPE	VARCHAR	What was written. All exporters report FILE events. In addition, the Parquet exporter reports ROW_GROUP events. Row groups are only logged if debugging is enabled.
FILE	VARCHAR	For EVENT_TYPE of FILE, name of the output file.
CREATED	TIMESTAMPZ	For EVENT_TYPE of FILE, when the file was created.
CLOSED	TIMESTAMPZ	For EVENT_TYPE of FILE, when the file was closed after writing.
ROWS	INTEGER	For EVENT_TYPE of FILE, the total number of rows in the file.
ROW_GROUPS	INTEGER	For EVENT_TYPE of FILE, the number of row groups, for formats that use them (Parquet and ORC).
SIZE_MB	FLOAT	For EVENT_TYPE of FILE, file size.
ROW_GROUP_FILE	VARCHAR	For EVENT_TYPE of ROW_GROUP, name of the file containing the row group.
ROW_GROUP_N	INTEGER	For EVENT_TYPE of ROW_GROUP, row group number.
ROW_GROUP_ROWS	INTEGER	For EVENT_TYPE of ROW_GROUP, number of rows written in this row group.
ROW_GROUP_BYTES	INTEGER	For EVENT_TYPE of ROW_GROUP, number of bytes written in this row group.
ROW_GROUP_EXPECTED_SIZE_MB	INTEGER	For Parquet exports and an EVENT_TYPE of FILE, target size of each row group.

ROW_GROUPS_EXCEEDING_TARGET	INTEGER	For Parquet exports and an EVENT_TYPE of FILE, number of row groups exceeding the target size.
-----------------------------	---------	--

The following example shows the results of a single export.

```

-> SELECT file,rows,row_groups,size_mb FROM PARQUET_EXPORT_EVENTS;
      file                | rows | row_groups | size_mb
-----|-----|-----|-----
/data/out/gZxN3irt/450c4213-v_vmart_node0001-139770732459776-0.parquet | 29696 | 1          | 0.667203
/data/out/gZxN3irt/9df1e797-v_vmart_node0001-139770860660480-0.parquet | 29364 | 1          | 0.660922
(2 rows)

```

In this table, the output directory name (/data/out) is appended with a generated string (gZxN3irt). For exports to HDFS or to local file systems (including NFS), EXPORT TO PARQUET first writes data into a scratch directory and then renames it at the end of the operation. The events are logged during export and so show the temporary name. Some output destinations, such as AWS S3, do not support rename operations, so in those cases this table does not show generated names.

ROW_GROUP events are only recorded when debugging is enabled:

```

-> SELECT SET_DEBUG_LOG_ALLNODES(UDX, 'ALL');

```

Database export and import

Vertica can easily import data from and export data to other Vertica databases. Importing and exporting data is useful for common tasks such as moving data back and forth between a development or test database and a production database, or between databases that have different purposes but need to share data on a regular basis.

Moving data directly between databases

To move data between databases you first establish a connection using [CONNECT TO VERTICA](#) and then use one of the following statements to move data:

- [COPY FROM VERTICA](#)
- [EXPORT TO VERTICA](#)

These statements are symmetric; copying from cluster A to cluster B is the same as exporting from cluster B to cluster A. The difference is only in which cluster drives the operation.

To configure TLS settings for the connection, see [Configuring connection security between clusters](#).

Creating SQL scripts to export data

Three functions return a SQL script you can use to export database objects to recreate elsewhere:

- [EXPORT_CATALOG](#)
- [EXPORT_OBJECTS](#)
- [EXPORT_TABLES](#)

While copying and exporting data is similar to [Backing up and restoring the database](#), you should use them for different purposes, outlined below:

Task	Backup and Restore	COPY and EXPORT Statements
Back up or restore an entire database, or incremental changes	YES	NO
Manage database objects (a single table or selected table rows)	YES	YES
Use external locations to back up and restore your database	YES	NO
Use direct connections between two databases	OBJECT RESTORE ONLY	YES
Use external shell scripts to back up and restore your database	YES	NO
Use SQL commands to incorporate copy and export tasks into DB operations	NO	YES

The following sections explain how you import and export data between Vertica databases.

When importing from or exporting to a Vertica database, you can connect only to a database that uses trusted (username only) or password-based authentication, as described in [Security and authentication](#). OAuth and Kerberos authentication methods are not supported.

Other exports

This section is about exporting data to another Vertica database. For information about exporting data to files, which can then be used in external tables or COPY statements, see [File export](#).

In this section

- [Configuring connection security between clusters](#)
- [Exporting data to another database](#)
- [Copying data from another Vertica database](#)
- [Copy and export data on AWS](#)
- [Changing node export addresses](#)
- [Using public and private IP networks](#)
- [Handling node failure during copy/export](#)
- [Using EXPORT functions](#)

Configuring connection security between clusters

When copying data between clusters, Vertica can encrypt both data and plan metadata.

Data is encrypted if you configure internode encryption (see [Internode TLS](#)).

For metadata, by default Vertica tries TLS first and falls back to plaintext. You can configure Vertica to require TLS and to fail if the connection cannot be made. You can also have Vertica verify the certificate and hostname before connecting.

Enabling TLS between clusters

To use TLS between clusters, you must first configure TLS between nodes:

1. Set the [EncryptSpreadComms](#) parameter.
2. Configure the [data_channel](#) TLS Configuration.
3. Set the [ImportExportTLSMode](#) parameter.

To specify the level of strictness when connecting to another cluster, set the [ImportExportTLSMode](#) configuration parameter. This parameter applies for both importing and exporting data. The possible values are:

- **PREFER** : Try TLS but fall back to plaintext if TLS fails.
- **REQUIRE** : Use TLS and fail if the server does not support TLS.
- **VERIFY_CA** : Require TLS (as with REQUIRE), and also validate the other server's certificate using the CA specified by the "server" TLS

Configuration's CA certificates (in this case, "ca_cert" and "ica_cert"):

```
=> SELECT name, certificate, ca_certificate, mode FROM tls_configurations WHERE name = 'server';
name | certificate | ca_certificate | mode
-----+-----+-----+-----
server | server_cert | ca_cert,ica_cert | VERIFY_CA
(1 row)
```

- **VERIFY_FULL** : Require TLS and validate the certificate (as with VERIFY_CA), and also validate the server certificate's hostname.
- **REQUIRE_FORCE**, **VERIFY_CA_FORCE**, and **VERIFY_FULL_FORCE** : Same behavior as **REQUIRE**, **VERIFY_CA**, and **VERIFY_FULL**, respectively, and cannot be overridden by [CONNECT TO VERTICA](#).

[ImportExportTLSMode](#) is a global parameter that applies to all import and export connections you make using [CONNECT TO VERTICA](#). You can override it for an individual connection.

For more information about these and other configuration parameters, see [Security parameters](#).

Exporting data to another database

[EXPORT TO VERTICA](#) exports table data from one Vertica database to another. The following requirements apply:

- You already opened a connection to the target database with [CONNECT TO VERTICA](#).
- The source database is no more than one major release behind the target database.
- The table in the target database must exist.
- Source and target table columns must have the same or [compatible](#) data types.

Each EXPORT TO VERTICA statement exports data from only one table at a time. You can use the same database connection for multiple export operations.

Export process

Exporting is a three-step process:

1. Connect to the target database with [CONNECT TO VERTICA](#).

For example:

```
=> CONNECT TO VERTICA testdb USER dbadmin PASSWORD " ON 'VertTest01', 5433;
CONNECT
```

2. Export the desired data with EXPORT TO VERTICA. For example, the following statement exports all table data in `customer_dimension` to a table of the same name in target database `testdb` :

```
=> EXPORT TO VERTICA testdb.customer_dimension FROM customer_dimension;
Rows Exported
-----
      23416
(1 row)
```

3. [DISCONNECT](#) disconnects from the target database when all export and [import](#) operations are complete:

```
=> DISCONNECT testdb;
DISCONNECT
```

Note

Closing your session also closes the database connection. However, it is a good practice to explicitly close the connection to the other database, both to free up resources and to prevent issues with other SQL scripts that might be running in your session. Always closing the connection prevents potential errors if you run a script in the same session that attempts to open a connection to the same database, since each session can only have one connection to a given database at a time.

Mapping between source and target columns

If you export all table data from one database to another as in the previous example, EXPORT TO VERTICA can omit specifying column lists. This is possible only if column definitions in both tables comply with the following conditions:

- Same number of columns
- Identical column names
- Same sequence of columns
- Matching or [compatible](#) column data types

If any of these conditions is not true, the EXPORT TO VERTICA statement must include column lists that explicitly map source and target columns to each other, as follows:

- Contain the same number of columns.
- List source and target columns in the same order.
- Pair columns with the same (or [compatible](#)) data types.

For example:

```
=> EXPORT TO VERTICA testdb.people (name, gender, age)
FROM customer_dimension (customer_name, customer_gender, customer_age);
```

Exporting subsets of table data

In general, you can export a subset of table data in two ways:

- Export data of specific source table columns.
- Export the result set of a query (including [historical queries](#)) on the source table.

In both cases, the EXPORT TO VERTICA statement typically must specify column lists for the source and target tables.

The following example exports data from three columns in the source table to three columns in the target table. Accordingly, the EXPORT TO VERTICA statement specifies a column list for each table. The order of columns in each list determines how Vertica maps target columns to source columns. In this case, target columns `name`, `gender`, and `age` map to source columns `customer_name`, `customer_gender`, and `customer_age`, respectively:

```
=> EXPORT TO VERTICA testdb.people (name, gender, age) FROM customer_dimension
(customer_name, customer_gender, customer_age);
Rows Exported
```

```
-----
      23416
(1 row)
```

The next example queries source table `customer_dimension`, and exports the result set to table `ma_customers` in target database `testdb`:

```
=> EXPORT TO VERTICA testdb.ma_customers(customer_key, customer_name, annual_income)
AS SELECT customer_key, customer_name, annual_income FROM customer_dimension WHERE customer_state = 'MA';
```

Rows Exported

```
-----
      3429
(1 row)
```

Note

In this example, the source and target column names are identical, so specifying a columns list for target table `ma_customers` is optional. If one or more of the queried source columns did not have a match in the target table, the statement would be required to include a columns list for the target table.

Exporting IDENTITY columns

You can export tables (or columns) that contain [IDENTITY](#) values, but the sequence values are not incremented automatically at the target table. You must use [ALTER SEQUENCE](#) to make updates.

Export IDENTITY columns as follows:

- If both source and destination tables have an IDENTITY column and configuration parameter `CopyFromVerticaWithIdentity` is set to true (1), you do not need to list them.
- If source table has an IDENTITY column, but target table does not, you must explicitly list the source and target columns.

Caution

Failure to list which IDENTITY columns to export can cause an error, because the IDENTITY column will be interpreted as missing in the destination table.

By default, EXPORT TO VERTICA exports all IDENTITY columns. To disable this behavior globally, set the `CopyFromVerticaWithIdentity` configuration parameter.

Copying data from another Vertica database

[COPY FROM VERTICA](#) imports table data from one Vertica database to another. The following requirements apply:

- You already opened a connection to the target database with [CONNECT TO VERTICA](#).
- The source database is no more than one major release behind the target database.
- The table in the target database must exist.
- Source and target table columns must have the same or [compatible](#) data types.

Import process

Importing is a three-step process:

1. Connect to the source database with [CONNECT TO VERTICA](#). For example:

```
=> CONNECT TO VERTICA vmart USER dbadmin PASSWORD " ON 'VertTest01',5433;
CONNECT
```

2. Import the desired data with COPY FROM VERTICA. For example, the following statement imports all table data in `customer_dimension` to a table of the same name:

```
=> COPY customer_dimension FROM VERTICA vmart.customer_dimension;
Rows Loaded
-----
    500000
(1 row)
=> DISCONNECT vmart;
DISCONNECT
```

Note

Successive COPY FROM VERTICA statements in the same session can import data from multiple tables over the same connection.

3. [DISCONNECT](#) disconnects from the source database when all import and [export](#) operations are complete:

```
=> DISCONNECT vmart;
DISCONNECT
```

Note

Closing your session also closes the database connection. However, it is a good practice to explicitly close the connection to the other database, both to free up resources and to prevent issues with other SQL scripts that might be running in your session. Always closing the connection prevents potential errors if you run a script in the same session that attempts to open a connection to the same database, since each session can only have one connection to a given database at a time.

Importing IDENTITY columns

You can import [IDENTITY](#) columns as follows:

- If both source and destination tables have an IDENTITY column and configuration parameter CopyFromVerticaWithIdentity is set to true (1), you do not need to list them.
- If source table has an IDENTITY column, but target table does not, you must explicitly list the source and target columns.

Caution

Failure to list which IDENTITY columns to export can cause an error, because the IDENTITY column will be interpreted as missing in the destination table.

After importing the columns, the IDENTITY column values do not increment automatically. Use [ALTER SEQUENCE](#) to make updates.

The default behavior for this statement is to import IDENTITY columns by specifying them directly in the source table. To disable this behavior globally, set the [CopyFromVerticaWithIdentity](#) configuration parameter.

Copy and export data on AWS

There are common issues that occur when exporting or copying on AWS clusters, as described below. Except for these specific issues as they relate to AWS, copying and exporting data works as documented in [Database export and import](#).

To copy or export data on AWS:

1. **Verify that all nodes in source and destination clusters have their own elastic IPs (or public IPs) assigned.**

If your destination cluster is located within the same VPC as your source cluster, proceed to step 3. Each node in one cluster must be able to communicate with each node in the other cluster. Thus, each source and destination node needs an elastic IP (or public IP) assigned.

2. (For non-CloudFormation Template installs) Create an S3 gateway endpoint.

If you aren't using a CloudFormation Template (CFT) to install Vertica, you must create an S3 gateway endpoint in your VPC. For more information, see [the AWS documentation](#).

For example, the Vertica CFT has the following VPC endpoint:

```

"S3Endpoint" : {
  "Type" : "AWS::EC2::VPCEndpoint",
  "Properties" : {
    "PolicyDocument" : {
      "Version": "2012-10-17",
      "Statement": [{
        "Effect": "Allow",
        "Principal": "*",
        "Action": "*",
        "Resource": "*"
      }]
    },
    "RouteTableIds" : [ {"Ref" : "RouteTable"} ],
    "ServiceName" : { "Fn::Join": [ "", [ "com.amazonaws.", { "Ref": "AWS::Region" }, ".s3" ] ] },
    "VpcId" : { "Ref" : "VPC" }
  }
}

```

3. Verify that your security group allows the AWS clusters to communicate.

Check your security groups for both your source and destination AWS clusters. Verify that ports 5433 and 5434 are open. If one of your AWS clusters is on a separate VPC, verify that your network access control list (ACL) allows communication on port 5434.

Note

Note: This communication method exports and copies (imports) data across the Internet. You can alternatively use non-public IPs and gateways, or VPN to connect the source and destination clusters.

- If there are one or more elastic load balancers (ELBs) between the clusters, verify that port 5433 is open between the ELBs and clusters.
- If you use the Vertica client to connect to one or more ELBs, the ELBs only distribute incoming connections. The data transmission path occurs between clusters.

Changing node export addresses

You can change the export address for your Vertica cluster. You might need to do so to export data between clusters in different network subnets.

- Create a subnet for importing and exporting data between Vertica clusters. The CREATE SUBNET statement identifies the public network IP addresses residing on the same subnet.

```
=> CREATE SUBNET kv_subnet with '10.10.10.0';
```

- Alter the database to specify the subnet name of a public network for import/export.

```
=> ALTER DATABASE DEFAULT EXPORT ON kv_subnet;
```

- Create network interfaces for importing and exporting data from individual nodes to other Vertica clusters. The CREATE NETWORK INTERFACE statement identifies the public network IP addresses residing on multiple subnets.

```

=> CREATE NETWORK INTERFACE kv_node1 on v_VMartDB_node0001 with '10.10.10.1';
=> CREATE NETWORK INTERFACE kv_node2 on v_VMartDB_node0002 with '10.10.10.2';
=> CREATE NETWORK INTERFACE kv_node3 on v_VMartDB_node0003 with '10.10.10.3';
=> CREATE NETWORK INTERFACE kv_node4 on v_VMartDB_node0004 with '10.10.10.4';

```

For users on Amazon Web Services (AWS) or using Network Address Translation (NAT), refer to [Vertica on Amazon Web Services](#).

- Alter the node settings to change the export address. When used with the EXPORT ON clause, the ALTER NODE specifies the network interface of the public network on individual nodes for importing and exporting data.

```

=> ALTER NODE v_VMartDB_node0001 export on kv_node1;
=> ALTER NODE v_VMartDB_node0002 export on kv_node2;
=> ALTER NODE v_VMartDB_node0003 export on kv_node3;
=> ALTER NODE v_VMartDB_node0004 export on kv_node4;

```

- Verify if the node address and the export address are different on different network subnets of the Vertica cluster.

```

=> SELECT node_name, node_address, export_address FROM nodes;
node_name | node_address | export_address
-----+-----+-----
v_VMartDB_node0001 | 192.168.100.101 | 10.10.10.1
v_VMartDB_node0002 | 192.168.100.102 | 10.10.10.2
v_VMartDB_node0003 | 192.168.100.103 | 10.10.10.3
v_VMartDB_node0004 | 192.168.100.104 | 10.10.10.4

```

Creating a network interface and altering the node settings to change the export address takes precedence over creating a subnet and altering the database for import/export.

Using public and private IP networks

In many configurations, Vertica cluster hosts use two network IP addresses as follows:

- A private address for communication between the cluster hosts.
- A public IP address for communication with client connections.

By default, importing from and exporting to another Vertica database uses the private network.

Note

Ensure port 5433 or the port the Vertica database is using is not blocked.

To use the public network address for copy and export activities, as well as moving large amounts of data, configure the system to use the public network to support exporting to or importing from another Vertica cluster:

- [Identify the Public Network to Vertica](#)
- [Identify the database or nodes used for import/export](#)

Vertica encrypts data during transmission (if you have configured a certificate). Vertica attempts to also encrypt plan metadata but, by default, falls back to plaintext if needed. You can configure Vertica to require encryption for metadata too; see [Configuring connection security between clusters](#).

In certain instances, both public and private addresses exceed the demand capacity of a single Local Area Network (LAN). If you encounter this type of scenario, then configure your Vertica cluster to use two LANs: one for public network traffic and one for private network traffic.

In this section

- [Identify the public network to Vertica](#)
- [Identify the database or nodes used for import/export](#)

Identify the public network to Vertica

To be able to import to or export from a public network, Vertica needs to be aware of the IP addresses of the nodes or clusters on the public network that will be used for import/export activities. Your public network might be configured in either of these ways:

- Public network IP addresses reside on the same subnet (create a subnet)
- Public network IP addresses are on multiple subnets (create a network interface)

To identify public network IP addresses residing on the same subnet:

- Use the [CREATE SUBNET](#) statement provide your subnet with a name and to identify the subnet routing prefix.

To identify public network IP addresses residing on multiple subnets:

- Use the [CREATE NETWORK INTERFACE](#) statement to configure import/export from specific nodes in the Vertica cluster.

After you've identified the subnet or network interface to be used for import/export, you must [Identify the Database Or Nodes Used For Import/Export](#).

See also

- [CREATE SUBNET](#)
- [ALTER SUBNET](#)
- [DROP SUBNET](#)
- [CREATE NETWORK INTERFACE](#)
- [ALTER NETWORK INTERFACE](#)

- [DROP NETWORK INTERFACE](#)

Identify the database or nodes used for import/export

After you identify the public network to Vertica, you can configure a database and its nodes to use it for import and export operations:

- Use [ALTER DATABASE](#) to [specify a subnet](#) on the public network for the database. After doing so, all nodes in the database automatically use the network interface on the subnet for import/export operations.
- On each database node, use [ALTER NODE](#) to specify a network interface of the public network.

See also

- [CREATE PROCEDURE \(external\)](#)
- [CREATE NETWORK ADDRESS](#)
- [NETWORK_INTERFACES](#)

Handling node failure during copy/export

When an export ([EXPORT TO VERTICA](#)) or import from Vertica ([COPY FROM VERTICA](#)) task is in progress, and a non-initiator node fails, Vertica does not complete the task automatically. A non-initiator node is any node that is not the source or target node in your export or import statement. To complete the task, you must run the statement again.

You address the problem of a non-initiator node failing during an import or export as follows:

Note

Both Vertica databases must be running in a safe state.

1. You export or import from one cluster to another using the [EXPORT TO VERTICA](#) or [COPY FROM VERTICA](#) statement. During the export or import, a non-initiating node on the target or source cluster fails. Vertica issues an error message that indicates possible node failure, one of the following:
 - [ERROR 4534: Receive on v_tpchdb1_node0002: Message receipt from v_tpchdb2_node0005 failed](#)
 - [WARNING 4539: Received no response from v_tpchdb1_node0004 in abandon plan](#)
 - [ERROR 3322: \[tpchdb2\] Execution canceled by operator](#)
2. Complete your import or export by running the statement again. The failed node does not need to be up for Vertica to successfully complete the export or import.

Using EXPORT functions

Vertica provides several `EXPORT_` functions that let you recreate a database, or specific schemas and tables, in a target database. For example, you can use the `EXPORT_` functions to transfer some or all of the designs and objects you create in a development or test environment to a production database.

The `EXPORT_` functions create SQL scripts that you can run to generate the exported database designs or objects. These functions serve different purposes to the export statements, [COPY FROM VERTICA](#) (pull data) and [EXPORT TO VERTICA](#) (push data). These statements transfer data directly from source to target database across a network connection between both. They are dynamic actions and do not generate SQL scripts.

The `EXPORT_` functions appear in the following table. Depending on what you need to export, you can use one or more of the functions. `EXPORT_CATALOG` creates the most comprehensive SQL script, while `EXPORT_TABLES` and `EXPORT_OBJECTS` are subsets of that function to narrow the export scope.

Use this function...	To recreate...
EXPORT_CATALOG	These catalog items: <ul style="list-style-type: none"> • An existing schema design, tables, projections, constraints, views, and stored procedures. • The Database Designer-created schema design, tables, projections, constraints, and views • A design on a different cluster.
EXPORT_TABLES	Non-virtual objects up to, and including, the schema of one or more tables.

[EXPORT_OBJECTS](#)

Catalog objects in order dependency for replication.

The designs and object definitions that the script creates depend on the EXPORT_ function scope you specify. The following sections give examples of the commands and output for each function and the scopes it supports.

Saving scripts for export functions

All of the examples in this section were generated using the standard Vertica VMART database, with some additional test objects and tables. One output directory was created for all SQL scripts that the functions created:

```
/home/dbadmin/xtest
```

If you specify the destination argument as an empty string (""), the function writes the export results to STDOUT.

Note

A superuser can export all available database output to a file with the EXPORT_ functions. For a non-superuser, the EXPORT_ functions generate a script containing only the objects to which the user has access.

In this section

- [Exporting the catalog](#)
- [Exporting tables](#)
- [Exporting objects](#)

Exporting the catalog

The [EXPORT_CATALOG](#) function generates a SQL script that copies a database design to another cluster. This script replicates the physical schema design of the source database. For example:

```
-> SELECT EXPORT_CATALOG (
  '/home/dbadmin/xtest/sql_cat_tables.sql',
  'TABLES');
      EXPORT_CATALOG
-----
Catalog data exported successfully
(1 row)
```

The last argument specifies what to export:

- TABLES: Tables, schemas, and table-dependent objects: constraints, and access policies.
- DESIGN (default): All catalog objects.
- DIRECTED_QUERIES: All directed queries that are stored in the catalog. For details, see [Managing directed queries](#).

Use the DESIGN scope to export all design elements of a source database in order of their dependencies. This scope exports all catalog objects, including schemas, tables, constraints, projections, views, access policies, stored procedures, and data loaders:

```
-> SELECT EXPORT_CATALOG(
  '/home/dbadmin/xtest/sql_cat_design.sql',
  'DESIGN' );
      EXPORT_CATALOG
-----
Catalog data exported successfully
(1 row)
```

This function can generate the following types of statements:

- [CREATE SCHEMA](#)
- [CREATE TABLE](#)
- [ALTER TABLE \(constraints\)](#)
- [CREATE PROJECTION](#)
- [CREATE VIEW](#)
- [CREATE SEQUENCE](#)
- [CREATE ACCESS POLICY](#)

- [CREATE PROCEDURE \(stored\)](#)
- [CREATE SCHEDULE](#)
- [CREATE TRIGGER](#)
- [CREATE DATA LOADER](#)

The SQL script:

- Only includes objects to which the user has access.
- Orders CREATE statements based on object dependencies so they can be recreated in the correct sequence. For example, if a table is in a non-public schema, the required CREATE SCHEMA statement precedes the CREATE TABLE statement. Similarly, a table's CREATE ACCESS POLICY statement follows the table's CREATE TABLE statement.
- If possible, creates projections with a KSAFE clause, if any, otherwise with an OFFSET clause.

Projection considerations

If a projection to export was created with no ORDER BY clause, the SQL script reflects the default behavior for projections. Vertica implicitly creates projections using a sort order based on the SELECT columns in the projection definition.

The EXPORT_CATALOG script is portable if all projections are created using UNSEGMENTED ALL NODES or SEGMENTED ALL NODES.

See also

- [Exporting objects](#)
- [Exporting tables](#)

Exporting tables

Vertica function [EXPORT TABLES](#) exports DDL for tables and related objects in the current database. The generated SQL includes all non-virtual table objects to which you have access. You can use this SQL to recreate tables and related non-virtual objects on a different cluster.

You execute EXPORT_TABLES as follows:

```
EXPORT_TABLES( ['[destination]' ], ['scope'] )
```

The SQL script conforms to the following requirements:

- Only includes objects to which the user has access.
- Orders CREATE statements according to object dependencies so they can be recreated in the correct sequence. For example, if a table references a named sequence, a CREATE SEQUENCE statement precedes the CREATE TABLE statement. Similarly, a table's CREATE ACCESS POLICY statement follows the table's CREATE TABLE statement.

Setting export scope

The EXPORT_TABLES *scope* argument specifies the scope of the export operation:

To export...	Set scope to...
All tables to which you have access, including constraints	Empty string (' ')
One or more named tables	Comma-delimited list of table objects. For example: <code>myschema.newtable, yourschema.oldtable</code> You can optionally qualify the schema with the name of the current database: <code>mydb.myschema.newtable</code>
A named table object in the current search path: a schema, table, or sequence. If you specify a schema, EXPORT_TABLES exports all table objects in that schema to which you have access.	Table object's name and, optionally, its path: <code>VMart.myschema</code>

Note

EXPORT_TABLES does not export views. If you specify a view name, Vertica silently ignores it and the view is omitted from the generated script. To export views, use [EXPORT_OBJECTS](#).

Exporting all table objects

If you set the scope parameter to an empty string (""), EXPORT_TABLES exports all tables and their related objects. For example, the following call to EXPORT_TABLES exports all table objects in the VMart database to the specified output file.

```
=> SELECT EXPORT_TABLES(  
    '/home/dbadmin/xtest/sql_tables_empty.sql', '');  
    EXPORT_TABLES
```

Catalog data exported successfully
(1 row)

The exported SQL includes the following types of statements, depending on what is required to recreate the tables and related objects, such as schemas, sequences and access policies:

- CREATE SCHEMA
- CREATE TABLE
- CREATE SEQUENCE
- CREATE ACCESS POLICY
- ALTER TABLE (to add foreign key constraints)

Exporting individual table objects

EXPORT_TABLES can specify a comma-separated list of tables and table-related objects such as sequences or schemas to export. The generated SQL script includes the CREATE statements for the specified objects and their dependent objects:

- CREATE SCHEMA
- CREATE TABLE
- CREATE SEQUENCE
- CREATE ACCESS POLICY
- ALTER TABLE (to add foreign keys)

For example, the following call to EXPORT_TABLES exports two VMart tables: `store.store_sales_fact` and `store.store_dimension` :

```
=> SELECT export_tables('store.store_sales_fact, store.store_dimension');
      export_tables
```

```
-----
CREATE TABLE store.store_dimension
```

```
(
  store_key int NOT NULL,
  store_name varchar(64),
  store_number int,
  store_address varchar(256),
  store_city varchar(64),
  store_state char(2),
  store_region varchar(64),
  floor_plan_type varchar(32),
  photo_processing_type varchar(32),
  financial_service_type varchar(32),
  selling_square_footage int,
  total_square_footage int,
  first_open_date date,
  last_remodel_date date,
  number_of_employees int,
  annual_shrinkage int,
  foot_traffic int,
  monthly_rent_cost int,
  CONSTRAINT C_PRIMARY PRIMARY KEY (store_key) DISABLED
);
```

```
CREATE TABLE store.store_sales_fact
```

```
(
  date_key int NOT NULL,
  product_key int NOT NULL,
  product_version int NOT NULL,
  store_key int NOT NULL,
  promotion_key int NOT NULL,
  customer_key int NOT NULL,
  employee_key int NOT NULL,
  pos_transaction_number int NOT NULL,
  sales_quantity int,
  sales_dollar_amount int,
  cost_dollar_amount int,
  gross_profit_dollar_amount int,
  transaction_type varchar(16),
  transaction_time time,
  tender_type varchar(8)
);
```

```
ALTER TABLE store.store_sales_fact ADD CONSTRAINT fk_store_sales_date FOREIGN KEY (date_key) references public.date_dimension (date_key);
ALTER TABLE store.store_sales_fact ADD CONSTRAINT fk_store_sales_product FOREIGN KEY (product_key, product_version) references
public.product_dimension (product_key, product_version);
ALTER TABLE store.store_sales_fact ADD CONSTRAINT fk_store_sales_store FOREIGN KEY (store_key) references store.store_dimension (store_key);
ALTER TABLE store.store_sales_fact ADD CONSTRAINT fk_store_sales_promotion FOREIGN KEY (promotion_key) references
public.promotion_dimension (promotion_key);
ALTER TABLE store.store_sales_fact ADD CONSTRAINT fk_store_sales_customer FOREIGN KEY (customer_key) references public.customer_dimension
(customer_key);
ALTER TABLE store.store_sales_fact ADD CONSTRAINT fk_store_sales_employee FOREIGN KEY (employee_key) references public.employee_dimension
(employee_key);
```

The following call to EXPORT_TABLES specifies to export all tables in the VMart schema **store** :

```

=> select export_tables('', 'store');
      export_tables
-----
CREATE SCHEMA store;

CREATE TABLE store.store_dimension
(
...
);

CREATE TABLE store.store_sales_fact
(
...
);

CREATE TABLE store.store_orders_fact
(
...
);

ALTER TABLE store.store_sales_fact ADD CONSTRAINT fk_store_sales_date FOREIGN KEY (date_key) references public.date_dimension (date_key);
ALTER TABLE store.store_sales_fact ADD CONSTRAINT fk_store_sales_product FOREIGN KEY (product_key, product_version) references
public.product_dimension (product_key, product_version);
ALTER TABLE store.store_sales_fact ADD CONSTRAINT fk_store_sales_store FOREIGN KEY (store_key) references store.store_dimension (store_key);
ALTER TABLE store.store_sales_fact ADD CONSTRAINT fk_store_sales_promotion FOREIGN KEY (promotion_key) references
public.promotion_dimension (promotion_key);
ALTER TABLE store.store_sales_fact ADD CONSTRAINT fk_store_sales_customer FOREIGN KEY (customer_key) references public.customer_dimension
(customer_key);
ALTER TABLE store.store_sales_fact ADD CONSTRAINT fk_store_sales_employee FOREIGN KEY (employee_key) references public.employee_dimension
(employee_key);
ALTER TABLE store.store_orders_fact ADD CONSTRAINT fk_store_orders_product FOREIGN KEY (product_key, product_version) references
public.product_dimension (product_key, product_version);
ALTER TABLE store.store_orders_fact ADD CONSTRAINT fk_store_orders_store FOREIGN KEY (store_key) references store.store_dimension (store_key);
ALTER TABLE store.store_orders_fact ADD CONSTRAINT fk_store_orders_vendor FOREIGN KEY (vendor_key) references public.vendor_dimension
(vendor_key);
ALTER TABLE store.store_orders_fact ADD CONSTRAINT fk_store_orders_employee FOREIGN KEY (employee_key) references
public.employee_dimension (employee_key);

(1 row)

```

See also

- [Exporting objects](#)
- [Exporting the catalog](#)

Exporting objects

The [EXPORT_OBJECTS](#) function generates a SQL script that recreates non-virtual catalog objects on a different cluster. It takes arguments for the output file, scope, and K-safety enforcement. For example:

```

=> SELECT EXPORT_OBJECTS(
  '/home/dbadmin/xtest/sql_objects_all.sql',
  '', -- what to export (all, in this case)
  'true'); -- enforce K-safety
      EXPORT_OBJECTS
-----
Catalog data exported successfully
(1 row)

```

If you set the scope to an empty string (") as in this example, Vertica exports all non-virtual objects to which you have access in order of dependencies. To specify the objects to export, use a comma-delimited list. The function automatically exports objects on which the target objects depend. For example, if you export `myschema.mytable` , you do not also need to specify `myschema` .

If you specify a schema, EXPORT_OBJECTS exports all objects in that schema to which you have access. If you name a table that references a [sequence](#), the generated script exports the sequence, then the table that references the sequence, and finally any projections of that table.

Running the generated SQL script on another cluster creates all referenced objects and their dependent objects.

The SQL script:

- Only includes objects to which the user has access.
- Orders CREATE statements based on object dependencies so they can be recreated in the correct sequence. For example, if a table is in a non-public schema, the required CREATE SCHEMA statement precedes the CREATE TABLE statement. Similarly, a table's CREATE ACCESS POLICY statement follows the table's CREATE TABLE statement.
- If possible, creates projections with a KSAFE clause, if any, otherwise with an OFFSET clause.

This function can generate the following types of statements:

- [CREATE SCHEMA](#)
- [CREATE TABLE](#)
- [ALTER TABLE \(constraints\)](#)
- [CREATE PROJECTION](#)
- [CREATE VIEW](#)
- [CREATE SEQUENCE](#)
- [CREATE ACCESS POLICY](#)
- [CREATE PROCEDURE \(stored\)](#)
- [CREATE SCHEDULE](#)
- [CREATE TRIGGER](#)
- [CREATE DATA LOADER](#)

Note

EXPORT_OBJECTS does not export grants. Preserving grants on libraries can be especially important when you upgrade your database: if the prototypes of UDX libraries change, Vertica drops the grants on them. In order to preserve grants on UDX libraries, back up the grants before upgrading, and then restore them in the upgraded database. For details, see [Backing up and restoring grants](#).

K-safety

By default, the function's KSAFE argument is set to true. In this case, the generated script calls MARK_DESIGN_KSAFE, which replicates K-safety of the original database.

The following example output includes the start and end of an output SQL file:

```
CREATE SCHEMA store;
CREATE SCHEMA online_sales;
CREATE SEQUENCE public.my_seq ;
CREATE TABLE public.customer_dimension
(
  customer_key int NOT NULL,
  customer_type varchar(16),
  customer_name varchar(256),
  customer_gender varchar(8),
  title varchar(8),
  household_id int,
);
SELECT MARK_DESIGN_KSAFE(1);
```

Exporting individual objects

You can specify one or more objects to export in a comma-delimited list. The names of objects in any non-public schema must include their respective schemas.

If listed objects have overlapping scopes—for example, the list includes a table and one of its projections—EXPORT_OBJECTS exports the projection only once:

```

=> SELECT EXPORT_OBJECTS ('','customer_dimension, customer_dimension_super');

      export_objects
-----
CREATE TABLE public.customer_dimension
(
  customer_key int NOT NULL,
  customer_type varchar(16),
  customer_name varchar(256),
  ...
  CONSTRAINT C_PRIMARY PRIMARY KEY (customer_key) DISABLED
);

CREATE ACCESS POLICY ON public.customer_dimension FOR COLUMN customer_address CASE WHEN enabled_role('administrator') THEN customer_a

CREATE PROJECTION public.customer_dimension_super /*+basename(customer_dimension),createtype(L)*/
(
  customer_key,
  customer_type,
  customer_name,
  ...
)
AS
SELECT customer_dimension.customer_key,
       customer_dimension.customer_type,
       customer_dimension.customer_name,
       ...
FROM public.customer_dimension
ORDER BY customer_dimension.customer_key
SEGMENTED BY hash(customer_dimension.customer_key) ALL NODES OFFSET 0;

SELECT MARK_DESIGN_KSAFE(0);

```

You can export [stored procedures](#) by specifying their names and the types of their formal parameters. For stored procedures with the same name but different formal parameters, you can export all implementations by exporting the parent schema.

To export a particular implementation of a stored procedure, specify either the types or both the names and types of the procedure's formal parameters. The following example specifies the types:

```

=> SELECT EXPORT_OBJECTS('','raiseXY(int, int)');
      EXPORT_OBJECTS
-----
CREATE PROCEDURE public.raiseXY(x int, y int)
LANGUAGE 'PLvSQL'
SECURITY INVOKER
AS '
BEGIN
RAISE NOTICE 'x = %', x;
RAISE NOTICE 'y = %', y;
-- some processing statements
END
';

SELECT MARK_DESIGN_KSAFE(0);

(1 row)

```

To export all implementations of an overloaded stored procedure, export its parent schema:

```
=> SELECT EXPORT_OBJECTS('public');
EXPORT_OBJECTS
```

```
-----
+
CREATE PROCEDURE public.raiseXY(x int, y varchar)
LANGUAGE 'PLvSQL'
SECURITY INVOKER
AS '
BEGIN
RAISE NOTICE "x = %", x;
RAISE NOTICE "y = %", y;
-- some processing statements
END
;
```

```
CREATE PROCEDURE public.raiseXY(x int, y int)
LANGUAGE 'PLvSQL'
SECURITY INVOKER
AS '
BEGIN
RAISE NOTICE "x = %", x;
RAISE NOTICE "y = %", y;
-- some processing statements
END
;
```

```
SELECT MARK_DESIGN_KSAFE(0);
```

```
(1 row)
```

[Exporting tables](#)

Replication

Replication copies data from one Vertica database to another in native format. Usually, you use replication to keep a table or schema in the target database up to date with corresponding table or schema in the source database. Replication automatically determines what has changed in the source database and only transfers those changes to the target database.

Replication is also useful for disaster recovery (DR) and isolating workloads. For example:

- Keep a "hot spare" Vertica database that can fill in if the primary database goes down.
- Give geographically separated teams their own local databases.
- Fully isolate ETL workloads from analytics workloads by giving each their own Vertica database.

Vertica supports two forms of replication:

- vbr-based replication that uses the backup script to copy ROS containers from one database to another.
- Server-based replication that copies shards directly from one database's communal storage to another.

vbr-based replication

The vbr-replication method works between either Eon Mode or Enterprise Mode databases. You cannot replicate data between databases running in different modes or cloud platforms. The databases must have the same number of nodes (when in Enterprise Mode) or primary nodes (in Eon Mode). If replicating between Eon Mode databases, the databases must have the same shard segmentation and primary subcluster node subscriptions.

For more information about vbr-based replication, see [Replicating objects to another database cluster](#).

Server-based replication

Server-based replication transfers data between Eon Mode databases by copying shard files one communal storage location to another. This method supports Eon Mode databases in different clouds or on-premises. The target database must have access to the source database's communal storage, and the shard count and shard segmentation of the source and target [namespaces](#) must be the same.

Choosing between vbr-based and server-based replication

As server-based replication only works between Eon Mode databases, you only have to choose between the two types of replication if both the source and target database run in Eon Mode.

When choosing between the two modes, consider:

- Server-based replication is usually more efficient because it works within Vertica. Also, unlike vbr-based replication, server-based replication does not use SSH tunneling for encryption, avoiding potential security risks.
- For vbr-based replication, your databases must have more in common than databases using server-based replication. For example, in vbr-based replication, the source and target databases must have the same shard segmentation, primary subcluster node subscriptions, communal storage type, and number of nodes in their primary subcluster. For server-based replication, the only requirement is that the two databases have the same shard segmentation.

In this section

- [Server-based replication](#)

Server-based replication

Eon Mode Only

Server-based replication lets you copy data from one Eon Mode database to another. This replication method copies shard data directly from the source communal storage location to the target communal storage location. Copying native data means there is less overhead than other data copying methods.

You can replicate data between Eon Mode databases in different clouds and on-premises.

Caution

Replication overwrites any data in the target table. You do not receive any notification that the data in the target database will be overwritten, even if the target table's design does not match the source table. Verify that the tables you want to replicate either do not exist in the target database or do not contain data that you need. Be especially cautious when replicating entire schemas to prevent overwriting data in the target database.

Similarly, changes to a replicated table in the target database are overwritten each time you replicate the table. When performing scheduled replications, only grant read access to replicated tables in the target database. Limiting these tables to read-only access will help prevent confusion if a user makes changes to a replicated table.

Requirements

The Eon Mode databases you want to replicate data between must meet the following requirements:

- The source and target [namespaces](#) of the replicated tables must have the same shard count and segmentation. The REPLICATE command accepts an optional target namespace parameter that specifies the namespace to which the tables are replicated in the target cluster. If you do not specify a target namespace, objects are replicated to a namespace with the same name as the source namespace. If no such namespace exists in the target cluster, it is created with the same name and shard count as the source namespace.
- The user running the commands must have superuser privileges in the source and target databases.
- The target database must be able to access the source database and its communal storage. If there are firewalls between the source and target database, configure them to give the target access to the source. Additionally, the target database must have credentials to access the source database's communal storage. See [Configuration](#).
- The two databases must be running compatible versions of the Vertica server. The target database's version of the server has to be the same version or up to one major version higher than the source database.
- The table or tables you replicate must not have columns with foreign constraints that are not part of the replication. For example, if you try to replicate the store.store_sales_fact table of the VMart sample database without also replicating the public.date_dimension table, Vertica returns this error:

```
ERROR 3437: [database_name] Foreign constraint fk_store_sales_date
of Table store. store_sales_fact referencing public.date_dimension
detected, but only one table is included in the snapshot
```

Configuration

As mentioned above, your target database must be able to access the source database's communal storage. The necessary configuration steps depend on the type of communal storage used by the source database:

- For S3-based storage (including S3-compatible systems such as FlashBlade), create a separate configuration for the source communal storage. See [Per-bucket S3 configurations](#) for more information.

- For other systems, such as Google Cloud Storage (GCS), that use identities to control access, give the target database's identity access to the source database's communal storage. For example, if both databases use GCS storage, grant the identity the target database uses to access its own communal storage access to the source communal storage. If the databases do not use the same type of storage, configure the target database with the credentials necessary to access the source storage. See [Azure Blob Storage object store](#) and [Google Cloud Storage \(GCS\) object store](#) for instructions on how to set up authentication for these object stores.

If you are attempting to replicate data from an on-premises database to a cloud-based database, you must create a connection that grants your cloud access to your on-premises data store.

To secure the connections between your databases, you must secure two separate connections:

- Before transferring data using client-server and command channels, you must either connect the target database to the source database or the source database to the target database. See [Configuring client-server TLS](#) and [Control channel Spread TLS](#) for instructions on encrypting these connections.
- You can encrypt the connections that transfer the data between the communal data stores by setting parameters in the target database for the object store used by the source database. These parameters are [AWSEnableHttps](#) for S3 (and compatible), [AzureStorageEndpointConfig](#) for Azure, and [GCSEnableHttps](#) for GCS.

Replication steps

Follow these steps to replicate data between two Eon Mode databases:

1. Connect to the target or source database and log in as a user with superuser privileges.
2. Connect to the other database using the [CONNECT TO VERTICA](#) statement.
3. Use the [REPLICATE](#) statement, passing it the name of the table to replicate, or use the INCLUDE and EXCLUDE options to select several tables or schemas. The format of the replication call depends on whether you connected to the target or source database in step 1:

Note

If a table does not exist in the `default_namespace`, you must specify its namespace in the REPLICATE command. For replication, you provide the namespace name using a front-qualified period. For example, to specify table `t` in schema `s` in namespace `n`, you would write `".n.s.t"`.

* Connected to target: specify the source database in the REPLICATE statement using a ``FROM` **source_db`` clause.

* Connected to source: specify the target database in the REPLICATE statement using a ``TO` **target_db`` clause.

Both of these methods copy the shard data directly from the source communal storage location to the target communal storage location.

4. Optionally, use the [DISCONNECT](#) statement to disconnect.

This example, initiated on the target database, replicates a table named `customers` from the source database named `verticadb`:

```
-> CONNECT TO VERTICA source_db USER dbadmin
      PASSWORD 'mypassword' ON 'vertica_node01', 5433;
CONNECT

-> REPLICATE customers FROM source_db;
REPLICATE
```

The following statements execute the same data replication as the previous example, but this replication is initiated from the source database instead of the target database:

```
-> CONNECT TO VERTICA target_db USER dbadmin
      PASSWORD 'mypassword' ON 'vertica_node01', 5433;
CONNECT

-> REPLICATE customers TO target_db;
REPLICATE
```

To replicate more than one table at a time, use the INCLUDE option to include tables or schemas using wildcards. This example replicates all tables in the `public` schema starting with the letter `t`:

Note

You can only replicate tables in the `public` schema to the `default_namespace` in the target cluster.

```
-> REPLICATE INCLUDE "public:" FROM source_db;
```

Use the EXCLUDE option with INCLUDE to limit the tables that Vertica replicates. This example replicates all tables in the **public** schema except those that start with the string **customer_**.

```
-> REPLICATE INCLUDE "public:" EXCLUDE ".customer_" FROM source_db;
```

Scheduled replication

You can use replication to keep one or more tables in the target database up-to-date with tables in the source database by scheduling automatic replications. When you call the REPLICATE statement repeatedly, it automatically determines what has changed in the source table since the last replication and only transfers the data that has changed in the source database.

Important

Scheduled replication between the main cluster and a [sandboxed cluster](#) is non-incremental. Each REPLICATE statement between these clusters runs the full replication, regardless of previous REPLICATE calls.

When determining the interval between scheduled replications, you should consider the amount of data being transferred, the resources assigned to the [Tuple Mover](#), and data transfer concurrency. If replicating across platforms, you should also take into account your network bandwidth. Based on these factors, you can tune your resources and environment to find an optimal interval between scheduled replications.

Note

Frequent calls to REPLICATE can increase the size of the database's catalog. A larger catalog can increase the amount of metadata your database must process for each query. This added overhead can affect performance.

In many cases, the best option is to balance the time sensitivity of the queries in the target database that use the replicated data with the amount of data that each replication must process. After you decide how often to run replications, create a script to perform the replications. The script simply needs to follow the steps in [Replication steps](#) to replicate the table a single time. Then set up a scheduled task to run the script.

Monitoring replication

The [V_MONITOR.REPLICATION_STATUS](#) system table in the target database shows information about database replications. You can use it to monitor ongoing replications and the results of prior replications:

```
-> SELECT node_name, status, transaction_id FROM REPLICATION_STATUS
```

```
ORDER BY start_time ASC;
```

node_name	status	transaction_id
v_target_db_node0001	completed	45035996273706044
v_target_db_node0002	completed	45035996273706044
v_target_db_node0003	completed	45035996273706044
v_target_db_node0001	completed	45035996273706070
v_target_db_node0002	completed	45035996273706070
v_target_db_node0003	completed	45035996273706070
v_target_db_node0002	data transferring	45035996273706136
v_target_db_node0003	data transferring	45035996273706136
v_target_db_node0001	data transferring	45035996273706136

Management Console

Management Console (MC) is the Vertica in-browser monitoring and management tool. Its graphical user interface provides a unified view of your Vertica database operations. Through user-friendly, step-by-step screens, you can create, configure, manage, and monitor your Vertica databases and their associated clusters. You can use MC to operate your Vertica database in Eon Mode or in Enterprise Mode. You can use MC to provision and deploy a Vertica Eon Mode database.

To get started using MC, see [Getting started with MC](#).

What you can do with Management Console

Use Management Console to create:

- A database cluster on hosts that do not have Vertica installed.
- Multiple Vertica databases on one or more clusters from a single point of control.
- MC users and grant them access to MC and databases managed by MC

Use Management Console to configure:

- Database parameters and user settings dynamically.
- Resource pools.

Use Management Console to monitor:

- License usage and conformance.
- Dynamic metrics about your database cluster.
- Resource Pools.
- User information and activity on MC.
- Alerts by accessing a single message box of alerts for all managed databases.
- Recent databases and clusters through a quick link.
- Multiple Vertica databases on one or more clusters from a single point of control

You can import and export:

- Export all database messages or log/query details to a file.
- Import multiple Vertica databases on one or more clusters from a single point of control.

Management Console provides some, but not all, the functionality that [Administration tools](#) provides. Management Console also includes extended functionality not available in admintools. This additional functionality includes a graphical view of your Vertica database and detailed monitoring charts and graphs. See [Administration Tools and Management Console](#) for more information.

Getting Management Console

Download the Vertica server RPM and the MC package from [myVertica Portal](#). You then have two options:

- Install Vertica and MC at the command line and import one or more Vertica database clusters into the MC interface
- Install Vertica directly through MC

In this section

- [Installing Management Console](#)
- [Management Console architecture](#)
- [Configuring Management Console](#)
- [Getting started with MC](#)
- [Users, roles, and privileges in MC](#)
- [Database management](#)
- [Cloud platforms](#)
- [Monitoring with MC](#)
- [Troubleshooting with MC diagnostics](#)
- [Uninstalling Management Console](#)

Installing Management Console

Management Console (MC) 24.2.x is compatible with the latest supported versions of Vertica server. Read the following documents for more information:

- [Vertica server and Management Console](#). Lists supported platforms and browsers for Management Console.
- [Installation overview and checklist](#). Make sure you have everything ready for your Vertica configuration.
- [Before you install Vertica](#). Read for required prerequisites for *all* Vertica configurations, including Management Console.

Cloud installations

Vertica supports Management Console for both Enterprise Mode and Eon Mode on [supported cloud providers](#).

Amazon Web Services

Deploy a Management Console instance on AWS with a [CloudFormation Template](#) (CFT). After you deploy the MC instance, you can provision an Eon Mode or Enterprise Mode database with AWS resources.

In some environments, you might automate custom MC deployments without the AWS CFT. To automate a custom MC, add the following properties to the `/opt/vconsole/config/console.properties` file:

```
vertica.database.mode = eon
cloud.authentication = IAM
mc.iaas = AWS
provisioning.service.enabled = true
```

Note

Set the cloud.authentication property only if you use IAM roles to authenticate requests. You do not need to set this property if you use access keys.

Additionally, complete the following to deploy custom MC instances:

- Set the required ports for Vertica and the Management Console. For details, see [General Requirements](#).
- Set the IAM role for Vertica and the MC instance. For details, see [AWS authentication](#).

Microsoft Azure

Deploy a Management Console instance from the [Azure Marketplace](#). After you deploy the MC instance, you can provision an Eon Mode database, or monitor an Enterprise Mode database.

Google Cloud Platform

Deploy a Management Console [instance on GCP](#). After you deploy the MC instance, you can provision an Eon Mode database on GCP. For details, see [Provision an Eon Mode cluster and database on GCP in MC](#).

Enterprise Mode or Eon Mode on-premises

Before you install Management Console, review the following hardware, software, and network requirements.

General requirements

- **Ports** : Management Console has the following port requirements:
 - Port 22 is the default SSH port. The [Create Cluster Wizard](#) uses SSH on port 22 when you use MC to create a Vertica.
 - Port 5444 is the default agent port and must be available for MC-to-node and node-to-node communications.
 - Port 5450 is the default MC port and must be available for node-to-MC communications.See [Reserved ports](#) for more information about port and firewall considerations.
- **Firewall** : Make sure that a firewall or iptables are not blocking communications between the cluster's database, Management Console, and Management Console agents on each cluster node
- **IP Address** : If you install MC on a server outside the Vertica cluster it will be monitoring, that server must be accessible to at least the public network interfaces on the cluster.
- **TLS Requirements** : The Schannel package must be installed on your Linux environment so TLS can be set up during the MC configuration process. See [TLS protocol](#).
- **File Permissions** : On your local workstation, you must have at least read/write privileges on any files you plan to upload to MC through the [Cluster Installation Wizard](#). These files include the Vertica server package, the license key (if needed), the private key file, and an optional CSV file of IP addresses.
- **Perl** : The MC cluster installer requires [Perl 5](#).

Hardware requirements

You can install MC on any node in the cluster, or its own dedicated node. When running the MC on a node in the cluster, note that MC shares RAM and time on CPU cores with other Vertica processes.

The following table provides minimum and recommended hardware requirements:

Requirements	CPU	RAM	Disk Space
Minimum	4-core	4G	2G
Recommended	8-core	8G	2G

See [Disk Space Requirements for Vertica](#).

Time synchronization and MC's self-signed certificate

When you [connect to MC](#) through a client browser, Vertica assigns each HTTPS request a self-signed certificate, which includes a timestamp. To increase security and protect against password replay attacks, the timestamp is valid for several seconds only, after which it expires.

To avoid being blocked out of MC, synchronize time on the hosts in your Vertica cluster, and on the MC host if it resides on a dedicated server. To recover from loss or lack of synchronization, resync system time and the Network Time Protocol.

Installing Management Console

Install Management Console (MC) to manage a new cluster, or add it to an existing cluster.

1. Download the MC package from the [Vertica website](#) :

```
vertica-console-current-version.Linux-distro)
```

Save the package to a location on the target server, such as `/tmp`.

2. On the target server, log in as root or a user with sudo privileges.
3. Change to the directory where you saved the MC package.
4. Install MC using your local Linux distribution package management system—rpm, yum, zypper, apt, dpkg. For example:

Red Hat 8

```
# rpm -Uvh vertica-console-current-version.x86_64.rpm
```

Debian and Ubuntu

```
# dpkg -i vertica-console-current-version.deb
```

5. If you stopped the database before upgrading MC, restart the database.

As the root user, use the following command:

```
/etc/init.d/verticad start
```

For versions of Red Hat 8/CentOS 8 and above, run:

```
# systemctl start verticad
```

6. Open a browser and enter the URL of the MC installation, one of the following:

- IP address:

```
https://ip-address:mc-port/
```

- Server host name:

```
https://hostname:mc-port/
```

By default, `mc-port` is 5450.

If MC was not previously configured, the Configuration Wizard dialog box appears. Configuration steps are described in [Configuring MC](#).

If MC was previously configured, Vertica prompts you to accept the end-user license agreement (EULA) when you first log in to MC after the upgrade.

Additionally, you can choose to provide Vertica with analytic information about your MC usage. For details, see [Management Console settings](#).

Management Console architecture

MC accepts HTTP requests from a client web browser, gathers information from the Vertica database cluster, and returns that information to the browser for monitoring.

MC components

The primary components that drive Management Console are an application/web server and agents that get installed on each node in the Vertica cluster.

The following diagram is a logical representation of MC, the MC user's interface, and the database cluster nodes.

Application/web server

The application server hosts MC's web application and uses port 5450 for node-to-MC communication and to perform the following:

- Manage one or more Vertica database clusters
- Send rapid updates from MC to the web browser
- Store and report MC metadata, such as alerts and events, current node state, and MC users, on a lightweight, embedded (Derby) database
- Retain workload history

MC agents

MC agents are internal daemon process that run on each Vertica cluster node. The default agent port, 5444, must be available for MC-to-node and node-to-node communications. Agents monitor MC-managed Vertica database clusters and communicate with MC to provide the following functionality:

- Provide local access, command, and control over database instances on a given node, using functionality similar to Administration Tools.
- Report log-level data from the Administration Tools and Vertica log files.
- Cache details from long-running jobs—such as create/start/stop database operations—that you can view through your browser.
- Track changes to data-collection and monitoring utilities and communicate updates to MC .
- Communicate between all cluster nodes and MC through a webhook subscription, which automates information sharing and reports on cluster-specific issues like node state, alerts, and events.

Configuring Management Console

After you complete the steps in [Installing Management Console \(MC\)](#), you need to configure it through a client browser connection. An MC configuration assistant walks you through creating the Linux [MC super](#) administrator account, storage locations, and other settings that MC needs to run. Information you provide during the configuration process is stored in the `/opt/vconsole/config/console.properties` file.

If you need to change settings after the configuration assistant ends, such as port assignments, use the **Home > MC Settings** page.

Configure the MC Super user

1. Open a browser session.
2. Enter the IP address or host name of the server on which you installed MC and include the default MC port 5450. For example, enter the following using a IP address:

`https://10.20.30.40:5450/`

Or enter the following for a host name:

`https://hostname:5450/`

3. Accept the license agreement.
 1. You must accept the **End-user license Agreement terms** .
 2. Optionally, you can consent to the collection of anonymous data about your MC usage.
4. On **Configure Management Console** , complete the fields to create a local MC Superuser. Local user credentials are stored internally in the MC.
5. On **Configure authentication** , select **Use Management Console for authentication** .
6. Select **Finish** .

Shortly after you click **Finish** , you should see a status in the browser. However, you might see only an empty page for several seconds. During this brief period, MC runs as the local user 'root' long enough to bind to port number 5450. Then MC switches to the [MC super](#) administrator account that you just created, restarts MC, and displays the MC login page.

For instructions on adding other users, see [User administration in MC](#) .

In this section

- [Changing MC or agent ports](#)
- [Management Console settings](#)
- [Backing up MC](#)
- [Connecting securely from MC to a Vertica database](#)
- [Upgrading Management Console manually](#)
- [Upgrading MC automatically on AWS](#)
- [Localizing user interface text](#)

Changing MC or agent ports

When you configure MC, the Configuration Wizard sets up the following default ports:

- 5450—Used to connect a web browser session to MC and allows communication from Vertica cluster nodes to the MC application/web server
- 5444—Provides MC-to-node and node-to-node (agent) communications for database create/import and monitoring activities

If you need to change the MC default ports

A scenario might arise where you need to change the default port assignments for MC or its agents. For example, perhaps one of the default ports is not available on your Vertica cluster, or you encounter connection problems between MC and the agents. The following topics describe how to change port assignments for MC or its agents.

Changing the MC port

Use this procedure to change the default port for MC's application server from 5450 to a different value.

1. Open a web browser and [connect to MC](#) as a user with [MC ADMIN](#) privileges.
2. On the MC Home page, navigate to **MC Settings > Configuration** and change the **Application server running port** value from 5450 to a new value.
3. In the change-port dialog, click **OK**.
4. [Restart MC](#).
5. Reconnect your browser session using the new port. For example, if you changed the port from 5450 to 5555, use one of the following formats:

```
https://00.00.00.00:5555/
```

OR

```
https://hostname:5555/
```

Changing the agent port

Changing the agent port takes place in two steps: at the command line, where you modify the config.py file and through a browser, where you modify MC settings.

Change the agent port in config.py

1. Log in as root on any cluster node and change to the agent directory:

```
$ cd /opt/vertica/oss/python3/lib/python3.9/site-packages/vertica/agent/
```

2. Use any text editor to open `config.py`.
3. Scroll down to the `agent_port = 5444` entry and replace 5444 with a different port number.
4. Save and close the file.
5. Copy `config.py` to the `/opt/vertica/oss/python3/lib/python3.9/site-packages/vertica/agent/` directory on all nodes in the cluster.
6. Restart the agent process by running the following command:

```
$/etc/init.d/vertica_agent restart
```

Note

If you are using Red Hat Enterprise Linux/CentOS 7, use the following command instead:

```
$/opt/vertica/sbin/vertica_agent restart
```

7. Repeat (as root) Step 6 on each cluster node where you copied the `config.py` file.

Change the agent port on MC

1. Open a web browser and [connect to MC](#) as a user with [MC ADMIN](#) privileges.
2. Navigate to **MC Settings > Configuration**.
3. Change Default Vertica agent port from 5444 to the new value you specified in the `config.py` file.
4. Click **Apply** and click **Done**.
5. Restart MC so MC can connect to the agent at its new port. See [Restarting MC](#).

Management Console settings

The **MC Settings** page allows you to configure properties specific to Management Console. To access **MC Settings**, go to the Management Console home page > **MC Tools > MC Settings**.

Configuration settings

The **Configuration** tab contains the following sections:

System User configurations

View the user name, user group, and user home path for the MC user.

Vertica database configurations

Edit the following database paths:

- License path
- Catalog path
- Data path

MC and Agent Port settings

Configure the server port and the default port the Vertica agent uses.

Application Server JVM settings

Set the initial and maximum heap size for the JVM.

Browser connections settings

Enable and disable username and password auto-complete at Management Console login. After disabling, clear your browser's cache.

MC Password configuration settings

Set password requirements to log into the Management Console. This includes length, expiration, and login attempt settings.

User Analytics and Tracking

Choose if you want to provide Vertica with analytic information about your MC usage. Vertica uses this information to improve the MC in future releases.

Note

When you accept the End-User License Agreement Terms for the MC, you are given the option to provide Vertica with your anonymous user data. If you want to stop providing data, clear the checkbox in **User Analytics and Tracking** .

Vertica collects the following information:

- Database type (Eon Mode or Enterprise Mode)
- License type (Community Edition, Paid, By the Hour)
- Cloud provider name
- Vertica version
- MC version
- Current page
- Interactions with MC page components, including buttons, drop-down lists, checkboxes, and radio buttons.

To protect your privacy, all collected information is stored and processed anonymously, and in compliance with GDPR regulations. It is stored securely on Vertica servers, and never shared with third-party organizations.

Monitoring settings

Control the following monitoring settings in Management Console:

- Enable checks and set alert thresholds for spread retransmit rate. This setting is disabled by default. The recommended alert threshold for spread retransmit rate is 10%.
- Set alert thresholds for free Management Console disk space checks. The recommended alert threshold is 500 MB.
- Exclude MC queries from activity charts.
- Set refresh intervals for MC charts and pages.

Security and authentication settings

- On the SSL/TLS Certificates tab, upload a new SSL certificate or view the current certificate.

Note

LDAPS authentication requires a certificate. For details, see [User administration in MC](#) .

- Use LDAP for user authentication (Authentication tab).

User Federation

You can authenticate users to MC with the following federated servers:

- Kerberos
- LDAP

- LDAPS

For implementation details, see [User administration in MC](#).

Identity Providers

You can authenticate users to MC with an identity provider (IDP). You can configure the MC to use a user-defined authentication protocol for your corporate IDP, or you can select a list of social IDPs, such as GitHub, Facebook, or Google.

For implementation details, see [User administration in MC](#).

User management settings

Create new Management Console users and, with their user credentials, map them to an database managed by Management Console on the Vertica server. See [User administration in MC](#) and <https://converturl/mc/users-roles-and-privileges.html>.

Extended monitoring settings

Configure [Extended monitoring](#), which allows you to monitor more long-term data in Management Console:

- Set up an external storage database for Extended Monitoring. See [Managing the storage database](#).
- Enable or disable Extended Monitoring on your databases. See [Managing extended monitoring on a database](#).

Email Gateway

[Local users](#) require an email so they can manage their passwords. Local user profiles require that you complete the following fields:

- **Host**
- **Port**
- **From Display Name**
- **From**
- **EnableSSL**

After the administrator completes the email gateway configuration, the user receives an email to reset their password.

Other MC settings

- View your version of Vertica or upload a new Vertica binary file
- Customize the look and feel of Management Console on the **Themes** tab.
- Configure Management Console to use an alternative data source to monitor your database. See [Monitoring external data sources with MC](#).
- Enable Management Console to send email alerts. See [Setting up SMTP for email alerts](#).

Modifying database-specific settings

To inspect or modify settings related to a database managed by Management Console, go to the **Existing Infrastructure** page. On this page, select a running database to see its Overview page. From the bottom of the Overview page, click the **Settings** tab to make modifications to database-specific settings.

Backing up MC

Before you [upgrade MC](#), Vertica recommends that you back up your MC metadata (configuration and user settings). Use a storage location external to the server on which you installed MC.

1. On the target server (where you want to store MC metadata), log in as root or a user with sudo privileges.
2. Create a backup directory:

```
# mkdir /backups/mc/mc-backup-20130425
```

3. Copy the `/opt/vconsole` directory to the new backup folder:

```
# cp -ar /opt/vconsole /backups/mc/mc-backup-20130425
```

Connecting securely from MC to a Vertica database

When you use MC to monitor and manage a Vertica database, MC (running in a browser) connects as the client to the Vertica database server.

MC uses JDBC for most database connections

MC uses Java Database Connectivity (JDBC) for most connections to a Vertica database, including:

- Retrieving database information to display in charts
- Running SQL queries through JDBC
- Configuring and updating database properties
- Configuring the database for extended monitoring

Exception

When MC uses Agents to perform AdminTools tasks, MC does not use JDBC to connect to the database.

Vertica software supports TLS

Vertica databases and Vertica MC support TLS up to version 1.2. This topic and its subtopics describe configuring TLS in MC for JDBC connections to a Vertica database.

About certificate file formats

MC requires that all certificate and key files for upload to MC must be in PEM (Privacy-enhanced Electronic Mail) format.

Vertica database security dictates how MC connects

The TLS/SSL security you configure for a database in MC must be consistent with the security configured on the database itself.

Whether the Vertica database has TLS/SSL configured in server mode or mutual mode, you should configure TLS/SSL for that database in MC to match.

To find out how a Vertica database is configured, see [Determining the TLS mode of a Vertica database](#).

You can configure TLS/SSL in either server mode or mutual mode in MC.

The rest of this topic and related topics use the term TLS, TLS/SSL, and SSL interchangeably.

TLS server mode

When the MC client connects to a Vertica database configured in [server mode](#):

- The client requests and verifies the server's credentials.
- The client does not need to present a client certificate and private key file to the server.
- The MC administrator must configure the CA certificate that can verify server's certificate on MC when MC connects to the database over JDBC.

TLS mutual mode

When the MC client connects to a Vertica database configured in [mutual mode](#):

- The MC client requests and verifies the database server's credentials.
- The server also requests and verifies the MC client's credentials.
- Each MC user is a separate client, and must present a valid client certificate file and private key file pair (*keypair*), namely a certificate signed by a CA recognized by the Vertica database server as valid.
- The MC administrator must configure:
 - The CA certificate to verify the Vertica database server certificate.
 - A client certificate and private key file (*keypair*) for each MC user. The keypair can be unique for each user, or shared by multiple users, depending on how client authentication is configured on the Vertica database. See [Configuring client authentication](#).
- Each MC user must be configured to map correctly to a user who is configured on the Vertica database server.

For more information on how Vertica supports TLS/SSL security, see [TLS protocol](#).

MC administrator configures MC security

Only MC users having Admin or Super privileges on a database are able to configure TLS certificates and keys on MC for database connections. The topics in this section use "MC administrator" to refer to both of these roles. For more information about MC user roles and privileges, see [User administration in MC](#).

As the MC administrator, when you first configure security in MC for a Vertica database that requires mutual mode, you configure these certificates for the Vertica database:

- The server certificate and public key of the database.
- Your own client certificate and private key, as the first configured MC user mapped to a Vertica database user.

Configuring TLS/SSL on MC

MC provides the Certificates wizard for configuring TLS certificates for all JDBC connections to the database, to ensure those connections are secure.

In MC, there are three scenarios in which you need to configure TLS security for a Vertica database:

- While you are importing a database to monitor in MC. See [Configuring TLS while importing a database on MC](#).
- When you want to add security for a database that is already monitored by MC. See [Configuring TLS for a monitored database in MC](#).
- When you need to configure client security for an individual MC user who is mapped to a user who has privileges on the Vertica database server, because the database requires mutual authentication. See [Configuring mutual TLS for MC users](#).

Adding certificates to MC for later use

You may want to add multiple CA certificates or client certificates to MC all at one time, to streamline the configuration of security when you are importing databases to MC or creating MC users. For details, see [and](#) .

To connect successfully, MC and database security must match

MC Security	Vertica Database Security	Does the connection succeed?
None	None	Connection succeeds, and it is open and therefore unsecured.
TLS server mode	TLS server mode	Connection succeeds provided MC can verify the server's certificate using the CA certificate configured on MC.
TLS mutual mode	TLS mutual mode	Connection succeeds provided: <ul style="list-style-type: none"> • MC can verify the server's certificate using the CA certificate configured on MC. • The server can verify the client certificate and private key that MC presents as belonging to a mapped user on the Vertica database.
None	TLS server mode	MC attempts to establish an open connection. The connection fails if the Vertica database requires TLS for client connections. For more information, see: <ul style="list-style-type: none"> • Client authentication with TLS • CREATE AUTHENTICATION
None	TLS mutual mode	MC attempts to establish an open connection. The connection fails if the Vertica database requires TLS for client connections. The connection fails because MC does not present what the database requires: a valid client certificate and private key that the database can verify as belonging to a mapped database user.
TLS server mode	None	MC attempts to connect to the database securely, however the connection fails as the database is not configured with TLS certificates.
TLS mutual mode	None	MC attempts to connect to the database securely, however the connection fails as the database is not configured with TLS certificates.
