See [Manually consume data from Kafka](#) for more information.

Default: 1 second

--fix-config

Repairs the configuration and re-creates any missing tables. Valid only with the `--update` shared configuration option.

--frame-duration *HH:MM:SS*

The interval of time that all individual frames last with this scheduler. The scheduler must have enough time to run each microbatch (each of which execute a COPY statement). You can approximate the average available time per microbatch using the following equation:

$$\text{TimePerMicrobatch} = (\text{FrameDuration} * \text{Parallelism}) / \text{Microbatches}$$

This is just a rough estimate as there are many factors that impact the amount of time that each microbatch will be able to run.

The `vkconfig` utility warns you if the time allocated per microbatch is below 2 seconds. You usually should allocate more than two seconds per microbatch to allow the scheduler to load all of the data in the data stream.

Note

In versions of Vertica earlier than 10.0, the default frame duration was 10 seconds. In version 10.0, this default value was increased to 5 minutes in part to compensate for the removal of WOS. If you created your scheduler with the default frame duration in a version prior to 10.0, the frame duration is not updated to the new default value. In this case, consider adjusting the frame duration manually. See [Choosing a frame duration](#) for more information.

Default: 00:05:00

--message_max_bytes *max_message_size*

Specifies the maximum size, in bytes, of a Kafka protocol batch message.

Default: 25165824

--new-source-policy {FAIR|START|END}

Determines how Vertica allocates resources to the newly added source, one of the following:

- FAIR: Takes the average length of time from the previous batches and schedules itself appropriately.
- START: All new sources start at the beginning of the frame. The batch receives the minimal amount of time to run.
- END: All new sources start at the end of the frame. The batch receives the maximum amount of time to run.

Default: FAIR

--operator *username*

Allows the `dbadmin` to grant privileges to a previously created Vertica user or role.

This option gives the specified user all privileges on the scheduler instance and EXECUTE privileges on the `libkafka` library and all its UDxs. Granting operator privileges gives the user the right to read data off any source in any cluster that can be reached from the Vertica node.

The `dbadmin` must grant the user separate permission for them to have write privileges on the target tables.

Requires the `--create` shared utility option. Use the `--add-operator` option to grant operate privileges after the scheduler has been created.

To revoke privileges, use the `--remove-operator` option.

--remove-operator *user_name*

Removes access to the scheduler from a Vertica user account. Requires the `--update` shared utility option.

--resource-pool *pool_name*

The resource pool to be used by all queries executed by this scheduler. You must create this pool in advance.

Default: [GENERAL](#) pool

Note

The scheduler can use only one-fourth of GENERAL pool's [PLANNEDCONCURRENCY](#).

--upgrade

Upgrades the existing scheduler and configuration schema to the current Vertica version. The upgraded version of the scheduler is not backwards compatible with earlier versions. To upgrade a scheduler to an alternate schema, use the [upgrade-to-schema](#) parameter. See [Updating schedulers after Vertica upgrades](#) for more information.

--upgrade-to-schema *schema name*

Copies the scheduler's schema to a new schema specified by *schema name* and then upgrades it to be compatible with the current version of Vertica. Vertica does not alter the old schema. Requires the [--upgrade](#) scheduler utility option.

--validation-type {ERROR|WARN|SKIP}

Renamed from [--skip-validation](#), specifies the level of validation performed on the scheduler. Invalid SQL syntax and other errors can cause invalid microbatches. Vertica supports the following validation types:

- ERROR: Cancel configuration or creation if validation fails.
- WARN: Proceed with task if validation fails, but display a warning.
- SKIP: Perform no validation.

For more information on validation, refer to [Automatically consume data from Kafka with a scheduler](#).

Default: ERROR

See [Common vkconfig script options](#) for options that are available in all of the vkconfig tools.

Examples

These examples show how you can use the scheduler utility options.

Give a user, Jim, privileges on the StreamConfig scheduler. Specify that you are making edits to the stream_config scheduler with the [--config-schema](#) option:

```
$ /opt/vertica/packages/kafka/bin/vkconfig scheduler --update --config-schema stream_config --add-operator Jim
```

Edit the default stream_config scheduler so that every microbatch waits for data for one second before ending:

```
$ /opt/vertica/packages/kafka/bin/vkconfig scheduler --update --eof-timeout-ms 1000
```

Upgrade the scheduler named `iot_scheduler_8.1` to a new scheduler named `iot_scheduler_9.0` that is compatible with the current version of Vertica:

```
$ /opt/vertica/packages/kafka/bin/vkconfig scheduler --upgrade --config-schema iot_scheduler_8.1 \  
--upgrade-to-schema iot_scheduler_9.0
```

Drop the schema scheduler219a:

```
$ /opt/vertica/packages/kafka/bin/vkconfig scheduler --drop --config-schema scheduler219a --username dbadmin
```

Read the current setting of the options you can set using the scheduler tool for the scheduler defined in `weblogs.conf`.

```
$ vkconfig scheduler --read --conf weblog.conf  
{  
  "version":"v9.2.0", "frame_duration":"00:00:10", "resource_pool":"weblog_pool",  
  "config_refresh":"00:05:00", "new_source_policy":"FAIR",  
  "pushback_policy":"LINEAR", "pushback_max_count":5, "auto_sync":true,  
  "consumer_group_id":null  
}
```

Cluster tool options

The vkconfig script's cluster tool lets you define the streaming hosts your scheduler connects to.

Syntax

```
vkconfig cluster {--create | --read | --update | --delete} \  
  [--cluster cluster_name] [other_options...]
```

--create

Creates a new cluster. Cannot be used with [--delete](#), [--read](#), or [--update](#).

--read

Outputs the settings of all clusters defined in the scheduler. This output is in JSON format. Cannot be used with [--create](#), [--delete](#), or [--update](#).

You can limit the output to specific clusters by supplying one or more cluster names in the `--cluster` option. You can also limit the output to clusters that contain one or more specific hosts using the `--hosts` option. Use commas to separate multiple values.

You can use LIKE wildcards in these options. See [LIKE](#) for more information about using wildcards.

--update

Updates the settings of `cluster_name`. Cannot be used with `--create`, `--delete`, or `--read`.

--delete

Deletes the cluster `cluster_name`. Cannot be used with `--create`, `--read`, or `--update`.

--dump

When you use this option along with the `--read` option, `vkconfig` outputs the Vertica query it would use to retrieve the data, rather than outputting the data itself. This option is useful if you want to access the data from within Vertica without having to go through `vkconfig`. This option has no effect if not used with `--read`.

--cluster `cluster_name`

A unique, case-insensitive name for the cluster to operate on. This option is required for `--create`, `--update`, and `--delete`.

--hosts `b1 : port` [, `b2 : port` ...]

Identifies the broker hosts that you want to add, edit, or remove from a Kafka cluster. To identify multiple hosts, use a comma delimiter.

--kafka_conf ' `kafka_configuration_setting` '

A JSON string of property/value pairs to pass directly to the `rdkafka`, the library that Vertica uses to communicate with Kafka. This parameter directly sets global configuration properties that are not available through the Vertica integration with Kafka.

For details, see [Directly setting Kafka library options](#).

--kafka_conf_secret ' `kafka_configuration_setting` '

Conceals sensitive configuration data that you must pass directly to the `rdkafka` library, such as passwords. This parameter accepts settings in the same format as `kafka_conf`.

Values passed to this parameter are not logged or stored in system tables.

--new-cluster `cluster_name`

The updated name for the cluster. Requires the `--update` shared utility option.

--validation-type {ERROR|WARN|SKIP}

Specifies the level of validation performed on a created or updated cluster:

- ERROR - Cancel configuration or creation if `vkconfig` cannot validate that the cluster exists. This is the default setting.
- WARN - Proceed with task if validation fails, but display a warning.
- SKIP - Perform no validation.

Renamed from `--skip-validation`.

See [Common vkconfig script options](#) for options that are available in all of the `vkconfig` tools.

Examples

This example shows how you can create the cluster, `StreamCluster1`, and assign two hosts:

```
$ /opt/vertica/packages/kafka/bin/vkconfig cluster --create --cluster StreamCluster1 \  
    --hosts 10.10.10.10:9092,10.10.10.11:9092 \  
    --conf myscheduler.config
```

This example shows how you can list all of the clusters associated with the scheduler defined in the `weblogs.conf` file:

```
$ vkconfig cluster --read --conf weblog.conf \  
{ "cluster": "kafka_weblog", \  
  "hosts": "kafka01.example.com:9092,kafka02.example.com:9092" }
```

Source tool options

Use the `vkconfig` script's source tool to create, update, or delete a source.

Syntax

```
vkconfig source {--create | --read | --update | --delete} \  
    --source source_name [other_options...]
```

--create

Creates a new source. Cannot be used with `--delete` , `--read` , or `--update` .

--read

Outputs the current setting of the sources defined in the scheduler. The output is in JSON format. Cannot be used with `--create` , `--delete` , or `--update` .

By default this option outputs all of the sources defined in the scheduler. You can limit the output by using the `--cluster` , `--enabled` , `--partitions` , and `--source` options. The output will only contain sources that match the values in these options. The `--enabled` option can only have a true or false value. The `--source` option is case-sensitive.

You can use LIKE wildcards in these options. See [LIKE](#) for more information about using wildcards.

--update

Updates the settings of `source_name` . Cannot be used with `--create` , `--delete` , or `--read` .

--delete

Deletes the source named `source_name` . Cannot be used with `--create` , `--read` , or `--update` .

--source *source_name*

Identifies the source to create or alter in the scheduler's configuration. This option is case-sensitive. You can use any name you like for a new source. Most people use the name of the Kafka topic the scheduler loads its data from. This option is required for `--create` , `--update` , and `--delete` .

--cluster *cluster_name*

Identifies the cluster containing the source that you want to create or edit. You must have already defined this cluster in the scheduler.

--dump

When you use this option along with the `--read` option, vkconfig outputs the Vertica query it would use to retrieve the data, rather than outputting the data itself. This option is useful if you want to access the data from within Vertica without having to go through vkconfig. This option has no effect if not used with `--read` .

--enabled TRUE|FALSE

When TRUE, the source is available for use.

--new-cluster *cluster_name*

Changes the cluster this source belongs to.

All sources referencing the old cluster source now target this cluster.

Requires: `--update` and `--source` options

--new-source *source_name*

Updates the name of an existing source to the name specified by this parameter.

Requires: `--update` shared utility option

--partitions *count*

Sets the number of partitions in the source.

Default:

The number of partitions defined in the cluster.

Requires: `--create` and `--source` options

You must keep this consistent with the number of partitions in the Kafka topic.

Renamed from `--num-partitions` .

--validation-type{ERROR|WARN|SKIP}

Controls the validation performed on a created or updated source:

- ERROR - Cancel configuration or creation if vkconfig cannot validate the source. This is the default setting.
- WARN - Proceed with task if validation fails, but display a warning.
- SKIP - Perform no validation.

Renamed from `--skip-validation` .

See [Common vkconfig script options](#) for options that are available in all of the vkconfig tools.

Examples

The following examples show how you can create or update SourceFeed.

Create the source SourceFeed and assign it to the cluster, StreamCluster1 in the scheduler defined by the myscheduler.conf config file:

```
$ /opt/vertica/packages/kafka/bin/vkconfig source --create --source SourceFeed \  
    --cluster StreamCluster1 --partitions 3 \  
    --conf myscheduler.conf
```

Update the existing source SourceFeed to use the existing cluster, StreamCluster2 in the scheduler defined by the myscheduler.conf config file:

```
$ /opt/vertica/packages/kafka/bin/vkconfig source --update --source SourceFeed \  
    --new-cluster StreamCluster2 \  
    --conf myscheduler.conf
```

The following example reads the sources defined in the scheduler defined by the weblog.conf file.

```
$ vkconfig source --read --conf weblog.conf  
{  
  "source": "web_hits", "partitions": 1, "src_enabled": true,  
  "cluster": "kafka_weblog",  
  "hosts": "kafka01.example.com:9092,kafka02.example.com:9092"}  
}
```

Target tool options

Use the target tool to configure a Vertica table to receive data from your streaming data application.

Syntax

```
vkconfig target [--create | --read | --update | --delete] \  
    [--target-table table --table_schema schema] \  
    [other_options...]
```

--create

Adds a new target table for the scheduler. Cannot be used with **--delete**, **--read**, or **--update**.

--read

Outputs the targets defined in the scheduler. This output is in JSON format. Cannot be used with **--create**, **--delete**, or **--update**.

By default this option outputs all of the targets defined in the configuration schema. You can limit the output to specific targets by using the **--target-schema** and **--target-table** options. The vkconfig script only outputs targets that match the values you set in these options.

You can use LIKE wildcards in these options. See [LIKE](#) for more information about using wildcards.

--update

Updates the settings for the targeted table. Use with the **--new-target-schema** and **--new-target-table** options. Cannot be used with **--create**, **--delete**, or **--read**.

--delete

Removes the scheduler's association with the target table *table*. Cannot be used with **--create**, **--read**, or **--update**.

--target-table *table*

The existing Vertica table for the scheduler to target. This option is required for **--create**, **--update**, and **--delete**.

--target-schema *schema*

The existing Vertica schema containing the target table. This option is required for **--create**, **--update**, and **--delete**.

--dump

When you use this option along with the **--read** option, vkconfig outputs the Vertica query it would use to retrieve the data, rather than outputting the data itself. This option is useful if you want to access the data from within Vertica without having to go through vkconfig. This option has no effect if not used with **--read**.

--new-target-schema *schema_name*

Changes the schema containing the target table to a another existing schema.

Requires: **--update** option.

--new-target-table *table_name*

Changes the Vertica target table associated with this schema to a another existing table.

Requires: `--update` option.

`--validation-type {ERROR|WARN|SKIP}`

Controls validation performed on a created or updated target:

- `ERROR` - Cancel configuration or creation if vkconfig cannot validate that the table exists. This is the default setting.
- `WARN` - Creates or updates the target if validation fails, but display a warning.
- `SKIP` - Perform no validation.

Renamed from `--skip-validation` .

Important

Avoid having columns with primary key restrictions in your target table. The scheduler stops loading data if it encounters a row that has a value which violates this restriction. If you must have a primary key restricted column, try to filter out any redundant values for that column in the streamed data before it is loaded by the scheduler.

See [Common vkconfig script options](#) for options that are available in all of the vkconfig tools.

Examples

This example shows how you can create a target for the scheduler defined in the myscheduler.conf configuration file from public.streamtarget table:

```
$ /opt/vertica/packages/kafka/bin/vkconfig target --create \  
--target-table streamtarget --conf myscheduler.conf
```

This example lists all of the targets in the scheduler defined in the weblogs.conf configuration file.

```
$ vkconfig target --read --conf weblog.conf  
{"target_schema":"public", "target_table":"web_hits"}
```

Load spec tool options

The vkconfig script's load spec tool lets you provide parameters for a COPY statement that loads streaming data.

Syntax

```
$ vkconfig load-spec [--create | --read | --update | --delete] \  
[--load-spec spec-name] [other-options...]
```

`--create`

Creates a new load spec. Cannot be used with `--delete` , `--read` , or `--update` .

`--read`

Outputs the current settings of the load specs defined in the scheduler. This output is in JSON format. Cannot be used with `--create` , `--delete` , or `--update` .

By default, this option outputs all load specs defined in the scheduler. You can limit the output by supplying a single value or a comma-separated list of values to these options:

- `--load-spec`
- `--filters`
- `--uds-kv-parameters`
- `--parser`
- `--message-max-bytes`
- `--parser-parameters`

The vkconfig script only outputs the configuration of load specs that match the values you supply.

You can use LIKE wildcards in these options. See [LIKE](#) for more information about using wildcards.

`--update`

Updates the settings of *spec-name* . Cannot be used with `--create` , `--delete` , or `--read` .

`--delete`

Deletes the load spec named *spec-name* . Cannot be used with `--create` , `--read` , or `--update` .

`--load-spec spec-name`

A unique name for copy load spec to operate on. This option is required for `--create` , `--update` , and `--delete` .

`--dump`

When you use this option along with the `--read` option, `vkconfig` outputs the Vertica query it would use to retrieve the data, rather than outputting the data itself. This option is useful if you want to access the data from within Vertica without having to go through `vkconfig`. This option has no effect if not used with `--read`.

--filters " *filter-name* "

A Vertica FILTER chain containing all of the UDFilters to use in the COPY statement. For more information on filters, refer to [Parsing custom formats](#).

--message-max-bytes *max-size*

Specifies the maximum size, in bytes, of a Kafka protocol batch message.

Default: 25165824

--new-load-spec *new-name*

A new, unique name for an existing load spec. Requires the `--update` parameter.

--parser-parameters " *key = value* [...]"

A list of parameters to provide to the parser specified in the `--parser` parameter. When you use a Vertica native parser, the scheduler passes these parameters to the COPY statement where they are in turn passed to the parser.

--parser *parser-name*

Identifies a Vertica UDFParser to use with a specified target. This parser is used within the COPY statement that the scheduler runs to load data. If you are using a Vertica native parser, the values supplied to the `--parser-parameters` option are passed through to the COPY statement.

****Default:**** KafkaParser

--uds-kv-parameters *key = value* [...]

A comma separated list of key value pairs for the user-defined source.

--validation-type {ERROR|WARN|SKIP}

Specifies the validation performed on a created or updated load spec, to one of the following:

- **ERROR** : Cancel configuration or creation if `vkconfig` cannot validate the load spec. This is the default setting.
- **WARN** : Proceed with task if validation fails, but display a warning.
- **SKIP** : Perform no validation.

Renamed from `--skip-validation`.

See [Common vkconfig script options](#) for options that are available in all of the `vkconfig` tools.

Examples

These examples show how you can use the Load Spec utility options.

Create load spec `Streamspec1` :

```
$ /opt/vertica/packages/kafka/bin/vkconfig load-spec --create --load-spec Streamspec1 --conf myscheduler.conf
```

Rename load spec `Streamspec1` to `Streamspec2` :

```
$ /opt/vertica/packages/kafka/bin/vkconfig load-spec --update --load-spec Streamspec1 \  
    --new-load-spec Streamspec2 \  
    --conf myscheduler.conf
```

Update load spec `Filterspec` to use the `KafkaInsertLengths` filter and a custom decryption filter:

```
$ /opt/vertica/packages/kafka/bin/vkconfig load-spec --update --load-spec Filterspec \  
    --filters "KafkaInsertLengths() DecryptFilter(parameter=Key)" \  
    --conf myscheduler.conf
```

Read the current settings for load spec `streamspec1` :

```
$ vkconfig load-spec --read --load-spec streamspec1 --conf weblog.conf  
{  
  "load_spec": "streamspec1",  
  "filters": null,  
  "parser": "KafkaParser",  
  "parser_parameters": null,  
  "load_method": "TRICKLE",  
  "message_max_bytes": null,  
  "uds_kv_parameters": null  
}
```

Microbatch tool options

The vkconfig script's microbatch tool lets you configure a scheduler's microbatches.

Syntax

```
vkconfig microbatch {--create | --read | --update | --delete} \  
  [--microbatch microbatch_name] [other_options...]
```

--create

Creates a new microbatch. Cannot be used with `--delete`, `--read`, or `--update`.

--read

Outputs the current settings of all microbatches defined in the scheduler. This output is in JSON format. Cannot be used with `--create`, `--delete`, or `--update`.

You can limit the output to specific microbatches by using the `--consumer-group-id`, `--enabled`, `--load-spec`, `--microbatch`, `--rejection-schema`, `--rejection-table`, `--target-schema`, `--target-table`, and `--target-columns` options. The `--enabled` option only accepts a true or false value. You can use LIKE wildcards in these options. See [LIKE](#) for more information about using wildcards.

--update

Updates the settings of *microbatch_name*. Cannot be used with `--create`, `--delete`, or `--read`.

--delete

Deletes the microbatch named *microbatch_name*. Cannot be used with `--create`, `--read`, or `--update`.

--microbatch *microbatch_name*

A unique, case insensitive name for the microbatch. This option is required for `--create`, `--update`, and `--delete`.

--add-source-cluster *cluster_name*

The name of a cluster to assign to the microbatch you specify with the `--microbatch` option. You can use this parameter once per command. You can also use it with `--update` to add sources to a microbatch. You can only add sources from the same cluster to a single microbatch. Requires `--add-source`.

--add-source *source_name*

The name of a source to assign to this microbatch. You can use this parameter once per command. You can also use it with `--update` to add sources to a microbatch. Requires `--add-source-cluster`.

--cluster *cluster_name*

The name of the cluster to which the `--offset` option applies. Only required if the microbatch defines more than one cluster or the `--source` parameter is supplied. Requires the `--offset` option.

--consumer-group-id *id_name*

The name of the Kafka consumer group to which Vertica reports its progress consuming messages. Set this value to disable progress reports to a Kafka consumer group. For details, see [Monitoring Vertica message consumption with consumer groups](#).

Default: `vertica_database-name`

--dump

When you use this option along with the `--read` option, vkconfig outputs the Vertica query it would use to retrieve the data, rather than outputting the data itself. This option is useful if you want to access the data from within Vertica without having to go through vkconfig. This option has no effect if not used with `--read`.

--enabled TRUE|FALSE

When TRUE, allows the microbatch to execute.

--load-spec *loadspect_name*

The load spec to use while processing this microbatch.

--max-parallelism *max_num_loads*

The maximum number of simultaneous COPY statements created for the microbatch. The scheduler dynamically splits a single microbatch with multiple partitions into *max_num_loads* COPY statements with fewer partitions.

This option allows you to:

- Control the transaction size.
- Optimize your loads according to your scheduler's [scheduler's resource pool](#) settings, such as [PLANNEDCONCURRENCY](#).

--new-microbatch *updated_name*

The updated name for the microbatch. Requires the `--update` option.

--offset *partition_offset* [...]

The offset of the message in the source where the microbatch starts its load. If you use this parameter, you must supply an offset value for each partition in the source or each partition you list in the **--partition** option.

You can use this option to skip some messages in the source or reload previously read messages. See [Special Starting Offset Values](#) below for more information.

Important

You cannot set an offset for a microbatch while the scheduler is running. If you attempt to do so, the vkconfig utility returns an error. Use the shutdown utility to shut the scheduler down before setting an offset for a microbatch.

--partition *partition* [...]

One or more partitions to which the offsets given in the **--offset** option apply. If you supply this option, then the offset values given in the **--offset** option applies to the partitions you specify. Requires the **--offset** option.

--rejection-schema *schema_name*

The existing Vertica schema that contains a table for storing rejected messages.

--rejection-table *table_name*

The existing Vertica table that stores rejected messages.

--remove-source-cluster *cluster_name*

The name of a cluster to remove from this microbatch. You can use this parameter once per command. Requires **--remove-source** .

--remove-source *source_name*

The name of a source to remove from this microbatch. You can use this parameter once per command. You can also use it with **--update** to remove multiple sources from a microbatch. Requires **--remove-source-cluster** .

--source *source_name*

The name of the source to which the offset in the **--offset** option applies. Required when the microbatch defines more than one source or the **--cluster** parameter is given. Requires the **--offset** option.

--target-columns *column_expression*

A column expression for the target table, where *column_expression* can be a comma-delimited list of columns or a complete expression.

See the COPY statement [Parameters](#) for a description of column expressions.

--target-schema *schema_name*

The existing Vertica target schema associated with this microbatch.

--target-table *table_name*

The name of a Vertica table corresponding to the target. This table must belong to the target schema.

--validation-type {ERROR|WARN|SKIP}

Controls the validation performed on a created or updated microbatch:

- ERROR - Cancel configuration or creation if vkconfig cannot validate the microbatch. This is the default setting.
- WARN - Proceed with task if validation fails, but display a warning.
- SKIP - Perform no validation.

Renamed from **--skip-validation** .

See [Common vkconfig script options](#) for options that are available in all of the vkconfig tools.

Special starting offset values

The *start_offset* portion of the **stream** parameter lets you start loading messages from a specific point in the topic's partition. It also accepts one of two special offset values:

- -2 tells the scheduler to start loading at the earliest available message in the topic's partition. This value is useful when you want to load as many messages as you can from the Kafka topic's partition.
- -3 tells the scheduler to start loading from the consumer group's saved offset. If the consumer group does not have a saved offset, it starts loading from the earliest available message in the topic partition. See [Monitoring Vertica message consumption with consumer groups](#) for more information.

Examples

This example shows how you can create the microbatch, mbatch1. This microbatch identifies the schema, target table, load spec, and source for the microbatch:

```
$ /opt/vertica/packages/kafka/bin/vkconfig microbatch --create --microbatch mbatch1 \  
    --target-schema public \  
    --target-table BatchTarget \  
    --load-spec Filterspec \  
    --add-source SourceFeed \  
    --add-source-cluster StreamCluster1 \  
    --conf myscheduler.conf
```

This example demonstrates listing the current settings for the microbatches in the scheduler defined in the weblog.conf configuration file.

```
$ vkconfig microbatch --read --conf weblog.conf  
{  
  "microbatch": "weblog",  
  "target_columns": null,  
  "rejection_schema": null,  
  "rejection_table": null,  
  "enabled": true,  
  "consumer_group_id": null,  
  "load_spec": "weblog_load",  
  "filters": null,  
  "parser": "KafkaJSONParser",  
  "parser_parameters": null,  
  "load_method": "TRICKLE",  
  "message_max_bytes": null,  
  "uds_kv_parameters": null,  
  "target_schema": "public",  
  "target_table": "web_hits",  
  "source": "web_hits",  
  "partitions": 1,  
  "src_enabled": true,  
  "cluster": "kafka_weblog",  
  "hosts": "kafka01.example.com:9092,kafka02.example.com:9092"  
}
```

Launch tool options

Use the vkconfig script's launch tool to assign a name to a scheduler instance.

Syntax

```
vkconfig launch [options...]
```

--enable-ssl {true|false}

(Optional) Enables SSL authentication between Kafka and Vertica . For more information, refer to [TLS/SSL encryption with Kafka](#) .

--ssl-ca-alias *alias*

The user-defined alias of the root certifying authority you are using to authenticate communication between Vertica and Kafka. This parameter is used only when SSL is enabled.

--ssl-key-alias *alias*

The user-defined alias of the key/certificate pair you are using to authenticate communication between Vertica and Kafka. This parameter is used only when SSL is enabled.

--ssl-key-password *password*

The password used to create your SSL key. This parameter is used only when SSL is enabled.

--instance-name *name*

(Optional) Allows you to name the process running the scheduler. You can use this command when viewing the scheduler_history table, to find which instance is currently running.

--refresh-interval *hours*

(Optional) The time interval at which the connection between Vertica and Kafka is refreshed (24 hours by default).

--kafka_conf ' *kafka_configuration_setting* '

A JSON string of property/value pairs to pass directly to the rdkafka, the library that Vertica uses to communicate with Kafka. This parameter directly sets global configuration properties that are not available through the Vertica integration with Kafka.

For details, see [Directly setting Kafka library options](#) .

--kafka_conf_secret ' *kafka_configuration_setting* '

Conceals sensitive configuration data that you must pass directly to the rdkafka library, such as passwords. This parameter accepts settings in the same format as `kafka_conf` .

Values passed to this parameter are not logged or stored in system tables.

See [Common vkconfig script options](#) for options that are available in all of the vkconfig tools.

Examples

This example shows how you can launch the scheduler defined in the myscheduler.conf config file and give it the instance name PrimaryScheduler:

```
$ nohup /opt/vertica/packages/kafka/bin/vkconfig launch --instance-name PrimaryScheduler \  
    --conf myscheduler.conf >/dev/null 2>&1 &
```

This example shows how you can launch an instance named SecureScheduler with SSL enabled:

```
$ nohup /opt/vertica/packages/kafka/bin/vkconfig launch --instance-name SecureScheduler --enable-SSL true \  
--ssl-ca-alias authenticcert --ssl-key-alias ourkey \  
--ssl-key-password secret \  
--conf myscheduler.conf \  
>/dev/null 2>&1 &
```

Shutdown tool options

Use the vkconfig script's shutdown tool to terminate one or all Vertica schedulers running on a host. Always run this command before restarting a scheduler to ensure the scheduler has shutdown correctly.

Syntax

```
vkconfig shutdown [options...]
```

See [Common vkconfig script options](#) for options that are available in all vkconfig tools.

Examples

To terminate all schedulers running on a host, use the **shutdown** command with no options:

```
$ /opt/vertica/packages/kafka/bin/vkconfig shutdown
```

Use the **--conf** or **--config-schema** option to specify a scheduler to shut down. The following command terminates the scheduler that was launched with the same **--conf myscheduler.conf** option:

```
$ /opt/vertica/packages/kafka/bin/vkconfig shutdown --conf myscheduler.conf
```

Statistics tool options

The statistics tool lets you access the history of microbatches that your scheduler has run. This tool outputs the log of the microbatches in JSON format to the standard output. You can use its options to filter the list of microbatches to get just the microbatches that interest you.

Note

The statistics tool can sometimes produce confusing output if you have altered the scheduler configuration over time. For example, suppose you have microbatch-a target a table. Later, you change the scheduler's configuration so that microbatch-b targets the table. Afterwards, you run the statistics tool and filter the microbatch log based on target table. Then the log output will show entries from both microbatch-a and microbatch-b.

Syntax

```
vkconfig statistics [options]
```

--cluster " *cluster* "[, " *cluster2* "...]

Only return microbatches that retrieved data from a cluster whose name matches one in the list you supply.

--dump

Instead of returning microbatch data, return the SQL query that vkconfig would execute to extract the data from the scheduler tables. You can use this option if you want use a Vertica client application to get the microbatch log instead of using vkconfig's JSON output.

--from-timestamp " *timestamp* "

Only return microbatches that began after *timestamp*. The timestamp value is in *yyyy -[m] m -[d] d hh : mm : ss* format.

Cannot be used in conjunction with **--last**.

--last *number*

Returns the *number* most recent microbatches that meet all other filters. Cannot be used in conjunction with **--from-timestamp** or **--to-timestamp**.

--microbatch " *name* "[, " *name2* "...]

Only return microbatches whose name matches one of the names in the comma-separated list.

--partition *partition#* [, *partition#2* ...]

Only return microbatches that accessed data from the topic partition that matches ones of the values in the partition list.

--source " *source* "[, " *source2* "...]

Only return microbatches that accessed data from a source whose name matches one of the names in the list you supply to this argument.

--target-schema "schema"["schema2"...]

Only return microbatches that wrote data to the Vertica schemas whose name matches one of the names in the target schema list argument.

--target-table "table"["table2"...]

Only return microbatches that wrote data to Vertica tables whose name match one of the names in the target schema list argument.

--to-timestamp " *timestamp* "

Only return microbatches that began before *timestamp* . The timestamp value is in `yyyy-[m] m -[d] d hh : mm : ss` format.

Cannot be used in conjunction with `--last` .

See [Common vkconfig script options](#) for options that are available in all of the vkconfig tools.

Usage considerations

- You can use LIKE wildcards in the values you supply to the `--cluster` , `--microbatch` , `--source` , `--target-schema` , and `--target-table` arguments. This feature lets you match partial strings in the microbatch data. See [LIKE](#) for more information about using wildcards.
- The string comparisons for the `--cluster` , `--microbatch` , `--source` , `--target-schema` , and `--target-table` arguments are case-insensitive.
- The date and time values you supply to the `--from-timestamp` and `--to-timestamp` arguments use the [java.sql.timestamp](#) format for parsing the value. This format's parsing can accept values that you may consider invalid and would expect it to reject. For example, if you supply a timestamp of 01-01-2018 24:99:99, the Java timestamp parser silently converts the date to 2018-01-02 01:40:39 instead of returning an error.

Examples

This example gets the last microbatch that the scheduler defined in the weblog.conf file ran:

```
$ /opt/vertica/packages/kafka/bin/vkconfig statistics --last 1 --conf weblog.conf
{"microbatch":"weblog", "target_schema":"public", "target_table":"web_hits",
"source_name":"web_hits", "source_cluster":"kafka_weblog", "source_partition":0,
"start_offset":80000, "end_offset":79999, "end_reason":"END_OF_STREAM",
"end_reason_message":null, "partition_bytes":0, "partition_messages":0,
"timeslice":"00:00:09.793000", "batch_start":"2018-11-06 09:42:00.176747",
"batch_end":"2018-11-06 09:42:00.437787", "source_duration":"00:00:00.214314",
"consecutive_error_count":null, "transaction_id":45035996274513069,
"frame_start":"2018-11-06 09:41:59.949", "frame_end":null}
```

If your scheduler is reading from more than partition, the `--last 1` option lists the last microbatch from each partition:

```

$ /opt/vertica/packages/kafka/bin/vkconfig statistics --last 1 --conf iot.conf
{"microbatch":"iotlog", "target_schema":"public", "target_table":"iot_data",
"source_name":"iot_data", "source_cluster":"kafka_iot", "source_partition":0,
"start_offset":-2, "end_offset":-2, "end_reason":"DEADLINE",
"end_reason_message":null, "partition_bytes":0, "partition_messages":0,
"timeslice":"00:00:09.842000", "batch_start":"2018-11-06 12:52:49.387567",
"batch_end":"2018-11-06 12:52:59.400219", "source_duration":"00:00:09.950127",
"consecutive_error_count":null, "transaction_id":45035996274537015,
"frame_start":"2018-11-06 12:52:49.213", "frame_end":null}
{"microbatch":"iotlog", "target_schema":"public", "target_table":"iot_data",
"source_name":"iot_data", "source_cluster":"kafka_iot", "source_partition":1,
"start_offset":1604, "end_offset":1653, "end_reason":"END_OF_STREAM",
"end_reason_message":null, "partition_bytes":4387, "partition_messages":50,
"timeslice":"00:00:09.842000", "batch_start":"2018-11-06 12:52:49.387567",
"batch_end":"2018-11-06 12:52:59.400219", "source_duration":"00:00:00.220329",
"consecutive_error_count":null, "transaction_id":45035996274537015,
"frame_start":"2018-11-06 12:52:49.213", "frame_end":null}
{"microbatch":"iotlog", "target_schema":"public", "target_table":"iot_data",
"source_name":"iot_data", "source_cluster":"kafka_iot", "source_partition":2,
"start_offset":1603, "end_offset":1652, "end_reason":"END_OF_STREAM",
"end_reason_message":null, "partition_bytes":4383, "partition_messages":50,
"timeslice":"00:00:09.842000", "batch_start":"2018-11-06 12:52:49.387567",
"batch_end":"2018-11-06 12:52:59.400219", "source_duration":"00:00:00.318997",
"consecutive_error_count":null, "transaction_id":45035996274537015,
"frame_start":"2018-11-06 12:52:49.213", "frame_end":null}
{"microbatch":"iotlog", "target_schema":"public", "target_table":"iot_data",
"source_name":"iot_data", "source_cluster":"kafka_iot", "source_partition":3,
"start_offset":1604, "end_offset":1653, "end_reason":"END_OF_STREAM",
"end_reason_message":null, "partition_bytes":4375, "partition_messages":50,
"timeslice":"00:00:09.842000", "batch_start":"2018-11-06 12:52:49.387567",
"batch_end":"2018-11-06 12:52:59.400219", "source_duration":"00:00:00.219543",
"consecutive_error_count":null, "transaction_id":45035996274537015,
"frame_start":"2018-11-06 12:52:49.213", "frame_end":null}

```

You can use the `--partition` argument to get just the partitions you want:

```

$ /opt/vertica/packages/kafka/bin/vkconfig statistics --last 1 --partition 2 --conf iot.conf
{"microbatch":"iotlog", "target_schema":"public", "target_table":"iot_data",
"source_name":"iot_data", "source_cluster":"kafka_iot", "source_partition":2,
"start_offset":1603, "end_offset":1652, "end_reason":"END_OF_STREAM",
"end_reason_message":null, "partition_bytes":4383, "partition_messages":50,
"timeslice":"00:00:09.842000", "batch_start":"2018-11-06 12:52:49.387567",
"batch_end":"2018-11-06 12:52:59.400219", "source_duration":"00:00:00.318997",
"consecutive_error_count":null, "transaction_id":45035996274537015,
"frame_start":"2018-11-06 12:52:49.213", "frame_end":null}

```

If your scheduler reads from more than one source, the `--last 1` option outputs the last microbatch from each source:

```

$ /opt/vertica/packages/kafka/bin/vkconfig statistics --last 1 --conf weblog.conf
{"microbatch":"weberrors", "target_schema":"public", "target_table":"web_errors",
"source_name":"web_errors", "source_cluster":"kafka_weblog",
"source_partition":0, "start_offset":10000, "end_offset":9999,
"end_reason":"END_OF_STREAM", "end_reason_message":null,
"partition_bytes":0, "partition_messages":0, "timeslice":"00:00:04.909000",
"batch_start":"2018-11-06 10:58:02.632624",
"batch_end":"2018-11-06 10:58:03.058663", "source_duration":"00:00:00.220618",
"consecutive_error_count":null, "transaction_id":45035996274523991,
"frame_start":"2018-11-06 10:58:02.394", "frame_end":null}
{"microbatch":"weblog", "target_schema":"public", "target_table":"web_hits",
"source_name":"web_hits", "source_cluster":"kafka_weblog", "source_partition":0,
"start_offset":80000, "end_offset":79999, "end_reason":"END_OF_STREAM",
"end_reason_message":null, "partition_bytes":0, "partition_messages":0,
"timeslice":"00:00:09.128000", "batch_start":"2018-11-06 10:58:03.322852",
"batch_end":"2018-11-06 10:58:03.63047", "source_duration":"00:00:00.226493",
"consecutive_error_count":null, "transaction_id":45035996274524004,
"frame_start":"2018-11-06 10:58:02.394", "frame_end":null}

```

You can use wildcards to enable partial matches. This example demonstrates getting the last microbatch for all microbatches whose names end with "log":

```

~$ /opt/vertica/packages/kafka/bin/vkconfig statistics --microbatch "%log" \
--last 1 --conf weblog.conf
{"microbatch":"weblog", "target_schema":"public", "target_table":"web_hits",
"source_name":"web_hits", "source_cluster":"kafka_weblog", "source_partition":0,
"start_offset":80000, "end_offset":79999, "end_reason":"END_OF_STREAM",
"end_reason_message":null, "partition_bytes":0, "partition_messages":0,
"timeslice":"00:00:04.874000", "batch_start":"2018-11-06 11:37:16.17198",
"batch_end":"2018-11-06 11:37:16.460844", "source_duration":"00:00:00.213129",
"consecutive_error_count":null, "transaction_id":45035996274529932,
"frame_start":"2018-11-06 11:37:15.877", "frame_end":null}

```

To get microbatches from a specific period of time, use the `--from-timestamp` and `--to-timestamp` arguments. This example gets the microbatches that read from partition #2 between 12:52:30 and 12:53:00 on 2018-11-06 for the scheduler defined in `iot.conf`.

```

$ /opt/vertica/packages/kafka/bin/vkconfig statistics --partition 1 \
--from-timestamp "2018-11-06 12:52:30" \
--to-timestamp "2018-11-06 12:53:00" --conf iot.conf
{"microbatch":"iotlog", "target_schema":"public", "target_table":"iot_data",
"source_name":"iot_data", "source_cluster":"kafka_iot", "source_partition":1,
"start_offset":1604, "end_offset":1653, "end_reason":"END_OF_STREAM",
"end_reason_message":null, "partition_bytes":4387, "partition_messages":50,
"timeslice":"00:00:09.842000", "batch_start":"2018-11-06 12:52:49.387567",
"batch_end":"2018-11-06 12:52:59.400219", "source_duration":"00:00:00.220329",
"consecutive_error_count":null, "transaction_id":45035996274537015,
"frame_start":"2018-11-06 12:52:49.213", "frame_end":null}
{"microbatch":"iotlog", "target_schema":"public", "target_table":"iot_data",
"source_name":"iot_data", "source_cluster":"kafka_iot", "source_partition":1,
"start_offset":1554, "end_offset":1603, "end_reason":"END_OF_STREAM",
"end_reason_message":null, "partition_bytes":4371, "partition_messages":50,
"timeslice":"00:00:09.788000", "batch_start":"2018-11-06 12:52:38.930428",
"batch_end":"2018-11-06 12:52:48.932604", "source_duration":"00:00:00.231709",
"consecutive_error_count":null, "transaction_id":45035996274536981,
"frame_start":"2018-11-06 12:52:38.685", "frame_end":null}

```

This example demonstrates using the `--dump` argument to get the SQL statement `vkconfig` executed to retrieve the output from the previous example:

```
$ /opt/vertica/packages/kafka/bin/vkconfig statistics --dump --partition 1 \  
    --from-timestamp "2018-11-06 12:52:30" \  
    --to-timestamp "2018-11-06 12:53:00" --conf iot.conf  
SELECT microbatch, target_schema, target_table, source_name, source_cluster,  
source_partition, start_offset, end_offset, end_reason, end_reason_message,  
partition_bytes, partition_messages, timeslice, batch_start, batch_end,  
last_batch_duration AS source_duration, consecutive_error_count, transaction_id,  
frame_start, frame_end FROM "iot_sched".stream_microbatch_history WHERE  
(source_partition = '1') AND (frame_start >= '2018-11-06 12:52:30.0') AND  
(frame_start < '2018-11-06 12:53:00.0') ORDER BY frame_start DESC, microbatch,  
source_cluster, source_name, source_partition;
```

Sync tool options

The sync utility immediately updates all source definitions by querying the Kafka cluster's brokers defined by the source. By default, it updates all of the sources defined in the target schema. To update just specific sources, use the `--source` and `--cluster` options to specify which sources to update.

Syntax

```
vkconfig sync [options...]
```

`--source source_name`

The name of the source sync. This source must already exist in the target schema.

`--cluster cluster_name`

Identifies the cluster containing the source that you want to sync. You must have already defined this cluster in the scheduler.

`--kafka_conf ' kafka_configuration_setting '`

A JSON string of property/value pairs to pass directly to the rdkafka, the library that Vertica uses to communicate with Kafka. This parameter directly sets global configuration properties that are not available through the Vertica integration with Kafka.

For details, see [Directly setting Kafka library options](#).

`--kafka_conf_secret ' kafka_configuration_setting '`

Conceals sensitive configuration data that you must pass directly to the rdkafka library, such as passwords. This parameter accepts settings in the same format as `kafka_conf`.

Values passed to this parameter are not logged or stored in system tables.

See the [Common vkconfig script options](#) for options available in all of the vkconfig tools..

Kafka function reference

This section lists the functions that make up Vertica's Kafka integration feature.

In this section

- [KafkaAvroParser](#)
- [KafkaCheckBrokers](#)
- [KafkaExport](#)
- [KafkaJSONParser](#)
- [KafkaListManyTopics](#)
- [KafkaListTopics](#)
- [KafkaOffsets](#)
- [KafkaParser](#)
- [KafkaSource](#)
- [KafkaTopicDetails](#)

KafkaAvroParser

The KafkaAvroParser parses Avro-formatted Kafka messages and loads them into a regular Vertica table or a Vertica flex table.

Syntax

```
KafkaAvroParser(param=value[...])
```

`enforce_length`

When set to TRUE, rejects the row if any value is too wide to fit into its column. When using the default setting (FALSE), the parser truncates any value that is too wide to fit within the column's maximum width.

reject_on_materialized_type_error

When set to TRUE, rejects the row if it contains a materialized column value that cannot be mapped into the materialized column's data type.

flatten_maps

If set to TRUE, flattens all Avro maps.

flatten_arrays

If set to TRUE, flattens Avro arrays.

flatten_records

If set to TRUE, flattens all Avro records.

external_schema

The schema of the Avro file as a JSON string. If this parameter is not specified, the parser assumes that each message has the schema on it. If you are using a schema registry, do not use this parameter.

codec

The codec in which the Avro file was written. Valid values are:

- **default** : Data is not compressed and codec is not needed
- **deflate** : Data is compressed using the deflate codec
- **snappy** : Snappy compression

Note

This option is mainly provided for backwards compatibility. You usually have Kafka compress data at the message level, and have KafkaSource decompress the message for you.

with_metadata

If set to TRUE, messages include Avro datum, schema, and object metadata. By default, the KafkaAvroParser parses messages without including schema and metadata. If you enable this parameter, write your messages using the Avro API and confirm they contain only Avro datum. The default value is FALSE.

schema_registry_url

Required, the URL of the Confluent schema registry. This parameter is required to load data based on a schema registry version. If you are using an external schema, do not use this parameter. For more information, refer to [Avro Schema Registry](#).

Note

TLS connections must use the HTTPS protocol.

schema_registry_ssl_ca_path

Required for TLS connections, the path on the Vertica node's file system to a directory containing one or more hashed certificate authority (CA) certificates that signed the schema registry's server certificate. Each Vertica node must store hashed CA certificates on the same path.

Important

In some circumstances, you might receive a validation error stating that the KafkaAvroParser cannot locate your CA certificate. To correct this error, store your CA certificate in your operating system's default bundle. For example, store the CA certificate in `/etc/pki/tls/certs/ca-bundle.crt` on Red Hat operating systems.

For details on hashed CA certificates, see [Hashed CA Certificates](#).

schema_registry_ssl_cert_path

Path on the Vertica node's file system to a client certificate issued by a certificate authority (CA) that the schema registry trusts.

schema_registry_ssl_key_path

Path on the Vertica server file system to the private key for the client certificate defined with `schema_registry_ssl_cert_path`.

schema_registry_ssl_key_password_path

Path on the Vertica server file system to the optional password for the private key defined with `schema_registry_ssl_key_path`.

schema_registry_subject

In the schema registry, the subject of the schema to use for data loading.

schema_registry_version

In the schema registry, the version of the schema to use for data loading.

key_separator

Sets the character to use as the separator between keys.

Data types

KafkaAvroParser supports the same data types as the [favroparser](#). For details, see [Avro data](#).

Example

The following example demonstrates loading data from Kafka in an Avro format. The statement:

- Loads data into an existing flex table named weather_logs.
- Copies data from the default Kafka broker (running on the local system on port 9092).
- The source is named temperature.
- The source has a single partition.
- The load starts from offset 0.
- The load ends either after 10 seconds or the load reaches the end of the source, whichever occurs first.
- The KafkaAvroParser does not flatten any arrays, maps, or records it finds in the source.
- The schema for the data is provided in the statement as a JSON string. It defines a record type named Weather that contains fields for a station name, a time, and a temperature.
- Rejected rows of data are saved to a table named t_rejects1.

```
=> COPY weather_logs
SOURCE KafkaSource(stream='temperature|0|0', stop_on_eof=true,
  duration=interval '10 seconds')
PARSER KafkaAvroParser(flatten_arrays=False, flatten_maps=False, flatten_records=False,
  external_schema=E'{"type": "record", "name": "Weather", "fields": [
    {"name": "station", "type": "string"},
    {"name": "time", "type": "long"},
    {"name": "temp", "type": "int"}]}'
REJECTED DATA AS TABLE "t_rejects1";
```

Hashed CA certificates

Some parameters like [schema_registry_ssl_ca_path](#) require hashed CA certificates rather than the CA certificates themselves. A hashed CA certificate is a [symbolic link](#) to the original CA certificate. This symbolic link must have the following naming scheme:

```
CA_hash.0
```

For example, if the hash for [ca_cert.pem](#) is [9741086f](#), the hashed CA certificate would be [9741086f.0](#), a symbolic link to [ca_cert.pem](#).

For details, see the OpenSSL [1.1](#) or [1.0](#) documentation.

Hashing CA certificates

The procedure for hashing CA certificates varies between versions of [openssl](#). You can find your version of [openssl](#) with:

```
$ openssl version
```

For [openssl](#) 1.1 or higher, use [openssl rehash](#). For example, if the directory [/my_ca_certs/](#) contains [ca_cert.pem](#), you can hash and symbolically link to it with:

```
$ openssl rehash /my_ca_certs/
```

This adds the hashed CA certificate to the directory:

```
$ ls -l
total 8
lrwxrwxrwx 1 ver ver 8 Mar 13 14:41 9da13359.0 -> ca_cert.pem
-rw-r--r-- 1 ver ver 1245 Mar 13 14:41 ca_cert.pem
```

For [openssl](#) 1.0, you can use [openssl x509 -hash -noout -in ca_cert.pem](#) to retrieve the hash and then create a symbolic link to the CA certificate. For example:

1. Run the following command to retrieve the hash of the CA certificate [ca_cert.pem](#) :

```
$ openssl x509 -hash -noout -in /my_ca_certs/ca_cert.pem
9741086f
```

2. Create a symbolic link to `/my_ca_certs/ca_cert.pem` :

```
$ ln /my_ca_certs/ca_cert.pem /my_ca_certs/9741086f.0
```

This adds the hashed CA certificate to the directory:

```
$ ls -l
total 8
-rw-r--r-- 2 ver ver 1220 Mar 13 13:41 9741086f.0 -> ca_cert.pem

```

KafkaCheckBrokers

Retrieves information about the brokers in a Kafka cluster. This function is intended mainly for internal use—it is used by the streaming job scheduler to get the list of brokers in the Kafka cluster. You can call the function to determine which brokers Vertica knows about.

Syntax

```
KafkaCheckBrokers(USING PARAMETERS brokers='hostname:port[,hostname2:port...]'
                  [, kafka_conf='kafka_configuration_setting']
                  [, timeout=timeout_sec])
```

brokers

The host name and port number of a broker in the Kafka cluster used to retrieve the list of brokers. You can supply more than one broker as a comma-separated list. If the list includes brokers from more than one Kafka cluster, the cluster containing the last host in the list is queried.

kafka_conf

A JSON string of property/value pairs to pass directly to the rdkafka, the library that Vertica uses to communicate with Kafka. This parameter directly sets global configuration properties that are not available through the Vertica integration with Kafka.

For details, see [Directly setting Kafka library options](#).

kafka_conf_secret

Conceals sensitive configuration data that you must pass directly to the rdkafka library, such as passwords. This parameter accepts settings in the same format as `kafka_conf`.

Values passed to this parameter are not logged or stored in system tables.

timeout

Integer number of seconds to wait for a response from the Kafka cluster.

Example

```
=> SELECT KafkaCheckBrokers(USING PARAMETERS brokers='kafka01.example.com:9092')
       OVER ();
broker_id | hostname | port
-----+-----+-----
2 | kafka03.example.com | 9092
1 | kafka02.example.com | 9092
3 | kafka04.example.com | 9092
0 | kafka01.example.com | 9092
(4 rows)
```

KafkaExport

Sends Vertica data to Kafka.

If Vertica successfully exports all of the rows of data to Kafka, this function returns zero rows. You can use the output of this function to copy failed messages to a secondary table for evaluation and reprocessing.

Syntax

```
SELECT KafkaExport(partitionColumn, keyColumn, valueColumn
  USING PARAMETERS brokers='host[:port][.host...]',
  topic='topicname'
  [,kafka_conf='kafka_configuration_setting']
  [,kafka_topic_conf='kafka_configuration_setting']
  [,kafka_conf_secret='kafka_configuration_setting']
  [,fail_on_conf_parse_error=Boolean])
OVER (partition_clause) FROM table;
```

Parameters

partitionColumn

The target partition for the export. If you set this value to NULL, Vertica uses the default partitioning scheme. You can use the partition argument to send messages to partitions that map to Vertica segments.

keyColumn

The user defined key value associated with the valueColumn. Use NULL to skip this argument.

valueColumn

The message itself. The column is a LONG VARCHAR, allowing you to send up to 32MB of data to Kafka. However, Kafka may impose its own limits on message size.

brokers

A string containing a comma-separated list of one or more host names or IP addresses (with optional port number) of brokers in the Kafka cluster.

topic

The Kafka topic to which you are exporting.

kafka_conf

A JSON string of property/value pairs to pass directly to the rdkafka, the library that Vertica uses to communicate with Kafka. This parameter directly sets global configuration properties that are not available through the Vertica integration with Kafka.

For details, see [Directly setting Kafka library options](#).

kafka_topic_conf

A JSON string of property/value pairs to pass directly to the rdkafka, the library that Vertica uses to communicate with Kafka. This parameter directly sets topic-level configuration properties that are not available through the Vertica integration with Kafka.

For details, see [Directly setting Kafka library options](#).

kafka_conf_secret

Conceals sensitive configuration data that you must pass directly to the rdkafka library, such as passwords. This parameter accepts settings in the same format as [kafka_conf](#).

Values passed to this parameter are not logged or stored in system tables.

fail_on_conf_parse_error

Determines whether the function fails when [kafka_conf](#) contains incorrectly formatted options and values, or invalid configuration properties.

Default Value : FALSE

For accepted option and value formats, see [Directly setting Kafka library options](#).

For a list of valid configuration properties, see the [rdkafka GitHub repository](#).

Example

The following example converts each row from the `iot_report` table into a JSON object, and exports it to a Kafka topic named `iot-report`.

The `iot_report` table contains the following columns and data:

```
=> SELECT * FROM iot_report;
server | date | location | id
-----+-----+-----+-----
1 | 2016-10-11 04:09:28 | -14.86058, 112.75848 | 70982027
1 | 2017-07-02 12:37:48 | -21.42197, -127.17672 | 49494918
2 | 2017-01-20 03:05:24 | 37.17372, 136.14026 | 36670100
2 | 2017-07-29 11:38:37 | -38.99517, 171.72671 | 52049116
1 | 2017-10-19 14:04:33 | -71.72156, -36.27381 | 94328189
(5 rows)
```

To build the `KafkaExport` function, provide the following values to define the Kafka message:

- **partitionColumn**: Use the `server` column. Because the `server` column values are one-based and Kafka partitions are zero-based, subtract 1 from the `server` value.
- **keyColumn**: Use the `id` column. This requires that you [explicitly cast](#) the `id` value to a `VARCHAR` type.
- **valueColumn**: Each message formats the date and location columns as the key/value pairs in the exported JSON object. To convert these rows to JSON format, use the [ROW](#) function to convert the date and location columns to structured data. Then, pass the [ROW](#) function to the [TO_JSON](#) function to encode the data structure as a JSON object.

Complete the remaining required function arguments and execute the `KafkaExport` function. If it succeeds, it returns 0 rows:

```
=> SELECT KafkaExport(server - 1, id::VARCHAR, TO_JSON(ROW(date, location))
      USING PARAMETERS brokers='broker01:9092,broker02:9092',
      topic='iot-results')
OVER (PARTITION BEST)
FROM iot_report;
partition | key | message | failure_reason
-----+-----+-----+-----
(0 rows)
```

Use [kafkacat](#) to verify that the consumer contains the JSON-formatted data in the `iot-results` topic:

```
$ /opt/vertica/packages/kafka/bin/kafkacat -C -t iot-results -b broker01:9092,broker02:9092
{"date":"2017-01-20 03:05:24","location":" 37.17372, 136.14026 "}
{"date":"2017-07-29 11:38:37","location":" -38.99517, 171.72671 "}
{"date":"2016-10-11 04:09:28","location":" -14.86058, 112.75848 "}
{"date":"2017-10-19 14:04:33","location":" -71.72156, -36.27381 "}
{"date":"2017-07-02 12:37:48","location":" -21.42197, -127.17672 "}
```

[Producing data using KafkaExport](#)

`KafkaJSONParser`

The `KafkaJSONParser` parses JSON-formatted Kafka messages and loads them into a regular Vertica table or a Vertica flex table.

Syntax

```
KafkaJSONParser(
  [enforce_length=Boolean]
  [, flatten_maps=Boolean]
  [, flatten_arrays=Boolean]
  [, start_point=string]
  [, start_point_occurrence=integer]
  [, omit_empty_keys=Boolean]
  [, reject_on_duplicate=Boolean]
  [, reject_on_materialized_type_error=Boolean]
  [, reject_on_empty_key=Boolean]
  [, key_separator=char]
  [, suppress_nonalphanumeric_key_chars=Boolean]
)
```

enforce_length

If set to `TRUE`, rejects the row if data being loaded is too wide to fit into its column. Defaults to `FALSE`, which truncates any data that is too wide to fit into its column.

flatten_maps

If set to TRUE, flattens all JSON maps.

flatten_arrays

If set to TRUE, flattens JSON arrays.

start_point

Specifies the key in the JSON data that the parser should parse. The parser only extracts data that is within the value associated with the **start_point** key. It parses the values of all instances of the **start_point** key within the data.

start_point_occurrence

Integer value indicating which the occurrence of the key specified by the **start_point** parameter where the parser should begin parsing. For example, if you set this value to 4, the parser will only begin loading data from the fifth occurrence of the **start_point** key. Only has an effect if you also supply the **start_point** parameter.

omit_empty_keys

If set to TRUE, omits any key from the load data that does not have a value set.

reject_on_duplicate

If set to TRUE, rejects the row that contains duplicate key names. Key names are case-insensitive, so the keys "mykey" and "MyKey" are considered duplicates.

reject_on_materialized_type_error

If set to TRUE, rejects the row if the data includes keys matching an existing materialized column and has a key that cannot be mapped into the materialized column's data type.

reject_on_empty_key

If set to TRUE, rejects any row containing a key without a value.

key_separator

A single character to use as the separator between key values instead of the default period (.) character.

suppress_nonalphanumeric_key_chars

If set to TRUE, replaces all non-alphanumeric characters in JSON key values with an underscore (_) character.

See [JSON data](#) for more information.

The following example demonstrates loading JSON data from Kafka. The parameters in the statement define to the load to:

- Load data into the pre-existing table named logs.
- The KafkaSource streams the data from a single partition in the source called server_log.
- The Kafka broker for the data load is running on the host named kafka01 on port 9092.
- KafkaSource stops loading data after either 10 seconds or on reaching the end of the stream, whichever happens first.
- The KafkJSONParser flattens any arrays or maps in the JSON data.

```
=> COPY logs SOURCE KafkaSource(stream='server_log|0|0',
    stop_on_eof=true,
    duration=interval '10 seconds',
    brokers='kafka01:9092')
PARSER KafkaJSONParser(flatten_arrays=True, flatten_maps=True);
```

KafkaListManyTopics

Retrieves information about all topics from a Kafka broker. This function lists all of the topics defined in the Kafka cluster as well the number of partitions it contains and which brokers serve the topic.

Syntax

```
KafkaListManyTopics('broker:port[;...]'
    [USING PARAMETERS
    [kafka_conf='kafka_configuration_setting'
    [, timeout=timeout_sec]])
```

broker

The hostname (or ip address) of a broker in the Kafka cluster

port

The port number on which the broker is running.

kafka_conf

A JSON string of property/value pairs to pass directly to the rdkafka, the library that Vertica uses to communicate with Kafka. This parameter directly sets global configuration properties that are not available through the Vertica integration with Kafka.

For details, see [Directly setting Kafka library options](#).

kafka_conf_secret

Conceals sensitive configuration data that you must pass directly to the rdkafka library, such as passwords. This parameter accepts settings in the same format as [kafka_conf](#).

Values passed to this parameter are not logged or stored in system tables.

timeout

Integer number of seconds to wait for a response from the Kafka cluster.

Example

```
=> \x
Expanded display is on.
=> SELECT KafkaListManyTopics('kafka01.example.com:9092')
  OVER (PARTITION AUTO);
-[ RECORD 1 ]--+-----
brokers      | kafka01.example.com:9092,kafka02.example.com:9092
topic        | __consumer_offsets
num_partitions | 50
-[ RECORD 2 ]--+-----
brokers      | kafka01.example.com:9092,kafka02.example.com:9092
topic        | iot_data
num_partitions | 1
-[ RECORD 3 ]--+-----
brokers      | kafka01.example.com:9092,kafka02.example.com:9092
topic        | test
num_partitions | 1
```

KafkaListTopics

Gets the list of topics available from a Kafka broker.

Syntax

```
KafkaListTopics(USING PARAMETERS brokers='hostname:port[,hostname2:port2...]'
                [, kafka_conf='kafka_configuration_setting']
                [, timeout=timeout_sec])
```

brokers

The host name and port number of the broker to query for a topic list. You can supply more than one broker as a comma-separated list. However, the returned list will only contains the topics served by the last broker in the list.

kafka_conf

A JSON string of property/value pairs to pass directly to the rdkafka, the library that Vertica uses to communicate with Kafka. This parameter directly sets global configuration properties that are not available through the Vertica integration with Kafka.

For details, see [Directly setting Kafka library options](#).

kafka_conf_secret

Conceals sensitive configuration data that you must pass directly to the rdkafka library, such as passwords. This parameter accepts settings in the same format as [kafka_conf](#).

Values passed to this parameter are not logged or stored in system tables.

timeout

Integer number of seconds to wait for a response from the Kafka cluster.

Example

```
=> SELECT KafkaListTopics(USING PARAMETERS brokers='kafka1-01.example.com:9092')
      OVER ();
      topic      | num_partitions
-----+-----
test            |              1
iot_data       |              1
__consumer_offsets |            50
vertica_notifications |            1
web_hits       |              1
(5 rows)
```

KafkaOffsets

The `KafkaOffsets` user-defined transform function returns load operation statistics generated by the most recent invocation of `KafkaSource`. Query `KafkaOffsets` to see the metadata produced by your most recent load operation. You can query `KafkaOffsets` after each `KafkaSource` invocation to view information about that load. If you are using the scheduler, you can also view historical load information in the [stream_microbatch_history](#) table.

For each load operation, `KafkaOffsets` returns the following:

- source kafka topic
- source kafka partition
- starting offset
- ending offset
- number of messages loaded
- number of bytes read
- duration of the load operation
- end message
- end reason

The following example demonstrates calling `KafkaOffsets` to show partition information that was loaded using `KafkaSource`:

```
=> SELECT kpartition, start_offset, end_offset, msg_count, ending FROM (select KafkaOffsets() over()) AS stats ORDER BY kpartition;
kpartition | start_offset | end_offset | msg_count | ending
-----+-----+-----+-----+-----
0 | -2 | 9999 | 1068 | END_OFFSET
```

The output shows that `KafkaSource` loaded 1068 messages (rows) from Kafka in a single partition. The `KafkaSource` ended the data load because it reached the ending offset.

Note

The values shown in the `start_offset` column are exclusive (the message with the shown offset was not loaded) and the values in the `end_offset` column are inclusive (the message with the shown offset was loaded). This is the opposite of the values specified in the `KafkaSource`'s `stream` parameter. The difference between the inclusiveness of `KafkaSource`'s and `KafkaOffset`'s start and end offsets are based on the needs of the job scheduler. `KafkaOffset` is primarily intended for the job scheduler's use, so the start and end offset values are defined so the scheduler can easily start streaming from where left off.

KafkaParser

The `KafkaParser` does not parse data loaded from Kafka. Instead, it passes the messages through as `LONG VARCHAR` values. Use this parser when you want to load raw Kafka messages into Vertica for further processing. You can use this parser as a catch-all for unsupported formats.

`KafkaParser` does not take any parameters.

Example

The following example loads raw messages from a Kafka topic named `iot-data` into a table named `raw_iot`.

```

=> CREATE TABLE raw_iot(message LONG VARCHAR);
CREATE TABLE
=> COPY raw_iot SOURCE KafkaSource(stream='iot-data|0|-2,iot-data|1|-2,iot-data|2|-2',
    brokers='docd01:6667,docd03:6667', stop_on_eof=TRUE)
    PARSER KafkaParser();
Rows Loaded
-----
    5000
(1 row)

=> select * from raw_iot limit 10;
    message
-----
10039, 59, -68.951406, -19.270126
10042, 40, -82.688712, 4.7187705
10054, 6, -153.805268, -10.5173935
10054, 71, -135.613150, 58.286458
10081, 44, 130.288419, -77.344405
10104, -5, 77.882598, -56.600744
10132, 87, 103.530616, -69.672863
10135, 6, -121.420382, 15.3229855
10166, 77, -179.592211, 42.0477075
10183, 62, 17.225394, -55.6644765
(10 rows)

```

KafkaSource

The KafkaSource UDL accesses data from a Kafka cluster. All Kafka parsers must use KafkaSource. Messages processed by KafkaSource must be at least one byte in length. KafkaSource writes an error message to vertica.log for zero-length messages.

The output of KafkaSource does not work directly with any of the non-Kafka parsers in Vertica (such as the FCSVPARSER). The KafkaParser produces additional metadata about the stream that parsers need to use in order to correctly parse the data. You must use filters such as KafkaInsertDelimiters to transform the data into a format that can be processed by other parsers. See [Parsing custom formats](#) for more an example.

You can cancel a running KafkaSource data load by using a close session function such as [CLOSE_ALL_SESSIONS](#).

Syntax

```
KafkaSource(stream='topic_name|partition|start_offset|[end_offset]', param=value [...])
```

stream

Required. Defines the data to be loaded as a comma-separated list of one or more partitions. Each partition is defined by three required values and one optional value separated by pipe characters (|):

- **topic_name**: the name of the Kafka topic to load data from. You can read from different Kafka topics in the same stream parameter, with some limitations. See [Loading from Multiple Topics in the Same Stream Parameter](#) below for more information.
- **partition**: the partition in the Kafka topic to copy.
- **start_offset**: the offset in the Kafka topic where the load will begin. This offset is inclusive (the message with the offset **start_offset** is loaded). See [Special Starting Offset Values](#) below for additional options.
- **end_offset**: the optional offset where the load should end. This offset is exclusive (the message with the offset **end_offset** will not be loaded).

To end a load using **end_offset**, you must supply an ending offset value for all partitions in the stream parameter. Attempting to set an ending offset for some partitions and not set offset values for others results in an error.

If you do not specify an ending offset, you must supply at least one other ending condition using **stop_on_eof** or **duration**.

brokers

A comma-separated list of host:port pairs of the brokers in the Kafka cluster. Vertica recommends running Kafka on a different machine than Vertica.

Default: localhost:9092

duration

AN INTERVAL that specifies the duration of the frame. After this specified amount of time, KafkaSource terminates the COPY statements. If this parameter is not set, you must set at least one other ending condition by using stop_on_eof or specify an ending offset instead. See [Duration Note](#) below for more information.

executionparallelism

The number of threads to use when loading data. Normally, you set this to an integer value between 1 and the number of partitions the node is loading from. Setting this parameter to a reduced value limits the number of threads used to process any COPY statement. It also increases the throughput of short queries issued in the pool, especially if the queries are executed concurrently.

If you do not specify this parameter, Vertica automatically creates a thread for every partition, up to the limit allowed by the resource pool. If the value you specify for the KafkaSource is lower than the value specified for the scheduler resource pool, the KafkaSource value applies. This value cannot exceed the value specified for the scheduler's resource pool.

stop_on_eof

Determines whether KafkaSource should terminate the COPY statement after it reaches the end of a file. If this value is not set, you must set at least one other ending condition using [duration](#) or by supplying ending offsets instead.

Default: FALSE

group_id

The name of the Kafka consumer group to which Vertica reports its progress consuming messages. Set this value to disable progress reports to a Kafka consumer group. For details, see [Monitoring Vertica message consumption with consumer groups](#).

Default: `vertica_ database-name`

kafka_conf

A JSON string of property/value pairs to pass directly to the rdkafka, the library that Vertica uses to communicate with Kafka. This parameter directly sets global configuration properties that are not available through the Vertica integration with Kafka.

For details, see [Directly setting Kafka library options](#).

kafka_topic_conf

A JSON string of property/value pairs to pass directly to the rdkafka, the library that Vertica uses to communicate with Kafka. This parameter directly sets topic-level configuration properties that are not available through the Vertica integration with Kafka.

For details, see [Directly setting Kafka library options](#).

kafka_conf_secret

Conceals sensitive configuration data that you must pass directly to the rdkafka library, such as passwords. This parameter accepts settings in the same format as `kafka_conf`.

Values passed to this parameter are not logged or stored in system tables.

fail_on_conf_parse_error

Determines whether the function fails when `kafka_conf` contains incorrectly formatted options and values, or invalid configuration properties.

Default Value : FALSE

For accepted option and value formats, see [Directly setting Kafka library options](#).

For a list of valid configuration properties, see the [rdkafka GitHub repository](#).

Special starting offset values

The `start_offset` portion of the `stream` parameter lets you start loading messages from a specific point in the topic's partition. It also accepts one of two special offset values:

- -2 tells KafkaSource to start loading at the earliest available message in the topic's partition. This value is useful when you want to load as many messages as you can from the Kafka topic's partition.
- -3 tells KafkaSource to start loading from the consumer group's saved offset. If the consumer group does not have a saved offset, it starts loading from the earliest available message in the topic partition. See [Monitoring Vertica message consumption with consumer groups](#) for more information.

Loading from multiple topics in the same stream parameter

You can load from multiple Kafka topics in a single stream parameter as long as you follow these guidelines:

- The data for the topics must be in the same format because you pass the data from KafkaSource to a single parser. For example, you cannot load data from one topic that is in Avro format and another in JSON format.
- Similarly, you need to be careful if you are loading Avro data and specifying an external schema from a registry. The Avro parser accepts a single schema per data load. If the data from the separate topics have different schemas, then all of the data from one of the topics will be rejected.

- The data in the different topics should have the same (or very similar) schemas, especially if you are loading data into a traditional Vertica table. While you can load data with different schemas into a flex table, there are only a few scenarios where it makes sense to combine dissimilar data into a single table.

Duration note

The `duration` parameter applies to the length of time that Vertica allows the `KafkaSource` function to run. It usually reflects the amount of time the overall load statement takes. However, if `KafkaSource` is loading a large volume of data or the data needs extensive processing and parsing, the overall runtime of the query can exceed the amount of time specified in `duration`.

Example

The following example demonstrates calling `KafkaSource` to load data from Kafka into an existing flex table named `web_table` with the following options:

- The stream is named `web_hits` which has a single partition.
- The load starts at the earliest message in the stream (identified by passing `-2` as the start offset).
- The load ends when it reaches the message with offset 1000.
- The Kafka cluster's brokers are `kafka01` and `kafka03` in the `example.com` domain.
- The brokers are listening on port 9092.
- The load ends if it reaches the end of the stream before reaching the message with offset 1000. If you do not supply this option, the connector waits until Kafka sends a message with offset 1000.
- The loaded data is sent to the `KafkaJSONParser` for processing.

```
=> COPY web_table
SOURCE KafkaSource(stream='web_hits|0|-2|1000',
                    brokers='kafka01.example.com:9092,kafka03.example.com:9092',
                    stop_on_eof=true)
PARSER KafkaJSONParser();
Rows Loaded
-----
      1000
(1 row)
```

To view details about this load operation, query [KafkaOffsets](#). `KafkaOffsets` returns metadata about the messages that Vertica consumed from Kafka during the most recent `KafkaSource` invocation:

```
=> SELECT KafkaOffsets() OVER();
 ktopic | kpartition | start_offset | end_offset | msg_count | bytes_read | duration | ending | end_msg
-----+-----+-----+-----+-----+-----+-----+-----+-----
web_hits | 0 | 0 | 999 | 1000 | 197027 | 00:00:00.385365 | END_OFFSET | Last message read
(1 row)
```

The `msg_count` column verifies that Vertica loaded 1000 messages, and the `ending` column indicates that Vertica stopped consuming messages when it reached the message with the offset 1000.

KafkaTopicDetails

Retrieves information about the specified topic from one or more Kafka brokers. This function lists details about the topic partitions, and the Kafka brokers that serve each partition in the Kafka cluster.

Syntax

```
KafkaTopicDetails(USING PARAMETERS brokers='hostname:port[,hostname2:port2...]'
                  , topic=topic_name
                  [, kafka_conf='option=value[:option2=value2...]'
                  [, timeout=timeout_sec])
```

brokers

The hostname (or IP address) of a broker in the Kafka cluster.

port

The port number on which the broker is running.

topic

Kafka topic that you want details for.

kafka_conf

A semicolon-delimited list of *option = value* pairs to pass directly to the rdkafka library. This is the library Vertica uses to communicate with Kafka. You can use this parameter to directly set configuration options that are not available through the Vertica integration with Kafka. See [Directly setting Kafka library options](#) for details.

kafka_conf_secret

Conceals sensitive configuration data that you must pass directly to the rdkafka library, such as passwords. This parameter accepts settings in the same format as `kafka_conf`.

Values passed to this parameter are not logged or stored in system tables.

timeout

Integer number of seconds to wait for a response from the Kafka cluster.

Example

```
=> SELECT KafkaTopicDetails(USING PARAMETERS brokers='kafka1-01.example.com:9092',topic='iot_data') OVER();
partition_id | lead_broker | replica_brokers | in_sync_replica_brokers
-----+-----+-----+-----
0 | 0 | 0 | 0
1 | 1 | 1 | 1
2 | 0 | 0 | 0
3 | 1 | 1 | 1
4 | 0 | 0 | 0
(5 rows)
```

Data streaming schema tables

Every time you create a scheduler (`--create`), Vertica creates a schema for that scheduler with the name you specify or the default `stream_config`. Each schema has the following tables:

- [stream_clusters](#)
- [stream_events](#)
- [stream_load_specs](#)
- [stream_microbatch_history](#)
- [stream_microbatch_source_map](#)
- [stream_microbatches](#)
- [stream_scheduler](#)
- [stream_scheduler_history](#)
- [stream_sources](#)
- [stream_targets](#)

Caution

Vertica recommends that you do not alter these tables except in consultation with support.

stream_clusters

This table lists clusters and hosts. You change settings in this table using the vkconfig cluster tool. See [Cluster tool options](#) for more information.

Column	Data Type	Description
id	INTEGER	The identification number assigned to the cluster.
cluster	VARCHAR	The name of the cluster.
hosts	VARCHAR	A comma-separated list of hosts associated with the cluster.

Examples

This example shows a cluster and its associated hosts.

```
=> SELECT * FROM stream_config.stream_clusters;
```

```
id | cluster | hosts
-----+-----+-----
2250001 | streamcluster1 | 10.10.10.10:9092,10.10.10.11:9092
(1 rows)
```

stream_events

This table logs microbatches and other important events from the scheduler in an internal log table.

This table was renamed from kafka_config.kafka_events.

Column	Data Type	Description
event_time	TIMESTAMP	The time the event was logged.
log_level	VARCHAR	The type of event that was logged. Valid Values: <ul style="list-style-type: none">• TRACE• DEBUG• FATAL• ERROR• WARN• INFO Default: INFO
frame_start	TIMESTAMP	The time when the frame executed.
frame_end	TIMESTAMP	The time when the frame completed.
microbatch	INTEGER	The identification number of the associated microbatch.
message	VARCHAR	A description of the event.
exception	VARCHAR	If this log is in the form of a stack trace, this column lists the exception.

Examples

This example shows typical rows from the stream_events table.

```

=> SELECT * FROM stream_config.stream_events;
-[ RECORD 1 ]-+-----
event_time | 2016-07-17 13:28:35.548-04
log_level  | INFO
frame_start |
frame_end   |
microbatch  |
message     | New leader registered for schema stream_config. New ID: 0, new Host: 10.20.30.40
exception   |
-[ RECORD 2 ]-+-----
event_time | 2016-07-17 13:28:45.643-04
log_level  | INFO
frame_start | 2015-07-17 12:28:45.633
frame_end   | 2015-07-17 13:28:50.701-04
microbatch  |
message     | Generated tuples: test3|2|-2,test3|1|-2,test3|0|-2
exception   |
-[ RECORD 3 ]-+-----
event_time | 2016-07-17 14:28:50.701-04
log_level  | INFO
frame_start | 2016-07-17 13:28:45.633
frame_end   | 2016-07-17 14:28:50.701-04
microbatch  |
message     | Total rows inserted: 0
exception   |

```

stream_load_specs

This table describes user-created load specs. You change the entries in this table using the vkconfig utility's [load_spec tool](#).

Column	Data Type	Description
id	INTEGER	The identification number assigned to the cluster.
load_spec	VARCHAR	The name of the load spec.
filters	VARCHAR	A comma-separated list of UDFilters for the scheduler to include in the COPY statement it uses to load data from Kafka.
parser	VARCHAR	A Vertica UDFParser to use with a specified target. If you are using a Vertica native parser, parser parameters serve as a COPY statement parameters.
parser_parameters	VARCHAR	A list of parameters to provide to the parser.
load_method	VARCHAR	The COPY load method to use for all loads with this scheduler. <div style="background-color: #f0f0f0; padding: 10px; margin-top: 10px;"> <p>Deprecated In Vertica 10.0, load methods are no longer used due to the removal of the WOS. The value shown in this column has no effect.</p> </div>
message_max_bytes	INTEGER	The maximum size, in bytes, of a message.
uds_kv_parameters	VARCHAR	A list of parameters that are supplied to the KafkaSource statement. If the value in this column is in the format <i>key = value</i> , the scheduler it to the COPY statement's KafkaSource call.

Examples

This example shows the load specs that you can use with a Vertica instance.

```
SELECT * FROM stream_config.stream_load_specs;
-[ RECORD 1 ]-----+-----
id          | 1
load_spec   | loadspec2
filters     |
parser      | KafkaParser
parser_parameters |
load_method | direct
message_max_bytes | 1048576
uds_kv_parameters |
-[ RECORD 2 ]-----+-----
id          | 750001
load_spec   | streamspec1
filters     |
parser      | KafkaParser
parser_parameters |
load_method | TRICKLE
message_max_bytes | 1048576
uds_kv_parameters |
```

stream_lock

This table is locked by the scheduler. This locks prevent multiple schedulers from running at the same time. The scheduler that locks this table updates it with its own information.

Important

Do not use this table in a serializable transaction that locks this table. Locking this table can interfere with the operation of the scheduler.

Column	Data Type	Description
scheduler_id	INTEGER	A unique ID for the scheduler instance that is currently running.
update_time	TIMESTAMP	The time the scheduler took ownership of writing to the schema.
process_info	VARCHAR	Information about the scheduler process. Currently unused.

Example

```
=> SELECT * FROM weblog_sched.stream_lock;
scheduler_id | update_time | process_info
-----+-----
2 | 2018-11-08 10:12:36.033 |
(1 row)
```

stream_microbatch_history

This table contains a history of every microbatch executed within this scheduler configuration.

Column	Data Type	Description
source_name	VARCHAR	The name of the source.
source_cluster	VARCHAR	The name of the source cluster. The clusters are defined in stream_clusters .
source_partition	INTEGER	The number of the data streaming partition.
start_offset	INTEGER	The starting offset of the microbatch.

end_offset	INTEGER	The ending offset of the microbatch.
end_reason	VARCHAR	An explanation for why the batch ended. The following are valid end reasons: <ul style="list-style-type: none"> • DEADLINE - The batch ran out of time. • END_OFFSET - The load reached the ending offset specified in the KafkaSource. This reason is never used by the scheduler, as it does not specify an end offset. • END_OF_STREAM - There are no messages available to the scheduler or the eof_timeout has been reached. • NETWORK_ERROR - The scheduler could not connect to Kafka. • RESET_OFFSET - The start offset was changed using the <code>--update</code> and <code>--offset</code> parameters to the KafkaSource. This state does not occur during normal scheduler operations. • SOURCE_ISSUE - The Kafka service returned an error. • UNKNOWN - The batch ended for an unknown reason.
end_reason_message	VARCHAR	If the end reason is a network or source issue, this column contains a brief description of the issue.
partition_bytes	INTEGER	The number of bytes transferred from a source partition to a Vertica target table.
partition_messages	INTEGER	The number of messages transferred from a source partition to a Vertica target table.
microbatch_id	INTEGER	The Vertica transaction id for the batch session.
microbatch	VARCHAR	The name of the microbatch.
target_schema	VARCHAR	The name of the target schema.
target_table	VARCHAR	The name of the target table.
timeslice	INTERVAL	The amount of time spent in the KafkaSource operator.
batch_start	TIMESTAMP	The time the batch executed.
batch_end	TIMESTAMP	The time the batch completed.
last_batch_duration	INTERVAL	The length of time required to run the complete COPY statement.
last_batch_parallelism	INTEGER	The number of parallel COPY statements generated to process the microbatch during the last frame.
microbatch_sub_id	INTEGER	The identifier for the COPY statement that processed the microbatch.
consecutive_error_count	INTEGER	(Currently not used.) The number of times a microbatch has encountered an error on an attempt to load. This value increases over multiple attempts.
transaction_id	INTEGER	The identifier for the transaction within the session.
frame_start	TIMESTAMP	The time the frame started. A frame can contain multiple microbatches.
frame_end	TIMESTAMP	The time the frame completed.

Examples

This example shows typical rows from the `stream_microbatch_history` table.

```
=> SELECT * FROM stream_config.stream_microbatch_history;
```

```
-[ RECORD 1 ]--+-+-----  
source_name      | streamsource1  
source_cluster   | kafka-1  
source_partition | 0  
start_offset     | 196  
end_offset       | 196  
end_reason       | END_OF_STREAM

frame_end        |  
end_reason_message | Local: All brokers are down
```

stream_microbatch_source_map

This table maps microbatches to the their associated sources.

Column	Data Type	Description
microbatch	INTEGER	The identification number of the microbatch.

source	INTEGER	The identification number of the associated source.
--------	---------	---

Examples

This example shows typical rows from the stream_microbatch table.

```
SELECT * FROM stream_config.stream_microbatch_source_map;
```

```
microbatch | source
```

```
-----+-----
```

```
1 | 4
```

```
3 | 2
```

```
(2 rows)
```

stream_microbatches

This table contains configuration data related to microbatches.

Column	Data Type	Description
id	INTEGER	The identification number of the microbatch.
microbatch	VARCHAR	The name of the microbatch.
target	INTEGER	The identification number of the target associated with the microbatch.
load_spec	INTEGER	The identification number of the load spec associated with the microbatch.
target_columns	VARCHAR	The table columns associated with the microbatch.
rejection_schema	VARCHAR	The schema that contains the rejection table.
rejection_table	VARCHAR	The table where Vertica stores messages that are rejected by the database.
max_parallelism	INTEGER	The number of parallel COPY statements the scheduler uses to process the microbatch.
enabled	BOOLEAN	When TRUE, the microbatch is enabled for use.
consumer_group_id	VARCHAR	The name of the Kafka consumer group to report loading progress to. This value is NULL if the microbatch reports its progress to the default consumer group for the scheduler. See Monitoring Vertica message consumption with consumer groups for more information.

Examples

This example shows a row from a typical stream_microbatches table.

```

=> select * from weblog_sched.stream_microbatches;
-[ RECORD 1 ]-----+-----
id          | 750001
microbatch  | weberrors
target      | 750001
load_spec   | 2250001
target_columns |
rejection_schema |
rejection_table |
max_parallelism | 1
enabled     | t
consumer_group_id |
-[ RECORD 2 ]-----+-----
id          | 1
microbatch  | weblog
target      | 1
load_spec   | 1
target_columns |
rejection_schema |
rejection_table |
max_parallelism | 1
enabled     | t
consumer_group_id | weblog_group

```

stream_scheduler

This table contains metadata related to a single scheduler.

This table was renamed from `kafka_config.kafka_scheduler`. This table used to contain a column named `eof_timeout_ms`. It has been removed.

Column	Data Type	Description
version	VARCHAR	The version of the scheduler.
frame_duration	INTERVAL	The length of time of the frame. The default is 00:00:10.
resource_pool	VARCHAR	The resource pool associated with this scheduler.
config_refresh	INTERVAL	The interval of time that the scheduler runs before applying any changes to its metadata, such as, changes made using the <code>--update</code> option. For more information, refer to <code>--config-refresh</code> in Scheduler tool options .
new_source_policy	VARCHAR	When during the frame that the source runs. Set this value with the <code>--new-source-policy</code> in Source tool options . Valid Values: <ul style="list-style-type: none"> FAIR: Takes the average length of time from the previous batches and schedules itself appropriately. START: Runs all new sources at the beginning of the frame. In this case, Vertica gives the minimal amount of time to run. END: Runs all new sources starting at the end of the frame. In this case, Vertica gives the maximum amount of time to run. Default: FAIR

pushback_policy	VARCHAR	(Not currently used.) How Vertica handles delays for microbatches that continually fail. Valid Values: <ul style="list-style-type: none"> • FLAT • LINEAR • EXPONENTIAL Default: LINEAR
pushback_max_count	INTEGER	(Currently not used.) The maximum number of times a microbatch can fail before Vertica terminates it.
auto_sync	BOOLEAN	When TRUE, the scheduler automatically synchronizes source information with host clusters. For more information, refer to Automatically consume data from Kafka with a scheduler . Default: TRUE
consumer_group_id	VARCHAR	The name of the Kafka consumer group to which the scheduler reports its progress in consuming messages. This value is NULL if the scheduler reports to the default consumer group named <code>vertica-<i>database_name</i></code> . See Monitoring Vertica message consumption with consumer groups for more information.

Examples

This example shows a typical row in the `stream_scheduler` table.

```
=> SELECT * FROM weblog_sched.stream_scheduler;
-[ RECORD 1 ]-----+-----
version          | v9.2.1
frame_duration   | 00:05:00
resource_pool    | weblog_pool
config_refresh   | 00:05
new_source_policy | FAIR
pushback_policy  | LINEAR
pushback_max_count | 5
auto_sync        | t
consumer_group_id | vertica-consumer-group
```

stream_scheduler_history

This table shows the history of launched scheduler instances.

This table was renamed from `kafka_config.kafka_scheduler_history`.

Column	Data Type	Description
elected_leader_time	TIMESTAMP	The time when this instance took began scheduling operations.
host	VARCHAR	The host name of the machine running the scheduler instance.
launcher	VARCHAR	The name of the currently active scheduler instance. Default: NULL
scheduler_id	INTEGER	The identification number of the scheduler.
version	VARCHAR	The version of the scheduler.

Examples

This example shows typical rows from the stream_scheduler_history table.

```
SELECT * FROM stream_config.stream_scheduler_history;
  elected_leader_time | host | launcher | scheduler_id | version
-----+-----+-----+-----+-----
2016-07-26 13:19:42.692 | 10.20.100.62 | | 0 | v8.0.0
2016-07-26 13:54:37.715 | 10.20.100.62 | | 1 | v8.0.0
2016-07-26 13:56:06.785 | 10.20.100.62 | | 2 | v8.0.0
2016-07-26 13:56:56.033 | 10.20.100.62 | SchedulerInstance | 3 | v8.0.0
2016-07-26 15:51:20.513 | 10.20.100.62 | SchedulerInstance | 4 | v8.0.0
2016-07-26 15:51:35.111 | 10.20.100.62 | SchedulerInstance | 5 | v8.0.0
(6 rows)
```

stream_sources

This table contains metadata related to data streaming sources.

This table was formerly named kafka_config.kafka_scheduler.

Column	Data Type	Description
id	INTEGER	The identification number of the source
source	VARCHAR	The name of the source.
cluster	INTEGER	The identification number of the cluster associated with the source.
partitions	INTEGER	The number of partitions in the source.
enabled	BOOLEAN	When TRUE, the source is enabled for use.

Examples

This example shows a typical row from the stream_sources table.

```
select * from stream_config.stream_sources;
-[ RECORD 1 ]-----
 id      | 1
 source  | SourceFeed1
 cluster | 1
 partitions | 1
 enabled | t
-[ RECORD 2 ]-----
 id      | 250001
 source  | SourceFeed2
 cluster | 1
 partitions | 1
 enabled | t
```

stream_targets

This table contains the metadata for all Vertica target tables.

The table was formerly named kafka_config.kafka_targets.

Column	Data Type	Description
id	INTEGER	The identification number of the target table
target_schema	VARCHAR	The name of the schema for the target table.
target_table	VARCHAR	The name of the target table.

Examples

This example shows typical rows from the stream_tables table.

```
=> SELECT * FROM stream_config.stream_targets;
-[ RECORD 1 ]-----+-----
id          | 1
target_schema | public
target_table | stream_flex1
-[ RECORD 2 ]-----+-----
id          | 2
target_schema | public
target_table | stream_flex2
```

Apache Spark integration

Apache Spark is an open-source, general-purpose cluster-computing framework. See the [Apache Spark website](#) for more information. Vertica provides a Spark connector that you install into Spark that lets you transfer data between Vertica and Spark.

Using the connector, you can:

- Copy large volumes of data from Spark DataFrames to Vertica tables. This feature lets you save your Spark analytics in Vertica.
- Copy data from Vertica to Spark RDDs or DataFrames for use with Python, R, Scala and Java. The connector efficiently pushes down column selection and predicate filtering to Vertica before loading the data.

The connector lets you use Spark to preprocess data for Vertica and to use Vertica data in your Spark application. You can even round-trip data from Vertica to Spark—copy data from Vertica to Spark for analysis, and then save the results of that analysis back to Vertica.

See the [spark-connector project](#) on GitHub for more information about the connector.

How the connector works

The Spark connector is a library that you incorporate into your Spark applications to read data from and write data to Vertica. When transferring data, the connector uses an intermediate storage location as a buffer between the Vertica and Spark clusters. Using the intermediate storage location lets both Vertica and Spark use all of the nodes in their clusters to transfer data in parallel.

When transferring data from Vertica to Spark, the connector tells Vertica to write the data as Parquet files in the intermediate storage location. As part of this process, the connector pushes down the required columns and any Spark data filters into Vertica as SQL. This push down lets Vertica pre-filter the data so it only copies the data that Spark needs. Once Vertica finishes copying the data, the connector has Spark load it into DataFrames from the intermediate location.

When transferring data from Spark to Vertica, the process is reversed. Spark writes data into the intermediate storage location. It then connects to Vertica and runs a COPY statement to load the data from the intermediate location into a table.

Getting the connector

The Spark connector is an open source project. For the latest information on it, visit the [spark-connector project](#) on GitHub. To get an alert when there are updates to the connector, you can log into a GitHub account and click the **Notifications** button on any of the project's pages.

You have three options to get the Spark connector:

- Get the connector from [Maven Central](#). If you use Gradle, Maven, or SBT to manage your Spark applications, you can add a dependency to your project to automatically get the connector and its dependencies and add them into your Spark application. See [Getting the Connector from Maven Central](#) below.
- Download a precompiled assembly from the GitHub project's [releases page](#). Once you have downloaded the connector, you must configure Spark to use it. See [Deploy the Connector to the Spark Cluster](#) below.
- Clone the connector project and compile it. This option is useful if you want features or bugfixes that have not been released yet. See [Compiling the Connector](#) below.

See the [Spark connector project](#) on GitHub for detailed instructions on deploying and using the connector.

Getting the connector from maven central

The Vertica Spark connector is available from the Maven Central Repository. Using Maven Central is the easiest method of getting the connector if your build tool supports downloading dependencies from it.

If your Spark project is managed by Gradle, Maven, or SBT you can add the Spark connector to it by listing it as a dependency in its configuration file. You may also have to enable Maven Central if your build tool does not automatically do so.

For example, suppose you use SBT to manage your Spark application. In this case, the Maven Central repository is enabled by default. All you need to do is add the `com.vertica.spark` dependency to your `build.sbt` file.

See the [com.vertica.spark](#) page on the Maven Repository site for more information on the available Spark connector versions and dependency information for your build system.

Compiling the connector

You may choose to compile the Spark connector if you want to test new features or bugfixes that have not yet been released. Compiling the connector is necessary if you plan on contributing your own features.

To compile the connector, you need:

- The SBT build tool. In order to compile the connector, you must install SBT and all of its dependencies (including a version of the Java SDK). See the [SBT documentation](#) for requirements and installation instructions.
- [git](#) to clone the Spark connector V2 source from the GitHub.

As a quick overview, executing the following commands on a Linux command line will download the source and compile it into an assembly file:

```
$ git clone https://github.com/vertica/spark-connector.git
$ cd spark-connector/connector
$ sbt assembly
```

Once compiled, the connector is located at `target/scala-n.n/spark-vertica-connector-assembly-x.x.jar`. The *n.n* is the currently-supported version of Scala and *x.x* is the current version of the Spark connector.

See the [CONTRIBUTING](#) document in the connector's GitHub project for detailed requirements and compiling instructions.

Once you compile the connector, you must deploy it to your Spark cluster. See the next section for details.

Deploy the connector to the Spark cluster

If you downloaded the Spark connector from GitHub or compiled it yourself, you must deploy it to your Spark cluster before you can use it. Two options include copying it to a Spark node and including it in a `spark-submit` or `spark-shell` command or deploying it to the entire cluster and having it loaded automatically.

Loading the Spark connector from the command line

The quickest way to use the connector is to include it in the `--jars` argument when executing a `spark-submit` or `spark-shell` command. To be able to use the connector in the command line, you must first copy its assembly JAR to the Spark node on which you will run the commands. Then add the path to the assembly JAR file as part of the `--jars` command line argument.

For example, suppose you copied the assembly file to your current directory on a Spark node. Then you could load the connector when starting `spark-shell` with the command:

```
spark-shell --jars spark-vertica-connector-assembly-x.x.jar
```

You could also enable the connector when submitting a Spark job using `spark-submit` with the command:

```
spark-submit --jars spark-vertica-connector-assembly-x.x.jar
```

Configure Spark to automatically load the connector

You can configure your Spark cluster to automatically load the connector. Deploying the connector this way ensures that the Spark connector is available to all Spark applications on your cluster.

To have Spark automatically load the Spark connector:

1. Copy the Spark connector's assembly JAR file to the same path on all of the nodes in your Spark cluster. For example, on Linux you could copy the `spark-vertica-connector-assembly-x.x.jar` file to the `/usr/local/lib` directory on every Spark node. The file must be in the same location on each node.
2. In your Spark installation directories on each node in your cluster, edit the `conf/spark-defaults.conf` file to add or alter the following line:

```
spark.jars /path_to_assembly/spark-vertica-connector-assembly-x.x.jar
```

For example, if you copied the assembly JAR file to `/usr/local/lib`, you would add:

```
spark.jars /usr/local/lib/spark-vertica-connector-assembly-x.x.jar
```

Note

If the `spark.jars` line already exists in the configuration file, add a comma to the end of the line, then add the path to the assembly file. Do not add a space between the comma and the surrounding values.

If you have the JAR files for the Spark connector V1 in your configuration file, you do not need to remove them. Both connector versions can be loaded into Spark at the same time without a conflict.

3. Test your configuration by starting a Spark shell and entering the statement:

```
import com.vertica.spark._
```

If the statement completes successfully, then Spark was able to locate and load the Spark connector library correctly.

Prior connector versions

The Vertica Spark connector is an open source project available from GitHub. It is released on a separate schedule than the Vertica server.

Versions of Vertica prior to 11.0.2 distributed a closed-source proprietary version of the Spark connector. This legacy version is no longer supported, and is not distributed with the Vertica server install package.

The newer open source Spark connector differs from the old one in the following ways:

- The new connector uses the Spark V2 API. Using this newer API makes it more future-proof than the legacy connector, which uses an older Spark API.
- The primary class name has changed. Also, the primary class has several renamed configuration options and a few removed options. See [Migrating from the legacy Vertica Spark connector](#) for a list of these changes.
- It supports more features than the older connector, such as Kerberos authentication and S3 intermediate storage.
- It comes compiled as an assembly which contains supporting libraries such as the Vertica JDBC library.
- It is distributed separate from the Vertica server. You can directly download it from the GitHub project. It is also available from the Maven Central Repository, making it easier for you to integrate it into your Gradle, Maven, or SBT workflows.
- It is an open-source project that is not tied to the Vertica server release cycle. New features and bug fixes do not have to wait for a Vertica release. You can also contribute your own features and fixes.

If you have Spark applications that used the previous version of the Spark connector, see [Migrating from the legacy Vertica Spark connector](#) for instructions on how to update your Spark code to work with the new connector.

If you are still using a version of Spark earlier than 3.0, you must use the legacy version of the Spark connector. The new open source version is incompatible with older versions of Spark. You can get the older connector by downloading and extracting a Vertica installation package earlier than version 11.0.2.

In this section

- [Migrating from the legacy Vertica Spark connector](#)

Migrating from the legacy Vertica Spark connector

If you have existing Spark applications that used the closed-source Vertica Spark connector, you must update them to work with the newer open source connector. The new connector offers new features, better performance, and is under ongoing development. The old connector has been removed from service.

Deployment changes between the old and connectors

The legacy connector was only distributed with the Vertica server install. The new connector is distributed via several channels giving you more ways to deploy it.

The new Spark connector is available from Maven Central. If you use Gradle, Maven, or SBT to manage your Spark applications, you may find it more convenient to deploy the Spark connector using a dependency rather than manually installing it on your Spark cluster. Integrating the connector into your Spark project as a dependency makes updating to newer versions of the connector easy—just update the required version in the dependency. See [Getting the Connector from Maven Central](#) for more information.

You can also download the precompiled connector assembly or build it from source. In this case, you must deploy the connector to your Spark cluster. The legacy connector depended on the Vertica JDBC driver and required that you separately include it. The new connector is an assembly that incorporates all of its dependencies, including the JDBC driver. You only need to deploy a single JAR file containing the Spark connector to your Spark cluster.

You can have Spark load both the legacy and new connector at the same time because the new connector's primary class name is different (see below). This renaming lets you add the new connector to your Spark configuration files without having to immediately port all of your Spark applications that use the legacy connector to the new API. You can just add the new assembly JAR file to spark-jars list in the [spark-defaults.conf](#) file.

API changes

There are several API changes from the legacy connector to the new connector require changes to your Spark application.

VerticaRDD class no longer supported

The legacy connector supported a class named [VerticaRDD](#) to load data from Vertica using the Spark resilient distributed dataset (RDD) feature. The new connector does not support this separate class. Instead, if you want to directly manipulate an RDD, access it through the [DataFrame](#) object you create using the [DataSource](#) API.

DefaultSource class renamed VerticaSource

The primary class in the legacy connector is named [DataSource](#). In the new connector, this class has been renamed to [VerticaSource](#). This renaming lets both connectors coexist, allowing you to gradually transition your Spark applications.

For your existing Spark application to use the new connector, you must change calls to the [DataSource](#) class to the [VerticaSource](#) class. For example, suppose your Spark application has this method call to read data from the legacy connector:

```
spark.read.format("com.vertica.spark.datasource.DefaultSource").options(opts).load()
```

Then to have it use the new connector, use this method call:

```
spark.read.format("com.vertica.spark.datasource.VerticaSource").options(opts).load()
```

Changed API options

In addition to renaming of the [DataSource](#) class to [VerticaSource](#), some of the names for options for the primary connector class have changed. Other options are no longer supported. If you are porting a Spark application from the legacy to the new connector that uses one of the following options, you must update your code:

Legacy DataSource Option	New VerticaSource Option	Description
fileformat	none	The new connector does not support the fileformat option. The files that Vertica and Spark write to the intermediate storage location are always in parquet format.
hdfs_url	staging_fs_url	The location of the intermediate storage location that Vertica and Spark use to exchange data. Renamed to be more general, as the new connector supports storage platforms in addition to HDFS.
logging_level	none	The connector no longer supports setting a logging level. Instead, set the logging level in Spark.
numpartitions	num_partitions	The number of Spark partitions to use when reading data from Vertica.
target_table_ddl	target_table_sql	A SQL statement for Vertica to execute before loading data from Spark.
web_hdfs_url	staging_fs_url	Use the same option for a web HDFS URL as you would for an S3 or HDFS storage location.

In addition, the new connector has added options to support new features such as Kerberos authentication. For details on the connector's VerticaSource options API, see the [Vertica Spark connector GitHub project](#).

Take advantage of new features

The new Vertica Spark connector offers new features that you may want to take advantage of.

Currently, the most notable new features are:

- Kerberos authentication. This feature lets you configure the connector for passwordless connections to Vertica. See the [Kerberos documentation](#) in the Vertica Spark connector GitHub project for details of using this feature.
- Support for using S3 for intermediate storage. This option lets you avoid having to set up a Hadoop cluster solely to host an HDFS storage location. See the [S3 user guide](#) at the connector GitHub site.

Voltage SecureData integration

Voltage SecureData is a suite of encryption technologies that let you integrate end-to-end data encryption into other applications. It uses Format-Preserving Encryption (FPE): the encrypted values have the same overall format as the unencrypted data. This feature means you do not have to change the data types of table columns that you want to encrypt. It also preserves reference integrity: the encrypted values have the same sort order as unencrypted data, and encrypted values can be cross-referenced between tables, as long as each instance of the value is encrypted with the same key.

See the [Voltage web site](#) for more about SecureData.

This section explains how you can integrate the SecureData encryption feature into Vertica.

In this section

How Vertica and SecureData work together

Vertica provides functions to encrypt and decrypt data using SecureData.

Voltage SecureData supplies a number of interfaces for applications to use its encryption: web-based APIs, command-line tools, and SDKs for C, C#, and Java. Vertica has developed a connector that calls the SecureData API that lets you:

- Encrypt sensitive data as it is being loaded into Vertica using SecureData's FPE feature. You can ensure data is stored in Vertica in its encrypted state (referred to as "encrypted at rest"). Authorized users can decrypt the data as needed. Unauthorized users only see the encrypted values. Decryption for authorized users can be automated using views or access policies. The data is transparently decrypted for them.
- Encrypt semi-sensitive data that is stored unencrypted in Vertica so unauthorized users only see a masked version of the data. You can also automate this on-the-fly encryption using access policies.

The encryption method you choose depends on the data you are processing. For example, regulations or contracts may require you to encrypt specific pieces of data. In these cases, use SecureData to encrypt your data as it is loaded, so it is never stored in an unencrypted format within Vertica.

In other cases, you may have semi-sensitive data that you can choose between the two options. In these cases, choose the method that requires the least number of encryptions or decryptions (and therefore of calls to SecureData). If most of the queries on the data need to be masked from users who should not see the unencrypted values, then encrypt the data at rest. Alternatively, if the most of the queries will be from authorized users, with only occasional queries where the data should be masked, then store the data in an unencrypted format and use on-the-fly encryption to mask the data.

Requirements for integrating with SecureData

Before you can use SecureData with Vertica, you must verify the following:

- You are using version 6.0 or later of SecureData. The Vertica integration functions use APIs introduced in version 6.0 of SecureData.
- All of the nodes in your Vertica cluster are able to communicate with all of your SecureData appliance hosts. Any firewalls between your Vertica cluster and your SecureData appliance must allow connections on the ports that SecureData uses for communications. See "Ensuring Access to SecureData Services" in the *Voltage SecureData Appliance Installation Guide* (downloadable with the SecureData ISO) for a list of the ports reserved by SecureData.
- Your Vertica database is not using [Federal information processing standard](#) (FIPS) mode. FIPS is incompatible with the Voltage SecureData integration. When FIPS mode is active, the SecureData integration library is not installed by default. Do not manually install this library if you are using FIPS.
- You are following the [best practices](#) when using Safe Unicode FPE formats.

Best practices for safe unicode FPE

Starting with Voltage SecureData Simple API 6.0, you can use Safe Unicode Format Preserving Encryption (FPE) formats to encrypt and decrypt Unicode strings.

When encrypting Unicode with Safe Unicode FPE formats, the plaintext passed into the [VoltageSecureProtect](#) function is first encrypted with an alphabet of all Unicode code points, and then encoded with the Base32K-encoding to produce encrypted text in [Unicode Normalization Form C](#) (NFC). The encrypted text will generally consist of 3-byte Chinese and Japanese characters, as they account for a significant portion of the NFC-stable alphabet. [VoltageSecureAccess](#) reverses this process.

Unlike regular FPE, which handles ASCII strings consisting of single bytes, Safe Unicode FPE handles strings consisting of variable-length code points. This variability introduces an important complication: Safe Unicode FPE formats like `UNICODE_BASE32K` are not length-preserving. The encryption algorithm guarantees that the encrypted text will be larger than the original, and failing to account for this expansion can lead to truncated or otherwise improperly stored encrypted text, making decryption impossible.

Additionally, Unicode allows semantically equivalent characters to be encoded in different ways, which means that unnormalized, semantically equivalent plaintexts can have different forms when encrypted, compromising [referential integrity](#). To prevent this, you should always normalize your plaintext strings into their NFC forms before encryption. For more information on Unicode normalization, see the Unicode Consortium's [Normalization FAQ](#).

The encrypted text is guaranteed to be larger than the plaintext in the following ways:

- 16/15ths longer in character-length (rounded up)
- up to 4-times larger (in bytes)

For a list of predefined formats for Safe Unicode FPE, consult your copy of the Voltage SecureData Simple API documentation.

Checklist for safe unicode FPE

Before using Safe Unicode FPE:

- Normalize your plaintext to its NFC form before encryption.
- For fixed-length [data types](#): remove any padding from the plaintext string.
- To store the encrypted text, ensure that the columns storing the encrypted text can handle:
 - strings 16/15ths times longer than your longest plaintext string
 - strings up to 4-times larger (in bytes) than your largest plaintext string

Verifying the Vertica server's access to the SecureData CA certificate

Before you can use SecureData with Vertica, you must verify that the root certificate authority (CA) and any intermediate certificate authority used to sign the SecureData Appliance's certificate are rehashed and stored in the Vertica server's trust store (`/opt/vertica/packages/voltagesecure/trustStore/`). Vertica supplies many standard root certificates in this directory. If your SecureData Appliance uses a certificate signed by a standard CA authority, it is likely already in the trust store.

If your SecureData Appliance is using a certificate signed by your own internal CA authority , you must add this CA Certificate to the Vertica trust store.

If you are unsure whether your CA Certificate is in the Vertica trust store, follow the steps under [Troubleshooting Certificate Problems](#) to test whether the Vertica already has the CA certificate. If you are able to retrieve the client policy XML file from the SecureData Appliance, then your Vertica cluster has the correct CA certificate to access SecureData.

Adding the CA certificate to Vertica

You must add the CA to Vertica trust store before using the SecureData Integration if you used:

- Your own CA certificate to sign your SecureData Appliance's certificate.
- A third-party CA that is not in the Vertica trust store.

To add the CA certificate to the Vertica trust store, you need:

- The certificate authority (CA) file used to sign the SecureData Appliance's certificate. This file must be in `.pem` format.
- The `openssl` or `c_rehash` utility.
- Access to the dbadmin account on the Vertica nodes. This access is required in order to copy the certificate file to trust store directory in the Vertica installation.

To add the CA file to Vertica:

1. Run either `openssl rehash` or `c_rehash` , specifying the directory containing the CA certificate. This creates a symbolic link `hash .0` :

```
openssl rehash directory_of_certificate
```

```
$ c_rehash directory_of_certificate
```

2. On all nodes, use `cp -L` to copy the certificate to `/opt/vertica/packages/voltagesecure/trustStore/`. If the previous step produced more than one symbolic link, run the following command on all of them:

```
$ cp -L hash_0 /opt/vertica/packages/voltagesecure/trustStore/
```

3. Reinstall the SecureData integration library:

```
$ admintools -t install_package -d database_name -p 'password' --package voltagesecure --force-reinstall
```

When Vertica reinstalls the SecureData integration library, it copies the CA authority file to the all nodes in the cluster. After the file is distributed, all Vertica nodes can authenticate with the SecureData Appliance.

For example, for a database `VMart` and a certificate file `my_ca_cert.pem` :

1. Rehash the certificate:

```
$ openssl rehash my_certs
$ ls -l my_certs
total 4
-rwxrwxrwx 1 dbadmin dbadmin  8 Oct 12 14:35 9da13359.0 -> my_ca_cert.pem
-rw-rw-r-- 1 dbadmin dbadmin 1245 Oct 12 14:16 my_ca_cert.pem
```

2. On all nodes, copy the file certificate to the trust store:

```
$ cp -L 9da13359.0 /opt/vertica/packages/voltagesecure/trustStore/
```

3. Run the following on one node:

```
$ admintools -t install_package -d VMart -p dbadmin_password --package voltagesecure --force-reinstall
installing package voltagesecure...
..Success!
```

Troubleshooting certificate problems

You can test whether the Vertica trust store has the correct certificate by executing the following statement from the Linux command line:

```
curl --capath /vertica_catalog_directory/Libraries/\
$(vsq -A -t -c "SELECT sa1_storage_id from user_libraries WHERE lib_name = 'VoltageSecureLib';")\
https://SecureData_appliance_hostname/policy/clientPolicy.xml
```

Where:

- `vertica_catalog_directory` is the absolute path to the Vertica catalog directory. See [Understanding the catalog directory](#) for more information about the catalog directory.
- `SecureData_appliance_hostname` is the host name of your Voltage SecureData Appliance.

For example, suppose you are connected to node0001 of the example VMart database. Also, your Voltage SecureData appliance's host name is `voltage-pp-0000.example.com`. Then you would use the following command to test your certificate installation.

```

$ curl --capath /home/dbadmin/VMart/v_vmart_node0001_catalog/Libraries/
$(vsq -A -t -c "SELECT sa_storage_id from user_libraries WHERE lib_name = 'VoltageSecureLib';") \
https://voltage-pp-0000.example.com/policy/clientPolicy.xml

<clientPolicy version="2">

<server name="SecureDataAppliance" version="6.4.2.232000" />

<localDomains>example.com</localDomains>

<userWhitelist></userWhitelist>

<defaultDistrict value="0" />

<sendUniversalReader value="1" />

<messageFooterGlobal></messageFooterGlobal>

<parameterAggressiveDistricts>example.com</parameterAggressiveDistricts>

<localPolicyLocked value="0" />

<trustedDistricts></trustedDistricts>

<fallThroughDistrict>example.com</fallThroughDistrict>

. . .

```

The `<clientPolicy>...` output (which is the content of the `clientPolicy.xml` file) indicates that the Vertica node was able to use its CA certificate to connect to the SecureData Appliance.

Tip

If you are unsure which Format Preserving Encryption (FPE) formats are defined in your SecureData Appliance, examine the output of the `curl` command. Look for the tags with `formatName` attributes which describe each of the formats.

If the CA certificate you installed on Vertica does not match the certificate installed on the SecureData Appliance, you will see an error similar to the following:

```

$ curl --capath /home/dbadmin/VMart/v_vmart_node0001_catalog/Libraries/$(vsq \
-A -t -c "SELECT sa_storage_id from user_libraries WHERE lib_name = 'VoltageSecureLib';") \
https://voltage-pp-0000.example.com/policy/clientPolicy.xml

curl: (60) Peer certificate cannot be authenticated with known CA certificates
More details here: http://curl.haxx.se/docs/sslcerts.html

```

In this case, verify that you have installed the correct CA certificate in Vertica, and that its file name has a `.pem` extension.

If you see other errors, such as "couldn't connect to host," verify that your firewall configuration allows your Vertica nodes to access your SecureData Appliance.

Configuring access to SecureData

The Vertica integration functions require several pieces of information in order to connect to and authenticate with SecureData.

SecureData global configuration settings

The SecureData integration has one required setting and two optional settings that you set globally using the [VoltageSecureConfigureGlobal](#) function. This function saves the settings to a configuration file named `/voltagesecure/conf.global` stored in the Vertica Distributed File System (DFS). This file system is used by Vertica to store data that can be accessed by all nodes. You must use the function to create this file before you use any of the other SecureData integration functions. All users who have access to the SecureData functions are able to access the settings in this file.

The one required setting is the URL of the SecureData policy file. This file provides the SecureData integration library with details of how the SecureData Appliance is configured. The library also uses this URL to determine the address of the SecureData Appliance.

The two optional settings are:

- **allow_short_fpe** : When set to True, SecureData ignores the lower length limit for encoding FPE values. Usually, SecureData does not use FPE to encrypt data shorter than a lower limit (usually, 8 bits). See the *SecureData Architecture Guide*'s section on Data Length Restrictions for more information.
- **enable_file_cache** : When set to True, Vertica caches the SecureData policy file and encryption keys to disk, rather than just to memory. Defaults to false.

This example sets the policy URL globally to <https://voltage-pp-0000.example.com/policy/clientPolicy.xml> and the network timeout to 200 seconds.

```
=> SELECT VoltageSecureConfigureGlobal(USING PARAMETERS
      policy_url='https://voltage-pp-0000.example.com/policy/clientPolicy.xml',
      NETWORK_TIMEOUT=200)
      OVER ();
```

policy_url	allow_short_fpe	enable_file_cache	network_timeout
https://voltage-pp-0000.example.com/policy/clientPolicy.xml			200

(1 row)

Manually refresh the client policy across the nodes:

```
=> SELECT VoltageSecureRefreshPolicy() OVER ();
      PolicyRefresh
```

Successfully refreshed policy on node [v_sandbox_node0001]. Policy on other nodes will be refreshed the next time a Voltage operation is run on them.

(1 row)

Important

The SecureData integration only supports one configuration for the SecureData Appliance at a time.

SecureData user configuration settings

The remaining SecureData settings define SecureData user information. They are usually specific to each user accessing the integration functions. However, you can have all Vertica users share the same SecureData user configuration. These settings are:

- Your authentication credentials for SecureData. The exact information you need depends on your SecureData Appliance's configuration. There are four potential settings you that you can use:
 - **username** : a username that you use to identify yourself. Your user name is either defined by LDAP (when using LDAP authentication) or by the SecureData appliance when using shared secret authentication.
 - **identity** : the SecureData identity to use. See the *SecureData Administrator Guide* for more information about identities in SecureData. The identity usually takes the form of an email address. When your SecureData Appliance uses LDAP authentication, your LDAP account must have access to this identity.
 - **shared_secret** : a password set in SecureData.
 - **password** : the LDAP password to use to authenticate with SecureData.

You can supply both a username and identity, depending on the SecureData Appliance's configuration. Your SecureData Appliance can be configured to supply the identity based on your SecureData username.

However, you can only use a shared_secret or a password. If you set both parameters, the Vertica SecureData functions exit with an error.

You have two options for setting these configuration values: setting them in [user-defined session parameters](#), or saving the values in a configuration file stored in the Vertica distributed file system.

Setting SecureDate user session parameters

Use the [ALTER SESSION](#) statement to set parameters for the voltagesecurelib library. This library contains all of the SecureData functions. The following example demonstrates configuring the session to access SecureData using shared secret authentication.

```
=> ALTER SESSION SET UDPARAMETER FOR voltagesecurelib identity='alice@example.com';
ALTER SESSION
=> ALTER SESSION SET UDPARAMETER FOR voltagesecurelib username='alice';
ALTER SESSION
=> ALTER SESSION SET UDPARAMETER FOR voltagesecurelib shared_secret='my_shared_secret';
ALTER SESSION
```

Once set, these parameters only last for the duration of your session.

Saving parameters in configuration files

You can use the [VoltageSecureConfigure](#) function to save SecureData user parameters to a configuration file in the DFS. You must supply a file name for your configuration file. You can choose to store your SecureData parameters in a user-specific file by supplying just a file name, such as [securedata.conf](#) . Behind the scenes, your configuration file is stored in DFS under a directory named for your username. This directory prevents your configuration file from conflicting with other users' files. You do not use this directory name when accessing your configuration file.

You can also store the configuration parameters in an absolute file named [/voltagesecure/conf](#) . All users who have access to the SecureData integration functions can use this configuration file in their function calls. You can use this file if all of the users accessing the SecureData functions share the same SecureData user settings.

Important

All users that have access to the VoltageSecureConfigure function can write to the global [/voltagesecure/conf](#) file. Users do not need to be able to write to this file in order to use it in calls to the other SecureData integration functions. You will usually choose to either grant users access to VoltageSecureConfigure in order to save their own configuration files, or you will use the global [/voltagesecure/conf](#) file and not grant users access to VoltageSecureConfigure.

Values in the session parameters override values in configuration files.

You call VoltageSecureConfigure with the parameters you want to save to the configuration file. Values that you do not set in this function call are not set in the configuration file. You must supply those values to the other SecureData integration functions using session parameters.

If you choose to save either the password or shared secret to your configuration file, you do not directly pass them to the VoltageSecureConfigure function. Instead, you set the value in the appropriate session variable, and then set either VoltageSecureConfigure's [store_password](#) or [store_shared_secret](#) parameter to true. When either of these parameters are true, VoltageSecureConfigure reads the value from the session variable and saves it in the configuration file.

Caution

Under normal circumstances, users are not able to directly read data from files stored in DFS. However, all users who have access to UDX functions that read from the DFS could access these files from within Vertica.

In addition, these files are stored as plain text in every node's file system. Anyone with the proper file system access on the nodes can read the file's contents.

You should take both of these facts into consideration when deciding whether to store sensitive information such as passwords or shared secrets in either the shared or per-user configuration files.

Example: creating a user-specific configuration file

The following example shows how you can create a user-specific configuration file. This example does not store information such as the password or shared secret, so you must still set session parameters for these values before you can call the other SecureData integration functions.

```
=> \x
Expanded display is on.
=> SELECT VoltageSecureConfigure(USING PARAMETERS config_dfs_path='voltage.conf',
                                username='alice', identity='alice@example.com', store_password=false
                                ) OVER ();
-[ RECORD 1 ]-----+-----
config_dfs_path | voltage.conf
identity        | alice@example.com
username        | alice
```

Encrypting, decrypting, and hashing data

Once you have set up authentication with the SecureData Appliance (SDA), call the [VoltageSecureProtect](#) and [VoltageSecureAccess](#) functions to encrypt/hash or decrypt your data, respectively. At a minimum, you pass these functions the value to be encrypted, hashed, or decrypted and value's FPE format as defined in the Voltage SDA. You can also capture these parameters in [SQL Macros](#) and [access policies](#).

Connecting Vertica to the SecureData appliance

The following example demonstrates how to fetch the SDA client policy with Vertica and then how to set the session parameters for authentication to the SDA.

1. [Add the SecureData CA certificate to Vertica](#).
2. Set the client policy with [VoltageSecureConfigureGlobal](#).

```
=> SELECT VoltageSecureConfigureGlobal(USING PARAMETERS
  policy_url='https://voltage-pp-0000.example.com/policy/clientPolicy.xml')
  OVER ();
```

policy_url	allow_short_fpe	enable_file_cache
https://voltage-pp-0000.example.com/policy/clientPolicy.xml		

(1 row)

3. (Optional) Retrieve the latest version of the client policy with [VoltageSecureRefreshPolicy](#).

```
=> SELECT VoltageSecureRefreshPolicy() OVER ();
```

PolicyRefresh
Successfully refreshed policy on node [v_node0001]. Policy on other nodes will be refreshed the next time a Voltage operation is run on them.

(1 row)

4. Set the authentication parameters to authenticate to the SDA as a Vertica user with [ALTER SESSION](#) or [VoltageSecureConfigure](#). For details on this process, see [Configuring access to SecureData](#).

`ALTER SESSION` sets these parameters for the duration of your session and override parameters set in configuration files.

```
=> ALTER SESSION SET UDPARAMETER FOR voltagesecurelib identity='alice@example.com';
ALTER SESSION
=> ALTER SESSION SET UDPARAMETER FOR voltagesecurelib username='alice';
ALTER SESSION
=> ALTER SESSION SET UDPARAMETER FOR voltagesecurelib shared_secret='my_secret';
ALTER SESSION
```

`VoltageSecureConfigure` saves these parameters to the specified `config_dfs_path`. This configuration file can then be passed to other Voltage functions.

```
=> SELECT VoltageSecureConfigure(USING PARAMETERS config_dfs_path='voltage.conf',
  username='alice', identity='alice@example.com', store_password=false) OVER ();
```

config_dfs_path	identity	username
voltage.conf	alice@example.com	alice

```
=> SELECT VoltageSecureProtect('123-45-6789' USING PARAMETERS
  format='ssn',
  config_dfs_path='voltage.conf');
```

VoltageSecureProtect
376-69-6789

Encrypting and decrypting data

[VoltageSecureProtect](#) takes a format-preserving encryption (FPE) format defined in your SDA and VARCHAR data and returns format-preserved ciphertext, which can then be decrypted with [VoltageSecureAccess](#). That is, if the plaintext follows the form of a phone number (###-###-####), the resulting ciphertext will be in the same form. Formats can be customized in various ways, like masking certain values, leaving some part of the string unencrypted, etc.

One of the many predefined formats in the SDA is `ssn`. The `ssn` format encrypts all but the last four digits of the social security number, which can be useful for certain roles like customer support, which may need the last four digits of the SSN to authenticate individuals over the phone.

```
=> SELECT VoltageSecureProtect('123-45-6789' USING PARAMETERS format='ssn');
VoltageSecureProtect
-----
376-69-6789
(1 row)

=> SELECT VoltageSecureAccess('376-69-6789' USING PARAMETERS format='ssn');
VoltageSecureAccess
-----
123-45-6789
(1 row)
```

Another predefined format is `auto`, which can handle a wide variety of data, including SSNs. In contrast to `ssn`, `auto` is configured in the SDA to encrypt all characters in the plaintext.

```
=> SELECT VoltageSecureProtect('123-45-6789' USING PARAMETERS format='auto');
VoltageSecureProtect
-----
820-31-5110
(1 row)
```

Note that you can only decrypt ciphertext with the same format that generated it. In this case, ciphertext created with `ssn` must be decrypted with `ssn`. Passing the format `auto` with a ciphertext generated with `ssn`, for instance, would simply return an incorrect plaintext.

Encrypting data during load

When handling sensitive data, you often want to encrypt it as you load it so the unencrypted values are never stored in your database.

The following example demonstrates loading data using `COPY`. Suppose you have a data filled with customer information with the following fields: id number, first name, last name, social security number, card verification number, and date of birth:

```
5345,Thane,Ross,559-32-0670,376765616314013,618,05-09-1996
5346,Talon,Wilkins,540-48-0784,4716511603424923,111,09-17-1941
5347,Daquan,Phelps,785-34-0092,342226134491834,294,05-08-1963
5348,Basia,Lopez,011-85-0705,4595818418314603,503,04-29-1940
5349,Kaseem,Hendrix,672-57-0309,4556 078 73 7944,693,03-11-1942
5350,Omar,Lott,825-45-0131,6462 0541 0799 6261,555,02-17-1956
5351,Nell,Cooke,637-50-0105,646 59756 30903 530,818,02-14-1995
5352,Illana,Middleton,831-47-0929,648 23640 86684 267,883,12-29-1949
5353,Garrett,Williamson,408-73-0207,5334 2702 1360 8370,869,11-06-1955
5354,Hanna,Ware,694-97-0394,543 38494 19219 254,586,08-08-1967
```

To encrypt the social security number and the credit card number columns, call `VoltageSecureProtect` to encrypt these columns in the `COPY` statement you use to load the data:

```
=> CREATE TABLE customers (id INTEGER, first_name VARCHAR, last_name VARCHAR,
    ssn VARCHAR(11), cc_num VARCHAR(25), cvv VARCHAR(5), dob DATE);
```

```
CREATE TABLE
```

```
=> COPY customers (id, first_name, last_name, ssn_raw FILLER VARCHAR(11),
    cc_num_raw FILLER VARCHAR(25), cvv, dob,
    ssn AS VoltageSecureProtect(ssn_raw USING PARAMETERS format='ssn',
        config_dfs_path='voltage.conf'),
    cc_num AS VoltageSecureProtect(cc_num_raw USING PARAMETERS format='cc',
        config_dfs_path='voltage.conf'))
    FROM '/home/dbadmin/customer_data.csv' DELIMITER ',';
```

```

Caution

Always use the same FPE format to encrypt data in a column. If you use different FPE formats in the same column (such as loading some data using `ssn` and other data using `auto`) there is no way to tell which format was used for any particular row, and properly and improperly encrypted ciphertexts will be indistinguishable.

Encrypting Non-VARCHAR data

VoltageSecureProtect function only encrypts VARCHAR values, so if you need to encrypt other data types, such as DATE or INTEGER, you must cast these values to VARCHAR in your function call and then cast them back to DATE or INTEGER when storing them.

Building off the previous example, the following encrypts the date of birth (dob) column, which holds date type DATE.

```
=> CREATE TABLE customers2 (id INTEGER, first_name VARCHAR, last_name VARCHAR, ssn VARCHAR(11),
                             cc_num VARCHAR(25), cvv VARCHAR(5), dob DATE);
```

```
CREATE TABLE
```

```
=> COPY customers2 (id, first_name, last_name, ssn, cc_num, cvv, dob_raw FILLER DATE,
                   dob AS VoltageSecureProtect(dob_raw::VARCHAR USING PARAMETERS
                                               format='birthday',
                                               config_dfs_path='voltage.conf'))::DATE)
   FROM '/home/dbadmin/customer_data.csv' DELIMITER ',';
```

```

(10 rows)
```

Note

To encrypt dates, you must create your own FPE format. Be sure to match your custom FPE format to standard Vertica date format of YYYY-MM-DD. The example's `birthday` is one such custom format.

Note that you cannot use the `auto` format for DATE types; ciphertext generated by `auto` uses the full range of numbers and letters and only preserves the number of characters and any separators, so the resulting ciphertext cannot typically be cast to a date.

```
=> SELECT VoltageSecureProtect('07-16-1969' USING PARAMETERS format='auto',
                               config_dfs_path='/voltagesecure/conf');
```

```
VoltageSecureProtect
```

```
-----
45-86-8651
(1 row)
```

```
=> SELECT VoltageSecureProtect('07-16-1969' USING PARAMETERS format='auto',
                               config_dfs_path='/voltagesecure/conf')::DATE;
```

```
ERROR 2992: Date/time field value out of range: "45-86-8651"
```

```
HINT: Perhaps you need a different "datestyle" setting
```

Decrypting values in queries

To decrypt ciphertext stored in tables, call `VoltageSecureAccess` on the encrypted column in your query.

The following example queries a table and decrypts the SSN column:

```
=> SELECT id,
       first_name,
       last_name,
       VoltageSecureAccess(ssn USING PARAMETERS format='ssn',
                           config_dfs_path='/voltagesecure/conf') AS ssn_plaintext,
       dob
FROM customers
WHERE dob < '1970-1-1'
ORDER BY id ASC
LIMIT 10;
```

id	first_name	last_name	ssn_plaintext	dob
5346	Talon	Wilkins	540-48-0784	1941-09-17
5347	Daquan	Phelps	785-34-0092	1963-05-08
5348	Basia	Lopez	011-85-0705	1940-04-29
5349	Kaseem	Hendrix	672-57-0309	1942-03-11
5350	Omar	Lott	825-45-0131	1956-02-17
5352	Illana	Middleton	831-47-0929	1949-12-29
5353	Garrett	Williamson	408-73-0207	1955-11-06
5354	Hanna	Ware	694-97-0394	1967-08-08
5355	Quinn	Pruitt	818-91-0359	1965-11-14
5356	Clayton	Santiago	102-56-0010	1958-02-02

(10 rows)

Important
The VoltageSecureAccess function has no way of determining if the values you are passing it are actually encrypted or not; the function simply takes the input and transforms it using the decryption key. If you pass it values from an unencrypted column, you will get back scrambled values. For example:

```
=> SELECT first_name,
       VoltageSecureAccess(first_name USING PARAMETERS format='auto',
                           config_dfs_path='/voltagesecure/conf')
       AS decrypted_first_name
FROM customers LIMIT 10;
```

first_name	decrypted_first_name
Omar	Rftd
Illana	Clfkow
Hanna	Bodng
Keith	Hklnw
Constance	Cicgtmgtw
Kirk	Jwdv
Eagan	Hiksm
Branden	Ytqngp
Hope	Tqzc
Keane	Pdcax

(10 rows)

Decrypting Non-VARCHAR columns

Like VoltageSecureProtect, VoltageSecureAccess can only handle VARCHAR values. When you decrypt ciphertext from a non-VARCHAR column, you must cast it to a VARCHAR before passing it to VoltageSecureAccess. If your query or client application depends on the original data type of the column, you must then cast the returned plaintext back to the column's original data type.

The following example decrypts the dob column by casting the column data from DATE to VARCHAR, passing it to VoltageSecureAccess, and then casting the plaintext back to DATE.

```
=> SELECT id, first_name, last_name,
       VoltageSecureAccess(dob::VARCHAR USING PARAMETERS format='birthday',
                           config_dfs_path='/voltagesecure/conf')::DATE AS dob
       FROM customers2 ORDER BY id LIMIT 10;
id | first_name | last_name | dob
```

```
-----+-----+-----+-----
5345 | Thane     | Ross      | 1996-05-09
5346 | Talon     | Wilkins   | 1941-09-17
5347 | Daquan    | Phelps    | 1963-05-08

5349 | Kaseem    | Hendrix   | 1942-03-11
5350 | Omar      | Lott      | 1956-02-17
5351 | Nell      | Cooke     | 1995-02-14
5352 | Illana    | Middleton | 1949-12-29
5353 | Garrett   | Williamson| 1955-11-06
5354 | Hanna     | Ware      | 1967-08-08
(10 rows)
```

Masking decrypted values

If the ciphertext was created with a format that specifies a form of "masking," plaintexts returned by VoltageSecureAccess can be masked by using the `mask=true` parameter. If you don't specify this parameter, the full plaintext will be returned regardless of the format.

This format, as defined in the Voltage SDA, obscures all but the last two characters of the decrypted plaintext.

```
=> SELECT VoltageSecureAccess('g3kbx6ru19', USING PARAMETERS
                               format='maskedFormat',
                               config_dfs_path='voltage.conf');
```

```
VoltageSecureAccess
```

```
-----
1234567890
```

```
=> SELECT VoltageSecureAccess('g3kbx6ru19', USING PARAMETERS
                               format='maskedFormat',
                               config_dfs_path='voltage.conf',
                               mask=true);
```

```
VoltageSecureAccess
```

```
-----
XXXXXXXXX90
```

Tweaking ciphertext

Analogous to a [salt](#), you can pass an additional "tweak" value to add to the key used by VoltageSecureProtect to create unique ciphertexts from the same plaintext. This "tweaked" ciphertext can then only be decrypted by passing the same format and "tweak" value to VoltageSecureAccess. Support for this feature is set in the SDA.

The following example uses the custom format `ssn-tweak` and the value `tweakvalue123` to tweak the ciphertext.

```
=> SELECT VoltageSecureProtect('681-09-2913', 'tweakvalue123' USING PARAMETERS
                               format='ssn-tweak');
```

```
VoltageSecureProtect
```

```
-----
721-21-2913
```

```
=> SELECT VoltageSecureAccess('721-21-2913', 'tweakvalue123' USING PARAMETERS
                               format='ssn-tweak');
```

```
VoltageSecureProtect
```

```
-----
681-09-2913
```

Tweaking an entire column

A common use case is to use the values from one column to tweak the ciphertext in another.

The following example loads the data in a similar manner to the previous section, but uses the values from the last_name column to tweak the dates of birth of each customer.

```
=> CREATE TABLE customers (id INTEGER, first_name VARCHAR, last_name VARCHAR, ssn VARCHAR(11),
  cc_num VARCHAR(25), cvv VARCHAR(5), dob DATE);
CREATE TABLE
=> COPY customers (id, first_name, last_name, ssn_raw FILLER VARCHAR(11),
  cc_num_raw FILLER VARCHAR(25), cvv,
  dob_raw FILLER DATE, ssn AS VoltageSecureProtect(ssn_raw USING PARAMETERS format='ssn',
    config_dfs_path='voltage.conf'),
  /* cast the dob_raw to VARCHAR and tweak with last_name, then cast back to DATE */
  dob AS VoltageSecureProtect(dob_raw::VARCHAR , last_name USING PARAMETERS format='date-tweak',
    config_dfs_path='voltage.conf')::DATE,
  cc_num AS VoltageSecureProtect(cc_num_raw USING PARAMETERS format='cc', config_dfs_path='voltage.conf'))
  FROM 'customers.csv' DELIMITER ',';
```

Rows Loaded

```
-----
      100
(1 row)
```

```
=> SELECT id, first_name, last_name, dob FROM customers ORDER BY id;
 id | first_name | last_name | dob
```

```
-----+-----+-----+-----
5345 | Thane     | Ross     | 2086-03-07
5346 | Talon    | Wilkins  | 1936-06-09
5347 | Daquan   | Phelps   | 1953-12-01
5348 | Basia    | Lopez    | 1979-11-30
5349 | Kaseem   | Hendrix  | 2090-01-07
5350 | Omar     | Lott     | 1984-07-27
5351 | Nell     | Cooke    | 2053-03-20
5352 | Illana   | Middleton | 1988-03-06
5353 | Garrett  | Williamson | 1927-03-03
5354 | Hanna    | Ware     | 1998-08-28
5355 | James    | May      | 1941-10-24
(11 rows)
```

To decrypt the column, include the tweak column in the call to VoltageSecureAccess. The tweak column must contain the same data it did when it was used to encrypt the column.

```
=> SELECT id, first_name, last_name,
  VoltageSecureAccess(dob::VARCHAR , last_name USING PARAMETERS format='date-tweak',
  config_dfs_path='voltage.conf')::DATE AS dob
  FROM customers ORDER BY id;
id | first_name | last_name | dob
-----+-----+-----+-----
5345 | Thane     | Ross     | 1996-05-09
5346 | Talon    | Wilkins  | 1941-09-17
5347 | Daquan   | Phelps   | 1963-05-08
5348 | Basia    | Lopez    | 1940-04-29
5349 | Kaseem   | Hendrix  | 1942-03-11

5351 | Nell     | Cooke    | 1995-02-14
5352 | Illana   | Middleton | 1949-12-29
5353 | Garrett  | Williamson | 1955-11-06
5354 | Hanna    | Ware     | 1967-08-08
5355 | James    | May      | 1967-08-08
(11 rows)
```

Tweaking columns with stored procedures

Since tweak values become part of the encryption key, a tweak column's contents must be the same at the time of both encryption and decryption. To avoid losing access to the plaintext, when modifying a tweak column, you must:

1. decrypt the ciphertext
2. modify the tweak column
3. re-encrypt the plaintext data with the contents of the modified tweak column

You can automate this process by using stored procedures. For example, a stored procedure to update a customer's date of birth when tweaked with their last name might be:

```
=> CREATE PROCEDURE update_dob (employee_id INT, tweak_value VARCHAR) AS $$
BEGIN
  PERFORM UPDATE customers
  SET dob = (
    WITH dob_ AS (SELECT VoltageSecureAccess(dob::VARCHAR , last_name
    USING PARAMETERS format='date-tweak', config_dfs_path='voltage.conf')::DATE AS dob
    FROM customers
    WHERE id = employee_id)
  SELECT VoltageSecureProtect(dob::VARCHAR, tweak_value
  USING PARAMETERS format='date-tweak', config_dfs_path='voltage.conf')::DATE
  FROM dob_)
  WHERE ID = employee_id;

  PERFORM UPDATE customers SET last_name = tweak_value WHERE ID = employee_id;

  PERFORM COMMIT;
END;
$$;
```

You can then call the procedure to update the encrypted value and the tweak value:

```
=> CALL update_dob(5349, 'Henderson');
```

Hashing data

VoltageSecureProtect can also hash your data while preserving its format, which can be useful in contexts where you need to anonymize data to comply with privacy standards while retaining accessibility for client code.

You should keep in mind the following:

- hashing is a one way operation, so the original plaintext is unrecoverable
- the nature of format-preserving hash functions and plaintexts with low entropy (names, dates, SSNs, etc.) mean that collisions are much more likely than with standard hashing functions

The following example encrypts an SSN using a custom FPH format, `ssnHash` .

```
=> SELECT VoltageSecureProtect('681-09-2913' USING PARAMETERS
      format='ssnHash',
      config_dfs_path='voltage.conf');
VoltageSecureProtect
-----
841-68-2913
```

Encapsulating encryption business logic with SQL macros

The [VoltageSecureProtect](#) and [VoltageSecureAccess](#) functions are fairly low-level functions and require a lot of preparation to use correctly. This includes, but is not limited to, information on the data type you're decrypting/encrypting, which Voltage format to use, casting the input to VARCHAR and then back to your desired data type, and identity management. Writing queries with this many moving parts can be tedious.

To streamline this process, you can encapsulate this information in SQL macros and decide its behavior in a more dynamic way with case expressions. This approach offers several benefits:

- You can associate a Voltage format with the data's purpose and Vertica will automatically encrypt and decrypt the value accordingly.
- You can automate the required type casting to and from your desired data type to VARCHAR.
- The [THROW_ERROR](#) function can provide a form of input validation for your macros.
- You can specify an [identity](#) for a given case expression during encryption which restricts decryption privileges to the same identity.

Note

SQL macros are incompatible with User-Defined Transform Functions, such as [VoltageSecureProtectAllKeys](#) .

To view your macros, query the [USER_FUNCTIONS](#) system table.

Encryption and decryption macro templates

In the following macros, the `data_purpose` parameter describes what the data is used for (e.g. `temperature`) and the `value` parameter indicates value being encrypted and its `data_type` (e.g. INT). The `data_type` must be the same across the entire macro.

The `data_purpose` parameter is also associated with both the `voltage_format` and `voltage_identity` parameters, which control how the data is encrypted/decrypted and which identity has access to it, respectively.

If you pass into the function a `data_purpose` without a corresponding case expression, the `THROW_ERROR` function will return a user-specified error, which itself must be casted to the function's return `data_type` .

Note that the standard casting operator `::` will terminate the query entirely if it encounters types incompatible with the specified cast, which can be problematic when casting larger datasets. To prevent the query from terminating, you can use the `::!` operator to first attempt the specified cast, but to return a NULL value for incompatible types. For more information, see [Cast failures](#) .

Encryption macro with VoltageSecureProtect

```
=> CREATE FUNCTION encryptDataType(data_purpose VARCHAR, value data_type) RETURN data_type
AS BEGIN
RETURN(CASE
  WHEN (data_purpose='data_purpose')
    then VoltageSecureProtect(value::VARCHAR USING PARAMETERS
      format='voltage_format',
      identity='voltage_identity')::data_type
  ELSE
    THROW_ERROR('no matching data_purpose')::data_type
  END);
END;
```

Decryption macro with VoltageSecureAccess

```
=> CREATE FUNCTION decryptDataType(data_purpose VARCHAR, value data_type) RETURN data_type
AS BEGIN
RETURN(CASE
WHEN (data_purpose='data_purpose')
then VoltageSecureAccess(value::VARCHAR USING PARAMETERS
format='voltage_format',
identity='voltage_identity')::data_type
ELSE
THROW_ERROR('no matching data_purpose')::data_type
END);
END;
```

Example

The following example shows how to manage encryption and decryption for a column with dates of birth. In this case, you might want to define a separate identity for encrypting customer and employee data.

```
=> SELECT * FROM customer_dob;
dates
-----
1955-11-04
1991-12-01
1977-07-07
(3 rows)
```

For encryption, define the following macro.

```
=> CREATE FUNCTION encryptDOB(data_purpose VARCHAR, value DATE) RETURN DATE
AS BEGIN
RETURN
(CASE
--The data_purpose parameter controls which identity is used during encryption;
WHEN (data_purpose='customer')
--Format, identities, and casting from DATE to VARCHAR and back to DATE are all encapsulated in the case expression;
then VoltageSecureProtect(value::VARCHAR USING PARAMETERS
format='birthday',
identity='customer_data@example.com')::DATE
WHEN (data_purpose='employee')
then VoltageSecureProtect(value::VARCHAR USING PARAMETERS
format='birthday',
identity='employee_data@example.com')::DATE
ELSE
THROW_ERROR('Unsupported data_purpose -- You must pass "customer" when
encrypting customer data or "employee" when encrypting employee data')::DATE
--Because the return type of this macro is DATE, THROW_ERROR must also be casted to type DATE;
END);
END;
```

To encrypt the dates column in the customer_dob table:

```
=> SELECT encryptDOB('customer', dates) FROM customer_dob;
encryptDOB
-----
2048-08-09
1917-03-05
2022-01-07
```

To encrypt a value individually:

```
=> SELECT encryptDOB('customer', '1955-11-04');
encryptDOB
-----
2048-08-09
```

You can define a matching macro for decryption. Since encrypted data can only be decrypted with matching identities, these case expressions use the same `data_purpose` and identities for decryption.

For decryption, define the following macro:

```
=> CREATE FUNCTION decryptDOB(data_purpose VARCHAR, value DATE) RETURN DATE
AS BEGIN
RETURN
(CASE
--The case expressions and parameters must match the ones for encryption;
WHEN (data_purpose='customer')
then VoltageSecureAccess(value::VARCHAR USING PARAMETERS
format='birthday',
identity='customer_data@example.com')::DATE
WHEN (data_purpose='employee')
then VoltageSecureAccess(value::VARCHAR USING PARAMETERS
format='birthday',
identity='employee_data@example.com')::DATE
ELSE
THROW_ERROR('Unsupported data_purpose -- You must pass "customer" when
decrypting customer data or "employee" when decrypting employee data')::DATE
END);
END;
```

To decrypt an encrypted column in a nested call:

```
=> SELECT decryptDOB('customer', encryptDOB('customer', dates)) FROM customer_dob;
decryptDOB
-----
1955-11-04
1991-12-01
1977-07-07
(3 rows)
```

To decrypt a value individually:

```
=> SELECT decryptDOB('customer', '2048-08-09');
decryptDOB
-----
1955-11-04
```

To drop these macros:

```
=> DROP FUNCTION encryptDOB(VARCHAR, DATE);
DROP FUNCTION
=> DROP FUNCTION decryptDOB(VARCHAR, DATE);
DROP FUNCTION
```

Granting users access to the Voltage SecureData integration functions

By default, Vertica users do not have access to the Voltage SecureData Integration Functions. Users attempting to call the integration functions without the correct privileges will receive the following error:

```
=> SELECT id,
       first_name,
       last_name,
       VoltageSecureAccess(ssn USING PARAMETERS format='ssn',
                           config_dfs_path='/voltagesecure/conf') AS ssn,
       dob
FROM customers
WHERE dob < '1970-1-1'
ORDER BY id ASC
LIMIT 10;
```

ERROR 6482: Failed to parse Access Policies for table "customers" [Function public.VoltageSecureProtect(varchar) does not exist, or permission is denied for public.VoltageSecureProtect(varchar)]

Users must have EXECUTE access to the integration functions in order to use them. These functions are part of the PUBLIC schema. The functions in the Voltage SecureData integration library are:

Function Signature	Function Type
VoltageSecureAccess (VARCHAR)	Function
VoltageSecureConfigure ()	Transform Function
VoltageSecureProtect (VARCHAR)	Function
VoltageSecureProtectAllKeys (VARCHAR)	Transform Function

The following example demonstrates granting the user named Alice access to the VoltageSecureAccess function to be able to decrypt data.

```
=> \c vmart dbadmin
You are now connected to database "vmart" as user "dbadmin".
=> GRANT EXECUTE ON FUNCTION public.VoltageSecureProtect(VARCHAR) TO alice;
GRANT PRIVILEGE
=> \c vmart alice
You are now connected to database "vmart" as user "alice".
=> SELECT id, first_name, last_name,
       VoltageSecureAccess(ssn USING PARAMETERS format='ssn',
                           config_dfs_path='/voltagesecure/conf')
       AS ssn,
       dob
FROM customers
WHERE dob < '1970-1-1'
ORDER BY id ASC
LIMIT 10;
id | first_name | last_name | ssn | dob

```

See [GRANT \(user defined extension\)](#) for a detailed explanation of granting access to UDxs to users.

Creating roles for SecureData users

Instead of granting access to each function to individual users, you can create roles that you grant access to the functions. Then you can grant users who need to access the SecureData functions access to these roles.

Consider creating at least two roles: one for access to the VoltageSecureConfigure function and another for access to the other functions. In most cases, not all users need to access VoltageSecureConfigure, especially if you choose to create a single, global configuration file. See [Configuring access to SecureData](#) for more information about using VoltageSecureConfigure.

The following example:

- Creates two roles: `secure_data_users`, who are granted access to the protect and access functions, and `secure_data_admins`, who are granted access to the `SecureDataConfigure` function.
- Grants the `secure_data_user` role to a user named Alice
- Sets the new role as her default role.
- Switches to Alice
- Calls several of the SecureData functions.

```

=> \c vmart dbadmin
You are now connected to database "vmart" as user "dbadmin".
=> CREATE ROLE secure_data_users;
CREATE ROLE
=> GRANT EXECUTE ON FUNCTION public.VoltageSecureAccess(varchar)
    TO secure_data_users;
GRANT PRIVILEGE
=> GRANT EXECUTE ON FUNCTION public.VoltageSecureProtect(varchar)
    TO secure_data_users;
GRANT PRIVILEGE
=> GRANT EXECUTE ON TRANSFORM FUNCTION
    public.VoltageSecureProtectAllKeys(varchar)
    TO secure_data_users;
GRANT PRIVILEGE
=> CREATE ROLE secure_data_admins;
CREATE ROLE
=> GRANT EXECUTE ON TRANSFORM FUNCTION public.VoltageSecureConfigure()
    TO secure_data_admins;
GRANT PRIVILEGE
=> GRANT secure_data_users TO ALICE;
GRANT ROLE
=> ALTER USER alice DEFAULT ROLE secure_data_users;
ALTER USER
=> \c vmart alice
You are now connected to database "vmart" as user "alice".
=> SET ROLE secure_data_users;
SET
=> SELECT VoltageSecureProtect('123-45-6789'
    USING PARAMETERS format='ssn',
    config_dfs_path='/voltagesecure/conf');
VoltageSecureProtect
-----
376-69-6789
(1 row)
=> SELECT VoltageSecureAccess('376-69-6789'
    USING PARAMETERS format='ssn',
    config_dfs_path='/voltagesecure/conf');
VoltageSecureAccess
-----
123-45-6789
(1 row)
=> SELECT VoltageSecureConfigure(USING PARAMETERS config_dfs_path='voltage.conf',
    username='alice', identity='alice@example.com',
    ) OVER ();
ERROR 3457: Function VoltageSecureConfigure() does not exist, or permission
is denied for VoltageSecureConfigure()
HINT: No function matches the given name and argument types. You may need to
add explicit type casts

```

Note that Alice can use the global configuration file, despite not being able to access the VoltageSecureConfigure function.

Note

In the previous example, the global configuration file includes the shared secret or password. See [Configuring access to SecureData](#) for a discussion of the security implications of saving sensitive information to a SecureData configuration file.

You can automate encryption and decryption by creating [access policies](#). These policies let you show users with specific roles unencrypted values while users without those roles see encrypted ones. Alternatively, you can create an access policy that masks unencrypted data stored in the database when queried by users who lack a specific role.

Users do not explicitly call the SecureData integration functions when you create access policies to automatically encrypt and decrypt data. However, they still must have access to the SecureData functions and have any necessary session variables set. See [Configuring access to SecureData](#) and [Granting users access to the Voltage SecureData integration functions](#) for the necessary configuration for the access policies to work. If a user who does not have access to the SecureData integration functions queries a table with an access policy that calls these functions, the query generates an error.

Automatically decrypting table columns for privileged users

To decrypt an encrypted column automatically, create an access policy for the encrypted column that calls [VoltageSecureAccess](#) if the user has a role enabled. If the user does not have the role enabled, just return the encrypted value.

The following example:

1. Creates a role named see_ssn and grants it to the user named Alice, as well as granting Alice access to the customers table.
2. Creates an access policy on the customers table's ssn column that decrypts the column's value if the user has the see_ssn role enabled.
3. Switches to the user named Alice.
4. Queries the customers table, without the see_ssn role enabled.
5. Enables the see_ssn role and queries the table again.

```
=> CREATE ROLE see_ssn;
CREATE ROLE

=> GRANT see_ssn TO alice;
GRANT ROLE

=> GRANT ALL ON TABLE customers TO alice;
GRANT PRIVILEGE

=> CREATE ACCESS POLICY ON customers FOR COLUMN ssn
CASE
  WHEN enabled_role('see_ssn') THEN VoltageSecureAccess(ssn USING PARAMETERS format='ssn',
                                                         config_dfs_path='/voltagesecure/conf')
  ELSE ssn
END ENABLE;
CREATE ACCESS POLICY

=> \c vmart alice;
Password:
You are now connected to database "vmart" as user "alice".

=> SELECT first_name, last_name, ssn FROM customers WHERE id < 5355 ORDER BY id ASC;
first_name | last_name | ssn
-----+-----+-----
Gil      | Reeves   | 997-92-0657
Robert   | Moran    | 715-02-0455
Hall     | Rice    | 938-83-0659
Micah    | Trevino  | 495-57-0860
(4 rows)

=> SET ROLE see_ssn;
SET
=> SELECT first_name, last_name, ssn FROM customers WHERE id < 5355 ORDER BY id ASC;
first_name | last_name | ssn
-----+-----+-----
Gil      | Reeves   | 232-28-0657
Robert   | Moran    | 725-79-0455
Hall     | Rice    | 285-90-0659
Micah    | Trevino  | 853-60-0860
(4 rows)
```

In the above example, you could combine the `see_ssn` role with a role that grants users access to the SecureData integration functions. Users who do not have the `see_ssn` role do not need to have access to the SecureData functions in order to see the encrypted values.

Note

The above example assumes that the shared configuration file (`/voltagesecure/conf`) contains all of the credentials necessary to authenticate with the SecureData Appliance, including the password or shared secret. This configuration may not be secure enough to meet your requirements. See the caution in [VoltageSecureConfigure](#) for more information. In production use, consider having each privileged user set their identity, username, and password or shared secret in session variables. Unprivileged users do not need to set these values.

Automatically encrypting columns for unprivileged users

You can also create access policies that encrypt values. Use this technique to prevent some users from seeing values in columns that aren't sensitive enough to require encryption in the database, but should not be seen by all users. This technique is the opposite of the encryption-on-the-fly: users that have a specific role enabled get the value from the table; if they do not have the role, the access policy encrypts the value.

The following example:

1. Creates a role named `see_dob` and assigns it to the user Alice.
2. Creates an access policy on the `dob` column of the `customers` table. It returns the value in the column if the user has the `see_dob` role active and encrypts the value if not.
3. Switches to the user named Alice.
4. Queries the `customers` table including the `dob` column.
5. Sets the `see_dob` role and queries `customers` again.

```

=> CREATE ROLE see_dob;
CREATE ROLE

=> GRANT see_dob TO alice;
GRANT ROLE

=> CREATE ACCESS POLICY ON customers FOR COLUMN dob
CASE
  WHEN enabled_role('see_dob') THEN dob
  ELSE VoltageSecureProtect(dob::varchar USING PARAMETERS format='birthday',
                             config_dfs_path='/voltagesecure/conf')::date
END ENABLE;
CREATE ACCESS POLICY

=> \c vmart alice
Password:
You are now connected to database "vmart" as user "alice".

=> SELECT first_name, last_name, dob FROM customers ORDER BY id ASC LIMIT 10;
first_name | last_name | dob
-----+-----+-----
Gil      | Reeves   | 2048-08-09
Robert   | Moran    | 1917-03-05
Hall     | Rice     | 2022-01-07
Micah    | Trevino  | 2018-06-01
Kuame    | Stephenson | 2053-02-13
Hedda    | Cooper   | 2002-03-12
MacKenzie | Burks    | 2061-10-30
Anne     | Marquez  | 2078-08-02
Dominic  | Avery    | 1940-08-10
Alfreda  | Mcdaniel | 1904-04-27
(10 rows)

=> SET ROLE see_dob;
SET

=> SELECT first_name, last_name, dob FROM customers ORDER BY id ASC LIMIT 10;
first_name | last_name | dob
-----+-----+-----
Gil      | Reeves   | 1955-11-04
Robert   | Moran    | 1991-12-01
Hall     | Rice     | 1977-07-07
Micah    | Trevino  | 1980-12-05
Kuame    | Stephenson | 1979-09-12
Hedda    | Cooper   | 1987-05-02
MacKenzie | Burks    | 1982-11-07
Anne     | Marquez  | 1949-07-09
Dominic  | Avery    | 1976-12-02
Alfreda  | Mcdaniel | 1975-02-08
(10 rows)

```

Note

The values you pass to `VoltageSecureProtect` and `VoltageSecureAccess` must be `VARCHARs`. In the previous example, the `dob` column's data type is `DATE`, so its value has to be cast to `VARCHAR` when passed to `VoltageSecureProtect`. The encrypted value has to be cast back to a `DATE` value because its output needs to match the table schema.

In the previous example, users who do not have the `see_dob` role enabled must have access to the `SecureData` functions in order to see the masked values. If they do not have access to the `SecureData` functions, querying the `customers` table results in an error message. The following example creates a new user named `Bob` and grants him access to the `customers` table, without any access to the `SecureData` functions.

```

=> CREATE USER bob;
CREATE USER
=> GRANT ALL ON TABLE customers TO bob;
GRANT PRIVILEGE
=> \c vmart bob
You are now connected to database "vmart" as user "bob".
=> SELECT * FROM customers LIMIT 10;
ERROR 6482: Failed to parse Access Policies for table "customers"
[Function public.VoltageSecureProtect(varchar) does not exist, or permission
is denied for public.VoltageSecureProtect(varchar)]

```

Querying eFPE encrypted columns

You can use a feature in Voltage SecureData called Embedded Format Preserving Encryption to encrypt your data. You choose to use eFPE when you define the format in your SecureData Appliance. This format is slightly different than the standard FPE format. It uses key rotation, and embeds identification information in the encrypted value. Due to these factors, calls to [VoltageSecureProtect](#) using an eFPE format may not result in the same encrypted value, depending on key rotation schedules and the identity of the caller. This feature makes querying columns encrypted using an eFPE format more challenging.

When you want to search a standard FPE encrypted column for a value, you can just encrypt the plain text with `VoltageSecureProtect` and use the output in your query. For example, suppose you want to search for the customers table for an entry with the social security number 559-32-0670. Then you could use the following query:

```

=> SELECT id, first_name, last_name FROM customers
      WHERE ssn = VoltageSecureProtect('559-32-0670' USING PARAMETERS
                                     format='ssn',
                                     config_dfs_path='voltage.conf');

```

```

id | first_name | last_name
-----+-----
5345 | Thane      | Ross
(1 row)

```

Querying a column that uses eFPE format encryption is not as simple, as you do not know which embedded key was used to encrypt the data. You could just use the `VoltageSecureAccess` function to decrypt the entire contents of the table column and search the result for the value you need. However, this is inefficient, as the SecureData function has to be called for every row of data in the table.

A better solution is to use the [VoltageSecureProtectAllKeys](#) function. This function is similar to `VoltageSecureProtect`. However, instead of returning a single encrypted value, it returns a table containing the value encrypted with each of the keys defined for the eFPE format.

```

=> SELECT VoltageSecureProtectAllKeys('376765616314013' USING PARAMETERS
                                     format='cc_num',
                                     config_dfs_path='/voltagesecure/conf')
      OVER ();

```

```

data | protected
-----+-----
376765616314013 | XMVMRU9RJVU4013
376765616314013 | X5FD4KO1UEE4013
376765616314013 | M7ZXTIQVCPB4013
376765616314013 | UBOSC9K3EXZ4013
376765616314013 | ZJ1C50C9L9R4013
(5 rows)

```

In the previous example, the `cc_num` column is encrypted using an eFPE format. The output from `VoltageSecureProtectAllKeys` shows that this eFPE format has 5 keys defined. The content of the protected column contains the same value encrypted with each of the keys.

To use this function in a query for a value in an eFPE column, use a [JOIN](#) on the table you are searching and the result table from `VoltageSecureProtectAllKeys`. The following example demonstrates querying the customers table to find all rows that have a `cc_num` value that matches the unencrypted credit card value 376765616314013.

```
=> SELECT id, first_name, last_name FROM customers3 u
      JOIN (SELECT VoltageSecureProtectAllKeys('376765616314013' USING PARAMETERS
              format='cc_num',
              config_dfs_path='/voltagesecure/conf')
            OVER ()) pak
      ON u.cc_num = pak.protected;
```

```
id | first_name | last_name
```

```
-----+-----+-----
5345 | Thane      | Ross
```

```
(1 row)
```

Voltage SecureData integration function reference

The functions in this section are part of the Vertica `voltagesecure` library for integrating with Voltage SecureData. These functions are automatically installed when you install or upgrade Vertica. However, you must re-install the `voltagesecure` library to distribute the CA certificate to all nodes in the Vertica cluster. See [Verifying the Vertica server's access to the SecureData CA certificate](#) for instructions.

In this section

- [VoltageSecureAccess](#)
- [VoltageSecureConfigure](#)
- [VoltageSecureConfigureGlobal](#)
- [VoltageSecureProtect](#)
- [VoltageSecureProtectAllKeys](#)
- [VoltageSecureRefreshPolicy](#)

VoltageSecureAccess

Calls SecureData to decrypt ciphertexts encrypted with [VoltageSecureProtect](#).

Syntax

```
VoltageSecureAccess('ciphertext' [, 'tweak'] USING PARAMETERS
                    format='format_name'
                    [, mask=is_masked]
                    [, config_dfs_path='config_file']
                    [, identity=sd_identity]);
```

Parameters

<i>ciphertext</i>	A VARCHAR value that was encrypted using SecureData. You must cast other data types (for example DATE values) to VARCHAR when calling this function.
<i>tweak</i>	<p>VARCHAR value analogous to a salt that allows equivalent * <i>plaintext</i> *s to produce different ciphertexts. The same <i>tweak</i> value must for encryption and decryption of a given plaintext.</p> <p>When encrypting or hashing an entire column, you can pass another column for a set of <i>tweak</i> values.</p> <div style="background-color: #ffe6e6; padding: 10px; margin-top: 10px;"> <p>Caution Never use two columns as tweak values for each other or else the original plaintext for both columns will be unrecoverable.</p> </div>
<i>format_name</i>	A string specifying the original FPE format used to generate the ciphertext. Note that SecureData has no way to tell if the value passed to it was actually encrypted or not, or what FPE format was used.

<i>is_masked</i>	A boolean, whether to mask the value when decrypting the <i>ciphertext</i> . Masking is defined on a per-format basis on the SecureData Appliance. Note that since masking is optional, you must specify whether to decrypt with masking enabled. If you omit the masking parameter, the plaintext will be unmasked by default:
<i>config_file</i>	String containing the file name of the configuration file to use when authenticating with the SecureData appliance. You must create this file using VoltageSecureConfigure. If you do not supply this parameter, you must set session parameters to configure access to SecureData. See Configuring access to SecureData . Any values set in session parameters override the values in this file.
<i>sd_identity</i>	A string containing the identity to use when decrypting the data. Because SecureData uses the identity to determine encryption keys, this identity must match the identity used to encrypt the data. If supplied, this value overrides any identity value set in the configuration file or session parameter.

Examples

The following example decrypts a Social Security Number (SSN) originally encrypted with a predefined format.

```
=> SELECT VoltageSecureAccess('376-69-6789' USING PARAMETERS format='ssn');

VoltageSecureAccess
-----
123-45-6789
(1 row)
```

This example demonstrates decrypting an encrypted column within a query.

```
=> SELECT id,
       first_name,
       last_name,
       VoltageSecureAccess(ssn USING PARAMETERS format='ssn',
                           config_dfs_path='/voltagesecure/conf') AS ssn,
       dob
FROM customers
WHERE dob < '1970-1-1'
ORDER BY id ASC
LIMIT 10;

id | first_name | last_name | ssn | dob
-----+-----+-----+-----+-----
5346 | Talon | Wilkins | 540-48-0784 | 1941-09-17
5347 | Daquan | Phelps | 785-34-0092 | 1963-05-08
5348 | Basia | Lopez | 011-85-0705 | 1940-04-29
5349 | Kaseem | Hendrix | 672-57-0309 | 1942-03-11
5350 | Omar | Lott | 825-45-0131 | 1956-02-17
5352 | Illana | Middleton | 831-47-0929 | 1949-12-29
5353 | Garrett | Williamson | 408-73-0207 | 1955-11-06
5354 | Hanna | Ware | 694-97-0394 | 1967-08-08
5355 | Quinn | Pruitt | 818-91-0359 | 1965-11-14
5356 | Clayton | Santiago | 102-56-0010 | 1958-02-02
(10 rows)
```

The following example decrypts Unicode using a predefined format. For a full list of predefined formats, consult the Voltage SecureData documentation.

```
=> SELECT VoltageSecureAccess('607-0d1cç-ふてびねら' using parameters format='PREDEFINED::JU_AUTO_TYPE');
```

```
VoltageSecureAccess
```

```
-----  
123-Hello-こんにちは
```

Decrypt a SSN ciphertext with the original FPE format and tweak value:

```
=> SELECT VoltageSecureAccess('721-21-2913', 'tweakvalue123' USING PARAMETERS  
        format='ssn-tweak',  
        config_dfs_path='voltage.conf');
```

```
VoltageSecureProtect
```

```
-----  
681-09-2913
```

Decrypt a ciphertext that was encrypted with a masking format. This format obscures all but the last two characters of the decrypted plaintext.

```
=> SELECT VoltageSecureAccess('g3kxb6ru19', USING PARAMETERS  
        format='maskedFormat',  
        config_dfs_path='voltage.conf');
```

```
VoltageSecureAccess
```

```
-----  
1234567890
```

```
=> SELECT VoltageSecureAccess('g3kxb6ru19', USING PARAMETERS  
        format='maskedFormat',  
        config_dfs_path='voltage.conf',  
        mask=true);
```

```
VoltageSecureAccess
```

```
-----  
XXXXXXXXX90
```

- [Best practices for safe unicode FPE](#)

VoltageSecureConfigure

Saves SecureData user access configuration parameters to a file in the Vertica Distributed File System (DFS). You then pass the file's name to the other SecureData integration functions. This function can store the configuration file in the user's own DFS directory or in a globally-accessible file named [/voltagesecure/conf](#).

Syntax

```
VoltageSecureConfigure(USING PARAMETERS config_dfs_path='filename'  
        [, identity=sd_identity]  
        [, store_password=Boolean]  
        [, store_shared_secret=Boolean]  
        [, username=sd_user]  
        ) OVER ();
```

Parameters

<code>config_dfs_path = 'filename'</code>	<p>Required. A string containing the path for the configuration file in DFS. This is either:</p> <ul style="list-style-type: none"> A file name (without any path information). The function automatically stores the file in a DFS directory named for the user. Creating this directory prevents different user's files from overwriting one another. The absolute path <code>/voltagesecure/conf</code>. All users can use this file in calls to the other functions in the SecureData library. This path is the only absolute one that VoltageSecureConfigure allows for this parameter.
<code>identity= sd_boolean</code>	A string containing identity to use with the SecureData Appliance. This is usually in the form of an email address. When SecureData uses LDAP authentication, it uses this value to authenticate the user.
<code>store_password= Boolean</code>	A Boolean value. When set to true, Vertica stores the LDAP password stored in the password session parameter in the configuration file. Defaults to false.
<code>store_shared_secret= Boolean</code>	A Boolean value. When set to true, Vertica stores the shared secret set in the shared_secret session parameter in the configuration file. Defaults to false.
<code>username= sd_user</code>	A string containing the user name for authenticating with SecureData.

Notes

- Any SecureData session variables that are set override values from the configuration file. See [Configuring access to SecureData](#) for more information.
- The SecureData integration only supports one configuration for the SecureData Appliance at a time.
- Under normal circumstances, users are not able to directly read data from files stored in DFS. However, all users who have access to UDX functions that read from the DFS could access these files from within Vertica. In addition, these files are stored as plain text in every node's file system. Anyone with the proper file system access on the nodes can read the file's contents. You should take both of these facts into consideration when deciding whether to store sensitive information such as passwords or shared secrets in either the shared or per-user configuration files.

Example

The following example demonstrates saving configuration information to a configuration file named `voltage.conf` in the user's own Vertica DFS directory.

```
=> \x
Expanded display is on.
=> SELECT VoltageSecureConfigure(USING PARAMETERS config_dfs_path='voltage.conf',
                                username='alice', identity='alice@example.com', store_password=false
                                ) OVER ();
-[ RECORD 1 ]-----+-----
config_dfs_path | voltage.conf
identity        | alice@example.com
username        | alice
```

VoltageSecureConfigureGlobal

Saves global SecureData access configuration parameters for all users to a file in the Vertica Distributed File System (DFS). This function stores the configuration file named `/voltagesecure/conf.global` in the distributed file system (DFS). You must use this function to configure at least the SecureData policy URL before you can use any of the other Voltage SecureData integration functions.

To refresh the client policy, see [VoltageSecureRefreshPolicy](#).

Syntax

```
VoltageSecureConfigureGlobal(USING PARAMETERS policy_url=url
                             [, allow_short_fpe=Boolean]
                             [, allow_file_cache=Boolean]
                             [, network_timeout=Integer]
                             ) OVER ();
```

Parameters

<i>policy_url= url</i>	A string containing the URL of the SecureData policy file. The Vertica SecureData library uses the contents of this file, such as the formats that the SecureData Appliance supports. It also uses the URL of this file to determine the location of the SecureData Appliance.
<i>allow_short_fpe= Boolean</i>	A Boolean value. When set to True, SecureData ignores the lower length limit for encoding FPE values. Usually, SecureData does not use FPE to encrypt data shorter than a lower limit (usually, 8 bits). See the <i>SecureData Architecture Guide</i> 's section on Data Length Restrictions for more information.
<i>enable_file_cache= Boolean</i>	A Boolean value. When set to True, Vertica caches the SecureData policy file and encryption keys to disk, rather than just to memory. Defaults to false.
<i>network_timeout= Integer</i>	An Integer value. Configures the network timeout in seconds. Defaults to its maximum value of 300 seconds.

Example
 To set the policy URL to <https://voltage-pp-0000.example.com/policy/clientPolicy.xml> and set the network timeout to 200 seconds:

```
=> SELECT VoltageSecureConfigureGlobal(USING PARAMETERS
      policy_url='https://voltage-pp-0000.example.com/policy/clientPolicy.xml',
      NETWORK_TIMEOUT=200)
      OVER ();
```

policy_url	allow_short_fpe	enable_file_cache	network_timeout
https://voltage-pp-0000.example.com/policy/clientPolicy.xml			200

(1 row)

To view the current policy:

```
=> SELECT VoltageSecureConfigureGlobal() OVER();
```

policy_url	allow_short_fpe	enable_file_cache	network_timeout
https://voltage-pp-0000.example.com/policy/clientPolicy.xml			200

(1 row)

Manually refresh the client policy across the nodes:

```
=> SELECT VoltageSecureRefreshPolicy() OVER ();
```

PolicyRefresh

Successfully refreshed policy on node [v_sandbox_node0001]. Policy on other nodes will be refreshed the next time a Voltage operation is run on them.

(1 row)

VoltageSecureProtect

Calls SecureData to encrypt or hash a value while preserving the structure of the original plaintext.

Syntax

```
VoltageSecureProtect('plaintext' [, 'tweak'] USING PARAMETERS
      format='format_name'
      [, config_dfs_path='config_file']
      [, identity=sd_identity]);
```

Parameters

<i>plaintext</i>	VARCHAR value to encrypt. You must cast other data types (for example DATE values) to VARCHAR when calling this function. NULL values return NULL.
------------------	---

<i>tweak</i>	<p>VARCHAR value analogous to a salt that allows equivalent * <i>plaintext</i> *s to produce different ciphertexts. The same <i>tweak</i> value must for encryption and decryption of a given plaintext.</p> <p>When encrypting or hashing an entire column, you can pass another column for a set of <i>tweak</i> values.</p> <div style="background-color: #ffe6e6; padding: 10px; margin-top: 10px;"> <p>Caution Never use two columns as tweak values for each other or else the original plaintext for both columns will be unrecoverable.</p> </div>
<i>format_name</i>	<p>String specifying a format-preserving encryption (FPE) or format-preserving hash (FPH) format to encrypt or hash the <i>plaintext</i>.</p> <p>To encrypt your data, pass an FPE format defined in your SecureData Appliance.</p> <p>To hash your data, pass an FPH format defined in your SecureData Appliance (version 6.6+). Note that hashing operations are one-way and cannot be reversed with VoltageSecureAccess.</p> <div style="background-color: #ffe6e6; padding: 10px; margin-top: 10px;"> <p>Caution Always use the same FPE format to encrypt data in a column. If you use different FPE formats in the same column (such as loading some data using <i>ssn</i> and other data using <i>auto</i>) there is no way to tell which format was used for any particular row, and properly and improperly encrypted ciphertexts will be indistinguishable.</p> </div>
<i>config_file</i>	<p>String containing the file name of the configuration file to use when authenticating with the SecureData appliance. You must create this file using VoltageSecureConfigure. If you do not supply this parameter, you must set session parameters to configure access to SecureData. See Configuring access to SecureData. Any values set in session parameters override the values in this file.</p>
<i>sd_identity</i>	<p>String containing the identity to use when authenticating with SecureData. SecureData uses this value as a basis for the encryption key. This value usually takes the form of an email address. If supplied, it overrides any values set in the configuration file or session parameters.</p>

Examples

Encrypt a social security number (SSN) value using both the *ssn* and *auto* FPE formats (this example assumes that all of the necessary SecureData authentication information has been set in session variables):

```
=> SELECT VoltageSecureProtect('123-45-6789' USING PARAMETERS format='ssn');
VoltageSecureProtect
-----
376-69-6789
(1 row)

=> SELECT VoltageSecureProtect('123-45-6789' USING PARAMETERS format='auto');
VoltageSecureProtect
-----
820-31-5110
(1 row)
```

Encrypt two table columns in a COPY statement, authenticating to the SecureData Appliance with the user's private configuration file saved in DFS:

```
=> COPY customers (id, first_name, last_name, ssn_raw FILLER VARCHAR(11),
    cc_num_raw FILLER VARCHAR(25), cvv, dob,
    ssn AS VoltageSecureProtect(ssn_raw USING PARAMETERS
        format='ssn',
        config_dfs_path='voltage.conf'),
    cc_num AS VoltageSecureProtect(cc_num_raw USING PARAMETERS
        format='cc',
        config_dfs_path='voltage.conf'))
FROM '/home/dbadmin/customer_data.csv' DELIMITER ',';
```

Rows Loaded

```
-----
      100
(1 row)
```

Query for a particular value in an encrypted column:

```
=> SELECT id, first_name, last_name FROM customers
    WHERE ssn = VoltageSecureProtect('559-32-0670' USING PARAMETERS
        format='ssn',
        config_dfs_path='voltage.conf');
```

```
id | first_name | last_name
-----+-----+-----
5345 | Thane      | Ross
(1 row)
```

Encrypting NULL values returns NULL:

```
=> CREATE TABLE nulltable(n VARCHAR (20));
=> INSERT INTO nulltable VALUES (NULL);

=> SELECT VoltageSecureProtect(n USING PARAMETERS format='auto') FROM nulltable;
```

```
VoltageSecureProtect
-----
(1 row)
```

Encrypt a Unicode string using a predefined format. For a full list of predefined formats, consult the Voltage SecureData documentation.

```
=> SELECT VoltageSecureProtect('123-Hello-こんにちは' USING PARAMETERS format='PREDEFINED::JU_AUTO_TYPE');
```

```
VoltageSecureProtect
-----
607-Ôdiçç-ぶてびねら
```

Encrypt a SSN with a tweak value:

```
=> SELECT VoltageSecureProtect('681-09-2913', 'tweakvalue123' USING PARAMETERS
    format='ssn-tweak');
```

```
VoltageSecureProtect
-----
721-21-2913
```

```
=> SELECT VoltageSecureAccess('721-21-2913', 'tweakvalue123' USING PARAMETERS
    format='ssn-tweak');
```

```
VoltageSecureProtect
-----
681-09-2913
```

Hash a SSN with a FPH format and a tweak value:

```
=> SELECT VoltageSecureProtect('681-09-2913', 'tweakvalue123' USING PARAMETERS
        format='ssnHash',
        config_dfs_path='voltage.conf');
VoltageSecureProtect
-----
841-68-2913
```

VoltageSecureProtectAllKeys

This function helps you locate values in a column encrypted using an Embedded Format Preserving Encryption (eFPE) format. These formats use key rotation, so the encrypted value you get back for a piece of plain text changes over time. You pass this function an unencrypted value. It returns a table consisting of two columns: the unencrypted value and the value encrypted with each of the keys defined for the eFPE. The number of rows in the table are determined by the number of keys the eFPE format contains. Usually, you use the output of this function in a join to locate a matching encrypted value in a table.

Syntax

```
VoltageSecureProtectAllKeys(value USING PARAMETERS format='eFPE_format'
        [, config_dfs_path=config_file]
        [, identity=sd_identity])
```

Parameters

<i>value</i>	VARCHAR containing the value to encrypt. You must cast other data types (for example DATE values) to VARCHAR when calling this function.
<i>format=</i> <i>eFPE_format</i>	String containing the name of an eFPE format defined by SecureData. This format must be an eFPE format defined by your SecureData Appliance, or the function returns an error. This format must also match the format of value. VoltageSecureProtectAllKeys returns an error if <i>value</i> 's format does not match the one you specify in <i>eFPE_format</i> .
<i>config_dfs_path=</i> <i>config_file</i>	String containing the file name of the configuration file to use when authenticating with the SecureData appliance. You must create this file using VoltageSecureConfigure. If you do not supply this parameter, you must set session parameters to configure access to SecureData. See Configuring access to SecureData . Any values set in session parameters override the values in this file.
<i>identity=</i> <i>sd_identity</i>	String containing the identity to use when authenticating with SecureData. SecureData uses this value as a basis for the encryption key. This value usually takes the form of an email address. If supplied, it overrides any values set in the configuration file or session parameters.

Examples

The following example demonstrates a simple call to VoltageSecureProtectAllKeys.

```
=> SELECT VoltageSecureProtectAllKeys('376765616314013' USING PARAMETERS
        format='cc_num',
        config_dfs_path='/voltagesecure/conf')
OVER ();

data | protected
-----+-----
376765616314013 | XMVMRU9RJVU4013
376765616314013 | X5FD4KO1UEE4013
376765616314013 | M7ZXTIQVCPB4013
376765616314013 | UBOSC9K3EXZ4013
376765616314013 | ZJ1C50C9L9R4013
(5 rows)
```

In this example, the cc_num eFPE format has five keys defined for it, so the return value is a table containing five rows.

The following example shows a more common use: querying a table column that is encrypted using an eFPE format.

```
=> SELECT id, first_name, last_name FROM customers3 u
JOIN (SELECT VoltageSecureProtectAllKeys('376765616314013' USING PARAMETERS
        format='cc_num',
        config_dfs_path='/voltagesecure/conf')
OVER ()) pak
ON u.cc_num = pak.protected;

id | first_name | last_name
-----+-----
5345 | Thane | Ross
(1 row)
```

In the previous example, the customers3 table is joined to the output from VoltageSecureProtectAllKeys. Any rows in the customers3 table where the encrypted cc_num column value matches values from the protected column of VoltageSecureProtectAllKeys matches appear in the output.

This function returns an error if you use it on a non-eFPE format:

```
=> SELECT first_name, last_name, ssn FROM customers u
JOIN (
SELECT VoltageSecureProtectAllKeys('232-28-0657' USING PARAMETERS format='ssn',
        config_dfs_path='/voltagesecure/conf')
OVER ()
)
pak ON u.ssn = pak.protected;
ERROR 5861: Error calling processPartition() in User Function VoltageSecureProtectAllKeys
at [ProtectAllKeys.cpp:21], error code: 1711, message: Error getting key numbers:
eFPE format required
```

VoltageSecureRefreshPolicy

Immediately refreshes the client policy on the initiator node. Policies on non-initiator nodes are refreshed the next time a Voltage function is called on them.

Syntax

```
VoltageSecureRefreshPolicy()
```

Parameters

None

Example

Manually refresh the client policy across the nodes:

```
=> SELECT VoltageSecureRefreshPolicy() OVER ();
      PolicyRefresh
```

Successfully refreshed policy on node [v_sandbox_node0001]. Policy on other nodes will be refreshed the next time a Voltage operation is run on them.

(1 row)

SQL reference

Vertica offers a robust set of SQL elements that allow you to manage and analyze massive volumes of data quickly and reliably, including:

- [Language elements](#) such as keywords, operators, expressions, predicates, and hints
- [Data types](#) including complex types
- [Functions](#) including Vertica-specific functions that take advantage of Vertica's unique column-store architecture
- [SQL statements](#) that let you write robust queries to quickly return large volumes of data

In this section

- [System limits](#)
- [Language elements](#)
- [Data types](#)
- [Configuration parameters](#)
- [File systems and object stores](#)
- [Functions](#)
- [Statements](#)
- [Vertica system tables](#)

System limits

This section describes system limits on the size and number of objects in a Vertica database. In most cases, computer memory and disk drive are the limiting factors.

Item	Maximum
Nodes	128 (without Vertica assistance)
Database size	Dependent on maximum disk configuration, approximately: <i>numFiles * platformFileSize</i>
Table size	Smaller of: <ul style="list-style-type: none">• 2^{64} rows per node• 2^{63} bytes per column
Row size	$(2^{31}) - 1$ Row size is approximately the sum of its maximum column sizes. For example, a VARCHAR(80) has a maximum size of 80 bytes.
Key size	Dependent on row size

Tables/projections per database	Dependent on physical RAM, as the catalog must fit in memory.
Concurrent connections per node	Dependent on physical RAM (or threads per process), typically 1024 Default: 50
Concurrent connections per cluster	Dependent on physical RAM of a single node (or threads per process), typically 1024
Columns per table/view	9800
Arguments per function call	9800
Rows per load	2^{63}
ROS containers per projection	1024 See Minimizing partitions .
Length of fixed-length column	65000 bytes
Length of variable-length column	32 MB
Length of basic names	128 bytes. Basic names include table names, column names, etc.
Query length	None
Depth of nesting subqueries	None in FROM , WHERE , and HAVING clauses

Language elements

The following topics provide detailed descriptions of the language elements and conventions of Vertica SQL.

In this section

- [Keywords](#)
- [Identifiers](#)
- [Literals](#)
- [Operators](#)
- [Expressions](#)
- [Lambda functions](#)
- [Predicates](#)
- [Hints](#)
- [Window clauses](#)

Keywords

Keywords are words that have a specific meaning in the SQL language. Every SQL statement contains one or more keywords. Although SQL is not case-sensitive with respect to keywords, they are generally shown in uppercase letters throughout this documentation for readability purposes.

Note

If you use a keyword as the name of an identifier or an alias in your SQL statements, you may have to qualify the keyword with **AS** or double-quotes. Vertica requires **AS** or double-quotes for certain reserved and non-reserved words to prevent confusion with expression syntax, or where the use of a word would be ambiguous.

Many keywords are also reserved words.

Vertica recommends that you not use reserved words as names for objects, or as identifiers. Including reserved words can make your SQL statements confusing. Reserved words that are used as names for objects or identifiers must be enclosed in double-quotes.

Note

All reserved words are also keywords, but Vertica can add reserved words that are not keywords. A reserved word can simply be a word that is reserved for future use.

Non-reserved keywords

Non-reserved keywords have a special meaning in some contexts, but can be used as identifiers in others. You can use non-reserved keywords as aliases—for example, **SOURCE** :

```
=> SELECT my_node AS SOURCE FROM nodes;
```

Note

Vertica uses several non-reserved keywords in [directed queries](#) to specify special join types. You can use these keywords as table aliases only if they are double-quoted; otherwise, double-quotes can be omitted:

- **ANTI**
- **NULLAWARE**
- **SEMI**
- **SEMIALL**
- **UNI**

Viewing the list of reserved and non-reserved keywords

To view the current list of Vertica reserved and non-reserved words, query system table [KEYWORDS](#). Vertica lists keywords alphabetically and identifies them as reserved (R) or non-reserved (N).

For example, the following query gets all reserved keywords that begin with B:

```
=> SELECT * FROM keywords WHERE reserved = 'R' AND keyword ilike 'B%';
```

```
keyword | reserved
```

```
-----+-----  
BETWEEN | R  
BIGINT  | R  
BINARY  | R  
BIT     | R  
BOOLEAN | R  
BOTH    | R  
(6 rows)
```

Identifiers

Identifiers (names) of objects such as schema, table, projection, column names, and so on, can be up to 128 bytes in length.

Unquoted identifiers

Unquoted SQL identifiers must begin with one of the following:

- Non-Unicode letters: A–Z or a–z
- Underscore (`_`)

Subsequent characters in an identifier can be any combination of the following:

- Non-Unicode letters: A–Z or a–z
- Underscore (`_`)
- Digits(0–9)
- Unicode letters (letters with diacriticals or not in the Latin alphabet), unsupported for model names
- Dollar sign (`$`), unsupported for model names

Caution

The SQL standard does not support dollar sign in identifiers, so usage can cause application portability problems.

Quoted identifiers

Note

Quoted identifiers are not supported for model names

Identifiers enclosed in double quote (") characters can contain any character. If you want to include a double quote, you need a pair of them; for example """". You can use names that would otherwise be invalid—for example, names that include only numeric characters ("123") or contain space characters, punctuation marks, and SQL or [Vertica-reserved](#) keywords. For example:

```
CREATE SEQUENCE "my sequence!";
```

Double quotes are required for non-alphanumerics and SQL keywords such as "1time", "Next week" and "Select".

Case sensitivity

Identifiers are not case-sensitive. Thus, identifiers "ABC", "ABc", and "aBc" are synonymous, as are ABC, ABc, and aBc.

Non-ASCII characters

Vertica accepts non-ASCII UTF-8 Unicode characters for table names, column names, and other identifiers, extending the cases where upper/lower case distinctions are ignored (case-folded) to all alphabets, including Latin, Cyrillic, and Greek.

For example, the following [CREATE TABLE](#) statement uses the ß (German eszett) in the table name:

```
=> CREATE TABLE straÙe(x int, y int);
CREATE TABLE
```

Identifiers are stored as created

SQL identifiers, such as table and column names, are not converted to lowercase. They are stored as created, and references to them are resolved using case-insensitive compares. For example, the following statement creates table ALLCAPS .

```
=> CREATE TABLE ALLCAPS(c1 varchar(30));
=> INSERT INTO ALLCAPS values('upper case');
```

The following statements are variations of the same query:

```
=> SELECT * FROM ALLCAPS;
=> SELECT * FROM allcaps;
=> SELECT * FROM "allcaps";
```

The three queries all return the same result:

```
c1
-----
upper case
(1 row)
```

Note that Vertica returns an error if you try to create table AllCaps :

```
=> CREATE TABLE AllCaps(c1 varchar(30));
ROLLBACK: table "AllCaps" already exists
```

See [QUOTE_IDENT](#) for additional information.

Literals

Literals are numbers or strings used in SQL as constants. Literals are included in the select-list, along with expressions and built-in functions and can also be constants.

Vertica provides support for number-type literals (integers and numerics), string literals, VARBINARY string literals, and date/time literals. The various

string literal formats are discussed in this section.

In this section

- [Number-type literals](#)
- [String literals](#)
- [Date/time literals](#)

Number-type literals

Vertica supports three types of numbers: integers, numerics, and floats.

- [Integers](#) are whole numbers less than 2^{63} and must be digits.
- [Numerics](#) are whole numbers larger than 2^{63} or that include a decimal point with a precision and a scale. Numerics can contain exponents. Numbers that begin with 0x are hexadecimal numerics.

Numeric-type values can also be generated using casts from character strings. This is a more general syntax. See the Examples section below, as well as [Data type coercion operators \(CAST\)](#).

Syntax

```
digits
digits.[digits] | [digits].digits
digits e[+]-digits | [digits].digits e[+]-digits | digits.[digits] e[+]-digits
```

Parameters

digits

One or more numeric characters, 0 through 9

e

Exponent marker

Notes

- At least one digit must follow the exponent marker (**e**), if **e** is present.
- There cannot be any spaces or other characters embedded in the constant.
- Leading plus (+) or minus (-) signs are not considered part of the constant; they are unary operators applied to the constant.
- In most cases a numeric-type constant is automatically coerced to the most appropriate type depending on context. When necessary, you can force a numeric value to be interpreted as a specific data type by casting it as described in [Data type coercion operators \(CAST\)](#).
- Floating point literals are not supported. If you specifically need to specify a float, you can cast as described in [Data type coercion operators \(CAST\)](#).
- Vertica follows the IEEE specification for floating point, including NaN (not a number) and Infinity (Inf).
- A NaN is not greater than and at the same time not less than anything, even itself. In other words, comparisons always return false whenever a NaN is involved.
- Dividing INTEGERS (x / y) yields a NUMERIC result. You can use the // operator to truncate the result to a whole number.

Examples

The following are examples of number-type literals:

```
42
3.5
4.
.001
5e2
1.925e-3
```

Scientific notation :

```
=> SELECT NUMERIC '1e10';
?column?
-----
10000000000
(1 row)
```

BINARY scaling :

```
=> SELECT NUMERIC '1p10';  
?column?
```

```
-----  
1024
```

```
(1 row)
```

```
=> SELECT FLOAT 'Infinity';
```

```
?column?
```

```
-----  
Infinity
```

```
(1 row)
```

The following examples illustrated using the / and // operators to divide integers:

```
=> SELECT 40/25;
```

```
?column?
```

```
-----  
1.60000000000000000000
```

```
(1 row)
```

```
=> SELECT 40//25;
```

```
?column?
```

```
-----  
1
```

```
(1 row)
```

See also

[Data type coercion](#)

String literals

String literals are string values surrounded by single or double quotes. Double-quoted strings are subject to the backslash, but single-quoted strings do not require a backslash, except for `\` and `\\`.

You can embed single quotes and backslashes into single-quoted strings.

To include other backslash (escape) sequences, such as `\t` (tab), you must use the double-quoted form.

Precede single-quoted strings with a space between the string and its preceding word, since single quotes are allowed in identifiers.

See also

- [SET STANDARD_CONFORMING_STRINGS](#)
- [SET ESCAPE_STRING_WARNING](#)
- [Internationalization parameters](#)
- [Implement locales for international data sets](#)

In this section

- [Character string literals](#)
- [Dollar-quoted string literals](#)
- [Unicode string literals](#)
- [VARBINARY string literals](#)
- [Extended string literals](#)

Character string literals

Character string literals are a sequence of characters from a predefined character set, enclosed by single quotes.

Syntax

```
'character-seq'
```

Parameters

character-seq

Arbitrary sequence of characters

Embedded single quotes

If a character string literal includes a single quote, it must be doubled. For example:

```
=> SELECT 'Chester's gorilla';
?column?
```

```
-----
Chester's gorilla
(1 row)
```

Standard-conforming strings and escape characters

Vertica uses standard-conforming strings as specified in the SQL standard, so backslashes are treated as string literals and not escape characters.

Note

Earlier versions of Vertica did not use standard conforming strings, and backslashes were always considered escape sequences. To revert to this older behavior, set the configuration parameter [StandardConformingStrings](#) to 0. You can also use the [EscapeStringWarning](#) parameter to locate back slashes which have been incorporated into string literals, in order to remove them.

Examples

```
=> SELECT 'This is a string';
?column?
```

```
-----
This is a string
(1 row)
```

```
=> SELECT 'This \is a string';
```

```
WARNING: nonstandard use of escape in a string literal at character 8
```

```
HINT: Use the escape string syntax for escapes, e.g., E'\n'.
```

```
?column?
```

```
-----
This is a string
(1 row)
```

```
vmartdb=> SELECT E'This \is a string';
```

```
?column?
```

```
-----
This is a string
```

```
=> SELECT E'This is a \n new line';
```

```
?column?
```

```
-----
This is a
new line
(1 row)
```

```
=> SELECT 'String"s characters';
```

```
?column?
```

```
-----
String's characters
(1 row)
```

See also

- [SET STANDARD_CONFORMING_STRINGS](#)
- [SET ESCAPE_STRING_WARNING](#)
- [Implement locales for international data sets](#)

Dollar-quoted string literals

Dollar-quoted string literals are rarely used, but are provided here for your convenience.

The standard syntax for specifying string literals can be difficult to understand. To allow more readable queries in such situations, Vertica SQL provides **dollar quoting**. Dollar quoting is not part of the SQL standard, but it is often a more convenient way to write complicated string literals than the standard-compliant single quote syntax.

Syntax

```
$$characters$$
```

Parameters

characters

Arbitrary sequence of characters bounded by paired dollar signs (\$\$)

Dollar-quoted string content is treated as a literal. Single quote, backslash, and dollar sign characters have no special meaning within a dollar-quoted string.

Notes

A dollar-quoted string that follows a keyword or identifier must be separated from the preceding word by whitespace; otherwise, the dollar-quoting delimiter is taken as part of the preceding identifier.

Examples

```
=> SELECT $$Fred's\n car$$;  
?column?
```

```
-----  
Fred's\n car  
(1 row)
```

```
=> SELECT 'SELECT 'fact';'  
ERROR: syntax error at or near "' at character 21  
LINE 1: SELECT 'SELECT 'fact';'
```

```
=> SELECT 'SELECT $$fact';$$;  
?column?
```

```
-----  
SELECT $$fact  
(1 row)
```

```
=> SELECT 'SELECT "fact";'  
?column?
```

```
-----  
SELECT 'fact';  
(1 row)
```

Unicode string literals

Syntax

```
U&'characters' [ UESCAPE '<Unicode escape character>' ]
```

Parameters

characters

Arbitrary sequence of UTF-8 characters bounded by single quotes (')

Unicode escape character

A single character from the source language character set other than a hexit, plus sign (+), quote ('), double quote ("), or white space

Using standard conforming strings

With [StandardConformingStrings](#) enabled, Vertica supports SQL standard Unicode character string literals (the character set is UTF-8 only).

Before you enter a Unicode character string literal, enable standard conforming strings in one of the following ways.

- To enable for all sessions, update the configuration parameter [StandardConformingStrings](#).
- To treat backslashes as escape characters for the current session, use the [SET STANDARD_CONFORMING_STRINGS](#) statement.

See also [Extended String Literals](#).

Examples

To enter a Unicode character in hexadecimal, such as the Russian phrase for "thank you, use the following syntax:

```
=> SET STANDARD_CONFORMING_STRINGS TO ON;
=> SELECT U&'\0441\043F\0430\0441\0438\0431\043E' as 'thank you';
thank you
-----
спасибо
(1 row)
```

To enter the German word **müde** (where **u** is really u-umlaut) in hexadecimal:

```
=> SELECT U&'m\00fcde';
?column?
-----
müde
(1 row)
=> SELECT 'ü';
?column?
-----
ü
(1 row)
```

To enter the **LINEAR B IDEOGRAM B240 WHEELED CHARIOT** in hexadecimal:

```
=> SELECT E'\xF0\x90\x83\x8C';
?column?
-----
(wheeled chariot character)
(1 row)
```

Note

Not all fonts support the wheeled chariot character.

- [Internationalization parameters](#)
- [Implement locales for international data sets](#)

VARBINARY string literals

VARBINARY string literals allow you to specify hexadecimal or binary digits in a string literal.

Syntax

```
X''
B''
```

Parameters

X or x

Specifies hexadecimal digits. The *<hexadecimal digits>* string must be enclosed in single quotes (').

B or b

Specifies binary digits. The *<binary digits>* string must be enclosed in single quotes (').

Examples

```
=> SELECT X'abcd';
?column?
```

```
-----
\253\315
(1 row)
```

```
=> SELECT B'101100';
?column?
```

```
-----
,
(1 row)
```

Extended string literals

Syntax

```
E'characters'
```

Parameters

characters

Arbitrary sequence of characters bounded by single quotes (!) You can use C-style backslash sequence in extended string literals, which are an extension to the SQL standard. You specify an extended string literal by writing the letter E as a prefix (before the opening single quote); for example:

```
E'extended character string\n'
```

Within an extended string, the backslash character (\) starts a C-style backslash sequence, in which the combination of backslash and following character or numbers represent a special byte value, as shown in the following list. Any other character following a backslash is taken literally; for example, to include a backslash character, write two backslashes (\).

- \ is a backslash
- \b is a backspace
- \f is a form feed
- \n is a newline
- \r is a carriage return
- \t is a tab
- \x##, where ## is a 1 or 2-digit hexadecimal number; for example \x07 is a tab
- \###, where ### is a 1, 2, or 3-digit octal number representing a byte with the corresponding code.

When an extended string literal is concatenated across lines, write only E before the first opening quote:

```
=> SELECT E'first part o'
' a long line';
?column?
```

```
-----
first part of a long line
(1 row)
```

Two adjacent single quotes are used as one single quote:

```
=> SELECT 'Aren"t string literals fun?';
?column?
```

```
-----
Aren't string literals fun?
(1 row)
```

Standard conforming strings and escape characters

When interpreting commands, such as those entered in [vsq](#) or in queries passed via JDBC or ODBC, Vertica uses standard conforming strings as specified in the SQL standard. In standard conforming strings, backslashes are treated as string literals (ordinary characters), not escape characters.

Note

Text read in from files or streams (such as the data inserted using the [COPY](#) statement) are not treated as literal strings. The COPY command defines its own escape characters for the data it reads. See the [COPY](#) statement documentation for details.

The following options are available, but Vertica recommends that you migrate your application to use standard conforming strings at your earliest convenience, after warnings have been addressed.

- To treat back slashes as escape characters, set configuration parameter [StandardConformingStrings](#) to 0.
- To enable standard conforming strings permanently, set the [StandardConformingStrings](#) parameter to '1', as described [below](#).
- To enable standard conforming strings per session, use [SET STANDARD_CONFORMING_STRING TO ON](#), which treats backslashes as escape characters for the current session only.

Identifying strings that are not standard conforming

The following procedure can be used to identify nonstandard conforming strings in your application so that you can convert them into standard conforming strings:

1. Be sure the [StandardConformingStrings](#) parameter is off, as described in [Internationalization parameters](#).

```
=> ALTER DATABASE DEFAULT SET StandardConformingStrings = 0;
```

Note

Vertica recommends that you migrate your application to use standard conforming strings .

2. If necessary, turn on the [EscapeStringWarning](#) parameter.

```
=> ALTER DATABASE DEFAULT SET EscapeStringWarning = 1;
```

Vertica now returns a warning each time it encounters an escape string within a string literal. For example, Vertica interprets the `\n` in the following example as a new line:

```
=> SELECT 'a\nb';
WARNING: nonstandard use of escape in a string literal at character 8
HINT: Use the escape string syntax for escapes, e.g., E'\n'.
?column?
-----
a
b
(1 row)
```

When [StandardConformingStrings](#) is **ON** , the string is interpreted as four characters: `a \ n b` .

Modify each string that Vertica flags by extending it as in the following example:

```
E'a\nb'
```

Or if the string has quoted single quotes, double them; for example, `'one" double'`.

3. Turn on the [StandardConformingStrings](#) parameter for all sessions:

```
=> ALTER DATABASE DEFAULT SET StandardConformingStrings = 1;
```

Doubled single quotes

This section discusses vsql inputs that are not passed on to the server. Vertica recognizes two consecutive single quotes within a string literal as one single quote character. For example, the following inputs, `'You"re here!` ignored the second consecutive quote and returns the following:

```
=> SELECT 'You"re here!';
?column?
-----
You're here!at
(1 row)
```

This is the SQL standard representation and is preferred over the form, `'You\re here!` , because backslashes are not parsed as before. You need to escape the backslash:

```
=> SELECT (E'You\re here!');
?column?
-----
You're here!
(1 row)
```

This behavior change introduces a potential incompatibility in the use of the vsql meta-command `\set`, which automatically concatenates its arguments. For example:

```
\set file \" `pwd` '/file.txt' \"\`echo :file
```

vsql takes the four arguments and outputs the following:

```
'/home/vertica/file.txt'
```

Vertica parses the adjacent single quotes as follows:

```
\set file \"`pwd`/file.txt\"`\`echo :file
'/home/vertica/file.txt'
```

Note the extra single quote at the end. This is due to the pair of adjacent single quotes together with the backslash-quoted single quote.

The extra quote can be resolved either as in the first example above, or by combining the literals as follows:

```
\set file \"`pwd`'/file.txt'\"\`echo :file
'/home/vertica/file.txt'
```

In either case the backslash-quoted single quotes should be changed to doubled single quotes as follows:

```
\set file "" `pwd` '/file.txt'
```

Additional examples

```
=> SELECT 'This \is a string';
?column?
```

```
-----
This \is a string
(1 row)
```

```
=> SELECT E'This \is a string';
?column?
```

```
-----
This is a string
```

```
=> SELECT E'This is a \n new line';
?column?
```

```
-----
This is a
new line
(1 row)
```

```
=> SELECT 'String"s characters';
?column?
```

```
-----
String's characters
(1 row)
```

Date/time literals

Date or time literal input must be enclosed in single quotes. Input is accepted in almost any reasonable format, including ISO 8601, SQL-compatible, traditional POSTGRES, and others.

Vertica handles date/time input more flexibly than the SQL standard requires. The exact parsing rules of date/time input and for the recognized text fields including months, days of the week, and time zones are described in [Date/time expressions](#).

In this section

- [Time zone values](#)
- [Day of the week names](#)
- [Month names](#)
- [Interval literal](#)

Time zone values

Vertica attempts to be compatible with the SQL standard definitions for time zones. However, the SQL standard has an odd mix of date and time types and capabilities. Obvious problems are:

- Although the [DATE](#) type does not have an associated time zone, the [TIME](#) type can. Time zones in the real world have little meaning unless associated with a date as well as a time, since the offset can vary through the year with daylight-saving time boundaries.
- Vertica assumes your local time zone for any data type containing only date or time.
- The default time zone is specified as a constant numeric offset from UTC. It is therefore not possible to adapt to daylight-saving time when doing date/time arithmetic across DST boundaries.

To address these difficulties, OpenText recommends using Date/Time types that contain both date and time when you use time zones. OpenText recommends that you do *not* use the type [TIME WITH TIME ZONE](#), even though it is supported for legacy applications and for compliance with the SQL standard.

Time zones and time-zone conventions are influenced by political decisions, not just earth geometry. Time zones around the world became somewhat standardized during the 1900's, but continue to be prone to arbitrary changes, particularly with respect to daylight-savings rules.

Vertica currently supports daylight-savings rules over the time period 1902 through 2038, corresponding to the full range of conventional UNIX system time. Times outside that range are taken to be in "standard time" for the selected time zone, no matter what part of the year in which they occur.

Example	Description
PST	Pacific Standard Time
-8:00	ISO-8601 offset for PST
-800	ISO-8601 offset for PST
-8	ISO-8601 offset for PST
zulu	Military abbreviation for UTC
z	Short form of zulu

Day of the week names

The following tokens are recognized as names of days of the week:

Day	Abbreviations
SUNDAY	SUN
MONDAY	MON
TUESDAY	TUE, TUES
WEDNESDAY	WED, WEDS
THURSDAY	THU, THUR, THURS
FRIDAY	FRI
SATURDAY	SAT

Month names

The following tokens are recognized as names of months:

Month	Abbreviations
-------	---------------

JANUARY	JAN
FEBRUARY	FEB
MARCH	MAR
APRIL	APR
MAY	MAY
JUNE	JUN
JULY	JUL
AUGUST	AUG
SEPTEMBER	SEP, SEPT
OCTOBER	OCT
NOVEMBER	NOV
DECEMBER	DEC

Interval literal

A literal that represents a time span.

Syntax

```
[ @ ] [-] { quantity subtype-unit }[...][ AGO ]
```

Parameters

@

Ignored

- (**minus**)

Specifies a negative interval value.

quantity

Integer [numeric constant](#)

subtype-unit

See [Interval subtype units](#) for valid values. Subtype units must be specified for [year-month](#) intervals; they are optional for [day-time](#) intervals.

AGO

Specifies a negative interval value. **AGO** and - (minus) are synonymous.

Notes

- The amounts of different units are implicitly added up with appropriate sign accounting.
- The boundaries of an interval constant are:
 - `9223372036854775807 usec` to `-9223372036854775807 usec`
 - `296533 years 3 mons 21 days 04:00:54.775807` to `-296533 years -3 mons -21 days -04:00:54.775807`
- The range of an interval constant is $\pm 2^{63} - 1$ microseconds.
- In Vertica, interval fields are additive and accept large floating-point numbers.

Examples

See [Specifying interval input](#).

In this section

- [Interval subtype units](#)
- [Interval qualifier](#)

Interval subtype units

The following tables lists subtype units that you can specify in an interval literal, divided into major categories:

- [Year-month subtype units](#)
- [Day-time subtype units](#)

Year-month subtype units

Subtypes	Units	Notes
Millennium	mil , millennium , millennia , mils , millenniums	
Century	c , cent , century , centuries	
Decade	dec , decs , decade , decades	
Year	a	Julian year: 365.25 days
	ka	Julian kilo-year: 365250 days
	y , yr , yrs , year , years	Calendar year: 365 days
Quarter	q , qtr , qtrs , quarter , quarters	
Month	m , mon , mons , months , month	Vertica can interpret m as minute or month, depending on context. See Processing m Input below.
Week	w , wk , week , wks , weeks	

Day-time subtype units

Subtypes	Units	Notes
Day	d , day , days	
Hour	h , hr , hrs , hour , hours	
Minute	m , min , mins , minute , minutes	Vertica can interpret input unit m as minute or month, depending on context. See Processing m Input below.
Second	s , sec , secs , second , seconds	
Millisecond	ms , msec , msecs , msecond , mseconds , millisecond , milliseconds	
Microsecond	us , usec , usecs , usecond , useconds , microseconds , microsecond	

Processing m input

Vertica uses context to interpret the input unit [m](#) as months or minutes. For example, the following command creates a one-column table with an interval value:

```
=> CREATE TABLE int_test(i INTERVAL YEAR TO MONTH);
```

Given the following INSERT statement, Vertica interprets the interval literal [1y 6m](#) as 1 year 6 months:

```
=> INSERT INTO int_test VALUES('1y 6m');
```

```
OUTPUT
```

```
-----  
 1  
(1 row)  
=> COMMIT;  
COMMIT  
=> SET INTERVALSTYLE TO UNITS;  
SET  
=> SELECT * FROM int_test;  
  i  
-----  
1 year 6 months  
(1 row)
```

Tip

The [SET INTERVALSTYLE](#) statement changes interval output to include subtype unit identifiers. For details, see [Setting interval unit display](#).

The following [ALTER TABLE](#) statement adds a **DAY TO MINUTE** interval column to table `int_test` :

```
=> ALTER TABLE int_test ADD COLUMN x INTERVAL DAY TO MINUTE;  
ALTER TABLE
```

The next INSERT statement sets the first and second columns to 3y 20m and 1y 6m, respectively. In this case, Vertica interprets the **m** input literals in two ways:

- For column `i`, Vertica interprets the **m** input as months, and displays 4 years 8 months.
- For column `x`, Vertica interprets the **m** input as minutes. Because the interval is defined as DAY TO MINUTE, it converts the inserted input value **1y 6m** to 365 days 6 minutes:

```
=> INSERT INTO int_test VALUES ('3y 20m', '1y 6m');
```

```
OUTPUT
```

```
-----  
 1  
(1 row)  
=> SELECT * FROM int_test;  
  i | x  
-----+-----  
1 year 6 months |  
4 years 8 months | 365 days 6 mins  
(2 rows)
```

Interval qualifier

Specifies how to interpret and format an [interval literal](#) for output, and optionally sets precision. Interval qualifiers are composed of one or two units:

```
unit [ TO unit ] [ (p) ]
```

where:

- *unit* specifies a day-time or year-month [subtype](#).
- *p* specifies precision, an integer between 0 and 6.

Note

Precision only applies to SECOND units, specifying the number of decimal digits to show after the seconds value decimal point. The default precision for SECOND is 6.

When SECOND is the second unit of a qualifier—for example, DAY TO SECOND or MINUTE TO SECOND—it has a precision of 2 places before the decimal point.

For example:

```
=> SELECT INTERVAL '6 122.538987' MINUTE TO SECOND (5);
?column?
-----
08:02.53899
(1 row)
```

For details, see [Specifying interval precision](#).

If an interval omits an interval qualifier, the default is `DAY TO SECOND(6)`.

Interval qualifiers are divided into two categories:

- [day-time](#)
- [year-month](#)

Day-time interval qualifiers

Qualifier	Description
<code>DAY</code>	Unconstrained
<code>DAY TO HOUR</code>	Span of days and hours
<code>DAY TO MINUTE</code>	Span of days and minutes
<code>DAY TO SECOND [(p)]</code>	Span of days, hours, minutes, seconds, and fractions of a second.
<code>HOUR</code>	Hours within days
<code>HOUR TO MINUTE</code>	Span of hours and minutes
<code>HOUR TO SECOND [(p)]</code>	Span of hours and seconds
<code>MINUTE</code>	Minutes within hours
<code>MINUTE TO SECOND [(p)]</code>	Span of minutes and seconds
<code>SECOND [(p)]</code>	Seconds within minutes

Year-month interval qualifiers

YEAR

Unconstrained

MONTH

Months within year

YEAR TO MONTH

Span of years and months

Note

Vertica also supports `INTERVALYM`, which is an alias for `INTERVAL YEAR TO MONTH`. Thus, the following two statements are equivalent:

```
=> SELECT INTERVALYM '1 2';
?column?
-----
1-2
(1 row)
=> SELECT INTERVAL '1 2' YEAR TO MONTH;
?column?
-----
1-2
(1 row)
```

Examples

See [Controlling interval format](#).

Operators

Operators are logical, mathematical, and equality symbols used in SQL to evaluate, compare, or calculate values.

In this section

- [Bitwise operators](#)
- [Logical operators](#)
- [Comparison operators](#)
- [Data type coercion operators \(CAST\)](#)
- [Date/time operators](#)
- [Mathematical operators](#)
- [NULL operators](#)
- [String concatenation operators](#)

Bitwise operators

Bitwise operators perform bit manipulations on INTEGER and BINARY/VARBINARY data types:

Operator	Description	Example	Result
&	AND	12 & 4	4
	OR	32 3	35
#	XOR	17 # 5	20
~	NOT	~1	-2
<< †	Bitwise shift left	1 << 4	16
>> †	Bitwise shift right	8 >> 2	2

† Invalid for BINARY/VARBINARY data types

String argument handling

String arguments must be explicitly cast as BINARY or VARBINARY data types for all bitwise operators. For example:

```
=> SELECT 'xyz'::VARBINARY & 'zyx'::VARBINARY AS AND;
AND
-----
xyx
(1 row)

=> SELECT 'xyz'::VARBINARY | 'zyx'::VARBINARY AS OR;
OR
-----
zyz
(1 row)
```

Bitwise operators treats all string arguments as equal in length. If the arguments have different lengths, the operator function right-pads the smaller string with one or more zero bytes to equal the length of the larger string.

For example, the following statement ANDs unequal strings `xyz` and `zy`. Vertica right-pads string `zy` with one zero byte. The last character in the result is represented accordingly, as `\000`:

```
=> SELECT 'xyz'::VARBINARY & 'zy'::VARBINARY AS AND;
AND
-----
xy\000
(1 row)
```

Logical operators

Vertica supports the logical operators AND, OR, and NOT:

- AND evaluates to true when both of the conditions joined by AND are true.
- OR evaluates to true when either condition is true.
- NOT negates the result of any Boolean expression.

AND and OR are commutative—that is, you can switch left and right operands without affecting the result. However, the order of evaluation of sub-expressions is not defined. To force evaluation order, use a [CASE](#) construct.

Caution

Do not confuse Boolean operators with the [Boolean predicate](#) or [Boolean](#) data type, which can have only two values: true and false.

Logic

SQL uses a three-valued Boolean logic where `NULL` represents "unknown":

- `true AND NULL = NULL`
- `true OR NULL = true`
- `false AND NULL = false`
- `false OR NULL = NULL`
- `NULL AND NULL = NULL`
- `NULL OR NULL = NULL`
- `NOT NULL = NULL`

Comparison operators

Comparison operators are available for all data types where comparison makes sense. All comparison operators are binary operators that return values of true, false, or NULL (unknown).

Operator	Description	Binary function
<	less than	<code>binary_lt</code>

>	greater than	binary_gt
<=	less than or equal to	binary_le
>=	greater than or equal to	binary_ge
= , <=>	equal	binary_eq
<div style="background-color: #e1f5fe; padding: 10px; border: 1px solid #cfcfcf;"> <p>Note</p> <p>Do not use the negation operator (!) with the <=> operator. Instead, use != to test for inequality. ! , except as part of != , is the factorial operator.</p> </div>		
!= , <>	not equal (unsupported for correlated subqueries)	binary_ne

NULL handling

Comparison operators return NULL (unknown) if either or both operands are null. One exception applies: <=> returns true if both operands are NULL, and false if one operand is NULL.

Collections

When comparing collections, null collections are ordered last. Otherwise, collections are compared element by element until there is a mismatch, and then they are ordered based on the non-matching elements. If all elements are equal up to the length of the shorter one, then the shorter one is ordered first.

Data type coercion operators (CAST)

Data type coercion (casting) passes an expression value to an input conversion routine for a specified data type, resulting in a constant of the indicated type. In Vertica, data type coercion can be invoked by an explicit cast request that uses one of the following constructs:

Syntax

```
SELECT CAST ( expression AS data-type )
SELECT expression::data-type
SELECT data-type 'string'
```

Parameters

<i>expression</i>	An expression of any type
<i>data-type</i>	An SQL data type that Vertica supports to convert <i>expression</i> .

Truncation

If a binary value is cast (implicitly or explicitly) to a binary type with a smaller length, the value is silently truncated. For example:

```
=> SELECT 'abcd'::BINARY(2);
?column?
-----
ab
(1 row)
```

Similarly, if a character value is cast (implicitly or explicitly) to a character value with a smaller length, the value is silently truncated. For example:

```
=> SELECT 'abcd'::CHAR(3);
?column?
-----
abc
(1 row)
```

Binary casting and resizing

Vertica supports only casts and resize operations as follows:

- BINARY to and from VARBINARY
- VARBINARY to and from LONG VARBINARY
- BINARY to and from LONG VARBINARY

On binary data that contains a value with fewer bytes than the target column, values are right-extended with the zero byte '\0' to the full width of the column. Trailing zeros on variable-length binary values are not right-extended:

```
=> SELECT 'ab'::BINARY(4), 'ab'::VARBINARY(4), 'ab'::LONG VARBINARY(4);
?column? | ?column? | ?column?
-----+-----+-----
ab\000\000 | ab      | ab
(1 row)
```

Automatic coercion

The explicit type cast can be omitted if there is no ambiguity as to the type the constant must be. For example, when a constant is assigned directly to a column, it is automatically coerced to the column's data type.

Examples

```
=> SELECT CAST((2 + 2) AS VARCHAR);
?column?
-----
4
(1 row)

=> SELECT (2 + 2)::VARCHAR;
?column?
-----
4
(1 row)

=> SELECT INTEGER '123';
?column?
-----
123
(1 row)

=> SELECT (2 + 2)::LONG VARCHAR
?column?
-----
4
(1 row)

=> SELECT '2.2' + 2;
ERROR: invalid input syntax for integer: "2.2"

=> SELECT FLOAT '2.2' + 2;
?column?
-----
4.2
(1 row)
```

See also

- [Data Type Conversions](#)
- [Data Type Coercion Chart](#)
- [CAST Failures](#)

In this section

- [Cast failures](#)

Cast failures

When you invoke data type coercion (casting) by an explicit cast and the cast fails, the result returns either an error or NULL. Cast failures commonly occur when you try to cast conflicting conversions, such as coercing a VARCHAR expression that contains letters to an integer.

When a cast fails, the result returned depends on the data type.

Data type	Cast failure default
date, time	NULL
literals	error
all other types	error

Enabling strict time casts

You can enable all cast failures to result in an error, including those for date/time data types. Doing so lets you see the reason why some or all of the cast failed. To return an error instead of NULL, set the configuration parameter EnableStrictTimeCasts to 1:

```
ALTER SESSION SET EnableStrictTimeCasts=1;
```

By default, EnableStrictTimeCasts is set to 0. Thus, the following attempt to cast a VARCHAR to a TIME data type returns NULL:

```
==> SELECT current_value from configuration_parameters WHERE parameter_name ilike '%EnableStrictTimeCasts%';
current_value
-----
0
(1 row)

=> CREATE TABLE mytable (a VARCHAR);
CREATE TABLE
=> INSERT INTO mytable VALUES('one');
INSERT
OUTPUT
-----
1
(1 row)

=> INSERT INTO mytable VALUES('1');
INSERT
OUTPUT
-----
1
(1 row)

=> COMMIT;
COMMIT
=> SELECT a::time FROM mytable;
a
---
(2 rows)
```

If EnableStrictTimeCasts is enabled, the cast failure returns an error:

```
==> ALTER SESSION SET EnableStrictTimeCasts=1;
ALTER SESSION
=> SELECT a::time FROM mytable;
ERROR 3679: Invalid input syntax for time: "1"
```

Returning all cast failures as NULL

To explicitly cast an expression to a requested data type, use the following construct:

```
SELECT expression::data-type
```

Using this command to cast any values to a conflicting data type returns the following error:

```
=> SELECT 'one'::time;  
ERROR 3679: Invalid input syntax for time: "one"
```

Vertica also supports the use of the coercion operator `::!`, which is useful when you want to return:

- NULL instead of an error for any non-date/time data types
- NULL instead of an error after setting `EnableStrictTimeCasts`

Returning all cast failures as NULL allows those expressions that succeed during the cast to appear in the result. Those expressions that fail during the cast, however, have a NULL value.

The following example queries `mytable` using the coercion operator `::!`. The query returns NULL where column `a` contains the string `one`, and returns `1` where the column contains `1`. Query results are identical no matter how `EnableStrictTimeCasts` is set:

```
=> SELECT current_value FROM configuration_parameters WHERE parameter_name ilike '%EnableStrictTimeCasts%';  
current_value  
-----  
0  
(1 row)  
  
=> SELECT a::int FROM mytable;  
a  
---  
1  
(2 rows)  
  
ALTER SESSION SET EnableStrictTimeCasts=1;  
ALTER SESSION  
=> SELECT a::int FROM mytable;  
a  
---  
1  
(2 rows)
```

You can use `::!` for casts of arrays and sets. The cast resolves each element individually, producing NULL for elements that cannot be cast.

Note that this functionality only applies to table data. It does not work on inline constant casts and in expressions automatically reduced to such. For example,

```
SELECT constant ::! FLOAT from (select 'some string' as constant) a;
```

results in **ERROR 2826: Could not convert "some string" to a float8**. However, the following returns cast failures as NULL as described:

```
SELECT string_field ::! float FROM (SELECT 'a string' as string_field UNION ALL SELECT 'another string' ) a;
```

Date/time operators

Vertica supports usage of arithmetic operators on DATE/TIME operands:

- `+` (addition)
- `-` (subtraction)
- `*` (multiplication)
- `/` (division)

Examples

The operators described below that take `TIME` or `TIMESTAMP` input have two variants:

- Operators that take `TIME WITH TIME ZONE` or `TIMESTAMP WITH TIME ZONE` input.

- Operators that take **TIME WITHOUT TIME ZONE** or **TIMESTAMP WITHOUT TIME ZONE** input.

For brevity, these variants are not shown separately.

The **+** and ***** operators come in commutative pairs—for example, both **DATE + INTEGER** and **INTEGER + DATE** . Only one of each pair is shown.

Example	Result Type	Result
<code>DATE '2001-09-28' + INTEGER '7'</code>	DATE	'2001-10-05'
<code>DATE '2001-09-28' + INTERVAL '1 HOUR'</code>	TIMESTAMP	'2001-09-28 01:00:00'
<code>DATE '2001-09-28' + TIME '03:00'</code>	TIMESTAMP	'2001-09-28 03:00:00'
<code>INTERVAL '1 DAY' + INTERVAL '1 HOUR'</code>	INTERVAL	'1 DAY 01:00:00'
<code>TIMESTAMP '2001-09-28 01:00' + INTERVAL '23 HOURS'</code>	TIMESTAMP	'2001-09-29 00:00:00'
<code>TIME '01:00' + INTERVAL '3 HOURS'</code>	TIME	'04:00:00'
<code>- INTERVAL '23 HOURS'</code>	INTERVAL	'-23:00:00'
<code>DATE '2001-10-01' - DATE '2001-09-28'</code>	INTEGER	'3'
<code>DATE '2001-10-01' - INTEGER '7'</code>	DATE	'2001-09-24'
<code>DATE '2001-09-28' - INTERVAL '1 HOUR'</code>	TIMESTAMP	'2001-09-27 23:00:00'
<code>TIME '05:00' - TIME '03:00'</code>	INTERVAL	'02:00:00'
<code>TIME '05:00' - INTERVAL '2 HOURS'</code>	TIME	'03:00:00'
<code>TIMESTAMP '2001-09-28 23:00' - INTERVAL '23 HOURS'</code>	TIMESTAMP	'2001-09-28 00:00:00'
<code>INTERVAL '1 DAY' - INTERVAL '1 HOUR'</code>	INTERVAL	'1 DAY -01:00:00'
<code>TIMESTAMP '2001-09-29 03:00' - TIMESTAMP '2001-09-27 12:00'</code>	INTERVAL	'1 DAY 15:00:00'
<code>900 * INTERVAL '1 SECOND'</code>	INTERVAL	'00:15:00'
<code>21 * INTERVAL '1 DAY'</code>	INTERVAL	'21 DAYS'

DOUBLE PRECISION '3.5' * INTERVAL '1 HOUR'	INTERVAL	'03:30:00'
INTERVAL '1 HOUR' / DOUBLE PRECISION '1.5'	INTERVAL	'00:40:00'

Mathematical operators

Mathematical operators are provided for many data types.

Operator	Description	Example	Result
!	Factorial	5 !	120
+	Addition	2 + 3	5
-	Subtraction	2 - 3	-1
*	Multiplication	2 * 3	6
/	Division (integer division produces NUMERIC results).	4 / 2	2.00...
//	With integer division, returns an INTEGER rather than a NUMERIC.	117.32 // 2.5	46
%	Modulo (remainder). For details, see MOD .	5 % 4	1
^	Exponentiation	2.0 ^ 3.0	8
/	Square root	/ 25.0	5
/	Cube root	/ 27.0	3
!!	Factorial (prefix operator)	!! 5	120
@	Absolute value	@ -5.0	5

Factorial operator support

Vertica supports use of factorial operators on positive and negative floating point ([DOUBLE PRECISION](#)) numbers and integers. For example:

```
=> SELECT 4.98!;
?column?
-----
115.978600750905
(1 row)
```

Factorial is defined in terms of the gamma function, where (-1) = Infinity and the other negative integers are undefined. For example:

```
(-4)! = NaN
-(4!) = -24
```

Factorial is defined as follows for all complex numbers z :

```
z! = gamma(z+1)
```

For details, see [Abramowitz and Stegun: Handbook of Mathematical Functions](#).

NULL operators

To check whether a value is or is not NULL, use the following equivalent constructs:

Standard:

```
[expression IS NULL | expression IS NOT NULL]
```

Non-standard:

```
[expression ISNULL | expression NOTNULL]
```

Do not write `expression = NULL` : NULL represents an unknown value, and two unknown values are not necessarily equal. This behavior conforms to the SQL standard.

Note

Some applications might expect that `expression = NULL` returns true if `expression` evaluates to NULL. In this case, modify the application to comply with the SQL standard.

String concatenation operators

To concatenate two strings on a single line, use the concatenation operator (two consecutive vertical bars).

Syntax

```
string || string
```

Parameters

string

Expression of type **CHAR** or **VARCHAR**

Notes

- `||` is used to concatenate expressions and constants. The expressions are cast to **VARCHAR** if possible, otherwise to **VARBINARY** , and must both be one or the other.
- Two consecutive strings within a single SQL statement on separate lines are automatically concatenated

Examples

The following example is a single string written on two lines:

```
=> SELECT E'xx' -> '\';  
?column?  
-----  
xx\  
(1 row)
```

The following examples show two strings concatenated:

```

=> SELECT E'xx' ||-> '\';
?column?
-----
xx\
(1 row)

=> SELECT 'auto' || 'mobile';
?column?
-----
automobile
(1 row)

=> SELECT 'auto'-> 'mobile';
?column?
-----
automobile
(1 row)

=> SELECT 1 || 2;
?column?
-----
12
(1 row)

=> SELECT '1' || '2';
?column?
-----
12
(1 row)

=> SELECT '1'-> '2';
?column?
-----
12
(1 row)

```

Expressions

SQL expressions are the components of a query that compare a value or values against other values. They can also perform calculations. An expression found inside a SQL statement is usually in the form of a conditional statement.

Some functions also use [Lambda functions](#).

Operator precedence

The following table shows operator precedence in decreasing (high to low) order.

When an expression includes more than one operator, specify the order of operation using parentheses, rather than relying on operator precedence.

Operator/Element	Associativity	Description
.	left	table/column name separator
::	left	typecast
[]	left	array element selection
-	right	unary minus
^	left	exponentiation

* / %	left	multiplication, division, modulo
+ -	left	addition, subtraction
IS		IS TRUE, IS FALSE, IS UNKNOWN, IS NULL
IN		set membership
BETWEEN		range containment
OVERLAPS		time interval overlap
LIKE		string pattern matching
< >		less than, greater than
=	right	equality, assignment
NOT	right	logical negation
AND	left	logical conjunction
OR	left	logical disjunction

Expression evaluation rules

The order of evaluation of subexpressions is not defined. In particular, the inputs of an operator or function are not necessarily evaluated left-to-right or in any other fixed order. To force evaluation in a specific order, use a [CASE](#) construct. For example, this is an untrustworthy way of trying to avoid division by zero in a WHERE clause:

```
=> SELECT x, y WHERE x <> 0 AND y/x > 1.5; --- unsafe
```

But this is safe:

```
=> SELECT x, y
WHERE
CASE
WHEN x <> 0 THEN y/x > 1.5
ELSE false
END;
```

A CASE construct used in this fashion defeats optimization attempts, so use it only when necessary. (In this particular example, it would be best to avoid the issue by writing $y > 1.5 \cdot x$ instead.)

Limits to SQL expressions

Expressions are limited by the available stack. Vertica requires at least 100KB of free stack. If this limit is exceeded then the error "The query contains an expression that is too complex to analyze" might be thrown. Adding physical memory and/or increasing the value of `ulimit -s` can increase the available stack and prevent the error.

Analytic expressions have a maximum recursion depth of 2000. If this limit is exceeded then the error "The query contains an expression that is too complex to analyze" might be thrown. This limit cannot be increased.

In this section

- [Aggregate expressions](#)
- [CASE expressions](#)
- [Column references](#)
- [Comments](#)
- [Date/time expressions](#)
- [NULL value](#)

Aggregate expressions

An aggregate expression applies an aggregate function across the rows or groups of rows selected by a query.

An aggregate expression only can appear in the select list or **HAVING** clause of a **SELECT** statement. It is invalid in other clauses such as **WHERE** , because those clauses are evaluated before the results of aggregates are formed.

Syntax

An aggregate expression has the following format:

```
aggregate-function ( [ * ] [ ALL | DISTINCT ] expression )
```

Parameters

<i>aggregate-function</i>	A Vertica function that aggregates data over groups of rows from a query result set.
ALL DISTINCT	Specifies which input rows to process: <ul style="list-style-type: none">• ALL (default): Invokes <i>aggregate-function</i> across all input rows where <i>expression</i> evaluates to a non-null value.• DISTINCT : Invokes <i>aggregate-function</i> across all input rows where <i>expression</i> evaluates to a unique non-null value.
<i>expression</i>	A value expression that does not itself contain an aggregate expression.

Examples

The AVG aggregate function returns the average income from the customer_dimension table:

```
=> SELECT AVG(annual_income) FROM customer_dimension;
AVG
-----
2104270.6485
(1 row)
```

The following example shows how to use the COUNT aggregate function with the DISTINCT keyword to return all distinct values of evaluating the expression x+y for all inventory_fact records.

```
=> SELECT COUNT (DISTINCT date_key + product_key) FROM inventory_fact;
COUNT
-----
21560
(1 row)
```

CASE expressions

The **CASE** expression is a generic conditional expression that can be used wherever an expression is valid. It is similar to **CASE** and **IF/THEN/ELSE** statements in other languages.

Syntax (form 1)

```
CASE
  WHEN condition THEN result
  [ WHEN condition THEN result ]
  ...
  [ ELSE result ]
END
```

Parameters

* <i>condition</i>	An expression that returns a Boolean (true/false) result. If the result is false, subsequent WHEN clauses are evaluated in the same way.
* <i>result</i>	Specifies the value to return when the associated <i>condition</i> is true.
ELSE <i>result</i>	If no <i>condition</i> is true then the value of the CASE expression is the result in the ELSE clause. If the ELSE clause is omitted and no condition matches, the result is NULL.

Syntax (form 2)

```
CASE expression
WHEN value THEN result
[ WHEN value THEN result ]
...
[ ELSE result ]
END
```

Parameters

* <i>expression</i>	An expression that is evaluated and compared to all the <i>value</i> specifications in WHEN clauses until one is found that is equal.
* <i>value</i>	Specifies a value to compare to the <i>expression</i> .
* <i>result</i>	Specifies the value to return when the <i>expression</i> is equal to the specified <i>value</i> .
<i>ELSE result</i>	Specifies the value to return when the <i>expression</i> is not equal to any <i>value</i> ; if no ELSE clause is specified, the value returned is null.

Notes

The data types of all result expressions must be convertible to a single output type.

Examples

The following examples show two uses of the **CASE** statement.

```
=> SELECT * FROM test;
a
---
1
2
3
=> SELECT a,
  CASE WHEN a=1 THEN 'one'
        WHEN a=2 THEN 'two'
        ELSE 'other'
  END
FROM test;
a | case
---+-----
1 | one
2 | two
3 | other
=> SELECT a,
  CASE a WHEN 1 THEN 'one'
        WHEN 2 THEN 'two'
        ELSE 'other'
  END
FROM test;
a | case
---+-----
1 | one
2 | two
3 | other
```

Special example

A **CASE** expression does not evaluate subexpressions that are not needed to determine the result. You can use this behavior to avoid division-by-zero errors:

```
=> SELECT x FROM T1 WHERE
    CASE WHEN x <> 0 THEN y/x > 1.5
    ELSE false
END;
```

Column references

Syntax

```
[[[database.]schema.]table-name.]column-name
```

Parameters

<i>schema</i>	Database and schema . The default schema is <code>public</code> . If you specify a database, it must be the current database.
<i>table-name</i>	One of the following: <ul style="list-style-type: none">• Name of a table• Table alias defined in the query's <code>FROM</code> clause
<i>column-name</i>	A column name that is unique among all queried tables.

Restrictions

A column reference cannot contain any spaces.

Comments

A comment is an arbitrary sequence of characters beginning with two consecutive hyphen characters and extending to the end of the line. For example:

```
-- This is a standard SQL comment
```

A comment is removed from the input stream before further syntax analysis and is effectively replaced by white space.

Alternatively, C-style block comments can be used where the comment begins with `/*` and extends to the matching occurrence of `*/`.

```
/* multiline comment
 * with nesting: /* nested block comment */
 */
```

These block comments nest, as specified in the SQL standard. Unlike C, you can comment out larger blocks of code that might contain existing block comments.

Date/time expressions

Vertica uses an internal heuristic parser for all date/time input support. Dates and times are input as strings, and are broken up into distinct fields with a preliminary determination of what kind of information might be in the field. Each field is interpreted and either assigned a numeric value, ignored, or rejected. The parser contains internal lookup tables for all textual fields, including months, days of the week, and time zones.

Vertica parses date/time type inputs as follows:

1. Break the input string into tokens and categorize each token as a string, time, time zone, or number.
2. Numeric token contains:
 - colon (:) — Parse as a time string, include all subsequent digits and colons.
 - dash (-), slash (/), or two or more dots (.) — Parse as a date string which might have a text month.
 - Numeric only — Parse as a single field or an ISO 8601 concatenated date (19990113 for January 13, 1999) or time (141516 for 14:15:16).
3. Token starts with a plus (+) or minus (-): Parse as a time zone or a special field.
4. Token is a text string: match up with possible strings.
 - Perform a binary-search table lookup for the token as either a special string (for example, today), day (for example, Thursday), month (for example, January), or noise word (for example, at, on).
 - Set field values and bit mask for fields. For example, set year, month, day for today, and additionally hour, minute, second for now.
 - If not found, do a similar binary-search table lookup to match the token with a time zone.
 - If still not found, throw an error.
5. Token is a number or number field:

- If eight or six digits, and if no other date fields were previously read, interpret as a "concatenated date" (19990118 or 990118). The interpretation is **YYYYMMDD** or **YYMMDD**.
 - If token is three digits and a year was already read, interpret as day of year.
 - If four or six digits and a year was already read, interpret as a time (**HHMM** or **HHMMSS**).
 - If three or more digits and no date fields were found yet, interpret as a year (this forces yy-mm-dd ordering of the remaining date fields).
 - Otherwise the date field ordering is assumed to follow the **DateStyle** setting: mm-dd-yy, dd-mm-yy, or yy-mm-dd. Throw an error if a month or day field is found to be out of range.
6. If BC is specified: negate the year and add one for internal storage. (In the Vertica implementation, 1 BC = year zero.)
 7. If BC is not specified, and year field is two digits in length: adjust the year to four digits. If field is less than 70, add 2000, otherwise add 1900.

Tip

Gregorian years AD 1–99 can be entered as 4 digits with leading zeros— for example, 0099 = AD 99.

Month day year ordering

For some formats, ordering of month, day, and year in date input is ambiguous and there is support for specifying the expected ordering of these fields.

Special date/time values

Vertica supports several special date/time values for convenience, as shown below. All of these values need to be written in single quotes when used as constants in SQL statements.

The values **INFINITY** and **-INFINITY** are specially represented inside the system and are displayed the same way. The others are simply notational shorthands that are converted to ordinary date/time values when read. (In particular, **NOW** and related strings are converted to a specific time value as soon as they are read.)

String	Valid Data Types	Description
epoch	DATE , TIMESTAMP	1970-01-01 00:00:00+00 (UNIX SYSTEM TIME ZERO)
INFINITY	TIMESTAMP	Later than all other time stamps
-INFINITY	TIMESTAMP	Earlier than all other time stamps
NOW	DATE , TIME , TIMESTAMP	Current transaction's start time Note: NOW is not the same as the NOW function.
TODAY	DATE , TIMESTAMP	Midnight today
TOMORROW	DATE , TIMESTAMP	Midnight tomorrow
YESTERDAY	DATE , TIMESTAMP	Midnight yesterday
ALLBALLS	TIME	00:00:00.00 UTC

The following SQL-compatible functions can also be used to obtain the current time value for the corresponding data type:

- [CURRENT_DATE](#)
- [CURRENT_TIME](#)
- [CURRENT_TIMESTAMP](#)
- [LOCALTIME](#)
- [LOCALTIMESTAMP](#)

The latter four accept an optional precision specification. (See [Date/time functions](#).) However, these functions are SQL functions and are not recognized as data input strings.

NULL value

NULL is a reserved keyword used to indicate that a data value is unknown. It is the ASCII abbreviation for NULL characters (\0).

Usage in expressions

Vertica does not treat an empty string as a NULL value. An expression must specify NULL to indicate that a column value is unknown.

The following considerations apply to using NULL in expressions:

- NULL is not greater than, less than, equal to, or not equal to any other expression. Use the [Boolean](#) to determine whether an expression value is NULL.
- You can write queries with expressions that contain the `<=>` operator for `NULL=NULL` joins. See [Equi-joins and non equi-joins](#).
- Vertica accepts NULL characters (`'\0'`) in constant strings and does not remove null characters from VARCHAR fields on input or output.

Projection ordering of NULL data

Vertica sorts NULL values in projection columns as follows:

Column data type	NULL values placed at...
NUMERIC INTEGER DATE TIME TIMESTAMP INTERVAL	Beginning of sorted column (NULLS FIRST)
FLOAT STRING BOOLEAN	End of sorted column (NULLS LAST)

See also

[NULL-handling functions](#).

Lambda functions

Some SQL functions have arguments that are lambda functions. A lambda function is an unnamed inline function that is evaluated by the containing SQL function and returns a value.

Syntax

Lambda with one argument:

```
argument -> expression
```

Lambda with more than one argument:

```
(argument, ...) -> expression
```

Arguments

<i>argument</i>	Name to use for an input value for the expression. The name cannot be a reserved keyword, the name of an argument to a parent or nested lambda, or a column name or alias.
<i>expression</i>	Expression that uses the input arguments and returns a result to the containing SQL function. See the documentation of individual SQL functions for restrictions on return values. For example, some functions require a Boolean result.

Examples

The [ARRAY_FIND](#) function returns the first index that matches the element being searched for. Instead of a literal element, you can write a lambda function that returns a Boolean. The lambda function is applied to each element in the array until a match is found or all elements have been tested. In the following example, each person in the table has an array of email addresses, and the function locates fake addresses:

```
=> CREATE TABLE people (id INT, name VARCHAR, email ARRAY[VARCHAR,5]);  
  
=> SELECT name, ARRAY_FIND(email, e -> REGEXP_LIKE(e,'example.com','i'))  
   AS 'example.com'  
 FROM people;  
   name | example.com  
-----+-----  
Alice Adams |      1  
Bob Adams   |      1  
Carol Collins |      0  
Dave Jones  |      0  
(4 rows)
```

The argument `e` represents the individual element, and the body of the lambda expression is the regular-expression comparison. The input table has

four rows; in each row, the lambda function is called once per array element.

In the following example, a schedules table includes an array of events, where each event is a ROW with several fields:

```
=> CREATE TABLE schedules
  (guest VARCHAR,
   events ARRAY[ROW(e_date DATE, e_name VARCHAR, price NUMERIC(8,2))]);
```

You can use the [CONTAINS](#) function with a lambda expression to find people who have more than one event on the same day. The second argument, `idx`, is the index of the current element:

```
=> SELECT guest FROM schedules
WHERE CONTAINS(events, (e, idx) ->
  (idx < ARRAY_LENGTH(events) - 1)
  AND (e.e_date = events[idx + 1].e_date));
 guest
-----
Alice Adams
(1 row)
```

Predicates

Predicates are truth-tests. If the predicate test is true, it returns a value. Each predicate is evaluated per row, so that when the predicate is part of an entire table SELECT statement, the statement can return multiple results.

Predicates consist of a set of parameters and arguments. For example, in the following WHERE clause:

```
WHERE name = 'Smith'
```

- `name = 'Smith'` is the predicate
- `'Smith'` is an expression

In this section

- [ANY and ALL](#)
- [BETWEEN](#)
- [Boolean](#)
- [EXISTS](#)
- [IN](#)
- [INTERPOLATE](#)
- [LIKE](#)
- [NULL](#)

ANY and ALL

ANY and ALL are logical operators that let you make comparisons on subqueries that return one or more rows. Both operators must be preceded by a [comparison operator](#) and followed by a subquery:

```
expression comparison-operator { ANY | ALL } (subquery)
```

- ANY returns true if the comparison between *expression* and any value returned by *subquery* evaluates to true.
- ALL returns true only if the comparison between *expression* and all values returned by *subquery* evaluates to true.

Equivalent operators

You can use the following operators instead of ANY or ALL:

This operator...	Is equivalent to:
SOME	ANY
IN	= ANY
NOT IN	<> ALL

NULL handling

Vertica supports multicolumn <> ALL subqueries where the columns are not marked **NOT NULL** . If any column contains a NULL value, Vertica returns a run-time error.

Vertica does not support ANY subqueries that are nested in another expression if any column values are NULL.

Examples

Examples below use the following tables and data:

```
=> SELECT * FROM t1 ORDER BY c1;
c1 | c2
---+---
 1 | cab
 1 | abc
 2 | fed
 2 | def
 3 | ihg
 3 | ghi
 4 | jkl
 5 | mno
(8 rows)
```

```
=> SELECT * FROM t2 ORDER BY c1;
c1 | c2
---+---
 1 | abc
 2 | fed
 3 | jkl
 3 | stu
 3 | zzz
(5 rows)
```

ANY subqueries

Subqueries that use the ANY keyword return true when any value retrieved in the subquery matches the value of the left-hand expression.

ANY subquery within an expression:

```
=> SELECT c1, c2 FROM t1 WHERE COALESCE((t1.c1 > ANY (SELECT c1 FROM t2)));
c1 | c2
---+---
 2 | fed
 2 | def
 3 | ihg
 3 | ghi
 4 | jkl
 5 | mno
(6 rows)
```

ANY noncorrelated subqueries without aggregates:

```
=> SELECT c1 FROM t1 WHERE c1 = ANY (SELECT c1 FROM t2) ORDER BY c1;
c1
--
 1
 1
 2
 2
 3
 3
(6 rows)
```

ANY noncorrelated subqueries with aggregates:

```
=> SELECT c1, c2 FROM t1 WHERE c1 <> ANY (SELECT MAX(c1) FROM t2) ORDER BY c1;
```

```
c1 | c2  
---+---  
1 | cab  
1 | abc  
2 | fed  
2 | def  
4 | jkl  
5 | mno  
(6 rows)
```

```
=> SELECT c1 FROM t1 GROUP BY c1 HAVING c1 <> ANY (SELECT MAX(c1) FROM t2) ORDER BY c1;
```

```
c1  
---  
1  
2  
4  
5  
(4 rows)
```

ANY noncorrelated subqueries with aggregates and a GROUP BY clause:

```
=> SELECT c1, c2 FROM t1 WHERE c1 <> ANY (SELECT MAX(c1) FROM t2 GROUP BY c2) ORDER BY c1;
```

```
c1 | c2  
---+---  
1 | cab  
1 | abc  
2 | fed  
2 | def  
3 | ihg  
3 | ghi  
4 | jkl  
5 | mno  
(8 rows)
```

ANY noncorrelated subqueries with a GROUP BY clause:

```
=> SELECT c1, c2 FROM t1 WHERE c1 <=> ANY (SELECT c1 FROM t2 GROUP BY c1) ORDER BY c1;
```

```
c1 | c2  
---+---  
1 | cab  
1 | abc  
2 | fed  
2 | def  
3 | ihg  
3 | ghi  
(6 rows)
```

ANY correlated subqueries with no aggregates or GROUP BY clause:

```
=> SELECT c1, c2 FROM t1 WHERE c1 >= ANY (SELECT c1 FROM t2 WHERE t2.c2 = t1.c2) ORDER BY c1;
```

```
c1 | c2  
---+---  
1 | abc  
2 | fed  
4 | jkl  
(3 rows)
```

ALL subqueries

A subquery that uses the ALL keyword returns true when all values retrieved by the subquery match the left-hand expression, otherwise it returns false.

ALL noncorrelated subqueries without aggregates:

```
=> SELECT c1, c2 FROM t1 WHERE c1 >= ALL (SELECT c1 FROM t2) ORDER BY c1;
```

```
c1 | c2  
----  
3 | ihg  
3 | ghi  
4 | jkl  
5 | mno  
(4 rows)
```

ALL noncorrelated subqueries with aggregates:

```
=> SELECT c1, c2 FROM t1 WHERE c1 = ALL (SELECT MAX(c1) FROM t2) ORDER BY c1;
```

```
c1 | c2  
----  
3 | ihg  
3 | ghi  
(2 rows)
```

```
=> SELECT c1 FROM t1 GROUP BY c1 HAVING c1 <> ALL (SELECT MAX(c1) FROM t2) ORDER BY c1;
```

```
c1  
--  
1  
2  
4  
5  
(4 rows)
```

ALL noncorrelated subqueries with aggregates and a GROUP BY clause:

```
=> SELECT c1, c2 FROM t1 WHERE c1 <= ALL (SELECT MAX(c1) FROM t2 GROUP BY c2) ORDER BY c1;
```

```
c1 | c2  
----  
1 | cab  
1 | abc  
(2 rows)
```

ALL noncorrelated subqueries with a GROUP BY clause:

```
=> SELECT c1, c2 FROM t1 WHERE c1 <> ALL (SELECT c1 FROM t2 GROUP BY c1) ORDER BY c1;
```

```
c1 | c2  
----  
4 | jkl  
5 | mno  
(2 rows)
```

BETWEEN

Checks whether an expression is within the range of two other expressions, inclusive. All expressions must be of the same or compatible data types.

Syntax

```
WHERE a BETWEEN x AND y
```

Equivalent predicates

The following BETWEEN predicates can be rewritten in conventional SQL with logical operators AND and OR.

This BETWEEN predicate...	Is equivalent to...
WHERE a BETWEEN x AND y	WHERE a >= x AND a <= y
WHERE a NOT BETWEEN x AND y	WHERE a < x OR a > y

Examples

The BETWEEN predicate can be especially useful for querying date ranges, as shown in the following examples:

```
=> SELECT NOW()::DATE;
      NOW
-----
2022-12-15
(1 row)

=> CREATE TABLE t1 (a INT, b varchar(12), c DATE);
CREATE TABLE
=> INSERT INTO t1 VALUES
  (0,'today',NOW()),
  (1,'today+1',NOW()+1),
  (2,'today+2',NOW()+2),
  (3,'today+3',NOW()+3),
  (4,'today+4',NOW()+4),
  (5,'today+5',NOW()+5),
  (6,'today+6',NOW()+6);
OUTPUT
-----
      7
(1 row)

=> COMMIT;
COMMIT
=> SELECT * FROM t1;
 a | b | c
---+-----+-----
 0 | today | 2022-12-15
 1 | today+1 | 2022-12-16
 2 | today+2 | 2022-12-17
 3 | today+3 | 2022-12-18
 4 | today+4 | 2022-12-19
 5 | today+5 | 2022-12-20
 6 | today+6 | 2022-12-21
(7 rows)

=> SELECT * FROM t1 WHERE c BETWEEN '2022-12-17' AND '2022-12-20';
 a | b | c
---+-----+-----
 2 | today+2 | 2022-12-17
 3 | today+3 | 2022-12-18
 4 | today+4 | 2022-12-19
 5 | today+5 | 2022-12-20
(4 rows)
```

Use the NOW and INTERVAL keywords to query a date range:

```
=> SELECT * FROM t1 WHERE c BETWEEN NOW()::DATE AND NOW()::DATE + INTERVAL '2 days';
 a | b | c
---+-----+-----
 0 | today | 2022-12-15
 1 | today+1 | 2022-12-16
 2 | today+2 | 2022-12-17
(3 rows)
```

Boolean

Retrieves rows where the value of an expression is true, false, or unknown (NULL).

Syntax

```
expression IS [NOT] TRUE
expression IS [NOT] FALSE
expression IS [NOT] UNKNOWN
```

Notes

- NULL input is treated as the value **UNKNOWN**.
- **IS UNKNOWN** and **IS NOT UNKNOWN** are effectively the same as the [NULL predicate](#), except that the input expression does not have to be a single column value. To check a single column value for NULL, use the NULL predicate.
- Do not confuse the Boolean predicate with [Boolean operators](#) or the [Boolean](#) data type, which can have only two values: true and false.

EXISTS

EXISTS and NOT EXISTS predicates compare an expression against a subquery:

- EXISTS returns true if the subquery returns one or more rows.
- NOT EXISTS returns true if the subquery returns no rows.

Syntax

```
expression [ NOT ] EXISTS ( subquery )
```

Usage

EXISTS results only depend on whether any or no records are returned, and not on the contents of those records. Because the subquery output is usually of no interest, EXISTS tests are commonly written in one of the following ways:

```
EXISTS (SELECT 1 WHERE...)
```

```
EXISTS (SELECT * WHERE...)
```

In the first case, the subquery returns 1 for every record found by the subquery. For example, the following query retrieves a list of all customers whose store purchases were greater than 550 dollars:

```
-> SELECT customer_key, customer_name, customer_state
FROM public.customer_dimension WHERE EXISTS
  (SELECT 1 FROM store.store_sales_fact
  WHERE customer_key = public.customer_dimension.customer_key
  AND sales_dollar_amount > 550)
AND customer_state = 'MA' ORDER BY customer_key;
customer_key | customer_name | customer_state
-----|-----|-----
2 | Anna G. Li | CA
4 | Daniel I. Fortin | TX
7 | David H. Greenwood | MA
8 | Wendy S. Young | IL
9 | Theodore X. Brown | MA
...
49902 | Amy O. Pavlov | MA
49922 | Doug C. Carcetti | MA
49930 | Theodore G. McNulty | MA
49979 | Ben Z. Miller | MA
(1058 rows)
```

EXISTS versus IN

Whether you use EXISTS or IN subqueries depends on which predicates you select in outer and inner query blocks. For example, the following query gets a list of all the orders placed by all stores on January 2, 2007 for vendors with records in the vendor table:

```

=> SELECT store_key, order_number, date_ordered
   FROM store.store_orders_fact WHERE EXISTS
     (SELECT 1 FROM public.vendor_dimension vd JOIN store.store_orders_fact ord ON vd.vendor_key = ord.vendor_key)
   AND date_ordered = '2007-01-02';
store_key | order_number | date_ordered
-----+-----+-----
  114 |    271071 | 2007-01-02
    19 |    290888 | 2007-01-02
   132 |    58942 | 2007-01-02
   232 |     9286 | 2007-01-02
   126 |   224474 | 2007-01-02
   196 |    63482 | 2007-01-02
   ...
   196 |    83327 | 2007-01-02
   138 |   278373 | 2007-01-02
   179 |   293586 | 2007-01-02
   155 |   213413 | 2007-01-02
(506 rows)

```

The above query looks for existence of the vendor and date ordered. To return a particular value, rather than simple existence, the query looks for orders placed by the vendor who got the best deal on January 2, 2007:

```

=> SELECT store_key, order_number, date_ordered, vendor_name
   FROM store.store_orders_fact ord JOIN public.vendor_dimension vd ON ord.vendor_key = vd.vendor_key
   WHERE vd.deal_size IN (SELECT MAX(deal_size) FROM public.vendor_dimension) AND date_ordered = '2007-01-02';
store_key | order_number | date_ordered | vendor_name
-----+-----+-----+-----
    50 |    99234 | 2007-01-02 | Everything Wholesale
    81 |   200802 | 2007-01-02 | Everything Wholesale
   115 |   13793 | 2007-01-02 | Everything Wholesale
   204 |   41842 | 2007-01-02 | Everything Wholesale
   133 |   169025 | 2007-01-02 | Everything Wholesale
   163 |   208580 | 2007-01-02 | Everything Wholesale
    29 |   154972 | 2007-01-02 | Everything Wholesale
   145 |   236790 | 2007-01-02 | Everything Wholesale
   249 |    54838 | 2007-01-02 | Everything Wholesale
     7 |   161536 | 2007-01-02 | Everything Wholesale
(10 rows)

```

See also

[IN](#)
IN

Checks whether a single value is found (or not found) within a set of values.

Syntax

```
(column-list) [ NOT ] IN ( values-list )
```

Arguments

column-list

One or more comma-delimited columns in the queried tables.

values-list

Comma-delimited list of constant values to find in the *column-list* columns. Each *values-list* value maps to a *column-list* column according to their order in *values-list* and *column-list*, respectively. Column/value pairs must have [compatible](#) data types.

You can specify multiple sets of values as follows:

```
( ( values-list ), ( values-list ) [...] )
```

Null handling

Vertica supports multicolumn NOT IN subqueries where the columns are not marked [NOT NULL](#). If one of the columns is found to contain a NULL value during query execution, Vertica returns a run-time error.

Similarly, IN subqueries nested within another expression are not supported if any column values are NULL. For example, if in the following statement column **x** from either table contains a NULL value, Vertica returns a run-time error:

```
-> SELECT * FROM t1 WHERE (x IN (SELECT x FROM t2)) IS FALSE;
ERROR: NULL value found in a column used by a subquery
```

EXISTS versus IN

Whether you use EXISTS or IN subqueries depends on which predicates you select in outer and inner query blocks. For example, the following query gets a list of all the orders placed by all stores on January 2, 2007 for vendors with records in the vendor table:

```
-> SELECT store_key, order_number, date_ordered
FROM store.store_orders_fact WHERE EXISTS
  (SELECT 1 FROM public.vendor_dimension vd JOIN store.store_orders_fact ord ON vd.vendor_key = ord.vendor_key)
AND date_ordered = '2007-01-02';
store_key | order_number | date_ordered
-----+-----+-----
  114 |    271071 | 2007-01-02
   19 |    290888 | 2007-01-02
  132 |    58942 | 2007-01-02
  232 |     9286 | 2007-01-02
  126 |   224474 | 2007-01-02
  196 |    63482 | 2007-01-02
...
  196 |    83327 | 2007-01-02
  138 |   278373 | 2007-01-02
  179 |   293586 | 2007-01-02
  155 |   213413 | 2007-01-02
(506 rows)
```

The above query looks for existence of the vendor and date ordered. To return a particular value, rather than simple existence, the query looks for orders placed by the vendor who got the best deal on January 2, 2007:

```
-> SELECT store_key, order_number, date_ordered, vendor_name
FROM store.store_orders_fact ord JOIN public.vendor_dimension vd ON ord.vendor_key = vd.vendor_key
WHERE vd.deal_size IN (SELECT MAX(deal_size) FROM public.vendor_dimension) AND date_ordered = '2007-01-02';
store_key | order_number | date_ordered | vendor_name
-----+-----+-----+-----
   50 |    99234 | 2007-01-02 | Everything Wholesale
   81 |   200802 | 2007-01-02 | Everything Wholesale
  115 |    13793 | 2007-01-02 | Everything Wholesale
  204 |    41842 | 2007-01-02 | Everything Wholesale
  133 |   169025 | 2007-01-02 | Everything Wholesale
  163 |   208580 | 2007-01-02 | Everything Wholesale
   29 |   154972 | 2007-01-02 | Everything Wholesale
  145 |   236790 | 2007-01-02 | Everything Wholesale
  249 |    54838 | 2007-01-02 | Everything Wholesale
   7 |   161536 | 2007-01-02 | Everything Wholesale
(10 rows)
```

Examples

The following SELECT statement queries all data in table **t11**.

```

-> SELECT * FROM t11 ORDER BY pk;
pk | col1 | col2 | SKIP_ME_FLAG
-----
1 | 2 | 3 | t
2 | 3 | 4 | t
3 | 4 | 5 | t
4 | 5 | 6 | t
5 | 6 | 7 | t
6 |   | 8 | f
7 | 8 |   | t
(7 rows)

```

The following query specifies an **IN** predicate, to find all rows in **t11** where columns **col1** and **col2** contain values of **(2,3)** or **(6,7)** :

```

-> SELECT * FROM t11 WHERE (col1, col2) IN ((2,3), (6,7)) ORDER BY pk;
pk | col1 | col2 | SKIP_ME_FLAG
-----
1 | 2 | 3 | t
5 | 6 | 7 | t
(2 rows)

```

The following query uses the **VMart** schema to illustrate the use of outer expressions referring to different inner expressions:

```

-> SELECT product_description, product_price FROM product_dimension
WHERE (product_dimension.product_key, product_dimension.product_key) IN
(SELECT store.store_orders_fact.order_number,
store.store_orders_fact.quantity_ordered
FROM store.store_orders_fact);
product_description | product_price
-----
Brand #73 wheelchair | 454
Brand #72 box of candy | 326
Brand #71 vanilla ice cream | 270
(3 rows)

```

INTERPOLATE

Joins two [event series](#) using some ordered attribute. Event series joins let you compare values from two series directly, rather than having to normalize the series to the same measurement interval.

An event series join is an extension of a regular [outer join](#). The difference between expressing a regular outer join and an event series join is the **INTERPOLATE** predicate, which is used in the **ON** clause (see [Examples](#) below). Instead of padding the non-preserved side with null values when there is no match, the event series join pads the non-preserved side with the previous/next values from the table.

Interpolated values come from the table that contains the null, not from the other table. Vertica does not guarantee that the output contains no null values. If there is no previous/next value for a mismatched row, that row is padded with nulls.

Syntax

```

expression1 INTERPOLATE { PREVIOUS | NEXT } VALUE expression2

```

Arguments

expression1 ,
expression2

A [column reference](#) from one of the tables specified in the [FROM clause](#).

The columns can be of any data type. Because event series are time-based, the type is typically **DATE/TIME** or **TIMESTAMP**.

{ PREVIOUS | NEXT
} VALUE

Pads the non-preserved side with the previous/next values when there is no match. If previous is called on the first row (or next on the last row), will pad with null values.

Input rows are sorted in ascending logical order of the join column.

Note

An ORDER BY clause, if used, does not determine the input order but only determines query output order.

Notes

- Data is logically partitioned on the table in which it resides, based on other ON clause equality predicates.
- Event series join requires that the joined tables are both sorted on columns in equality predicates, in any order, followed by the INTERPOLATED column. If data is already sorted in this order, then an explicit sort is avoided, which can improve query performance. For example, given the following tables:

```
ask: exchange, stock, ts, pricebid: exchange,  
stock, ts, price
```

In the query that follows:

- **ask** is sorted on **exchange, stock** (or the reverse), **ts**
- **bid** is sorted on **exchange, stock** (or the reverse), **ts**

```
SELECT ask.price - bid.price, ask.ts, ask.stock, ask.exchange  
FROM ask FULL OUTER JOIN bid  
ON ask.stock = bid.stock AND ask.exchange =  
bid.exchange AND ask.ts INTERPOLATE PREVIOUS  
VALUE bid.ts;
```

Restrictions

- Only one INTERPOLATE expression is allowed per join.
- INTERPOLATE expressions are used only with ANSI SQL-99 syntax (the ON clause), which is already true for full outer joins.
- INTERPOLATE can be used with equality predicates only.
- The AND operator is supported but not the OR and NOT operators.
- Expressions and implicit or explicit casts are not supported, but subqueries are allowed.

Semantics

When you write an event series join in place of normal join, values are evaluated as follows (using the schema in the examples below):

- **t** is the outer, preserved table.
- **t1** is the inner, non-preserved table.
- For each row in outer table **t**, the ON clause predicates are evaluated for each combination of each row in the inner table **t1**.
- If the ON clause predicates evaluate to true for any combination of rows, those combination rows are produced at the output.
- If the ON clause is false for all combinations, a single output row is produced with the values of the row from **t** along with the columns of **t1** chosen from the row in **t1** with the greatest **t1.y** value such that **t1.y < t.x**; If no such row is found, pad with nulls.

Note

t LEFT OUTER JOIN t1 is equivalent to **t1 RIGHT OUTER JOIN t**.

In the case of a full outer join, all values from both tables are preserved.

Examples

The examples that follow use this simple schema.

```
CREATE TABLE t(x TIME);
CREATE TABLE t1(y TIME);
INSERT INTO t VALUES('12:40:23');
INSERT INTO t VALUES('13:40:25');
INSERT INTO t VALUES('13:45:00');
INSERT INTO t VALUES('14:49:55');
INSERT INTO t1 VALUES('12:40:23');
INSERT INTO t1 VALUES('14:00:00');
COMMIT;
```

Normal full outer join

```
=> SELECT * FROM t FULL OUTER JOIN t1 ON t.x = t1.y;
```

Notice the null rows from the non-preserved table:

```
x | y
-----+-----
12:40:23 | 12:40:23
13:40:25 |
13:45:00 |
14:49:55 |
      | 14:00:00
(5 rows)
```

Full outer join with interpolation

```
=> SELECT * FROM t FULL OUTER JOIN t1 ON t.x INTERPOLATE PREVIOUS VALUE t1.y;
```

In this case, the rows with no entry point are padded with values from the previous row.

```
x | y
-----+-----
12:40:23 | 12:40:23
13:40:25 | 12:40:23
13:45:00 | 12:40:23
14:49:55 | 12:40:23
13:40:25 | 14:00:00
(5 rows)
```

Likewise, interpolate next is also supported:

```
=> SELECT * FROM t FULL OUTER JOIN t1 ON t.x INTERPOLATE NEXT VALUE t1.y;
```

In this case, the rows with no entry point are padded with values from the next row.

```
x | y
-----+-----
12:40:23 | 12:40:23
13:40:25 | 14:00:00
13:45:00 | 14:00:00
14:49:55 |
14:49:55 | 14:00:00
(5 rows)
```

Normal left outer join

```
=> SELECT * FROM t LEFT OUTER JOIN t1 ON t.x = t1.y;
```

Again, there are nulls in the non-preserved table

x	y
12:40:23	12:40:23
13:40:25	
13:45:00	
14:49:55	

(4 rows)

Left outer join with interpolation

```
=> SELECT * FROM t LEFT OUTER JOIN t1 ON t.x INTERPOLATE PREVIOUS VALUE t1.y;
```

Nulls have been padded with interpolated values.

x	y
12:40:23	12:40:23
13:40:25	12:40:23
13:45:00	12:40:23
14:49:55	14:00:00

(4 rows)

Likewise, interpolate next is also supported:

```
=> SELECT * FROM t LEFT OUTER JOIN t1 ON t.x INTERPOLATE NEXT VALUE t1.y;
```

Nulls have been padded with interpolated values here as well.

x	y
12:40:23	12:40:23
13:40:25	14:00:00
13:45:00	14:00:00
14:49:55	

(4 rows)

Inner joins

For inner joins, there is no difference between a regular inner join and an event series inner join. Since null values are eliminated from the result set, there is nothing to interpolate.

A regular inner join returns only the single matching row at 12:40:23:

```
=> SELECT * FROM t INNER JOIN t1 ON t.x = t1.y;
```

x	y
12:40:23	12:40:23

(1 row)

An event series inner join finds the same single-matching row at 12:40:23:

```
=> SELECT * FROM t INNER JOIN t1 ON t.x INTERPOLATE PREVIOUS VALUE t1.y;
```

x	y
12:40:23	12:40:23

(1 row)

[Event series joins](#)

In this section

- [Join predicate](#)

Join predicate

Specifies the columns on which records from two or more tables are joined. You can connect multiple join predicates with logical operators **AND**, **OR**, and **NOT**.

Syntax

```
ON column-ref = column-ref [ { AND | OR | NOT } column-ref = column-ref ]...
```

Parameters

[column-ref](#) Specifies a column in a queried table. For best performance, do not join on **LONG VARBINARY** and **LONG VARCHAR** columns.

See also

[Joins](#)

LIKE

Retrieves rows where a string expression—typically a column—matches the specified pattern or, if qualified by ANY or ALL, set of patterns. Patterns can contain one or more wildcard characters.

If an ANY or ALL pattern is qualified with NOT, the negation is pushed down to each clause. **NOT LIKE ANY (a, b)** is equivalent to **NOT LIKE a OR NOT LIKE b**. See the examples.

Syntax

```
string-expression [ NOT ] { LIKE | ILIKE | LIKEB | ILIKEB }  
{ pattern | { ANY | SOME | ALL } ( pattern,... ) } [ ESCAPE 'char' ]
```

Arguments

string-expression

String expression, typically a column, to test for instances of the specified [pattern or patterns](#).

NOT

Returns true if the LIKE predicate returns false and vice-versa. When used with ANY or ALL, applies to each value individually.

LIKE | ILIKE | LIKEB | ILIKEB

Type of comparison:

- **LIKE**: Complies with the SQL standard, case-sensitive, operates on UTF-8 character strings, exact behavior depends on collation parameters such as strength. LIKE is [stable](#) for character strings, but [immutable](#) for binary strings
- **ILIKE**: Same as LIKE but case-insensitive.
- **LIKEB**: Performs case-sensitive byte-at-a-time ASCII comparisons, [immutable](#) for character and binary strings.
- **ILIKEB**: Same as LIKEB but case-insensitive.

pattern

A pattern to test against the expression. Pattern strings can contain the following wildcard characters:

- **_** (underscore): Match any single character.
- **%** (percent): Match any string of zero or more characters.

ANY | SOME | ALL

Apply a comma-delimited list of patterns, where:

- **ANY** and **SOME** return true if any pattern matches, equivalent to logical OR. These options are synonyms.
- **ALL** returns true only if all patterns match, equivalent to logical AND.

ESCAPE char

Escape character, by default backslash (\), used to escape reserved characters: wildcard characters (underscore and percent), and the escape character itself.

This option is enforced only for non-default collations; it is currently unsupported with ANY/ALL pattern matching.

Note

Backslash is not valid for binary data type characters. To embed an escape character for binary data types, use **ESCAPE** to specify a valid binary character.

Substitute symbols

You can substitute the following symbols for LIKE and its variants:

Note

ESCAPE usage is not valid for these symbols.

Symbol	Equivalent to:
~~	LIKE
~#	LIKEB
~~*	ILIKE
~#*	ILIKEB
!~~	NOT LIKE
!~#	NOT LIKEB
!~~*	NOT ILIKE
!~#*	NOT ILIKEB

Pattern matching

LIKE and its variants require that the entire string expression match the specified patterns. To match a sequence of characters anywhere within a string, the pattern must start and end with a percent sign.

LIKE does not ignore trailing white space characters. If the data values to match end with an indeterminate amount of white space, append the wildcard character `%` to *pattern*.

Locale dependencies

In the default locale, LIKE and ILIKE handle UTF-8 character-at-a-time, locale-insensitive comparisons. ILIKE handles language-independent case-folding.

In non-default locales, LIKE and ILIKE perform locale-sensitive string comparisons, including some automatic normalization, using the same algorithm as the `=` operator on VARCHAR types.

ESCAPE expressions evaluate to exactly one octet—or one UTF-8 character for non-default locales.

Examples

Basic pattern matching

The following query searches for names with a common prefix:

```
=> SELECT name FROM people WHERE name LIKE 'Ann%';
 name
-----
 Ann
 Ann Marie
 Anna
(3 rows)
```

LIKE ANY/ALL

LIKE operators support the keywords ANY and ALL, which let you specify multiple patterns to test against a string expression. For example, the following query finds all names that begin or end with the letter 'A':

```
-> SELECT name FROM people WHERE name LIKE ANY ('A%', '%a');
 name
-----
Alice
Ann
Ann Marie
Anna
Roberta
(5 rows)
```

LIKE ANY usage is equivalent to individual LIKE conditions combined with OR:

```
-> SELECT name FROM people WHERE name LIKE 'A%' OR name LIKE '%a';
 name
-----
Alice
Ann
Ann Marie
Anna
Roberta
(5 rows)
```

Similarly, LIKE ALL is equivalent to individual LIKE conditions combined with AND.

NOT LIKE ANY/ALL

You can use NOT with LIKE ANY or LIKE ALL. NOT does not negate the LIKE expression; instead it negates each clause.

Consider a table with the following contents:

```
-> SELECT name FROM people;
 name
-----
Alice
Ann
Ann Marie
Anna
Richard
Rob
Robert
Roberta
(8 rows)
```

In the following query, **NOT LIKE ANY ('A%', '%a')** is equivalent to **NOT LIKE 'A%' OR NOT LIKE '%a'** , so the only result that is eliminated is **Anna** , which matches both patterns:

```
-> SELECT name FROM people WHERE name NOT LIKE ANY ('A%', '%a');
 name
-----
Alice
Ann
Ann Marie
Richard
Rob
Robert
Roberta
(7 rows)

-- same results:
-> SELECT name FROM people WHERE name NOT LIKE 'A%' OR name NOT LIKE '%a';
```

NOT LIKE ALL eliminates results that satisfy any pattern:

```
=> SELECT name FROM people WHERE name NOT LIKE ALL ('A%', '%a');
 name
-----
Richard
Rob
Robert
(3 rows)
```

-- same results:

```
=> SELECT name FROM people WHERE name NOT LIKE 'A%' AND name NOT LIKE '%a';
```

Pattern matching in locales

The following example illustrates pattern matching in locales.

```
=> \locale default
INFO 2567: Canonical locale: 'en_US'
Standard collation: 'LEN_KBINARY'
English (United States)
=> CREATE TABLE src(c1 VARCHAR(100));
=> INSERT INTO src VALUES (U&'^00DF'); --The sharp s (ß)
=> INSERT INTO src VALUES ('ss');
=> COMMIT;
```

Querying the `src` table in the default locale returns both `ss` and sharp `s`.

```
=> SELECT * FROM src;
 c1
--
ß
ss
(2 rows)
```

The following query combines pattern-matching predicates to return the results from column `c1` :

```
=> SELECT c1, c1 = 'ss' AS equality, c1 LIKE 'ss'
 AS LIKE, c1 ILIKE 'ss' AS ILIKE FROM src;
 c1 | equality | LIKE | ILIKE
-----+-----+-----+-----
ß | f       | f     | f
ss | t       | t     | t
(2 rows)
```

The next query specifies unicode format for `c1` :

```
=> SELECT c1, c1 = U&'^00DF' AS equality,
 c1 LIKE U&'^00DF' AS LIKE,
 c1 ILIKE U&'^00DF' AS ILIKE from src;
 c1 | equality | LIKE | ILIKE
-----+-----+-----+-----
ß | t       | t     | t
ss | f       | f     | f
(2 rows)
```

Now change the locale to German with a strength of 1 (ignore case and accents):

```

=> \locale LDE_S1
INFO 2567: Canonical locale: 'de'
Standard collation: 'LDE_S1'
German Deutsch
=> SELECT c1, c1 = 'ss' AS equality,
c1 LIKE 'ss' AS LIKE, c1 ILIKE 'ss' AS ILIKE from src;
c1 | equality | LIKE | ILIKE
-----+-----
0 | t       | t     | t
ss | t       | t     | t
(2 rows)

```

This example illustrates binary data types with pattern-matching predicates:

```

=> CREATE TABLE t (c BINARY(1));
CREATE TABLE
=> INSERT INTO t VALUES (HEX_TO_BINARY('0x00')), (HEX_TO_BINARY('0xFF'));
OUTPUT
-----
  2
(1 row)

=> COMMIT;
COMMIT
=> SELECT TO_HEX(c) FROM t;
TO_HEX
-----
00
ff
(2 rows)

=> SELECT * FROM t;
 c
-----
\000
\377
(2 rows)

=> SELECT c, c = '000', c LIKE '000', c ILIKE '000' from t;
 c | ?column? | ?column? | ?column?
-----+-----
\000 | t       | t       | t
\377 | f       | f       | f
(2 rows)

=> SELECT c, c = '377', c LIKE '377', c ILIKE '377' FROM t;
 c | ?column? | ?column? | ?column?
-----+-----
\000 | f       | f       | f
\377 | t       | t       | t
(2 rows)

```

NULL

Tests for null values. The expression can be a column name, literal, or function.

Syntax

```
value-expression IS [ NOT ] NULL
```

Examples

Column name:

```
=> SELECT date_key FROM date_dimension WHERE date_key IS NOT NULL;
```

```
date_key
-----
1
366
1462
1097
2
3
6
7
8
```

Function:

```
=> SELECT MAX(household_id) IS NULL FROM customer_dimension;
```

```
?column?
-----
1
(1 row)
```

Literal:

```
=> SELECT 'a' IS NOT NULL;
```

```
?column?
-----
1
(1 row)
```

Hints

Hints are directives that you embed within a query or [directed query](#). They conform to the following syntax:

```
/*+hint-name[, hint-name]...*/
```

Hints are bracketed by comment characters `/*+` and `*/`, which can enclose multiple comma-delimited hints. For example:

```
SELECT /*+syntactic_join,verbatim*/
```

Restrictions

When embedding hints in a query, be aware of the following restrictions:

- Do not embed spaces in the comment characters `/*` and `*/`.
- In general, spaces are allowed before and after the plus (+) character and *hint-name*; however, some third-party tools do not support spaces embedded inside `/*` +.

Supported hints

Vertica supports the following hints:

General hints

Hint	Description
ALLNODES	Qualifies an EXPLAIN statement to request a query plan that assumes all nodes are active.
EARLY_MATERIALIZATION	Specifies early materialization of a table for the current query.
ENABLE_WITH_CLAUSE_MATERIALIZATION	Enables and disables WITH clause materialization for a specific query.
LABEL	Labels a query so you can identify it for profiling and debugging.
SKIP_STATISTICS	Directs the optimizer to produce a query plan that incorporates only minimal statistics.

Eon Mode hints

Hint	Description
DEPOT_FETCH	Specifies whether a query fetches data to the depot from communal storage when the depot lacks data for this query.
ECSMODE	Specifies the elastic crunch scaling (ECS) strategy for dividing shard data among its subscribers.

Join hints

Hint	Description
SYNTACTIC_JOIN	Enforces join order and enables other join hints.
DISTRIB	Sets the input operations for a distributed join to broadcast, resegment, local, or filter.
GBYTYPE	Specifies which algorithm—GROUPBY HASH or GROUPBY PIPELINED—the Vertica query optimizer should use to implement a GROUP BY clause.
JTYPE	Enforces the join type: merge or hash join.
UTYPE	Specifies how to combine UNION ALL input.

Projection hints

Hint	Description
PROJS	Specifies one or more projections to use for a queried table.
SKIP_PROJS	Specifies which projections to avoid using for a queried table.

Directed query hints

The following hints are only supported by directed queries:

Hint	Description
:c	Marks a query constant that must be included in an input query; otherwise, that input query is disqualified from using the directed query.
:v	Maps an input query constant to one or more annotated query constants.
VERBATIM	Enforces execution of an annotated query exactly as written.

In this section

- [:c](#)
- [:v](#)

- [PROJS](#)
- [SKIP_PROJS](#)
- [SKIP_STATISTICS](#)
- [SYNTACTIC_JOIN](#)
- [UTYPE](#)

- [VERBATIM](#)

:c

In a directed query, marks a query constant that must be included in an input query; otherwise, that input query is disqualified from using the directed query.

Syntax

```
/*+:c*/
```

Usage

By default, optimizer-generated directed queries set ignore constant (:v) hints on predicate constants. You can override this behavior by setting the :c hint on input query constants that must not be ignored. For example, the following statement creates a directed query that can be used only for input queries where the join predicate constant is the same as in the original input query— 8 :

```
=> CREATE DIRECTED QUERY OPTIMIZER simpleJoin_KeepPredicateConstant SELECT * FROM S JOIN T ON S.a = T.b WHERE S.a = 8 /*+:c*/;  
CREATE DIRECTED QUERY  
=> ACTIVATE DIRECTED QUERY simpleJoin_KeepPredicateConstant;
```

See also

[Conserving Predicate Constants in Directed Queries](#)

:v

In a directed query, marks an input query constant that the optimizer ignores when it considers whether to use the directed query for a given query. Use this hint to create a directed query that can be used for multiple variants of an input query.

Vertica also supports **IGNORECONST** as an alias of :v . Optimizer-generated directed queries automatically mark predicate constants in input and annotated queries with :v hints.

For details, see [Ignoring constants in directed queries](#).

Syntax

```
/*+:v(arg)*/  
/*+IGNORECONST(arg)*/
```

arg

Integer argument that is used in the directed query to pair each input query :v hint with one or more annotated query :v hints.

Examples

See [Ignoring constants in directed queries](#).

ALLNODES

Qualifies an **EXPLAIN** statement to request a query plan that assumes all nodes are active. If you omit this hint, the **EXPLAIN** statement produces a query plan that takes into account any nodes that are currently down.

Syntax

```
EXPLAIN /*+ALLNODES*/
```

Examples

In the following example, the **ALLNODES** hint requests a query plan that assumes all nodes are active.

QUERY PLAN DESCRIPTION:

Opt Vertica Options

PLAN_ALL_NODES_ACTIVE

EXPLAIN /*+ALLNODES*/ select * from Emp_Dimension;

Access Path:

+--STORAGE ACCESS for Emp_Dimension [Cost: 125, Rows: 10K (NO STATISTICS)] (PATH ID: 1)

| Projection: public.Emp_Dimension_b0

| Materialize: Emp_Dimension.Employee_key, Emp_Dimension.Employee_gender, Emp_Dimension.Courtesy_title, Emp_Dimension.Employee_first_name, Emp_Dimension.Employee_middle_initial, Emp_Dimension.Employee_last_name, Emp_Dimension.Employee_age, Emp_Dimension.Employee_birthdate, Emp_Dimension.Employee_street, Emp_Dimension.Employee_city, Emp_Dimension.Employee_state, Emp_Dimension.Employee_region, Emp_Dimension.Employee_position

| Execute on: All Nodes

DEPOT_FETCH

Eon Mode only

Specifies whether a query fetches data to the depot from communal storage when the depot lacks data for this query. This hint overrides configuration parameter [DepotOperationsForQuery](#).

Syntax

```
SELECT /*+DEPOT_FETCH (option)*/
```

Arguments

*** option ***

Specifies behavior when the depot does not contain queried file data, one of the following:

- **ALL** (default): Fetch file data from communal storage, if necessary displace existing files by evicting them from the depot.
- **FETCHES** : Fetch file data from communal storage only if space is available; otherwise, read the queried data directly from communal storage.
- **NONE** : Do not fetch file data to the depot, read the queried data directly from communal storage.

Examples

```
SELECT /*+DEPOT_FETCH(All)*/ count(*) FROM bar;  
SELECT /*+DEPOT_FETCH(FETCHES)*/ count(*) FROM bar;  
SELECT /*+DEPOT_FETCH(NONE)*/ count(*) FROM bar;
```

DISTRIB

The DISTRIB hint specifies to the optimizer how to distribute join key data in order to implement a join. If a specified distribution is not feasible, the optimizer ignores the hint and throws a warning.

The following requirements apply:

- Queries that include the DISTRIB hint must also include the SYNTACTIC_JOIN hint. Otherwise, the optimizer ignores the DISTRIB hint and throws a warning.
- Join syntax must conform with ANSI SQL-92 join conventions.

Syntax

```
JOIN /*+DISTRIB(outer-join, inner-join)*/
```

Arguments

outer-join

inner-join

Specifies how to distribute data on the outer and inner joins:

- **L** (local): Inner and outer join keys are identically segmented on each node, join locally.
- **R** (resegment): Inner and outer join keys are not identically segmented. Resegment join-key data before implementing the join.

- **B** (broadcast): Inner and outer join keys are not identically segmented. Broadcast data of this join key to other nodes before implementing the join.
- **F** (filter): Join table is unsegmented. Filter data as needed by the other join key before implementing the join.
- **A** (any): Let the optimizer choose the distribution method that it considers to be most cost-effective.

Examples

In the following query, the join is qualified with a **DISTRIB** hint of `/*+DISTRIB(L,R)*/`. This hint tells the optimizer to resegment data of join key `stores.store_key` before joining it to the `sales.store_key` data:

```
SELECT /*+SYNTACTIC_JOIN*/ sales.store_key, stores.store_name, sales.product_description, sales.sales_quantity, sales.sale_date
FROM (store.storeSales AS sales JOIN /*+DISTRIB(L,R),JTYPE(H)*/ store.store_dimension AS stores ON (sales.store_key = stores.store_key))
WHERE (sales.sale_date = '2014-12-01'::date) ORDER BY sales.store_key, sales.sale_date;
```

EARLY_MATERIALIZATION

Specifies early materialization of a table for the current query. A query can include this hint for any number of tables. Typically, the query optimizer delays materialization until late in the query execution process. This hint overrides any choices that the optimizer otherwise would make.

This hint can be useful in cases where late materialization of join inputs precludes other optimizations—for example, pushing aggregation down the joins, or using live aggregate projections. In these cases, qualifying a join input with **EARLY_MATERIALIZATION** can enable the optimizations.

Syntax

```
table-name [ [AS] alias ] /*+EARLY_MATERIALIZATION*/
```

ECSMODE

Eon Mode only

Sets the [ECS strategy](#) that the optimizer uses when it divides responsibility for processing shard data among subscriber nodes. This hint is applied only if the subcluster uses [elastic crunch scaling](#) (ECS).

Syntax

```
SELECT /*+ECSMODE(option)*/
```

Arguments

* option *

Specifies the strategy to use when dividing shard data among its subscribing nodes, one of the following:

- **AUTO** : The optimizer chooses the strategy to use, useful only if ECS mode is set at the session level (see [Setting the ECS Strategy for the Session or Database](#)).
- **IO_OPTIMIZED** : Use I/O-optimized strategy.
- **COMPUTE_OPTIMIZED** : Use compute-optimized strategy.
- **NONE** : Disable use of ECS for this query. Only participating nodes are involved in query execution; collaborating nodes are not.

Example

The following example shows the query plan for a simple single-table query that is forced to use the compute-optimized strategy:

```
=> EXPLAIN SELECT /*+ECSMODE(COMPUTE_OPTIMIZED)*/ employee_last_name,
employee_first_name,employee_age
FROM employee_dimension
ORDER BY employee_age DESC;
```

QUERY PLAN

QUERY PLAN DESCRIPTION:

The execution of this query involves non-participating nodes.
Crunch scaling strategy preserves data segmentation

ENABLE_WITH_CLAUSE_MATERIALIZATION

Enables materialization of all queries in the current WITH clause. Otherwise, materialization is set by configuration parameter `WithClauseMaterialization`, by default set to 0 (disabled). If `WithClauseMaterialization` is disabled, materialization is automatically cleared when the primary query of the WITH clause returns. For details, see [Materialization of WITH clause](#).

Syntax

```
WITH /*+ENABLE_WITH_CLAUSE_MATERIALIZATION*/
```

GBYTYPE

Specifies which algorithm—GROUPBY HASH or GROUPBY PIPELINED—the Vertica query optimizer should use to implement a [GROUP BY](#) clause. If both algorithms are valid for this query, the query optimizer chooses the specified algorithm over the algorithm that the query optimizer might otherwise choose in its query plan.

Note

Vertica uses the GROUPBY PIPELINED algorithm only if the query and one of its projections comply with GROUPBY PIPELINED [requirements](#). Otherwise, Vertica issues a warning and uses GROUPBY HASH.

For more information about both algorithms, see [GROUP BY implementation options](#).

Syntax

```
GROUP BY /*+GBYTYPE( HASH | PIPE )*/
```

Arguments

HASH

Use the GROUPBY HASH algorithm.

PIPE

Use the GROUPBY PIPELINED algorithm.

Examples

See [Controlling GROUPBY Algorithm Choice](#).

JFMT

Specifies how to size VARCHAR column data when joining tables on those columns, and buffer that data accordingly. The JFMT hint overrides the default behavior that is set by configuration parameter [JoinDefaultTupleFormat](#), which can be set at database and session levels.

For more information, see [Joining variable length string data](#).

Syntax

```
JOIN /*+JFMT(format-type)*/
```

Arguments

format-type

Specifies how to format VARCHAR column data when joining tables on those columns, and buffers the data accordingly. Set to one of the following:

- **f** (fixed): Use join column metadata to size column data to a fixed length, and buffer accordingly.
- **v** (variable): Use the actual length of join column data, so buffer size varies for each join.

For example:

```
SELECT /*+SYNTACTIC_JOIN*/ s.store_region, SUM(e.vacation_days) TotalVacationDays
FROM public.employee_dimension e
JOIN /*+JFMT(f)*/ store.store_dimension s ON s.store_region=e.employee_region
GROUP BY s.store_region ORDER BY TotalVacationDays;
```

Requirements

- Queries that include the **JFMT** hint must also include the **SYNTACTIC_JOIN** hint. Otherwise, the optimizer ignores the **JFMT** hint and throws a warning.
- Join syntax must conform with ANSI SQL-92 join conventions.

JTYPE

Specifies the join algorithm as hash or merge.

Use the JTYPE hint to specify the algorithm the optimizer uses to join table data. If the specified algorithm is not feasible, the optimizer ignores the hint and throws a warning.

Syntax

```
JOIN /*+JTYPE(join-type)*/
```

Arguments

join-type

One of the following:

- **H** : Hash join
- **M** : Merge join, valid only if both join inputs are already sorted on the join columns, otherwise Vertica ignores it and throws a warning. The optimizer relies upon the query or DDL to verify whether input data is sorted, rather than the actual runtime order of the data.
- **FM** : Forced merge join. Before performing the merge, the optimizer re-sorts the join inputs. Join columns must be of the same type and precision or scale, except that string columns can have different lengths.

A value of **FM** is valid only for simple join conditions. For example:

```
=> SELECT /*+SYNTACTIC_JOIN*/ * FROM x JOIN /*+JTYPE(FM)*/ y ON x.c1 = y.c1;
```

Requirements

- Queries that include the JTYPE hint must also include the SYNTACTIC_JOIN hint. Otherwise, the optimizer ignores the JTYPE hint and throws a warning.
- Join syntax must conform with ANSI SQL-92 join conventions.

LABEL

Assigns a label to a statement so it can [easily be identified](#) to evaluate performance and debug problems.

LABEL hints are valid in the following statements:

- [COPY](#)
- [DELETE](#)
- EXPORT statements:
 - [EXPORT TO DELIMITED](#)
 - [EXPORT TO ORC](#)
 - [EXPORT TO PARQUET](#)
 - [EXPORT TO VERTICA](#)
- [INSERT](#)
- [MERGE](#)
- [SELECT](#)
- [UPDATE](#)
- [UNION](#) : Valid in the UNION's first SELECT statement. Vertica ignores labels in subsequent SELECT statements.

Syntax

```
statement-name /*+LABEL (label-string)*/
```

Arguments

label-string

A string that is up to 128 octets long. If enclosed with single quotes, *label-string* can contain embedded spaces.

Examples

See [Labeling statements](#).

PROJS

Specifies one or more projections to use for a queried table.

The PROJS hint can specify multiple projections; the optimizer determines which ones are valid and uses the one that is most cost-effective for the queried table. If no hinted projection is valid, the query returns a warning and ignores projection hints.

Syntax

```
FROM ``table-name`` /*+PROJS( [[ ``database``.``]`` schema.``]`` projection``[,...] )*/
```

Arguments

[**database** .] **schema**

Database and [schema](#). The default schema is **public**. If you specify a database, it must be the current database.

projection

The projection to use. You can specify a list of comma-delimited projections.

Examples

The **employee_dimension** table has two projections: segmented superprojection **public.employee_dimension**, which includes all table columns; and the unsegmented projection **public.employee_dimension_rep**, which includes a subset of the columns:

```
=> SELECT export_objects(", 'employee_dimension');  
      export_objects
```

```
CREATE TABLE public.employee_dimension  
(  
  employee_key int NOT NULL,  
  employee_gender varchar(8),  
  courtesy_title varchar(8),  
  employee_first_name varchar(64),  
  employee_middle_initial varchar(8),  
  employee_last_name varchar(64),  
  employee_age int,  
  hire_date date,  
  employee_street_address varchar(256),  
  employee_city varchar(64),  
  employee_state char(2),  
  employee_region char(32),  
  job_title varchar(64),  
  reports_to int,  
  salaried_flag int,  
  annual_salary int,  
  hourly_rate float,  
  vacation_days int,  
  CONSTRAINT C_PRIMARY PRIMARY KEY (employee_key) DISABLED  
);
```

```
CREATE PROJECTION public.employee_dimension
```

```
...
```

```
AS
```

```
SELECT employee_dimension.employee_key,  
       employee_dimension.employee_gender,  
       employee_dimension.courtesy_title,  
       employee_dimension.employee_first_name,  
       employee_dimension.employee_middle_initial,  
       employee_dimension.employee_last_name,  
       employee_dimension.employee_age,  
       employee_dimension.hire_date,  
       employee_dimension.employee_street_address,  
       employee_dimension.employee_city,  
       employee_dimension.employee_state,  
       employee_dimension.employee_region,  
       employee_dimension.job_title,  
       employee_dimension.reports_to,  
       employee_dimension.salaried_flag,  
       employee_dimension.annual_salary,  
       employee_dimension.hourly_rate,  
       employee_dimension.vacation_days  
FROM public.employee_dimension
```

```

ORDER BY employee_dimension.employee_key
SEGMENTED BY hash(employee_dimension.employee_key) ALL NODES KSAFE 1;

CREATE PROJECTION public.employee_dimension_rep
...
AS
SELECT employee_dimension.employee_key,
       employee_dimension.employee_gender,
       employee_dimension.employee_first_name,
       employee_dimension.employee_middle_initial,
       employee_dimension.employee_last_name,
       employee_dimension.employee_age,
       employee_dimension.employee_street_address,
       employee_dimension.employee_city,
       employee_dimension.employee_state,
       employee_dimension.employee_region
FROM public.employee_dimension
ORDER BY employee_dimension.employee_key
UNSEGMENTED ALL NODES;

SELECT MARK_DESIGN_KSAFE(1);

(1 row)

```

The following query selects all table columns from `employee_dimension` and includes the `PROJS` hint, which specifies both projections. `public.employee_dimension_rep` does not include all columns in the queried table, so the optimizer cannot use it. The segmented projection includes all table columns so the optimizer uses it, as verified by the following query plan:

```

=> EXPLAIN SELECT * FROM employee_dimension /*+PROJS('public.employee_dimension_rep', 'public.employee_dimension')*/;

QUERY PLAN DESCRIPTION:
-----
EXPLAIN SELECT * FROM employee_dimension /*+PROJS('public.employee_dimension_rep', 'public.employee_dimension')*/;

Access Path:
+-STORAGE ACCESS for employee_dimension [Cost: 177, Rows: 10K (NO STATISTICS)] (PATH ID: 1)
 | Projection: public.employee_dimension_b0

```

SKIP_PROJS

Specifies which projections to avoid using for a queried table. If `SKIP_PROJS` excludes all available projections that are valid for the query, the optimizer issues a warning and ignores the projection hints.

Syntax

```
FROM table-name /*+SKIP_PROJS( [[database.]schema.]projection[,...] )*/
```

Arguments

[***database.***] ***schema***

Database and `schema`. The default schema is `public`. If you specify a database, it must be the current database.

projection

A projection to skip. You can specify a list of comma-delimited projections.

Examples

In this example, the EXPLAIN output shows that the optimizer uses the projection `public.employee_dimension_b0` for a given query:

QUERY PLAN DESCRIPTION:

```
EXPLAIN SELECT employee_last_name, employee_first_name, employee_city, job_title FROM employee_dimension;
```

Access Path:

+--STORAGE ACCESS for employee_dimension [Cost: 59, Rows: 10K (NO STATISTICS)] (PATH ID: 1)

| **Projection: public.employee_dimension_b0**

| Materialize: employee_dimension.employee_first_name, employee_dimension.employee_last_name, employee_dimension.employee_city, employee_dimension.job_title

| Execute on: All Nodes

You can use the [SKIP_PROJS](#) hint to avoid using this projection. If another projection is available that is valid for this query, the optimizer uses it instead:

QUERY PLAN DESCRIPTION:

```
EXPLAIN SELECT employee_last_name, employee_first_name, employee_city, job_title FROM employee_dimension  
/*+SKIP_PROJS('public.employee_dimension')*/;
```

Access Path:

+--STORAGE ACCESS for employee_dimension [Cost: 156, Rows: 10K (NO STATISTICS)] (PATH ID: 1)

| **Projection: public.employee_dimension_super**

| Materialize: employee_dimension.employee_first_name, employee_dimension.employee_last_name, employee_dimension.employee_city, employee_dimension.job_title

| Execute on: Query Initiator

SKIP_STATISTICS

Directs the optimizer to produce a query plan that incorporates only the minimal statistics that are collected by [ANALYZE_ROW_COUNT](#). The optimizer ignores other statistics that would otherwise be used, that are generated by [ANALYZE_STATISTICS](#) and [ANALYZE_STATISTICS_PARTITION](#). This hint is especially useful when used in queries on small tables, where the amount of time required to collect full statistics is often greater than actual execution time.

Syntax

```
SELECT /*+SKIP_STAT[ISTICS]S*/
```

EXPLAIN output

EXPLAIN returns the following output for a query that includes [SKIP_STATISTICS](#) (using its shortened form [SKIP_STATS](#)):

```
=> EXPLAIN SELECT /*+ SKIP_STATS*/ customer_key, customer_name, customer_gender, customer_city||', '||customer_state, customer_age
FROM customer_dimension WHERE customer_region = 'East' AND customer_age > 60;
```

QUERY PLAN DESCRIPTION:

```
EXPLAIN SELECT /*+ SKIP_STATS*/ customer_key, customer_name, customer_gender, customer_city||', '||customer_state,
customer_age FROM customer_dimension WHERE customer_region = 'East' AND customer_age > 60;
```

Access Path:

```
+--STORAGE ACCESS for customer_dimension [Cost: 2K, Rows: 10K (STATISTICS SKIPPED)] (PATH ID: 1)
```

```
| Projection: public.customer_dimension_b0
```

```
| Materialize: public.customer_dimension.customer_age, public.customer_dimension.customer_key, public.customer_dimensi
on.customer_name, public.customer_dimension.customer_gender, public.customer_dimension.customer_city, public.customer_di
mension.customer_state
```

```
| Filter: (public.customer_dimension.customer_region = 'East')
```

```
| Filter: (public.customer_dimension.customer_age > 60)
```

```
| Execute on: All Nodes
```

...

SYNTACTIC_JOIN

Enforces join order and enables other join hints.

In order to achieve optimal performance, the optimizer often overrides a query's specified join order. By including the **SYNTACTIC_JOIN** hint, you can ensure that the optimizer enforces the query's join order exactly as specified. One requirement applies: the join syntax must conform with ANSI SQL-92 conventions.

The **SYNTACTIC_JOIN** hint must immediately follow **SELECT** . If the annotated query includes another hint that must also follow **SELECT** , such as **VERBATIM** , combine the two hints together. For example:

```
SELECT /*+ syntactic_join,verbatim*/
```

Syntax

```
SELECT /*+SYN[TACTIC]_JOIN*/
```

Examples

In the following examples, the optimizer produces different plans for two queries that differ only by including or excluding the **SYNTACTIC_JOIN** hint.

Excludes SYNTACTIC_JOIN:

```
EXPLAIN SELECT sales.store_key, stores.store_name, products.product_description, sales.sales_quantity, sales.sale_date
FROM (store.store_sales sales JOIN products ON sales.product_key=products.product_key)
JOIN store.store_dimension stores ON sales.store_key=stores.store_key
WHERE sales.sale_date='2014-12-01' order by sales.store_key, sales.sale_date;
```

Access Path:

```
+--SORT [Cost: 14K, Rows: 100K (NO STATISTICS)] (PATH ID: 1)
| Order: sales.store_key ASC, sales.sale_date ASC
| Execute on: All Nodes
| +---> JOIN HASH [Cost: 11K, Rows: 100K (NO STATISTICS)] (PATH ID: 2) Outer (RESEGMENT)(LOCAL ROUND ROBIN) Inner (RESEGMENT)
||   Join Cond: (sales.product_key = products.product_key)
||   Materialize at Input: sales.store_key, sales.product_key, sales.sale_date, sales.sales_quantity
||   Execute on: All Nodes
|| +-- Outer -> JOIN HASH [Cost: 1K, Rows: 100K (NO STATISTICS)] (PATH ID: 3)
|||   Join Cond: (sales.store_key = stores.store_key)
|||   Execute on: All Nodes
||| +-- Outer -> STORAGE ACCESS for sales [Cost: 1K, Rows: 100K (NO STATISTICS)] (PATH ID: 4)
||||   Projection: store.store_sales_b0
||||   Materialize: sales.store_key
||||   Filter: (sales.sale_date = '2014-12-01'::date)
||||   Execute on: All Nodes
||||   Runtime Filter: (SIP1(HashJoin): sales.store_key)
||| +-- Inner -> STORAGE ACCESS for stores [Cost: 34, Rows: 250] (PATH ID: 5)
||||   Projection: store.store_dimension_DBD_10_rep_VMartDesign_node0001
||||   Materialize: stores.store_key, stores.store_name
||||   Execute on: All Nodes
|| +-- Inner -> STORAGE ACCESS for products [Cost: 3K, Rows: 60K (NO STATISTICS)] (PATH ID: 6)
|||   Projection: public.products_b0
|||   Materialize: products.product_key, products.product_description
|||   Execute on: All Nodes
```

Includes SYNTACTIC_JOIN:

```
EXPLAIN SELECT /*+SYNTACTIC_JOIN*/ sales.store_key, stores.store_name, products.product_description, sales.sales_quantity, sales.sale_date
FROM (store.store_sales sales JOIN products ON sales.product_key=products.product_key)
JOIN store.store_dimension stores ON sales.store_key=stores.store_key
WHERE sales.sale_date='2014-12-01' order by sales.store_key, sales.sale_date;
```

Access Path:

```
+--SORT [Cost: 11K, Rows: 100K (NO STATISTICS)] (PATH ID: 1)
| Order: sales.store_key ASC, sales.sale_date ASC
| Execute on: All Nodes
| +---> JOIN HASH [Cost: 8K, Rows: 100K (NO STATISTICS)] (PATH ID: 2)
||   Join Cond: (sales.store_key = stores.store_key)
||   Execute on: All Nodes
|| +-- Outer -> JOIN HASH [Cost: 7K, Rows: 100K (NO STATISTICS)] (PATH ID: 3) Outer (BROADCAST)(LOCAL ROUND ROBIN)
|||   Join Cond: (sales.product_key = products.product_key)
|||   Execute on: All Nodes
|||   Runtime Filter: (SIP1(HashJoin): sales.store_key)
||| +-- Outer -> STORAGE ACCESS for sales [Cost: 2K, Rows: 100K (NO STATISTICS)] (PATH ID: 4)
||||   Projection: store.store_sales_b0
||||   Materialize: sales.sale_date, sales.store_key, sales.product_key, sales.sales_quantity
||||   Filter: (sales.sale_date = '2014-12-01'::date)
||||   Execute on: All Nodes
||| +-- Inner -> STORAGE ACCESS for products [Cost: 3K, Rows: 60K (NO STATISTICS)] (PATH ID: 5)
||||   Projection: public.products_b0
||||   Materialize: products.product_key, products.product_description
||||   Execute on: All Nodes
|| +-- Inner -> STORAGE ACCESS for stores [Cost: 34, Rows: 250] (PATH ID: 6)
|||   Projection: store.store_dimension_DBD_10_rep_VMartDesign_node0001
|||   Materialize: stores.store_key, stores.store_name
|||   Execute on: All Nodes
```

UTYPE

Specifies how to combine [UNION ALL](#) input.

Syntax

```
UNION ALL /*+UTYPE(union-type)*/
```

Arguments

union-type

One of the following values:

- **U** : Concatenates [UNION ALL](#) input (default).
- **M** : Merges [UNION ALL](#) input in the same sort order as the source query results. This option requires all input from the source queries to use the same sort order; otherwise, Vertica throws a warning and concatenates the [UNION ALL](#) input.

Note

The optimizer relies upon the query or DDL to verify whether input data is sorted, rather than the actual runtime order of the data.

Requirements

Queries that include the [UTYPE](#) hint must also include the [SYNTACTIC_JOIN](#) hint. Otherwise, the optimizer ignores the [UTYPE](#) hint and throws a warning.

VERBATIM

Enforces execution of an annotated query exactly as written.

VERBATIM directs the optimizer to create a query plan that incorporates all hints in a annotated query. Furthermore, it directs the optimizer not to apply its own plan development processing on query plan components that pertain to those hints.

Usage of this hint varies between [optimizer-generated](#) and [custom](#) directed queries, as described below.

Syntax

```
SELECT /*+ VERBATIM*/
```

Requirements

The VERBATIM hint must immediately follow SELECT. If the annotated query includes another hint that must also follow SELECT, such as SYNTACTIC_JOIN, combine the two hints together. For example:

```
SELECT /*+ syntactic_join,verbatim*/
```

Optimizer-generated directed queries

The optimizer always includes the VERBATIM hint in the annotated queries that it [generates for directed queries](#). For example, given the following CREATE DIRECTED QUERY OPTIMIZER statement:

```
=> CREATE DIRECTED QUERY OPTIMIZER getStoreSales SELECT sales.store_key, stores.store_name, sales.product_description, sales.sales_quantity, sales.sale_date FROM store.storesales sales JOIN store.store_dimension stores ON sales.store_key=stores.store_key WHERE sales.sale_date='2014-12-01' /*+IGNORECONST(1)*/ AND stores.store_name='Store1' /*+IGNORECONST(2)*/ ORDER BY sales.store_key, sales.sale_date;
CREATE DIRECTED QUERY
```

The optimizer generates an annotated query that includes the VERBATIM hint:

```
=> SELECT query_name, annotated_query FROM V_CATALOG.DIRECTED_QUERIES WHERE query_name = 'getStoreSales';
-[ RECORD 1 ]---+-----
query_name      | getStoreSales
annotated_query | SELECT /*+ syntactic_join,verbatim*/ sales.store_key AS store_key, stores.store_name AS store_name, sales.product_description AS product_description, sales.sales_quantity AS sales_quantity, sales.sale_date AS sale_date
FROM (store.storeSales AS sales/*+projs('store.storeSales')*/ JOIN /*+Distrib(L,L),JType(H)*/ store.store_dimension AS stores/*+projs('store.store_dimension_DBD_10_rep_VMartDesign')*/ ON (sales.store_key = stores.store_key))
WHERE (sales.sale_date = '2014-12-01'::date /*+IgnoreConst(1)*/) AND (stores.store_name = 'Store1'::varchar(6) /*+IgnoreConst(2)*/)
ORDER BY 1 ASC, 5 ASC
```

When the optimizer uses this directed query, it produces a query plan that is equivalent to the query plan that it used when it created the directed query:

```
=> ACTIVATE DIRECTED QUERYgetStoreSales;
```

```
ACTIVATE DIRECTED QUERY
```

```
=> EXPLAIN SELECT sales.store_key, stores.store_name, sales.product_description, sales.sales_quantity, sales.sale_date FROM store.storesales sales JOIN store.store_dimension stores ON sales.store_key=stores.store_key WHERE sales.sale_date='2014-12-04' AND stores.store_name='Store14' ORDER BY sales.store_key, sales.sale_date;
```

QUERY PLAN DESCRIPTION:

```
EXPLAIN SELECT sales.store_key, stores.store_name, sales.product_description, sales.sales_quantity, sales.sale_date FROM store.storesales sales JOIN store.store_dimension stores ON sales.store_key=stores.store_key WHERE sales.sale_date='2014-12-04' AND stores.store_name='Store14' ORDER BY sales.store_key, sales.sale_date;
```

The following active directed query(query name: getStoreSales) is being executed:

```
SELECT /*+syntactic_join,verbatim*/ sales.store_key, stores.store_name, sales.product_description, sales.sales_quantity, sales.sale_date FROM (store.storeSales sales/*+projs('store.storeSales')*/ JOIN /*+Distrib('L', 'L'), JType('H')*/store.store_dimension stores /*+projs('store.store_dimension_DBD_10_rep_VMartDesign')*/ ON ((sales.store_key = stores.store_key))) WHERE ((sales.sale_date = '2014-12-04'::date) AND (stores.store_name = 'Store14'::varchar(7))) ORDER BY sales.store_key, sales.sale_date
```

Access Path:

```
+JOIN HASH [Cost: 463, Rows: 622 (NO STATISTICS)] (PATH ID: 2)
| Join Cond: (sales.store_key = stores.store_key)
| Materialize at Output: sales.sale_date, sales.sales_quantity, sales.product_description
| Execute on: All Nodes
| +- Outer -> STORAGE ACCESS for sales [Cost: 150, Rows: 155K (NO STATISTICS)] (PATH ID: 3)
|| Projection: store.storeSales_b0
|| Materialize: sales.store_key
|| Filter: (sales.sale_date = '2014-12-04'::date)
|| Execute on: All Nodes
|| Runtime Filter: (SIP1(HashJoin): sales.store_key)
| +- Inner -> STORAGE ACCESS for stores [Cost: 35, Rows: 2] (PATH ID: 4)
|| Projection: store.store_dimension_DBD_10_rep_VMartDesign_node0001
|| Materialize: stores.store_name, stores.store_key
|| Filter: (stores.store_name = 'Store14')
|| Execute on: All Nodes
```

Custom directed queries

The VERBATIM hint is included in a [custom directed query](#) only if you explicitly include it in the annotated query that you write for that directed query. When the optimizer uses that directed query, it respects the VERBATIM hint and creates a query plan accordingly.

If you omit the VERBATIM hint when you create a custom directed query, the hint is not stored with the annotated query. When the optimizer uses that directed query, it applies its own plan development processing on the annotated query before it generates a query plan. This query plan might not be equivalent to the query plan that the optimizer would have generated for the Vertica version in which the directed query was created.

Window clauses

When used with an [analytic function](#), window clauses specify how to partition and sort function input, as well as how to frame input with respect to the current row. When used with a single-phase transform function, the PARTITION ROW and PARTITION LEFT JOIN window clauses support single-row partitions for single-phase transform functions, rather than analytic functions.

In this section

- [Window partition clause](#)
- [Window order clause](#)
- [Window frame clause](#)
- [Window name clause](#)

Window partition clause

When specified, a window partition clause divides the rows of the function input based on user-provided expressions. If no expression is provided, the partition clause can improve query performance by using parallelism. If you do not specify a window partition clause, all input rows are treated as a single partition.

Window partitioning is similar to the GROUP BY clause. However, PARTITION BEST and PARTITION NODES may only be used with analytic functions and return only one result per input row, while PARTITION ROW and PARTITION LEFT JOIN can be used for single-phase transform functions and return multiple values per input row.

When used with analytic functions, results are computed per partition and start over again (reset) at the beginning of each subsequent partition.

Syntax

```
{ PARTITION BY expression[,...]  
  | PARTITION BEST  
  | PARTITION NODES  
  | PARTITION ROW  
  | PARTITION LEFT JOIN }
```

Arguments

PARTITION BY *expression*

Expression on which to sort the partition, where *expression* can be a column, constant, or an arbitrary expression formed on columns. Use **PARTITION BY** for functions with specific partitioning requirements.

PARTITION BEST

Use parallelism to improve performance for multi-threaded queries across multiple nodes.

OVER(PARTITION BEST) provides the best performance on multi-threaded queries across multiple nodes.

The following considerations apply to using **PARTITION BEST** :

- Use **PARTITION BEST** for analytic functions that have no partitioning requirements and are thread safe—for example, a one-to-many transform.
- Do not use **PARTITION BEST** on user-defined transform functions (UDTFs) that are not thread-safe. Doing so can produce an error or incorrect results. If a UDTF is not thread safe, use **PARTITION NODES** .

PARTITION NODES

Use parallelism to improve performance for single-threaded queries across multiple nodes.

OVER(PARTITION NODES) provides the best performance on single-threaded queries across multiple nodes.

PARTITION ROW , PARTITION LEFT JOIN

Use to feed input partitions of exactly one row. If used, any arbitrary expression may be used in the query target list alongside the UDTF. PARTITION LEFT JOIN returns a row of NULLs if an input row would otherwise produce no output.

May not be used for analytic functions or multi-phase transform functions. Note that only one PARTITION ROW transform function is allowed in the target list for each level of the query.

Examples

See [Window partitioning](#).

Window order clause

Specifies how to sort rows that are supplied to an analytic function. If the OVER clause also includes a [window partition clause](#), rows are sorted within each partition.

The window order clause only specifies order within a window result set. The query can have its own [ORDER BY](#) clause outside the OVER clause. This has precedence over the window order clause and orders the final result set.

A window order clause also creates a default [window frame](#) if none is explicitly specified.

Syntax

```
ORDER BY { expression [ ASC | DESC [ NULLS { FIRST | LAST | AUTO } ] ]  
  }[,...]
```

Arguments

expression

A column, constant, or arbitrary expression formed on columns on which to sort input rows.

ASC | DESC

Sort order: ascending (default) or descending.

NULLS {FIRST | LAST | AUTO}

How to position nulls. **NULLS AUTO** means to choose the positioning that is most efficient for this query.

ASC defaults to **NULLS LAST** and **DESC** defaults to **NULLS FIRST** .

If you omit all sort qualifiers, Vertica uses **ASC NULLS LAST** .

For more information, see [NULL sort order](#) and [Runtime sorting of NULL values in analytic functions](#) .

Examples

See [Window ordering](#) .

Window frame clause

Specifies a window frame, which comprises a set of rows relative to the row that is currently being evaluated by an analytic function. After the function processes that row and its window, Vertica advances the current row and adjusts the window boundaries accordingly. If the **OVER** clause also specifies a [partition](#) , Vertica also checks that window boundaries do not cross partition boundaries. This process repeats until the function evaluates the last row of the last partition.

Syntax

```
{ ROWS | RANGE } { BETWEEN start-point AND end-point } | start-point
```

start-point | *end-point*:

```
{ UNBOUNDED {PRECEDING | FOLLOWING}  
  | CURRENT ROW  
  | constant-value {PRECEDING | FOLLOWING}}
```

Arguments

ROWS | RANGE

Whether to interpret window frame dimensions as physical (**ROWS**) or logical (**RANGE**) offsets from the current row. See [ROWS versus RANGE](#) below for details.

BETWEEN *start-point* AND *end-point*

First and last rows of the window, where *start-point* and *end-point* can be one of the following:

- **UNBOUNDED {PRECEDING | FOLLOWING}** : The current partition's first (**PRECEDING**) or last (**FOLLOWING**) row.
- **CURRENT ROW** : The current row or value.
- ***constant-value* {PRECEDING | FOLLOWING}** : A constant value or expression that evaluates to a constant value. This value is interpreted as either a physical or logical offset from the current row, depending on whether you use **ROWS** or **RANGE**. See [ROWS versus RANGE](#) for other restrictions.

start-point must resolve to a row or value that is less than or equal to *end-point* .

start-point

If **ROWS** or **RANGE** specifies only a start point, Vertica uses the current row as the end point and creates the window frame accordingly. In this case, *start-point* must resolve to a row that is less than or equal to the current row.

Requirements

In order to specify a window frame, the **OVER** must also specify a [window order \(ORDER BY\) clause](#) . If the **OVER** clause omits specifying a window frame, the function creates a default window that extends from the current row to the first row in the current partition. This is equivalent to the following clause:

```
RANGE UNBOUNDED PRECEDING AND CURRENT ROW
```

ROWS versus RANGE

The window frame's offset from the current row can be physical or logical:

- **ROWS** (physical): the start and end points are relative to the current row. If either is a constant value, it must evaluate to a positive integer.
- **RANGE** (logical): the start and end points represent a logical offset, such as time. The range value must match the [window order \(ORDER BY\) clause](#) data type: NUMERIC, DATE/TIME, FLOAT or INTEGER.

When setting constant values for **ROWS** , the constant must evaluate to a positive INTEGER.

When setting constant values for **RANGE** , the following requirements apply:

- The constant must evaluate to a positive numeric value or INTERVAL literal.

- If the constant evaluates to a NUMERIC value, the ORDER BY column type must be a NUMERIC data type.
- If the constant evaluates to an INTERVAL DAY TO SECOND subtype, the ORDER BY column type must be one of the following: TIMESTAMP, TIME, DATE, or INTERVAL DAY TO SECOND.
- If the constant evaluates to an INTERVAL YEAR TO MONTH, the ORDER BY column type must be one of the following: TIMESTAMP, DATE, or INTERVAL YEAR TO MONTH.
- The [window order clause](#) can specify only one expression.

Examples

See [Window framing](#).

Window name clause

Defines a named window that specifies window partition and order clauses for an analytic function. This window is specified in the function's **OVER** clause. Named windows can be useful when you write queries that invoke multiple analytic functions with similar **OVER** clauses, such as functions that use the same partition (**PARTITION BY**) clauses.

Syntax

```
WINDOW window-name AS ( window-partition-clause [window-order-clause] )
```

Arguments

WINDOW *window-name*

A window name that is unique within the same query.

[window-partition-clause](#) [[window-order-clause](#)]

Clauses to invoke when an **OVER** clause references this window.

If the window definition omits a [window order clause](#), the **OVER** clause can specify its own order clause.

Requirements

- A **WINDOW** clause cannot include a [window frame clause](#).
- Each **WINDOW** clause within the same query must have a unique name.
- A **WINDOW** clause can reference another window that is already named. For example, the following query names window **w1** before **w2**. Thus, the **WINDOW** clause that defines **w2** can reference **w1**:

```
=> SELECT RANK() OVER(w1 ORDER BY sal DESC), RANK() OVER w2
FROM EMP WINDOW w1 AS (PARTITION BY deptno), w2 AS (w1 ORDER BY sal);
```

Examples

See [Named windows](#).

[Analytic functions](#).

Data types

The following table summarizes the internal data types that Vertica supports. It also shows the default placement of null values in projections. The Size column lists uncompressed bytes.

Data Type	Size / bytes	Description	NULL Sorting
Binary			
BINARY	1 to 65,000	Fixed-length binary string	NULLS LAST
VARBINARY (synonyms: BYTEA , RAW)	1 to 65,000	Variable-length binary string	NULLS LAST
LONG VARBINARY	1 to 32,000,000	Long variable-length binary string	NULLS LAST
Boolean			

BOOLEAN	1	True or False or NULL	NULLS LAST
Character / Long			
CHAR	1 to 65,000	Fixed-length character string	NULLS LAST
VARCHAR	1 to 65,000	Variable-length character string	NULLS LAST
LONG VARCHAR	1 to 32,000,000	Long variable-length character string	NULLS LAST
Date/Time			
DATE	8	A month, day, and year	NULLS FIRST
TIME	8	A time of day without timezone	NULLS FIRST
TIME WITH TIMEZONE	8	A time of day with timezone	NULLS FIRST
TIMESTAMP (synonyms: DATETIME , SMALLDATETIME)	8	A date and time without timezone	NULLS FIRST
TIMESTAMP WITH TIMEZONE	8	A date and time with timezone	NULLS FIRST
INTERVAL	8	The difference between two points in time	NULLS FIRST
INTERVAL DAY TO SECOND	8	An interval measured in days and seconds	NULLS FIRST
INTERVAL YEAR TO MONTH	8	An interval measured in years and months	NULLS FIRST
Approximate Numeric			
DOUBLE PRECISION	8	Signed 64-bit IEEE floating point number, requiring 8 bytes of storage	NULLS LAST
FLOAT	8	Signed 64-bit IEEE floating point number, requiring 8 bytes of storage	NULLS LAST
FLOAT(n)	8	Signed 64-bit IEEE floating point number, requiring 8 bytes of storage	NULLS LAST
FLOAT8	8	Signed 64-bit IEEE floating point number, requiring 8 bytes of storage	NULLS LAST
REAL	8	Signed 64-bit IEEE floating point number, requiring 8 bytes of storage	NULLS LAST
Exact Numeric			
INTEGER	8	Signed 64-bit integer, requiring 8 bytes of storage	NULLS FIRST
INT	8	Signed 64-bit integer, requiring 8 bytes of storage	NULLS FIRST
BIGINT	8	Signed 64-bit integer, requiring 8 bytes of storage	NULLS FIRST
INT8	8	Signed 64-bit integer, requiring 8 bytes of storage	NULLS FIRST
SMALLINT	8	Signed 64-bit integer, requiring 8 bytes of storage	NULLS FIRST

TINYINT	8	Signed 64-bit integer, requiring 8 bytes of storage	NULLS FIRST
DECIMAL	8+	8 bytes for the first 18 digits of precision, plus 8 bytes for each additional 19 digits	NULLS FIRST
NUMERIC	8+	8 bytes for the first 18 digits of precision, plus 8 bytes for each additional 19 digits	NULLS FIRST
NUMBER	8+	8 bytes for the first 18 digits of precision, plus 8 bytes for each additional 19 digits	NULLS FIRST
MONEY	8+	8 bytes for the first 18 digits of precision, plus 8 bytes for each additional 19 digits	NULLS FIRST
Spatial			
GEOMETRY	1 to 10,000,000	Coordinates expressed as (<i>x</i> , <i>y</i>) pairs, defined in the Cartesian plane.	NULLS LAST
GEOGRAPHY	1 to 10,000,000	Coordinates expressed in longitude/latitude angular values, measured in degrees	NULLS LAST
UUID			
UUID	16	Stores universally unique identifiers (UUIDs).	NULLS FIRST
Complex			
ARRAY	1 to 32,000,000	Collection of values of a primitive or complex type.	Native array: same as the element type Non-native array: cannot be used to order projections
ROW	1 to 32,000,000	Structure of property-value pairs.	Cannot be used to order projections
SET	1 to 32,000,000	Collection of unique values of a primitive type.	Same as the primitive type

Binary data types (BINARY and VARBINARY)

Store raw-byte data, such as IP addresses, up to 65000 bytes. The BINARY and BINARY VARYING (VARBINARY) data types are collectively referred to as *binary string types* and the values of binary string types are referred to as *binary strings* . A binary string is a sequence of octets or bytes.

BYTEA and RAW are synonyms for VARBINARY .

Syntax

```
BINARY ( length )  
{ VARBINARY | BINARY VARYING | BYTEA | RAW } ( max-length )
```

Arguments

length , **max-length**

The length of the string or column width, in bytes (octets).

BINARY and VARBINARY data types

BINARY and VARBINARY data types have the following attributes:

- **BINARY** : A fixed-width string of *length* bytes, where the number of bytes is declared as an optional specifier to the type. If *length* is omitted, the default is 1. Where necessary, values are right-extended to the full width of the column with the zero byte. For example:

```
=> SELECT TO_HEX('ab'::BINARY(4));  
to_hex  
-----  
61620000
```

- **VARBINARY** : A variable-width string up to a length of *max-length* bytes, where the maximum number of bytes is declared as an optional specifier to the type. The default is the default attribute size, which is 80, and the maximum length is 65000 bytes. VARBINARY values are not extended to the full width of the column. For example:

```
=> SELECT TO_HEX('ab'::VARBINARY(4));  
to_hex  
-----  
6162
```

Input formats

You can use several formats when working with binary values. The hexadecimal format is generally the most straightforward and is emphasized in Vertica documentation.

Binary values can also be represented in octal format by prefixing the value with a backslash `\`.

Note

If you use `vsq`, you must use the escape character (`\`) when you insert another backslash on input; for example, input `'\141'` as `'\\141'`.

You can also input values represented by printable characters. For example, the hexadecimal value `'0x61'` can also be represented by the symbol `a`.

See [Data load](#).

On input, strings are translated from:

- Hexadecimal representation to a binary value using the function [HEX_TO_BINARY](#).
- [Bitstring](#) representation to a binary value using the function [BITSTRING_TO_BINARY](#).

Both functions take a VARCHAR argument and return a VARBINARY value.

Output formats

Like the input format, the output format is a hybrid of octal codes and printable ASCII characters. A byte in the range of printable ASCII characters (the range `[0x20, 0x7e]`) is represented by the corresponding ASCII character, with the exception of the backslash (`\`), which is escaped as `\\`. All other byte values are represented by their corresponding octal values. For example, the bytes {97,92,98,99}, which in ASCII are `{a,\,b,c}`, are translated to text as `'a\bc'`.

Binary operators and functions

The binary operators `&`, `~`, `|`, and `#` have special behavior for binary data types, as described in [Bitwise operators](#).

The following aggregate functions are supported for binary data types:

- [BIT_AND](#)
- [BIT_OR](#)
- [BIT_XOR](#)
- [MAX](#)
- [MIN](#)

BIT_AND , BIT_OR , and BIT_XOR are bit-wise operations that are applied to each non-null value in a group, while MAX and MIN are byte-wise comparisons of binary values.

Like their [binary operator](#) counterparts, if the values in a group vary in length, the aggregate functions treat the values as though they are all equal in length by extending shorter values with zero bytes to the full width of the column. For example, given a group containing the values 'ff', null, and 'f' , a binary aggregate ignores the null value and treats the value 'f' as 'f0' . Also, like their binary operator counterparts, these aggregate functions operate on VARBINARY types explicitly and operate on BINARY types implicitly through casts. See [Data type coercion operators \(CAST\)](#).

Binary versus character data types

The BINARY and VARBINARY binary types are similar to the CHAR and VARCHAR [character data types](#), respectively. They differ as follows:

- Binary data types contain byte strings (a sequence of octets or bytes).
- Character data types contain character strings (text).
- The lengths of binary data types are measured in bytes, while character data types are measured in characters.

Examples

The following example shows [HEX_TO_BINARY](#) and [TO_HEX](#) usage.

Table `t` and its projection are created with binary columns:

```
=> CREATE TABLE t (c BINARY(1));
=> CREATE PROJECTION t_p (c) AS SELECT c FROM t;
```

Insert minimum byte and maximum byte values:

```
=> INSERT INTO t values(HEX_TO_BINARY('0x00'));
=> INSERT INTO t values(HEX_TO_BINARY('0xFF'));
```

Binary values can then be formatted in hex on output using the `TO_HEX` function:

```
=> SELECT TO_HEX(c) FROM t;
to_hex
-----
00
ff
(2 rows)
```

The `BIT_AND` , `BIT_OR` , and `BIT_XOR` functions are interesting when operating on a group of values. For example, create a sample table and projections with binary columns:

The example that follows uses table `t` with a single column of `VARBINARY` data type:

```
=> CREATE TABLE t ( c VARBINARY(2) );
=> INSERT INTO t values(HEX_TO_BINARY('0xFF00'));
=> INSERT INTO t values(HEX_TO_BINARY('0xFFFF'));
=> INSERT INTO t values(HEX_TO_BINARY('0xF00F'));
```

Query table `t` to see column `c` output:

```
=> SELECT TO_HEX(c) FROM t;
TO_HEX
-----
ff00
ffff
f00f
(3 rows)
```

Now issue the bitwise AND operation. Because these are aggregate functions, an implicit GROUP BY operation is performed on results using `(ff00&(ffff)&f00f)` :

```
=> SELECT TO_HEX(BIT_AND(c)) FROM t;
TO_HEX
-----
f000
(1 row)
```

Issue the bitwise OR operation on `(ff00|(ffff)|f00f)` :

```
=> SELECT TO_HEX(BIT_OR(c)) FROM t;
TO_HEX
-----
ffff
(1 row)
```

Issue the bitwise XOR operation on `(ff00#(ffff)#f00f)` :

```
=> SELECT TO_HEX(BIT_XOR(c)) FROM t;
TO_HEX
-----
f0f0
(1 row)
```

Boolean data type

Vertica provides the standard SQL type `BOOLEAN`, which has two states: true and false. The third state in SQL boolean logic is unknown, which is represented by the `NULL` value.

Syntax

```
BOOLEAN
```

Parameters

Valid literal data values for input are:

<code>TRUE</code>	<code>'t'</code>	<code>'true'</code>	<code>'y'</code>	<code>'yes'</code>	<code>'1'</code>	1
<code>FALSE</code>	<code>'f'</code>	<code>'false'</code>	<code>'n'</code>	<code>'no'</code>	<code>'0'</code>	0

Notes

- Do not confuse the `BOOLEAN` data type with [Logical operators](#) or the [Boolean](#).
- The keywords `TRUE` and `FALSE` are preferred and are SQL-compliant.
- A Boolean value of `NULL` appears last (largest) in ascending order.
- All other values must be enclosed in single quotes.
- Boolean values are output using the letters t and f.

See also

- [NULL value](#)
- [Data type coercion chart](#)

Character data types (CHAR and VARCHAR)

Stores strings of letters, numbers, and symbols. The `CHARACTER (CHAR)` and `CHARACTER VARYING (VARCHAR)` data types are collectively referred to as *character string types*, and the values of character string types are known as *character strings*.

Character data can be stored as fixed-length or variable-length strings. Fixed-length strings are right-extended with spaces on output; variable-length strings are not extended.

String literals in SQL statements must be enclosed in single quotes.

Syntax

```
{ CHAR | CHARACTER } [ (octet-length) ]
{ VARCHAR | CHARACTER VARYING } [ (octet-length) ]
```

Arguments

`octet-length`

Length of the string or column width, declared in bytes (octets).

This argument is optional.

CHAR versus VARCHAR data types

The following differences apply to CHAR and VARCHAR data:

- CHAR is conceptually a fixed-length, blank-padded string. Trailing blanks (spaces) are removed on input and are restored on output. The default length is 1, and the maximum length is 65000 octets (bytes).
- VARCHAR is a variable-length character data type. The default length is 80, and the maximum length is 65000 octets. For string values longer than 65000, use [Long data types](#). Values can include trailing spaces.

Normally, you use VARCHAR for all of string data. Use CHAR when you need fixed-width string output. For example, you can use CHAR columns for data to be transferred to a legacy system that requires fixed-width strings.

Setting maximum length

When you define character columns, specify the maximum size of any string to be stored in a column. For example, to store strings up to 24 octets in length, use one of the following definitions:

```
CHAR(24) --- fixed-length
VARCHAR(24) --- variable-length
```

The maximum length parameter for VARCHAR and CHAR data types refers to the number of octets that can be stored in that field, not the number of characters (Unicode code points). When using multibyte UTF-8 characters, the fields must be sized to accommodate from 1 to 4 octets per character, depending on the data. If the data loaded into a VARCHAR or CHAR column exceeds the specified maximum size for that column, data is truncated on UTF-8 character boundaries to fit within the specified size. See [COPY](#).

Note

Remember to include the extra octets required for multibyte characters in the column-width declaration, keeping in mind the 65000 octet column-width limit.

Due to compression in Vertica, the cost of overestimating the length of these fields is incurred primarily at load time and during sorts.

NULL versus NUL

NULL and NUL differ as follows:

- NUL represents a character whose ASCII/Unicode code is 0, sometimes qualified "ASCII NUL".
- NULL means no value, and is true of a field (column) or constant, not of a character.

CHAR, LONG VARCHAR, and VARCHAR string data types accept ASCII NUL values.

In ascending sorts, NULL appears last (largest).

For additional information about NULL ordering, see [NULL sort order](#).

The following example casts the input string containing NUL values to VARCHAR :

```
=> SELECT 'vert\0ica'::CHARACTER VARYING AS VARCHAR;
VARCHAR
-----
vert\0ica
(1 row)
```

The result contains 9 characters:

```
=> SELECT LENGTH('vert\0ica'::CHARACTER VARYING);
length
-----
9
(1 row)
```

If you use an [extended string literal](#), the length is 8 characters:

```

=> SELECT E'vert\0ica'::CHARACTER VARYING AS VARCHAR;
VARCHAR
-----
vertica
(1 row)
=> SELECT LENGTH(E'vert\0ica'::CHARACTER VARYING);
LENGTH
-----
      8
(1 row)

```

Date/time data types

Vertica supports the full set of SQL date and time data types.

The following rules apply to all date/time data types:

- All have a size of 8 bytes.
- A date/time value of NULL is smallest relative to all other date/time values,.
- Vertica uses Julian dates for all date/time calculations, which can correctly predict and calculate any date more recent than 4713 BC to far into the future, based on the assumption that the average length of the year is 365.2425 days.
- All the date/time data types accept the special literal value **NOW** to specify the current date and time. For example:

```

=> SELECT TIMESTAMP 'NOW';
?column?
-----
2020-09-23 08:23:50.42325
(1 row)

```

- By default, Vertica rounds with a maximum precision of six decimal places. You can substitute an integer between 0 and 6 for **p** to [specify your preferred level of precision](#).

The following table lists specific attributes of date/time data types:

Name	Description	Low Value	High Value	Resolution
DATE	Dates only (no time of day)	~ 25e+15 BC	~ 25e+15 AD	1 day
TIME [(p)]	Time of day only (no date)	00:00:00.00	23:59:60.999999	1 μs
TIMETZ [(p)]	Time of day only, with time zone	00:00:00.00+14	23:59:59.999999-14	1 μs
TIMESTAMP [(p)]	Both date and time, without time zone	290279-12-22 19:59:05.224194 BC	294277-01-09 04:00:54.775806 AD	1 μs
TIMESTAMPTZ [(p)]*	Both date and time, with time zone	290279-12-22 19:59:05.224194 BC UTC	294277-01-09 04:00:54.775806 AD UTC	1 μs
INTERVAL DAY TO SECOND [(p)]	Time intervals	-106751991 days 04:00:54.775807	+106751991 days 04:00:54.775807	1 μs
INTERVAL YEAR TO MONTH	Time intervals	~ -768e15 yrs	~ 768e15 yrs	1 month

Time zone abbreviations for input

Vertica recognizes the files in [/opt/vertica/share/timezonesets](#) as date/time input values and defines the default list of strings accepted in the AT TIME ZONE *zone* parameter. The names are not necessarily used for date/time output—output is driven by the official time zone abbreviations associated with the currently selected time zone parameter setting.

In this section

- [DATE](#)

- [DATETIME](#)
- [INTERVAL](#)
- [SMALLDATETIME](#)
- [TIME/TIMETZ](#)
- [TIME AT TIME_ZONE](#)
- [TIMESTAMP/TIMESTAMPZ](#)
- [TIMESTAMP AT TIME_ZONE](#)

DATE

Consists of a month, day, and year. The following limits apply:

- Lowest value: ~ 25e+15 BC
- Highest value: ~ 25e+15 AD
- Resolution: 1 DAY

See [SET DATESTYLE](#) for information about ordering.

Note

'0000-00-00' is not valid. If you try to insert that value into a DATE or TIMESTAMP field, an error occurs. If you copy '0000-00-00' into a DATE or TIMESTAMP field, Vertica converts the value to 0001-01-01 00:00:00 BC.

Syntax

DATE

Examples

Example	Description
January 8, 1999	Unambiguous in any <code>datestyle</code> input mode
1999-01-08	ISO 8601; January 8 in any mode (recommended format)
1/8/1999	January 8 in <code>MDY</code> mode; August 1 in <code>DMY</code> mode
1/18/1999	January 18 in <code>MDY</code> mode; rejected in other modes
01/02/03	January 2, 2003 in <code>MDY</code> mode February 1, 2003 in <code>DMY</code> mode February 3, 2001 in <code>YMD</code> mode
1999-Jan-08	January 8 in any mode
Jan-08-1999	January 8 in any mode
08-Jan-1999	January 8 in any mode
99-Jan-08	January 8 in <code>YMD</code> mode, else error
08-Jan-99	January 8, except error in <code>YMD</code> mode
Jan-08-99	January 8, except error in <code>YMD</code> mode
19990108	ISO 8601; January 8, 1999 in any mode
990108	ISO 8601; January 8, 1999 in any mode
1999.008	Year and day of year

J2451187	Julian day
January 8, 99 BC	Year 99 before the Common Era

DATETIME

DATETIME is an alias for [TIMESTAMP/TIMESTAMPTZ](#).

INTERVAL

Measures the difference between two points in time. Intervals can be positive or negative. The **INTERVAL** data type is SQL:2008 compliant, and supports [interval qualifiers](#) that are divided into two major subtypes:

- [Year-month](#): Span of years and months
- [Day-time](#): Span of days, hours, minutes, seconds, and fractional seconds

Intervals are represented internally as some number of microseconds and printed as up to 60 seconds, 60 minutes, 24 hours, 30 days, 12 months, and as many years as necessary. You can [control the output format](#) of interval units with [SET INTERVALSTYLE](#) and [SET DATESTYLE](#).

Syntax

```
INTERVAL 'interval-literal' [ interval-qualifier ] [ (p) ]
```

Parameters

[interval-literal](#)

A character string that expresses an interval, conforming to this format:

```
[ - ] { quantity subtype-unit } [ ... ] [ AGO ]
```

For details, see [Interval literal](#).

[interval-qualifier](#)

Optionally specifies how to interpret and format an interval literal for output, and, optionally, sets precision. If omitted, the default is **DAY TO SECOND(6)**. For details, see [Interval qualifier](#).

p

Specifies precision of the seconds field, where *p* is an integer between 0 - 6. For details, see [Specifying interval precision](#).

Default: 6

Limits

Name	Low Value	High Value	Resolution
INTERVAL DAY TO SECOND [(<i>p</i>)]	-106751991 days 04:00:54.775807	+/-106751991 days 04:00:54.775807	1 microsecond
INTERVAL YEAR TO MONTH	~/ -768e15 yrs	~ 768e15 yrs	1 month

In this section

- [Setting interval unit display](#)
- [Specifying interval input](#)
- [Controlling interval format](#)
- [Specifying interval precision](#)
- [Fractional seconds in interval units](#)
- [Processing signed intervals](#)
- [Casting with intervals](#)
- [Operations with intervals](#)

Setting interval unit display

[SET INTERVALSTYLE](#) and [SET DATESTYLE](#) control the output format of interval units.

Important

DATESTYLE settings supersede INTERVALSTYLE. If DATESTYLE is set to SQL, interval unit display always conforms to the SQL:2008 standard, which omits interval unit display. If DATESTYLE is set to ISO, you can use [SET INTERVALSTYLE](#) to omit or display interval unit display, as described below.

Omitting interval units

To omit interval units from the output, set `INTERVALSTYLE` to `PLAIN`. This is the default setting, which conforms with the SQL:2008 standard:

```
=> SET INTERVALSTYLE TO PLAIN;
SET
=> SELECT INTERVAL '3 2';
?column?
-----
3 02:00
```

When `INTERVALSTYLE` is set to `PLAIN`, units are omitted from the output, even if the query specifies input units:

```
=> SELECT INTERVAL '3 days 2 hours';
?column?
-----
3 02:00
```

If `DATESTYLE` is set to `SQL`, Vertica conforms with SQL:2008 standard and always omits interval units from output:

```
=> SET DATESTYLE TO SQL;
SET
=> SET INTERVALSTYLE TO UNITS;
SET
=> SELECT INTERVAL '3 2';
?column?
-----
3 02:00
```

Displaying interval units

To enable display of interval units, `DATESTYLE` must be set to `ISO`. You can then display interval units by setting `INTERVALSTYLE` to `UNITS`:

```
=> SET DATESTYLE TO ISO;
SET
=> SET INTERVALSTYLE TO UNITS;
SET
=> SELECT INTERVAL '3 2';
?column?
-----
3 days 2 hours
```

Checking INTERVALSTYLE and DATESTYLE settings

Use `SHOW` statements to check `INTERVALSTYLE` and `DATESTYLE` settings:

```
=> SHOW INTERVALSTYLE;
 name | setting
-----+-----
intervalstyle | units
=> SHOW DATESTYLE;
 name | setting
-----+-----
datestyle | ISO, MDY
```

Specifying interval input

Interval values are expressed through [interval literals](#). An interval literal is composed of one or more interval fields, where each field represents a span of days and time, or years and months, as follows:

```
[ - ] { quantity subtype-unit } [ ... ] [ AGO ]
```

Using subtype units

Subtype units are optional for [day-time](#) intervals; they must be specified for [year-month](#) intervals.

For example, the first statement below implicitly specifies days and time; the second statement explicitly identifies day and time units. Both statements return the same result:

```
=> SET INTERVALSTYLE TO UNITS;
=> SELECT INTERVAL '1 12:59:10:05';
   ?column?
-----
1 day 12:59:10.005
(1 row)

=> SELECT INTERVAL '1 day 12 hours 59 min 10 sec 5 milliseconds';
   ?column?
-----
1 day 12:59:10.005
(1 row)
```

The following two statements add 28 days and 4 weeks to the current date, respectively. The intervals in both cases are equal and the statements return the same result. However, in the first statement, the interval literal omits the subtype (implicitly [days](#)); in the second statement, the interval literal must include the subtype unit [weeks](#) :

```
=> SELECT CURRENT_DATE;
   ?column?
-----
2016-08-15
(1 row)

=> SELECT CURRENT_DATE + INTERVAL '28';
   ?column?
-----
2016-09-12 00:00:00
(1 row)

dbadmin=> SELECT CURRENT_DATE + INTERVAL '4 weeks';
   ?column?
-----
2016-09-12 00:00:00
(1 row)
```

An interval literal can include day-time and year-month fields. For example, the following statement adds an interval of 4 years, 4 weeks, 4 days and 14 hours to the current date. The years and weeks fields must include subtype units; the days and hours fields omit them:

```
> SELECT CURRENT_DATE + INTERVAL '4 years 4 weeks 4 14';
   ?column?
-----
2020-09-15 14:00:00
(1 row)
```

Omitting subtype units

You can specify quantities of days, hours, minutes, and seconds without specifying units. Vertica recognizes colons in interval literals as part of the timestamp:

```
=> SELECT INTERVAL '1 4 5 6';
```

```
?column?
```

```
-----  
1 day 04:05:06
```

```
=> SELECT INTERVAL '1 4:5:6';
```

```
?column?
```

```
-----  
1 day 04:05:06
```

```
=> SELECT INTERVAL '1 day 4 hour 5 min 6 sec';
```

```
?column?
```

```
-----  
1 day 04:05:06
```

If Vertica cannot determine the units, it applies the quantity to any missing units based on the interval qualifier. In the next two examples, Vertica uses the default interval qualifier ([DAY TO SECOND\(6\)](#)) and assigns the trailing **1** to days, since it has already processed hours, minutes, and seconds in the output:

```
=> SELECT INTERVAL '4:5:6 1';
```

```
?column?
```

```
-----  
1 day 04:05:06
```

```
=> SELECT INTERVAL '1 4:5:6';
```

```
?column?
```

```
-----  
1 day 04:05:06
```

In the next two examples, Vertica recognizes **4:5** as **hours:minutes** . The remaining values in the interval literal are assigned to the missing units: **1** is assigned to days and **2** is assigned to seconds.

```
SELECT INTERVAL '4:5 1 2';
```

```
?column?
```

```
-----  
1 day 04:05:02
```

```
=> SELECT INTERVAL '1 4:5 2';
```

```
?column?
```

```
-----  
1 day 04:05:02
```

Specifying the interval qualifier can change how Vertica interprets **4:5** :

```
=> SELECT INTERVAL '4:5' MINUTE TO SECOND;
```

```
?column?
```

```
-----  
00:04:05
```

Controlling interval format

[Interval qualifiers](#) specify a range of options that Vertica uses to interpret and format an [interval literal](#) . The interval qualifier can also specify precision. Each interval qualifier is composed of one or two units:

```
unit[p] [ TO unit[p] ]
```

where:

- *unit* specifies a day-time or year-month [subtype](#) .
- *p* specifies precision, an integer between 0 and 6. In general, precision only applies to **SECOND** units. The default precision for **SECOND** is 6. For details, see [Specifying interval precision](#) .

If an interval omits an interval qualifier, Vertica uses the default [DAY TO SECOND\(6\)](#) .

Interval qualifier categories

Interval qualifiers belong to one of the following categories:

- [Year-month](#) : Span of years and months

- [Day-time](#): Span of days, hours, minutes, seconds, and fractional seconds

Note

All examples below assume that [INTERVALSTYLE](#) is set to plain.

Year-Month

Vertica supports two year-month subtypes: [YEAR](#) and [MONTH](#) .

In the following example, [YEAR TO MONTH](#) qualifies the interval literal `1 2` to indicate a span of 1 year and two months:

```
=> SELECT interval '1 2' YEAR TO MONTH;
?column?
-----
1-2
(1 row)
```

If you omit the qualifier, Vertica uses the default interval qualifier [DAY TO SECOND](#) and returns a different result:

```
=> SELECT interval '1 2';
?column?
-----
1 02:00
(1 row)
```

The following example uses the interval qualifier [YEAR](#) . In this case, Vertica extracts only the year from the interval literal `1y 10m` :

```
=> SELECT INTERVAL '1y 10m' YEAR;
?column?
-----
1
(1 row)
```

In the next example, the interval qualifier [MONTH](#) converts the same interval literal to months:

```
=> SELECT INTERVAL '1y 10m' MONTH;
?column?
-----
22
(1 row)
```

Day-time

Vertica supports four day-time subtypes: [DAY](#) , [HOUR](#) , [MINUTE](#) , and [SECOND](#) .

In the following example, the interval qualifier [DAY TO SECOND\(4\)](#) qualifies the interval literal `1h 3m 6s 5msecs 57us` . The qualifier also sets precision on seconds to 4:

```
=> SELECT INTERVAL '1h 3m 6s 5msecs 57us' DAY TO SECOND(4);
?column?
-----
01:03:06.0051
(1 row)
```

If no interval qualifier is specified, Vertica uses the default subtype [DAY TO SECOND\(6\)](#) , regardless of how you specify the interval literal. For example, as an extension to SQL:2008, both of the following commands return `910 days` :

```
=> SELECT INTERVAL '2-6';  
?column?
```

```
-----  
910
```

```
=> SELECT INTERVAL '2 years 6 months';  
?column?
```

```
-----  
910
```

An interval qualifier can extract other values from the input parameters. For example, the following command extracts the **HOUR** value from the interval literal **3 days 2 hours** :

```
=> SELECT INTERVAL '3 days 2 hours' HOUR;  
?column?
```

```
-----  
74
```

The primary day/time (**DAY TO SECOND**) and year/month (**YEAR TO MONTH**) subtype ranges can be restricted to more specific range of types by an interval qualifier. For example, **HOUR TO MINUTE** is a limited form of day/time interval, which can be used to express time zone offsets.

```
=> SELECT INTERVAL '1 3' HOUR to MINUTE;  
?column?
```

```
-----  
01:03
```

hh:mm:ss and **hh:mm** formats are used only when at least two of the fields specified in the interval qualifier are non-zero and there are no more than 23 hours or 59 minutes:

```
=> SELECT INTERVAL '2 days 12 hours 15 mins' DAY TO MINUTE;  
?column?
```

```
-----  
2 12:15
```

```
=> SELECT INTERVAL '15 mins 20 sec' MINUTE TO SECOND;  
?column?
```

```
-----  
15:20
```

```
=> SELECT INTERVAL '1 hour 15 mins 20 sec' MINUTE TO SECOND;  
?column?
```

```
-----  
75:20
```

Specifying interval precision

In general, interval precision only applies to seconds. If no precision is explicitly specified, Vertica rounds precision to a maximum of six decimal places. For example:

```
=> SELECT INTERVAL '2 hours 4 minutes 3.709384766 seconds' DAY TO SECOND;  
?column?
```

```
-----  
02:04:03.709385
```

```
(1 row)
```

Vertica lets you specify interval precision in two ways:

- After the **INTERVAL** keyword
- After the **SECOND** unit of an interval qualifier, one of the following:
 - **DAY TO SECOND**
 - **HOUR TO SECOND**
 - **MINUTE TO SECOND**
 - **SECOND**

For example, the following statements use both methods to set precision, and return identical results:

```
=> SELECT INTERVAL(4) '2 hours 4 minutes 3.709384766 seconds' DAY TO SECOND;
?column?
-----
02:04:03.7094
(1 row)

=> SELECT INTERVAL '2 hours 4 minutes 3.709384766 seconds' DAY TO SECOND(4);
?column?
-----
02:04:03.7094
(1 row)
```

If the same statement specifies precision more than once, Vertica uses the lesser precision. For example, the following statement specifies precision twice: the **INTERVAL** keyword specifies precision of 1, while the interval qualifier **SECOND** specifies precision of 2. Vertica uses the lesser precision of 1:

```
=> SELECT INTERVAL(1) '1.2467' SECOND(2);
?column?
-----
1.2 secs
```

Setting precision on interval table columns

If you create a table with an interval column, the following restrictions apply to the column definition:

- You can set precision on the **INTERVAL** keyword only if you omit specifying an interval qualifier. If you try to set precision on the **INTERVAL** keyword and include an interval qualifier, Vertica returns an error.
- You can set precision only on the last unit of an interval qualifier. For example:

```
CREATE TABLE public.testint2
(
  i INTERVAL HOUR TO SECOND(3)
);
```

If you specify precision on another unit, Vertica discards it when it saves the table definition.

Fractional seconds in interval units

Vertica supports intervals in milliseconds (hh:mm:ss:ms), where **01:02:03:25** represents 1 hour, 2 minutes, 3 seconds, and 025 milliseconds. Milliseconds are converted to fractional seconds as in the following example, which returns 1 day, 2 hours, 3 minutes, 4 seconds, and 25.5 milliseconds:

```
=> SELECT INTERVAL '1 02:03:04:25.5';
?column?
-----
1 day 02:03:04.0255
```

Vertica allows fractional minutes. The fractional minutes are rounded into seconds:

```
=> SELECT INTERVAL '10.5 minutes';
?column?
-----
00:10:30
=> select interval '10.659 minutes';
?column?
-----
00:10:39.54
=> select interval '10.333333333333333 minutes';
?column?
-----
00:10:20
```

Considerations

- An **INTERVAL** can include only the subset of units that you need; however, year/month intervals represent calendar years and months with no fixed number of days, so year/month interval values cannot include days, hours, minutes. When year/month values are specified for day/time intervals, the intervals extension assumes 30 days per month and 365 days per year. Since the length of a given month or year varies, day/time intervals are never output as months or years, only as days, hours, minutes, and so on.
- Day/time and year/month intervals are logically independent and cannot be combined with or compared to each other. In the following example, an interval-literal that contains **DAYS** cannot be combined with the **YEAR TO MONTH** type:

```
=> SELECT INTERVAL '1 2 3' YEAR TO MONTH;
ERROR 3679: Invalid input syntax for interval year to month: "1 2 3"
```

- Vertica accepts intervals up to $2^{63} - 1$ microseconds or months (about 18 digits).
- **INTERVAL YEAR TO MONTH** can be used in an analytic **RANGE window** when the **ORDER BY** column type is **TIMESTAMP/TIMESTAMP WITH TIMEZONE**, or **DATE**. Using **TIME/TIME WITH TIMEZONE** are not supported.
- You can use **INTERVAL DAY TO SECOND** when the **ORDER BY** column type is **TIMESTAMP/TIMESTAMP WITH TIMEZONE**, **DATE**, and **TIME/TIME WITH TIMEZONE**.

Examples

Examples in this section assume that **INTERVALSTYLE** is set to **PLAIN**, so results omit [subtype units](#). Interval values that omit an [interval qualifier](#) use the default to **DAY TO SECOND(6)**.

```
=> SELECT INTERVAL '00:2500:00';
?column?
-----
1 17:40
(1 row)

=> SELECT INTERVAL '2500' MINUTE TO SECOND;
?column?
-----
2500
(1 row)

=> SELECT INTERVAL '2500' MINUTE;
?column?
-----
2500
(1 row)

=> SELECT INTERVAL '28 days 3 hours' HOUR TO SECOND;
?column?
-----
675:00
(1 row)

=> SELECT INTERVAL(3) '28 days 3 hours';
?column?
-----
28 03:00
(1 row)

=> SELECT INTERVAL(3) '28 days 3 hours 1.234567';
?column?
-----
28 03:01:14.074
(1 row)

=> SELECT INTERVAL(3) '28 days 3 hours 1.234567 sec';
?column?
-----
28 03:00:01.235
(1 row)

SELECT INTERVAL(3) '28 days 3 hours' HOUR TO SECOND;
```

```
=> SELECT INTERVAL(3) '28 days 3.3 hours' HOUR TO SECOND;  
?column?
```

```
-----  
675:18  
(1 row)
```

```
=> SELECT INTERVAL(3) '28 days 3.35 hours' HOUR TO SECOND;  
?column?
```

```
-----  
675:21  
(1 row)
```

```
=> SELECT INTERVAL(3) '28 days 3.37 hours' HOUR TO SECOND;  
?column?
```

```
-----  
675:22:12  
(1 row)
```

```
=> SELECT INTERVAL '1.234567 days' HOUR TO SECOND;  
?column?
```

```
-----  
29:37:46.5888  
(1 row)
```

```
=> SELECT INTERVAL '1.23456789 days' HOUR TO SECOND;  
?column?
```

```
-----  
29:37:46.665696  
(1 row)
```

```
=> SELECT INTERVAL(3) '1.23456789 days' HOUR TO SECOND;  
?column?
```

```
-----  
29:37:46.666  
(1 row)
```

```
=> SELECT INTERVAL(3) '1.23456789 days' HOUR TO SECOND(2);  
?column?
```

```
-----  
29:37:46.67  
(1 row)
```

```
=> SELECT INTERVAL(3) '01:00:01.234567' as "one hour+";  
one hour+
```

```
-----  
01:00:01.235  
(1 row)
```

```
=> SELECT INTERVAL(3) '01:00:01.234567' = INTERVAL(3) '01:00:01.234567';  
?column?
```

```
-----  
t  
(1 row)
```

```
=> SELECT INTERVAL(3) '01:00:01.234567' = INTERVAL '01:00:01.234567';  
?column?
```

```
-----  
f  
(1 row)
```

```
=> SELECT INTERVAL(3) '01:00:01.234567' = INTERVAL '01:00:01.234567'  
HOUR TO SECOND(2);
```

```
FLOOR TO SECOND(3);
```

```
?column?
```

```
-----  
t  
(1 row)
```

```
=> SELECT INTERVAL(3) '01:00:01.234567' = INTERVAL '01:00:01.234567'  
MINUTE TO SECOND(3);
```

```
?column?
```

```
-----  
t  
(1 row)
```

```
=> SELECT INTERVAL '255 1.1111' MINUTE TO SECOND(3);
```

```
?column?
```

```
-----  
255:01.111  
(1 row)
```

```
=> SELECT INTERVAL '@ - 5 ago';
```

```
?column?
```

```
-----  
5  
(1 row)
```

```
=> SELECT INTERVAL '@ - 5 minutes ago';
```

```
?column?
```

```
-----  
00:05  
(1 row)
```

```
=> SELECT INTERVAL '@ 5 minutes ago';
```

```
?column?
```

```
-----  
-00:05  
(1 row)
```

```
=> SELECT INTERVAL '@ ago -5 minutes';
```

```
?column?
```

```
-----  
00:05  
(1 row)
```

```
=> SELECT DATE_PART('month', INTERVAL '2-3' YEAR TO MONTH);
```

```
DATE_PART
```

```
-----  
3  
(1 row)
```

```
=> SELECT FLOOR((TIMESTAMP '2005-01-17 10:00'  
- TIMESTAMP '2005-01-01')  
/ INTERVAL '7');
```

```
FLOOR
```

```
-----  
2  
(1 row)
```

In the SQL:2008 standard, a minus sign before an interval-literal or as the first character of the interval-literal negates the entire literal, not just the first component. In Vertica, a leading minus sign negates the entire interval, not just the first component. The following commands both return the same value:

```
=> SELECT INTERVAL '-1 month - 1 second';
?column?
-----
-29 days 23:59:59

=> SELECT INTERVAL '-1 month - 1 second';
?column?
-----
-29 days 23:59:59
```

Use one of the following commands instead to return the intended result:

```
=> SELECT INTERVAL '-1 month 1 second';
?column?
-----
-30 days 1 sec

=> SELECT INTERVAL '-30 00:00:01';
?column?
-----
-30 days 1 sec
```

Two negatives together return a positive:

```
=> SELECT INTERVAL '--1 month - 1 second';
?column?
-----
29 days 23:59:59

=> SELECT INTERVAL '--1 month 1 second';
?column?
-----
30 days 1 sec
```

You can use the year-month syntax with no spaces. Vertica allows the input of negative months but requires two negatives when paired with years.

```
=> SELECT INTERVAL '3-3' YEAR TO MONTH;
?column?
-----
3 years 3 months

=> SELECT INTERVAL '3--3' YEAR TO MONTH;
?column?
-----
2 years 9 months
```

When the interval-literal looks like a year/month type, but the type is day/second, or vice versa, Vertica reads the interval-literal from left to right, where number-number is years-months, and number <space> <signed number> is whatever the units specify. Vertica processes the following command as (-) 1 year 1 month = (-) 365 + 30 = -395 days:

```
=> SELECT INTERVAL '-1-1' DAY TO HOUR;
?column?
-----
-395 days
```

If you insert a space in the interval-literal, Vertica processes it based on the subtype **DAY TO HOUR** : (-) 1 day - 1 hour = (-) 24 - 1 = -23 hours:

```
=> SELECT INTERVAL '-1 -1' DAY TO HOUR;
?column?
-----
-23 hours
```

Two negatives together returns a positive, so Vertica processes the following command as (-) 1 year - 1 month = (-) 365 - 30 = -335 days:

```
=> SELECT INTERVAL '-1--1' DAY TO HOUR;
?column?
-----
-335 days
```

If you omit the value after the hyphen, Vertica assumes 0 months and processes the following command as 1 year 0 month -1 day = 365 + 0 - 1 = -364 days:

```
=> SELECT INTERVAL '1- -1' DAY TO HOUR;
?column?
-----
364 days
```

Casting with intervals

You can use **CAST** to convert strings to intervals, and vice versa.

String to interval

You cast a string to an interval as follows:

```
CAST( [ INTERVAL[(p)] ] [-] ] interval-literal AS INTERVAL[(p)] interval-qualifier )
```

For example:

```
=> SELECT CAST('3700 sec' AS INTERVAL);
?column?
-----
01:01:40
```

You can cast intervals within day-time or the year-month subtypes but not between them:

```
=> SELECT CAST(INTERVAL '4440' MINUTE as INTERVAL);
?column?
-----
3 days 2 hours
=> SELECT CAST(INTERVAL '-01:15' as INTERVAL MINUTE);
?column?
-----
-75 mins
```

Interval to string

You cast an interval to a string as follows:

```
CAST( (SELECT interval) AS VARCHAR[(n)] )
```

For example:

```
=> SELECT CONCAT(
'Tomorrow at this time: ',
CAST((SELECT INTERVAL '24 hours') + CURRENT_TIMESTAMP(0) AS VARCHAR));
CONCAT
-----
Tomorrow at this time: 2016-08-17 08:41:23-04
(1 row)
```

Operations with intervals

If you divide an interval by an interval, you get a **FLOAT** :

```
=> SELECT INTERVAL '28 days 3 hours' HOUR(4) / INTERVAL '27 days 3 hours' HOUR(4);
?column?
-----
1.036866359447
```

An **INTERVAL** divided by **FLOAT** returns an **INTERVAL** :

```
=> SELECT INTERVAL '3' MINUTE / 1.5;
?column?
-----
2 mins
```

INTERVAL MODULO (remainder) **INTERVAL** returns an **INTERVAL** :

```
=> SELECT INTERVAL '28 days 3 hours' HOUR % INTERVAL '27 days 3 hours' HOUR;
?column?
-----
24 hours
```

If you add **INTERVAL** and **TIME** , the result is **TIME** , modulo 24 hours:

```
=> SELECT INTERVAL '1' HOUR + TIME '1:30';
?column?
-----
02:30:00
```

SMALLDATETIME

SMALLDATETIME is an alias for [TIMESTAMP/TIMESTAMPTZ](#).

TIME/TIMETZ

Stores the specified time of day. **TIMETZ** is the same as **TIME WITH TIME ZONE** : both data types store the UTC offset of the specified time.

Syntax

```
TIME [ ( p ) ] [ { WITHOUT | WITH } TIME ZONE ] 'input-string' [ AT TIME ZONE zone ]
```

Parameters

p

Optional precision value that specifies the number of fractional digits retained in the seconds field, an integer value between 0 and 6. If you omit specifying precision, Vertica returns up to 6 fractional digits.

WITHOUT TIME ZONE

Ignore any time zone in the input string and use a value without a time zone (default).

WITH TIME ZONE

Convert the time to UTC. If the input string includes a time zone, use its UTC offset for the conversion. If the input string omits a time zone, Vertica uses the UTC offset of the time zone that is [configured for your system](#).

input-string

See [Input String](#) below.

AT TIME ZONE zone

See [TIME AT TIME ZONE](#) and [TIMESTAMP AT TIME ZONE](#).

TIMETZ vs. TIMESTAMPTZ

TIMETZ and [TIMESTAMPTZ](#) are not parallel SQL constructs. **TIMESTAMPTZ** records a time and date in GMT, converting from the specified **TIME ZONE**. **TIMETZ** records the specified time and the specified time zone, in minutes, from GMT.

Limits

Name	Low Value	High Value	Resolution
TIME [p]	00:00:00.00	23:59:60.999999	1 μs
TIME [p] WITH TIME ZONE	00:00:00.00+14	23:59:59.999999-14	1 μs

Input string

A **TIME** input string can be set to any of the formats shown below:

Example	Description
---------	-------------

04:05:06.789	ISO 8601
04:05:06	ISO 8601
04:05	ISO 8601
040506	ISO 8601
04:05 AM	Same as 04:05; AM does not affect value
04:05 PM	Same as 16:05
04:05:06.789-8	ISO 8601
04:05:06-08:00	ISO 8601
04:05-08:00	ISO 8601
040506-08	ISO 8601
04:05:06 PST	Time zone specified by name

Data type coercion

You can cast a **TIME** or **TIMETZ** interval to a **TIMESTAMP** . This returns the local date and time as follows:

```
=> SELECT (TIME '3:01am')::TIMESTAMP;
?column?
```

```
-----
2012-08-30 03:01:00
(1 row)
```

```
=> SELECT (TIMETZ '3:01am')::TIMESTAMP;
?column?
```

```
-----
2012-08-22 03:01:00
(1 row)
```

Casting the same **TIME** or **TIMETZ** interval to a **TIMESTAMPTZ** returns the local date and time, appended with the UTC offset—in this example, **-05** :

```
=> SELECT (TIME '3:01am')::TIMESTAMPTZ;
?column?
```

```
-----
2016-12-08 03:01:00-05
(1 row)
```

TIME AT TIME ZONE

Converts the specified **TIME** to the time in another time zone.

Syntax

```
TIME [WITH TIME ZONE] 'input-string' AT TIME ZONE 'zone'
```

Parameters

WITH TIME ZONE

Converts the input string to UTC, using the UTC offset for the specified time zone. If the input string omits a time zone, Vertica uses the UTC offset of the time zone that is [configured for your system](#), and converts the input string accordingly

zone

Specifies the time zone to use in the conversion, either as a literal or interval that specifies UTC offset:

- **AT TIME ZONE INTERVAL** ' *utc-offset* '

- `AT TIME ZONE 'time-zone-literal'`

For details, see [Specifying Time Zones](#) below.

Note

Vertica treats literals `TIME ZONE` and `TIMEZONE` as synonyms.

Specifying time zones

You can specify time zones in two ways:

- A string literal such as `America/Chicago` or `PST`
- An interval that specifies a UTC offset—for example, `INTERVAL '-08:00'`

It is generally good practice to specify time zones with literals that indicate a geographic location. Vertica makes the necessary seasonal adjustments, and thereby avoids inconsistent results. For example, the following two queries are issued when daylight time is in effect. Because the local UTC offset during daylight time is `-04`, both queries return the same results:

```
=> SELECT CURRENT_TIME(0) "EDT";
      EDT
-----
12:34:35-04
(1 row)

=> SELECT CURRENT_TIME(0) AT TIME ZONE 'America/Denver' "Mountain Time";
      Mountain Time
-----
10:34:35-06
(1 row)

=> SELECT CURRENT_TIME(0) AT TIME ZONE INTERVAL '-06:00' "Mountain Time";
      Mountain Time
-----
10:34:35-06
(1 row)
```

If you issue a use the UTC offset in a similar query when standard time is in effect, you must adjust the UTC offset accordingly—for Denver time, to `-07`—otherwise, Vertica returns a different (and erroneous) result:

```
=> SELECT CURRENT_TIME(0) "EST";
      EST
-----
14:18:22-05
(1 row)

=> SELECT CURRENT_TIME(0) AT TIME ZONE INTERVAL '-06:00' "Mountain Time";
      Mountain Time
-----
13:18:22-06
(1 row)
```

You can show and set the session's time zone with [SHOW TIMEZONE](#) and [SET TIME ZONE](#), respectively:

```
=> SHOW TIMEZONE;
```

```
name | setting
```

```
-----+-----  
timezone | America/New_York
```

```
(1 row)
```

```
=> SELECT CURRENT_TIME(0) "Eastern Daylight Time";
```

```
Eastern Daylight Time
```

```
-----  
12:18:24-04
```

```
(1 row)
```

```
=> SET TIMEZONE 'America/Los_Angeles';
```

```
SET
```

```
=> SELECT CURRENT_TIME(0) "Pacific Daylight Time";
```

```
Pacific Daylight Time
```

```
-----  
09:18:24-07
```

```
(1 row)
```

Time zone literals

To view the default list of valid literals, see the files in the following directory:

```
opt/vertica/share/timezonesets
```

For example:

```
$ cat Antarctica.txt
```

```
...
```

```
# src/timezone/tznames/Antarctica.txt
```

```
#
```

```
AWST 28800 # Australian Western Standard Time
```

```
# (Antarctica/Casey)
```

```
# (Australia/Perth)
```

```
...
```

```
NZST 43200 # New Zealand Standard Time
```

```
# (Antarctica/McMurdo)
```

```
# (Pacific/Auckland)
```

```
ROTT -10800 # Rothera Time
```

```
# (Antarctica/Rothera)
```

```
SYOT 10800 # Syowa Time
```

```
# (Antarctica/Syowa)
```

```
VOST 21600 # Vostok time
```

```
# (Antarctica/Vostok)
```

Examples

The following example assumes that local time is EST (Eastern Standard Time). The query converts the specified time to MST (mountain standard time):

```
=> SELECT CURRENT_TIME(0);
```

```
timezone
```

```
10:10:56-05
```

```
(1 row)
```

```
=> SELECT TIME '10:10:56' AT TIME ZONE 'America/Denver' "Denver Time";
```

```
Denver Time
```

```
08:10:56-07
```

```
(1 row)
```

The next example adds a time zone literal to the input string—in this case, [Europe/Vilnius](#) —and converts the time to MST:

```
=> SELECT TIME '09:56:13 Europe/Vilnius' AT TIME ZONE 'America/Denver';
```

```
Denver Time
```

```
00:56:13-07
```

```
(1 row)
```

See also

- [TIMESTAMP AT TIME ZONE](#)
- [TZ environment variable](#)
- [Using time zones with Vertica](#)
- [Sources for Time Zone and Daylight Saving Time Data](#)

TIMESTAMP/TIMESTAMPTZ

Stores the specified date and time. **TIMESTAMPTZ** is the same as **TIMESTAMP WITH TIME ZONE** : both data types store the UTC offset of the specified time.

TIMESTAMP is an alias for **DATETIME** and **SMALLDATETIME** .

Syntax

```
TIMESTAMP [ (p) ] [ { WITHOUT | WITH } TIME ZONE ] 'input-string' [ AT TIME ZONE zone ]
```

```
TIMESTAMPTZ [ (p) ] 'input-string' [ AT TIME ZONE zone ]
```

Parameters

p

Optional precision value that specifies the number of fractional digits retained in the seconds field, an integer value between 0 and 6. If you omit specifying precision, Vertica returns up to 6 fractional digits.

WITHOUT TIME ZONE

WITH TIME ZONE

Specifies whether to include a time zone with the stored value:

- **WITHOUT TIME ZONE** (default): Specifies that *input-string* does not include a time zone. If the input string contains a time zone, Vertica ignores this qualifier. Instead, it conforms to **WITH TIME ZONE** behavior.
- **WITH TIME ZONE** : Specifies to convert *input-string* to UTC, using the UTC offset for the specified time zone. If the input string omits a time zone, Vertica uses the UTC offset of the time zone that is [configured for your system](#) .

input-string

See [Input String](#) below.

AT TIME ZONE zone

See [TIMESTAMP AT TIME ZONE](#) .

Limits

In the following table, values are rounded. See [Date/time data types](#) for more detail.

Name	Low Value	High Value	Resolution
TIMESTAMP [(p)] [WITHOUT TIME ZONE]	290279 BC	294277 AD	1 μ s

TIMESTAMP [(p)] WITH TIME ZONE	290279 BC	294277 AD	1 μs
----------------------------------	-----------	-----------	------

Input string

The date/time input string concatenates a date and a time. The input string can include a time zone, specified as a literal such as `America/Chicago` , or as a UTC offset.

The following list represents typical date/time input variations:

- `1999-01-08 04:05:06`
- `1999-01-08 04:05:06 -8:00`
- `January 8 04:05:06 1999 PST`

Note

`0000-00-00` is invalid input. If you try to insert that value into a DATE or TIMESTAMP field, an error occurs. If you copy `0000-00-00` into a DATE or TIMESTAMP field, Vertica converts the value to `0001-01-01 00:00:00 BC` .

The input string can also specify the calendar era, either `AD` (default) or `BC` . If you omit the calendar era, Vertica assumes the current calendar era (`AD`). The calendar era typically follows the time zone; however, the input string can include it in various locations. For example, the following queries return the same results:

```
=> SELECT TIMESTAMP WITH TIME ZONE 'March 1, 44 12:00 CET BC ' "Caesar's Time of Death EST";
Caesar's Time of Death EST
-----
0044-03-01 06:00:00-05 BC
(1 row)

=> SELECT TIMESTAMP WITH TIME ZONE 'March 1, 44 12:00 BC CET' "Caesar's Time of Death EST";
Caesar's Time of Death EST
-----
0044-03-01 06:00:00-05 BC
(1 row)
```

Examples

```
=> SELECT (TIMESTAMP '2014-01-17 10:00' - TIMESTAMP '2014-01-01');
?column?
-----
16 10:00
(1 row)

=> SELECT (TIMESTAMP '2014-01-17 10:00' - TIMESTAMP '2014-01-01') / 7;
?column?
-----
2 08:17:08.571429
(1 row)

=> SELECT TIMESTAMP '2009-05-29 15:21:00.456789'-TIMESTAMP '2009-05-28';
?column?
-----
1 15:21:00.456789
(1 row)

=> SELECT (TIMESTAMP '2009-05-29 15:21:00.456789'-TIMESTAMP '2009-05-28')(3);
?column?
-----
1 15:21:00.457
(1 row)

=> SELECT '2017-03-18 07:00'::TIMESTAMPTZ(0) + INTERVAL '1.5 day';
?column?
```

2017-03-19 19:00:00-04

(1 row)

=> SELECT (TIMESTAMP '2014-01-17 10:00' - TIMESTAMP '2014-01-01') day;
?column?

16

(1 row)

=> SELECT cast((TIMESTAMP '2014-01-17 10:00' - TIMESTAMP '2014-01-01')
day as integer) / 7;
?column?

2.285714285714285714

(1 row)

=> SELECT floor((TIMESTAMP '2014-01-17 10:00' - TIMESTAMP '2014-01-01')
/ interval '7');
floor

2

(1 row)

=> SELECT (TIMESTAMP '2009-05-29 15:21:00.456789'-TIMESTAMP '2009-05-28') second;
?column?

141660.456789

(1 row)

=> SELECT (TIMESTAMP '2012-05-29 15:21:00.456789'-TIMESTAMP '2009-01-01') year;
?column?

3

(1 row)

=> SELECT (TIMESTAMP '2012-05-29 15:21:00.456789'-TIMESTAMP '2009-01-01') month;
?column?

40

(1 row)

=> SELECT (TIMESTAMP '2012-05-29 15:21:00.456789'-TIMESTAMP '2009-01-01')
year to month;
?column?

3-4

(1 row)

=> SELECT (TIMESTAMP '2012-05-29 15:21:00.456789'-TIMESTAMP '2009-01-01')
second(3);
?column?

107536860.457

(1 row)

=> SELECT (TIMESTAMP '2012-05-29 15:21:00.456789'-TIMESTAMP '2009-01-01') minute;
?column?

1792281

(1 row)

```
=> SELECT (TIMESTAMP '2012-05-29 15:21:00.456789'-TIMESTAMP '2009-01-01')
minute to second(3);
?column?
-----
1792281:00.457
(1 row)
```

```
=> SELECT TIMESTAMP 'infinity';
?column?
-----
infinity
(1 row)
```

TIMESTAMP AT TIME ZONE

Converts the specified **TIMESTAMP** or **TIMESTAMPTZ** (**TIMESTAMP WITH TIMEZONE**) to another time zone. Vertica executes **AT TIME ZONE** differently, depending on whether the date input is a **TIMESTAMP** or **TIMESTAMPTZ** . See [TIMESTAMP versus TIMESTAMPTZ Behavior](#) below.

Syntax

```
timestamp-clause AT TIME ZONE 'zone'
```

Parameters

[*timestamp-clause*](/sql-reference/data-types/datetime-data-types/timestamptimestampz.html)

Specifies the timestamp to convert, either **TIMESTAMP** or **TIMESTAMPTZ** .

For details, see [TIMESTAMP/TIMESTAMPTZ](#) .

AT TIME ZONE *zone*

Specifies the time zone to use in the timestamp conversion, where *zone* is a literal or interval that specifies a UTC offset:

- **AT TIME ZONE INTERVAL ' *utc-offset* '**
- **AT TIME ZONE ' *time-zone-literal* '**

For details, see [Specifying Time Zones](#) below.

Note

Vertica treats literals **TIME ZONE** and **TIMEZONE** as synonyms.

TIMESTAMP versus TIMESTAMPTZ behavior

How Vertica interprets **AT TIME ZONE** depends on whether the date input is a **TIMESTAMP** or **TIMESTAMPTZ** :

Date input	Action
------------	--------

TIMESTAMP

If the input string specifies no time zone, Vertica performs two actions:

1. Converts the input string to the time zone of the **AT TIME ZONE** argument.
2. Returns the time for the current session's time zone.

If the input string includes a time zone, Vertica implicitly casts it to a **TIMESTAMPTZ** and converts it accordingly (see **TIMESTAMPTZ** below).

For example, the following statement specifies a **TIMESTAMP** with no time zone. Vertica executes the statement as follows:

1. Converts the input string to PDT (Pacific Daylight Time).
2. Returns that time in the local time zone, which is three hours later:

```
=> SHOW TIMEZONE;
name | setting
-----+-----
timezone | America/New_York
(1 row)

SELECT TIMESTAMP '2017-3-14 5:30' AT TIME ZONE 'PDT';
    timezone
-----
2017-03-14 08:30:00-04
(1 row)
```

TIMESTAMPTZ

Vertica converts the input string to the time zone of the **AT TIME ZONE** argument and returns that time.

For example, the following statement specifies a **TIMESTAMPTZ** data type. The input string omits any time zone expression, so Vertica assumes the input string to be in local time zone (**America/New_York**) and returns the time of the **AT TIME ZONE** argument:

```
=> SHOW TIMEZONE;
name | setting
-----+-----
timezone | America/New_York
(1 row)

=> SELECT TIMESTAMP WITH TIME ZONE '2001-02-16 20:38:40' AT TIME ZONE 'America/Denver';
    timezone
-----
2001-02-16 18:38:40
(1 row)
```

The input string in the next statement explicitly specifies a time zone, so Vertica coerces the **TIMESTAMP** to a **TIMESTAMPTZ** and returns the time of the **AT TIME ZONE** argument:

```
=> SELECT TIMESTAMP '2001-02-16 20:38:40 America/Mexico_City' AT TIME ZONE 'Asia/Tokyo';
    timezone
-----
2001-02-17 11:38:40
(1 row)
```

Specifying time zones

You can specify time zones in two ways:

- A string literal such as **America/Chicago** or **PST**
- An interval that specifies a UTC offset—for example, **INTERVAL '-08:00'**

It is generally good practice to specify time zones with literals that indicate a geographic location. Vertica makes the necessary seasonal adjustments, and thereby avoids inconsistent results. For example, the following two queries are issued when daylight time is in effect. Because the local UTC offset during daylight time is **-04**, both queries return the same results:

```
=> SELECT TIMESTAMPTZ '2017-03-16 09:56:13' AT TIME ZONE 'America/Denver' "Denver Time";
 Denver Time
-----
2017-03-16 07:56:13
(1 row)

=> SELECT TIMESTAMPTZ '2017-03-16 09:56:13' AT TIME ZONE INTERVAL '-06:00' "Denver Time";
 Denver Time
-----
2017-03-16 07:56:13
(1 row)
```

If you issue a use the UTC offset in a similar query when standard time is in effect, you must adjust the UTC offset accordingly—for Denver time, to **-07**—otherwise, Vertica returns a different (and erroneous) result:

```
=> SELECT TIMESTAMPTZ '2017-01-16 09:56:13' AT TIME ZONE 'America/Denver' "Denver Time";
 Denver Time
-----
2017-0-16 07:56:13
(1 row)

=> SELECT TIMESTAMPTZ '2017-01-16 09:56:13' AT TIME ZONE INTERVAL '-06:00' "Denver Time";
 Denver Time
-----
2017-01-16 08:56:13
(1 row)
```

You can show and set the session's time zone with [SHOW TIMEZONE](#) and [SET TIME ZONE](#), respectively:

```
=> SHOW TIMEZONE;
 name | setting
-----+-----
timezone | America/New_York
(1 row)

=> SELECT CURRENT_TIMESTAMP(0) "Eastern Daylight Time";
 Eastern Daylight Time
-----
2017-03-20 12:18:24-04
(1 row)

=> SET TIMEZONE 'America/Los_Angeles';
SET

=> SELECT CURRENT_TIMESTAMP(0) "Pacific Daylight Time";
 Pacific Daylight Time
-----
2017-03-20 09:18:24-07
(1 row)
```

Time zone literals

To view the default list of valid literals, see the files in the following directory:

```
opt/vertica/share/timezonesets
```

For example:

```
$ cat Antarctica.txt
```

```
...  
# src/timezone/tznames/Antarctica.txt  
#  
AWST 28800 # Australian Western Standard Time  
# (Antarctica/Casey)  
# (Australia/Perth)  
...  
NZST 43200 # New Zealand Standard Time  
# (Antarctica/McMurdo)  
# (Pacific/Auckland)  
ROTT -10800 # Rothera Time  
# (Antarctica/Rothera)  
SYOT 10800 # Syowa Time  
# (Antarctica/Syowa)  
VOST 21600 # Vostok time  
# (Antarctica/Vostok)
```

See also

- [TIME AT TIME ZONE](#)
- [TZ environment variable](#)
- [Using time zones with Vertica](#)
- [Sources for Time Zone and Daylight Saving Time Data](#)

Long data types

Store data up to 32000000 octets. Vertica supports two long data types:

- **LONG VARBINARY** : Variable-length raw-byte data, such as spatial data. **LONG VARBINARY** values are not extended to the full width of the column.
- **LONG VARCHAR** : Variable-length strings, such as log files and unstructured data. **LONG VARCHAR** values are not extended to the full width of the column.

Use **LONG** data types only when you need to store data greater than the maximum size of **VARBINARY** and **VARCHAR** data types (65 KB). Long data can include unstructured data, online comments or posts, or small log files.

Flex tables have a default **LONG VARBINARY __raw__** column, with a **NOT NULL** constraint. For more information, see [Flex tables](#).

Syntax

```
LONG VARBINARY [(max-length)]  
LONG VARCHAR [(octet-length)]
```

Parameters

max-length

Length of the byte string or column width, declared in bytes (octets), up to 32000000.

Default: 1 MB

octet-length

Length of the string or column width, declared in bytes (octets), up to 32000000.

Default: 1 MB

Optimized performance

For optimal performance of **LONG** data types, Vertica recommends that you:

- Use the **LONG** data types as *storage only* containers; Vertica supports operations on the content of **LONG** data types, but does not support all the operations that **VARCHAR** and **VARBINARY** take.
- Use **VARBINARY** and **VARCHAR** data types, instead of their **LONG** counterparts, whenever possible. **VARBINARY** and **VARCHAR** data types are more flexible and have a wider range of operations.
- Do not sort, segment, or partition projections on **LONG** data type columns.

- Do not add constraints, such as a primary key, to any **LONG VARBINARY** or **LONG VARCHAR** columns.
- Do not join or aggregate any **LONG** data type columns.

Examples

The following example creates a table `user_comments` with a **LONG VARCHAR** column and inserts data into it:

```
=> CREATE TABLE user_comments
      (id INTEGER,
       username VARCHAR(200),
       time_posted TIMESTAMP,
       comment_text LONG VARCHAR(200000));
=> INSERT INTO user_comments VALUES
      (1,
       'User1',
       TIMESTAMP '2013-06-25 12:47:32.62',
       'The weather tomorrow will be cold and rainy and then
       on the day after, the sun will come and the temperature
       will rise dramatically.');
```

Numeric data types

Numeric data types are numbers stored in database columns. These data types are typically grouped by:

- **Exact** numeric types, values where the precision and scale need to be preserved. The exact numeric types are **INTEGER** , **BIGINT** , **DECIMAL** , **NUMERIC** , **NUMBER** , and **MONEY** .
- **Approximate** numeric types, values where the precision needs to be preserved and the scale can be floating. The approximate numeric types are **DOUBLE PRECISION** , **FLOAT** , and **REAL** .

Implicit casts from **INTEGER** , **FLOAT** , and **NUMERIC** to **VARCHAR** are not supported. If you need that functionality, write an explicit cast using one of the following forms:

```
CAST(numeric-expression AS data-type)
numeric-expression::data-type
```

For example, you can cast a float to an integer as follows:

```
=> SELECT(FLOAT '123.5')::INT;
?column?
-----
    124
(1 row)
```

String-to-numeric data type conversions accept formats of quoted constants for scientific notation, binary scaling, hexadecimal, and combinations of numeric-type literals:

- Scientific notation :

```
=> SELECT FLOAT '1e10';
?column?
-----
10000000000
(1 row)
```

- **BINARY** scaling :

```
=> SELECT NUMERIC '1p10';
?column?
-----
    1024
(1 row)
```

- hexadecimal:

```
=> SELECT NUMERIC '0x0abc';
?column?
-----
 2748
(1 row)
```

In this section

- [DOUBLE PRECISION \(FLOAT\)](#)
- [INTEGER](#)
- [NUMERIC](#)
- [Numeric data type overflow](#)
- [Numeric data type overflow with SUM, SUM_FLOAT, and AVG](#)

DOUBLE PRECISION (FLOAT)

Vertica supports the numeric data type **DOUBLE PRECISION**, which is the IEEE-754 8-byte floating point type, along with most of the usual floating point operations.

Syntax

```
[ DOUBLE PRECISION | FLOAT | FLOAT(n) | FLOAT8 | REAL ]
```

Parameters

Note

On a machine whose floating-point arithmetic does not follow IEEE-754, these values probably do not work as expected.

Double precision is an inexact, variable-precision numeric type. In other words, some values cannot be represented exactly and are stored as approximations. Thus, input and output operations involving double precision might show slight discrepancies.

- All of the **DOUBLE PRECISION** data types are synonyms for 64-bit IEEE FLOAT.
- The *n* in **FLOAT(n)** must be between 1 and 53, inclusive, but a 53-bit fraction is always used. See the IEEE-754 standard for details.
- For exact numeric storage and calculations (money for example), use **NUMERIC**.
- Floating point calculations depend on the behavior of the underlying processor, operating system, and compiler.
- Comparing two floating-point values for equality might not work as expected.
- While Vertica treats decimal values as **FLOAT** internally, if a column is defined as **FLOAT** then you cannot read decimal values from ORC and Parquet files. In those formats, **FLOAT** and **DECIMAL** are different types.

Values

COPY accepts floating-point data in the following format:

- Optional leading white space
- An optional plus ("+") or minus sign ("-")
- A decimal number, a hexadecimal number, an infinity, a NAN, or a null value

Decimal Number

A decimal number consists of a non-empty sequence of decimal digits possibly containing a radix character (decimal point "."), optionally followed by a decimal exponent. A decimal exponent consists of an "E" or "e", followed by an optional plus or minus sign, followed by a non-empty sequence of decimal digits, and indicates multiplication by a power of 10.

Hexadecimal Number

A hexadecimal number consists of a "0x" or "0X" followed by a non-empty sequence of hexadecimal digits possibly containing a radix character, optionally followed by a binary exponent. A binary exponent consists of a "P" or "p", followed by an optional plus or minus sign, followed by a non-empty sequence of decimal digits, and indicates multiplication by a power of 2. At least one of radix character and binary exponent must be present.

Infinity

An infinity is either **INF** or **INFINITY**, disregarding case.

NaN (Not A Number)

A NaN is **NAN** (disregarding case) optionally followed by a sequence of characters enclosed in parentheses. The character string specifies the value of NaN in an implementation-dependent manner. (The Vertica internal representation of NaN is 0xffff800000000000LL on x86 machines.)

When writing infinity or NaN values as constants in a SQL statement, enclose them in single quotes. For example:

```
=> UPDATE table SET x = 'Infinity'
```

Note

Vertica follows the IEEE definition of NaNs (IEEE 754). The SQL standards do not specify how floating point works in detail.

IEEE defines NaNs as a set of floating point values where each one is not equal to anything, even to itself. A NaN is not greater than and at the same time not less than anything, even itself. In other words, comparisons always return false whenever a NaN is involved.

However, for the purpose of sorting data, NaN values must be placed somewhere in the result. The value generated 'NaN' appears in the context of a floating point number matches the NaN value generated by the hardware. For example, Intel hardware generates (0xffff800000000000LL), which is technically a Negative, Quiet, Non-signaling NaN.

Vertica uses a different NaN value to represent floating point NULL (0x7ffffffffffffeLL). This is a Positive, Quiet, Non-signaling NaN and is reserved by Vertica

A NaN example follows.

```
=> SELECT CBRT('NaN'); -- cube root
CBRT
-----
NaN
(1 row)
=> SELECT 'NaN' > 1.0;
?column?
-----
f
(1 row)
```

Null Value

The load file format of a null value is user defined, as described in the [COPY](#) command. The Vertica internal representation of a null value is 0x7ffffffffffffeLL. The interactive format is controlled by the [vsq!](#) printing option null. For example:

```
\pset null '(null)'
```

The default option is not to print anything.

Rules

- -0 == +0
- 1/0 = Infinity
- 0/0 == Nan
- NaN != anything (even NaN)

To search for NaN column values, use the following predicate:

```
... WHERE column != column
```

This is necessary because **WHERE** *column* = 'NaN' cannot be true by definition.

Sort order (ascending)

- NaN
- -Inf
- numbers
- +Inf
- NULL

Notes

- **NULL** appears last (largest) in ascending order.

- All overflows in floats generate +/-infinity or NaN, per the IEEE floating point standard.

INTEGER

A signed 8-byte (64-bit) data type.

Syntax

```
[ INTEGER | INT | BIGINT | INT8 | SMALLINT | TINYINT ]
```

Parameters

INT , **INTEGER** , **INT8** , **SMALLINT** , **TINYINT** , and **BIGINT** are all synonyms for the same signed 64-bit integer data type. Automatic compression techniques are used to conserve disk space in cases where the full 64 bits are not required.

Notes

- The range of values is $-2^{63}+1$ to $2^{63}-1$.
- $2^{63} = 9,223,372,036,854,775,808$ (19 digits).
- The value -2^{63} is reserved to represent NULL.
- **NULL** appears first (smallest) in ascending order.
- Vertica does not have an explicit 4-byte (32-bit integer) or smaller types. Vertica's encoding and compression automatically eliminate the storage overhead of values that fit in less than 64 bits.

Restrictions

- The JDBC type INTEGER is 4 bytes and is not supported by Vertica. Use **BIGINT** instead.
- Vertica does not support the SQL/JDBC types **NUMERIC** , **SMALLINT** , or **TINYINT** .
- Vertica does not check for overflow (positive or negative) except in the aggregate function **SUM()** . If you encounter overflow when using **SUM** , use **SUM_FLOAT()** , which converts to floating point.

[Data Type Coercion Chart](#)

NUMERIC

Numeric data types store fixed-point numeric data. For example, a value of \$123.45 can be stored in a **NUMERIC(5,2)** field. Note that the first number, the precision, specifies the *total* number of digits.

Syntax

```
numeric-type [ ( precision[, scale] ) ]
```

Parameters

numeric-type

One of the following:

- NUMERIC
- DECIMAL
- NUMBER
- MONEY

precision

An unsigned integer that specifies the total number of significant digits that the data type stores, where *precision* is ≤ 1024 . If omitted, the [default precision](#) depends on numeric type that you specify. If you assign a value that exceeds *precision* , Vertica returns an error.

If a data type's precision is ≤ 18 , performance is equivalent to an INTEGER data type, regardless of scale. When possible, Vertica recommends using a precision ≤ 18 .

scale

An unsigned integer that specifies the maximum number of digits to the right of the decimal point to store. *scale* must be \leq *precision* . If omitted, the [default scale](#) depends on numeric type that you specify. If you assign a value with more decimal digits than *scale* , the scale is rounded to *scale* digits.

When using ALTER to modify the data type of a numeric column, *scale* cannot be changed.

Default precision and scale

NUMERIC , **DECIMAL** , **NUMBER** , and **MONEY** differ in their default precision and scale values:

Type	Precision	Scale
NUMERIC	37	15
DECIMAL	37	15
NUMBER	38	0
MONEY	18	4

Supported encoding

Vertica supports the following encoding for [numeric data types](#) :

- Precision \leq 18: [AUTO](#) , [BLOCK_DICT](#) , [BLOCKDICT_COMP](#) , [COMMONDELTA_COMP](#) , [DELTAVAL](#) , [GCDDELTA](#) , and [RLE](#)
- Precision $>$ 18: [AUTO](#) , [BLOCK_DICT](#) , [BLOCKDICT_COMP](#) , [RLE](#)

For details, see [Encoding types](#) .

Numeric versus integer and floating data types

Numeric data types are *exact* data types that store values of a specified precision and scale, expressed with a number of digits before and after a decimal point. This contrasts with the Vertica integer and floating data types:

- [DOUBLE PRECISION \(FLOAT\)](#) supports ~15 digits, variable exponent, and represents numeric values approximately. It can be less precise than NUMERIC data types.
- [INTEGER](#) supports ~18 digits, whole numbers only.

The NUMERIC data type is preferred for non-integer constants, because it is always exact. For example:

```
=> SELECT 1.1 + 2.2 = 3.3;
?column?
-----
t
(1 row)

=> SELECT 1.1::float + 2.2::float = 3.3::float;
?column?
-----
f
(1 row)
```

Numeric operations

Supported numeric operations include the following:

- [Basic math](#) : + , - , * , /
- [Aggregation](#) : [SUM](#) , [MIN](#) , [MAX](#) , [COUNT](#)
- [Comparison](#) : < , <= , = , <=> , <> , > , >=

NUMERIC divide operates directly on numeric values, without converting to floating point. The result has at least 18 decimal places and is rounded.

NUMERIC mod (including %) operates directly on numeric values, without converting to floating point. The result has the same scale as the numerator and never needs rounding.

Some complex operations used with numeric data types result in an implicit cast to FLOAT. When using SQRT, STDDEV, transcendental functions such as LOG, and TO_CHAR/TO_NUMBER formatting, the result is always FLOAT.

Examples

The following series of commands creates a table that contains a numeric data type and then performs some mathematical operations on the data:

```
=> CREATE TABLE num1 (id INTEGER, amount NUMERIC(8,2));
```

Insert some values into the table:

```
=> INSERT INTO num1 VALUES (1, 123456.78);
```

Query the table:

```
=> SELECT * FROM num1;
 id | amount
-----+-----
  1 | 123456.78
(1 row)
```

The following example returns the NUMERIC column, amount, from table num1:

```
=> SELECT amount FROM num1;
 amount
-----
123456.78
(1 row)
```

The following syntax adds one (1) to the amount:

```
=> SELECT amount+1 AS 'amount' FROM num1;
 amount
-----
123457.78
(1 row)
```

The following syntax multiplies the amount column by 2:

```
=> SELECT amount*2 AS 'amount' FROM num1;
 amount
-----
246913.56
(1 row)
```

The following syntax returns a negative number for the amount column:

```
=> SELECT -amount FROM num1;
?column?
-----
-123456.78
(1 row)
```

The following syntax returns the absolute value of the amount argument:

```
=> SELECT ABS(amount) FROM num1;
 ABS
-----
123456.78
(1 row)
```

The following syntax casts the NUMERIC amount as a FLOAT data type:

```
=> SELECT amount::float FROM num1;
 amount
-----
123456.78
(1 row)
```

See also

[Mathematical functions](#)

Numeric data type overflow

Vertica does not check for overflow (positive or negative) except in the aggregate function [SUM\(\)](#) . If you encounter overflow when using [SUM](#) , use [SUM_FLOAT\(\)](#) which converts to floating point.

For a detailed discussion of how Vertica handles overflow when you use the functions [SUM](#), [SUM_FLOAT](#), and [AVG](#) with numeric data types, see [Numeric data type overflow with SUM, SUM_FLOAT, and AVG](#) . The discussion includes directives for turning off silent numeric overflow and setting precision for numeric data types. Dividing by zero returns an error:

```

=> SELECT 0/0;
ERROR 3117: Division by zero

=> SELECT 0.0/0;
ERROR 3117: Division by zero

=> SELECT 0 // 0;
ERROR 3117: Division by zero

=> SELECT 200.0/0;
ERROR 3117: Division by zero

=> SELECT 116.43 // 0;
ERROR 3117: Division by zero

```

Dividing zero as a FLOAT by zero returns NaN:

```

=> SELECT 0.0::float/0;
?column?
-----
NaN
=> SELECT 0.0::float//0;
?column?
-----
NaN

```

Dividing a non-zero FLOAT by zero returns Infinity:

```

=> SELECT 2.0::float/0;
?column?
-----
Infinity
=> SELECT 200.0::float//0;
?column?
-----
Infinity

```

Add, subtract, and multiply operations ignore overflow. Sum and average operations use 128-bit arithmetic internally. [SUM\(\)](#) reports an error if the final result overflows, suggesting the use of [SUM_FLOAT\(INT\)](#), which converts the 128-bit sum to a [FLOAT](#). For example:

```

=> CREATE TEMP TABLE t (i INT);
=> INSERT INTO t VALUES (1<<62);
=> INSERT INTO t VALUES (1<<62);
=> INSERT INTO t VALUES (1<<62);
=> INSERT INTO t VALUES (1<<62);
=> INSERT INTO t VALUES (1<<62);
=> SELECT SUM(i) FROM t;
ERROR: sum() overflowed
HINT: try sum_float() instead
=> SELECT SUM_FLOAT(i) FROM t;
SUM_FLOAT
-----
2.30584300921369e+19

```

Numeric data type overflow with SUM, SUM_FLOAT, and AVG

When you use the SUM, SUM_FLOAT, and AVG functions (aggregate and analytic) to query a [numeric](#) column, overflow can occur. How Vertica responds to that overflow depends on the settings of two configuration parameters:

- [AllowNumericOverflow](#) (Boolean, default 1) allows numeric overflow. Vertica does not implicitly extend precision of numeric data types.
- [NumericSumExtraPrecisionDigits](#) (integer, default 6) determines whether to return an overflow error if a result exceeds the specified precision. This parameter is ignored if AllowNumericOverflow is set to 1 (true).

Vertica also allows numeric overflow when you use SUM or SUM_FLOAT to query pre-aggregated data. See [Impact on Pre-Aggregated Data Projections](#) below.

Default overflow handling

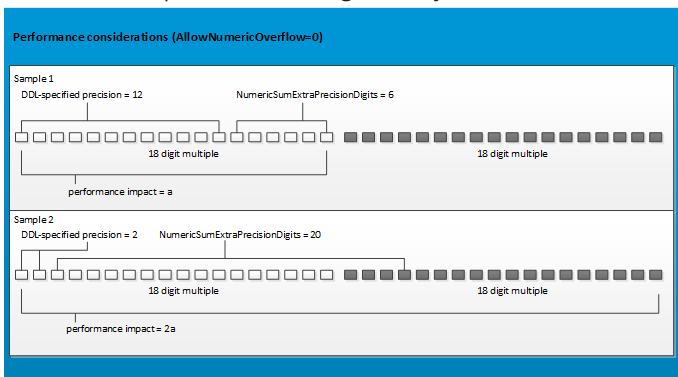

With numeric columns, Vertica internally works with multiples of 18 digits. If specified precision is less than 18—for example, `x(12,0)`—Vertica allows overflow up to and including the first multiple of 18. In some situations, if you sum a column, you can exceed the number of digits Vertica internally reserves for the result. In this case, Vertica allows silent overflow.

Turning off silent numeric overflow

You can turn off silent numeric overflow by setting `AllowNumericOverflow` to 0. In this case, Vertica checks the value of configuration parameter `NumericSumExtraPrecisionDigits`. By default, this parameter is set to 6, which means that Vertica internally adds extra digit places beyond a column's DDL-specified precision. Adding extra precision digits enables Vertica to consistently return results that overflow the column's precision. However, crossing into the second multiple of 18 internally can adversely impact performance.

For example, if `AllowNumericOverflow` is set to 0 :

- Column `x` is defined as `x(12,0)` and `NumericSumExtraPrecisionDigits` is set to 6: Vertica internally stays within the first multiple of 18 digits and no additional performance impact occurs (`a`).
- Column `x` is defined as `x(2,0)` and `NumericSumExtraPrecisionDigits` is set to 20: Vertica internally crosses a threshold into the second multiple of 18. In this case, performance is significantly affected (`2a`). Performance beyond the second multiple of 18 continues to be `2a` .

Tip

Vertica recommends that you turn off silent numeric overflow and set the parameter `NumericSumExtraPrecisionDigits` if you expect query results to exceed the precision specified in the DDL of numeric columns. Be aware of the following considerations:

- If you turn off `AllowNumericOverflow` and exceed the number of extra precision digits set by `NumericSumExtraPrecisionDigits`, Vertica returns an error.
- Be careful to set `NumericSumExtraPrecisionDigits` only as high as necessary to return the SUM of numeric columns.

Impact on pre-aggregated data projections

Vertica supports silent numeric overflow for queries that use SUM or SUM_FLOAT on projections with [pre-aggregated data](#) such as [live aggregate](#) or [Top-K](#) projections. To turn off silent numeric overflow for these queries:

1. Set `AllowNumericOverflow` to 0.
2. Set `NumericSumExtraPrecisionDigits` to the desired number of implicit digits. Alternatively, use the default setting of 6.
3. Drop and re-create the affected projections.

If you turn off silent numeric overflow, be aware that overflow can sometimes cause rollback or errors:

- Overflow occurs during load operations, such as COPY, MERGE, or INSERT:
Vertica aggregates data before loading the projection with data. If overflow occurs while data is aggregated, , Vertica rolls back the load operation.
- Overflow occurs after load, while Vertica sums existing data.
Vertica computes the sum of existing data separately from the computation that it does during data load. If the projection selects a column with SUM or SUM_FLOAT and overflow occurs, Vertica produces an error message. This response resembles the way Vertica produces an error for a query that uses SUM or SUM_FLOAT.
- Overflow occurs during [mergeout](#).
Vertica logs a message during mergeout if overflow occurs while Vertica computes a final sum during the mergeout operation. If an error occurs, Vertica marks the projection as out of date and disqualifies it from further mergeout operations.

Spatial data types

Vertica supports two spatial data types. These data types store two- and three-dimensional spatial objects in a table column:

- **GEOMETRY** : Spatial object with coordinates expressed as (*x* , *y*) pairs, defined in the Cartesian plane. All calculations use Cartesian coordinates.
- **GEOGRAPHY** : Spatial object defined as on the surface of a perfect sphere, or a spatial object in the WGS84 coordinate system. Coordinates are expressed in longitude/latitude angular values, measured in degrees. All calculations are in meters. For perfect sphere calculations, the sphere has a radius of 6371 kilometers, which approximates the shape of the earth.

Note

Some spatial programs use an ellipsoid to model the earth, resulting in slightly different data.

The maximum size of a **GEOMETRY** or **GEOGRAPHY** data type is 10,000,000 bytes (10 MB). You cannot use either data type as a table's primary key.

Syntax

```
GEOMETRY [ (length) ]  
GEOGRAPHY [ (length) ]
```

Parameters

length

The maximum amount of spatial data that a **GEOMETRY** or **GEOGRAPHY** column can store, up to 10 MB.

Default: 1 MB

UUID data type

Stores universally unique identifiers (UUIDs). UUIDs are 16-byte (128-bit) numbers used to uniquely identify records. To generate UUIDs, Vertica provides the function [UUID_GENERATE](#), which returns UUIDs based on high-quality randomness from `/dev/urandom`.

Syntax

```
UUID
```

UUID input and output formats

UUIDs support input of case-insensitive string literal formats, as specified by [RFC 4122](#). In general, a UUID is written as a sequence of hexadecimal digits, in several groups optionally separated by hyphens, for a total of 32 digits representing 128 bits.

The following input formats are valid:

```
6bbf0744-74b4-46b9-bb05-53905d4538e7  
{6bbf0744-74b4-46b9-bb05-53905d4538e7}  
6BBF074474B446B9BB0553905D4538E7  
6BBf-0744-74B4-46B9-BB05-5390-5D45-38E7
```

On output, Vertica always uses the following format:

```
xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx
```

For example, the following table defines column `cust_id` as a UUID:

```
=> CREATE TABLE public.Customers  
(  
  cust_id uuid,  
  lname varchar(36),  
  fname varchar(24)  
);
```

The following input for `cust_id` uses several valid formats:

```
=> COPY Customers FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> {cede66b7-3d29-4da6-b700-871fc0ac57be}|Kearney|Thomas
>> 34462732ed5649838f3be735b0c32d50|Pham|Duc
>> 9fb0-1de0-1d63-4d09-9415-90e0-b4e9-3b9a|Steinberg|Jeremy
>> \.
```

On querying this table, Vertica formats all `cust_id` data in the same way:

```
=> SELECT cust_id, fname, lname FROM Customers;
      cust_id          | fname | lname
-----+-----+-----
9fb01de0-1d63-4d09-9415-90e0b4e93b9a | Jeremy | Steinberg
34462732-ed56-4983-8f3b-e735b0c32d50 | Duc    | Pham
cede66b7-3d29-4da6-b700-871fc0ac57be | Thomas | Kearney
(3 rows)
```

Generating UUIDs

You can use the Vertica function [UUID_GENERATE](#) to automatically generate UUIDs that uniquely identify table records. For example:

```
=> INSERT INTO Customers SELECT UUID_GENERATE(),'Rostova','Natasha';
OUTPUT
-----
      1
(1 row)

=> COMMIT;
COMMIT
=> SELECT cust_id, fname, lname FROM Customers;
      cust_id          | fname | lname
-----+-----+-----
9fb01de0-1d63-4d09-9415-90e0b4e93b9a | Jeremy | Steinberg
34462732-ed56-4983-8f3b-e735b0c32d50 | Duc    | Pham
cede66b7-3d29-4da6-b700-871fc0ac57be | Thomas | Kearney
9aad6757-fe1b-473a-a109-b89b7b358c69 | Natasha | Rostova
(4 rows)
```

NULL input and output

The following string is reserved as NULL for UUID columns:

```
00000000-0000-0000-0000-000000000000
```

Vertica always renders NULL as blank.

The following `COPY` statements insert NULL values into the UUID column, explicitly and implicitly:

```
=> COPY Customers FROM STDIN NULL AS 'null';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> null|Doe|Jane
>> 00000000-0000-0000-0000-000000000000|Man|Nowhere
>> \.
=> COPY Customers FROM STDIN;
>> |Doe|John
>> \.
```

In all cases, Vertica renders NULL as blank:

```
=> SELECT cust_id, fname, lname FROM Customers WHERE cust_id IS NULL;
```

```
cust_id | fname | lname
```

```
-----+-----+-----  
      | Nowhere | Man  
      | Jane   | Doe  
      | John   | Doe
```

```
(3 rows)
```

Usage restrictions

UUID data types only support relational operators and functions that are also supported by CHAR and VARCHAR data types—for example, [MIN](#), [MAX](#), and [COUNT](#). UUID data types do not support mathematical operators or functions, such as [SUM](#) and [AVG](#).

Data type coercion

Vertica supports two types of data type casting:

- *Implicit casting*: The expression automatically converts the data from one type to another.
- *Explicit casting*: A SQL statement specifies the target data type for the conversion.

Implicit casting

The ANSI SQL-92 standard supports implicit casting among similar data types:

- Number types
- CHAR, VARCHAR, LONG VARCHAR
- BINARY, VARBINARY, LONG VARBINARY

Vertica supports two types of nonstandard implicit casts of scalar types:

- From CHAR to FLOAT, to match the one from VARCHAR to FLOAT. The following example converts the CHAR '3' to a FLOAT so it can add the number 4.33 to the FLOAT result of the second expression:

```
=> SELECT '3'::CHAR + 4.33::FLOAT;
```

```
?column?
```

```
-----  
      7.33
```

```
(1 row)
```

- Between DATE and TIMESTAMP. The following example DATE to a TIMESTAMP and calculates the time 6 hours, 6 minutes, and 6 seconds back from 12:00 AM:

```
=> SELECT DATE('now') - INTERVAL '6:6:6';
```

```
?column?
```

```
-----  
2013-07-30 17:53:54
```

```
(1 row)
```

When there is no ambiguity about the data type of an expression value, it is implicitly coerced to match the expected data type. In the following statement, the quoted string constant '2' is implicitly coerced into an INTEGER value so that it can be the operand of an arithmetic operator (addition):

```
=> SELECT 2 + '2';
```

```
?column?
```

```
-----  
      4
```

```
(1 row)
```

A concatenate operation explicitly takes arguments of any data type. In the following example, the concatenate operation implicitly coerces the arithmetic expression `2 + 2` and the INTEGER constant `2` to VARCHAR values so that they can be concatenated.

```
=> SELECT 2 + 2 || 2;
```

```
?column?
```

```
-----  
      42
```

```
(1 row)
```

Another example is to first get today's date:

```
=> SELECT DATE 'now';
?column?
```

```
-----
2013-07-31
(1 row)
```

The following command converts DATE to a TIMESTAMP and adds a day and a half to the results by using INTERVAL:

```
=> SELECT DATE 'now' + INTERVAL '1 12:00:00';
?column?
```

```
-----
2013-07-31 12:00:00
(1 row)
```

Most implicit casts stay within their relational family and go in one direction, from less detailed to more detailed. For example:

- DATE to TIMESTAMP/TZ
- INTEGER to NUMERIC to FLOAT
- CHAR to FLOAT
- CHAR to VARCHAR
- CHAR and/or VARCHAR to FLOAT
- CHAR to LONG VARCHAR
- VARCHAR to LONG VARCHAR
- BINARY to VARBINARY
- BINARY to LONG VARBINARY
- VARBINARY to LONG VARBINARY

More specifically, data type coercion works in this manner in Vertica:

Conversion	Notes
INT8 > FLOAT8	Implicit, can lose significance
FLOAT8 > INT8	Explicit, rounds
VARCHAR <-> CHAR	Implicit, adjusts trailing spaces
VARBINARY <-> BINARY	Implicit, adjusts trailing NULs
VARCHAR > LONG VARCHAR	Implicit, adjusts trailing spaces
VARBINARY > LONG VARBINARY	Implicit, adjusts trailing NULs

No other types cast to or from LONGVARBINARY, VARBINARY, or BINARY. In the following list, <any> means one these types: INT8, FLOAT8, DATE, TIME, TIMETZ, TIMESTAMP, TIMESTAMPTZ, INTERVAL:

- <any> -> VARCHAR—implicit
- VARCHAR -> <any>—explicit, except that VARCHAR->FLOAT is implicit
- <any> <-> CHAR—explicit
- DATE -> TIMESTAMP/TZ—implicit
- TIMESTAMP/TZ -> DATE—explicit, loses time-of-day
- TIME -> TIMETZ—implicit, adds local timezone
- TIMETZ -> TIME—explicit, loses timezone
- TIME -> INTERVAL—implicit, day to second with days=0
- INTERVAL -> TIME—explicit, truncates non-time parts
- TIMESTAMP <-> TIMESTAMPTZ—implicit, adjusts to local timezone
- TIMESTAMP/TZ -> TIME—explicit, truncates non-time parts
- TIMESTAMPTZ -> TIMETZ—explicit
- VARBINARY -> LONG VARBINARY—implicit
- LONG VARBINARY -> VARBINARY—explicit
- VARCHAR -> LONG VARCHAR—implicit
- LONG VARCHAR -> VARCHAR—explicit

Important

Implicit casts from INTEGER, FLOAT, and NUMERIC to VARCHAR are not supported. If you need that functionality, write an explicit cast:

```
CAST(x AS data-type-name)
```

or

```
x::data-type-name
```

The following example casts a FLOAT to an INTEGER:

```
=> SELECT(FLOAT '123.5')::INT;
?column?
-----
    124
(1 row)
```

String-to-numeric data type conversions accept formats of quoted constants for scientific notation, binary scaling, hexadecimal, and combinations of numeric-type literals:

- Scientific notation :

```
=> SELECT FLOAT '1e10';
?column?
-----
10000000000
(1 row)
```

- **BINARY** scaling :

```
=> SELECT NUMERIC '1p10';
?column?
-----
    1024
(1 row)
```

- hexadecimal:

```
=> SELECT NUMERIC '0x0abc';
?column?
-----
    2748
(1 row)
```

Complex types

Collections ([arrays](#) and [sets](#)) can be cast implicitly and explicitly. Casting a collection casts each element of the collection. You can, for example, cast an ARRAY[VARCHAR] to an ARRAY[INT] or a SET[DATE] to SET[TIMESTAMPZ]. You can cast between arrays and sets.

When casting to a bounded native array, inputs that are too long are truncated. When casting to a non-native array (an array containing complex data types including other arrays), if the new bounds are too small for the data the cast fails

[Rows](#) (structs) can be cast implicitly and explicitly. Casting a ROW casts each field value. You can specify new field names in the cast or specify only the field types to use the existing field names.

Casting can increase the storage needed for a column. For example, if you cast an array of INT to an array of VARCHAR(50), each element takes more space and thus the array takes more space. If the difference is extreme or the array has many elements, this could mean that the array no longer fits within the space allotted for the column. In this case the operation reports an error and fails.

Examples

The following example casts three strings as NUMERICs:

```
=> SELECT NUMERIC '12.3e3', '12.3p10'::NUMERIC, CAST('0x12.3p-10e3' AS NUMERIC);
?column? | ?column? | ?column?
-----+-----+-----
 12300 | 12595.2 | 17.76123046875000
(1 row)
```

This example casts a VARBINARY string into a LONG VARBINARY data type:

```

=> SELECT B'101111000'::LONG VARBINARY;
?column?
-----
\001x
(1 row)

```

The following example concatenates a CHAR with a LONG VARCHAR, resulting in a LONG VARCHAR:

```

=> \set s ""cat longfile.txt""
=> SELECT length ('a' || :s ::LONG VARCHAR);
length
-----
65002
(1 row)

```

The following example casts a combination of NUMERIC and INTEGER data into a NUMERIC result:

```

=> SELECT (18. + 3./16)/1024*1000;
?column?
-----
17.76123046875000000000000000000000000000
(1 row)

```

Note
 In SQL expressions, pure numbers between $(-2^{63}-1)$ and $(2^{63}-1)$ are INTEGERS. Numbers with decimal points are NUMERIC.

Data type coercion chart

Conversion types

The following table defines all possible type conversions that Vertica supports. The data types in the first column of the table are the inputs to convert, and the remaining columns indicate the result for the different conversion types.

Source Data Type	Implicit	Explicit	Assignment	Assignment without numeric meaning	Conversion without explicit casting
BOOLEAN			INTEGER, LONG VARCHAR, VARCHAR, CHAR		
INTEGER	BOOLEAN, NUMERIC, FLOAT		INTERVAL DAY/SECOND, INTERVAL YEAR/MONTH	LONG VARCHAR, VARCHAR, CHAR	
NUMERIC	FLOAT		INTEGER	LONG VARCHAR, VARCHAR, CHAR	NUMERIC

FLOAT			INTEGER, NUMERIC	LONG VARCHAR, VARCHAR, CHAR	
LONG VARCHAR	FLOAT, CHAR	BOOLEAN, INTEGER, NUMERIC, VARCHAR, TIMESTAMP, TIMESTAMPTZ, DATE, TIME, TIMETZ, INTERVAL DAY/SECOND, INTERVAL YEAR/MONTH, LONG VARBINARY			LONG VARCHAR
VARCHAR	CHAR, FLOAT, LONG VARCHAR	BOOLEAN, INTEGER, NUMERIC, TIMESTAMP, TIMESTAMPTZ, DATE, TIME, TIMETZ, UUID, BINARY, VARBINARY, INTERVAL DAY/SECOND, INTERVAL YEAR/MONTH			VARCHAR
CHAR	FLOAT, LONG VARCHAR, VARCHAR	BOOLEAN, INTEGER, NUMERIC, TIMESTAMP, TIMESTAMPTZ, DATE, TIME, TIMETZ, UUID (CHAR length \geq 36), BINARY, VARBINARY, INTERVAL DAY/SECOND, INTERVAL YEAR/MONTH			CHAR
TIMESTAMP	TIMESTAMPTZ		LONG CHAR, VARCHAR, CHAR, DATE, TIME		TIMESTAMP
TIMESTAMPTZ	TIMESTAMP		LONG CHAR, VARCHAR, CHAR, DATE, TIME, TIMETZ		TIMESTAMPTZ
DATE	TIMESTAMP		LONG CHAR, VARCHAR, CHAR, TIMESTAMPTZ		
TIME	TIMETZ	TIMESTAMP, TIMESTAMPTZ, INTERVAL DAY/SECOND	LONG CHAR, VARCHAR, CHAR		TIME
TIMETZ		TIMESTAMP, TIMESTAMPTZ	LONG CHAR, VARCHAR, CHAR, TIME		TIMETZ
INTERVAL DAY/SECOND		TIME	INTEGER, LONG CHAR, VARCHAR, CHAR		INTERVAL DAY/SECOND
INTERVAL YEAR/MONTH			INTEGER, LONG CHAR, VARCHAR, CHAR		INTERVAL YEAR/MONTH
LONG VARBINARY		VARBINARY			LONG VARBINARY
VARBINARY	LONG VARBINARY, BINARY				VARBINARY
BINARY	VARBINARY				BINARY

UUID		CHAR(36), VARCHAR			UUID
------	--	-------------------	--	--	------

Implicit and explicit conversion

Vertica supports data type conversion of values without explicit casting, such as `NUMERIC(10,6) -> NUMERIC(18,4)`. Implicit data type conversion occurs automatically when converting values of different, but compatible, types to the target column's data type. For example, when adding values, (`INTEGER + NUMERIC`), the result is implicitly cast to a `NUMERIC` type to accommodate the prominent type in the statement. Depending on the input data types, different precision and scale can occur.

An explicit type conversion must occur when the source data cannot be cast implicitly to the target column's data type.

Assignment conversion

In data assignment conversion, coercion implicitly occurs when values are assigned to database columns in an `INSERT` or `UPDATE...SET` statement. For example, in a statement that includes `INSERT...VALUES('2.5')`, where the target column data type is `NUMERIC(18,5)`, a cast from `VARCHAR` to the column data type is inferred.

In an assignment without numeric meaning, the value is subject to `CHAR/VARCHAR/LONG VARCHAR` comparisons.

- [Data type coercion](#)
- [Data type coercion operators \(CAST\)](#)

Complex types

Complex types such as structures (also known as rows), arrays, and maps are composed of primitive types and sometimes other complex types. Complex types can be used in the following ways:

- Arrays and rows (in any combination) can be used as column data types in both native and external tables.
- Sets of primitive element types can be used as column data types in native and external tables.
- Arrays and rows, but not combinations of them, can be created as literals, for example to use in query expressions.

The `MAP` type is a legacy type. To represent maps, use `ARRAY[ROW]`.

If a flex table has a real column that uses a complex type, the values from that column are not included in the `__raw__` column. For more information, see [Loading Data into Flex Table Real Columns](#).

In this section

- [ARRAY](#)
- [MAP](#)
- [ROW](#)
- [SET](#)

ARRAY

Represents array data. There are two types of arrays in Vertica:

- Native array: a one-dimensional array of a primitive type. Native arrays are tracked in the `TYPES` system table and used in native tables.
- Non-native array: all other supported arrays, including arrays that contain other arrays (multi-dimensional arrays) or structs (`ROW`s). Non-native arrays have some usage restrictions. Non-native arrays are tracked in the `COMPLEX_TYPES` system table.

Both types of arrays operate in the same way, but they have different OIDs.

Arrays can be bounded, meaning they specify a maximum element count, or unbounded. Unbounded arrays have a maximum binary size, which can be set explicitly or defaulted. See [Limits on Element Count and Collection Size](#).

Selected parsers support using `COPY` to load arrays. See the documentation of individual parsers for more information.

Syntax

In [column definitions](#):

```
ARRAY[data_type, max_elements] |
ARRAY[data_type](max_size) |
ARRAY[data_type]
```

In [literals](#):

```
ARRAY[value[, ...]]
```

Restrictions

- Native arrays support only data of primitive types, for example, int, UUID, and so on.
- Array dimensionality is enforced. A column cannot contain arrays of varying dimensions. For example, a column that contains a three-dimensional array can only contain other three-dimensional arrays; it cannot simultaneously include a one-dimensional array. However, the arrays in a column can vary in size, where one array can contain four elements while another contains ten.
- Array bounds, if specified, are enforced for all operations that load or alter data. Unbounded arrays may have as many elements as will fit in the allotted binary size.
- An array has a maximum binary size. If this size is not set when the array is defined, a default value is used.
- Arrays do not support LONG types (like LONG VARBINARY or LONG VARCHAR) or user-defined types (like Geometry).

Syntax for column definition

Arrays used in column definitions can be either bounded or unbounded. Bounded arrays must specify a maximum number of elements. Unbounded arrays can specify a maximum binary size (in bytes) for the array, or the value of [DefaultArrayBinarySize](#) is used. You can specify a bound or a binary size but not both. For more information about these values, see [Limits on Element Count and Collection Size](#).

Type	Syntax	Semantics
Bounded array	<p><i>ARRAY[data_type , max_elements]</i></p> <p>Example:</p> <p><i>ARRAY[VARCHAR(50),100]</i></p>	<p>Can contain no more than <i>max_elements</i> elements. Attempting to add more is an error.</p> <p>Has a binary size of the size of the data type multiplied by the maximum number of elements (possibly rounded up).</p>
Unbounded array with maximum binary size	<p><i>ARRAY[data_type](max_size)</i></p> <p>Example:</p> <p><i>ARRAY[VARCHAR(50)](32000)</i></p>	<p>Can contain as many elements as fit in <i>max_size</i> . Ignores the value of DefaultArrayBinarySize.</p>
Unbounded array with default binary size	<p><i>ARRAY[data_type]</i></p> <p>Example:</p> <p><i>ARRAY[VARCHAR(50)]</i></p>	<p>Can contain as many elements as fit in the default binary size.</p> <p>Equivalent to:</p> <p><i>ARRAY[data_type](DefaultArrayBinarySize)</i></p>

The following example defines a table for customers using an unbounded array:

```
=> CREATE TABLE customers (id INT, name VARCHAR, email ARRAY[VARCHAR(50)]);
```

The following example uses a bounded array for customer email addresses and an unbounded array for order history:

```
=> CREATE TABLE customers (id INT, name VARCHAR, email ARRAY[VARCHAR(50),5], orders ARRAY[INT]);
```

The following example uses an array that has ROW elements:

```
=> CREATE TABLE orders(
  orderid INT,
  accountid INT,
  shipments ARRAY[
    ROW(
      shipid INT,
      address ROW(
        street VARCHAR,
        city VARCHAR,
        zip INT
      ),
      shipdate DATE
    )
  ]
);
```

To declare a multi-dimensional array, use nesting. For example, ARRAY[ARRAY[int]] specifies a two-dimensional array.

Syntax for direct construction (literals)

Use the ARRAY keyword to construct an array value. The following example creates an array of integer values.

```
=> SELECT ARRAY[1,2,3];
array
-----
[1,2,3]
(1 row)
```

You can nest an array inside another array, as in the following example.

```
=> SELECT ARRAY[ARRAY[1],ARRAY[2]];
array
-----
[[1],[2]]
(1 row)
```

If an array of arrays contains no null elements and no function calls, you can abbreviate the syntax:

```
=> SELECT ARRAY[[1,2],[3,4]];
array
-----
[[1,2],[3,4]]
(1 row)
```

---not valid:

```
=> SELECT ARRAY[[1,2],null,[3,4]];
```

ERROR 4856: Syntax error at or near "null" at character 20

```
LINE 1: SELECT ARRAY[[1,2],null,[3,4]];
                ^
```

Array literals can contain elements of all scalar types, ROW, and ARRAY. ROW elements must all have the same set of fields:

```
=> SELECT ARRAY[ROW(1,2),ROW(1,3)];
array
-----
[{"f0":1,"f1":2},{f0":1,"f1":3}]
(1 row)
```

```
=> SELECT ARRAY[ROW(1,2),ROW(1,3,'abc')];
```

ERROR 3429: For 'ARRAY', types ROW(int,int) and ROW(int,int,unknown) are inconsistent

Because the elements are known at the time you directly construct an array, these arrays are implicitly bounded.

You can use ARRAY literals in comparisons, as in the following example:

```
=> SELECT id.name, id.num, GPA FROM students
  WHERE major = ARRAY[ROW('Science','Physics')];
name | num | GPA
-----+-----
bob  | 121 | 3.3
carol | 123 | 3.4
(2 rows)
```

Output format

Queries of array columns return JSON format, with the values shown in comma-separated lists in brackets. The following example shows a query that includes array columns.

```
=> SELECT cust_custkey,cust_custstaddress,cust_custcity,cust_custstate from cust;
cust_custkey | cust_custstaddress | cust_custcity | cust_custstate
-----+-----
342176 | ["668 SW New Lane","518 Main Ave","7040 Campfire Dr"] | ["Winchester","New Hyde Park","Massapequa"] | ["VA","NY","NY"]
342799 | ["2400 Hearst Avenue","3 Cypress Street"] | ["Berkeley","San Antonio"] | ["CA","TX"]
342845 | ["336 Boylston Street","180 Clarkhill Rd"] | ["Boston","Amherst"] | ["MA","MA"]
342321 | ["95 Fawn Drive"] | ["Allen Park"] | ["MI"]
342989 | ["5 Thompson St"] | ["Massillon"] | ["OH"]
(5 rows)
```

Note that JSON format escapes some characters that would not be escaped in native VARCHARs. For example, if you insert `"c:\users\data"` into an array, the JSON output for that value is `"c:\\users\\data"`.

Element access

Arrays are 0-indexed. The first element's ordinal position is 0, second is 1, and so on.

You can access (dereference) elements from an array by index:

```
=> SELECT (ARRAY['a','b','c','d','e'])[1];
array
-----
b
(1 row)
```

To specify a range, use the format `start: end`. The end of the range is non-inclusive.

```
=> SELECT(ARRAY['a','b','c','d','e','f','g'])[1:4];
array
-----
["b","c","d"]
(1 row)
```

To dereference an element from a multi-dimensional array, put each index in brackets:

```
=> SELECT(ARRAY[ARRAY[1,2],ARRAY[3,4]])[0][0];
array
-----
1
(1 row)
```

Out-of-bound index references return NULL.

Limits on element count and collection size

When declaring a collection type for a table column, you can limit either the number of elements or the total binary size of the collection. During query processing, Vertica always reserves the maximum memory needed for the column, based on either the element count or the binary size. If this size is much larger than your data actually requires, setting one of these limits can improve query performance by reducing the amount of memory that must be reserved for the column.

You can change the bounds of a collection, including changing between bounded and unbounded collections, by casting. See [Casting](#).

A bounded collection specifies a maximum element count. A value in a bounded collection column may contain fewer elements, but it may not contain more. Any attempt to insert more elements into a bounded collection than the declared maximum is an error. A bounded collection has a binary size that is the product of the data-type size and the maximum number of elements, possibly rounded up.

An unbounded collection specifies a binary size in bytes, explicitly or implicitly. It may contain as many elements as can fit in that binary size.

If a nested array specifies bounds for all dimensions, Vertica sets a single bound that is the product of the bounds. In the following example, the inner and outer arrays each have a bound of 10, but only a total element count of 100 is enforced.

```
ARRAY[ARRAY[INT,10],10]
```

If a nested array specifies a bound for only the outer collection, it is treated as the total bound. The previous example is equivalent to the following:

```
ARRAY[ARRAY[INT],100]
```

You must either specify bounds for all nested collections or specify a bound only for the outer one. For any other distribution of bounds, Vertica treats the collection as unbounded.

Instead of specifying a bound, you can specify a maximum binary size for an unbounded collection. The binary size acts as an absolute limit, regardless of how many elements the collection contains. Collections that do not specify a maximum binary size use the value of [DefaultArrayBinarySize](#). This size is set at the time the collection is defined and is not affected by later changes to the value of `DefaultArrayBinarySize`.

You cannot set a maximum binary size for a bounded collection, only an unbounded one.

You can change the bounds or the binary size of an array column using [ALTER TABLE](#) as in the following example:

```
=> ALTER TABLE cust ALTER COLUMN orders SET DATA TYPE ARRAY[INTEGER](100);
```

If the change reduces the size of the collection and would result in data loss, the change fails.

Comparisons

All collections support equality (=), inequality (<>), and null-safe equality (<=>). 1D collections also support comparison operators (< , <= , > , >=) between collections of the same type (arrays or sets). Comparisons follow these rules:

- A null collection is ordered last.
- Non-null collections are compared element by element, using the ordering rules of the element's data type. The relative order of the first pair of non-equal elements determines the order of the two collections.
- If all elements in both collections are equal up to the length of the shorter collection, the shorter collection is ordered before the longer one.
- If all elements in both collections are equal and the collections are of equal length, the collections are equal.

Null-handling

Null semantics for collections are consistent with normal columns in most regards. See [NULL sort order](#) for more information on null-handling.

The null-safe equality operator (<=>) behaves differently from equality (=) when the collection is null rather than empty. Comparing a collection to NULL strictly returns null:

```
=> SELECT ARRAY[1,3] = NULL;
```

```
?column?
```

```
-----
```

```
(1 row)
```

```
=> SELECT ARRAY[1,3] <=> NULL;
```

```
?column?
```

```
-----
```

```
f  
(1 row)
```

In the following example, the grants column in the table is null for employee 99:

```
=> SELECT grants = NULL FROM employees WHERE id=99;
?column?
```

```
-----
(1 row)
```

```
=> SELECT grants <=> NULL FROM employees WHERE id=99;
?column?
```

```
-----
t
(1 row)
```

Empty collections are not null and behave as expected:

```
=> SELECT ARRAY[]::ARRAY[INT] = ARRAY[]::ARRAY[INT];
?column?
```

```
-----
t
(1 row)
```

Collections are compared element by element. If a comparison depends on a null element, the result is unknown (null), not false. For example, `ARRAY[1,2,null]=ARRAY[1,2,null]` and `ARRAY[1,2,null]=ARRAY[1,2,3]` both return null, but `ARRAY[1,2,null]=ARRAY[1,4,null]` returns false because the second elements do not match.

Casting

Casting an array casts each element of the array. You can therefore cast between data types following the same rules as for casts of scalar values.

You can cast both literal arrays and array columns explicitly:

```
=> SELECT ARRAY['1','2','3']::ARRAY[INT];
array
```

```
-----
[1,2,3]
(1 row)
```

You can change the bound of an array or set by casting. When casting to a bounded native array, inputs that are too long are truncated. When casting to a non-native array (an array containing complex data types including other arrays), if the new bounds are too small for the data the cast fails:

```
=> SELECT ARRAY[1,2,3]::ARRAY[VARCHAR,2];
array
```

```
-----
["1","2"]
(1 row)
```

```
=> SELECT ARRAY[ARRAY[1,2,3],ARRAY[4,5,6]]::ARRAY[ARRAY[VARCHAR,2],2];
```

ERROR 9227: Output array isn't big enough

DETAIL: Type limit is 4 elements, but value has 6 elements

If you cast to a bounded multi-dimensional array, you must specify the bounds at all levels:

```
=> SELECT ARRAY[ARRAY[1,2,3],ARRAY[4,5,6]]::ARRAY[ARRAY[VARCHAR,5],10];
array
```

```
-----
[["1","2","3"],["4","5","6"]]
(1 row)
```

```
=> SELECT ARRAY[ARRAY[1,2,3],ARRAY[4,5,6]]::ARRAY[ARRAY[VARCHAR,2]];
```

WARNING 9753: Collection type bound will not be used

DETAIL: A bound was provided for an inner dimension, but not for an outer dimension

```
array
-----
[["1","2","3"],["4","5","6"]]
(1 row)
```

Assignment casts and implicit casts work the same way as for scalars:

```
=> CREATE TABLE transactions (tid INT, prod_ids ARRAY[VARCHAR,100], quantities ARRAY[INT,100]);
CREATE TABLE

=> INSERT INTO transactions VALUES (12345, ARRAY['p1265', 'p4515'], ARRAY[15,2]);
OUTPUT
-----
  1
(1 row)

=> CREATE TABLE txreport (prod_ids ARRAY[VARCHAR(12),100], quants ARRAY[VARCHAR(32),100]);
CREATE TABLE

=> INSERT INTO txreport SELECT prod_ids, quantities FROM transactions;
OUTPUT
-----
  1
(1 row)

=> SELECT * FROM txreport;
  prod_ids  | quants
-----+-----
["p1265","p4515"] | ["15","2"]
(1 row)
```

You can perform explicit casts, but not implicit casts, between the ARRAY and [SET](#) types (native arrays only). If the collection is unbounded and the data type does not change, the binary size is preserved. For example, if you cast an ARRAY[INT] to a SET[INT], the set has the same binary size as the array.

If you cast from one element type to another, the resulting collection uses the default binary size. If this would cause the data not to fit, the cast fails.

You cannot cast from an array to an array with a different dimensionality, for example from a two-dimensional array to a one-dimensional array.

Functions and operators

See [Collection functions](#) for a comprehensive list of functions that can be used to manipulate arrays and sets.

Collections can be used in the following ways:

- As the grouping column in a [GROUP BY clause](#).
- For native arrays only, as the sort key in an [ORDER BY clause](#) in a query, in an OVER clause (see [Window partitioning](#)), or in a [CREATE PROJECTION](#) statement.
- As the sort key in the PARTITION BY part of an OVER clause.
- As a JOIN key (see [Joined-table](#)).
- In [CASE expressions](#).

Collections cannot be used in the following ways:

- As part of an IN or NOT IN expression.
- As partition columns when creating tables.
- With ANALYZE_STATISTICS or TopK projections.
- Non-native arrays only: ORDER BY, PARTITION BY, DEFAULT, SET USING, or constraints.

MAP

Represents map data in external tables in the Parquet, ORC, and Avro formats only. A MAP must use only primitive types and may not contain other complex types. You can use the MAP type in a table definition to consume columns in the data, but you cannot query those columns.

A superior alternative to MAP is [ARRAY \[ROW \]](#). An array of rows can use all supported complex types and can be queried. This is the representation that [INFER_TABLE_DDL](#) suggests. For Avro data, the ROW must have fields named **key** and **value**.

Within a single table you must define all map columns using the same approach, MAP or ARRAY[ROW].

Syntax

In column definitions:

```
MAP<key,value>
```

Map input format for column definition

In a column definition in an external table, a MAP consists of a key-value pair, specified as types. The table in the following example defines a map of product IDs to names.

```
=> CREATE EXTERNAL TABLE store (storeID INT, inventory MAP<INT,VARCHAR(100)>)
AS COPY FROM '...' PARQUET;
```

ROW

Represents structured data (structs). A ROW can contain fields of any primitive or complex type supported by Vertica.

Syntax

In [column definitions](#):

```
ROW([field] type[, ...])
```

If the field name is omitted, Vertica generates names starting with "f0".

In [literals](#):

```
ROW(value [AS field] [, ...]) [AS name(field[, ...])]
```

Syntax for column definition

In a column definition, a ROW consists of one or more comma-separated pairs of field names and types. In the following example, the Parquet data file contains a struct for the address, which is read as a ROW in an external table:

```
=> CREATE EXTERNAL TABLE customers (name VARCHAR,
address ROW(street VARCHAR, city VARCHAR, zipcode INT))
AS COPY FROM '...' PARQUET;
```

ROWS can be nested; a field can have a type of ROW:

```
=> CREATE TABLE employees(
employeeID INT,
personal ROW(
name VARCHAR,
address ROW(street VARCHAR, city VARCHAR, zipcode INT),
taxID INT),
department VARCHAR);
```

ROWS can contain arrays:

```
=> CREATE TABLE customers(
name VARCHAR,
contact ROW(
street VARCHAR,
city VARCHAR,
zipcode INT,
email ARRAY[VARCHAR]
),
accountid INT );
```

When loading data, the primitive types in the table definition must match those in the data. The ROW structure must also match; a ROW must contain all and only the fields in the struct in the data.

Restrictions on ROW columns

ROW columns have several restrictions:

- Maximum nesting depth is 100.
- Vertica tables support up to 9800 columns and fields. The ROW itself is not counted, only its fields.
- ROW columns cannot use any constraints (such as NOT NULL) or defaults.
- ROW fields cannot be auto_increment or setof.

- ROW definition must include at least one field.
- **Row** is a reserved keyword within a ROW definition, but is permitted as the name of a table or column.
- Tables containing ROW columns cannot also contain IDENTITY, default, SET USING, or named sequence columns.

Syntax for direct construction (literals)

In a literal, such as a value in a comparison operation, a ROW consists of one or more values. If you omit field names in the ROW expression, Vertica generates them automatically. If you do not coerce types, Vertica infers the types from the data values.

```
=> SELECT ROW('Amy',2,false);
      row
-----
{"f0":"Amy","f1":2,"f2":false}
(1 row)
```

You can use an AS clause to name the ROW and its fields:

```
=> SELECT ROW('Amy',2,false) AS student(name, id, current);
      student
-----
{"name":"Amy","id":2,"current":false}
(1 row)
```

You can also name individual fields using AS. This query produces the same output as the previous one:

```
=> SELECT ROW('Amy' AS name, 2 AS id, false AS current) AS student;
```

You do not need to name all fields.

In an array of ROW elements, if you use AS to name fields and the names differ among the elements, Vertica uses the right-most names for all elements:

```
=> SELECT ARRAY[ROW('Amy' AS name, 2 AS id),ROW('Fred' AS first_name, 4 AS id)];
      array
-----
[{"first_name":"Amy","id":2},{first_name:"Fred","id":4}]
(1 row)
```

You can coerce types explicitly:

```
=> SELECT ROW('Amy',2.5::int,false::varchar);
      row
-----
{"f0":"Amy","f1":3,"f2":"f"}
(1 row)
```

Escape single quotes in literal inputs using single quotes, as in the following example:

```
=> SELECT ROW('Howard's house',2,false);
      row
-----
{"f0":"Howard's house","f1":2,"f2":false}
(1 row)
```

You can use fields of all scalar types, ROW, and ARRAY, as in the following example:

```
=> SELECT id.name, major, GPA FROM students
WHERE id = ROW('alice',119, ARRAY['alice@example.com','ap16@cs.example.edu']);
name |      major      | GPA
-----+-----+-----
alice | [{"school":"Science","dept":"CS"}] | 3.8
(1 row)
```

Output format

ROW values are output in JSON format as in the following example.

```
=> CREATE EXTERNAL TABLE customers (name VARCHAR,
  address ROW(street VARCHAR, city VARCHAR, zipcode INT))
  AS COPY FROM '...' PARQUET;

=> SELECT address FROM customers WHERE address.city ='Pasadena';
      address
-----
{"street":"100 Main St Apt 4B","city":"Pasadena","zipcode":91001}
{"street":"100 Main St Apt 4A","city":"Pasadena","zipcode":91001}
{"street":"23 Fifth Ave Apt 8C","city":"Pasadena","zipcode":91001}
{"street":"15 Raymond Dr","city":"Pasadena","zipcode":91003}
(4 rows)
```

The following table specifies the mappings from Vertica data types to JSON data types.

Vertica Type	JSON Type
Integer	Integer
Float	Numeric
Numeric	Numeric
Boolean	Boolean
All others	String

Comparisons

ROW supports equality (=), inequality (<>), and null-safe equality (<=>) between inputs that have the same set of fields. ROWs that contain only primitive types, including nested ROWs of primitive types, also support comparison operators (< , <= , > , >=).

Two ROWs are equal if and only if all fields are equal. Vertica compares fields in order until an inequality is found or all fields have been compared. The evaluation of the first non-equal field determines which ROW is greater:

```
=> SELECT ROW(1, 'joe') > ROW(2, 'bob');
?column?
-----
f
(1 row)
```

Comparisons between ROWs with different schemas fail:

```
=> SELECT ROW(1, 'joe') > ROW(2, 'bob', 123);
ERROR 5162: Unequal number of entries in row expressions
```

If the result of a comparison depends on a null field, the result is null:

```
=> select row(1, null, 3) = row(1, 2, 3);
?column?
-----
(1 row)
```

Null-handling

If a struct exists but a field value is null, Vertica assigns NULL as its value in the ROW. A struct where all fields are null is treated as a ROW with null fields. If the struct itself is null, Vertica reads the ROW as NULL.

Casting

Casting a ROW casts each field. You can therefore cast between data types following the same rules as for casts of scalar values.

The following example casts the `contact` ROW in the `customers` table, changing the `zipcode` field from INT to VARCHAR and adding a bound to the array:

```
=> SELECT contact::ROW(VARCHAR,VARCHAR,VARCHAR,ARRAY[VARCHAR,20]) FROM customers;
```

contact

```
-----  
-----  
{ "street": "911 San Marcos St", "city": "Austin", "zipcode": "73344", "email": ["missy@mit.edu", "mcooper@cern.gov"] }  
{ "street": "100 Main St Apt 4B", "city": "Pasadena", "zipcode": "91001", "email": ["shelly@meemaw.name", "cooper@caltech.edu"] }  
{ "street": "100 Main St Apt 4A", "city": "Pasadena", "zipcode": "91001", "email": ["hofstadter@caltech.edu"] }  
{ "street": "23 Fifth Ave Apt 8C", "city": "Pasadena", "zipcode": "91001", "email": [] }  
{ "street": null, "city": "Pasadena", "zipcode": "91001", "email": ["raj@available.com"] }
```

(6 rows)

You can specify new field names to change them in the output:

```
=> SELECT contact::ROW(str VARCHAR, city VARCHAR, zip VARCHAR, email ARRAY[VARCHAR,  
20]) FROM customers;
```

contact

```
-----  
-----  
{ "str": "911 San Marcos St", "city": "Austin", "zip": "73344", "email": ["missy@mit.edu", "mcooper@cern.gov"] }  
{ "str": "100 Main St Apt 4B", "city": "Pasadena", "zip": "91001", "email": ["shelly@meemaw.name", "cooper@caltech.edu"] }  
{ "str": "100 Main St Apt 4A", "city": "Pasadena", "zip": "91001", "email": ["hofstadter@caltech.edu"] }  
{ "str": "23 Fifth Ave Apt 8C", "city": "Pasadena", "zip": "91001", "email": [] }  
{ "str": null, "city": "Pasadena", "zip": "91001", "email": ["raj@available.com"] }
```

(6 rows)

Supported operators and predicates

ROW values may be used in queries in the following ways:

- INNER and OUTER JOIN
- [Comparisons](#), IN, BETWEEN (non-nullable filters only)
- IS NULL, IS NOT NULL
- CASE
- GROUP BY, ORDER BY
- SELECT DISTINCT
- Arguments to user-defined scalar, transform, and analytic functions

The following operators and predicates are not supported for ROW values:

- Math operators
- Type coercion of whole rows (coercion of field values is supported)
- BITWISE, LIKE
- MLA (ROLLUP, CUBE, GROUPING SETS)
- Aggregate functions including MAX, MIN, and SUM
- Set operators including UNION, UNION ALL, MINUS, and INTERSECT

COUNT is not supported for ROWs returned from user-defined scalar functions, but is supported for ROW columns and literals.

In comparison operations (including implicit comparisons like ORDER BY), a ROW literal is treated as the sequence of its field values. For example, the following two statements are equivalent:

```
GROUP BY ROW(zipcode, city)  
GROUP BY zipcode, city
```

Using rows in views and subqueries

You can use ROW columns to construct views and in subqueries. Consider employee and customer tables with the following definitions:

```
=> CREATE EXTERNAL TABLE customers(name VARCHAR,
  address ROW(street VARCHAR, city VARCHAR, zipcode INT), accountID INT)
  AS COPY FROM '...' PARQUET;
```

```
=> CREATE EXTERNAL TABLE employees(employeeID INT,
  personal ROW(name VARCHAR,
  address ROW(street VARCHAR, city VARCHAR, zipcode INT),
  taxID INT), department VARCHAR)
  AS COPY FROM '...' PARQUET;
```

The following example creates a view and queries it.

```
=> CREATE VIEW neighbors (num_neighbors, area(city, zipcode))
  AS SELECT count(*), ROW(address.city, address.zipcode)
  FROM customers GROUP BY address.city, address.zipcode;
CREATE VIEW
=> SELECT employees.personal.name, neighbors.area FROM neighbors, employees
  WHERE employees.personal.address.zipcode=neighbors.area.zipcode AND neighbors.num_neighbors > 1;
  name      |          area
  -----+-----
Sheldon Cooper | {"city":"Pasadena","zipcode":91001}
Leonard Hofstadter | {"city":"Pasadena","zipcode":91001}
(2 rows)
```

SET

Represents a collection of unordered, unique elements. Sets may contain only primitive types. In sets, unlike in arrays, element position is not meaningful.

Sets do not support LONG types (like LONG VARBINARY or LONG VARCHAR) or user-defined types (like Geometry).

If you populate a set from an array, Vertica sorts the values and removes duplicate elements. If you do not care about element position and plan to run queries that check for the presence of specific elements (find, contains), using a set could improve query performance.

Sets can be bounded, meaning they specify a maximum element count, or unbounded. Unbounded sets have a maximum binary size, which can be set explicitly or defaulted. See [Limits on Element Count and Collection Size](#).

Syntax

In [column definitions](#) :

```
SET[data_type, max_elements] |
SET[data_type](max_size) |
SET[data_type]
```

In [literals](#) :

```
SET[value[, ...] ]
```

Restrictions

- Sets support only data of primitive (scalar) types.
- Bounds, if specified, are enforced for all operations that load or alter data. Unbounded sets may have as many elements as will fit in the allotted binary size.
- A set has a maximum binary size. If this size is not set when the set is defined, a default value is used.

Syntax for column definition

Sets used in column definitions can be either bounded or unbounded. Bounded sets must specify a maximum number of elements. Unbounded sets can specify a maximum binary size for the set, or the value of [DefaultArrayBinarySize](#) is used. You can specify a bound or a binary size but not both. For more information about these values, see [Limits on Element Count and Collection Size](#).

Type	Syntax	Semantics
------	--------	-----------

Bounded set	<p><code>SET[<i>data_type</i> , <i>max_elements</i>]</code></p> <p>Example:</p> <p><code>SET[VARCHAR(50),100]</code></p>	<p>Can contain no more than <i>max_elements</i> elements. Attempting to add more is an error.</p> <p>Has a binary size of the size of the data type multiplied by the maximum number of elements (possibly rounded up).</p>
Unbounded set with maximum size	<p><code>SET[<i>data_type</i>](<i>max_size</i>)</code></p> <p>Example:</p> <p><code>SET[VARCHAR(50)](32000)</code></p>	<p>Can contain as many elements as fit in <i>max_size</i> . Ignores the value of <code>DefaultArrayBinarySize</code>.</p>
Unbounded set	<p><code>SET[<i>data_type</i>]</code></p> <p>Example:</p> <p><code>SET[VARCHAR(50)]</code></p>	<p>Can contain as many elements as fit in the default binary size.</p> <p>Equivalent to:</p> <p><code>SET[<i>data_type</i>](DefaultArrayBinarySize)</code></p>

The following example defines a table with an unbounded set column.

```
=> CREATE TABLE users
(
  user_id INTEGER,
  display_name VARCHAR,
  email_addrs SET[VARCHAR]
);
```

When you load array data into a column defined as a set, the array data is automatically converted to a set.

Syntax for direct construction (literals)

Use the SET keyword to construct a set value. Literal set values are contained in brackets. For example, to create a set of INT, you would do the following:

```
=> SELECT SET[1,2,3];
  set
-----
[1,2,3]
(1 row)
```

You can explicitly convert an array to a set by casting, as in the following example:

```
=> SELECT ARRAY[1, 5, 2, 6, 3, 0, 6, 4]::SET[INT];
  set
-----
[0,1,2,3,4,5,6]
(1 row)
```

Notice that duplicate elements have been removed and the elements have been sorted.

Because the elements are known at the time you directly construct a set, these sets are implicitly bounded.

Output format

Sets are shown in a JSON-like format, with comma-separated elements contained in brackets (like arrays). In the following example, the email_addrs column is a set.

```
=> SELECT custkey,email_addrs FROM customers LIMIT 4;
custkey |          email_addrs
-----+-----
342176  | ["joe.smith@example.com"]
342799  | ["bob@example.com","robert.jones@example.com"]
342845  | ["br92@cs.example.edu"]
342321  | ["789123@example-isp.com","sjohnson@eng.example.com","sara@johnson.example.name"]
```

Limits on element count and collection size

When declaring a collection type for a table column, you can limit either the number of elements or the total binary size of the collection. During query processing, Vertica always reserves the maximum memory needed for the column, based on either the element count or the binary size. If this size is much larger than your data actually requires, setting one of these limits can improve query performance by reducing the amount of memory that must be reserved for the column.

You can change the bounds of a collection, including changing between bounded and unbounded collections, by casting. See [Casting](#).

A bounded collection specifies a maximum element count. A value in a bounded collection column may contain fewer elements, but it may not contain more. Any attempt to insert more elements into a bounded collection than the declared maximum is an error. A bounded collection has a binary size that is the product of the data-type size and the maximum number of elements, possibly rounded up.

An unbounded collection specifies a binary size in bytes, explicitly or implicitly. It may contain as many elements as can fit in that binary size.

Instead of specifying a bound, you can specify a maximum binary size for an unbounded collection. The binary size acts as an absolute limit, regardless of how many elements the collection contains. Collections that do not specify a maximum binary size use the value of [DefaultArrayBinarySize](#). This size is set at the time the collection is defined and is not affected by later changes to the value of `DefaultArrayBinarySize`.

You cannot set a maximum binary size for a bounded collection, only an unbounded one.

Comparisons

All collections support equality (=), inequality (<>), and null-safe equality (<=>). 1D collections also support comparison operators (< , <= , > , >=) between collections of the same type (arrays or sets). Comparisons follow these rules:

- A null collection is ordered last.
- Non-null collections are compared element by element, using the ordering rules of the element's data type. The relative order of the first pair of non-equal elements determines the order of the two collections.
- If all elements in both collections are equal up to the length of the shorter collection, the shorter collection is ordered before the longer one.
- If all elements in both collections are equal and the collections are of equal length, the collections are equal.

Null handling

Null semantics for collections are consistent with normal columns in most regards. See [NULL sort order](#) for more information on null-handling.

The null-safe equality operator (<=>) behaves differently from equality (=) when the collection is null rather than empty. Comparing a collection to NULL strictly returns null:

```
=> SELECT ARRAY[1,3] = NULL;
?column?
-----
(1 row)

=> SELECT ARRAY[1,3] <=> NULL;
?column?
-----
f
(1 row)
```

In the following example, the grants column in the table is null for employee 99:

```
=> SELECT grants = NULL FROM employees WHERE id=99;
?column?
```

```
-----
(1 row)
```

```
=> SELECT grants <=> NULL FROM employees WHERE id=99;
?column?
```

```
-----
t
(1 row)
```

Empty collections are not null and behave as expected:

```
=> SELECT ARRAY[]::ARRAY[INT] = ARRAY[]::ARRAY[INT];
?column?
```

```
-----
t
(1 row)
```

Collections are compared element by element. If a comparison depends on a null element, the result is unknown (null), not false. For example, `ARRAY[1,2,null]=ARRAY[1,2,null]` and `ARRAY[1,2,null]=ARRAY[1,2,3]` both return null, but `ARRAY[1,2,null]=ARRAY[1,4,null]` returns false because the second elements do not match.

Casting

Casting a set casts each element of the set. You can therefore cast between data types following the same rules as for casts of scalar values.

You can cast both literal sets and set columns explicitly:

```
=> SELECT SET['1','2','3']::SET[INT];
set
```

```
-----
[1,2,3]
(1 row)
```

```
=> CREATE TABLE transactions (tid INT, prod_ids SET[VARCHAR], quantities SET[VARCHAR(32)]);
```

```
=> INSERT INTO transactions VALUES (12345, SET['p1265', 'p4515'], SET['15','2']);
```

```
=> SELECT quantities :: SET[INT] FROM transactions;
quantities
```

```
-----
[15,2]
(1 row)
```

Assignment casts and implicit casts work the same way as for scalars.

You can perform explicit casts, but not implicit casts, between [ARRAY](#) and SET types. If the collection is unbounded and the data type does not change, the binary size is preserved. For example, if you cast an `ARRAY[INT]` to a `SET[INT]`, the set has the same binary size as the array.

When casting an array to a set, Vertica first casts each element and then sorts the set and removes duplicates. If two source values are cast to the same target value, one of them will be removed. For example, if you cast an array of `FLOAT` to a set of `INT`, two values in the array might be rounded to the same integer and then be treated as duplicates. This also happens if the array contains more than one value that is cast to `NULL`.

If you cast from one element type to another, the resulting collection uses the default binary size. If this would cause the data not to fit, the cast fails.

Functions and operators

See [Collection functions](#) for a comprehensive list of functions that can be used to manipulate arrays and sets.

Collections can be used in the following ways:

- As the grouping column in a [GROUP BY clause](#).
- For native arrays only, as the sort key in an [ORDER BY clause](#) in a query, in an `OVER` clause (see [Window partitioning](#)), or in a [CREATE PROJECTION](#) statement.

- As the sort key in the PARTITION BY part of an OVER clause.
- As a JOIN key (see [Joined-table](#)).
- In [CASE expressions](#).

Collections cannot be used in the following ways:

- As part of an IN or NOT IN expression.
- As partition columns when creating tables.
- With ANALYZE_STATISTICS or TopK projections.
- Non-native arrays only: ORDER BY, PARTITION BY, DEFAULT, SET USING, or constraints.

Data type mappings between Vertica and Oracle

Oracle uses proprietary data types for all main data types, such as VARCHAR, INTEGER, FLOAT, DATE. Before migrating a database from Oracle to Vertica, first convert the schema to minimize errors and time spent fixing erroneous data issues.

The following table compares the behavior of Oracle data types to Vertica data types.

Oracle	Vertica	Notes
NUMBER (no explicit precision)	INTEGER	<p>In Oracle, the NUMBER data type with no explicit precision stores each number N as an integer M, together with a scale S. The scale can range from -84 to 127, while the precision of M is limited to 38 digits. Thus:</p> $N = M * 10^S$ <p>When precision is specified, precision/scale applies to all entries in the column. If omitted, the scale defaults to 0.</p> <p>For the common case—Oracle NUMBER with no explicit precision used to store only integer values—the Vertica INTEGER data type is the most appropriate and the fastest equivalent data type. However, INTEGER is limited to a little less than 19 digits, with a scale of 0: [-9223372036854775807, +9223372036854775807].</p>
	NUMERIC	<p>If an Oracle column contains integer values outside of the range [-9223372036854775807, +9223372036854775807], then use the Vertica data type NUMERIC(p,0) where p is the maximum number of digits required to represent values of the source data.</p> <p>If the data is exact with fractional places—for example dollar amounts—Vertica recommends NUMERIC(p, s) where p is the precision (total number of digits) and s is the maximum scale (number of decimal places).</p> <p>Vertica conforms to standard SQL, which requires that $p \geq s$ and $s \geq 0$. Vertica's NUMERIC data type is most effective for $p=18$, and increasingly expensive for $p=37, 58, 67$, etc., where $p \leq 1024$.</p> <div style="background-color: #f0f0f0; padding: 10px; border: 1px solid #ccc;"> <p>Tip Vertica recommends against using the data type NUMERIC(38, s) as a default "failsafe" mapping to guarantee no loss of precision. NUMERIC(18, s) is better, and INTEGER or FLOAT better yet, if one of these data types will do the job.</p> </div>
	FLOAT	<p>Even though no explicit scale is specified for an Oracle NUMBER column, Oracle allows non-integer values, each with its own scale. If the data stored in the column is approximate, Vertica recommends using the Vertica data type FLOAT, which is standard IEEE floating point, like ORACLE BINARY_DOUBLE.</p>
NUMBER(P ,0) $P \leq 18$	INTEGER	For Oracle NUMBER data types with 0 scale and a precision less than or equal to 18, use the Vertica INTEGER data type.
NUMBER(P ,0) $P > 18$	NUMERIC (p ,0)	In the rare case where a Oracle column specifies precision greater than 18, use the Vertica data type NUMERIC(p , 0), where $p = P$.

NUMBER(<i>P</i> , <i>S</i>) All cases other than above	NUMERIC (<i>p</i> , <i>s</i>) FLOAT	<ul style="list-style-type: none"> When $P \geq S$ and $S \geq 0$, use $p = P$ and $s = S$, unless the data allows reducing P or using FLOAT as discussed above. If $S > P$, use $p = S$, $s = S$. If $S < 0$, use $p = P - S$, $s = 0$.
NUMERIC(<i>P</i> , <i>S</i>)		Rarely used in Oracle, see notes for Oracle NUMBER .
DECIMAL(<i>P</i> , <i>S</i>)		Synonym for Oracle NUMERIC.
BINARY_FLOAT	FLOAT	Same as FLOAT(53) or DOUBLE PRECISION
BINARY_DOUBLE	FLOAT	Same as FLOAT(53) or DOUBLE PRECISION
RAW	VARBINARY	Maximum sizes compared: <ul style="list-style-type: none"> Oracle RAW data type: 2000 bytes Vertica VARBINARY: 65000 bytes
LONG RAW	LONG VARBINARY	Maximum sizes compared: <ul style="list-style-type: none"> Oracle's LONG RAW is 2GB Vertica LONG VARBINARY is 32M bytes/octetes (~30MB) <div style="background-color: #ffe6e6; padding: 10px; margin-top: 10px;"> <p>Caution Be careful to avoid truncation when migrating Oracle LONG RAW data to Vertica.</p> </div>
CHAR(<i>n</i>)	CHAR (<i>n</i>)	Maximum sizes compared: <ul style="list-style-type: none"> Oracle CHAR: 2000 bytes Vertica CHAR : 65000 bytes
NCHAR(<i>n</i>)	CHAR (<i>n**3</i>)	Vertica supports national characters with CHAR(<i>n</i>) as variable-length UTF8-encoded UNICODE character string. UTF-8 represents ASCII in 1 byte, most European characters in 2 bytes, and most oriental and Middle Eastern characters in 3 bytes.
VARCHAR2(<i>n</i>)	VARCHAR (<i>n</i>)	Maximum sizes compared: <ul style="list-style-type: none"> Oracle VARCHAR2: 4000 bytes Vertica VARCHAR: 65000 bytes <p>Important The Oracle VARCHAR2 and Vertica VARCHAR data types are semantically different:</p> <ul style="list-style-type: none"> VARCHAR exhibits standard SQL behavior VARCHAR2 is inconsistent with standard SQL behavior in that it treats an empty string as NULL value, and uses non-padded comparison if one operand is VARCHAR2.
NVARCHAR2(<i>n</i>)	VARCHAR (<i>n**3</i>)	See notes for NCHAR .
DATE	TIMESTAMP DATE	Oracle's DATE is different from the SQL standard DATE data type implemented by Vertica. Oracle's DATE includes the time (no fractional seconds), while Vertica DATE data types include only date as per the SQL standard.

TIMESTAMP	TIMESTAMP	TIMESTAMP defaults to six places—that is, to microseconds.
TIMESTAMP WITH TIME ZONE	TIMESTAMP WITH TIME ZONE	TIME ZONE defaults to the currently SET or system time zone.
INTERVAL YEAR TO MONTH	INTERVAL YEAR TO MONTH	As per the SQL standard, you can qualify Vertica INTERVAL data types with the YEAR TO MONTH subtype.
INTERVAL DAY TO SECOND	INTERVAL DAY TO SECOND	The default subtype for Vertica INTERVAL data types is DAY TO SECOND.
CLOB	LONG VARCHAR	You can store a CLOB (character large object) or BLOB (binary large object) value in a table or in an external location. The maximum size of a CLOB or BLOB is 128 TB.
BLOB	LONG VARBINARY	You can store Vertica LONG data types only in LONG VARCHAR and LONG VARBINARY columns. The maximum size of LONG data types is 32M bytes.
LONG	LONG VARCHAR	Oracle recommends using CLOB and BLOB data types instead of LONG and LONG RAW data types.
LONG RAW	LONG VARBINARY	An Oracle table can contain only one LONG column, The maximum size of a LONG or LONG RAW data type is 2 GB.

Configuration parameters

Vertica supports a wide variety of configuration parameters that affect many facets of database behavior. These parameters can be set with the appropriate ALTER statements at one or more levels, listed here in descending order of precedence:

1. User ([ALTER USER](#))
2. Session ([ALTER SESSION](#))
3. Node ([ALTER NODE](#))
4. Database ([ALTER DATABASE](#))

Not all parameters can be set at all levels. Consult the documentation of individual parameters for restrictions.

You can query the [CONFIGURATION_PARAMETERS](#) system table to obtain the current settings for all user-accessible parameters. For example, the following query returns settings for partitioning parameters: their current and default values, which levels they can be set at, and whether changes require a database restart to take effect:

```

=> SELECT parameter_name, current_value, default_value, allowed_levels, change_requires_restart
   FROM configuration_parameters WHERE parameter_name ILIKE '%partitioncount%';
parameter_name | current_value | default_value | allowed_levels | change_requires_restart
-----
MaxPartitionCount | 1024         | 1024         | NODE, DATABASE | f
ActivePartitionCount | 1           | 1           | NODE, DATABASE | f
(2 rows)

```

General parameters

The following parameters configure basic database operations. Query the [CONFIGURATION_PARAMETERS](#) system table to determine what levels (node, session, user, database) are valid for a given parameter.

ApplyEventsDuringSALCheck

Boolean, specifies whether Vertica uses catalog events to filter out dropped corrupt partitions during node startup. Dropping corrupt partitions can speed node recovery.

When disabled (0), Vertica reports corrupt partitions, but takes no action. Leaving corrupt partitions in place can reset the current projection checkpoint epoch to the epoch before the corruption occurred.

This parameter has no effect on unpartitioned tables.

Default: 0

ApportionedFileMinimumPortionSizeKB

Specifies the minimum portion size (in kilobytes) for use with apportioned file loads. Vertica apports a file load across multiple nodes only if:

- The load can be divided into portions at least equaling this value.
- EnableApportionedFileLoad and EnableApportionLoad are set to 1 (enabled).

See also EnableApportionLoad and EnableApportionedFileLoad.

Default: 1024

BlockedSocketGracePeriod

Sets how long a session socket remains blocked while awaiting client input or output for a given query. See [Handling session socket blocking](#).

Default: None (Socket blocking can continue indefinitely.)

CatalogCheckpointPercent

Specifies the threshold at which a checkpoint is created for the database catalog.

By default, this parameter is set to 50 (percent), so when transaction logs reach 50% of the size of the last checkpoint, Vertica adds a checkpoint. Each checkpoint demarcates all changes to the catalog since the last checkpoint.

Default: 50 (percent)

ClusterSequenceCacheMode

Boolean, specifies whether the initiator node requests cache for other nodes in a cluster, and then sends cache to other nodes along with the execution plan, one of the following.

- 1 (enabled): Initiator node requests cache.
- 0: (disabled): All nodes request their own cache.

See [Distributing sequences](#).

Default: 1 (enabled)

CompressCatalogOnDisk

Whether to compress the size of the catalog on disk, one of the following:

- 0: Do not compress.
- 1: Compress checkpoints, but not logs.
- 2: Compress checkpoints and logs.

This parameter is most effective if the catalog disk partition is small (<50 GB) and the metadata is large (hundreds of tables, partitions, or nodes).

Default: 1

CompressNetworkData

Boolean, specifies whether to compress all data sent over the internal network when enabled (set to 1). This compression speeds up network traffic at the expense of added CPU load. If the network is throttling database performance, enable compression to correct the issue.

Default: 0

CopyFaultTolerantExpressions

Boolean, indicates whether to report record rejections during transformations and proceed (true) or abort COPY operations if a transformation fails.

Default: 0 (false)

CopyFromVerticaWithIdentity

Allows [COPY FROM VERTICA](#) and [EXPORT TO VERTICA](#) to load values into [IDENTITY](#) columns. The destination IDENTITY column is not incremented automatically. To disable the default behavior, set this parameter to 0 (zero).

Default: 1

DatabaseHeartbeatInterval

Determines the interval (in seconds) at which each node performs a health check and communicates a heartbeat. If a node does not receive a message within five times of the specified interval, the node is evicted from the cluster. Setting the interval to 0 disables the feature.

See [Automatic eviction of unhealthy nodes](#).

Default: 120

DataLoaderDefaultRetryLimit

Default number of times a [data loader](#) retries failed loads. Changing this value changes the retry limit for existing data loaders that do not specify another limit.

Default: 3

DefaultArrayBinarySize

The maximum binary size, in bytes, for an unbounded collection, if a maximum size is not specified at creation time.

Default: 65000

DefaultResourcePoolForUsers

Resource pool that is assigned to the profile of a new user, whether [created in Vertica](#) or LDAP. This pool is also assigned to users when their assigned resource pool is dropped.

You can set DefaultResourcePoolForUsers only to a global resource pool; attempts to set it to a subcluster resource pool return with an error.

Note

If an LDAP user is merged with an existing Vertica user, the resource pool setting on the existing user remains unchanged.

For details, see [User resource allocation](#).

Default: [GENERAL](#)

DefaultTempTableLocal

Boolean, specifies whether [CREATE TEMPORARY TABLE](#) creates a local or global temporary table, one of the following:

- 0: Create global temporary table.
- 1: Create local temporary table.

For details, see [Creating temporary tables](#).

Default: 0

DivideZeroByZeroThrowsError

Boolean, specifies whether to return an error if a division by zero operation is requested:

- 0: Return 0.
- 1: Returns an error.

Default: 1

EnableApportionedChunkingInDefaultLoadParser

Boolean, specifies whether to enable the built-in parser for delimited files to take advantage of both apportioned load and cooperative parse for potentially better performance.

Default: 1 (enable)

EnableApportionedFileLoad

Boolean, specifies whether to enable automatic apportioning across nodes of file loads using [COPY FROM VERTICA](#). Vertica attempts to apportion the load if:

- This parameter and [EnableApportionLoad](#) are both enabled.
- The parser supports apportioning.
- The load is divisible into portion sizes of at least the value of `ApportionedFileMinimumPortionSizeKB`.

Setting this parameter does not guarantee that loads will be apportioned, but disabling it guarantees that they will not be. See [Distributing a load](#).

Default: 1 (enable)

EnableApportionLoad

Boolean, specifies whether to enable automatic apportioning across nodes of data loads using [COPY...WITH SOURCE](#). Vertica attempts to apportion the load if:

- This parameter is enabled.
- The source and parser both support apportioning.

Setting this parameter does not guarantee that loads will be apportioned, but disabling it guarantees that they will not be. For details, see [Distributing a load](#).

Default: 1 (enable)

EnableBetterFlexTypeGuessing

Boolean, specifies whether to enable more accurate type guessing when assigning data types to non-string keys in a flex table `__raw__` column with [COMPUTE_FLEXTABLE_KEYS](#) or [COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW](#). If this parameter is disabled (0), Vertica uses a limited set of Vertica data type assignments.

Default: 1 (enable)

EnableCooperativeParse

Boolean, specifies whether to implement multi-threaded parsing capabilities on a node. You can use this parameter for both delimited and fixed-width loads.

Default: 1 (enable)

EnableForceOuter

Boolean, specifies whether Vertica uses a table's `force_outer` value to implement a join. For more information, see [Controlling join inputs](#).

Default: 0 (forced join inputs disabled)

EnableMetadataMemoryTracking

Boolean, specifies whether to enable Vertica to track memory used by database metadata in the [METADATA resource pool](#).

Default: 1 (enable)

EnableResourcePoolCPUAffinity

Boolean, specifies whether Vertica aligns queries to the resource pool of the processing CPU. When disabled (0), queries run on any CPU, regardless of the `CPU_AFFINITY_SET` of the resource pool.

Default: 1

EnableStrictTimeCasts

Specifies whether all [cast failures](#) result in an error.

Default: 0 (disable)

EnableUniquenessOptimization

Boolean, specifies whether to enable query optimization that is based on guaranteed uniqueness of column values. Columns that can be guaranteed to include unique values include:

- Columns that are defined with [IDENTITY](#) constraints
- Primary key columns where [key constraints are enforced](#)
- Columns that are [constrained to unique values](#), either individually or as a set

Default: 1 (enable)

EnableWithClauseMaterialization

Superseded by [WithClauseMaterialization](#).

ExternalTablesExceptionsLimit

Determines the maximum number of **COPY** exceptions and rejections allowed when a **SELECT** statement references an external table. Set to **1** to remove any exceptions limit. See [Querying external tables](#).

Default: 100

FailoverToStandbyAfter

Specifies the length of time that an active standby node waits before taking the place of a failed node.

This parameter is set to an [interval literal](#).

Default: None

FencedUDxMemoryLimitMB

Sets the maximum amount of memory, in megabytes (MB), that a fenced-mode **UDF** can use. If a UDF attempts to allocate more memory than this limit, that attempt triggers an exception. For more information, see [Fenced and unfenced modes](#).

Default: -1 (no limit)

FlexTableDataTypeGuessMultiplier

Specifies a multiplier that the `COMPUTE_FLEXTABLE_KEYS` and `COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW` functions use when assigning a data type and column width for the flex keys table. Both functions assign each key a data type, and multiply the longest key value by this factor to estimate column width. This value is not used to calculate the width of any real columns in a flex table.

Default: 2.0

FlexTableRowSize

Specifies the default column width for the `__raw__` column of new flex tables, a value between 1 and 32000000, inclusive.

Default: 130000

ForceUDxFencedMode

When enabled (1), forces all UDxs that support fenced mode to run in fenced mode even if their definitions specify NOT FENCED.

[File exporters](#) cannot be run in fenced mode.

Default: 0

HTTPServerPortOffset

Controls the offset for the [HTTPS](#) port. The default HTTPS port is 8443, the sum of the client port (5433) and default HTTPServerPortOffset (3010).

Caution

This parameter should not be changed without support guidance.

Default: 3010

HTTPSlowRequestThreshold

Threshold in milliseconds for logging HTTP requests in [UDFS_STATISTICS](#). Requests that take longer than this value are logged; faster ones are not.

Default: 500

IcebergPathMapping

For external tables using Iceberg data, a map of URI prefixes used by Iceberg to prefixes accessible to Vertica. The value is a JSON object:

```
{ "source-prefix": "new-prefix" [, ...] }
```

Specify prefixes only (up through port number), not complete paths.

IdleTimeoutInitializingConnectionsMs

The length of time (in milliseconds) that the server waits before timing out, during each step in connection initialization. After connection initialization, the session is created.

Default : 10000

JavaBinaryForUDx

Sets the full path to the Java executable that Vertica uses to run Java UDxs. See [Installing Java on Vertica hosts](#).

JoinDefaultTupleFormat

Specifies how to size VARCHAR column data when joining tables on those columns, and buffers accordingly, one of the following:

- **fixed** : Use join column metadata to size column data to a fixed length, and buffer accordingly.
- **variable** : Use the actual length of join column data, so buffer size varies for each join.

Default: **fixed**

KeepAliveIdleTime

Length (in seconds) of the idle period before the first TCP keepalive probe is sent to ensure that the client is still connected. If set to 0, Vertica uses the kernel's tcp_keepalive_time parameter setting.

Default: 0

KeepAliveProbeCount

Number of consecutive keepalive probes that must go unacknowledged by the client before the client connection is considered lost and closed. If set to 0, Vertica uses the kernel's tcp_keepalive_probes parameter setting.

Default: 0

KeepAliveProbeInterval

Time interval (in seconds) between keepalive probes. If set to 0, Vertica uses the kernel's tcp_keepalive_intvl parameter setting.

Default: 0

LockTimeout

Specifies in seconds how long a table waits to acquire a lock.

Default: 300

LoadSourceStatisticsLimit

Specifies the maximum number of sources per load operation that are profiled in the [LOAD_SOURCES](#) system table. Set it to 0 to disable profiling.

Default: 256

MaxBundleableROSSizeKB

Specifies the minimum size, in kilobytes, of an independent ROS file. Vertica bundles storage container ROS files below this size into a single file. Bundling improves the performance of any file-intensive operations, including backups, restores, and mergeouts.

If you set this parameter to a value of 0, Vertica bundles .fdb and .pidx files without bundling other storage container files.

Default: 1024

MaxClientSessions

Determines the maximum number of client sessions that can run on a single node of the database. The default value allows for five additional administrative logins. These logins prevent DBAs from being locked out of the system if non-dbadmin users reach the login limit.

Tip

Setting this parameter to 0 prevents new client sessions from being opened while you are shutting down the database. Restore the parameter to its original setting after you restart the database. For details, see [Managing Sessions](#).

Default: 50 user logins and 5 additional administrative logins

ObjectStoreGlobStrategy

For partitioned external tables in object stores, the strategy to use for expanding globs before pruning partitions:

- **Flat** : COPY fetches a list of all full object names with a given prefix, which can incur latency if partitions are numerous or deeply nested.
- **Hierarchical** : COPY fetches object names one partition layer at a time, allowing earlier pruning but possibly requiring more calls to the object store when queries are not selective or there are not many partition directory levels.

For details, see [Partitions on Object Stores](#).

Default: Flat

ObjStoreUploadParallelism

Integer (maximum 1000), size of the thread pool used when writing files to S3. Using more threads parallelizes uploads, but uses more memory. Each node has a single thread pool used for all file writes.

This configuration parameter can be set only at the database level.

Default: 0 (disabled)

ParquetMetadataCacheSizeMB

Size of the cache used for metadata when reading Parquet data. The cache uses local TEMP storage.

Default: 4096

PatternMatchingUsejit

Boolean, specifies whether to enable just-in-time compilation (to machine code) of regular expression pattern matching functions used in queries. Enabling this parameter can usually improve pattern matching performance on large tables. The Perl Compatible Regular Expressions (PCRE) pattern-match library evaluates regular expressions. Restart the database for this parameter to take effect.

See also [Regular expression functions](#).

Default: 1 (enable)

PatternMatchStackAllocator

Boolean, specifies whether to override the stack memory allocator for the pattern-match library. The Perl Compatible Regular Expressions (PCRE) pattern-match library evaluates regular expressions. Restart the database for this parameter to take effect.

See also [Regular expression functions](#).

Default: 1 (enable override)

TerraceRoutingFactor

Specifies whether to enable or disable terrace routing on any Enterprise Mode large cluster that implements rack-based fault groups.

- To enable, set as follows:

$$\text{TerraceRoutingFactor} < \frac{(\text{numRackNodes}-1) + (\text{numRacks}-1)}{(\text{numRacks} * \text{numRackNodes}) - 1}$$
 where: * *numRackNodes* : Number of nodes in a rack * *numRacks* : Number of racks in the cluster

- To disable, set to a value so large that terrace routing cannot be enabled for the largest clusters—for example, 1000.

For details, see [Terrace routing](#).

Default: 2

TransactionIsolationLevel

Changes the isolation level for the database. After modification, Vertica uses the new transaction level for every new session. Existing sessions and their transactions continue to use the original isolation level.

See also [Change transaction isolation levels](#).

Default: READ COMMITTED

TransactionMode

Whether transactions are in read/write or read-only modes. Read/write is the default. Existing sessions and their transactions continue to use the original isolation level.

Default: READ WRITE

UDFSSlowRequestThreshold

Threshold in milliseconds for logging events in [UDFS_EVENTS](#). Requests that take longer than this value are logged; faster ones are not.

Default: 1000

UDxFencedBlockTimeout

Number of seconds to wait for output before aborting a UDX running in [Fenced and unfenced modes](#). If the server aborts a UDX for this reason, it produces an error message similar to "ERROR 3399: Failure in UDX RPC call: timed out in receiving a UDX message". If you see this error frequently, you can increase this limit. UDXs running in fenced mode do not run in the server process, so increasing this value does not impede server performance.

Default: 60

UseLocalTzForParquetTimestampConversion

Boolean, specifies whether to do timezone conversion when reading Parquet files. Hive version 1.2.1 introduced an option to localize timezones when writing Parquet files. Previously it wrote them in UTC and Vertica adjusted the value when reading the files.

Set to 0 if Hive already adjusted the timezones.

Default: 1 (enable conversion)

UseServerIdentityOverUserIdentity

Boolean, specifies whether to ignore user-supplied credentials for non-Linux file systems and always use a USER storage location to govern

access to data. See [Creating a Storage Location for USER Access](#).

Default: 0 (disable)

WithClauseMaterialization

Boolean, specifies whether to enable [materialization of WITH clause](#) results. When materialization is enabled (1), Vertica evaluates each WITH clause once and stores results in a temporary table.

For WITH queries with complex types, temp relations are disabled.

Note

You can enable materialization of a given WITH clause with the hint [ENABLE_WITH_CLAUSE_MATERIALIZATION](#).

Default: 0 (disable)

WithClauseRecursionLimit

Specifies the maximum number of times a [WITH RECURSIVE clause](#) iterates over the content of its own result set before it exits. For details, see [WITH clause recursion](#).

Important

Be careful to set WithClauseRecursionLimit only as high as needed to traverse the deepest hierarchies. Vertica sets no limit on this parameter; however, a high value can incur considerable overhead that adversely affects performance and exhausts system resources.

If a high recursion count is required, then consider enabling materialization. For details, see [WITH RECURSIVE Materialization](#).

Default: 8

Azure parameters

Use the following parameters to configure reading from Azure blob storage. For more information about reading data from Azure, see [Azure Blob Storage object store](#).

For external tables using highly partitioned data in an object store, see the [ObjectStoreGlobStrategy](#) configuration parameter and [Partitions on Object Stores](#).

Query the [CONFIGURATION_PARAMETERS](#) system table to determine what levels (node, session, user, database) are valid for a given parameter.

AzureStorageCredentials

Collection of JSON objects, each of which specifies connection credentials for one endpoint. This parameter takes precedence over Azure managed identities.

The collection must contain at least one object and may contain more. Each object must specify at least one of `accountName` or `blobEndpoint`, and at least one of `accountKey` or `sharedAccessSignature`.

- `accountName`: If not specified, uses the label of `blobEndpoint`.
- `blobEndpoint`: Host name with optional port (`host:port`). If not specified, uses `account.blob.core.windows.net`.
- `accountKey`: Access key for the account or endpoint.
- `sharedAccessSignature`: Access token for finer-grained access control, if being used by the Azure endpoint.

AzureStorageEndpointConfig

Collection of JSON objects, each of which specifies configuration elements for one endpoint. Each object must specify at least one of `accountName` or `blobEndpoint`.

- `accountName`: If not specified, uses the label of `blobEndpoint`.
- `blobEndpoint`: Host name with optional port (`host:port`). If not specified, uses `account.blob.core.windows.net`.
- `protocol`: HTTPS (default) or HTTP.
- `isMultiAccountEndpoint`: true if the endpoint supports multiple accounts, false otherwise (default is false). To use multiple-account access, you must include the account name in the URI. If a URI path contains an account, this value is assumed to be true unless explicitly set to false.

Constraints parameters

The following configuration parameters control how Vertica evaluates and enforces constraints. All parameters are set at the database level through [ALTER DATABASE](#).

Three of these parameters—`EnableNewCheckConstraintsByDefault`, `EnableNewPrimaryKeysByDefault`, and `EnableNewUniqueKeysByDefault`—can be used to enforce CHECK, PRIMARY KEY, and UNIQUE constraints, respectively. For details, see [Constraint enforcement](#).

EnableNewCheckConstraintsByDefault

Boolean parameter, set to 0 or 1:

- 0: Disable enforcement of new CHECK constraints except where the table DDL explicitly enables them.
- 1 (default): Enforce new CHECK constraints except where the table DDL explicitly disables them.

EnableNewPrimaryKeysByDefault

Boolean parameter, set to 0 or 1:

- 0 (default): Disable enforcement of new PRIMARY KEY constraints except where the table DDL explicitly enables them.
- 1: Enforce new PRIMARY KEY constraints except where the table DDL explicitly disables them.

Note

Vertica recommends enforcing constraints PRIMARY KEY and UNIQUE together.

EnableNewUniqueKeysByDefault

Boolean parameter, set to 0 or 1:

- 0 (default): Disable enforcement of new UNIQUE constraints except where the table DDL explicitly enables them.
- 1: Enforce new UNIQUE constraints except where the table DDL explicitly disables them.

MaxConstraintChecksPerQuery

Sets the maximum number of constraints that `ANALYZE_CONSTRAINTS` can handle with a single query:

- -1 (default): No maximum set, `ANALYZE_CONSTRAINTS` uses a single query to evaluate all constraints within the specified scope.
- Integer > 0: The maximum number of constraints per query. If the number of constraints to evaluate exceeds this value, `ANALYZE_CONSTRAINTS` handles it with multiple queries.

For details, see [Distributing Constraint Analysis](#).

Database Designer parameters

The following table describes the parameters for configuring the Vertica Database Designer.

DBDCorrelationSampleRowCount

Minimum number of table rows at which Database Designer discovers and records correlated columns.

Default: 4000

DBDLogInternalDesignProcess

Enables or disables Database Designer logging.

Default: 0 (False)

DBDUseOnlyDesignerResourcePool

Enables use of the DBD pool by the Vertica Database Designer.

When set to false, design processing is mostly contained by the user's resource pool, but might spill over into some system resource pools for less-intensive tasks

Default: 0 (False)

Eon Mode parameters

The following parameters configure how the database operates when running in Eon Mode. Query the `CONFIGURATION_PARAMETERS` system table to determine what levels (node, session, user, database) are valid for a given parameter.

BackgroundDepotWarming

Specifies background depot warming behavior:

- 1: The depot loads objects while it is warming, and continues to do so in the background after the node becomes active and starts executing queries.
- 0: Node activation is deferred until the depot fetches and loads all queued objects

For details, see [Depot Warming](#).

Default: 1

CatalogSyncInterval

Specifies in minutes how often the transaction log sync service syncs metadata to communal storage. If you change this setting, Vertica restarts the interval count.

Default: 5

DelayForDeletes

Specifies in hours how long to wait before deleting a file from communal storage. Vertica first deletes a file from the depot. After the specified time interval, the delete also occurs in communal storage.

Default: 0. Deletes the file from communal storage as soon as it is not in use by shard subscribers.

DepotOperationsForQuery

Specifies behavior when the depot does not contain queried file data, one of the following:

- **ALL** (default): Fetch file data from communal storage, if necessary displace existing files by evicting them from the depot.
- **FETCHES** : Fetch file data from communal storage only if space is available; otherwise, read the queried data directly from communal storage.
- **NONE** : Do not fetch file data to the depot, read the queried data directly from communal storage.

You can also specify query-level behavior with the hint [DEPOT_FETCH](#).

ECSType

String parameter that sets the strategy Vertica uses when dividing the data in a shard among subscribing nodes during an ECS-enabled query, one of the following:

- **AUTO** : Optimizer automatically determines the strategy to use.
- **COMPUTE_OPTIMIZED** : Force use of the compute-optimized strategy.
- **IO_OPTIMIZED** : Force use of the I/O-optimized strategy.

For details, see [Manually choosing an ECS strategy](#).

Default: **AUTO**

ElasticKSafety

Boolean parameter that controls whether Vertica adjusts shard subscriptions due to the loss of a [primary node](#):

- 1: When a primary node is lost, Vertica subscribes other primary nodes to the down node's shard subscriptions. This action helps reduce the chances of a database into going read-only mode due to loss of shard coverage.
- 0: Vertica does not change shard subscriptions in reaction to the loss of a primary node.

Default: 1

For details, see [Maintaining Shard Coverage](#).

EnableDepotWarmingFromPeers

Boolean parameter, specifies whether Vertica warms a node depot while the node is starting up and not ready to process queries:

- 1: Warm the depot while a node comes up.
- 0: Warm the depot only after the node is up.

For details, see [Depot Warming](#).

Default: 0

FileDeletionServiceInterval

Specifies in seconds the interval between each execution of the reaper cleaner service task.

Default: 60 seconds

MaxDepotSizePercent

An integer value that specifies the maximum size of the depot as a percentage of disk size,

Default: 80

PreFetchPinnedObjectsToDepotAtStartup

If enabled (set to 1), a warming depot fetches objects that are pinned on its subcluster. For details, see [Depot Warming](#).

Default: 0

ReaperCleanupTimeoutAtShutdown

Specifies in seconds how long Vertica waits for the reaper to delete files from communal storage before shutting down. If set to a negative value, Vertica shuts down without waiting for the reaper.

The reaper is a service task that deletes disk files.

Default: 300

StorageMergeMaxTempCacheMB

The size of temp space allocated per query to the StorageMerge operator for caching the data of S3 storage containers.

Note

The actual temp space that is allocated is the lesser of:

- StorageMergeMaxTempCacheMB
- A user's [TEMPSPACECAP](#) setting
- The session [TEMPSPACECAP](#) setting

For details, see [Local caching of storage containers](#).

UseCommunalStorageForBatchDepotWarming

Boolean parameter, specifies whether where a node retrieves data when warming its depot:

- 1: Retrieve data from communal storage.
- 0: Retrieve data from a peer.

Note

The actual temp space that is allocated is the lesser of two settings:

Default: 1

Important

This parameter is for internal use only. Do not change it unless directed to do so by Vertica support.

UseDepotForReads

Boolean parameter, specifies whether Vertica accesses the depot to answer queries, or accesses only communal storage:

- 1: Vertica first searches the depot for the queried data; if not there, Vertica fetches the data from communal storage for this and future queries.
- 0: Vertica bypasses the depot and always obtains queried data from communal storage.

Note

Enable depot reads to improve query performance and support K-safety.

Default: 1

UseDepotForWrites

Boolean parameter, specifies whether Vertica writes loaded data to the depot and then uploads files to communal storage:

- 1: Write loaded data to the depot, upload files to communal storage.
- 0: Bypass the depot and always write directly to communal storage.

Default: 1

UsePeerToPeerDataTransfer

Boolean parameter, specifies whether Vertica pushes loaded data to other shard subscribers:

- 1: Send loaded data to all shard subscribers.
- 0: Do not push data to other shard subscribers.

Note

Setting to 1 helps improve performance when a node is down.

Default: 0

Important

This parameter is for internal use only. Do not change it unless directed to do so by Vertica support.

Epoch management parameters

The following table describes the epoch management parameters for configuring Vertica.

Query the [CONFIGURATION_PARAMETERS](#) system table to determine what levels (node, session, user, database) are valid for a given parameter.

AdvanceAHMInterval

Determines how frequently (in seconds) Vertica checks the history retention status.

AdvanceAHMInterval cannot be set to a value that is less than the EpochMapInterval.

Default: 180 (seconds)

AHMBackupManagement

Blocks the advancement of the Ancient History Mark (AHM). When this parameter is enabled, the AHM epoch cannot be later than the epoch of your latest full backup. If you advance the AHM to purge and delete data, do not enable this parameter.

Caution

Do not enable this parameter before taking full backups, as it would prevent the AHM from advancing.

Default: 0

EpochMapInterval

Determines the granularity of mapping between epochs and time available to [historical queries](#). When a historical queries **AT TIME T** request is issued, Vertica maps it to an epoch within a granularity of EpochMapInterval seconds. It similarly affects the time reported for [Last Good Epoch](#) during [Failure recovery](#). Note that it does not affect internal precision of epochs themselves.

Tip

Decreasing this interval increases the number of epochs saved on disk. Therefore, consider reducing the HistoryRetentionTime parameter to limit the number of history epochs that Vertica retains.

Default: 180 (seconds)

HistoryRetentionTime

Determines how long deleted data is saved (in seconds) as an historical reference. When the specified time since the deletion has passed, you can purge the data. Use the -1 setting if you prefer to use [HistoryRetentionEpochs](#) to determine which deleted data can be purged.

Note

The default setting of 0 effectively prevents the use of the [Administration tools](#) 'Roll Back Database to Last Good Epoch' option because the [AHM](#) remains close to the current epoch and a rollback is not permitted to an epoch prior to the AHM.

Tip

If you rely on the Roll Back option to remove recently loaded data, consider setting a day-wide window to remove loaded data. For example:

```
ALTER DATABASE DEFAULT SET HistoryRetentionTime = 86400;
```

Default: 0 (Data saved when nodes are down.)

HistoryRetentionEpochs

Specifies the number of historical [epochs](#) to save, and therefore, the amount of deleted data.

Unless you have a reason to limit the number of epochs, Vertica recommends that you specify the time over which deleted data is saved.

If you specify both [History](#) parameters, [HistoryRetentionTime](#) takes precedence. Setting both parameters to -1, preserves all historical data.

See [Setting a purge policy](#).

Default: -1 (disabled)

Google Cloud Storage parameters

Use the following parameters to configure reading from Google Cloud Storage (GCS) using COPY FROM. For more information about reading data from S3, see [Specifying where to load data from](#).

For external tables using highly partitioned data in an object store, see the [ObjectStoreGlobStrategy](#) configuration parameter and [Partitions on Object Stores](#).

Query the [CONFIGURATION_PARAMETERS](#) system table to determine what levels (node, session, user, database) are valid for a given parameter.

GCSAuth

An ID and secret key to authenticate to GCS. You can set parameters globally and for the current session with [ALTER DATABASE...SET PARAMETER](#) and [ALTER SESSION...SET PARAMETER](#), respectively. For extra security, do not store credentials in the database; instead, set it for the current session with ALTER SESSION. For example:

```
=> ALTER SESSION SET GCSAuth='ID:secret';
```

If you use a shared credential, set it in the database with ALTER DATABASE.

GCSEnableHttps

Specifies whether to use the HTTPS protocol when connecting to GCS, can be set only at the database level with [ALTER DATABASE...SET PARAMETER](#).

Default: 1 (enabled)

GCSEndpoint

The connection endpoint address.

Default: [storage.googleapis.com](#)

Hadoop parameters

The following table describes general parameters for configuring integration with Apache Hadoop. See [Apache Hadoop integration](#) for more information.

Query the [CONFIGURATION_PARAMETERS](#) system table to determine what levels (node, session, user, database) are valid for a given parameter.

EnableHDFSBlockInfoCache

Boolean, whether to distribute block location metadata collected during planning on the initiator to all database nodes for execution. Distributing this metadata reduces name node accesses, and thus load, but can degrade database performance somewhat in deployments where the name node isn't contended. This performance effect is because the data must be serialized and distributed. Enable distribution if protecting the name node is more important than query performance; usually this applies to large HDFS clusters where name node contention is already an issue.

Default: 0 (disabled)

HadoopConfDir

Directory path containing the XML configuration files copied from Hadoop. The same path must be valid on every Vertica node. You can use the [VERIFY_HADOOP_CONF_DIR](#) meta-function to test that the value is set correctly. Setting this parameter is required to read data from HDFS.

For all Vertica users, the files are accessed by the Linux user under which the Vertica server process runs.

When you set this parameter, previously-cached configuration information is flushed.

You can set this parameter at the session level. Doing so overrides the database value; it does not append to it. For example:

```
=> ALTER SESSION SET HadoopConfDir='/test/conf:/hadoop/hcat/conf';
```

To append, get the current value and include it on the new path after your additions. Setting this parameter at the session level does not change how the files are accessed.

Default: obtained from environment if possible

HadoopFSAuthentication

How (or whether) to use Kerberos authentication with HDFS. By default, if [KerberosKeytabFile](#) is set, Vertica uses that credential for both Vertica

and HDFS. Usually this is the desired behavior. However, if you are using a Kerberized Vertica cluster with a non-Kerberized HDFS cluster, set this parameter to "none" to indicate that Vertica should not use the Vertica Kerberos credential to access HDFS.

Default: "keytab" if KerberosKeytabFile is set, otherwise "none"

HadoopFSBlockSizeBytes

Block size to write to HDFS. Larger files are divided into blocks of this size.

Default: 64MB

HadoopFSNNOperationRetryTimeout

Number of seconds a metadata operation (such as list directory) waits for a response before failing. Accepts float values for millisecond precision.

Default: 6 seconds

HadoopFSReadRetryTimeout

Number of seconds a read operation waits before failing. Accepts float values for millisecond precision. If you are confident that your file system will fail more quickly, you can improve performance by lowering this value.

Default: 180 seconds

HadoopFSReplication

Number of replicas HDFS makes. This is independent of the replication that Vertica does to provide K-safety. Do not change this setting unless directed otherwise by Vertica support.

Default: 3

HadoopFSRetryWaitInterval

Initial number of seconds to wait before retrying read, write, and metadata operations. Accepts float values for millisecond precision. The retry interval increases exponentially with every retry.

Default: 3 seconds

HadoopFSTokenRefreshFrequency

How often, in seconds, to refresh the Hadoop tokens used to hold Kerberos tickets (see [Token expiration](#)).

Default: 0 (refresh when token expires)

HadoopFSWriteRetryTimeout

Number of seconds a write operation waits before failing. Accepts float values for millisecond precision. If you are confident that your file system will fail more quickly, you can improve performance by lowering this value.

Default: 180 seconds

HadoopImpersonationConfig

Session parameter specifying the delegation token or Hadoop user for HDFS access. See [HadoopImpersonationConfig format](#) for information about the value of this parameter and [Proxy users and delegation tokens](#) for more general context.

HDFSUseWebHDFS

Boolean, whether URLs in the `hdfs` scheme use WebHDFS instead of LibHDFS++ to access data.

Deprecated

This parameter is deprecated because LibHDFS++ is deprecated. In the future, Vertica will use WebHDFS for all `hdfs` URLs.

Default: 1 (enabled)

WebhdfsClientCertConf

mTLS configurations for accessing one or more WebHDFS servers. The value is a JSON string; each member has the following properties:

- `nameservice`: WebHDFS name service
- `authority`: `host:port`
- `certName`: name of a certificate defined by [CREATE CERTIFICATE](#)

`nameservice` and `authority` are mutually exclusive.

For example:

```
=> ALTER SESSION SET WebhdfsClientCertConf =
  [{"authority" : "my.authority.com:50070", "certName" : "myCert"},
  {"nameservice" : "prod", "certName" : "prodCert"}];
```

HCatalog Connector parameters

The following table describes the parameters for configuring the HCatalog Connector. See [Using the HCatalog Connector](#) for more information.

Note

You can override HCatalog configuration parameters when you create an HCatalog schema with [CREATE HCATALOG SCHEMA](#).

EnableHCatImpersonation

Boolean, whether the HCatalog Connector uses (impersonates) the current Vertica user when accessing Hive. If impersonation is enabled, the HCatalog Connector uses the Kerberos credentials of the logged-in Vertica user to access Hive data. Disable impersonation if you are using an authorization service to manage access without also granting users access to the underlying files. For more information, see [Configuring security](#).

Default: 1 (enabled)

HCatalogConnectorUseHiveServer2

Boolean, whether Vertica internally uses HiveServer2 instead of WebHCat to get metadata from Hive.

Default: 1 (enabled)

HCatalogConnectorUseLibHDFSPP

Boolean, whether the HCatalog Connector should use the `hdfs` scheme instead of `webhdfs` with the HCatalog Connector.

Deprecated

Vertica uses the `hdfs` scheme by default. To use `webhdfs`, set the `HDFSUseWebHDFS` parameter.

Default: 1 (enabled)

HCatConnectionTimeout

The number of seconds the HCatalog Connector waits for a successful connection to the HiveServer2 (or WebHCat) server before returning a timeout error.

Default: 0 (Wait indefinitely)

HCatSlowTransferLimit

Lowest transfer speed (in bytes per second) that the HCatalog Connector allows when retrieving data from the HiveServer2 (or WebHCat) server. In some cases, the data transfer rate from the server to Vertica is below this threshold. In such cases, after the number of seconds specified in the `HCatSlowTransferTime` parameter pass, the HCatalog Connector cancels the query and closes the connection.

Default: 65536

HCatSlowTransferTime

Number of seconds the HCatalog Connector waits before testing whether the data transfer from the server is too slow. See the `HCatSlowTransferLimit` parameter.

Default: 60

Internationalization parameters

The following table describes internationalization parameters for configuring Vertica.

Query the [CONFIGURATION_PARAMETERS](#) system table to determine what levels (node, session, user, database) are valid for a given parameter.

DefaultIntervalStyle

Sets the default interval style to use. If set to 0 (default), the interval is in PLAIN style (the SQL standard), no interval units on output. If set to 1, the interval is in UNITS on output. This parameter does not take effect until the database is restarted.

Default: 0

DefaultSessionLocale

Sets the default session startup locale for the database. This parameter does not take effect until the database is restarted.

Default: `en_US@collation=binary`

EscapeStringWarning

Issues a warning when backslashes are used in a string literal. This can help locate backslashes that are being treated as escape characters so they can be fixed to follow the SQL standard-conforming string syntax instead.

Default: 1

StandardConformingStrings

Determines whether [character string literals](#) treat backslashes () as string literals or escape characters. When set to -1, backslashes are treated as string literals; when set to 0, backslashes are treated as escape characters.

Tip

To treat backslashes as escape characters, use the Extended string syntax

```
(E'...');
```

Default: -1

Kafka user-defined session parameters

Set Vertica user-defined session parameters to configure Kafka SSL when not using a scheduler, using [ALTER SESSION SET UDPARAMETER](#). The `kafka_`-prefixed parameters configure SSL authentication for Kafka. For details, see [TLS/SSL encryption with Kafka](#).

Query the [CONFIGURATION_PARAMETERS](#) system table to determine what levels (node, session, user, database) are valid for a given parameter.

kafka_SSL_CA

The contents of the certificate authority certificate. For example:

```
=> ALTER SESSION SET UDPARAMETER kafka_SSL_CA='MIIBOQIBAAJBAIOL';
```

Default: none

kafka_SSL_Certificate

The contents of the SSL certificate. For example:

```
=> ALTER SESSION SET UDPARAMETER kafka_SSL_Certificate='XrM07O4dV/nJ5g';
```

This parameter is optional when the Kafka server's parameter `ssl.client.auth` is set to `none` or `requested`.

Default: none

kafka_SSL_PrivateKey_secret

The private key used to encrypt the session. Vertica does not log this information. For example:

```
=> ALTER SESSION SET UDPARAMETER kafka_SSL_PrivateKey_secret='A60iThKtezaCk7F';
```

This parameter is optional when the Kafka server's parameter `ssl.client.auth` is set to `none` or `requested`.

Default: none

kafka_SSL_PrivateKeyPassword_secret

The password used to create the private key. Vertica does not log this information.

For example:

```
ALTER SESSION SET UDPARAMETER kafka_SSL_PrivateKeyPassword_secret='secret';
```

This parameter is optional when the Kafka server's parameter `ssl.client.auth` is set to `none` or `requested`.

Default: none

kafka_Enable_SSL

Enables SSL authentication for Vertica-Kafka integration. For example:

```
=> ALTER SESSION SET UDPARAMETER kafka_Enable_SSL=1;
```

Default: 0

MaxSessionUDParameterSize

Sets the maximum length of a value in a user-defined session parameter. For example:

```
=> ALTER SESSION SET MaxSessionUDPParameterSize = 2000
```

Default: 1000

Related topics

[User-defined session parameters](#)

Kerberos parameters

The following parameters let you configure the Vertica principal for Kerberos authentication and specify the location of the Kerberos [keytab](#) file.

Query the [CONFIGURATION_PARAMETERS](#) system table to determine what levels (node, session, user, database) are valid for a given parameter.

KerberosEnableKeytabPermissionCheck

Whether the Vertica server verifies permissions on the keytab file. By default, the Vertica server verifies these permissions.

In a [hybrid Kubernetes cluster](#), set this parameter to `0` so that there is no permissions check. Otherwise, Kerberos authentication fails because the keytab file is stored in a Secret, and the VerticaDB operator cannot verify permissions on a Secret.

Default : 1

KerberosHostname

Instance or host name portion of the Vertica Kerberos principal. For example:

```
vertica/host@EXAMPLE.COM
```

If you omit the optional [KerberosHostname](#) parameter, Vertica uses the return value from the function `gethostname()`. Assuming each cluster node has a different host name, those nodes will each have a different principal, which you must manage in that node's keytab file.

KerberosKeytabFile

Location of the [keytab](#) file that contains credentials for the Vertica Kerberos principal. By default, this file is located in `/etc`. For example:

```
KerberosKeytabFile=/etc/krb5.keytab
```

Note

- The principal must take the form `KerberosServiceName/KerberosHostName@KerberosRealm`
- The [keytab](#) file must be readable by the file owner who is running the process (typically the Linux dbadmin user assigned file permissions 0600).

KerberosRealm

Realm portion of the Vertica Kerberos principal. A realm is the authentication administrative domain and is usually formed in uppercase letters.

For example:

```
vertica/hostEXAMPLE.COM
```

KerberosServiceName

Service name portion of the Vertica Kerberos principal. By default, this parameter is `vertica`. For example:

```
vertica/host@EXAMPLE.COM
```

Default: vertica

KerberosTicketDuration

Lifetime of the ticket retrieved from performing a kinit. The default is 0 (zero) which disables this parameter.

If you omit setting this parameter, the lifetime is determined by the default Kerberos configuration.

Machine learning parameters

You use machine learning parameters to configure various aspects of machine learning functionality in Vertica.

MaxModelSizeKB

Sets the maximum size of models that can be imported. The sum of the size of files specified in the metadata.json file determines the model size. The unit of this parameter is KBytes. The native Vertica model (category=VERTICA_MODELS) is exempted from this limit. If you can export the model from Vertica, and the model is not altered while outside Vertica, you can import it into Vertica again.

The MaxModelSizeKB parameter can be set only by a superuser and only at the database level. It is visible only to a superuser. Its default value is 4GB, and its valid range is between 1KB and 64GB (inclusive).

Examples:

To set this parameter to 3KB:

```
=> ALTER DATABASE DEFAULT SET MaxModelSizeKB = 3;
```

To set this parameter to 64GB (the maximum allowed):

```
=> ALTER DATABASE DEFAULT SET MaxModelSizeKB = 67108864;
```

To reset this parameter to the default value:

```
=> ALTER DATABASE DEFAULT CLEAR MaxModelSizeKB;
```

Default: 4GB

Memory management parameters

The following table describes parameters for managing Vertica memory usage.

Caution

Modify these parameters only under guidance from Vertica Support.

Query the [CONFIGURATION_PARAMETERS](#) system table to determine what levels (node, session, user, database) are valid for a given parameter.

MemoryPollerIntervalSec

Specifies in seconds how often the Vertica memory poller checks whether Vertica memory usage is below the thresholds of several configuration parameters (see below):

- [MemoryPollerMallocBloatThreshold](#)
- [MemoryPollerReportThreshold](#)
- [MemoryPollerTrimThreshold](#)

Important

To disable polling of all thresholds, set this parameter to 0. Doing so effectively disables automatic memory usage [reporting](#) and [trimming](#).

Default: 2

MemoryPollerMallocBloatThreshold

Threshold of [glibc memory bloat](#).

The memory poller calls glibc function `malloc_info()` to obtain the amount of free memory in malloc. It then compares [MemoryPollerMallocBloatThreshold](#) —by default, set to 0.3—with the following expression:

```
free-memory-in-malloc / RSS
```

If this expression evaluates to a value higher than [MemoryPollerMallocBloatThreshold](#), the memory poller calls glibc function `malloc_trim()`. This function reclaims free memory from malloc and returns it to the operating system. Details on calls to `malloc_trim()` are written to system table [MEMORY_EVENTS](#).

To disable polling of this threshold, set the parameter to 0.

Default: 0.3

MemoryPollerReportThreshold

Threshold of memory usage that determines whether the Vertica memory poller [writes a report](#).

The memory poller compares [MemoryPollerReportThreshold](#) with the following expression:

```
RSS / available-memory
```

When this expression evaluates to a value higher than [MemoryPollerReportThreshold](#) —by default, set to 0.93, then the memory poller writes a report to [MemoryReport.log](#), in the Vertica working directory. This report includes information about Vertica memory pools, how much memory is consumed by individual queries and session, and so on. The memory poller also logs the report as an event in system table [MEMORY_EVENTS](#), where it sets `EVENT_TYPE` to `MEMORY_REPORT`.

To disable polling of this threshold, set the parameter to 0.

Default: 0.93

MemoryPollerTrimThreshold

Threshold for the memory poller to start checking whether to [trim glibc-allocated memory](#).

The memory poller compares `MemoryPollerTrimThreshold` —by default, set to 0.83— with the following expression:

```
RSS / available-memory
```

If this expression evaluates to a value higher than `MemoryPollerTrimThreshold`, then the memory poller starts checking the next threshold—set in `MemoryPollerMallocBloatThreshold` —for glibc memory bloat.

To disable polling of this threshold, set the parameter to 0. Doing so also disables polling of `MemoryPollerMallocBloatThreshold`.

Default: 0.83

Monitoring parameters

The following parameters control options for monitoring the Vertica database.

Query the [CONFIGURATION_PARAMETERS](#) system table to determine what levels (node, session, user, database) are valid for a given parameter.

EnableDataCollector

Enables the Data Collector, which is the [Workload Analyzer](#)'s internal diagnostics utility. Affects all sessions on all nodes. To disable, set to 0.

Default: 1 (enabled)

EnableLogRotate

Enables and disables the timed [LogRotate service](#).

Default: 1 (enabled)

LogRotateInterval

[Interval literal](#), how often the [LogRotate service](#) runs.

Default: 8h (runs every 8 hours)

LogRotateMaxAge

[Interval literal](#), the maximum age of rotated logs (`.gz`) to keep. Rotated logs with an age greater than this value are rotated. For details, see [Rotating log files](#).

Default: 7 days

LogRotateMaxSize

String, the maximum size of a log (`.log`) file. The string has format `integer {K|M|G|T}`, where **K** is kibibytes, **M** is mebibytes, **G** is gibibytes, and **T** is tebibytes. Logs larger than this value are rotated. For details, see [Rotating log files](#).

Default: 100M

SnmpTrapDestinationsList

Defines where Vertica sends traps for SNMP. See [Configuring reporting for SNMP](#). For example:

```
=> ALTER DATABASE DEFAULT SET SnmpTrapDestinationsList = 'localhost 162 public';
```

Default: none

SnmpTrapsEnabled

Enables event trapping for SNMP. See [Configuring reporting for SNMP](#).

Default: 0

SnmpTrapEvents

Defines which events Vertica traps through SNMP. See [Configuring reporting for SNMP](#). For example:

```
=> ALTER DATABASE DEFAULT SET SnmpTrapEvents = 'Low Disk Space, Recovery Failure';
```

Default: Low Disk Space, Read Only File System, Loss of K Safety, Current Fault Tolerance at Critical Level, Too Many ROS Containers, Node State Change, Recovery Failure, Stale Checkpoint, and CRC Mismatch.

SyslogEnabled

Enables event trapping for syslog. See [Configuring reporting for syslog](#).

Default: 0 (disabled)

SyslogEvents

Defines events that generate a syslog entry. See [Configuring reporting for syslog](#). For example:

```
-> ALTER DATABASE DEFAULT SET SyslogEvents = 'Low Disk Space, Recovery Failure';
```

Default: none

SyslogFacility

Defines which SyslogFacility Vertica uses. See [Configuring reporting for syslog](#).

Default: user

Numeric precision parameters

The following configuration parameters let you configure numeric precision for numeric data types. For more about using these parameters, see [Numeric data type overflow with SUM, SUM_FLOAT, and AVG](#).

Query the [CONFIGURATION_PARAMETERS](#) system table to determine what levels (node, session, user, database) are valid for a given parameter.

AllowNumericOverflow

Boolean, set to one of the following:

- 1 (true): Allows silent numeric overflow. Vertica does not implicitly extend precision of numeric data types. Vertica ignores the value of NumericSumExtraPrecisionDigits.
- 0 (false): Vertica produces an overflow error, if a result exceeds the precision set by NumericSumExtraPrecisionDigits.

Default: 1 (true)

NumericSumExtraPrecisionDigits

An integer between 0 and 20, inclusive. Vertica produces an overflow error if a result exceeds the specified precision. This parameter setting only applies if AllowNumericOverflow is set to 0 (false).

Default: 6 (places beyond the DDL-specified precision)

Profiling parameters

The following table describes the profiling parameters for configuring Vertica. See [Profiling database performance](#) for more information on profiling queries.

Query the [CONFIGURATION_PARAMETERS](#) system table to determine what levels (node, session, user, database) are valid for a given parameter.

GlobalEEProfiling

Enables profiling for query execution runs in all sessions on all nodes.

Default: 0

GlobalQueryProfiling

Enables query profiling for all sessions on all nodes.

Default: 0

GlobalSessionProfiling

Enables session profiling for all sessions on all nodes.

Default: 0

SaveDCEProfileThresholdUS

Sets in microseconds the query duration threshold for saving profiling information to system tables [QUERY_CONSUMPTION](#) and [EXECUTION_ENGINE_PROFILES](#). You can set this parameter to a maximum value of 2147483647 ($2^{31} - 1$, or ~35.79 minutes).

Default: 60000000 (60 seconds)

Projection parameters

The following configuration parameters help you manage projections.

Query the [CONFIGURATION_PARAMETERS](#) system table to determine what levels (node, session, user, database) are valid for a given parameter.

AnalyzeRowCountInterval

Specifies how often Vertica checks the number of projection rows and whether the threshold set by [ARCCommitPercentage](#) has been crossed.

For more information, see [Collecting database statistics](#).

Default: 86400 seconds (24 hours)

ARCCommitPercentage

Sets the threshold percentage of difference between the last-recorded aggregate projection row count and current row count for a given table. When the difference exceeds this threshold, Vertica updates the catalog with the current row count.

Default: 3 (percent)

ContainersPerProjectionLimit

Specifies how many ROS containers Vertica creates per projection before ROS pushback occurs.

Caution

Increasing this parameter's value can cause serious degradation of database performance. Vertica strongly recommends that you not modify this parameter without first consulting with Customer Support professionals.

Default: 1024

MaxAutoSegColumns

Specifies the number of columns (0 –1024) to use in an [auto-projection](#)'s hash segmentation clause. Set to 0 to use all columns.

Default: 8

MaxAutoSortColumns

Specifies the number of columns (0 –1024) to use in an [auto-projection](#)'s sort expression. Set to 0 to use all columns.

Default: 8

RebalanceQueryStorageContainers

By default, prior to performing a rebalance, Vertica performs a system table query to compute the size of all projections involved in the rebalance task. This query enables Vertica to optimize the rebalance to most efficiently utilize available disk space. This query can, however, significantly increase the time required to perform the rebalance.

By disabling the system table query, you can reduce the time required to perform the rebalance. If your nodes are low on disk space, disabling the query increases the chance that a node runs out of disk space. In that situation, the rebalance fails.

Default: 1 (enable)

RewriteQueryForLargeDim

If enabled (1), Vertica rewrites a SET USING or DEFAULT USING query during a [REFRESH_COLUMNS](#) operation by reversing the inner and outer join between the target and source tables. Doing so can optimize refresh performance in cases where the source data is in a table that is larger than the target table.

Important

Enable this parameter only if the SET USING source data is in a table that is larger than the target table. If the source data is in a table smaller than the target table, then enabling RewriteQueryForLargeDim can adversely affect refresh performance.

Default: 0

SegmentAutoProjection

Determines whether [auto-projections](#) are segmented if the table definition omits a segmentation clause. You can set this parameter at database and session scopes.

Default: 1 (create segmented auto projections)

S3 parameters

Use the following parameters to configure reading from S3 file systems and on-premises storage with S3-compatible APIs. For more information about reading data from S3, see [S3 Object Store](#).

For external tables using highly partitioned data in an object store, see the [ObjectStoreGlobStrategy](#) configuration parameter and [Partitions on Object Stores](#).

Query the [CONFIGURATION_PARAMETERS](#) system table to determine what levels (node, session, user, database) are valid for a given parameter.

AWSAuth

ID and secret key for authentication. For extra security, do not store credentials in the database; use [ALTER SESSION...SET PARAMETER](#) to set this value for the current session only. If you use a shared credential, you can set it in the database with [ALTER DATABASE...SET PARAMETER](#). For example:

```
=> ALTER SESSION SET AWSAuth='ID:secret';
```

In AWS, these arguments are named `AccessKeyId` and `SecretAccessKey`.

To use admintools `create_db` or `revive_db` for Eon Mode on-premises, create a configuration file called `auth_params.conf` with these settings:

```
AWSAuth = key:secret
AWSEndpoint = IP:port
```

AWSCAFile

File name of the TLS server certificate bundle to use. If set, this parameter overrides the Vertica default CA bundle path specified in the [SystemCABundlePath](#) parameter.

```
=> ALTER DATABASE DEFAULT SET AWSCAFile = '/etc/ssl/ca-bundle.pem';
```

Default: system-dependent

AWSCAPath

Path Vertica uses to look up TLS server certificate bundles. If set, this parameter overrides the Vertica default CA bundle path specified in the [SystemCABundlePath](#) parameter.

```
=> ALTER DATABASE DEFAULT SET AWSCAPath = '/etc/ssl/';
```

Default: system-dependent

AWSEnableHttps

Boolean, specifies whether to use the HTTPS protocol when connecting to S3, can be set only at the database level with [ALTER DATABASE](#). If you choose not to use TLS, this parameter must be set to 0.

Default : 1 (enabled)

AWSEndpoint

Endpoint to use when interpreting S3 URLs, set as follows.

Important

Do not include `http(s)://` for AWS endpoints.

- AWS: `hostname_or_ip : port_number` .
- AWS with a [FIPS-compliant S3 Endpoint](#) : `S3_hostname` and enable virtual addressing:

Important

Do not include `http(s)://`

```
AWSEndpoint = s3-fips.dualstack.us-east-1.amazonaws.com
S3EnableVirtualAddressing = 1
```

- On-premises/Pure: IP address of the Pure Storage server. If using admintools `create_db` or `revive_db` , create configuration file `auth_params.conf` and include these settings:

```
awsauth = key:secret
awsendpoint = IP:port
```

- When `AWSEndpoint` is not set, the default behavior is to use virtual-hosted request URLs.

Default: `s3.amazonaws.com`

AWSLogLevel

Log level, one of the following:

- OFF
- FATAL
- ERROR
- WARN
- INFO
- DEBUG
- TRACE

****Default:****ERROR

AWSRegion

[AWS region](#) containing the S3 bucket from which to read files. This parameter can only be configured with one region at a time. If you need to access buckets in multiple regions, change the parameter each time you change regions.

If you do not set the correct region, you might experience a delay before queries fail because Vertica retries several times before giving up.

Default: us-east-1

AWSSessionToken

Temporary security token generated by running the `get-session-token` command, which generates temporary credentials you can use to configure multi-factor authentication.

Set this parameter in a user session using `ALTER SESSION`. You can set this parameter at the database level, but be aware that session tokens are temporary. When the token expires, any attempt to access AWS fails.

Note

If you use session tokens at the session level, you must set all parameters at the session level, even if some of them are set at the database level. Use `ALTER SESSION` to set session parameters.

AWSStreamingConnectionPercentage

Controls the number of connections to the communal storage that Vertica uses for streaming reads. In a cloud environment, this setting helps prevent streaming data from communal storage using up all available file handles. It leaves some file handles available for other communal storage operations.

Due to the low latency of on-premises object stores, this option is unnecessary for an Eon Mode database that uses on-premises communal storage. In this case, disable the parameter by setting it to 0.

S3BucketConfig

A JSON array of objects specifying per-bucket configuration overrides. Each property other than the bucket name has a corresponding configuration parameter (shown in parentheses). If both the database-level parameter and its equivalent in `S3BucketConfig` are set, the value in `S3BucketConfig` takes precedence.

Properties:

- **bucket** : Name of the bucket
- **region** (AWSRegion): Name of the region
- **protocol** (AWSEnableHttps): Connection protocol, either `http` or `https`
- **endpoint** (AWSEndpoint): Endpoint URL or IP address
- **enableVirtualAddressing** (S3EnableVirtualAddressing): Whether to rewrite the S3 URL to use a virtual hosted path
- **requesterPays** (S3RequesterPays): Whether requester (instead of bucket owner) pays the cost of accessing data on the bucket
- **serverSideEncryption** (S3ServerSideEncryption): Encryption algorithm if using SSE-S3 or SSE-KMS, one of `AES256`, `aws:kms`, or an empty string
- **sseCustomerAlgorithm** (S3SseCustomerAlgorithm): Encryption algorithm if using SSE-C; must be `AES256`
- **sseCustomerKey** (S3SseCustomerKey): Key if using SSE-C encryption, either 32-character plaintext or 44-character base64-encoded
- **sseKmsKeyId** (S3SseKmsKeyId): Key ID if using SSE-KMS encryption
- **proxy** (S3Proxy): HTTP(S) proxy string

The configuration properties for a given bucket might differ based on its type. For example, the following `S3BucketConfig` is for an AWS bucket `AWSBucket` and a Pure Storage bucket `PureStorageBucket`. `AWSBucket` doesn't specify an endpoint, so Vertica uses the value of `AWSEndpoint`, which defaults to `s3.amazonaws.com`:

```
ALTER DATABASE DEFAULT SET S3BucketConfig=
```

```
[
  {
    "bucket": "AWSBucket",
    "region": "us-east-2",
    "protocol": "https",
    "requesterPays": true
  },
  {
    "bucket": "PureStorageBucket",
    "endpoint": "pure.mycorp.net:1234",
    "protocol": "http",
    "enableVirtualAddressing": false
  }
];
```

S3BucketCredentials

Contains credentials for accessing an S3 bucket. Each property in S3BucketCredentials has an equivalent parameter (shown in parentheses). When set, S3BucketCredentials takes precedence over both AWSAuth and AWSSessionToken.

Providing credentials for more than one bucket authenticates to them simultaneously, allowing you to perform cross-endpoint joins, export from one bucket to another, etc.

Properties:

- **bucket** : Name of the bucket
- **accessKey** : Access key for the bucket (the *ID* in AWSAuth)
- **secretAccessKey** : Secret access key for the bucket (the *secret* in AWSAuth)
- **sessionToken** : Session token, only used when S3BucketCredentials is set at the session level (AWSSessionToken)

For example, the following S3BucketCredentials is for an AWS bucket **AWSBucket** and a Pure Storage bucket **PureStorageBucket** and sets all possible properties:

```
ALTER SESSION SET S3BucketCredentials='
[
  {
    "bucket": "AWSBucket",
    "accessKey": "<AK0>",
    "secretAccessKey": "<SAK0>",
    "sessionToken": "1234567890"
  },
  {
    "bucket": "PureStorageBucket",
    "accessKey": "<AK1>",
    "secretAccessKey": "<SAK1>"
  }
];
```

This parameter is only visible to the superuser. Users can set this parameter at the session level with [ALTER SESSION](#).

S3EnableVirtualAddressing

Boolean, specifies whether to rewrite S3 URLs to use virtual-hosted paths. For example, if you use AWS, the S3 URLs change to **bucketname.s3.amazonaws.com** instead of **s3.amazonaws.com/bucketname**. This configuration setting takes effect only when you have specified a value for [AWSEndpoint](#).

If you set AWSEndpoint to a [FIPS-compliant S3 Endpoint](#), you must enable S3EnableVirtualAddressing in `auth_params.conf`:

```
AWSEndpoint = s3-fips.dualstack.us-east-1.amazonaws.com
S3EnableVirtualAddressing = 1
```

The value of this parameter does not affect how you specify S3 paths.

Default: 0 (disabled)

Note

As of September 30, 2020, AWS requires virtual address paths for newly created buckets.

S3Proxy

HTTP(S) proxy settings, if needed, a string in the following format:

```
http[s]://[user:password@]host[:port]
```

Default: "" (empty string)

S3RequesterPays

Boolean, specifies whether requester (instead of bucket owner) pays the cost of accessing data on the bucket. When true, the bucket owner is only responsible for paying the cost of storing the data, rather than all costs associated with the bucket; must be set in order to access S3 buckets configured as Requester Pays buckets. By setting this property to true, you are accepting the charges for accessing data. If not specified, the default value is false.

S3ServerSideEncryption

String, encryption algorithm to use when reading or writing to S3. The value depends on which type of encryption at rest is configured for S3:

- **AES256** : Use for SSE-S3 encryption
- **aws:kms** : Use for SSE-KMS encryption
- Empty string (""): No encryption

SSE-C encryption does not use this parameter. Instead, see `S3SseCustomerAlgorithm`. For details on using SSE parameters, see [S3 object store](#).

Default: "" (no encryption)

S3SseCustomerAlgorithm

String, the encryption algorithm to use when reading or writing to S3 using SSE-C encryption. The only supported values are **AES256** and "" .

For SSE-S3 and SSE-KMS, instead use `S3ServerSideEncryption`.

Default: "" (no encryption)

S3SseCustomerKey

If using SSE-C encryption, the client key for S3 access.

S3SseKmsKeyId

If using SSE-KMS encryption, the key identifier (not the key) to pass to the Key Management Server. Vertica must have permission to use the key, which is managed through KMS.

SNS parameters

The following parameters configure [Amazon Simple Notification Service \(SNS\) notifiers](#). These parameters can only be set at the database level and some, if unset, fall back to their equivalent [S3 parameters](#).

Notifiers must be disabled and then reenabled for these parameters to take effect:

```
-> ALTER NOTIFIER sns_notifier DISABLE;
-> ALTER NOTIFIER sns_notifier ENABLE;
```

SNSAuth (falls back to AWSAuth)

ID and secret key for authentication, equivalent to the `AccessKeyId` and `SecretAccessKey` in AWS. For example:

```
-> ALTER DATABASE DEFAULT SET SNSAuth='myID.mySecret';
```

Default: "" (empty string)

SNSCAFile (falls back to AWSCAFile)

File name of the TLS server certificate bundle to use. If set, this parameter overrides the Vertica default CA bundle path specified in the [SystemCABundlePath](#) parameter.

```
-> ALTER DATABASE DEFAULT SET SNSCAFile = 'etc/ssl/ca-bundle.pem';
```

Default: "" (empty string)

SNSCAPath (falls back to AWSCAPath)

Path Vertica uses to look up TLS server certificate bundles. If set, this parameter overrides the Vertica default CA bundle path specified in the [SystemCABundlePath](#) parameter.

```
-> ALTER DATABASE DEFAULT SET SNSCAPath = 'etc/ssl/';
```

Default: "" (empty string)

SNSEnableHttps

Boolean, specifies whether to use the HTTPS protocol when connecting to S3, can be set only at the database level with [ALTER DATABASE](#). If you choose not to use TLS, this parameter must be set to 0.

Default : 1 (enabled)

SNSEndpoint

URL of the SNS API endpoint. If this parameter is set to an empty string and the region is specified (either by `SNSRegion` or its fallback to `AWSRegion`), Vertica automatically infers the appropriate endpoint.

If you use FIPS, you must manually specify a [FIPS-compliant endpoint](#).

Default: "" (empty string)

SNSRegion (falls back to AWSRegion)

[AWS region](#) for the SNS endpoint. This parameter can only be configured with one region at a time.

Default: "" (empty string)

SQS parameters

The following parameters configure access to [Amazon Simple Queue Service](#) (SQS) queues. SQS is used with [CREATE DATA LOADER](#) to automatically load data from a queue into Vertica. These parameters can be set at the database or session level and some, if unset, fall back to their equivalent [S3 parameters](#).

SQSAuth (falls back to AWSAuth)

ID and secret key for authentication, equivalent to the AccessKeyID and SecretAccessKey in AWS. For example:

```
-> ALTER DATABASE DEFAULT SET SQSAuth=myID.mySecret;
```

Default: "" (empty string)

SQSQueueCredentials

Per-queue credentials for accessing SQS queues, a JSON array. When set, these values take precedence over SQSAuth.

Properties:

- **accessKey** : Access key for the queue (the *ID* in AWSAuth)
- **secretAccessKey** : Secret access key for the queue (the *secret* in AWSAuth)
- **sessionToken** : AWS session token, only used when SQSQueueCredentials is set at the session level

The following example sets credentials for two queues:

```
-> ALTER SESSION SET SQSQueueCredentials=[  
  ['queue','queue1','accessKey','<AK0>','secretAccessKey','<SAK0>','sessionToken','1234567890'],  
  ['queue','queue1','accessKey','foo','secretAccessKey','bar']];
```

Default: "" (empty string)

SQSSessionToken

Temporary, session-level SQS access token. Set this parameter in a user session using [ALTER SESSION](#).

If you set a session token at the [session level](#), you must also set SQSAuth at the session level, even if it is already set at the [database level](#). In general, SQSSessionToken should be set only at the session level. While you can set this parameter at the database level, session tokens are ephemeral, so when the database-level token expires, you must set it again either at the session or database level.

Security parameters

Use these client authentication configuration parameters and general security parameters to configure TLS.

- To configure Vertica for client-server TLS, see [Configuring client-server TLS](#).
- To configure JDBC and ODBC clients for TLS, see [Configuring TLS for JDBC clients](#) and [Configuring TLS for ODBC Clients](#).
- For Kerberos-related parameters, see [Kerberos parameters](#).

Query the [CONFIGURATION_PARAMETERS](#) system table to determine what levels (node, session, user, database) are valid for a given parameter.

Database parameters

DataSSLParams

This parameter has been deprecated. Use the [data_channel](#) TLS Configuration instead.

Enables encryption using SSL on the data channel. The value of this parameter is a comma-separated list of the following:

- An SSL certificate (chainable)
- The corresponding SSL private key
- The SSL CA (Certificate Authority) certificate.

You should set **EncryptSpreadComm** before setting this parameter.

In the following example, the SSL Certificate contains two certificates, where the certificate for the non-root CA verifies the certificate for the cluster. This is called an SSL Certificate Chain.

```
=> ALTER DATABASE DEFAULT SET PARAMETER DataSSLParams =
'-----BEGIN CERTIFICATE-----<certificate for Cluster>-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----<certificate for non-root CA>-----END CERTIFICATE-----,
-----BEGIN RSA PRIVATE KEY-----<private key for Cluster>-----END RSA PRIVATE KEY-----,
-----BEGIN CERTIFICATE-----<certificate for public CA>-----END CERTIFICATE-----';
```

DefaultIdleSessionTimeout

Indicates a default session timeout value for all users where [IDLESESSIONTIMEOUT](#) is not set. For example:

```
=> ALTER DATABASE DEFAULT SET defaultidlesessiontimeout = '300 secs';
```

DHParams

Deprecated

This parameter has been deprecated and will be removed in a future release.

String, a Diffie-Hellman group of at least 2048 bits in the form:

```
-----BEGIN DH PARAMETERS-----...-----END DH PARAMETERS-----
```

You can generate your own or use the pre-calculated Modular Exponential (MODP) Diffie-Hellman groups specified in [RFC 3526](#).

Changes to this parameter do not take effect until you restart the database.

Default: RFC 3526 2048-bit MODP Group 14:

```
-----BEGIN DH PARAMETERS-----MIIBCACAKCAQEA//////////
JD9qiIWjCNMTGYouA3BzRKQJOC|pnzHQCC76mOxObIIFKCHmONAT
d75UZs806QxswKwpt8l8UN0/hNW1tUcJF5IW1dmJefsb0TElppjf
tawv/XLb0Brft7jhr+1qJn6WunyQRfEsf5kkoZIHs5Fs9wgB8uKF
jvwWY2kg2HFXTmmkWP6j9JM9fg2Vdl9yjrZYcYvNWIIVSu57VKQd
wlpZtZww1Tkq8mATxdGwlyhghfDKQXkYuNs474553LBgOhgObJ4O
i7Aeij7XFxfBvTFLJ3ivL9pVYFyg5UI86pVq5RXSJhiY+gUQFXK
OWoqsqmj//////////wIBAg==-----END DH PARAMETERS-----
```

DisableInheritedPrivileges

Boolean, whether to disable [privilege inheritance](#) at the database level (enabled by default).

DoUserSpecificFilteringInSysTables

Boolean, specifies whether a non-superuser can view details of another user:

- 0: Users can view details of other users.
- 1: Users can only view details about themselves.

Default: 0

EnableAllRolesOnLogin

Boolean, specifies whether to automatically enable all roles granted to a user on login:

- 0: Do not automatically enable roles
- 1: Automatically enable roles. With this setting, users do not need to run [SET ROLE](#).

Default: 0 (disable)

EnabledCipherSuites

Specifies which SSL cipher suites to use for secure client-server communication. Changes to this parameter apply only to new connections.

Default: Vertica uses the Microsoft Schannel default cipher suites. For more information, see the [Schannel documentation](#).

EnableConnectCredentialForwarding

When using [CONNECT TO VERTICA](#), whether to use the password of the current user to authenticate to a target database.

Default: 0 (disable)

EnableOAuth2JITCleanup

If enabled, users created by [just-in-time OAuth provisioning](#) are automatically dropped if the user does not log in after the number of days specified by `OAuth2UserExpiredInterval`.

To view provisioned users, see [USERS](#).

Default : 0 (disable)

EncryptSpreadComm

Enables Spread encryption on the control channel, set to one of the following strings:

- **vertica** : Specifies that Vertica generates the Spread encryption key for the database cluster.
- **aws-kms| key-name** , where **key-name** is a named key in the iAWS Key Management Service (KMS). On database restart, Vertica fetches the named key from the KMS instead of generating its own.

If the parameter is empty, Spread communication is unencrypted. In general, you should enable this parameter before modifying other security parameters.

Enabling this parameter requires database restart.

GlobalHeirUsername

A string that specifies which user inherits objects after their owners are dropped. This setting ensures preservation of data that would otherwise be lost.

Set this parameter to one of the following string values:

- Empty string: Objects of dropped users are removed from the database.
- **username** : Reassigns objects of dropped users to **username** . If **username** does not exist, Vertica creates that user and sets **GlobalHeirUsername** to it.
- **<auto>** : Reassigns objects of dropped LDAP or just-in-time-provisioned users to the **dbadmin** user. The brackets (< and >) are required for this option.

For more information about usage, see [Examples](#).

Default: <auto>

ImportExportTLSMode

When using [CONNECT TO VERTICA](#) to connect to another Vertica cluster for import or export, specifies the degree of stringency for using TLS.

Possible values are:

- **PREFER** : Try TLS but fall back to plaintext if TLS fails.
- **REQUIRE** : Use TLS and fail if the server does not support TLS.
- **VERIFY_CA** : Require TLS (as with REQUIRE), and also validate the other server's certificate using the CA specified by the "server" TLS

Configuration's CA certificates (in this case, "ca_cert" and "ica_cert"):

```
=> SELECT name, certificate, ca_certificate, mode FROM tls_configurations WHERE name = 'server';
 name | certificate | ca_certificate | mode
-----+-----+-----+-----
server | server_cert | ca_cert,ica_cert | VERIFY_CA
(1 row)
```

- **VERIFY_FULL** : Require TLS and validate the certificate (as with VERIFY_CA), and also validate the server certificate's hostname.
- **REQUIRE_FORCE** , **VERIFY_CA_FORCE** , and **VERIFY_FULL_FORCE** : Same behavior as **REQUIRE** , **VERIFY_CA** , and **VERIFY_FULL** , respectively, and cannot be overridden by [CONNECT TO VERTICA](#).

Default: PREFER

InternodeTLSConfig

The [TLS Configuration](#) to use for [internode encryption](#).

For example:

```
=> ALTER DATABASE DEFAULT SET InternodeTLSConfig = my_tls_config;
```

Default: data_channel

LDAPAuthTLSConfig

The [TLS Configuration](#) to use for [TLS with LDAP authentication](#).

For example:

```
=> ALTER DATABASE DEFAULT SET LDAPAuthTLSConfig = my_tls_config;
```

Default: ldapauth

LDAPLinkTLSConfig

The [TLS Configuration](#) to use for [TLS for the LDAP Link service](#).

For example:

```
=> ALTER DATABASE DEFAULT SET LDAPLinkTLSConfig = my_tls_config;
```

Default: `ldaplink`

OAuth2JITClient

Deprecated

This parameter is deprecated. Use the `OAuth2JITRolesClaimName` parameter instead.

The client/application name that contains Vertica roles in the Keycloak identity provider. The Vertica roles under `resource_access.OAuth2JITClient.roles` are automatically [granted](#) to and set as [default roles](#) for users created by just-in-time provisioning. Roles that do not exist in Vertica are ignored.

For details, see [Just-in-time user provisioning](#).

Default : `vertica`

OAuth2JITRolesClaimName

Specifies an IdP client with one or more roles that correspond to a Vertica database role. During just-in-time user provisioning, each client role that matches an existing Vertica role is automatically assigned to the user. Roles that do not exist in Vertica are ignored.

For authentication records that use JWT validation, Vertica retrieves the client roles from the access token.

To retrieve client roles for authentication records that use IdP validation, Vertica sends a request to either the `introspect_url` or the `userinfo_url` set in the authentication record. This parameter requires the full path to the roles claim in that request. For example, the full path to the roles claim in a Keycloak request uses the following format:

```
resource_access.clientName.roles
```

For details, see [Just-in-time user provisioning](#).

Default : `resource_access.vertica.roles`

OAuth2JITForbiddenRoles

Vertica database roles that you do not want Vertica to automatically assign to users during [just-in-time provisioning](#). This parameter accepts one or more roles as a comma-separated list.

OAuth2JITGroupsClaimName

The name of the IdP group whose name or role mappings correspond to Vertica database roles. During [just-in-time user provisioning](#), each group name or group role mapping that matches an existing Vertica role is automatically assigned to the user. Roles that do not exist in Vertica are ignored.

For authentication records that use JWT validation, Vertica retrieves the JIT-provisioned user's groups from the access token.

To retrieve the JIT-provisioned user's groups for authentication records that use IdP validation, Vertica sends a request to either the `introspect_url` or the `userinfo_url` set in the authentication record.

Default : `groups`

OAuth2UserExpiredInterval

If `EnableOAuth2JITCleanup` is enabled, users created by just-in-time OAuth provisioning are automatically dropped after not logging in for the number of days specified by `OAuth2UserExpiredInterval`. The number of days the user has not logged in is calculated relative to the `LAST_LOGIN_TIME` column in the `USERS` system table.

Note

The `LAST_LOGIN_TIME` as recorded by the `USERS` system table is not persistent; if the database is restarted, the `LAST_LOGIN_TIME` for users created by just-in-time user provisioning is set to the database start time (this appears as an empty value in `LAST_LOGIN_TIME`).

You can view the database start time by querying the `DATABASES` system table:

```
=> SELECT database_name, start_time FROM databases
```

database_name	start_time
VMart	2023-02-06 14:26:50.63064-05

(1 row)

Default : 14

PasswordLockTimeUnit

The time units for which an [account is locked](#) by `PASSWORD_LOCK_TIME` after `FAILED_LOGIN_ATTEMPTS`, one of the following:

- 'd': days (default)
- 'h': hours
- 'm': minutes
- 's': seconds

For example, to configure the [default profile](#) to lock user accounts for 30 minutes after three unsuccessful login attempts:

```
=> ALTER DATABASE DEFAULT SET PasswordLockTimeUnit = 'm'  
=> ALTER PROFILE DEFAULT LIMIT PASSWORD_LOCK_TIME 30;
```

RequireFIPS

Boolean, specifies whether the FIPS mode is enabled:

- 0 (disable)
- 1: (enable)

On startup, Vertica automatically sets this parameter from the contents of the file `crypto.fips_enabled`. You cannot modify this parameter. For details, see [FIPS compliance for the Vertica server](#).

Default: 0

SecurityAlgorithm

Sets the algorithm for the function that hash authentication uses, one of the following:

- SHA512
- MD5

For example:

```
=> ALTER DATABASE DEFAULT SET SecurityAlgorithm = 'SHA512';
```

Default: SHA512

ServerTLSConfig

The [TLS Configuration](#) to use for [client-server TLS](#).

For example:

```
=> ALTER DATABASE DEFAULT SET ServerTLSConfig = my_tls_config;
```

Default: server

SystemCABundlePath

The absolute path to a certificate bundle of trusted CAs. This CA bundle is used when establishing TLS connections to external services such as AWS or Azure through their respective SDKs and libcurl. The CA bundle file must be in the same location on all nodes.

If this parameter is empty, Vertica searches the "standard" paths for the CA bundles, which differs between distributions:

- Red Hat-based: `/etc/pki/tls/certs/ca-bundle.crt`
- Debian-based: `/etc/ssl/certs/ca-certificates.crt`
- SUSE: `/var/lib/ca-certificates/ca-bundle.pem`

Example :

```
=> ALTER DATABASE DEFAULT SET SystemCABundlePath = 'path/to/ca_bundle.pem';
```

Default: Empty

TLS parameters

To set your Vertica database's TLSMode, private key, server certificate, and CA certificate(s), see [TLS configurations](#). In versions prior to 11.0.0, these parameters were known as EnableSSL, SSLPrivateKey, SSLCertificate, and SSLCA, respectively.

Examples

Set the database parameter `GlobalHeirUsername` :

```
=> \du
      List of users
User name | Is Superuser
-----+-----
Joe       | f
SuzyQ    | f
dbadmin  | t
(3 rows)

=> ALTER DATABASE DEFAULT SET PARAMETER GlobalHeirUsername='SuzyQ';
ALTER DATABASE
=> \c - Joe
You are now connected as user "Joe".
=> CREATE TABLE t1 (a int);
CREATE TABLE

=> \c
You are now connected as user "dbadmin".
=> \dt t1
      List of tables
Schema | Name | Kind | Owner | Comment
-----+-----+-----+-----+-----
public | t1  | table | Joe   |
(1 row)

=> DROP USER Joe;
NOTICE 4927: The Table t1 depends on User Joe
ROLLBACK 3128: DROP failed due to dependencies
DETAIL: Cannot drop User Joe because other objects depend on it
HINT: Use DROP ... CASCADE to drop the dependent objects too
=> DROP USER Joe CASCADE;
DROP USER
=> \dt t1
      List of tables
Schema | Name | Kind | Owner | Comment
-----+-----+-----+-----+-----
public | t1  | table | SuzyQ |
(1 row)
```

Stored procedure parameters

The following parameters configure the behavior of [stored procedures](#) and [triggers](#) .

EnableNestedStoredProcedures

Boolean, whether to enable [nested stored procedures](#) .

Default: 0

EnableStoredProcedureScheduler

Boolean, whether to enable the scheduler. For details, see [Scheduled execution](#) .

Default: 1

PLvSQLCoerceNull

Boolean, whether to allow NULL-to-false type coercion to improve compatibility with PLpgSQL. For details, see [PL/pgSQL to PL/vSQL migration guide](#) .

Default: 0

Text search parameters

You can configure Vertica for text search using the following parameter.

TextIndexMaxTokenLength

Controls the maximum size of a token in a text index.

For example:

```
ALTER DATABASE database_name SET PARAMETER TextIndexMaxTokenLength=760;
```

If the parameter is set to a value greater than 65000 characters, then the tokenizer truncates the token at 65000 characters.

Caution

Avoid setting this parameter near its maximum value, 65000. Doing so can result in a significant decrease in performance. For optimal performance, set this parameter to the maximum token value of your tokenizer.

Default: 128 (characters)

Tuple mover parameters

These parameters control how the [Tuple Mover](#) operates.

Query the [CONFIGURATION_PARAMETERS](#) system table to determine what levels (node, session, user, database) are valid for a given parameter.

ActivePartitionCount

Sets the number of [active partitions](#). The active partitions are those most recently created. For example:

```
=> ALTER DATABASE DEFAULT SET ActivePartitionCount = 2;
```

For information about how the Tuple Mover treats active and inactive partitions during a mergeout operation, see [Partition mergeout](#).

Default: 1

CancelTTimeout

When partition, copy table, and rebalance operations encounter a conflict with an internal Tuple Mover job, those operations attempt to cancel the conflicting Tuple Mover job. This parameter specifies the amount of time, in seconds, that the blocked operation waits for the Tuple Mover cancellation to take effect. If the operation is unable to cancel the Tuple Mover job within limit specified by this parameter, the operation displays an error and rolls back.

Default: 300

EnableTMonRecoveringNode

Boolean, specifies whether Tuple Mover performs [mergeout](#) activities on nodes with a [node state](#) of RECOVERING. Enabling Tuple Mover reduces the number of ROS containers generated during recovery. Having fewer than 1024 ROS containers per projection allows Vertica to maintain optimal recovery performance.

Default: 1 (enabled)

MaxMrgOutROSSizeMB

Specifies in MB the maximum size of ROS containers that are candidates for [mergeout](#) operations. The Tuple Mover avoids merging ROS containers that are larger than this setting.

Note

After a [rebalance operation](#), Tuple Mover groups ROS containers in batches that are smaller than MaxMrgOutROSSizeMB. ROS containers that are larger than MaxMrgOutROSSizeMB are merged individually

Default: -1 (no maximum limit)

MergeOutInterval

Specifies in seconds how frequently the Tuple Mover checks the [mergeout request queue](#) for pending requests:

1. If the queue contains mergeout requests, the Tuple Mover does nothing and goes back to sleep.
2. If the queue is empty, the Tuple Mover:
 - Processes pending storage location move requests.
 - Checks for new unqueued purge requests and adds them to the queue.

It then goes back to sleep.

Default: 600

PurgeMergeoutPercent

Specifies as a percentage the threshold of deleted records in a ROS container that invokes an automatic [mergeout](#) operation, to purge those records. Vertica only counts the number of 'aged-out' delete vectors—that is, delete vectors that are as 'old' or older than the ancient history mark (AHM) epoch.

This threshold applies to all ROS containers for non-partitioned tables. It also applies to ROS containers of all inactive partitions. In both cases, aged-out delete vectors are permanently purged from the ROS container.

Note

This configuration parameter only applies to automatic mergeout operations. It does not apply to manual mergeout operations that are invoked by calling meta-functions [DO_TM_TASK\('mergeout'\)](#) and [PURGE](#).

Default: 20 (percent)

File systems and object stores

Vertica supports access to several file systems and object stores in addition to the Linux file system. The reference pages in this section provide information on URI syntax, configuration parameters, and authentication.

Vertica accesses the file systems in this section in one of two ways:

- If user-provided credentials are present, Vertica uses them to access the storage. Note that on HDFS, user credentials are always present because Vertica accesses HDFS using the Vertica user identity.
- If user-provided credentials are not present, or if the [UseServerIdentityOverUserIdentity](#) configuration parameter is set, Vertica checks for a configured USER storage location. When access is managed through USER storage locations, Vertica uses the server credential to access the file system. For more information about USER storage locations, see [CREATE LOCATION](#).

Not all file systems are supported in all contexts. See the documentation of specific features for the file systems those features support.

In this section

- [Azure Blob Storage object store](#)
- [Google Cloud Storage \(GCS\) object store](#)
- [HDFS file system](#)
- [S3 object store](#)

Azure Blob Storage object store

Azure has several interfaces for accessing data. Vertica reads and always writes Block Blobs in Azure Storage. Vertica can read external data created using ADLS Gen2, and data that Vertica exports can be read using ADLS Gen2.

URI format

One of the following:

- `azb://account/container/path`
- `azb://[account@]host[:port]/container/path`

In the first version, a URI like 'azb://myaccount/mycontainer/path' treats the first token after the '/' as the account name. In the second version, you can specify account and must specify host explicitly.

The following rules apply to the second form:

- If *account* is not specified, the first label of the host is used. For example, if the URI is 'azb://myaccount.blob.core.windows.net/mycontainer/my/object', then 'myaccount' is used for *account*.
- If *account* is not specified and *host* has a single label and no port, the endpoint is *host.blob.core.windows.net*. Otherwise, the endpoint is the host and port specified in the URI.

The protocol (HTTP or HTTPS) is specified in the `AzureStorageEndpointConfig` configuration parameter.

Authentication

If you are using Azure managed identities, no further configuration in Vertica is needed. If your Azure storage uses multiple managed identities, you must tag the one to be used. Vertica looks for an Azure tag with a key of `VerticaManagedIdentityClientId`, the value of which must be the `client_id` attribute of the managed identity to be used. If you update the Azure tag, call [AZURE_TOKEN_CACHE_CLEAR](#).

If you are not using managed identities, use the `AzureStorageCredentials` configuration parameter to provide credentials to Azure. If loading data, you can set the parameter at the session level. If using Eon Mode communal storage on Azure, you must set this configuration parameter at the database level.

In Azure you must also grant access to the containers for the identities used from Vertica.

Configuration parameters

The following database configuration parameters apply to the Azure blob file system. You can set parameters at different levels with the appropriate `ALTER` statement, such as `ALTER SESSION...SET PARAMETER`. Query the `CONFIGURATION_PARAMETERS` system table to determine what levels (node, session, user, database) are valid for a given parameter.

For external tables using highly partitioned data in an object store, see the `ObjectStoreGlobStrategy` configuration parameter and [Partitions on Object Stores](#).

AzureStorageCredentials

Collection of JSON objects, each of which specifies connection credentials for one endpoint. This parameter takes precedence over Azure managed identities.

The collection must contain at least one object and may contain more. Each object must specify at least one of `accountName` or `blobEndpoint`, and at least one of `accountKey` or `sharedAccessSignature`.

- `accountName`: If not specified, uses the label of `blobEndpoint`.
- `blobEndpoint`: Host name with optional port (`host:port`). If not specified, uses `account.blob.core.windows.net`.
- `accountKey`: Access key for the account or endpoint.
- `sharedAccessSignature`: Access token for finer-grained access control, if being used by the Azure endpoint.

AzureStorageEndpointConfig

Collection of JSON objects, each of which specifies configuration elements for one endpoint. Each object must specify at least one of `accountName` or `blobEndpoint`.

- `accountName`: If not specified, uses the label of `blobEndpoint`.
- `blobEndpoint`: Host name with optional port (`host:port`). If not specified, uses `account.blob.core.windows.net`.
- `protocol`: HTTPS (default) or HTTP.
- `isMultiAccountEndpoint`: true if the endpoint supports multiple accounts, false otherwise (default is false). To use multiple-account access, you must include the account name in the URI. If a URI path contains an account, this value is assumed to be true unless explicitly set to false.

Examples

The following examples use these values for the configuration parameters. `AzureStorageCredentials` contains sensitive information and is set at the session level in this example.

```
=> ALTER SESSION SET AzureStorageCredentials =
  [{"accountName": "myaccount", "accountKey": "REAL_KEY"},
  {"accountName": "myaccount", "blobEndpoint": "localhost:8080", "accountKey": "TEST_KEY"}];

=> ALTER DATABASE default SET AzureStorageEndpointConfig =
  [{"accountName": "myaccount", "blobEndpoint": "localhost:8080", "protocol": "http"}];
```

The following example creates an external table using data from Azure. The URI specifies an account name of "myaccount".

```
=> CREATE EXTERNAL TABLE users (id INT, name VARCHAR(20))
  AS COPY FROM 'azb://myaccount/mycontainer/my/object/*';
```

Vertica uses `AzureStorageEndpointConfig` and the account name to produce the following location for the files:

```
https://myaccount.blob.core.windows.net/mycontainer/my/object/*
```

Data is accessed using the `REAL_KEY` credential.

If the URI in the `COPY` statement is instead `azb://myaccount.blob.core.windows.net/mycontainer/my/object`, then the resulting location is `https://myaccount.blob.core.windows.net/mycontainer/my/object`, again using the `REAL_KEY` credential.

However, if the URI in the `COPY` statement is `azb://myaccount@localhost:8080/mycontainer/my/object`, then the host and port specify a different endpoint: `http://localhost:8080/myaccount/mycontainer/my/object`. This endpoint is configured to use a different credential, `TEST_KEY`.

Google Cloud Storage (GCS) object store

File system using the Google Cloud Storage platform.

URI format

```
gs://bucket/path
```

Authentication

To access data in Google Cloud Storage (GCS) you must first do the following tasks:

- Create a default project, obtain a developer key, and enable S3 interoperability mode as described in [the GCS documentation](#).
- Set the GCSAuth configuration parameter as in the following example.

```
=> ALTER SESSION SET GCSAuth='id:secret';
```

Configuration parameters

The following database configuration parameters apply to the GCS file system. You can set parameters at different levels with the appropriate ALTER statement, such as [ALTER SESSION...SET PARAMETER](#). Query the [CONFIGURATION_PARAMETERS](#) system table to determine what levels (node, session, user, database) are valid for a given parameter. For information about all parameters related to GCS, see [Google Cloud Storage parameters](#).

For external tables using highly partitioned data in an object store, see the [ObjectStoreGlobStrategy](#) configuration parameter and [Partitions on Object Stores](#).

GCSAuth

An ID and secret key to authenticate to GCS. For extra security, do not store credentials in the database; instead, use [ALTER SESSION...SET PARAMETER](#) to set this value for the current session only.

GCSEnableHttps

Boolean, whether to use the HTTPS protocol when connecting to GCS, can be set only at the database level with [ALTER DATABASE...SET PARAMETER](#).

Default: 1 (enabled)

GCSEndpoint

The connection endpoint address.

Default: [storage.googleapis.com](#)

Examples

The following example loads data from GCS:

```
=> ALTER SESSION SET GCSAuth='my_id:my_secret_key';  
  
=> COPY t FROM 'gs://DataLake/clicks.parquet' PARQUET;
```

HDFS file system

HDFS is the Hadoop Distributed File System. You can use the [webhdfs](#) and [swebhdfs](#) schemes to access data through the WebHDFS service. Vertica also supports the [hdfs](#) scheme, which by default uses WebHDFS. To have [hdfs](#) URIs use the deprecated LibHDFS++ package, set the [HDFSUseWebHDFS](#) configuration parameter to 0 (disabled).

If you specify a [webhdfs](#) URI but the Hadoop HTTP policy ([dfs.http.policy](#)) is set to HTTPS_ONLY, Vertica automatically uses [swebhdfs](#) instead.

If you use LibHDFS++, the WebHDFS service must still be available because Vertica falls back to WebHDFS for operations not supported by LibHDFS++.

Deprecated

Support for LibHDFS++ is deprecated. In the future, HDFSUseWebHDFS will be enabled in all cases and [hdfs](#) URIs will be equivalent to [webhdfs](#) URIs.

URI format

URIs in the [webhdfs](#) , [swebhdfs](#) , and [hdfs](#) schemes all have two formats, depending on whether you specify a name service or the host and port of a name node:

- `[[s]web]hdfs://[nameservice]/ path`
- `[[s]web]hdfs:// namenode-host:port / path`

Characters may be URL-encoded (%NN where NN is a two-digit hexadecimal number) but are not required to be, except that the '%' character must be encoded.

To use the default name service specified in the HDFS configuration files, omit `nameservice`. Use this shorthand only for reading external data, not for creating a storage location.

Always specify a name service or host explicitly when using Vertica with more than one HDFS cluster. The name service or host name must be globally unique. Using `[web]hdfs://` could produce unexpected results because Vertica uses the first value of `fs.defaultFS` that it finds.

Authentication

Vertica can use Kerberos authentication with Cloudera or Hortonworks HDFS clusters. See [Accessing kerberized HDFS data](#).

For loading and exporting data, Vertica can access HDFS clusters protected by mTLS through the `webhdfs` scheme. You must create a certificate and key and set the `WebhdfsClientCertConf` configuration parameter.

You can use [CREATE KEY](#) and [CREATE CERTIFICATE](#) to create temporary, session-scoped values if you specify the `TEMPORARY` keyword. Temporary keys and certificates are stored in memory, not on disk.

The `WebhdfsClientCertConf` configuration parameter holds client credentials for one or more HDFS clusters. The value is a JSON string listing name services or authorities and their corresponding keys. You can set the configuration parameter at the session or database level. Setting the parameter at the database level has the following additional requirements:

- The [UseServerIdentityOverUserIdentity](#) configuration parameter must be set to 1 (true).
- The user must be `dbadmin` or must have access to the user storage location on HDFS.

The following example shows how to use mTLS. The key and certificate values themselves are not shown, just the beginning and end markers:

```
=> CREATE TEMPORARY KEY client_key TYPE 'RSA'
AS '-----BEGIN PRIVATE KEY-----END PRIVATE KEY-----';

-> CREATE TEMPORARY CERTIFICATE client_cert
AS '-----BEGIN CERTIFICATE-----END CERTIFICATE-----' key client_key;

=> ALTER SESSION SET WebhdfsClientCertConf =
'[{ "authority": "my.hdfs.namenode1:50088", "certName": "client_cert" }];

=> COPY people FROM 'webhdfs://my.hdfs.namenode1:50088/path/to/file/1.txt';
Rows Loaded
-----
1
(1 row)
```

To configure access to more than one HDFS cluster, define the keys and certificates and then include one object per cluster in the value of `WebhdfsClientCertConf`:

```
=> ALTER SESSION SET WebhdfsClientCertConf =
'[{ "authority" : "my.authority.com:50070", "certName" : "myCert"},
{ "nameservice" : "prod", "certName" : "prodCert" }];
```

Configuration parameters

The following database configuration parameters apply to the HDFS file system. You can set parameters at different levels with the appropriate `ALTER` statement, such as [ALTER SESSION...SET PARAMETER](#). Query the [CONFIGURATION_PARAMETERS](#) system table to determine what levels (node, session, user, database) are valid for a given parameter. For information about all parameters related to Hadoop, see [Hadoop parameters](#).

EnableHDFSBlockInfoCache

Boolean, whether to distribute block location metadata collected during planning on the initiator to all database nodes for execution, reducing name node contention. Disabled by default.

HadoopConfDir

Directory path containing the XML configuration files copied from Hadoop. The same path must be valid on every Vertica node. The files are accessed by the Linux user under which the Vertica server process runs.

HadoopImpersonationConfig

Session parameter specifying the delegation token or Hadoop user for HDFS access. See [HadoopImpersonationConfig format](#) for information about the value of this parameter and [Proxy users and delegation tokens](#) for more general context.

HDFSUseWebHDFS

Boolean. If true (the default), URIs in the `hdfs` scheme are treated as if they were in the `webhdfs` scheme. If false, Vertica uses LibHDFS++ where possible, though some operations can still use WebHDFS if not supported by LibHDFS++.

WebhdfsClientCertConf

mTLS configurations for accessing one or more WebHDFS servers, a JSON string. Each object must specify either a `nameservice` or `authority` field and a `certName` field. See [Authentication](#).

Configuration files

The path specified in `HadoopConfDir` must include a directory containing the files listed in the following table. Vertica reads these files at database start time. If you do not set a value, Vertica looks for the files in `/etc/hadoop/conf`.

If a property is not defined, Vertica uses the defaults shown in the table. If no default is specified for a property, the configuration files must specify a value.

File	Properties	Default
core-site.xml	<code>fs.defaultFS</code>	none
	(for doAs users:) <code>hadoop.proxyuser.<i>username</i>.users</code>	none
	(for doAs users:) <code>hadoop.proxyuser.<i>username</i>.hosts</code>	none
hdfs-site.xml	<code>dfs.client.failover.max.attempts</code>	15
	<code>dfs.client.failover.sleep.base.millis</code>	500
	<code>dfs.client.failover.sleep.max.millis</code>	15000
	(For HA NN:) <code>dfs.nameservices</code>	none
	(WebHDFS:) <code>dfs.namenode.http-address</code> or <code>dfs.namenode.https-address</code>	none
	(WebHDFS:) <code>dfs.datanode.http.address</code> or <code>dfs.datanode.https.address</code>	none
	(WebHDFS:) <code>dfs.http.policy</code>	HTTP_ONLY

If using High Availability (HA) Name Nodes, the individual name nodes must also be defined in `hdfs-site.xml`.

Note

If you are using Eon Mode with communal storage on HDFS, then if you set `dfs.encrypt.data.transfer` you must use the `swebhdfs` scheme for communal storage.

To verify that Vertica can find configuration files in `HadoopConfDir`, use the [VERIFY_HADOOP_CONF_DIR](#) function.

To test access through the `hdfs` scheme, use the [HDFS_CLUSTER_CONFIG_CHECK](#) function.

For more information about testing your configuration, see [Verifying HDFS configuration](#).

To reread the configuration files, use the [CLEAR_HDFS_CACHES](#) function.

Name nodes and name services

You can access HDFS data using the default name node by not specifying a name node or name service:

```
=> COPY users FROM 'webhdfs:///data/users.csv';
```

Vertica uses the `fs.defaultFS` Hadoop configuration parameter to find the name node. (It then uses that name node to locate the data.) You can instead specify a host and port explicitly using the following format:

```
webhdfs://nn-host:nn-port/
```

The specified host is the name node, not an individual data node. If you are using High Availability (HA) Name Nodes you should not use an explicit host because high availability is provided through name services instead.

If the HDFS cluster uses High Availability Name Nodes or defines name services, use the name service instead of the host and port, in the format `webhdfs://nameservice/`. The name service you specify must be defined in `hdfs-site.xml`.

The following example shows how you can use a name service, `hadoopNS`:

```
=> CREATE EXTERNAL TABLE users (id INT, name VARCHAR(20))
AS COPY FROM 'webhdfs://hadoopNS/data/users.csv';
```

If you are using Vertica to access data from more than one HDFS cluster, always use explicit name services or hosts in the URL. Using the `///` shorthand could produce unexpected results because Vertica uses the first value of `fs.defaultFS` that it finds. To access multiple HDFS clusters, you must use host and service names that are globally unique. See [Configuring HDFS access](#) for more information.

S3 object store

File systems using the S3 protocol, including AWS, Pure Storage, and MinIO.

URI format

```
s3://bucket/path
```

For AWS, specify the region using the `AWSRegion` configuration parameter, not the URI. If the region is incorrect, you might experience a delay before the load fails because Vertica retries several times before giving up. The default region is `us-east-1`.

Authentication

For AWS:

- To access S3 you must create an [IAM role](#) and grant that role permission to access your S3 resources.
- By default, bucket access is restricted to the communal storage bucket. Use an [AWS access key](#) to load data from non-communal storage buckets.
- Either set the `AWSAuth` configuration parameter to provide credentials or create a `USER` storage location for the S3 path (see [CREATE LOCATION](#)) and grant users access.
- You can use AWS STS temporary session tokens to load data. Because they are session tokens, do not use them for access to storage locations.
- You can configure S3 buckets individually with the per-bucket parameters `S3BucketConfig` and `S3BucketCredentials`. For details, see [Per-bucket S3 configurations](#).

Configuration parameters

The following database configuration parameters apply to the S3 file system. You can set parameters at different levels with the appropriate `ALTER` statement, such as [ALTER SESSION...SET PARAMETER](#). Query the [CONFIGURATION_PARAMETERS](#) system table to determine what levels (node, session, user, database) are valid for a given parameter.

You can configure individual buckets using the `S3BucketConfig` and `S3BucketCredentials` parameters instead of the global parameters.

For external tables using highly partitioned data in an object store, see the [ObjectStoreGlobStrategy](#) configuration parameter and [Partitions on Object Stores](#).

The following descriptions are summaries. For details about all parameters specific to S3, see [S3 parameters](#).

AWSAuth

An ID and secret key for authentication. AWS calls these `AccessKeyId` and `SecretAccessKey`. For extra security, do not store credentials in the database; use [ALTER SESSION...SET PARAMETER](#) to set this value for the current session only.

AWSCAFile

The file name of the TLS server certificate bundle to use. You must set a value when installing a CA certificate on a SUSE Linux Enterprise Server.

AWSCAPath

The path Vertica uses to look up TLS server certificates. You must set a value when installing a CA certificate on a SUSE Linux Enterprise Server.

AWSEnableHttps

Boolean, whether to use the HTTPS protocol when connecting to S3. Can be set only at the database level. You can set the protocol for individual buckets using `S3BucketConfig`.

Default: 1 (enabled)

AWSEndpoint

String, the endpoint host for all S3 URLs, set as follows:

- AWS: `hostname_or_IP:port`. Do not include the scheme (http(s)).

- AWS with a FIPS-compliant S3 Endpoint: Hostname of a [FIPS-compliant S3 endpoint](#). You must also enable `S3EnableVirtualAddressing`.
- On-premises/Pure: IP address of the Pure Storage server.

If not set, Vertica uses virtual-hosted request URLs.

Default: 's3.amazonaws.com'

AWSLogLevel

The log level, one of: OFF, FATAL, ERROR, WARN, INFO, DEBUG, or TRACE.

Default: ERROR

AWSRegion

The AWS region containing the S3 bucket from which to read files. This parameter can only be configured with one region at a time. Failure to set the correct region can lead to a delay before queries fail.

Default: 'us-east-1'

AWSSessionToken

A temporary security token generated by running the `get-session-token` command, used to configure multi-factor authentication.

Note

If you use session tokens at the session level, you must set all parameters at the session level, even if some of them are set at the database level.

AWSStreamingConnectionPercentage

In Eon Mode, the number of connections to the communal storage to use for streaming reads. In a cloud environment, this setting helps prevent streaming data from using up all available file handles. This setting is unnecessary when using on-premises object stores because of their lower latency.

S3BucketConfig

A JSON array of objects specifying per-bucket configuration overrides. Each property other than the bucket name has a corresponding configuration parameter (shown in parentheses). If both the database-level parameter and its equivalent in `S3BucketConfig` are set, the value in `S3BucketConfig` takes precedence.

Properties:

- `bucket` : Bucket name
- `region` (AWSRegion)
- `protocol` (AWSEnableHttp): Connection protocol, one of `http` or `https`
- `endpoint` (AWSEndpoint)
- `enableVirtualAddressing` (S3BucketCredentials): Boolean, whether to rewrite the S3 URL to use a virtual hosted path
- `requesterPays` (S3RequesterPays)
- `serverSideEncryption` (S3ServerSideEncryption)
- `sseCustomerAlgorithm` (S3SseCustomerAlgorithm)
- `sseCustomerKey` (S3SseCustomerKey)
- `sseKmsKeyId` (S3SseKmsKeyId)
- `proxy` (S3Proxy)

S3BucketCredentials

A JSON object specifying per-bucket credentials. Each property other than the bucket name has a corresponding configuration parameter. If both the database-level parameter and its equivalent in `S3BucketCredentials` are set, the value in `S3BucketCredentials` takes precedence.

Properties:

- `bucket` : Bucket name
- `accessKey` : Access key for the bucket (the `ID` in AWSAuth)
- `secretAccessKey` : Secret access key for the bucket (the `secret` in AWSAuth)
- `sessionToken` : Session token, only used when `S3BucketCredentials` is set at the session level (`AWSSessionToken`)

This parameter is only visible to superusers. Users can set this parameter at the session level with [ALTER SESSION](#).

S3EnableVirtualAddressing

Boolean, whether to rewrite S3 URLs to use virtual-hosted paths (disabled by default). This configuration setting takes effect only when you have specified a value for `AWSEndpoint`.

If you set `AWSEndpoint` to a [FIPS-compliant S3 endpoint](#), you must enable `S3EnableVirtualAddressing`. The value of this parameter does not affect how you specify S3 paths.

S3Proxy

HTTP(S) proxy settings, if needed, a string in the following format: `http[s]://[user:password@]host[:port]`.

S3RequesterPays

Boolean, whether requester (instead of bucket owner) pays the cost of accessing data on the bucket.

S3ServerSideEncryption

String, encryption algorithm to use when reading or writing to S3. Supported values are `AES256` (for SSE-S3), `aws:kms` (for SSE-KMS), and an empty string (for no encryption). See [Server-Side Encryption](#).

Default: "" (no encryption)

S3SseCustomerAlgorithm

String, the encryption algorithm to use when reading or writing to S3 using SSE-C encryption. The only supported values are `AES256` and "". For SSE-S3 and SSE-KMS, instead use `S3ServerSideEncryption`.

Default: "" (no encryption)

S3SseCustomerKey

If using SSE-C encryption, the client key for S3 access.

S3SseKmsKeyId

If using SSE-KMS encryption, the key identifier (not the key) to pass to the Key Management Service. Vertica must have permission to use the key, which is managed through KMS.

Write performance

By default, Vertica performs writes using a single thread, but a single write usually includes multiple files or parts of files. For writes to S3, you can use a larger thread pool to perform writes in parallel. This thread pool is used for all file writes to S3, including file exports and writes to communal storage.

The size of the thread pool is controlled by the [ObjStoreUploadParallelism](#) configuration parameter. Each node has a single thread pool used for all file writes. In general, one or two threads per concurrent writer produces good results.

Server-side encryption

By default, Vertica reads and writes S3 data that is not encrypted. If the S3 bucket uses server-side encryption (SSE), you can configure Vertica to access it. S3 supports three types of server-side encryption: SSE-S3, SSE-KMS, and SSE-C.

Vertica must also have read or write permissions (depending on the operation) on the bucket.

SSE-S3

With SSE-S3, the S3 service manages encryption keys. Reads do not require additional configuration. To write to S3, the client (Vertica, in this case) must specify only the encryption algorithm.

If the S3 bucket is configured with the default encryption settings, Vertica can read and write data to them with no further changes. If the bucket does not use the default encryption settings, set the `S3ServerSideEncryption` configuration parameter or the `serverSideEncryption` field in `S3BucketConfig` to `AES256`.

SSE-KMS

With SSE-KMS, encryption keys are managed by the Key Management Service (KMS). The client must supply a KMS key identifier (not the actual key) when writing data. For all operations, the client must have permission to use the KMS key. These permissions are managed in KMS, not in Vertica.

To use SSE-KMS:

- Set the `S3ServerSideEncryption` configuration parameter or the `serverSideEncryption` field in `S3BucketConfig` to `aws:kms`.
- Set the `S3SseKmsKeyId` configuration parameter or the `sseKmsKeyId` field in `S3BucketConfig` to the key ID.

SSE-C

With SSE-C, the client manages encryption keys and provides them to S3 for each operation.

To use SSE-C:

- Set the `S3SseCustomerAlgorithm` configuration parameter or the `sseCustomerAlgorithm` field in `S3BucketConfig` to `AES256`.
- Set the `S3SseCustomerKey` configuration parameter or the `sseCustomerKey` field in `S3BucketConfig` to the access key. The value can be either a 32-character plaintext key or a 44-character base64-encoded key.

HTTP(S) logging (AWS)

When a request to AWS fails or is retried, or Vertica detects a performance degradation, Vertica logs the event in the [UDFS_EVENTS](#) system table. The event type for these records is `HttpRequestAttempt`, and the description is a JSON object with more details. For example:

```
-> SELECT filesystem, event, description FROM UDFS_EVENTS;
filesystem | event | description
-----
S3 | HttpRequestAttempt | [{"AttemptStartTimeGMT":"2024-01-18 16:45:52.663","RetryCount":0,"HttpMethod":"GET","URIString":"s3://mybucket/s3_2.d...
S3 | HttpRequestAttempt | [{"AttemptStartTimeGMT":"2024-01-18 16:46:02.663","RetryCount":1,"HttpMethod":"GET","URIString":"s3://mybucket/s3_2.d...
(2 rows)
```

To extract fields from this description, use the [MAPJSONEXTRACTOR](#) function:

```
-> SELECT filesystem, event,
       (Map.JSONExtractor(description))["RetryCount"] as RetryCount,
       (Map.JSONExtractor(description))["HttpStatusCode"] as HttpStatusCode
FROM UDFS_EVENTS;
filesystem | event | RetryCount | HttpStatusCode
-----
S3 | HttpRequestAttempt | 0 | 404
S3 | HttpRequestAttempt | 1 | 206
(2 rows)
```

For details on AWS-specific fields such as `AmzRequestId`, see the [AWS documentation](#).

The [UDFS_STATISTICS](#) system table records the accumulated duration for all HTTP requests in the `TOTAL_REQUEST_DURATION_MS` column. This table also provides computed values for average duration and throughput.

Examples

The following example sets a database-wide AWS region and credentials:

```
-> ALTER DATABASE DEFAULT SET AWSRegion='us-west-1';
-> ALTER DATABASE DEFAULT SET AWSAuth = 'myaccesskeyid123456:mysecretaccesskey123456789012345678901234';
```

The following example loads data from S3. You can use a glob if all files in the glob can be loaded together. In the following example, `AWS_DataLake` contains only ORC files.

```
-> COPY I FROM 's3://datalake/' ORC;
```

You can specify a list of comma-separated S3 buckets as in the following example. All buckets must be in the same region. To load from more than one region, use separate COPY statements and change the value of `AWSRegion` between calls.

```
-> COPY I FROM 's3://AWS_Data_1/sales.parquet', 's3://AWS_Data_2/sales.parquet' PARQUET;
```

The following example creates a user storage location and a role, so that users without their own S3 credentials can read data from S3 using the server credential.

```
-- set database-level credential (once);
-> ALTER DATABASE DEFAULT SET AWSAuth = 'myaccesskeyid123456:mysecretaccesskey123456789012345678901234';
-> CREATE LOCATION 's3://datalake' SHARED USAGE 'USER' LABEL 's3user';
-> CREATE ROLE ExtUsers;
-- Assign users to this role using GRANT (Role);
-> GRANT READ ON LOCATION 's3://datalake' TO ExtUsers;
```

The configuration properties for a given bucket may differ based on its type. The following `S3BucketConfig` setting is for an `AWSBucket` (`AWSBucket`) and a `PureStorageBucket` (`PureStorageBucket`). `AWSBucket` doesn't specify an endpoint, so Vertica uses the `AWSEndpoint` configuration parameter, which defaults to `s3.amazonaws.com` :

```
=> ALTER DATABASE DEFAULT SET S3BucketConfig=
```

```
{  
  {  
    "bucket": "AWSBucket",  
    "region": "us-east-2",  
    "protocol": "https",  
    "requesterPays": true,  
    "serverSideEncryption": "aes256"  
  },  
  {  
    "bucket": "PureStorageBucket",  
    "endpoint": "pure.mycorp.net:1234",  
    "protocol": "http",  
    "enableVirtualAddressing": false  
  }  
};
```

The following example sets S3BucketCredentials for these two buckets:

```
=> ALTER SESSION SET S3BucketCredentials=
```

```
{  
  {  
    "bucket": "AWSBucket",  
    "accessKey": "<AK0>",  
    "secretAccessKey": "<SAK0>",  
    "sessionToken": "1234567890"  
  },  
  {  
    "bucket": "PureStorageBucket",  
    "accessKey": "<AK1>",  
    "secretAccessKey": "<SAK1>"  
  }  
};
```

The following example sets an STS temporary session token. Vertica uses the session token to access S3 with the specified credentials and bypasses checking for a USER storage location.

```
$ aws sts get-session-token
```

```
{  
  "Credentials": {  
    "AccessKeyId": "ASIAJZQNDV5727EHDHOQ",  
    "SecretAccessKey": "F+xnpkHbst6UPorlGj/iJhO5J2n3Yo7Mp4vYvd",  
    "SessionToken": "FOoDYXdzEKv////////wEaDMWKxakEkGyuDH0UjyKsAe6/3REgW5VbWtpuYyVvSnEK1jzGPHI/jPOPNT7Kd+ftSnD3qdaQ7j28SUW9Y",  
    "Expiration": "2018-07-18T05:56:33Z"  
  }  
}
```

```
$ vsql
```

```
=> ALTER SESSION SET AWSSAuth = 'ASIAJZQNDV5727EHDHOQ:F+xnpkHbst6UPorlGj/iJhO5J2n3Yo7Mp4vYvd';
```

```
=> ALTER SESSION SET AWSSessionToken = 'FOoDYXdzEKv////////wEaDMWKxakEkGyuDH0UjyKsAe6/3REgW5VbWtpuYyVvSnEK1jzGPHI/jPOPNT7Kd';
```

[Per-Bucket S3 Configurations](#)

In this section

- [Per-bucket S3 configurations](#)

Per-bucket S3 configurations

You can manage configurations and credentials for individual buckets with the S3BucketConfig and S3BucketCredentials configuration parameters. These parameters each take a JSON object, whose respective properties behave like the related S3 configuration parameters.

For example, you can create a different configuration for each of your S3 buckets by setting `S3BucketConfig` at the database level with [ALTER DATABASE](#). The following `S3BucketConfig` specifies several common bucket properties:

```
-> ALTER DATABASE DEFAULT SET S3BucketConfig=  
{  
  "bucket": "exampleAWS",  
  "region": "us-east-2",  
  "protocol": "https",  
  "requesterPays": true  
},  
{  
  "bucket": "examplePureStorage",  
  "endpoint": "pure.mycorp.net:1234",  
  "protocol": "http",  
  "enableVirtualAddressing": false  
}  
;
```

Users can then access a bucket by setting `S3BucketCredentials` at the session level with [ALTER SESSION](#). The following `S3BucketCredentials` specifies all properties and authenticates to both `exampleAWS` and `examplePureStorage` simultaneously:

```
-> ALTER SESSION SET S3BucketCredentials=  
{  
  "bucket": "exampleAWS",  
  "accessKey": "<AK0>",  
  "secretAccessKey": "<SAK0>",  
  "sessionToken": "1234567890"  
},  
{  
  "bucket": "examplePureStorage",  
  "accessKey": "<AK1>",  
  "secretAccessKey": "<SAK1>"  
}  
;
```

Recommended usage

The recommended usage is as follows:

- Define in your S3 storage system one set of credentials per principal, per storage system.
- It is often most convenient to set `S3BucketConfig` once at the database level and have users authenticate by setting `S3BucketCredentials` at the session level.
- To access buckets outside those configured at the database level, set both `S3BucketConfig` and `S3BucketCredentials` at the session level.

If you cannot define credentials for your S3 storage, you can set `S3BucketCredentials` or `AWSAuth` at the database level with [ALTER DATABASE](#), but this comes with certain drawbacks:

- Storing credentials statically in another location (in this case, in the Vertica catalog) always incurs additional risk.
- This increases overhead for the dbadmin, who needs to create user storage locations and grant access to each user or role.
- Users share one set of credentials, increasing the potential impact if the credentials are compromised.

Note

If you set `AWSEndpoint` to a non-Amazon S3 storage system like Pure Storage or MinIO and you want to configure `S3BucketConfig` for real Amazon S3, the following requirements apply:

- If your real Amazon S3 region is not `us-east-1` (the default), you must specify the `region`.
- Set `endpoint` to an empty string (`""`).

```
=> ALTER DATABASE DEFAULT SET S3BucketConfig='
{
  "bucket": "additionalAWSBucket",
  "region": "us-east-2",
  "endpoint": ""
}
';
```

Precedence of per-bucket and standard parameters

Vertica uses the following rules to determine the effective set of properties for an S3 connection:

- If set, `S3BucketCredentials` takes priority over its standard parameters. `S3BucketCredentials` is checked first at the session level and then at the database level.
- The level/source of the S3 credential parameters determines the source of the S3 configuration parameters:
 - If credentials come from the session level, then the configuration can come from either the session or database level (with the session level taking priority).
 - If your credentials come from the database level, then the configuration can only come from the database level.
- If `S3BucketConfig` is set, it takes priority over its standard parameters. If an `S3BucketConfig` property isn't specified, Vertica falls back to the missing property's equivalent parameter. For example, if `S3BucketConfig` specifies every property except `protocol`, Vertica falls back to the standard parameter `AWSEnableHttps`.

Examples

Multiple buckets

This example configures a real Amazon S3 bucket `AWSBucket` and a Pure Storage bucket `PureStorageBucket` with `S3BucketConfig`.

`AWSBucket` does not specify an `endpoint` or protocol, so Vertica falls back to `AWSEndpoint` (defaults to `s3.amazonaws.com`) and `AWSEnableHttps` (defaults to `1`).

In this example environment, access to the `PureStorageBucket` is over a secure network, so HTTPS is disabled:

```
=> ALTER DATABASE DEFAULT SET S3BucketConfig='
{
  "bucket": "AWSBucket",
  "region": "us-east-2"
},
{
  "bucket": "PureStorageBucket",
  "endpoint": "pure.mycorp.net:1234",
  "protocol": "http",
  "enableVirtualAddressing": false
}
';
```

Bob can then set `S3BucketCredentials` at the session level to authenticate to `AWSBucket`:

```
=> ALTER SESSION SET S3BucketCredentials='
{
  "bucket": "AWSBucket",
  "accessKey": "<AK0>",
  "secretAccessKey": "<SAK0>",
  "sessionToken": "1234567890"
}
';
```

Similarly, Alice can authenticate to `PureStorageBucket`:

```
-> ALTER SESSION SET S3BucketCredentials=
```

```
{
  "bucket": "PureStorageBucket",
  "accessKey": "<AK1>",
  "secretAccessKey": "<SAK1>"
}
```

Charlie provides credentials for both **AWSBucket** and **PureStorageBucket** and authenticates to them simultaneously. This allows him to perform cross-endpoint joins, export from one bucket to another, etc.

```
-> ALTER SESSION SET S3BucketCredentials=
```

```
{
  "bucket": "AWSBucket",
  "accessKey": "<AK0>",
  "secretAccessKey": "<SAK0>",
  "sessionToken": "1234567890"
},
{
  "bucket": "PureStorageBucket",
  "accessKey": "<AK1>",
  "secretAccessKey": "<SAK1>"
}
```

S3 server-side encryption

S3 has three types of server-side encryption: SSE-S3, SSE-KMS, and SSE-C. The following example configures access using SSE-KMS:

```
-> ALTER DATABASE DEFAULT SET S3BucketConfig=
```

```
{
  "bucket": "AWSBucket",
  "region": "us-east-2",
  "serverSideEncryption": "aws:kms",
  "sseKmsKeyId": "1234abcd-12ab-34cd-56ef-1234567890ab"
}
```

For more information, see [Server-Side Encryption](#).

Non-amazon S3 storage with AWSEndpoint and S3BucketConfig

If **AWSEndpoint** is set to a non-Amazon S3 bucket like Pure Storage or MinIO and you want to configure **S3BucketConfig** for a real Amazon S3 bucket, the following requirements apply:

- If your real Amazon S3 region is not **us-east-1** (the default), you must specify the **region**.
- Set **endpoint** to an empty string ("").

In this example, **AWSEndpoint** is set to a Pure Storage bucket.

```
-> ALTER DATABASE DEFAULT SET AWSEndpoint=pure.mycorp.net:1234;
```

To configure **S3BucketConfig** for a real Amazon S3 bucket **realAmazonS3Bucket** in region " **us-east-2** ":

```
-> ALTER DATABASE DEFAULT SET S3BucketConfig=
```

```
{
  "bucket": "realAmazonS3Bucket",
  "region": "us-east-2",
  "endpoint": ""
}
```

Functions

Functions return information from the database. This section describes functions that Vertica supports. Except for meta-functions, you can use a function anywhere an expression is allowed.

Meta-functions usually access the internal state of Vertica. They can be used in a top-level SELECT statement only, and the statement cannot contain other clauses such as FROM or WHERE. Meta-functions are labeled on their reference pages.

The Behavior Type section on each reference page categorizes the function's return behavior as one or more of the following:

- **Immutable** (invariant): When run with a given set of arguments, immutable functions always produce the same result, regardless of environment or session settings such as locale.
- **Stable** : When run with a given set of arguments, stable functions produce the same result within a single query or scan operation. However, a stable function can produce different results when issued under different environments or at different times, such as change of locale and time zone—for example, [SYSDATE](#).
- **Volatile** : Regardless of their arguments or environment, volatile functions can return a different result with each invocation—for example, [UUID_GENERATE](#).

List of all functions

The following list contains all Vertica SQL functions.

Jump to letter: [A](#) - [B](#) - [C](#) - [D](#) - [E](#) - [F](#) - [G](#) - [H](#) - [I](#) - [J](#) - [K](#) - [L](#) - [M](#) - [N](#) - [O](#) - [P](#) - [Q](#) - [R](#) - [S](#) - [T](#) - [U](#) - [V](#) - [W](#) - [X](#) - [Y](#) - [Z](#)

A

[ABS](#)

Returns the absolute value of the argument. [[Mathematical functions](#)]

[ACOS](#)

Returns a DOUBLE PRECISION value representing the trigonometric inverse cosine of the argument. [[Mathematical functions](#)]

[ACOSH](#)

Returns a DOUBLE PRECISION value that represents the inverse (arc) hyperbolic cosine of the function argument. [[Mathematical functions](#)]

[ACTIVE_SCHEDULER_NODE](#)

Returns the active scheduler node. [[Stored procedure functions](#)]

[ADD_MONTHS](#)

Adds the specified number of months to a date and returns the sum as a DATE. [[Date/time functions](#)]

[ADVANCE_EPOCH](#)

Manually closes the current epoch and begins a new epoch. [[Epoch functions](#)]

[AGE_IN_MONTHS](#)

Returns the difference in months between two dates, expressed as an integer. [[Date/time functions](#)]

[AGE_IN_YEARS](#)

Returns the difference in years between two dates, expressed as an integer. [[Date/time functions](#)]

[ALTER_LOCATION_LABEL](#)

Adds a label to a storage location, or changes or removes an existing label. [[Storage functions](#)]

[ALTER_LOCATION_SIZE](#)

Resizes on one node, all nodes in a subcluster, or all nodes in the database. [[Eon Mode functions](#)]

[ALTER_LOCATION_USE](#)

Alters the type of data that a storage location holds. [[Storage functions](#)]

[ANALYZE_CONSTRAINTS](#)

Analyzes and reports on constraint violations within the specified scope. [[Table functions](#)]

[ANALYZE_CORRELATIONS](#)

This function is deprecated and will be removed in a future release. [[Table functions](#)]

[ANALYZE_EXTERNAL_ROW_COUNT](#)

Calculates the exact number of rows in an external table. [[Statistics management functions](#)]

[ANALYZE_STATISTICS](#)

Collects and aggregates data samples and storage information from all nodes that store projections associated with the specified table. [[Statistics management functions](#)]

[ANALYZE_STATISTICS_PARTITION](#)

Collects and aggregates data samples and storage information for a range of partitions in the specified table. [[Statistics management functions](#)]

[ANALYZE_WORKLOAD](#)

Runs Workload Analyzer, a utility that analyzes system information held in system tables. [[Workload management functions](#)]

[APPLY_AVG](#)

Returns the average of all elements in a with numeric values. [[Collection functions](#)]

[APPLY_BISECTING_KMEANS](#)

Applies a trained bisecting k-means model to an input relation, and assigns each new data point to the closest matching cluster in the trained model. [[Transformation functions](#)]

[APPLY_COUNT \(ARRAY_COUNT\)](#)

Returns the total number of non-null elements in a. [[Collection functions](#)]

[APPLY_COUNT_ELEMENTS \(ARRAY_LENGTH\)](#)

Returns the total number of elements in a , including NULLs. [[Collection functions](#)]

[APPLY_IFOREST](#)

Applies an isolation forest (iForest) model to an input relation. [[Transformation functions](#)]

[APPLY_INVERSE_PCA](#)

Inverts the APPLY_PCA-generated transform back to the original coordinate system. [[Transformation functions](#)]

[APPLY_INVERSE_SVD](#)

Transforms the data back to the original domain. [[Transformation functions](#)]

[APPLY_KMEANS](#)

Assigns each row of an input relation to a cluster center from an existing k-means model. [[Transformation functions](#)]

[APPLY_KPROTOTYPES](#)

Assigns each row of an input relation to a cluster center from an existing k-prototypes model. [[Transformation functions](#)]

[APPLY_MAX](#)

Returns the largest non-null element in a. [[Collection functions](#)]

[APPLY_MIN](#)

Returns the smallest non-null element in a. [[Collection functions](#)]

[APPLY_NORMALIZE](#)

A UDTF function that applies the normalization parameters saved in a model to a set of specified input columns. [[Transformation functions](#)]

[APPLY_ONE_HOT_ENCODER](#)

A user-defined transform function (UDTF) that loads the one hot encoder model and writes out a table that contains the encoded columns. [[Transformation functions](#)]

[APPLY_PCA](#)

Transforms the data using a PCA model. [[Transformation functions](#)]

[APPLY_SUM](#)

Computes the sum of all elements in a of numeric values (INTEGER, FLOAT, NUMERIC, or INTERVAL). [[Collection functions](#)]

[APPLY_SVD](#)

Transforms the data using an SVD model. [[Transformation functions](#)]

[APPROXIMATE_COUNT_DISTINCT](#)

Returns the number of distinct non-NULL values in a data set. [[Aggregate functions](#)]

[APPROXIMATE_COUNT_DISTINCT_OF_SYNOPSIS](#)

Calculates the number of distinct non-NULL values from the synopsis objects created by APPROXIMATE_COUNT_DISTINCT_SYNOPSIS. [[Aggregate functions](#)]

[APPROXIMATE_COUNT_DISTINCT_SYNOPSIS](#)

Summarizes the information of distinct non-NULL values and materializes the result set in a VARBINARY or LONG VARBINARY synopsis object. [[Aggregate functions](#)]

[APPROXIMATE_COUNT_DISTINCT_SYNOPSIS_MERGE](#)

Aggregates multiple synopses into one new synopsis. [[Aggregate functions](#)]

[APPROXIMATE_MEDIAN \[aggregate\]](#)

Computes the approximate median of an expression over a group of rows. [[Aggregate functions](#)]

[APPROXIMATE_PERCENTILE \[aggregate\]](#)

Computes the approximate percentile of an expression over a group of rows. [[Aggregate functions](#)]

[APPROXIMATE_QUANTILES](#)

Computes an array of weighted, approximate percentiles of a column within some user-specified error. [[Aggregate functions](#)]

[ARGMAX \[analytic\]](#)

This function is patterned after the mathematical function $\operatorname{argmax}(f(x))$, which returns the value of x that maximizes $f(x)$. [[Analytic functions](#)]

[ARGMAX_AGG](#)

Takes two arguments `target` and `arg`, where both are columns or column expressions in the queried dataset. [[Aggregate functions](#)]

[ARGMIN \[analytic\]](#)

This function is patterned after the mathematical function $\operatorname{argmin}(f(x))$, which returns the value of x that minimizes $f(x)$. [[Analytic functions](#)]

[ARGMIN_AGG](#)

Takes two arguments `target` and `arg`, where both are columns or column expressions in the queried dataset. [[Aggregate functions](#)]

[ARIMA](#)

Creates and trains an autoregressive integrated moving average (ARIMA) model from a time series with consistent timesteps. [[Machine learning algorithms](#)]

[ARRAY_CAT](#)

Concatenates two arrays of the same element type and dimensionality. [[Collection functions](#)]

[ARRAY_CONTAINS](#)

Returns true if the specified element is found in the array and false if not. [[Collection functions](#)]

[ARRAY_DIMS](#)

Returns the dimensionality of the input array. [[Collection functions](#)]

[ARRAY_FIND](#)

Returns the ordinal position of a specified element in an array, or -1 if not found. [[Collection functions](#)]

[ASCII](#)

Converts the first character of a VARCHAR datatype to an INTEGER. [[String functions](#)]

[ASIN](#)

Returns a DOUBLE PRECISION value representing the trigonometric inverse sine of the argument. [[Mathematical functions](#)]

[ASINH](#)

Returns a DOUBLE PRECISION value that represents the inverse (arc) hyperbolic sine of the function argument. [[Mathematical functions](#)]

[ATAN](#)

Returns a DOUBLE PRECISION value representing the trigonometric inverse tangent of the argument. [[Mathematical functions](#)]

[ATAN2](#)

Returns a DOUBLE PRECISION value representing the trigonometric inverse tangent of the arithmetic dividend of the arguments. [[Mathematical functions](#)]

[ATANH](#)

Returns a DOUBLE PRECISION value that represents the inverse hyperbolic tangent of the function argument. [[Mathematical functions](#)]

[AUDIT](#)

Returns the raw data size (in bytes) of a database, schema, or table as it is counted in an audit of the database size. [[License functions](#)]

[AUDIT_FLEX](#)

Returns the estimated ROS size of `__raw__` columns, equivalent to the export size of the flex data in the audited objects. [[License functions](#)]

[AUDIT_LICENSE_SIZE](#)

Triggers an immediate audit of the database size to determine if it is in compliance with the raw data storage allowance included in your Vertica licenses. [[License functions](#)]

[AUDIT_LICENSE_TERM](#)

Triggers an immediate audit to determine if the Vertica license has expired. [[License functions](#)]

[AUTOREGRESSOR](#)

Creates an autoregressive (AR) model from a stationary time series with consistent timesteps that can then be used for prediction via `PREDICT_AR`. [[Machine learning algorithms](#)]

[AVG \[aggregate\]](#)

Computes the average (arithmetic mean) of an expression over a group of rows. [[Aggregate functions](#)]

[AVG \[analytic\]](#)

Computes an average of an expression in a group within a. [[Analytic functions](#)]

[AZURE_TOKEN_CACHE_CLEAR](#)

Clears the cached access token for Azure. [[Cloud functions](#)]

B

[BACKGROUND_DEPOT_WARMING](#)

Vertica version 10.0.0 removes support for foreground depot warming. [[Eon Mode functions](#)]

[BALANCE](#)

Returns a view with an equal distribution of the input data based on the response_column. [[Data preparation](#)]

[BISECTING_KMEANS](#)

Executes the bisecting k-means algorithm on an input relation. [[Machine learning algorithms](#)]

[BIT_AND](#)

Takes the bitwise AND of all non-null input values. [[Aggregate functions](#)]

[BIT_LENGTH](#)

Returns the length of the string expression in bits (bytes * 8) as an INTEGER. [[String functions](#)]

[BIT_OR](#)

Takes the bitwise OR of all non-null input values. [[Aggregate functions](#)]

[BIT_XOR](#)

Takes the bitwise XOR of all non-null input values. [[Aggregate functions](#)]

[BITCOUNT](#)

Returns the number of one-bits (sometimes referred to as set-bits) in the given VARBINARY value. [[String functions](#)]

[BITSTRING_TO_BINARY](#)

Translates the given VARCHAR bitstring representation into a VARBINARY value. [[String functions](#)]

[BOOL_AND \[aggregate\]](#)

Processes Boolean values and returns a Boolean value result. [[Aggregate functions](#)]

[BOOL_AND \[analytic\]](#)

Returns the Boolean value of an expression within a. [[Analytic functions](#)]

[BOOL_OR \[aggregate\]](#)

Processes Boolean values and returns a Boolean value result. [[Aggregate functions](#)]

[BOOL_OR \[analytic\]](#)

Returns the Boolean value of an expression within a. [[Analytic functions](#)]

[BOOL_XOR \[aggregate\]](#)

Processes Boolean values and returns a Boolean value result. [[Aggregate functions](#)]

[BOOL_XOR \[analytic\]](#)

Returns the Boolean value of an expression within a. [[Analytic functions](#)]

[BTRIM](#)

Removes the longest string consisting only of specified characters from the start and end of a string. [[String functions](#)]

[BUILD_FLEXTABLE_VIEW](#)

Creates, or re-creates, a view for a default or user-defined keys table, ignoring any empty keys. [[Flex data functions](#)]

C

[CALENDAR_HIERARCHY_DAY](#)

Groups DATE partition keys into a hierarchy of years, months, and days. [[Partition functions](#)]

[CANCEL_DEPOT_WARMING](#)

Cancels depot warming on a node. [[Eon Mode functions](#)]

[CANCEL_DRAIN_SUBCLUSTER](#)

Cancels the draining of a subcluster or subclusters. [[Eon Mode functions](#)]

[CANCEL_REBALANCE_CLUSTER](#)

Stops any rebalance task that is currently in progress or is waiting to execute. [[Cluster functions](#)]

[CANCEL_REFRESH](#)

Cancels refresh-related internal operations initiated by START_REFRESH and REFRESH. [[Session functions](#)]

[CBRT](#)

Returns the cube root of the argument. [[Mathematical functions](#)]

[CEILING](#)

Rounds up the returned value up to the next whole number. [[Mathematical functions](#)]

[CHANGE_CURRENT_STATEMENT_RUNTIME_PRIORITY](#)

Changes the run-time priority of an active query. [[Workload management functions](#)]

[CHANGE_MODEL_STATUS](#)

Changes the status of a registered model. [[Model management](#)]

[CHANGE_RUNTIME_PRIORITY](#)

Changes the run-time priority of a query that is actively running. [[Workload management functions](#)]

[CHARACTER_LENGTH](#)

The CHARACTER_LENGTH() function:. [[String functions](#)]

[CHI_SQUARED](#)

Computes the conditional chi-Square independence test on two categorical variables to find the likelihood that the two variables are independent. [[Data preparation](#)]

[CHR](#)

Converts the first character of an INTEGER datatype to a VARCHAR. [[String functions](#)]

[CLEAN_COMMUNAL_STORAGE](#)

Marks for deletion invalid data in communal storage, often data that leaked due to an event where Vertica cleanup mechanisms failed. [[Eon Mode functions](#)]

[CLEAR_CACHES](#)

Clears the Vertica internal cache files. [[Storage functions](#)]

[CLEAR_DATA_COLLECTOR](#)

Clears all memory and disk records from Data Collector tables and logs, and resets collection statistics in system table DATA_COLLECTOR. [[Data Collector functions](#)]

[CLEAR_DATA_DEPOT](#)

Deletes the specified depot data. [[Eon Mode functions](#)]

[CLEAR_DEPOT_ANTI_PIN_POLICY_PARTITION](#)

Removes an anti-pinning policy from the specified partition. [[Eon Mode functions](#)]

[CLEAR_DEPOT_ANTI_PIN_POLICY_PROJECTION](#)

Removes an anti-pinning policy from the specified projection. [[Eon Mode functions](#)]

[CLEAR_DEPOT_ANTI_PIN_POLICY_TABLE](#)

Removes an anti-pinning policy from the specified table. [[Eon Mode functions](#)]

[CLEAR_DEPOT_PIN_POLICY_PARTITION](#)

Clears a depot pinning policy from the specified table or projection partitions. [[Eon Mode functions](#)]

[CLEAR_DEPOT_PIN_POLICY_PROJECTION](#)

Clears a depot pinning policy from the specified projection. [[Eon Mode functions](#)]

[CLEAR_DEPOT_PIN_POLICY_TABLE](#)

Clears a depot pinning policy from the specified table. [[Eon Mode functions](#)]

[CLEAR_DIRECTED_QUERY_USAGE](#)

Resets the counter in the DIRECTED_QUERY_STATUS table. [[Directed queries functions](#)]

[CLEAR_FETCH_QUEUE](#)

Removes all entries or entries for a specific transaction from the queue of fetch requests of data from the communal storage. [[Eon Mode functions](#)]

[CLEAR_HDFS_CACHES](#)

Clears the configuration information copied from HDFS and any cached connections. [[Hadoop functions](#)]

[CLEAR_OBJECT_STORAGE_POLICY](#)

Removes a user-defined storage policy from the specified database, schema or table. [[Storage functions](#)]

[CLEAR_PROFILING](#)

Clears from memory data for the specified profiling type. [[Profiling functions](#)]

[CLEAR_PROJECTION_REFRESHES](#)

Clears information projection refresh history from system table PROJECTION_REFRESHES. [[Projection functions](#)]

[CLEAR_RESOURCE_REJECTIONS](#)

Clears the content of the RESOURCE_REJECTIONS and DISK_RESOURCE_REJECTIONS system tables. [[Database functions](#)]

[CLOCK_TIMESTAMP](#)

Returns a value of type TIMESTAMP WITH TIMEZONE that represents the current system-clock time. [[Date/time functions](#)]

[CLOSE_ALL_RESULTSETS](#)

Closes all result set sessions within Multiple Active Result Sets (MARS) and frees the MARS storage for other result sets. [[Client connection functions](#)]

[CLOSE_ALL_SESSIONS](#)

Closes all external sessions except the one that issues this function. [[Session functions](#)]

[CLOSE_RESULTSET](#)

Closes a specific result set within Multiple Active Result Sets (MARS) and frees the MARS storage for other result sets. [[Client connection functions](#)]

[CLOSE_SESSION](#)

Interrupts the specified external session, rolls back the current transaction if any, and closes the socket. [[Session functions](#)]

[CLOSE_USER_SESSIONS](#)

Stops the session for a user, rolls back any transaction currently running, and closes the connection. [[Session functions](#)]

[COALESCE](#)

Returns the value of the first non-null expression in the list. [[NULL-handling functions](#)]

[COLLATION](#)

Applies a collation to two or more strings. [[String functions](#)]

[COMPACT_STORAGE](#)

Bundles existing data (.fdb) and index (.pidx) files into the .gt file format. [[Database functions](#)]

[COMPUTE_FLEXTABLE_KEYS](#)

Computes the virtual columns (keys and values) from flex table VMap data. [[Flex data functions](#)]

[COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW](#)

Combines the functionality of BUILD_FLEXTABLE_VIEW and COMPUTE_FLEXTABLE_KEYS to compute virtual columns (keys) from the VMap data of a flex table and construct a view. [[Flex data functions](#)]

[CONCAT](#)

Concatenates two strings and returns a varchar data type. [[String functions](#)]

[CONDITIONAL_CHANGE_EVENT](#) [analytic]

Assigns an event window number to each row, starting from 0, and increments by 1 when the result of evaluating the argument expression on the current row differs from that on the previous row. [[Analytic functions](#)]

[CONDITIONAL_TRUE_EVENT](#) [analytic]

Assigns an event window number to each row, starting from 0, and increments the number by 1 when the result of the boolean argument expression evaluates true. [[Analytic functions](#)]

[CONFUSION_MATRIX](#)

Computes the confusion matrix of a table with observed and predicted values of a response variable. [[Model evaluation](#)]

[CONTAINS](#)

Returns true if the specified element is found in the collection and false if not. [[Collection functions](#)]

[COPY_PARTITIONS_TO_TABLE](#)

Copies partitions from one table to another. [[Partition functions](#)]

[COPY_TABLE](#)

Copies one table to another. [[Table functions](#)]

[CORR](#)

Returns the DOUBLE PRECISION coefficient of correlation of a set of expression pairs, as per the Pearson correlation coefficient. [[Aggregate functions](#)]

[CORR_MATRIX](#)

Takes an input relation with numeric columns, and calculates the Pearson Correlation Coefficient between each pair of its input columns. [[Data preparation](#)]

[COS](#)

Returns a DOUBLE PRECISION value that represents the trigonometric cosine of the passed parameter. [[Mathematical functions](#)]

[COSH](#)

Returns a DOUBLE PRECISION value that represents the hyperbolic cosine of the passed parameter. [[Mathematical functions](#)]

[COT](#)

Returns a DOUBLE PRECISION value representing the trigonometric cotangent of the argument. [[Mathematical functions](#)]

[COUNT](#) [aggregate]

Returns as a BIGINT the number of rows in each group where the expression is not NULL. [[Aggregate functions](#)]

[COUNT](#) [analytic]

Counts occurrences within a group within a. [[Analytic functions](#)]

[COVAR_POP](#)

Returns the population covariance for a set of expression pairs. [[Aggregate functions](#)]

[COVAR_SAMP](#)

Returns the sample covariance for a set of expression pairs. [[Aggregate functions](#)]

[CROSS_VALIDATE](#)

Performs k-fold cross validation on a learning algorithm using an input relation, and grid search for hyper parameters. [[Model evaluation](#)]

[CUME_DIST \[analytic\]](#)

Calculates the cumulative distribution, or relative rank, of the current row with regard to other rows in the same partition within a . [[Analytic functions](#)]

[CURRENT_DATABASE](#)

Returns the name of the current database, equivalent to DBNAME. [[System information functions](#)]

[CURRENT_DATE](#)

Returns the date (date-type value) on which the current transaction started. [[Date/time functions](#)]

[CURRENT_LOAD_SOURCE](#)

When called within the scope of a COPY statement, returns the file name or path part used for the load. [[System information functions](#)]

[CURRENT_SCHEMA](#)

Returns the name of the current schema. [[System information functions](#)]

[CURRENT_SESSION](#)

Returns the ID of the current client session. [[System information functions](#)]

[CURRENT_TIME](#)

Returns a value of type TIME WITH TIMEZONE that represents the start of the current transaction. [[Date/time functions](#)]

[CURRENT_TIMESTAMP](#)

Returns a value of type TIME WITH TIMEZONE that represents the start of the current transaction. [[Date/time functions](#)]

[CURRENT_TRANS_ID](#)

Returns the ID of the transaction currently in progress. [[System information functions](#)]

[CURRENT_USER](#)

Returns a VARCHAR containing the name of the user who initiated the current database connection. [[System information functions](#)]

[CURRVAL](#)

Returns the last value across all nodes that was set by NEXTVAL on this sequence in the current session. [[Sequence functions](#)]

D

[DATA_COLLECTOR_HELP](#)

Returns online usage instructions about the Data Collector, the V_MONITOR.DATA_COLLECTOR system table, and the Data Collector control functions. [[Data Collector functions](#)]

[DATE](#)

Converts the input value to a DATE data type. [[Date/time functions](#)]

[DATE_PART](#)

Extracts a sub-field such as year or hour from a date/time expression, equivalent to the the SQL-standard function EXTRACT. [[Date/time functions](#)]

[DATE_TRUNC](#)

Truncates date and time values to the specified precision. [[Date/time functions](#)]

[DATEDIFF](#)

Returns the time span between two dates, in the intervals specified. [[Date/time functions](#)]

[DAY](#)

Returns as an integer the day of the month from the input value. [[Date/time functions](#)]

[DAYOFMONTH](#)

Returns the day of the month as an integer. [[Date/time functions](#)]

[DAYOFWEEK](#)

Returns the day of the week as an integer, where Sunday is day 1. [[Date/time functions](#)]

[DAYOFWEEK_ISO](#)

Returns the ISO 8061 day of the week as an integer, where Monday is day 1. [[Date/time functions](#)]

[DAYOFYEAR](#)

Returns the day of the year as an integer, where January 1 is day 1. [[Date/time functions](#)]

[DAYS](#)

Returns the integer value of the specified date, where 1 AD is 1. [[Date/time functions](#)]

[DBNAME \(function\)](#)

Returns the name of the current database, equivalent to CURRENT_DATABASE. [[System information functions](#)]

[DECODE](#)

Compares expression to each search value one by one. [[String functions](#)]

[DEGREES](#)

Converts an expression from radians to fractional degrees, or from degrees, minutes, and seconds to fractional degrees. [[Mathematical functions](#)]

[DELETE_TOKENIZER_CONFIG_FILE](#)

Deletes a tokenizer configuration file. [[Text search functions](#)]

[DEMOTE_SUBCLUSTER_TO_SECONDARY](#)

Converts a to a . [[Eon Mode functions](#)]

[DENSE_RANK](#) [analytic]

Within each window partition, ranks all rows in the query results set according to the order specified by the window's ORDER BY clause. [[Analytic functions](#)]

[DESCRIBE_LOAD_BALANCE_DECISION](#)

Evaluates if any load balancing routing rules apply to a given IP address and This function is useful when you are evaluating connection load balancing policies you have created, to ensure they work the way you expect them to. [[Client connection functions](#)]

[DESIGNER_ADD_DESIGN_QUERIES](#)

Reads and evaluates queries from an input file, and adds the queries that it accepts to the specified design. [[Database Designer functions](#)]

[DESIGNER_ADD_DESIGN_QUERIES_FROM_RESULTS](#)

Executes the specified query and evaluates results in the following columns:. [[Database Designer functions](#)]

[DESIGNER_ADD_DESIGN_QUERY](#)

Reads and parses the specified query, and if accepted, adds it to the design. [[Database Designer functions](#)]

[DESIGNER_ADD_DESIGN_TABLES](#)

Adds the specified tables to a design. [[Database Designer functions](#)]

[DESIGNER_CANCEL_POPULATE_DESIGN](#)

Cancels population or deployment operation for the specified design if it is currently running. [[Database Designer functions](#)]

[DESIGNER_CREATE_DESIGN](#)

Creates a design with the specified name. [[Database Designer functions](#)]

[DESIGNER_DESIGN_PROJECTION_ENCODINGS](#)

Analyzes encoding in the specified projections, creates a script to implement encoding recommendations, and optionally deploys the recommendations. [[Database Designer functions](#)]

[DESIGNER_DROP_ALL_DESIGNS](#)

Removes all Database Designer-related schemas associated with the current user. [[Database Designer functions](#)]

[DESIGNER_DROP_DESIGN](#)

Removes the schema associated with the specified design and all its contents. [[Database Designer functions](#)]

[DESIGNER_OUTPUT_ALL_DESIGN_PROJECTIONS](#)

Displays the DDL statements that define the design projections to standard output. [[Database Designer functions](#)]

[DESIGNER_OUTPUT_DEPLOYMENT_SCRIPT](#)

Displays the deployment script for the specified design to standard output. [[Database Designer functions](#)]

[DESIGNER_RESET_DESIGN](#)

Discards all run-specific information of the previous Database Designer build or deployment of the specified design but keeps its configuration. [[Database Designer functions](#)]

[DESIGNER_RUN_POPULATE_DESIGN_AND_DEPLOY](#)

Populates the design and creates the design and deployment scripts. [[Database Designer functions](#)]

[DESIGNER_SET_DESIGN_KSAFETY](#)

Sets K-safety for a comprehensive design and stores the K-safety value in the DESIGNS table. [[Database Designer functions](#)]

[DESIGNER_SET_DESIGN_TYPE](#)

Specifies whether Database Designer creates a comprehensive or incremental design. [[Database Designer functions](#)]

[DESIGNER_SET_OPTIMIZATION_OBJECTIVE](#)

Valid only for comprehensive database designs, specifies the optimization objective Database Designer uses. [[Database Designer functions](#)]

[DESIGNER_SET_PROPOSE_UNSEGMENTED_PROJECTIONS](#)

Specifies whether a design can include unsegmented projections. [[Database Designer functions](#)]

[DESIGNER_SINGLE_RUN](#)

Evaluates all queries that completed execution within the specified timespan, and returns with a design that is ready for deployment. [[Database Designer functions](#)]

[DESIGNER_WAIT_FOR_DESIGN](#)

Waits for completion of operations that are populating and deploying the design. [[Database Designer functions](#)]

[DETECT_OUTLIERS](#)

Returns the outliers in a data set based on the outlier threshold. [[Data preparation](#)]

[DISABLE_DUPLICATE_KEY_ERROR](#)

Disables error messaging when Vertica finds duplicate primary or unique key values at run time (for use with key constraints that are not automatically enabled). [[Table functions](#)]

[DISABLE_LOCAL_SEGMENTS](#)

Disables local data segmentation, which breaks projections segments on nodes into containers that can be easily moved to other nodes. [[Cluster functions](#)]

[DISABLE_PROFILING](#)

Disables for the current session collection of profiling data of the specified type. [[Profiling functions](#)]

[DISPLAY_LICENSE](#)

Returns the terms of your Vertica license. [[License functions](#)]

[DISTANCE](#)

Returns the distance (in kilometers) between two points. [[Mathematical functions](#)]

[DISTANCEV](#)

Returns the distance (in kilometers) between two points using the Vincenty formula. [[Mathematical functions](#)]

[DO_LOGROTATE_LOCAL](#)

Rotates logs and removes rotated logs on the current node. [[Database functions](#)]

[DO_TM_TASK](#)

Runs a (TM) operation and commits current transactions. [[Storage functions](#)]

[DROP_EXTERNAL_ROW_COUNT](#)

Removes external table row count statistics compiled by ANALYZE_EXTERNAL_ROW_COUNT. [[Statistics management functions](#)]

[DROP_LICENSE](#)

Drops a license key from the global catalog. [[Catalog functions](#)]

[DROP_LOCATION](#)

Permanently removes a retired storage location. [[Storage functions](#)]

[DROP_PARTITIONS](#)

Drops the specified table partition keys. [[Partition functions](#)]

[DROP_STATISTICS](#)

Removes statistical data on database projections previously generated by ANALYZE_STATISTICS. [[Statistics management functions](#)]

[DROP_STATISTICS_PARTITION](#)

Removes statistical data on database projections previously generated by ANALYZE_STATISTICS_PARTITION. [[Statistics management functions](#)]

[DUMP_CATALOG](#)

Returns an internal representation of the Vertica catalog. [[Catalog functions](#)]

[DUMP_LOCKTABLE](#)

Returns information about deadlocked clients and the resources they are waiting for. [[Database functions](#)]

[DUMP_PARTITION_KEYS](#)

Dumps the partition keys of all projections in the system. [[Database functions](#)]

[DUMP_PROJECTION_PARTITION_KEYS](#)

Dumps the partition keys of the specified projection. [[Partition functions](#)]

[DUMP_TABLE_PARTITION_KEYS](#)

Dumps the partition keys of all projections for the specified table. [[Partition functions](#)]

E

[EDIT_DISTANCE](#)

Calculates and returns the Levenshtein distance between two strings. [[String functions](#)]

[EMPTYMAP](#)

Constructs a new VMap with one row but without keys or data. [[Flex map functions](#)]

[ENABLE_ELASTIC_CLUSTER](#)

Enables elastic cluster scaling, which makes enlarging or reducing the size of your database cluster more efficient by segmenting a node's data into chunks that can be easily moved to other hosts. [[Cluster functions](#)]

[ENABLE_LOCAL_SEGMENTS](#)

Enables local storage segmentation, which breaks projections segments on nodes into containers that can be easily moved to other nodes. [[Cluster functions](#)]

[ENABLE_PROFILING](#)

Enables collection of profiling data of the specified type for the current session. [[Profiling functions](#)]

[ENABLE_SCHEDULE](#)

Enables or disables a schedule. [[Stored procedure functions](#)]

[ENABLE_TRIGGER](#)

Enables or disables a trigger. [[Stored procedure functions](#)]

[ENABLED_ROLE](#)

Checks whether a Vertica user role is enabled, and returns true or false. [[Privileges and access functions](#)]

[ENFORCE_OBJECT_STORAGE_POLICY](#)

Applies storage policies of the specified object immediately. [[Storage functions](#)]

[ERROR_RATE](#)

Using an input table, returns a table that calculates the rate of incorrect classifications and displays them as FLOAT values. [[Model evaluation](#)]

[EVALUATE_DELETE_PERFORMANCE](#)

Evaluates projections for potential DELETE and UPDATE performance issues. [[Projection functions](#)]

[EVENT_NAME](#)

Returns a VARCHAR value representing the name of the event that matched the row. [[MATCH clause functions](#)]

[EXECUTE_TRIGGER](#)

Manually executes the stored procedure attached to a trigger. [[Stored procedure functions](#)]

[EXP](#)

Returns the exponential function, e to the power of a number. [[Mathematical functions](#)]

[EXPLODE](#)

Expands the elements of one or more collection columns (ARRAY or SET) into individual table rows, one row per element. [[Collection functions](#)]

[EXPONENTIAL_MOVING_AVERAGE \[analytic\]](#)

Calculates the exponential moving average (EMA) of expression E with smoothing factor X. [[Analytic functions](#)]

[EXPORT_CATALOG](#)

This function and EXPORT_OBJECTS return equivalent output. [[Catalog functions](#)]

[EXPORT_DIRECTED_QUERIES](#)

Generates SQL for creating directed queries from a set of input queries. [[Directed queries functions](#)]

[EXPORT_MODELS](#)

Exports machine learning models. [[Model management](#)]

[EXPORT_OBJECTS](#)

This function and EXPORT_CATALOG return equivalent output. [[Catalog functions](#)]

[EXPORT_STATISTICS](#)

Generates statistics in XML format from data previously collected by ANALYZE_STATISTICS. [[Statistics management functions](#)]

[EXPORT_STATISTICS_PARTITION](#)

Generates partition-level statistics in XML format from data previously collected by ANALYZE_STATISTICS_PARTITION. [[Statistics management functions](#)]

[EXPORT_TABLES](#)

Generates a SQL script that can be used to recreate a logical schema—schemas, tables, constraints, and views—on another cluster. [[Catalog functions](#)]

[EXTERNAL_CONFIG_CHECK](#)

Tests the Hadoop configuration of a Vertica cluster. [[Hadoop functions](#)]

[EXTRACT](#)

Retrieves sub-fields such as year or hour from date/time values and returns values of type NUMERIC. [[Date/time functions](#)]

F

[FILTER](#)

Takes an input array and returns an array containing only elements that meet a specified condition. [[Collection functions](#)]

[FINISH_FETCHING_FILES](#)

Fetches to the depot all files that are queued for download from communal storage. [[Eon Mode functions](#)]

[FIRST_VALUE \[analytic\]](#)

Lets you select the first value of a table or partition (determined by the window-order-clause) without having to use a self join. [[Analytic functions](#)]

[FLOOR](#)

Rounds down the returned value to the previous whole number. [[Mathematical functions](#)]

[FLUSH_DATA_COLLECTOR](#)

Waits until memory logs are moved to disk and then flushes the Data Collector, synchronizing the log with disk storage. [[Data Collector functions](#)]

[FLUSH_REAPER_QUEUE](#)

Deletes all data marked for deletion in the database. [[Eon Mode functions](#)]

G

[GET_AHM_EPOCH](#)

Returns the number of the in which the is located. [[Epoch functions](#)]

[GET_AHM_TIME](#)

Returns a TIMESTAMP value representing the. [[Epoch functions](#)]

[GET_AUDIT_TIME](#)

Reports the time when the automatic audit of database size occurs. [[License functions](#)]

[GET_CLIENT_LABEL](#)

Returns the client connection label for the current session. [[Client connection functions](#)]

[GET_COMPLIANCE_STATUS](#)

Displays whether your database is in compliance with your Vertica license agreement. [[License functions](#)]

[GET_CONFIG_PARAMETER](#)

Gets the value of a configuration parameter at the specified level. [[Database functions](#)]

[GET_CURRENT_EPOCH](#)

Returns the number of the current epoch. [[Epoch functions](#)]

[GET_DATA_COLLECTOR_NOTIFY_POLICY](#)

Lists any notification policies set on a component. [[Notifier functions](#)]

[GET_DATA_COLLECTOR_POLICY](#)

Retrieves a brief statement about the retention policy for the specified component. [[Data Collector functions](#)]

[GET_LAST_GOOD_EPOCH](#)

Returns the number. [[Epoch functions](#)]

[GET_METADATA](#)

Returns the metadata of a Parquet file. [[Hadoop functions](#)]

[GET_MODEL_ATTRIBUTE](#)

Extracts either a specific attribute from a model or all attributes from a model. [[Model management](#)]

[GET_MODEL_SUMMARY](#)

Returns summary information of a model. [[Model management](#)]

[GET_NUM_ACCEPTED_ROWS](#)

Returns the number of rows loaded into the database for the last completed load for the current session. [[Session functions](#)]

[GET_NUM_REJECTED_ROWS](#)

Returns the number of rows that were rejected during the last completed load for the current session. [[Session functions](#)]

[GET_PRIVILEGES_DESCRIPTION](#)

Returns the effective privileges the current user has on an object, including explicit, implicit, inherited, and role-based privileges. [[Privileges and access functions](#)]

[GET_PROJECTION_SORT_ORDER](#)

Returns the order of columns in a projection's ORDER BY clause. [[Projection functions](#)]

[GET_PROJECTION_STATUS](#)

Returns information relevant to the status of a :. [[Projection functions](#)]

[GET_PROJECTIONS](#)

Returns contextual and projection information about projections of the specified anchor table. [[Projection functions](#)]

[GET_TOKENIZER_PARAMETER](#)

Returns the configuration parameter for a given tokenizer. [[Text search functions](#)]

[GETDATE](#)

Returns the current statement's start date and time as a TIMESTAMP value. [[Date/time functions](#)]

[GETUTCDATE](#)

Returns the current statement's start date and time as a TIMESTAMP value. [[Date/time functions](#)]

[GREATEST](#)

Returns the largest value in a list of expressions of any data type. [[String functions](#)]

[GREATESTB](#)

Returns the largest value in a list of expressions of any data type, using binary ordering. [[String functions](#)]

[GROUP_ID](#)

Uniquely identifies duplicate sets for GROUP BY queries that return duplicate grouping sets. [[Aggregate functions](#)]

[GROUPING](#)

Disambiguates the use of NULL values when GROUP BY queries with multilevel aggregates generate NULL values to identify subtotals in grouping columns. [[Aggregate functions](#)]

[GROUPING_ID](#)

Concatenates the set of Boolean values generated by the GROUPING function into a bit vector. [[Aggregate functions](#)]

H

[HADOOP_IMPERSONATION_CONFIG_CHECK](#)

Reports the delegation tokens Vertica will use when accessing Kerberized data in HDFS. [[Hadoop functions](#)]

[HAS_ROLE](#)

Checks whether a Vertica user role is granted to the specified user or role, and returns true or false. [[Privileges and access functions](#)]

[HAS_TABLE_PRIVILEGE](#)

Returns true or false to verify whether a user has the specified privilege on a table. [[System information functions](#)]

[HASH](#)

Calculates a hash value over the function arguments, producing a value in the range $0 \leq x < 263$. [[Mathematical functions](#)]

[HASH_EXTERNAL_TOKEN](#)

Returns a hash of a string token, for use with HADOOP_IMPERSONATION_CONFIG_CHECK. [[Hadoop functions](#)]

[HCATALOGCONNECTOR_CONFIG_CHECK](#)

Tests the configuration of a Vertica cluster that uses the HCatalog Connector to access Hive data. [[Hadoop functions](#)]

[HDFS_CLUSTER_CONFIG_CHECK](#)

Tests the configuration of a Vertica cluster that uses HDFS. [[Hadoop functions](#)]

[HEX_TO_BINARY](#)

Translates the given VARCHAR hexadecimal representation into a VARBINARY value. [[String functions](#)]

[HEX_TO_INTEGER](#)

Translates the given VARCHAR hexadecimal representation into an INTEGER value. [[String functions](#)]

[HOUR](#)

Returns the hour portion of the specified date as an integer, where 0 is 00:00 to 00:59. [[Date/time functions](#)]

I

[IFNULL](#)

Returns the value of the first non-null expression in the list. [[NULL-handling functions](#)]

[IFOREST](#)

Trains and returns an isolation forest (iForest) model. [[Data preparation](#)]

[IMPLODE](#)

Takes a column of any scalar type and returns an unbounded array. [[Collection functions](#)]

[IMPORT_DIRECTED_QUERIES](#)

Imports to the database catalog directed queries from a SQL file that was generated by EXPORT_DIRECTED_QUERIES. [[Directed queries functions](#)]

[IMPORT_MODELS](#)

Imports models into Vertica, either Vertica models that were exported with EXPORT_MODELS, or models in Predictive Model Markup Language (PMML) or TensorFlow format. [[Model management](#)]

[IMPORT_STATISTICS](#)

Imports statistics from the XML file that was generated by EXPORT_STATISTICS. [[Statistics management functions](#)]

[IMPUTE](#)

Imputes missing values in a data set with either the mean or the mode, based on observed values for a variable in each column. [[Data preparation](#)]

[INET_ATON](#)

Converts a string that contains a dotted-quad representation of an IPv4 network address to an INTEGER. [[IP address functions](#)]

[INET_NTOA](#)

Converts an INTEGER value into a VARCHAR dotted-quad representation of an IPv4 network address. [[IP address functions](#)]

[INFER_EXTERNAL_TABLE_DDL](#)

This function is deprecated and will be removed in a future release. [[Table functions](#)]

[INFER_TABLE_DDL](#)

Inspects a file in Parquet, ORC, JSON, or Avro format and returns a CREATE TABLE or CREATE EXTERNAL TABLE statement based on its contents. [[Table functions](#)]

[INITCAP](#)

Capitalizes first letter of each alphanumeric word and puts the rest in lowercase. [[String functions](#)]

[INITCAPB](#)

Capitalizes first letter of each alphanumeric word and puts the rest in lowercase. [[String functions](#)]

[INSERT](#)

Inserts a character string into a specified location in another character string. [[String functions](#)]

[INSTALL_LICENSE](#)

Installs the license key in the global catalog. [[Catalog functions](#)]

[INSTR](#)

Searches string for substring and returns an integer indicating the position of the character in string that is the first character of this occurrence. [[String functions](#)]

[INSTRB](#)

Searches string for substring and returns an integer indicating the octet position within string that is the first occurrence. [[String functions](#)]

[INTERRUPT_STATEMENT](#)

Interrupts the specified statement in a user session, rolls back the current transaction, and writes a success or failure message to the log file. [[Session functions](#)]

[ISFINITE](#)

Tests for the special TIMESTAMP constant INFINITY and returns a value of type BOOLEAN. [[Date/time functions](#)]

[ISNULL](#)

Returns the value of the first non-null expression in the list. [[NULL-handling functions](#)]

[ISUTF8](#)

Tests whether a string is a valid UTF-8 string. [[String functions](#)]

J

[JARO_DISTANCE](#)

Calculates and returns the Jaro similarity, an edit distance between two sequences. [[String functions](#)]

[JARO_WINKLER_DISTANCE](#)

Calculates and returns the Jaro-Winkler similarity, an edit distance between two sequences. [[String functions](#)]

[JULIAN_DAY](#)

Returns the integer value of the specified day according to the Julian calendar, where day 1 is the first day of the Julian period, January 1, 4713 BC (on the Gregorian calendar, November 24, 4714 BC). [[Date/time functions](#)]

K

[KERBEROS_CONFIG_CHECK](#)

Tests the Kerberos configuration of a Vertica cluster. [[Database functions](#)]

[KERBEROS_HDFS_CONFIG_CHECK](#)

This function is deprecated and will be removed in a future release. [[Hadoop functions](#)]

[KMEANS](#)

Executes the k-means algorithm on an input relation. [[Machine learning algorithms](#)]

[KPROTOTYPES](#)

Executes the k-prototypes algorithm on an input relation. [[Machine learning algorithms](#)]

L

[LAG \[analytic\]](#)

Returns the value of the input expression at the given offset before the current row within a. [[Analytic functions](#)]

[LAST_DAY](#)

Returns the last day of the month in the specified date. [[Date/time functions](#)]

[LAST_INSERT_ID](#)

Returns the last value of an IDENTITY column. [[Table functions](#)]

[LAST_VALUE \[analytic\]](#)

Lets you select the last value of a table or partition (determined by the window-order-clause) without having to use a self join. [[Analytic functions](#)]

[LDAP_LINK_DRYRUN_CONNECT](#)

Takes a set of LDAP Link connection parameters as arguments and begins a dry run connection between the LDAP server and Vertica. [[LDAP link functions](#)]

[LDAP_LINK_DRYRUN_SEARCH](#)

Takes a set of LDAP Link connection and search parameters as arguments and begins a dry run search for users and groups that would get imported from the LDAP server. [[LDAP link functions](#)]

[LDAP_LINK_DRYRUN_SYNC](#)

Takes a set of LDAP Link connection and search parameters as arguments and begins a dry run synchronization between the database and the LDAP server, which maps and synchronizes the LDAP server's users and groups with their equivalents in Vertica. [[LDAP link functions](#)]

[LDAP_LINK_SYNC_CANCEL](#)

Cancels in-progress LDAP Link synchronizations (including those started by LDAP_LINK_DRYRUN_SYNC) between the LDAP server and Vertica. [[LDAP link functions](#)]

[LDAP_LINK_SYNC_START](#)

Begins the synchronization between the LDAP and Vertica servers immediately rather than waiting for the next scheduled run set by the parameters LDAPLinkInterval and LDAPLinkCron. [[LDAP link functions](#)]

[LEAD \[analytic\]](#)

Returns values from the row after the current row within a , letting you access more than one row in a table at the same time. [[Analytic functions](#)]

[LEAST](#)

Returns the smallest value in a list of expressions of any data type. [[String functions](#)]

[LEASTB](#)

Returns the smallest value in a list of expressions of any data type, using binary ordering. [[String functions](#)]

[LEFT](#)

Returns the specified characters from the left side of a string. [[String functions](#)]

[LENGTH](#)

Returns the length of a string. [[String functions](#)]

[LIFT_TABLE](#)

Returns a table that compares the predictive quality of a machine learning model. [[Model evaluation](#)]

[LINEAR_REG](#)

Executes linear regression on an input relation, and returns a linear regression model. [[Machine learning algorithms](#)]

[LIST_ENABLED_CIPHERS](#)

Returns a list of enabled cipher suites, which are sets of algorithms used to secure TLS/SSL connections. [[System information functions](#)]

[LISTAGG](#)

Transforms non-null values from a group of rows into a list of values that are delimited by commas (default) or a configurable separator. [[Aggregate functions](#)]

[LN](#)

Returns the natural logarithm of the argument. [[Mathematical functions](#)]

[LOCALTIME](#)

Returns a value of type TIME that represents the start of the current transaction. [[Date/time functions](#)]

[LOCALTIMESTAMP](#)

Returns a value of type TIMESTAMP/TIMESTAMPTZ that represents the start of the current transaction, and remains unchanged until the transaction is closed. [[Date/time functions](#)]

[LOG](#)

Returns the logarithm to the specified base of the argument. [[Mathematical functions](#)]

[LOG10](#)

Returns the base 10 logarithm of the argument, also known as the common logarithm. [[Mathematical functions](#)]

[LOGISTIC_REG](#)

Executes logistic regression on an input relation. [[Machine learning algorithms](#)]

[LOWER](#)

Takes a string value and returns a VARCHAR value converted to lowercase. [[String functions](#)]

[LOWERB](#)

Returns a character string with each ASCII character converted to lowercase. [[String functions](#)]

[LPAD](#)

Returns a VARCHAR value representing a string of a specific length filled on the left with specific characters. [[String functions](#)]

[LTRIM](#)

Returns a VARCHAR value representing a string with leading blanks removed from the left side (beginning). [[String functions](#)]

M

[MAKE_AHM_NOW](#)

Sets the (AHM) to the greatest allowable value. [[Epoch functions](#)]

[MAKEUTF8](#)

Coerces a string to UTF-8 by removing or replacing non-UTF-8 characters. [[String functions](#)]

[MAPAGGREGATE](#)

Returns a LONG VARBINARY VMap with key and value pairs supplied from two VARCHAR input columns. [[Flex map functions](#)]

[MAPCONTAINSKEY](#)

Determines whether a VMap contains a virtual column (key). [[Flex map functions](#)]

[MAPCONTAINSVALUE](#)

Determines whether a VMap contains a specific value. [[Flex map functions](#)]

[MAPDELIMITEDEXTRACTOR](#)

Extracts data with a delimiter character and other optional arguments, returning a single VMap value. [[Flex extractor functions](#)]

[MAPITEMS](#)

Returns information about items in a VMap. [[Flex map functions](#)]

[MAPJSONEXTRACTOR](#)

Extracts content of repeated JSON data objects,, including nested maps, or data with an outer list of JSON elements. [[Flex extractor functions](#)]

[MAPKEYS](#)

Returns the virtual columns (and values) present in any VMap data. [[Flex map functions](#)]

[MAPKEYSINFO](#)

Returns virtual column information from a given map. [[Flex map functions](#)]

[MAPLOOKUP](#)

Returns single-key values from VMAP data. [[Flex map functions](#)]

[MAPPUT](#)

Accepts a VMap and one or more key/value pairs and returns a new VMap with the key/value pairs added. [[Flex map functions](#)]

[MAPREGEXEXTRACTOR](#)

Extracts data with a regular expression and returns results as a VMap. [[Flex extractor functions](#)]

[MAPSIZE](#)

Returns the number of virtual columns present in any VMap data. [[Flex map functions](#)]

[MAPTOSTRING](#)

Recursively builds a string representation of VMap data, including nested JSON maps. [[Flex map functions](#)]

[MAPVALUES](#)

Returns a string representation of the top-level values from a VMap. [[Flex map functions](#)]

[MAPVERSION](#)

Returns the version or invalidity of any map data. [[Flex map functions](#)]

[MARK_DESIGN_KSAFE](#)

Enables or disables high availability in your environment, in case of a failure. [[Catalog functions](#)]

[MATCH_COLUMNS](#)

Specified as an element in a SELECT list, returns all columns in queried tables that match the specified pattern. [[Regular expression functions](#)]

MATCH_ID

Returns a successful pattern match as an INTEGER value. [[MATCH clause functions](#)]

MATERIALIZED_FLEXTABLE_COLUMNS

Materializes virtual columns listed as key_names in the flextable_keys table you compute using either COMPUTE_FLEXTABLE_KEYS or COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW. [[Flex data functions](#)]

MAX [aggregate]

Returns the greatest value of an expression over a group of rows. [[Aggregate functions](#)]

MAX [analytic]

Returns the maximum value of an expression within a. [[Analytic functions](#)]

MD5

Calculates the MD5 hash of string, returning the result as a VARCHAR string in hexadecimal. [[String functions](#)]

MEASURE_LOCATION_PERFORMANCE

Measures a storage location's disk performance. [[Storage functions](#)]

MEDIAN [analytic]

For each row, returns the median value of a value set within each partition. [[Analytic functions](#)]

MEMORY_TRIM

Calls glibc function malloc_trim() to reclaim free memory from malloc and return it to the operating system. [[Database functions](#)]

MICROSECOND

Returns the microsecond portion of the specified date as an integer. [[Date/time functions](#)]

MIDNIGHT_SECONDS

Within the specified date, returns the number of seconds between midnight and the date's time portion. [[Date/time functions](#)]

MIGRATE_ENTERPRISE_TO_EON

Migrates an Enterprise database to an Eon Mode database. [[Eon Mode functions](#)]

MIN [aggregate]

Returns the smallest value of an expression over a group of rows. [[Aggregate functions](#)]

MIN [analytic]

Returns the minimum value of an expression within a. [[Analytic functions](#)]

MINUTE

Returns the minute portion of the specified date as an integer. [[Date/time functions](#)]

MOD

Returns the remainder of a division operation. [[Mathematical functions](#)]

MONTH

Returns the month portion of the specified date as an integer. [[Date/time functions](#)]

MONTHS_BETWEEN

Returns the number of months between two dates. [[Date/time functions](#)]

MOVE_PARTITIONS_TO_TABLE

Moves partitions from one table to another. [[Partition functions](#)]

MOVE_RETIRED_LOCATION_DATA

Moves all data from the specified retired storage location or from all retired storage locations in the database. [[Storage functions](#)]

MOVE_STATEMENT_TO_RESOURCE_POOL

Attempts to move the specified query to the specified target pool. [[Workload management functions](#)]

MOVING_AVERAGE

Creates a moving-average (MA) model from a stationary time series with consistent timesteps that can then be used for prediction via PREDICT_MOVING_AVERAGE. [[Machine learning algorithms](#)]

MSE

Returns a table that displays the mean squared error of the prediction and response columns in a machine learning model. [[Model evaluation](#)]

N

NAIVE_BAYES

Executes the Naive Bayes algorithm on an input relation and returns a Naive Bayes model. [[Machine learning algorithms](#)]

NEW_TIME

Converts a timestamp value from one time zone to another and returns a TIMESTAMP. [[Date/time functions](#)]

NEXT_DAY

Returns the date of the first instance of a particular day of the week that follows the specified date. [[Date/time functions](#)]

[NEXTVAL](#)

Returns the next value in a sequence. [[Sequence functions](#)]

[NORMALIZE](#)

Runs a normalization algorithm on an input relation. [[Data preparation](#)]

[NORMALIZE_FIT](#)

This function differs from NORMALIZE, which directly outputs a view with normalized results, rather than storing normalization parameters into a model for later operation. [[Data preparation](#)]

[NOTIFY](#)

Sends a specified message to a NOTIFIER. [[Notifier functions](#)]

[NOW \[date/time\]](#)

Returns a value of type TIMESTAMP WITH TIME ZONE representing the start of the current transaction. [[Date/time functions](#)]

[NTH_VALUE \[analytic\]](#)

Returns the value evaluated at the row that is the nth row of the window (counting from 1). [[Analytic functions](#)]

[NTILE \[analytic\]](#)

Equally divides an ordered data set (partition) into a {value} number of subsets within a , where the subsets are numbered 1 through the value in parameter constant-value. [[Analytic functions](#)]

[NULLIF](#)

Compares two expressions. [[NULL-handling functions](#)]

[NULLIFZERO](#)

Evaluates to NULL if the value in the column is 0. [[NULL-handling functions](#)]

[NVL](#)

Returns the value of the first non-null expression in the list. [[NULL-handling functions](#)]

[NVL2](#)

Takes three arguments. [[NULL-handling functions](#)]

O

[OCTET_LENGTH](#)

Takes one argument as an input and returns the string length in octets for all string types. [[String functions](#)]

[ONE_HOT_ENCODER_FIT](#)

Generates a sorted list of each of the category levels for each feature to be encoded, and stores the model. [[Data preparation](#)]

[OVERLAPS](#)

Evaluates two time periods and returns true when they overlap, false otherwise. [[Date/time functions](#)]

[OVERLAY](#)

Replaces part of a string with another string and returns the new string value as a VARCHAR. [[String functions](#)]

[OVERLAYB](#)

Replaces part of a string with another string and returns the new string as an octet value. [[String functions](#)]

P

[PARTITION_PROJECTION](#)

Splits containers for a specified projection. [[Partition functions](#)]

[PARTITION_TABLE](#)

Invokes the to reorganize ROS storage containers as needed to conform with the current partitioning policy. [[Partition functions](#)]

[PATTERN_ID](#)

Returns an integer value that is a partition-wide unique identifier for the instance of the pattern that matched. [[MATCH clause functions](#)]

[PCA](#)

Computes principal components from the input table/view. [[Data preparation](#)]

[PERCENT_RANK \[analytic\]](#)

Calculates the relative rank of a row for a given row in a group within a by dividing that row's rank less 1 by the number of rows in the partition, also less 1. [[Analytic functions](#)]

[PERCENTILE_CONT \[analytic\]](#)

An inverse distribution function where, for each row, PERCENTILE_CONT returns the value that would fall into the specified percentile among a set of values in each partition within a. [[Analytic functions](#)]

[PERCENTILE_DISC \[analytic\]](#)

An inverse distribution function where, for each row, PERCENTILE_DISC returns the value that would fall into the specified percentile among a set of values in each partition within a. [[Analytic functions](#)]

[PI](#)

Returns the constant pi (P), the ratio of any circle's circumference to its diameter in Euclidean geometry The return type is DOUBLE PRECISION. [[Mathematical functions](#)]

[PLS_REG](#)

Executes PLS regression on an input relation, and returns a PLS regression model. [[Machine learning algorithms](#)]

[POISSON_REG](#)

Executes Poisson regression on an input relation, and returns a Poisson regression model. [[Machine learning algorithms](#)]

[POSITION](#)

Returns an INTEGER value representing the character location of a specified substring with a string (counting from one). [[String functions](#)]

[POSITIONB](#)

Returns an INTEGER value representing the octet location of a specified substring with a string (counting from one). [[String functions](#)]

[POWER](#)

Returns a DOUBLE PRECISION value representing one number raised to the power of another number. [[Mathematical functions](#)]

[PRC](#)

Returns a table that displays the points on a receiver precision recall (PR) curve. [[Model evaluation](#)]

[PREDICT_ARIMA](#)

Applies an autoregressive integrated moving average (ARIMA) model to an input relation or makes predictions using the in-sample data. [[Transformation functions](#)]

[PREDICT_AUTOREGRESSOR](#)

Applies an autoregressor (AR) model to an input relation. [[Transformation functions](#)]

[PREDICT_LINEAR_REG](#)

Applies a linear regression model on an input relation and returns the predicted value as a FLOAT. [[Transformation functions](#)]

[PREDICT_LOGISTIC_REG](#)

Applies a logistic regression model on an input relation. [[Transformation functions](#)]

[PREDICT_MOVING_AVERAGE](#)

Applies a moving-average (MA) model, created by MOVING_AVERAGE, to an input relation. [[Transformation functions](#)]

[PREDICT_NAIVE_BAYES](#)

Applies a Naive Bayes model on an input relation. [[Transformation functions](#)]

[PREDICT_NAIVE_BAYES_CLASSES](#)

Applies a Naive Bayes model on an input relation and returns the probabilities of classes:. [[Transformation functions](#)]

[PREDICT_PLS_REG](#)

Applies a PLS regression model on an input relation and returns the predicted values. [[Transformation functions](#)]

[PREDICT_PMML](#)

Applies an imported PMML model on an input relation. [[Transformation functions](#)]

[PREDICT_POISSON_REG](#)

Applies a Poisson regression model on an input relation and returns the predicted value as a FLOAT. [[Transformation functions](#)]

[PREDICT_RF_CLASSIFIER](#)

Applies a random forest model on an input relation. [[Transformation functions](#)]

[PREDICT_RF_CLASSIFIER_CLASSES](#)

Applies a random forest model on an input relation and returns the probabilities of classes:. [[Transformation functions](#)]

[PREDICT_RF_REGRESSOR](#)

Applies a random forest model on an input relation, and returns with a FLOAT data type that specifies the predicted value of the random forest model—the average of the prediction of the trees in the forest. [[Transformation functions](#)]

[PREDICT_SVM_CLASSIFIER](#)

Uses an SVM model to predict class labels for samples in an input relation, and returns the predicted value as a FLOAT data type. [[Transformation functions](#)]

[PREDICT_SVM_REGRESSOR](#)

Uses an SVM model to perform regression on samples in an input relation, and returns the predicted value as a FLOAT data type. [[Transformation functions](#)]

[PREDICT_TENSORFLOW](#)

Applies a TensorFlow model on an input relation, and returns with the result expected for the encoded model type. [[Transformation functions](#)]

[PREDICT_TENSORFLOW_SCALAR](#)

Applies a TensorFlow model on an input relation, and returns with the result expected for the encoded model type. This function supports 1D complex types as input and output. [[Transformation functions](#)]

[PREDICT_XGB_CLASSIFIER](#)

Applies an XGBoost classifier model on an input relation. [[Transformation functions](#)]

[PREDICT_XGB_CLASSIFIER_CLASSES](#)

Applies an XGBoost classifier model on an input relation and returns the probabilities of classes:. [[Transformation functions](#)]

[PREDICT_XGB_REGRESSOR](#)

Applies an XGBoost regressor model on an input relation. [[Transformation functions](#)]

[PROMOTE_SUBCLUSTER_TO_PRIMARY](#)

Converts a secondary subcluster to a. [[Eon Mode functions](#)]

[PURGE](#)

Permanently removes delete vectors from ROS storage containers so disk space can be reused. [[Database functions](#)]

[PURGE_PARTITION](#)

Purges a table partition of deleted rows. [[Partition functions](#)]

[PURGE_PROJECTION](#)

PURGE_PROJECTION can use significant disk space while purging the data. [[Projection functions](#)]

[PURGE_TABLE](#)

This function was formerly named PURGE_TABLE_PROJECTIONS(). [[Table functions](#)]

Q

[QUARTER](#)

Returns calendar quarter of the specified date as an integer, where the January-March quarter is 1. [[Date/time functions](#)]

[QUOTE_IDENT](#)

Returns the specified string argument in the format required to use the string as an identifier in an SQL statement. [[String functions](#)]

[QUOTE_LITERAL](#)

Returns the given string suitably quoted for use as a string literal in a SQL statement string. [[String functions](#)]

[QUOTE_NULLABLE](#)

Returns the given string suitably quoted for use as a string literal in an SQL statement string; or if the argument is null, returns the unquoted string NULL. [[String functions](#)]

R

[RADIANS](#)

Returns a DOUBLE PRECISION value representing an angle expressed in radians. [[Mathematical functions](#)]

[RANDOM](#)

Returns a uniformly-distributed random DOUBLE PRECISION value x , where $0 \leq x < 1$. [[Mathematical functions](#)]

[RANDOMINT](#)

Accepts and returns an integer between 0 and the integer argument expression-1. [[Mathematical functions](#)]

[RANDOMINT_CRYPTO](#)

Accepts and returns an INTEGER value from a set of values between 0 and the specified function argument -1. [[Mathematical functions](#)]

[RANK \[analytic\]](#)

Within each window partition, ranks all rows in the query results set according to the order specified by the window's ORDER BY clause. [[Analytic functions](#)]

[READ_CONFIG_FILE](#)

Reads and returns the key-value pairs of all the parameters of a given tokenizer. [[Text search functions](#)]

[READ_TREE](#)

Reads the contents of trees within the random forest or XGBoost model. [[Model evaluation](#)]

[REALIGN_CONTROL_NODES](#)

Causes Vertica to re-evaluate which nodes in the cluster or subcluster are and which nodes are assigned to them as dependents when large cluster is enabled. [[Cluster functions](#)]

[REBALANCE_CLUSTER](#)

Rebalances the database cluster synchronously as a session foreground task. [[Cluster functions](#)]

[REBALANCE_SHARDS](#)

Rebalances shard assignments in a subcluster or across the entire cluster in Eon Mode. [[Eon Mode functions](#)]

[REBALANCE TABLE](#)

Synchronously rebalances data in the specified table. [[Table functions](#)]

[REENABLE_DUPLICATE_KEY_ERROR](#)

Restores the default behavior of error reporting by reversing the effects of DISABLE_DUPLICATE_KEY_ERROR. [[Table functions](#)]

[REFRESH](#)

Synchronously refreshes one or more table projections in the foreground, and updates the PROJECTION_REFRESHES system table. [[Projection functions](#)]

[REFRESH_COLUMNS](#)

Refreshes table columns that are defined with the constraint SET USING or DEFAULT USING. [[Projection functions](#)]

[REGEXP_COUNT](#)

Returns the number times a regular expression matches a string. [[Regular expression functions](#)]

[REGEXP_ILIKE](#)

Returns true if the string contains a match for the regular expression. [[Regular expression functions](#)]

[REGEXP_INSTR](#)

Returns the starting or ending position in a string where a regular expression matches. [[Regular expression functions](#)]

[REGEXP_LIKE](#)

Returns true if the string matches the regular expression. [[Regular expression functions](#)]

[REGEXP_NOT_ILIKE](#)

Returns true if the string does not match the case-insensitive regular expression. [[Regular expression functions](#)]

[REGEXP_NOT_LIKE](#)

Returns true if the string does not contain a match for the regular expression. [[Regular expression functions](#)]

[REGEXP_REPLACE](#)

Replaces all occurrences of a substring that match a regular expression with another substring. [[Regular expression functions](#)]

[REGEXP_SUBSTR](#)

Returns the substring that matches a regular expression within a string. [[Regular expression functions](#)]

[REGISTER_MODEL](#)

Registers a trained model and adds it to Model Versioning environment with a status of 'under_review'. [[Model management](#)]

[REGR_AVGX](#)

Returns the DOUBLE PRECISION average of the independent expression in an expression pair. [[Aggregate functions](#)]

[REGR_AVGY](#)

Returns the DOUBLE PRECISION average of the dependent expression in an expression pair. [[Aggregate functions](#)]

[REGR_COUNT](#)

Returns the count of all rows in an expression pair. [[Aggregate functions](#)]

[REGR_INTERCEPT](#)

Returns the y-intercept of the regression line determined by a set of expression pairs. [[Aggregate functions](#)]

[REGR_R2](#)

Returns the square of the correlation coefficient of a set of expression pairs. [[Aggregate functions](#)]

[REGR_SLOPE](#)

Returns the slope of the regression line, determined by a set of expression pairs. [[Aggregate functions](#)]

[REGR_SXX](#)

Returns the sum of squares of the difference between the independent expression (expression2) and its average. [[Aggregate functions](#)]

[REGR_SXY](#)

Returns the sum of products of the difference between the dependent expression (expression1) and its average and the difference between the independent expression (expression2) and its average. [[Aggregate functions](#)]

[REGR_SYY](#)

Returns the sum of squares of the difference between the dependent expression (expression1) and its average. [[Aggregate functions](#)]

[RELEASE_ALL_JVM_MEMORY](#)

Forces all sessions to release the memory consumed by their Java Virtual Machines (JVM). [[Session functions](#)]

[RELEASE_JVM_MEMORY](#)

Terminates a Java Virtual Machine (JVM), making available the memory the JVM was using. [[Session functions](#)]

[RELEASE_SYSTEM_TABLES_ACCESS](#)

Enables non-superuser access to all system tables. [[Privileges and access functions](#)]

[RELOAD_ADMINTOOLS_CONF](#)

Updates the admintools.conf on each UP node in the cluster. [[Catalog functions](#)]

[RELOAD_SPREAD](#)

Updates cluster changes to the catalog's Spread configuration file. [[Cluster functions](#)]

[REPEAT](#)

Replicates a string the specified number of times and concatenates the replicated values as a single string. [[String functions](#)]

[REPLACE](#)

Replaces all occurrences of characters in a string with another set of characters. [[String functions](#)]

[RESERVE_SESSION_RESOURCE](#)

Reserves memory resources from the general resource pool for the exclusive use of the Vertica backup and restore process. [[Session functions](#)]

[RESET_LOAD_BALANCE_POLICY](#)

Resets the counter each host in the cluster maintains, to track which host it will refer a client to when the native connection load balancing scheme is set to ROUNDROBIN. [[Client connection functions](#)]

[RESET_SESSION](#)

Applies your default connection string configuration settings to your current session. [[Session functions](#)]

[RESHARD_DATABASE](#)

Changes the number of shards in a database. [[Eon Mode functions](#)]

[RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW](#)

Restores the keys table and the view. [[Flex data functions](#)]

[RESTORE_LOCATION](#)

Restores a storage location that was previously retired with RETIRE_LOCATION. [[Storage functions](#)]

[RESTRICT_SYSTEM_TABLES_ACCESS](#)

Checks system table SYSTEM_TABLES to determine which system tables non-superusers can access. [[Privileges and access functions](#)]

[RETIRE_LOCATION](#)

Deactivates the specified storage location. [[Storage functions](#)]

[REVERSE_NORMALIZE](#)

Reverses the normalization transformation on normalized data, thereby de-normalizing the normalized data. [[Transformation functions](#)]

[RF_CLASSIFIER](#)

Trains a random forest model for classification on an input relation. [[Machine learning algorithms](#)]

[RF_PREDICTOR_IMPORTANCE](#)

Measures the importance of the predictors in a random forest model using the Mean Decrease Impurity (MDI) approach. [[Model evaluation](#)]

[RF_REGRESSOR](#)

Trains a random forest model for regression on an input relation. [[Machine learning algorithms](#)]

[RIGHT](#)

Returns the specified characters from the right side of a string. [[String functions](#)]

[ROC](#)

Returns a table that displays the points on a receiver operating characteristic curve. [[Model evaluation](#)]

[ROUND](#)

Rounds the specified date or time. [[Date/time functions](#)]

[ROUND](#)

Rounds a value to a specified number of decimal places, retaining the original precision and scale. [[Mathematical functions](#)]

[ROW_NUMBER \[analytic\]](#)

Assigns a sequence of unique numbers to each row in a partition, starting with 1. [[Analytic functions](#)]

[RPAD](#)

Returns a VARCHAR value representing a string of a specific length filled on the right with specific characters. [[String functions](#)]

[RSQUARED](#)

Returns a table with the R-squared value of the predictions in a regression model. [[Model evaluation](#)]

[RTRIM](#)

Returns a VARCHAR value representing a string with trailing blanks removed from the right side (end). [[String functions](#)]

[RUN_INDEX_TOOL](#)

Runs the Index tool on a Vertica database to perform one of these tasks:. [[Database functions](#)]

[SANDBOX_SUBCLUSTER](#)

Creates a sandbox for a secondary subcluster. [[Eon Mode functions](#)]

[SAVE_PLANS](#)

Creates optimizer-generated directed queries from the most frequently executed queries, up to the maximum specified. [[Directed queries functions](#)]

[SECOND](#)

Returns the seconds portion of the specified date as an integer. [[Date/time functions](#)]

[SECURITY_CONFIG_CHECK](#)

Returns the status of various security-related parameters. [[Database functions](#)]

[SESSION_USER](#)

Returns a VARCHAR containing the name of the user who initiated the current database session. [[System information functions](#)]

[SET_AHM_EPOCH](#)

Sets the (AHM) to the specified epoch. [[Epoch functions](#)]

[SET_AHM_TIME](#)

Sets the (AHM) to the epoch corresponding to the specified time on the initiator node. [[Epoch functions](#)]

[SET_AUDIT_TIME](#)

Sets the time that Vertica performs automatic database size audit to determine if the size of the database is compliant with the raw data allowance in your Vertica license. [[License functions](#)]

[SET_CLIENT_LABEL](#)

Assigns a label to a client connection for the current session. [[Client connection functions](#)]

[SET_CONFIG_PARAMETER](#)

Sets or clears a configuration parameter at the specified level. [[Database functions](#)]

[SET_CONTROL_SET_SIZE](#)

Sets the number of that participate in the spread service when large cluster is enabled. [[Cluster functions](#)]

[SET_DATA_COLLECTOR_NOTIFY_POLICY](#)

Creates/enables notification policies for a component. [[Notifier functions](#)]

[SET_DATA_COLLECTOR_POLICY](#)

Updates the following retention policy properties for the specified component:. [[Data Collector functions](#)]

[SET_DATA_COLLECTOR_POLICY \(using parameters\)](#)

Updates selected retention policy properties for a component. [[Data Collector functions](#)]

[SET_DATA_COLLECTOR_TIME_POLICY](#)

Updates the retention policy property INTERVAL_TIME for the specified component. [[Data Collector functions](#)]

[SET_DEPOT_ANTI_PIN_POLICY_PARTITION](#)

Assigns the highest depot eviction priority to a partition. [[Eon Mode functions](#)]

[SET_DEPOT_ANTI_PIN_POLICY_PROJECTION](#)

Assigns the highest depot eviction priority to a projection. [[Eon Mode functions](#)]

[SET_DEPOT_ANTI_PIN_POLICY_TABLE](#)

Assigns the highest depot eviction priority to a table. [[Eon Mode functions](#)]

[SET_DEPOT_PIN_POLICY_PARTITION](#)

Pins the specified partitions of a table or projection to a subcluster depot, or all database depots, to reduce exposure to depot eviction. [[Eon Mode functions](#)]

[SET_DEPOT_PIN_POLICY_PROJECTION](#)

Pins a projection to a subcluster depot, or all database depots, to reduce its exposure to depot eviction. [[Eon Mode functions](#)]

[SET_DEPOT_PIN_POLICY_TABLE](#)

Pins a table to a subcluster depot, or all database depots, to reduce its exposure to depot eviction. [[Eon Mode functions](#)]

[SET_LOAD_BALANCE_POLICY](#)

Sets how native connection load balancing chooses a host to handle a client connection. [[Client connection functions](#)]

[SET_LOCATION_PERFORMANCE](#)

Sets disk performance for a storage location. [[Storage functions](#)]

[SET_OBJECT_STORAGE_POLICY](#)

Creates or changes the storage policy of a database object by assigning it a labeled storage location. [[Storage functions](#)]

[SET_SCALING_FACTOR](#)

Sets the scaling factor that determines the number of storage containers used when rebalancing the database and when using local data segmentation is enabled. [[Cluster functions](#)]

[SET_SPREAD_OPTION](#)

Changes daemon settings. [[Database functions](#)]

[SET_TOKENIZER_PARAMETER](#)

Configures the tokenizer parameters. [[Text search functions](#)]

[SET_UNION](#)

Returns a SET containing all elements of two input sets. [[Collection functions](#)]

[SHA1](#)

Uses the US Secure Hash Algorithm 1 to calculate the SHA1 hash of string. [[String functions](#)]

[SHA224](#)

Uses the US Secure Hash Algorithm 2 to calculate the SHA224 hash of string. [[String functions](#)]

[SHA256](#)

Uses the US Secure Hash Algorithm 2 to calculate the SHA256 hash of string. [[String functions](#)]

[SHA384](#)

Uses the US Secure Hash Algorithm 2 to calculate the SHA384 hash of string. [[String functions](#)]

[SHA512](#)

Uses the US Secure Hash Algorithm 2 to calculate the SHA512 hash of string. [[String functions](#)]

[SHOW_PROFILING_CONFIG](#)

Shows whether profiling is enabled. [[Profiling functions](#)]

[SHUTDOWN](#)

Shuts down a Vertica database. [[Database functions](#)]

[SHUTDOWN_SUBCLUSTER](#)

Shuts down a subcluster. [[Eon Mode functions](#)]

[SHUTDOWN_WITH_DRAIN](#)

Gracefully shuts down a subcluster or subclusters. [[Eon Mode functions](#)]

[SIGN](#)

Returns a DOUBLE PRECISION value of -1, 0, or 1 representing the arithmetic sign of the argument. [[Mathematical functions](#)]

[SIN](#)

Returns a DOUBLE PRECISION value that represents the trigonometric sine of the passed parameter. [[Mathematical functions](#)]

[SINH](#)

Returns a DOUBLE PRECISION value that represents the hyperbolic sine of the passed parameter. [[Mathematical functions](#)]

[SLEEP](#)

Waits a specified number of seconds before executing another statement or command. [[Workload management functions](#)]

[SOUNDEX](#)

Takes a VARCHAR argument and returns a four-character code that enables comparison of that argument with other SOUNDEX-encoded strings that are spelled differently in English, but are phonetically similar. [[String functions](#)]

[SOUNDEX_MATCHES](#)

Compares the Soundex encodings of two strings. [[String functions](#)]

[SPACE](#)

Returns the specified number of blank spaces, typically for insertion into a character string. [[String functions](#)]

[SPLIT_PART](#)

Splits string on the delimiter and returns the string at the location of the beginning of the specified field (counting from 1). [[String functions](#)]

[SPLIT_PARTB](#)

Divides an input string on a delimiter character and returns the Nth segment, counting from 1. [[String functions](#)]

[SQRT](#)

Returns a DOUBLE PRECISION value representing the arithmetic square root of the argument. [[Mathematical functions](#)]

[ST_Area](#)

Calculates the area of a spatial object. [[Geospatial functions](#)]

[ST_AsBinary](#)

Creates the Well-Known Binary (WKB) representation of a spatial object. [[Geospatial functions](#)]

ST_AsText

Creates the Well-Known Text (WKT) representation of a spatial object. [[Geospatial functions](#)]

ST_Boundary

Calculates the boundary of the specified GEOMETRY object. [[Geospatial functions](#)]

ST_Buffer

Creates a GEOMETRY object greater than or equal to a specified distance from the boundary of a spatial object. [[Geospatial functions](#)]

ST_Centroid

Calculates the geometric center—the centroid—of a spatial object. [[Geospatial functions](#)]

ST_Contains

Determines if a spatial object is entirely inside another spatial object without existing only on its boundary. [[Geospatial functions](#)]

ST_ConvexHull

Calculates the smallest convex GEOMETRY object that contains a GEOMETRY object. [[Geospatial functions](#)]

ST_Crosses

Determines if one GEOMETRY object spatially crosses another GEOMETRY object. [[Geospatial functions](#)]

ST_Difference

Calculates the part of a spatial object that does not intersect with another spatial object. [[Geospatial functions](#)]

ST_Disjoint

Determines if two GEOMETRY objects do not intersect or touch. [[Geospatial functions](#)]

ST_Distance

Calculates the shortest distance between two spatial objects. [[Geospatial functions](#)]

ST_Envelope

Calculates the minimum bounding rectangle that contains the specified GEOMETRY object. [[Geospatial functions](#)]

ST_Equals

Determines if two spatial objects are spatially equivalent. [[Geospatial functions](#)]

ST_GeographyFromText

Converts a Well-Known Text (WKT) string into its corresponding GEOGRAPHY object. [[Geospatial functions](#)]

ST_GeographyFromWKB

Converts a Well-Known Binary (WKB) value into its corresponding GEOGRAPHY object. [[Geospatial functions](#)]

ST_GeoHash

Returns a GeoHash in the shape of the specified geometry. [[Geospatial functions](#)]

ST_GeometryN

Returns the n geometry within a geometry object. [[Geospatial functions](#)]

ST_GeometryType

Determines the class of a spatial object. [[Geospatial functions](#)]

ST_GeomFromGeoHash

Returns a polygon in the shape of the specified GeoHash. [[Geospatial functions](#)]

ST_GeomFromGeoJSON

Converts the geometry portion of a GeoJSON record in the standard format into a GEOMETRY object. [[Geospatial functions](#)]

ST_GeomFromText

Converts a Well-Known Text (WKT) string into its corresponding GEOMETRY object. [[Geospatial functions](#)]

ST_GeomFromWKB

Converts the Well-Known Binary (WKB) value to its corresponding GEOMETRY object. [[Geospatial functions](#)]

ST_Intersection

Calculates the set of points shared by two GEOMETRY objects. [[Geospatial functions](#)]

ST_Intersects

Determines if two GEOMETRY or GEOGRAPHY objects intersect or touch at a single point. [[Geospatial functions](#)]

ST_IsEmpty

Determines if a spatial object represents the empty set. [[Geospatial functions](#)]

ST_IsSimple

Determines if a spatial object does not intersect itself or touch its own boundary at any point. [[Geospatial functions](#)]

ST_IsValid

Determines if a spatial object is well formed or valid. [[Geospatial functions](#)]

[ST_Length](#)

Calculates the length of a spatial object. [[Geospatial functions](#)]

[ST_NumGeometries](#)

Returns the number of geometries contained within a spatial object. [[Geospatial functions](#)]

[ST_NumPoints](#)

Calculates the number of vertices of a spatial object, empty objects return NULL. [[Geospatial functions](#)]

[ST_Overlaps](#)

Determines if a GEOMETRY object shares space with another GEOMETRY object, but is not completely contained within that object. [[Geospatial functions](#)]

[ST_PointFromGeoHash](#)

Returns the center point of the specified GeoHash. [[Geospatial functions](#)]

[ST_PointN](#)

Finds the n point of a spatial object. [[Geospatial functions](#)]

[ST_Relate](#)

Determines if a given GEOMETRY object is spatially related to another GEOMETRY object, based on the specified DE-9IM pattern matrix string. [[Geospatial functions](#)]

[ST_SRID](#)

Identifies the spatial reference system identifier (SRID) stored with a spatial object. [[Geospatial functions](#)]

[ST_SymDifference](#)

Calculates all the points in two GEOMETRY objects except for the points they have in common, but including the boundaries of both objects. [[Geospatial functions](#)]

[ST_Touches](#)

Determines if two GEOMETRY objects touch at a single point or along a boundary, but do not have interiors that intersect. [[Geospatial functions](#)]

[ST_Transform](#)

Returns a new GEOMETRY with its coordinates converted to the spatial reference system identifier (SRID) used by the srid argument. [[Geospatial functions](#)]

[ST_Union](#)

Calculates the union of all points in two spatial objects. [[Geospatial functions](#)]

[ST_Within](#)

If spatial object g1 is completely inside of spatial object g2, then ST_Within returns true. [[Geospatial functions](#)]

[ST_X](#)

Determines the x- coordinate for a GEOMETRY point or the longitude value for a GEOGRAPHY point. [[Geospatial functions](#)]

[ST_XMax](#)

Returns the maximum x-coordinate of the minimum bounding rectangle of the GEOMETRY or GEOGRAPHY object. [[Geospatial functions](#)]

[ST_XMin](#)

Returns the minimum x-coordinate of the minimum bounding rectangle of the GEOMETRY or GEOGRAPHY object. [[Geospatial functions](#)]

[ST_Y](#)

Determines the y-coordinate for a GEOMETRY point or the latitude value for a GEOGRAPHY point. [[Geospatial functions](#)]

[ST_YMax](#)

Returns the maximum y-coordinate of the minimum bounding rectangle of the GEOMETRY or GEOGRAPHY object. [[Geospatial functions](#)]

[ST_YMin](#)

Returns the minimum y-coordinate of the minimum bounding rectangle of the GEOMETRY or GEOGRAPHY object. [[Geospatial functions](#)]

[START_DRAIN_SUBCLUSTER](#)

Drains a subcluster or subclusters. [[Eon Mode functions](#)]

[START_REAPING_FILES](#)

Starts the disk file deletion in the background as an asynchronous function. [[Eon Mode functions](#)]

[START_REBALANCE_CLUSTER](#)

Asynchronously rebalances the database cluster as a background task. [[Cluster functions](#)]

[START_REFRESH](#)

Refreshes projections in the current schema with the latest data of their respective. [[Projection functions](#)]

[STATEMENT_TIMESTAMP](#)

Similar to TRANSACTION_TIMESTAMP, returns a value of type TIMESTAMP WITH TIME ZONE that represents the start of the current statement. [

[Date/time functions](#).]

[STDDEV \[aggregate\]](#)

Evaluates the statistical sample standard deviation for each member of the group. [[Aggregate functions](#)]

[STDDEV \[analytic\]](#)

Computes the statistical sample standard deviation of the current row with respect to the group within a. [[Analytic functions](#)]

[STDDEV_POP \[aggregate\]](#)

Evaluates the statistical population standard deviation for each member of the group. [[Aggregate functions](#)]

[STDDEV_POP \[analytic\]](#)

Evaluates the statistical population standard deviation for each member of the group. [[Analytic functions](#)]

[STDDEV_SAMP \[aggregate\]](#)

Evaluates the statistical sample standard deviation for each member of the group. [[Aggregate functions](#)]

[STDDEV_SAMP \[analytic\]](#)

Computes the statistical sample standard deviation of the current row with respect to the group within a. [[Analytic functions](#)]

[STRING_TO_ARRAY](#)

Splits a string containing array values and returns a native one-dimensional array. [[Collection functions](#)]

[STRPOS](#)

Returns an INTEGER value that represents the location of a specified substring within a string (counting from one). [[String functions](#)]

[STRPOSB](#)

Returns an INTEGER value representing the location of a specified substring within a string, counting from one, where each octet in the string is counted (as opposed to characters). [[String functions](#)]

[STV_AsGeoJSON](#)

Returns the geometry or geography argument as a Geometry Javascript Object Notation (GeoJSON) object. [[Geospatial functions](#)]

[STV_Create_Index](#)

Creates a spatial index on a set of polygons to speed up spatial intersection with a set of points. [[Geospatial functions](#)]

[STV_Describe_Index](#)

Retrieves information about an index that contains a set of polygons. [[Geospatial functions](#)]

[STV_Drop_Index](#)

Deletes a spatial index. [[Geospatial functions](#)]

[STV_DWithin](#)

Determines if the shortest distance from the boundary of one spatial object to the boundary of another object is within a specified distance. [[Geospatial functions](#)]

[STV_Export2Shapefile](#)

Exports GEOGRAPHY or GEOMETRY data from a database table or a subquery to a shapefile. [[Geospatial functions](#)]

[STV_Extent](#)

Returns a bounding box containing all of the input data. [[Geospatial functions](#)]

[STV_ForceLHR](#)

Alters the order of the vertices of a spatial object to follow the left-hand-rule. [[Geospatial functions](#)]

[STV_Geography](#)

Casts a GEOMETRY object into a GEOGRAPHY object. [[Geospatial functions](#)]

[STV_GeographyPoint](#)

Returns a GEOGRAPHY point based on the input values. [[Geospatial functions](#)]

[STV_Geometry](#)

Casts a GEOGRAPHY object into a GEOMETRY object. [[Geospatial functions](#)]

[STV_GeometryPoint](#)

Returns a GEOMETRY point, based on the input values. [[Geospatial functions](#)]

[STV_GetExportShapefileDirectory](#)

Returns the path of the export directory. [[Geospatial functions](#)]

[STV_Intersect scalar function](#)

Spatially intersects a point or points with a set of polygons. [[Geospatial functions](#)]

[STV_Intersect transform function](#)

Spatially intersects points and polygons. [[Geospatial functions](#)]

[STV_IsValidReason](#)

Determines if a spatial object is well formed or valid. [[Geospatial functions](#)]

[STV_LineStringPoint](#)

Retrieves the vertices of a linestring or multilinestring. [[Geospatial functions](#)]

[STV_MemSize](#)

Returns the length of the spatial object in bytes as an INTEGER. [[Geospatial functions](#)]

[STV_NN](#)

Calculates the distance of spatial objects from a reference object and returns (object, distance) pairs in ascending order by distance from the reference object. [[Geospatial functions](#)]

[STV_PolygonPoint](#)

Retrieves the vertices of a polygon as individual points. [[Geospatial functions](#)]

[STV_Refresh_Index](#)

Appends newly added or updated polygons and removes deleted polygons from an existing spatial index. [[Geospatial functions](#)]

[STV_Rename_Index](#)

Renames a spatial index. [[Geospatial functions](#)]

[STV_Reverse](#)

Reverses the order of the vertices of a spatial object. [[Geospatial functions](#)]

[STV_SetExportShapefileDirectory](#)

Specifies the directory to export GEOMETRY or GEOGRAPHY data to a shapefile. [[Geospatial functions](#)]

[STV_ShpCreateTable](#)

Returns a CREATE TABLE statement with the columns and types of the attributes found in the specified shapefile. [[Geospatial functions](#)]

[STV_ShpSource and STV_ShpParser](#)

These two functions work with COPY to parse and load geometries and attributes from a shapefile into a Vertica table, and convert them to the appropriate GEOMETRY data type. [[Geospatial functions](#)]

[SUBSTR](#)

Returns VARCHAR or VARBINARY value representing a substring of a specified string. [[String functions](#)]

[SUBSTRB](#)

Returns an octet value representing the substring of a specified string. [[String functions](#)]

[SUBSTRING](#)

Returns a value representing a substring of the specified string at the given position, given a value, a position, and an optional length. [[String functions](#)]

[SUM \[aggregate\]](#)

Computes the sum of an expression over a group of rows. [[Aggregate functions](#)]

[SUM \[analytic\]](#)

Computes the sum of an expression over a group of rows within a. [[Analytic functions](#)]

[SUM_FLOAT \[aggregate\]](#)

Computes the sum of an expression over a group of rows and returns a DOUBLE PRECISION value. [[Aggregate functions](#)]

[SUMMARIZE_CATCOL](#)

Returns a statistical summary of categorical data input, in three columns:. [[Data preparation](#)]

[SUMMARIZE_NUMCOL](#)

Returns a statistical summary of columns in a Vertica table:. [[Data preparation](#)]

[SVD](#)

Computes singular values (the diagonal of the S matrix) and right singular vectors (the V matrix) of an SVD decomposition of the input relation. [[Data preparation](#)]

[SVM_CLASSIFIER](#)

Trains the SVM model on an input relation. [[Machine learning algorithms](#)]

[SVM_REGRESSOR](#)

Trains the SVM model on an input relation. [[Machine learning algorithms](#)]

[SWAP_PARTITIONS_BETWEEN_TABLES](#)

Swaps partitions between two tables. [[Partition functions](#)]

[SYNC_CATALOG](#)

Synchronizes the catalog to communal storage to enable reviving the current catalog version in the case of an imminent crash. [[Eon Mode functions](#)]

[SYNC_WITH_HCATALOG_SCHEMA](#)

Copies the structure of a Hive database schema available through the HCatalog Connector to a Vertica schema. [[Hadoop functions](#)]

[SYNC_WITH_HCATALOG_SCHEMA_TABLE](#)

Copies the structure of a single table in a Hive database schema available through the HCatalog Connector to a Vertica table. [[Hadoop functions](#)]

[SYSDATE](#)

Returns the current statement's start date and time as a `TIMESTAMP` value. [[Date/time functions](#)]

T

[TAN](#)

Returns a `DOUBLE PRECISION` value that represents the trigonometric tangent of the passed parameter. [[Mathematical functions](#)]

[TANH](#)

Returns a `DOUBLE PRECISION` value that represents the hyperbolic tangent of the passed parameter. [[Mathematical functions](#)]

[Template patterns for date/time formatting](#)

In an output template string (for `TO_CHAR`), certain patterns are recognized and replaced with appropriately formatted data from the value to format. [[Formatting functions](#)]

[Template patterns for numeric formatting](#)

A sign formatted using `SG`, `PL`, or `MI` is not anchored to the number. [[Formatting functions](#)]

[THROW_ERROR](#)

Returns a user-defined error message. [[Error-handling functions](#)]

[TIME_SLICE](#)

Aggregates data by different fixed-time intervals and returns a rounded-up input `TIMESTAMP` value to a value that corresponds with the start or end of the time slice interval. [[Date/time functions](#)]

[TIMEOFDAY](#)

Returns the wall-clock time as a text string. [[Date/time functions](#)]

[TIMESTAMP_ROUND](#)

Rounds the specified `TIMESTAMP`. [[Date/time functions](#)]

[TIMESTAMP_TRUNC](#)

Truncates the specified `TIMESTAMP`. [[Date/time functions](#)]

[TIMESTAMPADD](#)

Adds the specified number of intervals to a `TIMESTAMP` or `TIMESTAMPTZ` value and returns a result of the same data type. [[Date/time functions](#)]

[TIMESTAMPDIFF](#)

Returns the time span between two `TIMESTAMP` or `TIMESTAMPTZ` values, in the intervals specified. [[Date/time functions](#)]

[TO_BITSTRING](#)

This topic is shared in two locations: [Formatting Functions](#) and [String Functions](#). [[Formatting functions](#)]

[TO_CHAR](#)

Converts date/time and numeric values into text strings. [[Formatting functions](#)]

[TO_DATE](#)

This topic shared in two places: [Date/Time functions](#) and [Formatting Functions](#). [[Formatting functions](#)]

[TO_HEX](#)

This topic is shared in two locations: [Formatting Functions](#) and [String Functions](#). [[Formatting functions](#)]

[TO_JSON](#)

Returns the JSON representation of a complex-type argument, including mixed and nested complex types. [[Collection functions](#)]

[TO_NUMBER](#)

Converts a string value to `DOUBLE PRECISION`. [[Formatting functions](#)]

[TO_TIMESTAMP](#)

Converts a string value or a UNIX/POSIX epoch value to a `TIMESTAMP` type. [[Formatting functions](#)]

[TO_TIMESTAMP_TZ](#)

Converts a string value or a UNIX/POSIX epoch value to a `TIMESTAMP WITH TIME ZONE` type. [[Formatting functions](#)]

[TRANSACTION_TIMESTAMP](#)

Returns a value of type `TIME WITH TIMEZONE` that represents the start of the current transaction. [[Date/time functions](#)]

[TRANSLATE](#)

Replaces individual characters in `string_to_replace` with other characters. [[String functions](#)]

[TRIM](#)

Combines the BTRIM, LTRIM, and RTRIM functions into a single function. [[String functions](#)]

[TRUNC](#)

Truncates the specified date or time. [[Date/time functions](#)]

[TRUNC](#)

Returns the expression value fully truncated (toward zero). [[Mathematical functions](#)]

[TS_FIRST_VALUE](#)

Processes the data that belongs to each time slice. [[Aggregate functions](#)]

[TS_LAST_VALUE](#)

Processes the data that belongs to each time slice. [[Aggregate functions](#)]

U

[UNNEST](#)

Expands the elements of one or more collection columns (ARRAY or SET) into individual rows. [[Collection functions](#)]

[UNSANDBOX_SUBCLUSTER](#)

Removes a subcluster from a sandbox. [[Eon Mode functions](#)]

[UPGRADE_MODEL](#)

Upgrades a model from a previous Vertica version. [[Model management](#)]

[UPPER](#)

Returns a VARCHAR value containing the argument converted to uppercase letters. [[String functions](#)]

[UPPERB](#)

Returns a character string with each ASCII character converted to uppercase. [[String functions](#)]

[URI_PERCENT_DECODE](#)

Decodes a percent-encoded Universal Resource Identifier (URI) according to the RFC 3986 standard. [[URI functions](#)]

[URI_PERCENT_ENCODE](#)

Encodes a Universal Resource Identifier (URI) according to the RFC 3986 standard for percent encoding. [[URI functions](#)]

[USER](#)

Returns a VARCHAR containing the name of the user who initiated the current database connection. [[System information functions](#)]

[USERNAME](#)

Returns a VARCHAR containing the name of the user who initiated the current database connection. [[System information functions](#)]

[UUID_GENERATE](#)

Returns a new universally unique identifier (UUID) that is generated based on high-quality randomness from /dev/urandom. [[UUID functions](#)]

V

[V6_ATON](#)

Converts a string containing a colon-delimited IPv6 network address into a VARBINARY string. [[IP address functions](#)]

[V6_NTOA](#)

Converts an IPv6 address represented as varbinary to a character string. [[IP address functions](#)]

[V6_SUBNETA](#)

Returns a VARCHAR containing a subnet address in CIDR (Classless Inter-Domain Routing) format from a binary or alphanumeric IPv6 address. [[IP address functions](#)]

[V6_SUBNETN](#)

Calculates a subnet address in CIDR (Classless Inter-Domain Routing) format from a varbinary or alphanumeric IPv6 address. [[IP address functions](#)]

[V6_TYPE](#)

Returns an INTEGER value that classifies the type of the network address passed to it as defined in IETF RFC 4291 section 2.4. [[IP address functions](#)]

[VALIDATE_STATISTICS](#)

Validates statistics in the XML file generated by EXPORT_STATISTICS. [[Statistics management functions](#)]

[VAR_POP \[aggregate\]](#)

Evaluates the population variance for each member of the group. [[Aggregate functions](#)]

[VAR_POP \[analytic\]](#)

Returns the statistical population variance of a non-null set of numbers (nulls are ignored) in a group within a. [[Analytic functions](#)]

[VAR_SAMP \[aggregate\]](#)

Evaluates the sample variance for each row of the group. [[Aggregate functions](#)]

[VAR_SAMP \[analytic\]](#)

Returns the sample variance of a non-NULL set of numbers (NULL values in the set are ignored) for each row of the group within a. [[Analytic functions](#)]

[VARIANCE \[aggregate\]](#)

Evaluates the sample variance for each row of the group. [[Aggregate functions](#)]

[VARIANCE \[analytic\]](#)

Returns the sample variance of a non-NULL set of numbers (NULL values in the set are ignored) for each row of the group within a. [[Analytic functions](#)]

[VERIFY_HADOOP_CONF_DIR](#)

Verifies that the Hadoop configuration that is used to access HDFS is valid on all Vertica nodes. [[Hadoop functions](#)]

[VERSION](#)

Returns a VARCHAR containing a Vertica node's version information. [[System information functions](#)]

W

[WEEK](#)

Returns the week of the year for the specified date as an integer, where the first week begins on the first Sunday on or preceding January 1. [[Date/time functions](#)]

[WEEK_ISO](#)

Returns the week of the year for the specified date as an integer, where the first week starts on Monday and contains January 4. [[Date/time functions](#)]

[WIDTH_BUCKET](#)

Constructs equiwidth histograms, in which the histogram range is divided into intervals (buckets) of identical sizes. [[Mathematical functions](#)]

[WITHIN GROUP ORDER BY clause](#)

Specifies how to sort rows that are grouped by aggregate functions, one of the following:. [[Aggregate functions](#)]

X

[XGB_CLASSIFIER](#)

Trains an XGBoost model for classification on an input relation. [[Machine learning algorithms](#)]

[XGB_PREDICTOR_IMPORTANCE](#)

Measures the importance of the predictors in an XGBoost model. [[Model evaluation](#)]

[XGB_REGRESSOR](#)

Trains an XGBoost model for regression on an input relation. [[Machine learning algorithms](#)]

Y

[YEAR](#)

Returns an integer that represents the year portion of the specified date. [[Date/time functions](#)]

[YEAR_ISO](#)

Returns an integer that represents the year portion of the specified date. [[Date/time functions](#)]

Z

[ZEROIFNULL](#)

Evaluates to 0 if the column is NULL. [[NULL-handling functions](#)]

Aggregate functions

Aggregate functions summarize data over groups of rows from a query result set. The groups are specified using the [GROUP BY](#) clause. They are allowed only in the select list and in the [HAVING](#) and [ORDER BY](#) clauses of a [SELECT](#) statement (as described in [Aggregate expressions](#)).

Except for COUNT, these functions return a null value when no rows are selected. In particular, SUM of no rows returns NULL, not zero.

In some cases, you can replace an expression that includes multiple aggregates with a single aggregate of an expression. For example [SUM\(x\) + SUM\(y\)](#) can be expressed as [SUM\(x+y\)](#) if neither argument is NULL.

Vertica does not support nested aggregate functions.

You can use some of the simple aggregate functions as analytic (window) functions. See [Analytic functions](#) for details. See also [SQL analytics](#).

Some [collection functions](#) also behave as aggregate functions.

Note

All functions in this section that have an [analytic](#) function counterpart are appended with [aggregate] to avoid confusion between the two.

APPROXIMATE_COUNT_DISTINCT

Returns the number of distinct non-NULL values in a data set.

Behavior type

[Immutable](#)

Syntax

```
APPROXIMATE_COUNT_DISTINCT ( expression[, error-tolerance ] )
```

Parameters

expression

Value to be evaluated using any data type that supports equality comparison.

error-tolerance

Numeric value that represents the desired percentage of error tolerance, distributed around the value returned by this function. The smaller the error tolerance, the closer the approximation.

You can set ***error-tolerance*** to a minimum value of 0.88. Vertica imposes no maximum restriction, but any value greater than 5 is implemented with 5% error tolerance.

If you omit this argument, Vertica uses an error tolerance of 1.25(%)

Restrictions

APPROXIMATE_COUNT_DISTINCT and DISTINCT aggregates cannot be in the same query block.

Error tolerance

APPROXIMATE_COUNT_DISTINCT(*x* , ***error-tolerance***) returns a value equal to **COUNT(DISTINCT *x*)** , with an error that is lognormally distributed with standard deviation.

Parameter ***error-tolerance*** is optional. Supply this argument to specify the desired standard deviation. ***error-tolerance*** is defined as 2.17 standard deviations, which corresponds to a 97 percent confidence interval:

```
standard-deviation = error-tolerance / 2.17
```

For example:

- ***error-tolerance* = 1**

Default setting, corresponds to a standard deviation

97 percent of the time, **APPROXIMATE_COUNT_DISTINCT(*x*,5)** returns a value between:

- **COUNT(DISTINCT *x*) * 0.99**
- **COUNT(DISTINCT *x*) * 1.01**

- ***error-tolerance* = 5**

97 percent of the time, **APPROXIMATE_COUNT_DISTINCT(*x*)** returns a value between:

- **COUNT(DISTINCT *x*) * 0.95**
- **COUNT(DISTINCT *x*) * 1.05**

A 99 percent confidence interval corresponds to **2.58** standard deviations. To set ***error-tolerance*** confidence level corresponding to 99 (instead of a 97) percent , multiply ***error-tolerance*** by $2.17 / 2.58 = 0.841$.

For example, if you specify *error-tolerance* as $5 * 0.841 = 4.2$, `APPROXIMATE_COUNT_DISTINCT(x,4.2)` returns values 99 percent of the time between:

- `COUNT (DISTINCT x) * 0.95`
- `COUNT (DISTINCT x) * 1.05`

Examples

Count the total number of distinct values in column `product_key` from table `store.store_sales_fact` :

```
=> SELECT COUNT(DISTINCT product_key) FROM store.store_sales_fact;
COUNT
-----
19982
(1 row)
```

Count the approximate number of distinct values in `product_key` with various error tolerances. The smaller the error tolerance, the closer the approximation:

```
=> SELECT APPROXIMATE_COUNT_DISTINCT(product_key,5) AS five_pct_accuracy,
       APPROXIMATE_COUNT_DISTINCT(product_key,1) AS one_pct_accuracy,
       APPROXIMATE_COUNT_DISTINCT(product_key,.88) AS point_eighteight_pct_accuracy
FROM store.store_sales_fact;

five_pct_accuracy | one_pct_accuracy | point_eighteight_pct_accuracy
-----+-----+-----
19431 | 19921 | 19921
(1 row)
```

See also

[Approximate count distinct functions](#)

`APPROXIMATE_COUNT_DISTINCT_OF_SYNOPSIS`

Calculates the number of distinct non-NULL values from the synopsis objects created by [APPROXIMATE_COUNT_DISTINCT_SYNOPSIS](#).

Behavior type

[Immutable](#)

Syntax

```
APPROXIMATE_COUNT_DISTINCT_OF_SYNOPSIS ( synopsis-obj[, error-tolerance ] )
```

Parameters

synopsis-obj

A synopsis object created by `APPROXIMATE_COUNT_DISTINCT_SYNOPSIS`.

error-tolerance

Numeric value that represents the desired percentage of error tolerance, distributed around the value returned by this function. The smaller the error tolerance, the closer the approximation.

You can set *error-tolerance* to a minimum value of 0.88. Vertica imposes no maximum restriction, but any value greater than 5 is implemented with 5% error tolerance.

If you omit this argument, Vertica uses an error tolerance of 1.25(%)

For more details, see [APPROXIMATE_COUNT_DISTINCT](#).

Restrictions

`APPROXIMATE_COUNT_DISTINCT_OF_SYNOPSIS` and `DISTINCT` aggregates cannot be in the same query block.

Examples

The following examples review and compare different ways to obtain a count of unique values in a table column:

Return an exact count of unique values in column `product_key`, from table `store.store_sales_fact` :

```
=> \timing
Timing is on.
=> SELECT COUNT(DISTINCT product_key) from store.store_sales_fact;
count
-----
19982
(1 row)

Time: First fetch (1 row): 553.033 ms. All rows formatted: 553.075 ms
```

Return an approximate count of unique values in column `product_key` :

```
=> SELECT APPROXIMATE_COUNT_DISTINCT(product_key) as unique_product_keys
FROM store.store_sales_fact;
unique_product_keys
-----
19921
(1 row)

Time: First fetch (1 row): 394.562 ms. All rows formatted: 394.600 ms
```

Create a synopsis object that represents a set of `store.store_sales_fact` data with unique `product_key` values, store the synopsis in the new table `my_summary` :

```
=> CREATE TABLE my_summary AS SELECT APPROXIMATE_COUNT_DISTINCT_SYNOPSIS (product_key) syn
FROM store.store_sales_fact;
CREATE TABLE
Time: First fetch (0 rows): 582.662 ms. All rows formatted: 582.682 ms
```

Return a count from the saved synopsis:

```
=> SELECT APPROXIMATE_COUNT_DISTINCT_OF_SYNOPSIS(syn) FROM my_summary;
ApproxCountDistinctOfSynopsis
-----
19921
(1 row)

Time: First fetch (1 row): 105.295 ms. All rows formatted: 105.335 ms
```

See also

[Approximate count distinct functions](#)

`APPROXIMATE_COUNT_DISTINCT_SYNOPSIS`

Summarizes the information of distinct non-NULL values and materializes the result set in a VARBINARY or LONG VARBINARY *synopsis* object. The calculated result is within a specified range of error tolerance. You save the synopsis object in a Vertica table for use by [APPROXIMATE_COUNT_DISTINCT_OF_SYNOPSIS](#).

Behavior type

[Immutable](#)

Syntax

```
APPROXIMATE_COUNT_DISTINCT_SYNOPSIS ( expression [, error-tolerance] )
```

Parameters

expression

Value to evaluate using any data type that supports equality comparison.

error-tolerance

Numeric value that represents the desired percentage of error tolerance, distributed around the value returned by this function. The smaller the error tolerance, the closer the approximation.

You can set `error-tolerance` to a minimum value of 0.88. Vertica imposes no maximum restriction, but any value greater than 5 is implemented with 5% error tolerance.

If you omit this argument, Vertica uses an error tolerance of 1.25(%)

For more details, see [APPROXIMATE_COUNT_DISTINCT](#).

Restrictions

APPROXIMATE_COUNT_DISTINCT_SYNOPSIS and DISTINCT aggregates cannot be in the same query block.

Examples

See [APPROXIMATE_COUNT_DISTINCT_OF_SYNOPSIS](#).

See also

[Approximate count distinct functions](#)

APPROXIMATE_COUNT_DISTINCT_SYNOPSIS_MERGE

Aggregates multiple synopses into one new synopsis. This function is similar to [APPROXIMATE_COUNT_DISTINCT_OF_SYNOPSIS](#) but returns one synopsis instead of the count estimate. The benefit of this function is that it speeds up final estimation when calling APPROXIMATE_COUNT_DISTINCT_OF_SYNOPSIS.

For example, if you need to regularly estimate count distinct of users for a long period of time (such as several years) you can pre-accumulate synopses of days into one synopsis for a year.

Behavior type

[Immutable](#)

Syntax

```
APPROXIMATE_COUNT_DISTINCT_SYNOPSIS_MERGE ( synopsis-obj [, error-tolerance] )
```

Parameters

synopsis-obj

An expression that can be evaluated to one or more synopses. Typically a *synopsis-obj* is generated as a binary string by either the [APPROXIMATE_COUNT_DISTINCT](#) or APPROXIMATE_COUNT_DISTINCT_SYNOPSIS_MERGE function and is stored in a table column of type VARBINARY or LONG VARBINARY.

error-tolerance

Numeric value that represents the desired percentage of error tolerance, distributed around the value returned by this function. The smaller the error tolerance, the closer the approximation.

You can set **error-tolerance** to a minimum value of 0.88. Vertica imposes no maximum restriction, but any value greater than 5 is implemented with 5% error tolerance.

If you omit this argument, Vertica uses an error tolerance of 1.25(%)

For more details, see [APPROXIMATE_COUNT_DISTINCT](#).

Examples

See [Approximate count distinct functions](#).

APPROXIMATE_MEDIAN [aggregate]

Computes the approximate median of an expression over a group of rows. The function returns a FLOAT value.

APPROXIMATE_MEDIAN is an alias of [APPROXIMATE_PERCENTILE \[aggregate\]](#) with a parameter of 0.5.

Note

Note : This function is best suited for large groups of data. If you have a small group of data, use the exact [MEDIAN \[analytic\]](#) function.

Behavior type

[Immutable](#)

Syntax

```
APPROXIMATE_MEDIAN ( expression )
```

Parameters

expression

Any FLOAT or INTEGER data type. The function returns the approximate middle value or an interpolated value that would be the approximate

middle value once the values are sorted. Null values are ignored in the calculation.

Examples

Tip

For optimal performance when using **GROUP BY** in your query, verify that your table is sorted on the **GROUP BY** column.

The following examples uses this table:

```
CREATE TABLE allsales(state VARCHAR(20), name VARCHAR(20), sales INT) ORDER BY state;
INSERT INTO allsales VALUES('MA', 'A', 60);
INSERT INTO allsales VALUES('NY', 'B', 20);
INSERT INTO allsales VALUES('NY', 'C', 15);
INSERT INTO allsales VALUES('MA', 'D', 20);
INSERT INTO allsales VALUES('MA', 'E', 50);
INSERT INTO allsales VALUES('NY', 'F', 40);
INSERT INTO allsales VALUES('MA', 'G', 10);
COMMIT;
```

Calculate the approximate median of all sales in this table:

```
=> SELECT APPROXIMATE_MEDIAN (sales) FROM allsales;
APROXIMATE_MEDIAN
-----
          20
(1 row)
```

Modify the query to group sales by state, and obtain the approximate median for each one:

```
=> SELECT state, APPROXIMATE_MEDIAN(sales) FROM allsales GROUP BY state;
state | APPROXIMATE_MEDIAN
-----+-----
MA    |          35
NY    |          20
(2 rows)
```

See also

- [MEDIAN \[analytic\]](#)
- [PERCENTILE_CONT \[analytic\]](#)
- [APPROXIMATE_PERCENTILE \[aggregate\]](#)
- [SQL analytics](#)

APPROXIMATE_PERCENTILE [aggregate]

Computes the approximate percentile of an expression over a group of rows. This function returns a FLOAT value.

Note

Note : Use this function when many rows are aggregated into groups. If the number of aggregated rows is small, use the analytic function [PERCENTILE_CONT](#).

Behavior type

[Immutable](#)

Syntax

```
APPROXIMATE_PERCENTILE ( column-expression USING PARAMETERS percentiles='percentile-values' )
```

Arguments

column-expression

A column of FLOAT or INTEGER data types whose percentiles will be calculated. NULL values are ignored.

Parameters

percentiles

One or more (up to 1000) comma-separated **FLOAT** constants ranging from 0 to 1 inclusive, specifying the percentile values to be calculated.

Note

Note : The deprecated parameter **percentile** , which takes only a single float, continues to be supported for backwards-compatibility.

Examples

Tip

For optimal performance when using **GROUP BY** in your query, verify that your table is sorted on the **GROUP BY** column.

The following examples use this table:

```
=> CREATE TABLE allsales(state VARCHAR(20), name VARCHAR(20), sales INT) ORDER BY state;
INSERT INTO allsales VALUES('MA', 'A', 60);
INSERT INTO allsales VALUES('NY', 'B', 20);
INSERT INTO allsales VALUES('NY', 'C', 15);
INSERT INTO allsales VALUES('MA', 'D', 20);
INSERT INTO allsales VALUES('MA', 'E', 50);
INSERT INTO allsales VALUES('NY', 'F', 40);
INSERT INTO allsales VALUES('MA', 'G', 10);
COMMIT;
```

```
=> SELECT * FROM allsales;
```

```
state | name | sales
```

```
-----+-----+-----
MA  | A  | 60
NY  | B  | 20
NY  | C  | 15
NY  | F  | 40
MA  | D  | 20
MA  | E  | 50
MA  | G  | 10
```

(7 rows)

Calculate the approximate percentile for sales in each state:

```
=> SELECT state, APPROXIMATE_PERCENTILE(sales USING PARAMETERS percentiles='0.5') AS median
FROM allsales GROUP BY state;
```

```
state | median
```

```
-----+-----
MA  | 35
NY  | 20
```

(2 rows)

Calculate multiple approximate percentiles for sales in each state:

```
=> SELECT state, APPROXIMATE_PERCENTILE(sales USING PARAMETERS percentiles='0.5,1.0')
FROM allsales GROUP BY state;
```

```
state | APPROXIMATE_PERCENTILE
```

```
-----+-----
MA  | [35.0,60.0]
NY  | [20.0,40.0]
```

(2 rows)

Calculate multiple approximate percentiles for sales in each state and show results for each percentile in separate columns:

```
=> SELECT ps[0] as q0, ps[1] as q1, ps[2] as q2, ps[3] as q3, ps[4] as q4
FROM (SELECT APPROXIMATE_PERCENTILE(sales USING PARAMETERS percentiles='0, 0.25, 0.5, 0.75, 1')
AS ps FROM allsales GROUP BY state) as s1;
q0 | q1 | q2 | q3 | q4
-----+-----+-----+-----+-----
10.0 | 17.5 | 35.0 | 52.5 | 60.0
15.0 | 17.5 | 20.0 | 30.0 | 40.0
(2 rows)
```

See also

- [APPROXIMATE_QUANTILES](#)
- [MEDIAN](#)
- [PERCENTILE_CONT](#)
- [SQL analytics](#)

APPROXIMATE_QUANTILES

Computes an array of weighted, approximate percentiles of a column within some user-specified error. This algorithm is similar to [APPROXIMATE_PERCENTILE \[aggregate\]](#), which instead returns a single percentile.

The performance of this function depends entirely on the specified epsilon and the size of the provided array.

The OVER clause for this function must be empty.

Behavior type

[Immutable](#)

Syntax

```
APPROXIMATE_QUANTILES ( column USING PARAMETERS [nquantiles=n], [epsilon=error] ) OVER() FROM table
```

Parameters

column

The **INTEGER** or **FLOAT** column for which to calculate the percentiles. NULL values are ignored.

n

An integer that specifies the number of desired quantiles in the returned array.

Default: 11

error

The allowed error for any returned percentile. Specifically, for an array of size N , the specified error ϵ (epsilon) for the φ -quantile guarantees that the rank r of the return value with respect to the rank $\lfloor \varphi N \rfloor$ of the exact value is such that:

$$\lfloor (\varphi - \epsilon)N \rfloor \leq r \leq \lfloor (\varphi + \epsilon)N \rfloor$$

For n quantiles, if the error ϵ is specified such that $\epsilon > 1/n$, this function will return non-deterministic results.

Default: 0.001

table

The table containing *column*.

Examples

The following example uses this table:

```
=> CREATE TABLE allsales(state VARCHAR(20), name VARCHAR(20), sales INT) ORDER BY state;
INSERT INTO allsales VALUES('MA', 'A', 60);
INSERT INTO allsales VALUES('NY', 'B', 20);
INSERT INTO allsales VALUES('NY', 'C', 15);
INSERT INTO allsales VALUES('MA', 'D', 20);
INSERT INTO allsales VALUES('MA', 'E', 50);
INSERT INTO allsales VALUES('NY', 'F', 40);
INSERT INTO allsales VALUES('MA', 'G', 10);
COMMIT;
```

```
=> SELECT * FROM allsales;
```

```
state | name | sales
```

```
-----+-----
MA | A | 60
NY | B | 20
NY | C | 15
NY | F | 40
MA | D | 20
MA | E | 50
MA | G | 10
(7 rows)
```

This call to APPROXIMATE_QUANTILES returns a 6-element array of approximate percentiles, one for each quantile. Each quantile relates to the percentile by a factor of 100. For example, the second entry in the output indicates that 15 is the 0.2-quantile of the input column, so 15 is the 20th percentile of the input column.

```
=> SELECT APPROXIMATE_QUANTILES(sales USING PARAMETERS nquantiles=6) OVER() FROM allsales;
```

```
Quantile | Value
```

```
-----+-----
0 | 10
0.2 | 15
0.4 | 20
0.6 | 40
0.8 | 50
1 | 60
(6 rows)
```

ARGMAX_AGG

Takes two arguments *target* and *arg*, where both are columns or column expressions in the queried dataset. ARGMAX_AGG finds the row with the highest non-null value in *target* and returns the value of *arg* in that row. If multiple rows contain the highest *target* value, ARGMAX_AGG returns *arg* from the first row that it finds. Use the WITHIN GROUP ORDER BY clause to control which row ARGMAX_AGG finds first.

Behavior type

[Immutable](#) if the WITHIN GROUP ORDER BY clause specifies a column or set of columns that resolves to unique values within the group; otherwise [Volatile](#).

Syntax

```
ARGMAX_AGG ( target, arg ) [ within-group-order-by-clause ]
```

Arguments

target, *arg*

Columns in the queried dataset.

Note

The *target* argument cannot reference a [spatial data type](#) column, GEOMETRY or GEOGRAPHY.

[\[within-group-order-by-clause\]\(/sql-reference/functions/aggregate-functions/within-group-order-by-clause.html\)](#)

Sorts target values within each group of rows:

```
WITHIN GROUP (ORDER BY { column-expression[ sort-qualifiers ] }[,...])
```

sort-qualifiers :

```
{ ASC | DESC [ NULLS { FIRST | LAST | AUTO } ] }
```

Use this clause to determine which row is returned when multiple rows contain the highest target value; otherwise, results are likely to vary with each iteration of the same query.

Tip

WITHIN GROUP ORDER BY can consume a large amount of memory per group. To minimize memory consumption, create projections that support [GROUPBY PIPELINED](#).

Examples

The following example calls ARGMAX_AGG in a [WITH clause](#) to find which employees in each region are at or near retirement age. If multiple employees within each region have the same age, ARGMAX_AGG chooses the employees with the highest salary level and returns with their IDs. The primary query returns with details on the employees selected from each region:

```
=> WITH r AS (SELECT employee_region, ARGMAX_AGG(employee_age, employee_key)
  WITHIN GROUP (ORDER BY annual_salary DESC) emp_id
  FROM employee_dim GROUP BY employee_region ORDER BY employee_region)
SELECT r.employee_region, ed.annual_salary AS highest_salary, employee_key,
ed.employee_first_name||' '||ed.employee_last_name AS employee_name, ed.employee_age
FROM r JOIN employee_dim ed ON r.emp_id = ed.employee_key ORDER BY ed.employee_region;
employee_region      | highest_salary | employee_key | employee_name | employee_age
```

```
-----+-----+-----+-----+-----+
East                | 927335 | 70 | Sally Gauthier | 65
MidWest             | 177716 | 869 | Rebecca McCabe | 65
NorthWest           | 100300 | 7597 | Kim Jefferson | 65
South               | 196454 | 275 | Alexandra Harris | 65
SouthWest           | 198669 | 1043 | Seth Stein | 65
West                | 197203 | 681 | Seth Jones | 65
(6 rows)
```

See also

[ARGMIN_AGG](#)

ARGMIN_AGG

Takes two arguments *target* and *arg*, where both are columns or column expressions in the queried dataset. ARGMIN_AGG finds the row with the lowest non-null value in *target* and returns the value of *arg* in that row. If multiple rows contain the lowest *target* value, ARGMIN_AGG returns *arg* from the first row that it finds. Use the WITHIN GROUP ORDER BY clause to control which row ARGMIN_AGG finds first.

Behavior type

[Immutable](#) if the WITHIN GROUP ORDER BY clause specifies a column or set of columns that resolves to unique values within the group; otherwise [Volatile](#).

Syntax

```
ARGMIN_AGG ( target, arg ) [ within-group-order-by-clause ]
```

Arguments

target, arg

Columns in the queried dataset.

Note

The *target* argument cannot reference a [spatial data type](#) column, GEOMETRY or GEOGRAPHY.

[\[within-group-order-by-clause\]\(/sql-reference/functions/aggregate-functions/within-group-order-by-clause.html\)](#)

Sorts target values within each group of rows:

```
WITHIN GROUP (ORDER BY { column-expression[ sort-qualifiers ] }{...})
```

sort-qualifiers :

```
{ ASC | DESC [ NULLS { FIRST | LAST | AUTO } ] }
```

Use this clause to determine which row is returned when multiple rows contain the lowest target value; otherwise, results are likely to vary with each iteration of the same query.

Tip

WITHIN GROUP ORDER BY can consume a large amount of memory per group. To minimize memory consumption, create projections that support [GROUPBY PIPELINED](#).

Examples

The following example calls ARGMIN_AGG in a [WITH clause](#) to find the lowest salary among all employees in each region, and returns with the lowest-paid employee IDs. The primary query returns with the salary amounts and employee names:

```
=> WITH msr (employee_region, emp_id) AS
  (SELECT employee_region, argmin_agg(annual_salary, employee_key) lowest_paid_employee FROM employee_dim GROUP BY employee_region)
SELECT msr.employee_region, ed.annual_salary AS lowest_salary, ed.employee_first_name||' '||ed.employee_last_name AS employee_name
FROM msr JOIN employee_dim ed ON msr.emp_id = ed.employee_key ORDER BY annual_salary DESC;
  employee_region | lowest_salary | employee_name
-----+-----+-----
NorthWest        |      20913 | Raja Garnett
SouthWest        |      20750 | Seth Moore
West              |      20443 | Midori Taylor
South             |      20363 | David Bauer
East              |      20306 | Craig Jefferson
MidWest          |      20264 | Dean Vu
(6 rows)
```

See also

[ARGMAX_AGG](#)

AVG [aggregate]

Computes the average (arithmetic mean) of an expression over a group of rows. AVG always returns a DOUBLE PRECISION value.

The AVG aggregate function differs from the [AVG](#) analytic function, which computes the average of an expression over a group of rows within a [window](#).

Behavior type

[Immutable](#)

Syntax

```
AVG ( [ ALL | DISTINCT ] expression )
```

Parameters

ALL

Invokes the aggregate function for all rows in the group (default).

DISTINCT

Invokes the aggregate function for all distinct non-null values of the expression found in the group.

expression

The value whose average is calculated over a set of rows, any expression that can have a DOUBLE PRECISION result.

Overflow handling

By default, Vertica allows silent numeric overflow when you call this function on numeric data types. For more information on this behavior and how to change it, see [Numeric data type overflow with SUM, SUM_FLOAT, and AVG](#).

Examples

The following query returns the average income from the customer table:

```
=> SELECT AVG(annual_income) FROM customer_dimension;
  AVG
-----
2104270.6485
(1 row)
```

See also

- [COUNT \[aggregate\]](#)
- [SUM \[aggregate\]](#)
- [Numeric data types](#)

BIT_AND

Takes the bitwise AND of all non-null input values. If the input parameter is NULL, the return value is also NULL.

Behavior type

[Immutable](#)

Syntax

```
BIT_AND ( expression )
```

Parameters

expression

The BINARY or VARBINARY input value to evaluate. BIT_AND operates on VARBINARY types explicitly and on BINARY types implicitly through [casts](#).

Returns

BIT_AND returns:

- The same value as the argument data type.
- 1 for each bit compared, if all bits are 1; otherwise 0.

If the columns are different lengths, the return values are treated as though they are all equal in length and are right-extended with zero bytes. For example, given a group containing hex values `ff`, `null`, and `f`, BIT_AND ignores the null value and extends the value `f` to `f0`.

Examples

The example that follows uses table `t` with a single column of VARBINARY data type:

```
=> CREATE TABLE t ( c VARBINARY(2) );
=> INSERT INTO t values(HEX_TO_BINARY('0xFF00'));
=> INSERT INTO t values(HEX_TO_BINARY('0xFFFF'));
=> INSERT INTO t values(HEX_TO_BINARY('0xF00F'));
```

Query table `t` to see column `c` output:

```
=> SELECT TO_HEX(c) FROM t;
TO_HEX
-----
ff00
ffff
f00f
(3 rows)
```

Query table `t` to get the AND value for column `c`:

```
=> SELECT TO_HEX(BIT_AND(c)) FROM t;
TO_HEX
-----
f000
(1 row)
```

The function is applied pairwise to all values in the group, resulting in `f000`, which is determined as follows:

1. `ff00` (record 1) is compared with `ffff` (record 2), which results in `ff00`.
2. The result from the previous comparison is compared with `f00f` (record 3), which results in `f000`.

See also

[Binary data types \(BINARY and VARBINARY\)](#)

BIT_OR

Takes the bitwise OR of all non-null input values. If the input parameter is NULL, the return value is also NULL.

Behavior type

[Immutable](#)

Syntax

```
BIT_OR ( expression )
```

Parameters

expression

The BINARY or VARBINARY input value to evaluate. BIT_OR operates on VARBINARY types explicitly and on BINARY types implicitly through [casts](#).

Returns

BIT_OR returns:

- The same value as the argument data type.
- 1 for each bit compared, if any bit is 1; otherwise 0.

If the columns are different lengths, the return values are treated as though they are all equal in length and are right-extended with zero bytes. For example, given a group containing hex values **ff**, **null**, and **f**, the function ignores the null value and extends the value **f** to **f0**.

Examples

The example that follows uses table **t** with a single column of **VARBINARY** data type:

```
=> CREATE TABLE t ( c VARBINARY(2) );
=> INSERT INTO t values(HEX_TO_BINARY('0xFF00'));
=> INSERT INTO t values(HEX_TO_BINARY('0xFFFF'));
=> INSERT INTO t values(HEX_TO_BINARY('0xF00F'));
```

Query table **t** to see column **c** output:

```
=> SELECT TO_HEX(c) FROM t;
TO_HEX
-----
ff00
ffff
f00f
(3 rows)
```

Query table **t** to get the OR value for column **c** :

```
=> SELECT TO_HEX(BIT_OR(c)) FROM t;
TO_HEX
-----
ffff
(1 row)
```

The function is applied pairwise to all values in the group, resulting in **ffff**, which is determined as follows:

1. **ff00** (record 1) is compared with **ffff**, which results in **ffff**.
2. The **ff00** result from the previous comparison is compared with **f00f** (record 3), which results in **ffff**.

See also

[Binary data types \(BINARY and VARBINARY\)](#)

BIT_XOR

Takes the bitwise **XOR** of all non-null input values. If the input parameter is **NULL**, the return value is also **NULL**.

Behavior type

[Immutable](#)

Syntax

```
BIT_XOR ( expression )
```

Parameters

expression

The BINARY or VARBINARY input value to evaluate. BIT_XOR operates on VARBINARY types explicitly and on BINARY types implicitly through [casts](#).

Returns

BIT_XOR returns:

- The same value as the argument data type.
- 1 for each bit compared, if there are an odd number of arguments with set bits; otherwise 0.

If the columns are different lengths, the return values are treated as though they are all equal in length and are right-extended with zero bytes. For example, given a group containing hex values **ff**, **null**, and **f**, the function ignores the null value and extends the value **f** to **f0**.

Examples

First create a sample table and projections with binary columns:

The example that follows uses table **t** with a single column of **VARBINARY** data type:

```
=> CREATE TABLE t ( c VARBINARY(2) );
=> INSERT INTO t values(HEX_TO_BINARY('0xFF00'));
=> INSERT INTO t values(HEX_TO_BINARY('0xFFFF'));
=> INSERT INTO t values(HEX_TO_BINARY('0xF00F'));
```

Query table **t** to see column **c** output:

```
=> SELECT TO_HEX(c) FROM t;
TO_HEX
-----
ff00
ffff
f00f
(3 rows)
```

Query table **t** to get the XOR value for column **c**:

```
=> SELECT TO_HEX(BIT_XOR(c)) FROM t;
TO_HEX
-----
f0f0
(1 row)
```

See also

[Binary data types \(BINARY and VARBINARY\)](#)

BOOL_AND [aggregate]

Processes Boolean values and returns a Boolean value result. If all input values are true, **BOOL_AND** returns **t**. Otherwise it returns **f** (false).

Behavior type

[Immutable](#)

Syntax

```
BOOL_AND ( expression )
```

Parameters

expression

A [Boolean data type](#) or any non-Boolean data type that can be implicitly coerced to a Boolean data type.

Examples

The following example shows how to use aggregate functions **BOOL_AND**, **BOOL_OR**, and **BOOL_XOR**. The sample table **mixers** includes columns for models and colors.

```
=> CREATE TABLE mixers(model VARCHAR(20), colors VARCHAR(20));
CREATE TABLE
```

Insert sample data into the table. The sample adds two color fields for each model.

```

=> INSERT INTO mixers
SELECT 'beginner', 'green'
UNION ALL
SELECT 'intermediate', 'blue'
UNION ALL
SELECT 'intermediate', 'blue'
UNION ALL
SELECT 'advanced', 'green'
UNION ALL
SELECT 'advanced', 'blue'
UNION ALL
SELECT 'professional', 'blue'
UNION ALL
SELECT 'professional', 'green'
UNION ALL
SELECT 'beginner', 'green';
OUTPUT
-----
      8
(1 row)

```

Query the table. The result shows models that have two blue (**BOOL_AND**), one or two blue (**BOOL_OR**), and specifically not more than one blue (**BOOL_XOR**) mixer.

```

=> SELECT model,
BOOL_AND(colors= 'blue')AS two_blue,
BOOL_OR(colors= 'blue')AS one_or_two_blue,
BOOL_XOR(colors= 'blue')AS specifically_not_more_than_one_blue
FROM mixers
GROUP BY model;

```

model	two_blue	one_or_two_blue	specifically_not_more_than_one_blue
advanced	f	t	t
beginner	f	f	f
intermediate	t	t	f
professional	f	t	t

(4 rows)

BOOL_OR [aggregate]

Processes Boolean values and returns a Boolean value result. If at least one input value is true, **BOOL_OR** returns **t** . Otherwise, it returns **f** .

Behavior type

[Immutable](#)

Syntax

```

BOOL_OR ( expression )

```

Parameters

expression

A [Boolean data type](#) or any non-Boolean data type that can be implicitly coerced to a Boolean data type.

Examples

The following example shows how to use aggregate functions **BOOL_AND** , **BOOL_OR** , and **BOOL_XOR** . The sample table **mixers** includes columns for models and colors.

```
=> CREATE TABLE mixers(model VARCHAR(20), colors VARCHAR(20));
CREATE TABLE
```

Insert sample data into the table. The sample adds two color fields for each model.

```
=> INSERT INTO mixers
SELECT 'beginner', 'green'
UNION ALL
SELECT 'intermediate', 'blue'
UNION ALL
SELECT 'intermediate', 'blue'
UNION ALL
SELECT 'advanced', 'green'
UNION ALL
SELECT 'advanced', 'blue'
UNION ALL
SELECT 'professional', 'blue'
UNION ALL
SELECT 'professional', 'green'
UNION ALL
SELECT 'beginner', 'green';
OUTPUT
-----
      8
(1 row)
```

Query the table. The result shows models that have two blue (**BOOL_AND**), one or two blue (**BOOL_OR**), and specifically not more than one blue (**BOOL_XOR**) mixer.

```
=> SELECT model,
BOOL_AND(colors= 'blue')AS two_blue,
BOOL_OR(colors= 'blue')AS one_or_two_blue,
BOOL_XOR(colors= 'blue')AS specifically_not_more_than_one_blue
FROM mixers
GROUP BY model;
```

model	two_blue	one_or_two_blue	specifically_not_more_than_one_blue
advanced	f	t	t
beginner	f	f	f
intermediate	t	t	f
professional	f	t	t

BOOL_XOR [aggregate]

Processes Boolean values and returns a Boolean value result. If specifically only one input value is true, **BOOL_XOR** returns **t**. Otherwise, it returns **f**.

Behavior type

[Immutable](#)

Syntax

```
BOOL_XOR ( expression )
```

Parameters

expression

A [Boolean data type](#) or any non-Boolean data type that can be implicitly coerced to a Boolean data type.

Examples

The following example shows how to use aggregate functions `BOOL_AND` , `BOOL_OR` , and `BOOL_XOR` . The sample table `mixers` includes columns for models and colors.

```
=> CREATE TABLE mixers(model VARCHAR(20), colors VARCHAR(20));
CREATE TABLE
```

Insert sample data into the table. The sample adds two color fields for each model.

```
=> INSERT INTO mixers
SELECT 'beginner', 'green'
UNION ALL
SELECT 'intermediate', 'blue'
UNION ALL
SELECT 'intermediate', 'blue'
UNION ALL
SELECT 'advanced', 'green'
UNION ALL
SELECT 'advanced', 'blue'
UNION ALL
SELECT 'professional', 'blue'
UNION ALL
SELECT 'professional', 'green'
UNION ALL
SELECT 'beginner', 'green';
OUTPUT
-----
      8
(1 row)
```

Query the table. The result shows models that have two blue (`BOOL_AND`), one or two blue (`BOOL_OR`), and specifically not more than one blue (`BOOL_XOR`) mixer.

```
=> SELECT model,
BOOL_AND(colors= 'blue')AS two_blue,
BOOL_OR(colors= 'blue')AS one_or_two_blue,
BOOL_XOR(colors= 'blue')AS specifically_not_more_than_one_blue
FROM mixers
GROUP BY model;
```

model	two_blue	one_or_two_blue	specifically_not_more_than_one_blue
advanced	f	t	t
beginner	f	f	f
intermediate	t	t	f
professional	f	t	t

(4 rows)

CORR

Returns the `DOUBLE PRECISION` coefficient of correlation of a set of expression pairs, as per the [Pearson correlation coefficient](#). `CORR` eliminates expression pairs where either expression in the pair is `NULL` . If no rows remain, the function returns `NULL` .

Syntax

```
CORR ( expression1, expression2 )
```

Parameters

expression1

The dependent **DOUBLE PRECISION** expression

expression2

The independent **DOUBLE PRECISION** expression

Examples

```
=> SELECT CORR (Annual_salary, Employee_age) FROM employee_dimension;
CORR
-----
-0.00719153413192422
(1 row)
```

COUNT [aggregate]

Returns as a BIGINT the number of rows in each group where the expression is not NULL. If the query has no GROUP BY clause, COUNT returns the number of table rows.

The COUNT aggregate function differs from the [COUNT](#) analytic function, which returns the number over a group of rows within a [window](#).

Behavior type

[Immutable](#)

Syntax

```
COUNT ( [ * ] [ ALL | DISTINCT ] expression )
```

Parameters

*

Specifies to count all rows in the specified table or each group.

ALL | DISTINCT

Specifies how to count rows where *expression* has a non-null value:

- **ALL** (default): Counts all rows where *expression* evaluates to a non-null value.
- **DISTINCT** : Counts all rows where *expression* evaluates to a distinct non-null value.

expression

The column or expression whose non-null values are counted.

Examples

The following query returns the number of distinct values in a column:

```
=> SELECT COUNT (DISTINCT date_key) FROM date_dimension;
COUNT
-----
1826
(1 row)
```

This example returns the number of distinct return values from an expression:

```
=> SELECT COUNT (DISTINCT date_key + product_key) FROM inventory_fact;
COUNT
-----
21560
(1 row)
```

You can create an equivalent query using the LIMIT keyword to restrict the number of rows returned:

```
=> SELECT COUNT(date_key + product_key) FROM inventory_fact GROUP BY date_key LIMIT 10;
```

COUNT

```
-----  
173  
31  
321  
113  
286  
84  
244  
238  
145  
202  
(10 rows)
```

The following query uses GROUP BY to count distinct values within groups:

```
=> SELECT product_key, COUNT (DISTINCT date_key) FROM inventory_fact  
GROUP BY product_key LIMIT 10;
```

product_key | count

```
-----+-----  
1 | 12  
2 | 18  
3 | 13  
4 | 17  
5 | 11  
6 | 14  
7 | 13  
8 | 17  
9 | 15  
10 | 12  
(10 rows)
```

The following query returns the number of distinct products and the total inventory within each date key:

```
=> SELECT date_key, COUNT (DISTINCT product_key), SUM(qty_in_stock) FROM inventory_fact  
GROUP BY date_key LIMIT 10;
```

date_key | count | sum

```
-----+-----+-----  
1 | 173 | 88953  
2 | 31 | 16315  
3 | 318 | 156003  
4 | 113 | 53341  
5 | 285 | 148380  
6 | 84 | 42421  
7 | 241 | 119315  
8 | 238 | 122380  
9 | 142 | 70151  
10 | 202 | 95274  
(10 rows)
```

This query selects each distinct `product_key` value and then counts the number of distinct `date_key` values for all records with the specific `product_key` value. It also counts the number of distinct `warehouse_key` values in all records with the specific `product_key` value:

```
=> SELECT product_key, COUNT (DISTINCT date_key), COUNT (DISTINCT warehouse_key) FROM inventory_fact
GROUP BY product_key LIMIT 15;
```

```
product_key | count | count
```

```
-----+-----+-----
 1 | 12 | 12
 2 | 18 | 18
 3 | 13 | 12
 4 | 17 | 18
 5 | 11 | 9
 6 | 14 | 13
 7 | 13 | 13
 8 | 17 | 15
 9 | 15 | 14
10 | 12 | 12
11 | 11 | 11
12 | 13 | 12
13 | 9 | 7
14 | 13 | 13
15 | 18 | 17
```

(15 rows)

This query selects each distinct `product_key` value, counts the number of distinct `date_key` and `warehouse_key` values for all records with the specific `product_key` value, and then sums all `qty_in_stock` values in records with the specific `product_key` value. It then returns the number of `product_version` values in records with the specific `product_key` value:

```
=> SELECT product_key, COUNT (DISTINCT date_key),
COUNT (DISTINCT warehouse_key),
SUM (qty_in_stock),
COUNT (product_version)
FROM inventory_fact GROUP BY product_key LIMIT 15;
```

```
product_key | count | count | sum | count
```

```
-----+-----+-----+-----+-----
 1 | 12 | 12 | 5530 | 12
 2 | 18 | 18 | 9605 | 18
 3 | 13 | 12 | 8404 | 13
 4 | 17 | 18 | 10006 | 18
 5 | 11 | 9 | 4794 | 11
 6 | 14 | 13 | 7359 | 14
 7 | 13 | 13 | 7828 | 13
 8 | 17 | 15 | 9074 | 17
 9 | 15 | 14 | 7032 | 15
10 | 12 | 12 | 5359 | 12
11 | 11 | 11 | 6049 | 11
12 | 13 | 12 | 6075 | 13
13 | 9 | 7 | 3470 | 9
14 | 13 | 13 | 5125 | 13
15 | 18 | 17 | 9277 | 18
```

(15 rows)

- [APPROXIMATE_COUNT_DISTINCT_OF_SYNOPSIS](#)

Returns the population covariance for a set of expression pairs. The return value is of type **DOUBLE PRECISION** . **COVAR_POP** eliminates expression pairs where either expression in the pair is **NULL** . If no rows remain, the function returns **NULL** .

Syntax

```
SELECT COVAR_POP ( expression1, expression2 )
```

Parameters

expression1

The dependent **DOUBLE PRECISION** expression

expression2

The independent **DOUBLE PRECISION** expression

Examples

```
=> SELECT COVAR_POP (Annual_salary, Employee_age)
      FROM employee_dimension;
      COVAR_POP
-----
-9032.34810730019
(1 row)
```

COVAR_SAMP

Returns the sample covariance for a set of expression pairs. The return value is of type **DOUBLE PRECISION** . **COVAR_SAMP** eliminates expression pairs where either expression in the pair is **NULL** . If no rows remain, the function returns **NULL** .

Syntax

```
SELECT COVAR_SAMP ( expression1, expression2 )
```

Parameters

expression1

The dependent **DOUBLE PRECISION** expression

expression2

The independent **DOUBLE PRECISION** expression

Examples

```
=> SELECT COVAR_SAMP (Annual_salary, Employee_age)
      FROM employee_dimension;
      COVAR_SAMP
-----
-9033.25143244343
(1 row)
```

GROUP_ID

Uniquely identifies duplicate sets for GROUP BY queries that return duplicate grouping sets. This function returns one or more integers, starting with zero (0), as identifiers.

For the number of duplicates *n* for a particular grouping, GROUP_ID returns a range of sequential numbers, 0 to *n*-1. For the first each unique group it encounters, GROUP_ID returns the value 0. If GROUP_ID finds the same grouping again, the function returns 1, then returns 2 for the next found grouping, and so on.

Note

Use **GROUP_ID** only in **SELECT** statements that contain a **GROUP BY** aggregate: **CUBE**, **GROUPING SETS**, and **ROLLUP**.

Behavior type

[Immutable](#)

Syntax

```
GROUP_ID ()
```

Examples

This example shows how GROUP_ID creates unique identifiers when a query produces duplicate groupings. For an expenses table, the following query groups the results by category of expense and year and rolls up the sum for those two columns. The results have duplicate groupings for category and NULL. The first grouping has a GROUP_ID of 0, and the second grouping has a GROUP_ID of 1.

```
=> SELECT Category, Year, SUM(Amount), GROUPING_ID(Category, Year),
  GROUP_ID() FROM expenses GROUP BY Category, ROLLUP(Category, Year)
  ORDER BY Category, Year, GROUPING_ID();
Category | Year | SUM | GROUPING_ID | GROUP_ID
```

Category	Year	SUM	GROUPING_ID	GROUP_ID
Books	2005	39.98	0	0
Books	2007	29.99	0	0
Books	2008	29.99	0	0
Books		99.96	1	0
Books		99.96	1	1
Electricity	2005	109.99	0	0
Electricity	2006	109.99	0	0
Electricity	2007	229.98	0	0
Electricity		449.96	1	1
Electricity		449.96	1	0

See also

- [CUBE aggregate](#)
- [GROUPING](#)
- [GROUPING_ID](#)
- [GROUPING SETS aggregate](#)
- [GROUP BY clause](#)
- [ROLLUP aggregate](#)

GROUPING

Disambiguates the use of **NULL** values when **GROUP BY** queries with multilevel aggregates generate NULL values to identify subtotals in grouping columns. Such **NULL** values from the original data can also occur in rows. **GROUPING** returns 1, if the value of *expression* is:

- **NULL**, representing an aggregated value
- 0 for any other value, including **NULL** values in rows

Note

Use **GROUPING** only in **SELECT** statements that contain a **GROUP BY** aggregate: [CUBE](#), [GROUPING SETS](#), and [ROLLUP](#).

Behavior type

[Immutable](#)

Syntax

```
GROUPING ( expression )
```

Parameters

expression

An expression in the **GROUP BY** clause

Examples

The following query uses the **GROUPING** function, taking one of the **GROUP BY** expressions as an argument. For each row, **GROUPING** returns one of the following:

- **0**: The column is part of the group for that row
- **1**: The column is not part of the group for that row

The 1 in the **GROUPING(Year)** column for electricity and books indicates that these values are subtotals. The right-most column values for both **GROUPING(Category)** and **GROUPING(Year)** are **1**. This value indicates that neither column contributed to the **GROUP BY**. The final row represents the total sales.

```
=> SELECT Category, Year, SUM(Amount),
       GROUPING(Category), GROUPING(Year) FROM expenses
       GROUP BY ROLLUP(Category, Year) ORDER BY Category, Year, GROUPING_ID();
Category | Year | SUM | GROUPING | GROUPING
```

Category	Year	SUM	GROUPING	GROUPING
Books	2005	39.98	0	0
Books	2007	29.99	0	0
Books	2008	29.99	0	0
Books		99.96	0	1
Electricity	2005	109.99	0	0
Electricity	2006	109.99	0	0
Electricity	2007	229.98	0	0
Electricity		449.96	0	1
		549.92	1	1

See also

- [CUBE aggregate](#)
- [GROUP_ID](#)
- [GROUPING_ID](#)
- [GROUPING SETS aggregate](#)
- [GROUP BY clause](#)
- [ROLLUP aggregate](#)

GROUPING_ID

Concatenates the set of Boolean values generated by the [GROUPING](#) function into a bit vector. [GROUPING_ID](#) treats the bit vector as a binary number and returns it as a base-10 value that identifies the grouping set combination.

By using [GROUPING_ID](#) you avoid the need for multiple, individual [GROUPING](#) functions. [GROUPING_ID](#) simplifies row-filtering conditions, because rows of interest are identified using a single return from [GROUPING_ID = n](#). Use [GROUPING_ID](#) to identify grouping combinations.

Note

Use [GROUPING_ID](#) only in [SELECT](#) statements that contain a [GROUP BY](#) aggregate: [CUBE](#), [GROUPING SETS](#), and [ROLLUP](#).

Behavior type

[Immutable](#)

Syntax

```
GROUPING_ID ( [expression[,...]] )
```

expression

An expression that matches one of the expressions in the [GROUP BY](#) clause.

If the [GROUP BY](#) clause includes a list of expressions, [GROUPING_ID](#) returns a number corresponding to the [GROUPING](#) bit vector associated with a row.

Examples

This example shows how calling [GROUPING_ID](#) without an expression returns the [GROUPING](#) bit vector associated with a full set of multilevel aggregate expressions. The [GROUPING_ID](#) value is comparable to [GROUPING_ID\(a,b\)](#) because [GROUPING_ID\(\)](#) includes all columns in the [GROUP BY ROLLUP](#) :

```
=> SELECT a,b,COUNT(*), GROUPING_ID() FROM T GROUP BY ROLLUP(a,b);
```

In the following query, the [GROUPING\(Category\)](#) and [GROUPING\(Year\)](#) columns have three combinations:

- 0,0
- 0,1
- 1,1

```
=> SELECT Category, Year, SUM(Amount),
       GROUPING(Category), GROUPING(Year) FROM expenses
       GROUP BY ROLLUP(Category, Year) ORDER BY Category, Year, GROUPING_ID();
Category | Year | SUM | GROUPING | GROUPING
-----+-----+-----+-----+-----
Books   | 2005 | 39.98 | 0 | 0
Books   | 2007 | 29.99 | 0 | 0
Books   | 2008 | 29.99 | 0 | 0
Books   |      | 99.96 | 0 | 1
Electricity | 2005 | 109.99 | 0 | 0
Electricity | 2006 | 109.99 | 0 | 0
Electricity | 2007 | 229.98 | 0 | 0
Electricity |      | 449.96 | 0 | 1
         |      | 549.92 | 1 | 1
```

GROUPING_ID converts these values as follows:

Binary Set Values	Decimal Equivalents
00	0
01	1
11	3
0	Category, Year

The following query returns the single number for each **GROUP BY** level that appears in the `gr_id` column:

```
=> SELECT Category, Year, SUM(Amount),
       GROUPING(Category),GROUPING(Year),GROUPING_ID(Category,Year) AS gr_id
       FROM expenses GROUP BY ROLLUP(Category, Year);
Category | Year | SUM | GROUPING | GROUPING | gr_id
-----+-----+-----+-----+-----+-----
Books   | 2008 | 29.99 | 0 | 0 | 0
Books   | 2005 | 39.98 | 0 | 0 | 0
Electricity | 2007 | 229.98 | 0 | 0 | 0
Books   | 2007 | 29.99 | 0 | 0 | 0
Electricity | 2005 | 109.99 | 0 | 0 | 0
Electricity |      | 449.96 | 0 | 1 | 1
         |      | 549.92 | 1 | 1 | 3
Electricity | 2006 | 109.99 | 0 | 0 | 0
Books   |      | 99.96 | 0 | 1 | 1
```

The `gr_id` value determines the **GROUP BY** level for each row:

GROUP BY Level

GROUP BY Row Level

3

Total sum

1

Category

0

Category, year

You can also use the [DECODE](#) function to give the values more meaning by comparing each search value individually:

```
=> SELECT Category, Year, SUM(AMOUNT), DECODE(GROUPING_ID(Category, Year),
    3, 'Total',
    1, 'Category',
    0, 'Category,Year')
AS GROUP_NAME FROM expenses GROUP BY ROLLUP(Category, Year);
Category | Year | SUM | GROUP_NAME
-----+-----+-----+-----
Electricity | 2006 | 109.99 | Category,Year
Books | | 99.96 | Category
Electricity | 2007 | 229.98 | Category,Year
Books | 2007 | 29.99 | Category,Year
Electricity | 2005 | 109.99 | Category,Year
Electricity | | 449.96 | Category
| | 549.92 | Total
Books | 2005 | 39.98 | Category,Year
Books | 2008 | 29.99 | Category,Year
```

See also

- [GROUP_ID](#)
- [GROUPING](#)
- [GROUPING SETS aggregate](#)
- [GROUP BY clause](#)
- [ROLLUP aggregate](#)

LISTAGG

Transforms non-null values from a group of rows into a list of values that are delimited by commas (default) or a configurable separator. LISTAGG can be used to denormalize rows into a string of concatenated values.

Behavior type

[Immutable](#) if the WITHIN GROUP ORDER BY clause specifies a column or set of columns that resolves to unique values within the aggregated list; otherwise [Volatile](#).

Syntax

```
LISTAGG ( aggregate-expression [ USING PARAMETERS parameter=value[,...] ] ) [ within-group-order-by-clause ]
```

Arguments

aggregate-expression

Aggregation of one or more columns or column expressions to select from the source table or view.

LISTAGG does not support [spatial data types](#) directly. In order to pass column data of this type, convert the data to strings with the geospatial function [ST_AsText](#).

Caution

Converted spatial data frequently contains commas. LISTAGG uses comma as the default separator character. To avoid ambiguous output, override this default by setting the function's [separator](#) parameter to another character.

[within-group-order-by-clause] ([/sql-reference/functions/aggregate-functions/within-group-order-by-clause.html](#))

Sorts aggregated values within each group of rows, where *column-expression* is typically a column in *aggregate-expression* :

```
WITHIN GROUP (ORDER BY { column-expression[ sort-qualifiers ] }[,...])
```

sort-qualifiers :

```
{ ASC | DESC [ NULLS { FIRST | LAST | AUTO } ] }
```

Tip

WITHIN GROUP ORDER BY can consume a large amount of memory per group. Including wide strings in the aggregate expression can also adversely affect performance. To minimize memory consumption, create projections that support [GROUPBY PIPELINED](#).

Parameters

Parameter name	Set to...
<code>max_length</code>	An integer or integer expression that specifies in bytes the maximum length of the result, up to 32M. Default: 1024
<code>separator</code>	Separator string of length 0 to 80, inclusive. A length of 0 concatenates the output with no separators. Default: comma (,)
<code>on_overflow</code>	Specifies behavior when the result overflows the <code>max_length</code> setting, one of the following strings: <ul style="list-style-type: none">• ERROR (default): Return an error when overflow occurs.• TRUNCATE : Remove any characters that exceed <code>max_length</code> setting from the query result, and return the truncated string.

Privileges

None

Examples

In the following query, the aggregated results in the `CityState` column use the string " | " as a separator. The outer GROUP BY clause groups the output rows according to their `Region` values. Within each group, the aggregated list items are sorted according to their `city` values, as per the WITHIN GROUP ORDER BY clause:

```

=> \x
Expanded display is on.
=> WITH cd AS (SELECT DISTINCT (customer_city) city, customer_state, customer_region FROM customer_dimension)
SELECT customer_region Region, LISTAGG(city||', '||customer_state USING PARAMETERS separator='|')
  WITHIN GROUP (ORDER BY city) CityAndState FROM cd GROUP BY region ORDER BY region;
-[ RECORD 1 ]+-----

```

MAX [aggregate]

Returns the greatest value of an expression over a group of rows. The return value has the same type as the expression data type.

The [MAX analytic function](#) differs from the aggregate function, in that it returns the maximum value of an expression over a group of rows within a [window](#).

Aggregate functions **MIN** and **MAX** can operate with Boolean values. **MAX** can act upon a [Boolean data type](#) or a value that can be implicitly converted to a Boolean. If at least one input value is true, **MAX** returns **t** (true). Otherwise, it returns **f** (false). In the same scenario, **MIN** returns **t** (true) if all input values are true. Otherwise it returns **f**.

Behavior type

[Immutable](#)

Syntax

```
MAX ( expression )
```

Parameters

expression

Any expression for which the maximum value is calculated, typically a [column reference](#).

Examples

The following query returns the largest value in column `sales_dollar_amount`.

```
=> SELECT MAX(sales_dollar_amount) AS highest_sale FROM store.store_sales_fact;
highest_sale
-----
        600
(1 row)
```

The following example shows you the difference between the **MIN** and **MAX** aggregate functions when you use them with a Boolean value. The sample creates a table, adds two rows of data, and shows sample output for **MIN** and **MAX**.

```
=> CREATE TABLE min_max_functions (torf BOOL);

=> INSERT INTO min_max_functions VALUES (1);
=> INSERT INTO min_max_functions VALUES (0);

=> SELECT * FROM min_max_functions;
torf
-----
t
f
(2 rows)

=> SELECT min(torf) FROM min_max_functions;
min
-----
f
(1 row)

=> SELECT max(torf) FROM min_max_functions;
max
-----
t
(1 row)
```

See also

[Data aggregation](#)

MIN [aggregate]

Returns the smallest value of an expression over a group of rows. The return value has the same type as the expression data type.

The **MIN analytic function** differs from the aggregate function, in that it returns the minimum value of an expression over a group of rows within a [window](#).

Aggregate functions **MIN** and **MAX** can operate with Boolean values. **MAX** can act upon a [Boolean data type](#) or a value that can be implicitly converted to a Boolean. If at least one input value is true, **MAX** returns **t** (true). Otherwise, it returns **f** (false). In the same scenario, **MIN** returns **t** (true) if all input values are true. Otherwise it returns **f**.

Behavior type

[Immutable](#)

Syntax

```
MIN ( expression )
```

Parameters

expression

Any expression for which the minimum value is calculated, typically a [column reference](#).

Examples

The following query returns the lowest salary from the **employee** dimension table.

This example shows how you can query to return the lowest salary from the **employee** dimension table.

```
=> SELECT MIN(annual_salary) AS lowest_paid FROM employee_dimension;
lowest_paid
-----
      1200
(1 row)
```

The following example shows you the difference between the **MIN** and **MAX** aggregate functions when you use them with a Boolean value. The sample creates a table, adds two rows of data, and shows sample output for **MIN** and **MAX** .

```
=> CREATE TABLE min_max_functions (torf BOOL);
=> INSERT INTO min_max_functions VALUES (1);
=> INSERT INTO min_max_functions VALUES (0);

=> SELECT * FROM min_max_functions;
torf
-----
t
f
(2 rows)

=> SELECT min(torf) FROM min_max_functions;
min
-----
f
(1 row)

=> SELECT max(torf) FROM min_max_functions;
max
-----
t
(1 row)
```

[Data aggregation](#)

REGR_AVGX

Returns the **DOUBLE PRECISION** average of the independent expression in an expression pair. **REGR_AVGX** eliminates expression pairs where either expression in the pair is **NULL** . If no rows remain, **REGR_AVGX** returns **NULL** .

Syntax

```
SELECT REGR_AVGX ( expression1, expression2 )
```

Parameters

expression1

The dependent **DOUBLE PRECISION** expression

expression2

The independent **DOUBLE PRECISION** expression

Examples

```
=> SELECT REGR_AVGX (Annual_salary, Employee_age)
      FROM employee_dimension;
REGR_AVGX
-----
      39.321
(1 row)
```

REGR_AVGY

Returns the **DOUBLE PRECISION** average of the dependent expression in an expression pair. The function eliminates expression pairs where either expression in the pair is **NULL** . If no rows remain, the function returns **NULL** .

Syntax

```
REGR_AVGY ( expression1, expression2 )
```

Parameters

expression1

The dependent **DOUBLE PRECISION** expression

expression2

The independent **DOUBLE PRECISION** expression

Examples

```
=> SELECT REGR_AVGY (Annual_salary, Employee_age)
      FROM employee_dimension;
REGR_AVGY
-----
58354.4913
(1 row)
```

REGR_COUNT

Returns the count of all rows in an expression pair. The function eliminates expression pairs where either expression in the pair is **NULL** . If no rows remain, the function returns **0** .

Syntax

```
SELECT REGR_COUNT ( expression1, expression2 )
```

Parameters

expression1

The dependent **DOUBLE PRECISION** expression

expression2

The independent **DOUBLE PRECISION** expression

Examples

```
=> SELECT REGR_COUNT (Annual_salary, Employee_age) FROM employee_dimension;
REGR_COUNT
-----
10000
(1 row)
```

REGR_INTERCEPT

Returns the y-intercept of the regression line determined by a set of expression pairs. The return value is of type **DOUBLE PRECISION** . **REGR_INTERCEPT** eliminates expression pairs where either expression in the pair is **NULL** . If no rows remain, **REGR_INTERCEPT** returns **NULL** .

Syntax

```
SELECT REGR_INTERCEPT ( expression1, expression2 )
```

Parameters

expression1

The dependent **DOUBLE PRECISION** expression

expression2

The independent **DOUBLE PRECISION** expression

Examples

```
=> SELECT REGR_INTERCEPT (Annual_salary, Employee_age) FROM employee_dimension;
      REGR_INTERCEPT
```

```
-----
59929.5490163437
(1 row)
```

REGR_R2

Returns the square of the correlation coefficient of a set of expression pairs. The return value is of type **DOUBLE PRECISION** . **REGR_R2** eliminates expression pairs where either expression in the pair is **NULL** . If no rows remain, **REGR_R2** returns **NULL** .

Syntax

```
SELECT REGR_R2 ( expression1, expression2 )
```

Parameters

expression1

The dependent **DOUBLE PRECISION** expression

expression2

The independent **DOUBLE PRECISION** expression

Examples

```
=> SELECT REGR_R2 (Annual_salary, Employee_age) FROM employee_dimension;
      REGR_R2
```

```
-----
5.17181631706311e-05
(1 row)
```

REGR_SLOPE

Returns the slope of the regression line, determined by a set of expression pairs. The return value is of type **DOUBLE PRECISION** . **REGR_SLOPE** eliminates expression pairs where either expression in the pair is **NULL** . If no rows remain, **REGR_SLOPE** returns **NULL** .

Syntax

```
SELECT REGR_SLOPE ( expression1, expression2 )
```

Parameters

expression1

The dependent **DOUBLE PRECISION** expression

expression2

The independent **DOUBLE PRECISION** expression

Examples

```
=> SELECT REGR_SLOPE (Annual_salary, Employee_age) FROM employee_dimension;
      REGR_SLOPE
```

```
-----
-40.056400303749
(1 row)
```

REGR_SXX

Returns the sum of squares of the difference between the independent expression (*expression2*) and its average.

That is, **REGR_SXX** returns: $\sum[(\textit{expression2} - \text{average}(\textit{expression2}))(\textit{expression2} - \text{average}(\textit{expression2}))]$

The return value is of type **DOUBLE PRECISION** . **REGR_SXX** eliminates expression pairs where either expression in the pair is **NULL** . If no rows remain, **REGR_SXX** returns **NULL** .

Syntax

```
SELECT REGR_SXX ( expression1, expression2 )
```

Parameters

expression1

The dependent **DOUBLE PRECISION** expression

expression2

The independent **DOUBLE PRECISION** expression

Examples

```
=> SELECT REGR_SXX (Annual_salary, Employee_age) FROM employee_dimension;
REGR_SXX
-----
2254907.59
(1 row)
```

REGR_SXY

Returns the sum of products of the difference between the dependent expression (*expression1*) and its average and the difference between the independent expression (*expression2*) and its average.

That is, REGR_SXY returns: $\sum[(\textit{expression1} - \text{average}(\textit{expression1}))(\textit{expression2} - \text{average}(\textit{expression2}))]$

The return value is of type **DOUBLE PRECISION** . REGR_SXY eliminates expression pairs where either expression in the pair is **NULL** . If no rows remain, REGR_SXY returns **NULL** .

Syntax

```
SELECT REGR_SXY ( expression1, expression2 )
```

Parameters

expression1

The dependent **DOUBLE PRECISION** expression

expression2

The independent **DOUBLE PRECISION** expression

Examples

```
=> SELECT REGR_SXY (Annual_salary, Employee_age) FROM employee_dimension;
REGR_SXY
-----
-90323481.0730019
(1 row)
```

REGR_SYY

Returns the sum of squares of the difference between the dependent expression (*expression1*) and its average.

That is, REGR_SYY returns: $\sum[(\textit{expression1} - \text{average}(\textit{expression1}))(\textit{expression1} - \text{average}(\textit{expression1}))]$

The return value is of type **DOUBLE PRECISION** . REGR_SYY eliminates expression pairs where either expression in the pair is **NULL** . If no rows remain, REGR_SYY returns **NULL** .

Syntax

```
SELECT REGR_SYY ( expression1, expression2 )
```

Parameters

expression1

The dependent **DOUBLE PRECISION** expression

expression2

The independent **DOUBLE PRECISION** expression

Examples

```
=> SELECT REGR_SYY (Annual_salary, Employee_age) FROM employee_dimension;  
      REGR_SYY
```

```
-----  
69956728794707.2
```

```
(1 row)
```

STDDEV [aggregate]

Evaluates the statistical sample standard deviation for each member of the group. The return value is the same as the square root of [VAR_SAMP](#) :

```
STDDEV(expression) = SQRT(VAR_SAMP(expression))
```

Behavior type

[Immutable](#)

Syntax

```
STDDEV ( expression )
```

Parameters

expression

Any [NUMERIC data type](#) or any non-numeric data type that can be implicitly converted to a numeric data type. **STDDEV** returns the same data type as *expression* .

Related functions

- Nonstandard function **STDDEV** is provided for compatibility with other databases. It is semantically identical to [STDDEV_SAMP](#) .
- This aggregate function differs from analytic function [STDDEV](#) , which computes the statistical sample standard deviation of the current row with respect to the group of rows within a [window](#) .
- When [VAR_SAMP](#) returns **NULL** , **STDDEV** returns **NULL** .

Examples

The following example returns the statistical sample standard deviation for each household ID from the [customer_dimension](#) table of the VMart example database:

```
=> SELECT STDDEV(household_id) FROM customer_dimension;
```

```
STDDEV
```

```
-----  
8651.5084240071
```

STDDEV_POP [aggregate]

Evaluates the statistical population standard deviation for each member of the group.

Behavior type

[Immutable](#)

Syntax

```
STDDEV_POP ( expression )
```

Parameters

expression

Any [NUMERIC data type](#) or any non-numeric data type that can be implicitly converted to a numeric data type. **STDDEV_POP** returns the same data type as *expression* .

Related functions

- This function differs from the analytic function [STDDEV_POP](#) , which evaluates the statistical population standard deviation for each member of the group of rows within a [window](#) .
- **STDDEV_POP** returns the same value as the square root of [VAR_POP](#) :

```
STDDEV_POP(expression) = SQRT(VAR_POP(expression))
```

- When [VAR_SAMP](#) returns **NULL** , this function returns **NULL** .

Examples

The following example returns the statistical population standard deviation for each household ID in the [customer](#) table.

```
=> SELECT STDDEV_POP(household_id) FROM customer_dimension;
      STDDEV_POP
```

```
-----
8651.41895973367
(1 row)
```

See also

- [Analytic functions](#)
- [SQL analytics](#)

STDDEV_SAMP [aggregate]

Evaluates the statistical sample standard deviation for each member of the group. The return value is the same as the square root of [VAR_SAMP](#):

```
STDDEV_SAMP(expression) = SQRT(VAR_SAMP(expression))
```

Behavior type

[Immutable](#)

Syntax

```
STDDEV_SAMP ( expression )
```

Parameters

expression

Any [NUMERIC data type](#) or any non-numeric data type that can be implicitly converted to a numeric data type. **STDDEV_SAMP** returns the same data type as *expression*.

Related functions

- **STDDEV_SAMP** is semantically identical to nonstandard function [STDDEV](#), which is provided for compatibility with other databases.
- This aggregate function differs from analytic function [STDDEV_SAMP](#), which computes the statistical sample standard deviation of the current row with respect to the group of rows within a [window](#).
- When [VAR_SAMP](#) returns **NULL**, **STDDEV_SAMP** returns **NULL**.

Examples

The following example returns the statistical sample standard deviation for each household ID from the **customer** dimension table.

```
=> SELECT STDDEV_SAMP(household_id) FROM customer_dimension;
      stddev_samp
```

```
-----
8651.50842400771
(1 row)
```

SUM [aggregate]

Computes the sum of an expression over a group of rows. **SUM** returns a **DOUBLE PRECISION** value for a floating-point expression. Otherwise, the return value is the same as the expression data type.

The **SUM** aggregate function differs from the [SUM](#) analytic function, which computes the sum of an expression over a group of rows within a [window](#).

Behavior type

[Immutable](#)

Syntax

```
SUM ( [ ALL | DISTINCT ] expression )
```

Parameters

ALL

Invokes the aggregate function for all rows in the group (default)

DISTINCT

Invokes the aggregate function for all distinct non-null values of the expression found in the group

expression

Any [NUMERIC data type](#) or any non-numeric data type that can be implicitly converted to a numeric data type. The function returns the same data type as the numeric data type of the argument.

Overflow handling

If you encounter data overflow when using `SUM()`, use `SUM_FLOAT` which converts the data to a floating point.

By default, Vertica allows silent numeric overflow when you call this function on numeric data types. For more information on this behavior and how to change it, see [Numeric data type overflow with SUM, SUM_FLOAT, and AVG](#).

Examples

The following query returns the total sum of the `product_cost` column.

```
=> SELECT SUM(product_cost) AS cost FROM product_dimension;
cost
-----
9042850
(1 row)
```

See also

- [AVG \[aggregate\]](#)
- [COUNT \[aggregate\]](#)

SUM_FLOAT [aggregate]

Computes the sum of an expression over a group of rows and returns a `DOUBLE PRECISION` value.

Behavior type

[Immutable](#)

Syntax

```
SUM_FLOAT ( [ ALL | DISTINCT ] expression )
```

Parameters

ALL

Invokes the aggregate function for all rows in the group (default).

DISTINCT

Invokes the aggregate function for all distinct non-null values of the expression found in the group.

expression

Any expression whose result is type `DOUBLE PRECISION`.

Overflow handling

By default, Vertica allows silent numeric overflow when you call this function on numeric data types. For more information on this behavior and how to change it, see [Numeric data type overflow with SUM, SUM_FLOAT, and AVG](#).

Examples

The following query returns the floating-point sum of the average price from the product table:

```
=> SELECT SUM_FLOAT(average_competitor_price) AS cost FROM product_dimension;
cost
-----
18181102
(1 row)
```

TS_FIRST_VALUE

Processes the data that belongs to each time slice. A time series aggregate (TSA) function, `TS_FIRST_VALUE` returns the value at the start of the time slice, where an interpolation scheme is applied if the timeslice is missing, in which case the value is determined by the values corresponding to the previous (and next) timeslices based on the interpolation scheme of `const` (linear).

`TS_FIRST_VALUE` returns one output row per time slice, or one output row per partition per time slice if partition expressions are specified

Behavior type

[Immutable](#)

Syntax

```
TS_FIRST_VALUE ( expression [ IGNORE NULLS ] [, { 'CONST' | 'LINEAR' } ] )
```

Parameters

expression

An **INTEGER** or **FLOAT** expression on which to aggregate and interpolate.

IGNORE NULLS

The **IGNORE NULLS** behavior changes depending on a **CONST** or **LINEAR** interpolation scheme. See [When Time Series Data Contains Nulls](#) in *Analyzing Data* for details.

'CONST' | 'LINEAR'

Specifies the interpolation value as constant or linear:

- **CONST** (default): New value is interpolated based on previous input records.
- **LINEAR**: Values are interpolated in a linear slope based on the specified time slice.

Requirements

You must use an **ORDER BY** clause with a **TIMESTAMP** column.

Multiple time series aggregate functions

The same query can call multiple time series aggregate functions. They share the same gap-filling policy as defined by the [TIMESERIES clause](#); however, each time series aggregate function can specify its own interpolation policy. For example:

```
=> SELECT slice_time, symbol,
TS_FIRST_VALUE(bid, 'const') fv_c,
   TS_FIRST_VALUE(bid, 'linear') fv_l,
   TS_LAST_VALUE(bid, 'const') lv_c
FROM TickStore
TIMESERIES slice_time AS '3 seconds'
OVER(PARTITION BY symbol ORDER BY ts);
```

Examples

See [Gap Filling and Interpolation](#) in *Analyzing Data*.

See also

- [TS_LAST_VALUE](#)
- [Time series analytics](#)

TS_LAST_VALUE

Processes the data that belongs to each time slice. A time series aggregate (TSA) function, **TS_LAST_VALUE** returns the value at the end of the time slice, where an interpolation scheme is applied if the timeslice is missing. In this case the value is determined by the values corresponding to the previous (and next) timeslices based on the interpolation scheme of const (linear).

TS_LAST_VALUE returns one output row per time slice, or one output row per partition per time slice if partition expressions are specified.

Behavior type

[Immutable](#)

Syntax

```
TS_LAST_VALUE ( expression [ IGNORE NULLS ] [, { 'CONST' | 'LINEAR' } ] )
```

Parameters

expression

An **INTEGER** or **FLOAT** expression on which to aggregate and interpolate.

IGNORE NULLS

The **IGNORE NULLS** behavior changes depending on a **CONST** or **LINEAR** interpolation scheme. See [When Time Series Data Contains Nulls](#) in *Analyzing Data* for details.

'CONST' | 'LINEAR'

Specifies the interpolation value as constant or linear:

- **CONST** (default): New value is interpolated based on previous input records.
- **LINEAR**: Values are interpolated in a linear slope based on the specified time slice.

Requirements

You must use the **ORDER BY** clause with a **TIMESTAMP** column.

Multiple time series aggregate functions

The same query can call multiple time series aggregate functions. They share the same gap-filling policy as defined by the [TIMESERIES clause](#); however, each time series aggregate function can specify its own interpolation policy. For example:

```
=> SELECT slice_time, symbol,
TS_FIRST_VALUE(bid, 'const') fv_c,
   TS_FIRST_VALUE(bid, 'linear') fv_l,
   TS_LAST_VALUE(bid, 'const') lv_c
FROM TickStore
TIMESERIES slice_time AS '3 seconds'
OVER(PARTITION BY symbol ORDER BY ts);
```

Examples

See [Gap Filling and Interpolation](#) in Analyzing Data.

See also

- [TS_FIRST_VALUE](#)
- [Time series analytics](#)

VAR_POP [aggregate]

Evaluates the population variance for each member of the group. This is defined as the sum of squares of the difference of * **expression** * from the mean of **expression**, divided by the number of remaining rows:

```
(SUM(expression*expression) - SUM(expression)*SUM(expression) / COUNT(expression)) / COUNT(expression)
```

Behavior type

[Immutable](#)

Syntax

```
VAR_POP ( expression )
```

Parameters

expression

Any [NUMERIC data type](#) or any non-numeric data type that can be implicitly converted to a numeric data type. **VAR_POP** returns the same data type as **expression**.

Related functions

This aggregate function differs from analytic function [VAR_POP](#), which computes the population variance of the current row with respect to the group of rows within a [window](#).

Examples

The following example returns the population variance for each household ID in the **customer** table.

```
=> SELECT VAR_POP(household_id) FROM customer_dimension;
var_pop
-----
74847050.0168393
(1 row)
```

VAR_SAMP [aggregate]

Evaluates the sample variance for each row of the group. This is defined as the sum of squares of the difference of **expression** from the mean of **expression** divided by the number of remaining rows minus 1:

```
(SUM(expression*expression) - SUM(expression) *SUM(expression) / COUNT(expression)) / (COUNT(expression) -1)
```

Behavior type

[Immutable](#)

Syntax

```
VAR_SAMP ( expression )
```

Parameters

expression

Any [NUMERIC data type](#) or any non-numeric data type that can be implicitly converted to a numeric data type. **VAR_SAMP** returns the same data type as *expression*.

Related functions

- **VAR_SAMP** is semantically identical to nonstandard function [VARIANCE](#), which is provided for compatibility with other databases.
- This aggregate function differs from analytic function [VAR_SAMP](#), which computes the sample variance of the current row with respect to the group of rows within a [window](#).

Examples

The following example returns the sample variance for each household ID in the **customer** table.

```
=> SELECT VAR_SAMP(household_id) FROM customer_dimension;
   var_samp
-----
74848598.0106764
(1 row)
```

See also

[VARIANCE \[aggregate\]](#)

VARIANCE [aggregate]

Evaluates the sample variance for each row of the group. This is defined as the sum of squares of the difference of *expression* from the mean of *expression* divided by the number of remaining rows minus 1.

$$\frac{(\text{SUM}(\text{expression} * \text{expression}) - \text{SUM}(\text{expression}) * \text{SUM}(\text{expression}) / \text{COUNT}(\text{expression}))}{(\text{COUNT}(\text{expression}) - 1)}$$

Behavior type

[Immutable](#)

Syntax

```
VARIANCE ( expression )
```

Parameters

expression

Any [NUMERIC data type](#) or any non-numeric data type that can be implicitly converted to a numeric data type. **VARIANCE** returns the same data type as *expression*.

Related functions

The nonstandard function **VARIANCE** is provided for compatibility with other databases. It is semantically identical to [VAR_SAMP](#).

This aggregate function differs from analytic function [VARIANCE](#), which computes the sample variance of the current row with respect to the group of rows within a [window](#).

Examples

The following example returns the sample variance for each household ID in the **customer** table.

```
=> SELECT VARIANCE(household_id) FROM customer_dimension;
   variance
-----
74848598.0106764
(1 row)
```

See also

- [Analytic functions](#)
- [VAR_SAMP \[aggregate\]](#)
- [SQL analytics](#)

WITHIN GROUP ORDER BY clause

Specifies how to sort rows that are grouped by aggregate functions, one of the following:

- [ARGMAX_AGG](#)
- [ARGMIN_AGG](#)
- [IMplode](#)
- [LISTAGG](#)

This clause is also supported for user-defined aggregate functions.

The order clause only specifies order within the result set of each group. The query can have its own [ORDER BY](#) clause, which has precedence over order that is specified by WITHIN GROUP ORDER BY, and orders the final result set.

Syntax

```
WITHIN GROUP (ORDER BY
 { column-expression [ ASC | DESC [ NULLS { FIRST | LAST | AUTO } ] ]
 }[,...])
```

Parameters

column-expression

A column, constant, or arbitrary expression formed on columns, on which to sort grouped rows.

ASC | DESC

Specifies the ordering sequence as ascending (default) or descending.

NULLS {FIRST | LAST | AUTO}

Specifies whether to position null values first or last. Default positioning depends on whether the sort order is ascending or descending:

- Ascending default: **NULLS LAST**
- Descending default: **NULLS FIRST**

If you specify **NULLS AUTO**, Vertica chooses the positioning that is most efficient for this query, either **NULLS FIRST** or **NULLS LAST**.

If you omit all sort qualifiers, Vertica uses **ASC NULLS LAST**.

Examples

For usage examples, see these functions:

- [ARGMAX_AGG](#)
- [ARGMIN_AGG](#)
- [IMPLODE](#)
- [LISTAGG](#)

Analytic functions

Note

All analytic functions in this section with an aggregate counterpart are appended with [Analytics] in the heading to avoid confusion between the two function types.

Vertica analytics are SQL functions based on the ANSI 99 standard. These functions handle complex analysis and reporting tasks—for example:

- Rank the longest-standing customers in a particular state.
- Calculate the moving average of retail volume over a specified time.
- Find the highest score among all students in the same grade.
- Compare the current sales bonus that salespersons received against their previous bonus.

Analytic functions return aggregate results but they do not group the result set. They return the group value multiple times, once per record. You can sort group values, or partitions, using a window **ORDER BY** clause, but the order affects only the function result set, not the entire query result set.

Syntax

General

```
analytic-function(arguments) OVER(
 [ window-partition-clause ]
 [ window-order-clause [ window-frame-clause ] ]
)
```

With named window

```
analytic-function(arguments) OVER(  
  [ named-window [ window-frame-clause ] ]  
)
```

Parameters

analytic-function (arguments)

A Vertica analytic function and its arguments.

OVER

Specifies how to partition, sort, and window frame function input with respect to the current row. The input data is the result set that the query returns after it evaluates **FROM** , **WHERE** , **GROUP BY** , and **HAVING** clauses.

An empty **OVER** clause provides the best performance for single threaded queries on a single node.

[window-partition-clause](#)

Groups input rows according to one or more columns or expressions.

If you omit this clause, no grouping occurs and the analytic function processes all input rows as a single partition.

[window-order-clause](#)

Optionally specifies how to sort rows that are supplied to the analytic function. If the **OVER** clause also includes a partition clause, rows are sorted within each partition.

[window-frame-clause](#)

Only valid for some analytic functions, specifies as input a set of rows relative to the row that is currently being evaluated by the analytic function. After the function processes that row and its window, Vertica advances the current row and adjusts the window boundaries accordingly.

[named-window](#)

The name of a window that you define in the same query with a [window-name-clause](#) . This definition encapsulates window partitioning and sorting. Named windows are useful when the query invokes multiple analytic functions with similar **OVER** clauses.

A window name clause cannot specify a window frame clause. However, you can qualify the named window in an **OVER** clause with a window frame clause.

Requirements

The following requirements apply to analytic functions:

- All require an **OVER** clause. Each function has its own **OVER** clause requirements. For example, you can supply an empty **OVER** clause for some analytic aggregate functions such as **SUM** . For other functions, window frame and order clauses might be required, or might be invalid.
- Analytic functions can be invoked only in a query's **SELECT** and **ORDER BY** clauses.
- Analytic functions cannot be nested. For example, the following query is not allowed:

```
=> SELECT MEDIAN(RANK() OVER(ORDER BY sal) OVER()).
```
- **WHERE** , **GROUP BY** and **HAVING** operators are technically not part of the analytic function. However, they determine input to that function.

ARGMAX [analytic]

This function is patterned after the mathematical function $\operatorname{argmax}(f(x))$, which returns the value of x that maximizes $f(x)$. Similarly, ARGMAX takes two arguments *target* and *arg*, where both are columns or column expressions in the queried dataset. ARGMAX finds the row with the largest non-null value in *target* and returns the value of *arg* in that row. If multiple rows contain the largest *target* value, ARGMAX returns *arg* from the first row that it finds.

Behavior type

[Immutable](#)

Syntax

```
ARGMAX ( target, arg ) OVER ( [ PARTITION BY expression[,...] ] [ window-order-clause ] )
```

Arguments

target, *arg*

Columns in the queried dataset.

Note

ARGMAX does not support [spatial data types](#): GEOMETRY and GEOGRAPHY.

OVER()

Specifies the following window clauses:

- **PARTITION BY *expression***: Groups (partitions) input rows according to the values in *expression*, which resolves to one or more columns in the queried dataset. If you omit this clause, ARGMAX processes all input rows as a single partition.
- **[window-order-clause](#)**: Specifies how to sort input rows. If the OVER clause also includes a partition clause, rows are sorted separately within each partition.

Important

To ensure consistent results when multiple rows contain the largest *target* value, include a window order clause that sorts on *arg*.

For details, see [Analytic Functions](#).

Examples

Create and populate table `service_info`, which contains information on various services, their respective development groups, and their userbase. A NULL in the `users` column indicates that the service has not been released, and so it cannot have users.

```

=> CREATE TABLE service_info(dev_group VARCHAR(10), product_name VARCHAR(30), users INT);
=> COPY t FROM stdin NULL AS 'null';
>> iris|chat|48193
>> aspen|trading|3000
>> orchid|cloud|990322
>> iris|video call| 10203
>> daffodil|streaming|44123
>> hydrangea|password manager|null
>> hydrangea|totp|1837363
>> daffodil|clip share|3000
>> hydrangea|e2e sms|null
>> rose|crypto|null
>> iris|forum|48193
>> \.

```

ARGMAX returns the value in the `product_name` column that maximizes the value in the `users` column. In this case, ARGMAX returns `totp`, which indicates that the `totp` service has the largest user base:

```

=> SELECT dev_group, product_name, users, ARGMAX(users, product_name) OVER (ORDER BY dev_group ASC) FROM service_info;
dev_group | product_name | users | ARGMAX
-----+-----+-----+-----
aspen | trading | 3000 | totp
daffodil | clip share | 3000 | totp
daffodil | streaming | 44123 | totp
hydrangea | e2e sms | | totp
hydrangea | password manager | | totp
hydrangea | totp | 1837363 | totp
iris | chat | 48193 | totp
iris | forum | 48193 | totp
iris | video call | 10203 | totp
orchid | cloud | 990322 | totp
rose | crypto | | totp
(11 rows)

```

The next query partitions the data on `dev_group` to identify the most popular service created by each development group. ARGMAX returns NULL if the partition's `users` column contains only NULL values and breaks ties using the first value in `product_name` from the top of the partition.

```

=> SELECT dev_group, product_name, users, ARGMAX(users, product_name) OVER (PARTITION BY dev_group ORDER BY product_name ASC) FROM
service_info;
dev_group | product_name | users | ARGMAX
-----+-----+-----+-----
iris | chat | 48193 | chat
iris | forum | 48193 | chat
iris | video call | 10203 | chat
orchid | cloud | 990322 | cloud
aspen | trading | 3000 | trading
daffodil | clip share | 3000 | streaming
daffodil | streaming | 44123 | streaming
rose | crypto | | 
hydrangea | e2e sms | | totp
hydrangea | password manager | | totp
hydrangea | totp | 1837363 | totp
(11 rows)

```

See also

[ARGMIN \[analytic\]](#)

ARGMIN [analytic]

This function is patterned after the mathematical function `argmin(f(x))`, which returns the value of `x` that minimizes `f(x)`. Similarly, ARGMIN takes two arguments `target` and `arg`, where both are columns or column expressions in the queried dataset. ARGMIN finds the row with the smallest non-null value in `target` and returns the value of `arg` in that row. If multiple rows contain the smallest `target` value, ARGMIN returns `arg` from the first row that it finds.

Behavior type

[Immutable](#)

Syntax

```
ARGMIN ( target, arg ) OVER ( [ PARTITION BY expression[,...] ] [ window-order-clause ] )
```

Arguments

target , arg

Columns in the queried dataset.

Note

ARGMIN does not support [spatial data types](#): GEOMETRY and GEOGRAPHY.

OVER()

Specifies the following window clauses:

- **PARTITION BY expression**: Groups (partitions) input rows according to the values in `expression`, which resolves to one or more columns in the queried dataset. If you omit this clause, ARGMIN processes all input rows as a single partition.
- **window-order-clause**: Specifies how to sort input rows. If the **OVER** clause also includes a partition clause, rows are sorted separately within each partition.

Important

To ensure consistent results when multiple rows contain the smallest `target` value, include a window order clause that sorts on `arg`.

For details, see [Analytic Functions](#).

Examples

Create and populate table `service_info`, which contains information on various services, their respective development groups, and their userbase. A NULL in the `users` column indicates that the service has not been released, and so it cannot have users.

```
=> CREATE TABLE service_info(dev_group VARCHAR(10), product_name VARCHAR(30), users INT);
=> COPY t FROM stdin NULL AS 'null';
>> iris|chat|48193
>> aspen|trading|3000
>> orchid|cloud|990322
>> iris|video call| 10203
>> daffodil|streaming|44123
>> hydrangea|password manager|null
>> hydrangea|totp|1837363
>> daffodil|clip share|3000
>> hydrangea|e2e sms|null
>> rose|crypto|null
>> iris|forum|48193
>> \.
```

ARGMIN returns the value in the `product_name` column that minimizes the value in the `users` column. In this case, ARGMIN returns `totp`, which indicates that the `totp` service has the smallest user base:

```
=> SELECT dev_group, product_name, users, ARGMIN(users, product_name) OVER (ORDER BY dev_group ASC) FROM service_info;
dev_group | product_name | users | ARGMIN
-----+-----+-----+-----
aspen    | trading      | 3000  | trading
daffodil | clip share   | 3000  | trading
daffodil | streaming    | 44123 | trading
hydrangea | e2e sms      |       | trading
hydrangea | password manager |       | trading
hydrangea | totp         | 1837363 | trading
iris     | chat         | 48193 | trading
iris     | forum        | 48193 | trading
iris     | video call   | 10203 | trading
orchid   | cloud        | 990322 | trading
rose     | crypto       |       | trading
(11 rows)
```

The next query partitions the data on `dev_group` to identify the least popular service created by each development group. ARGMIN returns NULL if the partition's `users` column contains only NULL values and breaks ties using the first value in `product_name` from the top of the partition.

```
=> SELECT dev_group, product_name, users, ARGMIN(users, product_name) OVER (PARTITION BY dev_group ORDER BY product_name ASC) FROM
service_info;
dev_group | product_name | users | ARGMIN
-----+-----+-----+-----
iris     | chat         | 48193 | video call
iris     | forum        | 48193 | video call

orchid   | cloud        | 990322 | cloud
aspen    | trading      | 3000  | trading
daffodil | clip share   | 3000  | clip share
daffodil | streaming    | 44123 | clip share
rose     | crypto       |       |
hydrangea | e2e sms      |       | totp
hydrangea | password manager |       | totp
hydrangea | totp         | 1837363 | totp
(11 rows)
```

See also

[ARGMAX \[analytic\]](#)

[AVG \[analytic\]](#)

Computes an average of an expression in a group within a [window](#). `AVG` returns the same data type as the expression's numeric data type.

The `AVG` analytic function differs from the [AVG](#) aggregate function, which computes the average of an expression over a group of rows.

Behavior type

[Immutable](#)

Syntax

```
AVG ( expression ) OVER (
  [ window-partition-clause ]
  [ window-order-clause ]
  [ window-frame-clause ] )
```

Parameters

expression

Any data that can be implicitly converted to a numeric data type.

OVER()

See [Analytic Functions](#).

Overflow handling

By default, Vertica allows silent numeric overflow when you call this function on numeric data types. For more information on this behavior and how to change it, see [Numeric data type overflow with SUM, SUM_FLOAT, and AVG](#).

Examples

The following query finds the sales for that calendar month and returns a running/cumulative average (sometimes called a moving average) using the default window of **RANGE UNBOUNDED PRECEDING AND CURRENT ROW** :

```
=> SELECT calendar_month_number_in_year Mo, SUM(product_price) Sales,
  AVG(SUM(product_price)) OVER (ORDER BY calendar_month_number_in_year)::INTEGER Average
  FROM product_dimension pd, date_dimension dm, inventory_fact if
  WHERE dm.date_key = if.date_key AND pd.product_key = if.product_key GROUP BY Mo;
Mo | Sales | Average
-----+-----+-----
 1 | 23869547 | 23869547
 2 | 19604661 | 21737104
 3 | 22877913 | 22117374
 4 | 22901263 | 22313346
 5 | 23670676 | 22584812
 6 | 22507600 | 22571943
 7 | 21514089 | 22420821
 8 | 24860684 | 22725804
 9 | 21687795 | 22610470
10 | 23648921 | 22714315
11 | 21115910 | 22569005
12 | 24708317 | 22747281
(12 rows)
```

To return a moving average that is not a running (cumulative) average, the window can specify **ROWS BETWEEN 2 PRECEDING AND 2 FOLLOWING** :

```
=> SELECT calendar_month_number_in_year Mo, SUM(product_price) Sales,
  AVG(SUM(product_price)) OVER (ORDER BY calendar_month_number_in_year
  ROWS BETWEEN 2 PRECEDING AND 2 FOLLOWING)::INTEGER Average
  FROM product_dimension pd, date_dimension dm, inventory_fact if
  WHERE dm.date_key = if.date_key AND pd.product_key = if.product_key GROUP BY Mo;
Mo | Sales | Average
-----+-----+-----
 1 | 23869547 | 22117374
 2 | 19604661 | 22313346
 3 | 22877913 | 22584812
 4 | 22901263 | 22312423
 5 | 23670676 | 22694308
 6 | 22507600 | 23090862
 7 | 21514089 | 22848169
 8 | 24860684 | 22843818
 9 | 21687795 | 22565480
10 | 23648921 | 23204325
11 | 21115910 | 22790236
12 | 24708317 | 23157716
(12 rows)
```

- [COUNT \[analytic\]](#)
- [SUM \[analytic\]](#)
- [SQL analytics](#)

BOOL_AND [analytic]

Returns the Boolean value of an expression within a [window](#). If all input values are true, **BOOL_AND** returns **t**. Otherwise, it returns **f**.

Behavior type

[Immutable](#)

Syntax

```
BOOL_AND ( expression ) OVER (
  [ window-partition-clause ]
  [ window-order-clause ]
  [ window-frame-clause ] )
```

Parameters

expression

A [Boolean data type](#) or any non-Boolean data type that can be implicitly converted to a Boolean data type. The function returns a Boolean value.

OVER()

See [Analytic Functions](#).

Examples

The following example illustrates how you can use the **BOOL_AND** , **BOOL_OR** , and **BOOL_XOR** analytic functions. The sample table, employee, includes a column for type of employee and years paid.

```
=> CREATE TABLE employee(emptytype VARCHAR, yearspaid VARCHAR);
CREATE TABLE
```

Insert sample data into the table to show years paid. In more than one case, an employee could be paid more than once within one year.

```
=> INSERT INTO employee
SELECT 'contractor1', '2014'
UNION ALL
SELECT 'contractor2', '2015'
UNION ALL
SELECT 'contractor3', '2014'
UNION ALL
SELECT 'contractor1', '2014'
UNION ALL
SELECT 'contractor2', '2014'
UNION ALL
SELECT 'contractor3', '2015'
UNION ALL
SELECT 'contractor4', '2014'
UNION ALL
SELECT 'contractor4', '2014'
UNION ALL
SELECT 'contractor5', '2015'
UNION ALL
SELECT 'contractor5', '2016';
OUTPUT
-----
  10
(1 row)
```

Query the table. The result shows employees that were paid twice in 2014 (**BOOL_AND**), once or twice in 2014 (**BOOL_OR**), and specifically not more than once in 2014 (**BOOL_XOR**).

```
=> SELECT DISTINCT emptytype,
BOOL_AND(yearspaid='2014') OVER (PARTITION BY emptytype) AS paidtwicein2014,
BOOL_OR(yearspaid='2014') OVER (PARTITION BY emptytype) AS paidonceortwicein2014,
BOOL_XOR(yearspaid='2014') OVER (PARTITION BY emptytype) AS paidjustoncein2014
FROM employee;
```

emptytype	paidtwicein2014	paidonceortwicein2014	paidjustoncein2014
contractor1	t	t	f
contractor2	f	t	t
contractor3	f	t	t
contractor4	t	t	f
contractor5	f	f	f

(5 rows)

See also

- [BOOL_AND \[aggregate\]](#)
- [BOOL_OR \[analytic\]](#)
- [BOOL_XOR \[analytic\]](#)
- [Boolean data type](#)

BOOL_OR [analytic]

Returns the Boolean value of an expression within a [window](#). If at least one input value is true, **BOOL_OR** returns **t**. Otherwise, it returns **f**.

Behavior type

[Immutable](#)

Syntax

```
BOOL_OR ( expression ) OVER (
  [ window-partition-clause ]
  [ window-order-clause ]
  [ window-frame-clause ] )
```

Parameters

expression

A [Boolean data type](#) or any non-Boolean data type that can be implicitly converted to a Boolean data type. The function returns a Boolean value.

OVER()

See [Analytic Functions](#).

Examples

The following example illustrates how you can use the **BOOL_AND**, **BOOL_OR**, and **BOOL_XOR** analytic functions. The sample table, `employee`, includes a column for type of employee and years paid.

```
=> CREATE TABLE employee(emptytype VARCHAR, yearspaid VARCHAR);
CREATE TABLE
```

Insert sample data into the table to show years paid. In more than one case, an employee could be paid more than once within one year.

```
=> INSERT INTO employee
SELECT 'contractor1', '2014'
UNION ALL
SELECT 'contractor2', '2015'
UNION ALL
SELECT 'contractor3', '2014'
UNION ALL
SELECT 'contractor1', '2014'
UNION ALL
SELECT 'contractor2', '2014'
UNION ALL
SELECT 'contractor3', '2015'
UNION ALL
SELECT 'contractor4', '2014'
UNION ALL
SELECT 'contractor4', '2014'
UNION ALL
SELECT 'contractor5', '2015'
UNION ALL
SELECT 'contractor5', '2016';
OUTPUT
-----
  10
(1 row)
```

Query the table. The result shows employees that were paid twice in 2014 ([BOOL_AND](#)), once or twice in 2014 ([BOOL_OR](#)), and specifically not more than once in 2014 ([BOOL_XOR](#)).

```
=> SELECT DISTINCT emptype,
BOOL_AND(yearspaid='2014') OVER (PARTITION BY emptype) AS paidtwicein2014,
BOOL_OR(yearspaid='2014') OVER (PARTITION BY emptype) AS paidonceortwicein2014,
BOOL_XOR(yearspaid='2014') OVER (PARTITION BY emptype) AS paidjustoncein2014
FROM employee;
```

emptype	paidtwicein2014	paidonceortwicein2014	paidjustoncein2014
contractor1	t	t	f
contractor2	f	t	t
contractor3	f	t	t
contractor4	t	t	f
contractor5	f	f	f

(5 rows)

See also

- [BOOL_OR \[aggregate\]](#)
- [BOOL_AND \[analytic\]](#)
- [BOOL_XOR \[analytic\]](#)
- [Boolean data type](#)

[BOOL_XOR \[analytic\]](#)

Returns the Boolean value of an expression within a [window](#). If only one input value is true, [BOOL_XOR](#) returns [t](#). Otherwise, it returns [f](#).

Behavior type

[Immutable](#)

Syntax

```
BOOL_XOR ( expression ) OVER (
  [ window-partition-clause ]
  [ window-order-clause ]
  [ window-frame-clause ] )
```

Parameters

expression

A [Boolean data type](#) or any non-Boolean data type that can be implicitly converted to a Boolean data type. The function returns a Boolean value.

OVER()

See [Analytic Functions](#).

Examples

The following example illustrates how you can use the [BOOL_AND](#) , [BOOL_OR](#) , and [BOOL_XOR](#) analytic functions. The sample table, employee, includes a column for type of employee and years paid.

```
=> CREATE TABLE employee(emptytype VARCHAR, yearspaid VARCHAR);
CREATE TABLE
```

Insert sample data into the table to show years paid. In more than one case, an employee could be paid more than once within one year.

```
=> INSERT INTO employee
SELECT 'contractor1', '2014'
UNION ALL
SELECT 'contractor2', '2015'
UNION ALL
SELECT 'contractor3', '2014'
UNION ALL
SELECT 'contractor1', '2014'
UNION ALL
SELECT 'contractor2', '2014'
UNION ALL
SELECT 'contractor3', '2015'
UNION ALL
SELECT 'contractor4', '2014'
UNION ALL
SELECT 'contractor4', '2014'
UNION ALL
SELECT 'contractor5', '2015'
UNION ALL
SELECT 'contractor5', '2016';
OUTPUT
```

```
-----
  10
(1 row)
```

Query the table. The result shows employees that were paid twice in 2014 ([BOOL_AND](#)), once or twice in 2014 ([BOOL_OR](#)), and specifically not more than once in 2014 ([BOOL_XOR](#)).

```
=> SELECT DISTINCT emptytype,
BOOL_AND(yearspaid='2014') OVER (PARTITION BY emptytype) AS paidtwicein2014,
BOOL_OR(yearspaid='2014') OVER (PARTITION BY emptytype) AS paidonceortwicein2014,
BOOL_XOR(yearspaid='2014') OVER (PARTITION BY emptytype) AS paidjustoncein2014
FROM employee;
```

emptytype	paidtwicein2014	paidonceortwicein2014	paidjustoncein2014
contractor1	t	t	f
contractor2	f	t	t
contractor3	f	t	t
contractor4	t	t	f
contractor5	f	f	f

- [BOOL_AND \[analytic\]](#)
- [BOOL_OR \[analytic\]](#)
- [Boolean data type](#)

CONDITIONAL_CHANGE_EVENT [analytic]

Assigns an event window number to each row, starting from 0, and increments by 1 when the result of evaluating the argument expression on the current row differs from that on the previous row.

Behavior type

[Immutable](#)

Syntax

```
CONDITIONAL_CHANGE_EVENT ( expression ) OVER (
  [ window-partition-clause ]
  window-order-clause )
```

Parameters

expression

SQL scalar expression that is evaluated on an input record. The result of * **expression** * can be of any data type.

OVER()

See [Analytic Functions](#).

Notes

The analytic [window-order-clause](#) is required but the [window-partition-clause](#) is optional.

Examples

```
=> SELECT CONDITIONAL_CHANGE_EVENT(bid)
      OVER (PARTITION BY symbol ORDER BY ts) AS cce
FROM TickStore;
```

The system returns an error when no **ORDER BY** clause is present:

```
=> SELECT CONDITIONAL_CHANGE_EVENT(bid)
      OVER (PARTITION BY symbol) AS cce
FROM TickStore;
```

ERROR: conditional_change_event must contain an ORDER BY clause within its analytic clause

For more examples, see [Event-based windows](#).

See also

- [CONDITIONAL_TRUE_EVENT \[analytic\]](#)
- [ROW_NUMBER \[analytic\]](#)
- [Time series analytics](#)
- [Event-based windows](#)

CONDITIONAL_TRUE_EVENT [analytic]

Assigns an event window number to each row, starting from 0, and increments the number by 1 when the result of the boolean argument expression evaluates true. For example, given a sequence of values for column a, as follows:

```
( 1, 2, 3, 4, 5, 6 )
```

CONDITIONAL_TRUE_EVENT(a > 3) returns 0, 0, 0, 1, 2, 3 .

Behavior type

[Immutable](#)

Syntax

```
CONDITIONAL_TRUE_EVENT ( boolean-expression ) OVER (
  [ window-partition-clause ]
  window-order-clause )
```

Parameters

boolean-expression

SQL scalar expression that is evaluated on an input record, type BOOLEAN.

OVER()

See [Analytic functions](#).

Notes

The analytic *window-order-clause* is required but the *window-partition-clause* is optional.

Examples

```
> SELECT CONDITIONAL_TRUE_EVENT(bid > 10.6)
   OVER(PARTITION BY bid ORDER BY ts) AS cte
FROM Tickstore;
```

The system returns an error if the **ORDER BY** clause is omitted:

```
> SELECT CONDITIONAL_TRUE_EVENT(bid > 10.6)
   OVER(PARTITION BY bid) AS cte
FROM Tickstore;
```

ERROR: conditional_true_event must contain an ORDER BY clause within its analytic clause

For more examples, see [Event-based windows](#).

See also

- [CONDITIONAL_CHANGE_EVENT \[analytic\]](#)
- [Time series analytics](#)
- [Event-based windows](#)

COUNT [analytic]

Counts occurrences within a group within a [window](#). If you specify * or some non-null constant, **COUNT()** counts all rows.

Behavior type

[Immutable](#)

Syntax

```
COUNT ( expression ) OVER (
  [ window-partition-clause ]
  [ window-order-clause ]
  [ window-frame-clause ] )
```

Parameters

expression

Returns the number of rows in each group for which the *expression* is not null. Can be any expression resulting in BIGINT.

OVER()

See [Analytic Functions](#).

Examples

Using the schema defined in [Window framing](#), the following **COUNT** function omits window order and window frame clauses; otherwise Vertica would treat it as a window aggregate. Think of the window of reporting aggregates as **RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW**.

```
=> SELECT deptno, sal, empno, COUNT(sal)
      OVER (PARTITION BY deptno) AS count FROM emp;
```

```
deptno | sal | empno | count
```

```
-----+-----+-----+-----
10 | 101 | 1 | 2
10 | 104 | 4 | 2
20 | 110 | 10 | 6
20 | 110 | 9 | 6
20 | 109 | 7 | 6
20 | 109 | 6 | 6
20 | 109 | 8 | 6
20 | 109 | 11 | 6
30 | 105 | 5 | 3
30 | 103 | 3 | 3
30 | 102 | 2 | 3
```

Using **ORDER BY sal** creates a moving window query with default window: **RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW** .

```
=> SELECT deptno, sal, empno, COUNT(sal)
      OVER (PARTITION BY deptno ORDER BY sal) AS count
FROM emp;
```

```
deptno | sal | empno | count
```

```
-----+-----+-----+-----
10 | 101 | 1 | 1
10 | 104 | 4 | 2
20 | 100 | 11 | 1
20 | 109 | 7 | 4
20 | 109 | 6 | 4
20 | 109 | 8 | 4
20 | 110 | 10 | 6
20 | 110 | 9 | 6
30 | 102 | 2 | 1
30 | 103 | 3 | 2
30 | 105 | 5 | 3
```

Using the VMart schema, the following query finds the number of employees who make less than or equivalent to the hourly rate of the current employee. The query returns a running/cumulative average (sometimes called a moving average) using the default window of **RANGE UNBOUNDED PRECEDING AND CURRENT ROW** :

```
=> SELECT employee_last_name AS "last_name", hourly_rate, COUNT(*)  
OVER (ORDER BY hourly_rate) AS moving_count from employee_dimension;
```

```
last_name | hourly_rate | moving_count
```

```
-----+-----+-----  
Gauthier |      6 |      4  
Taylor   |      6 |      4  
Jefferson |      6 |      4  
Nielson  |      6 |      4  
McNulty  |     6.01 |     11  
Robinson |     6.01 |     11  
Dobisz   |     6.01 |     11  
Williams |     6.01 |     11  
Kramer   |     6.01 |     11  
Miller   |     6.01 |     11  
Wilson   |     6.01 |     11  
Vogel    |     6.02 |     14  
Moore    |     6.02 |     14  
Vogel    |     6.02 |     14  
Carcetti |     6.03 |     19  
...
```

To return a moving average that is not also a running (cumulative) average, the window should specify **ROWS BETWEEN 2 PRECEDING AND 2 FOLLOWING** :

```
=> SELECT employee_last_name AS "last_name", hourly_rate, COUNT(*)  
OVER (ORDER BY hourly_rate ROWS BETWEEN 2 PRECEDING AND 2 FOLLOWING)  
AS moving_count from employee_dimension;
```

CUME_DIST [analytic]

Calculates the cumulative distribution, or relative rank, of the current row with regard to other rows in the same partition within a [window](#).

CUME_DIST() returns a number greater than 0 and less than or equal to 1, where the number represents the relative position of the specified row within a group of *n* rows. For a row *x* (assuming **ASC** ordering), the **CUME_DIST** of *x* is the number of rows with values lower than or equal to the value of *x*, divided by the number of rows in the partition. For example, in a group of three rows, the cumulative distribution values returned would be 1/3, 2/3, and 3/3.

Note

Because the result for a given row depends on the number of rows preceding that row in the same partition, you should always specify a **window-order-clause** when you call this function.

Behavior type

[Immutable](#)

Syntax

```
CUME_DIST ( ) OVER (  
 [ window-partition-clause ]  
 window-order-clause )
```

Parameters

OVER()

See [Analytic Functions](#).

Examples

The following example returns the cumulative distribution of sales for different transaction types within each month of the first quarter.

```
=> SELECT calendar_month_name AS month, tender_type, SUM(sales_quantity),
       CUME_DIST()
       OVER (PARTITION BY calendar_month_name ORDER BY SUM(sales_quantity)) AS
CUME_DIST
FROM store.store_sales_fact JOIN date_dimension
USING(date_key) WHERE calendar_month_name IN ('January','February','March')
AND tender_type NOT LIKE 'Other'
GROUP BY calendar_month_name, tender_type;
```

month	tender_type	SUM	CUME_DIST
March	Credit	469858	0.25
March	Cash	470449	0.5
March	Check	473033	0.75
March	Debit	475103	1
January	Cash	441730	0.25
January	Debit	443922	0.5
January	Check	446297	0.75
January	Credit	450994	1
February	Check	425665	0.25
February	Debit	426726	0.5
February	Credit	430010	0.75
February	Cash	430767	1

- [PERCENTILE_DISC \[analytic\]](#)
- [SQL analytics](#)

DENSE_RANK [analytic]

Within each window partition, ranks all rows in the query results set according to the order specified by the window's **ORDER BY** clause. A **DENSE_RANK** function returns a sequence of ranking numbers without any gaps.

DENSE_RANK executes as follows:

1. Sorts partition rows as specified by the **ORDER BY** clause.
2. Compares the **ORDER BY** values of the preceding row and current row and ranks the current row as follows:
 - If **ORDER BY** values are the same, the current row gets the same ranking as the preceding row.

Note

Null values are considered equal. For detailed information on how null values are sorted, see [NULL sort order](#).

- If the **ORDER BY** values are different, **DENSE_RANK** increments or decrements the current row's ranking by 1, depending whether sort order is ascending or descending.

DENSE_RANK always changes the ranking by 1, so no gaps appear in the ranking sequence. The largest rank value is the number of unique **ORDER BY** values returned by the query.

Behavior type

[Immutable](#)

Syntax

```
DENSE_RANK() OVER (
  [ window-partition-clause ]
  window-order-clause )
```

Parameters

OVER()

See [Analytic Functions](#).

See [Analytic Functions](#)

Compared with RANK

[RANK](#) leaves gaps in the ranking sequence, while [DENSE_RANK](#) does not. The example below compares the behavior of the two functions.

Examples

The following query invokes [RANK](#) and [DENSE_RANK](#) to rank customers by annual income. The two functions return different rankings, as follows:

- If [annual_salary](#) contains duplicate values, [RANK\(\)](#) inserts duplicate rankings and then skips one or more values—for example, from 4 to 6 and 7 to 9.
- In the parallel column [Dense Rank](#), [DENSE_RANK\(\)](#) also inserts duplicate rankings, but leaves no gaps in the rankings sequence:

```
=> SELECT employee_region region, employee_key, annual_salary,
RANK() OVER (PARTITION BY employee_region ORDER BY annual_salary) Rank,
DENSE_RANK() OVER (PARTITION BY employee_region ORDER BY annual_salary) "Dense Rank"
FROM employee_dimension;
```

region	employee_key	annual_salary	Rank	Dense Rank
West	5248	1200	1	1
West	6880	1204	2	2
West	5700	1214	3	3
West	9857	1218	4	4
West	6014	1218	4	4
West	9221	1220	6	5
West	7646	1222	7	6
West	6621	1222	7	6
West	6488	1224	9	7
West	7659	1226	10	8
West	7432	1226	10	8
West	9905	1226	10	8
West	9021	1228	13	9
...				
West	56	963104	2794	2152
West	100	992363	2795	2153
East	8353	1200	1	1
East	9743	1202	2	2
East	9975	1202	2	2
East	9205	1204	4	3
East	8894	1206	5	4
East	7740	1206	5	4
East	7324	1208	7	5
East	6505	1208	7	5
East	5404	1208	7	5
East	5010	1208	7	5
East	9114	1212	11	6
...

[SQL analytics](#)

EXPONENTIAL_MOVING_AVERAGE [analytic]

Calculates the exponential moving average (EMA) of expression *E* with smoothing factor *X*. An EMA differs from a simple moving average in that it provides a more stable picture of changes to data over time.

The EMA is calculated by adding the previous EMA value to the current data point scaled by the smoothing factor, as in the following formula:

$$EMA = EMA0 + (X * (E - EMA0))$$

where:

- *E* is the current data point
- *EMA0* is the previous row's EMA value.
- *X* is the smoothing factor.

This function also works at the row level. For example, EMA assumes the data in a given column is sampled at uniform intervals. If the users' data points are sampled at non-uniform intervals, they should run the time series [gap filling and interpolation \(GFI\)](#) operations before EMA()

Behavior type

[Immutable](#)

Syntax

```
EXPONENTIAL_MOVING_AVERAGE ( E, X ) OVER (
  [ window-partition-clause ]
  window-order-clause )
```

Parameters

E

The value whose average is calculated over a set of rows. Can be **INTEGER** , **FLOAT** or **NUMERIC** type and must be a constant.

X

A positive **FLOAT** value between 0 and 1 that is used as the smoothing factor.

OVER()

See [Analytic Functions](#).

Examples

The following example uses time series [gap filling and interpolation](#) (GFI) first in a subquery, and then performs an **EXPONENTIAL_MOVING_AVERAGE** operation on the subquery result.

Create a simple four-column table:

```
=> CREATE TABLE ticker(
  time TIMESTAMP,
  symbol VARCHAR(8),
  bid1 FLOAT,
  bid2 FLOAT );
```

Insert some data, including nulls, so GFI can do its interpolation and gap filling:

```
=> INSERT INTO ticker VALUES ('2009-07-12 03:00:00', 'ABC', 60.45, 60.44);
=> INSERT INTO ticker VALUES ('2009-07-12 03:00:01', 'ABC', 60.49, 65.12);
=> INSERT INTO ticker VALUES ('2009-07-12 03:00:02', 'ABC', 57.78, 59.25);
=> INSERT INTO ticker VALUES ('2009-07-12 03:00:03', 'ABC', null, 65.12);
=> INSERT INTO ticker VALUES ('2009-07-12 03:00:04', 'ABC', 67.88, null);
=> INSERT INTO ticker VALUES ('2009-07-12 03:00:00', 'XYZ', 47.55, 40.15);
=> INSERT INTO ticker VALUES ('2009-07-12 03:00:01', 'XYZ', 44.35, 46.78);
=> INSERT INTO ticker VALUES ('2009-07-12 03:00:02', 'XYZ', 71.56, 75.78);
=> INSERT INTO ticker VALUES ('2009-07-12 03:00:03', 'XYZ', 85.55, 70.21);
=> INSERT INTO ticker VALUES ('2009-07-12 03:00:04', 'XYZ', 45.55, 58.65);
=> COMMIT;
```

Note

During gap filling and interpolation, Vertica takes the closest non null value on either side of the time slice and uses that value. For example, if you use a linear interpolation scheme and you do not specify **IGNORE NULLS** , and your data has one real value and one null, the result is null. If the value on either side is null, the result is null. See [When Time Series Data Contains Nulls](#) for details.

Query the table that you just created to you can see the output:

```
=> SELECT * FROM ticker;
   time      | symbol | bid1 | bid2
-----+-----+-----+-----
2009-07-12 03:00:00 | ABC   | 60.45 | 60.44
2009-07-12 03:00:01 | ABC   | 60.49 | 65.12
2009-07-12 03:00:02 | ABC   | 57.78 | 59.25
2009-07-12 03:00:03 | ABC   |      | 65.12
2009-07-12 03:00:04 | ABC   | 67.88 |
2009-07-12 03:00:00 | XYZ   | 47.55 | 40.15
2009-07-12 03:00:01 | XYZ   | 44.35 | 46.78
2009-07-12 03:00:02 | XYZ   | 71.56 | 75.78
2009-07-12 03:00:03 | XYZ   | 85.55 | 70.21
2009-07-12 03:00:04 | XYZ   | 45.55 | 58.65
(10 rows)
```

The following query processes the first and last values that belong to each 2-second time slice in table `trades` ' column `a` . The query then calculates the exponential moving average of expression `fv` and `lv` with a smoothing factor of 50%:

```
=> SELECT symbol, slice_time, fv, lv,
   EXponential_Moving_Average(fv, 0.5)
   OVER (PARTITION BY symbol ORDER BY slice_time) AS ema_first,
   EXponential_Moving_Average(lv, 0.5)
   OVER (PARTITION BY symbol ORDER BY slice_time) AS ema_last
FROM (
  SELECT symbol, slice_time,
   TS_FIRST_VALUE(bid1 IGNORE NULLS) as fv,
   TS_LAST_VALUE(bid2 IGNORE NULLS) AS lv
  FROM ticker TIMESERIES slice_time AS '2 seconds'
  OVER (PARTITION BY symbol ORDER BY time ) AS sq;
```

```
symbol | slice_time | fv | lv | ema_first | ema_last
-----+-----+-----+-----+-----+-----
ABC | 2009-07-12 03:00:00 | 60.45 | 65.12 | 60.45 | 65.12
ABC | 2009-07-12 03:00:02 | 57.78 | 65.12 | 59.115 | 65.12
ABC | 2009-07-12 03:00:04 | 67.88 | 65.12 | 63.4975 | 65.12
XYZ | 2009-07-12 03:00:00 | 47.55 | 46.78 | 47.55 | 46.78
XYZ | 2009-07-12 03:00:02 | 71.56 | 70.21 | 59.555 | 58.495
XYZ | 2009-07-12 03:00:04 | 45.55 | 58.65 | 52.5525 | 58.5725
(6 rows)
```

FIRST_VALUE [analytic]

Lets you select the first value of a table or partition (determined by the *window-order-clause*) without having to use a self join. This function is useful when you want to use the first value as a baseline in calculations.

Use `FIRST_VALUE()` with the *window-order-clause* to produce deterministic results. If no *window* is specified for the current row, the default window is **UNBOUNDED PRECEDING AND CURRENT ROW** .

Behavior type

[Immutable](#)

Syntax

```
FIRST_VALUE ( expression [ IGNORE NULLS ] ) OVER (
  [ window-partition-clause ]
  [ window-order-clause ]
  [ window-frame-clause ] )
```

Parameters

expression

Expression to evaluate—or example, a constant, column, nonanalytic function, function expression, or expressions involving any of these.

IGNORE NULLS

Specifies to return the first non-null value in the set, or **NULL** if all values are **NULL**. If you omit this option and the first value in the set is null, the function returns **NULL**.

OVER()

See [Analytic Functions](#).

Examples

The following query asks for the first value in the partitioned day of week, and illustrates the potential nondeterministic nature of **FIRST_VALUE()**:

```
=> SELECT calendar_year, date_key, day_of_week, full_date_description,  
FIRST_VALUE(full_date_description)  
OVER(PARTITION BY calendar_month_number_in_year ORDER BY day_of_week)  
AS "first_value"  
FROM date_dimension  
WHERE calendar_year=2003 AND calendar_month_number_in_year=1;
```

The first value returned is January 31, 2003; however, the next time the same query is run, the first value might be January 24 or January 3, or the 10th or 17th. This is because the analytic **ORDER BY** column **day_of_week** returns rows that contain ties (multiple Fridays). These repeated values make the **ORDER BY** evaluation result nondeterministic, because rows that contain ties can be ordered in any way, and any one of those rows qualifies as being the first value of **day_of_week**.

calendar_year	date_key	day_of_week	full_date_description	first_value
2003	31	Friday	January 31, 2003	January 31, 2003
2003	24	Friday	January 24, 2003	January 31, 2003
2003	3	Friday	January 3, 2003	January 31, 2003
2003	10	Friday	January 10, 2003	January 31, 2003
2003	17	Friday	January 17, 2003	January 31, 2003
2003	6	Monday	January 6, 2003	January 31, 2003
2003	27	Monday	January 27, 2003	January 31, 2003
2003	13	Monday	January 13, 2003	January 31, 2003
2003	20	Monday	January 20, 2003	January 31, 2003
2003	11	Saturday	January 11, 2003	January 31, 2003
2003	18	Saturday	January 18, 2003	January 31, 2003
2003	25	Saturday	January 25, 2003	January 31, 2003
2003	4	Saturday	January 4, 2003	January 31, 2003
2003	12	Sunday	January 12, 2003	January 31, 2003
2003	26	Sunday	January 26, 2003	January 31, 2003
2003	5	Sunday	January 5, 2003	January 31, 2003
2003	19	Sunday	January 19, 2003	January 31, 2003
2003	23	Thursday	January 23, 2003	January 31, 2003
2003	2	Thursday	January 2, 2003	January 31, 2003
2003	9	Thursday	January 9, 2003	January 31, 2003
2003	16	Thursday	January 16, 2003	January 31, 2003
2003	30	Thursday	January 30, 2003	January 31, 2003
2003	21	Tuesday	January 21, 2003	January 31, 2003
2003	14	Tuesday	January 14, 2003	January 31, 2003
2003	7	Tuesday	January 7, 2003	January 31, 2003
2003	28	Tuesday	January 28, 2003	January 31, 2003
2003	22	Wednesday	January 22, 2003	January 31, 2003
2003	29	Wednesday	January 29, 2003	January 31, 2003
2003	15	Wednesday	January 15, 2003	January 31, 2003
2003	1	Wednesday	January 1, 2003	January 31, 2003
2003	8	Wednesday	January 8, 2003	January 31, 2003

(31 rows)

The `day_of_week` results are returned in alphabetical order because of lexical rules. The fact that each day does not appear ordered by the 7-day week cycle (for example, starting with Sunday followed by Monday, Tuesday, and so on) has no effect on results.

To return deterministic results, modify the query so that it performs its analytic `ORDER BY` operations on a **unique** field, such as `date_key` :

```
=> SELECT calendar_year, date_key, day_of_week, full_date_description,  
       FIRST_VALUE(full_date_description) OVER  
       (PARTITION BY calendar_month_number_in_year ORDER BY date_key) AS "first_value"  
FROM date_dimension WHERE calendar_year=2003;
```

`FIRST_VALUE()` returns a first value of January 1 for the January partition and the first value of February 1 for the February partition. Also, the `full_date_description` column contains no ties:

calendar_year	date_key	day_of_week	full_date_description	first_value
2003	1	Wednesday	January 1, 2003	January 1, 2003
2003	2	Thursday	January 2, 2003	January 1, 2003
2003	3	Friday	January 3, 2003	January 1, 2003
2003	4	Saturday	January 4, 2003	January 1, 2003
2003	5	Sunday	January 5, 2003	January 1, 2003
2003	6	Monday	January 6, 2003	January 1, 2003
2003	7	Tuesday	January 7, 2003	January 1, 2003
2003	8	Wednesday	January 8, 2003	January 1, 2003
2003	9	Thursday	January 9, 2003	January 1, 2003
2003	10	Friday	January 10, 2003	January 1, 2003

- [LAST_VALUE \[analytic\]](#)
- [TIME_SLICE](#)
- [SQL analytics](#)

[LAG \[analytic\]](#)

Returns the value of the input expression at the given offset before the current row within a [window](#). This function lets you access more than one row in a table at the same time. This is useful for comparing values when the relative positions of rows can be reliably known. It also lets you avoid the more costly self join, which enhances query processing speed.

For information on getting the rows that follow, see [LEAD](#).

Behavior type

[Immutable](#)

Syntax

```
LAG ( expression[, offset ] [, default ] ) OVER (
  [ window-partition-clause ]
  window-order-clause )
```

Parameters

expression

The expression to evaluate—for example, a constant, column, non-analytic function, function expression, or expressions involving any of these.

offset

Indicates how great is the lag. The default value is 1 (the previous row). This parameter must evaluate to a constant positive integer.

default

The value returned if *offset* falls outside the bounds of the table or partition. This value must be a constant value or an expression that can be evaluated to a constant; its data type is coercible to that of the first argument.

Examples

This example sums the current balance by date in a table and also sums the previous balance from the last day. Given the inputs that follow, the data satisfies the following conditions:

- For each *some_id*, there is exactly 1 row for each date represented by *month_date*.
- For each *some_id*, the set of dates is consecutive; that is, if there is a row for February 24 and a row for February 26, there would also be a row for February 25.
- Each *some_id* has the same set of dates.

```
=> CREATE TABLE balances (
  month_date DATE,
  current_bal INT,
  some_id INT);
=> INSERT INTO balances values ('2009-02-24', 10, 1);
=> INSERT INTO balances values ('2009-02-25', 10, 1);
=> INSERT INTO balances values ('2009-02-26', 10, 1);
=> INSERT INTO balances values ('2009-02-24', 20, 2);
=> INSERT INTO balances values ('2009-02-25', 20, 2);
=> INSERT INTO balances values ('2009-02-26', 20, 2);
=> INSERT INTO balances values ('2009-02-24', 30, 3);
=> INSERT INTO balances values ('2009-02-25', 20, 3);
=> INSERT INTO balances values ('2009-02-26', 30, 3);
```

Now run LAG to sum the current balance for each date and sum the previous balance from the last day:

```
=> SELECT month_date,
  SUM(current_bal) as current_bal_sum,
  SUM(previous_bal) as previous_bal_sum FROM
  (SELECT month_date, current_bal,
  LAG(current_bal, 1, 0) OVER
  (PARTITION BY some_id ORDER BY month_date)
  AS previous_bal FROM balances) AS subQ
  GROUP BY month_date ORDER BY month_date;
```

month_date	current_bal_sum	previous_bal_sum
2009-02-24	60	0
2009-02-25	50	60
2009-02-26	60	50

(3 rows)

Using the same example data, the following query would not be allowed because LAG is nested inside an aggregate function:

```
=> SELECT month_date,
       SUM(current_bal) as current_bal_sum,
       SUM(LAG(current_bal, 1, 0) OVER
          (PARTITION BY some_id ORDER BY month_date)) AS previous_bal_sum
       FROM some_table GROUP BY month_date ORDER BY month_date;
```

The following example uses the [VMart database](#). LAG first returns the annual income from the previous row, and then it calculates the difference between the income in the current row from the income in the previous row:

```
=> SELECT occupation, customer_key, customer_name, annual_income,
       LAG(annual_income, 1, 0) OVER (PARTITION BY occupation
          ORDER BY annual_income) AS prev_income, annual_income -
       LAG(annual_income, 1, 0) OVER (PARTITION BY occupation
          ORDER BY annual_income) AS difference
       FROM customer_dimension ORDER BY occupation, customer_key LIMIT 20;
```

occupation	customer_key	customer_name	annual_income	prev_income	difference
Accountant	15	Midori V. Peterson	692610	692535	75
Accountant	43	Midori S. Rodriguez	282359	280976	1383

(20 rows)

The next example uses [LEAD](#) and LAG to return the third row after the salary in the current row and fifth salary before the salary in the current row:

```
=> SELECT hire_date, employee_key, employee_last_name,
       LEAD(hire_date, 1) OVER (ORDER BY hire_date) AS "next_hired" ,
       LAG(hire_date, 1) OVER (ORDER BY hire_date) AS "last_hired"
       FROM employee_dimension ORDER BY hire_date, employee_key;
```

hire_date	employee_key	employee_last_name	next_hired	last_hired
1956-04-11	2694	Farmer	1956-05-12	
1956-05-12	5486	Winkler	1956-09-18	1956-04-11

- [SQL analytics](#)

LAST_VALUE [analytic]

Lets you select the last value of a table or partition (determined by the *window-order-clause*) without having to use a self join. **LAST_VALUE** takes the last record from the partition after the window order clause. The function then computes the expression against the last record, and returns the results. This function is useful when you want to use the last value as a baseline in calculations.

Use **LAST_VALUE()** with the *window-order-clause* to produce deterministic results. If no [window](#) is specified for the current row, the default window is **UNBOUNDED PRECEDING AND CURRENT ROW** .

Tip

Due to default window semantics, **LAST_VALUE** does not always return the last value of a partition. If you omit *window-frame-clause* from the analytic clause, **LAST_VALUE** operates on this default window. Although results can seem non-intuitive by not returning the bottom of the current partition, it returns the bottom of the window, which continues to change along with the current input row being processed. If you want to return the last value of a partition, use **UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING** . See examples below.

Behavior type

[Immutable](#)

Syntax

```
LAST_VALUE ( expression [ IGNORE NULLS ] ) OVER (
  [ window-partition-clause ]
  [ window-order-clause ]
  [ window-frame-clause ] )
```

Parameters

expression

Expression to evaluate—for example, a constant, column, nonanalytic function, function expression, or expressions involving any of these.

IGNORE NULLS

Specifies to return the last non-null value in the set, or **NULL** if all values are **NULL** . If you omit this option and the last value in the set is null, the function returns **NULL** .

OVER()

See [Analytic Functions](#).

Examples

Using the schema defined in [Window framing](#) in Analyzing Data, the following query does not show the highest salary value by department; instead it shows the highest salary value by department by salary.

```
=> SELECT deptno, sal, empno, LAST_VALUE(sal)
   OVER (PARTITION BY deptno ORDER BY sal) AS lv
 FROM emp;
deptno | sal | empno | lv
-----+-----+-----+-----
 10 | 101 | 1 | 101
 10 | 104 | 4 | 104
 20 | 100 | 11 | 100
 20 | 109 | 7 | 109
 20 | 109 | 6 | 109
 20 | 109 | 8 | 109
 20 | 110 | 10 | 110
 20 | 110 | 9 | 110
 30 | 102 | 2 | 102
 30 | 103 | 3 | 103
 30 | 105 | 5 | 105
```

If you include the window frame clause **ROWS BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING** , **LAST_VALUE()** returns the highest salary by department, an accurate representation of the information:

```
=> SELECT deptno, sal, empno, LAST_VALUE(sal)
       OVER (PARTITION BY deptno ORDER BY sal
            ROWS BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING) AS lv
FROM emp;
```

deptno	sal	empno	lv
10	101	1	104
10	104	4	104
20	100	11	110
20	109	7	110
20	109	6	110
20	109	8	110
20	110	10	110
20	110	9	110
30	102	2	105
30	103	3	105
30	105	5	105

For more examples, see [FIRST_VALUE\(\)](#).

- [FIRST_VALUE \[analytic\]](#)
- [TIME_SLICE](#)
- [SQL analytics](#)

LEAD [analytic]

Returns values from the row after the current row within a [window](#), letting you access more than one row in a table at the same time. This is useful for comparing values when the relative positions of rows can be reliably known. It also lets you avoid the more costly self join, which enhances query processing speed.

Behavior type

[Immutable](#)

Syntax

```
LEAD ( expression [, offset ] [, default ] ) OVER (
  [ window-partition-clause ]
  window-order-clause )
```

Parameters

expression

The expression to evaluate—for example, a constant, column, non-analytic function, function expression, or expressions involving any of these.

offset

Is an optional parameter that defaults to 1 (the next row). This parameter must evaluate to a constant positive integer.

default

The value returned if *offset* falls outside the bounds of the table or partition. This value must be a constant value or an expression that can be evaluated to a constant; its data type is coercible to that of the first argument.

Examples

LEAD finds the hire date of the employee hired just after the current row:

```
=> SELECT employee_region, hire_date, employee_key, employee_last_name,
       LEAD(hire_date, 1) OVER (PARTITION BY employee_region ORDER BY hire_date) AS "next_hired"
       FROM employee_dimension ORDER BY employee_region, hire_date, employee_key;
employee_region | hire_date | employee_key | employee_last_name | next_hired
```

```
-----+-----+-----+-----+-----
East      | 1956-04-08 | 9218 | Harris      | 1957-02-06

1957-11-21 | 3874 | Martin      | 1958-02-06 | 1957-11-11
```

(10 rows)

The following example returns employee name and salary, along with the next highest and lowest salaries.

```
=> SELECT employee_last_name, annual_salary,
       NVL(LEAD(annual_salary) OVER (ORDER BY annual_salary),
          MIN(annual_salary) OVER()) "Next Highest",
       NVL(LAG(annual_salary) OVER (ORDER BY annual_salary),
          MAX(annual_salary) OVER()) "Next Lowest"
       FROM employee_dimension;
employee_last_name | annual_salary | Next Highest | Next Lowest
```

```
-----+-----+-----+-----
Nielson      | 1200 | 1200 | 995533
Lewis        | 1200 | 1200 | 1200

Martin       | 1204 | 1204 | 1204
```

(10 rows)

The next example returns, for each assistant director in the employees table, the hire date of the director hired just after the director on the current row. For example, Jackson was hired on 2016-12-28, and the next director hired was Bauer:

```
=> SELECT employee_last_name, hire_date,
       LEAD(hire_date, 1) OVER (ORDER BY hire_date DESC) as "NextHired"
FROM employee_dimension WHERE job_title = 'Assistant Director';
employee_last_name | hire_date | NextHired
-----+-----+-----
Jackson            | 2016-12-28 | 2016-12-26
Bauer              | 2016-12-26 | 2016-12-11
Miller             | 2016-12-11 | 2016-12-07
Fortin             | 2016-12-07 | 2016-11-27
Harris             | 2016-11-27 | 2016-11-15
Goldberg           | 2016-11-15 |
(5 rows)
```

See also

- [LAG](#)
- [SQL analytics](#)

MAX [analytic]

Returns the maximum value of an expression within a [window](#). The return value has the same type as the expression data type.

The analytic functions [MIN\(\)](#) and [MAX\(\)](#) can operate with Boolean values. The [MAX\(\)](#) function acts upon a [Boolean data type](#) or a value that can be implicitly converted to a Boolean value. If at least one input value is true, [MAX\(\)](#) returns **t** (true). Otherwise, it returns **f** (false). In the same scenario, the [MIN\(\)](#) function returns **t** (true) if all input values are true. Otherwise, it returns **f**.

Behavior type

[Immutable](#)

Syntax

```
MAX ( expression ) OVER (
  [ window-partition-clause ]
  [ window-order-clause ]
  [ window-frame-clause ] )
```

Parameters

expression

Any expression for which the maximum value is calculated, typically a [column reference](#).

OVER()

See [Analytic Functions](#).

Examples

The following query computes the deviation between the employees' annual salary and the maximum annual salary in Massachusetts:

```
=> SELECT employee_state, annual_salary,
       MAX(annual_salary)
       OVER(PARTITION BY employee_state ORDER BY employee_key) max,
       annual_salary- MAX(annual_salary)
       OVER(PARTITION BY employee_state ORDER BY employee_key) diff
FROM employee_dimension
WHERE employee_state = 'MA';
employee_state | annual_salary | max | diff
-----+-----+-----+-----
MA | 1918 | 995533 | -993615
MA | 2058 | 995533 | -993475
MA | 2586 | 995533 | -992947
MA | 2500 | 995533 | -993033
MA | 1318 | 995533 | -994215
MA | 2072 | 995533 | -993461
MA | 2656 | 995533 | -992877
MA | 2148 | 995533 | -993385
MA | 2366 | 995533 | -993167
MA | 2664 | 995533 | -992869
(10 rows)
```

The following example shows you the difference between the **MIN** and **MAX** analytic functions when you use them with a Boolean value. The sample creates a table with two columns, adds two rows of data, and shows sample output for **MIN** and **MAX** .

```
CREATE TABLE min_max_functions (emp VARCHAR, torf BOOL);

INSERT INTO min_max_functions VALUES ('emp1', 1);
INSERT INTO min_max_functions VALUES ('emp1', 0);

SELECT DISTINCT emp,
min(torf) OVER (PARTITION BY emp) AS worksasbooleanand,
Max(torf) OVER (PARTITION BY emp) AS worksasbooleanor
FROM min_max_functions;

emp | worksasbooleanand | worksasbooleanor
-----+-----+-----
emp1 | f | t
(1 row)
```

See also

- [SQL analytics](#)
- [MAX \[aggregate\]](#)
- [MIN \[analytic\]](#)

MEDIAN [analytic]

For each row, returns the median value of a value set within each partition. **MEDIAN** determines the argument with the highest numeric precedence, implicitly converts the remaining arguments to that data type, and returns that data type.

MEDIAN is an alias of [PERCENTILE_CONT \[analytic\]](#) with an argument of 0.5 (50%).

Behavior type

[Immutable](#)

Syntax

```
MEDIAN ( expression ) OVER ( [ window-partition-clause ] )
```

Parameters

expression

Any [NUMERIC data type](#) or any non-numeric data type that can be implicitly converted to a numeric data type. The function returns the middle value or an interpolated value that would be the middle value once the values are sorted. Null values are ignored in the calculation.

OVER()

If the **OVER** clause specifies *window-partition-clause*, **MEDIAN** groups input rows according to one or more columns or expressions. If this clause is omitted, no grouping occurs and **MEDIAN** processes all input rows as a single partition.

Examples

See [Calculating a median value](#)

See also

- [PERCENTILE_CONT \[analytic\]](#)
- [SQL analytics](#)

MIN [analytic]

Returns the minimum value of an expression within a [window](#). The return value has the same type as the expression data type.

The analytic functions **MIN()** and **MAX()** can operate with Boolean values. The **MAX()** function acts upon a [Boolean data type](#) or a value that can be implicitly converted to a Boolean value. If at least one input value is true, **MAX()** returns **t** (true). Otherwise, it returns **f** (false). In the same scenario, the **MIN()** function returns **t** (true) if all input values are true. Otherwise, it returns **f**.

Behavior type

[Immutable](#)

Syntax

```
MIN ( expression ) OVER (
  [ window-partition-clause ]
  [ window-order-clause ]
  [ window-frame-clause ] )
```

Parameters

expression

Any expression for which the minimum value is calculated, typically a [column reference](#).

OVER()

See [Analytic Functions](#).

Examples

The following example shows how you can query to determine the deviation between the employees' annual salary and the minimum annual salary in Massachusetts:

```
=> SELECT employee_state, annual_salary,
       MIN(annual_salary)
       OVER(PARTITION BY employee_state ORDER BY employee_key) min,
       annual_salary- MIN(annual_salary)
       OVER(PARTITION BY employee_state ORDER BY employee_key) diff
FROM employee_dimension
WHERE employee_state = 'MA';
```

```
employee_state | annual_salary | min | diff
```

```
-----+-----+-----+-----
MA      |      1918 | 1204 | 714
MA      |      2058 | 1204 | 854
MA      |      2586 | 1204 | 1382
MA      |      2500 | 1204 | 1296
MA      |      1318 | 1204 | 114
MA      |      2072 | 1204 | 868
MA      |      2656 | 1204 | 1452
MA      |      2148 | 1204 | 944
MA      |      2366 | 1204 | 1162
MA      |      2664 | 1204 | 1460
```

(10 rows)

The following example shows you the difference between the **MIN** and **MAX** analytic functions when you use them with a Boolean value. The sample creates a table with two columns, adds two rows of data, and shows sample output for **MIN** and **MAX**.

```
CREATE TABLE min_max_functions (emp VARCHAR, torf BOOL);
```

```
INSERT INTO min_max_functions VALUES ('emp1', 1);
```

```
INSERT INTO min_max_functions VALUES ('emp1', 0);
```

```
SELECT DISTINCT emp,  
min(torf) OVER (PARTITION BY emp) AS worksasbooleanand,  
Max(torf) OVER (PARTITION BY emp) AS worksasbooleanor  
FROM min_max_functions;
```

```
emp | worksasbooleanand | worksasbooleanor
```

```
-----+-----+-----  
emp1 | f           | t
```

```
(1 row)
```

See also

- [SQL analytics](#)
- [MIN \[aggregate\]](#)
- [MAX \[analytic\]](#)

NTH_VALUE [analytic]

Returns the value evaluated at the row that is the * *n* *th row of the window (counting from 1). If the specified row does not exist, NTH_VALUE returns **NULL** .

Behavior type

[Immutable](#)

Syntax

```
NTH_VALUE ( expression, row-number [ IGNORE NULLS ] ) OVER (  
  [ window-frame-clause ]  
  [ window-order-clause ])
```

Parameters

expression

Expression to evaluate. The expression can be a constant, column name, nonanalytic function, function expression, or expressions that include any of these.

row-number

Specifies the row to evaluate, where *row-number* evaluates to an integer ≥ 1 .

IGNORE NULLS

Specifies to return the first non- **NULL** value in the set, or **NULL** if all values are **NULL** .

OVER()

See [Analytic Functions](#).

Examples

In the following example, for each tuple (current row) in table **t1** , the window frame clause defines the window as follows:

```
ORDER BY b ROWS BETWEEN 3 PRECEDING AND CURRENT ROW
```

For each window, *n* for * *n* *th value is **a+1** . *a* is the value of column *a* in the tuple.

NTH_VALUE returns the result of the expression **b+1** , where *b* is the value of column *b* in the * *n* *th row, which is the **a+1** row within the window.

```
=> SELECT * FROM t1 ORDER BY a;
```

```
a | b  
---+----  
1 | 10  
2 | 20  
2 | 21  
3 | 30  
4 | 40  
5 | 50  
6 | 60  
(7 rows)
```

```
=> SELECT NTH_VALUE(b+1, a+1) OVER  
  (ORDER BY b ROWS BETWEEN 3 PRECEDING AND CURRENT ROW) FROM t1;  
?column?
```

```
-----  
  
 22  
 31  
  
(7 rows)
```

NTILE [analytic]

Equally divides an ordered data set (partition) into a { *value* } number of subsets within a [window](#), where the subsets are numbered 1 through the value in parameter *constant-value*. For example, if *constant-value* = 4 and the partition contains 20 rows, **NTILE** divides the partition rows into four equal subsets of five rows. **NTILE** assigns each row to a subset by giving row a number from 1 to 4. The rows in the first subset are assigned 1, the next five are assigned 2, and so on.

If the number of partition rows is not evenly divisible by the number of subsets, the rows are distributed so no subset is more than one row larger than any other subset, and the lowest subsets have extra rows. For example, if *constant-value* = 4 and the number of rows = 21, the first subset has six rows, the second subset has five rows, and so on.

If the number of subsets is greater than the number of rows, then a number of subsets equal to the number of rows is filled, and the remaining subsets are empty.

Behavior type

[Immutable](#)

Syntax

```
NTILE ( constant-value ) OVER (  
  [ window-partition-clause ]  
  window-order-clause )
```

Parameters

constant-value

Specifies the number of subsets, where *constant-value* must resolve to a positive constant for each partition.

OVER()

See [Analytic Functions](#).

Examples

The following query assigns each month's sales total into one of four subsets:

```
=> SELECT calendar_month_name AS MONTH, SUM(sales_quantity),
       NTILE(4) OVER (ORDER BY SUM(sales_quantity)) AS NTILE
FROM store.store_sales_fact JOIN date_dimension
USING(date_key)
GROUP BY calendar_month_name
ORDER BY NTILE;
MONTH | SUM | NTILE
```

```
-----+-----+-----
November | 2040726 | 1
June | 2088528 | 1
February | 2134708 | 1

- [PERCENTILE_CONT \[analytic\]](#)
- [WIDTH_BUCKET](#)
- [SQL analytics](#)

PERCENT_RANK [analytic]

Calculates the relative rank of a row for a given row in a group within a [window](#) by dividing that row's rank less 1 by the number of rows in the partition, also less 1. **PERCENT_RANK** always returns values from 0 to 1 inclusive. The first row in any set has a **PERCENT_RANK** of 0. The return value is **NUMBER** .

$$(rank - 1) / ([rows] - 1)$$

In the preceding formula, **rank** is the rank position of a row in the group and **rows** is the total number of rows in the partition defined by the **OVER()** clause.

Behavior type

[Immutable](#)

Syntax

```
PERCENT_RANK ( ) OVER (
  [ window-partition-clause ]
  window-order-clause )
```

Parameters

OVER()

See [Analytic Functions](#)

Examples

The following example finds the percent rank of gross profit for different states within each month of the first quarter:

```
=> SELECT calendar_month_name AS MONTH, store_state,
       SUM(gross_profit_dollar_amount),
       PERCENT_RANK() OVER (PARTITION BY calendar_month_name
        ORDER BY SUM(gross_profit_dollar_amount)) AS PERCENT_RANK
FROM store.store_sales_fact JOIN date_dimension
USING(date_key)
JOIN store.store_dimension
USING (store_key)
WHERE calendar_month_name IN ('January','February','March')
AND store_state IN ('OR','IA','DC','NV','WI')
GROUP BY calendar_month_name, store_state
ORDER BY calendar_month_name, PERCENT_RANK;
MONTH | store_state | SUM | PERCENT_RANK
```

```
-----+-----+-----+-----
February | IA      | 418490 | 0
February | OR      | 460588 | 0.25
February | DC      | 616553 | 0.5
February | WI      | 619204 | 0.75
February | NV      | 838039 | 1
January  | OR      | 446528 | 0
January  | IA      | 474501 | 0.25
January  | DC      | 628496 | 0.5
January  | WI      | 679382 | 0.75
January  | NV      | 871824 | 1
March    | IA      | 460282 | 0
March    | OR      | 481935 | 0.25
March    | DC      | 716063 | 0.5
March    | WI      | 771575 | 0.75
March    | NV      | 970878 | 1
(15 rows)
```

The following example calculates, for each employee, the percent rank of the employee's salary by their job title:

```
=> SELECT job_title, employee_last_name, annual_salary,
       PERCENT_RANK()
       OVER (PARTITION BY job_title ORDER BY annual_salary DESC) AS percent_rank
FROM employee_dimension
ORDER BY percent_rank, annual_salary;
 job_title | employee_last_name | annual_salary | percent_rank
```

- [CUME_DIST \[analytic\]](#)
- [SQL analytics](#)

PERCENTILE_CONT [analytic]

An inverse distribution function where, for each row, PERCENTILE_CONT returns the value that would fall into the specified percentile among a set of values in each partition within a [window](#). For example, if the argument to the function is 0.5, the result of the function is the median of the data set (50th percentile). PERCENTILE_CONT assumes a continuous distribution data model. NULL values are ignored.

PERCENTILE_CONT computes the percentile by first computing the row number where the percentile row would exist. For example:

$$row-number = 1 + percentile-value * (num-partition-rows - 1)$$

If *row-number* is a whole number (within an error of 0.00001), the percentile is the value of row *row-number*.

Otherwise, Vertica interpolates the percentile value between the value of the `CEILING(row-number)` row and the value of the `FLOOR(row-number)` row. In other words, the percentile is calculated as follows:

$$(CEILING(row-number) - row-number) * (value\ of\ FLOOR(row-number)\ row) + (row-number - FLOOR(row-number)) * (value\ of\ CEILING(row-number)\ row)$$

Note

If the percentile value is 0.5, PERCENTILE_CONT returns the same result set as the function [MEDIAN](#).

Behavior type

[Immutable](#)

Syntax

```
PERCENTILE_CONT ( percentile ) WITHIN GROUP ( ORDER BY expression [ ASC | DESC ] ) OVER ( [ window-partition-clause ] )
```

Parameters

percentile

Percentile value, a FLOAT constant that ranges from 0 to 1 (inclusive).

WITHIN GROUP (ORDER BY *expression*)

Specifies how to sort data within each group. ORDER BY takes only one column/expression that must be INTEGER, FLOAT, INTERVAL, or NUMERIC data type. NULL values are discarded.

The **WITHIN GROUP(ORDER BY)** clause does not guarantee the order of the SQL result. To order the final result, use the SQL [ORDER BY](#) clause set.

ASC | DESC

Specifies the ordering sequence as ascending (default) or descending.

Specifying ASC or DESC in the **WITHIN GROUP** clause affects results as long as the *percentile* is not **0.5**.

OVER()

See [Analytic Functions](#)

Examples

This query computes the median annual income per group for the first 300 customers in Wisconsin and the District of Columbia.

```
=> SELECT customer_state, customer_key, annual_income, PERCENTILE_CONT(0.5) WITHIN GROUP(ORDER BY annual_income)
   OVER (PARTITION BY customer_state) AS PERCENTILE_CONT
   FROM customer_dimension WHERE customer_state IN ('DC','WI') AND customer_key < 300
   ORDER BY customer_state, customer_key;
customer_state | customer_key | annual_income | PERCENTILE_CONT
-----+-----+-----+-----
DC      |      52 |    168312 |    483266.5
DC      |     118 |    798221 |    483266.5
WI      |      62 |    283043 |    377691
WI      |     139 |    472339 |    377691
(4 rows)
```

This query computes the median annual income per group for all customers in Wisconsin and the District of Columbia.

```
=> SELECT customer_state, customer_key, annual_income, PERCENTILE_CONT(0.5) WITHIN GROUP(ORDER BY annual_income)
    OVER (PARTITION BY customer_state) AS PERCENTILE_CONT
    FROM customer_dimension WHERE customer_state IN ('DC','WI') ORDER BY customer_state, customer_key;
customer_state | customer_key | annual_income | PERCENTILE_CONT
```

```

PERCENTILE_DISC [analytic]

An inverse distribution function where, for each row, **PERCENTILE_DISC** returns the value that would fall into the specified percentile among a set of values in each partition within a [window](#). **PERCENTILE_DISC()** assumes a discrete distribution data model. **NULL** values are ignored.

PERCENTILE_DISC examines the cumulative distribution values in each group until it finds one that is greater than or equal to the specified percentile. Vertica computes the percentile where, for each row, **PERCENTILE_DISC** outputs the first value of the **WITHIN GROUP(ORDER BY)** column whose **CUME_DIST** (cumulative distribution) value is \geq the argument **FLOAT** value—for example, **0.4** :

```
PERCENTILE_DIST(0.4) WITHIN GROUP (ORDER BY salary) OVER(PARTITION BY deptno)...
```

Given the following query:

```
SELECT CUME_DIST() OVER(ORDER BY salary) FROM table-name;
```

The smallest **CUME_DIST** value that is greater than 0.4 is also the **PERCENTILE_DISC** .

Behavior type

[Immutable](#)

Syntax

```
PERCENTILE_DISC ( percentile ) WITHIN GROUP (
    ORDER BY expression [ ASC | DESC ] ) OVER (
    [ window-partition-clause ] )
```

Parameters

percentile

Percentile value, a **FLOAT** constant that ranges from 0 to 1 (inclusive).

WITHIN GROUP(ORDER BY *expression*)

Specifies how to sort data within each group. **ORDER BY** takes only one column/expression that must be **INTEGER** , **FLOAT** , **INTERVAL** , or **NUMERIC** data type. **NULL** values are discarded.

The **WITHIN GROUP(ORDER BY)** clause does not guarantee the order of the SQL result. To order the final result , use the SQL [ORDER BY](#) clause set.

ASC | DESC

Specifies the ordering sequence as ascending (default) or descending.

OVER()

See [Analytic Functions](#)

Examples

This query computes the 20th percentile annual income by group for first 300 customers in Wisconsin and the District of Columbia.

```
=> SELECT customer_state, customer_key, annual_income,
  PERCENTILE_DISC(.2) WITHIN GROUP(ORDER BY annual_income)
  OVER (PARTITION BY customer_state) AS PERCENTILE_DISC
FROM customer_dimension
WHERE customer_state IN ('DC','WI')
AND customer_key < 300
ORDER BY customer_state, customer_key;
customer_state | customer_key | annual_income | PERCENTILE_DISC
-----+-----+-----+-----
DC      |      104 |    658383 |    417092
DC      |      168 |    417092 |    417092
DC      |      245 |    670205 |    417092
WI      |      106 |    227279 |    227279
WI      |      127 |    703889 |    227279
WI      |      209 |    458607 |    227279
(6 rows)
```

- [PERCENTILE_CONT \[analytic\]](#)
- [SQL analytics](#)

RANK [analytic]

Within each window partition, ranks all rows in the query results set according to the order specified by the window's **ORDER BY** clause.

RANK executes as follows:

1. Sorts partition rows as specified by the **ORDER BY** clause.
2. Compares the **ORDER BY** values of the preceding row and current row and ranks the current row as follows:
 - If **ORDER BY** values are the same, the current row gets the same ranking as the preceding row.

Note

Null values are considered equal. For detailed information on how null values are sorted, see [NULL sort order](#).

- If the **ORDER BY** values are different, **DENSE_RANK** increments or decrements the current row's ranking by 1, plus the number of consecutive duplicate values in the rows that precede it.

The largest rank value is the equal to the total number of rows returned by the query.

Behavior type

[Immutable](#)

Syntax

```
RANK() OVER (
  [ window-partition-clause ]
  window-order-clause )
```

Parameters

OVER()

See [Analytic Functions](#)

Compared with **DENSE_RANK**

RANK can leave gaps in the ranking sequence, while [DENSE_RANK](#) does not.

Examples

The following query ranks by state all company customers that have been customers since 2007. In rows where the `customer_since` dates are the same, **RANK** assigns the rows equal ranking. When the `customer_since` date changes, **RANK** skips one or more rankings—for example, within **CA**, from 12 to 14, and from 17 to 19.

```
=> SELECT customer_state, customer_name, customer_since,
       RANK() OVER (PARTITION BY customer_state ORDER BY customer_since) AS rank
FROM customer_dimension WHERE customer_type='Company' AND customer_since > '01/01/2007'
ORDER BY customer_state;
customer_state | customer_name | customer_since | rank

[SQL analytics](#)

`ROW_NUMBER` [analytic]

Assigns a sequence of unique numbers to each row in a [window](#) partition, starting with 1. `ROW_NUMBER` and [RANK](#) are generally interchangeable, with the following differences:

- `ROW_NUMBER` assigns a unique ordinal number to each row in the ordered set, starting with 1.
- `ROW_NUMBER()` is a Vertica extension, while `RANK` conforms to the SQL-99 standard.

Behavior type

[Immutable](#)

Syntax

```
ROW_NUMBER () OVER (
  [ window-partition-clause ]
  [ window-order-clause ] )
```

Parameters

OVER()

See [Analytic Functions](#)

Examples

The following `ROW_NUMBER` query partitions customers in the VMart table `customer_dimension` by `customer_region`. Within each partition, the function ranks those customers in order of seniority, as specified by its window order clause:

```
=> SELECT * FROM
  (SELECT ROW_NUMBER() OVER (PARTITION BY customer_region ORDER BY customer_since) AS most_senior,
   customer_region, customer_name, customer_since FROM public.customer_dimension WHERE customer_type = 'Individual') sq
 WHERE most_senior <= 5;
```

```
most_senior | customer_region | customer_name | customer_since
```

```

- [RANK \[analytic\]](#)
- [SQL analytics](#)

STDDEV [analytic]

Computes the statistical sample standard deviation of the current row with respect to the group within a [window](#). **STDDEV_SAMP** returns the same value as the square root of the variance defined for the [VAR_SAMP](#) function:

```
STDDEV( expression ) = SQRT(VAR_SAMP( expression ))
```

When **VAR_SAMP** returns **NULL** , this function returns **NULL** .

Note

The nonstandard function **STDDEV** is provided for compatibility with other databases. It is semantically identical to [STDDEV_SAMP](#) .

Behavior type

[Immutable](#)

Syntax

```
STDDEV ( expression ) OVER (
  [ window-partition-clause ]
  [ window-order-clause ]
  [ window-frame-clause ] )
```

Parameters

expression

Any [NUMERIC data type](#) or any non-numeric data type that can be implicitly converted to a numeric data type. The function returns the same data type as the numeric data type of the argument.

OVER()

See [Analytic Functions](#)

Examples

The following example returns the standard deviations of salaries in the employee dimension table by job title Assistant Director:

```
=> SELECT employee_last_name, annual_salary,
       STDDEV(annual_salary) OVER (ORDER BY hire_date) as "stddev"
FROM employee_dimension
WHERE job_title = 'Assistant Director';
employee_last_name | annual_salary | stddev

- [SQL analytics](#)

STDDEV_POP [analytic]

Computes the statistical population standard deviation and returns the square root of the population variance within a [window](#). The `STDDEV_POP()` return value is the same as the square root of the `VAR_POP()` function:

```
STDDEV_POP( expression ) = SQRT(VAR_POP( expression ))
```

When `VAR_POP` returns null, `STDDEV_POP` returns null.

Behavior type

[Immutable](#)

Syntax

```
STDDEV_POP ( expression ) OVER (
  [ window-partition-clause ]
  [ window-order-clause ]
  [ window-frame-clause ] )
```

Parameters

expression

Any [NUMERIC data type](#) or any non-numeric data type that can be implicitly converted to a numeric data type. The function returns the same data type as the numeric data type of the argument.

OVER()

See [Analytic Functions](#).

Examples

The following example returns the population standard deviations of salaries in the employee dimension table by job title Assistant Director:

```
=> SELECT employee_last_name, annual_salary,
       STDDEV_POP(annual_salary) OVER (ORDER BY hire_date) as "stddev_pop"
FROM employee_dimension WHERE job_title = 'Assistant Director';
employee_last_name | annual_salary | stddev_pop
-----+-----+-----
Goldberg           | 61859         | 0
Miller             | 79582         | 8861.5
Goldberg           | 74236         | 7422.74712548456
Campbell           | 66426         | 6850.22125098891
Moore              | 66630         | 6322.08223926257
Nguyen             | 53530         | 8356.55480080699
Harris             | 74115         | 8122.72288970008
Lang               | 59981         | 8053.54776538731
Farmer             | 60597         | 7858.70140687825
Nguyen             | 78941         | 8360.63150784682
```

See also

- [STDDEV_POP \[aggregate\]](#)
- [SQL analytics](#)

STDDEV_SAMP [analytic]

Computes the statistical sample standard deviation of the current row with respect to the group within a [window](#). **STDDEV_SAMP**'s return value is the same as the square root of the variance defined for the **VAR_SAMP** function:

```
STDDEV( expression ) = SQRT(VAR_SAMP( expression ))
```

When **VAR_SAMP** returns **NULL**, **STDDEV_SAMP** returns **NULL**.

Note

STDDEV_SAMP() is semantically identical to the nonstandard function, [STDDEV\(\)](#).

Behavior type

[Immutable](#)

Syntax

```
STDDEV_SAMP ( expression ) OVER (
  [ window-partition-clause ]
  [ window-order-clause ]
  [ window-frame-clause ] )
```

Parameters

expression

Any [NUMERIC data type](#) or any non-numeric data type that can be implicitly converted to a numeric data type. The function returns the same data type as the numeric data type of the argument..

OVER()

See [Analytic Functions](#)

Examples

The following example returns the sample standard deviations of salaries in the `employee` dimension table by job title Assistant Director:

```
=> SELECT employee_last_name, annual_salary,
       STDDEV(annual_salary) OVER (ORDER BY hire_date) as "stddev_samp"
   FROM employee_dimension WHERE job_title = 'Assistant Director';
employee_last_name | annual_salary | stddev_samp
-----+-----+-----
Bauer              |      85003 |          NaN
Reyes              |      91051 | 4276.58181261624
Overstreet         |      53296 | 20278.6923394976

- [STDDEV \[aggregate\]](#)
- [STDDEV_SAMP \[aggregate\]](#)
- [SQL analytics](#)

SUM [analytic]

Computes the sum of an expression over a group of rows within a [window](#). It returns a **DOUBLE PRECISION** value for a floating-point expression. Otherwise, the return value is the same as the expression data type.

Behavior type

[Immutable](#)

Syntax

```
SUM ( expression ) OVER (
  [ window-partition-clause ]
  [ window-order-clause ]
  [ window-frame-clause ] )
```

Parameters

expression

Any [NUMERIC data type](#) or any non-numeric data type that can be implicitly converted to a numeric data type. The function returns the same data type as the numeric data type of the argument.

OVER()

See [Analytic Functions](#)

Overflow handling

If you encounter data overflow when using `SUM`, use `SUM_FLOAT` which converts data to a floating point.

By default, Vertica allows silent numeric overflow when you call this function on numeric data types. For more information on this behavior and how to change it, see [Numeric data type overflow with SUM, SUM_FLOAT, and AVG](#).

Examples

The following query returns the cumulative sum all of the returns made to stores in January:

```
=> SELECT calendar_month_name AS month, transaction_type, sales_quantity,
SUM(sales_quantity)
OVER (PARTITION BY calendar_month_name ORDER BY date_dimension.date_key) AS SUM
FROM store.store_sales_fact JOIN date_dimension
USING(date_key) WHERE calendar_month_name IN ('January')
AND transaction_type= 'return';
month | transaction_type | sales_quantity | SUM
-----+-----+-----+-----
January | return          | 7              | 651
January | return          | 3              | 651
January | return          | 7              | 651
January | return          | 7              | 651
January | return          | 7              | 651
January | return          | 3              | 651
January | return          | 7              | 651
January | return          | 5              | 651
January | return          | 1              | 651
January | return          | 6              | 651
January | return          | 6              | 651
January | return          | 3              | 651
January | return          | 9              | 651
January | return          | 7              | 651
January | return          | 6              | 651
January | return          | 8              | 651
January | return          | 7              | 651
January | return          | 2              | 651
January | return          | 4              | 651
January | return          | 5              | 651
January | return          | 7              | 651
January | return          | 8              | 651
January | return          | 4              | 651
January | return          | 10             | 651
January | return          | 6              | 651
...
```

See also

- [SUM \[aggregate\]](#)
- [Numeric data types](#)
- [SQL analytics](#)

VAR_POP [analytic]

Returns the statistical population variance of a non-null set of numbers (nulls are ignored) in a group within a [window](#). Results are calculated by the sum of squares of the difference of *expression* from the mean of *expression*, divided by the number of rows remaining:

$$\frac{(\text{SUM}(expression * expression) - \text{SUM}(expression) * \text{SUM}(expression) / \text{COUNT}(expression))}{\text{COUNT}(expression)}$$

Behavior type

[Immutable](#)

Syntax

```
VAR_POP ( expression ) OVER (
  [ window-partition-clause ]
  [ window-order-clause ]
  [ window-frame-clause ] )
```

Parameters

expression

Any [NUMERIC data type](#) or any non-numeric data type that can be implicitly converted to a numeric data type. The function returns the same data type as the numeric data type of the argument

OVER()

See [Analytic Functions](#)

Examples

The following example calculates the cumulative population in the store orders fact table of sales in January 2007:

```
=> SELECT date_ordered,
  VAR_POP(SUM(total_order_cost))
  OVER (ORDER BY date_ordered) "var_pop"
FROM store.store_orders_fact s
WHERE date_ordered BETWEEN '2007-01-01' AND '2007-01-31'
GROUP BY s.date_ordered;
date_ordered | var_pop
-----+-----
2007-01-01 | 0
2007-01-02 | 89870400
2007-01-03 | 3470302472
2007-01-04 | 4466755450.6875
2007-01-05 | 3816904780.80078
2007-01-06 | 25438212385.25
2007-01-07 | 22168747513.1016
2007-01-08 | 23445191012.7344
2007-01-09 | 39292879603.1113
2007-01-10 | 48080574326.9609
(10 rows)
```

See also

- [VAR_POP \[aggregate\]](#)
- [SQL analytics](#)

VAR_SAMP [analytic]

Returns the sample variance of a non- **NULL** set of numbers (**NULL** values in the set are ignored) for each row of the group within a [window](#) . Results are calculated as follows:

$$\frac{(\text{SUM}(expression * expression) - \text{SUM}(expression) * \text{SUM}(expression) / \text{COUNT}(expression))}{(\text{COUNT}(expression) - 1)}$$

This function and [VARIANCE](#) differ in one way: given an input set of one element, **VARIANCE** returns 0 and **VAR_SAMP** returns **NULL** .

Behavior type

[Immutable](#)

Syntax

```
VAR_SAMP ( expression ) OVER (
  [ window-partition-clause ]
  [ window-order-clause ]
  [ window-frame-clause ] )
```

Parameters

expression

Any [NUMERIC data type](#) or any non-numeric data type that can be implicitly converted to a numeric data type. The function returns the same data type as the numeric data type of the argument

OVER()

See [Analytic Functions](#)

Null handling

- **VAR_SAMP** returns the sample variance of a set of numbers after it discards the **NULL** values in the set.
- If the function is applied to an empty set, then it returns **NULL** .

Examples

The following example calculates the sample variance in the store orders fact table of sales in December 2007:

```
=> SELECT date_ordered,
       VAR_SAMP(SUM(total_order_cost))
       OVER (ORDER BY date_ordered) "var_samp"
FROM store.store_orders_facts
WHERE date_ordered BETWEEN '2007-12-01' AND '2007-12-31'
GROUP BY s.date_ordered;
date_ordered | var_samp
```

```
-----+-----
2007-12-01 |      NaN
2007-12-02 |  90642601088
2007-12-03 | 48030548449.3359
2007-12-04 | 32740062504.2461
2007-12-05 | 32100319112.6992
2007-12-06 |  26274166814.668
2007-12-07 | 23017490251.9062
2007-12-08 | 21099374085.1406
2007-12-09 | 27462205977.9453
2007-12-10 | 26288687564.1758
(10 rows)
```

See also

- [VARIANCE \[analytic\]](#)
- [VAR_SAMP \[aggregate\]](#)
- [SQL analytics](#)

VARIANCE [analytic]

Returns the sample variance of a non- **NULL** set of numbers (**NULL** values in the set are ignored) for each row of the group within a [window](#). Results are calculated as follows:

$$\frac{(\text{SUM}(expression * expression) - \text{SUM}(expression) * \text{SUM}(expression) / \text{COUNT}(expression))}{(\text{COUNT}(expression) - 1)}$$

VARIANCE returns the variance of *expression*, which is calculated as follows:

- 0 if the number of rows in *expression* = 1
- [VAR_SAMP](#) if the number of rows in *expression* > 1

Note

The nonstandard function **VARIANCE** is provided for compatibility with other databases. It is semantically identical to [VAR_SAMP](#).

Behavior type

[Immutable](#)

Syntax

```
VAR_SAMP ( expression ) OVER (
  [ window-partition-clause ]
  [ window-order-clause ]
  [ window-frame-clause ] )
```

Parameters

expression

Any [NUMERIC data type](#) or any non-numeric data type that can be implicitly converted to a numeric data type. The function returns the same data type as the numeric data type of the argument.

OVER()

See [Analytic Functions](#)

Examples

The following example calculates the cumulative variance in the store orders fact table of sales in December 2007:

```
=> SELECT date_ordered,
       VARIANCE(SUM(total_order_cost))
       OVER (ORDER BY date_ordered) "variance"
FROM store.store_orders_facts
WHERE date_ordered BETWEEN '2007-12-01' AND '2007-12-31'
GROUP BY s.date_ordered;
date_ordered | variance
```

```
-----+-----
2007-12-01 |      NaN
2007-12-02 |  2259129762
2007-12-03 | 1809012182.33301
2007-12-04 |  35138165568.25
2007-12-05 | 26644110029.3003
2007-12-06 |  25943125234
2007-12-07 | 23178202223.9048
2007-12-08 | 21940268901.1431
2007-12-09 | 21487676799.6108
2007-12-10 | 21521358853.4331
(10 rows)
```

Client connection functions

This section contains client connection management functions specific to Vertica.

In this section

- [CLOSE_ALL_RESULTSETS](#)
- [CLOSE_RESULTSET](#)
- [DESCRIBE_LOAD_BALANCE_DECISION](#)
- [GET_CLIENT_LABEL](#)
- [RESET_LOAD_BALANCE_POLICY](#)
- [SET_CLIENT_LABEL](#)
- [SET_LOAD_BALANCE_POLICY](#)

CLOSE_ALL_RESULTSETS

Closes all result set sessions within Multiple Active Result Sets (MARS) and frees the MARS storage for other result sets.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
SELECT CLOSE_ALL_RESULTSETS ('session_id')
```

Parameters

session_id

A string that specifies the Multiple Active Result Sets session.

Privileges

None; however, without superuser privileges, you can only close your own session's results.

Examples

This example shows how you can view a MARS result set, then close the result set, and then confirm that the result set has been closed.

Query the MARS storage table. One session ID is open and three result sets appear in the output.

```
=> SELECT * FROM SESSION_MARS_STORE;
```

node_name	session_id	user_name	resultset_id	row_count	remaining_row_count	bytes_used
v_vmart_node0001	server1.company.-83046:1y28gu9	dbadmin	7	777460	776460	89692848
v_vmart_node0001	server1.company.-83046:1y28gu9	dbadmin	8	324349	323349	81862010
v_vmart_node0001	server1.company.-83046:1y28gu9	dbadmin	9	277947	276947	32978280

(1 row)

Close all result sets for session server1.company.-83046:1y28gu9:

```
=> SELECT CLOSE_ALL_RESULTSETS('server1.company.-83046:1y28gu9');
       close_all_resultsets
```

Closing all result sets from server1.company.-83046:1y28gu9
(1 row)

Query the MARS storage table again for the current status. You can see that the session and result sets have been closed:

```
=> SELECT * FROM SESSION_MARS_STORE;
```

node_name	session_id	user_name	resultset_id	row_count	remaining_row_count	bytes_used
-----------	------------	-----------	--------------	-----------	---------------------	------------

(0 rows)

CLOSE_RESULTSET

Closes a specific result set within Multiple Active Result Sets (MARS) and frees the MARS storage for other result sets.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
SELECT CLOSE_RESULTSET ('session_id', ResultSetID)
```

Parameters

session_id

A string that specifies the Multiple Active Result Sets session containing the ResultSetID to close.

ResultSetID

An integer that specifies which result set to close.

Privileges

None; however, without superuser privileges, you can only close your own session's results.

Examples

This example shows a MARS storage table opened. One session_id is currently open, and one result set appears in the output.

```
=> SELECT * FROM SESSION_MARS_STORE;
```

node_name	session_id	user_name	resultset_id	row_count	remaining_row_count	bytes_used
v_vmart_node0001	server1.company.-83046:1y28gu9	dbadmin	1	318718	312718	80441904

(1 row)

Close user session server1.company.-83046:1y28gu9 and result set 1:

```
=> SELECT CLOSE_RESULTSET('server1.company.-83046:1y28gu9', 1);
       close_resultset
```

Closing result set 1 from server1.company.-83046:1y28gu9
(1 row)

Query the MARS storage table again for current status. You can see that result set 1 is now closed:

```
SELECT * FROM SESSION_MARS_STORE;
```

node_name	session_id	user_name	resultset_id	row_count	remaining_row_count	bytes_used
(0 rows)						

DESCRIBE_LOAD_BALANCE_DECISION

Evaluates if any load balancing routing rules apply to a given IP address and describes how the client connection would be handled. This function is useful when you are evaluating connection load balancing policies you have created, to ensure they work the way you expect them to.

You pass this function an IP address of a client connection, and it uses the load balancing routing rules to determine how the connection will be handled. The logic this function uses is the same logic used when Vertica load balances client connections, including determining which nodes are available to handle the client connection.

This function assumes the client connection has opted into being load balanced. If actual clients have not opted into load balancing, the connections will not be redirected. See [Load balancing in ADO.NET](#), [Load balancing in JDBC](#), and [Load balancing](#), for information on enabling load balancing on the client. For vsql, use the `-C` command-line option to enable load balancing.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
DESCRIBE_LOAD_BALANCE_DECISION('ip_address')
```

Arguments

'ip_address'

An IP address of a client connection to be tested against the load balancing rules. This can be either an IPv4 or IPv6 address.

Return value

A step-by-step description of how the load balancing rules are being evaluated, including the final decision of which node in the database has been chosen to service the connection.

Privileges

None.

Examples

The following example demonstrates calling `DESCRIBE_LOAD_BALANCE_DECISION` with three different IP addresses, two of which are handled by different routing rules, and one which is not handled by any rule.

```
=> SELECT describe_load_balance_decision('192.168.1.25');
        describe_load_balance_decision
-----
Describing load balance decision for address [192.168.1.25]
Load balance cache internal version id (node-local): [2]
Considered rule [etl_rule] source ip filter [10.20.100.0/24]... input address
does not match source ip filter for this rule.
Considered rule [internal_clients] source ip filter [192.168.1.0/24]... input
address matches this rule
Matched to load balance group [group_1] the group has policy [ROUNDROBIN]
number of addresses [2]
(0) LB Address: [10.20.100.247]:5433
(1) LB Address: [10.20.100.248]:5433
Chose address at position [1]
Routing table decision: Success. Load balance redirect to: [10.20.100.248] port [5433]
```

(1 row)

```
=> SELECT describe_load_balance_decision('192.168.2.25');
        describe_load_balance_decision
-----
Describing load balance decision for address [192.168.2.25]
Load balance cache internal version id (node-local): [2]
Considered rule [etl_rule] source ip filter [10.20.100.0/24]... input address
does not match source ip filter for this rule.
Considered rule [internal_clients] source ip filter [192.168.1.0/24]... input
address does not match source ip filter for this rule.

No rules matched. Falling back to classic load balancing.
Classic load balance decision: Classic load balancing considered, but either
the policy was NONE or no target was available. Details: [NONE or invalid]
```

(1 row)

The following example demonstrates calling DESCRIBE_LOAD_BALANCE_DECISION repeatedly with the same IP address. You can see that the load balance group's ROUNDROBIN load balance policy has it switch between the two nodes in the load balance group:

```
=> SELECT describe_load_balance_decision('192.168.1.25');
        describe_load_balance_decision
```

```
-----
Describing load balance decision for address [192.168.1.25]
Load balance cache internal version id (node-local): [1]
Considered rule [etl_rule] source ip filter [10.20.100.0/24]... input address
does not match source ip filter for this rule.
Considered rule [internal_clients] source ip filter [192.168.1.0/24]... input
address matches this rule
Matched to load balance group [group_1] the group has policy [ROUNDROBIN]
number of addresses [2]
(0) LB Address: [10.20.100.247]:5433
(1) LB Address: [10.20.100.248]:5433
Chose address at position [1]
Routing table decision: Success. Load balance redirect to: [10.20.100.248]
port [5433]
```

(1 row)

```
=> SELECT describe_load_balance_decision('192.168.1.25');
        describe_load_balance_decision
```

```
-----

- [GET_CLIENT_LABEL](#)
- [RESET_LOAD_BALANCE_POLICY](#)
- [SET_CLIENT_LABEL](#)

- [SET_LOAD_BALANCE_POLICY](#)

GET_CLIENT_LABEL

Returns the client connection label for the current session.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
GET_CLIENT_LABEL()
```

Privileges

None

Examples

Return the current client connection label:

```
=> SELECT GET_CLIENT_LABEL();
   GET_CLIENT_LABEL
-----
data_load_application
(1 row)
```

See also

[Setting a client connection label](#)

[RESET_LOAD_BALANCE_POLICY](#)

Resets the counter each host in the cluster maintains, to track which host it will refer a client to when the native [connection load balancing scheme](#) is set to **ROUNDROBIN** . To reset the counter, run this function on all cluster nodes.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
RESET_LOAD_BALANCE_POLICY()
```

Privileges

Superuser

Examples

```
=> SELECT RESET_LOAD_BALANCE_POLICY();
   RESET_LOAD_BALANCE_POLICY
-----
Successfully reset stateful client load balance policies: "roundrobin".
(1 row)
```

SET_CLIENT_LABEL

Assigns a label to a client connection for the current session. You can use this label to distinguish client connections.

Labels appear in the [SESSIONS](#) system table. However, only certain [Data collector](#) tables show new client labels set by SET_CLIENT_LABEL. For example, DC_REQUESTS_ISSUED reflects changes by SET_CLIENT_LABEL, while DC_SESSION_STARTS, which collects login data before SET_CLIENT_LABEL can be run, does not.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
SET_CLIENT_LABEL('label-name')
```

Parameters

label-name

VARCHAR name assigned to the client connection label.

Privileges

None

Examples

Assign label `data_load_application` to the current client connection:

```
=> SELECT SET_CLIENT_LABEL('data_load_application');
      SET_CLIENT_LABEL
-----
client_label set to data_load_application
(1 row)
```

See also

[Setting a client connection label](#)

`SET_LOAD_BALANCE_POLICY`

Sets how native connection load balancing chooses a host to handle a client connection.

This is a meta-function. You must call meta-functions in a top-level `SELECT` statement.

Behavior type

[Volatile](#)

Syntax

```
SET_LOAD_BALANCE_POLICY('policy')
```

Parameters

policy

The name of the load balancing policy to use, one of the following:

- **NONE** (default): Disables native connection load balancing.
- **ROUNDROBIN** : Chooses the next host from a circular list of hosts in the cluster that are up—for example, in a three-node cluster, iterates over node1, node2, and node3, then wraps back to node1. Each host in the cluster maintains its own pointer to the next host in the circular list, rather than there being a single cluster-wide state.
- **RANDOM** : Randomly chooses a host from among all hosts in the cluster that are up.

Note

Even if the load balancing policy is set on the server to something other than **NONE** , clients must indicate they want their connections to be load balanced by setting a connection property.

Privileges

Superuser

Examples

The following example demonstrates enabling native connection load balancing on the server by setting the load balancing scheme to **ROUNDROBIN** :

```
=> SELECT SET_LOAD_BALANCE_POLICY('ROUNDROBIN');
      SET_LOAD_BALANCE_POLICY
-----
Successfully changed the client initiator load balancing policy to: roundrobin
(1 row)
```

[About native connection load balancing](#)

Data-type-specific functions

Vertica provides functions for use with specific data types, described in this section.

In this section

- [Collection functions](#)
- [Date/time functions](#)
- [IP address functions](#)
- [Sequence functions](#)
- [String functions](#)
- [URI functions](#)
- [UUID functions](#)

Collection functions

The functions in this section apply to collection types (arrays and sets).

Some functions apply aggregation operations (such as sum) to collections. These function names all begin with APPLY.

Other functions in this section operate specifically on arrays or sets, as indicated on the individual reference pages. Array functions operate on both native array values and array values in external tables.

Notes

- Arrays are 0-indexed. The first element's ordinal position is 0, second is 1, and so on. Indexes are not meaningful for sets.
- Unless otherwise stated, functions operate on one-dimensional (1D) collections only. To use multidimensional arrays, you must first dereference to a 1D array type. Sets can only be one-dimensional.

In this section

- [APPLY_AVG](#)
- [APPLY_COUNT \(ARRAY_COUNT\)](#)
- [APPLY_COUNT_ELEMENTS \(ARRAY_LENGTH\)](#)
- [APPLY_MAX](#)
- [APPLY_MIN](#)
- [APPLY_SUM](#)
- [ARRAY_CAT](#)
- [ARRAY_CONTAINS](#)
- [ARRAY_DIMS](#)
- [ARRAY_FIND](#)
- [CONTAINS](#)
- [EXPLODE](#)
- [FILTER](#)
- [IMPLODE](#)
- [SET_UNION](#)
- [STRING_TO_ARRAY](#)
- [TO_JSON](#)
- [UNNEST](#)

APPLY_AVG

Returns the average of all elements in a collection (array or set) with numeric values.

Behavior type

[Immutable](#)

Syntax

```
APPLY_AVG(collection)
```

Arguments

collection

Target collection

Null-handling

The following cases return NULL:

- if the input collection is NULL
- if the input collection contains only null values
- if the input collection is empty

If the input collection contains a mix of null and non-null elements, only the non-null values are considered in the calculation of the average.

Examples

```
=> SELECT apply_avg(ARRAY[1,2.4,5,6]);
apply_avg
-----
3.6
(1 row)
```

See also

- [APPLY_SUM](#)

APPLY_COUNT (ARRAY_COUNT)

Returns the total number of non-null elements in a collection (array or set). To count all elements including nulls, use [APPLY_COUNT_ELEMENTS \(ARRAY_LENGTH\)](#).

Behavior type

[Immutable](#)

Syntax

```
APPLY_COUNT(collection)
```

ARRAY_COUNT is a synonym of APPLY_COUNT .

Arguments

collection

Target collection

Null-handling

Null values are not included in the count.

Examples

The array in this example contains six elements, one of which is null:

```
=> SELECT apply_count(ARRAY[1,NULL,3,7,8,5]);
apply_count
-----
5
(1 row)
```

APPLY_COUNT_ELEMENTS (ARRAY_LENGTH)

Returns the total number of elements in a collection (array or set), including NULLs. To count only non-null values, use [APPLY_COUNT \(ARRAY_COUNT\)](#).

Behavior type

[Immutable](#)

Syntax

```
APPLY_COUNT_ELEMENTS(collection)
```

ARRAY_LENGTH is a synonym of APPLY_COUNT_ELEMENTS .

Arguments

collection

Target collection

Null-handling

This function counts all members, including nulls.

An empty collection ([ARRAY\[\]](#) or [SET\[\]](#)) has a length of 0. A collection containing a single null ([ARRAY\[null\]](#) or [SET\[null\]](#)) has a length of 1.

Examples

The following array has six elements including one null:

```
=> SELECT apply_count_elements(ARRAY[1,NULL,3,7,8,5]);
```

```
apply_count_elements
```

```
-----  
          6
```

```
(1 row)
```

As the previous example shows, a null element is an element. Thus, an array containing only a null element has one element:

```
=> SELECT apply_count_elements(ARRAY[null]);
```

```
apply_count_elements
```

```
-----  
          1
```

```
(1 row)
```

A set does not contain duplicates. If you construct a set and pass it directly to this function, the result could differ from the number of inputs:

```
=> SELECT apply_count_elements(SET[1,1,3]);
```

```
apply_count_elements
```

```
-----  
          2
```

```
(1 row)
```

APPLY_MAX

Returns the largest non-null element in a collection (array or set). This function is similar to the [MAX \[aggregate\]](#) function; APPLY_MAX operates on elements of a collection and MAX operates on an expression such as a column selection.

Behavior type

[Immutable](#)

Syntax

```
APPLY_MAX(collection)
```

Arguments

collection

Target collection

Null-handling

This function ignores null elements. If all elements are null or the collection is empty, this function returns null.

Examples

```
=> SELECT apply_max(ARRAY[1,3.4,15]);
```

```
apply_max
```

```
-----  
      15.0
```

```
(1 row)
```

APPLY_MIN

Returns the smallest non-null element in a collection (array or set). This function is similar to the [MIN \[aggregate\]](#) function; APPLY_MIN operates on elements of a collection and MIN operates on an expression such as a column selection.

Behavior type

[Immutable](#)

Syntax

```
APPLY_MIN(collection)
```

Arguments

collection

Target collection

Null-handling

This function ignores null elements. If all elements are null or the collection is empty, this function returns null.

Examples

```
=> SELECT apply_min(ARRAY[1,3.4,15]);
```

```
apply_min
```

```
-----  
      1.0
```

```
(1 row)
```

APPLY_SUM

Computes the sum of all elements in a collection (array or set) of numeric values (INTEGER, FLOAT, NUMERIC, or INTERVAL).

Behavior type

[Immutable](#)

Syntax

```
APPLY_SUM(collection)
```

Arguments

collection

Target collection

Null-handling

The following cases return NULL:

- if the input collection is NULL
- if the input collection contains only null values
- if the input collection is empty

Examples

```
=> SELECT apply_sum(ARRAY[12.5,3,4,1]);
```

```
apply_sum
```

```
-----  
      20.5
```

```
(1 row)
```

See also

- [APPLY_AVG](#)

ARRAY_CAT

Concatenates two arrays of the same element type and dimensionality. For example, ROW elements must have the same fields.

If the inputs are both bounded, the bound for the result is the sum of the bounds of the inputs.

If any input is unbounded, the result is unbounded with a binary size that is the sum of the sizes of the inputs.

Behavior type

[Immutable](#)

Syntax

```
ARRAY_CAT(array1,array2)
```

Arguments

array1 , array2

Arrays of matching dimensionality and element type

Null-handling

If either input is NULL, the function returns NULL.

Examples

Types are coerced if necessary, as shown in the second example.

```
=> SELECT array_cat(ARRAY[1,2], ARRAY[3,4,5]);
```

```
array_cat
```

```
-----  
[1,2,3,4,5]
```

```
(1 row)
```

```
=> SELECT array_cat(ARRAY[1,2], ARRAY[3,4,5.0]);
```

```
array_cat
```

```
-----  
["1.0","2.0","3.0","4.0","5.0"]
```

```
(1 row)
```

ARRAY_CONTAINS

Returns true if the specified element is found in the array and false if not. Both arguments must be non-null, but the array may be empty.

Deprecated

This function has been renamed to [CONTAINS](#).

ARRAY_DIMS

Returns the dimensionality of the input array.

Behavior type

[Immutable](#)

Syntax

```
ARRAY_DIMS(array)
```

Arguments

array

Target array

Examples

```
=> SELECT array_dims(ARRAY[[1,2],[2,3]]);
```

```
array_dims
```

```
-----  
2
```

```
(1 row)
```

ARRAY_FIND

Returns the ordinal position of a specified element in an array, or -1 if not found. This function uses null-safe equality checks when testing elements.

Behavior type

[Immutable](#)

Syntax

```
ARRAY_FIND(array, { value | lambda-expression })
```

Arguments

array

Target array.

value

Value to search for; type must match or be coercible to the element type of the array.

lambda-expression

[Lambda function](#) to apply to each element. The function must return a Boolean value. The first argument to the function is the element, and the optional second element is the index of the element.

Examples

The function returns the first occurrence of the specified element. However, nothing ensures that value is unique in the array:

```
=> SELECT array_find(ARRAY[1,2,7,5,7],7);
array_find
-----
      2
(1 row)
```

The function returns -1 if the specified element is not found:

```
=> SELECT array_find(ARRAY[1,3,5,7],4);
array_find
-----
     -1
(1 row)
```

You can search for complex element types:

```
=> SELECT ARRAY_FIND(ARRAY[ARRAY[1,2,3],ARRAY[1,null,4]],
                    ARRAY[1,2,3]);
ARRAY_FIND
-----
      0
(1 row)

=> SELECT ARRAY_FIND(ARRAY[ARRAY[1,2,3],ARRAY[1,null,4]],
                    ARRAY[1,null,4]);
ARRAY_FIND
-----
      1
(1 row)
```

The second example, comparing arrays with null elements, finds a match because ARRAY_FIND uses a null-safe equality check when evaluating elements.

Lambdas

Consider a table of departments where each department has an array of ROW elements representing employees. The following example searches for a specific employee name in those records. The results show that Alice works (or has worked) for two departments:

```
=> SELECT deptID, ARRAY_FIND(employees, e -> e.name = 'Alice Adams') AS 'has_alice'
FROM departments;
deptID | has_alice
-----+-----
      1 |         0
      2 |        -1
      3 |         0
(3 rows)
```

In the following example, each person in the table has an array of email addresses, and the function locates fake addresses. The function takes one argument, the array element to test, and calls a regular-expression function that returns a Boolean:

```
=> SELECT name, ARRAY_FIND(email, e -> REGEXP_LIKE(e,'example.com','i'))
      AS 'example.com'
FROM people;
name   | example.com
-----+-----
Elaine Jackson |        -1
Frank Adams   |         0
Lee Jones     |        -1
M Smith       |         0
(4 rows)
```

See also

- [CONTAINS](#)

- [FILTER](#)

CONTAINS

Returns true if the specified element is found in the collection and false if not. This function uses null-safe equality checks when testing elements.

Behavior type

[Immutable](#)

Syntax

```
CONTAINS(collection, { value | lambda-expression })
```

Arguments

collection

Target collection ([ARRAY](#) or [SET](#)).

value

Value to search for; type must match or be coercible to the element type of the collection.

lambda-expression

[Lambda function](#) to apply to each element. The function must return a Boolean value. The first argument to the function is the element, and the optional second element is the index of the element.

Examples

```
=> SELECT CONTAINS(SET[1,2,3,4],2);
contains
-----
t
(1 row)
```

You can search for NULL as an element value:

```
=> SELECT CONTAINS(ARRAY[1,null,2],null);
contains
-----
t
(1 row)
```

You can search for complex element types:

```
=> SELECT CONTAINS(ARRAY[ARRAY[1,2,3],ARRAY[1,null,4]],
                  ARRAY[1,2,3]);
CONTAINS
-----
t
(1 row)

=> SELECT CONTAINS(ARRAY[ARRAY[1,2,3],ARRAY[1,null,4]],
                  ARRAY[1,null,4]);
CONTAINS
-----
t
(1 row)
```

The second example, comparing arrays with null elements, returns true because CONTAINS uses a null-safe equality check when evaluating elements.

In the following example, the orders table has the following definition:

```
=> CREATE EXTERNAL TABLE orders(
  orderid int,
  accountid int,
  shipments Array[
    ROW(
      shipid int,
      address ROW(
        street varchar,
        city varchar,
        zip int
      ),
      shipdate date
    )
  ]
) AS COPY FROM '...' PARQUET;
```

The following query tests for a specific order. When passing a ROW literal as the second argument, cast any ambiguous fields to ensure type matches:

```
=> SELECT CONTAINS(shipments,
  ROW(1,ROW('911 San Marcos St'::VARCHAR,
    'Austin'::VARCHAR, 73344),
    '2020-11-05'::DATE))
FROM orders;
CONTAINS
-----
t
f
f
(3 rows)
```

Lambdas

Consider a table of departments where each department has an array of ROW elements representing employees. The following query finds departments with early hires (low employee IDs):

```
=> SELECT deptID FROM departments
WHERE CONTAINS(employees, e -> e.id < 20);
deptID
-----
1
3
(2 rows)
```

In the following example, a schedules table includes an array of events, where each event is a ROW with several fields:

```
=> CREATE TABLE schedules
  (guest VARCHAR,
  events ARRAY[ROW(e_date DATE, e_name VARCHAR, price NUMERIC(8,2))]);
```

You can use the [CONTAINS](#) function with a lambda expression to find people who have more than one event on the same day. The second argument, `idx`, is the index of the current element:

```
=> SELECT guest FROM schedules
WHERE CONTAINS(events, (e, idx) ->
  (idx < ARRAY_LENGTH(events) - 1
  AND (e.e_date = events[idx + 1].e_date));
guest
-----
Alice Adams
(1 row)
```

See also

- [ARRAY_FIND](#)
- [FILTER](#)

EXPLODE

Expands the elements of one or more collection columns ([ARRAY](#) or [SET](#)) into individual table rows, one row per element. For each exploded collection, the results include two columns, one for the element index, and one for the value at that position. If the function explodes a single collection, these columns are named `position` and `value` by default. If the function explodes two or more collections, the columns for each collection are named `pos_ column-name` and `val_ column-name` . You can use an AS clause in the SELECT to change these column names.

EXPLODE and [UNNEST](#) both expand collections. They have the following differences:

- By default, EXPLODE expands only the first collection it is passed and UNNEST expands all of them. See the [explode_count](#) and [explode_all](#) parameters.
- By default, EXPLODE returns element positions in an `index` column and UNNEST does not. See the [with_offsets](#) parameter.
- By default, EXPLODE requires an OVER clause and UNNEST ignores an OVER clause if present. See the [skip_partitioning](#) parameter.

Behavior type

[Immutable](#)

Syntax

```
EXPLODE (column[,...] [USING PARAMETERS param=value])  
[ OVER ( [window-partition-clause] ) ]
```

Arguments

column

Column in the table being queried. Unless [explode_all](#) is true, you must specify at least as many collection columns as the value of the [explode_count](#) parameter. Columns that are not collections are passed through without modification.

Passthrough columns are not needed if [skip_partitioning](#) is true.

OVER(...)

How to partition and sort input data. The input data is the result set that the query returns after it evaluates FROM, WHERE, GROUP BY, and HAVING clauses. For EXPLODE, use OVER() or OVER(PARTITION BEST).

This clause is ignored if [skip_partitioning](#) is true.

Parameters

explode_all (BOOLEAN)

If true, explode all collection columns. When [explode_all](#) is true, passthrough columns are not permitted.

Default: false

explode_count (INT)

The number of collection columns to explode. The function checks each column, up to this value, and either explodes it if it is a collection or passes it through if it is not a collection or if this limit has been reached. If the value of [explode_count](#) is greater than the number of collection columns specified, the function returns an error.

If [explode_all](#) is true, you cannot specify [explode_count](#) .

Default: 1

skip_partitioning (BOOLEAN)

Whether to skip partitioning and ignore the OVER clause if present. EXPLODE translates a single row of input into multiple rows of output, one per collection element. There is, therefore, usually no benefit to partitioning the input first. Skipping partitioning can help a query avoid an expensive sort or merge operation. Even so, setting this parameter can negatively affect performance in rare cases.

Default: false

with_offset (BOOLEAN)

Whether to return the index of each element.

Default: true

Null-handling

This function expands each element in a collection into a row, including null elements. If the input column is NULL or an empty collection, the function produces no rows for that column:

```
=> SELECT EXPLODE(ARRAY[1,2,null,4]) OVER();
```

```
position | value
```

```
-----+-----  
0 | 1  
1 | 2  
2 |  
3 | 4
```

```
(4 rows)
```

```
=> SELECT EXPLODE(ARRAY[]::ARRAY[INT]) OVER();
```

```
position | value
```

```
-----+-----  
(0 rows)
```

```
=> SELECT EXPLODE(NULL::ARRAY[INT]) OVER();
```

```
position | value
```

```
-----+-----  
(0 rows)
```

Joining on results

To use JOIN with this function you must set the `skip_partitioning` parameter, either in the function call or as a session parameter.

You can use the output of this function as if it were a relation by using CROSS JOIN or LEFT JOIN LATERAL in a query. Other JOIN types are not supported.

Consider the following table of students and exam scores:

```
=> SELECT * FROM tests;
```

```
student | scores | questions
```

```
-----+-----+-----  
Bob | [92,78,79] | [20,20,100]  
Lee | |  
Pat | [] | []  
Sam | [97,98,85] | [20,20,100]  
Tom | [68,75,82,91] | [20,20,100,100]
```

```
(5 rows)
```

The following query finds the best test scores across all students who have scores:

```
=> ALTER SESSION SET UDPARAMETER FOR ComplexTypesLib skip_partitioning = true;
```

```
=> SELECT student, score FROM tests  
CROSS JOIN EXPLODE(scores) AS t (pos, score)  
ORDER BY score DESC;
```

```
student | score
```

```
-----+-----  
Sam | 98  
Sam | 97  
Bob | 92  
Tom | 91  
Sam | 85  
Tom | 82  
Bob | 79  
Bob | 78  
Tom | 75  
Tom | 68
```

```
(10 rows)
```

The following query returns maximum and average per-question scores, considering both the exam score and the number of questions:

```
=> SELECT student, MAX(score/qcount), AVG(score/qcount) FROM tests
      CROSS JOIN EXPLODE(scores, questions USING PARAMETERS explode_count=2)
      AS t(pos_s, score, pos_q, qcount)
      GROUP BY student;
student |      MAX      |      AVG
-----+-----+-----
Bob    | 4.6000000000000000 | 3.04333333333333
Sam    | 4.9000000000000000 | 3.42222222222222
Tom    | 4.5500000000000000 |      2.37
(3 rows)
```

These queries produce results for three of the five students. One student has a null value for scores and another has an empty array. These rows are not included in the function's output.

To include null and empty arrays in output, use LEFT JOIN LATERAL instead of CROSS JOIN:

```
=> SELECT student, MIN(score), AVG(score) FROM tests
      LEFT JOIN LATERAL EXPLODE(scores) AS t (pos, score)
      GROUP BY student;
student | MIN |      AVG
-----+-----+-----
Bob    | 78 |      83
Lee    |   |
Pat    |   |
Sam    | 85 | 93.33333333333333
Tom    | 68 |      79
(5 rows)
```

The LATERAL keyword is required with LEFT JOIN. It is optional for CROSS JOIN.

Examples

Consider an orders table with the following contents:

```
=> SELECT orderkey, custkey, prodkey, orderprices, email_addrs
      FROM orders LIMIT 5;
orderkey | custkey |      prodkey      |      orderprices      |      email_addrs
-----+-----+-----+-----+-----
113-341987 | 342799 | ["MG-7190 ", "VA-4028 ", "EH-1247 ", "MS-7018 "] | ["60.00", "67.00", "22.00", "14.99"] | ["bob@example.com", "robert.jones@example.com"]
111-952000 | 342845 | ["ID-2586 ", "IC-9010 ", "MH-2401 ", "JC-1905 "] | ["22.00", "35.00", null, "12.00"] | ["br92@cs.example.edu"]
111-345634 | 342536 | ["RS-0731 ", "SJ-2021 "] | ["50.00", null] | [null]
113-965086 | 342176 | ["GW-1808 "] | ["108.00"] | ["joe.smith@example.com"]
111-335121 | 342321 | ["TF-3556 "] | ["50.00"] | ["789123@example-isp.com", "alexjohnson@example.com", "monica@eng.example.com", "sara@johnson.example.name", null]
(5 rows)
```

The following query explodes the order prices for a single customer. The other two columns are passed through and are repeated for each returned row:

```
=> SELECT EXPLODE(orderprices, custkey, email_addrs
      USING PARAMETERS skip_partitioning=true)
      AS (position, orderprices, custkey, email_addrs)
      FROM orders WHERE custkey='342845' ORDER BY orderprices;
position | orderprices | custkey |      email_addrs
-----+-----+-----+-----
2 |      | 342845 | ["br92@cs.example.edu", null]
3 | 12.00 | 342845 | ["br92@cs.example.edu", null]
0 | 22.00 | 342845 | ["br92@cs.example.edu", null]
1 | 35.00 | 342845 | ["br92@cs.example.edu", null]
(4 rows)
```

The previous example uses the `skip_partitioning` parameter. Instead of setting it for each call to `EXPLODE`, you can set it as a session parameter. `EXPLODE` is part of the `ComplexTypesLib` UDX library. The following example returns the same results:

```
=> ALTER SESSION SET UDPARAMETER FOR ComplexTypesLib skip_partitioning=true;

=> SELECT EXPLODE(orderprices, custkey, email_addrs)
       AS (position, orderprices, custkey, email_addrs)
   FROM orders WHERE custkey='342845' ORDER BY orderprices;
```

You can explode more than one column by specifying the `explode_count` parameter:

```
=> SELECT EXPLODE(orderkey, prodkey, orderprices
                 USING PARAMETERS explode_count=2, skip_partitioning=true)
       AS (orderkey,pk_idx,pk_val,ord_idx,ord_val)
   FROM orders
  WHERE orderkey='113-341987';

orderkey | pk_idx | pk_val | ord_idx | ord_val
-----+-----+-----+-----+-----
113-341987 | 0 | MG-7190 | 0 | 60.00
113-341987 | 0 | MG-7190 | 1 | 67.00
113-341987 | 0 | MG-7190 | 2 | 22.00
113-341987 | 0 | MG-7190 | 3 | 14.99
113-341987 | 1 | VA-4028 | 0 | 60.00
113-341987 | 1 | VA-4028 | 1 | 67.00
113-341987 | 1 | VA-4028 | 2 | 22.00
113-341987 | 1 | VA-4028 | 3 | 14.99
113-341987 | 2 | EH-1247 | 0 | 60.00
113-341987 | 2 | EH-1247 | 1 | 67.00
113-341987 | 2 | EH-1247 | 2 | 22.00
113-341987 | 2 | EH-1247 | 3 | 14.99
113-341987 | 3 | MS-7018 | 0 | 60.00
113-341987 | 3 | MS-7018 | 1 | 67.00
113-341987 | 3 | MS-7018 | 2 | 22.00
113-341987 | 3 | MS-7018 | 3 | 14.99
(16 rows)
```

The following example uses a multi-dimensional array:

```
=> SELECT name, pingtimes FROM network_tests;

name |          pingtimes
-----+-----
eng1 | [[24.24,25.27,27.16,24.97],[23.97,25.01,28.12,29.5]]
eng2 | [[27.12,27.91,28.11,26.95],[29.01,28.99,30.11,31.56]]
qa1  | [[23.15,25.11,24.63,23.91],[22.85,22.86,23.91,31.52]]
(3 rows)

=> SELECT EXPLODE(name, pingtimes USING PARAMETERS explode_count=1) OVER()
       FROM network_tests;

name | position |          value
-----+-----+-----
eng1 | 0 | [24.24,25.27,27.16,24.97]
eng1 | 1 | [23.97,25.01,28.12,29.5]
eng2 | 0 | [27.12,27.91,28.11,26.95]
eng2 | 1 | [29.01,28.99,30.11,31.56]
qa1  | 0 | [23.15,25.11,24.63,23.91]
qa1  | 1 | [22.85,22.86,23.91,31.52]
(6 rows)
```

You can rewrite the previous query as follows to produce the same results:

```
=> SELECT name, EXPLODE(pingtimes USING PARAMETERS skip_partitioning=true)
       FROM network_tests;
```

FILTER

Takes an input array and returns an array containing only elements that meet a specified condition. This function uses null-safe equality checks when testing elements.

Behavior type

[Immutable](#)

Syntax

```
FILTER(array, lambda-expression )
```

Arguments

array

Input array.

lambda-expression

[Lambda function](#) to apply to each element. The function must return a Boolean value. The first argument to the function is the element, and the optional second element is the index of the element.

Examples

Given a table that contains names and arrays of email addresses, the following query filters out fake email addresses and returns the rest:

```
=> SELECT name, FILTER(email, e -> NOT REGEXP_LIKE(e,'example.com','i')) AS 'real_email'
FROM people;
  name |          real_email
-----+-----
Elaine Jackson | ["ejackson@somewhere.org","elaine@jackson.com"]
Frank Adams   | []
Lee Jones     | ["lee.jones@somewhere.org"]
M Smith       | ["ms@msmith.com"]
(4 rows)
```

You can use the results in a WHERE clause to exclude rows that no longer contain any email addresses:

```
=> SELECT name, FILTER(email, e -> NOT REGEXP_LIKE(e,'example.com','i')) AS 'real_email'
FROM people
WHERE ARRAY_LENGTH(real_email) > 0;
  name |          real_email
-----+-----
Elaine Jackson | ["ejackson@somewhere.org","elaine@jackson.com"]
Lee Jones     | ["lee.jones@somewhere.org"]
M Smith       | ["ms@msmith.com"]
(3 rows)
```

See also

- [CONTAINS](#)
- [ARRAY_FIND](#)

IMPLODE

Takes a column of any scalar type and returns an unbounded array. Combined with GROUP BY, this function can be used to reverse an [EXPLODE](#) operation.

Behavior type

- [Immutable](#) if the WITHIN GROUP ORDER BY clause specifies a column or set of columns that resolves to unique element values within each output array group.
- [Volatile](#) otherwise because results are non-commutative.

Syntax

```
IMPLODE (input-column [ USING PARAMETERS param=value[,...] ]
 [ within-group-order-by-clause ]
```

Arguments

input-column

Column of any scalar type from which to create the array.

[\[within-group-order-by-clause\]/\(sql-reference/functions/aggregate-functions/within-group-order-by-clause.html\)](#)

Sorts elements within each output array group:

```
WITHIN GROUP (ORDER BY { column-expression[ sort-qualifiers ] }{...})
```

sort-qualifiers : { ASC | DESC [NULLS { FIRST | LAST | AUTO }] }

Tip

WITHIN GROUP ORDER BY can consume a large amount of memory per group. To minimize memory consumption, create projections that support [GROUPBY PIPELINED](#).

Parameters

allow_truncate

Boolean, if true truncates results when output length exceeds column size. If false (the default), the function returns an error if the output array is too large.

Even if this parameter is set to true, IMplode returns an error if any single array element is too large. Truncation removes elements from the output array but does not alter individual elements.

max_binary_size

The maximum binary size in bytes for the returned array. If you omit this parameter, IMplode uses the value of the configuration parameter [DefaultArrayBinarySize](#).

Examples

Consider a table with the following contents:

```
=> SELECT * FROM filtered;
```

position	itemprice	itemkey
0	14.99	345
0	27.99	567
1	18.99	567
1	35.99	345
2	14.99	123

(5 rows)

The following query calls IMplode to assemble prices into arrays (grouped by keys):

```
=> SELECT itemkey AS key, IMplode(itemprice) AS prices  
FROM filtered GROUP BY itemkey ORDER BY itemkey;
```

key	prices
123	["14.99"]
345	["35.99","14.99"]
567	["27.99","18.99"]

(3 rows)

You can modify this query by including a WITHIN GROUP ORDER BY clause, which specifies how to sort array elements within each group:

```
=> SELECT itemkey AS key, IMplode(itemprice) WITHIN GROUP (ORDER BY itemprice) AS prices  
FROM filtered GROUP BY itemkey ORDER BY itemkey;
```

key	prices
123	["14.99"]
345	["14.99","35.99"]
567	["18.99","27.99"]

(3 rows)

See [Arrays and sets \(collections\)](#) for a fuller example.

SET_UNION

Returns a [SET](#) containing all elements of two input sets.

If the inputs are both bounded, the bound for the result is the sum of the bounds of the inputs.

If any input is unbounded, the result is unbounded with a binary size that is the sum of the sizes of the inputs.

Behavior type

[Immutable](#)

Syntax

```
SET_UNION(set1,set2)
```

Arguments

set1 , ***set2***

Sets of matching element type

Null-handling

- Null arguments are ignored. If one of the inputs is null, the function returns the non-null input. In other words, an argument of NULL is equivalent to SET[*i*].
- If both inputs are null, the function returns null.

Examples

```
=> SELECT SET_UNION(SET[1,2,4], SET[2,3,4,5.9]);
set_union
-----
["1.0","2.0","3.0","4.0","5.9"]
(1 row)
```

STRING_TO_ARRAY

Splits a string containing array values and returns a native one-dimensional array. The output does not include the "ARRAY" keyword. This function does not support nested (multi-dimensional) arrays.

This function returns array elements as strings by default. You can cast to other types, as in the following example:

```
=> SELECT STRING_TO_ARRAY('[1,2,3]')::ARRAY[INT];
```

Behavior

[Immutable](#)

Syntax

```
STRING_TO_ARRAY(string [USING PARAMETERS param=value[,...]])
```

The following syntax is deprecated:

```
STRING_TO_ARRAY(string, delimiter)
```

Arguments

string

String representation of a one-dimensional array; can be a VARCHAR or LONG VARCHAR column, a literal string, or the string output of an expression.

Spaces in the string are removed unless elements are individually quoted. For example, 'a,b,c' is equivalent to 'a,b,c' . To preserve the space, use "' a','b','c' " .

Parameters

These parameters behave the same way as the corresponding options when loading delimited data (see [DELIMITED](#)).

No parameter may have the same value as any other parameter.

collection_delimiter

The character or character sequence used to separate array elements (VARCHAR(8)). You can use any ASCII values in the range E'000' to E'177', inclusive.

Default: Comma (',').

collection_open , collection_close

The characters that mark the beginning and end of the array (VARCHAR(8)). It is an error to use these characters elsewhere within the list of elements without escaping them. These characters can be omitted from the input string.

Default: Square brackets ('[' and ']').

collection_null_element

The string representing a null element value (VARCHAR(65000)). You can specify a null value using any ASCII values in the range E'\001' to E'\177' inclusive (any ASCII value except NULL: E'\000').

Default: 'null'

collection_enclose

An optional quote character within which to enclose individual elements, allowing delimiter characters to be embedded in string values. You can choose any ASCII value in the range E'\001' to E'\177' inclusive (any ASCII character except NULL: E'\000'). Elements do not need to be enclosed by this value.

Default: double quote ('"')

Examples

The function uses comma as the default delimiter. You can specify a different value:

```
=> SELECT STRING_TO_ARRAY('[1,3,5]');
STRING_TO_ARRAY
-----
["1","3","5"]
(1 row)

=> SELECT STRING_TO_ARRAY('[t|f|t]' USING PARAMETERS collection_delimiter = '|');
STRING_TO_ARRAY
-----
["t","f","t"]
(1 row)
```

The bounding brackets are optional:

```
=> SELECT STRING_TO_ARRAY('t|f|t' USING PARAMETERS collection_delimiter = '|');
STRING_TO_ARRAY
-----
["t","f","t"]
(1 row)
```

The input can use other characters for open and close:

```
=> SELECT STRING_TO_ARRAY('{NASA-1683,NASA-7867,SPX-76}' USING PARAMETERS collection_open = '{', collection_close = '}');
STRING_TO_ARRAY
-----
["NASA-1683","NASA-7867","SPX-76"]
(1 row)
```

By default the string 'null' in input is treated as a null value:

```
=> SELECT STRING_TO_ARRAY('{us-1672,null,darpa-1963}' USING PARAMETERS collection_open = '{', collection_close = '}');
STRING_TO_ARRAY
-----
["us-1672",null,"darpa-1963"]
(1 row)
```

In the following example, the input comes from a column:

```
=> SELECT STRING_TO_ARRAY(name USING PARAMETERS collection_delimiter=' ') FROM employees;
STRING_TO_ARRAY
-----
["Howard","Wolowitz"]
["Sheldon","Cooper"]
(2 rows)
```

TO_JSON

Returns the JSON representation of a complex-type argument, including mixed and nested complex types. This is the same format that queries of complex-type columns return.

Behavior

[Immutable](#)

Syntax

```
TO_JSON(value)
```

Arguments

value

Column or literal of a complex type

Examples

These examples query the following table:

```
=> SELECT name, contact FROM customers;
  name      |                               contact
-----+-----
Missy Cooper | {"street":"911 San Marcos St","city":"Austin","zipcode":73344,"email":["missy@mit.edu","mcooper@cern.gov"]}
Sheldon Cooper | {"street":"100 Main St Apt 4B","city":"Pasadena","zipcode":91001,"email":["shelly@meemaw.name","cooper@caltech.edu"]}
Leonard Hofstadter | {"street":"100 Main St Apt 4A","city":"Pasadena","zipcode":91001,"email":["hofstadter@caltech.edu"]}
Leslie Winkle | {"street":"23 Fifth Ave Apt 8C","city":"Pasadena","zipcode":91001,"email":[]}
Raj Koothrappali | {"street":null,"city":"Pasadena","zipcode":91001,"email":["raj@available.com"]}
Stuart Bloom |
(6 rows)
```

You can call TO_JSON on a column or on specific fields or array elements:

```
=> SELECT TO_JSON(contact) FROM customers;
  to_json
-----
{"street":"911 San Marcos St","city":"Austin","zipcode":73344,"email":["missy@mit.edu","mcooper@cern.gov"]}
{"street":"100 Main St Apt 4B","city":"Pasadena","zipcode":91001,"email":["shelly@meemaw.name","cooper@caltech.edu"]}
{"street":"100 Main St Apt 4A","city":"Pasadena","zipcode":91001,"email":["hofstadter@caltech.edu"]}
{"street":"23 Fifth Ave Apt 8C","city":"Pasadena","zipcode":91001,"email":[]}
{"street":null,"city":"Pasadena","zipcode":91001,"email":["raj@available.com"]}
(6 rows)

=> SELECT TO_JSON(contact.email) FROM customers;
  to_json
-----
["missy@mit.edu","mcooper@cern.gov"]
["shelly@meemaw.name","cooper@caltech.edu"]
["hofstadter@caltech.edu"]
[]
["raj@available.com"]
(6 rows)
```

When calling TO_JSON with a SET, note that duplicates are removed and elements can be reordered:

```
=> SELECT TO_JSON(SET[1683,7867,76,76]);
  TO_JSON
-----
[76,1683,7867]
(1 row)
```

UNNEST

Expands the elements of one or more collection columns ([ARRAY](#) or [SET](#)) into individual rows. If called with a single array, UNNEST returns the

elements in a column named `value` . If called with two or more arrays, it returns columns named `val_ column-name` . You can use an AS clause in the SELECT to change these names.

UNNEST and [EXPLODE](#) both expand collections. They have the following differences:

- By default, UNNEST expands all passed collections and EXPLODE expands only the first. See the `explode_count` and `explode_all` parameters.
- By default, UNNEST returns only the elements and EXPLODE also returns their positions in an `index` column. See the `with_offsets` parameter.
- By default, UNNEST does not partition its input and ignores an OVER() clause if present. See the `skip_partitioning` parameter.

Behavior type

[Immutable](#)

Syntax

```
UNNEST (column[,...])  
[USING PARAMETERS param=value]  
[ OVER ( [window-partition-clause
```

Arguments

column

Column in the table being queried. If `explode_all` is false, you must specify at least as many collection columns as the value of the `explode_count` parameter. Columns that are not collections are passed through without modification.

Passthrough columns are not needed if `skip_partitioning` is true.

OVER(...)

How to partition and sort input data. The input data is the result set that the query returns after it evaluates FROM, WHERE, GROUP BY, and HAVING clauses.

This clause only applies if `skip_partitioning` is false.

Parameters

explode_all (BOOLEAN)

If true, explode all collection columns. When `explode_all` is true, passthrough columns are not permitted.

Default: true

explode_count (INT)

The number of collection columns to explode. The function checks each column, up to this value, and either explodes it if it is a collection or passes it through if it is not a collection or if this limit has been reached. If the value of `explode_count` is greater than the number of collection columns specified, the function returns an error.

If `explode_all` is true, you cannot specify `explode_count` .

Default: 1

skip_partitioning (BOOLEAN)

Whether to skip partitioning and ignore the OVER clause if present. UNNEST translates a single row of input into multiple rows of output, one per collection element. There is, therefore, usually no benefit to partitioning the input first. Skipping partitioning can help a query avoid an expensive sort or merge operation.

Default: true

with_offset (BOOLEAN)

Whether to return the index of each element as an additional column.

Default: false

Null-handling

This function expands each element in a collection into a row, including null elements. If the input column is NULL or an empty collection, the function produces no rows for that column:

```
=> SELECT UNNEST(ARRAY[1,2,null,4]) OVER();
```

```
value
```

```
-----  
 1  
 2  
  
 4
```

```
(4 rows)
```

```
=> SELECT UNNEST(ARRAY[]::ARRAY[INT]) OVER();
```

```
value
```

```
-----  
(0 rows)
```

```
=> SELECT UNNEST(NULL::ARRAY[INT]) OVER();
```

```
value
```

```
-----  
(0 rows)
```

Joining on results

You can use the output of this function as if it were a relation by using CROSS JOIN or LEFT JOIN LATERAL in a query. Other JOIN types are not supported.

Consider the following table of students and exam scores:

```
=> SELECT * FROM tests;
```

```
student | scores | questions
```

```
-----+-----  
Bob | [92,78,79] | [20,20,100]  
Lee | |  
Pat | [] | []  
Sam | [97,98,85] | [20,20,100]  
Tom | [68,75,82,91] | [20,20,100,100]
```

```
(5 rows)
```

The following query finds the best test scores across all students who have scores:

```
=> SELECT student, score FROM tests
```

```
CROSS JOIN UNNEST(scores) AS t (score)
```

```
ORDER BY score DESC;
```

```
student | score
```

```
-----+-----  
Sam | 98  
Sam | 97  
Bob | 92  
Tom | 91  
Sam | 85  
Tom | 82  
Bob | 79  
Bob | 78  
Tom | 75  
Tom | 68
```

```
(10 rows)
```

The following query returns maximum and average per-question scores, considering both the exam score and the number of questions:

```
=> SELECT student, MAX(score/qcount), AVG(score/qcount) FROM tests
CROSS JOIN UNNEST(scores, questions) AS t(score, qcount)
GROUP BY student;
student |    MAX    |    AVG
-----+-----+-----
Bob    | 4.600000000000000000 | 3.04333333333333
Sam    | 4.900000000000000000 | 3.42222222222222
Tom    | 4.550000000000000000 |      2.37
(3 rows)
```

These queries produce results for three of the five students. One student has a null value for scores and another has an empty array. These rows are not included in the function's output.

To include null and empty arrays in output, use LEFT JOIN LATERAL instead of CROSS JOIN:

```
=> SELECT student, MIN(score), AVG(score) FROM tests
LEFT JOIN LATERAL UNNEST(scores) AS t (score)
GROUP BY student;
student | MIN |    AVG
-----+-----+-----
Bob    | 78 |      83
Lee    |   |
Pat    |   |
Sam    | 85 | 93.33333333333333
Tom    | 68 |      79
(5 rows)
```

The LATERAL keyword is required with LEFT JOIN. It is optional for CROSS JOIN.

Examples

Consider a table with the following definition:

```
=> CREATE TABLE orders (
  orderkey VARCHAR, custkey INT,
  prodkey ARRAY[VARCHAR], orderprices ARRAY[DECIMAL(12,2)],
  email_addrs ARRAY[VARCHAR]);
```

The following query expands one of the array columns. One of the elements is null:

```
=> SELECT UNNEST(orderprices) AS price, custkey, email_addrs
FROM orders WHERE custkey='342845' ORDER BY price;
price | custkey |    email_addrs
-----+-----+-----
      | 342845 | ["br92@cs.example.edu"]
12.00 | 342845 | ["br92@cs.example.edu"]
22.00 | 342845 | ["br92@cs.example.edu"]
35.00 | 342845 | ["br92@cs.example.edu"]
(4 rows)
```

UNNEST can expand more than one column:

```
=> SELECT orderkey, UNNEST(prodkey, orderprices)
   FROM orders WHERE orderkey='113-341987';
orderkey | val_prodkey | val_orderprices
-----+-----+-----
113-341987 | MG-7190 | 60.00
113-341987 | MG-7190 | 67.00
113-341987 | MG-7190 | 22.00
113-341987 | MG-7190 | 14.99
113-341987 | VA-4028 | 60.00
113-341987 | VA-4028 | 67.00
113-341987 | VA-4028 | 22.00
113-341987 | VA-4028 | 14.99
113-341987 | EH-1247 | 60.00
113-341987 | EH-1247 | 67.00
113-341987 | EH-1247 | 22.00
113-341987 | EH-1247 | 14.99
113-341987 | MS-7018 | 60.00
113-341987 | MS-7018 | 67.00
113-341987 | MS-7018 | 22.00
113-341987 | MS-7018 | 14.99
(16 rows)
```

Date/time functions

Date and time functions perform conversion, extraction, or manipulation operations on date and time data types and can return date and time information.

Usage

Functions that take **TIME** or **TIMESTAMP** inputs come in two variants:

- **TIME WITH TIME ZONE** or **TIMESTAMP WITH TIME ZONE**
- **TIME WITHOUT TIME ZONE** or **TIMESTAMP WITHOUT TIME ZONE**

For brevity, these variants are not shown separately.

The + and * operators come in commutative pairs; for example, both **DATE + INTEGER** and **INTEGER + DATE** . We show only one of each such pair.

Daylight savings time considerations

When adding an **INTERVAL** value to (or subtracting an **INTERVAL** value from) a **TIMESTAMP WITH TIME ZONE** value, the days component advances (or decrements) the date of the **TIMESTAMP WITH TIME ZONE** by the indicated number of days. Across daylight saving time changes (with the session time zone set to a time zone that recognizes DST), this means **INTERVAL '1 day'** does not necessarily equal **INTERVAL '24 hours'** .

For example, with the session time zone set to **CST7CDT** :

```
TIMESTAMP WITH TIME ZONE '2014-04-02 12:00-07' + INTERVAL '1 day'
```

produces

```
TIMESTAMP WITH TIME ZONE '2014-04-03 12:00-06'
```

Adding **INTERVAL '24 hours'** to the same initial **TIMESTAMP WITH TIME ZONE** produces

```
TIMESTAMP WITH TIME ZONE '2014-04-03 13:00-06'
```

This result occurs because there is a change in daylight saving time at **2014-04-03 02:00** in time zone **CST7CDT** .

Date/time functions in transactions

Certain date/time functions such as **CURRENT_TIMESTAMP** and **NOW** return the start time of the current transaction; for the duration of that transaction, they return the same value. Other date/time functions such as **TIMEOFDAY** always return the current time.

ADD_MONTHS

Adds the specified number of months to a date and returns the sum as a **DATE** . In general, ADD_MONTHS returns a date with the same day component as the start date. For example:

```
=> SELECT ADD_MONTHS ('2015-09-15'::date, -2) "2 Months Ago";
```

```
2 Months Ago
```

```
-----
```

```
2015-07-15
```

```
(1 row)
```

Two exceptions apply:

- If the start date's day component is greater than the last day of the result month, ADD_MONTHS returns the last day of the result month. For example:

```
=> SELECT ADD_MONTHS ('31-Jan-2016'::TIMESTAMP, 1) "Leap Month";
```

```
Leap Month
```

```
-----
```

```
2016-02-29
```

```
(1 row)
```

- If the start date's day component is the last day of that month, and the result month has more days than the start date month, ADD_MONTHS returns the last day of the result month. For example:

```
=> SELECT ADD_MONTHS ('2015-09-30'::date,-1) "1 Month Ago";
```

```
1 Month Ago
```

```
-----
```

```
2015-08-31
```

```
(1 row)
```

Behavior type

- [Immutable](#) if the *start-date* argument is a **TIMESTAMP** or **DATE**
- [Stable](#) if the *start-date* argument is a **TIMESTAMPTZ**

Syntax

```
ADD_MONTHS ( start-date, num-months );
```

Parameters

start-date

The date to process, an expression that evaluates to one of the following data types:

- **DATE**
- **TIMESTAMP**
- **TIMESTAMPTZ**

num-months

An integer expression that specifies the number of months to add to or subtract from *start-date* .

Examples

Add one month to the current date:

```
=> SELECT CURRENT_DATE Today;
```

```
Today
```

```
-----
```

```
2016-05-05
```

```
(1 row)
```

```
VMart=> SELECT ADD_MONTHS(CURRENT_TIMESTAMP,1);
```

```
ADD_MONTHS
```

```
-----
```

```
2016-06-05
```

```
(1 row)
```

Subtract four months from the current date:

```
=> SELECT ADD_MONTHS(CURRENT_TIMESTAMP, -4);
```

```
ADD_MONTHS
```

```
-----
```

```
2016-01-05
```

```
(1 row)
```

Add one month to January 31 2016:

```
=> SELECT ADD_MONTHS('31-Jan-2016'::TIMESTAMP, 1) "Leap Month";
Leap Month
-----
2016-02-29
(1 row)
```

The following example sets the timezone to EST; it then adds 24 months to a TIMESTAMPTZ that specifies a PST time zone, so `ADD_MONTHS` takes into account the time change:

```
=> SET TIME ZONE 'America/New_York';
SET
VMart=> SELECT ADD_MONTHS('2008-02-29 23:30 PST'::TIMESTAMPTZ, 24);
ADD_MONTHS
-----
2010-03-01
(1 row)
```

AGE_IN_MONTHS

Returns the difference in months between two dates, expressed as an integer.

Behavior type

- [Immutable](#) if both date arguments are of data type `TIMESTAMP`
- [Stable](#) if either date is a `TIMESTAMPTZ` or only one argument is supplied

Syntax

```
AGE_IN_MONTHS ( [ date1,] date2 )
```

Parameters

date1

date2

Specify the boundaries of the period to measure. If you supply only one argument, Vertica sets *date2* to the current date. Both parameters must evaluate to one of the following data types:

- `DATE`
- `TIMESTAMP`
- `TIMESTAMPTZ`

If *date1* < *date2*, `AGE_IN_MONTHS` returns a negative value.

Examples

Get the age in months of someone born March 2 1972, as of June 21 1990:

```
=> SELECT AGE_IN_MONTHS('1990-06-21'::TIMESTAMP, '1972-03-02'::TIMESTAMP);
AGE_IN_MONTHS
-----
219
(1 row)
```

If the first date is less than the second date, `AGE_IN_MONTHS` returns a negative value

```
=> SELECT AGE_IN_MONTHS('1972-03-02'::TIMESTAMP, '1990-06-21'::TIMESTAMP);
AGE_IN_MONTHS
-----
-220
(1 row)
```

Get the age in months of someone who was born November 21 1939, as of today:

```
=> SELECT AGE_IN_MONTHS ('1939-11-21'::DATE);
AGE_IN_MONTHS
```

```
-----
      930
(1 row)
```

AGE_IN_YEARS

Returns the difference in years between two dates, expressed as an integer.

Behavior type

- [Immutable](#) if both date arguments are of data type `TIMESTAMP`
- [Stable](#) if either date is a `TIMESTAMPTZ` or only one argument is supplied

Syntax

```
AGE_IN_YEARS( [ date1,] date2 )
```

Parameters

date1

date2

Specify the boundaries of the period to measure. If you supply only one argument, Vertica sets *date1* to the current date. Both parameters must evaluate to one of the following data types:

- `DATE`
- `TIMESTAMP`
- `TIMESTAMPTZ`

If $date1 < date2$, `AGE_IN_YEARS` returns a negative value.

Examples

Get the age of someone born March 2 1972, as of June 21 1990:

```
=> SELECT AGE_IN_YEARS('1990-06-21'::TIMESTAMP, '1972-03-02'::TIMESTAMP);
AGE_IN_YEARS
```

```
-----
      18
(1 row)
```

If the first date is earlier than the second date, `AGE_IN_YEARS` returns a negative number:

```
=> SELECT AGE_IN_YEARS('1972-03-02'::TIMESTAMP, '1990-06-21'::TIMESTAMP);
AGE_IN_YEARS
```

```
-----
     -19
(1 row)
```

Get the age of someone who was born November 21 1939, as of today:

```
=> SELECT AGE_IN_YEARS('1939-11-21'::DATE);
AGE_IN_YEARS
```

```
-----
      77
(1 row)
```

CLOCK_TIMESTAMP

Returns a value of type `TIMESTAMP WITH TIMEZONE` that represents the current system-clock time.

`CLOCK_TIMESTAMP` uses the date and time supplied by the operating system on the server to which you are connected, which should be the same across all servers. The value changes each time you call it.

Behavior type

[Volatile](#)

Syntax

```
CLOCK_TIMESTAMP()
```

Examples

The following command returns the current time on your system:

```
SELECT CLOCK_TIMESTAMP() "Current Time";
      Current Time
-----
2010-09-23 11:41:23.33772-04
(1 row)
```

Each time you call the function, you get a different result. The difference in this example is in microseconds:

```
SELECT CLOCK_TIMESTAMP() "Time 1", CLOCK_TIMESTAMP() "Time 2";
      Time 1      |      Time 2
-----+-----
2010-09-23 11:41:55.369201-04 | 2010-09-23 11:41:55.369202-04
(1 row)
```

See also

- [STATEMENT_TIMESTAMP](#)
- [TRANSACTION_TIMESTAMP](#)

CURRENT_DATE

Returns the date (date-type value) on which the current transaction started.

Behavior type

[Stable](#)

Syntax

```
CURRENT_DATE()
```

Note

You can call this function without parentheses.

Examples

```
SELECT CURRENT_DATE;
      ?column?
-----
2010-09-23
(1 row)
```

CURRENT_TIME

Returns a value of type **TIME WITH TIMEZONE** that represents the start of the current transaction.

The return value does not change during the transaction. Thus, multiple calls to `CURRENT_TIME` within the same transaction return the same timestamp.

Behavior type

[Stable](#)

Syntax

```
CURRENT_TIME [ ( precision ) ]
```

Note

If you specify a column label without precision, you must also omit parentheses.

Parameters

precision

An integer value between 0-6, specifies to round the seconds fraction field result to the specified number of digits.

Examples

```
=> SELECT CURRENT_TIME(1) AS Time;
   Time
-----
06:51:45.2-07
(1 row)
=> SELECT CURRENT_TIME(5) AS Time;
   Time
-----
06:51:45.18435-07
(1 row)
```

CURRENT_TIMESTAMP

Returns a value of type **TIME WITH TIMEZONE** that represents the start of the current transaction.

The return value does not change during the transaction. Thus, multiple calls to **CURRENT_TIMESTAMP** within the same transaction return the same timestamp.

Behavior type

[Stable](#)

Syntax

```
CURRENT_TIMESTAMP ( precision )
```

Parameters

precision

An integer value between 0-6, specifies to round the seconds fraction field result to the specified number of digits.

Examples

```
=> SELECT CURRENT_TIMESTAMP(1) AS time;
   time
-----
2017-03-27 06:50:49.7-07
(1 row)
=> SELECT CURRENT_TIMESTAMP(5) AS time;
   time
-----
2017-03-27 06:50:49.69967-07
(1 row)
```

DATE

Converts the input value to a [DATE](#) data type.

Behavior type

- [Immutable](#) if the input value is a **TIMESTAMP** , **DATE** , **VARCHAR** , or integer
- [Stable](#) if the input value is a **TIMESTAMPTZ**

Syntax

```
DATE ( value )
```

Parameters

value

The value to convert, one of the following:

- **TIMESTAMP** , **TIMESTAMPTZ** , **VARCHAR** , or another **DATE** .
- Integer: Vertica treats the integer as the number of days since 01/01/0001 and returns the date.

Examples

```
=> SELECT DATE (1);
    DATE
-----
0001-01-01
(1 row)

=> SELECT DATE (734260);
    DATE
-----
2011-05-03
(1 row)

=> SELECT DATE('TODAY');
    DATE
-----
2016-12-07
(1 row)
```

See also

- [TO_DATE](#)
- [TO_TIMESTAMP](#)
- [TO_TIMESTAMP_TZ](#)

DATE_PART

Extracts a sub-field such as year or hour from a date/time expression, equivalent to the the SQL-standard function [EXTRACT](#).

Behavior type

- [Immutable](#) if the specified date is a [TIMESTAMP](#), [DATE](#), or [INTERVAL](#)
- [Stable](#) if the specified date is a [TIMESTAMPTZ](#)

Syntax

```
DATE_PART ( 'field', date )
```

Parameters

field

A constant value that specifies the sub-field to extract from *date* (see [Field Values](#) below).

date

The date to process, an expression that evaluates to one of the following data types:

- [DATE](#) (cast to [TIMESTAMP](#))
- [TIMESTAMP/TIMESTAMPTZ](#)
- [INTERVAL](#)

Field values

CENTURY

The century number.

The first century starts at 0001-01-01 00:00:00 AD. This definition applies to all Gregorian calendar countries. There is no century number 0, you go from -1 to 1.

DAY

The day (of the month) field (1–31).

DECADE

The year field divided by 10.

DOQ

The day within the current quarter. DOQ recognizes leap year days.

DOW

Zero-based day of the week, where Sunday=0.

Note

EXTRACT 's day of week numbering differs from the function [TO_CHAR](#).

DOY

The day of the year (1-365/366)

EPOCH

Specifies to return one of the following:

- For **DATE** and **TIMESTAMP** values: the number of seconds before or since 1970-01-01 00:00:00-00 (if before, a negative number).
- For **INTERVAL** values, the total number of seconds in the interval.

HOUR

The hour field (0-23).

ISODOW

The ISO day of the week, an integer between 1 and 7 where Monday is 1.

ISOWEEK

The ISO week of the year, an integer between 1 and 53.

ISOYEAR

The ISO year.

MICROSECONDS

The seconds field, including fractional parts, multiplied by 1,000,000. This includes full seconds.

MILLENNIUM

The millennium number, where the first millennium is 1 and each millenium starts on **01-01- y001** . For example, millennium 2 starts on 01-01-1001.

MILLISECONDS

The seconds field, including fractional parts, multiplied by 1000. This includes full seconds.

MINUTE

The minutes field (0 - 59).

MONTH

For **TIMESTAMP** values, the number of the month within the year (1 - 12) ; for **interval** values the number of months, modulo 12 (0 - 11).

QUARTER

The calendar quarter of the specified date as an integer, where the January-March quarter is 1, valid only for **TIMESTAMP** values.

SECOND

The seconds field, including fractional parts, 0-59, or 0-60 if the operating system implements leap seconds.

TIME_ZONE

The time zone offset from UTC, in seconds. Positive values correspond to time zones east of UTC, negative values to zones west of UTC.

TIMEZONE_HOUR

The hour component of the time zone offset.

TIMEZONE_MINUTE

The minute component of the time zone offset.

WEEK

The number of the week of the calendar year that the day is in.

YEAR

The year field. There is no **0 AD** , so subtract **BC** years from **AD** years accordingly.

Notes

According to the ISO-8601 standard, the week starts on Monday, and the first week of a year contains January 4. Thus, an early January date can sometimes be in the week 52 or 53 of the previous calendar year. For example:

```
=> SELECT YEAR_ISO('01-01-2016'::DATE), WEEK_ISO('01-01-2016'), DAYOFWEEK_ISO('01-01-2016');
YEAR_ISO | WEEK_ISO | DAYOFWEEK_ISO
-----+-----+-----
2015 | 53 | 5
(1 row)
```

Examples

Extract the day value:

```
SELECT DATE_PART('DAY', TIMESTAMP '2009-02-24 20:38:40') "Day";
Day
-----
24
(1 row)
```

Extract the month value:

```
SELECT DATE_PART('MONTH', '2009-02-24 20:38:40'::TIMESTAMP) "Month";
Month
-----
2
(1 row)
```

Extract the year value:

```
SELECT DATE_PART('YEAR', '2009-02-24 20:38:40'::TIMESTAMP) "Year";
Year
-----
2009
(1 row)
```

Extract the hours:

```
SELECT DATE_PART('HOUR', '2009-02-24 20:38:40'::TIMESTAMP) "Hour";
Hour
-----
20
(1 row)
```

Extract the minutes:

```
SELECT DATE_PART('MINUTES', '2009-02-24 20:38:40'::TIMESTAMP) "Minutes";
Minutes
-----
38
(1 row)
```

Extract the day of quarter (DOQ):

```
SELECT DATE_PART('DOQ', '2009-02-24 20:38:40'::TIMESTAMP) "DOQ";
DOQ
-----
55
(1 row)
```

See also

[TO_CHAR](#)

[DATE_TRUNC](#)

Truncates date and time values to the specified precision. The return value is the same data type as the input value. All fields that are less than the specified precision are set to 0, or to 1 for day and month.

Behavior type

[Stable](#)

Syntax

```
DATE_TRUNC( precision, trunc-target )
```

Parameters

precision

A string constant that specifies precision for the truncated value. See [Precision Field Values](#) below. The precision must be valid for the *trunc-target* date or time.

trunc-target

Valid date/time expression.

Precision field values

MILLENNIUM

The millennium number.

CENTURY

The century number.

The first century starts at 0001-01-01 00:00:00 AD. This definition applies to all Gregorian calendar countries.

DECADE

The year field divided by 10.

YEAR

The year field. Keep in mind there is no **0 AD** , so subtract **BC** years from **AD** years with care.

QUARTER

The calendar quarter of the specified date as an integer, where the January-March quarter is 1.

MONTH

For **timestamp** values, the number of the month within the year (1–12) ; for **interval** values the number of months, modulo 12 (0–11).

WEEK

The number of the week of the year that the day is in.

According to the ISO-8601 standard, the week starts on Monday, and the first week of a year contains January 4. Thus, an early January date can sometimes be in the week 52 or 53 of the previous calendar year. For example:

```
=> SELECT YEAR_ISO('01-01-2016'::DATE), WEEK_ISO('01-01-2016'), DAYOFWEEK_ISO('01-01-2016');
YEAR_ISO | WEEK_ISO | DAYOFWEEK_ISO
-----+-----+-----
2015 | 53 | 5
(1 row)
```

DAY

The day (of the month) field (1–31).

HOURL

The hour field (0–23).

MINUTE

The minutes field (0–59).

SECOND

The seconds field, including fractional parts (0–59) (60 if leap seconds are implemented by the operating system).

MILLISECONDS

The seconds field, including fractional parts, multiplied by 1000. Note that this includes full seconds.

MICROSECONDS

The seconds field, including fractional parts, multiplied by 1,000,000. This includes full seconds.

Examples

The following example sets the field value as hour and returns the hour, truncating the minutes and seconds:

```
=> SELECT DATE_TRUNC('HOUR', TIMESTAMP '2012-02-24 13:38:40') AS HOUR;
HOUR
-----
2012-02-24 13:00:00
(1 row)
```

The following example returns the year from the input **timestampz** '2012-02-24 13:38:40' . The function also defaults the month and day to January 1, truncates the hour:minute:second of the timestamp, and appends the time zone (**-05**):

```
=> SELECT DATE_TRUNC('YEAR', TIMESTAMPTZ '2012-02-24 13:38:40') AS YEAR;
YEAR
```

```
-----
2012-01-01 00:00:00-05
(1 row)
```

The following example returns the year and month and defaults day of month to 1, truncating the rest of the string:

```
=> SELECT DATE_TRUNC('MONTH', TIMESTAMP '2012-02-24 13:38:40') AS MONTH;
MONTH
```

```
-----
2012-02-01 00:00:00
(1 row)
```

DATEDIFF

Returns the time span between two dates, in the intervals specified. **DATEDIFF** excludes the start date in its calculation.

Behavior type

- [Immutable](#) if start and end dates are **TIMESTAMP** , **DATE** , **TIME** , or **INTERVAL**
- [Stable](#) if start and end dates are **TIMESTAMPTZ**

Syntax

```
DATEDIFF ( datepart, start, end );
```

Parameters

datepart

Specifies the type of date or time intervals that **DATEDIFF** returns. If *datepart* is an expression, it must be enclosed in parentheses:

```
DATEDIFF(expression), start, end);
```

datepart must evaluate to one of the following string literals, either quoted or unquoted:

- **year** | **yy** | **yyyy**
- **quarter** | **qq** | **q**
- **month** | **mm** | **m**
- **day** | **dayofyear** | **dd** | **d** | **dy** | **y**
- **week** | **wk** | **ww**
- **hour** | **hh**
- **minute** | **mi** | **n**
- **second** | **ss** | **s**
- **millisecond** | **ms**
- **microsecond** | **mcs** | **us**

start , end

Specify the start and end dates, where *start* and *end* evaluate to one of the following data types:

- [TIMESTAMP/TIMESTAMPTZ](#)
- [DATE](#)
- [TIME/TIMETZ](#)
- [INTERVAL](#)

If *end* < *start* , **DATEDIFF** returns a negative value.

Note

TIME and **INTERVAL** data types are invalid for start and end dates if *datepart* is set to **year** , **quarter** , or **month** .

Compatible start and end date data types

The following table shows which data types can be matched as start and end dates:

	DATE	TIMESTAMP	TIMESTAMPTZ	TIME	INTERVAL

DATE	.	.	.		
TIMESTAMP	.	.	.		
TIMESTAMPTZ	.	.	.		
TIME				.	
INTERVAL					.

For example, if you set the start date to an **INTERVAL** data type, the end date must also be an **INTERVAL** , otherwise Vertica returns an error:

```
SELECT DATEDIFF(day, INTERVAL '26 days', INTERVAL '1 month');
```

```
datediff
```

```
-----
```

```
4
```

```
(1 row)
```

Date part intervals

DATEDIFF uses the *datepart* argument to calculate the number of intervals between two dates, rather than the actual amount of time between them.

DATEDIFF uses the following cutoff points to calculate those intervals:

- **year** : January 1
- **quarter** : January 1, April 1, July 1, October 1
- **month** : the first day of the month
- **week** : Sunday at midnight (24:00)

For example, if *datepart* is set to **year** , **DATEDIFF** uses January 01 to calculate the number of years between two dates. The following **DATEDIFF** statement sets *datepart* to **year** , and specifies a time span 01/01/2005 - 06/15/2008:

```
SELECT DATEDIFF(year, '01-01-2005'::date, '12-31-2008'::date);
```

```
datediff
```

```
-----
```

```
3
```

```
(1 row)
```

DATEDIFF always excludes the start date when it calculates intervals—in this case, 01/01//2005. **DATEDIFF** considers only calendar year starts in its calculation, so in this case it only counts years 2006, 2007, and 2008. The function returns 3, although the actual time span is nearly four years.

If you change the start and end dates to 12/31/2004 and 01/01/2009, respectively, **DATEDIFF** also counts years 2005 and 2009. This time, it returns 5, although the actual time span is just over four years:

```
=> SELECT DATEDIFF(year, '12-31-2004'::date, '01-01-2009'::date);
```

```
datediff
```

```
-----
```

```
5
```

```
(1 row)
```

Similarly, **DATEDIFF** uses month start dates when it calculates the number of months between two dates. Thus, given the following statement, **DATEDIFF** counts months February through September and returns 8:

```
=> SELECT DATEDIFF(month, '01-31-2005'::date, '09-30-2005'::date);
```

```
datediff
```

```
-----
```

```
8
```

```
(1 row)
```

See also

[TIMESTAMPDIFF](#)

DAY

Returns as an integer the day of the month from the input value.

Behavior type

- [Immutable](#) if the input value is a **TIMESTAMP** , **DATE** , **VARCHAR** , or **INTEGER**
- [Stable](#) if the specified date is a **TIMESTAMPTZ**

Syntax

```
DAY ( value )
```

Parameters

value

The value to convert, one of the following: **TIMESTAMP** , **TIMESTAMPTZ** , **INTERVAL** , **VARCHAR** , or **INTEGER** .

Examples

```
=> SELECT DAY (6);
```

```
DAY
```

```
-----
```

```
6
```

```
(1 row)
```

```

```

```
(1 row)
```

DAYOFMONTH

Returns the day of the month as an integer.

Behavior type

- [Immutable](#) if the target date is a **TIMESTAMP** , **DATE** , or **VARCHAR**
- [Stable](#) if the target date is a **TIMESTAMPTZ**

Syntax

```
DAYOFMONTH ( date )
```

Parameters

date

The date to process, one of the following data types:

- [VARCHAR](#)
- [DATE](#)
- [TIMESTAMP](#)
- [TIMESTAMPTZ](#)

Examples

```
=> SELECT DAYOFMONTH (TIMESTAMP 'sep 22, 2011 12:34');
```

```
DAYOFMONTH
```

```
-----  
      22
```

```
(1 row)
```

DAYOFWEEK

Returns the day of the week as an integer, where Sunday is day 1.

Behavior type

- [Immutable](#) if the target date is a **TIMESTAMP**, **DATE**, or **VARCHAR**
- [Stable](#) if the target date is a **TIMESTAMPTZ**

Syntax

```
DAYOFWEEK ( date )
```

Parameters

date

The date to process, one of the following data types:

- [VARCHAR](#)
- [DATE](#)
- [TIMESTAMP](#)
- [TIMESTAMPTZ](#)

Examples

```
=> SELECT DAYOFWEEK (TIMESTAMP 'sep 17, 2011 12:34');
```

```
DAYOFWEEK
```

```
-----  
      7
```

```
(1 row)
```

DAYOFWEEK_ISO

Returns the ISO 8061 day of the week as an integer, where Monday is day 1.

Behavior type

- [Immutable](#) if the target date is a **TIMESTAMP**, **DATE**, or **VARCHAR**
- [Stable](#) if the target date is a **TIMESTAMPTZ**

Syntax

```
DAYOFWEEK_ISO ( date )
```

Parameters

date

The date to process, one of the following data types:

- [VARCHAR](#)
- [DATE](#)
- [TIMESTAMP](#)
- [TIMESTAMPTZ](#)

Examples

```
=> SELECT DAYOFWEEK_ISO(TIMESTAMP 'Sep 22, 2011 12:34');
```

```
DAYOFWEEK_ISO
```

```
-----  
      4
```

```
(1 row)
```

The following example shows how to combine the `DAYOFWEEK_ISO`, `WEEK_ISO`, and `YEAR_ISO` functions to find the ISO day of the week, week, and year:

```
=> SELECT DAYOFWEEK_ISO('Jan 1, 2000'), WEEK_ISO('Jan 1, 2000'), YEAR_ISO('Jan1,2000');
DAYOFWEEK_ISO | WEEK_ISO | YEAR_ISO
```

```
-----+-----+-----
        6 |    52 | 1999
```

(1 row)

See also

- [WEEK_ISO](#)
- [DAYOFWEEK_ISO](#)
- http://en.wikipedia.org/wiki/ISO_8601

DAYOFYEAR

Returns the day of the year as an integer, where January 1 is day 1.

Behavior type

- [Immutable](#) if the specified date is a **TIMESTAMP**, **DATE**, or **VARCHAR**
- [Stable](#) if the specified date is a **TIMESTAMPTZ**

Syntax

```
DAYOFYEAR ( date )
```

Parameters

date

The date to process, one of the following data types:

- [VARCHAR](#)
- [DATE](#)
- [TIMESTAMP](#)
- [TIMESTAMPTZ](#)

Examples

```
=> SELECT DAYOFYEAR (TIMESTAMP 'SEPT 22,2011 12:34');
```

```
DAYOFYEAR
```

```
-----
      265
```

(1 row)

DAYS

Returns the integer value of the specified date, where 1 AD is 1. If the date precedes 1 AD, **DAYS** returns a negative integer.

Behavior type

- [Immutable](#) if the specified date is a **TIMESTAMP**, **DATE**, or **VARCHAR**
- [Stable](#) if the specified date is a **TIMESTAMPTZ**

Syntax

```
DAYS ( date )
```

Parameters

date

The date to process, one of the following data types:

- [VARCHAR](#)
- [DATE](#)
- [TIMESTAMP](#)
- [TIMESTAMPTZ](#)

Examples

```
=> SELECT DAYS (DATE '2011-01-22');
```

```
DAYS
```

```
-----
```

```
734159
```

```
(1 row)
```

```
=> SELECT DAYS (DATE 'March 15, 0044 BC');
```

```
DAYS
```

```
-----
```

```
-15997
```

```
(1 row)
```

EXTRACT

Retrieves sub-fields such as year or hour from date/time values and returns values of type [NUMERIC](#). **EXTRACT** is intended for computational processing, rather than for formatting date/time values for display.

Behavior type

- [Immutable](#) if the specified date is a [TIMESTAMP](#), [DATE](#), or [INTERVAL](#)
- [Stable](#) if the specified date is a [TIMESTAMPTZ](#)

Syntax

```
EXTRACT ( field FROM date )
```

Parameters

field

A constant value that specifies the sub-field to extract from *date* (see [Field Values](#) below).

date

The date to process, an expression that evaluates to one of the following data types:

- [DATE](#) (cast to [TIMESTAMP](#))
- [TIMESTAMP/TIMESTAMPTZ](#)
- [INTERVAL](#)

Field values

CENTURY

The century number.

The first century starts at 0001-01-01 00:00:00 AD. This definition applies to all Gregorian calendar countries. There is no century number 0, you go from -1 to 1.

DAY

The day (of the month) field (1–31).

DECADE

The year field divided by 10.

DOQ

The day within the current quarter. DOQ recognizes leap year days.

DOW

Zero-based day of the week, where Sunday=0.

Note

EXTRACT's day of week numbering differs from the function [TO_CHAR](#).

DOY

The day of the year (1–365/366)

EPOCH

Specifies to return one of the following:

- For [DATE](#) and [TIMESTAMP](#) values: the number of seconds before or since 1970-01-01 00:00:00-00 (if before, a negative number).
- For [INTERVAL](#) values, the total number of seconds in the interval.

HOUR

The hour field (0–23).

ISODOW

The ISO day of the week, an integer between 1 and 7 where Monday is 1.

ISOWEEK

The ISO week of the year, an integer between 1 and 53.

ISOYEAR

The ISO year.

MICROSECONDS

The seconds field, including fractional parts, multiplied by 1,000,000. This includes full seconds.

MILLENNIUM

The millennium number, where the first millennium is 1 and each millenium starts on **01-01- y001** . For example, millennium 2 starts on 01-01-1001.

MILLISECONDS

The seconds field, including fractional parts, multiplied by 1000. This includes full seconds.

MINUTE

The minutes field (0 - 59).

MONTH

For **TIMESTAMP** values, the number of the month within the year (1 - 12) ; for **interval** values the number of months, modulo 12 (0 - 11).

QUARTER

The calendar quarter of the specified date as an integer, where the January-March quarter is 1, valid only for **TIMESTAMP** values.

SECOND

The seconds field, including fractional parts, 0–59, or 0-60 if the operating system implements leap seconds.

TIME_ZONE

The time zone offset from UTC, in seconds. Positive values correspond to time zones east of UTC, negative values to zones west of UTC.

TIMEZONE_HOUR

The hour component of the time zone offset.

TIMEZONE_MINUTE

The minute component of the time zone offset.

WEEK

The number of the week of the calendar year that the day is in.

YEAR

The year field. There is no **0 AD** , so subtract **BC** years from **AD** years accordingly.

Examples

Extract the day of the week and day in quarter from the current **TIMESTAMP**:

```

=> SELECT CURRENT_TIMESTAMP AS NOW;
      NOW
-----
2016-05-03 11:36:08.829004-04
(1 row)
=> SELECT EXTRACT (DAY FROM CURRENT_TIMESTAMP);
 date_part
-----
        3
(1 row)
=> SELECT EXTRACT (DOQ FROM CURRENT_TIMESTAMP);
 date_part
-----
       33
(1 row)

```

Extract the timezone hour from the current time:

```
=> SELECT CURRENT_TIMESTAMP;  
      ?column?
```

```
-----  
2016-05-03 11:36:08.829004-04
```

```
(1 row)
```

```
=> SELECT EXTRACT(TIMEZONE_HOUR FROM CURRENT_TIMESTAMP);  
date_part
```

```
-----  
-4
```

```
(1 row)
```

Extract the number of seconds since 01-01-1970 00:00:

```
=> SELECT EXTRACT(EPOCH FROM '2001-02-16 20:38:40-08'::TIMESTAMPTZ);  
date_part
```

```
-----  
982384720.000000
```

```
(1 row)
```

Extract the number of seconds between 01-01-1970 00:00 and 5 days 3 hours before:

```
=> SELECT EXTRACT(EPOCH FROM '-5 days 3 hours'::INTERVAL);  
date_part
```

```
-----  
-442800.000000
```

```
(1 row)
```

Convert the results from the last example to a `TIMESTAMP`:

```
=> SELECT 'EPOCH'::TIMESTAMPTZ -442800 * '1 second'::INTERVAL;  
      ?column?
```

```
-----  
1969-12-26 16:00:00-05
```

```
(1 row)
```

GETDATE

Returns the current statement's start date and time as a `TIMESTAMP` value. This function is identical to [SYSDATE](#).

`GETDATE` uses the date and time supplied by the operating system on the server to which you are connected, which is the same across all servers.

Internally, `GETDATE` converts [STATEMENT_TIMESTAMP](#) from `TIMESTAMPTZ` to `TIMESTAMP`.

Behavior type

[Stable](#)

Syntax

```
GETDATE()
```

Examples

```
=> SELECT GETDATE();  
      GETDATE
```

```
-----  
2011-03-07 13:21:29.497742
```

```
(1 row)
```

See also

[Date/time expressions](#)

`GETUTCDATE`

Returns the current statement's start date and time as a `TIMESTAMP` value.

`GETUTCDATE` uses the date and time supplied by the operating system on the server to which you are connected, which is the same across all servers. Internally, `GETUTCDATE` converts [STATEMENT_TIMESTAMP](#) at TIME ZONE 'UTC'.

Behavior type

[Stable](#)

Syntax

```
GETUTCDATE()
```

Examples

```
=> SELECT GETUTCDATE();
      GETUTCDATE
-----
2011-03-07 20:20:26.193052
(1 row)
```

See also

- [Date/time expressions](#)

HOUR

Returns the hour portion of the specified date as an integer, where 0 is 00:00 to 00:59.

Behavior type

- [Immutable](#) if the specified date is a **TIMESTAMP**
- [Stable](#) if the specified date is a **TIMESTAMPTZ**

Syntax

```
HOUR( date )
```

Parameters

date

The date to process, one of the following data types:

- [VARCHAR](#)
- [DATE](#)
- [TIMESTAMP](#)
- [TIMESTAMPTZ](#)

- [INTERVAL](#)

Examples

```
=> SELECT HOUR (TIMESTAMP 'sep 22, 2011 12:34');
      HOUR
-----
      12
(1 row)
=> SELECT HOUR (INTERVAL '35 12:34');
      HOUR
-----
      12
(1 row)
=> SELECT HOUR ('12:34');
      HOUR
-----
      12
(1 row)
```

ISFINITE

Tests for the special **TIMESTAMP** constant **INFINITY** and returns a value of type **BOOLEAN**.

Behavior type

[Immutable](#)

Syntax

```
ISFINITE ( timestamp )
```

Parameters

timestamp

Expression of type `TIMESTAMP`

Examples

```
SELECT ISFINITE(TIMESTAMP '2009-02-16 21:28:30');
ISFINITE
-----
t
(1 row)
SELECT ISFINITE(TIMESTAMP 'INFINITY');
ISFINITE
-----
f
(1 row)
```

JULIAN_DAY

Returns the integer value of the specified day according to the Julian calendar, where day 1 is the first day of the Julian period, January 1, 4713 BC (on the Gregorian calendar, November 24, 4714 BC).

Behavior type

- [Immutable](#) if the specified date is a `TIMESTAMP`, `DATE`, or `VARCHAR`
- [Stable](#) if the specified date is a `TIMESTAMPTZ`

Syntax

```
JULIAN_DAY ( date )
```

Parameters

date

The date to process, one of the following data types:

- [VARCHAR](#)
- [DATE](#)
- [TIMESTAMP](#)
- [TIMESTAMPTZ](#)

Examples

```
=> SELECT JULIAN_DAY (DATE 'MARCH 15, 0044 BC');
JULIAN_DAY
-----
 1705428
(1 row)
=> SELECT JULIAN_DAY (DATE '2001-01-01');
JULIAN_DAY
-----
 2451911
(1 row)
```

LAST_DAY

Returns the last day of the month in the specified date.

Behavior type

- [Immutable](#) if the specified is a `TIMESTAMP` or `DATE`
- [Stable](#) if the specified date is a `TIMESTAMPTZ`

Syntax

```
LAST_DAY ( date )
```

Parameters

date

The date to process, one of the following data types:

- [DATE](#)
- [TIMESTAMP](#)
- [TIMESTAMPTZ](#)

Calculating first day of month

SQL does not support any function that returns the first day in the month of a given date. You must use other functions to work around this limitation. For example:

```
=> SELECT DATE ('2022/07/04') - DAYOFMONTH ('2022/07/04') +1;
?column?
-----
2022-07-01
(1 row)

=> SELECT LAST_DAY('1929/06/06') - (SELECT DAY(LAST_DAY('1929/06/06'))-1);
?column?
-----
1929-06-01
(1 row)
```

Examples

The following example returns the last day of February as 29 because 2016 is a leap year:

```
=> SELECT LAST_DAY('2016-02-28 23:30 PST') "Last Day";
Last Day
-----
2016-02-29
(1 row)
```

The following example returns the last day of February in a non-leap year:

```
> SELECT LAST_DAY('2017/02/03') "Last";
Last
-----
2017-02-28
(1 row)
```

The following example returns the last day of March, after converting the string value to the specified DATE type:

```
=> SELECT LAST_DAY('2003/03/15') "Last";
Last
-----
2012-03-31
(1 row)
```

LOCALTIME

Returns a value of type **TIME** that represents the start of the current transaction.

The return value does not change during the transaction. Thus, multiple calls to **LOCALTIME** within the same transaction return the same timestamp.

Behavior type

[Stable](#)

Syntax

```
LOCALTIME [ ( precision ) ]
```

Parameters

precision

Rounds the result to the specified number of fractional digits in the seconds field.

Examples

```

=> CREATE TABLE t1 (a int, b int);
CREATE TABLE

=> INSERT INTO t1 VALUES (1,2);
OUTPUT
-----
 1
(1 row)

=> SELECT LOCALTIME time;
  time
-----
15:03:14.595296
(1 row)

=> INSERT INTO t1 VALUES (3,4);
OUTPUT
-----
 1
(1 row)

=> SELECT LOCALTIME;
  time
-----
15:03:14.595296
(1 row)

=> COMMIT;
COMMIT

=> SELECT LOCALTIME;
  time
-----
15:03:49.738032
(1 row)

```

LOCALTIMESTAMP

Returns a value of type [TIMESTAMP/TIMESTAMPZ](#) that represents the start of the current transaction, and remains unchanged until the transaction is closed. Thus, multiple calls to LOCALTIMESTAMP within a given transaction return the same timestamp.

Behavior type

[Stable](#)

Syntax

```
LOCALTIMESTAMP [ ( precision ) ]
```

Parameters

precision

Rounds the result to the specified number of fractional digits in the seconds field.

Examples

```
=> CREATE TABLE t1 (a int, b int);
CREATE TABLE
=> INSERT INTO t1 VALUES (1,2);
OUTPUT
```

```
-----
1
(1 row)
```

```
=> SELECT LOCALTIMESTAMP(2) AS 'local timestamp';
local timestamp
```

```
-----
2021-03-05 10:48:58.26
(1 row)
```

```
=> INSERT INTO t1 VALUES (3,4);
OUTPUT
```

```
-----
1
(1 row)
```

```
=> SELECT LOCALTIMESTAMP(2) AS 'local timestamp';
local timestamp
```

```
-----
2021-03-05 10:48:58.26
(1 row)
```

```
=> COMMIT;
COMMIT
```

```
=> SELECT LOCALTIMESTAMP(2) AS 'local timestamp';
local timestamp
```

```
-----
2021-03-05 10:50:08.99
(1 row)
```

MICROSECOND

Returns the microsecond portion of the specified date as an integer.

Behavior type

- [Immutable](#) if the specified date is a [TIMESTAMP](#), [INTERVAL](#), or [VARCHAR](#)
- [Stable](#) if the specified date is a [TIMESTAMP TZ](#)

Syntax

```
MICROSECOND ( date )
```

Parameters

date

The date to process, one of the following data types:

- [VARCHAR](#)
- [TIMESTAMP](#)
- [TIMESTAMP TZ](#)
- [INTERVAL](#)

Examples

```
=> SELECT MICROSECOND (TIMESTAMP 'Sep 22, 2011 12:34:01.123456');
MICROSECOND
```

```
-----
123456
(1 row)
```

MIDNIGHT_SECONDS

Within the specified date, returns the number of seconds between midnight and the date's time portion.

Behavior type

- [Immutable](#) if the specified date is a **TIMESTAMP**, **DATE**, or **VARCHAR**
- [Stable](#) if the specified date is a **TIMESTAMPTZ**

Syntax

```
MIDNIGHT_SECONDS ( date )
```

Parameters

date

The date to process, one of the following data types:

- [VARCHAR](#)
- [DATE](#)
- [TIMESTAMP](#)
- [TIMESTAMPTZ](#)

Examples

Get the number of seconds since midnight:

```
=> SELECT MIDNIGHT_SECONDS(CURRENT_TIMESTAMP);
MIDNIGHT_SECONDS
-----
          36480
(1 row)
```

Get the number of seconds between midnight and noon on March 3 2016:

```
=> SELECT MIDNIGHT_SECONDS('3-3-2016 12:00'::TIMESTAMP);
MIDNIGHT_SECONDS
-----
          43200
(1 row)
```

MINUTE

Returns the minute portion of the specified date as an integer.

Behavior type

- [Immutable](#) if the specified date is a **TIMESTAMP**, **DATE**, **VARCHAR** or **INTERVAL**
- [Stable](#) if the specified date is a **TIMESTAMPTZ**

Syntax

```
MINUTE ( date )
```

Parameters

date

The date to process, one of the following data types:

- [VARCHAR](#)
- [DATE](#)
- [TIMESTAMP](#)
- [TIMESTAMPTZ](#)
- [INTERVAL](#)

Examples

```
=> SELECT MINUTE('12:34:03.456789');
```

```
MINUTE
```

```
-----  
34
```

```
(1 row)
```

```
=> SELECT MINUTE (TIMESTAMP 'sep 22, 2011 12:34');
```

```
MINUTE
```

```
-----  
34
```

```
(1 row)
```

```
=> SELECT MINUTE(INTERVAL '35 12:34:03.456789');
```

```
MINUTE
```

```
-----  
34
```

```
(1 row)
```

MONTH

Returns the month portion of the specified date as an integer.

Behavior type

- [Immutable](#) if the specified date is a [TIMESTAMP](#), [DATE](#), [VARCHAR](#) or [INTERVAL](#)
- [Stable](#) if the specified date is a [TIMESTAMPTZ](#)

Syntax

```
MONTH ( date )
```

Parameters

date

The date to process, one of the following data types:

- [VARCHAR](#)
- [DATE](#)
- [TIMESTAMP](#)
- [TIMESTAMPTZ](#)
- [INTERVAL](#)

Examples

In the following examples, Vertica returns the month portion of the specified string. For example, '6-9' represent September 6.

```
=> SELECT MONTH('6-9');
```

```
MONTH
```

```
-----  
9
```

```
(1 row)
```

```
=> SELECT MONTH (TIMESTAMP 'sep 22, 2011 12:34');
```

```
MONTH
```

```
-----  
9
```

```
(1 row)
```

```
=> SELECT MONTH(INTERVAL '2-35' year to month);
```

```
MONTH
```

```
-----  
11
```

```
(1 row)
```

MONTHS_BETWEEN

Returns the number of months between two dates. [MONTHS_BETWEEN](#) can return an integer or a [FLOAT](#):

- Integer: The day portions of *date1* and *date2* are the same, and neither date is the last day of the month. **MONTHS_BETWEEN** also returns an integer if both dates in *date1* and *date2* are the last days of their respective months. For example, **MONTHS_BETWEEN** calculates the difference between April 30 and March 31 as 1 month.
- FLOAT: The day portions of *date1* and *date2* are different and one or both dates are not the last day of their respective months. For example, the difference between April 2 and March 1 is 1.03225806451613 . To calculate month fractions, **MONTHS_BETWEEN** assumes all months contain 31 days.

MONTHS_BETWEEN disregards timestamp time portions.

Behavior type

- [Immutable](#) if both date arguments are of data type **TIMESTAMP** or **DATE**
- [Stable](#) if either date is a **TIMESTAMPTZ**

Syntax

```
MONTHS_BETWEEN ( date1 , date2 );
```

Parameters

date1

date2

Specify the dates to evaluate where *date1* and *date2* evaluate to one of the following data types:

- **DATE**
- **TIMESTAMP**
- **TIMESTAMPTZ**

If *date1* < *date2* , **MONTHS_BETWEEN** returns a negative value.

Examples

Return the number of months between April 7 2016 and January 7 2015:

```
=> SELECT MONTHS_BETWEEN ('04-07-16'::TIMESTAMP, '01-07-15'::TIMESTAMP);
MONTHS_BETWEEN
-----
          15
(1 row)
```

Return the number of months between March 31 2016 and February 28 2016 (**MONTHS_BETWEEN** assumes both months contain 31 days):

```
=> SELECT MONTHS_BETWEEN ('03-31-16'::TIMESTAMP, '02-28-16'::TIMESTAMP);
MONTHS_BETWEEN
-----
1.09677419354839
(1 row)
```

Return the number of months between March 31 2016 and February 29 2016:

```
=> SELECT MONTHS_BETWEEN ('03-31-16'::TIMESTAMP, '02-29-16'::TIMESTAMP);
MONTHS_BETWEEN
-----
          1
(1 row)
```

NEW_TIME

Converts a timestamp value from one time zone to another and returns a **TIMESTAMP**.

Behavior type

[Immutable](#)

Syntax

```
NEW_TIME( 'timestamp' , 'timezone1' , 'timezone2')
```

Parameters

timestamp

The timestamp to convert, conforms to one of the following formats:

- [TIMESTAMP](#) / [TIMESTAMPTZ](#)
- [DATE](#)
- Character string that can be converted to a [TIMESTAMP](#) —for example, [May 24, 2012 10:00](#) .

timezone1

timezone2

Specify the source and target timezones, one of the strings defined in `/opt/vertica/share/timezonesets` . For example:

- [GMT](#) : Greenwich Mean Time
- [AST](#) / [ADT](#) : Atlantic Standard/Daylight Time
- [EST](#) / [EDT](#) : Eastern Standard/Daylight Time
- [CST](#) / [CDT](#) : Central Standard/Daylight Time
- [MST](#) / [MDT](#) : Mountain Standard/Daylight Time
- [PST](#) / [PDT](#) : Pacific Standard/Daylight Time

Examples

Convert the specified time from Eastern Standard Time (EST) to Pacific Standard Time (PST):

```
=> SELECT NEW_TIME('05-24-12 13:48:00', 'EST', 'PST');
NEW_TIME
-----
2012-05-24 10:48:00
(1 row)
```

Convert 1:00 AM January 2012 from EST to PST:

```
=> SELECT NEW_TIME('01-01-12 01:00:00', 'EST', 'PST');
NEW_TIME
-----
2011-12-31 22:00:00
(1 row)
```

Convert the current time EST to PST:

```
=> SELECT NOW();
NOW
-----
2016-12-09 10:30:36.727307-05
(1 row)

=> SELECT NEW_TIME('NOW', 'EDT', 'CDT');
NEW_TIME
-----
2016-12-09 09:30:36.727307
(1 row)
```

The following example returns the year 45 before the Common Era in Greenwich Mean Time and converts it to Newfoundland Standard Time:

```
=> SELECT NEW_TIME('April 1, 45 BC', 'GMT', 'NST')::DATE;
NEW_TIME
-----
0045-03-31 BC
(1 row)
```

NEXT_DAY

Returns the date of the first instance of a particular day of the week that follows the specified date.

Behavior type

- [Immutable](#) if the specified date is a [TIMESTAMP](#) , [DATE](#) , or [VARCHAR](#)
- [Stable](#) if the specified date is a [TIMESTAMPTZ](#)

Syntax

```
NEXT_DAY( 'date', 'day-string')
```

Parameters

date

The date to process, one of the following data types:

- [VARCHAR](#)
- [DATE](#)
- [TIMESTAMP](#)
- [TIMESTAMPTZ](#)

day-string

The day of the week to process, a CHAR or VARCHAR string or character constant. Supply the full English name such as Tuesday, or any conventional abbreviation, such as Tue or Tues. *day-string* is not case sensitive and trailing spaces are ignored.

Examples

Get the date of the first Monday that follows April 29 2016:

```
=> SELECT NEXT_DAY('4-29-2016'::TIMESTAMP,'Monday') "NEXT DAY" ;
NEXT DAY
-----
2016-05-02
(1 row)
```

Get the first Tuesday that follows today:

```
SELECT NEXT_DAY(CURRENT_TIMESTAMP,'tues') "NEXT DAY" ;
NEXT DAY
-----
2016-05-03
(1 row)
```

NOW [date/time]

Returns a value of type [TIMESTAMP WITH TIME ZONE](#) representing the start of the current transaction. NOW is equivalent to [CURRENT_TIMESTAMP](#) except that it does not accept a precision parameter.

The return value does not change during the transaction. Thus, multiple calls to [CURRENT_TIMESTAMP](#) within the same transaction return the same timestamp.

Behavior type

[Stable](#)

Syntax

```
NOW()
```

Examples

```

=> CREATE TABLE t1 (a int, b int);
CREATE TABLE
=> INSERT INTO t1 VALUES (1,2);
OUTPUT
-----
      1
(1 row)

=> SELECT NOW();
      NOW
-----
2016-12-09 13:00:08.74685-05
(1 row)

=> INSERT INTO t1 VALUES (3,4);
OUTPUT
-----
      1
(1 row)

=> SELECT NOW();
      NOW
-----
2016-12-09 13:00:08.74685-05
(1 row)

=> COMMIT;
COMMIT
dbadmin=> SELECT NOW();
      NOW
-----
2016-12-09 13:01:31.420624-05
(1 row)

```

OVERLAPS

Evaluates two time periods and returns true when they overlap, false otherwise.

Behavior type

- [Stable](#) when **TIMESTAMP** and **TIMESTAMPTZ** are both used, or when **TIMESTAMPTZ** is used with **INTERVAL**
- [Immutable](#) otherwise

Syntax

```

( start, end ) OVERLAPS ( start, end )
( start, interval ) OVERLAPS ( start, interval )

```

Parameters

- start**
DATE , **TIME** , or **TIMESTAMP** / **TIMESTAMPTZ** value that specifies the beginning of a time period.
- end**
DATE , **TIME** , or **TIMESTAMP** / **TIMESTAMPTZ** value that specifies the end of a time period.
- interval**
Value that specifies the length of the time period.

Examples

Evaluate whether date ranges Feb 16 - Dec 21, 2016 and Oct 10 2008 - Oct 3 2016 overlap:

```
=> SELECT (DATE '2016-02-16', DATE '2016-12-21') OVERLAPS (DATE '2008-10-30', DATE '2016-10-30');
overlaps
-----
t
(1 row)
```

Evaluate whether date ranges Feb 16 - Dec 21, 2016 and Jan 01 - Oct 30 2008 - Oct 3, 2016 overlap:

```
=> SELECT (DATE '2016-02-16', DATE '2016-12-21') OVERLAPS (DATE '2008-01-30', DATE '2008-10-30');
overlaps
-----
f
(1 row)
```

Evaluate whether date range Feb 02 2016 + 1 week overlaps with date range Oct 16 2016 - 8 months:

```
=> SELECT (DATE '2016-02-16', INTERVAL '1 week') OVERLAPS (DATE '2016-10-16', INTERVAL '-8 months');
overlaps
-----
t
(1 row)
```

QUARTER

Returns calendar quarter of the specified date as an integer, where the January-March quarter is 1.

Syntax

```
QUARTER ( date )
```

Behavior type

- [Immutable](#) if the specified date is a **TIMESTAMP**, **DATE**, or **VARCHAR**.
- [Stable](#) if the specified date is a **TIMESTAMPTZ**.

Parameters

date

The date to process, one of the following data types:

- [VARCHAR](#)
- [DATE](#)
- [TIMESTAMP](#)
- [TIMESTAMPTZ](#)

Examples

```
=> SELECT QUARTER (TIMESTAMP 'sep 22, 2011 12:34');
QUARTER
-----
3
(1 row)
```

ROUND

Rounds the specified date or time. If you omit the precision argument, **ROUND** rounds to day (**DD**) precision.

Behavior type

- [Immutable](#) if the target date is a **TIMESTAMP** or **DATE**.
- [Stable](#) if the target date is a **TIMESTAMPTZ**.

Syntax

```
ROUND( rounding-target [, 'precision'] )
```

Parameters

* **rounding-target** *

An expression that evaluates to one of the following data types:

- [DATE](#)
- [TIMESTAMP/TIMESTAMPTZ](#)
- [TIMESTAMPTZ](#)

precision

A string constant that specifies precision for the rounded value, one of the following:

- **Century** : [CC](#) | [SCC](#)
- **Year** : [SYYY](#) | [YYYY](#) | [YEAR](#) | [YYY](#) | [YY](#) | [Y](#)
- **ISO Year** : [IYYY](#) | [IYY](#) | [IY](#) | [I](#)
- **Quarter** : [Q](#)
- **Month** : [MONTH](#) | [MON](#) | [MM](#) | [RM](#)
- **Same weekday as first day of year** : [WW](#)
- **Same weekday as first day of ISO year** : [IW](#)
- **Same weekday as first day of month** : [W](#)
- **Day** (default): [DDD](#) | [DD](#) | [J](#)
- **First weekday** : [DAY](#) | [DY](#) | [D](#)
- **Hour** : [HH](#) | [HH12](#) | [HH24](#)
- **Minute** : [MI](#)
- **Second** : [SS](#)

Note

Hour, minute, and second rounding is not supported by [DATE](#) expressions.

Examples

Round to the nearest hour:

```
=> SELECT ROUND(CURRENT_TIMESTAMP, 'HH');
       ROUND
-----
2016-04-28 15:00:00
(1 row)
```

Round to the nearest month:

```
=> SELECT ROUND('9-22-2011 12:34:00'::TIMESTAMP, 'MM');
       ROUND
-----
2011-10-01 00:00:00
(1 row)
```

See also

[TIMESTAMP_ROUND](#)

[SECOND](#)

Returns the seconds portion of the specified date as an integer.

Syntax

```
SECOND ( date )
```

Behavior type

[Immutable](#), except for [TIMESTAMPTZ](#) arguments where it is [stable](#).

Parameters

date

The date to process, one of the following data types:

- [VARCHAR](#)
- [TIMESTAMP](#)
- [TIMESTAMPTZ](#)
- [INTERVAL](#)

Examples

```
=> SELECT SECOND ('23:34:03.456789');
```

```
SECOND
```

```
-----  
3
```

```
(1 row)
```

```
=> SELECT SECOND (TIMESTAMP 'sep 22, 2011 12:34');
```

```
SECOND
```

```
-----  
0
```

```
(1 row)
```

```
=> SELECT SECOND (INTERVAL '35 12:34:03.456789');
```

```
SECOND
```

```
-----  
3
```

```
(1 row)
```

STATEMENT_TIMESTAMP

Similar to [TRANSACTION_TIMESTAMP](#), returns a value of type **TIMESTAMP WITH TIME ZONE** that represents the start of the current statement.

The return value does not change during statement execution. Thus, different stages of statement execution always have the same timestamp.

Behavior type

[Stable](#)

Syntax

```
STATEMENT_TIMESTAMP()
```

Examples

```
=> SELECT foo, bar FROM (SELECT STATEMENT_TIMESTAMP() AS foo)foo, (SELECT STATEMENT_TIMESTAMP() as bar)bar;
```

```
      foo      |      bar
```

```
-----+-----
```

```
2016-12-07 14:55:51.543988-05 | 2016-12-07 14:55:51.543988-05
```

```
(1 row)
```

See also

- [CLOCK_TIMESTAMP](#)
- [TRANSACTION_TIMESTAMP](#)

SYSDATE

Returns the current statement's start date and time as a **TIMESTAMP** value. This function is identical to [GETDATE](#).

SYSDATE uses the date and time supplied by the operating system on the server to which you are connected, which is the same across all servers.

Internally, [GETDATE](#) converts [STATEMENT_TIMESTAMP](#) from **TIMESTAMPZ** to **TIMESTAMP**.

Behavior type

[Stable](#)

Syntax

```
SYSDATE()
```

Note

You can call this function with no parentheses.

Examples

```
=> SELECT SYSDATE;
```

```
      sysdate
```

```
-----
```

```
2016-12-12 06:11:10.699642
```

```
(1 row)
```

[Date/time expressions](#)

TIME_SLICE

Aggregates data by different fixed-time intervals and returns a rounded-up input **TIMESTAMP** value to a value that corresponds with the start or end of the time slice interval.

Given an input **TIMESTAMP** value such as **2000-10-28 00:00:01** , the start time of a 3-second time slice interval is **2000-10-28 00:00:00** , and the end time of the same time slice is **2000-10-28 00:00:03** .

Behavior type

[Immutable](#)

Syntax

```
TIME_SLICE( expression, slice-length [, 'time-unit ' [, 'start-or-end' ] ] )
```

Parameters

expression

One of the following:

- Column of type **TIMESTAMP**
- String constant that can be parsed into a **TIMESTAMP** value. For example:
'2004-10-19 10:23:54'

Vertica evaluates *expression* on each row.

slice-length

A positive integer that specifies the slice length.

time-unit

Time unit of the slice, one of the following:

- **HOUR**
- **MINUTE**
- **SECOND** (default)
- **MILLISECOND**
- **MICROSECOND**

start-or-end

Specifies whether the returned value corresponds to the start or end time with one of the following strings:

- **START** (default)
- **END**

Note

This parameter can be included only if you also supply a non-null *time-unit* argument.

Null argument handling

TIME_SLICE handles null arguments as follows:

- **TIME_SLICE** returns an error when any one of *slice-length* , *time-unit* , or *start-or-end* parameters is null.
- If *expression* is null and **slice-length ** , **time-unit ** , or **start-or-end ** contain legal values, **TIME_SLICE** returns a NULL value instead of an error.

Usage

The following command returns the (default) start time of a 3-second time slice:

```
=> SELECT TIME_SLICE('2009-09-19 00:00:01', 3);
   TIME_SLICE
-----
2009-09-19 00:00:00
(1 row)
```

The following command returns the end time of a 3-second time slice:

```
=> SELECT TIME_SLICE('2009-09-19 00:00:01', 3, 'SECOND', 'END');
       TIME_SLICE
-----
2009-09-19 00:00:03
(1 row)
```

This command returns results in milliseconds, using a 3-second time slice:

```
=> SELECT TIME_SLICE('2009-09-19 00:00:01', 3, 'ms');
       TIME_SLICE
-----
2009-09-19 00:00:00.999
(1 row)
```

This command returns results in microseconds, using a 9-second time slice:

```
=> SELECT TIME_SLICE('2009-09-19 00:00:01', 3, 'us');
       TIME_SLICE
-----
2009-09-19 00:00:00.999999
(1 row)
```

The next example uses a 3-second interval with an input value of '00:00:01'. To focus specifically on seconds, the example omits date, though all values are implied as being part of the timestamp with a given input of '00:00:01':

- '00:00: **00** ' is the start of the 3-second time slice
- '00:00: **03** ' is the end of the 3-second time slice.
- '00:00:03' is also the start of the *second* 3-second time slice. In time slice boundaries, the end value of a time slice does not belong to that time slice; it starts the next one.

When the time slice interval is not a factor of 60 seconds, such as a given slice length of 9 in the following example, the slice does not always start or end on 00 seconds:

```
=> SELECT TIME_SLICE('2009-02-14 20:13:01', 9);
       TIME_SLICE
-----
2009-02-14 20:12:54
(1 row)
```

This is expected behavior, as the following properties are true for all time slices:

- Equal in length
- Consecutive (no gaps between them)
- Non-overlapping

To force the above example ('2009-02-14 20:13:01') to start at '2009-02-14 20:13:00', adjust the output timestamp values so that the remainder of 54 counts up to 60:

```
=> SELECT TIME_SLICE('2009-02-14 20:13:01', 9)+'6 seconds'::INTERVAL AS time;
       time
-----
2009-02-14 20:13:00
(1 row)
```

Alternatively, you could use a different slice length, which is divisible by 60, such as 5:

```
=> SELECT TIME_SLICE('2009-02-14 20:13:01', 5);
       TIME_SLICE
-----
2009-02-14 20:13:00
(1 row)
```

A TIMESTAMPTZ value is implicitly cast to TIMESTAMP. For example, the following two statements have the same effect.

```
=> SELECT TIME_SLICE('2009-09-23 11:12:01'::timestampz, 3);
```

```
TIME_SLICE
```

```
-----  
2009-09-23 11:12:00
```

```
(1 row)
```

```
=> SELECT TIME_SLICE('2009-09-23 11:12:01'::timestampz::timestamp, 3);
```

```
TIME_SLICE
```

```
-----  
2009-09-23 11:12:00
```

```
(1 row)
```

Examples

You can use the SQL analytic functions [FIRST_VALUE](#) and [LAST_VALUE](#) to find the first/last price within each time slice group (set of rows belonging to the same time slice). This structure can be useful if you want to sample input data by choosing one row from each time slice group.

```
=> SELECT date_key, transaction_time, sales_dollar_amount, TIME_SLICE(DATE '2000-01-01' + date_key + transaction_time, 3),  
FIRST_VALUE(sales_dollar_amount)  
OVER (PARTITION BY TIME_SLICE(DATE '2000-01-01' + date_key + transaction_time, 3)  
ORDER BY DATE '2000-01-01' + date_key + transaction_time) AS first_value  
FROM store.store_sales_fact  
LIMIT 20;
```

```
date_key | transaction_time | sales_dollar_amount | time_slice | first_value
```

```
-----+-----+-----+-----+-----  
1 | 00:41:16 | 164 | 2000-01-02 00:41:15 | 164  
1 | 00:41:33 | 310 | 2000-01-02 00:41:33 | 310  
1 | 15:32:51 | 271 | 2000-01-02 15:32:51 | 271  
1 | 15:33:15 | 419 | 2000-01-02 15:33:15 | 419  
1 | 15:33:44 | 193 | 2000-01-02 15:33:42 | 193  
1 | 16:36:29 | 466 | 2000-01-02 16:36:27 | 466  
1 | 16:36:44 | 250 | 2000-01-02 16:36:42 | 250  
2 | 03:11:28 | 39 | 2000-01-03 03:11:27 | 39  
3 | 03:55:15 | 375 | 2000-01-04 03:55:15 | 375  
3 | 11:58:05 | 369 | 2000-01-04 11:58:03 | 369  
3 | 11:58:24 | 174 | 2000-01-04 11:58:24 | 174  
3 | 11:58:52 | 449 | 2000-01-04 11:58:51 | 449  
3 | 19:01:21 | 201 | 2000-01-04 19:01:21 | 201  
3 | 22:15:05 | 156 | 2000-01-04 22:15:03 | 156  
4 | 13:36:57 | -125 | 2000-01-05 13:36:57 | -125  
4 | 13:37:24 | -251 | 2000-01-05 13:37:24 | -251  
4 | 13:37:54 | 353 | 2000-01-05 13:37:54 | 353  
4 | 13:38:04 | 426 | 2000-01-05 13:38:03 | 426  
4 | 13:38:31 | 209 | 2000-01-05 13:38:30 | 209  
5 | 10:21:24 | 488 | 2000-01-06 10:21:24 | 488
```

```
(20 rows)
```

TIME_SLICE rounds the transaction time to the 3-second slice length.

The following example uses the [analytic \(window\) OVER clause](#) to return the last trading price (the last row ordered by TickTime) in each 3-second time slice partition:

```
=> SELECT DISTINCT TIME_SLICE(TickTime, 3), LAST_VALUE(price)OVER (PARTITION BY TIME_SLICE(TickTime, 3)  
ORDER BY TickTime ROWS BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING);
```

Note

If you omit the windowing clause from an analytic clause, **LAST_VALUE** defaults to **RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW**. Results can seem non-intuitive, because instead of returning the value from the bottom of the current partition, the function returns the bottom of the *window*, which continues to change along with the current input row that is being processed. For more information,

see [Time series analytics](#) and [SQL analytics](#).

In the next example, **FIRST_VALUE** is evaluated once for each input record and the data is sorted by ascending values. Use **SELECT DISTINCT** to remove the duplicates and return only one output record per **TIME_SLICE** :

```
=> SELECT DISTINCT TIME_SLICE(TickTime, 3), FIRST_VALUE(price)OVER (PARTITION BY TIME_SLICE(TickTime, 3)
ORDER BY TickTime ASC)
FROM tick_store;
  TIME_SLICE  | ?column?
-----+-----
2009-09-21 00:00:06 | 20.00
2009-09-21 00:00:09 | 30.00
2009-09-21 00:00:00 | 10.00
(3 rows)
```

The information output by the above query can also return **MIN** , **MAX** , and **AVG** of the trading prices within each time slice.

```
=> SELECT DISTINCT TIME_SLICE(TickTime, 3),FIRST_VALUE(Price) OVER (PARTITION BY TIME_SLICE(TickTime, 3)
ORDER BY TickTime ASC),
  MIN(price) OVER (PARTITION BY TIME_SLICE(TickTime, 3)),
  MAX(price) OVER (PARTITION BY TIME_SLICE(TickTime, 3)),
  AVG(price) OVER (PARTITION BY TIME_SLICE(TickTime, 3))
FROM tick_store;
```

TIMEOFDAY

Returns the wall-clock time as a text string. Function results advance during transactions.

Behavior type

[Volatile](#)

Syntax

```
TIMEOFDAY()
```

Examples

```
=> SELECT TIMEOFDAY();
      TIMEOFDAY
-----
Mon Dec 12 08:18:01.022710 2016 EST
(1 row)
```

TIMESTAMP_ROUND

Rounds the specified **TIMESTAMP**. If you omit the precision argument, **TIMESTAMP_ROUND** rounds to day (**DD**) precision.

Behavior type

- [Immutable](#) if the target date is a **TIMESTAMP**
- [Stable](#) if the target date is a **TIMESTAMPPTZ**

Syntax

```
TIMESTAMP_ROUND ( rounding-target [, 'precision'] )
```

Parameters

rounding-target

An expression that evaluates to one of the following data types:

- [TIMESTAMP/TIMESTAMPTZ](#)
- [TIMESTAMPTZ](#)

precision

A string constant that specifies precision for the rounded value, one of the following:

- **Century** : [CC](#) | [SCC](#)
- **Year** : [SYYYY](#) | [YYYY](#) | [YEAR](#) | [YYY](#) | [YY](#) | [Y](#)
- **ISO Year** : [IYYY](#) | [IYY](#) | [IY](#) | [I](#)
- **Quarter** : [Q](#)
- **Month** : [MONTH](#) | [MON](#) | [MM](#) | [RM](#)
- **Same weekday as first day of year** : [WW](#)
- **Same weekday as first day of ISO year** : [IW](#)
- **Same weekday as first day of month** : [W](#)
- **Day** (default): [DDD](#) | [DD](#) | [J](#)
- **First weekday** : [DAY](#) | [DY](#) | [D](#)
- **Hour** : [HH](#) | [HH12](#) | [HH24](#)
- **Minute** : [MI](#)
- **Second** : [SS](#)

Note

Hour, minute, and second rounding is not supported by [DATE](#) expressions.

Examples

Round to the nearest hour:

```
=> SELECT TIMESTAMP_ROUND(CURRENT_TIMESTAMP, 'HH');
      ROUND
-----
2016-04-28 15:00:00
(1 row)
```

Round to the nearest month:

```
=> SELECT TIMESTAMP_ROUND('9-22-2011 12:34:00'::TIMESTAMP, 'MM');
      ROUND
-----
2011-10-01 00:00:00
(1 row)
```

See also

[ROUND](#)

[TIMESTAMP_TRUNC](#)

Truncates the specified [TIMESTAMP](#). If you omit the precision argument, [TIMESTAMP_TRUNC](#) truncates to day ([DD](#)) precision.

Behavior type

- [Immutable](#) if the target date is a [TIMESTAMP](#)
- [Stable](#) if the target date is a [TIMESTAMPTZ](#)

Syntax

```
TIMESTAMP_TRUNC( trunc-target[, 'precision'] )
```

Parameters

trunc-target

An expression that evaluates to one of the following data types:

- [TIMESTAMP/TIMESTAMPTZ](#)
- [TIMESTAMPTZ](#)

precision

A string constant that specifies precision for the truncated value, one of the following:

- **Century** : `CC` | `SCC`
- **Year** : `SYYY` | `YYYY` | `YEAR` | `YYY` | `YY` | `Y`
- **ISO Year** : `IYYY` | `IYY` | `IY` | `I`
- **Quarter** : `Q`
- **Month** : `MONTH` | `MON` | `MM` | `RM`
- **Same weekday as first day of year** : `WW`
- **Same weekday as first day of ISO year** : `IW`
- **Same weekday as first day of month** : `W`
- **Day** : `DDD` | `DD` | `J`
- **First weekday** : `DAY` | `DY` | `D`
- **Hour** : `HH` | `HH12` | `HH24`
- **Minute** : `MI`
- **Second** : `SS`

Note

Hour, minute, and second truncating is not supported by `DATE` expressions.

Examples

Truncate to the current hour:

```
=> SELECT TIMESTAMP_TRUNC(CURRENT_TIMESTAMP, 'HH');
TIMESTAMP_TRUNC
-----
2016-04-29 08:00:00
(1 row)
```

Truncate to the month:

```
=> SELECT TIMESTAMP_TRUNC('9-22-2011 12:34:00'::TIMESTAMP, 'MM');
TIMESTAMP_TRUNC
-----
2011-09-01 00:00:00
(1 row)
```

See also

[TRUNC](#)

[TIMESTAMPADD](#)

Adds the specified number of intervals to a `TIMESTAMP` or `TIMESTAMPTZ` value and returns a result of the same data type.

Behavior type

- [Immutable](#) if the input date is a `TIMESTAMP`
- [Stable](#) if the input date is a `TIMESTAMPTZ`

Syntax

```
TIMESTAMPADD ( datepart, count, start-date );
```

Parameters

datepart

Specifies the type of time intervals that `TIMESTAMPADD` adds to the specified start date. If *datepart* is an expression, it must be enclosed in parentheses:

```
TIMESTAMPADD(expression, interval, start;
```

datepart must evaluate to one of the following string literals, either quoted or unquoted:

- `year` | `yy` | `yyyy`
- `quarter` | `qq` | `q`
- `month` | `mm` | `m`
- `day` | `dayofyear` | `dd` | `d` | `dy` | `y`

- `week` | `wk` | `ww`
- `hour` | `hh`
- `minute` | `mi` | `n`
- `second` | `ss` | `s`
- `millisecond` | `ms`
- `microsecond` | `mcs` | `us`

count

Integer or integer expression that specifies the number of *datepart* intervals to add to *start-date* .

start-date

TIMESTAMP or TIMESTAMPTZ value.

Examples

Add two months to the current date:

```
=> SELECT CURRENT_TIMESTAMP AS Today;
      Today
-----
2016-05-02 06:56:57.923045-04
(1 row)

=> SELECT TIMESTAMPADD (MONTH, 2, (CURRENT_TIMESTAMP)) AS TodayPlusTwoMonths;;
      TodayPlusTwoMonths
-----
2016-07-02 06:56:57.923045-04
(1 row)
```

Add 14 days to the beginning of the current month:

```
=> SELECT TIMESTAMPADD (DD, 14, (SELECT TRUNC((CURRENT_TIMESTAMP), 'MM')));
      timestampadd
-----
2016-05-15 00:00:00
(1 row)
```

TIMESTAMPDIFF

Returns the time span between two TIMESTAMP or TIMESTAMPTZ values, in the intervals specified. **TIMESTAMPDIFF** excludes the start date in its calculation.

Behavior type

- [Immutable](#) if start and end dates are **TIMESTAMP**
- [Stable](#) if start and end dates are **TIMESTAMPTZ**

Syntax

```
TIMESTAMPDIFF ( datepart, start, end );
```

Parameters

datepart

Specifies the type of date or time intervals that **TIMESTAMPDIFF** returns. If *datepart* is an expression, it must be enclosed in parentheses:

```
TIMESTAMPDIFF(expression, start, end);
```

datepart must evaluate to one of the following string literals, either quoted or unquoted:

- `year` | `yy` | `yyyy`
- `quarter` | `qq` | `q`
- `month` | `mm` | `m`
- `day` | `dayofyear` | `dd` | `d` | `dy` | `y`
- `week` | `wk` | `ww`
- `hour` | `hh`
- `minute` | `mi` | `n`
- `second` | `ss` | `s`

- [millisecond](#) | `ms`
- [microsecond](#) | `mcs` | `us`

start, **end**

Specify the start and end dates, where *start* and *end* evaluate to one of the following data types:

- [TIMESTAMP/TIMESTAMPZ](#)
- [TIMESTAMPTZ](#)

If *end* < *start*, [TIMESTAMPDIFF](#) returns a negative value.

Date part intervals

[TIMESTAMPDIFF](#) uses the *datepart* argument to calculate the number of intervals between two dates, rather than the actual amount of time between them. For detailed information, see [DATEDIFF](#).

Examples

```
=> SELECT TIMESTAMPDIFF (YEAR,'1-1-2006 12:34:00', '1-1-2008 12:34:00');
timestampdiff
-----
                2
(1 row)
```

See also

[DATEDIFF](#)

TRANSACTION_TIMESTAMP

Returns a value of type `TIME WITH TIMEZONE` that represents the start of the current transaction.

The return value does not change during the transaction. Thus, multiple calls to [TRANSACTION_TIMESTAMP](#) within the same transaction return the same timestamp.

[TRANSACTION_TIMESTAMP](#) is equivalent to [CURRENT_TIMESTAMP](#), except it does not accept a precision parameter.

Behavior type

[Stable](#)

Syntax

```
TRANSACTION_TIMESTAMP()
```

Examples

```
=> SELECT foo, bar FROM (SELECT TRANSACTION_TIMESTAMP() AS foo)foo, (SELECT TRANSACTION_TIMESTAMP() as bar)bar;
      foo      |      bar
-----+-----
2016-12-12 08:18:00.988528-05 | 2016-12-12 08:18:00.988528-05
(1 row)
```

See also

- [CLOCK_TIMESTAMP](#)
- [STATEMENT_TIMESTAMP](#)

TRUNC

Truncates the specified date or time. If you omit the precision argument, [TRUNC](#) truncates to day (`DD`) precision.

Behavior type

- [Immutable](#) if the target date is a [TIMESTAMP](#) or [DATE](#)
- [Stable](#) if the target date is a [TIMESTAMPTZ](#)

Syntax

```
TRUNC( trunc-target[, 'precision'] )
```

Parameters

* *trunc-target* *

An expression that evaluates to one of the following data types:

- [DATE](#)

- [TIMESTAMP/TIMESTAMPZ](#)
- [TIMESTAMPZ](#)

precision

A string constant that specifies precision for the truncated value, one of the following:

- **Century** : [CC](#) | [SCC](#)
- **Year** : [SYYY](#) | [YYYY](#) | [YEAR](#) | [YYY](#) | [YY](#) | [Y](#)
- **ISO Year** : [IYYY](#) | [IYY](#) | [IY](#) | [I](#)
- **Quarter** : [Q](#)
- **Month** : [MONTH](#) | [MON](#) | [MM](#) | [RM](#)
- **Same weekday as first day of year** : [WW](#)
- **Same weekday as first day of ISO year** : [IW](#)
- **Same weekday as first day of month** : [W](#)
- **Day** (default): [DDD](#) | [DD](#) | [J](#)
- **First weekday** : [DAY](#) | [DY](#) | [D](#)
- **Hour** : [HH](#) | [HH12](#) | [HH24](#)
- **Minute** : [MI](#)
- **Second** : [SS](#)

Note

Hour, minute, and second truncating is not supported by [DATE](#) expressions.

Examples

Truncate to the current hour:

```
=> => SELECT TRUNC(CURRENT_TIMESTAMP, 'HH');
      TRUNC
-----
2016-04-29 10:00:00
(1 row)
```

Truncate to the month:

```
=> SELECT TRUNC('9-22-2011 12:34:00'::TIMESTAMP, 'MM');
      TIMESTAMP_TRUNC
-----
2011-09-01 00:00:00
(1 row)
```

See also

[TIMESTAMP_TRUNC](#)

WEEK

Returns the week of the year for the specified date as an integer, where the first week begins on the first Sunday on or preceding January 1.

Syntax

```
WEEK ( date )
```

Behavior type

- [Immutable](#) if the specified date is a [TIMESTAMP](#), [DATE](#), or [VARCHAR](#)
- [Stable](#) if the specified date is a [TIMESTAMPZ](#)

Parameters

date

The date to process, one of the following data types:

- [VARCHAR](#)
- [DATE](#)
- [TIMESTAMP](#)
- [TIMESTAMPZ](#)

Examples

January 2 is on Saturday, so **WEEK** returns 1:

```
=> SELECT WEEK ('1-2-2016'::DATE);
WEEK
-----
  1
(1 row)
```

January 3 is the second Sunday in 2016, so **WEEK** returns 2:

```
=> SELECT WEEK ('1-3-2016'::DATE);
WEEK
-----
  2
(1 row)
```

WEEK_ISO

Returns the week of the year for the specified date as an integer, where the first week starts on Monday and contains January 4. This function conforms with the ISO 8061 standard.

Syntax

```
WEEK_ISO ( date )
```

Behavior type

- [Immutable](#) if the specified date is a **TIMESTAMP**, **DATE**, or **VARCHAR**
- [Stable](#) if the specified date is a **TIMESTAMPTZ**

Parameters

date

The date to process, one of the following data types:

- [VARCHAR](#)
- [DATE](#)
- [TIMESTAMP](#)
- [TIMESTAMPTZ](#)

Examples

The first week of 2016 begins on Monday January 4:

```
=> SELECT WEEK_ISO ('1-4-2016'::DATE);
WEEK_ISO
-----
  1
(1 row)
```

January 3 2016 returns week 53 of the previous year (2015):

```
=> SELECT WEEK_ISO ('1-3-2016'::DATE);
WEEK_ISO
-----
  53
(1 row)
```

In 2015, January 4 is on Sunday, so the first week of 2015 begins on the preceding Monday (December 29 2014):

```
=> SELECT WEEK_ISO ('12-29-2014'::DATE);
WEEK_ISO
-----
  1
(1 row)
```

YEAR

Returns an integer that represents the year portion of the specified date.

Syntax

```
YEAR( date )
```

Behavior type

- [Immutable](#) if the specified date is a **TIMESTAMP** , **DATE** , **VARCHAR** , or **INTERVAL**
- [Stable](#) if the specified date is a **TIMESTAMPTZ**

Parameters

date

The date to process, one of the following data types:

- [VARCHAR](#)
- [DATE](#)
- [TIMESTAMP](#)
- [TIMESTAMPTZ](#)

- [INTERVAL](#)

Examples

```
=> SELECT YEAR(CURRENT_DATE::DATE);
YEAR
-----
2016
(1 row)
```

See also

[YEAR_ISO](#)

YEAR_ISO

Returns an integer that represents the year portion of the specified date. The return value is based on the ISO 8061 standard.

The first week of the ISO year is the week that contains January 4.

Syntax

```
YEAR_ISO ( date )
```

Behavior type

- [Immutable](#) if the specified date is a **TIMESTAMP** , **DATE** , or **VARCHAR**
- [Stable](#) if the specified date is a **TIMESTAMPTZ**

Parameters

date

The date to process, one of the following data types:

- [VARCHAR](#)
- [DATE](#)
- [TIMESTAMP](#)
- [TIMESTAMPTZ](#)

Examples

```
> SELECT YEAR_ISO(CURRENT_DATE::DATE);
YEAR_ISO
-----
2016
(1 row)
```

[YEAR](#)

IP address functions

IP functions perform conversion, calculation, and manipulation operations on IP, network, and subnet addresses.

In this section

- [INET_ATON](#)
- [INET_NTOA](#)
- [V6_ATON](#)
- [V6_NTOA](#)
- [V6_SUBNETA](#)
- [V6_SUBNETN](#)
- [V6_TYPE](#)

INET_ATON

Converts a string that contains a dotted-quad representation of an IPv4 network address to an INTEGER. It trims any surrounding white space from the string. This function returns NULL if the string is NULL or contains anything other than a quad dotted IPv4 address.

Behavior type

[Immutable](#)

Syntax

```
INET_ATON ( expression )
```

Arguments

expression

the string to convert.

Examples

```
=> SELECT INET_ATON('209.207.224.40');
inet_aton
-----
3520061480
(1 row)

=> SELECT INET_ATON('1.2.3.4');
inet_aton
-----
16909060
(1 row)

=> SELECT TO_HEX(INET_ATON('1.2.3.4'));
to_hex
-----
1020304
(1 row)
```

See also

- [INET_NTOA](#)
- [V6_ATON](#)
- [V6_NTOA](#)
- [V6_SUBNETA](#)
- [V6_SUBNETN](#)
- [V6_TYPE](#)

INET_NTOA

Converts an INTEGER value into a VARCHAR dotted-quad representation of an IPv4 network address. INET_NTOA returns NULL if the integer value is NULL, negative, or is greater than 2^{32} (4294967295).

Behavior type

[Immutable](#)

Syntax

```
INET_NTOA ( expression )
```

Arguments

expression

The integer network address to convert.

Examples

```
=> SELECT INET_NTOA(16909060);
inet_ntoa
-----
1.2.3.4
(1 row)

=> SELECT INET_NTOA(03021962);
inet_ntoa
-----
0.46.28.138
(1 row)
```

See also

- [INET_ATON](#)
- [V6_ATON](#)
- [V6_NTOA](#)
- [V6_SUBNETA](#)
- [V6_SUBNETN](#)
- [V6_TYPE](#)

V6_ATON

Converts a string containing a colon-delimited IPv6 network address into a VARBINARY string. Any spaces around the IPv6 address are trimmed. This function returns NULL if the input value is NULL or it cannot be parsed as an IPv6 address. This function relies on the Linux function [inet_pton](#).

Behavior type

[Immutable](#)

Syntax

```
V6_ATON ( expression )
```

Arguments

expression

(VARCHAR) the string containing an IPv6 address to convert.

Examples

```
=> SELECT V6_ATON('2001:DB8::8:800:200C:417A');
v6_aton
-----
\001\015\270\000\000\000\000\000\000\010\010\000 \014Az
(1 row)

=> SELECT V6_ATON('1.2.3.4');
v6_aton
-----
\000\000\000\000\000\000\000\000\000\000\000\000\377\377\001\002\003\004
(1 row)
SELECT TO_HEX(V6_ATON('2001:DB8::8:800:200C:417A'));
to_hex
-----
20010db8000000000000080800200c417a
(1 row)

=> SELECT V6_ATON('::1.2.3.4');
v6_aton
-----
\000\000\000\000\000\000\000\000\000\000\000\000\000\000\001\002\003\004
(1 row)
```

See also

- [V6_NTOA](#)
- [V6_SUBNETA](#)
- [V6_SUBNETN](#)
- [V6_TYPE](#)
- [INET_ATON](#)
- [INET_NTOA](#)

V6_NTOA

Converts an IPv6 address represented as varbinary to a character string.

Behavior type

[Immutable](#)

Syntax

```
V6_NTOA ( expression )
```

Arguments

expression

(**VARBINARY**) is the binary string to convert.

Notes

The following syntax converts an IPv6 address represented as **VARBINARY** B to a string A.

V6_NTOA right-pads B to 16 bytes with zeros, if necessary, and calls the Linux function [inet_ntop](#).

```
=> V6_NTOA(VARBINARY B) -> VARCHAR A
```

If B is NULL or longer than 16 bytes, the result is NULL.

Vertica automatically converts the form '::ffff:1.2.3.4' to '1.2.3.4'.

Examples

```
=> SELECT V6_NTOA('\001\015\270\000\000\000\000\000\010\010\000 \014Az');
```

```
    v6_ntoa
```

```
-----
2001:db8::8:800:200c:417a
```

```
(1 row)
```

```
=> SELECT V6_NTOA(V6_ATON('1.2.3.4'));
```

```
    v6_ntoa
```

```
-----
1.2.3.4
```

```
(1 row)
```

```
=> SELECT V6_NTOA(V6_ATON('::1.2.3.4'));
```

```
    v6_ntoa
```

```
-----
::1.2.3.4
```

```
(1 row)
```

See also

- [V6_ATON](#)

V6_SUBNETA

Returns a VARCHAR containing a subnet address in CIDR (Classless Inter-Domain Routing) format from a binary or alphanumeric IPv6 address. Returns NULL if either parameter is NULL, the address cannot be parsed as an IPv6 address, or the subnet value is outside the range of 0 to 128.

Behavior type

[Immutable](#)

Syntax

```
V6_SUBNETA ( address, subnet )
```

Arguments

address

VARBINARY or VARCHAR containing the IPv6 address.

subnet

The size of the subnet in bits as an INTEGER. This value must be greater than zero and less than or equal to 128.

Examples

```
=> SELECT V6_SUBNETA(V6_ATON('2001:db8::8:800:200c:417a'), 28);
v6_subneta
-----
2001:db0::/28
(1 row)
```

See also

- [V6_ATON](#)
- [V6_NTOA](#)
- [V6_SUBNETN](#)
- [V6_TYPE](#)
- [INET_ATON](#)
- [INET_NTOA](#)

V6_SUBNETN

Calculates a subnet address in CIDR (Classless Inter-Domain Routing) format from a varbinary or alphanumeric IPv6 address.

Behavior type

[Immutable](#)

Syntax

```
V6_SUBNETN ( address, subnet-size)
```

Arguments

address

The IPv6 address as a VARBINARY or VARCHAR. The format you pass in determines the data type of the output. If you pass in a VARBINARY address, V6_SUBNETN returns a VARBINARY value. If you pass in a VARCHAR value, it returns a VARCHAR.

subnet-size

The size of the subnet as an INTEGER.

Notes

The following syntax masks a BINARY IPv6 address **B** so that the **N** left-most bits of **S** form a subnet address, while the remaining right-most bits are cleared.

V6_SUBNETN right-pads **B** to 16 bytes with zeros, if necessary and masks **B**, preserving its **N**-bit subnet prefix.

```
=> V6_SUBNETN(VARBINARY B, INT8 N) -> VARBINARY(16) S
```

If **B** is NULL or longer than 16 bytes, or if **N** is not between 0 and 128 inclusive, the result is NULL.

S = **[B]/N** in [Classless Inter-Domain Routing](#) notation (CIDR notation).

The following syntax masks an alphanumeric IPv6 address **A** so that the **N** leftmost bits form a subnet address, while the remaining rightmost bits are cleared.

```
=> V6_SUBNETN(VARCHAR A, INT8 N) -> V6_SUBNETN(V6_ATON(A), N) -> VARBINARY(16) S
```

Examples

This example returns VARBINARY, after using V6_ATON to convert the VARCHAR string to VARBINARY:

```
=> SELECT V6_SUBNETN(V6_ATON('2001:db8::8:800:200c:417a'), 28);
v6_subnetn
-----
\001\015\260\000\000\000\000\000\000\000\000\000\000\000\000\000\000
```

See also

- [V6_ATON](#)
- [V6_NTOA](#)
- [V6_TYPE](#)
- [V6_SUBNETA](#)
- [INET_ATON](#)
- [INET_NTOA](#)

V6_TYPE

Returns an INTEGER value that classifies the type of the network address passed to it as defined in [IETF RFC 4291 section 2.4](#). For example, If you pass this function the string `127.0.0.1` , it returns 2 which indicates the address is a loopback address. This function accepts both IPv4 and IPv6 addresses.

Behavior type

[Immutable](#)

Syntax

```
V6_TYPE ( address)
```

Arguments

address

A VARBINARY or VARCHAR containing an IPv6 or IPv4 address to describe.

Returns

The values returned by this function are:

Return Value	Address Type	Description
0	GLOBAL	Global unicast addresses
1	LINKLOCAL	Link-Local unicast (and private-use) addresses
2	LOOPBACK	Loopback addresses
3	UNSPECIFIED	Unspecified addresses
4	MULTICAST	Multicast addresses

The return value is based on the following table of IP address ranges:

Address Family	CIDR	Type
IPv4	0.0.0.0/8	UNSPECIFIED
	10.0.0.0/8	LINKLOCAL
	127.0.0.0/8	LOOPBACK
	169.254.0.0/16	LINKLOCAL
	172.16.0.0/12	LINKLOCAL
	192.168.0.0/16	LINKLOCAL
	224.0.0.0/4	MULTICAST
	All other addresses	GLOBAL
IPv6	::0/128	UNSPECIFIED
	::1/128	LOOPBACK

	fe80::/10	LINKLOCAL
	ff00::/8	MULTICAST
	All other addresses	GLOBAL

This function returns NULL if you pass it a NULL value or an invalid address.

Examples

```
=> SELECT V6_TYPE(V6_ATON('192.168.2.10'));
v6_type
-----
      1
(1 row)

=> SELECT V6_TYPE(V6_ATON('2001:db8::8:800:200c:417a'));
v6_type
-----
      0
(1 row)
```

- [IPv4 Global Unicast Address Assignments](#)

Sequence functions

The sequence functions provide simple, multiuser-safe methods for obtaining successive sequence values from sequence objects.

In this section

- [CURRVAL](#)
- [NEXTVAL](#)

CURRVAL

Returns the last value across all nodes that was set by [NEXTVAL](#) on this sequence in the current session. If NEXTVAL was never called on this sequence since its creation, Vertica returns an error.

Syntax

```
CURRVAL ('[[database.]schema.]sequence-name')
```

Parameters

[*database* .] *schema*

Database and [schema](#). The default schema is [public](#). If you specify a database, it must be the current database.

sequence-name

The target sequence

Privileges

- SELECT privilege on sequence
- USAGE privilege on sequence schema

Restrictions

You cannot invoke CURRVAL in a SELECT statement, in the following contexts:

- WHERE clause

- GROUP BY clause
- ORDER BY clause
- DISTINCT clause
- UNION
- Subquery

You also cannot invoke CURRVAL to act on a sequence in:

- UPDATE or DELETE subqueries
- Views

Examples

See [Creating and using named sequences](#).

See also

[NEXTVAL](#)

NEXTVAL

Returns the next value in a sequence. Call NEXTVAL after creating a sequence to initialize the sequence with its default value. Thereafter, call NEXTVAL to increment the sequence value for ascending sequences, or decrement its value for descending sequences.

Syntax

```
NEXTVAL ('[[database.]schema.]sequence')
```

Parameters

[**database** .] **schema**

Database and [schema](#). The default schema is **public**. If you specify a database, it must be the current database.

sequence

Identifies the target sequence.

Privileges

- SELECT privilege on sequence
- USAGE privilege on sequence schema

Restrictions

You cannot invoke NEXTVAL in a SELECT statement, in the following contexts:

- WHERE clause
- GROUP BY clause
- ORDER BY clause
- DISTINCT clause
- UNION
- Subquery

You also cannot invoke NEXTVAL to act on a sequence in:

- UPDATE or DELETE subqueries
- Views

You can use subqueries to work around some of these restrictions. For example, to use sequences with a DISTINCT clause:

```
=> SELECT t.col1, shift_allocation_seq.NEXTVAL FROM (
    SELECT DISTINCT col1 FROM av_temp1) t;
```

Examples

See [Creating and using named sequences](#).

See also

[CURRVAL](#)

String functions

String functions perform conversion, extraction, or manipulation operations on strings, or return information about strings.

This section describes functions and operators for examining and manipulating string values. Strings in this context include values of the types CHAR, VARCHAR, BINARY, and VARBINARY.

Unless otherwise noted, all of the functions listed in this section work on all four data types. As opposed to some other SQL implementations, Vertica keeps CHAR strings unpadded internally, padding them only on final output. So converting a CHAR(3) 'ab' to VARCHAR(5) results in a VARCHAR of length 2, not one with length 3 including a trailing space.

Some of the functions described here also work on data of non-string types by converting that data to a string representation first. Some functions work only on character strings, while others work only on binary strings. Many work for both. BINARY and VARBINARY functions ignore multibyte UTF-8 character boundaries.

Non-binary character string functions handle normalized multibyte UTF-8 characters, as specified by the Unicode Consortium. Unless otherwise specified, those character string functions for which it matters can optionally specify whether VARCHAR arguments should be interpreted as octet (byte) sequences, or as (locale-aware) sequences of UTF-8 characters. This is accomplished by adding "USING OCTETS" or "USING CHARACTERS" (default) as a parameter to the function.

Some character string functions are [stable](#) because in general UTF-8 case-conversion, searching and sorting can be locale dependent. Thus, LOWER is stable, while LOWERB is [immutable](#). The USING OCTETS clause converts these functions into their "B" forms, so they become immutable. If the locale is set to collation=binary, which is the default, all string functions—except CHAR_LENGTH/CHARACTER_LENGTH, LENGTH, SUBSTR, and OVERLAY—are converted to their "B" forms and so are immutable.

BINARY implicitly converts to VARBINARY, so functions that take VARBINARY arguments work with BINARY.

For other functions that operate on strings (but not VARBINARY), see [Regular expression functions](#).

ASCII

Converts the first character of a VARCHAR datatype to an INTEGER. This function is the opposite of the [CHR](#) function.

ASCII operates on UTF-8 characters and single-byte ASCII characters. It returns the same results for the ASCII subset of UTF-8.

Behavior type

[Immutable](#)

Syntax

```
ASCII ( expression )
```

Arguments

expression

VARCHAR (string) to convert.

Examples

This example returns employee last names that begin with L. The ASCII equivalent of L is 76:

```
=> SELECT employee_last_name FROM employee_dimension
   WHERE ASCII(SUBSTR(employee_last_name, 1, 1)) = 76
   LIMIT 5;
employee_last_name
-----
Lewis
Lewis
Lampert
Lampert
Li
(5 rows)
```

BIT_LENGTH

Returns the length of the string expression in bits (bytes * 8) as an INTEGER. BIT_LENGTH applies to the contents of VARCHAR and VARBINARY fields.

Behavior type

[Immutable](#)

Syntax

```
BIT_LENGTH ( expression )
```

Arguments

expression

(CHAR or VARCHAR or BINARY or VARBINARY) is the string to convert.

Examples

Expression	Result
SELECT BIT_LENGTH('abc'::varbinary);	24
SELECT BIT_LENGTH('abc'::binary);	8
SELECT BIT_LENGTH(''::varbinary);	0
SELECT BIT_LENGTH(''::binary);	8
SELECT BIT_LENGTH(null::varbinary);	
SELECT BIT_LENGTH(null::binary);	
SELECT BIT_LENGTH(VARCHAR 'abc');	24
SELECT BIT_LENGTH(CHAR 'abc');	24
SELECT BIT_LENGTH(CHAR(6) 'abc');	48
SELECT BIT_LENGTH(VARCHAR(6) 'abc');	24
SELECT BIT_LENGTH(BINARY(6) 'abc');	48
SELECT BIT_LENGTH(BINARY 'abc');	24
SELECT BIT_LENGTH(VARBINARY 'abc');	24
SELECT BIT_LENGTH(VARBINARY(6) 'abc');	24

See also

- [CHARACTER_LENGTH](#)
- [LENGTH](#)
- [OCTET_LENGTH](#)

BITCOUNT

Returns the number of one-bits (sometimes referred to as set-bits) in the given VARBINARY value. This is also referred to as the population count.

Behavior type

[Immutable](#)

Syntax

```
BITCOUNT ( expression )
```

Arguments

expression

(BINARY or VARBINARY) is the string to return.

Examples

```
=> SELECT BITCOUNT(HEX_TO_BINARY('0x10'));
BITCOUNT
-----
      1
(1 row)
=> SELECT BITCOUNT(HEX_TO_BINARY('0xF0'));
BITCOUNT
-----
      4
(1 row)
=> SELECT BITCOUNT(HEX_TO_BINARY('0xAB'));
BITCOUNT
-----
      5
(1 row)
```

BITSTRING_TO_BINARY

Translates the given VARCHAR bitstring representation into a VARBINARY value. This function is the inverse of [TO_BITSTRING](#).

Behavior type

[Immutable](#)

Syntax

```
BITSTRING_TO_BINARY ( expression )
```

Arguments

expression

The VARCHAR string to process.

Examples

If there are an odd number of characters in the hex value, the first character is treated as the low nibble of the first (furthest to the left) byte.

```
=> SELECT BITSTRING_TO_BINARY('0110000101100010');
BITSTRING_TO_BINARY
-----
ab
(1 row)
```

BTRIM

Removes the longest string consisting only of specified characters from the start and end of a string.

Behavior type

[Immutable](#)

Syntax

```
BTRIM ( expression [ , characters-to-remove ] )
```

Arguments

expression

(CHAR or VARCHAR) is the string to modify

characters-to-remove

(CHAR or VARCHAR) specifies the characters to remove. The default is the space character.

Examples

```
=> SELECT BTRIM('xyxtrimyyx', 'xy');
BTRIM
-----
trim
(1 row)
```

See also

- [LTRIM](#)

- [RTRIM](#)
- [TRIM](#)

CHARACTER_LENGTH

The CHARACTER_LENGTH() function:

- Returns the string length in UTF-8 characters for CHAR and VARCHAR columns
- Returns the string length in bytes (octets) for BINARY and VARBINARY columns
- Strips the padding from CHAR expressions but not from VARCHAR expressions
- Is identical to [LENGTH\(\)](#) for CHAR and VARCHAR. For binary types, CHARACTER_LENGTH() is identical to [OCTET_LENGTH\(\)](#).

Behavior type

[Immutable](#) if **USING OCTETS**, [stable](#) otherwise.

Syntax

```
[ CHAR_LENGTH | CHARACTER_LENGTH ] ( expression ... [ USING { CHARACTERS | OCTETS } ] )
```

Arguments

expression

(CHAR or VARCHAR) is the string to measure

USING CHARACTERS | OCTETS

Determines whether the character length is expressed in characters (the default) or octets.

Examples

```
=> SELECT CHAR_LENGTH('1234 '::CHAR(10) USING OCTETS);
```

```
octet_length
```

```
-----
         4
```

```
(1 row)
```

```
=> SELECT CHAR_LENGTH('1234 '::VARCHAR(10));
```

```
char_length
```

```
-----
         6
```

```
(1 row)
```

```
=> SELECT CHAR_LENGTH(NULL::CHAR(10)) IS NULL;
```

```
?column?
```

```
-----
t
```

```
(1 row)
```

See also

- [BIT_LENGTH](#)

CHR

Converts the first character of an INTEGER datatype to a VARCHAR.

Behavior type

[Immutable](#)

Syntax

```
CHR ( expression )
```

Arguments

expression

(INTEGER) is the string to convert and is masked to a single character.

Notes

- CHR is the opposite of the [ASCII](#) function.
- CHR operates on UTF-8 characters, not only on single-byte ASCII characters. It continues to get the same results for the ASCII subset of UTF-8.

Examples

This example returns the VARCHAR datatype of the CHR expressions 65 and 97 from the employee table:

```
=> SELECT CHR(65), CHR(97) FROM employee;
CHR | CHR
-----+-----
A | a
A | a
A | a
A | a
A | a
A | a
A | a
A | a
A | a
A | a
A | a
A | a
A | a
A | a
(12 rows)
```

COLLATION

Applies a collation to two or more strings. Use **COLLATION** with **ORDER BY** , **GROUP BY** , and equality clauses.

Syntax

```
COLLATION ( 'expression' [ , 'locale_or_collation_name' ] )
```

Arguments

' **expression** '

Any expression that evaluates to a column name or to two or more values of type **CHAR** or **VARCHAR** .

' **locale_or_collation_name** '

The [ICU \(International Components for Unicode\)](#) locale or collation name to use when collating the string. If you omit this parameter, **COLLATION** uses the collation associated with the session locale.

To determine the current session locale, enter the vsqll meta-command **\locale** :

```
=> \locale
en_US@collation=binary
```

To set the locale and collation, use **\locale** as follows:

```
=> \locale en_US@collation=binary
INFO 2567: Canonical locale: 'en_US'
Standard collation: 'LEN_KBINARY'
English (United States)
```

Locales

The locale used for **COLLATION** can be one of the following:

- The default locale
- A session locale
- A locale that you specify when you call **COLLATION** . If you specify the locale, Vertica applies the collation associated with that locale to the data. **COLLATION** does not modify the collation for any other columns in the table.

For a list of valid ICU locales, go to [Locale Explorer \(ICU\)](#) .

Binary and non-binary collations

The Vertica default locale is **en_US@collation=binary** , which uses **binary collation** . Binary collation compares binary representations of strings. Binary collation is fast, but it can result in a sort order where **K** precedes **c** because the binary representation of **K** is lower than **c** .

For non-binary collation, Vertica transforms the data according to the rules of the locale or the specified collation, and then applies the sorting rules. Suppose the locale collation is non-binary and you request a GROUP BY on string data. In this case, Vertica calls **COLLATION**, whether or not you specify the function in your query.

For information about collation naming, see [Collator Naming Scheme](#).

Examples

Collating GROUP BY results

The following examples are based on a **Premium_Customer** table that contains the following data:

```
=> SELECT * FROM Premium_Customer;
```

ID	LName	FName
1	Mc Coy	Bob
2	Mc Coy	Janice
3	McCoy	Jody
4	McCoy	Peter
5	McCoy	Brendon
6	Mccoy	Cameron
7	Mccoy	Lisa

The first statement shows how **COLLATION** applies the collation for the **EN_US** locale to the **LName** column for the locale **EN_US**. Vertica sorts the **GROUP BY** output as follows:

- Last names with spaces
- Last names where "coy" starts with a lowercase letter
- Last names where "Coy" starts with an uppercase letter

```
=> SELECT * FROM Premium_Customer ORDER BY COLLATION(LName, 'EN_US'), FName;
```

ID	LName	FName
1	Mc Coy	Bob
2	Mc Coy	Janice
6	Mccoy	Cameron
7	Mccoy	Lisa
5	McCoy	Brendon
3	McCoy	Jody
4	McCoy	Peter

The next statement shows how **COLLATION** collates the **LName** column for the locale **LEN_AS**:

- **LEN** indicates the language (L) is English (**EN**).
- **AS** (Alternate Shifted) instructs **COLLATION** that lowercase letters come before uppercase (shifted) letters.

In the results, the last names in which "coy" starts with a lowercase letter precede the last names where "Coy" starts with an uppercase letter.

```
=> SELECT * FROM Premium_Customer ORDER BY COLLATION(LName, 'LEN_AS'), FName;
```

ID	LName	FName
6	Mccoy	Cameron
7	Mccoy	Lisa
1	Mc Coy	Bob
5	McCoy	Brendon
2	Mc Coy	Janice
3	McCoy	Jody
4	McCoy	Peter

Comparing strings with an equality clause

In the following query, **COLLATION** removes spaces and punctuation when comparing two strings in English. It then determines whether the two strings still have the same value after the punctuation has been removed:

```
=> SELECT COLLATION ('U.S.A', 'LEN_AS') = COLLATION('USA', 'LEN_AS');
?column?
-----
t
```

Sorting strings in non-english languages

The following table contains data that uses the German character eszett, ß:

```
=> SELECT * FROM t1;
 a   | b | c
-----+-----+-----
ßstringß | 1 | 10
SSstringSS | 2 | 20
random1 | 3 | 30
random1 | 4 | 40
random2 | 5 | 50
```

When you specify the collation `LDE_S1` :

- `LDE` indicates the language (`L`) is German (`DE`).
- `S1` indicates the strength (`S`) of 1 (primary). This value indicates that the collation does not need to consider accents and case.

The query returns the data in the following order:

```
=> SELECT a FROM t1 ORDER BY COLLATION(a, 'LDE_S1');
 a
-----
random1
random1
random2
SSstringSS
ßstringß
```

CONCAT

Concatenates two strings and returns a varchar data type. If either argument is null, concat returns null.

Syntax

```
CONCAT ('string-expression1', string-expression2)
```

Behavior type

[Immutable](#)

Arguments

string-expression1 , ***string-expression2***

The values to concatenate, any data type that can be cast to a string value.

Examples

The following examples use a sample table named `alphabet` with two varchar columns:

```
=> CREATE TABLE alphabet (letter1 varchar(2), letter2 varchar(2));
CREATE TABLE
=> COPY alphabet FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> A|B
>> C|D
>> \.
=> SELECT * FROM alphabet;
letter1 | letter2
-----+-----
C       | D
A       | B
(2 rows)
```

Concatenate the contents of the first column with a character string:

```
=> SELECT CONCAT(letter1, ' is a letter') FROM alphabet;
      CONCAT
-----
A is a letter
C is a letter
(2 rows)
```

Concatenate the output of two nested CONCAT functions:

```
=> SELECT CONCAT(CONCAT(letter1, ' and '), CONCAT(letter2, ' are both letters')) FROM alphabet;
      CONCAT
-----
C and D are both letters
A and B are both letters
(2 rows)
```

Concatenate a date and string:

```
=> SELECT current_date today;
      today
-----
2021-12-10
(1 row)

=> SELECT CONCAT('2021-12-31'::date - current_date, ' days until end of year 2021');
      CONCAT
-----
21 days until end of year 2021
(1 row)
```

DECODE

Compares * **expression** * to each search value one by one. If * **expression** * is equal to a search, the function returns the corresponding result. If no match is found, the function returns default. If default is omitted, the function returns null.

DECODE is similar to the IF-THEN-ELSE and [CASE](#) expressions:

```
CASE expression
[WHEN search THEN result]
[WHEN search THEN result]
...
[ELSE default];
```

The arguments can have any data type supported by Vertica. The result types of individual results are promoted to the least common type that can be used to represent all of them. This leads to a character string type, an exact numeric type, an approximate numeric type, or a DATETIME type, where all the various result arguments must be of the same type grouping.

Behavior type

[Immutable](#)

Syntax

```
DECODE ( expression, search, result [ , search, result ]...[, default ] )
```

Arguments

expression

The value to compare.

search

The value compared against *expression*.

result

The value returned, if * **expression** * is equal to search.

default

Optional. If no matches are found, DECODE returns default. If default is omitted, then DECODE returns NULL (if no matches are found).

Examples

The following example converts numeric values in the weight column from the product_dimension table to descriptive values in the output.

```
=> SELECT product_description, DECODE(weight,
    2, 'Light',
    50, 'Medium',
    71, 'Heavy',
    99, 'Call for help',
    'N/A')
FROM product_dimension
WHERE category_description = 'Food'
AND department_description = 'Canned Goods'
AND sku_number BETWEEN 'SKU-#49750' AND 'SKU-#49999'
LIMIT 15;
product_description | case
-----+-----
Brand #499 canned corn | N/A
Brand #49900 fruit cocktail | Medium
Brand #49837 canned tomatoes | Heavy
Brand #49782 canned peaches | N/A
Brand #49805 chicken noodle soup | N/A
Brand #49944 canned chicken broth | N/A
Brand #49819 canned chili | N/A
Brand #49848 baked beans | N/A
Brand #49989 minestrone soup | N/A
Brand #49778 canned peaches | N/A
Brand #49770 canned peaches | N/A
Brand #4977 fruit cocktail | N/A
Brand #49933 canned olives | N/A
Brand #49750 canned olives | Call for help
Brand #49777 canned tomatoes | N/A
(15 rows)
```

EDIT_DISTANCE

Calculates and returns the [Levenshtein distance](#) between two strings. The return value indicates the minimum number of single-character edits—insertions, deletions, or substitutions—that are required to change one string into the other. Compare to [Jaro distance](#) and [Jaro-Winkler distance](#).

Behavior type

[Immutable](#)

Syntax

```
EDIT_DISTANCE ( string-expression1, string-expression2 )
```

Arguments

string-expression1 , ***string-expression2***

The two VARCHAR expressions to compare.

Examples

The Levenshtein distance between **kitten** and **knitting** is 3:

```
=> SELECT EDIT_DISTANCE ('kitten', 'knitting');
EDIT_DISTANCE
-----
3
(1 row)
```

EDIT_DISTANCE calculates that no fewer than three changes are required to transform **kitten** to **knitting** :

1. **kitten** → **knitten** (insert **n** after **k**)
2. **knitten** → **knittin** (substitute **i** for **e**)

3. knittin → knitting (append g)

GREATEST

Returns the largest value in a list of expressions of any data type. All data types in the list must be the same or [compatible](#). A NULL value in any one of the expressions returns NULL. Results can vary, depending on the locale's collation setting.

Behavior type

[Stable](#)

Syntax

```
GREATEST ( { * | expression[,...] } )
```

Arguments

* | *expression* [...]

The expressions to evaluate, one of the following:

- * (asterisk)
Evaluates all columns in the queried table.
- *expression*
An expression of any data type. Functions that are included in *expression* must be deterministic.

Examples

GREATEST returns 10 as the largest value in the list:

```
=> SELECT GREATEST(7,5,10);
GREATEST
-----
      10
(1 row)
```

If you put quotes around the integer expressions, GREATEST compares the values as strings and returns '7' as the greatest value:

```
=> SELECT GREATEST('7', '5', '10');
GREATEST
-----
       7
(1 row)
```

The next example returns FLOAT 1.5 as the greatest because the integer is implicitly cast to float:

```
=> SELECT GREATEST(1, 1.5);
GREATEST
-----
      1.5
(1 row)
```

GREATEST queries all columns in a view based on the VMart table [product_dimension](#), and returns the largest value in each row:

```
=> CREATE VIEW query1 AS SELECT shelf_width, shelf_height, shelf_depth FROM product_dimension;
```

```
CREATE VIEW
```

```
=> SELECT shelf_width, shelf_height, shelf_depth, greatest(*) FROM query1 WHERE shelf_width = 1;  
shelf_width | shelf_height | shelf_depth | greatest
```

```
-----+-----+-----+-----  
1 | 3 | 1 | 3  
1 | 3 | 3 | 3  
1 | 5 | 4 | 5  
1 | 2 | 2 | 2  
1 | 1 | 3 | 3  
1 | 2 | 2 | 2  
1 | 2 | 3 | 3  
1 | 1 | 5 | 5  
1 | 1 | 4 | 4  
1 | 5 | 3 | 5  
1 | 4 | 2 | 4  
1 | 4 | 5 | 5  
1 | 5 | 3 | 5  
1 | 2 | 5 | 5  
1 | 4 | 2 | 4  
1 | 4 | 4 | 4  
1 | 1 | 2 | 2  
1 | 4 | 3 | 4  
...
```

See also

[LEAST](#)

[GREATESTB](#)

Returns the largest value in a list of expressions of any data type, using binary ordering. All data types in the list must be the same or [compatible](#). A NULL value in any one of the expressions returns NULL. Results can vary, depending on the locale's collation setting.

Behavior type

[Immutable](#)

Syntax

```
GREATEST ( { * | expression[...] } )
```

Arguments

* | ***expression*** [...]

The expressions to evaluate, one of the following:

- * (asterisk)
Evaluates all columns in the queried table.
- *expression*
An expression of any data type. Functions that are included in *expression* must be deterministic.

Examples

The following command selects *straße* as the greatest in the series of inputs:

```
=> SELECT GREATESTB('straße', 'strasse');
```

```
GREATESTB
```

```
-----  
straße  
(1 row)
```

GREATESTB returns 10 as the largest value in the list:

```
=> SELECT GREATESTB(7,5,10);
```

```
GREATESTB
```

```
-----  
10  
(1 row)
```

If you put quotes around the integer expressions, GREATESTB compares the values as strings and returns '7' as the greatest value:

```
=> SELECT GREATESTB('7', '5', '10');
GREATESTB
-----
7
(1 row)
```

The next example returns FLOAT 1.5 as the greatest because the integer is implicitly cast to float:

```
=> SELECT GREATESTB(1, 1.5);
GREATESTB
-----
1.5
(1 row)
```

GREATESTB queries all columns in a view based on the VMart table `product_dimension`, and returns the largest value in each row:

```
=> CREATE VIEW query1 AS SELECT shelf_width, shelf_height, shelf_depth FROM product_dimension;
CREATE VIEW
=> SELECT shelf_width, shelf_height, shelf_depth, greatestb(*) FROM query1 WHERE shelf_width = 1;
shelf_width | shelf_height | shelf_depth | greatestb
-----+-----+-----+-----
1 | 3 | 1 | 3
1 | 3 | 3 | 3
1 | 5 | 4 | 5
1 | 2 | 2 | 2
1 | 1 | 3 | 3
1 | 2 | 2 | 2
1 | 2 | 3 | 3
1 | 1 | 5 | 5
1 | 1 | 4 | 4
1 | 5 | 3 | 5
1 | 4 | 2 | 4
1 | 4 | 5 | 5
1 | 5 | 3 | 5
1 | 2 | 5 | 5
1 | 4 | 2 | 4
...
```

See also

[LEASTB](#)

[HEX_TO_BINARY](#)

Translates the given VARCHAR hexadecimal representation into a VARBINARY value.

Behavior type

[Immutable](#)

Syntax

```
HEX_TO_BINARY ( [ 0x ] expression )
```

Arguments

expression

(BINARY or VARBINARY) String to translate.

0x

Optional prefix.

Notes

VARBINARY HEX_TO_BINARY(VARCHAR) converts data from character type in hexadecimal format to binary type. This function is the inverse of [TO_HEX](#).

```
HEX_TO_BINARY(TO_HEX(x)) = x
```

```
TO_HEX(HEX_TO_BINARY(x)) = x
```

If there are an odd number of characters in the hexadecimal value, the first character is treated as the low nibble of the first (furthest to the left) byte.

Examples

If the given string begins with "0x" the prefix is ignored. For example:

```
=> SELECT HEX_TO_BINARY('0x6162') AS hex1, HEX_TO_BINARY('6162') AS hex2;
hex1 | hex2
-----+-----
ab   | ab
(1 row)
```

If an invalid hex value is given, Vertica returns an "invalid binary representation" error; for example:

```
=> SELECT HEX_TO_BINARY('0xffgf');
ERROR: invalid hex string "0xffgf"
```

See also

- [TO_HEX](#)

HEX_TO_INTEGER

Translates the given VARCHAR hexadecimal representation into an INTEGER value.

Vertica completes this conversion as follows:

- Adds the 0x prefix if it is not specified in the input
- Casts the VARCHAR string to a NUMERIC
- Casts the NUMERIC to an INTEGER

Behavior type

[Immutable](#)

Syntax

```
HEX_TO_INTEGER ( [ 0x ] expression )
```

Arguments

expression

VARCHAR is the string to translate.

0x

Is the optional prefix.

Examples

You can enter the string with or without the 0x prefix. For example:

```
=> SELECT HEX_TO_INTEGER ('0aecd')
      AS hex1,HEX_TO_INTEGER ('aecd') AS hex2;
hex1 | hex2
-----+-----
44764 | 44764
(1 row)
```

If you pass the function an invalid hex value, Vertica returns an [invalid input syntax](#) error; for example:

```
=> SELECT HEX_TO_INTEGER ('0xffgf');
ERROR 3691: Invalid input syntax for numeric: "0xffgf"
```

See also

- [TO_HEX](#)
- [HEX_TO_BINARY](#)

INITCAP

Capitalizes first letter of each alphanumeric word and puts the rest in lowercase.

Behavior type

[Immutable](#)

Syntax

INITCAP (*expression*)

Arguments

expression

(VARCHAR) is the string to format.

Notes

- Depends on collation setting of the locale.
- INITCAP is restricted to 32750 octet inputs, since it is possible for the UTF-8 representation of result to double in size.

Examples

Expression	Result
SELECT INITCAP('high speed database');	High Speed Database
SELECT INITCAP('LINUX TUTORIAL');	Linux Tutorial
SELECT INITCAP('abc DEF 123aVC 124Btd,IAsT');	Abc Def 123Avc 124Btd,Last
SELECT INITCAP('');	
SELECT INITCAP(null);	

INITCAPB

Capitalizes first letter of each alphanumeric word and puts the rest in lowercase. Multibyte characters are not converted and are skipped.

Behavior type

[Immutable](#)

Syntax

INITCAPB (*expression*)

Arguments

expression

(VARCHAR) is the string to format.

Notes

Depends on collation setting of the locale.

Examples

Expression	Result
SELECT INITCAPB('étudiant');	éTudiant
SELECT INITCAPB('high speed database');	High Speed Database
SELECT INITCAPB('LINUX TUTORIAL');	Linux Tutorial
SELECT INITCAPB('abc DEF 123aVC 124Btd,IAsT');	Abc Def 123Avc 124Btd,Last
SELECT INITCAPB('');	
SELECT INITCAPB(null);	

INSERT

Inserts a character string into a specified location in another character string.

Syntax

```
INSERT( 'string1', n, m, 'string2' )
```

Behavior type

[Immutable](#)

Arguments

string1

(VARCHAR) Is the string in which to insert the new string.

n

A character of type INTEGER that represents the starting point for the insertion within* **string1** *. You specify the number of characters from the first character in string1 as the starting point for the insertion. For example, to insert characters before "c", in the string "abcdef," enter 3.

m

A character of type INTEGER that represents the number of characters in* **string1** (if any) *that should be replaced by the insertion. For example,if you want the insertion to replace the letters "cd" in the string "abcdef, " enter 2.

string2

(VARCHAR) Is the string to be inserted.

Examples

The following example changes the string Warehouse to Storehouse using the INSERT function:

```
=> SELECT INSERT ('Warehouse',1,3,'Stor');
INSERT
-----
Storehouse
(1 row)
```

INSTR

Searches * **string** *for * **substring** *and returns an integer indicating the position of the character in * **string** *that is the first character of this **occurrence** . The return value is based on the character position of the identified character.

Behavior type

[Immutable](#)

Syntax

```
INSTR ( string , substring [, position [, occurrence ] ] )
```

Arguments

string

(CHAR or VARCHAR, or BINARY or VARBINARY) Text expression to search.

substring

(CHAR or VARCHAR, or BINARY or VARBINARY) String to search for.

position

Nonzero integer indicating the character of string where Vertica begins the search. If position is negative, then Vertica counts backward from the end of string and then searches backward from the resulting position. The first character of string occupies the default position 1, and position cannot be 0.

occurrence

Integer indicating which occurrence of string Vertica searches. The value of occurrence must be positive (greater than 0), and the default is 1.

Notes

Both **position** and **occurrence** must be of types that can resolve to an integer. The default values of both parameters are 1, meaning Vertica begins searching at the first character of string for the first occurrence of substring. The return value is relative to the beginning of string, regardless of the value of position, and is expressed in characters.

If the search is unsuccessful (that is, if substring does not appear * **occurrence** *times after the **position** character of **string**, the return value is 0.

Examples

The first example searches forward in string 'abc' for substring 'b'. The search returns the position in 'abc' where 'b' occurs, or position 2. Because no position parameters are given, the default search starts at 'a', position 1.

```
=> SELECT INSTR('abc', 'b');
INSTR
-----
      2
(1 row)
```

The following three examples use character position to search backward to find the position of a substring.

Note

Although it might seem intuitive that the function returns a negative integer, the position of *n* occurrence is read left to right in the string, even though the search happens in reverse (from the end—or right side—of the string).

In the first example, the function counts backward one character from the end of the string, starting with character 'c'. The function then searches backward for the first occurrence of 'a', which it finds it in the first position in the search string.

```
=> SELECT INSTR('abc', 'a', -1);
INSTR
-----
      1
(1 row)
```

In the second example, the function counts backward one byte from the end of the string, starting with character 'c'. The function then searches backward for the first occurrence of 'a', which it finds it in the first position in the search string.

```
=> SELECT INSTR(VARBINARY 'abc', VARBINARY 'a', -1);
INSTR
-----
      1
(1 row)
```

In the third example, the function counts backward one character from the end of the string, starting with character 'b', and searches backward for substring 'bc', which it finds in the second position of the search string.

```
=> SELECT INSTR('abcb', 'bc', -1);
INSTR
-----
      2
(1 row)
```

In the fourth example, the function counts backward one character from the end of the string, starting with character 'b', and searches backward for substring 'bcef', which it does not find. The result is 0.

```
=> SELECT INSTR('abcb', 'bcef', -1);
INSTR
-----
      0
(1 row)
```

In the fifth example, the function counts backward one byte from the end of the string, starting with character 'b', and searches backward for substring 'bcef', which it does not find. The result is 0.

```
=> SELECT INSTR(VARBINARY 'abcb', VARBINARY 'bcef', -1);
INSTR
-----
      0
(1 row)
```

Multibyte characters are treated as a single character:

```
=> SELECT INSTR('aébc', 'b');
INSTR
-----
    3
(1 row)
```

Use INSTRB to treat multibyte characters as binary:

```
=> SELECT INSTRB('aébc', 'b');
INSTRB
-----
    4
(1 row)
```

INSTRB

Searches *string* for *substring* and returns an integer indicating the octet position within string that is the first *occurrence*. The return value is based on the octet position of the identified byte.

Behavior type

[Immutable](#)

Syntax

```
INSTRB ( string , substring [, position [, occurrence ] ] )
```

Arguments

string

Is the text expression to search.

substring

Is the string to search for.

position

Is a nonzero integer indicating the character of string where Vertica begins the search. If position is negative, then Vertica counts backward from the end of string and then searches backward from the resulting position. The first byte of string occupies the default position 1, and position cannot be 0.

occurrence

Is an integer indicating which occurrence of string Vertica searches. The value of occurrence must be positive (greater than 0), and the default is 1.

Notes

Both *position* and *occurrence* must be of types that can resolve to an integer. The default values of both parameters are 1, meaning Vertica begins searching at the first byte of string for the first occurrence of substring. The return value is relative to the beginning of string, regardless of the value of position, and is expressed in octets.

If the search is unsuccessful (that is, if substring does not appear ** occurrence* *times after the ** position* *character of ** string*, *then the return value is 0.

Examples

```
=> SELECT INSTRB('straße', 'ß');
INSTRB
-----
    5
(1 row)
```

See also

- [INSTR](#)

ISUTF8

Tests whether a string is a valid UTF-8 string. Returns true if the string conforms to UTF-8 standards, and false otherwise. This function is useful to test strings for UTF-8 compliance before passing them to one of the regular expression functions, such as [REGEXP_LIKE](#), which expect UTF-8 characters by default.

ISUTF8 checks for invalid UTF8 byte sequences, according to UTF-8 rules:

- invalid bytes
- an unexpected continuation byte
- a start byte not followed by enough continuation bytes
- an Overload Encoding

The presence of an invalid UTF-8 byte sequence results in a return value of false.

To coerce a string to UTF-8, use [MAKEUTF8](#).

Syntax

```
ISUTF8( string );
```

Arguments

string

The string to test for UTF-8 compliance.

Examples

```
=> SELECT ISUTF8(E'\xC2\xBF'); -- UTF-8 INVERTED QUESTION MARK ISUTF8
-----
t
(1 row)

=> SELECT ISUTF8(E'\xC2\xC0'); -- UNDEFINED UTF-8 CHARACTER
ISUTF8
-----
f
(1 row)
```

JARO_DISTANCE

Calculates and returns the [Jaro similarity](#), an edit distance between two sequences. It is useful for queries designed for short strings, such as finding similar names. Also see [Jaro-Winkler distance](#), which adds a prefix scale favoring strings that match in the beginning, and [edit distance](#), which returns the Levenshtein distance between two strings.

Behavior type

[Immutable](#)

Syntax

```
JARO_DISTANCE (string-expression1, string-expression2)
```

Arguments

string-expression1 , ***string-expression2***

The two VARCHAR expressions to compare. Neither can be NULL.

Example

Return only the names with a Jaro distance from 'rode' that is greater than 0.6:

```
=> SELECT name FROM names WHERE JARO_DISTANCE('rode', name) > 0.6;
name
-----
fred
frieda
rodgers
rogers
(4 rows)
```

JARO_WINKLER_DISTANCE

Calculates and returns the [Jaro-Winkler similarity](#), an edit distance between two sequences. It is useful for queries designed for short strings, such as finding similar names. It is a variant of the [Jaro distance](#) metric, to which it adds a prefix scale giving more favorable ratings for strings that match from the beginning. See also [edit distance](#), which returns the Levenshtein distance between two strings.

Behavior type

[Immutable](#)

Syntax

```
JARO_WINKLER_DISTANCE (string-expression1 , string-expression2 [ USING PARAMETERS prefix_scale=scale, prefix_length=length])
```

Arguments

string-expression1* , *string-expression2

The two VARCHAR expressions to compare. Neither can be NULL.

Parameters

scale

A FLOAT specifying the scale value by which to weight the importance of matching prefixes. Optional.

default = 0.1

length

An non-negative INT representing the maximum matching prefix length. Optional.

default = 4

Examples

Return only the names with a Jaro-Winkler distance from 'rode' that is greater than 0.6:

```
=> SELECT name FROM names WHERE JARO_WINKLER_DISTANCE('rode', name) > 0.6;
name
-----
fred
frieda
rodgers
rogers
(4 rows)
```

The Jaro-Winkler distance between 'help' and 'hello' given a [prefix_scale](#) of 0.1 and [prefix_length](#) of 0 is 0.7833333333333333:

```
=> select JARO_WINKLER_DISTANCE('help', 'hello' USING PARAMETERS prefix_scale=0.1, prefix_length=0);
jaro_winkler_distance
-----
0.7833333333333333
(1 row)
```

LEAST

Returns the smallest value in a list of expressions of any data type. All data types in the list must be the same or [compatible](#). A NULL value in any one of the expressions returns NULL. Results can vary, depending on the locale's collation setting.

Behavior type

[Stable](#)

Syntax

```
LEAST ( { * | expression[,...] } )
```

Arguments

* | ***expression*** [...]

The expressions to evaluate, one of the following:

- * (asterisk)
Evaluates all columns in the queried table.
- *expression*
An expression of any data type. Functions that are included in *expression* must be deterministic.

Examples

LEASTB returns 5 as the smallest value in the list:

```
=> SELECT LEASTB(7, 5, 10);
LEASTB
-----
     5
(1 row)
```

If you put quotes around the integer expressions, LEASTB compares the values as strings and returns '10' as the smallest value:

```
=> SELECT LEASTB('7', '5', '10');
LEASTB
-----
    10
(1 row)
```

LEAST returns 1.5, as INTEGER 2 is implicitly cast to FLOAT:

```
=> SELECT LEAST(2, 1.5);
LEAST
-----
    1.5
(1 row)
```

LEAST queries all columns in a view based on the VMart table `product_dimension`, and returns the smallest value in each row:

```
=> CREATE VIEW query1 AS SELECT shelf_width, shelf_height, shelf_depth FROM product_dimension;
CREATE VIEW
=> SELECT shelf_height, shelf_width, shelf_depth, least(*) FROM query1 WHERE shelf_height = 5;
shelf_height | shelf_width | shelf_depth | least
-----+-----+-----+-----
     5 |      3 |      4 |  3
     5 |      4 |      3 |  3
     5 |      1 |      4 |  1
     5 |      4 |      1 |  1
     5 |      2 |      4 |  2
     5 |      2 |      3 |  2
     5 |      1 |      3 |  1
     5 |      1 |      3 |  1
     5 |      5 |      1 |  1
     5 |      2 |      4 |  2
     5 |      4 |      5 |  4
     5 |      2 |      4 |  2
     5 |      4 |      4 |  4
     5 |      3 |      4 |  3
...
```

See also

[GREATEST](#)

LEASTB

Returns the smallest value in a list of expressions of any data type, using binary ordering. All data types in the list must be the same or [compatible](#). A NULL value in any one of the expressions returns NULL. Results can vary, depending on the locale's collation setting.

Behavior type

[Immutable](#)

Syntax

```
LEASTB ( { * | expression[,...] } )
```

Arguments

* | ***expression*** [...]

The expressions to evaluate, one of the following:

- ***** (asterisk)
Evaluates all columns in the queried table.
- ***expression***

An expression of any data type. Functions that are included in *expression* must be deterministic.

Examples

The following command selects *strasse* as the smallest value in the list:

```
=> SELECT LEASTB('straße', 'strasse');
LEASTB
-----
strasse
(1 row)
```

LEASTB returns 5 as the smallest value in the list:

```
=> SELECT LEAST(7, 5, 10);
LEAST
-----
5
(1 row)
```

If you put quotes around the integer expressions, LEAST compares the values as strings and returns '10' as the smallest value:

```
=> SELECT LEASTB('7', '5', '10');
LEAST
-----
10
(1 row)
```

The next example returns 1.5, as INTEGER 2 is implicitly cast to FLOAT:

```
=> SELECT LEASTB(2, 1.5);
LEASTB
-----
1.5
(1 row)
```

LEASTB queries all columns in a view based on the VMart table *product_dimension*, and returns the smallest value in each row:

```
=> CREATE VIEW query1 AS SELECT shelf_width, shelf_height, shelf_depth FROM product_dimension;
CREATE VIEW
=> SELECT shelf_height, shelf_width, shelf_depth, leastb(*) FROM query1 WHERE shelf_height = 5;
shelf_height | shelf_width | shelf_depth | leastb
-----+-----+-----+-----
5 | 3 | 4 | 3
5 | 4 | 3 | 3
5 | 1 | 4 | 1
5 | 4 | 1 | 1
5 | 2 | 4 | 2
5 | 2 | 3 | 2
5 | 1 | 3 | 1
5 | 1 | 3 | 1
5 | 5 | 1 | 1
5 | 2 | 4 | 2
5 | 4 | 5 | 4
5 | 2 | 4 | 2
5 | 4 | 4 | 4
5 | 3 | 4 | 3
5 | 5 | 4 | 4
5 | 5 | 1 | 1
5 | 3 | 1 | 1
...
```

See also

[GREATESTB](#)

[LEFT](#)

Returns the specified characters from the left side of a string.

Behavior type

[Immutable](#)

Syntax

```
LEFT ( string-expr, length )
```

Arguments

string-expr

The string expression to return.

length

An integer value that specifies how many characters to return.

Examples

```
=> SELECT LEFT('vertica', 3);
```

```
LEFT
```

```
-----
```

```
ver
```

```
(1 row)
```

```
SELECT DISTINCT(
```

```
  LEFT (customer_name, 4)) FnameTruncated
```

```
FROM customer_dimension ORDER BY FnameTruncated LIMIT 10;
```

```
FnameTruncated
```

```
-----
```

```
Alex
```

```
Amer
```

```
Amy
```

```
Anna
```

```
Barb
```

```
Ben
```

```
Bett
```

```
Bria
```

```
Carl
```

```
Crai
```

```
(10 rows)
```

See also

[SUBSTR](#)

[LENGTH](#)

Returns the length of a string. The behavior of [LENGTH](#) varies according to the input data type:

- CHAR and VARCHAR: Identical to [CHARACTER_LENGTH](#), returns the string length in UTF-8 characters, .
- CHAR: Strips padding.
- BINARY and VARBINARY: Identical to [OCTET_LENGTH](#), returns the string length in bytes (octets).

Behavior type

[Immutable](#)

Syntax

```
LENGTH ( expression )
```

Arguments

expression

String to evaluate, one of the following: CHAR, VARCHAR, BINARY or VARBINARY.

Examples

Statement	Returns
<pre>SELECT LENGTH('1234 '::CHAR(10));</pre>	4

<code>SELECT LENGTH('1234 '::VARCHAR(10));</code>	6
<code>SELECT LENGTH('1234 '::BINARY(10));</code>	10
<code>SELECT LENGTH('1234 '::VARBINARY(10));</code>	6
<code>SELECT LENGTH(NULL::CHAR(10)) IS NULL;</code>	t

See also

[BIT_LENGTH](#)

LOWER

Takes a string value and returns a VARCHAR value converted to lowercase.

Behavior type

[stable](#)

Syntax

```
LOWER ( expression )
```

Arguments

expression

CHAR or VARCHAR string to convert, where the string width is ≤ 65000 octets.

Important

In practice, *expression* should not exceed 32,500 octets. LOWER does not use the locale's collation setting—for example, `collation=binary`—to identify its encoding; rather, it treats the input argument as a UTF-8 encoded string. The UTF-8 representation of the input value might be double its original width. As a result, LOWER returns an error if the input value exceeds 32,500 octets.

Note also that if *expression* is a table column, LOWER calculates its size from the column's defined width, and not from the column data. If the column width is greater than VARCHAR(32500), Vertica returns an error.

Examples

```
=> SELECT LOWER('AbCdEfG');
```

```
LOWER
```

```
-----
```

```
abcdefg
```

```
(1 row)
```

```
=> SELECT LOWER('The Bat In The Hat');
```

```
LOWER
```

```
-----
```

```
the bat in the hat
```

```
(1 row)
```

```
=> SELECT LOWER('ÉTUDIANT');
```

```
LOWER
```

```
-----
```

```
étudiant
```

```
(1 row)
```

LOWERB

Returns a character string with each ASCII character converted to lowercase. Multi-byte characters are skipped and not converted.

Behavior type

[Immutable](#)

Syntax

```
LOWERB ( expression )
```

Arguments

expression

CHAR or VARCHAR string to convert

Examples

In the following example, the multi-byte UTF-8 character É is not converted to lowercase:

```
=> SELECT LOWERB('ÉTUDIANT');
LOWERB
-----
Étudiant
(1 row)

=> SELECT LOWER('ÉTUDIANT');
LOWER
-----
étudiant
(1 row)

=> SELECT LOWERB('AbCdEfG');
LOWERB
-----
abcdefg
(1 row)

=> SELECT LOWERB('The Vertica Database');
LOWERB
-----
the vertica database
(1 row)
```

LPAD

Returns a VARCHAR value representing a string of a specific length filled on the left with specific characters.

Behavior type

[Immutable](#)

Syntax

```
LPAD ( expression , length [ , fill ] )
```

Arguments

expression

(CHAR OR VARCHAR) specifies the string to fill

length

(INTEGER) specifies the number of characters to return

fill

(CHAR OR VARCHAR) specifies the repeating string of characters with which to fill the output string. The default is the space character.

Examples

```
=> SELECT LPAD('database', 15, 'xyz');
LPAD
-----
xyzxyzdatabase
(1 row)
```

If the string is already longer than the specified length it is truncated on the right:

```
=> SELECT LPAD('establishment', 10, 'abc');
LPAD
-----
establishm
(1 row)
```

LTRIM

Returns a VARCHAR value representing a string with leading blanks removed from the left side (beginning).

Behavior type

[Immutable](#)

Syntax

```
LTRIM ( expression [ , characters ] )
```

Arguments

expression

(CHAR or VARCHAR) is the string to trim

characters

(CHAR or VARCHAR) specifies the characters to remove from the left side of *expression* . The default is the space character.

Examples

```
=> SELECT LTRIM('zzzyyyyyxxxxxxxxtrim', 'xyz');
LTRIM
-----
trim
(1 row)
```

See also

- [BTRIM](#)
- [RTRIM](#)
- [TRIM](#)

MAKEUTF8

Coerces a string to UTF-8 by removing or replacing non-UTF-8 characters.

MAKEUTF8 flags invalid UTF-8 characters byte by byte. For example, the byte sequence `0xE0 0x7F 0x80` is an invalid three-byte UTF-8 sequence, but the middle byte, `0x7F` , is a valid one-byte UTF-8 character. In this example, `0x7F` is preserved and the other two bytes are removed or replaced.

Syntax

```
MAKEUTF8( string-expression [USING PARAMETERS param=value] );
```

Arguments

string-expression

The string expression to evaluate for non-UTF-8 characters

Parameters

replacement_string

Specifies the VARCHAR(16) string that MAKEUTF8 uses to replace each non-UTF-8 character that it finds in *string-expression* . If this parameter is omitted, non-UTF-8 characters are removed. For example, the following SQL specifies to replace all non-UTF characters in the `name` column with the string `^` :

```
=> SELECT MAKEUTF8(name USING PARAMETERS replacement_string='^') FROM people;
```

MD5

Calculates the MD5 hash of string, returning the result as a VARCHAR string in hexadecimal.

Behavior type

[Immutable](#)

Syntax

```
MD5 ( string )
```

Arguments

string

Is the argument string.

Examples

```
=> SELECT MD5('123');
      MD5
```

```
-----
202cb962ac59075b964b07152d234b70
```

```
(1 row)
```

```
=> SELECT MD5('Vertica::bytea');
      MD5
```

```
-----
fc45b815747d8236f9f6fdb9c2c3f676
```

```
(1 row)
```

- [SHA224](#)
- [SHA256](#)
- [SHA384](#)
- [SHA512](#)

OCTET_LENGTH

Takes one argument as an input and returns the string length in octets for all string types.

Behavior type

[Immutable](#)

Syntax

```
OCTET_LENGTH ( expression )
```

Arguments

expression

(CHAR or VARCHAR or BINARY or VARBINARY) is the string to measure.

Notes

- If the data type of *expression* is a CHAR, VARCHAR or VARBINARY, the result is the same as the actual length of *expression* in octets. For CHAR, the length does not include any trailing spaces.
- If the data type of *expression* is BINARY, the result is the same as the fixed-length of *expression*.
- If the value of *expression* is NULL, the result is NULL.

Examples

Expression	Result
<code>SELECT OCTET_LENGTH(CHAR(10) '1234');</code>	4
<code>SELECT OCTET_LENGTH(CHAR(10) '1234');</code>	4
<code>SELECT OCTET_LENGTH(CHAR(10) ' 1234');</code>	6
<code>SELECT OCTET_LENGTH(VARCHAR(10) '1234');</code>	6
<code>SELECT OCTET_LENGTH(VARCHAR(10) '1234');</code>	5
<code>SELECT OCTET_LENGTH(VARCHAR(10) '1234');</code>	4
<code>SELECT OCTET_LENGTH(VARCHAR(10) ' 1234');</code>	7
<code>SELECT OCTET_LENGTH('abc'::VARBINARY);</code>	3
<code>SELECT OCTET_LENGTH(VARBINARY 'abc');</code>	3

SELECT OCTET_LENGTH(VARBINARY 'abc');	5
SELECT OCTET_LENGTH(BINARY(6) 'abc');	6
SELECT OCTET_LENGTH(VARBINARY "");	0
SELECT OCTET_LENGTH("::BINARY);	1
SELECT OCTET_LENGTH(null::VARBINARY);	
SELECT OCTET_LENGTH(null::BINARY);	

See also

- [BIT_LENGTH](#)
- [CHARACTER_LENGTH](#)
- [LENGTH](#)

OVERLAY

Replaces part of a string with another string and returns the new string value as a VARCHAR.

Behavior type

[Immutable](#) if using OCTETS, [Stable](#) otherwise

Syntax

```
OVERLAY ( input-string PLACING replace-string FROM position [ FOR extent ] [ USING { CHARACTERS | OCTETS } ] )
```

Arguments

input-string

The string to process, of type CHAR or VARCHAR.

replace-string

The string to replace the specified substring of *input-string*, of type CHAR or VARCHAR.

position

Integer ≥ 1 that specifies the first character or octet of *input-string* to overlay *replace-string*.

extent

Integer that specifies how many characters or octets of *input-string* to overlay with *replace-string*. If omitted, OVERLAY uses the length of *replace-string*.

For example, compare the following calls to OVERLAY:

- OVERLAY omits **FOR** clause. The number of characters replaced in the input string equals the number of characters in replacement string **ABC**:

```
dbadmin=> SELECT OVERLAY ('123456789' PLACING 'ABC' FROM 5);
overlay
-----
1234ABC89
(1 row)
```

- OVERLAY includes a **FOR** clause that specifies to replace four characters in the input string with the replacement string. The replacement string is three characters long, so OVERLAY returns a string that is one character shorter than the input string:

```
=> SELECT OVERLAY ('123456789' PLACING 'ABC' FROM 5 FOR 4);
overlay
-----
1234ABC9
(1 row)
```

- OVERLAY includes a **FOR** clause that specifies to replace -2 characters in the input string with the replacement string. The function returns a string that is two characters longer than the input string:

```
=> SELECT OVERLAY ('123456789' PLACING 'ABC' FROM 5 FOR -2);
overlay
-----
1234ABC3456789
(1 row)
```

USING CHARACTERS | OCTETS

Specifies whether OVERLAY uses characters (default) or octets.

Note

If you specify **USING OCTETS**, Vertica calls the [OVERLAYB](#) function.

Examples

```
=> SELECT OVERLAY('123456789' PLACING 'xxx' FROM 2);
overlay
-----
1xxx56789
(1 row)

=> SELECT OVERLAY('123456789' PLACING 'XXX' FROM 2 USING OCTETS);
overlayb
-----
1XXX56789
(1 row)

=> SELECT OVERLAY('123456789' PLACING 'xxx' FROM 2 FOR 4);
overlay
-----
1xxx6789
(1 row)

=> SELECT OVERLAY('123456789' PLACING 'xxx' FROM 2 FOR 5);
overlay
-----
1xxx789
(1 row)

=> SELECT OVERLAY('123456789' PLACING 'xxx' FROM 2 FOR 6);
overlay
-----
1xxx89
(1 row)
```

OVERLAYB

Replaces part of a string with another string and returns the new string as an octet value.

The OVERLAYB function treats the multibyte character string as a string of octets (bytes) and use octet numbers as incoming and outgoing position specifiers and lengths. The strings themselves are type VARCHAR, but they treated as if each byte was a separate character.

Behavior type

[Immutable](#)

Syntax

```
OVERLAYB ( input-string, replace-string, position [, extent ] )
```

Arguments

input-string

The string to process, of type CHAR or VARCHAR.

replace-string

The string to replace the specified substring of *input-string* , of type CHAR or VARCHAR.

position

Integer ≥ 1 that specifies the first octet of* *input-string* * to overlay *replace-string* .

extent

Integer that specifies how many octets of *input-string* to overlay with *replace-string* . If omitted, OVERLAY uses the length of *replace-string* .

Examples

```
=> SELECT OVERLAYB('123456789', 'ééé', 2);  
OVERLAYB
```

```
-----  
1ééé89
```

```
(1 row)
```

```
=> SELECT OVERLAYB('123456789', 'BBB', 2);  
OVERLAYB
```

```
-----  
1BBB89
```

```
(1 row)
```

```
=> SELECT OVERLAYB('123456789', 'xxx', 2);  
OVERLAYB
```

```
-----  
1xxx56789
```

```
(1 row)
```

```
=> SELECT OVERLAYB('123456789', 'xxx', 2, 4);  
OVERLAYB
```

```
-----  
1xxx6789
```

```
(1 row)
```

```
=> SELECT OVERLAYB('123456789', 'xxx', 2, 5);  
OVERLAYB
```

```
-----  
1xxx789
```

```
(1 row)
```

```
=> SELECT OVERLAYB('123456789', 'xxx', 2, 6);  
OVERLAYB
```

```
-----  
1xxx89
```

```
(1 row)
```

POSITION

Returns an INTEGER value representing the character location of a specified substring with a string (counting from one).

Behavior type

[Immutable](#)

Syntax 1

```
POSITION ( substring IN string [ USING { CHARACTERS | OCTETS } ] )
```

Arguments

substring

(CHAR or VARCHAR) is the substring to locate

string

(CHAR or VARCHAR) is the string in which to locate the substring

USING CHARACTERS | OCTETS

Determines whether the position is reported by using characters (the default) or octets.

Syntax 2

```
POSITION ( substring IN string )
```

Arguments

substring

(VARBINARY) is the substring to locate

string

(VARBINARY) is the string in which to locate the substring

Notes

- When the string and substring are CHAR or VARCHAR, the return value is based on either the character or octet position of the substring.
- When the string and substring are VARBINARY, the return value is always based on the octet position of the substring.
- The string and substring must be consistent. Do not mix VARBINARY with CHAR or VARCHAR.
- POSITION is similar to [STRPOS](#) although POSITION allows finding by characters and by octet.
- If the string is not found, the return value is zero.

Examples

```
=> SELECT POSITION('é' IN 'étudiant' USING CHARACTERS);
position
-----
      1
(1 row)
=> SELECT POSITION('ß' IN 'straße' USING OCTETS);
positionb
-----
      5
(1 row)
=> SELECT POSITION('c' IN 'abcd' USING CHARACTERS);
position
-----
      3
(1 row)
=> SELECT POSITION(VARBINARY '456' IN VARBINARY '123456789');
position
-----
      4
(1 row)
SELECT POSITION('n' in 'León') as 'default',
      POSITIONB('León', 'n') as 'POSITIONB',
      POSITION('n' in 'León' USING CHARACTERS) as 'pos_chars',
      POSITION('n' in 'León' USING OCTETS) as 'pos_oct', INSTR('León','n'),
      INSTRB('León','n'), REGEXP_INSTR('León','n');
default | POSITIONB | pos_chars | pos_oct | INSTR | INSTRB | REGEXP_INSTR
-----+-----+-----+-----+-----+-----+-----
      4 |      5 |      4 |      5 |      4 |      5 |      4
(1 row)
```

POSITIONB

Returns an INTEGER value representing the octet location of a specified substring with a string (counting from one).

Behavior type

[Immutable](#)

Syntax

```
POSITIONB ( string, substring )
```

Arguments

string

(CHAR or VARCHAR) is the string in which to locate the substring

substring

(CHAR or VARCHAR) is the substring to locate

Examples

```
=> SELECT POSITIONB('straße', 'ße');
```

```
POSITIONB
```

```
-----  
5
```

```
(1 row)
```

```
=> SELECT POSITIONB('étudiant', 'é');
```

```
POSITIONB
```

```
-----  
1
```

```
(1 row)
```

QUOTE_IDENT

Returns the specified string argument in the format required to use the string as an [identifier](#) in an SQL statement. Quotes are added as needed—for example, if the string contains non-identifier characters or is an SQL or [Vertica-reserved](#) keyword:

- **time**
- **Next week**
- **SELECT**

Embedded double quotes are doubled.

Note

- SQL identifiers such as table and column names are stored as created, and references to them are resolved using case-insensitive compares. Thus, you do not need to double-quote mixed-case identifiers.
- Vertica quotes all reserved keywords, even if unused.

Behavior type

[Immutable](#)

Syntax

```
QUOTE_IDENT( 'string' )
```

Arguments

string

String to quote

Examples

Quoted identifiers are case-insensitive, and Vertica does not supply the quotes:

```
=> SELECT QUOTE_IDENT('VertIcA');
```

```
QUOTE_IDENT
```

```
-----  
VertIcA
```

```
(1 row)
```

```
=> SELECT QUOTE_IDENT('Vertica database');
```

```
QUOTE_IDENT
```

```
-----  
"Vertica database"
```

```
(1 row)
```

Embedded double quotes are doubled:

```
=> SELECT QUOTE_IDENT('Vertica "!" database');
```

```
QUOTE_IDENT
```

```
-----  
"Vertica ""!"" database"
```

```
(1 row)
```

The following example uses the SQL keyword SELECT, so results are double quoted:

```
=> SELECT QUOTE_IDENT('select');
QUOTE_IDENT
-----
"select"
(1 row)
```

See also

- [QUOTE_LITERAL](#)
- [QUOTE_NULLABLE](#)

QUOTE_LITERAL

Returns the given string suitably quoted for use as a string literal in a SQL statement string. Embedded single quotes and backslashes are doubled. As per the SQL standard, the function recognizes two consecutive single quotes within a string literal as a single quote character.

Behavior type

[Immutable](#)

Syntax

```
QUOTE_LITERAL ( string )
```

Arguments

string-expression

Argument that resolves to one or more strings to format as string literals.

Examples

In the following example, the first query returns no first name for Cher or Sting; the second query uses QUOTE_LITERAL, which sets off string values with single quotes, including empty strings. In this case, `fname` for Sting is set to an empty string (`"`), while `fname` for Cher is empty, indicating that it is set to null value:

```
=> SELECT * FROM lead_vocalists ORDER BY Iname ASC;
fname | Iname |          band
-----+-----+-----
      | Cher  | ["Sonny and Cher"]
Mick  | Jagger | ["Rolling Stones"]
Diana | Ross   | ["Supremes"]
Grace | Slick  | ["Jefferson Airplane","Jefferson Starship"]
      | Sting  | ["Police"]
Stevie | Winwood | ["Spencer Davis Group","Traffic","Blind Faith"]
(6 rows)

=> SELECT QUOTE_LITERAL (fname) "First Name", QUOTE_NULLABLE (Iname) "Last Name", band FROM lead_vocalists ORDER BY Iname ASC;
First Name | Last Name |          band
-----+-----+-----
          | 'Cher'   | ["Sonny and Cher"]
'Mick'    | 'Jagger' | ["Rolling Stones"]
'Diana'   | 'Ross'   | ["Supremes"]
'Grace'   | 'Slick'  | ["Jefferson Airplane","Jefferson Starship"]
"         | 'Sting'  | ["Police"]
'Stevie'  | 'Winwood' | ["Spencer Davis Group","Traffic","Blind Faith"]
(6 rows)
```

See also

- [Character string literals](#)
- [QUOTE_NULLABLE](#)

QUOTE_NULLABLE

Returns the given string suitably quoted for use as a string literal in an SQL statement string; or if the argument is null, returns the unquoted string `NULL`. Embedded single-quotes and backslashes are properly doubled.

Behavior type

[Immutable](#)

Syntax

```
QUOTE_NULLABLE ( string-expression )
```

Arguments

string-expression

Argument that resolves to one or more strings to format as string literals. If *string-expression* resolves to null value, QUOTE_NULLABLE returns **NULL**.

Examples

The following examples use the table `lead_vocalists`, where the first names (`fname`) for Cher and Sting are set to **NULL** and an empty string, respectively

```
=> SELECT * from lead_vocalists ORDER BY lname DESC;
fname | lname |          band
-----+-----+-----
Stevie | Winwood | ["Spencer Davis Group","Traffic","Blind Faith"]
      | Sting  | ["Police"]
Grace  | Slick  | ["Jefferson Airplane","Jefferson Starship"]
Diana  | Ross   | ["Supremes"]
Mick   | Jagger | ["Rolling Stones"]
      | Cher   | ["Sonny and Cher"]
(6 rows)

=> SELECT * FROM lead_vocalists WHERE fname IS NULL;
fname | lname |          band
-----+-----+-----
      | Cher  | ["Sonny and Cher"]
(1 row)

=> SELECT * FROM lead_vocalists WHERE fname = "";
fname | lname |          band
-----+-----+-----
      | Sting | ["Police"]
(1 row)
```

The following query uses QUOTE_NULLABLE. Like [QUOTE_LITERAL](#), QUOTE_NULLABLE sets off string values with single quotes, including empty strings. Unlike QUOTE_LITERAL, QUOTE_NULLABLE outputs **NULL** for null values:

```
=> SELECT QUOTE_NULLABLE (fname) "First Name", QUOTE_NULLABLE (lname) "Last Name", band FROM lead_vocalists ORDER BY fname DESC;
First Name | Last Name |          band
-----+-----+-----
NULL       | 'Cher'   | ["Sonny and Cher"]
'Stevie'   | 'Winwood' | ["Spencer Davis Group","Traffic","Blind Faith"]
'Mick'     | 'Jagger' | ["Rolling Stones"]
'Grace'    | 'Slick'  | ["Jefferson Airplane","Jefferson Starship"]
'Diana'    | 'Ross'   | ["Supremes"]
"         | 'Sting'  | ["Police"]
(6 rows)
```

See also

[Character string literals](#)

REPEAT

Replicates a string the specified number of times and concatenates the replicated values as a single string. The return value takes on the data type of the string argument. Return values for non-LONG data types and LONG data types can be up to 65000 and 32000000 bytes in length, respectively. If the length of *string * count* exceeds these limits, Vertica silently truncates the results.

Behavior type

[Immutable](#)

Syntax

```
REPEAT ('string', count)
```

Arguments

string

The string to repeat, one of the following:

- CHAR
- VARCHAR
- BINARY
- VARBINARY
- LONG VARCHAR
- LONG VARBINARY

count

An integer expression that specifies how many times to repeat *string*.

Examples

The following example repeats **vmart** three times:

```
=> SELECT REPEAT ('vmart', 3);
      REPEAT
-----
vmartvmartvmart
(1 row)
```

REPLACE

Replaces all occurrences of characters in a string with another set of characters.

Behavior type

[Immutable](#)

Syntax

```
REPLACE ('string', 'target', 'replacement')
```

Arguments

string

The string to modify.

target

The characters in *string* to replace.

replacement

The characters to replace *target*.

Examples

```
=> SELECT REPLACE('Documentation%20Library', '%20', ' ');
      REPLACE
-----
Documentation Library
(1 row)

=> SELECT REPLACE('This &amp; That', '&amp;', 'and');
      REPLACE
-----
This and That
(1 row)

=> SELECT REPLACE('straße', 'ß', 'ss');
      REPLACE
-----
strasse
(1 row)
```

RIGHT

Returns the specified characters from the right side of a string.

Behavior type

[Immutable](#)

Syntax

```
RIGHT ( string-expr, length )
```

Arguments

string-expr

The string expression to return.

length

An integer value that specifies how many characters to return.

Examples

The following query returns the last three characters of the string 'vertica':

```
=> SELECT RIGHT('vertica', 3);
RIGHT
-----
ica
(1 row)
```

The following query queries date column `date_ordered` from table `store.store_orders_fact` . It coerces the dates to strings and extracts the last five characters from each string. It then returns all distinct strings:

```
SELECT DISTINCT(
  RIGHT(date_ordered::varchar, 5)) MonthDays
FROM store.store_orders_fact ORDER BY MonthDays;
MonthDays
-----
01-01
01-02
01-03
01-04
01-05
01-06
01-07
01-08
01-09
01-10
02-01
02-02
02-03
...
11-08
11-09
11-10
12-01
12-02
12-03
12-04
12-05
12-06
12-07
12-08
12-09
12-10
(120 rows)
```

See also

[SUBSTR](#)

RPAD

Returns a VARCHAR value representing a string of a specific length filled on the right with specific characters.

Behavior type

[Immutable](#)

Syntax

```
RPAD ( expression , length [ , fill ] )
```

Arguments

expression

(CHAR OR VARCHAR) specifies the string to fill

length

(INTEGER) specifies the number of characters to return

fill

(CHAR OR VARCHAR) specifies the repeating string of characters with which to fill the output string. The default is the space character.

Examples

```
=> SELECT RPAD('database', 15, 'xzy');
      RPAD
-----
databasexzyxzyx
(1 row)
```

If the string is already longer than the specified length it is truncated on the right:

```
=> SELECT RPAD('database', 6, 'xzy');
      RPAD
-----
databa
(1 row)
```

RTRIM

Returns a VARCHAR value representing a string with trailing blanks removed from the right side (end).

Behavior type

[Immutable](#)

Syntax

```
RTRIM ( expression [ , characters ] )
```

Arguments

expression

(CHAR or VARCHAR) is the string to trim

characters

(CHAR or VARCHAR) specifies the characters to remove from the right side of *expression* . The default is the space character.

Examples

```
=> SELECT RTRIM('trimzzzyyyyyyxxxxxxxx', 'xyz');
      RTRIM
-----
trim
(1 row)
```

See also

- [BTRIM](#)
- [LTRIM](#)
- [TRIM](#)

Uses the US Secure Hash Algorithm 1 to calculate the **SHA1** hash of string. Returns the result as a **VARCHAR** string in hexadecimal.

Behavior type

[Immutable](#)

Syntax

```
SHA1 ( string )
```

Arguments

string

The **VARCHAR** or **VARBINARY** string to be calculated.

Examples

The following examples calculate the **SHA1** hash of the provided strings:

```
=> SELECT SHA1('123');
      SHA1
-----
40bd001563085fc35165329ea1ff5c5ecbdbbeef
(1 row)
```

```
=> SELECT SHA1('Vertica'::bytea);
      SHA1
-----
ee2cff8d3444995c6c301546c4fc5ee152d77c11
(1 row)
```

SHA224

Uses the US Secure Hash Algorithm 2 to calculate the **SHA224** hash of string. Returns the result as a **VARCHAR** string in hexadecimal.

Behavior type

[Immutable](#)

Syntax

```
SHA224 ( string )
```

Arguments

string

The **VARCHAR** or **VARBINARY** string to be calculated.

Examples

The following examples calculate the **SHA224** hash of the provided strings:

```
=> SELECT SHA224('abc');
      SHA224
-----
78d8045d684abd2eece923758f3cd781489df3a48e1278982466017f
(1 row)
```

```
=> SELECT SHA224('Vertica'::bytea);
      SHA224
-----
135ac268f64ff3124aeeebc3cc0af0a29fd600a3be8e29ed97e45e25
(1 row)
```

```
=> SELECT sha224("::varbinary) = 'd14a028c2a3a2bc9476102bb288234c415a2b01f828ea62ac5b3e42f' AS "TRUE";
TRUE
-----
t
(1 row)
```

SHA256

Uses the US Secure Hash Algorithm 2 to calculate the **SHA256** hash of string. Returns the result as a **VARCHAR** string in hexadecimal.

Behavior type

[Immutable](#)

Syntax

```
SHA256 ( string )
```

Arguments

string

The **VARCHAR** or **VARBINARY** string to be calculated.

Examples

The following examples calculate the **SHA256** hash of the provided strings:

```
=> SELECT SHA256('abc');
          SHA256
-----
a665a45920422f9d417e4867efdc4fb8a04a1f3fff1fa07e998e86f7f7a27ae3
(1 row)
```

```
=> SELECT SHA256('Vertica'::bytea);
          SHA256
-----
9981b0b7df9f5be06e9e1a7f4ae2336a7868d9ab522b9a6ca6a87cd9ed95ba53
(1 row)
```

```
=> SELECT sha256("") = 'e3b0c44298fc1c149afb4c8996fb92427ae41e4649b934ca495991b7852b855' AS "TRUE";
TRUE
-----
t
(1 row)
```

SHA384

Uses the US Secure Hash Algorithm 2 to calculate the **SHA384** hash of string. Returns the result as a **VARCHAR** string in hexadecimal.

Behavior type

[Immutable](#)

Syntax

```
SHA384 ( string )
```

Arguments

string

The **VARCHAR** or **VARBINARY** string to be calculated.

Examples

The following examples calculate the **SHA384** hash of the provided strings:

```
=> SELECT SHA384('123');
          SHA384
-----
9a0a82f0c0cf31470d7affede3406cc9aa8410671520b727044eda15b4c25532a9b5cd8aaf9cec4919d76255b6bfb00f
(1 row)
```

```
=> SELECT SHA384('Vertica::bytea');
          SHA384
-----
3431a717dc3289862bbd636a064d26980b47ebe4684b800cff4756f0c24985866ef97763eafd548fedb0ce28722c96bb
(1 row)
```

- [SHA256](#)
- [SHA384](#)

SOUNDEX

Takes a VARCHAR argument and returns a four-character code that enables comparison of that argument with other SOUNDEX-encoded strings that are spelled differently in English, but are phonetically similar. SOUNDEX implements an algorithm that was developed by Robert C. Russell and Margaret King Odell, and is described in [The Art of Computer Programming, Vol. 3](#).

Behavior type

[Immutable](#)

Syntax

```
SOUNDEX ( string-expression )
```

Arguments

string-expression

The VARCHAR expression to encode.

Soundex encoding algorithm

Vertica uses the following Soundex encoding algorithm, which complies with most SQL implementations:

1. Save the first letter. Map all occurrences of a, e, i, o, u, y, h, w to zero (0).
2. Replace all consonants (include the first letter) with digits:
 - b, f, p, v → 1
 - c, g, j, k, q, s, x, z → 2
 - d, t → 3
 - l → 4
 - m, n → 5
 - r → 6
3. Replace all adjacent same digits with one digit, and then remove all zero (0) digits
4. If the saved letter's digit is the same as the resulting first digit, remove the digit (keep the letter).
5. Append 3 zeros if result contains less than 3 digits. Remove all except first letter and 3 digits after it.

Note

Encoding ignores all non-alphabetic characters—for example, the apostrophe in O'Connor.

Examples

Find last names in the `employee_dimension` table that are phonetically similar to `Lee` :

```
SELECT employee_last_name, employee_first_name, employee_state
FROM public.employee_dimension
WHERE SOUNDEX(employee_last_name) = SOUNDEX('Lee')
ORDER BY employee_state, employee_last_name, employee_first_name;
```

```
Lea      | James      | AZ
Li       | Sam        | AZ
Lee      | Darlene    | CA
Lee      | Juanita    | CA
Li       | Amy        | CA
Li       | Barbara    | CA
Li       | Ben        | CA
...
```

See also

[SOUNDEX_MATCHES](#)

SOUNDEX_MATCHES

Compares the Soundex encodings of two strings. The function then returns an integer that indicates the number of matching characters, in the same order. The return value is 0 to 4 inclusive, where 0 indicates no match, and 4 an exact match.

For details on how Vertica implements Soundex encoding, see [Soundex Encoding Algorithm](#).

Behavior type

[Immutable](#)

Syntax

```
SOUNDEX_MATCHES ( string-expression1, string-expression2 )
```

Arguments

string-expression1 , *string-expression2*

The two VARCHAR expressions to encode and compare.

Examples

Find how well the Soundex encodings of two strings match:

- Compare the Soundex encodings of **Lewis** and **Li** :

```
> SELECT SOUNDEX_MATCHES('Lewis', 'Li');
SOUNDEX_MATCHES
-----
          3
(1 row)
```

- Compare the Soundex encodings of **Lee** and **Li** :

```
=> SELECT SOUNDEX_MATCHES('Lee', 'Li');
SOUNDEX_MATCHES
-----
          4
(1 row)
```

Find last names in the **employee_dimension** table whose Soundex encodings match at least 3 characters in the encoding for **Lewis** :

```
=> SELECT DISTINCT(employee_last_name)
   FROM public.employee_dimension
   WHERE SOUNDEX_MATCHES (employee_last_name, 'Lewis' ) >= 3 ORDER BY employee_last_name;
employee_last_name
-----
Lea
Lee
Leigh
Lewis
Li
Reyes
(6 rows)
```

See also

[SOUNDEX](#)

[SPACE](#)

Returns the specified number of blank spaces, typically for insertion into a character string.

Behavior type

[Immutable](#)

Syntax

```
SPACE(n)
```

Arguments

n

An integer argument that specifies how many spaces to insert.

Examples

The following example concatenates strings **x** and **y** with 10 spaces inserted between them:

```
=> SELECT 'x' || SPACE(10) || 'y' AS Ten_spaces;
Ten_spaces
-----
x      y
(1 row)
```

SPLIT_PART

Splits string on the delimiter and returns the string at the location of the beginning of the specified field (counting from 1).

Behavior type

[Immutable](#)

Syntax

```
SPLIT_PART ( string , delimiter , field )
```

Arguments

string

Argument string

delimiter

Delimiter

field

(INTEGER) Number of the part to return

Notes

Use this with the character form of the subfield.

Examples

The specified integer of 2 returns the second string, or **def** .

```
=> SELECT SPLIT_PART('abc~@~def~@~ghi', '~@~', 2);
SPLIT_PART
-----
def
(1 row)
```

In the next example, specify 3, which returns the third string, or **789** .

```
=> SELECT SPLIT_PART('123~|~456~|~789', '~|~', 3);
SPLIT_PART
-----
789
(1 row)
```

The tildes are for readability only. Omitting them returns the same results:

```
=> SELECT SPLIT_PART('123|456|789', '|', 3);
SPLIT_PART
-----
789
(1 row)
```

See what happens if you specify an integer that exceeds the number of strings: The result is not null, it is an empty string.

```
=> SELECT SPLIT_PART('123|456|789', '|', 4);
SPLIT_PART
-----
(1 row)

=> SELECT SPLIT_PART('123|456|789', '|', 4) IS NULL;
?column?
-----
f
(1 row)
```

If SPLIT_PART had returned NULL, LENGTH would have returned 0.

```
=> SELECT LENGTH (SPLIT_PART('123|456|789', '|', 4));
LENGTH
-----
0
(1 row)
```

If the locale of your database is BINARY, SPLIT_PART calls SPLIT_PARTB:

```
=> SHOW LOCALE;
name |          setting
-----+-----
locale | en_US@collation=binary (LEN_KBINARY)
(1 row)
=> SELECT SPLIT_PART('123456789', '5', 1);
split_partb
-----
1234
(1 row)

=> SET LOCALE TO 'en_US@collation=standard';
INFO 2567: Canonical locale: 'en_US@collation=standard'
Standard collation: 'LEN'
English (United States, collation=standard)
SET

=> SELECT SPLIT_PART('123456789', '5', 1);
split_part
-----
1234
(1 row)
```

See also

- [SPLIT_PARTB](#)

SPLIT_PARTB

Divides an input string on a delimiter character and returns the Nth segment, counting from 1. The VARCHAR arguments are treated as octets rather than UTF-8 characters.

Behavior type

[Immutable](#)

Syntax

```
SPLIT_PARTB ( string, delimiter, part-number )
```

Arguments

string

VARCHAR, the string to split.

delimiter

VARCHAR, the delimiter between segments.

part-number

INTEGER, the part number to return. The first part is 1, not 0.

Examples

The following example returns the third part of its input:

```
=> SELECT SPLIT_PARTB('straße~@~café~@~soupçon', '~@~', 3);
SPLIT_PARTB
-----
soupçon
(1 row)
```

The tildes are for readability only. Omitting them returns the same results:

```
=> SELECT SPLIT_PARTB('straße @ café @ soupçon', '@', 3);
SPLIT_PARTB
-----
soupçon
(1 row)
```

If the requested part number is greater than the number of parts, the function returns an empty string:

```
=> SELECT SPLIT_PARTB('straße @ café @ soupçon', '@', 4);
SPLIT_PARTB
-----
(1 row)

=> SELECT SPLIT_PARTB('straße @ café @ soupçon', '@', 4) IS NULL;
?column?
-----
f
(1 row)
```

If the locale of your database is BINARY, SPLIT_PART calls SPLIT_PARTB:

```
=> SHOW LOCALE;
name |      setting
-----+-----
locale | en_US@collation=binary (LEN_KBINARY)
(1 row)

=> SELECT SPLIT_PART('123456789', '5', 1);
split_partb
-----
1234
(1 row)

=> SET LOCALE TO 'en_US@collation=standard';
INFO 2567: Canonical locale: 'en_US@collation=standard'
Standard collation: 'LEN'
English (United States, collation=standard)
SET

=> SELECT SPLIT_PART('123456789', '5', 1);
split_part
-----
1234
(1 row)
```

See also

- [SPLIT_PART](#)

STRPOS

Returns an INTEGER value that represents the location of a specified substring within a string (counting from one). If the substring is not found, STRPOS returns 0.

STRPOS is similar to [POSITION](#); however, POSITION allows finding by characters and by octet.

Behavior type

[Immutable](#)

Syntax

```
STRPOS ( string-expression , substring )
```

Arguments

string-expression

The string in which to locate *substring*

substring

The substring to locate in *string-expression*

Examples

```
=> SELECT ship_type, shipping_key, strpos (ship_type, 'DAY') FROM shipping_dimension WHERE strpos > 0 ORDER BY ship_type, shipping_key;
```

ship_type	shipping_key	strpos
-----------	--------------	--------

ship_type	shipping_key	strpos
NEXT DAY	1	6
NEXT DAY	13	6
NEXT DAY	19	6
NEXT DAY	22	6
NEXT DAY	26	6
NEXT DAY	30	6
NEXT DAY	34	6
NEXT DAY	38	6
NEXT DAY	45	6
NEXT DAY	51	6
NEXT DAY	67	6
NEXT DAY	69	6
NEXT DAY	80	6
NEXT DAY	90	6
NEXT DAY	96	6
NEXT DAY	98	6
TWO DAY	9	5
TWO DAY	21	5
TWO DAY	28	5
TWO DAY	32	5
TWO DAY	40	5
TWO DAY	43	5
TWO DAY	49	5
TWO DAY	50	5
TWO DAY	52	5
TWO DAY	53	5
TWO DAY	61	5
TWO DAY	73	5
TWO DAY	81	5
TWO DAY	83	5
TWO DAY	84	5
TWO DAY	85	5
TWO DAY	94	5
TWO DAY	100	5

(34 rows)

STRPOSB

Returns an INTEGER value representing the location of a specified substring within a string, counting from one, where each octet in the string is counted (as opposed to characters).

Behavior type

[Immutable](#)

Syntax

```
STRPOSB ( string , substring )
```

Arguments

string

(CHAR or VARCHAR) is the string in which to locate the substring

substring

(CHAR or VARCHAR) is the substring to locate

Notes

STRPOSB is identical to [POSITIONB](#) except for the order of the arguments.

Examples

```
=> SELECT STRPOSB('straße', 'e');
```

```
STRPOSB
```

```
-----  
7  
(1 row)
```

```
=> SELECT STRPOSB('étudiant', 'tud');
```

```
STRPOSB
```

```
-----  
3  
(1 row)
```

SUBSTR

Returns VARCHAR or VARBINARY value representing a substring of a specified string.

Behavior type

[Immutable](#)

Syntax

```
SUBSTR ( string , position [ , extent ] )
```

Arguments

string

(CHAR/VARCHAR or BINARY/VARBINARY) is the string from which to extract a substring. If null, Vertica returns no results.

position

(INTEGER or DOUBLE PRECISION) is the starting position of the substring (counting from one by characters). If 0 or negative, Vertica returns no results.

extent

(INTEGER or DOUBLE PRECISION) is the length of the substring to extract (in characters). The default is the end of the string.

Notes

SUBSTR truncates DOUBLE PRECISION input values.

Examples

```
=> SELECT SUBSTR('abc'::binary(3),1);
```

```
substr
```

```
-----  
abc  
(1 row)
```

```
=> SELECT SUBSTR('123456789', 3, 2);
```

```
substr
```

```
-----  
34  
(1 row)
```

```
=> SELECT SUBSTR('123456789', 3);
```

```
substr
```

```
-----  
3456789  
(1 row)
```

```
=> SELECT SUBSTR(TO_BITSTRING(HEX_TO_BINARY('0x10')), 2, 2);
```

```
substr
```

```
-----  
00  
(1 row)
```

```
=> SELECT SUBSTR(TO_HEX(10010), 2, 2);
```

```
substr
```

```
-----  
71  
(1 row)
```

SUBSTRB

Returns an octet value representing the substring of a specified string.

Behavior type

[Immutable](#)

Syntax

```
SUBSTRB ( string , position [ , extent ] )
```

Arguments

string

(CHAR/VARCHAR) is the string from which to extract a substring.

position

(INTEGER or DOUBLE PRECISION) is the starting position of the substring (counting from one in octets).

extent

(INTEGER or DOUBLE PRECISION) is the length of the substring to extract (in octets). The default is the end of the string

Notes

- This function treats the multibyte character string as a string of octets (bytes) and uses octet numbers as incoming and outgoing position specifiers and lengths. The strings themselves are type VARCHAR, but they treated as if each octet were a separate character.
- SUBSTRB truncates DOUBLE PRECISION input values.

Examples

```
=> SELECT SUBSTRB('soupçon', 5);  
SUBSTRB
```

```
-----  
çon  
(1 row)
```

```
=> SELECT SUBSTRB('soupçon', 5, 2);  
SUBSTRB
```

```
-----  
ç  
(1 row)
```

Vertica returns the following error message if you use BINARY/VARBINARY:

```
=>SELECT SUBSTRB('abc'::binary(3),1);  
ERROR: function substrb(binary, int) does not exist, or permission is denied for substrb(binary, int)  
HINT: No function matches the given name and argument types. You may need to add explicit type casts.
```

SUBSTRING

Returns a value representing a substring of the specified string at the given position, given a value, a position, and an optional length. SUBSTRING truncates DOUBLE PRECISION input values.

Behavior type

[Immutable](#) if USING OCTETS, [stable](#) otherwise.

Syntax

```
SUBSTRING ( string, position[, length] )  
  [USING {CHARACTERS | OCTETS} ] )  
SUBSTRING ( string FROM position [ FOR length ] )  
  [USING { CHARACTERS | OCTETS } ] )
```

Arguments

string

(CHAR/VARCHAR or BINARY/VARBINARY) is the string from which to extract a substring

position

(INTEGER or DOUBLE PRECISION) is the starting position of the substring (counting from one by either characters or octets). (The default is characters.) If position is greater than the length of the given value, an empty value is returned.

length

(INTEGER or DOUBLE PRECISION) is the length of the substring to extract in either characters or octets. (The default is characters.) The default is the end of the string. If a length is given the result is at most that many bytes. The maximum length is the length of the given value less the given position. If no length is given or if the given length is greater than the maximum length then the length is set to the maximum length.

USING CHARACTERS | OCTETS

Determines whether the value is expressed in characters (the default) or octets.

Examples

```
=> SELECT SUBSTRING('abc'::binary(3),1);
```

```
substring
```

```
-----  
abc
```

```
(1 row)
```

```
=> SELECT SUBSTRING('soupçon', 5, 2 USING CHARACTERS);
```

```
substring
```

```
-----  
çø
```

```
(1 row)
```

```
=> SELECT SUBSTRING('soupçon', 5, 2 USING OCTETS);
```

```
substring
```

```
-----  
ç
```

```
(1 row)
```

If you use a negative position, then the functions starts at a non-existent position. In this example, that means counting eight characters starting at position -4. So the function starts at the empty position -4 and counts five characters, including a position for zero which is also empty. This returns three characters.

```
=> SELECT SUBSTRING('1234567890', -4, 8);
```

```
substring
```

```
-----  
123
```

```
(1 row)
```

TRANSLATE

Replaces individual characters in *string_to_replace* with other characters.

Behavior type

[Immutable](#)

Syntax

```
TRANSLATE ( string_to_replace , from_string , to_string );
```

Arguments

string_to_replace

String to be translated.

from_string

Contains characters that should be replaced in *string_to_replace*.

to_string

Any character in *string_to_replace* that matches a character in *from_string* is replaced by the corresponding character in *to_string*.

Examples

```
=> SELECT TRANSLATE('straße', 'ß', 'ss');
```

```
TRANSLATE
```

```
-----  
strase
```

```
(1 row)
```

TRIM

Combines the BTRIM, LTRIM, and RTRIM functions into a single function.

Behavior type

[Immutable](#)

Syntax

```
TRIM ( [ [ LEADING | TRAILING | BOTH ] [ characters ] FROM ] expression )
```

Arguments

LEADING

Removes the specified characters from the left side of the string

TRAILING

Removes the specified characters from the right side of the string

BOTH

Removes the specified characters from both sides of the string (default)

characters

(CHAR or VARCHAR) specifies the characters to remove from *expression*. The default is the space character.

expression

(CHAR or VARCHAR) is the string to trim

Examples

```
=> SELECT '-' || TRIM(LEADING 'x' FROM 'xxdatabasexx') || '-';
?column?
-----
-xdatabasexx-
(1 row)

=> SELECT '-' || TRIM(TRAILING 'x' FROM 'xxdatabasexx') || '-';
?column?
-----
-xxdatabase-
(1 row)

=> SELECT '-' || TRIM(BOTH 'x' FROM 'xxdatabasexx') || '-';
?column?
-----
-database-
(1 row)

=> SELECT '-' || TRIM('x' FROM 'xxdatabasexx') || '-';
?column?
-----
-database-
(1 row)

=> SELECT '-' || TRIM(LEADING FROM ' database ') || '-';
?column?
-----
-database -
(1 row)

=> SELECT '-' || TRIM(' database ') || '-'; ?column?
-----
-database-
(1 row)
```

See also

- [BTRIM](#)
- [LTRIM](#)
- [RTRIM](#)

UPPER

Returns a VARCHAR value containing the argument converted to uppercase letters.

Starting in Release 5.1, this function treats the *string* argument as a UTF-8 encoded string, rather than depending on the collation setting of the locale (for example, collation=binary) to identify the encoding.

Behavior type

[stable](#)

Syntax

```
UPPER ( expression )
```

Arguments

expression

CHAR or VARCHAR containing the string to convert

Notes

UPPER is restricted to 32500 octet inputs, since it is possible for the UTF-8 representation of result to double in size.

Examples

```
=> SELECT UPPER('AbCdEfG');
   UPPER
-----
ABCDEFG
(1 row)
=> SELECT UPPER('étudiant');
   UPPER
-----
ÉTUDIANT
(1 row)
```

UPPERB

Returns a character string with each ASCII character converted to uppercase. Multibyte characters are not converted and are skipped.

Behavior type

[Immutable](#)

Syntax

```
UPPERB ( expression )
```

Arguments

expression

(CHAR or VARCHAR) is the string to convert

Examples

In the following example, the multibyte UTF-8 character é is not converted to uppercase:

```
=> SELECT UPPERB('étudiant');
   UPPERB
-----
éTUDIANT
(1 row)
=> SELECT UPPERB('AbCdEfG');
   UPPERB
-----
ABCDEFG
(1 row)
=> SELECT UPPERB('The Vertica Database');
   UPPERB
-----
THE VERTICA DATABASE
(1 row)
```

URI functions

The functions in this section follow the RFC 3986 standard for percent-encoding a Universal Resource Identifier (URI).

In this section

- [URI_PERCENT_DECODE](#)
- [URI_PERCENT_ENCODE](#)

URI_PERCENT_DECODE

Decodes a percent-encoded Universal Resource Identifier (URI) according to the RFC 3986 standard.

Syntax

```
URI_PERCENT_DECODE (expression)
```

Behavior type

[Immutable](#)

Parameters

expression

(VARCHAR) is the string to convert.

Examples

The following example invokes `uri_percent_decode` on the Websites column of the URI table and returns a decoded URI:

```
=> SELECT URI_PERCENT_DECODE(Websites) from URI;  
      URI_PERCENT_DECODE
```

```
-----  
http://www.faqs.org/rfcs/rfc3986.html x xj%a%
```

```
(1 row)
```

The following example returns the original URI in the Websites column and its decoded version:

```
=> SELECT Websites, URI_PERCENT_DECODE (Websites) from URI;
```

```
      Websites          |      URI_PERCENT_DECODE
```

```
-----+-----  
http://www.faqs.org/rfcs/rfc3986.html+x%20x%6a%a% | http://www.faqs.org/rfcs/rfc3986.html x xj%a%
```

```
(1 row)
```

URI_PERCENT_ENCODE

Encodes a Universal Resource Identifier (URI) according to the RFC 3986 standard for percent encoding. For compatibility with older encoders, this function converts `+` to space; space is converted to `%20`.

Syntax

```
URI_PERCENT_ENCODE (expression)
```

Behavior type

[Immutable](#)

Parameters

expression

(VARCHAR) is the string to convert.

Examples

The following example shows how the `uri_percent_encode` function is invoked on a the Websites column of the URI table and returns an encoded URI:

```
=> SELECT URI_PERCENT_ENCODE(Websites) from URI;  
      URI_PERCENT_ENCODE
```

```
-----  
http%3A%2F%2Fexample.com%2F%3F%3D11%2F15
```

```
(1 row)
```

The following example returns the original URI in the Websites column and it's encoded form:

```
=> SELECT Websites, URI_PERCENT_ENCODE(Websites) from URI;      Websites      |      URI_PERCENT_ENCODE
-----+-----
http://example.com/?=11/15 | http%3A%2F%2Fexample.com%2F%3F%3D11%2F15
(1 row)
```

UUID functions

Currently, Vertica provides one function to support [UUID](#) data types, [UUID_GENERATE](#).

In this section

- [UUID_GENERATE](#)

UUID_GENERATE

Returns a new universally unique identifier ([UUID](#)) that is generated based on high-quality randomness from [/dev/urandom](#) .

Behavior type

[Volatile](#)

Syntax

```
UUID_GENERATE()
```

Examples

```
=> CREATE TABLE Customers(
  cust_id UUID DEFAULT UUID_GENERATE(),
  lname VARCHAR(36),
  fname VARCHAR(24));
CREATE TABLE
=> INSERT INTO Customers VALUES (DEFAULT, 'Kearney', 'Thomas');
OUTPUT
-----
 1
(1 row)

=> COPY Customers (lname, fname) FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> Pham|Duc
>> Garcia|Mary
>> \.
=> SELECT * FROM Customers;
      cust_id      | lname | fname
-----+-----
03fe0794-ac5d-42d4-8246-54f7ec81ed0c | Pham  | Duc
6950313d-c77e-4c11-a86e-0a54aa3ec114 | Kearney | Thomas
9c9653ce-c2e4-4441-b0f7-0137b54cc28c | Garcia | Mary
(3 rows)
```

Database Designer functions

Database Designer functions perform the following operations, generally performed in the following order:

1. [Create a design](#) .
2. [Set design properties](#) .
3. [Populate a design](#) .
4. [Create design and deployment scripts](#) .
5. [Get design data](#) .
6. [Clean up](#) .

Important

You can also use meta-function [DESIGNER_SINGLE_RUN](#) , which encapsulates all of these steps with a single call. The meta-function iterates over all queries within a specified timespan, and returns with a design ready for deployment.

For detailed information, see [Workflow for running Database Designer programmatically](#). For information on required privileges, see [Privileges for running Database Designer functions](#)

Caution

Before running Database Designer functions on an existing schema, back up the current design by calling [EXPORT_CATALOG](#).

Create a design

[DESIGNER_CREATE_DESIGN](#) directs Database Designer to create a design.

Set design properties

The following functions let you specify design properties:

- [DESIGNER_SET_DESIGN_TYPE](#): Specifies whether the design is comprehensive or incremental.
- [DESIGNER_DESIGN_PROJECTION_ENCODINGS](#): Analyzes encoding in the specified projections and creates a script that implements encoding recommendations.
- [DESIGNER_SET_DESIGN_KSAFETY](#): Sets the [K-safety](#) value for a comprehensive design.
- [DESIGNER_SET_OPTIMIZATION_OBJECTIVE](#): Specifies whether the design optimizes for query or load performance.
- [DESIGNER_SET_PROPOSE_UNSEGMENTED_PROJECTIONS](#): Enables inclusion of unsegmented projections in the design.

Populate a design

The following functions let you add tables and queries to your Database Designer design:

- [DESIGNER_ADD_DESIGN_TABLES](#): Adds the specified tables to a design.
- [DESIGNER_ADD_DESIGN_QUERY](#), [DESIGNER_ADD_DESIGN_QUERIES](#), [DESIGNER_ADD_DESIGN_QUERIES_FROM_RESULTS](#): Adds queries to the design and weights them.

Create design and deployment scripts

The following functions populate the Database Designer workspace and create design and deployment scripts. You can also analyze statistics, deploy the design automatically, and drop the workspace after the deployment:

- [DESIGNER_RUN_POPULATE_DESIGN_AND_DEPLOY](#): Populates the design and creates design and deployment scripts.
- [DESIGNER_WAIT_FOR_DESIGN](#): Waits for a currently running design to complete.

Reset a design

[DESIGNER_RESET_DESIGN](#) discards all the run-specific information of the previous Database Designer build or deployment of the specified design but retains its configuration.

Get design data

The following functions display information about projections and scripts that the Database Designer created:

- [DESIGNER_OUTPUT_ALL_DESIGN_PROJECTIONS](#): Sends to standard output DDL statements that define design projections.
- [DESIGNER_OUTPUT_DEPLOYMENT_SCRIPT](#): Sends to standard output a design's deployment script.

Cleanup

The following functions cancel any running Database Designer operation or drop a Database Designer design and all its contents:

- [DESIGNER_CANCEL_POPULATE_DESIGN](#): Cancels population or deployment operation for the specified design if it is currently running.
- [DESIGNER_DROP_DESIGN](#): Removes the schema associated with the specified design and all its contents.
- [DESIGNER_DROP_ALL_DESIGNS](#): Removes all Database Designer-related schemas associated with the current user.

In this section

- [DESIGNER_ADD_DESIGN_QUERIES](#)
- [DESIGNER_ADD_DESIGN_QUERIES_FROM_RESULTS](#)
- [DESIGNER_ADD_DESIGN_QUERY](#)
- [DESIGNER_ADD_DESIGN_TABLES](#)
- [DESIGNER_CANCEL_POPULATE_DESIGN](#)
- [DESIGNER_CREATE_DESIGN](#)
- [DESIGNER_DESIGN_PROJECTION_ENCODINGS](#)
- [DESIGNER_DROP_ALL_DESIGNS](#)
- [DESIGNER_DROP_DESIGN](#)
- [DESIGNER_OUTPUT_ALL_DESIGN_PROJECTIONS](#)
- [DESIGNER_OUTPUT_DEPLOYMENT_SCRIPT](#)

- [DESIGNER_RESET_DESIGN](#)
- [DESIGNER_RUN_POPULATE_DESIGN_AND_DEPLOY](#)
- [DESIGNER_SET_DESIGN_KSAFETY](#)
- [DESIGNER_SET_DESIGN_TYPE](#)
- [DESIGNER_SET_OPTIMIZATION_OBJECTIVE](#)
- [DESIGNER_SET_PROPOSE_UNSEGMENTED_PROJECTIONS](#)
- [DESIGNER_SINGLE_RUN](#)
- [DESIGNER_WAIT_FOR_DESIGN](#)

DESIGNER_ADD_DESIGN_QUERIES

Reads and evaluates queries from an input file, and adds the queries that it accepts to the specified design. All accepted queries are assigned a weight of 1.

The following requirements apply:

- All queried tables must previously be added to the design with [DESIGNER_ADD_DESIGN_TABLES](#).
- If the [design_type](#) is incremental, the Database Designer reads only the first 100 queries in the input file, and ignores all queries beyond that number.

All accepted queries are added to the system table [DESIGN_QUERIES](#).

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
DESIGNER_ADD_DESIGN_QUERIES ( 'design-name', 'queries-file' [, return-results] )
```

Parameters

design-name

Name of the target design.

queries-file

Absolute path and name of the file that contains the queries to evaluate, on the local file system of the node where the session is connected, or [another file system or object store](#) that Vertica supports.

return-results

Boolean, optionally specifies whether to return results of the add operation to standard output. If set to true, Database Designer returns the following results:

- Number of accepted queries
- Number of queries referencing non-design tables
- Number of unsupported queries
- Number of illegal queries

Privileges

Non-superuser: design creator with all privileges required to execute the queries in *input-file*.

Errors

Database Designer returns an error in the following cases:

- The query contains illegal syntax.
- The query references:
 - External or system tables only
 - Local temporary or other non-design tables
- DELETE or UPDATE query has one or more subqueries.
- INSERT query does not include a SELECT clause.
- Database Designer cannot optimize the query.

Examples

The following example adds queries from [vmart_queries.sql](#) to the [VMART_DESIGN](#) design. This file contains nine queries. The statement includes a third argument of true, so Database Designer returns results of the add operation:

```
=> SELECT DESIGNER_ADD_DESIGN_QUERIES ('VMART_DESIGN', '/tmp/examples/vmart_queries.sql', 'true');
...
DESIGNER_ADD_DESIGN_QUERIES
-----
Number of accepted queries          =9
Number of queries referencing non-design tables =0
Number of unsupported queries       =0
Number of illegal queries           =0
(1 row)
```

See also

[Running Database Designer programmatically](#)

DESIGNER_ADD_DESIGN_QUERIES_FROM_RESULTS

Executes the specified query and evaluates results in the following columns:

- **QUERY_TEXT** (required): Text of potential design queries.
- **QUERY_WEIGHT** (optional): The weight assigned to each query that indicates its importance relative to other queries, a real number >0 and ≤ 1 . Database Designer uses this setting when creating the design to prioritize the query. If **DESIGNER_ADD_DESIGN_QUERIES_FROM_RESULTS** returns any results that omit this value, Database Designer sets their weight to 1.

After evaluating the queries in **QUERY_TEXT**, **DESIGNER_ADD_DESIGN_QUERIES_FROM_RESULTS** adds all accepted queries to the design. An unlimited number of queries can be added to the design.

Before you add queries to a design, you must add the queried tables with [DESIGNER_ADD_DESIGN_TABLES](#).

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
DESIGNER_ADD_DESIGN_QUERIES_FROM_RESULTS ( 'design-name', 'query' )
```

Parameters

design-name

Name of the target design.

query

A valid SQL query whose results contain columns named **QUERY_TEXT** and, optionally, **QUERY_WEIGHT**.

Privileges

Non-superuser: design creator with all privileges required to execute the specified query, and all queries returned by this function

Errors

Database Designer returns an error in the following cases:

- The query contains illegal syntax.
- The query references:
 - External or system tables only
 - Local temporary or other non-design tables
- DELETE or UPDATE query has one or more subqueries.
- INSERT query does not include a SELECT clause.
- Database Designer cannot optimize the query.

Examples

The following example queries the system table [QUERY_REQUESTS](#) for all long-running queries (> 1 million microseconds) and adds them to the **VMART_DESIGN** design. The query returns no information on query weights, so all queries are assigned a weight of 1:

```
=> SELECT DESIGNER_ADD_DESIGN_QUERIES_FROM_RESULTS ('VMART_DESIGN',
'SELECT request as query_text FROM query_requests where request_duration_ms > 1000000 AND request_type =
"QUERY";');
```

See also

[Running Database Designer programmatically](#)

DESIGNER_ADD_DESIGN_QUERY

Reads and parses the specified query, and if accepted, adds it to the design. Before you add queries to a design, you must add the queried tables with [DESIGNER_ADD_DESIGN_TABLES](#).

All accepted queries are added to the system table [DESIGN_QUERIES](#).

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
DESIGNER_ADD_DESIGN_QUERY ( 'design-name', 'design-query' [, query-weight] )
```

Parameters

design-name

Name of the target design.

design-query

Executable SQL query.

query-weight

Optionally assigns a weight to each query that indicates its importance relative to other queries, a real number >0 and ≤ 1 . Database Designer uses this setting to prioritize queries in the design .

If you omit this parameter, Database Designer assigns a weight of 1.

Privileges

Non-superuser: design creator with all privileges required to execute the specified query

Errors

Database Designer returns an error in the following cases:

- The query contains illegal syntax.
- The query references:
 - External or system tables only
 - Local temporary or other non-design tables
- DELETE or UPDATE query has one or more subqueries.
- INSERT query does not include a SELECT clause.
- Database Designer cannot optimize the query.

Examples

The following example adds the specified query to the **VMART_DESIGN** design and assigns that query a weight of 0.5:

```
=> SELECT DESIGNER_ADD_DESIGN_QUERY (
  'VMART_DESIGN',
  'SELECT customer_name, customer_type FROM customer_dimension ORDER BY customer_name ASC;', 0.5
);
```

See also

[Running Database Designer programmatically](#)

[DESIGNER_ADD_DESIGN_TABLES](#)

Adds the specified tables to a design. You must run [DESIGNER_ADD_DESIGN_TABLES](#) before adding design queries to the design. If no tables are added to the design, Vertica does not accept design queries.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
DESIGNER_ADD_DESIGN_TABLES ( 'design-name', ['table-spec[...]' ] [, 'analyze-statistics' ] )
```

Parameters

design-name

Name of the Database Designer design.

***table-spec* [...]**

One or more comma-delimited arguments that specify which tables to add to the design, where each *table-spec* argument can specify tables as follows:

- `[schema .] table`
Add *table* to the design.
- `schema .*`
Add all tables in *schema* .

If set to an empty string, Vertica adds all tables in the database to which the user has access.

analyze-statistics

Boolean that optionally specifies whether to run `ANALYZE_STATISTICS` after adding the specified tables to the design, by default set to `false` .

Accurate statistics help Database Designer optimize compression and query performance. Updating statistics takes time and resources.

Privileges

Non-superuser: design creator with USAGE privilege on the design table schema and owner of the design table

Examples

The following example adds to design `VMART_DESIGN` all tables from schemas `online_sales` and `store` , and analyzes statistics for those tables:

```
=> SELECT DESIGNER_ADD_DESIGN_TABLES('VMART_DESIGN', 'online_sales.*', 'store.*', 'true');
DESIGNER_ADD_DESIGN_TABLES
-----
              7
(1 row)
```

See also

[Running Database Designer programmatically](#)

`DESIGNER_CANCEL_POPULATE_DESIGN`

Cancels population or deployment operation for the specified design if it is currently running. When you cancel a deployment, the Database Designer cancels the projection refresh operation. It does not roll back projections that it already deployed and refreshed.

This is a meta-function. You must call meta-functions in a top-level `SELECT` statement.

Behavior type

[Volatile](#)

Syntax

```
DESIGNER_CANCEL_POPULATE_DESIGN ( 'design-name' )
```

Parameters

design-name

Name of the design operation to cancel.

Privileges

Non-superuser: design creator

Examples

The following example cancels a currently running design for `VMART_DESIGN` and then drops the design:

```
=> SELECT DESIGNER_CANCEL_POPULATE_DESIGN ('VMART_DESIGN');
=> SELECT DESIGNER_DROP_DESIGN ('VMART_DESIGN', 'true');
```

See also

[Running Database Designer programmatically](#)

`DESIGNER_CREATE_DESIGN`

Creates a design with the specified name.

This is a meta-function. You must call meta-functions in a top-level `SELECT` statement.

Behavior type

[Volatile](#)

Syntax

```
DESIGNER_CREATE_DESIGN ( 'design-name' )
```

Parameters

design-name

Name of the design to create, can contain only alphanumeric and underscore (_) characters.

Two users cannot have designs with the same name at the same time.

Privileges

- Superuser
- DBDUSER with WRITE privileges on storage location of *design-name* .

Database Designer system views

If any of the following [V_MONITOR](#) tables do not already exist from previous designs, [DESIGNER_CREATE_DESIGN](#) creates them:

- [DESIGNS](#)
- [DESIGN_TABLES](#)
- [DEPLOYMENT_PROJECTIONS](#)
- [DEPLOYMENT_PROJECTION_STATEMENTS](#)
- [DESIGN_QUERIES](#)
- [OUTPUT_DEPLOYMENT_STATUS](#)
- [OUTPUT_EVENT_HISTORY](#)

Examples

The following example creates the design **VMART_DESIGN** :

```
=> SELECT DESIGNER_CREATE_DESIGN('VMART_DESIGN');
DESIGNER_CREATE_DESIGN
-----
0
(1 row)
```

See also

[Running Database Designer programmatically](#)

[DESIGNER_DESIGN_PROJECTION_ENCODINGS](#)

Analyzes encoding in the specified projections, creates a script to implement encoding recommendations, and optionally deploys the recommendations.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
DESIGNER_DESIGN_PROJECTION_ENCODINGS ( '[' proj-spec[,...] ]', '[' destination' [, 'deploy'] [, 'reanalyze-encodings'] )
```

Parameters

proj-spec [...]

One or more comma-delimited projections to add to the design. Each projection can be specified in one of the following ways:

- `[[schema .] table .] projection`
Specifies to analyze *projection* .
- `schema .*`
Specifies to analyze all projections in the named schema.
- `[schema .] table`
Specifies to analyze all projections of the named table.

If set to an empty string, Vertica analyzes all projections in the database to which the user has access.

For example, the following statement specifies to analyze all projections in schema `private` , and send the results to the file `encodings.sql` :

```
=> SELECT DESIGNER_DESIGN_PROJECTION_ENCODINGS ('mydb.private.*','encodings.sql');
```

destination

Specifies where to send output, one of the following:

- Empty string (") writes the script to standard output.
- Pathname of a SQL output file. If you specify a file that does not exist, the function creates one. If you specify only a file name, Vertica creates it in the catalog directory. If the file already exists, the function silently overwrites its contents.

deploy

Boolean that specifies whether to deploy encoding changes.

Default: false

reanalyze-encodings

Boolean that specifies whether `DESIGNER_DESIGN_PROJECTION_ENCODINGS` analyzes encodings in a projection where all columns are already encoded:

- **false** : Analyzes no columns and generates no recommendations if all columns are encoded.
- **true** : Ignores existing encodings and generates recommendations.

Default: false

Privileges

Superuser, or DBDUSER with the following privileges:

- OWNER of all projections to analyze
- USAGE privilege on the schema for the specified projections

Examples

The following example requests that Database Designer analyze encodings of the table `online_sales.call_center_dimension` :

- The second parameter *destination* is set to an empty string, so the script is sent to standard output (shown truncated below).
- The last two parameters *deploy* and *reanalyze-encodings* are omitted, so Database Designer does not execute the script or reanalyze existing encodings:

```
=> SELECT DESIGNER_DESIGN_PROJECTION_ENCODINGS ('online_sales.call_center_dimension');
```

DESIGNER_DESIGN_PROJECTION_ENCODINGS

```
CREATE PROJECTION call_center_dimension_DBD_1_seg_EncodingDesign /*+createtype(D)*/
```

```
(  
  call_center_key ENCODING COMMONDELTA_COMP,  
  cc_closed_date,  
  cc_open_date,  
  cc_name ENCODING ZSTD_HIGH_COMP,  
  cc_class ENCODING ZSTD_HIGH_COMP,  
  cc_employees,  
  cc_hours ENCODING ZSTD_HIGH_COMP,  
  cc_manager ENCODING ZSTD_HIGH_COMP,  
  cc_address ENCODING ZSTD_HIGH_COMP,  
  cc_city ENCODING ZSTD_COMP,  
  cc_state ENCODING ZSTD_FAST_COMP,  
  cc_region ENCODING ZSTD_HIGH_COMP  
)
```

```
AS
```

```
SELECT call_center_dimension.call_center_key,  
       call_center_dimension.cc_closed_date,  
       call_center_dimension.cc_open_date,  
       call_center_dimension.cc_name,  
       call_center_dimension.cc_class,  
       call_center_dimension.cc_employees,  
       call_center_dimension.cc_hours,  
       call_center_dimension.cc_manager,  
       call_center_dimension.cc_address,  
       call_center_dimension.cc_city,  
       call_center_dimension.cc_state,  
       call_center_dimension.cc_region  
FROM online_sales.call_center_dimension  
ORDER BY call_center_dimension.call_center_key  
SEGMENTED BY hash(call_center_dimension.call_center_key) ALL NODES KSAFE 1;
```

```
select refresh('online_sales.call_center_dimension');
```

```
select make_ahm_now();
```

```
DROP PROJECTION online_sales.call_center_dimension CASCADE;
```

```
ALTER PROJECTION online_sales.call_center_dimension_DBD_1_seg_EncodingDesign RENAME TO call_center_dimension;
```

```
(1 row)
```

See also

[Running Database Designer programmatically](#)

DESIGNER_DROP_ALL_DESIGNS

Removes all Database Designer-related schemas associated with the current user. Use this function to remove database objects after one or more Database Designer sessions complete execution.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
DESIGNER_DROP_ALL_DESIGNS()
```

Parameters

None.

Privileges

Non-superuser: design creator

Examples

The following example removes all schema and their contents associated with the current user. `DESIGNER_DROP_ALL_DESIGNS` returns the number of designs dropped:

```
=> SELECT DESIGNER_DROP_ALL_DESIGNS();
DESIGNER_DROP_ALL_DESIGNS
-----
                2
(1 row)
```

See also

- [DESIGNER_CANCEL_POPULATE_DESIGN](#)
- [DESIGNER_DROP_DESIGN](#)

DESIGNER_DROP_DESIGN

Removes the schema associated with the specified design and all its contents. Use `DESIGNER_DROP_DESIGN` after a Database Designer design or deployment completes successfully. You must also use it to drop a design before creating another one under the same name.

To drop all designs that you created, use [DESIGNER_DROP_ALL_DESIGNS](#).

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
DESIGNER_DROP_DESIGN ( 'design-name' [, force-drop ] )
```

Parameters

design-name

Name of the design to drop.

force-drop

Boolean that overrides any dependencies that otherwise prevent Vertica from executing this function—for example, the design is in use or is currently being deployed. If you omit this parameter, Vertica sets it to `false`.

Privileges

Non-superuser: design creator

Examples

The following example deletes the Database Designer design `VMART_DESIGN` and all its contents:

```
=> SELECT DESIGNER_DROP_DESIGN ('VMART_DESIGN');
```

See also

[Running Database Designer programmatically](#)

DESIGNER_OUTPUT_ALL_DESIGN_PROJECTIONS

Displays the DDL statements that define the design projections to standard output.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
DESIGNER_OUTPUT_ALL_DESIGN_PROJECTIONS ( 'design-name' )
```

Parameters

design-name

Name of the target design.

Privileges

Superuser or DBUSER

Examples

The following example returns the design projection DDL statements for `vmart_design` :

```
=> SELECT DESIGNER_OUTPUT_ALL_DESIGN_PROJECTIONS('vmart_design');
CREATE PROJECTION customer_dimension_DBD_1_rep_VMART_DESIGN /*+createtype(D)*/
(
customer_key ENCODING DELTAVAL,
customer_type ENCODING AUTO,
customer_name ENCODING AUTO,
customer_gender ENCODING REL,

household_id ENCODING DELTAVAL,
customer_address ENCODING AUTO,
customer_city ENCODING AUTO,
customer_state ENCODING AUTO,
customer_region ENCODING AUTO,
marital_status ENCODING AUTO,
customer_age ENCODING DELTAVAL,
number_of_children ENCODING BLOCKDICT_COMP,
annual_income ENCODING DELTARANGE_COMP,
occupation ENCODING AUTO,
largest_bill_amount ENCODING DELTAVAL,
store_membership_card ENCODING BLOCKDICT_COMP,
customer_since ENCODING DELTAVAL,
deal_stage ENCODING AUTO,
deal_size ENCODING DELTARANGE_COMP,
last_deal_update ENCODING DELTARANGE_COMP
)
AS
SELECT customer_key,
       customer_type,
       customer_name,
       customer_gender,
       title,
       household_id,
       customer_address,
       customer_city,
       customer_state,
       customer_region,
       marital_status,
       customer_age,
       number_of_children,
       annual_income,
       occupation,
       largest_bill_amount,
       store_membership_card,
       customer_since,
       deal_stage,
       deal_size,
       last_deal_update
FROM public.customer_dimension
ORDER BY customer_gender,
       annual_income
UNSEGMENTED ALL NODES;
CREATE PROJECTION product_dimension_DBD_2_rep_VMART_DESIGN /*+createtype(D)*/
(
...
```

See also

[DESIGNER_OUTPUT_DEPLOYMENT_SCRIPT](#)

DESIGNER_OUTPUT_DEPLOYMENT_SCRIPT

Displays the deployment script for the specified design to standard output. If the design is already deployed, Vertica ignores this function.

To output only the **CREATE PROJECTION** commands in a design script, use [DESIGNER_OUTPUT_ALL_DESIGN_PROJECTIONS](#).

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
DESIGNER_OUTPUT_DEPLOYMENT_SCRIPT ( 'design-name' )
```

Parameters

design-name

Name of the target design.

Privileges

Non-superuser: design creator

Examples

The following example displays the deployment script for **VMART_DESIGN** :

```
=> SELECT DESIGNER_OUTPUT_DEPLOYMENT_SCRIPT('VMART_DESIGN');
CREATE PROJECTION customer_dimension_DBD_1_rep_VMART_DESIGN /*+createtype(D)*/
...
CREATE PROJECTION product_dimension_DBD_2_rep_VMART_DESIGN /*+createtype(D)*/
...
select refresh('public.customer_dimension,
               public.product_dimension,
               public.promotion.dimension,
               public.date_dimension');
select make_ahm_now();
DROP PROJECTION public.customer_dimension_super CASCADE;
DROP PROJECTION public.product_dimension_super CASCADE;
...
```

See also

[DESIGNER_OUTPUT_ALL_DESIGN_PROJECTIONS](#)

[DESIGNER_RESET_DESIGN](#)

Discards all run-specific information of the previous Database Designer build or deployment of the specified design but keeps its configuration. You can make changes to the design as needed, for example, by changing parameters or adding additional tables and/or queries, before running the design again.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
DESIGNER_RESET_DESIGN ( 'design-name' )
```

Parameters

design-name

Name of the design to reset.

Privileges

Non-superuser: design creator

Examples

The following example resets the Database Designer design VMART_DESIGN:

```
=> SELECT DESIGNER_RESET_DESIGN ('VMART_DESIGN');
```

[DESIGNER_RUN_POPULATE_DESIGN_AND_DEPLOY](#)

Populates the design and creates the design and deployment scripts. [DESIGNER_RUN_POPULATE_DESIGN_AND_DEPLOY](#) can also analyze statistics, deploy the design, and drop the workspace after the deployment.

The files output by this function have the permissions 666 or rw-rw-rw-, which allows any Linux user on the node to read or write to them. It is highly recommended that you keep the files in a secure directory.

Caution

DESIGNER_RUN_POPULATE_DESIGN_AND_DEPLOY does not create a backup copy of the current design before deploying the new design. Before running this function, back up the existing schema design with [EXPORT_CATALOG](#).

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
DESIGNER_RUN_POPULATE_DESIGN_AND_DEPLOY (  
  'design-name',  
  'output-design-file',  
  'output-deployment-file'  
  [ , 'analyze-statistics']  
  [ , 'deploy']  
  [ , 'drop-design-workspace']  
  [ , 'continue-after-error']  
)
```

Parameters

design-name

Name of the design to populate and deploy.

output-design-filename

Absolute path and name of the file to contain DDL statements that create design projections, on the local file system of the node where the session is connected, or [another file system or object store](#) that Vertica supports.

output-deployment-filename

Absolute path and name of the file to contain the deployment script, on the local file system of the node where the session is connected, or [another file system or object store](#) that Vertica supports.

analyze-statistics

Specifies whether to collect or refresh statistics for the tables before populating the design. If set to true, Vertica Invokes [ANALYZE_STATISTICS](#). Accurate statistics help Database Designer optimize compression and query performance. However, updating statistics requires time and resources.

Default: false

deploy

Specifies whether to deploy the Database Designer design using the deployment script created by this function.

Default: true

drop-design-workspace

Specifies whether to drop the design workspace after the design is deployed.

Default: true

continue-after-error

Specifies whether DESIGNER_RUN_POPULATE_DESIGN_AND_DEPLOY continues to run after an error occurs. By default, an error causes this function to terminate.

Default: false

Privileges

Non-superuser: design creator with WRITE privileges on storage locations of design and deployment scripts

Requirements

Before calling this function, you must:

- Create a design, a logical schema with tables.

- Associate tables with the design.
- Load queries to the design.
- Set design properties (K-safety level, mode, and policy).

Examples

The following example creates projections for and deploys the **VMART_DESIGN** design, and analyzes statistics about the design tables.

```
=> SELECT DESIGNER_RUN_POPULATE_DESIGN_AND_DEPLOY (
  'VMART_DESIGN',
  '/tmp/examples/vmart_design_files/design_projections.sql',
  '/tmp/examples/vmart_design_files/design_deploy.sql',
  'true',
  'true',
  'false',
  'false'
);
```

See also

[Running Database Designer programmatically](#)

DESIGNER_SET_DESIGN_KSAFETY

Sets [K-safety](#) for a comprehensive design and stores the K-safety value in the [DESIGNS](#) table. Database Designer ignores this function for incremental designs.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
DESIGNER_SET_DESIGN_KSAFETY ( 'design-name' [, k-level] )
```

Parameters

design-name

Name of the design for which you want to set the K-safety value, type VARCHAR.

k-level

An integer between 0 and 2 that specifies the level of K-safety for the target design. This value must be compatible with the number of nodes in the database cluster:

- *k-level* = 0 : ≥ 1 nodes
- *k-level* = 1 : ≥ 3 nodes
- *k-level* = 2 : ≥ 5 nodes

If you omit this parameter, Vertica sets K-safety for this design to 0 or 1, according to the number of nodes: 1 if the cluster contains ≥ 3 nodes, otherwise 0.

If you are a DBADMIN user and *k-level* differs from system K-safety, Vertica changes system K-safety as follows:

- If *k-level* is less than system K-safety, Vertica changes system K-safety to the lower level after the design is deployed.
- If *k-level* is greater than system K-safety and is valid for the database cluster, Vertica creates the required number of buddy projections for the tables in this design. If the design applies to all database tables, or all tables in the database have the required number of buddy projections, Database Designer changes system K-safety to *k-level*.

If the design excludes some database tables and the number of their buddy projections is less than *k-level*, Database Designer leaves system K-safety unchanged. Instead, it returns a warning and indicates which tables need new buddy projections in order to adjust system K-safety.

If you are a DBDUSER, Vertica ignores this parameter.

Privileges

Non-superuser: design creator

Examples

The following example set K-safety for the VMART_DESIGN design to 1:

```
=> SELECT DESIGNER_SET_DESIGN_KSAFETY('VMART_DESIGN', 1);
```

See also

[Running Database Designer programmatically](#)

DESIGNER_SET_DESIGN_TYPE

Specifies whether Database Designer creates a comprehensive or incremental design. **DESIGNER_SET_DESIGN_TYPE** stores the design mode in the [DESIGNS](#) table.

Important

If you do not explicitly set a design mode with this function, Database Designer creates a comprehensive design.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
DESIGNER_SET_DESIGN_TYPE ( 'design-name', 'mode' )
```

Parameters

design-name

Name of the target design.

mode

Name of the mode that Database Designer should use when designing the database, one of the following:

- **COMPREHENSIVE** : Creates an initial or replacement design for all tables in the specified schemas. You typically create a comprehensive design for a new database.
- **INCREMENTAL** : Modifies an existing design with additional projection that are optimized for new or modified queries.

Note

Incremental designs always inherit the K-safety value of the database.

For more information, see [Design Types](#) .

Privileges

Non-superuser: design creator

Examples

The following examples show the two design mode options for the **VMART_DESIGN** design:

```
=> SELECT DESIGNER_SET_DESIGN_TYPE(
  'VMART_DESIGN',
  'COMPREHENSIVE');
DESIGNER_SET_DESIGN_TYPE
-----
          0
(1 row)
=> SELECT DESIGNER_SET_DESIGN_TYPE(
  'VMART_DESIGN',
  'INCREMENTAL');
DESIGNER_SET_DESIGN_TYPE
-----
          0
(1 row)
```

See also

[Running Database Designer programmatically](#)

DESIGNER_SET_OPTIMIZATION_OBJECTIVE

Valid only for comprehensive database designs, specifies the optimization objective Database Designer uses. Database Designer ignores this function for incremental designs.

DESIGNER_SET_OPTIMIZATION_OBJECTIVE stores the optimization objective in the [DESIGNS](#) table.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
DESIGNER_SET_OPTIMIZATION_OBJECTIVE ( 'design-name', 'policy' )
```

Parameters

design-name

Name of the target design.

policy

Specifies the design's optimization policy, one of the following:

- **QUERY** : Optimize for query performance. This can result in a larger database storage footprint because additional projections might be created.
- **LOAD** : Optimize for load performance so database size is minimized. This can result in slower query performance.
- **BALANCED** : Balance the design between query performance and database size.

Privileges

Non-superuser: design creator

Examples

The following example sets the optimization objective option for the **VMART_DESIGN** design: to **QUERY** :

```
=> SELECT DESIGNER_SET_OPTIMIZATION_OBJECTIVE( 'VMART_DESIGN', 'QUERY');
DESIGNER_SET_OPTIMIZATION_OBJECTIVE
-----
0
(1 row)
```

See also

[Running Database Designer programmatically](#)

DESIGNER_SET_PROPOSE_UNSEGMENTED_PROJECTIONS

Specifies whether a design can include [unsegmented projections](#). Vertica ignores this function on a one-node cluster, where all projections must be unsegmented.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
DESIGNER_SET_PROPOSE_UNSEGMENTED_PROJECTIONS ( 'design-name', unsegmented )
```

Parameters

design-name

Name of the target design.

unsegmented

Boolean that specifies whether Database Designer can propose unsegmented projections for tables in this design. When you create a design, the **propose_unsegmented_projections** value in system table [DESIGNS](#) for this design is set to true. If

DESIGNER_SET_PROPOSE_UNSEGMENTED_PROJECTIONS sets this value to false, Database Designer proposes only segmented projections.

Privileges

Non-superuser: design creator

Examples

The following example specifies that Database Designer can propose only segmented projections for tables in the design **VMART_DESIGN** :

```
=> SELECT DESIGNER_SET_PROPOSE_UNSEGMENTED_PROJECTIONS('VMART_DESIGN', false);
```

See also

[Running Database Designer programmatically](#)

DESIGNER_SINGLE_RUN

Evaluates all queries that completed execution within the specified timespan, and returns with a design that is ready for deployment. This design includes projections that are recommended for optimizing the evaluated queries. Unless you redirect output, DESIGNER_SINGLE_RUN returns the design to stdout.

Tip

Before running DESIGNER_SINGLE_RUN, collect statistics on the queried data by calling [ANALYZE_STATISTICS](#) and [ANALYZE_STATISTICS_PARTITION](#).

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
DESIGNER_SINGLE_RUN ('interval')
```

interval

Specifies an interval of time that precedes the meta-function call. Database Designer evaluates all queries that ran to completion over the specified interval.

Privileges

Superuser or DBUSER

Examples

```
-----  
-- SSBM dataset test  
-----  
-- create ssbm schema  
\! $TARGET/bin/vsql -f 'sql/SSBM/SSBM_schema.sql' > /dev/null 2>&1  
\! $TARGET/bin/vsql -f 'sql/SSBM/SSBM_constraints.sql' > /dev/null 2>&1  
\! $TARGET/bin/vsql -f 'sql/SSBM/SSBM_funcdeps.sql' > /dev/null 2>&1  
  
-- run these queries  
\! $TARGET/bin/vsql -f 'sql/SSBM/SSBM_queries.sql' > /dev/null 2>&1  
-- Run single API  
select designer_single_run('1 minute');

FROM public.lineorder

ORDER BY lo_suppkey

UNSEGMENTED ALL NODES;

(1 row)

DESIGNER_WAIT_FOR_DESIGN

Waits for completion of operations that are populating and deploying the design. Ctrl+C cancels this operation and returns control to the user.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
DESIGNER_WAIT_FOR_DESIGN ( 'design-name' )
```

Parameters

design-name

Name of the running design.

Privileges

Superuser, or DBDUSER with USAGE privilege on the design schema

Examples

The following example requests to wait for the currently running design of VMART_DESIGN to complete:

```
=> SELECT DESIGNER_WAIT_FOR_DESIGN ('VMART_DESIGN');
```

See also

- [DESIGNER_CANCEL_POPULATE_DESIGN](#)
- [DESIGNER_DROP_ALL_DESIGNS](#)
- [DESIGNER_DROP_DESIGN](#)

Directed queries functions

The following meta-functions let you batch export query plans as directed queries from one Vertica database, and import those directed queries to another database.

In this section

- [CLEAR_DIRECTED_QUERY_USAGE](#)
- [EXPORT_DIRECTED_QUERIES](#)
- [IMPORT_DIRECTED_QUERIES](#)
- [SAVE_PLANS](#)

CLEAR_DIRECTED_QUERY_USAGE

Resets the counter in the [DIRECTED_QUERY_STATUS](#) table for a single query or for all queries.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
CLEAR_DIRECTED_QUERY_USAGE([ 'query-name' ])
```

Arguments

query-name

The name of the directed query to reset. If omitted, the function resets counters for all queries.

Privileges

[Superuser](#)

Examples

In the following example, three directed queries have been used:

```
=> SELECT query_name, sum(hits) FROM DIRECTED_QUERY_STATUS GROUP BY 1;
  query_name      | sum
-----+-----
findEmployeesCityJobTitle_OPT | 5
save_plans_nolabel_3_3      | 2
save_plans_nolabel_6_3      | 3
(3 rows)
```

After calling the function for one of the queries, its counter is reset to 0:

```
=> SELECT CLEAR_DIRECTED_QUERY_USAGE('findEmployeesCityJobTitle_OPT');
CLEAR_DIRECTED_QUERY_USAGE
-----
Usage cleared.
(1 row)

=> SELECT query_name, sum(hits) FROM DIRECTED_QUERY_STATUS GROUP BY 1;
  query_name      | sum
-----+-----
findEmployeesCityJobTitle_OPT | 0
save_plans_nolabel_3_3      | 2
save_plans_nolabel_6_3      | 3
(3 rows)
```

EXPORT_DIRECTED_QUERIES

Generates SQL for creating directed queries from a set of input queries.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
EXPORT_DIRECTED_QUERIES('input-file', '[output-file]')
```

Arguments

input-file

A SQL file that contains one or more input queries. See [Input Format](#) below for details on format requirements.

output-file

Specifies where to write the generated SQL for creating directed queries. If **output-file** already exists, EXPORT_DIRECTED_QUERIES returns with an error. If you supply an empty string, Vertica writes the SQL to standard output. See [Output Format](#) below for details.

Privileges

[Superuser](#)

Input format

The input file that you supply to EXPORT_DIRECTED_QUERIES contains one or more input queries. For each input query, you can optionally specify two fields that are used in the generated directed query:

- **DirQueryName** provides the directed query's unique identifier, a string that conforms to conventions described in [Identifiers](#).
- **DirQueryComment** specifies a quote-delimited string, up to 128 characters.

You format each input query as follows:

```
--DirQueryName=query-name
--DirQueryComment='comment'
input-query
```

Output format

EXPORT_DIRECTED_QUERIES generates SQL for creating directed queries, and writes the SQL to the specified file or to standard output. In both cases, output conforms to the following format:

```
/* Query: directed-query-name */
/* Comment: directed-query-comment */
SAVE QUERY input-query;
CREATE DIRECTED QUERY CUSTOM 'directed-query-name'
COMMENT 'directed-query-comment'
OPTVER 'vertica-release-num'
PSDATE 'timestamp'
annotated-query
```

If a given input query omits **DirQueryName** and **DirQueryComment** fields, EXPORT_DIRECTED_QUERIES automatically generates the following output:

- **/* Query: Autaname: *timestamp* . *n* */**, where *n* is a zero-based integer index that ensures uniqueness among auto-generated names with the same timestamp.
- **/* Comment: Optimizer-generated directed query */**

Error handling

If any errors or warnings occur during EXPORT_DIRECTED_QUERIES execution, it returns with a message like this one:

```
1 queries successfully exported.
1 warning message was generated.
Queries exported to /home/dbadmin/outputQueries.
See error report, /home/dbadmin/outputQueries.err for details.
```

EXPORT_DIRECTED_QUERIES writes all errors and warnings to a file that it creates on the same path as the output file, and uses the output file's base name.

For example:

```
-----
WARNING: Name field not supplied. Using auto-generated name: 'Autaname:2016-04-25 15:03:32.115317.0'
Input Query: SELECT employee_dimension.employee_first_name, employee_dimension.employee_last_name, employee_dimension.job_title FROM
public.employee_dimension WHERE (employee_dimension.employee_city = 'Boston'::varchar(6)) ORDER BY employee_dimension.job_title;
END WARNING
```

Examples

See [Exporting directed queries](#).

See also

- [Batch query plan export](#)
- [IMPORT_DIRECTED_QUERIES](#)

IMPORT_DIRECTED_QUERIES

Imports to the database catalog directed queries from a SQL file that was generated by [EXPORT_DIRECTED_QUERIES](#). If no directed queries are specified, Vertica lists all directed queries in the SQL file.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
IMPORT_DIRECTED_QUERIES( 'export-file', 'directed-query-name'[,...] )
```

Arguments

export-file

A SQL file generated by [EXPORT_DIRECTED_QUERIES](#). When you run this file, Vertica creates the specified directed queries in the current database catalog.

directed-query-name

The name of a directed query that is defined in *export-file*. You can specify multiple comma-delimited directed query names.

If you omit this parameter, Vertica lists the names of all directed queries in *export-file*.

Privileges

[Superuser](#)

Examples

See [Importing directed queries](#).

See also

[Batch query plan export](#)

SAVE_PLANS

Creates [optimizer-generated](#) directed queries from the most frequently executed queries, up to the maximum specified. You can also limit the scope of SAVE_PLANS to queries only issued after a specified date.

As SAVE_PLANS iterates over past queries, it tests them against various restrictions. In general, directed queries support only SELECT statements as input. Within this broad requirement, input queries are subject to other [restrictions](#). After qualifying all candidate input queries, SAVE_PLANS operates as follows:

1. Calls CREATE DIRECTED QUERY OPTIMIZER on all qualified input queries, which creates a directed query for each unique input query.
2. [Saves metadata](#) on the new set of directed queries to the system table [DIRECTED_QUERIES](#), where all directed queries of that set share the same integer identifier.

All directed queries created by SAVE_PLANS are initially inactive. You can activate them individually; you can also use [SAVE_PLANS_VERSION](#) identifiers to [activate](#), [deactivate](#), and [drop](#) one or more sets of directed queries.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
SAVE_PLANS( query-budget [, since-date] [, drop-old-plans[, 'comment']] )
```

Arguments

query-budget

Maximum number of input queries to save as directed queries, an integer between 1 and 100, inclusive.

since-date

The earliest timestamp of input queries to save as directed queries.

drop-old-plans

Boolean, specifies whether to drop all directed queries generated by earlier SAVE_PLANS invocations. Only directed queries that were generated by the current Vertica version are dropped; directed queries generated by earlier Vertica versions are untouched. To drop older

directed queries, use [DROP DIRECTED QUERY](#).

comment

String comment that is attached to all plans saved with this function call.

Privileges

[Superuser](#)

Generated metadata

For each set of directed queries that SAVE_PLANS creates, Vertica updates the system table [DIRECTED_QUERIES](#) with metadata on each directed query in the set:

Column name	SAVE_PLANS-generated data
QUERY_NAME	Concatenated from the following strings: <div style="border: 1px solid black; padding: 2px; margin: 5px 0;"><code>save_plans_query-label_query-number_save-plans-version</code></div> where: <ul style="list-style-type: none"><code>query-label</code> is a LABEL hint embedded in the input query associated with this directed query. If the input query contains no label, then this string is set to <code>nolabel</code>.<code>query-number</code> is an integer in a continuous sequence between 0 and <code>budget-query</code>, which uniquely identifies this directed query from others in the same SAVE_PLANS-generated set.<code>[save-plans-version]/(sql-reference/system-tables/v-catalog-schema/directed-queries.html#SAVE_PLANS_VERSION)</code> identifies the set of directed queries to which this directed query belongs.
SAVE_PLANS_VERSION	Identifies a set of directed queries that were generated by the same call to SAVE_PLANS. All directed queries of the set share the same <code>SAVE_PLANS_VERSION</code> integer, which increments by 1 the previous highest <code>SAVE_PLANS_VERSION</code> setting. Use this identifier to activate , deactivate , and drop a set of directed queries.
USERNAME	User who invoked SAVE_PLANS to create this set of directed queries.
SINCE_DATE	The <code>since-date</code> timestamp supplied to SAVE_PLANS, which specified the earliest timestamp of input queries to evaluate as directed query candidates.
DIGEST	Hash of saved query plan data, used by the optimizer to map identical input queries to the same active directed query.

Examples

See [Bulk-Creation of Directed Queries](#).

Error-handling functions

Error-handling functions take a string and return the string when the query is executed.

In this section

- [THROW_ERROR](#)

THROW_ERROR

Returns a user-defined error message.

In a multi-node cluster, race conditions might cause the order of error messages to differ.

Behavior type

[Immutable](#)

Syntax

```
THROW_ERROR ( message )
```

Parameters

message

The VARCHAR string to return.

Examples

Return an error message when a CASE statement is met:

```
=> CREATE TABLE pitcher_err (some_text varchar);
CREATE TABLE
=> COPY pitcher_err FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> big foo value
>> bigger foo other value
>> bar another foo value
>> \.
=> SELECT (CASE WHEN true THEN THROW_ERROR('Failure!!!') ELSE some_text END) FROM pitcher_err;
ERROR 7137: USER GENERATED ERROR: Failure!!!
```

Return an error message when a CASE statement using [REGEXP_LIKE](#) is met:

```
=> SELECT (CASE WHEN REGEXP_LIKE(some_text, 'other') THEN THROW_ERROR("Failure at " || some_text || ")") END) FROM pitcher_err;
ERROR 4566: USER GENERATED ERROR: Failure at "bar another foo value"
```

Flex functions

This section contains helper functions for use in working with flex tables and flexible columns for complex types. You can use these functions with flex tables, their associated *flex_table_keys* tables and *flex_table_view* views, and flexible columns in external tables. These functions do not apply to other tables.

For more information about flex tables, see [Flex tables](#). For more information about flexible columns for complex types, see [Flexible complex types](#).

Flex functions allow you to manage and query flex tables. You can also use the map functions to query flexible complex-type columns in non-flex tables.

In this section

- [Flex data functions](#)
- [Flex extractor functions](#)
- [Flex map functions](#)

Flex data functions

The flex table data helper functions supply information you need to directly query data in flex tables. After you compute keys and create views from the raw data, you can use field names directly in queries instead of using map functions to extract data. The data functions are:

- [COMPUTE_FLEXTABLE_KEYS](#): Computes map keys from the map data in a flex table and populates a keys table with the results. Use this function before building a view.
- [BUILD_FLEXTABLE_VIEW](#): Uses the keys in a table to create a view definition for the source table. Use this function after computing flex table keys.
- [COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW](#): Performs both of the preceding functions in one call.
- [MATERIALIZATE_FLEXTABLE_COLUMNS](#): Materializes a specified number of columns.
- [RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW](#): Replaces the *flextable_data_keys* table and the *flextable_data_view* view, linking both the keys table and the view to the parent flex table.

Flex table dependencies

Each flex table has two dependent objects, a keys table and a view. While both objects are dependent on their parent table, you can drop either object independently. Dropping the parent table removes both dependents, without a CASCADE option.

Associating flex tables and views

The helper functions automatically use the dependent table and view if they are internally linked with the parent table. You create both when you create the flex table. You can drop either the keys table or the view and re-create objects of the same name. However, if you do so, the new objects are not internally linked with the parent flex table.

In this case, you can restore the internal links of these objects to the parent table. To do so, drop the keys table and the view before calling the [RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW](#) function. Calling this function re-creates the keys table and view.

The remaining helper functions perform the tasks described in this section.

In this section

- [BUILD_FLEXTABLE_VIEW](#)
- [COMPUTE_FLEXTABLE_KEYS](#)
- [COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW](#)
- [MATERIALIZATE_FLEXTABLE_COLUMNS](#)
- [RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW](#)

BUILD_FLEXTABLE_VIEW

Creates, or re-creates, a view for a default or user-defined keys table, ignoring any empty keys.

Note

If the length of a key exceeds 65,000, Vertica truncates the key.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
BUILD_FLEXTABLE_VIEW ('[[database.]schema.]flex-table'  
 [ , 'view-name' ] [ , 'user-keys-table' ] )
```

Arguments

[**database .**] **schema**

Database and [schema](#). The default schema is [public](#). If you specify a database, it must be the current database.

flex-table

The flex table name. By default, this function builds or rebuilds a view for the input table with the current contents of the associated [flex_table_keys](#) table.

view-name

A custom view name. Use this option to build a new view for [flex-table](#) with the name you specify.

user-keys-table

Name of a keys table from which to create the view. Use this option if you created a custom keys table from the flex table map data, rather than from the default [flex_table_keys](#) table. The function builds a view from the keys in [user_keys](#), rather than from [flex_table_keys](#).

Examples

The following examples show how to call BUILD_FLEXTABLE_VIEW with 1, 2, or 3 arguments.

To create, or re-create, a default view:

1. Call the function with an input flex table:

```
=> SELECT BUILD_FLEXTABLE_VIEW('darkdata');  
      build_flextable_view  
-----  
The view public.darkdata_view is ready for querying  
(1 row)
```

The function creates a view with the default name ([darkdata_view](#)) from the [darkdata](#) _keys table.

2. Query a key name from the new or updated view:

```

=> SELECT "user.id" FROM darkdata_view;
user.id
-----
340857907
727774963
390498773
288187825
164464905
125434448
601328899
352494946
(12 rows)

```

To create, or re-create, a view with a custom name:

1. Call the function with two arguments, an input flex table, `darkdata`, and the name of the view to create, `dd_view` :

```

=> SELECT BUILD_FLEXTABLE_VIEW('darkdata', 'dd_view');
      build_flextable_view
-----
The view public.dd_view is ready for querying
(1 row)

```

2. Query a key name (`user.lang`) from the new or updated view (`dd_view`):

```

=> SELECT "user.lang" FROM dd_view;
user.lang
-----
tr
en
es
en
en
it
es
en
(12 rows)

```

To create a view from a custom keys table with `BUILD_FLEXTABLE_VIEW`, the custom table must have the same schema and table definition as the default table (`darkdata_keys`). Create a custom keys table, using any of these three approaches:

- Create a columnar table with all keys from the default keys table for a flex table (`darkdata_keys`):

```

=> CREATE TABLE new_darkdata_keys AS SELECT * FROM darkdata_keys;
CREATE TABLE

```

- Create a columnar table without content (`LIMIT 0`) from the default keys table for a flex table (`darkdata_keys`):

```

=> CREATE TABLE new_darkdata_keys AS SELECT * FROM darkdata_keys LIMIT 0;
CREATE TABLE
kdb=> SELECT * FROM new_darkdata_keys;
key_name | frequency | data_type_guess
-----+-----+-----
(0 rows)

```

- Create a columnar table without content (`LIMIT 0`) from the default keys table, and insert two values (' `user.lang` ', ' `user.name` ') into the `key_name` column:

```

=> CREATE TABLE dd_keys AS SELECT * FROM darkdata_keys limit 0;
CREATE TABLE
=> INSERT INTO dd_keys (key_name) values ('user.lang');
OUTPUT
-----
      1
(1 row)
=> INSERT INTO dd_keys (key_name) values ('user.name');
OUTPUT
-----
      1
(1 row)
=> SELECT * FROM dd_keys;
key_name | frequency | data_type_guess
-----+-----+-----
user.lang |          |
user.name |          |
(2 rows)

```

After creating a custom keys table, call BUILD_FLEXTABLE_VIEW with all arguments (an input flex table, the new view name, the custom keys table):

```

=> SELECT BUILD_FLEXTABLE_VIEW('darkdata', 'dd_view', 'dd_keys');
      build_flextable_view
-----
The view public.dd_view is ready for querying
(1 row)

```

Query the new view:

```

=> SELECT * FROM dd_view;

```

See also

- [COMPUTE_FLEXTABLE_KEYS](#)
- [COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW](#)
- [MATERIALIZE_FLEXTABLE_COLUMNS](#)
- [RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW](#)

COMPUTE_FLEXTABLE_KEYS

Computes the virtual columns (keys and values) from flex table VMap data. Use this function to compute keys without creating an associated table view. To also build a view, use [COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW](#).

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```

COMPUTE_FLEXTABLE_KEYS ('[[database.]schema.]flex-table')

```

Arguments

[**database** .] **schema**

Database and [schema](#). The default schema is [public](#). If you specify a database, it must be the current database.

flex-table

Name of the flex table.

Output

The function stores its results in a table named [flex-table_keys](#). The table has the following columns:

Column	Description
KEY_NAME	The name of the virtual column (key). Keys larger than 65,000 bytes are truncated.

FREQUENCY	The number of times the key occurs in the VMap.
DATA_TYPE_GUESS	Estimate of the data type for the key based on the non-null values found in the VMap. The function determines the type of each non-string value, depending on the length of the key, and whether the key includes nested maps. If the EnableBetterFlexTypeGuessing configuration parameter is 0 (OFF), this function instead treats all flex table keys as string types ([LONG] VARCHAR or [LONG] VARBINARY).

COMPUTE_FLEXTABLE_KEYS sets the column width for keys to the length of the largest value for each key multiplied by the [FlexTableDataTypeGuessMultiplier](#) factor.

Examples

In the following example, JSON data with consistent fields has been loaded into a flex table. Had the data been more varied, you would see different numbers of occurrences in the keys table:

```
=> SELECT COMPUTE_FLEXTABLE_KEYS('reviews_flex');
      COMPUTE_FLEXTABLE_KEYS
```

Please see public.reviews_flex_keys for updated keys

(1 row)

```
SELECT * FROM reviews_flex_keys;
```

```
key_name | frequency | data_type_guess
```

```
-----+-----
user_id  |    1000 | Varchar(44)
useful   |    1000 | Integer
text     |    1000 | Varchar(9878)
stars    |    1000 | Numeric(5,2)
review_id |    1000 | Varchar(44)
funny    |    1000 | Integer
date     |    1000 | Timestamp
cool     |    1000 | Integer
business_id |    1000 | Varchar(44)
```

(9 rows)

- [COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW](#)
- [MATERIALIZATE_FLEXTABLE_COLUMNS](#)
- [RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW](#)

COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW

Combines the functionality of [BUILD_FLEXTABLE_VIEW](#) and [COMPUTE_FLEXTABLE_KEYS](#) to compute virtual columns (keys) from the VMap data of a flex table and construct a view. Creating a view with this function ignores empty keys. If you do not need to perform both operations together, use one of the single-operation functions instead.

Note

If the length of a key exceeds 65,000, Vertica truncates the key.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW ('flex-table')
```

Arguments

flex-table

Name of a flex table

Examples

This example shows how to call the function for the darkdata flex table.

```
=> SELECT COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW('darkdata');
      compute_flexable_keys_and_build_view
```

Please see public.darkdata_keys for updated keys
The view public.darkdata_view is ready for querying
(1 row)

See also

- [BUILD_FLEXTABLE_VIEW](#)
- [COMPUTE_FLEXTABLE_KEYS](#)
- [MATERIALIZED_FLEXTABLE_COLUMNS](#)
- [RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW](#)

MATERIALIZED_FLEXTABLE_COLUMNS

Materializes virtual columns listed as *key_names* in the *flexable_keys* table you compute using either [COMPUTE_FLEXTABLE_KEYS](#) or [COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW](#).

Note

Each column that you materialize with this function counts against the data storage limit of your license. To check your Vertica license compliance, call the [AUDIT\(\)](#) or [AUDIT_FLEX\(\)](#) functions.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
MATERIALIZED_FLEXTABLE_COLUMNS ('[[database.]schema.]flex-table' [, n-columns [, keys-table-name] ])
```

Arguments

[**database** .] **schema**

Database and [schema](#). The default schema is [public](#). If you specify a database, it must be the current database.

flex-table

The name of the flex table with columns to materialize. The function:

- Skips any columns already materialized
- Ignores any empty keys

n-columns

The number of columns to materialize, up to 9800. The function attempts to materialize the number of columns from the keys table, skipping any columns already materialized. It orders the materialized results by frequency, descending. If not specified, the default is a maximum of 50 columns.

keys-table-name

The name of a keys from which to materialize columns. The function:

- Materializes *n-columns* columns from the keys table
- Skips any columns already materialized
- Orders the materialized results by frequency, descending

Examples

The following example shows how to call `MATERIALIZED_FLEXTABLE_COLUMNS` to materialize columns. First, load a sample file of tweets ([tweets_10000.json](#)) into the flex table `twitter_r`. After loading data and computing keys for the sample flex table, call `MATERIALIZED_FLEXTABLE_COLUMNS` to materialize the first four columns:

```
=> COPY twitter_r FROM '/home/release/KData/tweets_10000.json' parser fjsonparser();
```

Rows Loaded

```
-----  
      10000  
(1 row)
```

```
=> SELECT compute_flexible_keys ('twitter_r');  
      compute_flexible_keys
```

```
-----  
Please see public.twitter_r_keys for updated keys  
(1 row)
```

```
=> SELECT MATERIALIZE_FLEXIBLE_COLUMNS('twitter_r', 4);  
      MATERIALIZE_FLEXIBLE_COLUMNS
```

```
-----  
The following columns were added to the table public.twitter_r:
```

```
  contributors  
  entities.hashtags  
  entities.urls
```

For more details, run the following query:

```
SELECT * FROM v_catalog.materialize_flexible_columns_results WHERE table_schema = 'public' and table_name = 'twitter_r';
```

```
(1 row)
```

The last message in the example recommends querying the [MATERIALIZE_FLEXIBLE_COLUMNS_RESULTS](#) system table for the results of materializing the columns, as shown:

```
=> SELECT * FROM v_catalog.materialize_flexible_columns_results WHERE table_schema = 'public' and table_name = 'twitter_r';
```

table_id	table_schema	table_name	creation_time	key_name	status	message
45035996273733172	public	twitter_r	2013-11-20 17:00:27.945484-05	contributors	ADDED	Added successfully
45035996273733172	public	twitter_r	2013-11-20 17:00:27.94551-05	entities.hashtags	ADDED	Added successfully
45035996273733172	public	twitter_r	2013-11-20 17:00:27.945519-05	entities.urls	ADDED	Added successfully
45035996273733172	public	twitter_r	2013-11-20 17:00:27.945532-05	created_at	EXISTS	Column of same name already

(4 rows)

- [BUILD_FLEXIBLE_VIEW](#)
- [COMPUTE_FLEXIBLE_KEYS](#)
- [COMPUTE_FLEXIBLE_KEYS_AND_BUILD_VIEW](#)
- [RESTORE_FLEXIBLE_DEFAULT_KEYS_TABLE_AND_VIEW](#)

RESTORE_FLEXIBLE_DEFAULT_KEYS_TABLE_AND_VIEW

Restores the keys table and the view. The function also links the keys table with its associated flex table, in cases where either table is dropped. The function also indicates whether it restored one or both objects.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
RESTORE_FLEXIBLE_DEFAULT_KEYS_TABLE_AND_VIEW ('flex-table')
```

Arguments

flex-table

Name of a flex table

Examples

This example shows how to invoke this function with an existing flex table, restoring both the keys table and view:

```
=> SELECT RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW('darkdata');
        RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW
```

The keys table public.darkdata_keys was restored successfully.

The view public.darkdata_view was restored successfully.

(1 row)

This example illustrates that the function restored `darkdata_view`, but that `darkdata_keys` did not need restoring:

```
=> SELECT RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW('darkdata');
        RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW
```

The keys table public.darkdata_keys already exists and is linked to darkdata.

The view public.darkdata_view was restored successfully.

(1 row)

After restoring the keys table, there is no content. To populate the flex keys, call the [COMPUTE_FLEXTABLE_KEYS](#) function.

```
=> SELECT * FROM darkdata_keys;
key_name | frequency | data_type_guess
```

(0 rows)

Flex extractor functions

The flex extractor scalar functions process polystructured data. Each function accepts input data that is any of:

- Existing database content
- A table
- Returned from an expression
- Entered directly

These functions do not parse data from an external file source. All functions return a single VMap value. The extractor functions can return data with NULL-specified columns.

In this section

- [MAPDELIMITEXTRACTOR](#)
- [MAPJSONEXTRACTOR](#)
- [MAPREGEXEXTRACTOR](#)

MAPDELIMITEXTRACTOR

Extracts data with a delimiter character and other optional arguments, returning a single VMap value.

Syntax

```
MAPDELIMITEXTRACTOR (record-value [ USING PARAMETERS param=value[,...] ])
```

Arguments

record-value

String containing a JSON or delimited format record on which to apply the expression.

Parameters

delimiter

Single delimiter character.

Default: |

header_names

Delimiter-separated list of column header names.

Default: `ucol n`, where `n` is the column offset number, starting with `0` for the first column.

trim

Boolean, trim white space from header names and field values.

Default: `true`

treat_empty_val_as_null

Boolean, set empty fields to `NULL` rather than an empty string (`"`).

Default: `true`

Examples

These examples use a short set of delimited data:

```
Name|CITY|New city|State|zip
Tom|BOSTON|boston|MA|01
Eric|Burlington|BURLINGTON|MA|02
Jamie|cambridge|CAMBRIDGE|MA|08
```

To begin, save this data as `delim.dat` .

1. Create a flex table, `dflex` :

```
=> CREATE FLEX TABLE dflex();
CREATE TABLE
```

2. Use [COPY](#) to load the `delim.dat` file. Use the flex tables `fdelimitedparser` with the `header='false'` option:

```
=> COPY dflex FROM '/home/release/kmm/flextables/delim.dat' parser fdelimitedparser(header='false');
Rows Loaded
-----
      4
(1 row)
```

3. Create a columnar table, `dtab` , with an identity `id` column, a `delim` column, and a `vmap` column to hold a VMap:

```
=> CREATE TABLE dtab (id IDENTITY(1,1), delim varchar(128), vmap long varbinary(512));
CREATE TABLE
```

4. Use `COPY` to load the `delim.dat` file into the `dtab` table. `MAPDELIMITEDEXTRACTOR` uses the `header_names` parameter to specify a header row for the sample data, along with `delimiter '!'` :

```
=> COPY dtab(delim, vmap AS MAPDELIMITEDEXTRACTOR (delim
  USING PARAMETERS header_names='Name|CITY|New City|State|Zip')) FROM '/home/dbadmin/data/delim.dat'
DELIMITER '!';

Rows Loaded
-----
      4
(1 row)
```

5. Use [MAPTOSTRING](#) for the flex table `dflex` to view the `__raw__` column contents. Notice the default header names in use (`ucol0` – `ucol4`), since you specified `header='false'` when you loaded the flex table:

```
=> SELECT MAPTOSTRING(__raw__) FROM dflex limit 10;
```

```
maptostring
```

```
-----  
{  
  "ucol0" : "Jamie",  
  "ucol1" : "cambridge",  
  "ucol2" : "CAMBRIDGE",  
  "ucol3" : "MA",  
  "ucol4" : "08"  
}
```

```
{  
  "ucol0" : "Name",  
  "ucol1" : "CITY",  
  "ucol2" : "New city",  
  "ucol3" : "State",  
  "ucol4" : "zip"  
}
```

```
{  
  "ucol0" : "Tom",  
  "ucol1" : "BOSTON",  
  "ucol2" : "boston",  
  "ucol3" : "MA",  
  "ucol4" : "01"  
}
```

```
{  
  "ucol0" : "Eric",  
  "ucol1" : "Burlington",  
  "ucol2" : "BURLINGTON",  
  "ucol3" : "MA",  
  "ucol4" : "02"  
}
```

```
(4 rows)
```

6. Use MAPTOSTRING again, this time with the `dtab` table's `vmap` column. Compare the results of this output to those for the flex table. Note that MAPTOSTRING returns the `header_name` parameter values you specified when you loaded the data:

```
=> SELECT MAPTOSTRING(vmap) FROM dtab;
      maptostring
```

```
-----
{
  "CITY" : "CITY",
  "Name" : "Name",
  "New City" : "New city",
  "State" : "State",
  "Zip" : "zip"
}

{
  "CITY" : "BOSTON",
  "Name" : "Tom",
  "New City" : "boston",
  "State" : "MA",
  "Zip" : "02121"
}

{
  "CITY" : "Burlington",
  "Name" : "Eric",
  "New City" : "BURLINGTON",
  "State" : "MA",
  "Zip" : "02482"
}

{
  "CITY" : "cambridge",
  "Name" : "Jamie",
  "New City" : "CAMBRIDGE",
  "State" : "MA",
  "Zip" : "02811"
}
```

(4 rows)

7. Query the `delim` column to view the contents differently:

```
=> SELECT delim FROM dtab;
      delim
```

```
-----
Name|CITY|New city|State|zip
Tom|BOSTON|boston|MA|02121
Eric|Burlington|BURLINGTON|MA|02482
Jamie|cambridge|CAMBRIDGE|MA|02811
```

(4 rows)

See also

- [MAPJSONEXTRACTOR](#)
- [MAPREGEXEXTRACTOR](#)

MAPJSONEXTRACTOR

Extracts content of repeated JSON data objects,, including nested maps, or data with an outer list of JSON elements. You can set one or more optional parameters to control the extraction process.

Note

Empty input does not generate warnings or errors.

```
MAPJSONEXTRACTOR (record-value [ USING PARAMETERS param=value[,...] ])
```

Arguments

record-value

String containing a JSON or delimited format record on which to apply the expression.

Parameters

flatten_maps

Boolean, flatten sub-maps within the JSON data, separating map **levels** with a period (.).

Default: true

flatten_arrays

Boolean, convert lists to sub-maps with integer keys. Lists are not flattened by default.

Default value: false

reject_on_duplicate

Boolean, ignore duplicate records (false), or reject duplicates (true). In either case, loading is unaffected.

Default: false

reject_on_empty_key

Boolean, reject any row that contains a key without a value.

Default: false

omit_empty_keys

Boolean, omit any key from the load data without a value.

Default: false

start_point

Name of a key in the JSON load data at which to begin parsing. The parser ignores all data before the **start_point** value. The parser processes data after the first instance, and up to the second, ignoring any remaining data.

Default: none

Examples

These examples use the following sample JSON data:

```
{ "id": "5001", "type": "None" }
{ "id": "5002", "type": "Glazed" }
{ "id": "5005", "type": "Sugar" }
{ "id": "5007", "type": "Powdered Sugar" }
{ "id": "5004", "type": "Maple" }
```

Save this example data as **bake_single.json** , and load that file.

1. Create a flex table, **flexjson** :

```
=> CREATE FLEX TABLE flexjson();
CREATE TABLE
```

2. Use **COPY** to load the **bake_single.json** file with the **fjsonparser** parser:

```
=> COPY flexjson FROM '/home/dbadmin/data/bake_single.json' parser fjsonparser();
Rows Loaded
-----
      5
(1 row)
```

3. Create a columnar table, **coljson** , with an IDENTITY column (**id**), a **json** column, and a column to hold a VMap, called **vmap** :

```
=> CREATE TABLE coljson(id IDENTITY(1,1), json varchar(128), vmap long varbinary(10000));
CREATE TABLE
```

4. Use **COPY** to load the **bake_single.json** file into the **coljson** table, using **MAPJSONEXTRACTOR**:

```
=> COPY coljson (json, vmap AS MapJSONExtractor(json)) FROM '/home/dbadmin/data/bake_single.json';
```

Rows Loaded

```
-----  
5
```

(1 row)

5. Use the [MAPTOSTRING](#) function for the flex table `flexjson` to output the `__raw__` column contents as strings:

```
=> SELECT MAPTOSTRING(__raw__) FROM flexjson limit 5;
```

maptostring

```
-----  
{  
  "id" : "5001",  
  "type" : "None"  
}  
  
{  
  "id" : "5002",  
  "type" : "Glazed"  
}  
  
{  
  "id" : "5005",  
  "type" : "Sugar"  
}  
  
{  
  "id" : "5007",  
  "type" : "Powdered Sugar"  
}  
  
{  
  "id" : "5004",  
  "type" : "Maple"  
}
```

(5 rows)

6. Use `MAPTOSTRING` again, this time with the `coljson` table's `vmap` column and compare the results. The element order differs:

```
=> SELECT MAPTOSTRING(vmap) FROM coljson limit 5;
      maptostring
-----
{
  "id" : "5001",
  "type" : "None"
}

{
  "id" : "5002",
  "type" : "Glazed"
}

{
  "id" : "5004",
  "type" : "Maple"
}

{
  "id" : "5005",
  "type" : "Sugar"
}

{
  "id" : "5007",
  "type" : "Powdered Sugar"
}

(5 rows)
```

- [MAPDELIMITEXTRACTOR](#)
- [MAPREGEXEXTRACTOR](#)

MAPREGEXEXTRACTOR

Extracts data with a regular expression and returns results as a VMap.

Syntax

```
MAPREGEXEXTRACTOR (record-value [ USING PARAMETERS param=value[,...] ])
```

Arguments

record-value

String containing a JSON or delimited format record on which to apply the regular expression.

Parameters

pattern

Regular expression used to extract the desired data.

Default: Empty string (" ")

use_jit

Boolean, use just-in-time compiling when parsing the regular expression.

Default: `false`

record_terminator

Character used to separate input records.

Default: `\n`

logline_column

Destination column containing the full string that the regular expression matched.

Default: Empty string (")

Examples

These examples use the following regular expression, which searches for information that includes the `timestamp` , `date` , `thread_name` , and `thread_id` strings.

Caution

For display purposes, this sample regular expression adds new line characters to split long lines of text. To use this expression in a query, first copy and edit the example to remove any new line characters.

This example expression loads any `thread_id` hex value, regardless of whether it has a `0x` prefix, (`<thread_id>(?:0x)?[0-9a-f]+`) .

```
'(?:<time>\d\d\d\d\d\d-\d\d\d-\d\d\d \d\d:\d\d:\d\d\d\d\d\d+
(?:<thread_name>[A-Za-z ]+).(?:<thread_id>(?:0x)?[0-9a-f]+)
(?:<transaction_id>[0-9a-f])?(?:[(?<component>\w+)]
<(?:<level>\w+)> )?(?:<(?:<level>\w+)> @[(?:<enode>\w+)]?: )
(?:<text>.*)'
```

The following examples may include newline characters for display purposes.

1. Create a flex table, `flogs` :

```
=> CREATE FLEX TABLE flogs();
CREATE TABLE
```

2. Use [COPY](#) to load a sample log file (`vertica.log`), using the flex table `fregexparser` . Note that this example includes added line characters for displaying long text lines.

```
=> COPY flogs FROM '/home/dbadmin/tempdat/vertica.log' PARSER FREGEXPARSER(pattern='
^(?:<time>\d\d\d\d\d\d-\d\d\d-\d\d\d \d\d:\d\d:\d\d\d\d\d\d+
(?:<thread_name>[A-Za-z ]+):
(?:<thread_id>(?:0x)?[0-9a-f])-(?:<transaction_id>[0-9a-f])?(?:[(?<component>\w+)]
\\<(?:<level>\w+)> )?(?:<(?:<level>\w+)> @[(?:<enode>\w+)]?: )?(?:<text>.*)');
Rows Loaded
-----
81399
(1 row)
```

3. Use to return the results from calling `MAPREGEXEXTRACTOR` with a regular expression. The output returns the results of the function in string format.

```
=> SELECT MAPTOSTRING(MapregexExtractor(E'2014-04-02 04:02:51.011
TM Moveout:0x2aab9000f860-a000000002067 [Txn] <INFO>
Begin Txn: a000000002067 \Moveout: Tuple Mover\" using PARAMETERS
pattern=
```

```
{(?<time>[0-9]{4}-[0-9]{2}-[0-9]{2} [0-9]{2}:[0-9]{2}:[0-9]{3})
(?<thread_name>[A-Za-z ]+).(?(thread_id)(?0x)?[0-9a-f]{+})
.(?(transaction_id)[0-9a-f]{+})(?(component)[w+]{+})
.(?(level)[w+]{+})?(?(?<level>[w+]{+})@[(?(?<enode>[w+]{+})]?
)?(?(text>.*))
```

```
) FROM flogs where __identity__=13;
maptostring
```

```
-----
{
"component" : "Txn",
"level" : "INFO",
"text" : "Begin Txn: a000000002067 'Moveout: Tuple Mover'",
"thread_id" : "0x2aab9000f860",
"thread_name" : "TM Moveout",
"time" : "2014-04-02 04:02:51.011",
"transaction_id" : "a000000002067"
}
(1 row)
```

- [MAPJSONEXTRACTOR](#)

Flex map functions

The flex map functions let you extract and manipulate nested map data.

The first argument of all flex map functions (except EMPTYMAP and MAPAGGREGATE) takes a VMap. The VMap can originate from the `__raw__` column in a flex table or be returned from a map or extraction function.

All map functions (except EMPTYMAP and MAPAGGREGATE) accept either a LONG VARBINARY or a LONG VARCHAR map argument.

In the following example, the outer MAPLOOKUP function operates on the VMap data returned from the inner MAPLOOKUP function:

```
=> MAPLOOKUP(MAPLOOKUP(ret_map, 'batch'), 'scripts')
```

You can use flex map functions exclusively with:

- Flex tables
- Their associated `_keys` tables and `_view` views
- Flexible complex-type columns

In this section

- [EMPTYMAP](#)
- [MAPAGGREGATE](#)
- [MAPCONTAINSKEY](#)
- [MAPCONTAINSVALUE](#)
- [MAPITEMS](#)
- [MAPKEYS](#)
- [MAPKEYSINFO](#)
- [MAPLOOKUP](#)
- [MAPPUT](#)
- [MAPSIZE](#)
- [MAPTOSTRING](#)
- [MAPVALUES](#)
- [MAPVERSION](#)

EMPTYMAP

Constructs a new VMap with one row but without keys or data. Use this transform function to populate a map without using a flex parser. Instead, you use either from SQL queries or from map data present elsewhere in the database.

Syntax

```
EMPTYMAP()
```

Examples

Create an Empty Map

```
=> SELECT EMPTYMAP();
      emptymap
-----
\001\000\000\000\004\000\000\000\000\000\000\000\000\000\000\000
(1 row)
```

Create an Empty Map from an Existing Flex Table

If you create an empty map from an existing flex table, the new map has the same number of rows as the table from which it was created.

This example shows the result if you create an empty map from the [darkdata](#) table, which has 12 rows of JSON data:

```
=> SELECT EMPTYMAP() FROM darkdata;
      emptymap
-----
\001\000\000\000\004\000\000\000\000\000\000\000\000\000\000\000
\001\000\000\000\004\000\000\000\000\000\000\000\000\000\000\000
\001\000\000\000\004\000\000\000\000\000\000\000\000\000\000\000
\001\000\000\000\004\000\000\000\000\000\000\000\000\000\000\000
\001\000\000\000\004\000\000\000\000\000\000\000\000\000\000\000
\001\000\000\000\004\000\000\000\000\000\000\000\000\000\000\000
\001\000\000\000\004\000\000\000\000\000\000\000\000\000\000\000
\001\000\000\000\004\000\000\000\000\000\000\000\000\000\000\000
\001\000\000\000\004\000\000\000\000\000\000\000\000\000\000\000
\001\000\000\000\004\000\000\000\000\000\000\000\000\000\000\000
\001\000\000\000\004\000\000\000\000\000\000\000\000\000\000\000
\001\000\000\000\004\000\000\000\000\000\000\000\000\000\000\000
\001\000\000\000\004\000\000\000\000\000\000\000\000\000\000\000
\001\000\000\000\004\000\000\000\000\000\000\000\000\000\000\000
(12 rows)
```

- [MAPVERSION](#)

MAPAGGREGATE

Returns a LONG VARBINARY VMap with key and value pairs supplied from two VARCHAR input columns. This function requires an OVER clause.

Syntax

```
MAPAGGREGATE (keys-column1, values-column2 [USING PARAMETERS param=value[...]])
```

Arguments

keys-column

Table column with the keys for the key/value pairs of the returned **VMap** data. Keys with a NULL value are excluded. If there are duplicate keys, the duplicate key and value that appear first in the query result are used, while the other duplicates are omitted.

values-column

Table column with the values for the key/value pairs of the returned **VMap** data.

Parameters

max_vmap_length

Maximum length in bytes for the VMap result, an integer between 1-32000000 inclusive.

Default: 130000

on_overflow

Overflow behavior for cases when the VMap result is larger than the **max_vmap_length** . The value must be one of the following strings:

- 'ERROR': Returns an error when overflow occurs.
- 'TRUNCATE': Stops aggregating key/value pairs if the result exceeds **max_vmap_length** . The query executes, but the resulting VMap does not have all key/value pairs. When the provided **max_vmap_length** is not large enough to store an empty VMap, the result returned is NULL.

Note that you need to specify order criteria in the OVER clause to get consistent results.

- 'RETURN_NULL': Return NULL if overflow occurs.

Default: 'ERROR'

Examples

The following examples use this input table:

```
=> SELECT * FROM inventory;
product  | stock
-----+-----
Planes   | 100
Trains   | 50
Automobiles | 200
(3 rows)
```

Call MAPAGGREGATE as follows to return the **raw_map** data of the resulting VMap:

```
=> SELECT raw_map FROM (SELECT MAPAGGREGATE(product, stock) OVER(ORDER BY product) FROM inventory) inventory;
raw_map
-----
\001\000\000\000\030\000\000\000\003\000\000\000\020\000\000\000\023\000\000\000\026\000\000\000\00200\0050\003
\000\000\000\020\000\000\000\033\000\000\000\!000\000\000AutomobilesPlanesTrains
(1 row)
```

To transform the returned **raw_map** data into string representation, use MAPAGGREGATE with **MAPTOSTRING**:

```
=> SELECT MAPTOSTRING(raw_map) FROM (SELECT MAPAGGREGATE(product, stock) OVER(ORDER BY product) FROM
inventory) inventory;
MAPTOSTRING
-----
{
  "Automobiles": "200",
  "Planes": "100",
  "Trains": "50"
}
(1 row)
```

If you run the above query with **on_overflow** left as default and a **max_vmap_length** less than the returned VMap size, the function returns with an error message indicating the need to increase VMap length:

```
=> SELECT MAPTOSTRING(raw_map) FROM (SELECT MAPAGGREGATE(product, stock USING PARAMETERS max_vmap_length=60)
OVER(ORDER BY product) FROM inventory) inventory;
```

```
-----
ERROR 5861: Error calling processPartition() in User Function MapAggregate at [/data/jenkins/workspace
/RE-PrimaryBuilds/RE-Build-Master_2/server/udx/supported/flexible/Dict.cpp:1324], error code: 0, message:
Exception while finalizing map aggregation: Output VMap length is too small [60]. HINT: Set the parameter
max_vmap_length=71 and retry your query
```

Switching the value of `on_overflow` allows you to alter how MAPAGGREGATE behaves in the case of overflow. For example, changing `on_overflow` to 'RETURN_NULL' causes the above query to execute and return NULL:

```
SELECT raw_map IS NULL FROM (SELECT MAPAGGREGATE(product, stock USING PARAMETERS max_vmap_length=60,
on_overflow='RETURN_NULL') OVER(ORDER BY product) FROM inventory) inventory;
?column?
-----
t
(1 row)
```

If `on_overflow` is set to 'TRUNCATE', the resulting VMap has enough space for two of the key/value pairs, but must cut the third:

```
SELECT raw_map IS NULL FROM (SELECT MAPAGGREGATE(product, stock USING PARAMETERS max_vmap_length=60,
on_overflow='TRUNCATE') OVER(ORDER BY product) FROM inventory) inventory;
MAPTOSTRING
-----
{
  "Automobiles": "200",
  "Planes": "100"
}
(1 row)
```

- [MAPVALUES](#)
- [MAPVERSION](#)

MAPCONTAINSKEY

Determines whether a VMap contains a virtual column (key). This scalar function returns true (`t`), if the virtual column exists, or false (`f`) if it does not. Determining that a key exists before calling `maplookup()` lets you distinguish between NULL returns. The `maplookup()` function uses for both a non-existent key and an existing key with a NULL value.

Syntax

```
MAPCONTAINSKEY (VMap-data, 'virtual-column-name')
```

Arguments

VMap-data

Any VMap data. The VMap can exist as:

- The `__raw__` column of a flex table
- Data returned from a map function such as [MAPLOOKUP](#)
- Other database content

virtual-column-name

Name of the key to check.

Examples

This example shows how to use the `mapcontainskey()` functions with `maplookup()`. View the results returned from both functions. Check whether the empty fields that `maplookup()` returns indicate a `NULL` value for the row (`t`) or no value (`f`):

You can use `mapcontainskey()` to determine that a key exists before calling `maplookup()`. The `maplookup()` function uses both `NULL` returns and existing keys with `NULL` values to indicate a non-existent key.

```
=> SELECT MAPLOOKUP(__raw__, 'user.location'), MAPCONTAINSKEY(__raw__, 'user.location')
```

```
FROM darkdata ORDER BY 1;
```

```
maplookup | mapcontainskey
```

```
-----+-----
```

- [MAPVERSION](#)

MAPCONTAINSVALUE

Determines whether a VMap contains a specific value. Use this scalar function to return true (`t`) if the value exists, or false (`f`) if it does not.

Syntax

```
MAPCONTAINSVALUE ( VMap-data, 'virtual-column-value'
```

Arguments

VMap-data

Any VMap data. The VMap can exist as:

- The `__raw__` column of a flex table
- Data returned from a map function such as [MAPLOOKUP](#)
- Other database content

virtual-column-value

Value to confirm.

Examples

This example shows how to use `mapcontainsvalue()` to determine whether or not a virtual column contains a particular value. Create a flex table (`ftest`), and populate it with some virtual columns and values. Name both virtual columns `one` :

```
=> CREATE FLEX TABLE ftest();
CREATE TABLE
=> copy ftest from stdin parser fjsonparser();
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> {"one":1, "two":2}
>> {"one":"one", "2":"2"}
>> \.
```

Call `mapcontainsvalue()` on the `ftest` map data. The query returns false (`f`) for the first virtual column, and true (`t`) for the second , which contains the value `one` :

```
=> SELECT MAPCONTAINSVALUE(__row__, 'one') FROM ftest;
mapcontainsvalue
-----
f
t
(2 rows)
```

- [MAPTOSTRING](#)
- [MAPVALUES](#)
- [MAPVERSION](#)

MAPITEMS

Returns information about items in a VMap. Use this transform function with one or more optional arguments to access polystructured values within the VMap data. This function requires an `over()` clause.

Syntax

```
MAPITEMS (VMap-data [, passthrough-arg[,...] ])
```

Arguments

VMap-data

Any VMap data. The VMap can exist as:

- The `__row__` column of a flex table
- Data returned from a map function such as [MAPLOOKUP](#)
- Other database content

max_key_length

In a `__row__` column, determines the maximum length of keys that the function can return. Keys that are longer than `max_key_length` cause the query to fail. Defaults to the smaller of VMap column length and 65K.

max_value_length

In a `__row__` column, determines the maximum length of values the function can return. Values that are larger than `max_value_length` cause the query to fail. Defaults to the smaller of VMap column length and 65K.

passthrough-arg

One or more arguments indicating keys within the map data in `VMap-data` .

Examples

The following examples illustrate using `MAPITEMS()` with the `over(PARTITION BEST)` clause.

This example determines the number of virtual columns in the map data using a flex table, labeled `darkmountain`. Query using the `count()` function to return the number of virtual columns in the map data:

```
=> SELECT COUNT(keys) FROM (SELECT MAPITEMS(darkmountain.__raw__) OVER(PARTITION BEST) FROM
darkmountain) AS a;
count
-----
   19
(1 row)
```

The next example determines what items exist in the map data:

```
=> SELECT * FROM (SELECT MAPITEMS(darkmountain.__raw__) OVER(PARTITION BEST) FROM darkmountain) AS a;
 keys | values
-----+-----
hike_safety | 50.6
name       | Mt Washington
type       | mountain
height     | 17000
hike_safety | 12.2
name       | Denali
type       | mountain
height     | 29029
hike_safety | 34.1
name       | Everest
type       | mountain
height     | 14000
hike_safety | 22.8
name       | Kilimanjaro
type       | mountain
height     | 29029
hike_safety | 15.4
name       | Mt St Helens
type       | volcano
(19 rows)
```

The following example shows how to restrict the length of returned values to 100000:

```
=> SELECT LENGTH(keys), LENGTH(values) FROM (SELECT MAPITEMS(__raw__ USING PARAMETERS max_value_length=100000) OVER() FROM t1)
x;
LENGTH | LENGTH
-----+-----
   9 | 98899
(1 row)
```

Directly Query a Key Value in a VMap

Review the following JSON input file, `simple.json`. In particular, notice the array called `three_Array`, and its four values:

```
{
  "one": "one",
  "two": 2,
  "three_Array":
  [
    "three_One",
    "three_Two",
    3,
    "three_Four"
  ],
  "four": 4,
  "five_Map":
  {
    "five_One": 51,
    "five_Two": "Fifty-two",
    "five_Three": "fifty three",
    "five_Four": 54,
    "five_Five": "5 x 5"
  },
  "six": 6
}
```

1. Create a flex table, mapper:

```
=> CREATE FLEX TABLE mapper();
CREATE TABLE
```

Load [simple.json](#) into the flex table mapper:

```
=> COPY mapper FROM '/home/dbadmin/data/simple.json' parser fjsonparser (flatten_arrays=false,
flatten_maps=false);
Rows Loaded
-----
      1
(1 row)
```

Call MAPKEYS on the flex table's `__raw__` column to see the flex table's keys, but not the key submaps. The return values indicate [three_Array](#) as one of the virtual columns:

```
=> SELECT MAPKEYS(__raw__) OVER() FROM mapper;
keys
-----
five_Map
four
one
six
three_Array
two
(6 rows)
```

Call `mapitems` on flex table `mapper` with `three_Array` as a pass-through argument to the function. The call returns these array values:

```
=> SELECT __identity__, MAPITEMS(three_Array) OVER(PARTITION BY __identity__) FROM mapper;
__identity__ | keys | values
-----+-----+-----
      1 | 0 | three_One
      1 | 1 | three_Two
      1 | 2 | 3
      1 | 3 | three_Four
(4 rows)
```

- [MAPCONTAINSKEY](#)
- [MAPCONTAINSVALUE](#)

- [MAPKEYS](#)
- [MAPKEYSINFO](#)
- [MAPLOOKUP](#)
- [MAPSIZE](#)
- [MAPTOSTRING](#)
- [MAPVALUES](#)
- [MAPVERSION](#)

MAPKEYS

Returns the virtual columns (and values) present in any VMap data. This transform function requires an **OVER(PARTITION BEST)** clause.

Syntax

```
MAPKEYS (VMap-data)
```

Arguments

VMap-data

Any VMap data. The VMap can exist as:

- The `__raw__` column of a flex table
- Data returned from a map function such as [MAPLOOKUP](#)
- Other database content

max_key_length

In a `__raw__` column, specifies the maximum length of keys that the function can return. Keys that are longer than `max_key_length` cause the query to fail. Defaults to the smaller of VMap column length and 65K.

Examples

Determine Number of Virtual Columns in Map Data

This example shows how to create a query, using an **over(PARTITION BEST)** clause with a flex table, `darkdata` to find the number of virtual column in the map data. The table is populated with JSON tweet data.

```
=> SELECT COUNT(keys) FROM (SELECT MAPKEYS(darkdata.__raw__) OVER(PARTITION BEST) FROM darkdata) AS a;
count
-----
  550
(1 row)
```

Query Ordered List of All Virtual Columns in the Map

This example shows a snippet of the return data when you query an ordered list of all virtual columns in the map data:

```
=> SELECT * FROM (SELECT MAPKEYS(darkdata.__raw__) OVER(PARTITION BEST) FROM darkdata) AS a;
keys
-----
contributors
coordinates
created_at
delete.status.id
delete.status.id_str
delete.status.user_id
delete.status.user_id_str
entities.hashtags
entities.media
entities.urls
entities.user_mentions
favorited
geo
id
.
.
.
user.statuses_count
user.time_zone
user.url
user.utc_offset
user.verified
(125 rows)
```

Specify the Maximum Length of Keys that MAPKEYS Can Return

```
=> SELECT MAPKEYS(__raw__ USING PARAMETERS max_key_length=100000) OVER() FROM mapper;
keys
-----
five_Map
four
one
six
three_Array
two
(6 rows)
```

- [MAPITEMS](#)
- [MAPKEYSINFO](#)
- [MAPLOOKUP](#)
- [MAPSIZE](#)
- [MAPTOSTRING](#)
- [MAPVALUES](#)
- [MAPVERSION](#)

MAPKEYSINFO

Returns virtual column information from a given map. This transform function requires an **OVER(PARTITION BEST)** clause.

Syntax

```
MAPKEYSINFO (VMap-data)
```

Arguments

VMap-data

Any VMap data. The VMap can exist as:

- The `__raw__` column of a flex table
- Data returned from a map function such as [MAPLOOKUP](#)
- Other database content

max_key_length

In a `__raw__` column, determines the maximum length of keys that the function can return. Keys that are longer than `max_key_length` cause the query to fail. Defaults to the smaller of VMap column length and 65K.

Returns

This function is a superset of the [MAPKEYS\(\)](#) function. It returns the following information about each virtual column:

Column	Description
<code>keys</code>	The virtual column names in the raw data.
<code>length</code>	The data length of the key name, which can differ from the actual string length.
<code>type_oid</code>	The OID type into which the value should be converted. Currently, the type is always <code>116</code> for a <code>LONG VARCHAR</code> , or <code>199</code> for a nested map that is stored as a <code>LONG VARBINARY</code> .
<code>row_num</code>	The number of rows in which the key was found.
<code>field_num</code>	The field number in which the key exists.

Examples

This example shows a snippet of the return data you receive if you query an ordered list of all virtual columns in the map data:

```
=> SELECT * FROM (SELECT MAPKEYSINFO(darkdata.__raw__) OVER(PARTITION BEST) FROM darkdata) AS a;
```

keys	length	type_oid	row_num	field_num
contributors	0	116	1	0
coordinates	0	116	1	1
created_at	30	116	1	2
entities.hashtags	93	199	1	3
entities.media	772	199	1	4
entities.urls	16	199	1	5
entities.user_mentions	16	199	1	6
favorited	1	116	1	7
geo	0	116	1	8
id	18	116	1	9
id_str	18	116	1	10
.				
.				
.				
delete.status.id	18	116	11	0
delete.status.id_str	18	116	11	1
delete.status.user_id	9	116	11	2
delete.status.user_id_str	9	116	11	3
delete.status.id	18	116	12	0
delete.status.id_str	18	116	12	1
delete.status.user_id	9	116	12	2
delete.status.user_id_str	9	116	12	3

(550 rows)

Specify the Maximum Length of Keys that MAPKEYSINFO Can Return

```
=> SELECT MAPKEYSINFO(__raw__ USING PARAMETERS max_key_length=100000) OVER() FROM mapper;
keys
-----
five_Map
four
one
six
three_Array
two
(6 rows)
```

- [MAPSIZE](#)
- [MAPTOSTRING](#)
- [MAPVALUES](#)
- [MAPVERSION](#)

MAPLOOKUP

Returns single-key values from VMAP data. This scalar function returns a **LONG VARCHAR** , with values, or **NULL** if the virtual column does not have a value.

Using `maplookup` is case insensitive to virtual column names. To avoid loading same-name values, set the `fjsonparser` parser `reject_on_duplicate` parameter to `true` when data loading.

You can control the behavior for non-scalar values in a VMAP (like arrays), when loading data with the `fjsonparser` or `favroparser` parsers and its `flatten-arrays` argument. See [JSON data](#) and the [FJSONPARSER](#) reference.

For information about using `maplookup()` to access nested JSON data, see [Querying nested data](#) .

Syntax

```
MAPLOOKUP ( VMap-data, 'virtual-column-name' [USING PARAMETERS [case_sensitive={false | true}] [, buffer_size=n ] ] )
```

Parameters

VMap-data

Any VMap data. The VMap can exist as:

- The `__raw__` column of a flex table
- Data returned from a map function such as [MAPLOOKUP](#)
- Other database content

virtual-column-name

The name of the virtual column whose values this function returns.

buffer_size

[Optional parameter] Specifies the maximum length (in bytes) of each value returned for `virtual-column-name` . To return all values for `virtual-column-name` , specify a `buffer_size` equal to or greater than (`=>`) the number of bytes for any returned value. Any returned values greater in length than `buffer_size` are rejected.

Default: 0 (No limit on `buffer_size`)

case_sensitive

[Optional parameter]

Specifies whether to return values for `virtual-column-name` if keys with different cases exist.

Example:

```
(... USING PARAMETERS case_sensitive=true)
```

Default: `false`

Examples

This example returns the values of one virtual column, `user.location` :

```
=> SELECT MAPLOOKUP(__raw__, 'user.location') FROM darkdata ORDER BY 1;
maplookup
-----
Chile
Nesnia
Uptown
.
.
chicago
(12 rows)
```

Using maplookup buffer_size

Use the `buffer_size=` parameter to indicate the maximum length of any value that maplookup returns for the virtual column you specify. If none of the returned key values can be greater than `n` bytes, use this parameter to allocate `n` bytes as the `buffer_size` .

For the next example, save this JSON data to a file, `simple_name.json` :

```
{
  "name": "sierra",
  "age": "63",
  "eyes": "brown",
  "weapon": "doggie"
}
{
  "name": "janis",
  "age": "10",
  "eyes": "blue",
  "weapon": "humor"
}
{
  "name": "ben",
  "age": "43",
  "eyes": "blue",
  "weapon": "sword"
}
{
  "name": "jen",
  "age": "38",
  "eyes": "green",
  "weapon": "shopping"
}
```

1. Create a flex table, `logs` .
2. Load the `simple_name.json` data into `logs` , using the `fjsonparser` . Specify the `flatten_arrays` option as `True` :

```
=> COPY logs FROM '/home/dbadmin/data/simple_name.json'
PARSER fjsonparser(flatten_arrays=True);
```

3. Use `maplookup` with `buffer_size=0` for the `logs` table `name` key. This query returns all of the values:

```
=> SELECT MAPLOOKUP(__row__, 'name' USING PARAMETERS buffer_size=0) FROM logs;
MapLookup
-----
sierra
ben
janis
jen
(4 rows)
```

4. Next, call `maplookup()` three times, specifying the `buffer_size` parameter as `3`, `5`, and `6`, respectively. Now, `maplookup()` returns values with a byte length less than or equal to (`<=`) `buffer_size`:

```
=> SELECT MAPLOOKUP(__row__, 'name' USING PARAMETERS buffer_size=3) FROM logs;
MapLookup
-----

ben

jen
(4 rows)
=> SELECT MAPLOOKUP(__row__, 'name' USING PARAMETERS buffer_size=5) FROM logs;
MapLookup
-----

janis
jen
ben
(4 rows)
=> SELECT MAPLOOKUP(__row__, 'name' USING PARAMETERS buffer_size=6) FROM logs;
MapLookup
-----
sierra
janis
jen
ben
(4 rows)
```

Disambiguate Empty Output Rows

This example shows how to interpret empty rows. Using `maplookup` without first checking whether a key exists can be ambiguous. When you review the following output, 12 empty rows, you cannot determine whether a `user.location` key has:

- A non-NULL value
- A `NULL` value
- No value

```
=> SELECT MAPLOOKUP(__row__, 'user.location') FROM darkdata;
maplookup
-----

(12 rows)
```

To disambiguate empty output rows, use the `mapcontainskey()` function in conjunction with `maplookup()`. When `maplookup` returns an empty field, the corresponding value from `mapcontainskey` indicates `t` for a `NULL` or other value, or `f` for no value.

The following example output using both functions lists rows with `NULL` or a name value as `t`, and rows with no value as `f`:

```
=> SELECT MAPLOOKUP(__row__, 'user.location'), MAPCONTAINSKEY(__row__, 'user.location')
FROM darkdata ORDER BY 1;
maplookup | mapcontainskey
-----+-----
      | t
      | t
      | t
      | t
Chile  | t
Nesnia | t
Uptown | t
chicago | t
      | f >>>>>>>>>No value
      | f >>>>>>>>>No value
      | f >>>>>>>>>No value
      | f >>>>>>>>>No value
(12 rows)
```

Check for Case-Sensitive Virtual Columns

You can use `maplookup()` with the `case_sensitive` parameter to return results when key names with different cases exist.

1. Save the following sample content as a JSON file. This example saves the file as `repeated_key_name.json`:

```
{
  "test": "lower1"
}
{
  "TEST": "upper1"
}
{
  "TEst": "half1"
}
{
  "test": "lower2",
  "TEst": "half2"
}
{
  "TEST": "upper2",
  "TEst": "half3"
}
{
  "test": "lower3",
  "TEST": "upper3"
}
{
  "TEst": "half4",
  "test": "lower4",
  "TEST": "upper4"
}
{
  "TesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttest
TesttestTesttestTesttestTesttest": "1",
  "TesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttest
TesttestTesttestTesttestTesttestTest12345": "2"
}
```

2. Create a flex table, `dupe`, and load the JSON file:

```

=> CREATE FLEX TABLE dupe();
CREATE TABLE
dbt=> COPY dupe FROM '/home/release/KData/repeated_key_name.json' parser fjsonparser();
Rows Loaded
-----
      8
(1 row)

```

- [MAPTOSTRING](#)
- [MAPVALUES](#)
- [MAPVERSION](#)

MAPPUT

Accepts a VMap and one or more key/value pairs and returns a new VMap with the key/value pairs added. Keys must be set using the auxiliary function [SetMapKeys\(\)](#), and can only be constant strings. If the VMap has any of the new input keys, then the original values are replaced by the new ones.

Syntax

```
MAPPUT (VMap-data, value[...]) USING PARAMETERS keys=SetMapKeys('key[,...]')
```

Arguments

VMap-data

Any VMap data. The VMap can exist as:

- The `__raw__` column of a flex table
- Data returned from a map function such as [MAPLOOKUP](#).
- Other database content

value [...]

One or more values to add to the VMap specified in **VMap-data**.

Parameters

keys

The result of [SetMapKeys\(\)](#). [SetMapKeys\(\)](#) takes one or more constant string arguments.

The following example shows how to create a flex table and use COPY to enter some basic JSON data. After creating a second flex table, insert the new VMap results from [mapput\(\)](#), with additional key/value pairs.

1. Create sample table:

```

=> CREATE FLEX TABLE vmapdata1();
CREATE TABLE

```

2. Load sample JSON data from STDIN:

```

=> COPY vmapdata1 FROM stdin parser fjsonparser();
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> {"aaa": 1, "bbb": 2, "ccc": 3}
>> \.

```

3. Create another flex table and use the function to insert data into it: `=> CREATE FLEX TABLE vmapdata2(); => INSERT INTO vmapdata2 SELECT MAPPUT(__raw__, '7','8','9' using parameters keys=SetMapKeys('xxx','yyy','zzz')) from vmapdata1;`
4. View the difference between the original and the new flex tables:

```

=> SELECT MAPTOSTRING(__raw__) FROM vmapdata1;
      maptostring
-----
{
  "aaa" : "1",
  "bbb" : "2",
  "ccc" : "3"
}
(1 row)

=> SELECT MAPTOSTRING(__raw__) from vmapdata2;
      maptostring
-----
{
  "mapput" : {
    "aaa" : "1",
    "bbb" : "2",
    "ccc" : "3",
    "xxx" : "7",
    "yyy" : "8",
    "zzz" : "9"
  }
}

```

See also

- [MAPCONTAINSKEY](#)
- [MAPCONTAINSVALUE](#)
- [MAPITEMS](#)
- [MAPKEYS](#)
- [MAPKEYSINFO](#)
- [MAPLOOKUP](#)
- [MAPSIZE](#)
- [MAPVALUES](#)
- [MAPVERSION](#)

MAPSIZE

Returns the number of virtual columns present in any VMap data. Use this scalar function to determine the size of keys.

Syntax

```
MAPSIZE (VMap-data)
```

Arguments

VMap-data

Any VMap data. The VMap can exist as:

- The `__raw__` column of a flex table
- Data returned from a map function such as [MAPLOOKUP](#)
- Other database content

Examples

This example shows the returned sizes from the number of keys in the flex table `darkmountain` :

```
=> SELECT MAPSIZE(__raw__) FROM darkmountain;
mapsize
-----
 3
 4
 4
 4
 4
(5 rows)
```

See also

- [EMPTYMAP](#)
- [MAPAGGREGATE](#)
- [MAPCONTAINSKEY](#)
- [MAPCONTAINSVALUE](#)
- [MAPITEMS](#)
- [MAPKEYS](#)
- [MAPKEYSINFO](#)
- [MAPLOOKUP](#)
- [MAPTOSTRING](#)
- [MAPVALUES](#)
- [MAPVERSION](#)

MAPTOSTRING

Recursively builds a string representation of VMap data, including nested JSON maps. Use this transform function to display the VMap contents in a LONG VARCHAR format. You can use MAPTOSTRING to see how map data is nested before querying virtual columns with [MAPVALUES](#).

Syntax

```
MAPTOSTRING ( VMap-data [ USING PARAMETERS param=value ] )
```

Arguments

VMap-data

Any VMap data. The VMap can exist as:

- The `__raw__` column of a flex table
- Data returned from a map function such as [MAPLOOKUP](#)
- Other database content

Parameters

canonical_json

Boolean, whether to produce canonical JSON format, using the first instance of any duplicate keys in the map data. If false, the function returns duplicate keys and their values.

Default: true

Examples

The following example uses this table definition and sample data:

```
=> CREATE FLEX TABLE darkdata();
CREATE TABLE

=> COPY darkdata FROM stdin parser fjsonparser();
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> {"aaa": 1, "aaa": 2, "AAA": 3, "bbb": "aaa\bbb"}
>> \.
```

Calling MAPTOSTRING with the default value of `canonical_json` returns only the first instance of the duplicate key:

```
=> SELECT MAPTOSTRING (__raw__) FROM darkdata;
      maptostring
```

```
-----
{
  "AAA" : "3",
  "aaa" : "1",
  "bbb" : "aaa\"bbb"
}
(1 row)
```

With `canonical_json` set to false, the function returns all of the keys, including duplicates:

```
=> SELECT MAPTOSTRING(__raw__ using parameters canonical_json=false) FROM darkdata;
      maptostring
```

```
-----
{
  "aaa": "1",
  "aaa": "2",
  "AAA": "3",
  "bbb": "aaa\"bbb"
}
(1 row)
```

- [MAPITEMS](#)
- [MAPKEYS](#)
- [MAPKEYSINFO](#)
- [MAPLOOKUP](#)
- [MAPSIZE](#)
- [MAPVALUES](#)
- [MAPVERSION](#)

MAPVALUES

Returns a string representation of the top-level values from a VMap. This transform function requires an `OVER()` clause.

Syntax

```
MAPVALUES ( VMap-data )
```

Arguments

VMap-data

Any VMap data. The VMap can exist as:

- The `__raw__` column of a flex table
- Data returned from a map function such as [MAPLOOKUP](#)
- Other database content

max_value_length

In a `__raw__` column, specifies the maximum length of values the function can return. Values that are larger than `max_value_length` cause the query to fail. Defaults to the smaller of VMap column length and 65K.

Examples

The following example shows how to query a `darkmountain` flex table, using an `over()` clause (in this case, the `over(PARTITION BEST)` clause) with `mapvalues()` .

```
=> SELECT * FROM (SELECT MAPVALUES(darkmountain.__raw__) OVER(PARTITION BEST) FROM darkmountain) AS a;
  values
-----
29029
34.1
Everest
mountain
29029
15.4
Mt St Helens
volcano
17000
12.2
Denali
mountain
14000
22.8
Kilimanjaro
mountain
50.6
Mt Washington
mountain
(19 rows)
```

Specify the Maximum Length of Values that MAPVALUES Can Return

```
=> SELECT MAPVALUES(__raw__ USING PARAMETERS max_value_length=100000) OVER() FROM mapper;
  keys
-----
five_Map
four
one
six
three_Array
two
(6 rows)
```

- [MAPVERSION](#)

MAPVERSION

Returns the version or invalidity of any map data. This scalar function returns the map version (such as **1**) or **-1** , if the map data is invalid.

Syntax

```
MAPVERSION (VMap-data)
```

Arguments

VMap-data

Any VMap data. The VMap can exist as:

- The `__raw__` column of a flex table

- Data returned from a map function such as [MAPLOOKUP](#)
- Other database content

Examples

The following example shows how to use `mapversion()` with the `darkmountain` flex table, returning `mapversion 1` for the flex table map data:

```
=> SELECT MAPVERSION(__raw__) FROM darkmountain;
mapversion
-----
      1
      1
      1
      1
      1
(5 rows)
```

- [MAPVALUES](#)

Formatting functions

Formatting functions provide a powerful tool set for converting various data types (DATE/TIME, INTEGER, FLOATING POINT) to formatted strings and for converting from formatted strings to specific data types.

In this section

- [Template patterns for date/time formatting](#)
- [Template patterns for numeric formatting](#)
- [TO_BITSTRING](#)
- [TO_CHAR](#)
- [TO_DATE](#)
- [TO_HEX](#)
- [TO_NUMBER](#)
- [TO_TIMESTAMP](#)
- [TO_TIMESTAMP_TZ](#)

Template patterns for date/time formatting

In an output template string (for `TO_CHAR`), certain patterns are recognized and replaced with appropriately formatted data from the value to format. Any text that is not a template pattern is copied verbatim. Similarly, in an input template string (for anything other than `TO_CHAR`), template patterns identify the parts of the input data string to look at and the values to find there.

Note

Vertica uses the ISO 8601:2004 style for date/time fields in Vertica log files. For example:

```
2020-03-25 05:04:22.372 Init Session:0x7f8fcefec700-a000000013dcd4 [Txn] <INFO> Begin Txn: a000000013dcd4 'read role info'
```

Pattern	Description
---------	-------------

HH	Hour of day (00-23)
HH12	Hour of day (01-12)
HH24	Hour of day (00-23)
MI	Minute (00-59)
SS	Second (00-59)
MS	Millisecond (000-999)
US	Microsecond (000000-999999)
SSSS	Seconds past midnight (0-86399)
AM A.M. PM P.M.	Meridian indicator (uppercase)
am a.m. pm p.m.	Meridian indicator (lowercase)
Y YYYY	Year (4 and more digits) with comma
YYYY	Year (4 and more digits)
YYY	Last 3 digits of year
YY	Last 2 digits of year
Y	Last digit of year
IYYYY	ISO year (4 and more digits)
IYY	Last 3 digits of ISO year
IY	Last 2 digits of ISO year
I	Last digits of ISO year
BC B.C. AD A.D.	Era indicator (uppercase)
bc b.c. ad a.d.	Era indicator (lowercase)
MONTH	Full uppercase month name (blank-padded to 9 chars)
Month	Full mixed-case month name (blank-padded to 9 chars)
month	Full lowercase month name (blank-padded to 9 chars)
MON	Abbreviated uppercase month name (3 chars)
Mon	Abbreviated mixed-case month name (3 chars)
mon	Abbreviated lowercase month name (3 chars)
MM	Month number (01-12)
DAY	Full uppercase day name (blank-padded to 9 chars)

Day	Full mixed-case day name (blank-padded to 9 chars)
day	full lowercase day name (blank-padded to 9 chars)
DY	Abbreviated uppercase day name (3 chars)
Dy	Abbreviated mixed-case day name (3 chars)
dy	Abbreviated lowercase day name (3 chars)
DDD	Day of year (001-366)
DD	Day of month (01-31) for TIMESTAMP <div style="background-color: #e1f5fe; padding: 5px;"> <p>Note For INTERVAL, DD is day of year (001-366) because day of month is undefined.</p> </div>
D	Day of week (1-7; Sunday is 1)
W	Week of month (1-5) (The first week starts on the first day of the month.)
WW	Week number of year (1-53) (The first week starts on the first day of the year.)
IW	ISO week number of year (The first Thursday of the new year is in week 1.)
CC	Century (2 digits)
J	Julian Day (days since January 1, 4712 BC)
Q	Quarter
RM	Month in Roman numerals (I-XII; I=January) (uppercase)
rm	Month in Roman numerals (i-xii; i=January) (lowercase)
TZ	Time-zone name (uppercase)
tz	Time-zone name (lowercase)

Template pattern modifiers

Certain modifiers can be applied to any date/time template pattern to alter its behavior. For example, **FMMonth** is the **Month** pattern with the **FM** modifier.

Modifier	Description
AM	Time is before 12:00
AT	Ignored
JULIAN , JD , J	Next field is Julian Day

FM prefix	Fill mode (suppress padding blanks and zeros) For example: FMMonth Note: The FM modifier suppresses leading zeros and trailing blanks that would otherwise be added to make the output of a pattern fixed width.
FX prefix	Fixed format global option For example : FX Month DD Day
ON	Ignored
PM	Time is on or after 12:00
T	Next field is time
TH suffix	Uppercase ordinal number suffix For example: DDTH
th suffix	Lowercase ordinal number suffix For example: DDth
TM prefix	Translation mode (print localized day and month names based on lc_messages). For example: TMMonth

Examples

Use TO_TIMESTAMP to convert an expression using the pattern '**YYY MON**' :

```
=> SELECT TO_TIMESTAMP('2017 JUN', 'YYYY MON');
       TO_TIMESTAMP
-----
2017-06-01 00:00:00
(1 row)
```

Use TO_DATE to convert an expression using the pattern '**YYY-MMDD**' :

```
=> SELECT TO_DATE('2017-1231', 'YYYY-MMDD');
       TO_DATE
-----
2017-12-31
(1 row)
```

Template patterns for numeric formatting

Pattern	Description
9	Value with the specified number of digits
0	Value with leading zeros
.	Decimal point
,	Group (thousand) separator
PR	Negative value in angle brackets

S	Sign anchored to number (uses locale)
L	Currency symbol (uses locale)
D	Decimal point (uses locale)
G	Group separator (uses locale)
MI	Minus sign in specified position (if number < 0)
PL	Plus sign in specified position (if number > 0)
SG	Plus/minus sign in specified position
RN	Roman numeral (input between 1 and 3999)
TH/th	Ordinal number suffix
V	Shift specified number of digits
EEEE	Scientific notation (not implemented yet)

Usage

- A sign formatted using SG, PL, or MI is not anchored to the number. For example:

```
=> SELECT to_char(-12, 'S9999'), to_char(-12, 'MI9999');
```

```
to_char | to_char
```

```
-----+-----
```

```
-12 | - 12
```

```
(1 row)
```

- TO_CHAR(-12, 'S9999') produces '-12'
- TO_CHAR(-12, 'MI9999') produces '- 12'
- 9 results in a value with the same number of digits as there are 9s. If a digit is not available it outputs a space.
- TH does not convert values less than zero and does not convert fractional numbers.
- V effectively multiplies the input values by 10^n , where n is the number of digits following V. TO_CHAR does not support the use of V combined with a decimal point—for example: **99.9V99** .

TO_BITSTRING

Returns a VARCHAR that represents the given VARBINARY value in bitstring format. This function is the inverse of [BITSTRING_TO_BINARY](#).

Behavior type

[Immutable](#)

Syntax

```
TO_BITSTRING ( expression )
```

Arguments

expression

The VARCHAR string to process.

Examples

```
=> SELECT TO_BITSTRING('ab'::BINARY(2));
```

```
to_bitstring
```

```
-----  
0110000101100010
```

```
(1 row)
```

```
=> SELECT TO_BITSTRING(HEX_TO_BINARY('0x10'));
```

```
to_bitstring
```

```
-----  
00010000
```

```
(1 row)
```

```
=> SELECT TO_BITSTRING(HEX_TO_BINARY('0xF0'));
```

```
to_bitstring
```

```
-----  
11110000
```

```
(1 row)
```

See also

[BITCOUNT](#)

[TO_CHAR](#)

Converts date/time and numeric values into text strings.

Behavior type

[Stable](#)

Syntax

```
TO_CHAR ( expression [, pattern ] )
```

Parameters

expression

Specifies the value to convert, one of the following data types:

- [DOUBLE PRECISION](#)
- [INTEGER](#)
- [INTERVAL](#)
- [TIME/TIMETZ](#)
- [TIMESTAMP/TIMESTAMPTZ](#)

The following restrictions apply:

- TO_CHAR does not support binary data types BINARY and VARBINARY
- TO_CHAR does not support the use of V combined with a decimal point—for example, **99.9V99**

pattern

A CHAR or VARCHAR that specifies an output pattern string. See [Template patterns for date/time formatting](#).

Notes

- Vertica pads TO_CHAR output with a leading space, so positive and negative values have the same length. To suppress padding, use the [FM prefix](#).
- TO_CHAR accepts TIME and TIMETZ data types as inputs if you explicitly cast TIME to TIMESTAMP and TIMETZ to TIMESTAMPTZ.

```
=> SELECT TO_CHAR(TIME '14:34:06.4','HH12:MI am'), TO_CHAR(TIMETZ '14:34:06.4+6','HH12:MI am');
```

```
TO_CHAR | TO_CHAR
```

```
-----+-----  
02:34 pm | 04:34 am
```

```
(1 row)
```

- You can extract the timezone hour from TIMETZ:

```
=> SELECT EXTRACT(timezone_hour FROM TIMETZ '10:30+13:30');
```

```
date_part
```

```
-----  
13
```

```
(1 row)
```

- Ordinary text is allowed in TO_CHAR templates and is output literally. You can put a substring in double quotes to force it to be interpreted as literal text even if it contains pattern key words. In the following example, **YYYY** is replaced by the year data, but the Y in **Year** is not:

```
=> SELECT to_char(CURRENT_TIMESTAMP, 'Hello Year " YYYY');
```

```
to_char
```

```
-----  
Hello Year 2021
```

```
(1 row)
```

- TO_CHAR uses different day-of-the-week numbering (see the [D](#) template pattern) than [EXTRACT](#).
- Given an INTERVAL type, TO_CHAR formats **HH** and **HH12** as hours in a single day, while **HH24** can output hours exceeding a single day—for example, **>24** .
- To include a double quote (") character in output, precede it with a double backslash (\). This is necessary because the backslash already has a special meaning in a string constant. For example: `\\"YYYY Month\\"`
- When rounding, the last digit of the rounded representation is selected to be even if the number is exactly half way between the two.

Examples

TO_CHAR expression and pattern argument	Output
CURRENT_TIMESTAMP, 'Day, DD HH12:MI:SS'	Tuesday , 06 05:39:18
CURRENT_TIMESTAMP, 'FMDay, FMDD HH12:MI:SS'	Tuesday, 6 05:39:18
TIMETZ '14:34:06.4+6','HH12:MI am'	04:34 am
-0.1, '99.99'	-.10
-0.1, 'FM9.99'	-.1
0.1, '0.9'	0.1
12, '9990999.9'	0012.0
12, 'FM9990999.9'	0012.
485, '999'	485
-485, '999'	-485
485, '9 9 9'	4 8 5
1485, '9,999'	1,485
1485, '9G999'	1 485
148.5, '999.999'	148.500
148.5, 'FM999.999'	148.5
148.5, 'FM999.990'	148.500
148.5, '999D999'	148,500
3148.5, '9G999D999'	3 148,500
-485, '999S'	485-
-485, '999MI'	485-
485, '999MI'	485

485, 'FM999MI'	485
485, 'PL999'	+485
485, 'SG999'	+485
-485, 'SG999'	-485
-485, '9SG99'	4-85
-485, '999PR'	<485>
485, 'L999'	DM 485
485, 'RN'	<code>`CDLXXXV`</code>
485, 'FMRN'	CDLXXXV
5.2, 'FMRN'	V
482, '999th'	482nd
485, "'Good number:'999'	Good number: 485
485.8, "'Pre:'999' Post:' .999'	Pre: 485 Post: .800
12, '99V999'	12000
12.4, '99V999'	12400
12.45, '99V9'	125
-1234.567	-1234.567
'1999-12-25'::DATE	1999-12-25
'1999-12-25 11:31'::TIMESTAMP	1999-12-25 11:31:00
'1999-12-25 11:31 EST'::TIMESTAMPTZ	1999-12-25 11:31:00-05
'3 days 1000.333 secs'::INTERVAL	3 days 00:16:40.333

See also

[DATE_PART](#)

[TO_DATE](#)

Converts a string value to a DATE type.

Behavior type

[Stable](#)

Syntax

`TO_DATE (expression , pattern)`

Parameters

expression

Specifies the string value to convert, either **CHAR** or **VARCHAR** .

pattern

A **CHAR** or **VARCHAR** that specifies an output pattern string. See:

- [Template patterns for date/time formatting](#)
- [Template patterns for numeric formatting](#)

Input value considerations

TO_DATE requires a **CHAR** or **VARCHAR** expression. For other input types, use **TO_CHAR** to perform an explicit cast to a **CHAR** or **VARCHAR** before using this function.

Notes

- To use a double quote character in the output, precede it with a double backslash. This is necessary because the backslash already has a special meaning in a string constant. For example: `"\\\"YYYY Month\\\""`
- **TO_TIMESTAMP** , **TO_TIMESTAMP_TZ** , and **TO_DATE** skip multiple blank spaces in the input string if the FX option is not used. FX must be specified as the first item in the template. For example:
 - **TO_TIMESTAMP**('2000 JUN', 'YYYY MON') is correct.
 - **TO_TIMESTAMP**('2000 JUN', 'FXYYYY MON') returns an error, because **TO_TIMESTAMP** expects one space only.
- The **YYYY** conversion from string to **TIMESTAMP** or **DATE** has a restriction if you use a year with more than four digits. You must use a non-digit character or template after **YYYY** , otherwise the year is always interpreted as four digits. For example, given the following arguments, **TO_DATE** interprets the five-digit year 20000 as a four-digit year:

```
=> SELECT TO_DATE('200001131','YYYYMMDD');
TO_DATE
-----
2000-01-13
(1 row)
```

Instead, use a non-digit separator after the year. For example:

```
=> SELECT TO_DATE('20000-1131', 'YYYY-MMDD');
TO_DATE
-----
20000-12-01
(1 row)
```

- In conversions from string to **TIMESTAMP** or **DATE** , the CC field is ignored if there is a **YYY**, **YYYY** or **Y,YYY** field. If **CC** is used with **YY** or **Y**, then the year is computed as $(CC-1)*100+YY$.

Examples

```
=> SELECT TO_DATE('13 Feb 2000', 'DD Mon YYYY');
to_date
-----
2000-02-13
(1 row)
```

See also

[Date/time functions](#)

TO_HEX

Returns a **VARCHAR** or **VARBINARY** representing the hexadecimal equivalent of a number. This function is the inverse of [HEX_TO_BINARY](#).

Behavior type

[Immutable](#)

Syntax

```
TO_HEX ( number )
```

Arguments

number

An **INTEGER** or **VARBINARY** value to convert to hexadecimal. If you supply a **VARBINARY** argument, the function's return value is not preceded by **0x** .

Examples

```
=> SELECT TO_HEX(123456789);
TO_HEX
-----
75bcd15
(1 row)
```

For VARBINARY inputs, the returned value is not preceded by 0x . For example:

```
=> SELECT TO_HEX('ab'::binary(2));
TO_HEX
-----
6162
(1 row)
```

TO_NUMBER

Converts a string value to DOUBLE PRECISION.

Behavior type

[Stable](#)

Syntax

```
TO_NUMBER ( expression, [ pattern ] )
```

Parameters

expression

Specifies the string value to convert, either CHAR or VARCHAR.

pattern

A string value, either CHAR or VARCHAR, that specifies an output pattern string using one of the supported [Template patterns for numeric formatting](#). If you omit this parameter, **TO_NUMBER** returns a floating point.

Notes

To use a double quote character in the output, precede it with a double backslash. This is necessary because the backslash already has a special meaning in a string constant. For example: `"\\\"YYYY Month\\\""`

Note

To convert a date string to a numeric value, use the appropriate [date/time function](#), such as [EXTRACT](#).

Examples

```
=> SELECT TO_NUMBER('MCML', 'rn');
TO_NUMBER
-----
1950
(1 row)
```

It the *pattern* parameter is omitted, the function returns a floating point. For example:

```
=> SELECT TO_NUMBER('-123.456e-01');
TO_NUMBER
-----
-12.3456
```

TO_TIMESTAMP

Converts a string value or a UNIX/POSIX epoch value to a **TIMESTAMP** type.

Behavior type

[Stable](#)

Syntax

```
TO_TIMESTAMP ( { expression, pattern } | unix-epoch )
```

Parameters

expression

Specifies the string value to convert, of type CHAR or VARCHAR.

pattern

A CHAR or VARCHAR that specifies an output pattern string. See:

- [Template patterns for date/time formatting](#)
- [Template patterns for numeric formatting](#)

unix-epoch

DOUBLE PRECISION value that specifies some number of seconds elapsed since midnight UTC of January 1, 1970, excluding leap seconds. INTEGER values are implicitly cast to DOUBLE PRECISION.

Notes

- Millisecond (MS) and microsecond (US) values in a conversion from string to **TIMESTAMP** are used as part of the seconds after the decimal point. For example **TO_TIMESTAMP('12:3', 'SS:MS')** is not 3 milliseconds, but 300, because the conversion counts it as 12 + 0.3 seconds. This means for the format **SS:MS**, the input values **12:3**, **12:30**, and **12:300** specify the same number of milliseconds. To get three milliseconds, use **12:003**, which the conversion counts as **12 + 0.003 = 12.003** seconds.

Here is a more complex example: **TO_TIMESTAMP('15:12:02.020.001230', 'HH:MI:SS.MS.US')** is 15 hours, 12 minutes, and 2 seconds + 20 milliseconds + 1230 microseconds = 2.021230 seconds.

- To use a double quote character in the output, precede it with a double backslash. This is necessary because the backslash already has a special meaning in a string constant. For example: **"\\\"YYYY Month\\\""**
- **TO_TIMESTAMP**, **TO_TIMESTAMP_TZ**, and **TO_DATE** skip multiple blank spaces in the input string if the **FX** option is not used. **FX** must be specified as the first item in the template. For example:
 - **TO_TIMESTAMP('2000 JUN', 'YYYY MON')** is correct.
 - **TO_TIMESTAMP('2000 JUN', 'FXYYYY MON')** returns an error, because **TO_TIMESTAMP** expects one space only.
- The **YYYY** conversion from string to **TIMESTAMP** or **DATE** has a restriction if you use a year with more than four digits. You must use a non-digit character or template after **YYYY**, otherwise the year is always interpreted as four digits. For example, given the following arguments, **TO_DATE** interprets the five-digit year 20000 as a four-digit year:

```
=> SELECT TO_DATE('200001131','YYYYMMDD');
TO_DATE
-----
2000-01-13
(1 row)
```

Instead, use a non-digit separator after the year. For example:

```
=> SELECT TO_DATE('20000-1131', 'YYYY-MMDD');
TO_DATE
-----
20000-12-01
(1 row)
```

- In conversions from string to **TIMESTAMP** or **DATE**, the **CC** field is ignored if there is a **YYY**, **YYYY** or **Y,YYY** field. If **CC** is used with **YY** or **Y**, then the year is computed as $(CC-1)*100+YY$.

Examples

```
=> SELECT TO_TIMESTAMP('13 Feb 2009', 'DD Mon YYYY');
TO_TIMESTAMP
-----
1200-02-13 00:00:00
(1 row)
=> SELECT TO_TIMESTAMP(200120400);
TO_TIMESTAMP
-----
1976-05-05 01:00:00
(1 row)
```

See also

[Date/time functions](#)

TO_TIMESTAMP_TZ

Converts a string value or a UNIX/POSIX epoch value to a **TIMESTAMP WITH TIME ZONE** type.

Behavior type

[Immutable](#) if single argument form, [Stable](#) otherwise.

Syntax

TO_TIMESTAMP_TZ ({ *expression, pattern* } | *unix-epoch*)

Parameters

expression

Specifies the string value to convert, of type CHAR or VARCHAR.

pattern

A CHAR or VARCHAR that specifies an output pattern string. See:

- [Template patterns for date/time formatting](#)
- [Template patterns for numeric formatting](#)

unix-epoch

A DOUBLE PRECISION value that specifies some number of seconds elapsed since midnight UTC of January 1, 1970, excluding leap seconds. INTEGER values are implicitly cast to DOUBLE PRECISION.

Notes

- Millisecond (MS) and microsecond (US) values in a conversion from string to **TIMESTAMP** are used as part of the seconds after the decimal point. For example **TO_TIMESTAMP('12:3', 'SS:MS')** is not 3 milliseconds, but 300, because the conversion counts it as 12 + 0.3 seconds. This means for the format **SS:MS**, the input values **12:3**, **12:30**, and **12:300** specify the same number of milliseconds. To get three milliseconds, use **12:003**, which the conversion counts as **12 + 0.003 = 12.003** seconds. Here is a more complex example: **TO_TIMESTAMP('15:12:02.020.001230', 'HH:MI:SS.MS.US')** is 15 hours, 12 minutes, and 2 seconds + 20 milliseconds + 1230 microseconds = 2.021230 seconds.
- To use a double quote character in the output, precede it with a double backslash. This is necessary because the backslash already has a special meaning in a string constant. For example: **"\\\"YYYY Month\\\""**
- **TO_TIMESTAMP**, **TO_TIMESTAMP_TZ**, and **TO_DATE** skip multiple blank spaces in the input string if the **FX** option is not used. **FX** must be specified as the first item in the template. For example:
 - **TO_TIMESTAMP('2000 JUN', 'YYYY MON')** is correct.
 - **TO_TIMESTAMP('2000 JUN', 'FXYYYY MON')** returns an error, because **TO_TIMESTAMP** expects one space only.
- The **YYYY** conversion from string to **TIMESTAMP** or **DATE** has a restriction if you use a year with more than four digits. You must use a non-digit character or template after **YYYY**, otherwise the year is always interpreted as four digits. For example, given the following arguments, **TO_DATE** interprets the five-digit year 20000 as a four-digit year:

```
=> SELECT TO_DATE('200001131','YYYYMMDD');
TO_DATE
-----
2000-01-13
(1 row)
```

Instead, use a non-digit separator after the year. For example:

```
=> SELECT TO_DATE('20000-1131', 'YYYY-MMDD');
TO_DATE
-----
20000-12-01
(1 row)
```

- In conversions from string to **TIMESTAMP** or **DATE**, the **CC** field is ignored if there is a **YYY**, **YYYY** or **Y,YYY** field. If **CC** is used with **YY** or **Y**, then the year is computed as $(CC-1)*100+YY$.

Examples

```
=> SELECT TO_TIMESTAMP_TZ('13 Feb 2009', 'DD Mon YYYY');
TO_TIMESTAMP_TZ
-----
1200-02-13 00:00:00-05
(1 row)

=> SELECT TO_TIMESTAMP_TZ(200120400);
TO_TIMESTAMP_TZ
-----
1976-05-05 01:00:00-04
(1 row)
```

[Date/time functions](#)

Geospatial functions

Geospatial functions manipulate complex two-dimensional spatial objects and store them in a database according to the Open Geospatial Consortium (OGC) standards.

Function naming conventions

The geospatial functions use the following naming conventions:

- Most ST_ *function-name* functions are compliant with the latest OGC standard OGC SFA-SQL version 1.2.1 (reference number is OGC 06-104r4, date: 2010-08-04). Currently, some ST_ *function-name* functions may not support all data types. Each function page contains details about the supported data types.

Note

Some functions, such as ST_GeomFromText, are based on previous versions of the standard.

- The STV_ *function-name* functions are unique to Vertica and not compliant with OGC standards. Each function page explains its functionality in detail.

Verifying spatial objects validity

Many spatial functions do not validate their parameters. If you pass an invalid spatial object to an ST_ or STV_ function, the function might return an error or produce incorrect results.

To avoid this issue, Vertica recommends that you first run ST_IsValid on all spatial objects to validate the parameters. If your object is not valid, run STV_IsValidReason to get information about the location of the invalidity.

ST_Area

Calculates the area of a spatial object.

The units are:

- GEOMETRY objects: spatial reference system identifier (SRID) units
- GEOGRAPHY objects: square meters

Behavior type

[Immutable](#)

Syntax

```
ST_Area(g)
```

Arguments

g

Spatial object for which you want to calculate the area, type GEOMETRY or GEOGRAPHY

Returns

FLOAT

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)
Point	Yes	Yes
Multipoint	Yes	Yes
Linestring	Yes	Yes
Multilinestring	Yes	Yes
Polygon	Yes	Yes
Multipolygon	Yes	Yes
GeometryCollection	Yes	No

Examples

The following examples show how to use ST_Area.

Calculate the area of a polygon:

```
=> SELECT ST_Area(ST_GeomFromText('POLYGON((0 0,1 0,1 1,0 1,0 0))');
ST_Area
-----
      1
(1 row)
```

Calculate the area of a multipolygon:

```
=> SELECT ST_Area(ST_GeomFromText('MultiPolygon(((0 0,1 0,1 1,0 1,0 0)),
((2 2,2 3,4 6,3 3,2 2))))');
ST_Area
-----
      3
(1 row)
```

Suppose the polygon has a hole, as in the following figure.

Calculate the area, excluding the area of the hole:

```
=> SELECT ST_Area(ST_GeomFromText('POLYGON((2 2,5 5,8 2,2 2),
(4 3,5 4,6 3,4 3))))');
ST_Area
-----
      8
(1 row)
```

Calculate the area of a geometry collection:

```
=> SELECT ST_Area(ST_GeomFromText('GEOMETRYCOLLECTION(POLYGON((20.5 20.45,
20.51 20.52,20.69 20.32,20.5 20.45)),POLYGON((10 20,30 40,25 50,10 20))))');
ST_Area
-----
150.0073
(1 row)
```

Calculate the area of a geography object:

```
=> SELECT ST_Area(ST_GeographyFromText('POLYGON((20.5 20.45,20.51 20.52,
20.69 20.32,20.5 20.45))'));
ST_Area
-----
84627437.116037
(1 row)
```

ST_AsBinary

Creates the Well-Known Binary (WKB) representation of a spatial object. Use this function when you need to convert an object to binary form for porting spatial data to or from other applications.

The [Open Geospatial Consortium \(OGC\)](#) defines the format of a WKB representation in the [Simple Feature Access Part 1 - Common Architecture](#) specification.

Behavior type

[Immutable](#)

Syntax

```
ST_AsBinary( g )
```

Arguments

g

Spatial object for which you want the WKB, type GEOMETRY or GEOGRAPHY

Returns

LONG VARBINARY

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes	Yes
Multipoint	Yes	Yes	Yes
Linestring	Yes	Yes	Yes
Multilinestring	Yes	Yes	Yes
Polygon	Yes	Yes	Yes
Multipolygon	Yes	Yes	Yes
GeometryCollection	Yes	No	No

Examples

The following example shows how to use ST_AsBinary.

Retrieve WKB and WKT representations:

```

=> CREATE TABLE locations (id INTEGER, name VARCHAR(100), geom1 GEOMETRY(800), geom2 GEOGRAPHY);
CREATE TABLE
=> COPY locations
  (id, geom1x FILLER LONG VARCHAR(800), geom1 AS ST_GeomFromText(geom1x), geom2x FILLER LONG VARCHAR (800),
  geom2 AS ST_GeographyFromText(geom2x))
  FROM stdin;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 1|POINT(2 3)|
>> 2|LINESTRING(2 4,1 5)|
>> 3||POLYGON((-70.96 43.27,-70.67 42.95,-66.90 44.74,-67.81 46.08,-67.81 47.20,-69.22 47.43,-71.09 45.25,-70.96 43.27))
>> \.
=> SELECT id, ST_AsText(geom1),ST_AsText(geom2) FROM locations ORDER BY id ASC;
id |      ST_AsText      |      ST_AsText
-----+-----
 1 | POINT (2 3)         |
 2 | LINESTRING (2 4, 1 5) |
 3 |                      | POLYGON ((-70.96 43.27, -70.67 42.95, -66.9 44.74, -67.81 46.08, -67.81 47.2, -69.22 47.43, -71.09 45.25, -70.96 43.27))
=> SELECT id, ST_AsBinary(geom1),ST_AsBinary(geom2) FROM locations ORDER BY id ASC;
.
.
.
(3 rows)

```

Calculate the length of a WKB using the Vertica SQL function [LENGTH](#):

```

=> SELECT LENGTH(ST_AsBinary(St_GeomFromText('POLYGON ((-1 2, 0 3, 1 2,
                                0 1, -1 2)))));
LENGTH
-----
 93
(1 row)

```

See also

[ST_AsText](#)

ST_AsText

Creates the Well-Known Text (WKT) representation of a spatial object. Use this function when you need to specify a spatial object in ASCII form.

The [Open Geospatial Consortium \(OGC\)](#) defines the format of a WKT string in the [Simple Feature Access Part 1 - Common Architecture](#) specification.

Behavior type

[Immutable](#)

Syntax

```
ST_AsText(g)
```

Arguments

g

Spatial object for which you want the WKT string, type GEOMETRY or GEOGRAPHY

Returns

LONG VARCHAR

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes	Yes
Multipoint	Yes	Yes	Yes
Linestring	Yes	Yes	Yes

Multilinestring	Yes	Yes	Yes
Polygon	Yes	Yes	Yes
Multipolygon	Yes	Yes	Yes
GeometryCollection	Yes	No	No

Examples

The following example shows how to use ST_AsText.

Retrieve WKB and WKT representations:

```
=> CREATE TABLE locations (id INTEGER, name VARCHAR(100), geom1 GEOMETRY(800),
  geom2 GEOGRAPHY);
CREATE TABLE
=> COPY locations
  (id, geom1x FILLER LONG VARCHAR(800), geom1 AS ST_GeomFromText(geom1x), geom2x FILLER LONG VARCHAR (800),
  geom2 AS ST_GeographyFromText(geom2x))
  FROM stdin;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 1|POINT(2 3)|
>> 2|LINESTRING(2 4,1 5)|
>> 3||POLYGON((-70.96 43.27,-70.67 42.95,-66.90 44.74,-67.81 46.08,-67.81 47.20,-69.22 47.43,-71.09 45.25,-70.96 43.27))
>> \.
=> SELECT id, ST_AsText(geom1),ST_AsText(geom2) FROM locations ORDER BY id ASC;
id |  ST_AsText  |          ST_AsText
-----+-----+-----
 1 | POINT (2 3) |
 2 | LINESTRING (2 4, 1 5) |
 3 |          | POLYGON ((-70.96 43.27, -70.67 42.95, -66.9 44.74, -67.81 46.08, -67.81 47.2, -69.22 47.43, -71.09 45.25, -70.96 43.27))
(3 rows)
```

Calculate the length of a WKT using the Vertica SQL function [LENGTH](#):

```
=> SELECT LENGTH(ST_AsText(ST_GeomFromText('POLYGON ((-1 2, 0 3, 1 2,
          0 1, -1 2)'))));
LENGTH
-----
 37
(1 row)
```

See also

- [ST_AsBinary](#)

ST_Boundary

Calculates the boundary of the specified GEOMETRY object. An object's boundary is the set of points that define the limit of the object.

For a linestring, the boundary is the start and end points. For a polygon, the boundary is a linestring that begins and ends at the same point.

Behavior type

[Immutable](#)

Syntax

```
ST_Boundary( g )
```

Arguments

g

Spatial object for which you want the boundary, type GEOMETRY

Returns

GEOMETRY

Supported data types

Data Type	GEOMETRY
Point	Yes
Multipoint	Yes
Linestring	Yes
Multilinestring	Yes
Polygon	Yes
Multipolygon	Yes
GeometryCollection	No

Examples

The following examples show how to use ST_Boundary.

Returns a linestring that represents the boundary:

```
=> SELECT ST_AsText(ST_Boundary(ST_GeomFromText('POLYGON((-1 -1,2 2,
  0 1,-1 -1)'))));
ST_AsText
-----
LINESTRING(-1 -1, 2 2, 0 1, -1 -1)
(1 row)
```

Returns a multilinestring that contains the boundaries of both polygons:

```
=> SELECT ST_AsText(ST_Boundary(ST_GeomFromText('POLYGON((2 2,5 5,8 2,2 2),
  (4 3,5 4,6 3,4 3)'))));
ST_AsText
-----
MULTILINESTRING ((2 2, 5 5, 8 2, 2 2), (4 3, 5 4, 6 3, 4 3))
(1 row)
```

The boundary of a linestring is its start and end points:

```
=> SELECT ST_AsText(ST_Boundary(ST_GeomFromText(
  'LINESTRING(1 1,2 2,3 3,4 4)'));
ST_AsText
-----
MULTIPOINT (1 1, 4 4)
(1 row)
```

A closed linestring has no boundary because it has no start and end points:

```
=> SELECT ST_AsText(ST_Boundary(ST_GeomFromText(
  'LINESTRING(1 1,2 2,3 3,4 4,1 1)'));
ST_AsText
-----
MULTIPOINT EMPTY
(1 row)
```

ST_Buffer

Creates a GEOMETRY object greater than or equal to a specified distance from the boundary of a spatial object. The distance is measured in Cartesian coordinate units. ST_Buffer does not accept a distance size greater than +1e15 or less than -1e15.

Behavior type

[Immutable](#)

Syntax

```
ST_Buffer( g, d )
```

Arguments

g

Spatial object for which you want to calculate the buffer, type GEOMETRY

d

Distance from the object in Cartesian coordinate units, type FLOAT

Returns

GEOMETRY

Supported data types

Data Type	GEOMETRY
Point	Yes
Multipoint	Yes
Linestring	Yes
Multilinestring	Yes
Polygon	Yes
Multipolygon	Yes
GeometryCollection	Yes

Usage tips

- If you specify a positive distance, ST_Buffer returns a polygon that represents the points within or equal to the distance outside the object. If you specify a negative distance, ST_Buffer returns a polygon that represents the points within or equal to the distance inside the object.
- For points, multipoints, linestrings, and multilinestrings, if you specify a negative distance, ST_Buffer returns an empty polygon.
- The Vertica Place version of ST_Buffer returns the buffer as a polygon, so the buffer object has corners at its vertices. It does not contain rounded corners.

Examples

The following example shows how to use ST_Buffer.

Returns a GEOMETRY object:

```
=> SELECT ST_AsText(ST_Buffer(ST_GeomFromText('POLYGON((0 1,1 4,4 3,0 1)'),1));
      ST_AsText
-----
POLYGON ((-0.188847498856 -0.159920845081, -1.12155598386 0.649012935089, 0.290814745534 4.76344136152,
0.814758063466 5.02541302048, 4.95372324225 3.68665254814, 5.04124517538 2.45512549204, -0.188847498856 -0.159920845081))
(1 row)
```

ST_Centroid

Calculates the geometric center—the centroid—of a spatial object. If points or linestrings or both are present in a geometry with polygons, only the polygons contribute to the calculation of the centroid. Similarly, if points are present with linestrings, the points do not contribute to the calculation of the centroid.

To calculate the centroid of a GEOGRAPHY object, see the examples for [STV_Geometry](#) and [STV_Geography](#).

Behavior type

[Immutable](#)

Syntax

ST_Centroid(g)

Arguments

g

Spatial object for which you want to calculate the centroid, type GEOMETRY

Returns

GEOMETRY (POINT only)

Supported data types

Data Type	GEOMETRY
Point	Yes
Multipoint	Yes
Linestring	Yes
Multilinestring	Yes
Polygon	Yes
Multipolygon	Yes
GeometryCollection	Yes

Examples

The following examples show how to use ST_Centroid.

Calculate the centroid for a polygon:

```
=> SELECT ST_AsText(ST_Centroid(ST_GeomFromText('POLYGON((-1 -1,2 2,-1 2,-1 -1)'))));
ST_AsText
-----
POINT (-0 1)
(1 row)
```

Calculate the centroid for a multipolygon:

```
=> SELECT ST_AsText(ST_Centroid(ST_GeomFromText('MULTIPOLYGON(((1 0,2 1,2 0,1 0)),((-1 -1,2 2,-1 2,-1 -1)'))));
ST_AsText
-----
POINT (0.166666666667 0.933333333333)
(1 row)
```

This figure shows the centroid for the multipolygon.

ST_Contains

Determines if a spatial object is entirely inside another spatial object without existing only on its boundary. Both arguments must be the same spatial data type. Either specify two GEOMETRY objects or two GEOGRAPHY objects.

If an object such as a point or linestring only exists along a spatial object's boundary, then ST_Contains returns false. The interior of a linestring is all the points on the linestring except the start and end points.

ST_Contains(*g1* , *g2*) is functionally equivalent to ST_Within(*g2* , *g1*) .

GEOGRAPHY Polygons with a vertex or border on the International Date Line (IDL) or the North or South pole are not supported.

Behavior type

[Immutable](#)

Syntax

```
ST_Contains( g1, g2
            [USING PARAMETERS spheroid={true | false}] )
```

Arguments

g1

Spatial object, type GEOMETRY or GEOGRAPHY

g2

Spatial object, type GEOMETRY or GEOGRAPHY

Parameters

spheroid = {true | false}

(Optional) BOOLEAN that specifies whether to use a perfect sphere or WGS84.

Default : False

Returns

BOOLEAN

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes	Yes
Multipoint	Yes	No	No
Linestring	Yes	Yes	No
Multilinestring	Yes	No	No
Polygon	Yes	Yes	Yes
Multipolygon	Yes	Yes	No
GeometryCollection	Yes	No	No

Compatible GEOGRAPHY pairs:

Data Type	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point-Point	Yes	No
Linestring-Point	Yes	No
Polygon-Point	Yes	Yes
Multipolygon-Point	Yes	No

Examples

The following examples show how to use ST_Contains.

The first polygon does not completely contain the second polygon:

```
=> SELECT ST_Contains(ST_GeomFromText('POLYGON((0 2,1 1,0 -1,0 2))'),
  ST_GeomFromText('POLYGON((-1 3,2 1,0 -3,-1 3))');
ST_Contains
```

```
-----
f
(1 row)
```

If a point is on a linestring, but not on an end point:

```
=> SELECT ST_Contains(ST_GeomFromText('LINESTRING(20 20,30 30)'),
  ST_GeomFromText('POINT(25 25)');
ST_Contains
```

```
-----
t
(1 row)
```

If a point is on the boundary of a polygon:

```
=> SELECT ST_Contains(ST_GeographyFromText('POLYGON((20 20,30 30,30 25,20 20))'),
  ST_GeographyFromText('POINT(20 20)');
ST_Contains
```

```
-----
f
(1 row)
```

Two spatially equivalent polygons:

```
=> SELECT ST_Contains (ST_GeomFromText('POLYGON((-1 2, 0 3, 0 1, -1 2))'),
  ST_GeomFromText('POLYGON((0 3, -1 2, 0 1, 0 3))');
ST_Contains
```

```
-----
t
(1 row)
```

See also

- [ST_Overlaps](#)
- [ST_Within](#)

ST_ConvexHull

Calculates the smallest convex GEOMETRY object that contains a GEOMETRY object.

Behavior type

[Immutable](#)

Syntax

```
ST_ConvexHull( g )
```

Arguments

g
Spatial object for which you want the convex hull, type GEOMETRY

Returns

GEOMETRY

Supported data types

Data Type	GEOMETRY
Point	Yes
Multipoint	Yes
Linestring	Yes
Multilinestring	Yes
Polygon	Yes
Multipolygon	Yes
GeometryCollection	Yes

Examples

The following examples show how to use ST_ConvexHull.

For a pair of points in a geometry collection:

```
=> SELECT ST_AsText(ST_ConvexHull(ST_GeomFromText('GEOMETRYCOLLECTION(  
POINT(1 1),POINT(0 0)'))));  
ST_AsText  
-----  
LINESTRING (1 1, 0 0)  
(1 row)
```

For a geometry collection:

```
=> SELECT ST_AsText(ST_ConvexHull(ST_GeomFromText('GEOMETRYCOLLECTION(
  LINestring(2.5 3,-2 1.5), POLYGON((0 1,1 3,1 -2,0 1))))));
      ST_AsText
```

```
POLYGON ((1 -2, -2 1.5, 1 3, 2.5 3, 1 -2))
(1 row)
```

The solid lines represent the original geometry collection and the dashed lines represent the convex hull.

ST_Crosses

Determines if one GEOMETRY object spatially crosses another GEOMETRY object. If two objects touch only at a border, ST_Crosses returns FALSE.

Two objects spatially cross when both of the following are true:

- The two objects have some, but not all, interior points in common.
- The dimension of the result of their intersection is less than the maximum dimension of the two objects.

Behavior type

[Immutable](#)

Syntax

```
ST_Crosses( g1, g2 )
```

Arguments

g1

Spatial object, type GEOMETRY

g2

Spatial object, type GEOMETRY

Returns

BOOLEAN

Supported data types

Data Type	GEOMETRY
Point	Yes
Multipoint	Yes
Linestring	Yes
Multilinestring	Yes
Polygon	Yes
Multipolygon	Yes
GeometryCollection	Yes

Examples

The following examples show how to use ST_Crosses.

```
=> SELECT ST_Crosses(ST_GeomFromText('LINESTRING(-1 3,1 4)'),
  ST_GeomFromText('LINESTRING(-1 4,1 3)'));
ST_Crosses
-----
t
(1 row)
```

```
=> SELECT ST_Crosses(ST_GeomFromText('LINESTRING(-1 1,1 2)'),
  ST_GeomFromText('POLYGON((1 1,0 -1,3 -1,2 1,1 1)'));
ST_Crosses
-----
f
(1 row)
```

```
=> SELECT ST_Crosses(ST_GeomFromText('POINT(-1 4)'),
  ST_GeomFromText('LINESTRING(-1 4,1 3)'));
ST_Crosses
-----
f
(1 row)
```

ST_Difference

Calculates the part of a spatial object that does not intersect with another spatial object.

Behavior type

[Immutable](#)

Syntax

```
ST_Difference( g1, g2 )
```

Arguments

g1
Spatial object, type GEOMETRY

g2

Spatial object, type GEOMETRY

Returns

GEOMETRY

Supported data types

Data Type	GEOMETRY
Point	Yes
Multipoint	Yes
Linestring	Yes
Multilinestring	Yes
Polygon	Yes
Multipolygon	Yes
GeometryCollection	Yes

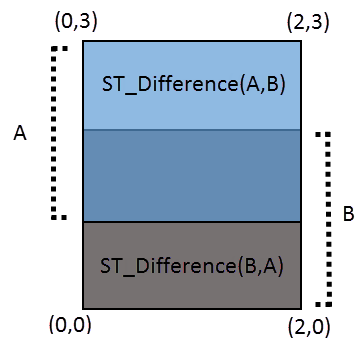

Examples

The following examples show how to use ST_Difference.

Two overlapping linestrings:

```
=> SELECT ST_AsText(ST_Difference(ST_GeomFromText('LINESTRING(0 0,0 2)'),
  ST_GeomFromText('LINESTRING(0 1,0 2)'));
  ST_AsText
-----
LINESTRING (0 0, 0 1)
(1 row)
=> SELECT ST_AsText(ST_Difference(ST_GeomFromText('LINESTRING(0 0,0 3)'),
  ST_GeomFromText('LINESTRING(0 1,0 2)'));
  ST_AsText
-----
MULTILINESTRING ((0 0, 0 1), (0 2, 0 3))
(1 row)
```

Two overlapping polygons:

```
=> SELECT ST_AsText(ST_Difference(ST_GeomFromText('POLYGON((0 1,0 3,2 3,2 1,0 1))'),
  ST_GeomFromText('POLYGON((0 0,0 2,2 2,2 0,0 0)')));
  ST_AsText
-----
POLYGON ((0 2, 0 3, 2 3, 2 2, 0 2))
(1 row)
```

Two non-intersecting polygons:

```
=> SELECT ST_AsText(ST_Difference(ST_GeomFromText('POLYGON((1 1,1 3,3 3,3 1,
  1 1)'),ST_GeomFromText('POLYGON((1 5,1 7,-1 7,-1 5,1 5)'))));
      ST_AsText
```

```
-----
POLYGON ((1 1, 1 3, 3 3, 3 1, 1 1))
(1 row)
```

ST_Disjoint

Determines if two GEOMETRY objects do not intersect or touch.

If ST_Disjoint returns TRUE for a pair of GEOMETRY objects, ST_Intersects returns FALSE for the same two objects.

GEOGRAPHY Polygons with a vertex or border on the International Date Line (IDL) or the North or South pole are not supported.

Behavior type

[Immutable](#)

Syntax

```
ST_Disjoint( g1, g2
            [USING PARAMETERS spheroid={true | false}] )
```

Arguments

g1

Spatial object, type GEOMETRY

g2

Spatial object, type GEOMETRY

Parameters

spheroid = {true | false}

(Optional) BOOLEAN that specifies whether to use a perfect sphere or WGS84.

Default : False

Returns

BOOLEAN

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (WGS84)
Point	Yes	Yes
Multipoint	Yes	No
Linestring	Yes	No
Multilinestring	Yes	No
Polygon	Yes	Yes
Multipolygon	Yes	No
GeometryCollection	Yes	No

Compatible GEOGRAPHY pairs:

Data Type

GEOGRAPHY (WGS84)

Point-Point

No

Linestring-Point

No

Polygon-Point

Yes

Multipolygon-Point

No

Examples

The following examples show how to use ST_Disjoint.

Two non-intersecting or touching polygons:

```
=> SELECT ST_Disjoint(ST_GeomFromText('POLYGON((-1 2,0 3,0 1,-1 2)'),
  ST_GeomFromText('POLYGON((1 0, 1 1, 2 2, 1 0)'));
ST_Disjoint
-----
t
(1 row)
```

Two intersecting linestrings:

```
=> SELECT ST_Disjoint(ST_GeomFromText('LINESTRING(-1 2,0 3)'),
  ST_GeomFromText('LINESTRING(0 2,-1 3)'));
ST_Disjoint
-----
f
(1 row)
```

Two polygons touching at a single point:

```
=> SELECT ST_Disjoint(ST_GeomFromText('POLYGON((-1 2, 0 3, 0 1, -1 2)'),
  ST_GeomFromText('POLYGON((0 2, 1 1, 1 2, 0 2)'));
ST_Disjoint
-----
f
(1 row)
```

See also

- [ST_Intersects](#)

ST_Distance

Calculates the shortest distance between two spatial objects. For GEOMETRY objects, the distance is measured in Cartesian coordinate units. For GEOGRAPHY objects, the distance is measured in meters.

Parameters **g1** and **g2** must be both GEOMETRY objects or both GEOGRAPHY objects.

Behavior type

[Immutable](#)

Syntax

```
ST_Distance(g1, g2)
  [USING PARAMETERS spheroid={ true | false } ] )
```

Arguments

g1

Spatial object, type GEOMETRY or GEOGRAPHY

g2

Spatial object, type GEOMETRY or GEOGRAPHY

Parameters

spheroid = { true | false }

(Optional) BOOLEAN that specifies whether to use a perfect sphere or WGS84.

Default : False

Returns

FLOAT

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes	Yes
Multipoint	Yes	Yes	Yes
Linestring	Yes	Yes	Yes
Multilinestring	Yes	Yes	Yes
Polygon	Yes	Yes	No
Multipolygon	Yes	Yes	No
GeometryCollection	Yes	No	No

Compatible GEOGRAPHY pairs:

Data Type	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point-Point	Yes	Yes
Linestring-Point	Yes	Yes
Multilinestring-Point	Yes	Yes
Polygon-Point	Yes	No
Multipoint-Point	Yes	Yes
Multipoint-Multilinestring	Yes	No
Multipolygon-Point	Yes	No

Recommendations

Vertica recommends pruning invalid data before using ST_Distance. Invalid geography values could return non-guaranteed results.

Examples

The following examples show how to use ST_Distance.

Distance between two polygons:

```
=> SELECT ST_Distance(ST_GeomFromText('POLYGON((-1 -1,2 2,0 1,-1 -1)'),
      ST_GeomFromText('POLYGON((5 2,7 4,5 5,5 2)'));
ST_Distance
-----
      3
(1 row)
```

Distance between a point and a linestring in meters:

```
=> SELECT ST_Distance(ST_GeographyFromText('POINT(31.75 31.25)'),
      ST_GeographyFromText('LINESTRING(32 32,32 35,40.5 35,32 35,32 32)'));
ST_Distance
-----
86690.3950562969
(1 row)
```

ST_Envelope

Calculates the minimum bounding rectangle that contains the specified GEOMETRY object.

Behavior type

[Immutable](#)

Syntax

```
ST_Envelope( g )
```

Arguments

g

Spatial object for which you want to find the minimum bounding rectangle, type GEOMETRY

Returns

GEOMETRY

Supported data types

Data Type	GEOMETRY
Point	Yes
Multipoint	Yes
Linestring	Yes
Multilinestring	Yes
Polygon	Yes
Multipolygon	Yes
GeometryCollection	Yes

Examples

The following example shows how to use ST_Envelope.

Returns the minimum bounding rectangle:

```
=> SELECT ST_AsText(ST_Envelope(ST_GeomFromText('POLYGON((0 0,1 1,2,2,2,2,3 0,1.5 -1.5,0 0)'))));
      ST_AsText
```

```
POLYGON ((0 -1.5, 3 -1.5, 3 2, 0 2, 0 -1.5))
```

```
(1 row)
```

ST_Equals

Determines if two spatial objects are spatially equivalent. The coordinates of the two objects and their WKT/WKB representations must match exactly for ST_Equals to return TRUE.

The order of the points do not matter in determining spatial equivalence:

- LINestring(1 2, 4 3) equals LINestring(4 3, 1 2).
- POLYGON ((0 0, 1 1, 1 2, 2 2, 2 1, 3 0, 1.5 -1.5, 0 0)) equals POLYGON((1 1 , 1 2, 2 2, 2 1, 3 0, 1.5 -1.5, 0 0, 1 1)).

- MULTILINESTRING((1 2, 4 3),(0 0, -1 -4)) equals MULTILINESTRING((0 0, -1 -4),(1 2, 4 3)).

Coordinates are stored as FLOAT types. Thus, rounding errors are expected when importing Well-Known Text (WKT) values because the limitations of floating-point number representation.

g1 and **g2** must both be GEOMETRY objects or both be GEOGRAPHY objects. Also, **g1** and **g2** cannot both be of type GeometryCollection.

Behavior type

[Immutable](#)

Syntax

```
ST_Equals( g1, g2 )
```

Arguments

g1
Spatial object to compare to **g2** , type GEOMETRY or GEOGRAPHY

g2
Spatial object to compare to **g1** , type GEOMETRY or GEOGRAPHY

Returns

BOOLEAN

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes	Yes
Multipoint	Yes	Yes	Yes
Linestring	Yes	Yes	Yes
Multilinestring	Yes	Yes	Yes
Polygon	Yes	Yes	Yes
Multipolygon	Yes	Yes	Yes
GeometryCollection	No	No	No

Examples

The following examples show how to use ST_Equals.

Two linestrings:

```
=> SELECT ST_Equals (ST_GeomFromText('LINESTRING(-1 2, 0 3)'),
  ST_GeomFromText('LINESTRING(0 3, -1 2)'));
ST_Equals
-----
t
(1 row)
```

Two polygons:

```
=> SELECT ST_Equals (ST_GeographyFromText('POLYGON((43.22 42.21,40.3 39.88,
  42.1 50.03,43.22 42.21))'),ST_GeographyFromText('POLYGON((43.22 42.21,
  40.3 39.88,42.1 50.31,43.22 42.21))'));
ST_Equals
-----
f
(1 row)
```

ST_GeographyFromText

Converts a Well-Known Text (WKT) string into its corresponding GEOGRAPHY object. Use this function to convert a WKT string into the format expected by the Vertica Place functions.

A GEOGRAPHY object is a spatial object with coordinates (longitude, latitude) defined on the surface of the earth. Coordinates are expressed in degrees (longitude, latitude) from reference planes dividing the earth.

The maximum size of a GEOGRAPHY object is 10 MB. If you pass a WKT to ST_GeographyFromText, the result is a spatial object whose size is greater than 10 MB, ST_GeographyFromText returns an error.

The [Open Geospatial Consortium \(OGC\)](#) defines the format of a WKT string in Section 7 in the [Simple Feature Access Part 1 - Common Architecture](#) specification.

Behavior type

[Immutable](#)

Syntax

```
ST_GeographyFromText( wkt [ USING PARAMETERS ignore_errors={'y'|'n'} ] )
```

Arguments

wkt

Well-Known Text (WKT) string of a GEOGRAPHY object, type LONG VARCHAR

ignore_errors

(Optional) ST_GeographyFromText returns the following, based on the parameters supplied:

- NULL—If **wkt** is invalid and **ignore_errors** = 'y'.
- Error—If **wkt** is invalid and **ignore_errors** = 'n' or is unspecified.

Returns

GEOGRAPHY

Supported data types

Data Type	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes
Multipoint	Yes	Yes
Linestring	Yes	Yes
Multilinestring	Yes	Yes
Polygon	Yes	Yes
Multipolygon	Yes	Yes
GeometryCollection	No	No

Examples

The following example shows how to use ST_GeographyFromText.

Convert WKT into a GEOGRAPHY object:

```
=> CREATE TABLE wkt_ex (g GEOGRAPHY);
CREATE TABLE
=> INSERT INTO wkt_ex VALUES(ST_GeographyFromText('POLYGON((1 2,3 4,2 3,1 2))'));
OUTPUT
-----
 1
(1 row)
```

ST_GeographyFromWKB

Converts a Well-Known Binary (WKB) value into its corresponding GEOGRAPHY object. Use this function to convert a WKB into the format expected by Vertica Place functions.

A GEOGRAPHY object is a spatial object defined on the surface of the earth. Coordinates are expressed in degrees (longitude, latitude) from reference planes dividing the earth. All calculations are in meters.

The maximum size of a GEOGRAPHY object is 10 MB. If you pass a WKB to ST_GeographyFromWKB that results in a spatial object whose size is greater than 10 MB, ST_GeographyFromWKB returns an error.

The [Open Geospatial Consortium \(OGC\)](#) defines the format of a WKB representation in Section 8 in the [Simple Feature Access Part 1 - Common Architecture](#) specification.

Behavior type

[Immutable](#)

Syntax

```
ST_GeographyFromWKB( wkb [ USING PARAMETERS ignore_errors='{y'|'n'} ] )
```

Arguments

wkb

Well-Known Binary (WKB) value of a GEOGRAPHY object, type LONG VARBINARY

ignore_errors

(Optional) ST_GeographyFromWKB returns the following, based on the parameters supplied:

- NULL—If **wkb** is invalid and **ignore_errors** = 'y' .
- Error—If **wkb** is invalid and **ignore_errors** = 'n' or is unspecified.

Returns

GEOGRAPHY

Supported data types

Data Type	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes
Multipoint	Yes	Yes
Linestring	Yes	Yes
Multilinestring	Yes	Yes
Polygon	Yes	Yes
Multipolygon	Yes	Yes
GeometryCollection	No	No

Examples

The following example shows how to use ST_GeographyFromWKB.

Convert WKB into a GEOGRAPHY object:

```
=> CREATE TABLE wkb_ex (g GEOGRAPHY);
CREATE TABLE
=> INSERT INTO wkb_ex VALUES(ST_GeographyFromWKB(X'0103000000010000000 ... ));
OUTPUT
-----
 1
(1 row)
```

ST_GeoHash

Returns a GeoHash in the shape of the specified geometry.

Behavior type

[Immutable](#)

Syntax

```
ST_GeoHash( SpatialObject [ USING PARAMETERS numchars=n ] )
```

Arguments

Spatial object

A GEOMETRY or GEOGRAPHY spatial object. Inputs must be in polar coordinates ($-180 \leq x \leq 180$ and $-90 \leq y \leq 90$) for all points inside the given geometry.

n

Specifies the length, in characters, of the returned GeoHash.

Returns

GEOHASH

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes	Yes
Multipoint	Yes	Yes	Yes
Linestring	Yes	Yes	Yes
Multilinestring	Yes	Yes	Yes
Polygon	Yes	Yes	Yes
Multipolygon	Yes	Yes	Yes
GeometryCollection	Yes	No	No

Examples

The following examples show how to use ST_PointFromGeoHash.

Generate a full precision GeoHash for the specified geometry:

```
=> SELECT ST_GeoHash(ST_GeographyFromText('POINT(3.14 -1.34)'));
ST_GeoHash
-----
kpf0rkn3zmcswks75010
(1 row)
```

Generate a GeoHash based on the first five characters of the specified geometry:

```
=> select ST_GeoHash(ST_GeographyFromText('POINT(3.14 -1.34)')USING PARAMETERS numchars=5);
ST_GeoHash
-----
kpf0r
(1 row)
```

ST_GeometryN

Returns the *n*th geometry within a geometry object.

If *n* is out of range of the index, then NULL is returned.

Behavior type

[Immutable](#)

Syntax

```
ST_GeometryN( g , n )
```

Arguments

g

Spatial object of type GEOMETRY.

n

The geometry's index number, 1-based.

Returns

GEOMETRY

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes	Yes
Multipoint	Yes	Yes	Yes
Linestring	Yes	Yes	Yes
Multilinestring	Yes	Yes	Yes
Polygon	Yes	Yes	Yes
Multipolygon	Yes	Yes	Yes
GeometryCollection	No	No	No

Examples

The following examples show how to use ST_GeometryN.

Return the second geometry in a multipolygon:

```
=> CREATE TABLE multipolygon_geom (gid int, geom GEOMETRY(1000));
CREATE TABLE
=> COPY multipolygon_geom(gid, gx FILLER LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>>9|MULTIPOLYGON(((2 6, 2 9, 6 9, 7 7, 4 6, 2 6)),((0 0, 0 5, 1 0, 0 0)),((0 2, 2 5, 4 5, 0 2)))
>>\.
=> SELECT gid, ST_AsText(ST_GeometryN(geom, 2)) FROM multipolygon_geom;
gid |      ST_AsText
-----+-----
  9 | POLYGON ((0 0, 0 5, 1 0, 0 0))
(1 row)
```

Return all the geometries within a multipolygon:

```

=> CREATE TABLE multipolygon_geom (gid int, geom GEOMETRY(1000));
CREATE TABLE
=> COPY multipolygon_geom(gid, gx FILLER LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>>9|MULTIPOLYGON(((2 6, 2 9, 6 9, 7 7, 4 6, 2 6)),((0 0, 0 5, 1 0, 0 0)),((0 2, 2 5, 4 5, 0 2)))
>>\.
=> CREATE TABLE series_numbers (numbs int);
CREATE TABLE
=> COPY series_numbers FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 1
>> 2
>> 3
>> 4
>> 5
>> \.
=> SELECT numbs, ST_AsText(ST_GeometryN(geom, numbs))
FROM multipolygon_geom, series_numbers
WHERE ST_AsText(ST_GeometryN(geom, numbs)) IS NOT NULL
ORDER BY numbs ASC;
numbs |          ST_AsText
-----+-----
 1 | POLYGON ((2 6, 2 9, 6 9, 7 7, 4 6, 2 6))
 2 | POLYGON ((0 0, 0 5, 1 0, 0 0))
 3 | POLYGON ((0 2, 2 5, 4 5, 0 2))
(3 rows)

```

See also

[ST_NumGeometries](#)

[ST_GeometryType](#)

Determines the class of a spatial object.

Behavior type

[Immutable](#)

Syntax

```
ST_GeometryType( g )
```

Arguments

g

Spatial object for which you want the class, type GEOMETRY or GEOGRAPHY

Returns

VARCHAR

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)
Point	Yes	Yes
Multipoint	Yes	Yes
Linestring	Yes	Yes
Multilinestring	Yes	Yes
Polygon	Yes	Yes

Multipolygon	Yes	Yes
GeometryCollection	Yes	No

Examples

The following example shows how to use ST_GeometryType.

Returns spatial class:

```
=> SELECT ST_GeometryType(ST_GeomFromText('GEOMETRYCOLLECTION(LINESTRING(1 1,
  2 2), POLYGON((1 3,4 5,2 2,1 3)))));
   ST_GeometryType
-----
ST_GeometryCollection
(1 row)
```

ST_GeomFromGeoHash

Returns a polygon in the shape of the specified GeoHash.

Behavior type

[Immutable](#)

Syntax

```
ST_GeomFromGeoHash(GeoHash)
```

Arguments

GeoHash

A valid GeoHash string of arbitrary length.

Returns

GEOGRAPHY

Examples

The following examples show how to use ST_GeomFromGeoHash.

Converts a GeoHash string to a Geography object and back to a GeoHash

```
=> SELECT ST_GeoHash(ST_GeomFromGeoHash('vert1c9'));
   ST_GeoHash
-----
vert1c9
(1 row)
```

Returns a polygon of the specified GeoHash and uses [ST_AsText](#) to convert the polygon, rectangle map tile, into Well-Known Text:

```
=> SELECT ST_AsText(ST_GeomFromGeoHash('drt3jj9n4dpcbcdef'));
   ST_AsText
-----
POLYGON((-71.1459699298 42.3945346513, -71.1459699297 42.3945346513, -71.1459699297 42.3945346513, -71.1459699298 42.3945346513, -71.1459699298 42.3945346513))
(1 row)
```

Returns multiple polygons and their areas for the specified GeoHashes. The polygon for the high level GeoHash (1234) has a significant area, while the low level GeoHash (1234567890bcdefghjkmn) has an area of zero.

```
=> SELECT ST_Area(short) short_area, ST_AsText(short) short_WKT, ST_Area(long) long_area, ST_AsText(long) long_WKT from (SELECT
ST_GeomFromGeoHash('1234') short, ST_GeomFromGeoHash('1234567890bcdefhijkmn') long) as foo;
-[ RECORD 1 ]-----
short_area | 24609762.8991076
short_WKT  | POLYGON ((-122.34375 -88.2421875, -121.9921875 -88.2421875, -121.9921875 -88.06640625, -122.34375 -88.06640625, -122.34375 -
88.2421875))
long_area  | 0
long_WKT   | POLYGON ((-122.196077187 -88.2297377551, -122.196077187 -88.2297377551, -122.196077187 -88.2297377551, -122.196077187 -
88.2297377551, -122.196077187 -88.2297377551))
```

ST_GeomFromGeoJSON

Converts the geometry portion of a GeoJSON record in the [standard format](#) into a GEOMETRY object. This function returns an error when you provide a GeoJSON Feature or FeatureCollection object.

Behavior type

[Immutable](#)

Syntax

```
ST_GeomFromGeoJSON( geojson [, srid] [ USING PARAMETERS param=value[,...] ] );
```

Arguments

geojson

String containing a GeoJSON GEOMETRY object, type LONG VARCHAR.

Vertica accepts the following GeoJSON key values:

- type
- coordinates
- geometries

Other key values are ignored.

srid

Spatial reference system identifier (SRID) of the GEOMETRY object, type INTEGER.

The SRID is stored in the GEOMETRY object, but does not influence the results of spatial computations.

This argument is optional when not performing operations.

Parameters

ignore_3d

(Optional) Boolean, whether to silently remove 3D and higher-dimensional data from the returned GEOMETRY object or return an error, based on the following values:

- true: Removes 3D and higher-dimensional data from the returned GEOMETRY object.
- false (default): Returns an error when the GeoJSON contains 3D or higher-dimensional data.

ignore_errors

(Optional) Boolean, whether to ignore errors on invalid GeoJSON objects or return an error, based on the following values:

- true: Ignores errors during GeoJSON parsing and returns NULL.
- false (default): Returns an error if GeoJSON parsing fails.

Note

The **ignore_errors** setting takes precedence over the **ignore_3d** setting. For example, if **ignore_errors** is set to true and **ignore_3d** is set to false, the function returns NULL if a GeoJSON object contains 3D and higher-dimensional data.

Returns

GEOMETRY

Supported data types

- Point
- Multipoint
- Linestring

- Multilinestring
- Polygon
- Multipolygon
- GeometryCollection

Examples

The following example shows how to use ST_GeomFromGeoJSON.

Validating a single record

The following example validates a ST_GeomFromGeoJSON statement with [ST_IsValid](#). The statement includes the SRID 4326 to indicate that the point data type represents latitude and longitude coordinates, and sets `ignore_3d` to true to ignore the last value that represents the altitude:

```
=> SELECT ST_IsValid(ST_GeomFromGeoJSON('{"type":"Point","coordinates":[35.3606, 138.7274, 29032]}', 4326 USING PARAMETERS ignore_3d=true));
ST_IsValid
-----
t
(1 row)
```

Loading data into a table

The following example processes GeoJSON types from STDIN and stores them in a GEOMETRY data type table column:

1. Create a table named polygons that stores GEOMETRY spatial types:

```
=> CREATE TABLE polygons(geom GEOMETRY(1000));
CREATE TABLE
```

2. Use COPY to read supported GEOMETRY data types from STDIN and store them in an object named geom :

```
=> COPY polygons(geojson filler VARCHAR(1000), geom as ST_GeomFromGeoJSON(geojson)) FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> { "type": "Polygon", "coordinates": [ [ [100.0, 0.0], [101.0, 0.0], [101.0, 1.0], [100.0, 1.0], [100.0, 0.0] ] ] }
>> { "type": "Point", "coordinates": [1, 2] }
>> { "type": "Polygon", "coordinates": [ [ [1, 3], [3, 2], [1, 1], [3, 0], [1, 0], [1, 3] ] ] }
>> \.
```

3. Query the polygons table. The following example uses [ST_AsText](#) to return the geom object in its [Well-known text \(WKT\)](#) representation, and uses [ST_IsValid](#) to validate each object:

```
=> SELECT ST_AsText(geom), ST_IsValid(geom) FROM polygons;
      ST_AsText      | ST_IsValid
-----+-----
POINT (1 2)         | t
POLYGON ((1 3, 3 2, 1 1, 3 0, 1 0, 1 3)) | f
POLYGON ((100 0, 101 0, 101 1, 100 1, 100 0)) | t
(3 rows)
```

ST_GeomFromText

Converts a Well-Known Text (WKT) string into its corresponding GEOMETRY object. Use this function to convert a WKT string into the format expected by the Vertica Place functions.

A GEOMETRY object is a spatial object defined by the coordinates of a plane. Coordinates are expressed as points on a Cartesian plane (x, y). SRID values of 0 to $2^{32}-1$ are valid. SRID values outside of this range will generate an error.

The maximum size of a GEOMETRY object is 10 MB. If you pass a WKT to ST_GeomFromText and the result is a spatial object whose size is greater than 10 MB, [ST_GeomFromText](#) returns an error.

The [Open Geospatial Consortium \(OGC\)](#) defines the format of a WKT representation. See section 7 in the [Simple Feature Access Part 1 - Common Architecture](#) specification.

Behavior type

[Immutable](#)

Syntax

```
ST_GeomFromText( wkt [, srid] [ USING PARAMETERS ignore_errors={'y'|'n'} ])
```

Arguments

wkt

Well-Known Text (WKT) string of a GEOMETRY object, type LONG VARCHAR.

srid

(Optional when not performing operations)

Spatial reference system identifier (SRID) of the GEOMETRY object, type INTEGER.

The SRID is stored in the GEOMETRY object, but does not influence the results of spatial computations.

ignore_errors

(Optional) ST_GeomFromText returns the following, based on parameters supplied:

- NULL—If **wkt** is invalid and **ignore_errors** = 'y'.
- Error—If **wkt** is invalid and **ignore_errors** = 'n' or is unspecified.

Returns

GEOMETRY

Supported data types

Data Type	GEOMETRY
Point	Yes
Multipoint	Yes
Linestring	Yes
Multilinestring	Yes
Polygon	Yes
Multipolygon	Yes
GeometryCollection	No

Examples

The following example shows how to use ST_GeomFromText.

Convert WKT into a GEOMETRY object:

```
=> SELECT ST_Area(ST_GeomFromText('POLYGON((1 1,2 3,3 5,0 5,1 -2,0 0,1 1))));
ST_Area
-----
      6
(1 row)
```

ST_GeomFromWKB

Converts the Well-Known Binary (WKB) value to its corresponding GEOMETRY object. Use this function to convert a WKB into the format expected by many of the Vertica Place functions.

A GEOMETRY object is a spatial object with coordinates (*x* , *y*) defined in the Cartesian plane.

The maximum size of a GEOMETRY object is 10 MB. If you pass a WKB to **ST_GeomFromWKB** and the result is a spatial object whose size is greater than 10 MB, **ST_GeomFromWKB** returns an error.

The [Open Geospatial Consortium \(OGC\)](#) defines the format of a WKB representation in section 8 in the [Simple Feature Access Part 1 - Common Architecture](#) specification.

Behavior type

[Immutable](#)

Syntax

```
ST_GeomFromWKB( wkb[, srid] [ USING PARAMETERS ignore_errors='{y'|'n'} ] )
```

Arguments

g1

Spatial object, type GEOMETRY

g2

Spatial object, type GEOMETRY

Returns

GEOMETRY

Supported data types

Data Type	GEOMETRY
Point	Yes
Multipoint	Yes
Linestring	Yes
Multilinestring	Yes
Polygon	Yes
Multipolygon	Yes
GeometryCollection	Yes

Examples

The following examples show how to use ST_Intersection.

Two polygons intersect at a single point:

```
=> SELECT ST_AsText(ST_Intersection(ST_GeomFromText('POLYGON((0 2,1 1,0 -1,
  0 2))'),ST_GeomFromText('POLYGON((-1 2,0 0,-2 0,-1 2)'))));
  ST_AsText
-----
POINT(0 0)
(1 row)
```

Two polygons:

```
=> SELECT ST_AsText(ST_Intersection(ST_GeomFromText('POLYGON((1 2,1 5,4 5,
  4 2,1 2)'), ST_GeomFromText('POLYGON((3 1,3 3,5 3,5 1,3 1)'))));
ST_AsText
-----
POLYGON ((4 3, 4 2, 3 2, 3 3, 4 3))
(1 row)
```

Two non-intersecting linestrings:

```
=> SELECT ST_AsText(ST_Intersection(ST_GeomFromText('LINESTRING(1 1,1 3,3 3)'),
  ST_GeomFromText('LINESTRING(1 5,1 7,-1 7)'));
ST_AsText
-----
GEOMETRYCOLLECTION EMPTY
(1 row)
```

ST_Intersects

Determines if two GEOMETRY or GEOGRAPHY objects intersect or touch at a single point. If ST_Disjoint returns TRUE, ST_Intersects returns FALSE for the same GEOMETRY or GEOGRAPHY objects.

GEOGRAPHY Polygons with a vertex or border on the International Date Line (IDL) or the North or South pole are not supported.

Behavior type

[Immutable](#)

Syntax

```
ST_Intersects( g1, g2
  [USING PARAMETERS bbox={true | false}, spheroid={true | false}])
```

Arguments

g1

Spatial object, type GEOMETRY

g2

Spatial object, type GEOMETRY

Parameters

bbox = {true | false}

Boolean. Intersects the bounding box of ***g1*** and ***g2*** .

Default: False

spheroid = {true | false}

(Optional) BOOLEAN that specifies whether to use a perfect sphere or WGS84.

Default : False

Returns

BOOLEAN

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (WGS84)
-----------	----------	-------------------

Point	Yes	Yes
Multipoint	Yes	No
Linestring	Yes	No
Multilinestring	Yes	No
Polygon	Yes	Yes
Multipolygon	Yes	No
GeometryCollection	Yes	No

Compatible GEOGRAPHY pairs:

Data Type	GEOGRAPHY (WGS84)
Point-Point	No
Linestring-Point	No
Polygon-Point	Yes
Multipolygon-Point	No

Examples

The following examples show how to use ST_Intersects.

Two polygons do not intersect or touch:

```
=> SELECT ST_Intersects (ST_GeomFromText('POLYGON((-1 2,0 3,0 1,-1 2)'),
  ST_GeomFromText('POLYGON((1 0,1 2,2 1 0)'));
ST_Intersects
-----
f
(1 row)
```

Two polygons touch at a single point:

```
=> SELECT ST_Intersects (ST_GeomFromText('POLYGON((-1 2,0 3,0 1,-1 2)'),
  ST_GeomFromText('POLYGON((1 0,1 1,0 1,1 0)'));
ST_Intersects
-----
t
(1 row)
```

Two polygons intersect:

```
=> SELECT ST_Intersects (ST_GeomFromText('POLYGON((-1 2, 0 3, 0 1, -1 2)'),
  ST_GeomFromText('POLYGON((0 2, -1 3, -2 0, 0 2)'));
ST_Intersects
-----
t
(1 row)
```

See also

[ST_Disjoint](#)

[ST_IsEmpty](#)

Determines if a spatial object represents the empty set. An empty object has no dimension.

Behavior type

[Immutable](#)

Syntax

```
ST_IsEmpty( g )
```

Arguments

g
Spatial object, type GEOMETRY or GEOGRAPHY

Returns

BOOLEAN

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes	Yes
Multipoint	Yes	Yes	Yes
Linestring	Yes	Yes	Yes
Multilinestring	Yes	Yes	Yes
Polygon	Yes	Yes	Yes
Multipolygon	Yes	Yes	Yes
GeometryCollection	Yes	No	No

Examples

The following example shows how to use ST_IsEmpty.

An empty polygon:

```
=> SELECT ST_IsEmpty(ST_GeomFromText('GeometryCollection EMPTY'));
ST_IsEmpty
-----
t
(1 row)
```

ST_IsSimple

Determines if a spatial object does not intersect itself or touch its own boundary at any point.

Behavior type

[Immutable](#)

Syntax

```
ST_IsSimple( g )
```

Arguments

g

Spatial object, type GEOMETRY or GEOGRAPHY

Returns

BOOLEAN

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)
Point	Yes	Yes
Multipoint	Yes	No
Linestring	Yes	Yes
Multilinestring	Yes	No
Polygon	Yes	Yes
Multipolygon	Yes	No
GeometryCollection	No	No

Examples

The following examples show how to use ST_IsSimple.

Polygon does not intersect itself:

```
=> SELECT ST_IsSimple(ST_GeomFromText('POLYGON((-1 2,0 3,1 2,1 -2,-1 2))));
```

```
ST_IsSimple
```

```
-----
```

```
t
```

```
(1 row)
```

Linestring intersects itself.:

```
=> SELECT ST_IsSimple(ST_GeographyFromText('LINESTRING(10 10,25 25,26 34.5,
10 30,10 20,20 10)'));
```

```
St_IsSimple
```

```
-----
```

```
f
```

```
(1 row)
```

Linestring touches its interior at one or more locations:

```
=> SELECT ST_IsSimple(ST_GeomFromText('LINESTRING(0 0,0 1,1 0,2 1,2 0,0 0)'));
```

```
ST_IsSimple
```

```
-----
```

```
f
```

```
(1 row)
```

ST_IsValid

Determines if a spatial object is well formed or valid. If the object is valid, ST_IsValid returns TRUE; otherwise, it returns FALSE. Use STV_IsValidReason to identify the location of the invalidity.

Spatial validity applies only to polygons and multipolygons. A polygon or multipolygon is valid if all of the following are true:

- The polygon is closed; its start point is the same as its end point.
- Its boundary is a set of linestrings.
- The boundary does not touch or cross itself.
- Any polygons in the interior do not touch the boundary of the exterior polygon except at a vertex.

The [Open Geospatial Consortium \(OGC\)](#) defines the validity of a polygon in section 6.1.11.1 of the [Simple Feature Access Part 1 - Common Architecture](#) specification.

If you are not sure if a polygon is valid, run ST_IsValid first. If you pass an invalid spatial object to a Vertica Place function, the function fails or returns incorrect results.

Behavior type

Immutable

Syntax

```
ST_IsValid( g )
```

Arguments

g

Geospatial object to test for validity, value of type GEOMETRY or GEOGRAPHY (WGS84).

Returns

BOOLEAN

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	No	No
Multipoint	Yes	No	No
Linestring	Yes	No	No
Multilinestring	Yes	No	No
Polygon	Yes	No	Yes
Multipolygon	Yes	No	No
GeometryCollection	Yes	No	No

Examples

The following examples show how to use ST_IsValid.

Valid polygon:

```
=> SELECT ST_IsValid(ST_GeomFromText('POLYGON((1 1,1 3,3 3,3 1,1 1))));
```

```
ST_IsValid
```

```
-----
```

```
t
```

```
(1 row)
```

Invalid polygon:

```
=> SELECT ST_IsValid(ST_GeomFromText('POLYGON((1 3,3 2,1 1,3 0,1 0,1 3))));
```

```
ST_IsValid
```

```
-----
```

```
f
```

```
(1 row)
```

Invalid polygon:

```
=> SELECT ST_IsValid(ST_GeomFromText('POLYGON((0 0,2 2,0 2,2 0,0 0))));
```

```
ST_IsValid
```

```
-----
```

```
f
```

```
(1 row)
```

Invalid multipolygon.:

```
=> SELECT ST_IsValid(ST_GeomFromText('MULTIPOLYGON(((0 0, 0 1, 1 1, 0 0)),  
((0.5 0.5, 0.7 0.5, 0.7 0.7, 0.5 0.7, 0.5 0.5))));
```

```
ST_IsValid
```

```
-----
```

```
t
```

```
(1 row)
```

Valid polygon with hole:

```
=> SELECT ST_IsValid(ST_GeomFromText('POLYGON((1 1,3 3,6 -1,0.5 -1,1 1),  
(1 1,3 1,2 0,1 1))));
```

```
ST_IsValid
```

```
-----
```

```
t
```

```
(1 row)
```

Invalid polygon with hole:

```
=> SELECT ST_IsValid(ST_GeomFromText('POLYGON((1 1,3 3,6 -1,0.5 -1,1 1),  
(1 1,4.5 1,2 0,1 1))));
```

```
ST_IsValid
```

```
-----
```

```
f
```

```
(1 row)
```

ST_Length

Calculates the length of a spatial object. For GEOMETRY objects, the length is measured in Cartesian coordinate units. For GEOGRAPHY objects, the length is measured in meters.

Calculates the length as follows:

- The length of a point or multipoint object is 0.
- The length of a linestring is the sum of the lengths of each line segment. The length of a line segment is the distance from the start point to the end point.
- The length of a polygon is the sum of the lengths of the exterior boundary and any interior boundaries.
- The length of a multilinestring, multipolygon, or geometrycollection is the sum of the lengths of all the objects it contains.

Note

ST_Length does not calculate the length of WKTs or WKBs. To calculate the lengths of those objects, use the Vertica [LENGTH](#) SQL function with ST_AsBinary or ST_AsText.

Behavior type

[Immutable](#)

Syntax

```
ST_Length( g )
```

Arguments

g

Spatial object for which you want to calculate the length, type GEOMETRY or GEOGRAPHY

Returns

FLOAT

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)
Point	Yes	Yes
Multipoint	Yes	Yes
Linestring	Yes	Yes
Multilinestring	Yes	Yes

Polygon	Yes	Yes
Multipolygon	Yes	Yes
GeometryCollection	Yes	No

Examples

The following examples show how to use ST_Length.

Returns length in Cartesian coordinate units:

```
=> SELECT ST_Length(ST_GeomFromText('LINESTRING(-1 -1,2 2,4 5,6 7)'));
   ST_Length
-----
10.6766190873295
(1 row)
```

Returns length in meters:

```
=> SELECT ST_Length(ST_GeographyFromText('LINESTRING(-56.12 38.26,-57.51 39.78,
-56.37 45.24)'));
   ST_Length
-----
821580.025733461
(1 row)
```

ST_NumGeometries

Returns the number of geometries contained within a spatial object. Single GEOMETRY or GEOGRAPHY objects return 1 and empty objects return NULL.

Behavior type

[Immutable](#)

Syntax

```
ST_NumGeometries( g )
```

Arguments

g

Spatial object of type GEOMETRY or GEOGRAPHY

Returns

INTEGER

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes	Yes
Multipoint	Yes	Yes	Yes
Linestring	Yes	Yes	Yes
Multilinestring	Yes	Yes	Yes
Polygon	Yes	Yes	Yes
Multipolygon	Yes	Yes	Yes
GeometryCollection	No	No	No

Examples

The following example shows how to use ST_NumGeometries.

Return the number of geometries:

```
=> SELECT ST_NumGeometries(ST_GeomFromText('MULTILINESTRING ((1 5, 2 4, 5 3, 6 6), (3 5, 3 7))'));
ST_NumGeometries
-----
      2
(1 row)
```

See also

[ST_GeometryN](#)

[ST_NumPoints](#)

Calculates the number of vertices of a spatial object, empty objects return NULL.

The first and last vertex of polygons and multipolygons are counted separately.

Behavior type

[Immutable](#)

Syntax

```
ST_NumPoints(g)
```

Arguments

g

Spatial object for which you want to count the vertices, type GEOMETRY or GEOGRAPHY

Returns

INTEGER

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes	Yes
Multipoint	Yes	Yes	Yes
Linestring	Yes	Yes	Yes
Multilinestring	Yes	Yes	Yes
Polygon	Yes	Yes	Yes
Multipolygon	Yes	Yes	Yes
GeometryCollection	No	No	No

Examples

The following examples show how to use ST_NumPoints.

Returns the number of vertices in a linestring:

```
=> SELECT ST_NumPoints(ST_GeomFromText('LINESTRING(1.33 1.56,2.31 3.4,2.78 5.82,
3.76 3.9,4.11 3.27,5.85 4.34,6.9 4.231,7.61 5.77)'));
ST_NumPoints
-----
      8
(1 row)
```

Use ST_Boundary and ST_NumPoints to return the number of vertices of a polygon:

```
=> SELECT ST_NumPoints(ST_Boundary(ST_GeomFromText('POLYGON((1 2,1 4,
  2 5,3 6,4 6,5 5,4 4,3 3,1 2)))));
ST_NumPoints
-----
          9
(1 row)
```

ST_Overlaps

Determines if a GEOMETRY object shares space with another GEOMETRY object, but is not completely contained within that object. They must overlap at their interiors. If two objects touch at a single point or intersect only along a boundary, they do not overlap. Both parameters must have the same dimension; otherwise, ST_Overlaps returns FALSE.

Behavior type

[Immutable](#)

Syntax

```
ST_Overlaps ( g1, g2 )
```

Arguments

g1

Spatial object, type GEOMETRY

g2

Spatial object, type GEOMETRY

Returns

BOOLEAN

Supported data types

Data Type

GEOMETRY

Point

Yes

Multipoint

Yes

Linestring

Yes

Multilinestring

Yes

Polygon

Yes

Multipolygon

Yes

GeometryCollection

Yes

Examples

The following examples show how to use ST_Overlaps.

Polygon_1 overlaps but does not completely contain Polygon_2:

```
=> SELECT ST_Overlaps(ST_GeomFromText('POLYGON((0 0, 0 1, 1 1, 0 0))'),
  ST_GeomFromText('POLYGON((0.5 0.5, 0.7 0.5, 0.7 0.7, 0.5 0.7, 0.5 0.5))'));
ST_Overlaps
-----
t
(1 row)
```

Two objects with different dimensions:

```
=> SELECT ST_Overlaps(ST_GeomFromText('LINESTRING(2 2,4 4)'),
  ST_GeomFromText('POINT(3 3)'));
ST_Overlaps
-----
f
(1 row)
```

ST_PointFromGeoHash

Returns the center point of the specified GeoHash.

Behavior type

[Immutable](#)

Syntax

```
ST_PointFromGeoHash(GeoHash)
```

Arguments

GeoHash

A valid GeoHash string of arbitrary length.

Returns

GEOGRAPHY POINT

Examples

The following examples show how to use ST_PointFromGeoHash.

Returns the geography point of a high-level GeoHash and uses [ST_AsText](#) to convert that point into Well-Known Text:

```
=> SELECT ST_AsText(ST_PointFromGeoHash('dr'));
ST_AsText
-----
POINT (-73.125 42.1875)
(1 row)
```

Returns the geography point of a detailed GeoHash and uses ST_AsText to convert that point into Well-Known Text:

```
=> SELECT ST_AsText(ST_PointFromGeoHash('1234567890bcdefhjkmn'));
ST_AsText
-----
POINT (-122.196077187 -88.2297377551)
(1 row)
```

ST_PointN

Finds the n^{th} point of a spatial object. If you pass a negative number, zero, or a number larger than the total number of points on the linestring, ST_PointN returns NULL.

The vertex order is based on the Well-Known Text (WKT) representation of the spatial object.

Behavior type

[Immutable](#)

Syntax

```
ST_PointN( g, n )
```

Arguments

g
Spatial object to search, type GEOMETRY or GEOGRAPHY

n
Point in the spatial object to be returned. The index is one-based, type INTEGER

Returns

GEOMETRY or GEOGRAPHY

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes	Yes
Multipoint	Yes	Yes	Yes
Linestring	Yes	Yes	Yes
Multilinestring	Yes	Yes	Yes
Polygon	Yes	Yes	Yes
Multipolygon	Yes	Yes	Yes
GeometryCollection	No	No	No

Examples

The following examples show how to use ST_PointN.

Returns the fifth point:

```
=> SELECT ST_AsText(ST_PointN(ST_GeomFromText('
    POLYGON(( 2 6, 2 9, 6 9, 7 7, 4 6, 2 6))', 5));
    ST_AsText
-----
POINT (4 6)
(1 row)
```

Returns the second point:

```
=> SELECT ST_AsText(ST_PointN(ST_GeographyFromText('
    LINESTRING(23.41 24.93,34.2 32.98,40.7 41.19)', 2));
    ST_AsText
-----
POINT (34.2 32.98)
(1 row)
```

ST_Relate

Determines if a given GEOMETRY object is spatially related to another GEOMETRY object, based on the specified DE-9IM pattern matrix string.

The DE-9IM standard identifies how two objects are spatially related to each other.

Behavior type

[Immutable](#)

Syntax

```
ST_Relate( g1, g2, matrix )
```

Arguments

g1

Spatial object, type GEOMETRY

g2

Spatial object, type GEOMETRY

matrix

DE-9IM pattern matrix string, type CHAR(9). This string represents a 3 x 3 matrix of restrictions on the dimensions of the respective intersections of the interior, boundary, and exterior of the two geometries. Must contain exactly 9 of the following characters:

- T
- F
- 0
- 1
- 2
- *

Returns

BOOLEAN

Supported data types

Data Type	GEOMETRY
Point	Yes
Multipoint	Yes
Linestring	Yes
Multilinestring	Yes
Polygon	Yes
Multipolygon	Yes
GeometryCollection	Yes

Examples

The following examples show how to use ST_Relate.

The DE-9IM pattern for "equals" is 'T*F**FFF2' :

```
=> SELECT ST_Relate(ST_GeomFromText('LINESTRING(0 1,2 2)'),
  ST_GeomFromText('LINESTRING(2 2,0 1)'), 'T*F**FFF2');
ST_Relate
-----
t
(1 row)
```

The DE-9IM pattern for "overlaps" is 'T*T***T**' :

```
=> SELECT ST_Relate(ST_GeomFromText('POLYGON((-1 -1,0 1,2 2,-1 -1))'),
  ST_GeomFromText('POLYGON((0 1,-1 -1,1 1,0 1))'), 'T*T***T**');
ST_Relate
-----
t
(1 row)
```

ST_SRID

Identifies the spatial reference system identifier (SRID) stored with a spatial object.

The SRID of a GEOMETRY object can only be determined when passing an SRID to either ST_GeomFromText or ST_GeomFromWKB. ST_SRID returns this stored value. SRID values of 0 to $2^{32}-1$ are valid.

Behavior type

[Immutable](#)

Syntax

```
ST_SRID( g )
```

Arguments

g

Spatial object for which you want the SRID, type GEOMETRY or GEOGRAPHY

Returns

INTEGER

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes	Yes
Multipoint	Yes	Yes	Yes
Linestring	Yes	Yes	Yes
Multilinestring	Yes	Yes	Yes
Polygon	Yes	Yes	Yes
Multipolygon	Yes	Yes	Yes
GeometryCollection	Yes	No	No

Examples

The following examples show how to use ST_SRID.

The default SRID of a GEOMETRY object is 0:

```
=> SELECT ST_SRID(ST_GeomFromText(
  'POLYGON((-1 -1,2 2,0 1,-1 -1))');
ST_SRID
-----
0
(1 row)
```

The default SRID of a GEOGRAPHY object is 4326:

```
=> SELECT ST_SRID(ST_GeographyFromText(
  'POLYGON((22 35,24 35,26 32,22 35))');
ST_SRID
-----
4326
(1 row)
```

ST_SymDifference

Calculates all the points in two GEOMETRY objects except for the points they have in common, but including the boundaries of both objects.

This result is called the symmetric difference and is represented mathematically as: $\text{Closure} (g1 - g2) \dot{\cup} \text{Closure} (g2 - g1)$

Behavior type

[Immutable](#)

Syntax

```
ST_SymDifference( g1, g2 )
```

Arguments

g1

Spatial object, type GEOMETRY

g2

Spatial object, type GEOMETRY

Returns

GEOMETRY

Supported data types

Data Type	GEOMETRY
Point	Yes
Multipoint	Yes
Linestring	Yes
Multilinestring	Yes
Polygon	Yes
Multipolygon	Yes
GeometryCollection	Yes

Examples

The following examples show how to use ST_SymDifference.

Returns the two linestrings:

```
=> SELECT ST_AsText(ST_SymDifference(ST_GeomFromText('LINESTRING(30 40,
  30 55)'),ST_GeomFromText('LINESTRING(30 32.5,30 47.5)'));
  ST_AsText
-----
MULTILINESTRING ((30 47.5, 30 55),(30 32.5,30 40))
(1 row)
```

Returns four squares:

```
=> SELECT ST_AsText(ST_SymDifference(ST_GeomFromText('POLYGON((2 1,2 4,3 4,
  3 1,2 1)'),ST_GeomFromText('POLYGON((1 2,1 3,4 3,4 2,1 2)'))));
      ST_AsText
```

```
-----
MULTIPOLYGON (((2 1, 2 2, 3 2, 3 1, 2 1)), ((1 2, 1 3, 2 3, 2 2, 1 2)),
((2 3, 2 4, 3 4, 3 3, 2 3)), ((3 2, 3 3, 4 3, 4 2, 3 2))
(1 row)
```

ST_Touches

Determines if two GEOMETRY objects touch at a single point or along a boundary, but do not have interiors that intersect.

GEOGRAPHY Polygons with a vertex or border on the International Date Line (IDL) or the North or South pole are not supported.

Behavior type

[Immutable](#)

Syntax

```
ST_Touches( g1, g2
            [USING PARAMETERS spheroid={true | false}] )
```

Arguments

g1
Spatial object, value of type GEOMETRY

g2
Spatial object, value of type GEOMETRY

Parameters

spheroid = {true | false}

(Optional) BOOLEAN that specifies whether to use a perfect sphere or WGS84.

Default : False

Returns

BOOLEAN

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (WGS84)
Point	Yes	Yes
Multipoint	Yes	No
Linestring	Yes	No
Multilinestring	Yes	No
Polygon	Yes	Yes
Multipolygon	Yes	No

GeometryCollection	Yes	No
--------------------	-----	----

Compatible GEOGRAPHY pairs:

Data Type	GEOGRAPHY (WGS84)
Point-Point	No
Linestring-Point	No
Polygon-Point	Yes
Multipolygon-Point	No

Examples

The following examples show how to use ST_Touches.

Two polygons touch at a single point:

```
=> SELECT ST_Touches(ST_GeomFromText('POLYGON((-1 2,0 3,0 1,-1 2)'),
  ST_GeomFromText('POLYGON((1 3,0 3,1 2,1 3))'));
ST_Touches
-----
t
(1 row)
```

Two polygons touch only along part of the boundary:

```
=> SELECT ST_Touches(ST_GeomFromText('POLYGON((-1 2,0 3,0 1,-1 2)'),
  ST_GeomFromText('POLYGON((1 2,0 3,0 1,1 2))'));
ST_Touches
-----
t
(1 row)
```

Two polygons do not touch at any point:

```
=> SELECT ST_Touches(ST_GeomFromText('POLYGON((-1 2,0 3,0 1,-1 2)'),
  ST_GeomFromText('POLYGON((0 2,-1 3,-2 0,0 2))'));
ST_Touches
-----
f
(1 row)
```

ST_Transform

Returns a new GEOMETRY with its coordinates converted to the spatial reference system identifier (SRID) used by the `srid` argument.

This function supports the following transformations:

- EPSG 4326 (WGS84) to EPSG 3857 (Web Mercator)
- EPSG 3857 (Web Mercator) to EPSG 4326 (WGS84)

For EPSG 4326 (WGS84), unless the coordinates fall within the following ranges, conversion results in failure:

- Longitude limits: -572 to +572
- Latitude limits: -89.9999999 to +89.9999999

Behavior type

[Immutable](#)

Syntax

```
ST_Transform( g1, srid )
```

Arguments

g1

Spatial object of type GEOMETRY.

srid

Spatial reference system identifier (SRID) to which you want to convert your spatial object, of type INTEGER.

Returns

GEOMETRY

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	No	No
Multipoint	Yes	No	No
Linestring	Yes	No	No
Multilinestring	Yes	No	No
Polygon	Yes	No	No
Multipolygon	Yes	No	No
GeometryCollection	Yes	No	No

Examples

The following example shows how you can transform data from Web Mercator (3857) to WGS84 (4326):

```
=> SELECT ST_AsText(ST_Transform(STV_GeometryPoint(7910240.56433, 5215074.23966, 3857), 4326));
   ST_AsText
-----
POINT (71.0589 42.3601)
(1 row)
```

The following example shows how you can transform linestring data in a table from WGS84 (4326) to Web Mercator (3857):

```
=> CREATE TABLE transform_line_example (g GEOMETRY);
CREATE TABLE
=> COPY transform_line_example (gx FILLER LONG VARCHAR, g AS ST_GeomFromText(gx, 4326)) FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> LINESTRING(0 0, 1 1, 2 2, 3 4)
>> \.
=> SELECT ST_AsText(ST_Transform(g, 3857)) FROM transform_line_example;
   ST_AsText
-----
LINESTRING (0 -7.08115455161e-10, 111319.490793 111325.142866, 222638.981587 222684.208506, 333958.47238 445640.109656)
(1 row)
```

The following example shows how you can transform point data in a table from WGS84 (4326) to Web Mercator (3857):

```

=> CREATE TABLE transform_example (x FLOAT, y FLOAT, srid INT);
CREATE TABLE
=> COPY transform_example FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 42.3601|71.0589|4326
>> 122.4194|37.7749|4326
>> 94.5786|39.0997|4326
>> \.
=> SELECT ST_AsText(ST_Transform(STV_GeometryPoint(x, y, srid), 3857)) FROM transform_example;
      ST_AsText
-----
POINT (4715504.76195 11422441.5961)
POINT (13627665.2712 4547675.35434)
POINT (10528441.5919 4735962.8206)
(3 rows)

```

ST_Union

Calculates the union of all points in two spatial objects.

This result is represented mathematically by: $g1 \cup g2$

Behavior type

[Immutable](#)

Syntax

```
ST_Union( g1, g2 )
```

Arguments

g1

Spatial object, type GEOMETRY

g2

Spatial object, type GEOMETRY

Returns

GEOMETRY

Supported data types

Data Type	GEOMETRY
Point	Yes
Multipoint	Yes
Linestring	Yes
Multilinestring	Yes
Polygon	Yes
Multipolygon	Yes
GeometryCollection	Yes

Examples

The following example shows how to use ST_Union.

Returns a polygon that represents all the points contained in these two polygons:

```
=> SELECT ST_AsText(ST_Union(ST_GeomFromText('POLYGON((0 2,1 1,0 -1,-1 1,0 2)'),
  ST_GeomFromText('POLYGON((-1 2, 0 0, -2 0, -1 2)'))));
      ST_AsText
-----
POLYGON ((0 2, 1 1, 0 -1, -0.5 0, -2 0, -1 2, -0.666666666667 1.333333333333, 0 2))
(1 row)
```

ST_Within

If spatial object **g1** is completely inside of spatial object **g2**, then ST_Within returns true. Both parameters must be the same spatial data type. Either specify two GEOMETRY objects or two GEOGRAPHY objects.

If an object such as a point or linestring only exists along a polygon's boundary, then ST_Within returns false. The interior of a linestring is all the points along the linestring except the start and end points.

ST_Within(**g`g**) is functionally equivalent to ST_Contains(**g`g**).

GEOGRAPHY Polygons with a vertex or border on the International Date Line (IDL) or the North or South pole are not supported.

Behavior type

[Immutable](#)

Syntax

```
ST_Within( g1, g2
           [USING PARAMETERS spheroid={true | false}] )
```

Arguments

g1
Spatial object, type GEOMETRY or GEOGRAPHY

g2
Spatial object, type GEOMETRY or GEOGRAPHY

Parameters

spheroid = {true | false}

(Optional) BOOLEAN that specifies whether to use a perfect sphere or WGS84.

Default : False

Returns

BOOLEAN

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes	Yes
Multipoint	Yes	No	No
Linestring	Yes	Yes	No
Multilinestring	Yes	No	No

Polygon	Yes	Yes	Yes
Multipolygon	Yes	Yes	No
GeometryCollection	Yes	No	No

Compatible GEOGRAPHY pairs:

Data Type	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point-Point	Yes	No
Point-Linestring	Yes	No
Point-Polygon	Yes	Yes
Point-Multipolygon	Yes	No

Examples

The following examples show how to use ST_Within.

The first polygon is completely contained within the second polygon:

```
=> SELECT ST_Within(ST_GeomFromText('POLYGON((0 2,1 1,0 -1,0 2))'),
  ST_GeomFromText('POLYGON((-1 3,2 1,0 -3,-1 3))');
ST_Within
-----
t
(1 row)
```

The point is on a vertex of the polygon, but not in its interior:

```
=> SELECT ST_Within (ST_GeographyFromText('POINT(30 25)'),
  ST_GeographyFromText('POLYGON((25 25,25 35,32.2 35,30 25,25 25))'));
ST_Within
-----
f
(1 row)
```

Two polygons are spatially equivalent:

```
=> SELECT ST_Within (ST_GeomFromText('POLYGON((-1 2, 0 3, 0 1, -1 2))'),
  ST_GeomFromText('POLYGON((0 3, -1 2, 0 1, 0 3))'));
ST_Within
-----
t
(1 row)
```

See also

- [ST_Contains](#)
- [ST_Overlaps](#)

ST_X

Determines the *x* - coordinate for a GEOMETRY point or the longitude value for a GEOGRAPHY point.

Behavior type

[Immutable](#)

Syntax

```
ST_X(g)
```

Arguments

g

Point of type GEOMETRY or GEOGRAPHY

Returns

FLOAT

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes	Yes
Multipoint	No	No	No
Linestring	No	No	No
Multilinestring	No	No	No
Polygon	No	No	No
Multipolygon	No	No	No
GeometryCollection	No	No	No

Examples

The following examples show how to use ST_X.

Returns the *x*-coordinate:

```
=> SELECT ST_X(ST_GeomFromText('POINT(3.4 1.25)'));
ST_X
-----
3.4
(1 row)
```

Returns the longitude value:

```
=> SELECT ST_X(ST_GeographyFromText('POINT(25.34 45.67)'));
ST_X
-----
25.34
(1 row)
```

ST_XMax

Returns the maximum *x*-coordinate of the minimum bounding rectangle of the GEOMETRY or GEOGRAPHY object.

For GEOGRAPHY types, Vertica Place computes maximum coordinates by calculating the maximum longitude of the great circle arc from (MAX(longitude), ST_YMin(GEOGRAPHY)) to (MAX(longitude), ST_YMax(GEOGRAPHY)). In this case, MAX(longitude) is the maximum longitude value of the geography object.

If either latitude or longitude is out of range, ST_XMax returns the maximum plain value of the geography object.

Behavior type

[Immutable](#)

Syntax

ST_XMax(*g*)

Arguments

gSpatial object for which you want to find the maximum *x*-coordinate, type GEOMETRY or GEOGRAPHY.

Returns

FLOAT

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)
Point	Yes	Yes
Multipoint	Yes	Yes
Linestring	Yes	Yes
Multilinestring	Yes	Yes
Polygon	Yes	Yes
Multipolygon	Yes	Yes
GeometryCollection	Yes	No

Examples

The following examples show how to use ST_XMax.

Returns the maximum *x*-coordinate within a rectangle:

```
=> SELECT ST_XMax(ST_GeomFromText('POLYGON((0 1,0 2,1 2,1 1,0 1))');
  ST_XMax
-----
    1
(1 row)
```

Returns the maximum longitude value within a rectangle:

```
=> SELECT ST_XMax(ST_GeographyFromText(
  'POLYGON((-71.50 42.35, -71.00 42.35, -71.00 42.38, -71.50 42.38, -71.50 42.35))');
  ST_XMax
-----
   -71
(1 row)
```

ST_XMin

Returns the minimum *x*-coordinate of the minimum bounding rectangle of the GEOMETRY or GEOGRAPHY object.

For GEOGRAPHY types, Vertica Place computes minimum coordinates by calculating the minimum longitude of the great circle arc from (MIN(longitude), ST_YMin(GEOGRAPHY)) to (MIN(longitude), ST_YMax(GEOGRAPHY)). In this case, MIN(longitude) represents the minimum longitude value of the geography object

If either latitude or longitude is out of range, ST_XMin returns the minimum plain value of the geography object.

Behavior type

[Immutable](#)

Syntax

```
ST_XMin( g )
```

Arguments

g

Spatial object for which you want to find the minimum *x*-coordinate, type GEOMETRY or GEOGRAPHY.

Returns

FLOAT

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)
Point	Yes	Yes
Multipoint	Yes	Yes
Linestring	Yes	Yes
Multilinestring	Yes	Yes
Polygon	Yes	Yes
Multipolygon	Yes	Yes
GeometryCollection	Yes	No

Examples

The following examples show how to use ST_XMin.

Returns the minimum *x*-coordinate within a rectangle:

```
=> SELECT ST_XMin(ST_GeomFromText('POLYGON((0 1,0 2,1 2,1 1,0 1))');
  ST_XMin
-----
      0
(1 row)
```

Returns the minimum longitude value within a rectangle:

```
=> SELECT ST_XMin(ST_GeographyFromText(
  'POLYGON((-71.50 42.35, -71.00 42.35, -71.00 42.38, -71.50 42.38, -71.50 42.35))');
  ST_XMin
-----
   -71.5
(1 row)
```

ST_Y

Determines the *y*-coordinate for a GEOMETRY point or the latitude value for a GEOGRAPHY point.

Behavior type

[Immutable](#)

Syntax

```
ST_Y(g)
```

Arguments

g
Point of type GEOMETRY or GEOGRAPHY

Returns

FLOAT

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes	Yes
Multipoint	No	No	No
Linestring	No	No	No

Multilinestring	No	No	No
Polygon	No	No	No
Multipolygon	No	No	No
GeometryCollection	No	No	No

Examples

The following examples show how to use ST_Y.

Returns the *y*-coordinate:

```
=> SELECT ST_Y(ST_GeomFromText('POINT(3 5.25)'));
ST_Y
-----
5.25
(1 row)
```

Returns the latitude value:

```
=> SELECT ST_Y(ST_GeographyFromText('POINT(35.44 51.04)'));
ST_Y
-----
51.04
(1 row)
```

ST_YMax

Returns the maximum *y*-coordinate of the minimum bounding rectangle of the GEOMETRY or GEOGRAPHY object.

For GEOGRAPHY types, Vertica Place computes maximum coordinates by calculating the maximum latitude of the great circle arc from (ST_XMin(GEOGRAPHY), MAX(latitude)) to (ST_XMax(GEOGRAPHY), MAX(latitude)). In this case, MAX(latitude) is the maximum latitude value of the geography object.

If either latitude or longitude is out of range, ST_YMax returns the maximum plain value of the geography object.

Behavior type

[Immutable](#)

Syntax

```
ST_YMax( g )
```

Arguments

g

Spatial object for which you want to find the maximum *y*-coordinate, type GEOMETRY or GEOGRAPHY.

Returns

FLOAT

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)
Point	Yes	Yes
Multipoint	Yes	Yes
Linestring	Yes	Yes
Multilinestring	Yes	Yes
Polygon	Yes	Yes

Multipolygon	Yes	Yes
GeometryCollection	Yes	No

Examples

The following examples show how to use ST_YMax.

Returns the maximum *y*-coordinate within a rectangle:

```
=> SELECT ST_YMax(ST_GeomFromText('POLYGON((0 1,0 4,1 4,1 1,0 1))'));
ST_YMax
-----
4
(1 row)
```

Returns the maximum latitude value within a rectangle:

```
=> SELECT ST_YMax(ST_GeographyFromText(
'POLYGON((-71.50 42.35, -71.00 42.35, -71.00 42.38, -71.50 42.38, -71.50 42.35))');
ST_YMax
-----
42.3802715689979
(1 row)
```

ST_YMin

Returns the minimum *y*-coordinate of the minimum bounding rectangle of the GEOMETRY or GEOGRAPHY object.

For GEOGRAPHY types, Vertica Place computes minimum coordinates by calculating the minimum latitude of the great circle arc from (ST_XMin(GEOGRAPHY), MIN(latitude)) to (ST_XMax(GEOGRAPHY), MIN(latitude)). In this case, MIN(latitude) represents the minimum latitude value of the geography object.

If either latitude or longitude is out of range, ST_YMin returns the minimum plain value of the geography object.

Behavior type

[Immutable](#)

Syntax

```
ST_YMin( g )
```

Arguments

g

Spatial object for which you want to find the minimum *y*-coordinate, type GEOMETRY or GEOGRAPHY.

Returns

FLOAT

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)
Point	Yes	Yes
Multipoint	Yes	Yes
Linestring	Yes	Yes
Multilinestring	Yes	Yes
Polygon	Yes	Yes
Multipolygon	Yes	Yes

GeometryCollection	Yes	No
---------------------------	-----	----

Examples

The following examples show how to use ST_YMin.

Returns the minimum *y*-coordinate within a rectangle:

```
=> SELECT ST_YMin(ST_GeomFromText('POLYGON((0 1,0 4,1 4,1 1,0 1))'));
ST_YMin
-----
1
(1 row)
```

Returns the minimum latitude value within a rectangle:

```
=> SELECT ST_YMin(ST_GeographyFromText(
'POLYGON((-71.50 42.35, -71.00 42.35, -71.00 42.38, -71.50 42.38, -71.50 42.35))'));
ST_YMin
-----
42.35
(1 row)
```

STV_AsGeoJSON

Returns the geometry or geography argument as a Geometry Javascript Object Notation (GeoJSON) object.

Behavior type

[Immutable](#)

Syntax

```
STV_AsGeoJSON(g, [USING PARAMETERS maxdecimals=[dec_value]])
```

Arguments

g

Spatial object of type GEOMETRY or GEOGRAPHY

maxdecimals = *dec_value*

(Optional) Integer value. Determines the maximum number of digits to output after the decimal of floating point coordinates.

Valid values ****:**** Between 0 and 15.

Default **** value****:**** 6

Returns

LONG VARCHAR

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes	Yes
Multipoint	Yes	Yes	Yes
Linestring	Yes	Yes	Yes
Multilinestring	Yes	Yes	Yes
Polygon	Yes	Yes	Yes
Multipolygon	Yes	Yes	Yes
GeometryCollection	No	No	No

Examples

The following examples show how you can use STV_AsGeoJSON.

Convert a geometry polygon to GeoJSON:

```
=> SELECT STV_AsGeoJSON(ST_GeomFromText('POLYGON((3 2, 4 3, 5 1, 3 2), (3.5 2, 4 2.5, 4.5 1.5, 3.5 2))'));
          STV_AsGeoJSON
-----
{"type":"Polygon","coordinates":[[[3,2],[4,3],[5,1],[3,2]],[[3.5,2],[4,2.5],[4.5,1.5],[3.5,2]]]}
(1 row)
```

Convert a geography point to GeoJSON:

```
=> SELECT STV_AsGeoJSON(ST_GeographyFromText('POINT(42.36011 71.05899)') USING PARAMETERS maxdecimals=4);
          STV_AsGeoJSON
-----
{"type":"Point","coordinates":[42.3601,71.059]}
(1 row)
```

STV_Create_Index

Creates a spatial index on a set of polygons to speed up spatial intersection with a set of points.

A spatial index is created from an input polygon set, which can be the result of a query. Spatial indexes are created in a global name space. Vertica uses a distributed plan whenever the input table or projection is segmented across nodes of the cluster.

The OVER() clause must be empty.

Important

You cannot access spatial indexes on newly added nodes without rebalancing your cluster. For more information, see [REBALANCE_CLUSTER](#).

Behavior type

[Immutable](#)

Note

Indexes are not connected to any specific table. Subsequent DML commands on the underlying table or tables of the input data source do not modify the index.

Syntax

```
STV_Create_Index( gid, g
                USING PARAMETERS index='index_name'
                        [, overwrite={ true | false } ]
                        [, max_mem_mb=maxmem_value]
                        [, skip_nonindexable_polygons={true | false } ] )
OVER()
  [ AS (polygons, srid, min_x, min_y, max_x, max_y, info) ]
```

Arguments

gid

Name of an integer column that uniquely identifies the polygon. The gid cannot be NULL.

g

Name of a geometry or geography (WGS84) column or expression that contains polygons and multipolygons. Only polygon and multipolygon can be indexed. Other shape types are excluded from the index.

Parameters

index = *'index_name'*

Name of the index, type VARCHAR. Index names cannot exceed 110 characters. The slash, backslash, and tab characters are not allowed in index names.

overwrite = [true | false]

Boolean, whether to overwrite the index, if an index exists. This parameter cannot be NULL.

Default: False

max_mem_mb = maxmem_value

A positive integer that assigns a limit to the amount of memory in megabytes that `STV_Create_Index` can allocate during index construction. On a multi-node database this is the memory limit per node. The default value is 256. Do not assign a value higher than the amount of memory in the GENERAL resource pool. For more information about this pool, see [Monitoring resource pools](#).

Setting a value for `max_mem_mb` that is at or near the maximum memory available on the node can negatively affect your system's performance. For example, it could cause other queries to time out waiting for memory resources during index construction.

skip_nonindexable_polygons = [true | false]

(Optional) BOOLEAN

In rare cases, intricate polygons (for instance, with too high resolution or anomalous spikes) cannot be indexed. These polygons are considered non-indexable. When set to False, non-indexable polygons cause the index creation to fail. When set to True, index creation can succeed by excluding non-indexable polygons from the index.

To review the polygons that were not able to be indexed, use `STV_Describe_Index` with the parameter `list_polygon`.

Default: False

Returns

polygons

Number of polygons indexed.

SRID

Spatial reference system identifier.

min_x, min_y, max_x, max_y

Coordinates of the minimum bounding rectangle (MBR) of the indexed geometries. (`min_x` , `min_y`) are the south-west coordinates, and (`max_x` , `max_y`) are the north-east coordinates.

info

Lists the number of excluded spatial objects as well as their type that were excluded from the index.

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (WGS84)
Point	No	No
Multipoint	No	No
Linestring	No	No
Multilinestring	No	No
Polygon	Yes	Yes
Multipolygon	Yes	No
GeometryCollection	No	No

Privileges

Any user with access to the `STV_*_Index` functions can describe, rename, or drop indexes created by any other user.

Recommendations

- Segment large polygon tables across multiple nodes. Table segmentation causes index creation to run in parallel, leveraging the Massively Parallel Processing (MPP) architecture in Vertica. This significantly reduces execution time on large tables. Vertica recommends that you segment the table from which you are building the index when the total number of polygons is large.
- `STV_Create_Index` can consume large amounts of processing time and memory. Vertica recommends that when indexing new data for the first time, you monitor memory usage to be sure it stays within safe limits. Memory usage depends on number of polygons, number of vertices, and the amount of overlap among polygons.

- STV_Create_Index tries to allocate memory before it starts creating the index. If it cannot allocate enough memory, the function fails. If not enough memory is available, try the following:
 - Create the index at a time of less load on the system.
 - Avoid concurrent index creation.
 - Try segmenting the input table across the nodes of the cluster.
- Ensure that all of the polygons you plan to index are valid polygons. STV_Create_Index and STV_Refresh_Index do not check polygon validity when building an index.

For more information, see [Ensuring polygon validity before creating or refreshing an index](#).

Limitations

- Any indexes created prior to 24.2.x need to re-created.
- Index creation fails if there are WGS84 polygons with vertices on the International Date Line (IDL) or the North and South Poles.
- The backslash or tab characters are not allowed in index names.
- Indexes cannot have names greater than 110 characters.
- The following geometries are excluded from the index:
 - Non-polygons
 - Geometries with NULL identifiers
 - NULL (multi) polygon
 - EMPTY (multi) polygon
 - Invalid (multi) polygon
- The following geographies are excluded from the index:
 - Polygons with holes
 - Polygons crossing the International Date Line
 - Polygons covering the north or south pole
 - Antipodal polygons

Usage tips

- To cancel an STV_Create_Index run, use **Ctrl + C**.
- If there are no valid polygons in the geom column, STV_Create_Index reports an error in vertica.log and stops index creation.
- If index creation uses a large amount of memory, consider segmenting your data to utilize parallel index creation.

Examples

The following examples show how to use STV_Create_Index.

Create an index with a single literal argument:

```
=> SELECT STV_Create_Index(1, ST_GeomFromText('POLYGON((0 0,0 15.2,3.9 15.2,3.9 0,0 0))')
  USING PARAMETERS index='my_polygon') OVER();
polygons | SRID | min_x | min_y | max_x | max_y | info
-----+-----+-----+-----+-----+-----+-----
      1 |    0 |    0 |    0 |    3.9 |   15.2 |
(1 row)
```

Create an index from a table:

```

=> CREATE TABLE pols (gid INT, geom GEOMETRY(1000));
CREATE TABLE
=> COPY pols(gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 1|POLYGON((-31 74,8 70,8 50,-36 53,-31 74))
>> 2|POLYGON((-38 50,4 13,11 45,0 65,-38 50))
>> 3|POLYGON((10 20,15 60,20 45,46 15,10 20))
>> 4|POLYGON((5 20,9 30,20 45,36 35,5 20))
>> 5|POLYGON((12 23,9 30,20 45,36 35,37 67,45 80,50 20,12 23))
>> \.
=> SELECT STV_Create_Index(gid, geom USING PARAMETERS index='my_polygons_1', overwrite=true,
    max_mem_mb=256) OVER() FROM pols;
polygons | SRID | min_x | min_y | max_x | max_y | info
-----+-----+-----+-----+-----+-----+-----
    5 |  0 | -38 |  13 |  50 |  80 |
(1 row)

```

Create an index in parallel from a partitioned table:

```

=> CREATE TABLE pols (p INT, gid INT, geom GEOMETRY(1000)) SEGMENTED BY HASH(p) ALL NODES;
CREATE TABLE
=> COPY pols (p, gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 1|10|POLYGON((-31 74,8 70,8 50,-36 53,-31 74))
>> 1|11|POLYGON((-38 50,4 13,11 45,0 65,-38 50))
>> 3|12|POLYGON((-12 42,-12 42,27 48,14 26,-12 42))
>> \.
=> SELECT STV_Create_Index(gid, geom USING PARAMETERS index='my_polygons', overwrite=true,
    max_mem_mb=256) OVER() FROM pols;
polygons | SRID | min_x | min_y | max_x | max_y | info
-----+-----+-----+-----+-----+-----+-----
    3 |  0 | -38 |  13 |  27 |  74 |
(1 row)

```

STV_Describe_Index

Retrieves information about an index that contains a set of polygons. If you do not pass any parameters, STV_Describe_Index returns all of the defined indexes.

The OVER() clause must be empty.

Behavior type

[Immutable](#)

Syntax

```

STV_Describe_Index ( [ USING PARAMETERS [index='index_name']
    [, list_polygons={true | false } ]] ) OVER ()

```

Arguments

index = 'index_name'

Name of the index, type VARCHAR. Index names cannot exceed 110 characters. The slash, backslash, and tab characters are not allowed in index names.

list_polygon

(Optional) BOOLEAN that specifies whether to list the polygons in the index. The index argument must be used with this argument.

Returns

polygons

Number of polygons indexed.

SRID

Spatial reference system identifier.

min_x , min_y , max_x , max_y

Coordinates of the minimum bounding rectangle (MBR) of the indexed geometries. (min_x , min_y) are the south-west coordinates, and (max_x , max_y) are the north-east coordinates.

name

The name of the spatial index(es).

gid

Name of an integer column that uniquely identifies the polygon. The gid cannot be NULL.

state

The spatial object's state in the index. Possible values are:

- INDEXED - The spatial object was successfully indexed.
- SELF_INTERSECT - (WGS84 Only) The spatial object was not indexed because one of its edges intersects with another of its edges.
- EDGE_CROSS_IDL - (WGS84 Only) The spatial object was not indexed because one of its edges crosses the International Date Line.
- EDGE_HALF_CIRCLE - (WGS84 Only) The spatial object was not indexed because it contains two adjacent vertices that are antipodal.
- NON_INDEXABLE - The spatial object was not able to be indexed.

geography

The Well-Known Binary (WKB) representation of the spatial object.

geometry

The Well-Known Binary (WKB) representation of the spatial object.

Privileges

Any user with access to the STV_*_Index functions can describe, rename, or drop indexes created by any other user.

Limitations

Some functionality will require the index to be rebuilt if the index was created with 24.2.x or earlier.

Examples

The following examples show how to use STV_Describe_Index.

Retrieve information about the index:

```
=> SELECT STV_Describe_Index (USING PARAMETERS index='my_polygons') OVER ();
 type | polygons | SRID | min_x | min_y | max_x | max_y
-----+-----+-----+-----+-----+-----+-----
GEOMETRY | 4 | 0 | -1 | -1 | 12 | 12
(1 row)
```

Return the names of all the defined indexes:

```
=> SELECT STV_Describe_Index() OVER ();
 name
-----
MA_counties_index
my_polygons
NY_counties_index
US_States_Index
(4 rows)
```

Return the polygons included in an index:

```
=> SELECT STV_Describe_Index(USING PARAMETERS index='my_polygons', list_polygons=TRUE) OVER ();
gid | state | geometry
-----+-----+-----
 12 | INDEXED | \260\000\000\000\000\000\000\ ...
 14 | INDEXED | \200\000\000\000\000\000\000\ ...
 10 | NON_INDEXABLE | \274\000\000\000\000\000\000\ ...
 11 | INDEXED | \260\000\000\000\000\000\000\ ...
(4 rows)
```

- [STV_Intersect scalar function](#)
- [STV_Intersect transform function](#)
- [STV_Drop_Index](#)
- [STV_Rename_Index](#)

STV_Drop_Index

Deletes a spatial index. If STV_Drop_Index cannot find the specified spatial index, it returns an error.

The OVER clause must be empty.

Behavior type

[Immutable](#)

Syntax

```
STV_Drop_Index( USING PARAMETERS index = 'index_name' ) OVER ()
```

Arguments

index = '*index_name*'

Name of the index, type VARCHAR. Index names cannot exceed 110 characters. The slash, backslash, and tab characters are not allowed in index names.

Examples

The following example shows how to use STV_Drop_Index.

Drop an index:

```
=> SELECT STV_Drop_Index(USING PARAMETERS index ='my_polygons') OVER ();
drop_index
-----
Index dropped
(1 row)
```

See also

- [STV_Describe_Index](#)
- [STV_Rename_Index](#)
- [STV_Intersect scalar function](#)
- [STV_Intersect transform function](#)

STV_DWithin

Determines if the shortest distance from the boundary of one spatial object to the boundary of another object is within a specified distance.

Parameters *g1* and *g2* must be both GEOMETRY objects or both GEOGRAPHY objects.

Behavior type

[Immutable](#)

Syntax

```
STV_DWithin( g1, g2, d )
```

Arguments

g1

Spatial object of type GEOMETRY or GEOGRAPHY

g2

Spatial object of type GEOMETRY or GEOGRAPHY

d

Value of type FLOAT indicating a distance. For GEOMETRY objects, the distance is measured in Cartesian coordinate units. For GEOGRAPHY objects, the distance is measured in meters.

Returns

BOOLEAN

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)
Point	Yes	Yes
Multipoint	Yes	Yes
Linestring	Yes	Yes
Multilinestring	Yes	Yes
Polygon	Yes	Yes
Multipolygon	Yes	Yes
GeometryCollection	Yes	No

Compatible GEOGRAPHY pairs:

Data Type

GEOGRAPHY (Perfect Sphere)

Point-Point

Yes

Point-Linestring

Yes

Point-Polygon

Yes

Point-Multilinestring

Yes

Point-Multipolygon

Yes

Examples

The following examples show how to use STV_DWithin.

Two geometries are one Cartesian coordinate unit from each other at their closest points:

```
=> SELECT STV_DWithin(ST_GeomFromText('POLYGON((-1 -1,2 2,0 1,-1 -1)'),
  ST_GeomFromText('POLYGON((4 3,2 3,4 5,4 3)'),1);
STV_DWithin
-----
t
(1 row)
```

If you reduce the distance to 0.99 units:

```
=> SELECT STV_DWithin(ST_GeomFromText('POLYGON((-1 -1,2 2,0 1,-1 -1)'),
  ST_GeomFromText('POLYGON((4 3,2 3,4 5,4 3)'),0.99);
STV_DWithin
-----
f
(1 row)
```

The first polygon touches the second polygon:

```
=> SELECT STV_DWithin(ST_GeomFromText('POLYGON((-1 -1,2 2,0 1,-1 -1)'),
  ST_GeomFromText('POLYGON((1 1,2 3,4 5,1 1)'),0.00001);
STV_DWithin
-----
t
(1 row)
```

The first polygon is not within 1000 meters from the second polygon:

```
=> SELECT STV_DWithin(ST_GeomFromText('POLYGON((45.2 40,50.65 51.29,
  55.67 47.6,50 47.6,45.2 40)'),ST_GeomFromText('POLYGON((25 25,25 30,
  30 30,30 25,25 25)'), 1000);
STV_DWithin
-----
t
(1 row)
```

STV_Export2Shapefile

Exports GEOGRAPHY or GEOMETRY data from a database table or a subquery to a shapefile. Output is written to the directory set with [STV_SetExportShapefileDirectory](#).

Behavior type

[Immutable](#)

Syntax

```
STV_Export2Shapefile( columns USING PARAMETERS shapefile = 'filename'
  [, overwrite = boolean ]
  [, shape = 'spatial-class' ] )
OVER()
```

Arguments

columns

The columns to export to the shapefile.

A value of asterisk (*) is the equivalent to listing all columns of the FROM clause.

Parameters

shapefile

Prefix of the component names of the shapefile. The following requirements apply:

- Must end with the file extension **.shp** .
- Limited to 128 octets in length—for example, **city-data.shp** .

To save the shapefile to a subdirectory, concatenate the subdirectory to **shapefile-name** —for example, **visualizations/city-data.shp** . The subdirectory must exist; this function does not create it.

overwrite

Boolean, whether to overwrite the index, if an index exists. This parameter cannot be NULL.

Default: False

shape

One of the following spatial classes:

- Point
- Polygon
- Linestring

- Multipoint
- Multipolygon
- Multilinestring

Polygons and multipolygons always have a clockwise orientation.

Default: Polygon

Returns

Three files in the shapefile export directory with the extensions `.shp` , `.shx` , and `.dbf` .

Limitations

- If a multipolygon, multilinestring, or multipoint contains only one element, then it is written as a polygon, line, or point, respectively.
- Column names longer than 10 characters are truncated.
- Empty POINTS cannot be exported.
- All rows with NULL geometry or geography data are skipped.
- Unsupported or invalid dates are replaced with NULLs.
- Numeric values may lose precision when they are exported. This loss occurs because the target field in the `.dbf` file is a 64-bit FLOAT column, which can only represent about 15 significant digits.
- Shapefiles cannot exceed 4GB in size. If your shapefile is too large, try splitting the data and exporting to multiple shapefiles.

Examples

The following example shows how you can use `STV_Export2Shapefile` to export all columns from the table `geo_data` to a shapefile named `city-data.shp`:

```
=> SELECT STV_Export2Shapefile(*
      USING PARAMETERS shapefile = 'visualizations/city-data.shp',
                      overwrite = true, shape = 'Point')
      OVER()
      FROM geo_data
      WHERE REVENUE > 25000;
Rows Exported |          File Path
-----+-----
6442892 | v_geo-db_node0001: /home/geo/temp/visualizations/city-data.shp
(1 row)
```

STV_Extent

Returns a bounding box containing all of the input data.

Use `STV_Extent` inside of a nested query for best results. The `OVER` clause must be empty.

Important

`STV_Extent` does not return a valid polygon when the input is a single point.

Behavior type

[Immutable](#)

Syntax

```
STV_Extent(g)
```

Arguments

g

Spatial object, type GEOMETRY.

Returns

GEOMETRY

Supported data types

Data Type	GEOMETRY
Point	Yes

Multipoint	Yes
Linestring	Yes
Multilinestring	Yes
Polygon	Yes
Multipolygon	Yes
GeometryCollection	Yes

Examples

The following examples show how you can use STV_Extent.

Return the bounding box of a linestring, and verify that it is a valid polygon:

```
=> SELECT ST_AsText(geom) AS bounding_box, ST_IsValid(geom)
FROM (SELECT STV_Extent(ST_GeomFromText('LineString(0 0, 1 1)')) OVER() AS geom) AS g;
      bounding_box      | ST_IsValid
-----+-----
POLYGON ((0 0, 1 0, 1 1, 0 1, 0 0)) | t
(1 row)
```

Return the bounding box of spatial objects in a table:

```
=> CREATE TABLE misc_geo_shapes (id IDENTITY, geom GEOMETRY);
CREATE TABLE
=> COPY misc_geo_shapes (gx FILLER LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> POINT(-71.03 42.37)
>> LINESTRING(-71.058849 42.367501, -71.062240 42.371276, -71.067938 42.371246)
>> POLYGON((-71.066030 42.380617, -71.055827 42.376734, -71.060811 42.376011, -71.066030 42.380617))
>> \.
=> SELECT ST_AsText(geom_col) AS bounding_box
FROM (SELECT STV_Extent(geom) OVER() AS geom_col FROM misc_geo_shapes) AS g;
      bounding_box
-----
POLYGON ((-71.067938 42.367501, -71.03 42.367501, -71.03 42.380617, -71.067938 42.380617, -71.067938 42.367501))
(1 row)
```

STV_ForceLHR

Alters the order of the vertices of a spatial object to follow the left-hand-rule.

Behavior type

[Immutable](#)

Syntax

```
STV_ForceLHR( g, [USING PARAMETERS skip_nonreorientable_polygons={true | false} ])
```

Arguments

g

Spatial object, type GEOGRAPHY.

skip_nonreorientable_polygons = { true | false }

(Optional) Boolean

When set to False, non-orientable polygons generate an error. For example, if you use STV_ForceLHR or STV_Reverse with [skip_nonorientable_polygons](#) set to False, a geography polygon containing a hole generates an error. When set to True, the result returned is the polygon, as passed to the API, without alteration.

This argument can help you when you are creating an index from a table containing polygons that cannot be re-oriented.

Vertica Place considers these polygons non-orientable:

- Polygons with a hole
- Multipolygons
- Multipolygons with a hole

Default value : False

Returns

GEOGRAPHY

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	No	No	No
Multipoint	No	No	No
Linestring	No	No	No
Multilinestring	No	No	No
Polygon	No	Yes	Yes
Multipolygon	No	Yes	Yes
GeometryCollection	No	No	No

Examples

The following example shows how you can use STV_ForceLHR.

Re-orient a geography polygon to left-hand orientation:

```
=> SELECT ST_AsText(STV_ForceLHR(ST_GeographyFromText('Polygon((1 1, 3 1, 2 2, 1 1))')));
      ST_AsText
-----
POLYGON ((1 1, 3 1, 2 2, 1 1))
(1 row)
```

Reverse the orientation of a geography polygon by forcing left-hand orientation:

```
=> SELECT ST_AsText(STV_ForceLHR(ST_GeographyFromText('Polygon((1 1, 2 2, 3 1, 1 1))')));
      ST_AsText
-----
POLYGON ((1 1, 3 1, 2 2, 1 1))
(1 row)
```

See also

[STV_Reverse](#)

STV_Geography

Casts a GEOMETRY object into a GEOGRAPHY object. The SRID value does not affect the results of Vertica Place queries.

When STV_Geography converts a GEOMETRY object to a GEOGRAPHY object, it sets its SRID to 4326.

Behavior type

[Immutable](#)

Syntax

```
STV_Geography( geom )
```

Arguments

geom

Spatial object that you want to cast into a GEOGRAPHY object, type GEOMETRY

Returns

GEOGRAPHY

Supported data types

Data Type	GEOMETRY
Point	Yes
Multipoint	Yes
Linestring	Yes
Multilinestring	Yes
Polygon	Yes
Multipolygon	Yes
GeometryCollection	No

Examples

The following example shows how to use STV_Geography.

To calculate the centroid of the GEOGRAPHY object, convert it to a GEOMETRY object, then convert it back to a GEOGRAPHY object:

```
=> CREATE TABLE geogs(g GEOGRAPHY);
CREATE TABLE
=> COPY geogs(gx filler LONG VARCHAR, geog AS ST_GeographyFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> MULTIPOINT(-108.619726 45.000284,-107.866813 45.00107,-106.363711 44.994223,-70.847746 41.205814)
>> \.
=> SELECT ST_AsText(STV_Geography(ST_Centroid(STV_Geometry(g)))) FROM geogs;
      ST_AsText
-----
POINT (-98.424499 44.05034775)
(1 row)
```

STV_GeographyPoint

Returns a GEOGRAPHY point based on the input values.

This is the optimal way to convert raw coordinates to GEOGRAPHY points.

Behavior type

[Immutable](#)

Syntax

```
STV_GeographyPoint( x, y )
```

Arguments

x
x-coordinate or longitude, FLOAT.

y
y-coordinate or latitude, FLOAT.

Returns

GEOGRAPHY

Examples

The following examples show how to use STV_GeographyPoint.

Return a GEOGRAPHY point:

```
=> SELECT ST_AsText(STV_GeographyPoint(-114.101588, 47.909677));
       ST_AsText
-----
POINT (-114.101588 47.909677)
(1 row)
```

Return GEOGRAPHY points using two columns:

```
=> CREATE TABLE geog_data (id IDENTITY, x FLOAT, y FLOAT);
CREATE TABLE
=> COPY geog_data FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> -114.101588|47.909677
>> -111.532377|46.430753
>> \.
=> SELECT id, ST_AsText(STV_GeographyPoint(x, y)) FROM geog_data;
id |      ST_AsText
-----+-----
 1 | POINT (-114.101588 47.909677)
 2 | POINT (-111.532377 46.430753)
(2 rows)
```

Create GEOGRAPHY points by manipulating data source columns during load:

```
=> CREATE TABLE geog_data_load (id IDENTITY, geog GEOGRAPHY);
CREATE TABLE
=> COPY geog_data_load (lon FILLER FLOAT,
                       lat FILLER FLOAT,
                       geog AS STV_GeographyPoint(lon, lat))
FROM 'test_coords.csv' DELIMITER ',';
Rows Loaded
-----
      2
(1 row)
=> SELECT id, ST_AsText(geog) FROM geog_data_load;
id |      ST_AsText
-----+-----
 1 | POINT (-75.101654451 43.363830536)
 2 | POINT (-75.106444487 43.367093798)
(2 rows)
```

See also

[STV_GeometryPoint](#)

STV_Geometry

Casts a GEOGRAPHY object into a GEOMETRY object.

The SRID value does not affect the results of Vertica Place queries.

Behavior type

[Immutable](#)

Syntax

```
STV_Geometry( geog )
```

Arguments

geog

Spatial object that you want to cast into a GEOMETRY object, type GEOGRAPHY

Returns

GEOMETRY

Supported data types

Data Type	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes
Multipoint	Yes	Yes
Linestring	Yes	Yes
Multilinestring	Yes	Yes
Polygon	Yes	Yes
Multipolygon	Yes	Yes
GeometryCollection	No	No

Examples

The following example shows how to use STV_Geometry.

Convert the GEOGRAPHY values to GEOMETRY values, then convert the result back to a GEOGRAPHY type:

```
=> CREATE TABLE geogs(g GEOGRAPHY);
CREATE TABLE
=> COPY geogs(gx filler LONG VARCHAR, geog AS ST_GeographyFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> MULTIPOINT(-108.619726 45.000284,-107.866813 45.00107,-106.363711 44.994223,-70.847746 41.205814)
>> \.
=> SELECT ST_AsText(STV_Geography(ST_Centroid(STV_Geometry(g)))) FROM geogs;
      ST_AsText
-----
POINT (-98.424499 44.05034775)
```

STV_GeometryPoint

Returns a GEOMETRY point, based on the input values.

This approach is the most-optimal way to convert raw coordinates to GEOMETRY points.

Behavior type

[Immutable](#)

Syntax

```
STV_GeometryPoint( x, y [, srid] )
```

Arguments

x

x-coordinate or longitude, FLOAT.

y

y-coordinate or latitude, FLOAT.

srid

(Optional) Spatial Reference Identifier (SRID) assigned to the point, INTEGER.

Returns

GEOMETRY

Examples

The following examples show how to use STV_GeometryPoint.

Return a GEOMETRY point with an SRID:

```
=> SELECT ST_AsText(STV_GeometryPoint(71.148562, 42.989374, 4326));
       ST_AsText
-----
POINT (-71.148562 42.989374)
(1 row)
```

Return GEOMETRY points using two columns:

```
=> CREATE TABLE geom_data (id IDENTITY, x FLOAT, y FLOAT, SRID int);
CREATE TABLE
=> COPY geom_data FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 42.36383053600048|-71.10165445099966|4326
>> 42.3670937980005|-71.10644448699964|4326
>> \.
=> SELECT id, ST_AsText(STV_GeometryPoint(x, y, SRID)) FROM geom_data;
id |          ST_AsText
-----+-----
  1 | POINT (-71.101654451 42.363830536)
  2 | POINT (-71.106444487 42.367093798)
(2 rows)
```

Create GEOMETRY points by manipulating data source columns during load:

```
=> CREATE TABLE geom_data_load (id IDENTITY, geom GEOMETRY);
CREATE TABLE
=> COPY geom_data_load (lon FILLER FLOAT,
                       lat FILLER FLOAT,
                       geom AS STV_GeometryPoint(lon, lat))
FROM 'test_coords.csv' DELIMITER ',';
Rows Loaded
-----
      2
(1 row)
=> SELECT id, ST_AsText(geom) FROM geom_data_load;
id |          ST_AsText
-----+-----
  1 | POINT (-75.101654451 43.363830536)
  2 | POINT (-75.106444487 43.367093798)
(2 rows)
```

See also

[STV_GeographyPoint](#)

[STV_GetExportShapefileDirectory](#)

Returns the path of the export directory.

Behavior type

[Immutable](#)

Syntax

```
STV_GetExportShapefileDirectory( )
```

Returns

The path of the shapefile export directory.

Examples

The following example shows how you can use `STV_GetExportShapefileDirectory` to query the path of the shapefile export directory:

```
=> SELECT STV_GetExportShapefileDirectory();
       STV_GetExportShapefileDirectory
```

```
Shapefile export directory: [/home/user/temp]
```

```
(1 row)
```

STV_Intersect scalar function

Spatially intersects a point or points with a set of polygons. The STV_Intersect scalar function returns the identifier associated with an intersecting polygon.

Behavior type

[Immutable](#)

Syntax

```
STV_Intersect( { g | x, y }
              USING PARAMETERS index= 'index_name')
```

Arguments

g

A geometry or geography (WGS84) column that contains points. The g column can contain only point geometries or geographies. If the column contains a different geometry or geography type, STV_Intersect terminates with an error.

x

x-coordinate or longitude, FLOAT.

y

y-coordinate or latitude, FLOAT.

Parameters

index = 'index_name'

Name of the spatial index, of type VARCHAR.

Returns

The identifier of a matching polygon. If the point does not intersect any of the index's polygons, then the STV_Intersect scalar function returns NULL.

Examples

The following examples show how you can use STV_Intersect scalar.

Using two floats, return the gid of a matching polygon or NULL:

```
=> CREATE TABLE pols (gid INT, geom GEOMETRY(1000));
CREATE TABLE
=> COPY pols(gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 1|POLYGON((31 74,8 70,8 50,36 53,31 74))
>> \.
=> SELECT STV_Create_Index(gid, geom USING PARAMETERS index='my_polygons_1', overwrite=true,
                          max_mem_mb=256) OVER() FROM pols;
 type | polygons | SRID | min_x | min_y | max_x | max_y | info
-----+-----+-----+-----+-----+-----+-----+-----
GEOMETRY | 1 | 0 | 8 | 50 | 36 | 74 |
(1 row)

=> SELECT STV_Intersect(12.5683, 55.6761 USING PARAMETERS index = 'my_polygons_1');
 STV_Intersect
-----
1
(1 row)
```

Using a GEOMETRY column, return the gid of a matching polygon or NULL:

```

=> CREATE TABLE polygons (gid INT, geom GEOMETRY(700));
CREATE TABLE
=> COPY polygons (gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 1|POLYGON((-31 74,8 70,8 50,-36 53,-31 74))
>> 2|POLYGON((-38 50,4 13,11 45,0 65,-38 50))
>> 3|POLYGON((-18 42,-10 65,27 48,14 26,-18 42))
>> \.
=> SELECT STV_Create_Index(gid, geom USING PARAMETERS index='my_polygons', overwrite=true,
    max_mem_mb=256) OVER() FROM polygons;
type | polygons | SRID | min_x | min_y | max_x | max_y | info
-----+-----
GEOMETRY | 3 | 0 | -38 | 13 | 27 | 74 |
(1 row)

=> CREATE TABLE points (gid INT, geom GEOMETRY(700));
CREATE TABLE
=> COPY points (gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 100|POINT(-1 52)
>> 101|POINT(-20 0)
>> 102|POINT(-8 25)
>> 103|POINT(0 0)
>> 104|POINT(1 5)
>> 105|POINT(20 45)
>> 106|POINT(-20 5)
>> 107|POINT(-20 1)
>> \.
=> SELECT gid AS pt_gid, STV_Intersect(geom USING PARAMETERS index='my_polygons') AS pol_gid
    FROM points ORDER BY pt_gid;
pt_gid | pol_gid
-----+-----
100 | 1
101 |
102 | 2
103 |
104 |
105 | 3
106 |
107 |
(8 rows)

```

- [STV_Intersect transform function](#)
- [STV_Create_Index](#)

STV_Intersect transform function

Spatially intersects points and polygons. The STV_Intersect transform function returns a tuple with matching point/polygon pairs. For every point, Vertica returns either one or many matching polygons.

You can improve performance when you parallelize the computation of the STV_Intersect transform function over multiple nodes. To parallelize the computation, use an OVER(PARTITION BEST) clause.

Behavior type

[Immutable](#)

Syntax

```
STV_Intersect ( { gid | i }, { g | x , y }
  USING PARAMETERS index='index_name')
OVER() AS (pt_gid, pol_gid)
```

Arguments

gid | i
An integer column or integer that uniquely identifies the spatial object(s) of *g* or *x* and *y*.

g
A geometry or geography (WGS84) column that contains points. The *g* column can contain only point geometries or geographies. If the column contains a different geometry or geography type, STV_Intersect terminates with an error.

x
x-coordinate or longitude, FLOAT.

y
y-coordinate or latitude, FLOAT.

Parameters

index = 'index_name'
Name of the spatial index, of type VARCHAR.

Returns

pt_gid
Unique identifier of the point geometry or geography, of type INTEGER.

pol_gid
Unique identifier of the polygon geometry or geography, of type INTEGER.

Examples

The following examples show how you can use STV_Intersect transform.

Using two floats, return the matching point-polygon pairs.

```
=> CREATE TABLE polys (gid INT, geom GEOMETRY(1000));
CREATE TABLE
=> COPY polys(gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 1|POLYGON((31 74,8 70,8 50,36 53,31 74))
>> \.
=> SELECT STV_Create_Index(gid, geom USING PARAMETERS index='my_polygons_1', overwrite=true,
      max_mem_mb=256) OVER() FROM polys;
 type | polygons | SRID | min_x | min_y | max_x | max_y | info
-----+-----+-----+-----+-----+-----+-----+-----
GEOMETRY | 1 | 0 | 8 | 50 | 36 | 74 |
(1 row)

=> SELECT STV_Intersect(56, 12.5683, 55.6761 USING PARAMETERS index = 'my_polygons_1') OVER();
pt_gid | pol_gid
-----+-----
56 | 1
(1 row)
```

Using a GEOMETRY column, return the matching point-polygon pairs.

```

=> CREATE TABLE polygons (gid int, geom GEOMETRY(700));
CREATE TABLE
=> COPY polygons (gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 10|POLYGON((5 5, 5 10, 10 10, 10 5, 5 5))
>> 11|POLYGON((0 0, 0 2, 2 2, 2 0, 0 0))
>> 12|POLYGON((1 1, 1 3, 3 3, 3 1, 1 1))
>> 14|POLYGON((-1 -1, -1 12, 12 12, 12 -1, -1 -1))
>> \.
=> SELECT STV_Create_Index(gid, geom USING PARAMETERS index='my_polygons', overwrite=true, max_mem_mb=256)
    OVER() FROM polygons;
   type | polygons | SRID | min_x | min_y | max_x | max_y | info
-----+-----+-----+-----+-----+-----+-----+-----
GEOMETRY |      4 |    0 |    -1 |    -1 |    12 |    12 |
(1 row)

```

```

=> CREATE TABLE points (gid INT, geom GEOMETRY(700));
CREATE TABLE
=> COPY points (gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 1|POINT(9 9)
>> 2|POINT(0 1)
>> 3|POINT(2.5 2.5)
>> 4|POINT(0 0)
>> 5|POINT(1 5)
>> 6|POINT(1.5 1.5)
>> \.
=> SELECT STV_Intersect(gid, geom USING PARAMETERS index='my_polygons') OVER (PARTITION BEST)
    AS (point_id, polygon_gid)
    FROM points;
point_id | polygon_gid
-----+-----
5 |      14
1 |      14
1 |      10
4 |      14
4 |      11
6 |      12
6 |      14
6 |      11
2 |      14
2 |      11
3 |      12
3 |      14
(12 rows)

```

You can improve query performance by using the STV_Intersect transform function in a WHERE clause. Performance improves because this syntax eliminates all points that do not intersect polygons in the index.

Return the count of points that intersect with the polygon, where gid = 14:

```

=> SELECT COUNT(pt_id) FROM
    (SELECT STV_Intersect(gid, geom USING PARAMETERS index='my_polygons')
    OVER (PARTITION BEST) AS (pt_id, pol_id) FROM points)
    AS T WHERE pol_id = 14;
COUNT
-----
6
(1 row)

```

- [STV_Create_Index](#)
- [STV_Intersect scalar function](#)

STV_IsValidReason

Determines if a spatial object is well formed or valid. If the object is not valid, STV_IsValidReason returns a string that explains where the invalidity occurs.

A polygon or multipolygon is valid if all of the following are true:

- The polygon is closed; its start point is the same as its end point.
- Its boundary is a set of linestrings.
- The boundary does not touch or cross itself.
- Any polygons in the interior that do not have more than one point touching the boundary of the exterior polygon.

If you pass an invalid object to a Vertica Place function, the function fails or returns incorrect results. To determine if a polygon is valid, first run ST_IsValid. ST_IsValid returns TRUE if the polygon is valid, FALSE otherwise.

Note

If you pass a valid polygon to STV_IsValidReason, it returns NULL.

Behavior type

[Immutable](#)

Syntax

```
STV_IsValidReason( g )
```

Arguments

g

Geospatial object to test for validity, value of type GEOMETRY or GEOGRAPHY (WGS84).

Returns

LONG VARCHAR

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	No	No
Multipoint	Yes	No	No
Linestring	Yes	No	No
Multilinestring	Yes	No	No
Polygon	Yes	No	Yes
Multipolygon	Yes	No	No
GeometryCollection	Yes	No	No

Examples

The following example shows how to use STV_IsValidReason.

Returns a string describing where the polygon is invalid:

```
=> SELECT STV_IsValidReason(ST_GeomFromText('POLYGON((1 3,3 2,1 1,
3 0,1 0,1 3))'));
      STV_IsValidReason
```

```
-----
Ring Self-intersection at or near POINT (1 1)
(1 row)
```

See also

[ST_IsValid](#)

STV_LineStringPoint

Retrieves the vertices of a linestring or multilinestring. The values returned are points of either GEOMETRY or GEOGRAPHY type depending on the input object's type. GEOMETRY points inherit the SRID of the input object.

STV_LineStringPoint is an analytic function. For more information, see [Analytic functions](#).

Behavior type

[Immutable](#)

Syntax

```
STV_LineStringPoint( g )
OVER( [PARTITION NODES] ) AS
```

Arguments

g

Linestring or multilinestring, value of type GEOMETRY or GEOGRAPHY

Returns

GEOMETRY or GEOGRAPHY

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	No	No	No
Multipoint	No	No	No
Linestring	Yes	Yes	Yes
Multilinestring	Yes	Yes	Yes
Polygon	No	No	No
Multipolygon	No	No	No
GeometryCollection	No	No	No

Examples

The following examples show how to use STV_LineStringPoint.

Returns the vertices of the geometry linestring and their SRID:

```
=> SELECT ST_AsText(Point), ST_SRID(Point)
      FROM (SELECT STV_LineStringPoint(
              ST_GeomFromText('MULTILINESTRING((1 2, 2 3, 3 1, 4 2),
              (10 20, 20 30, 30 10, 40 20))', 4269)) OVER () AS Point) AS foo;
ST_AsText | ST_SRID
-----+-----
POINT (1 2) | 4269
POINT (2 3) | 4269
POINT (3 1) | 4269
POINT (4 2) | 4269
POINT (10 20) | 4269
POINT (20 30) | 4269
POINT (30 10) | 4269
POINT (40 20) | 4269
(8 rows)
```

Returns the vertices of the geography linestring:

```
=> SELECT ST_AsText(g)
      FROM (SELECT STV_LineStringPoint(
              ST_GeographyFromText('MULTILINESTRING ((42.1 71.0, 41.4 70.0, 41.3 72.9),
              (42.99 71.46, 44.47 73.21)', 4269)) OVER () AS g) AS line_geog_points;
ST_AsText
-----
POINT (42.1 71.0)
POINT (41.4 70.0)
POINT (41.3 72.9)
POINT (42.99 71.46)
POINT (44.47 73.21)
(5 rows)
```

See also

[STV_PolygonPoint](#)

STV_MemSize

Returns the length of the spatial object in bytes as an INTEGER.

Use this function to determine the optimal column width for your spatial data.

Behavior type

[Immutable](#)

Syntax

```
STV_MemSize( g )
```

Arguments

g
 Spatial object, value of type GEOMETRY or GEOGRAPHY

Returns

INTEGER

Examples

The following example shows how you can optimize your table by sizing the GEOMETRY or GEOGRAPHY column to the maximum value returned by STV_MemSize:

```

=> CREATE TABLE mem_size_table (id int, geom geometry(800));
CREATE TABLE
=> COPY mem_size_table (id, gx filler LONG VARCHAR, geom as ST_GeomFromText(gx)) FROM STDIN DELIMITER '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>>1|POINT(3 5)
>>2|MULTILINESTRING(((1 5, 2 4, 5 3, 6 6),(3 5, 3 7))
>>3|MULTIPOLYGON(((2 6, 2 9, 6 9, 7 7, 4 6, 2 6)),((0 0, 0 5, 1 0, 0 0)),((0 2, 2 5, 4 5, 0 2)))
>>\.
=> SELECT max(STV_MemSize(geom)) FROM mem_size_table;
max
-----
336
(1 row)

=> CREATE TABLE production_table(id int, geom geometry(336));
CREATE TABLE
=> INSERT INTO production_table SELECT * FROM mem_size_table;
OUTPUT
-----
3
(1 row)
=> DROP mem_size_table;
DROP TABLE

```

STV_NN

Calculates the distance of spatial objects from a reference object and returns (object, distance) pairs in ascending order by distance from the reference object.

Parameters **g1** and **g2** must be both GEOMETRY objects or both GEOGRAPHY objects.

STV_NN is an analytic function. For more information, see [Analytic functions](#).

Behavior type

[Immutable](#)

Syntax

```
STV_NN(g, ref_obj, k) OVER()
```

Arguments

g
Spatial object, value of type GEOMETRY or GEOGRAPHY

ref_obj
Reference object, type GEOMETRY or GEOGRAPHY

k
Number of rows to return, type INTEGER

Returns

(Object, distance) pairs, in ascending order by distance. If a parameter is EMPTY or NULL, then 0 rows are returned.

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)
Point	Yes	Yes
Multipoint	Yes	Yes
Linestring	Yes	Yes
Multilinestring	Yes	Yes

Polygon	Yes	Yes
Multipolygon	Yes	Yes
GeometryCollection	Yes	No

Examples

The following example shows how to use STV_NN.

Create a table and insert nine GEOGRAPHY points:

```
=> CREATE TABLE points (g geography);
CREATE TABLE
=> COPY points (gx filler LONG VARCHAR, g AS ST_GeographyFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> POINT (21.5 18.4)
>> POINT (21.5 19.2)
>> POINT (21.5 20.7)
>> POINT (22.5 16.4)
>> POINT (22.5 17.15)
>> POINT (22.5 18.33)
>> POINT (23.5 13.68)
>> POINT (23.5 15.9)
>> POINT (23.5 18.4)
>> \.
```

Calculate the distances (in meters) of objects in table `points` from the GEOGRAPHY point (23.5, 20).

Returns the five objects that are closest to that point:

```
=> SELECT ST_AsText(nn), dist FROM (SELECT STV_NN(g,
  ST_GeographyFromText('POINT(23.5 20)'),5) OVER() AS (nn,dist) FROM points) AS example;
  ST_AsText  |  dist
-----+-----
POINT (23.5 18.4) | 177912.12757541
POINT (22.5 18.33) | 213339.210738322
POINT (21.5 20.7) | 222561.43679943
POINT (21.5 19.2) | 227604.371833335
POINT (21.5 18.4) | 275239.416790128
(5 rows)
```

STV_PolygonPoint

Retrieves the vertices of a polygon as individual points. The values returned are points of either GEOMETRY or GEOGRAPHY type depending on the input object's type. GEOMETRY points inherit the SRID of the input object.

STV_PolygonPoint is an analytic function. For more information, see [Analytic functions](#).

Behavior type

[Immutable](#)

Syntax

```
STV_PolygonPoint( g )
  OVER( [PARTITION NODES] ) AS
```

Arguments

g
Polygon, value of type GEOMETRY or GEOGRAPHY

Returns

GEOMETRY or GEOGRAPHY

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	No	No	No
Multipoint	No	No	No
Linestring	No	No	No
Multilinestring	No	No	No
Polygon	Yes	Yes	Yes
Multipolygon	Yes	Yes	Yes
GeometryCollection	No	No	No

Examples

The following examples show how to use STV_PolygonPoint.

Returns the vertices of the geometry polygon:

```
=> SELECT ST_AsText(g) FROM (SELECT STV_PolygonPoint(ST_GeomFromText('POLYGON((1 2, 2 3, 3 1, 1 2)))')
  OVER (PARTITION NODES) AS g) AS poly_points;
 ST_AsText
-----
POINT (1 2)
POINT (2 3)
POINT (3 1)
POINT (1 2)
(4 rows)
```

Returns the vertices of the geography polygon:

```
=> SELECT ST_AsText(g) FROM (SELECT STV_PolygonPoint(ST_GeographyFromText('
  POLYGON((25.5 28.76, 28.83 29.13, 27.2 30.99, 25.5 28.76)))')
  OVER (PARTITION NODES) AS g) AS poly_points;
 ST_AsText
-----
POINT (25.5 28.76)
POINT (28.83 29.13)
POINT (27.2 30.99)
POINT (25.5 28.76)
(4 rows)
```

See also

[STV_LineStringPoint](#)

[STV_Refresh_Index](#)

Appends newly added or updated polygons and removes deleted polygons from an existing spatial index.

The OVER() clause must be empty.

Behavior type

Mutable

Syntax

```

STV_Refresh_Index( gid, g
    USING PARAMETERS index='index_name'
    [, skip_nonindexable_polygons={ true | false } ] )

OVER()
    [ AS (type, polygons, srid, min_x, min_y, max_x, max_y, info,
indexed, appended, updated, deleted) ]

```

Arguments

gid

Name of an integer column that uniquely identifies the polygon. The gid cannot be NULL.

g

Name of a geometry or geography (WGS84) column or expression that contains polygons and multipolygons. Only polygon and multipolygon can be indexed. Other shape types are excluded from the index.

Parameters

index = 'index_name'

Name of the index, type VARCHAR. Index names cannot exceed 110 characters. The slash, backslash, and tab characters are not allowed in index names.

skip_nonindexable_polygons = { true | false }

(Optional) BOOLEAN

In rare cases, intricate polygons (for instance, with too high resolution or anomalous spikes) cannot be indexed. These polygons are considered non-indexable. When set to False, non-indexable polygons cause the index creation to fail. When set to True, index creation can succeed by excluding non-indexable polygons from the index.

To review the polygons that were not able to be indexed, use STV_Describe_Index with the parameter list_polygon.

Default: False

Returns

type

Spatial object type of the index.

polygons

Number of polygons indexed.

SRID

Spatial reference system identifier.

min_x*, *min_y*, *max_x*, *max_y

Coordinates of the minimum bounding rectangle (MBR) of the indexed geometries. (*min_x*, *min_y*) are the south-west coordinates, and (*max_x*, *max_y*) are the north-east coordinates.

info

Lists the number of excluded spatial objects as well as their type that were excluded from the index.

indexed

Number of polygons indexed during the operation.

appended

Number of appended polygons.

updated

Number of updated polygons.

deleted

Number of deleted polygons.

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (WGS84)
Point	No	No
Multipoint	No	No

Linestring	No	No
Multilinestring	No	No
Polygon	Yes	Yes
Multipolygon	Yes	No
GeometryCollection	No	No

Privileges

Any user with access to the STV_*_Index functions can describe, rename, or drop indexes created by any other user.

Limitations

- In rare cases, intricate polygons (such as those with too-high a resolution or anomalous spikes) cannot be indexed. See the parameter [skip_nonindexable_polygons](#).
- If you replace a valid polygon in the source table with an invalid polygon, STV_Refresh_Index ignores the invalid polygon. As a result, the polygon originally indexed persists in the index.
- The following geometries cannot be indexed:
 - Non-polygons
 - NULL gid
 - NULL (multi) polygon
 - EMPTY (multi) polygon
 - Invalid (multi) polygon
- The following geographies are excluded from the index:
 - Polygons with holes
 - Polygons crossing the International Date Line
 - Polygons covering the north or south pole
 - Antipodal polygons

Usage tips

- To cancel an STV_Refresh_Index run, use **Ctrl + C**.
- If you use source data not previously associated with the index, then the index will be overwritten.
- If STV_Refresh_Index has insufficient memory to process the query, then rebuild the index using STV_Create_Index.
- If there are no valid polygons in the geom column, STV_Refresh_Index reports an error in vertica.log and stops the index refresh.
- Ensure that all of the polygons you plan to index are valid polygons. STV_Create_Index and STV_Refresh_Index do not check polygon validity when building an index.

For more information, see [Ensuring polygon validity before creating or refreshing an index](#).

Examples

The following examples show how to use STV_Refresh_Index.

Refresh an index with a single literal argument:

```
=> SELECT STV_Create_Index(1, ST_GeomFromText('POLYGON((0 0,0 15.2,3.9 15.2,3.9 0,0 0))')
  USING PARAMETERS index='my_polygon') OVER();
 type | polygons | SRID | min_x | min_y | max_x | max_y | info
-----+-----+-----+-----+-----+-----+-----+-----
GEOMETRY | 1 | 0 | 0 | 0 | 3.9 | 15.2 |
(1 row)

=> SELECT STV_Refresh_Index(2, ST_GeomFromText('POLYGON((0 0,0 13.2,3.9 18.2,3.9 0,0 0))')
  USING PARAMETERS index='my_polygon') OVER();
 type | polygons | SRID | min_x | min_y | max_x | max_y | info | indexed | appended | updated | deleted
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----
GEOMETRY | 1 | 0 | 0 | 0 | 3.9 | 18.2 | | 1 | 1 | 0 | 1
(1 row)
```

Refresh an index from a table:

```

=> CREATE TABLE pols (gid INT, geom GEOMETRY);
CREATE TABLE
=> COPY pols(gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 1|POLYGON((-31 74,8 70,8 50,-36 53,-31 74))
>> 2|POLYGON((5 20,9 30,20 45,36 35,5 20))
>> 3|POLYGON((12 23,9 30,20 45,36 35,37 67,45 80,50 20,12 23))
>> \.
=> SELECT STV_Create_Index(gid, geom USING PARAMETERS index='my_polygons_1', overwrite=true)
OVER() FROM pols;
type | polygons | SRID | min_x | min_y | max_x | max_y | info
-----+-----+-----+-----+-----+-----+-----+-----
GEOMETRY | 3 | 0 | -36 | 20 | 50 | 80 |
(1 row)

=> COPY pols(gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 6|POLYGON((-32 74,8 70,8 50,-36 53,-32 74))
>> \.
=> SELECT STV_Refresh_Index(gid, geom USING PARAMETERS index='my_polygons_1') OVER() FROM pols;
type | polygons | SRID | min_x | min_y | max_x | max_y | info | indexed | appended | updated | deleted
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----
GEOMETRY | 4 | 0 | -36 | 20 | 50 | 80 | | 1 | 1 | 0 | 0
(1 row)

```

See also

- [STV_Create_Index](#)
- [STV_Describe_Index](#)
- [STV_Drop_Index](#)
- [STV_Rename_Index](#)
- [Ensuring polygon validity before creating or refreshing an index](#)

STV_Rename_Index

Renames a spatial index. If the index format is out of date, you cannot rename the index.

A spatial index is created from an input polygon set, which can be the result of a query. Spatial indexes are created in a global name space. Vertica uses a distributed plan whenever the input table or projection is segmented across nodes of the cluster.

The OVER() clause must be empty.

Behavior type

[Immutable](#)

Syntax

```

STV_Rename_Index( USING PARAMETERS
    source = 'old_index_name',
    dest = 'new_index_name',
    overwrite = [ 'true' | 'false' ]
)
OVER ()

```

Arguments

source = ' old_index_name '

Current name of the spatial index, type VARCHAR.

dest = ' new_index_name '

New name of the spatial index, type VARCHAR.

overwrite = ['true' | 'false']

Boolean, whether to overwrite the index, if an index exists. This parameter cannot be NULL.

Default: False

Privileges

Any user with access to the STV_*_Index functions can describe, rename, or drop indexes created by any other user.

Limitations

- Index names cannot exceed 110 characters.
- The backslash or tab characters are not allowed in index names.

Examples

The following example shows how to use STV_Rename_Index.

Rename an index:

```
=> SELECT STV_Rename_Index (  
    USING PARAMETERS  
    source = 'my_polygons',  
    dest = 'US_states',  
    overwrite = 'false'  
)  
OVER ();  
rename_index  
-----  
Index renamed  
(1 Row)
```

STV_Reverse

Reverses the order of the vertices of a spatial object.

Behavior type

[Immutable](#)

Syntax

```
STV_Reverse( g, [USING PARAMETERS skip_nonreorientable_polygons={true | false} ])
```

Arguments

g

Spatial object, type GEOGRAPHY.

skip_nonreorientable_polygons = { true | false }

(Optional) Boolean

When set to False, non-orientable polygons generate an error. For example, if you use STV_ForceLHR or STV_Reverse with [skip_nonorientable_polygons](#) set to False, a geography polygon containing a hole generates an error. When set to True, the result returned is the polygon, as passed to the API, without alteration.

This argument can help you when you are creating an index from a table containing polygons that cannot be re-oriented.

Vertica Place considers these polygons non-orientable:

- Polygons with a hole
- Multipolygons
- Multipolygons with a hole

Default value : False

Returns

GEOGRAPHY

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	No	No	No

Multipoint	No	No	No
Linestring	No	No	No
Multilinestring	No	No	No
Polygon	No	Yes	Yes
Multipolygon	No	Yes	Yes
GeometryCollection	No	No	No

Examples

The following examples show how you can use STV_Reverse.

Reverse vertices of a geography polygon:

```
=> SELECT ST_AsText(STV_Reverse(ST_GeographyFromText('Polygon((1 1, 3 1, 2 2, 1 1)'))));
       ST_AsText
-----
POLYGON ((1 1, 2 2, 3 1, 1 1))
(1 row)
```

Force the polygon to reverse orientation:

```
=> SELECT ST_AsText(STV_Reverse(ST_GeographyFromText('Polygon((1 1, 2 2, 3 1, 1 1)'))));
       ST_AsText
-----
POLYGON ((1 1, 3 1, 2 2, 1 1))
(1 row)
```

See also

[STV_ForceLHR](#)

[STV_SetExportShapefileDirectory](#)

Specifies the directory to export GEOMETRY or GEOGRAPHY data to a shapefile. The validity of the path is not checked, and the path cannot be empty.

Behavior type

[Immutable](#)

Syntax

```
STV_SetExportShapefileDirectory( USING PARAMETERS path='path' )
```

Parameters

path

Destination path for the exported shapefile. The path can be on any shared [file system or object store](#).

Returns

The path of the shapefile export directory.

Privileges

Only a [superuser](#) can use this function.

Examples

The following example shows how you can use STV_SetExportShapefileDirectory to set the shapefile export directory to /home/user/temp:

```
=> SELECT STV_SetExportShapefileDirectory(USING PARAMETERS path = '/home/user/temp');
       STV_SetExportShapefileDirectory
-----
SUCCESS. Set shapefile export directory: [/home/user/temp]
(1 row)
```

[STV_ShpCreateTable](#)

Returns a [CREATE TABLE](#) statement with the columns and types of the attributes found in the specified shapefile.

The column types are sized according to the shapefile metadata. The size of the column is based on the largest geometry found in the shapefile. The first column in the table is named `gid`, which is an [IDENTITY](#) primary key column. The cache value is set to 64 by default. The last column is a GEOMETRY data type for storing the actual geometry data.

Behavior type

[Immutable](#)

Syntax

```
STV_ShpCreateTable (USING PARAMETERS file='filename') OVER()
```

Parameters

file

Fully qualified path of the `.dbf`, `.shp`, or `.shx` file. The path can be on any shared [file system or object store](#).

Returns

CREATE TABLE statement that matches the specified shapefile

Usage tips

- STV_ShpCreateTable returns a CREATE TABLE statement; but it does not create the table. Modify the CREATE TABLE statement as needed, and then create the table before loading the shapefile into the table.
- To create a table with characters other than alphanumeric and underscore (`_`) characters, you must specify the table name enclosed in double quotes, such as `"counties%NY"`.
- The name of the table is the same as the name of the shapefile, without the directory name or extension.
- The shapefile must be accessible from the initiator node.
- If the `.shp` and `.shx` files are corrupt, STV_ShpCreateTable returns an error. If the `.shp` and `.shx` files are valid, but the `.dbf` file is corrupt, STV_ShpCreateTable ignores the `.dbf` file and does not create columns for that data.
- All the mandatory files (`.dbf`, `.shp`, `.shx`) must be in the same directory. If not, STV_ShpCreateTable returns an error.
- If the `.dbf` component of a shapefile contains a Numeric attribute, this field's values may lose precision when the Vertica shapefile loader loads it into a table. The target field is a 64-bit FLOAT column, which can only represent about 15 significant digits. In a `.dbf` file, numeric fields can be up to 30 digits.

Vertica records all instances of shapefile values that are too long in the `vertica.log` file.

Examples

The following example shows how to use STV_ShpCreateTable.

Returns a CREATE TABLE statement:

```
=> SELECT STV_ShpCreateTable
      (USING PARAMETERS file='/shapefiles/tl_2010_us_state10.shp')
      OVER() as create_table_states;
      create_table_states
```

```
-----
CREATE TABLE tl_2010_us_state10(
  gid IDENTITY(64) PRIMARY KEY,
  REGION10 VARCHAR(2),
  DIVISION10 VARCHAR(2),
  STATEFP10 VARCHAR(2),
  STATENS10 VARCHAR(8),
  GEOID10 VARCHAR(2),
  STUSPS10 VARCHAR(2),
  NAME10 VARCHAR(100),
  LSAD10 VARCHAR(2),
  MTFCC10 VARCHAR(5),
  FUNCSTAT10 VARCHAR(1),
  ALAND10 INT8,
  AWATER10 INT8,
  INTPTLAT10 VARCHAR(11),
  INTPTLON10 VARCHAR(12),
  geom GEOMETRY(940845)
);
(18 rows)
```

See also

- [STV_ShpSource and STV_ShpParser](#)

STV_ShpSource and STV_ShpParser

These two functions work with [COPY](#) to parse and load geometries and attributes from a shapefile into a Vertica table, and convert them to the appropriate GEOMETRY data type. You must use these two functions together.

The following restrictions apply:

- An empty multipoint or an invalid multipolygon can not be loaded from a shapefile.
- If the `.dbf` component of a shapefile contains a numeric attribute, this field's values might lose precision when the Vertica Place shapefile loader loads it into a table. The target field is a 64-bit FLOAT column, which can only represent about 15 significant digits; in a `.dbf` file, Numeric fields can be up to 30 digits.

Rejected records are saved to [CopyErrorLogs](#) subdirectory, under the Vertica catalog directory.

Behavior type

[Immutable](#)

Syntax

```
COPY table( columnlist )
  WITH SOURCE STV_ShpSource
    ( file = 'path'[, SRID=spatial-reference-identifier] [, flatten_2d={true | false } ] )
  PARSER STV_ShpParser()
```

Arguments

table

Name of the table in which to load the geometry data.

columnlist

Comma-delimited list of column names in the table that match fields in the external file. Run the CREATE TABLE command that [STV_ShpCreateTable](#) creates. When you do so, these columns correspond to the second through the second-to-last columns.

Parameters

file

Fully qualified path of a `.dbf` , `.shp` , or `.shx` file. The path can be on any shared [file system or object store](#) .

SRID

Specifies an integer spatial reference identifier (SRID) associated with the shape file.

flatten_2d

Specifies a BOOLEAN argument that excludes 3D or 4D coordinates during COPY commands:

- **true** : Excludes geometries with 3D or 4D coordinates before a COPY command.
- **false** : Causes the load to fail if a geometry with 3D or 4D coordinate is found.

Default: false

Privileges

- Source shapefile: Read
- Shapefile directory: Execute

COPY errors

The COPY command fails under one of the following conditions:

- The shapefile cannot be located or opened.
- The number of columns or the data types of the columns that STV_ShParser creates do not match the columns in the destination table. Use [STV_ShpCreateTable](#) to generate the appropriate CREATE TABLE command.
- One of the mandatory files is missing or cannot be opened. When opening a shapefile, you must have three files: **.dbf** , **.shp** , and **.shx** .

STV_ShpSource file corruption handling

- If the **.shp** and **.shx** files are corrupt, STV_ShpSource returns an error.
- If the **.shp** and **.shx** files are valid, but the **.dbf** file is corrupt, STV_ShpSource ignores the **.dbf** file and does not create columns for that data.

Examples

```
=> COPY tl_2010_us_state10 WITH SOURCE
STV_ShpSource(file='/shapefiles/tl_2010_us_state10.shp', SRID=4269) PARSER STV_ShParser();
```

Hadoop functions

This section contains functions to manage interactions with Hadoop.

In this section

- [CLEAR_HDFS_CACHES](#)
- [EXTERNAL_CONFIG_CHECK](#)
- [GET_METADATA](#)
- [HADOOP_IMPERSONATION_CONFIG_CHECK](#)
- [HASH_EXTERNAL_TOKEN](#)
- [HCATALOGCONNECTOR_CONFIG_CHECK](#)
- [HDFS_CLUSTER_CONFIG_CHECK](#)
- [KERBEROS_HDFS_CONFIG_CHECK](#)
- [SYNC_WITH_HCATALOG_SCHEMA](#)
- [SYNC_WITH_HCATALOG_SCHEMA_TABLE](#)
- [VERIFY_HADOOP_CONF_DIR](#)

CLEAR_HDFS_CACHES

Clears the configuration information copied from HDFS and any cached connections.

This function affects reads using the **hdfs** scheme in the following ways:

- This function flushes information loaded from configuration files copied from Hadoop (such as core-site.xml). These files are found on the path set by the HadoopConfDir configuration parameter.
- This function flushes information about which NameNode is active in a High Availability (HA) Hadoop cluster. Therefore, the first request to Hadoop after calling this function is slower than expected.

Vertica maintains a cache of open connections to NameNodes to reduce latency. This function flushes that cache.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
CLEAR_HDFS_CACHES ( )
```

Privileges

Superuser

Examples

The following example clears the Hadoop configuration information:

```
=> SELECT CLEAR_HDFS_CACHES();
CLEAR_HDFS_CACHES
-----
Cleared
(1 row)
```

See also

[Hadoop parameters](#)

[EXTERNAL_CONFIG_CHECK](#)

Tests the Hadoop configuration of a Vertica cluster. This function tests HDFS configuration files, HCatalog Connector configuration, and Kerberos configuration.

This function calls the following functions:

- [KERBEROS_CONFIG_CHECK](#)
- [HADOOP_IMPERSONATION_CONFIG_CHECK](#)
- [HDFS_CLUSTER_CONFIG_CHECK](#)
- [HCATALOGCONNECTOR_CONFIG_CHECK](#)

If you call this function with an argument, it passes the argument to functions it calls that also take an argument.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
EXTERNAL_CONFIG_CHECK( [what_to_test] )
```

Arguments

what_to_test

A string specifying the authorities, nameservices, and/or HCatalog schemas to test. The format is a comma-separated list of "key=value" pairs, where keys are "authority", "nameservice", and "schema". The value is passed to all of the sub-functions; see those reference pages for details on how values are interpreted.

Privileges

This function does not require privileges.

Examples

The following example tests the configuration of only the nameservice named "ns1". Output has been omitted due to length.

```
=> SELECT EXTERNAL_CONFIG_CHECK('nameservice=ns1');
```

[GET_METADATA](#)

Returns the metadata of a Parquet file. Metadata includes the number and sizes of row groups, column names, and information about chunks and compression. Metadata is returned as JSON.

This function inspects one file. Parquet data usually spans many files in a single directory; choose one. The function does not accept a directory name as an argument.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
GET_METADATA( 'filename' )
```

Arguments

filename

The name of a Parquet file. Any path that is valid for COPY is valid for this function. This function does not operate on files in other formats.

Privileges

Superuser, or non-superuser with READ privileges on the USER-accessible storage location (see [GRANT \(storage location\)](#)).

Examples

You must call this function with a single file, not a directory or glob:

```
=> SELECT GET_METADATA('/data/emp-row.parquet');
       GET_METADATA
-----
schema:
required group field_id=-1 spark_schema {
  optional int32 field_id=-1 employeeID;
  optional group field_id=-1 personal {
    optional binary field_id=-1 name (String);
    optional group field_id=-1 address {
      optional binary field_id=-1 street (String);
      optional binary field_id=-1 city (String);
      optional int32 field_id=-1 zipcode;
    }
    optional int32 field_id=-1 taxID;
  }
  optional binary field_id=-1 department (String);
}

(1 row)

HADOOP_IMPERSONATION_CONFIG_CHECK

Reports the delegation tokens Vertica will use when accessing Kerberized data in HDFS. The HadoopImpersonationConfig configuration parameter specifies one or more authorities, nameservices, and HCatalog schemas and their associated tokens. For each tested value, the function reports what doAs user or delegation token Vertica will use for access. Use this function to confirm that you have defined your delegation tokens as you intended.

You can call this function with an argument to specify the authority, nameservice, or HCatalog schema to test, or without arguments to test all configured values.

This function does not check that you can use these delegation tokens to access HDFS.

See [Proxy users and delegation tokens](#) for more about impersonation.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
HADOOP_IMPERSONATION_CONFIG_CHECK( [what_to_test] )
```

Arguments

what_to_test

A string specifying the authorities, nameservices, and/or HCatalog schemas to test. For example, a value of 'nameservice=ns1' means the function tests only access to the nameservice "ns1" and ignores any other authorities and schemas. A value of 'nameservice=ns1, schema=hcat1' means the function tests one nameservice and one HCatalog schema.

If you do not specify this argument, the function tests all authorities, nameservices, and schemas defined in HadoopImpersonationConfig.

Privileges

This function does not require privileges.

Examples

Consider the following definition of HadoopImpersonationConfig:

```
[{
  "nameservice": "ns1",
  "token": "RANDOM-TOKEN-STRING"
},
{
  "nameservice": "*",
  "doAs": "Paul"
},
{
  "schema": "hcat1",
  "doAs": "Fred"
}
]
```

The following query tests only the "ns1" name service:

```
=> SELECT HADOOP_IMPERSONATION_CONFIG_CHECK('nameservice=ns1');

-- hadoop_impersonation_config_check --
Connections to nameservice [ns1] will use a delegation token with hash [b3dd9e71cd695d91]
```

This function returns a hash of the token for security reasons. You can call [HASH_EXTERNAL_TOKEN](#) with the expected value and compare that hash to the one in this function's output.

A query with no argument tests all values:

```
=> SELECT HADOOP_IMPERSONATION_CONFIG_CHECK();

-- hadoop_impersonation_config_check --
Connections to nameservice [ns1] will use a delegation token with hash [b3dd9e71cd695d91]
JDBC connections for HCatalog schema [hcat1] will doAs [Fred]
[!] hadoop_impersonation_config_check : [PASS]
```

HASH_EXTERNAL_TOKEN

Returns a hash of a string token, for use with [HADOOP_IMPERSONATION_CONFIG_CHECK](#). Call [HASH_EXTERNAL_TOKEN](#) with the delegation token you expect Vertica to use and compare it to the hash in the output of [HADOOP_IMPERSONATION_CONFIG_CHECK](#).

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
HASH_EXTERNAL_TOKEN( 'token' )
```

Arguments

token

A string specifying the token to hash. The token is configured in the HadoopImpersonationConfig parameter.

Privileges

This function does not require privileges.

Examples

The following query tests the expected value shown in the example on the [HADOOP_IMPERSONATION_CONFIG_CHECK](#) reference page.

```
=> SELECT HASH_EXTERNAL_TOKEN('RANDOM-TOKEN-STRING');
hash_external_token
-----
b3dd9e71cd695d91
(1 row)
```

HCATALOGCONNECTOR_CONFIG_CHECK

Tests the configuration of a Vertica cluster that uses the HCatalog Connector to access Hive data. The function first verifies that the HCatalog

Connector is properly installed and reports on the values of several related configuration parameters. It then tests the connection using HiveServer2. This function does not support the WebHcat server.

If you specify an HCatalog schema, and if you have defined a delegation token for that schema, this function uses the delegation token. Otherwise, the function uses the default endpoint without a delegation token.

See [Proxy users and delegation tokens](#) for more about delegation tokens.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
HCATALOGCONNECTOR_CONFIG_CHECK( ['what_to_test' ] )
```

Arguments

what_to_test

A string specifying the HCatalog schemas to test. For example, a value of 'schema=hcat1' means the function tests only the "hcat1" schema and ignores any others that are found.

Privileges

This function does not require privileges.

Examples

The following query tests with the default endpoint and no delegation token.

```
=> SELECT HCATALOGCONNECTOR_CONFIG_CHECK();

-- hcatalogconnector_config_check --

HCatalogConnectorUseHiveServer2 : [1]
EnableHCatImpersonation : [1]
HCatalogConnectorUseORCReader : [1]
HCatalogConnectorUseParquetReader : [1]
HCatalogConnectorUseTxtReader : [0]
[INFO] Vertica is not configured to use its internal parsers for delimited files.
[INFO] This is off by default, but will be changed in a future release.
HCatalogConnectorUseLibHDFSPP : [1]

[OK] HCatalog connector library is properly installed.
[INFO] Creating JDBC connection as session user.
[OK] Successful JDBC connection to HiveServer2 as user [USER].

[!] hcatalogconnector_config_check : [PASS]
```

To test with the configured delegation token, pass the schema as an argument:

```
=> SELECT HCATALOGCONNECTOR_CONFIG_CHECK('schema=hcat1');
```

HDFS_CLUSTER_CONFIG_CHECK

Tests the configuration of a Vertica cluster that uses HDFS. The function scans the Hadoop configuration files found in HadoopConfDir and performs configuration checks on each cluster it finds. If you have more than one cluster configured, you can specify which one to test instead of testing all of them.

For each Hadoop cluster, it reports properties including:

- Nameservice name and associated NameNodes
- High-availability status
- RPC encryption status
- Kerberos authentication status
- HTTP(S) status

It then tests connections using [http\(s\)](#), [hdfs](#), and [webhdfs](#) URL schemes. It tests the latter two using both the Vertica and session user.

See [Configuring HDFS access](#) for information about configuration files and HadoopConfDir.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
HDFS_CLUSTER_CONFIG_CHECK( ['what_to_test' ] )
```

Arguments

what_to_test

A string specifying the authorities or nameservices to test. For example, a value of 'nameservice=ns1' means the function tests only "ns1" cluster. If you specify both an authority and a nameservice, the authority must be a NameNode in the specified nameservice for the check to pass.

If you do not specify this argument, the function tests all cluster configurations found in HadoopConfDir.

Privileges

This function does not require privileges.

Examples

The following example tests all clusters.

```
=> SELECT HDFS_CLUSTER_CONFIG_CHECK();

-- hdfs_cluster_config_check --

Hadoop Conf Path : [/conf/hadoop_conf]
[OK] HadoopConfDir verified on all nodes
Connection Timeout (seconds) : [60]
Token Refresh Frequency (seconds) : [0]
HadoopFSBlockSizeBytes (MiB) : [64]

[OK] Found [1] hadoop cluster configurations

----- Cluster 1 -----
Is DefaultFS : [true]
Nameservice : [vmns]
Namenodes : [node1.example.com:8020, node2.example.com:8020]
High Availability : [true]
RPC Encryption : [false]
Kerberos Authentication : [true]
HTTPS Only : [false]
[INFO] Checking connections to [hdfs://]
vertica : [OK]
dbuser : [OK]

[INFO] Checking connections to [http://node1.example.com:50070]
[INFO] Node is in standby
[INFO] Checking connections to [http://node2.example.com:50070]
[OK] Can make authenticated external curl connection
[INFO] Checking webhdfs
vertica : [OK]
USER : [OK]

[!] hdfs_cluster_config_check : [PASS]
```

KERBEROS_HDFS_CONFIG_CHECK

Deprecated

This function is deprecated and will be removed in a future release. Instead, use [EXTERNAL_CONFIG_CHECK](#).

Tests the Kerberos configuration of a Vertica cluster that uses HDFS. The function succeeds if it can use both the Vertica keytab file and the session user to access HDFS, and reports errors otherwise. This function is a more specific version of [KERBEROS_CONFIG_CHECK](#).

If the current session is not Kerberized, this function will not be able to use secured HDFS connections and will fail.

You can call this function with arguments to specify an HDFS configuration to test, or without arguments. If you call it with no arguments, this function reads the HDFS configuration files and fails if it does not find them. See [Configuring HDFS access](#). If it finds configuration files, it tests all configured nameservices.

The function performs the following tests, in order:

- Are Kerberos services available?
- Does a keytab file exist and are the Kerberos and HDFS configuration parameters set in the database?
- Can Vertica read and invoke kinit with the keys to authenticate to HDFS and obtain the database Kerberos ticket?
- Can Vertica perform `hdfs` and `webhdfs` operations using both the database Kerberos ticket and user-forwardable tickets for the current session?
- Can Vertica connect to HiveServer2? (This function does not support WebHCat.)

If any test fails, the function returns a descriptive error message.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
KERBEROS_HDFS_CONFIG_CHECK( ['hdfsHost:hdfsPort',  
'webhdfsHost:webhdfsPort', 'webhcatHost' ] )
```

Arguments

hdfsHost , hdfsPort

The hostname or IP address and port of the HDFS NameNode. Vertica uses this server to access data that is specified with `hdfs` URLs. If the value is `'`, the function skips this part of the check.

webhdfsHost , webhdfsPort

The hostname or IP address and port of the WebHDFS server. Vertica uses this server to access data that is specified with `webhdfs` URLs. If the value is `'`, the function skips this part of the check.

webhcatHost

Pass any value in this position. WebHCat is deprecated and this value is ignored but must be present.

Privileges

This function does not require privileges.

SYNC_WITH_HCATALOG_SCHEMA

Copies the structure of a Hive database schema available through the HCatalog Connector to a Vertica schema. If the HCatalog schema and the target Vertica schema have matching table names, `SYNC_WITH_HCATALOG_SCHEMA` overwrites the Vertica tables.

This function can synchronize the HCatalog schema directly. In this case, call it with the same schema name for the `vertica_schema` and `hcatalog_schema` parameters. The function can also synchronize a different schema to the HCatalog schema.

If you change the settings of [HCatalog Connector configuration parameters](#), you must call this function again.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
SYNC_WITH_HCATALOG_SCHEMA( vertica_schema, hcatalog_schema, [drop_non_existent] )
```

Parameters

vertica_schema

The target Vertica schema to store the copied HCatalog schema's metadata. This can be the same schema as `hcatalog_schema`, or it can be a separate one created with [CREATE SCHEMA](#).

Caution

Do not use the Vertica schema to store other data.

hcatalog_schema

The HCatalog schema to copy, created with [CREATE HCATALOG SCHEMA](#)

drop_non_existent

If `true`, drop any tables in `vertica_schema` that do not correspond to a table in `hcatalog_schema`

Privileges

Non-superuser: CREATE privileges on `vertica_schema`.

Users also require access to Hive data, one of the following:

- USAGE permissions on `hcat_schema`, if Hive does not use an authorization service to manage access.
- Permission through an authorization service (Sentry or Ranger), and access to the underlying files in HDFS. (Sentry can provide that access through ACL synchronization.)
- dbadmin user privileges, with or without an authorization service.

Data type matching

Hive STRING and BINARY data types are matched, in Vertica, to the VARCHAR(65000) and VARBINARY(65000) types. Adjust the data types with [ALTER TABLE](#) as needed after creating the schema. The maximum size of a VARCHAR or VARBINARY in Vertica is 65000, but you can use LONG VARCHAR and LONG VARBINARY to specify larger values.

Hive and Vertica define string length in different ways. In Hive the length is the number of characters; in Vertica it is the number of bytes. Thus, a character encoding that uses more than one byte, such as Unicode, can cause mismatches between the two. To avoid data truncation, set values in Vertica based on bytes, not characters.

If data size exceeds the column size, Vertica logs an event at read time in the QUERY_EVENTS system table.

Examples

The following example uses SYNC_WITH_HCATALOG_SCHEMA to synchronize an HCatalog schema named hcat:

```
=> CREATE HCATALOG SCHEMA hcat WITH hostname='hcatost' HCATALOG_SCHEMA='default'  
    HCATALOG_USER='hcatuser';
```

```
CREATE SCHEMA
```

```
=> SELECT sync_with_hcatalog_schema('hcat', 'hcat');
```

```
sync_with_hcatalog_schema
```

```
-----  
Schema hcat synchronized with hcat
```

```
tables in hcat = 56
```

```
tables altered in hcat = 0
```

```
tables created in hcat = 56
```

```
stale tables in hcat = 0
```

```
table changes erred in hcat = 0
```

```
(1 row)
```

```
=> -- Use vsq!s \d command to describe a table in the synced schema
```

```
=> \d hcat.messages
```

```
List of Fields by Tables
```

```
Schema | Table | Column | Type | Size | Default | Not Null | Primary Key | Foreign Key
```

```
-----+-----+-----+-----+-----+-----+-----+-----+-----  
hcat | messages | id | int | 8 | | f | f | |  
hcat | messages | userid | varchar(65000) | 65000 | | f | f | |  
hcat | messages | "time" | varchar(65000) | 65000 | | f | f | |  
hcat | messages | message | varchar(65000) | 65000 | | f | f | |
```

```
(4 rows)
```

The following example uses SYNC_WITH_HCATALOG_SCHEMA followed by ALTER TABLE to adjust a column value:

```

=> CREATE HCATALOG SCHEMA hcat WITH hostname='hcatost' HCATALOG_SCHEMA='default'
-> HCATALOG_USER='hcatuser';
CREATE SCHEMA
=> SELECT sync_with_hcatalog_schema('hcat', 'hcat');
...
=> ALTER TABLE hcat.t ALTER COLUMN a1 SET DATA TYPE long varchar(1000000);
=> ALTER TABLE hcat.t ALTER COLUMN a2 SET DATA TYPE long varbinary(1000000);

```

The following example uses SYNC_WITH_HCATALOG_SCHEMA with a local (non-HCatalog) schema:

```

=> CREATE HCATALOG SCHEMA hcat WITH hostname='hcatost' HCATALOG_SCHEMA='default'
-> HCATALOG_USER='hcatuser';
CREATE SCHEMA
=> CREATE SCHEMA hcat_local;
CREATE SCHEMA
=> SELECT sync_with_hcatalog_schema('hcat_local', 'hcat');

```

SYNC_WITH_HCATALOG_SCHEMA_TABLE

Copies the structure of a single table in a Hive database schema available through the HCatalog Connector to a Vertica table.

This function can synchronize the HCatalog schema directly. In this case, call it with the same schema name for the *vertica_schema* and *hcatalog_schema* parameters. The function can also synchronize a different schema to the HCatalog schema.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```

SYNC_WITH_HCATALOG_SCHEMA_TABLE( vertica_schema, hcatalog_schema, table_name )

```

Parameters

vertica_schema

The existing Vertica schema to store the copied HCatalog schema's metadata. This can be the same schema as *hcatalog_schema*, or it can be a separate one created with [CREATE SCHEMA](#).

hcatalog_schema

The HCatalog schema to copy, created with [CREATE_HCATALOG_SCHEMA](#).

table_name

The table in *hcatalog_schema* to copy. If *table_name* already exists in *vertica_schema*, the function overwrites it.

Privileges

Non-superuser: CREATE privileges on *vertica_schema*.

Users also require access to Hive data, one of the following:

- USAGE permissions on *hcat_schema*, if Hive does not use an authorization service to manage access.
- Permission through an authorization service (Sentry or Ranger), and access to the underlying files in HDFS. (Sentry can provide that access through ACL synchronization.)
- dbadmin user privileges, with or without an authorization service.

Data type matching

Hive STRING and BINARY data types are matched, in Vertica, to the VARCHAR(65000) and VARBINARY(65000) types. Adjust the data types with [ALTER TABLE](#) as needed after creating the schema. The maximum size of a VARCHAR or VARBINARY in Vertica is 65000, but you can use LONG VARCHAR and LONG VARBINARY to specify larger values.

Hive and Vertica define string length in different ways. In Hive the length is the number of characters; in Vertica it is the number of bytes. Thus, a character encoding that uses more than one byte, such as Unicode, can cause mismatches between the two. To avoid data truncation, set values in Vertica based on bytes, not characters.

If data size exceeds the column size, Vertica logs an event at read time in the QUERY_EVENTS system table.

Examples

The following example uses SYNC_WITH_HCATALOG_SCHEMA_TABLE to synchronize the "nation" table:

```

=> CREATE SCHEMA 'hcat_local';
CREATE SCHEMA

=> CREATE HCATALOG SCHEMA hcat WITH hostname='hcatost' HCATALOG_SCHEMA='hcat'
  HCATALOG_USER='hcatuser';
CREATE SCHEMA

=> SELECT sync_with_hcatalog_schema_table('hcat_local', 'hcat', 'nation');
sync_with_hcatalog_schema_table
-----
Schema hcat_local synchronized with hcat for table nation
table nation is created in schema hcat_local
(1 row)

```

The following example shows the behavior if the "nation" table already exists in the local schema:

```

=> SELECT sync_with_hcatalog_schema_table('hcat_local', 'hcat', 'nation');
sync_with_hcatalog_schema_table
-----
Schema hcat_local synchronized with hcat for table nation
table nation is altered in schema hcat_local
(1 row)

```

VERIFY_HADOOP_CONF_DIR

Verifies that the Hadoop configuration that is used to access HDFS is valid on all Vertica nodes. The configuration is valid if:

- all required configuration files are found on the path defined by the HadoopConfDir configuration parameter
- all properties needed by Vertica are set in those files

This function does not attempt to validate the settings of those properties; it only verifies that they have values.

It is possible for Hadoop configuration to be valid on some nodes and invalid on others. The function reports a validation failure if the value is invalid on any node; the rest of the output reports the details.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
VERIFY_HADOOP_CONF_DIR()
```

Parameters

This function has no parameters.

Privileges

This function does not require privileges.

Examples

The following example shows the results when the Hadoop configuration is valid.

```

=> SELECT VERIFY_HADOOP_CONF_DIR();
verify_hadoop_conf_dir
-----
Validation Success
v_vmart_node0001: HadoopConfDir [PG_TESTOUT/config] is valid
v_vmart_node0002: HadoopConfDir [PG_TESTOUT/config] is valid
v_vmart_node0003: HadoopConfDir [PG_TESTOUT/config] is valid
v_vmart_node0004: HadoopConfDir [PG_TESTOUT/config] is valid
(1 row)

```

In the following example, the Hadoop configuration is valid on one node, but on other nodes a needed value is missing.

```
=> SELECT VERIFY_HADOOP_CONF_DIR();
verify_hadoop_conf_dir
```

Validation Failure

```

```

Machine learning functions

Machine learning functions let you work with your data set in different stages of the data analysis process:

- Preparing models
- Training models
- Evaluating models
- Applying models
- Managing models

Some Vertica machine learning functions are implemented as Vertica UDX functions, while others are implemented as meta-functions:

- A UDX function accepts an input relation name from a **FROM** clause. The **SELECT** statement that calls the functions is composable—it can be used as a sub-query in another **SELECT** statement.
- A meta-function accepts the input relation name as a single-quoted string passed to it as an argument or a named parameter. The data that the **SELECT** statement returns cannot be used in a sub-query. Machine learning meta-functions do not support temporary tables.

All machine learning functions automatically cast NUMERIC arguments to FLOAT.

Important

Before using a machine learning function, be aware that any open transaction on the current session might be committed.

In this section

- [Model management](#)
- [Transformation functions](#)

Data preparation

Vertica supports machine learning functions that prepare data as needed before subjecting it to analysis.

In this section

- [BALANCE](#)
- [CHI_SQUARED](#)
- [CORR_MATRIX](#)
- [DETECT_OUTLIERS](#)
- [IFOREST](#)
- [IMPUTE](#)
- [NORMALIZE](#)
- [NORMALIZE_FIT](#)
- [ONE_HOT_ENCODER_FIT](#)
- [PCA](#)
- [SUMMARIZE_CATCOL](#)
- [SUMMARIZE_NUMCOL](#)
- [SVD](#)

BALANCE

Returns a view with an equal distribution of the input data based on the response_column.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
BALANCE ( 'output-view', 'input-relation', 'response-column', 'balance-method'  
[ USING PARAMETERS sampling_ratio=ratio ] )
```

Arguments

output-view

The name of the view where Vertica saves the balanced data from the input relation.

Note

Note : The view that results from this function employs a random function. Its content can differ each time it is used in a query. To make the operations on the view predictable, store it in a regular table.

input-relation

The table or view that contains the data the function uses to create a more balanced data set. If the input relation is defined in Hive, use [SYNC_WITH_HCATALOG_SCHEMA](#) to sync the `hcatalog` schema, and then run the machine learning function.

response-column

Name of the input column that represents the dependent variable, of type VARCHAR or INTEGER.

balance-method

Specifies a method to select data from the minority and majority classes, one of the following.

- **hybrid_sampling** : Performs over-sampling and under-sampling on different classes so each class is equally represented.
- **over_sampling** : Over-samples on all classes, with the exception of the most majority class, towards the most majority class's cardinality.
- **under_sampling** : Under-samples on all classes, with the exception of the most minority class, towards the most minority class's cardinality.
- **weighted_sampling** : An alias of **under_sampling** .

Parameters

ratio

The desired ratio between the majority class and the minority class. This value has no effect when used with balance method **hybrid_sampling** .

Default: 1.0

Privileges

Non-superusers:

- SELECT privileges on the input relation
- CREATE privileges on the output view schema

Examples

```
=> CREATE TABLE backyard_bugs (id identity, bug_type int, finder varchar(20));
```

```
CREATE TABLE
```

```
=> COPY backyard_bugs FROM STDIN;
```

Enter data to be copied followed by a newline.

End with a backslash and a period on a line by itself.

```
>> 1|Ants
>> 1|Beetles
>> 3|Ladybugs
>> 3|Ants
>> 3|Beetles
>> 3|Caterpillars
>> 2|Ladybugs
>> 3|Ants
>> 3|Beetles
>> 1|Ladybugs
>> 3|Ladybugs
>> \.
```

```
=> SELECT bug_type, COUNT(bug_type) FROM backyard_bugs GROUP BY bug_type;
```

```
bug_type | COUNT
```

```
-----+-----
      2 |    1
      1 |    3
      3 |    7
(3 rows)
```

```
=> SELECT BALANCE('backyard_bugs_balanced', 'backyard_bugs', 'bug_type', 'under_sampling');
      BALANCE
```

```
-----+-----
Finished in 1 iteration
```

```
(1 row)
```

```
=> SELECT bug_type, COUNT(bug_type) FROM backyard_bugs_balanced GROUP BY bug_type;
```

```
-----+-----
      2 |    1
      1 |    2
      3 |    1
(3 rows)
```

See also

- [Balancing imbalanced data](#)

CHI_SQUARED

Computes the conditional chi-square independence test on two categorical variables to find the likelihood that the two variables are independent. To condition the independence test on another set of variables, you can partition the data on these variables using a [PARTITION BY](#) clause.

Tip

If a categorical column is not of a [numeric data type](#), you can use the [HASH](#) function to convert it into a column of type INT, where each category is mapped to a unique integer. However, note that NULL values are hashed to zero, so they will be included in the test instead of skipped by the function.

This function is a [multi-phase transform function](#).

Syntax

```
CHI_SQUARED( 'x-column', 'y-column'
  [ USING PARAMETERS param=value[...] ] )
```

Arguments

x-column , y-column

Columns in the input relation to be tested for dependency with each other. These columns must contain categorical data in numeric format.

Parameters

x_cardinality

Integer in the range [1, 20], the cardinality of *x-column* . If the cardinality of *x-column* is less than the default value of 20, setting this parameter can decrease the amount memory used by the function.

Default: 20

y_cardinality

Integer in the range [1, 20], the cardinality of *y-column* . If the cardinality of *y-column* is less than the default value of 20, setting this parameter can decrease the amount memory used by the function.

Default: 20

alpha

Float in the range (0.0, 1.0), the significance level. If the returned **pvalue** is less than this value, the null hypothesis, which assumes the variables are independent, is rejected.

Default: 0.05

Returns

The function returns two values:

- **pvalue** (float): the confidence that the two variables are independent. If this value is greater than the **alpha** parameter value, the null hypothesis is accepted and the variables are considered independent.
- **independent** (boolean): true if the variables are independent; otherwise, false.

Privileges

SELECT privileges on the input relation

Examples

The following examples use the **titanic** dataset from the machine learning example data. If you have not downloaded these datasets, see [Download the machine learning example data](#) for instructions.

The **titanic_training** table contains data related to passengers on the Titanic, including:

- **pclass** : the ticket class of the passenger, ranging from 1st class to 3rd class
- **survived** : whether the passenger survived, where 1 is yes and 0 is no
- **gender** : gender of the passenger
- **sibling_and_spouse_count** : number of siblings aboard the Titanic
- **embarkation_point** : port of embarkation

To test whether the survival of a passenger is dependent on their ticket class, run the following chi-square test:

```
=> SELECT CHI_SQUARED(pclass, survived USING PARAMETERS x_cardinality=3, y_cardinality=2, alpha=0.05) OVER() FROM titanic_training;
pvalue | independent
-----
0 | f
(1 row)
```

With a returned **pvalue** of zero, the null hypothesis is rejected and you can conclude that the **survived** and **pclass** variables are dependent. To test whether this outcome is conditional on the gender of the passenger, partition by the **gender** column in the OVER clause:

```
=> SELECT CHI_SQUARED(pclass, survived USING PARAMETERS x_cardinality=3, y_cardinality=2) OVER(PARTITION BY gender) FROM titanic;
pvalue | independent
-----
0 | f
(1 row)
```

As the **pvalue** is still zero, it is clear that the dependence of the **pclass** and **survived** variables is not conditional on the gender of the passenger.

If one of the categorical columns that you want to test is not a numeric type, use the **HASH** function to convert it into type INT:

```
-> SELECT CHI_SQUARED(sibling_and_spouse_count, HASH(embarkation_point) USING PARAMETERS alpha=0.05) OVER() FROM titanic_training;
  pvalue      | independent
-----+-----
0.0753039994044853 | 1
(1 row)
```

The returned **pvalue** is greater than **alpha** , meaning the null hypothesis is accepted and the **sibling_and_spouse_count** and **embarkation_point** are independent.

CORR_MATRIX

Takes an input relation with numeric columns, and calculates the *Pearson Correlation Coefficient* between each pair of its input columns. The function is implemented as a Multi-Phase Transform function.

Syntax

```
CORR_MATRIX ( input-columns ) OVER()
```

Arguments

input-columns

A comma-separated list of the columns in the input table. The input columns can be of any numeric type or BOOL, but they will be converted internally to FLOAT. The number of input columns must be more than 1 and not more than 1600.

Returns

CORR_MATRIX returns the correlation matrix in triplet format. That is, each pair-wise correlation is identified by three returned columns: name of the first variable, name of the second variable, and the correlation value of the pair. The function also returns two extra columns: **number_of_ignored_input_rows** and **number_of_processed_input_rows** . The value of the fourth/fifth column indicates the number of rows from the input which are ignored/used to calculate the corresponding correlation value. Any input pair with NULL, Inf, or NaN is ignored.

The correlation matrix is symmetric with a value of 1 on all diagonal elements; therefore, it can return only the value of elements above the diagonals—that is, the upper triangle. Nevertheless, the function returns the entire matrix to simplify any later operations. Then, the number of output rows is:

```
(#input-columns)^2
```

The first two output columns are of type VARCHAR(128), the third one is of type FLOAT, and the last two are of type INT.

Notes

- The contents of the OVER clause must be empty.
- The function returns no rows when the input table is empty.
- When any of X_i and Y_i is NULL, Inf, or NaN, the pair will not be included in the calculation of CORR(X, Y). That is, any input pair with NULL, Inf, or NaN is ignored.
- For the pair of (X,X), regardless of the contents of X: $CORR(X,X) = 1$, $number_of_ignored_input_rows = 0$, and $number_of_processed_input_rows = \#input_rows$.
- When $(N \sum X^2 == \sum X \sum X)$ or $(N \sum Y^2 == \sum Y \sum Y)$ then value of CORR(X, Y) will be NULL. In theory it can happen in case of a column with constant values; nevertheless, it may not be always observed because of rounding error.
- In the special case where all pair values of (X_i, Y_i) contain NULL, inf, or NaN, and $X \neq Y$: $CORR(X,Y)=NULL$.

Examples

The following example uses the [iris](#) dataset.*

```

SELECT CORR_MATRIX("Sepal.Length", "Sepal.Width", "Petal.Length", "Petal.Width") OVER() FROM iris;
variable_name_1 | variable_name_2 | corr_value      | number_of_ignored_input_rows | number_of_processed_input_rows
-----+-----+-----+-----+-----+-----
Sepal.Length   | Sepal.Width     |-0.117569784133002 | 0                             | 150
Sepal.Width    | Sepal.Length    |-0.117569784133002 | 0                             | 150
Sepal.Length   | Petal.Length    |0.871753775886583 | 0                             | 150

Petal.Length   | Petal.Length    |1                  | 0                             | 150
Petal.Width    | Petal.Width     |1                  | 0                             | 150
(16 rows)

```

DETECT_OUTLIERS

Returns the outliers in a data set based on the outlier threshold. The output is a table that contains the outliers. **DETECT_OUTLIERS** uses the detection method **robust_score** to normalize each input column. The function then identifies as outliers all rows that contain a normalized value greater than the default or specified threshold.

Note

You can calculate normalized column values with Vertica functions [NORMALIZE](#) and [NORMALIZE_FIT](#).

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```

DETECT_OUTLIERS ( 'output-table', 'input-relation', 'input-columns', 'detection-method'
  [ USING PARAMETERS
    [outlier_threshold = threshold]
    [, exclude_columns = 'excluded-columns']
    [, partition_columns = 'partition-columns'] ] )

```

Arguments

output-table

The name of the table where Vertica saves rows that are outliers along the chosen `input_columns` . All columns are present in this table.

input-relation

The table or view that contains outlier data. If the input relation is defined in Hive, use `SYNC_WITH_HCATALOG_SCHEMA` to sync the `hcatalog` schema, and then run the machine learning function.

input-columns

Comma-separated list of columns to use from the input relation, or asterisk (*) to select all columns. Input columns must be of type `numeric` .

detection-method

The outlier detection method to use, set to `robust_zscore` .

Parameters

outlier_threshold

The minimum normalized value in a row that is used to identify that row as an outlier.

Default: 3.0

exclude_columns

Comma-separated list of column names from `input-columns` to exclude from processing.

partition_columns

Comma-separated list of column names from the input table or view that defines the partitions. `DETECT_OUTLIERS` detects outliers among each partition separately.

Default: empty list

Privileges

Non-superusers:

- SELECT privileges on the input relation
- CREATE privileges on the output table

Examples

The following example shows how to use `DETECT_OUTLIERS` :

```
=> CREATE TABLE baseball_roster (id identity, last_name varchar(30), hr int, avg float);
```

```
CREATE TABLE
```

```
=> COPY baseball_roster FROM STDIN;
```

```
Enter data to be copied followed by a newline.
```

```
End with a backslash and a period on a line by itself.
```

```
>> Polo|7|.233
>> Gloss|45|.170
>> Gus|12|.345
>> Gee|1|.125
>> Laus|3|.095
>> Hilltop|16|.222
>> Wicker|78|.333
>> Scooter|0|.121
>> Hank|999999|.8888
>> Popup|35|.378
>> \.
```

```
=> SELECT * FROM baseball_roster;
```

```
id | last_name | hr | avg
-----+-----+-----
 3 | Gus      | 12 | 0.345
 4 | Gee      |  1 | 0.125
 6 | Hilltop  | 16 | 0.222
10 | Popup    | 35 | 0.378
 1 | Polo     |  7 | 0.233
 7 | Wicker   | 78 | 0.333
 9 | Hank     |999999| 0.8888
 2 | Gloss    | 45 | 0.17
 5 | Laus     |  3 | 0.095
 8 | Scooter  |  0 | 0.121
(10 rows)
```

```
=> SELECT DETECT_OUTLIERS('baseball_outliers', 'baseball_roster', 'id, hr, avg', 'robust_zscore' USING PARAMETERS
outlier_threshold=3.0);
```

```
DETECT_OUTLIERS
```

```
-----
Detected 2 outliers
(1 row)
```

```
=> SELECT * FROM baseball_outliers;
```

```
id | last_name | hr | avg
-----+-----+-----
 7 | Wicker   | 78 | 0.333
 9 | Hank     |999999| 0.8888
(2 rows)
```

IFOREST

Trains and returns an isolation forest (iForest) model. After you train the model, you can use the [APPLY_IFOREST](#) function to predict outliers in an input relation.

For more information about how the iForest algorithm works, see [Isolation Forest](#).

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
IFOREST( 'model-name', 'input-relation', 'input-columns'[ USING PARAMETERS param=value[...]] )
```

Arguments

model-name

Identifies the model to create, where *model-name* conforms to conventions described in [Identifiers](#). It must also be unique among all names of sequences, tables, projections, views, and models within the same schema.

input-relation

The table or view that contains the input data for IFOREST.

input-columns

Comma-separated list of columns to use from the input relation, or asterisk (*) to select all columns. Columns must be of types CHAR, VARCHAR, BOOL, INT, or FLOAT.

Columns of types CHAR, VARCHAR, and BOOL are treated as categorical features; all others are treated as numeric features.

Parameters

exclude_columns

Comma-separated list of column names from *input-columns* to exclude from processing.

Default: Empty string ("")

ntree

Integer in the range [1, 1000], specifies the number of trees in the forest.

Default: 100

sampling_size

Float in the range (0.0, 1.0], specifies the portion of the input data set that is randomly picked, without replacement, for training each tree.

Default: 0.632

col_sample_by_tree

Float in the range (0.0, 1.0], specifies the fraction of columns that are randomly picked for training each tree.

Default: 1.0

max_depth

Integer in the range [1, 100], specifies the maximum depth for growing each tree.

Default: 10

nbins

Integer in the range [2, 1000], specifies the number of bins used to discretize continuous features.

Default: 32

Model Attributes

details

Details about the function's predictor columns, including:

- **predictor** : Names of the predictors in the same order specified when training the model.
- **type** : Types of the predictors in the same order as their names in **predictor** .

tree_count

Number of trees in the model.

rejected_row_count

Number of rows in *input-relation* that were skipped because they contained an invalid value.

accepted_row_count

Total number of rows in *input-relation* minus **rejected_row_count** .

call_string

Value of all input arguments that were specified at the time the function was called.

Privileges

Non-superusers:

- CREATE privileges on the schema where the model is created

- SELECT privileges on the input relation

Examples

In the following example, the input data to the function contains columns of type INT, VARCHAR, and FLOAT:

```
=> SELECT IFOREST('baseball_anomalies','baseball','team, hr, hits, avg, salary' USING PARAMETERS ntree=75, sampling_size=0.7,
max_depth=15);
IFOREST
-----
Finished
(1 row)
```

You can verify that all the input columns were read in correctly by calling [GET_MODEL_SUMMARY](#) and checking the details section:

```
=> SELECT GET_MODEL_SUMMARY(USING PARAMETERS model_name='baseball_anomalies');
GET_MODEL_SUMMARY
-----
=====
call_string
=====
SELECT iforest('public.baseball_anomalies', 'baseball', 'team, hr, hits, avg, salary' USING PARAMETERS exclude_columns="", ntree=75,
sampling_size=0.7, col_sample_by_tree=1, max_depth=15, nbins=32);

=====
details
=====
predictor|  type
-----+-----
 team |char or varchar
  hr |  int
 hits |  int
  avg |float or numeric
 salary |float or numeric

=====

rejected_row_count| 0
accepted_row_count|1000

(1 row)
```

See also

- [Detect outliers](#)
- [APPLY_IFOREST](#)
- [READ_TREE](#)

IMPUTE

Imputes missing values in a data set with either the mean or the mode, based on observed values for a variable in each column. This function supports [numeric](#) and categorical data types.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
IMPUTE('output-view', 'input-relation', 'input-columns', 'method'
 [ USING PARAMETERS [exclude_columns = 'excluded-columns'] [, partition_columns = 'partition-columns'] ] )
```

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Arguments

output-view

Name of the view that shows the input table with imputed values in place of missing values. In this view, rows without missing values are kept intact while the rows with missing values are modified according to the specified method.

input-relation

The table or view that contains the data for missing-value imputation. If the input relation is defined in Hive, use [SYNC_WITH_HCATALOG_SCHEMA](#) to sync the `hcatalog` schema, and then run the machine learning function.

input-columns

Comma-separated list of input columns where missing values will be replaced, or asterisk (*) to specify all columns. All columns must be of type [numeric](#) or BOOLEAN.

method

The method to compute the missing value replacements, one of the following:

- **mean** : The missing values in each column will be replaced by the mean of that column. This method can be used for [numeric](#) data only.
- **mode** : The missing values in each column will be replaced by the most frequent value in that column. This method can be used for categorical data only.

Parameters

exclude_columns

Comma-separated list of column names from *input-columns* to exclude from processing.

partition_columns

Comma-separated list of column names from the input relation that defines the partitions.

Privileges

Non-superusers:

- SELECT privileges on the input relation
- CREATE privileges on the output view schema

Examples

Execute **IMPUTE** on the `small_input_impute` table, specifying the mean method:

```
=> SELECT impute('output_view','small_input_impute', 'pid, x1,x2,x3,x4','mean'
USING PARAMETERS exclude_columns='pid');
impute
-----
Finished in 1 iteration
(1 row)
```

Execute **IMPUTE** , specifying the mode method:

```
=> SELECT impute('output_view3','small_input_impute', 'pid, x5,x6','mode' USING PARAMETERS exclude_columns='pid');
impute
-----
Finished in 1 iteration
(1 row)
```

See also

[Imputing missing values](#)

NORMALIZE

Runs a normalization algorithm on an input relation. The output is a view with the normalized data.

Note

Note : This function differs from `NORMALIZE_FIT`, which creates and stores a model rather than creating a view definition. This can lead to different performance characteristics between the two functions.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
NORMALIZE ( 'output-view', 'input-relation', 'input-columns', 'normalization-method'  
           [ USING PARAMETERS exclude_columns = 'excluded-columns' ] )
```

Arguments

output-view

The name of the view showing the input relation with normalized data replacing the specified input columns. .

input-relation

The table or view that contains the data to normalize. If the input relation is defined in Hive, use [SYNC_WITH_HCATALOG_SCHEMA](#) to sync the `hcatalog` schema, and then run the machine learning function.

input-columns

Comma-separated list of [numeric](#) input columns that contain the values to normalize, or asterisk (*) to select all columns.

normalization-method

The normalization method to use, one of the following:

- [minmax](#)
- [zscore](#)
- [robust_zscore](#)

If infinity values appear in the table, the method ignores those values.

Parameters

exclude_columns

Comma-separated list of column names from [input-columns](#) to exclude from processing.

Privileges

Non-superusers:

- SELECT privileges on the input relation
- CREATE privileges on the output view schema

Examples

These examples show how you can use the NORMALIZE function on the `wt` and `hp` columns in the `mtcars` table.

Execute the NORMALIZE function, and specify the [minmax](#) method:

```
=> SELECT NORMALIZE('mtcars_norm', 'mtcars',  
                  'wt, hp', 'minmax');  
      NORMALIZE  
-----  
Finished in 1 iteration  
  
(1 row)
```

Execute the NORMALIZE function, and specify the [zscore](#) method:

```
=> SELECT NORMALIZE('mtcars_normz', 'mtcars',  
                  'wt, hp', 'zscore');  
      NORMALIZE  
-----  
Finished in 1 iteration  
  
(1 row)
```

Execute the NORMALIZE function, and specify the [robust_zscore](#) method:

```
=> SELECT NORMALIZE('mtcars_normz', 'mtcars',
                   'wt, hp', 'robust_zscore');
NORMALIZE
```

Finished in 1 iteration

(1 row)

[Normalizing data](#)

NORMALIZE_FIT

Note

This function differs from [NORMALIZE](#), which directly outputs a view with normalized results, rather than storing normalization parameters into a model for later operation.

NORMALIZE_FIT computes normalization parameters for each of the specified columns in an input relation. The resulting model stores the normalization parameters. For example, for **MinMax** normalization, the minimum and maximum value of each column are stored in the model. The generated model serves as input to functions [APPLY_NORMALIZE](#) and [REVERSE_NORMALIZE](#).

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
NORMALIZE_FIT ( 'model-name', 'input-relation', 'input-columns', 'normalization-method'
               [ USING PARAMETERS [exclude_columns = 'excluded-columns'] [, output_view = 'output-view'] ] )
```

Arguments

model-name

Identifies the model to create, where *model-name* conforms to conventions described in [Identifiers](#). It must also be unique among all names of sequences, tables, projections, views, and models within the same schema.

input-relation

The table or view that contains the data to normalize. If the input relation is defined in Hive, use [SYNC_WITH_HCATALOG_SCHEMA](#) to sync the *hcatalog* schema, and then run the machine learning function.

input-columns

Comma-separated list of columns to use from the input relation, or asterisk (*) to select all columns. Input columns must be of data type [numeric](#).

normalization-method

The normalization method to use, one of the following:

- **minmax**
- **zscore**
- **robust_zscore**

If you specify **robust_zscore**, **NORMALIZE_FIT** uses the function [APPROXIMATE_MEDIAN \[aggregate\]](#).

All normalization methods ignore infinity, negative infinity, or NULL values in the input relation.

Parameters

exclude_columns

Comma-separated list of column names from *input-columns* to exclude from processing.

output_view

Name of the view that contains all columns from the input relation, with the specified input columns normalized.

Model attributes

data

Normalization method set to **minmax** :

- **colNames** : Model column names

- **mins** : Minimum value of each column
- **maxes** : Maximum value of each column

Privileges

Non-superusers:

- CREATE privileges on the schema where the model is created
- SELECT privileges on the input relation
- CREATE privileges on the output view schema

Examples

The following example creates a model with **NORMALIZE_FIT** using the **wt** and **hp** columns in table **mtcars**, and then uses this model in successive calls to **APPLY_NORMALIZE** and **REVERSE_NORMALIZE**.

```
=> SELECT NORMALIZE_FIT('mtcars_normfit', 'mtcars', 'wt, hp', 'minmax');
NORMALIZE_FIT
-----
Success
(1 row)
```

The following call to **APPLY_NORMALIZE** specifies the **hp** and **cyl** columns in table **mtcars**, where **hp** is in the normalization model and **cyl** is not in the normalization model:

```
=> CREATE TABLE mtcars_normalized AS SELECT APPLY_NORMALIZE (hp, cyl USING PARAMETERS model_name = 'mtcars_normfit') FROM mtcars;
CREATE TABLE
=> SELECT * FROM mtcars_normalized;
   hp      | cyl

[Normalizing data](#)

ONE_HOT_ENCODER_FIT

Generates a sorted list of each of the category levels for each feature to be encoded, and stores the model.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
ONE_HOT_ENCODER_FIT ( 'model-name', 'input-relation', 'input-columns'
  [ USING PARAMETERS
    [exclude_columns = 'excluded-columns']
    [, output_view = 'output-view']
    [, extra_levels = 'category-levels'] ] )
```

Arguments

model-name

Identifies the model to create, where *model-name* conforms to conventions described in [Identifiers](#). It must also be unique among all names of sequences, tables, projections, views, and models within the same schema.

input-relation

The table or view that contains the data for one hot encoding. If the input relation is defined in Hive, use [SYNC_WITH_HCATALOG_SCHEMA](#) to sync the *hcatalog* schema, and then run the machine learning function.

input-columns

Comma-separated list of columns to use from the input relation, or asterisk (*) to select all columns. Input columns must be INTEGER, BOOLEAN, VARCHAR, or dates.

Parameters

exclude_columns

Comma-separated list of column names from *input-columns* to exclude from processing.

output_view

The name of the view that stores the input relation and the one hot encodings. Columns are returned in the order they appear in the input relation, with the one-hot encoded columns appended after the original columns.

extra_levels

Additional levels in each category that are not in the input relation. This parameter should be passed as a string that conforms with the JSON standard, with category names as keys, and lists of extra levels in each category as values.

Model attributes

call_string

The value of all input arguments that were specified at the time the function was called.

varchar_categories integer_categories boolean_categories date_categories

Settings for all:

- **category_name** : Column name
- **category_level** : Levels of the category, sorted for each category
- **category_level_index** : Index of this categorical level in the sorted list of levels for the category.

Privileges

Non-superusers:

- CREATE privileges on the schema where the model is created
- SELECT privileges on the input relation
- CREATE privileges on the output view schema

Examples

```
=> SELECT ONE_HOT_ENCODER_FIT ('one_hot_encoder_model','mtcars','*'
USING PARAMETERS exclude_columns='mpg,disp,drat,wt,qsec,vs,am');
ONE_HOT_ENCODER_FIT
-----
Success
(1 row)
```

See also

- [APPLY_ONE_HOT_ENCODER](#)
- [Encoding categorical columns](#)

PCA

Computes principal components from the input table/view. The results are saved in a PCA model. Internally, PCA finds the components by using SVD on the co-variance matrix built from the input data. The singular values of this decomposition are also saved as part of the PCA model. The signs of all elements of a principal component could be flipped all together on different runs.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
PCA ( 'model-name', 'input-relation', 'input-columns'
[ USING PARAMETERS
  [exclude_columns = 'excluded-columns']
  [, num_components = num-components]
  [, scale = is-scaled]
  [, method = 'method'] ] )
```

Arguments

model-name

Identifies the model to create, where *model-name* conforms to conventions described in [Identifiers](#). It must also be unique among all names of sequences, tables, projections, views, and models within the same schema.

input-relation

The table or view that contains the input data for PCA.

input-columns

Comma-separated list of columns to use from the input relation, or asterisk (*) to select all columns. All input columns must be a [numeric](#) data type.

Parameters

exclude_columns

Comma-separated list of column names from *input-columns* to exclude from processing.

num_components

The number of components to keep in the model. If this value is not provided, all components are kept. The maximum number of components is the number of non-zero singular values returned by the internal call to SVD. This number is less than or equal to SVD (number of columns, number of rows).

scale

A Boolean value that specifies whether to standardize the columns during the preparation step:

- **True** : Use a correlation matrix instead of a covariance matrix.
- **False** (default)

method

The method used to calculate PCA, can be set to **LAPACK**.

Model attributes

columns

The information about columns from the input relation used for creating the PCA model:

- index
- name

singular_values

The information about singular values found. They are sorted in descending order:

- index
- value
- explained_variance : percentage of the variance in data that can be attributed to this singular value
- accumulated_explained_variance : percentage of the variance in data that can be retained if we drop all singular values after this current one

principal_components

The principal components corresponding to the singular values mentioned above:

- index: indices of the elements in each component
- PC1
- PC2
- ...

counters

The information collected during training the model, stored as name-value pairs:

- counter_name
 - accepted_row_count: number of valid rows in the data
 - rejected_row_count: number of invalid rows (having NULL, INF or NaN) in the data
 - iteration_count: number of iterations, always 1 for the current implementation of PCA
- counter_value

call_string

The function call that created the model.

Privileges

Non-superusers:

- CREATE privileges on the schema where the model is created
- SELECT privileges on the input relation

Examples

```
=> SELECT PCA ('pcamodel', 'world','country,HDI,em1970,em1971,em1972,em1973,em1974,em1975,em1976,em1977,

SUMMARIZE_CATCOL

Returns a statistical summary of categorical data input, in three columns:

- CATEGORY: Categorical levels, of the same SQL data type as the summarized column
- COUNT: The number of category levels, of type INTEGER
- PERCENT: Represents category percentage, of type FLOAT

Syntax

```
SUMMARIZE_CATCOL (target-column
[ USING PARAMETERS TOPK = topk-value [, WITH_TOTALCOUNT = show-total] ] )
OVER()
```

Arguments

target-column

The name of the input column to summarize, one of the following data types:

- BOOLEAN
- FLOAT
- INTEGER
- DATE
- CHAR/VARCHAR

Parameters

TOPK

Integer, specifies how many of the most frequent rows to include in the output.

WITH_TOTALCOUNT

A Boolean value that specifies whether the table contains a heading row that displays the total number of rows displayed in the target column, and a percent equal to 100.

Default: `true`

Examples

This example shows the categorical summary for the `current_salary` column in the `salary_data` table. The output of the query shows the column category, count, and percent. The first column gives the categorical levels, with the same SQL data type as the input column, the second column gives a count of that value, and the third column gives a percentage.

```
=> SELECT SUMMARIZE_CATCOL (current_salary USING PARAMETERS TOPK = 5) OVER() FROM salary_data;
CATEGORY | COUNT | PERCENT
-----+-----+-----
      | 1000 | 100
39004 | 2 | 0.2
35321 | 1 | 0.1
36313 | 1 | 0.1
36538 | 1 | 0.1
36562 | 1 | 0.1
(6 rows)
```

SUMMARIZE_NUMCOL

Returns a statistical summary of columns in a Vertica table:

- Count
- Mean
- Standard deviation
- Min/max values
- Approximate percentile
- Median

All summary values are FLOAT data types, except INTEGER for count.

Syntax

```
SUMMARIZE_NUMCOL (input-columns [ USING PARAMETERS exclude_columns = 'excluded-columns' ] ) OVER()
```

Arguments

input-columns

Comma-separated list of columns to use from the input relation, or asterisk (*) to select all columns. All columns must be a [numeric](#) data type. If you select all columns, `SUMMARIZE_NUMCOL` normalizes all columns in the model

Parameters

`exclude_columns`

Comma-separated list of column names from *input-columns* to exclude from processing.

Examples

Show the statistical summary for the `age` and `salary` columns in the `employee` table:

```
=> SELECT SUMMARIZE_NUMCOL(* USING PARAMETERS exclude_columns='id,name,gender,title') OVER() FROM employee;
COLUMN      | COUNT | MEAN  | STDDEV  | MIN  | PERC25 | MEDIAN | PERC75 | MAX
-----+-----+-----+-----+-----+-----+-----+-----+-----
age         | 5 | 63.4 | 19.3209730603818 | 44 | 45 | 67 | 71 | 90
salary      | 5 | 3456.76 | 1756.78754300285 | 1234.56 | 2345.67 | 3456.78 | 4567.89 | 5678.9
(2 rows)
```

SVD

Computes singular values (the diagonal of the S matrix) and right singular vectors (the V matrix) of an SVD decomposition of the input relation. The results are saved as an SVD model. The signs of all elements of a singular vector in SVD could be flipped all together on different runs.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
SVD ( 'model-name', 'input-relation', 'input-columns'  
  [ USING PARAMETERS  
    [exclude_columns = 'excluded-columns']  
    [, num_components = num-components]  
    [, method = 'method'] ] )
```

Arguments

model-name

Identifies the model to create, where *model-name* conforms to conventions described in [Identifiers](#). It must also be unique among all names of sequences, tables, projections, views, and models within the same schema.

input-relation

The table or view that contains the input data for SVD.

input-columns

Comma-separated list of columns to use from the input relation, or asterisk (*) to select all columns. Input columns must be a [numeric](#) data type.

Parameters

exclude_columns

Comma-separated list of column names from *input-columns* to exclude from processing.

num_components

The number of components to keep in the model. The maximum number of components is the number of non-zero singular values computed, which is less than or equal to min (number of columns, number of rows). If you omit this parameter, all components are kept.

method

The method used to calculate SVD, can be set to [LAPACK](#).

Model attributes

columns

The information about columns from the input relation used for creating the SVD model:

- index
- name

singular_values

The information about singular values found. They are sorted in descending order:

- index
- value
- explained_variance : percentage of the variance in data that can be attributed to this singular value
- accumulated_explained_variance : percentage of the variance in data that can be retained if we drop all singular values after this current one

right_singular_vectors

The right singular vectors corresponding to the singular values mentioned above:

- index: indices of the elements in each vector
- vector1
- vector2
- ...

counters

The information collected during training the model, stored as name-value pairs:

- counter_name
 - accepted_row_count: number of valid rows in the data
 - rejected_row_count: number of invalid rows (having NULL, INF or NaN) in the data
 - iteration_count: number of iterations, always 1 for the current implementation of SVD
- counter_value

call_string

The function call that created the model.

Privileges

Non-superusers:

- CREATE privileges on the schema where the model is created
- SELECT privileges on the input relation

Examples

```
=> SELECT SVD ('svdmodel', 'small_svd', 'x1,x2,x3,x4');
SVD
-----
Finished in 1 iterations.
Accepted Rows: 8 Rejected Rows: 0
(1 row)

=> CREATE TABLE transform_svd AS SELECT
  APPLY_SVD (id, x1, x2, x3, x4 USING PARAMETERS model_name='svdmodel', exclude_columns='id', key_columns='id')
  OVER () FROM small_svd;
CREATE TABLE

=> SELECT * FROM transform_svd;

Machine learning algorithms

Vertica supports a full range of machine learning functions that train a model on a set of data, and return a model that can be saved for later execution.

These functions require the following privileges for non-superusers:

- CREATE privileges on the schema where the model is created
- SELECT privileges on the input relation

Note

Machine learning algorithms contain a subset of four [classification](#) functions:

- [LOGISTIC_REG](#)
- [NAIVE_BAYES](#)
- [RF_CLASSIFIER](#)
- [SVM_CLASSIFIER](#)

In this section

- [ARIMA](#)
- [AUTOREGRESSOR](#)
- [BISECTING_KMEANS](#)
- [KMEANS](#)
- [KPROTOTYPES](#)
- [LINEAR_REG](#)
- [LOGISTIC_REG](#)
- [MOVING_AVERAGE](#)
- [NAIVE_BAYES](#)
- [PLS_REG](#)
- [POISSON_REG](#)
- [RF_CLASSIFIER](#)
- [RF_REGRESSOR](#)
- [SVM_CLASSIFIER](#)
- [SVM_REGRESSOR](#)
- [XGB_CLASSIFIER](#)
- [XGB_REGRESSOR](#)

ARIMA

Creates and trains an autoregressive integrated moving average (ARIMA) model from a time series with consistent timesteps. ARIMA models combine the abilities of [AUTOREGRESSOR](#) and [MOVING_AVERAGE](#) models by making future predictions based on both preceding time series values and errors of previous predictions. ARIMA models also provide the option to apply a differencing operation to the input data, which can turn a non-stationary time series into a stationary time series. After the model is trained, you can make predictions with the [PREDICT_ARIMA](#) function.

In Vertica, ARIMA is implemented using a Kalman Filter state-space approach, similar to [Gardner, G., et al.](#) This approach updates the state-space model with each element in the training data in order to calculate a loss score over the training data. A [BFGS optimizer](#) is then used to adjust the coefficients, and the state-space estimation is rerun until convergence. Because of this repeated estimation process, ARIMA consumes large amounts of memory when called with high values of p and q .

Given that the input data must be sorted by timestamp, this algorithm is single-threaded.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Immutable](#)

Syntax

```
ARIMA('model-name', 'input-relation', 'timeseries-column', 'timestamp-column'  
      USING PARAMETERS param=value[,...] )
```

Arguments

model-name

Model to create, where *model-name* conforms to conventions described in [Identifiers](#). It must also be unique among all names of sequences, tables, projections, views, and models within the same schema.

input-relation

Name of the table or view containing *timeseries-column* and *timestamp-column*.

timeseries-column

Name of a NUMERIC column in *input-relation* that contains the dependent variable or outcome.

timestamp-column

Name of an INTEGER, FLOAT, or TIMESTAMP column in *input-relation* that represents the timestamp variable. The timestep between consecutive entries should be consistent throughout the *timestamp-column*.

Tip

If your *timestamp-column* has varying timesteps, consider standardizing the step size with the [TIME_SLICE](#) function.

Parameters

p

Integer in the range [0, 1000], the number of lags to include in the autoregressive component of the computation. If *q* is unspecified or set to zero, *p* must be set to a nonzero value. In some cases, using a large *p* value can result in a memory overload error.

Note

The [AUTOREGRESSOR](#) and [ARIMA](#) models use different training techniques that produce distinct models when trained with matching parameter values on the same data. For example, if you train an autoregressor model using the same data and *p* value as an ARIMA model trained with *d* and *q* parameters set to zero, those two models will not be identical.

Default: 0

d

Integer in the range [0, 10], the difference order of the model.

If the *timeseries-column* is a non-stationary time series, whose statistical properties change over time, you can specify a non-zero *d* value to difference the input data. This operation can remove or reduce trends in the time series data.

Differencing computes the differences between consecutive time series values and then trains the model on these values. The difference order *d*, where 0 implies no differencing, determines how many times to repeat the differencing operation. For example, second-order differencing takes the results of the first-order operation and differences these values again to obtain the second-order values. For an example that trains an ARIMA model that uses differencing, see [ARIMA model example](#).

Default: 0

q

Integer in the range [0, 1000], the number of lags to include in the moving average component of the computation. If *p* is unspecified or set to zero, *q* must be set to a nonzero value. In some cases, using a large *q* value can result in a memory overload error.

Note

The [MOVING_AVERAGE](#) and [ARIMA](#) models use different training techniques that produce distinct models when trained with matching parameter values on the same data. For example, if you train a moving-average model using the same data and *q* value as an ARIMA model trained with *p* and *d* parameters set to zero, those two models will not be identical.

Default: 0

missing

Method for handling missing values, one of the following strings:

- 'drop': Missing values are ignored.
- 'raise': Missing values raise an error.
- 'zero': Missing values are set to zero.
- 'linear_interpolation': Missing values are replaced by a linearly interpolated value based on the nearest valid entries before and after the missing value. In cases where the first or last values in a dataset are missing, the function errors.

Default: 'linear_interpolation'

init_method

Initialization method, one of the following strings:

- 'Zero': Coefficients are initialized to zero.
- 'Hannan-Rissanen' or 'HR': Coefficients are initialized using the Hannan-Rissanen algorithm.

Default: 'Zero'

epsilon

Float in the range (0.0, 1.0), controls the convergence criteria of the optimization algorithm.

Default: 1e-6

max_iterations

Integer in the range [1, 1000000), the maximum number of training iterations. If you set this value too low, the algorithm might not converge.

Default: 100

Model attributes

coefficients

Coefficients of the model:

- **phi** : parameters for the autoregressive component of the computation. The number of returned **phi** values is equal to the value of **p**.
- **theta** : parameters for the moving average component of the computation. The number of returned **theta** values is equal to the value of **q**.

p, q, d

ARIMA component values:

- **p** : number of lags included in the autoregressive component of the computation
- **d** : difference order of the model
- **q** : number of lags included in the moving average component of the computation

mean

The model mean, average of the accepted sample values from *timeseries-column*

regularization

Type of regularization used when training the model

lambda

Regularization parameter. Higher values indicates stronger regularization.

mean_squared_error

Mean squared error of the model on the training set

rejected_row_count

Number of samples rejected during training

accepted_row_count

Number of samples accepted for training from the data set

timeseries_name

Name of the *timeseries-column* used to train the model

timestamp_name

Name of the *timestamp-column* used to train the model

missing_method

Method used for handling missing values

call_string

SQL statement used to train the model

Examples

The function requires that at least one of the **p** and **q** parameters be a positive, nonzero integer. The following example trains a model where both of these parameters are set to two:

```
=> SELECT ARIMA('arima_temp', 'temp_data', 'temperature', 'time' USING PARAMETERS p=2, q=2);
      ARIMA
-----
Finished in 24 iterations.
3650 elements accepted, 0 elements rejected.
(1 row)
```

To see a summary of the model, including all model coefficients and parameter values, call [GET_MODEL_SUMMARY](#):

```
=> SELECT GET_MODEL_SUMMARY(USING PARAMETERS model_name='arima_temp');
      GET_MODEL_SUMMARY
-----

For an in-depth example that trains and makes predictions with ARIMA models, see [ARIMA model example](#).

See also

- [Time series forecasting](#)
- [GET_MODEL_ATTRIBUTE](#)

AUTOREGRESSOR

Creates and trains an autoregression (AR) or vector autoregression (VAR) model, depending on the number of provided value columns:

- One value column: the function executes autoregression and returns a trained AR model. AR is a univariate autoregressive time series algorithm that predicts a variable's future values based on its preceding values. The user specifies the number of lagged timesteps taken into account during computation, and the model then predicts future values as a linear combination of the values at each lag.
- Multiple value columns: the function executes vector autoregression and returns a trained VAR model. VAR is a multivariate autoregressive time series algorithm that captures the relationship between multiple time series variables over time. Unlike AR, which only considers a single variable, VAR models incorporate feedback between different variables in the model, enabling the model to analyze how variables interact across lagged time steps. For example, with two variables—atmospheric pressure and rain accumulation—a VAR model could determine whether a drop in pressure tends to result in rain at a future date.

To make predictions with a VAR or AR model, use the [PREDICT_AUTOREGRESSOR](#) function.

Because the input data must be sorted by timestamp, this function is single-threaded.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
AUTOREGRESSOR ('model-name', 'input-relation', 'value-columns', 'timestamp-column'  
[ USING PARAMETERS param=value[...] ] )
```

Arguments

model-name

Identifies the model to create, where *model-name* conforms to conventions described in [Identifiers](#). It must also be unique among all names of sequences, tables, projections, views, and models within the same schema.

input-relation

The table or view containing *timestamp-column* and *value-columns*.

This algorithm expects a stationary time series as input; using a time series with a mean that shifts over time may lead to weaker results.

value-columns

Comma-separated list of one or more NUMERIC input columns that contain the dependent variables or outcomes.

The number of value columns determines whether the function performs the autoregression (AR) or vector autoregression (VAR) algorithm. If only one input column is provided, the function executes autoregression. For multiple input columns, the function performs the VAR algorithm.

timestamp-column

Name of an INTEGER, FLOAT, or TIMESTAMP column in *input-relation* that represents the timestamp variable. The timestep between consecutive entries must be consistent throughout the *timestamp-column*.

Tip

If your *timestamp-column* has varying timesteps, consider standardizing the step size with the [TIME_SLICE](#) function.

Parameters

p

INTEGER in the range [1, 1999], the number of lags to consider in the computation. Larger values for **p** weaken the correlation.

Note

The [AUTOREGRESSOR](#) and [ARIMA](#) models use different training techniques that produce distinct models when trained with matching parameter values on the same data. For example, if you train an autoregressor model using the same data and **p** value as an ARIMA model trained with **d** and **q** parameters set to zero, those two models will not be identical.

Default: 3

method

One of the following algorithms for training the model:

- 'OLS' (Ordinary Least Squares): default for AR models; not supported for VAR models.
- 'Yule-Walker': default for VAR models. Sets the alpha constant in the trained model to 0.0.

missing

One of the following methods for handling missing values:

- 'drop': Missing values are ignored.
- 'error': Missing values raise an error.
- 'zero': Missing values are replaced with 0.
- 'linear_interpolation': Missing values are replaced by linearly-interpolated values based on the nearest valid entries before and after the missing value. This means that in cases where the first or last values in a dataset are missing, they will simply be dropped. The VAR algorithm does not support linear interpolation.

The default method depends on the model type:

- AR: 'linear_interpolation'
- VAR: 'error'

regularization

For the OLS training method only, one of the following regularization methods used when fitting the data:

- None
- 'L2': Weight regularization term which penalizes the squared weight value

Default: None

lambda

For the OLS training method only, FLOAT in the range [0, 100000], the regularization value, lambda.

Default: 1.0

compute_mse

BOOLEAN, whether to calculate and output the mean squared error (MSE).

Default: False

subtract_mean

BOOLEAN, whether the mean of each column in *value-columns* is subtracted from its column values before calculating the model coefficients. This parameter only applies if *method* is set to 'Yule-Walker'. If set to False, the model saves the column means as zero.

Default: False

Examples

The following example creates and trains an autoregression model using the Yule-Walker training algorithm and a lag of 3:

```
-> SELECT AUTOREGRESSOR('AR_temperature_yw', 'temp_data', 'Temperature', 'time' USING PARAMETERS p=3, method='yule-walker');
      AUTOREGRESSOR
-----
Finished. 3650 elements accepted, 0 elements rejected.

(1 row)
```

The following example creates and trains a VAR model with a lag of 2:

```
-> SELECT AUTOREGRESSOR('VAR_temperature', 'temp_data_VAR', 'temp_location1', 'temp_location2', 'time' USING PARAMETERS p=2),
WARNING 0: Only the Yule Walker method is currently supported for Vector Autoregression, setting method to Yule Walker
      AUTOREGRESSOR
-----
Finished. 3650 elements accepted, 0 elements rejected.

(1 row)
```

See [Autoregressive model example](#) and [VAR model example](#) for extended examples that train and make predictions with AR and VAR models.

- [GET_MODEL_SUMMARY](#)

BISECTING_KMEANS

Executes the bisecting k-means algorithm on an input relation. The result is a trained model with a hierarchy of cluster centers, with a range of k values, each of which can be used for prediction.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
BISECTING_KMEANS('model-name', 'input-relation', 'input-columns', 'num-clusters'
  [ USING PARAMETERS
    [exclude_columns = 'exclude-columns']
    [, bisection_iterations = bisection-iterations]
    [, split_method = 'split-method']
    [, min_divisible_cluster_size = min-cluster-size]
    [, kmeans_max_iterations = kmeans-max-iterations]
    [, kmeans_epsilon = kmeans-epsilon]
    [, kmeans_center_init_method = 'kmeans-init-method']
    [, distance_method = 'distance-method']
    [, output_view = 'output-view']
    [, key_columns = 'key-columns' ] ] )
```

Arguments

model-name

Identifies the model to create, where *model-name* conforms to conventions described in [Identifiers](#). It must also be unique among all names of sequences, tables, projections, views, and models within the same schema.

input-relation

Table or view that contains the input data for k-means. If the input relation is defined in Hive, use [SYNC_WITH_HCATALOG_SCHEMA](#) to sync the `hcatalog` schema, and then run the machine learning function.

input-columns

Comma-separated list of columns to use from the input relation, or asterisk (*) to select all columns. Input columns must be of data type [numeric](#).

num-clusters

Number of clusters to create, an integer $\leq 10,000$. This argument represents the k in k-means.

Parameters

exclude_columns

Comma-separated list of column names from *input-columns* to exclude from processing.

bisection_iterations

Integer between 1 - 1MM inclusive, specifies number of iterations the bisecting k-means algorithm performs for each bisection step. This corresponds to how many times a standalone k-means algorithm runs in each bisection step.

A setting >1 allows the algorithm to run and choose the best k-means run within each bisection step. If you use `kmeanspp`, the value of `bisection_iterations` is always 1, because `kmeanspp` is more costly to run but also better than the alternatives, so it does not require multiple runs.

Default: 1

split_method

The method used to choose a cluster to bisect/split, one of:

- `size` : Choose the largest cluster to bisect.
- `sum_squares` : Choose the cluster with the largest within-cluster sum of squares to bisect.

Default: `sum_squares`

min_divisible_cluster_size

Integer ≥ 2 , specifies minimum number of points of a divisible cluster.

Default: 2

kmeans_max_iterations

Integer between 1 and 1MM inclusive, specifies the maximum number of iterations the k-means algorithm performs. If you set this value to a number lower than the number of iterations needed for convergence, the algorithm might not converge.

Default: 10

kmeans_epsilon

Integer between 1 and 1MM inclusive, determines whether the k-means algorithm has converged. The algorithm is considered converged after no center has moved more than a distance of *epsilon* from the previous iteration.

Default: 1e-4

kmeans_center_init_method

The method used to find the initial cluster centers in k-means, one of:

- **kmeanspp** (default): kmeans++ algorithm
- **pseudo** : Uses "pseudo center" approach used by Spark, bisects given center without iterating over points

distance_method

The measure for distance between two data points. Only Euclidean distance is supported at this time.

Default: **euclidean**

output_view

Name of the view where you save the assignment of each point to its cluster. You must have CREATE privileges on the view schema.

key_columns

Comma-separated list of column names that identify the output rows. Columns must be in the *input-columns* argument list. To exclude these and other input columns from being used by the algorithm, list them in parameter *exclude_columns* .

Model attributes

centers

A list of centers of the K centroids.

hierarchy

The hierarchy of K clusters, including:

- **ParentCluster**: Parent cluster centroid of each centroid—that is, the centroid of the cluster from which a cluster is obtained by bisection.
- **LeftChildCluster**: Left child cluster centroid of each centroid—that is, the centroid of the first sub-cluster obtained by bisecting a cluster.
- **RightChildCluster**: the right child cluster centroid of each centroid—that is, the centroid of the second sub-cluster obtained by bisecting a cluster.
- **BisectionLevel**: Specifies which bisection step a cluster is obtained from.
- **WithinSS**: Within-cluster sum of squares for the current cluster
- **TotalWithinSS**: Total within-cluster sum of squares of leaf clusters thus far obtained.

metrics

Several metrics related to the quality of the clustering, including

- Total sum of squares
- Total within-cluster sum of squares
- Between-cluster sum of squares
- Between-cluster sum of squares / Total sum of squares
- Sum of squares for cluster *x*, center_id *y* [...]

Examples

```
SELECT BISECTING_KMEANS('myModel', 'iris1', '**', '5'  
  USING PARAMETERS exclude_columns = 'Species,id', split_method = 'sum_squares', output_view = 'myBKmeansView');
```

See also

- [Clustering data hierarchically using bisecting k-means](#)
- [APPLY_BISECTING_KMEANS](#)

KMEANS

Executes the k-means algorithm on an input relation. The result is a model with a list of cluster centers.

You can export the resulting k-means model in VERTICA_MODELS or PMML format to apply it on data outside Vertica. You can also train a k-means model elsewhere, then import it to Vertica in PMML format to predict on data in Vertica.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
KMEANS ( 'model-name', 'input-relation', 'input-columns', 'num-clusters'  
  [ USING PARAMETERS  
    [exclude_columns = 'excluded-columns']  
    [, max_iterations = max-iterations]  
    [, epsilon = epsilon-value]  
    [, { init_method = 'init-method' } | { initial_centers_table = 'init-table' } ]  
    [, output_view = 'output-view']  
    [, key_columns = 'key-columns' ] ] )
```

Arguments

model-name

Identifies the model to create, where *model-name* conforms to conventions described in [Identifiers](#). It must also be unique among all names of sequences, tables, projections, views, and models within the same schema.

input-relation

The table or view that contains the input data for k-means. If the input relation is defined in Hive, use [SYNC_WITH_HCATALOG_SCHEMA](#) to sync the `hcatalog` schema, and then run the machine learning function.

input-columns

Comma-separated list of columns to use from the input relation, or asterisk (*) to select all columns. Input columns must be of data type [numeric](#).

num-clusters

The number of clusters to create, an integer $\leq 10,000$. This argument represents the *k* in k-means.

Parameters

Important

Parameters `init_method` and `initial_centers_table` are mutually exclusive. If you set both, the function returns an error.

exclude_columns

Comma-separated list of column names from *input-columns* to exclude from processing.

max_iterations

The maximum number of iterations the algorithm performs. If you set this value to a number lower than the number of iterations needed for convergence, the algorithm may not converge.

Default: 10

epsilon

Determines whether the algorithm has converged. The algorithm is considered converged after no center has moved more than a distance of 'epsilon' from the previous iteration.

Default: 1e-4

init_method

The method used to find the initial cluster centers, one of the following:

- `random`
- `kmeanspp` (default): kmeans++ algorithm

This value can be memory intensive for high *k*. If the function returns an error that not enough memory is available, decrease the value of *k* or use the `random` method.

initial_centers_table

The table with the initial cluster centers to use. Supply this value if you know the initial centers to use and do not want Vertica to find the initial cluster centers for you.

output_view

The name of the view where you save the assignments of each point to its cluster. You must have CREATE privileges on the schema where the view is saved.

key_columns

Comma-separated list of column names from *input-columns* that will appear as the columns of `output_view`. These columns should be picked

such that their contents identify each input data point. This parameter is only used if `output_view` is specified. Columns listed in `input-columns` that are only meant to be used as `key_columns` and not for training should be listed in `exclude_columns`.

Model attributes

centers

A list that contains the center of each cluster.

metrics

A string summary of several metrics related to the quality of the clustering.

Examples

The following example creates k-means model `myKmeansModel` and applies it to input table `iris1`. The call to `APPLY_KMEANS` mixes column names and constants. When a constant is passed in place of a column name, the constant is substituted for the value of the column in all rows:

```
=> SELECT KMEANS('myKmeansModel', 'iris1', '*', 5
USING PARAMETERS max_iterations=20, output_view='myKmeansView', key_columns='id', exclude_columns='Species, id');
      KMEANS
```

```
-----
Finished in 12 iterations
```

(1 row)

```
=> SELECT id, APPLY_KMEANS(Sepal_Length, 2.2, 1.3, Petal_Width
USING PARAMETERS model_name='myKmeansModel', match_by_pos='true') FROM iris2;
id | APPLY_KMEANS
```

```
-----+-----
5 |      1
10 |     1
14 |     1
15 |     1
21 |     1
22 |     1
24 |     1
25 |     1
32 |     1
33 |     1
34 |     1
35 |     1
38 |     1
39 |     1
42 |     1
...
(60 rows)
```

KPROTOTYPES

Executes the k-prototypes algorithm on an input relation. The result is a model with a list of cluster centers.

This is a meta-function. You must call meta-functions in a top-level `SELECT` statement.

Syntax

```
SELECT KPROTOTYPES ('*'`model-name`*', '*'`input-relation`*', '*'`input-columns`*', '*'`num-clusters`*'
  [USING PARAMETERS [exclude_columns = '*'`exclude-columns`*']
  [, max_iterations = '*'`max-iterations`*']
  [, epsilon = '*'`epsilon`*']
  [, {[init_method = '*'`init-method`*'} | { initial_centers_table = '*'`init-table`*'} ]
  [, gamma = '*'`gamma`*']
  [, output_view = '*'`output-view`*']
  [, key_columns = '*'`key-columns`*']);
```

Behavior type

[Volatile](#)

Arguments

model-name

Name of the model resulting from the training.

input-relation

Name of the table or view containing the training samples.

input-columns

String containing a comma-separated list of columns to use from the input-relation, or asterisk (*) to select all columns.

num-clusters

Integer $\leq 10,000$ representing the number of clusters to create. This argument represents the k in k-prototypes.

Parameters

exclude-columns

String containing a comma-separated list of column names from input-columns to exclude from processing.

Default: (empty)

max_iterations

Integer $\leq 1M$ representing the maximum number of iterations the algorithm performs.

Default: Integer $\leq 1M$

epsilon

Integer which determines whether the algorithm has converged.

Default: 1e-4

init_method

String specifying the method used to find the initial k-prototypes cluster centers.

Default: "random"

initial_centers_table

The table with the initial cluster centers to use.

gamma

Float between 0 and 10000 specifying the weighing factor for categorical columns. It can determine relative importance of numerical and categorical attributes

Default: Inferred from data.

output_view

The name of the view where you save the assignments of each point to its cluster

key_columns

Comma-separated list of column names that identify the output rows. Columns must be in the input-columns argument list

Examples

The following example creates k-prototypes model `small_model` and applies it to input table `small_test_mixed` :

```
=> SELECT KPROTOTYPES('small_model_initcenters', 'small_test_mixed', 'x0, country', 3 USING PARAMETERS
initial_centers_table='small_test_mixed_centers', key_columns='pid');
KPROTOTYPES
-----
Finished in 2 iterations

(1 row)

=> SELECT country, x0, APPLY_KPROTOTYPES(country, x0
USING PARAMETERS model_name='small_model')
FROM small_test_mixed;
country | x0 | apply_kprototypes
-----+-----+-----
'China' | 20 | 0
'US'    | 85 | 2
'Russia'| 80 | 1
'Brazil'| 78 | 1
'US'    | 23 | 0
'US'    | 50 | 0
'Canada'| 24 | 0
'Canada'| 18 | 0
'Russia'| 90 | 2
'Russia'| 98 | 2
'Brazil'| 89 | 2
...
(45 rows)
```

See also

- [APPLY_KPROTOTYPES](#)
- [KMEANS](#)
- [GET_MODEL_SUMMARY](#)

LINEAR_REG

Executes linear regression on an input relation, and returns a linear regression model.

You can export the resulting linear regression model in VERTICA_MODELS or PMML format to apply it on data outside Vertica. You can also train a linear regression model elsewhere, then import it to Vertica in PMML format to model on data inside Vertica.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
LINEAR_REG ( 'model-name', 'input-relation', 'response-column', 'predictor-columns'
[ USING PARAMETERS
  [exclude_columns = 'excluded-columns']
  [, optimizer = 'optimizer-method']
  [, regularization = 'regularization-method']
  [, epsilon = epsilon-value]
  [, max_iterations = iterations]
  [, lambda = lamda-value]
  [, alpha = alpha-value]
  [, fit_intercept = boolean-value] ] )
```

Arguments

model-name

Identifies the model to create, where *model-name* conforms to conventions described in [Identifiers](#). It must also be unique among all names of sequences, tables, projections, views, and models within the same schema.

input-relation

Table or view that contains the training data for building the model. If the input relation is defined in Hive, use

[SYNC_WITH_HCATALOG_SCHEMA](#) to sync the `hcatalog` schema, and then run the machine learning function.

response-column

Name of the input column that represents the dependent variable or outcome. All values in this column must be [numeric](#), otherwise the model is invalid.

predictor-columns

Comma-separated list of columns in the input relation that represent independent variables for the model, or asterisk (*) to select all columns. If you select all columns, the argument list for parameter `exclude_columns` must include `response-column`, and any columns that are invalid as predictor columns.

All predictor columns must be of type [numeric](#) or BOOLEAN; otherwise the model is invalid.

Note

All BOOLEAN predictor values are converted to FLOAT values before training: 0 for false, 1 for true. No type checking occurs during prediction, so you can use a BOOLEAN predictor column in training, and during prediction provide a FLOAT column of the same name. In this case, all FLOAT values must be either 0 or 1.

Parameters

exclude_columns

Comma-separated list of columns from `predictor-columns` to exclude from processing.

optimizer

Optimizer method used to train the model, one of the following:

- [Newton](#)
- [BFGS](#)
- [CGD](#)

Important

If you select `CGD`, `regularization-method` must be set to `L1` or `ENet`, otherwise the function returns an error.

Default: `CGD` if `regularization-method` is set to `L1` or `ENet`, otherwise `Newton`.

regularization

Method of regularization, one of the following:

- `None` (default)
- `L1`
- `L2`
- `ENet`

epsilon

FLOAT in the range (0.0, 1.0), the error value at which to stop training. Training stops if either the difference between the actual and predicted values is less than or equal to `epsilon` or if the number of iterations exceeds `max_iterations`.

Default: 1e-6

max_iterations

INTEGER in the range (0, 1000000), the maximum number of training iterations. Training stops if either the number of iterations exceeds `max_iterations` or if the difference between the actual and predicted values is less than or equal to `epsilon`.

Default: 100

lambda

Integer ≥ 0 , specifies the value of the `regularization` parameter.

Default: 1

alpha

Integer ≥ 0 , specifies the value of the ENET `regularization` parameter, which defines how much L1 versus L2 regularization to provide. A value of 1 is equivalent to L1 and a value of 0 is equivalent to L2.

Value range: [0,1]

Default: 0.5

fit_intercept

Boolean, specifies whether the model includes an intercept. By setting to false, no intercept will be used in training the model. Note that setting `fit_intercept` to false does not work well with the BFGS optimizer.

Default: True

Model attributes

data

The data for the function, including:

- `coeffNames` : Name of the coefficients. This starts with intercept and then follows with the names of the predictors in the same order specified in the call.
- `coeff` : Vector of estimated coefficients, with the same order as `coeffNames`
- `stdErr` : Vector of the standard error of the coefficients, with the same order as `coeffNames`
- `zValue` (for logistic regression): Vector of z-values of the coefficients, in the same order as `coeffNames`
- `tValue` (for linear regression): Vector of t-values of the coefficients, in the same order as `coeffNames`
- `pValue` : Vector of p-values of the coefficients, in the same order as `coeffNames`

regularization

Type of regularization to use when training the model.

lambda

Regularization parameter. Higher values enforce stronger regularization. This value must be nonnegative.

alpha

Elastic net mixture parameter.

iterations

Number of iterations that actually occur for the convergence before exceeding `max_iterations` .

skippedRows

Number of rows of the input relation that were skipped because they contained an invalid value.

processedRows

Total number of input relation rows minus `skippedRows` .

callStr

Value of all input arguments specified when the function was called.

Examples

```
=> SELECT LINEAR_REG('myLinearRegModel', 'faithful', 'eruptions', 'waiting'  
      USING PARAMETERS optimizer='BFGS', fit_intercept=true);  
      LINEAR_REG  
-----  
Finished in 10 iterations  
  
(1 row)
```

See also

- [Building a linear regression model](#)
- [PREDICT_LINEAR_REG](#)
- [PREDICT_PMML](#)
- [IMPORT_MODELS](#)
- [EXPORT_MODELS](#)

LOGISTIC_REG

Executes logistic regression on an input relation. The result is a logistic regression model.

You can export the resulting logistic regression model in VERTICA_MODELS or PMML format to apply it on data outside Vertica. You can also train a logistic regression model elsewhere, then import it to Vertica in PMML format to predict on data in Vertica.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
LOGISTIC_REG ( 'model-name', 'input-relation', 'response-column', 'predictor-columns'  
  [ USING PARAMETERS [exclude_columns = 'excluded-columns']  
    [, optimizer = 'optimizer-method']  
    [, regularization = 'regularization-method']  
    [, epsilon = epsilon-value]  
    [, max_iterations = iterations]  
    [, lambda = lamda-value]  
    [, alpha = alpha-value]  
    [, fit_intercept = boolean-value] ] )
```

Arguments

model-name

Identifies the model to create, where *model-name* conforms to conventions described in [Identifiers](#). It must also be unique among all names of sequences, tables, projections, views, and models within the same schema.

input-relation

The table or view that contains the training data for building the model. If the input relation is defined in Hive, use [SYNC_WITH_HCATALOG_SCHEMA](#) to sync the *hcatalog* schema, and then run the machine learning function.

response-column

The input column that represents the dependent variable or outcome. The column value must be 0 or 1, and of type [numeric](#) or BOOLEAN. The function automatically skips all other values.

predictor-columns

Comma-separated list of columns in the input relation that represent independent variables for the model, or asterisk (*) to select all columns. If you select all columns, the argument list for parameter *exclude_columns* must include *response-column*, and any columns that are invalid as predictor columns.

All predictor columns must be of type [numeric](#) or BOOLEAN; otherwise the model is invalid.

Note

All BOOLEAN predictor values are converted to FLOAT values before training: 0 for false, 1 for true. No type checking occurs during prediction, so you can use a BOOLEAN predictor column in training, and during prediction provide a FLOAT column of the same name. In this case, all FLOAT values must be either 0 or 1.

Parameters

exclude_columns

Comma-separated list of columns from *predictor-columns* to exclude from processing.

optimizer

The optimizer method used to train the model, one of the following:

- [Newton](#)
- [BFGS](#)
- [CGD](#)

Important

If you select *CGD*, *regularization-method* must be set to *L1* or *ENet*, otherwise the function returns an error.

Default: *CGD* if *regularization-method* is set to *L1* or *ENet*, otherwise *Newton*.

regularization

The method of regularization, one of the following:

- *None* (default)
- *L1*
- *L2*
- *ENet*

epsilon

FLOAT in the range (0.0, 1.0), the error value at which to stop training. Training stops if either the difference between the actual and predicted values is less than or equal to *epsilon* or if the number of iterations exceeds *max_iterations*.

Default: 1e-6

max_iterations

INTEGER in the range (0, 1000000), the maximum number of training iterations. Training stops if either the number of iterations exceeds **max_iterations** or if the difference between the actual and predicted values is less than or equal to **epsilon** .

Default: 100

lambda

Integer ≥ 0 , specifies the value of the **regularization** parameter.

Default: 1

alpha

Integer ≥ 0 , specifies the value of the ENET **regularization** parameter, which defines how much L1 versus L2 regularization to provide. A value of 1 is equivalent to L1 and a value of 0 is equivalent to L2.

Value range: [0,1]

Default: 0.5

fit_intercept

Boolean, specifies whether the model includes an intercept. By setting to false, no intercept will be used in training the model. Note that setting **fit_intercept** to false does not work well with the BFGS optimizer.

Default: True

Model attributes

data

The data for the function, including:

- **coeffNames** : Name of the coefficients. This starts with intercept and then follows with the names of the predictors in the same order specified in the call.
- **coeff** : Vector of estimated coefficients, with the same order as **coeffNames**
- **stdErr** : Vector of the standard error of the coefficients, with the same order as **coeffNames**
- **zValue** (for logistic regression): Vector of z-values of the coefficients, in the same order as **coeffNames**
- **tValue** (for linear regression): Vector of t-values of the coefficients, in the same order as **coeffNames**
- **pValue** : Vector of p-values of the coefficients, in the same order as **coeffNames**

regularization

Type of regularization to use when training the model.

lambda

Regularization parameter. Higher values enforce stronger regularization. This value must be nonnegative.

alpha

Elastic net mixture parameter.

iterations

Number of iterations that actually occur for the convergence before exceeding **max_iterations** .

skippedRows

Number of rows of the input relation that were skipped because they contained an invalid value.

processedRows

Total number of input relation rows minus **skippedRows** .

callStr

Value of all input arguments specified when the function was called.

Privileges

Superuser, or SELECT privileges on the input relation

Examples

```
=> SELECT LOGISTIC_REG('myLogisticRegModel', 'mtcars', 'am',
    'mpg, cyl, disp, hp, drat, wt, qsec, vs, gear, carb'
    USING PARAMETERS exclude_columns='hp', optimizer='BFGS', fit_intercept=true);
LOGISTIC_REG
```

Finished in 20 iterations

(1 row)

See also

- [Building a logistic regression model](#)
- [PREDICT_LOGISTIC_REG](#)
- [PREDICT_PMML](#)
- [IMPORT_MODELS](#)
- [EXPORT_MODELS](#)

MOVING_AVERAGE

Creates a moving-average (MA) model from a stationary time series with consistent timesteps that can then be used for prediction via [PREDICT_MOVING_AVERAGE](#).

Moving average models use the errors of previous predictions to make future predictions. More specifically, the user-specified *lag* determines how many previous predictions and errors it takes into account during computation.

Since its input data must be sorted by timestamp, this algorithm is single-threaded.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
MOVING_AVERAGE ('model-name', 'input-relation', 'data-column', 'timestamp-column'
  [ USING PARAMETERS
    [ q = lags ]
    [, missing = "imputation-method" ]
    [, regularization = "regularization-method" ]
    [, lambda = regularization-value ]
    [, compute_mse = boolean ]
  ])
```

Arguments

model-name

Identifies the model to create, where *model-name* conforms to conventions described in [Identifiers](#). It must also be unique among all names of sequences, tables, projections, views, and models within the same schema.

input-relation

The table or view containing the *timestamp-column*.

This algorithm expects a stationary time series as input; using a time series with a mean that shifts over time may lead to weaker results.

data-column

An input column of type NUMERIC that contains the dependent variables or outcomes.

timestamp-column

One INTEGER, FLOAT, or TIMESTAMP column that represent the timestamp variable. Timesteps must be consistent.

Parameters

q

INTEGER in the range [1, 67), the number of lags to consider in the computation.

Note

The [MOVING_AVERAGE](#) and [ARIMA](#) models use different training techniques that produce distinct models when trained with matching parameter values on the same data. For example, if you train a moving-average model using the same data and *q* value as an ARIMA model trained with *p* and *d* parameters set to zero, those two models will not be identical.

Default: 1

missing

One of the following methods for handling missing values:

- **drop** : Missing values are ignored.
- **error** : Missing values raise an error.
- **zero** : Missing values are replaced with 0.
- **linear_interpolation** : Missing values are replaced by linearly interpolated values based on the nearest valid entries before and after the missing value. This means that in cases where the first or last values in a dataset are missing, they will simply be dropped.

Default: linear_interpolation

regularization

One of the following regularization methods used when fitting the data:

- **None**
- **L2** : weight regularization term which penalizes the squared weight value

Default: None

lambda

FLOAT in the range [0, 100000], the regularization value, lambda.

Default: 1.0

compute_mse

BOOLEAN, whether to calculate and output the mean squared error (MSE).

This parameter only accepts "true" or "false" rather than the standard literal equivalents for BOOLEANS like 1 or 0.

Default: False

Examples

See [Moving-average model example](#).

See also

- [PREDICT_MOVING_AVERAGE](#)
- [GET_MODEL_SUMMARY](#)

NAIVE_BAYES

Executes the Naive Bayes algorithm on an input relation and returns a Naive Bayes model.

Columns are treated according to data type:

- **FLOAT**: Values are assumed to follow some Gaussian distribution.
- **INTEGER**: Values are assumed to belong to one multinomial distribution.
- **CHAR/VARCHAR**: Values are assumed to follow some categorical distribution. The string values stored in these columns must not be greater than 128 characters.
- **BOOLEAN**: Values are treated as categorical with two values.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
NAIVE_BAYES ( 'model-name', 'input-relation', 'response-column', 'predictor-columns'  
  [ USING PARAMETERS [exclude_columns = 'excluded-columns'] [, alpha = alpha-value] ] )
```

Arguments

model-name

Identifies the model to create, where *model-name* conforms to conventions described in [Identifiers](#). It must also be unique among all names of sequences, tables, projections, views, and models within the same schema.

input-relation

The table or view that contains the training data for building the model. If the input relation is defined in Hive, use

[SYNC_WITH_HCATALOG_SCHEMA](#) to sync the `hcatalog` schema, and then run the machine learning function.

response-column

Name of the input column that represents the dependent variable, or outcome. This column must contain discrete labels that represent different class labels.

The response column must be of type [numeric](#), CHAR/VARCHAR, or BOOLEAN; otherwise the model is invalid.

Note

Vertica automatically casts [numeric](#) response column values to VARCHAR.

predictor-columns

Comma-separated list of columns in the input relation that represent independent variables for the model, or asterisk (*) to select all columns. If you select all columns, the argument list for parameter `exclude_columns` must include `response-column`, and any columns that are invalid as predictor columns.

All predictor columns must be of type [numeric](#), CHAR/VARCHAR, or BOOLEAN; otherwise the model is invalid. BOOLEAN column values are converted to FLOAT values before training: 0 for false, 1 for true.

Parameters

exclude_columns

Comma-separated list of columns from `predictor-columns` to exclude from processing.

alpha

Float, specifies use of Laplace smoothing if the event model is categorical, multinomial, or Bernoulli.

Default: 1.0

Model attributes

colsInfo

The information from the response and predictor columns used in training:

- index: The index (starting at 0) of the column as provided in training. Index 0 is used for the response column.
- name: The column name.
- type: The label used for response with a value of Gaussian, Multinomial, Categorical, or Bernoulli.

alpha

The smooth parameter value.

prior

The percentage of each class among all training samples:

- label: The class label.
- value: The percentage of each class.

nRowsTotal

The number of samples accepted for training from the data set.

nRowsRejected

The number of samples rejected for training.

callStr

The SQL statement used to replicate the training.

Gaussian

The Gaussian model conditioned on the class indicated by the `class_name`:

- index: The index of the predictor column.
- mu: The mean value of the model.
- sigmaSq: The squared standard deviation of the model.

Multinomial

The Multinomial model conditioned on the class indicated by the `class_name`:

- index: The index of the predictor column.
- prob: The probability conditioned on the class indicated by the `class_name`.

Bernoulli

The Bernoulli model conditioned on the class indicated by the class_name:

- index: The index of the predictor column.
- probTrue: The probability of having the value TRUE in this predictor column.

Categorical

The Gaussian model conditioned on the class indicated by the class_name:

- category: The value in the predictor name.
- <class_name>: The probability of having that value conditioned on the class indicated by the class_name.

Privileges

Superuser, or SELECT privileges on the input relation.

Examples

```
=> SELECT NAIVE_BAYES('naive_house84_model', 'house84_train', 'party', '**'  
      USING PARAMETERS exclude_columns='party, id');  
      NAIVE_BAYES
```

```
-----  
Finished. Accepted Rows: 324 Rejected Rows: 0  
(1 row)
```

- [PREDICT_NAIVE_BAYES](#)
- [PREDICT_NAIVE_BAYES_CLASSES](#)

PLS_REG

Executes the Partial Least Squares (PLS) regression algorithm on an input relation, and returns a PLS regression model.

Combining aspects of [PCA \(principal component analysis\)](#) and [linear regression](#), the PLS regression algorithm extracts a set of latent components that explain as much covariance as possible between the predictor and response variables, and then performs a regression that predicts response values using the extracted components.

This technique is particularly useful when the number of predictor variables is greater than the number of observations or the predictor variables are highly collinear. If either of these conditions is true of the input relation, ordinary linear regression fails to converge to an accurate model.

The PLS_REG function supports PLS regression with only one response column, often referred to as PLS1. PLS regression with multiple response columns, known as PLS2, is not currently supported.

To make predictions with a PLS model, use the [PREDICT_PLS_REG](#) function.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Syntax

```
PLS_REG ( 'model-name', 'input-relation', 'response-column', 'predictor-columns'  
         [ USING PARAMETERS param=value[...] ] )
```

Arguments

model-name

Model to create, where *model-name* conforms to conventions described in [Identifiers](#). It must also be unique among all names of sequences, tables, projections, views, and models within the same schema.

input-relation

Table or view that contains the training data.

response-column

Name of the input column that represents the dependent variable or outcome. All values in this column must be [numeric](#).

predictor-columns

Comma-separated list of columns in the input relation that represent independent variables for the model, or asterisk (*) to select all columns. If you select all columns, the argument list for parameter *exclude_columns* must include *response-column*, and any columns that are invalid as predictor columns.

All predictor columns must be of type [numeric](#) or BOOLEAN; otherwise the model is invalid.

Note

All BOOLEAN predictor values are converted to FLOAT values before training: 0 for false, 1 for true. No type checking occurs during prediction, so you can use a BOOLEAN predictor column in training, and during prediction provide a FLOAT column of the same name. In this case, all FLOAT values must be either 0 or 1.

Parameters

exclude_columns

Comma-separated list of columns from *predictor-columns* to exclude from processing.

num_components

Number of components in the model. The value must be an integer in the range [1, min(N, P)], where N is the number of rows in *input-relation* and P is the number of columns in *predictor-columns*.

Default: 2

scale

Boolean, whether to standardize the response and predictor columns.

Default: True

Model attributes

details

Information about the model coefficients, including:

- **coeffNames** : Name of the coefficients, starting with the intercept and following with the names of the predictors in the same order specified in the call.
- **coeff** : Vector of estimated coefficients, with the same order as **coeffNames**.

responses

Name of the response column.

call_string

SQL statement used to train the model.

Additional Info

Additional information about the model, including:

- **is_scaled** : Whether the input columns were scaled before model training.
- **n_components** : Number of components in the model.
- **rejected_row_count** : Number of rows in *input-relation* that were rejected because they contained an invalid value.
- **accepted_row_count** : Number of rows in *input-relation* accepted for training the model.

Privileges

Non-superusers:

- CREATE privileges on the schema where the model is created
- SELECT privileges on the input relation

Examples

The following example trains a PLS regression model with the default number of components:

```

=> CREATE TABLE pls_data (y float, x1 float, x2 float, x3 float, x4 float, x5 float);

=> COPY pls_data FROM STDIN;
1|2|3|0|2|5
2|3|4|0|4|4
3|4|5|0|8|3
.

=> SELECT PLS_REG('pls_model', 'pls_data', 'y', 'x1,x2');
WARNING 0: There are not more than 1 meaningful component(s)
          PLS_REG
-----
Number of components 1.
Accepted Rows: 3 Rejected Rows: 0
(1 row)

```

For an in-depth example that trains and makes predictions with a PLS model, see [PLS regression](#).

See also

- [PREDICT_PLS_REG](#)
- [PLS regression](#)
- [GET_MODEL_SUMMARY](#)

POISSON_REG

Executes Poisson regression on an input relation, and returns a Poisson regression model.

You can export the resulting Poisson regression model in VERTICA_MODELS or PMML format to apply it on data outside Vertica. You can also train a Poisson regression model elsewhere, then import it to Vertica in PMML format to apply it on data inside Vertica.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```

POISSON_REG ( 'model-name', 'input-table', 'response-column', 'predictor-columns'
[ USING PARAMETERS
  [exclude_columns = 'excluded-columns']
  [, optimizer = 'optimizer-method']
  [, regularization = 'regularization-method']
  [, epsilon = epsilon-value]
  [, max_iterations = iterations]
  [, lambda = lamda-value]
  [, fit_intercept = boolean-value] ] )

```

Arguments

model-name

Identifies the model to create, where *model-name* conforms to conventions described in [Identifiers](#). It must also be unique among all names of sequences, tables, projections, views, and models within the same schema.

input-table

Table or view that contains the training data for building the model. If the input relation is defined in Hive, use [SYNC_WITH_HCATALOG_SCHEMA](#) to sync the *hcatalog* schema, and then run the machine learning function.

response-column

Name of input column that represents the dependent variable or outcome. All values in this column must be [numeric](#), otherwise the model is invalid.

predictor-columns

Comma-separated list of columns in the input relation that represent independent variables for the model, or asterisk (*) to select all columns. If you select all columns, the argument list for parameter *exclude_columns* must include *response-column*, and any columns that are invalid as predictor columns.

All predictor columns must be of type [numeric](#) or BOOLEAN; otherwise the model is invalid.

Note

All BOOLEAN predictor values are converted to FLOAT values before training: 0 for false, 1 for true. No type checking occurs during prediction, so you can use a BOOLEAN predictor column in training, and during prediction provide a FLOAT column of the same name. In this case, all FLOAT values must be either 0 or 1.

Parameters

exclude_columns

Comma-separated list of columns from *predictor-columns* to exclude from processing.

optimizer

Optimizer method used to train the model. The currently supported method is [Newton](#).

regularization

Method of regularization, one of the following:

- [None](#) (default)
- [L2](#)

epsilon

FLOAT in the range (0.0, 1.0), the error value at which to stop training. Training stops if either the relative change in Poisson deviance is less than or equal to epsilon or if the number of iterations exceeds [max_iterations](#).

Default: 1e-6

max_iterations

INTEGER in the range (0, 1000000), the maximum number of training iterations. Training stops if either the number of iterations exceeds [max_iterations](#) or the relative change in Poisson deviance is less than or equal to epsilon.

lambda

FLOAT ≥ 0 , specifies the [regularization](#) strength.

Default: 1.0

fit_intercept

Boolean, specifies whether the model includes an intercept. By setting to false, no intercept will be used in training the model."

Default: True

Model attributes

data

Data for the function, including:

- [coeffNames](#) : Name of the coefficients. This starts with intercept and then follows with the names of the predictors in the same order specified in the call.
- [coeff](#) : Vector of estimated coefficients, with the same order as [coeffNames](#)
- [stdErr](#) : Vector of the standard error of the coefficients, with the same order as [coeffNames](#)
- [zValue](#) : (for logistic and Poisson regression): Vector of z-values of the coefficients, in the same order as [coeffNames](#)
- [tValue](#) (for linear regression): Vector of t-values of the coefficients, in the same order as [coeffNames](#)
- [pValue](#) : Vector of p-values of the coefficients, in the same order as [coeffNames](#)

regularization

Type of regularization to use when training the model.

lambda

Regularization parameter. Higher values enforce stronger regularization. This value must be nonnegative.

iterations

Number of iterations that actually occur for the convergence before exceeding [max_iterations](#).

skippedRows

Number of rows of the input relation that were skipped because they contained an invalid value.

processedRows

Total number of input relation rows minus [skippedRows](#).

callStr

Value of all input arguments specified when the function was called.

Examples

```
=> SELECT POISSON_REG('myModel', 'numericFaithful', 'eruptions', 'waiting' USING PARAMETERS epsilon=1e-8);
poisson_reg
-----
Finished in 7 iterations

(1 row)
```

RF_CLASSIFIER

Trains a random forest model for classification on an input relation.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
RF_CLASSIFIER ( 'model-name', input-relation, 'response-column', 'predictor-columns'
  [ USING PARAMETERS
    [exclude_columns = 'excluded-columns']
    [, ntree = num-trees]
    [, mtry = num-features]
    [, sampling_size = sampling-size]
    [, max_depth = depth]
    [, max_breadth = breadth]
    [, min_leaf_size = leaf-size]
    [, min_info_gain = threshold]
    [, nbins = num-bins] ] )
```

Arguments

model-name

Identifies the model stored as a result of the training, where *model-name* conforms to conventions described in [Identifiers](#). It must also be unique among all names of sequences, tables, projections, views, and models within the same schema.

input-relation

The table or view that contains the training samples. If the input relation is defined in Hive, use [SYNC_WITH_HCATALOG_SCHEMA](#) to sync the *hcatalog* schema, and then run the machine learning function.

response-column

An input column of type [numeric](#), CHAR/VARCHAR, or BOOLEAN that represents the dependent variable.

Note

Vertica automatically casts [numeric](#) response column values to VARCHAR.

predictor-columns

Comma-separated list of columns in the input relation that represent independent variables for the model, or asterisk (*) to select all columns. If you select all columns, the argument list for parameter *exclude_columns* must include *response-column*, and any columns that are invalid as predictor columns.

All predictor columns must be of type [numeric](#), CHAR/VARCHAR, or BOOLEAN; otherwise the model is invalid.

Vertica XGBoost and Random Forest algorithms offer native support for categorical columns (BOOL/VARCHAR). Simply pass the categorical columns as predictors to the models and the algorithm will automatically treat the columns as categorical and will not attempt to split them into bins in the same manner as numerical columns; Vertica treats these columns as true categorical values and does not simply cast them to continuous values under-the-hood.

Parameters

exclude_columns

Comma-separated list of column names from *input-columns* to exclude from processing.

ntree

Integer in the range [1, 1000], the number of trees in the forest.

Default: 20

mtry

Integer in the range [1, *number-predictors*], the number of randomly chosen features from which to pick the best feature to split on a given tree node.

Default: Square root of the total number of predictors

sampling_size

Float in the range (0.0, 1.0], the portion of the input data set that is randomly picked for training each tree.

Default: 0.632

max_depth

Integer in the range [1, 100], the maximum depth for growing each tree. For example, a *max_depth* of 0 represents a tree with only a root node, and a *max_depth* of 2 represents a tree with four leaf nodes.

Default: 5

max_breadth

Integer in the range [1, 1e9], the maximum number of leaf nodes a tree can have.

Default: 32

min_leaf_size

Integer in the range [1, 1e6], the minimum number of samples each branch must have after splitting a node. A split that results in fewer remaining samples in its left or right branch is discarded, and the node is treated as a leaf node.

Default: 1

min_info_gain

Float in the range [0.0, 1.0), the minimum threshold for including a split. A split with information gain less than this threshold is discarded.

Default: 0.0

nbins

Integer in the range [2, 1000], the number of bins to use for discretizing continuous features.

Default: 32

Model attributes

data

Data for the function, including:

- *predictorNames* : The name of the predictors in the same order they were specified for training the model.
- *predictorTypes* : The type of the predictors in the same order as their names in *predictorNames*.

ntree

Number of trees in the model.

skippedRows

Number of rows in *input_relation* that were skipped because they contained an invalid value.

processedRows

Total number of rows in *input_relation* minus *skippedRows* .

callStr

Value of all input arguments that were specified at the time the function was called.

Examples

```
=> SELECT RF_CLASSIFIER ('myRFModel', 'iris', 'Species', 'Sepal_Length, Sepal_Width,
Petal_Length, Petal_Width' USING PARAMETERS ntree=100, sampling_size=0.3);
```

```
RF_CLASSIFIER
-----
```

```
Finished training
(1 row)
```

See also

- [Classifying data using random forest](#)
- [PREDICT_RF_CLASSIFIER](#)
- [PREDICT_RF_CLASSIFIER_CLASSES](#)

RF_REGRESSOR

Trains a random forest model for regression on an input relation.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
RF_REGRESSOR ( 'model-name', input-relation, 'response-column', 'predictor-columns'
  [ USING PARAMETERS
    [exclude_columns = 'excluded-columns']
    [, ntree = num-trees]
    [, mtry = num-features]
    [, sampling_size = sampling-size]
    [, max_depth = depth]
    [, max_breadth = breadth]
    [, min_leaf_size = leaf-size]
    [, min_info_gain = threshold]
    [, nbins = num-bins] ] )
```

Arguments

model-name

The model that is stored as a result of training, where *model-name* conforms to conventions described in [Identifiers](#). It must also be unique among all names of sequences, tables, projections, views, and models within the same schema.

input-relation

The table or view that contains the training samples. If the input relation is defined in Hive, use [SYNC_WITH_HCATALOG_SCHEMA](#) to sync the *hcatalog* schema, and then run the machine learning function.

response-column

A [numeric](#) input column that represents the dependent variable.

predictor-columns

Comma-separated list of columns in the input relation that represent independent variables for the model, or asterisk (*) to select all columns. If you select all columns, the argument list for parameter *exclude_columns* must include *response-column*, and any columns that are invalid as predictor columns.

All predictor columns must be of type [numeric](#), CHAR/VARCHAR, or BOOLEAN; otherwise the model is invalid.

Vertica XGBoost and Random Forest algorithms offer native support for categorical columns (BOOL/VARCHAR). Simply pass the categorical columns as predictors to the models and the algorithm will automatically treat the columns as categorical and will not attempt to split them into bins in the same manner as numerical columns; Vertica treats these columns as true categorical values and does not simply cast them to continuous values under-the-hood.

Parameters

exclude_columns

Comma-separated list of columns from [predictor-columns](#) to exclude from processing.

n_{tree}

Integer in the range [1, 1000], the number of trees in the forest.

Default: 20

m_{try}

Integer in the range [1, [number-predictors](#)], the number of features to consider at the split of a tree node.

Default: One-third the total number of predictors

sampling_size

Float in the range (0.0, 1.0], the portion of the input data set that is randomly picked for training each tree.

Default: 0.632

max_depth

Integer in the range [1, 100], the maximum depth for growing each tree. For example, a [max_depth](#) of 0 represents a tree with only a root node, and a [max_depth](#) of 2 represents a tree with four leaf nodes.

Default: 5

max_breadth

Integer in the range [1, 1e9], the maximum number of leaf nodes a tree can have.

Default: 32

min_leaf_size

Integer in the range [1, 1e6], the minimum number of samples each branch must have after splitting a node. A split that results in fewer remaining samples in its left or right branch is discarded, and the node is treated as a leaf node.

The default value of this parameter differs from that of analogous parameters in libraries like [sklearn](#) and will therefore yield a model with predicted values that differ from the original response values.

Default: 5

min_info_gain

Float in the range [0.0, 1.0), the minimum threshold for including a split. A split with information gain less than this threshold is discarded.

Default: 0.0

nbins

Integer in the range [2, 1000], the number of bins to use for discretizing continuous features.

Default: 32

Model attributes

data

Data for the function, including:

- [predictorNames](#) : The name of the predictors in the same order they were specified for training the model.
- [predictorTypes](#) : The type of the predictors in the same order as their names in [predictorNames](#).

n_{tree}

Number of trees in the model.

skippedRows

Number of rows in [input_relation](#) that were skipped because they contained an invalid value.

processedRows

Total number of rows in [input_relation](#) minus [skippedRows](#) .

callStr

Value of all input arguments that were specified at the time the function was called.

Examples

```
=> SELECT RF_REGRESSOR ('myRFRegressorModel', 'mtcars', 'carb', 'mpg, cyl, hp, drat, wt' USING PARAMETERS
ntree=100, sampling_size=0.3);
RF_REGRESSOR
-----
Finished
(1 row)
```

See also

- [Building a random forest regression model](#)
- [GET_MODEL_SUMMARY](#)
- [PREDICT_RF_REGRESSOR](#)

SVM_CLASSIFIER

Trains the SVM model on an input relation.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
SVM_CLASSIFIER ( 'model-name', input-relation, 'response-column', 'predictor-columns'
[ USING PARAMETERS
  [exclude_columns = 'excluded-columns']
  [, C = 'cost']
  [, epsilon = 'epsilon-value']
  [, max_iterations = 'max-iterations']
  [, class_weights = 'weight']
  [, intercept_mode = 'intercept-mode']
  [, intercept_scaling = 'scale' ] ] )
```

Arguments

model-name

Identifies the model to create, where *model-name* conforms to conventions described in [Identifiers](#). It must also be unique among all names of sequences, tables, projections, views, and models within the same schema.

input-relation

The table or view that contains the training data. If the input relation is defined in Hive, use [SYNC_WITH_HCATALOG_SCHEMA](#) to sync the *hcatalog* schema, and then run the machine learning function.

response-column

The input column that represents the dependent variable or outcome. The column value must be 0 or 1, and of type [numeric](#) or BOOLEAN, otherwise the function returns with an error.

predictor-columns

Comma-separated list of columns in the input relation that represent independent variables for the model, or asterisk (*) to select all columns. If you select all columns, the argument list for parameter *exclude_columns* must include *response-column*, and any columns that are invalid as predictor columns.

All predictor columns must be of type [numeric](#) or BOOLEAN; otherwise the model is invalid.

Note

All BOOLEAN predictor values are converted to FLOAT values before training: 0 for false, 1 for true. No type checking occurs during prediction, so you can use a BOOLEAN predictor column in training, and during prediction provide a FLOAT column of the same name. In this case, all FLOAT values must be either 0 or 1.

Parameters

exclude_columns

Comma-separated list of columns from *predictor-columns* to exclude from processing.

C

Weight for misclassification cost. The algorithm minimizes the regularization cost and the misclassification cost.

Default: 1.0

epsilon

Used to control accuracy.

Default: 1e-3

max_iterations

Maximum number of iterations that the algorithm performs.

Default: 100

class_weights

Specifies how to determine weights of the two classes, one of the following:

- **None** (default): No weights are used
- **value0 , value1** : Two comma-delimited strings that specify two positive FLOAT values, where **value0** assigns a weight to class 0, and **value1** assigns a weight to class 1.
- **auto** : Weights each class according to the number of samples.

intercept_mode

Specifies how to treat the intercept, one of the following:

- **regularized** (default): Fits the intercept and applies a regularization on it.
- **unregularized** : Fits the intercept but does not include it in regularization.

intercept_scaling

Float value that serves as the value of a dummy feature whose coefficient Vertica uses to calculate the model intercept. Because the dummy feature is not in the training data, its values are set to a constant, by default 1.

Model attributes

coeff

Coefficients in the model:

- **colNames** : Intercept, or predictor column name
- **coefficients** : Coefficient value

nAccepted

Number of samples accepted for training from the data set

nRejected

Number of samples rejected when training

nIteration

Number of iterations used in training

callStr

SQL statement used to replicate the training

Examples

The following example uses **SVM_CLASSIFIER** on the **mtcars** table:

```
=> SELECT SVM_CLASSIFIER(
  'mySvmClassModel', 'mtcars', 'am', 'mpg,cyl,disp,hp,drat,wt,qsec,vs,gear,carb'
  USING PARAMETERS exclude_columns = 'hp,drat');
```

SVM_CLASSIFIER

Finished in 15 iterations.

Accepted Rows: 32 Rejected Rows: 0

(1 row)

SVM_REGRESSOR

Trains the SVM model on an input relation.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
SVM_REGRESSOR ( 'model-name', input-relation, 'response-column', 'predictor-columns'  
  [ USING PARAMETERS  
    [exclude_columns = 'excluded-columns']  
    [, error_tolerance = error-tolerance]  
    [, C = cost]  
    [, epsilon = epsilon-value]  
    [, max_iterations = max-iterations]  
    [, intercept_mode = 'mode']  
    [, intercept_scaling = 'scale' ] ] )
```

Arguments

model-name

Identifies the model to create, where *model-name* conforms to conventions described in [Identifiers](#). It must also be unique among all names of sequences, tables, projections, views, and models within the same schema.

input-relation

The table or view that contains the training data. If the input relation is defined in Hive, use [SYNC_WITH_HCATALOG_SCHEMA](#) to sync the *hcatalog* schema, and then run the machine learning function.

response-column

An input column that represents the dependent variable or outcome. The column must be a [numeric](#) data type.

predictor-columns

Comma-separated list of columns in the input relation that represent independent variables for the model, or asterisk (*) to select all columns. If you select all columns, the argument list for parameter *exclude_columns* must include *response-column*, and any columns that are invalid as predictor columns.

All predictor columns must be of type [numeric](#) or BOOLEAN; otherwise the model is invalid.

Note

All BOOLEAN predictor values are converted to FLOAT values before training: 0 for false, 1 for true. No type checking occurs during prediction, so you can use a BOOLEAN predictor column in training, and during prediction provide a FLOAT column of the same name. In this case, all FLOAT values must be either 0 or 1.

Parameters

exclude_columns

Comma-separated list of columns from *predictor-columns* to exclude from processing.

error_tolerance

Defines the acceptable error margin. Any data points outside this region add a penalty to the cost function.

Default: 0.1

C

The weight for misclassification cost. The algorithm minimizes the regularization cost and the misclassification cost.

Default: 1.0

epsilon

Used to control accuracy.

Default: 1e-3

max_iterations

The maximum number of iterations that the algorithm performs.

Default: 100

intercept_mode

A string that specifies how to treat the intercept, one of the following

- **regularized** (default): Fits the intercept and applies a regularization on it.
- **unregularized** : Fits the intercept but does not include it in regularization.

intercept_scaling

A FLOAT value, serves as the value of a dummy feature whose coefficient Vertica uses to calculate the model intercept. Because the dummy feature is not in the training data, its values are set to a constant, by default set to 1.

Model attributes

coeff

Coefficients in the model:

- **colNames** : Intercept, or predictor column name
- **coefficients** : Coefficient value

nAccepted

Number of samples accepted for training from the data set

nRejected

Number of samples rejected when training

nIteration

Number of iterations used in training

callStr

SQL statement used to replicate the training

Examples

```
=> SELECT SVM_REGRESSOR('mySvmRegModel', 'faithful', 'eruptions', 'waiting'  
      USING PARAMETERS error_tolerance=0.1, max_iterations=100);  
SVM_REGRESSOR
```

Finished in 5 iterations.

Accepted Rows: 272 Rejected Rows: 0

(1 row)

- [PREDICT_SVM_REGRESSOR](#)

XGB_CLASSIFIER

Trains an XGBoost model for classification on an input relation.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
XGB_CLASSIFIER ('model-name', 'input-relation', 'response-column', 'predictor-columns'  
  [ USING PARAMETERS param=value[,...] ] )
```

Arguments

model-name

Name of the model (case-insensitive).

input-relation

The table or view that contains the training samples. If the input relation is defined in Hive, use [SYNC_WITH_HCATALOG_SCHEMA](#) to sync the **hcatalog** schema, and then run the machine learning function.

response-column

An input column of type CHAR or VARCHAR that represents the dependent variable or outcome.

predictor-columns

Comma-separated list of columns to use from the input relation, or asterisk (*) to select all columns. Columns must be of data types CHAR, VARCHAR, BOOL, INT, or FLOAT.

Columns of type CHAR, VARCHAR, and BOOL are treated as categorical features; all others are treated as numeric features.

Vertica XGBoost and Random Forest algorithms offer native support for categorical columns (BOOL/VARCHAR). Simply pass the categorical columns as predictors to the models and the algorithm will automatically treat the columns as categorical and will not attempt to split them into bins in the same manner as numerical columns; Vertica treats these columns as true categorical values and does not simply cast them to continuous values under-the-hood.

Parameters

exclude_columns

Comma-separated list of column names from *input-columns* to exclude from processing.

max_ntree

Integer in the range [1,1000] that sets the maximum number of trees to create.

Default: 10

max_depth

Integer in the range [1,40] that specifies the maximum depth of each tree.

Default: 6

objective

The objective/loss function used to iteratively improve the model. 'crossentropy' is the only option.

Default: 'crossentropy'

split_proposal_method

The splitting strategy for the feature columns. 'global' is the only option. This method calculates the split for each feature column only at the beginning of the algorithm. The feature columns are split into the number of bins specified by *nbins*.

Default: 'global'

learning_rate

Float in the range (0,1] that specifies the weight for each tree's prediction. Setting this parameter can reduce each tree's impact and thereby prevent earlier trees from monopolizing improvements at the expense of contributions from later trees.

Default: 0.3

min_split_loss

Float in the range [0,1000] that specifies the minimum amount of improvement each split must achieve on the model's objective function value to avoid being pruned.

If set to 0 or omitted, no minimum is set. In this case, trees are pruned according to positive or negative objective function values.

Default: 0.0 (disable)

weight_reg

Float in the range [0,1000] that specifies the regularization term applied to the weights of classification tree leaves. The higher the setting, the sparser or smoother the weights are, which can help prevent over-fitting.

Default: 1.0

nbins

Integer in the range (1,1000] that specifies the number of bins to use for finding splits in each column. More bins leads to longer runtime but more fine-grained and possibly better splits.

Default: 32

sampling_size

Float in the range (0,1] that specifies the fraction of rows to use in each training iteration.

A value of 1 indicates that all rows are used.

Default: 1.0

col_sample_by_tree

Float in the range (0,1] that specifies the fraction of columns (features), chosen at random, to use when building each tree.

A value of 1 indicates that all columns are used.

`col_sample_by` parameters "stack" on top of each other if several are specified. That is, given a set of 24 columns, for `col_sample_by_tree=0.5` and `col_sample_by_node=0.5`, `col_sample_by_tree` samples 12 columns, reducing the available, unsampled column pool to 12. `col_sample_by_node` then samples half of the remaining pool, so each node samples 6 columns.

This algorithm will always sample at least one column.

Default: 1

col_sample_by_node

Float in the range (0,1] that specifies the fraction of columns (features), chosen at random, to use when evaluating each split.

A value of 1 indicates that all columns are used.

`col_sample_by` parameters "stack" on top of each other if several are specified. That is, given a set of 24 columns, for `col_sample_by_tree=0.5` and `col_sample_by_node=0.5`, `col_sample_by_tree` samples 12 columns, reducing the available, unsampled column pool to 12. `col_sample_by_node` then samples half of the remaining pool, so each node samples 6 columns.

This algorithm will always sample at least one column.

Default: 1

Examples

See [XGBoost for classification](#).

XGB_REGRESSOR

Trains an XGBoost model for regression on an input relation.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
XGB_REGRESSOR ('model-name', 'input-relation', 'response-column', 'predictor-columns'  
  [ USING PARAMETERS param=value[,...] ] )
```

Arguments

model-name

Name of the model (case-insensitive).

input-relation

The table or view that contains the training samples. If the input relation is defined in Hive, use [SYNC_WITH_HCATALOG_SCHEMA](#) to sync the `hcatalog` schema, and then run the machine learning function.

response-column

An input column of type INTEGER or FLOAT that represents the dependent variable or outcome.

predictor-columns

Comma-separated list of columns to use from the input relation, or asterisk (*) to select all columns. Columns must be of data types CHAR, VARCHAR, BOOL, INT, or FLOAT.

Columns of type CHAR, VARCHAR, and BOOL are treated as categorical features; all others are treated as numeric features.

Vertica XGBoost and Random Forest algorithms offer native support for categorical columns (BOOL/VARCHAR). Simply pass the categorical columns as predictors to the models and the algorithm will automatically treat the columns as categorical and will not attempt to split them into bins in the same manner as numerical columns; Vertica treats these columns as true categorical values and does not simply cast them to continuous values under-the-hood.

Parameters

exclude_columns

Comma-separated list of column names from `input-columns` to exclude from processing.

max_ntree

Integer in the range [1,1000] that sets the maximum number of trees to create.

Default: 10

max_depth

Integer in the range [1,40] that specifies the maximum depth of each tree.

Default: 6

objective

The objective/loss function used to iteratively improve the model. 'squarederror' is the only option.

Default: 'squarederror'

split_proposal_method

The splitting strategy for the feature columns. 'global' is the only option. This method calculates the split for each feature column only at the beginning of the algorithm. The feature columns are split into the number of bins specified by `nbins`.

Default: 'global'

learning_rate

Float in the range (0,1] that specifies the weight for each tree's prediction. Setting this parameter can reduce each tree's impact and thereby prevent earlier trees from monopolizing improvements at the expense of contributions from later trees.

Default: 0.3

min_split_loss

Float in the range [0,1000] that specifies the minimum amount of improvement each split must achieve on the model's objective function value to avoid being pruned.

If set to 0 or omitted, no minimum is set. In this case, trees are pruned according to positive or negative objective function values.

Default: 0.0 (disable)

weight_reg

Float in the range [0,1000] that specifies the regularization term applied to the weights of classification tree leaves. The higher the setting, the sparser or smoother the weights are, which can help prevent over-fitting.

Default: 1.0

nbins

Integer in the range (1,1000] that specifies the number of bins to use for finding splits in each column. More bins leads to longer runtime but more fine-grained and possibly better splits.

Default: 32

sampling_size

Float in the range (0,1] that specifies the fraction of rows to use in each training iteration.

A value of 1 indicates that all rows are used.

Default: 1.0

col_sample_by_tree

Float in the range (0,1] that specifies the fraction of columns (features), chosen at random, to use when building each tree.

A value of 1 indicates that all columns are used.

`col_sample_by` parameters "stack" on top of each other if several are specified. That is, given a set of 24 columns, for `col_sample_by_tree=0.5` and `col_sample_by_node=0.5`, `col_sample_by_tree` samples 12 columns, reducing the available, unsampled column pool to 12.

`col_sample_by_node` then samples half of the remaining pool, so each node samples 6 columns.

This algorithm will always sample at least one column.

Default: 1

col_sample_by_node

Float in the range (0,1] that specifies the fraction of columns (features), chosen at random, to use when evaluating each split.

A value of 1 indicates that all columns are used.

`col_sample_by` parameters "stack" on top of each other if several are specified. That is, given a set of 24 columns, for `col_sample_by_tree=0.5` and `col_sample_by_node=0.5`, `col_sample_by_tree` samples 12 columns, reducing the available, unsampled column pool to 12.

`col_sample_by_node` then samples half of the remaining pool, so each node samples 6 columns.

This algorithm will always sample at least one column.

Default: 1

Examples

See [XGBoost for regression](#).

Model evaluation

A set of Vertica machine learning functions evaluate the prediction data that is generated by trained models, or return information about the models themselves.

In this section

- [CONFUSION_MATRIX](#)
- [CROSS_VALIDATE](#)
- [ERROR_RATE](#)
- [LIFT_TABLE](#)
- [MSE](#)
- [PRC](#)
- [READ_TREE](#)
- [RF_PREDICTOR_IMPORTANCE](#)
- [ROC](#)
- [RSQUARED](#)
- [XGB_PREDICTOR_IMPORTANCE](#)

CONFUSION_MATRIX

Computes the confusion matrix of a table with observed and predicted values of a response variable. **CONFUSION_MATRIX** produces a table with the following dimensions:

- Rows: Number of classes
- Columns: Number of classes + 2

Syntax

```
CONFUSION_MATRIX ( targets, predictions [ USING PARAMETERS num_classes = num-classes ] OVER()
```

Arguments

targets

An input column that contains the true values of the response variable.

predictions

An input column that contains the predicted class labels.

Arguments *targets* and *predictions* must be set to input columns of the same data type, one of the following: INTEGER, BOOLEAN, or CHAR/VARCHAR. Depending on their data type, these columns identify classes as follows:

- INTEGER: Zero-based consecutive integers between 0 and (*num-classes* -1) inclusive, where *num-classes* is the number of classes. For example, given the following input column values— {0, 1, 2, 3, 4}—Vertica assumes five classes.

Note

If input column values are not consecutive, Vertica interpolates the missing values. Thus, given the following input values— {0, 1, 3, 5, 6} — Vertica assumes seven classes.

- BOOLEAN: Yes or No
- CHAR/VARCHAR: Class names. If the input columns are of type CHAR/VARCHAR columns, you must also set parameter *num_classes* to the number of classes.

Note

Vertica computes the number of classes as the union of values in both input columns. For example, given the following sets of values in the *targets* and *predictions* input columns, Vertica counts four classes:

```
{'milk', 'soy milk', 'cream'}
{'soy milk', 'almond milk'}
```

Parameters

num_classes

An integer > 1, specifies the number of classes to pass to the function.

You must set this parameter if the specified input columns are of type CHAR/VARCHAR. Otherwise, the function processes this parameter according to the column data types:

- INTEGER: By default set to 2, you must set this parameter correctly if the number of classes is any other value.
- BOOLEAN: By default set to 2, cannot be set to any other value.

Examples

This example computes the confusion matrix for a logistic regression model that classifies cars in the `mtcars` data set as automatic or manual transmission. Observed values are in input column `obs`, while predicted values are in input column `pred`. Because this is a binary classification problem, all values are either 0 or 1.

In the table returned, all 19 cars with a value of 0 in column `am` are correctly predicted by `PREDICT_LOGISTIC_REGRESSION` as having a value of 0. Of the 13 cars with a value of 1 in column `am`, 12 are correctly predicted to have a value of 1, while 1 car is incorrectly classified as having a value of 0:

```
=> SELECT CONFUSION_MATRIX(obs::int, pred::int USING PARAMETERS num_classes=2) OVER()
FROM (SELECT am AS obs, PREDICT_LOGISTIC_REG(mpg, cyl, disp, drat, wt, qsec, vs, gear, carb
      USING PARAMETERS model_name='myLogisticRegModel') AS PRED
FROM mtcars) AS prediction_output;
```

actual_class	predicted_0	predicted_1	comment
0	19	0	
1	0	13	Of 32 rows, 32 were used and 0 were ignored

(2 rows)

CROSS_VALIDATE

Performs k-fold cross validation on a learning algorithm using an input relation, and grid search for hyper parameters. The output is an average performance indicator of the selected algorithm. This function supports SVM classification, naive bayes, and logistic regression.

This is a meta-function. You must call meta-functions in a top-level `SELECT` statement.

Behavior type

Volatile

Syntax

```
CROSS_VALIDATE ( 'algorithm', 'input-relation', 'response-column', 'predictor-columns'
[ USING PARAMETERS
  [exclude_columns = 'excluded-columns']
  [, cv_model_name = 'model']
  [, cv_metrics = 'metrics']
  [, cv_fold_count = num-folds]
  [, cv_hyperparams = 'hyperparams']
  [, cv_prediction_cutoff = prediction-cutoff] ] )
```

Arguments

algorithm

Name of the algorithm training function, one of the following:

- `LINEAR_REG`
- `LOGISTIC_REG`
- `NAIVE_BAYES`
- `SVM_CLASSIFIER`
- `SVM_REGRESSOR`

input-relation

The table or view that contains data used for training and testing. If the input relation is defined in Hive, use [SYNC_WITH_HCATALOG_SCHEMA](#) to sync the `hcatalog` schema, and then run the machine learning function.

response-column

Name of the input column that contains the response.

predictor-columns

Comma-separated list of columns in the input relation that represent independent variables for the model, or asterisk (*) to select all columns. If you select all columns, the argument list for parameter `exclude_columns` must include `response-column`, and any columns that are invalid as predictor columns.

Parameters

exclude_columns

Comma-separated list of columns from `predictor-columns` to exclude from processing.

cv_model_name

The name of a model that lets you retrieve results of the cross validation process. If you omit this parameter, results are displayed but not saved. If you set this parameter to a model name, you can retrieve the results with summary functions [GET_MODEL_ATTRIBUTE](#) and [GET_MODEL_SUMMARY](#).

cv_metrics

The metrics used to assess the algorithm, specified either as a comma-separated list of metric names or in a [JSON array](#). In both cases, you specify one or more of the following metric names:

- `accuracy` (default)
- `error_rate`
- `TP` : True positive, the number of cases of class 1 predicted as class 1
- `FP` : False positive, the number of cases of class 0 predicted as class 1
- `TN` : True negative, the number of cases of class 0 predicted as class 0
- `FN` : False negative, the number of cases of class 1 predicted as class 0
- `TPR` or `recall` : True positive rate, the correct predictions among class 1
- `FPR` : False positive rate, the wrong predictions among class 0
- `TNR` : True negative rate, the correct predictions among class 0
- `FNR` : False negative rate, the wrong predictions among class 1
- `PPV` or `precision` : The positive predictive value, the correct predictions among cases predicted as class 1
- `NPV` : Negative predictive value, the correct predictions among cases predicted as class 0

• `MSE` : Mean squared error

$$\text{MSE}(y, \hat{y}) = \frac{1}{n_{\text{samples}}} \sum_{i=0}^{n_{\text{samples}}-1} (y_i - \hat{y}_i)^2.$$

• `MAE` : Mean absolute error

$$\text{MAE}(y, \hat{y}) = \frac{1}{n_{\text{samples}}} \sum_{i=0}^{n_{\text{samples}}-1} |y_i - \hat{y}_i|.$$

• `rsquared` : coefficient of determination

$$R^2(y, \hat{y}) = 1 - \frac{\sum_{i=0}^{n_{\text{samples}}-1} (y_i - \hat{y}_i)^2}{\sum_{i=0}^{n_{\text{samples}}-1} (y_i - \bar{y})^2}$$

• `explained_variance`

$$\text{explained_variance}(y, \hat{y}) = 1 - \frac{\text{Var}\{y - \hat{y}\}}{\text{Var}\{y\}}$$

• `fscore`

$$(1 + \text{beta}^2) * \text{precision} * \text{recall} / (\text{beta}^2 * \text{precision} + \text{recall})$$

beta equals 1 by default

- `auc_roc` : AUC of ROC using the specified number of bins, by default 100
- `auc_prc` : AUC of PRC using the specified number of bins, by default 100
- `counts` : Shortcut that resolves to four other metrics: `TP`, `FP`, `TN`, and `FN`
- `count` : Valid only in JSON syntax, counts the number of cases labeled by one class (`case-class-label`) but predicted as another class (`predicted-class-label`):

$$\text{cv_metrics}=[\{\"count\":[\"case-class-label, predicted-class-label\"]}]$$

cv_fold_count

The number of folds to split the data.

Default: 5

cv_hyperparams

A JSON string that describes the combination of parameters for use in grid search of hyper parameters. The JSON string contains pairs of the hyper parameter name. The value of each hyper parameter can be specified as an array or sequence. For example:

```
{ "param1": [value1, value2, ...], "param2": { "first": first_value, "step": step_size, "count": number_of_values } }
```

Hyper parameter names and string values should be quoted using the JSON standard. These parameters are passed to the training function.

cv_prediction_cutoff

The cutoff threshold that is passed to the prediction stage of logistic regression, a FLOAT between 0 and 1, exclusive

Default: 0.5

Model attributes

call_string

The value of all input arguments that were specified at the time `CROSS_VALIDATE` was called.

run_average

The average across all folds of all metrics specified in parameter `cv_metrics`, if specified; otherwise, average accuracy.

fold_info

The number of rows in each fold:

- `fold_id`: The index of the fold.
- `row_count`: The number of rows held out for testing in the fold.

counters

All counters for the function, including:

- `accepted_row_count`: The total number of rows in the `input_relation`, minus the number of rejected rows.
- `rejected_row_count`: The number of rows of the `input_relation` that were skipped because they contained an invalid value.
- `feature_count`: The number of features input to the machine learning model.

run_details

Information about each run, where a run means training a single model, and then testing that model on the one held-out fold:

- `fold_id`: The index of the fold held out for testing.
- `iteration_count`: The number of iterations used in model training on non-held-out folds.
- `accuracy`: All metrics specified in parameter `cv_metrics`, or accuracy if `cv_metrics` is not provided.
- `error_rate`: All metrics specified in parameter `cv_metrics`, or accuracy if the parameter is omitted.

Privileges

Non-superusers:

- SELECT privileges on the input relation
- CREATE and USAGE privileges on the default schema where machine learning algorithms generate models. If `cv_model_name` is provided, the cross validation results are saved as a model in the same schema.

Specifying metrics in JSON

Parameter `cv_metrics` can specify metrics as an array of [JSON objects](#), where each object specifies a metric name. For example, the following expression sets `cv_metrics` to two metrics specified as JSON objects, `accuracy` and `error_rate`:

```
cv_metrics=['accuracy', 'error_rate']
```

In the next example, `cv_metrics` is set to two metrics, `accuracy` and `TPR` (true positive rate). Here, the `TPR` metric is specified as a JSON object that takes an array of two class label arguments, 2 and 3:

```
cv_metrics=[ 'accuracy', { "TPR": [2,3] } ]
```

Metrics specified as JSON objects can accept parameters. In the following example, the `fscore` metric specifies parameter `beta`, which is set to 0.5:

```
cv_metrics=[ { "fscore": { "beta": 0.5 } } ]
```

Parameter support can be especially useful for certain metrics. For example, metrics `auc_roc` and `auc_prc` build a curve, and then compute the area under that curve. For `ROC`, the curve is formed by plotting metrics `TPR` against `FPR`; for `PRC`, `PPV` (`precision`) against `TPR` (`recall`). The accuracy of such curves can be increased by setting parameter `num_bins` to a value greater than the default value of 100. For example, the following expression computes AUC for an ROC curve built with 1000 bins:

```
cv_metrics=[{"auc_roc":{"num_bins":1000}]'
```

Using metrics with Multi-class classifier functions

All supported metrics are defined for binary classifier functions [LOGISTIC_REG](#) and [SVM_CLASSIFIER](#). For multi-class classifier functions such as [NAIVE_BAYES](#), these metrics can be calculated for each *one-versus-the-rest* binary classifier. Use arguments to request the metrics for each classifier. For example, if training data has integer class labels, you can set `cv_metrics` with the [precision \(PPV\)](#) metric as follows:

```
cv_metrics=[{"precision":[0,4]]'
```

This setting specifies to return two columns with precision computed for two classifiers:

- Column 1: classifies 0 versus not 0
- Column 2: classifies 4 versus not 4

If you omit class label arguments, the class with index 1 is used. Instead of computing metrics for individual *one-versus-the-rest* classifiers, the average is computed in one of the following styles: [macro](#), [micro](#), or [weighted](#) (default). For example, the following `cv_metrics` setting returns the average weighted by class sizes:

```
cv_metrics=[{"precision":{"avg":"weighted"}}]
```

AUC-type metrics can be similarly defined for multi-class classifiers. For example, the following `cv_metrics` setting computes the area under the ROC curve for each *one-versus-the-rest* classifier, and then returns the average weighted by class sizes.

```
cv_metrics=[{"auc_roc":{"avg":"weighted", "num_bins":1000}]'
```

Examples

```
=> SELECT CROSS_VALIDATE('svm_classifier', 'mtcars', 'am', 'mpg'  
  USING PARAMETERS cv_fold_count= 6,  
                   cv_hyperparams={'C':[1,5]},  
                   cv_model_name='cv_svm',  
                   cv_metrics='accuracy, error_rate');  
CROSS_VALIDATE
```

(1 row)

ERROR_RATE

Using an input table, returns a table that calculates the rate of incorrect classifications and displays them as FLOAT values. `ERROR_RATE` returns a table with the following dimensions:

- Rows: Number of classes plus one row that contains the total error rate across classes
- Columns: 2

Syntax

```
ERROR_RATE ( targets, predictions [ USING PARAMETERS num_classes = num-classes ] ) OVER()
```

Arguments

targets

An input column that contains the true values of the response variable.

predictions

An input column that contains the predicted class labels.

Arguments `targets` and `predictions` must be set to input columns of the same data type, one of the following: INTEGER, BOOLEAN, or CHAR/VARCHAR. Depending on their data type, these columns identify classes as follows:

- **INTEGER**: Zero-based consecutive integers between 0 and (*num-classes* -1) inclusive, where *num-classes* is the number of classes. For example, given the following input column values— {0, 1, 2, 3, 4}—Vertica assumes five classes.

Note

If input column values are not consecutive, Vertica interpolates the missing values. Thus, given the following input values— {0, 1, 3, 5, 6,} — Vertica assumes seven classes.

- **BOOLEAN**: Yes or No
- **CHAR/VARCHAR**: Class names. If the input columns are of type CHAR/VARCHAR columns, you must also set parameter *num_classes* to the number of classes.

Note

Vertica computes the number of classes as the union of values in both input columns. For example, given the following sets of values in the *targets* and *predictions* input columns, Vertica counts four classes:

```
{'milk', 'soy milk', 'cream'}
{'soy milk', 'almond milk'}
```

Parameters

num_classes

An integer > 1, specifies the number of classes to pass to the function.

You must set this parameter if the specified input columns are of type CHAR/VARCHAR. Otherwise, the function processes this parameter according to the column data types:

- **INTEGER**: By default set to 2, you must set this parameter correctly if the number of classes is any other value.
- **BOOLEAN**: By default set to 2, cannot be set to any other value.

Privileges

Non-superusers: model owner, or USAGE privileges on the model

Examples

This example shows how to execute the **ERROR_RATE** function on an input table named *mtcars* . The response variables appear in the column *obs* , while the prediction variables appear in the column *pred* . Because this example is a classification problem, all response variable values and prediction variable values are either 0 or 1, indicating binary classification.

In the table returned by the function, the first column displays the class id column. The second column displays the corresponding error rate for the class id. The third column indicates how many rows were successfully used by the function and whether any rows were ignored.

```
=> SELECT ERROR_RATE(obs::int, pred::int USING PARAMETERS num_classes=2) OVER()
FROM (SELECT am AS obs, PREDICT_LOGISTIC_REG (mpg, cyl, disp, drat, wt, qsec, vs, gear, carb
      USING PARAMETERS model_name='myLogisticRegModel', type='response') AS pred
FROM mtcars) AS prediction_output;
class |  error_rate  |  comment
-----+-----+-----
0 | 0 |
1 | 0.0769230797886848 |
| 0.03125 | Of 32 rows, 32 were used and 0 were ignored
(3 rows)
```

LIFT_TABLE

Returns a table that compares the predictive quality of a machine learning model. This function is also known as a *lift chart* .

Syntax

```
LIFT_TABLE ( targets, probabilities
[ USING PARAMETERS [num_bins = num-bins] [, main_class = class-name] ])
OVER()
```

Arguments

targets

An input column that contains the true values of the response variable, one of the following data types: INTEGER, BOOLEAN, or CHAR/VARCHAR.

Depending on the column data type, the function processes column data as follows:

- INTEGER: Uses the input column as containing the true value of the response variable.
- BOOLEAN: Resolves Yes to 1, 0 to No.
- CHAR/VARCHAR: Resolves the value specified by parameter `main_class` to 1, all other values to 0.

Note

If the input column is of data type INTEGER or BOOLEAN, the function ignores parameter `main_class`.

probabilities

A FLOAT input column that contains the predicted probability of response being the main class, set to 1 if `targets` is of type INTEGER.

Parameters

num_bins

An integer value that determines the number of decision boundaries. Decision boundaries are set at equally spaced intervals between 0 and 1, inclusive. The function computes the table at each `num-bin + 1` point.

Default : 100

main_class

Used only if `targets` is of type CHAR/VARCHAR, specifies the class to associate with the `probabilities` argument.

Examples

Execute `LIFT_TABLE` on an input table `mtcars`.

```
=> SELECT LIFT_TABLE(obs::int, prob::float USING PARAMETERS num_bins=2) OVER()
FROM (SELECT am AS obs, PREDICT_LOGISTIC_REG(mpg, cyl, disp, drat, wt, qsec, vs, gear, carb
      USING PARAMETERS model_name='myLogisticRegModel',
      type='probability') AS prob
FROM mtcars) AS prediction_output;
```

decision_boundary	positive_prediction_ratio	lift	comment
1	0	NaN	
0.5	0.40625	2.46153846153846	
0	1	1	Of 32 rows, 32 were used and 0 were ignored

(3 rows)

The first column, `decision_boundary`, indicates the cut-off point for whether to classify a response as 0 or 1. For instance, for each row, if `prob` is greater than or equal to `decision_boundary`, the response is classified as 1. If `prob` is less than `decision_boundary`, the response is classified as 0.

The second column, `positive_prediction_ratio`, shows the percentage of samples in class 1 that the function classified correctly using the corresponding `decision_boundary` value.

For the third column, `lift`, the function divides the `positive_prediction_ratio` by the percentage of rows correctly or incorrectly classified as class 1.

MSE

Returns a table that displays the mean squared error of the prediction and response columns in a machine learning model.

Syntax

```
MSE ( targets, predictions ) OVER()
```

Arguments

targets

The model response variable, of type FLOAT.

predictions

A FLOAT input column that contains predicted values for the response variable.

Examples

Execute the MSE function on input table `faithful_testing` . The response variables appear in the column `obs` , while the prediction variables appear in the column `prediction` .

```
=> SELECT MSE(obs, prediction) OVER()
FROM (SELECT eruptions AS obs,
      PREDICT_LINEAR_REG (waiting USING PARAMETERS model_name='myLinearRegModel') AS prediction
FROM faithful_testing) AS prediction_output;
```

mse	Comments
0.252925741352641	Of 110 rows, 110 were used and 0 were ignored

(1 row)

PRC

Returns a table that displays the points on a receiver precision recall (PR) curve.

Syntax

```
PRC ( targets, probabilities
  [ USING PARAMETERS
    [num_bins = num-bins]
    [, f1_score = return-score ]
    [, main_class = class-name ] )
OVER()
```

Arguments

targets

An input column that contains the true values of the response variable, one of the following data types: INTEGER, BOOLEAN, or CHAR/VARCHAR. Depending on the column data type, the function processes column data as follows:

- INTEGER: Uses the input column as containing the true value of the response variable.
- BOOLEAN: Resolves Yes to 1, 0 to No.
- CHAR/VARCHAR: Resolves the value specified by parameter `main_class` to 1, all other values to 0.

Note

If the input column is of data type INTEGER or BOOLEAN, the function ignores parameter `main_class` .

probabilities

A FLOAT input column that contains the predicted probability of response being the main class, set to 1 if *targets* is of type INTEGER.

Parameters

num_bins

An integer value that determines the number of decision boundaries. Decision boundaries are set at equally spaced intervals between 0 and 1, inclusive. The function computes the table at each `num-bin + 1` point.

Default : 100

f1_score

A Boolean that specifies whether to return a column that contains the f1 score—the harmonic average of the precision and recall measures, where an F1 score reaches its best value at 1 (perfect precision and recall) and worst at 0.

Default: false

main_class

Used only if *targets* is of type CHAR/VARCHAR, specifies the class to associate with the *probabilities* argument.

Examples

Execute the PRC function on an input table named `mtcars` . The response variables appear in the column `obs` , while the prediction variables appear in column `pred` .

```
=> SELECT PRC(obs::int, prob::float USING PARAMETERS num_bins=2, f1_score=true) OVER()
FROM (SELECT am AS obs,
      PREDICT_LOGISTIC_REG (mpg, cyl, disp, drat, wt, qsec, vs, gear, carb
      USING PARAMETERS model_name='myLogisticRegModel',
      type='probability') AS prob
FROM mtcars) AS prediction_output;
decision_boundary | recall | precision | f1_score | comment
-----+-----+-----+-----+-----
0 | 1 | 0.40625 | 0.577777777777778 |
0.5 | 1 | 1 | 1 | Of 32 rows, 32 were used and 0 were ignored
(2 rows)
```

The first column, `decision_boundary`, indicates the cut-off point for whether to classify a response as 0 or 1. For example, in each row, if the probability is equal to or greater than `decision_boundary`, the response is classified as 1. If the probability is less than `decision_boundary`, the response is classified as 0.

READ_TREE

Reads the contents of trees within the random forest or XGBoost model.

Syntax

```
READ_TREE ( USING PARAMETERS model_name = 'model-name' [, tree_id = tree-id] [, format = 'format'] )
```

Parameters

model_name

Identifies the model that is stored as a result of training, where `model-name` conforms to conventions described in [Identifiers](#). It must also be unique among all names of sequences, tables, projections, views, and models within the same schema.

tree_id

The tree identifier, an integer between 0 and $n-1$, where n is the number of trees in the random forest or XGBoost model. If you omit this parameter, all trees are returned.

format

Output format of the returned tree, one of the following:

- `tabular`: Returns a table with the twelve output columns.
- `graphviz`: Returns DOT language source that can be passed to a graphviz tool and render a graphic visualization of the tree.

Privileges

Non-superusers: USAGE privileges on the model

Examples

Get tabular output from READ_TREE for a random forest model:

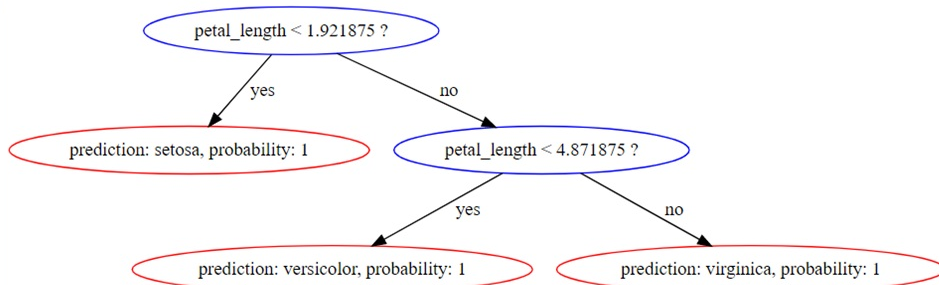

```
=> SELECT READ_TREE ( USING PARAMETERS model_name='myRFModel', tree_id=1 ,
format= 'tabular') LIMIT 2;
-[ RECORD 1 ]-----+-----
tree_id      | 1
node_id      | 1
node_depth   | 0
is_leaf      | f
is_categorical_split | f
split_predictor | petal_length
split_value  | 1.921875
weighted_information_gain | 0.111242236024845
left_child_id | 2
right_child_id | 3
prediction   |
probability/variance |

-[ RECORD 2 ]-----+-----
tree_id      | 1
node_id      | 2
node_depth   | 1
is_leaf      | t
is_categorical_split |
split_predictor |
split_value  |
weighted_information_gain |
left_child_id |
right_child_id |
prediction   | setosa
probability/variance | 1
```

Get [graphviz](#) -formatted output from READ_TREE:

```
=> SELECT READ_TREE ( USING PARAMETERS model_name='myRFModel', tree_id=1 ,
format= 'graphviz')LIMIT 1;
-[ RECORD 1 ]+-----
tree_id | 1
tree_digraph | digraph Tree{
1 [label="petal_length < 1.921875 ?", color="blue"];
1 -> 2 [label="yes", color="black"];
1 -> 3 [label="no", color="black"];
2 [label="prediction: setosa, probability: 1", color="red"];
3 [label="petal_length < 4.871875 ?", color="blue"];
3 -> 6 [label="yes", color="black"];
3 -> 7 [label="no", color="black"];
6 [label="prediction: versicolor, probability: 1", color="red"];
7 [label="prediction: virginica, probability: 1", color="red"];
}
```

This renders as follows:

- [RF_REGRESSOR](#)
- [XGB_CLASSIFIER](#)
- [XGB_REGRESSOR](#)

RF_PREDICTOR_IMPORTANCE

Measures the importance of the predictors in a random forest model using the Mean Decrease Impurity (MDI) approach. The importance vector is normalized to sum to 1.

Syntax

```
RF_PREDICTOR_IMPORTANCE ( USING PARAMETERS model_name = 'model-name' [, tree_id = tree-id] )
```

Parameters

model_name

Identifies the model that is stored as a result of the training, where *model-name* must be of type `rf_classifier` or `rf_regressor` .

tree_id

Identifies the tree to process, an integer between 0 and $n-1$, where n is the number of trees in the forest. If you omit this parameter, the function uses all trees to measure importance values.

Privileges

Non-superusers: USAGE privileges on the model

Examples

This example shows how you can use the RF_PREDICTOR_IMPORTANCE function.

```
=> SELECT RF_PREDICTOR_IMPORTANCE ( USING PARAMETERS model_name = 'myRFModel');
predictor_index | predictor_name | importance_value
-----+-----
0 | sepal.length | 0.106763318092655
1 | sepal.width | 0.0279536658041994
2 | petal.length | 0.499198722346586
3 | petal.width | 0.366084293756561
(4 rows)
```

See also

- [RF_CLASSIFIER](#)
- [RF_REGRESSOR](#)

ROC

Returns a table that displays the points on a receiver operating characteristic curve. The `ROC` function tells you the accuracy of a classification model as you raise the discrimination threshold for the model.

Syntax

```
ROC ( targets, probabilities
    [ USING PARAMETERS
      [num_bins = num-bins]
      [, AUC = output]
      [, main_class = class-name ] ] )
OVER()
```

Arguments

targets

An input column that contains the true values of the response variable, one of the following data types: INTEGER, BOOLEAN, or CHAR/VARCHAR. Depending on the column data type, the function processes column data as follows:

- INTEGER: Uses the input column as containing the true value of the response variable.
- BOOLEAN: Resolves Yes to 1, 0 to No.
- CHAR/VARCHAR: Resolves the value specified by parameter `main_class` to 1, all other values to 0.

Note

If the input column is of data type INTEGER or BOOLEAN, the function ignores parameter `main_class` .

probabilities

A FLOAT input column that contains the predicted probability of response being the main class, set to 1 if `targets` is of type INTEGER.

Parameters

num_bins

An integer value that determines the number of decision boundaries. Decision boundaries are set at equally spaced intervals between 0 and 1, inclusive. The function computes the table at each `num-bin + 1` point.

Default : 100

Greater values result in more precise approximations of the AUC.

AUC

A Boolean value that specifies whether to output the area under the curve (AUC) value.

Default: True

main_class

Used only if `targets` is of type CHAR/VARCHAR, specifies the class to associate with the `probabilities` argument.

Examples

Execute `ROC` on input table `mtcars` . Observed class labels are in column `obs` , predicted class labels are in column `prob` :

```
=> SELECT ROC(obs::int, prob::float USING PARAMETERS num_bins=5, AUC = True) OVER()
FROM (SELECT am AS obs,
      PREDICT_LOGISTIC_REG (mpg, cyl, disp, drat, wt, qsec, vs, gear, carb
      USING PARAMETERS
      model_name='myLogisticRegModel', type='probability') AS prob
FROM mtcars) AS prediction_output;
decision_boundary | false_positive_rate | true_positive_rate | AUC |comment
-----+-----+-----+-----+-----
0                | 1 | 1 | |
0.5              | 0 | 1 | |
1                | 0 | 0 | 1 | Of 32 rows,32 were used and 0 were ignored
(3 rows)
```

The function returns a table with the following results:

- `decision_boundary` indicates the cut-off point for whether to classify a response as 0 or 1. In each row, if `prob` is equal to or greater than `decision_boundary` , the response is classified as 1. If `prob` is less than `decision_boundary` , the response is classified as 0.
- `false_positive_rate` shows the percentage of false positives (when 0 is classified as 1) in the corresponding `decision_boundary` .
- `true_positive_rate` shows the percentage of rows that were classified as 1 and also belong to class 1.

RSQUARED

Returns a table with the R-squared value of the predictions in a regression model.

Syntax

```
RSQUARED ( targets, predictions ) OVER()
```

Important

The `OVER()` clause must be empty.

Arguments

targets

A FLOAT response variable for the model.

predictions

A FLOAT input column that contains the predicted values for the response variable.

Examples

This example shows how to execute the **RSQUARED** function on an input table named **faithful_testing** . The observed values of the response variable appear in the column, **obs** , while the predicted values of the response variable appear in the column, **pred** .

```
=> SELECT RSQUARED(obs, prediction) OVER()
FROM (SELECT eruptions AS obs,
      PREDICT_LINEAR_REG (waiting
        USING PARAMETERS model_name='myLinearRegModel') AS prediction
FROM faithful_testing) AS prediction_output;
rsq | comment
-----+-----
0.801392981147911 | Of 110 rows, 110 were used and 0 were ignored
(1 row)
```

XGB_PREDICTOR_IMPORTANCE

Measures the importance of the predictors in an XGBoost model. The function outputs three measures of importance for each predictor:

- **frequency** : relative number of times the model uses a predictor to split the data.
- **total_gain** : relative contribution of a predictor to the model based on the total [information gain](#) across a predictor's splits. A higher value means more predictive importance.
- **avg_gain** : relative contribution of a predictor to the model based on the average information gain across a predictor's splits.

The sum of each importance measure is normalized to one across all predictors.

Syntax

```
XGB_PREDICTOR_IMPORTANCE ( USING PARAMETERS param=value[,...])
```

Parameters

model_name

Name of the model, which must be of type **xgb_classifier** or **xgb_regressor** .

tree_id

Integer in the range [0, *n* -1], where *n* is the number of trees in **model_name** , that specifies the tree to process. If you omit this parameter, the function uses all trees in the model to measure predictor importance values.

Privileges

Non-superusers: USAGE privileges on the model

Examples

The following example measures the importance of the predictors in the model 'xgb_iris', an XGBoost classifier model, across all trees:

```
=> SELECT XGB_PREDICTOR_IMPORTANCE( USING PARAMETERS model_name = 'xgb_iris ');
predictor_index | predictor_name | frequency | total_gain | avg_gain
-----+-----+-----+-----+-----
0 | sepal_length | 0.15384615957737 | 0.0183021749937 | 0.0370849960701401
1 | sepal_width | 0.215384617447853 | 0.0154729501420881 | 0.0223944615251752
2 | petal_length | 0.369230777025223 | 0.607349886817728 | 0.512770753876444
3 | petal_width | 0.261538475751877 | 0.358874988046484 | 0.427749788528241
(4 rows)
```

To sort the predictors by importance values, you can use a nested query with an ORDER BY clause. The following sorts the model predictors by descending **avg_gain** :

```
=> SELECT * FROM (SELECT XGB_PREDICTOR_IMPORTANCE( USING PARAMETERS model_name = 'xgb_iris' )) AS importances ORDER BY avg_gain DESC;
```

predictor_index	predictor_name	frequency	total_gain	avg_gain
2	petal_length	0.369230777025223	0.607349886817728	0.512770753876444
3	petal_width	0.261538475751877	0.358874988046484	0.427749788528241
0	sepal_length	0.15384615957737	0.0183021749937	0.0370849960701401
1	sepal_width	0.215384617447853	0.0154729501420881	0.0223944615251752

(4 rows)

Model management

Vertica provides several functions for managing models.

In this section

- [CHANGE_MODEL_STATUS](#)
- [EXPORT_MODELS](#)
- [GET_MODEL_ATTRIBUTE](#)
- [GET_MODEL_SUMMARY](#)
- [IMPORT_MODELS](#)
- [REGISTER_MODEL](#)
- [UPGRADE_MODEL](#)

CHANGE_MODEL_STATUS

Changes the status of a registered model. Only dbadmin and users with the [MLSUPERVISOR](#) role can call this function.

The following diagram depicts the valid status transitions:

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Stable](#)

Syntax

```
CHANGE_MODEL_STATUS( 'registered_name', registered_version, 'new_status' )
```

Arguments

registered_name

Identifies the abstract name to which the model is registered. This *registered_name* can represent a group of models for a higher-level

application, where each model in the group has a unique version number.

registered_version

Unique version number of the model under the specified *registered_name*.

If there is no registered model with the given *registered_name* and *registered_version*, the function errors.

new_status

New status of the registered model. Must be one of the following strings and adhere to the valid status transitions depicted in the above [diagram](#):

- **under_review**: Status assigned to newly registered models.
- **staging**: Model is targeted for A/B testing against the model currently in production.
- **production**: Model is in production for its specified application. Only one model can be in production for a given *registered_name* at one time.
- **archived**: Status of models that were previously in production. Archived models can be returned to production at any time.
- **declined**: Model is no longer in consideration for production.
- **unregistered**: Model is removed from the versioning environment. The model does not appear in the REGISTERED_MODELS system table.

If you change the status of a model to 'production' and there is already a model in production under the given *registered_name*, the status of the model in production is set to 'archived' and the status of the new model is set to 'production'.

Privileges

One of the following:

- Superuser
- [MLSUPERVISOR](#)

Examples

In the following example, the **linear_reg_spark1** model, which is uniquely identified by the *registered_name* 'linear_reg_app' and the *registered_version* of two, is set to 'production' status:

```
=> SELECT * FROM REGISTERED_MODELS;
  registered_name | registered_version | status | registered_time | model_id | schema_name | model_name | model_type |
category
-----+-----+-----+-----+-----+-----+-----+-----+-----
linear_reg_app | 2 | STAGING | 2023-01-29 05:49:00.082166-04 | 45035996273714020 | public | linear_reg_spark1 |
PMML_REGRESSION_MODEL | PMML
linear_reg_app | 1 | PRODUCTION | 2023-01-24 09:19:04.553102-05 | 45035996273850350 | public | native_linear_reg |
LINEAR_REGRESSION | VERTICA_MODELS
logistic_reg_app | 1 | DECLINED | 2023-01-11 02:47:25.990626-02 | 45035996273853740 | public | log_reg_bfgs |
LOGISTIC_REGRESSION | VERTICA_MODELS
(3 rows)

=> SELECT CHANGE_MODEL_STATUS('linear_reg_app', 2, 'production');
CHANGE_MODEL_STATUS
-----
The status of model [linear_reg_app] - version [2] is changed to [production]
(1 row)
```

You can query the [REGISTERED_MODELS](#) system table to confirm that the **linear_reg_spark1** model is now in 'production' and the **native_linear_reg** model, which was currently in 'production', is moved to 'archived':

```
=> SELECT * FROM REGISTERED_MODELS;
  registered_name | registered_version | status | registered_time | model_id | schema_name | model_name | model_type |
category
-----+-----+-----+-----+-----+-----+-----+-----+-----
linear_reg_app | 2 | PRODUCTION | 2023-01-29 05:49:00.082166-04 | 45035996273714020 | public | linear_reg_spark1 |
PMML_REGRESSION_MODEL | PMML
linear_reg_app | 1 | ARCHIVED | 2023-01-24 09:19:04.553102-05 | 45035996273850350 | public | native_linear_reg |
LINEAR_REGRESSION | VERTICA_MODELS
logistic_reg_app | 1 | DECLINED | 2023-01-11 02:47:25.990626-02 | 45035996273853740 | public | log_reg_bfgs |
LOGISTIC_REGRESSION | VERTICA_MODELS
(2 rows)
```

If you change a model's status to 'unregistered', the model is removed from the model versioning environment and no longer appears in the REGISTERED_MODELS system table:

```
=> SELECT CHANGE_MODEL_STATUS('logistic_reg_app', 1, 'unregistered');
          CHANGE_MODEL_STATUS
-----
The status of model [logistic_reg_app] - version [1] is changed to [unregistered]
(1 row)

=> SELECT * FROM REGISTERED_MODELS;
 registered_name | registered_version | status | registered_time | model_id | schema_name | model_name | model_type |
category
-----+-----+-----+-----+-----+-----+-----+-----+
linear_reg_app | 2 | STAGING | 2023-01-29 05:49:00.082166-04 | 45035996273714020 | public | linear_reg_spark1 |
PMML_REGRESSION_MODEL | PMML
linear_reg_app | 1 | PRODUCTION | 2023-01-24 09:19:04.553102-05 | 45035996273850350 | public | native_linear_reg |
LINEAR_REGRESSION | VERTICA_MODELS
(2 rows)
```

See also

- [REGISTER_MODEL](#)
- [Model versioning](#)

EXPORT_MODELS

Exports machine learning models. Vertica supports three model formats:

- Native Vertica (VERTICA_MODELS)
- PMML
- TensorFlow

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
EXPORT_MODELS ( 'output-dir', 'export-target' [ USING PARAMETERS category = 'model-category' ] )
```

Arguments

output-dir

Absolute path of an output directory to store the exported models, either an absolute path on the initiator node file system or a URI for a [supported file system or object store](#).

export-target

Models to export:

```
[schema.]{model-name | * }
```

schema specifies the schema from which models are exported. If omitted, EXPORT_MODELS uses the default schema. Supply * (asterisk) to batch export all models from the schema.

If a model in a batch fails to export, the function issues a warning and then continues to export any remaining models in the batch. Details about any failed model exports are available in the log file generated at the *output-dir* location.

Parameters

category

The category of models to export, one of the following:

- **VERTICA_MODELS**
- **PMML**
- **TENSORFLOW**

EXPORT_MODELS exports models of the specified category according to the scope of the export operation—that is, whether it applies to a single model, or to all models within a schema. See [Export Scope and Category Processing](#) below.

[Exported Files](#) below describes the files that EXPORT_MODELS exports for each category.

If you omit this parameter, EXPORT_MODELS exports the model, or models in the specified schema, according to their model type.

Privileges

Superuser or [MLSUPERVISOR](#)

Export scope and category processing

EXPORT_MODELS executes according to the following parameter settings:

- Scope of the export operation: single model, or all models within a given schema
- Category specified or omitted

The following table shows how these two parameters control the export process:

Export scope	If category specified...	If category omitted...
Single model	Convert the model to the specified category, provided the model and category are compatible ; otherwise, return with a mismatch error.	Export the model according to model type.
All models in schema	Export only models that are compatible with the specified category and issue mismatch warnings on all other models in the schema.	Export all models in the schema according to model type.

Exported files

EXPORT_MODELS exports the following files for each model category:

VERTICA_MODELS

- Multiple binary files (exact number dependent on model type)
- [metadata.json](#) : Metadata file with model information, including model name, category, type, and Vertica version on export.
- [crc.json](#) : Used on import to validate other files of this model.

PMML

- XML file with the same name as the model and complying with PMML standard.
- [metadata.json](#) : Metadata file with model information, including model name, category, type, and Vertica version on export.
- [crc.json](#) : Used on import to validate other files of this model.

TENSORFLOW

- [model-name.pb](#) : Contains the TensorFlow model, saved in 'frozen graph' format.
- [metadata.json](#) : Metadata file with model information, including model name, category, type, and Vertica version on export.
- [tf_model_desc.json](#) : Summary model description.
- [model.json](#) : Verbose model description.
- [crc.json](#) : Used on import to validate other files of this model.

Categories and compatible models

If EXPORT_MODELS specifies a single model and also sets the [category](#) parameter, the function succeeds if the model type and category are compatible; otherwise, it returns with an error. The following model types are compatible with the listed categories:

PMML

[PMML](#)

TensorFlow

[TENSORFLOW](#)

VERTICA_MODELS

[PMML](#)

[VERTICA_MODELS](#)

If EXPORT_MODELS specifies to export all models from a schema and sets a category, it issues a warning message on each model that is incompatible with that category. The function then continues to process remaining models in that schema.

EXPORT_MODELS logs all errors and warnings in [output-dir/export_log.json](#) .

Examples

Export models without changing their category

Export model `myschema.mykmeansmodel` without changing its category:

```
=> SELECT EXPORT_MODELS ('/home/dbadmin', 'myschema.mykmeansmodel');
EXPORT_MODELS
-----
Success
(1 row)
```

Export all models in schema `myschema` without changing their categories:

```
=> SELECT EXPORT_MODELS ('/home/dbadmin', 'myschema.*');
EXPORT_MODELS
-----
Success
(1 row)
```

Export all the models in schema `models` to an S3 bucket without changing the model categories:

```
SELECT export_models('s3://vertica/ml_models', 'models.*');
EXPORT_MODELS
-----
Success
(1 row)
```

Export models that are compatible with the specified category

Note

When you import a model of category `VERTICA_MODELS` trained in a different version of Vertica, Vertica automatically upgrades the model version to match that of the database. If this fails, you must run [UPGRADE_MODEL](#).

If both methods fail, the model cannot be used for in-database scoring and cannot be exported as a PMML model.

The category is set to `PMML`. Models of type `PMML` and `VERTICA_MODELS` are compatible with the `PMML` category, so the export operation succeeds if `my_keans` is of either type:

```
=> SELECT EXPORT_MODELS ('/tmp', 'my_kmeans' USING PARAMETERS category='PMML');
```

The category is set to `VERTICA_MODELS`. Only models of type `VERTICA_MODELS` are compatible with the `VERTICA_MODELS` category, so the export operation succeeds only if `my_keans` is of that type:

```
=> SELECT EXPORT_MODELS ('/tmp', 'public.my_kmeans' USING PARAMETERS category='VERTICA_MODELS');
```

The category is set to `TENSORFLOW`. Only models of type `TensorFlow` are compatible with the `TENSORFLOW` category, so the model `tf_mnist_keras` must be of type `TensorFlow`:

```
=> SELECT EXPORT_MODELS ('/tmp', 'tf_mnist_keras', USING PARAMETERS category='TENSORFLOW');
export_models
-----
Success
(1 row)
```

After exporting the TensorFlow model `tf_mnist_keras`, list the exported files:

```
$ ls tf_mnist_keras/
crc.json metadata.json mnist_keras.pb model.json tf_model_desc.json
```

See also

[IMPORT_MODELS](#)

[GET_MODEL_ATTRIBUTE](#)

Extracts either a specific attribute from a model or all attributes from a model. Use this function to view a list of attributes and row counts or view detailed information about a single attribute. The output of `GET_MODEL_ATTRIBUTE` is a table format where users can select particular columns or rows.

Syntax

```
GET_MODEL_ATTRIBUTE ( USING PARAMETERS model_name = 'model-name' [, attr_name = 'attribute' ] )
```

Parameters

model_name

Name of the model (case-insensitive).

attr_name

Name of the model attribute to extract. If omitted, the function shows all available attributes. Attribute names are case-sensitive.

Privileges

Non-superusers: model owner, or USAGE privileges on the model

Examples

This example returns a summary of all model attributes.

```
=> SELECT GET_MODEL_ATTRIBUTE ( USING PARAMETERS model_name='myLinearRegModel');
attr_name      |      attr_fields      | #_of_rows
-----+-----+-----
details        | predictor, coefficient, std_err, t_value, p_value |      2
regularization | type, lambda          |      1
iteration_count | iteration_count       |      1
rejected_row_count | rejected_row_count   |      1
accepted_row_count | accepted_row_count   |      1
call_string    | call_string           |      1
(6 rows)
```

This example extracts the **details** attribute from the **myLinearRegModel** model.

```
=> SELECT GET_MODEL_ATTRIBUTE ( USING PARAMETERS model_name='myLinearRegModel', attr_name='details');
coeffNames | coeff | stdErr | zValue | pValue
-----+-----+-----+-----+-----
Intercept | -1.87401598641074 | 0.160143331525544 | -11.7021169008952 | 7.3592939615234e-26
waiting   | 0.0756279479518627 | 0.00221854185633525 | 34.0890336307608 | 8.13028381124448e-100
(2 rows)
```

GET_MODEL_SUMMARY

Returns summary information of a model.

Syntax

```
GET_MODEL_SUMMARY ( USING PARAMETERS model_name = 'model-name' )
```

Parameters

model_name

Name of the model (case-insensitive).

Privileges

Non-superusers: model owner, or USAGE privileges on the model

Examples

This example shows how you can view the summary of a linear regression model.

```
=> SELECT GET_MODEL_SUMMARY( USING PARAMETERS model_name='myLinearRegModel');
```

```

IMPORT_MODELS

Imports models into Vertica, either Vertica models that were exported with [EXPORT_MODELS](#), or models in Predictive Model Markup Language ([PMML](#)) or [TensorFlow](#) format. You can use this function to move models between Vertica clusters, or to import PMML and TensorFlow models trained elsewhere.

Other Vertica [model management operations](#) such as [GET_MODEL_SUMMARY](#) and [GET_MODEL_ATTRIBUTE](#) support imported models.

Caution

Changing the exported model files causes the import functionality to fail on attempted re-import.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
IMPORT_MODELS ( 'source'  
[ USING PARAMETERS [ new_schema = 'schema-name' ], category = 'model-category' ] ] )
```

Arguments

source

Path from which to import models, either an absolute path on the initiator node file system or a URI for a [supported file system or object store](#). The path format depends on whether you are importing a single model or a batch of models:

- To import a single model, provide the path to the model's directory:

```
path/model-directory
```

- To import a batch of models, provide the path to a parent directory that contains the model directories for each model in the batch:

```
parent-dir-path/*
```

If a model in a batch fails to import, the function issues a warning and then continues to import any remaining models in the batch. Details about any failed model import are available in the log file generated at the [source](#) location.

Parameters

new_schema

An existing schema where the machine learning models are imported. If omitted, models are imported to the default schema.

IMPORT_MODELS extracts the name of the imported model from its [metadata.json](#) file, if it exists. Otherwise, the function uses the name of the model directory.

category

Specifies the category of the model to import, one of the following:

- [VERTICA_MODELS](#)
- [PMML](#)
- [TENSORFLOW](#)

This parameter is required if the model directory has no [metadata.json](#) file. IMPORT_MODELS returns with an error if one of the following cases is true:

- No category is specified and the model directory has no [metadata.json](#) .
- The specified category does not match the model type.

Note

If the category is TENSORFLOW, IMPORT_MODELS only imports the following files from the model directory:

- [model-name.pb](#)
- [model-name.json](#)
- [model-name.pbtxt](#) (optional)

Privileges

Superuser or [MLSUPERVISOR](#)

Requirements and restrictions

The following requirements and restrictions apply:

- If you export a model, then import it again, the export and import model directory names must match. If naming conflicts occur, import the model to a different schema by using the [new_schema](#) parameter, and then rename the model.
- The machine learning configuration parameter [MaxModelSizeKB](#) sets the maximum size of a model that can be imported into Vertica.
- Some PMML features and attributes are not currently supported. See [PMML features and attributes](#) for details.
- If you import a PMML model with both [metadata.json](#) and [crc.json](#) files, the CRC file must contain the metadata file's CRC value. Otherwise, the import operation returns with an error.

Examples

If no model category is specified, IMPORT_MODELS uses the model's [metadata.json](#) file to determine its category.

Import a single model [mykmeansmodel](#) into the [newschema](#) schema:

```
=> SELECT IMPORT_MODELS ('/home/dbadmin/myschema/mykmeansmodel' USING PARAMETERS new_schema='newschema')
IMPORT_MODELS
-----
Success
(1 row)
```

Import all models in the [myschema](#) directory into the [newschema](#) schema:

```
=> SELECT IMPORT_MODELS ('/home/dbadmin/myschema/' USING PARAMETERS new_schema='newschema')
IMPORT_MODELS
-----
Success
(1 row)
```

Import the model `tf_mnsit_estimator` from an S3 bucket into the `ml_models` schema:

```
=> SELECT IMPORT_MODELS ('s3://ml-models/tensorflow/mnist' USING PARAMETERS new_schema='ml_models')
IMPORT_MODELS
-----
Success
(1 row)
```

When you set the `category` parameter, the specified category must match the model type of the imported models; otherwise, the function returns an error.

Import `kmeans_pmml` as a PMML model:

```
SELECT IMPORT_MODELS ('/root/user/kmeans_pmml' USING PARAMETERS category='PMML')
import_models
-----
Success
(1 row)
```

Attempt to import `kmeans_pmml`, a PMML model, as a TENSORFLOW model:

```
SELECT IMPORT_MODELS ('/root/user/kmeans_pmml' USING PARAMETERS category='TENSORFLOW')
import_models
-----
Has failure. Please check import_log.json file
(1 row)
```

Import `tf_mnist_estimator` as a TensorFlow model:

```
=> SELECT IMPORT_MODELS ('/path/tf_models/tf_mnist_estimator' USING PARAMETERS category='TENSORFLOW');
import_models
-----
Success
(1 row)
```

Import all TensorFlow models from the specified directory:

```
=> SELECT IMPORT_MODELS ('/path/tf_models/' USING PARAMETERS category='TENSORFLOW');
import_models
-----
Success
(1 row)
```

See also

[EXPORT_MODELS](#)

[REGISTER_MODEL](#)

Registers a trained model and adds it to [Model versioning](#) environment with a status of 'under_review'. The model must be registered by the owner of the model, dbadmin, or `MLSUPERVISOR`.

After a model is registered, the model owner is automatically changed to Superuser and the previous owner is given USAGE privileges. Users with the `MLSUPERVISOR` role or dbamin can call the [CHANGE_MODEL_STATUS](#) function to alter the status of registered models.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Stable](#)

Syntax

```
REGISTER_MODEL( 'model_name', 'registered_name' )
```

Arguments

model_name

Identifies the model to register. If the model has already been registered, the function throws an error.

registered_name

Identifies an abstract name to which the model is registered. This *registered_name* can represent a group of models for a higher-level application, where each model in the group has a unique version number.

If a model is the first to be registered to a given *registered_name*, the model is assigned a *registered_version* of one. Otherwise, newly registered models are assigned an incremented *registered_version* of $n + 1$, where n is the number of models already registered to the given *registered_name*. Each registered model can be uniquely identified by the combination of *registered_name* and *registered_version*.

Privileges

Non-superusers: model owner

Examples

In the following example, the model `log_reg_bfgs` is registered to the `logistic_reg_app` application:

```
=> SELECT REGISTER_MODEL('log_reg_bfgs', 'logistic_reg_app');
          REGISTER_MODEL
-----
Model [log_reg_bfgs] is registered as [logistic_reg_app], version [1]
(1 row)
```

You can query the [REGISTERED_MODELS](#) system table to view details about the newly registered model:

```
=> SELECT * FROM REGISTERED_MODELS;
 registered_name | registered_version | status | registered_time | model_id | schema_name | model_name | model_type |
category
-----+-----+-----+-----+-----+-----+-----+-----
logistic_reg_app |          1 | UNDER_REVIEW | 2023-01-22 09:49:25.990626-02 | 45035996273853740 | public | log_reg_bfgs |
LOGISTIC_REGRESSION | VERTICA_MODELS
(1 row)
```

See also

- [CHANGE_MODEL_STATUS](#)
- [Model versioning](#)

UPGRADE_MODEL

Upgrades a model from a previous Vertica version. Vertica automatically runs this function during a database upgrade and if you run the [IMPORT_MODELS](#) function. Manually call this function to upgrade models after a backup or restore.

If `UPGRADE_MODEL` fails to upgrade the model and the model is of category `VERTICA_MODELS`, it cannot be used for in-database scoring and cannot be [exported](#) as a PMML model.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
UPGRADE_MODEL ( [ USING PARAMETERS [model_name = 'model-name' ] ] )
```

Parameters

model_name

Name of the model to upgrade. If you omit this parameter, Vertica upgrades all models on which you have privileges.

Privileges

Non-superuser: Upgrades only models that the user owns.

Examples

Upgrade model `myLogisticRegModel` :

```
=> SELECT UPGRADE_MODEL( USING PARAMETERS model_name = 'myLogisticRegModel');
      UPGRADE_MODEL
```

```
-----
1 model(s) upgrade
```

```
(1 row)
```

Upgrade all models that the user owns:

```
=> SELECT UPGRADE_MODEL();
      UPGRADE_MODEL
```

```
-----
20 model(s) upgrade
```

```
(1 row)
```

Transformation functions

The machine learning API includes a set of UDX functions that transform the columns of each input row to one or more corresponding output columns. These transformations follow rules that are defined in models that were created earlier. For example, [APPLY_SVD](#) uses an SVD model to transform input data.

Unless otherwise indicated, these functions require the following privileges for non-superusers:

- USAGE privileges on the model
- SELECT privileges on the input relation

In general, given an invalid input row, the return value for these functions is NULL.

In this section

- [APPLY_BISECTING_KMEANS](#)
- [APPLY_IFOREST](#)
- [APPLY_INVERSE_PCA](#)
- [APPLY_INVERSE_SVD](#)
- [APPLY_KMEANS](#)

- [PREDICT_POISSON_REG](#)
- [PREDICT_RF_CLASSIFIER](#)
- [PREDICT_RF_CLASSIFIER_CLASSES](#)
- [PREDICT_RF_REGRESSOR](#)
- [PREDICT_SVM_CLASSIFIER](#)
- [PREDICT_SVM_REGRESSOR](#)
- [PREDICT_TENSORFLOW](#)
- [PREDICT_TENSORFLOW_SCALAR](#)
- [PREDICT_XGB_CLASSIFIER](#)
- [PREDICT_XGB_CLASSIFIER_CLASSES](#)
- [PREDICT_XGB_REGRESSOR](#)
- [REVERSE_NORMALIZE](#)

APPLY_BISECTING_KMEANS

Applies a trained bisecting k-means model to an input relation, and assigns each new data point to the closest matching cluster in the trained model.

Note

If the input relation is defined in Hive, use [SYNC_WITH_HCATALOG_SCHEMA](#) to sync the `hcatalog` schema, and then run the machine learning function.

Syntax

```
SELECT APPLY_BISECTING_KMEANS( 'input-columns'  
    USING PARAMETERS model_name = 'model-name'  
    [, num_clusters = 'num-clusters']  
    [, match_by_pos = match-by-position] ] )
```

Arguments

input-columns

Comma-separated list of columns to use from the input relation, or asterisk (*) to select all columns. Input columns must be of data type [numeric](#).

Parameters

model_name

Name of the model (case-insensitive).

num_clusters

Integer between 1 and *k* inclusive, where *k* is the number of centers in the model, specifies the number of clusters to use for prediction.

Default: Value that the model specifies for *k*

match_by_pos

Boolean value that specifies how input columns are matched to model features:

- **true** : Match by the position of columns in the input columns list.
- **false** (default): Match by name.

Privileges

Non-superusers: model owner, or USAGE privileges on the model

APPLY_IFOREST

Applies an isolation forest (iForest) model to an input relation. For each input row, the function returns an output row with two fields:

- **anomaly_score** : A float value that represents the average path length across all trees in the model normalized by the training sample size.
- **is_anomaly** : A Boolean value that indicates whether the input row is an anomaly. This value is true when **anomaly_score** is equal to or larger than a given threshold; otherwise, it's false.

Syntax

```
APPLY_IFOREST( input-columns USING PARAMETERS param=value[,...] )
```

Arguments

input-columns

Comma-separated list of columns to use from the input relation, or asterisk (*) to select all columns. Column types must match the types of the predictors in **model_name**.

Parameters

model_name

Name of the model (case-insensitive).

threshold

Optional. Float in the range (0.0, 1.0), specifies the threshold that determines if a data point is an anomaly. If the **anomaly_score** for a data point is equal to or larger than the value of **threshold**, the data point is marked as an outlier.

Alternatively, you can specify a **contamination** value that sets a threshold where the percentage of training data points labeled as outliers is approximately equal to the value of **contamination** . You cannot set both **contamination** and **threshold** in the same function call.

Default: 0.7

match_by_pos

Optional. Boolean value that specifies how input columns are matched to model columns:

- **false** : Match by name.
- **true** : Match by the position of columns in the input columns list.

Default: false

contamination

Optional. Float in the range (0.0, 1.0), the approximate ratio of data points in the training data that are labeled as outliers. The function calculates a threshold based on this **contamination** value. If you do not set this parameter, the function marks outliers using the specified or default **threshold** value.

You cannot set both **contamination** and **threshold** in the same function call.

Privileges

Non-superusers:

- USAGE privileges on the model
- SELECT privileges on the input relation

Examples

The following example demonstrates how different **threshold** values can affect outlier detection on an input relation:

```
=> SELECT * FROM (SELECT first_name, last_name, APPLY_IFOREST(team, hr, hits, avg, salary USING PARAMETERS
model_name='baseball_anomalies',
  threshold=0.75) AS predictions FROM baseball) AS outliers WHERE predictions.is_anomaly IS true;
first_name | last_name |          predictions
-----+-----+-----
Jacqueline | Richards | {"anomaly_score":0.777757463074347,"is_anomaly":true}
(1 row)

=> SELECT * FROM (SELECT first_name, last_name, APPLY_IFOREST(team, hr, hits, avg, salary USING PARAMETERS
model_name='baseball_anomalies',
  threshold=0.55) AS predictions FROM baseball) AS outliers WHERE predictions.is_anomaly IS true;
first_name | last_name |          predictions
-----+-----+-----
Jacqueline | Richards | {"anomaly_score":0.777757463074347,"is_anomaly":true}
Debra      | Hall     | {"anomaly_score":0.5714649698133808,"is_anomaly":true}
Gerald     | Fuller  | {"anomaly_score":0.5980549926114661,"is_anomaly":true}
(3 rows)
```

You can also use different **contamination** values to alter the outlier threshold:

```
=> SELECT * FROM (SELECT first_name, last_name, APPLY_IFOREST(team, hr, hits, avg, salary USING PARAMETERS
model_name='baseball_anomalies',
  contamination = 0.1) AS predictions FROM baseball) AS outliers WHERE predictions.is_anomaly IS true;
first_name | last_name |                predictions
-----+-----+-----
Marie      | Fields    | {"anomaly_score":0.5307715717521868,"is_anomaly":true}
Jacqueline | Richards  | {"anomaly_score":0.777757463074347,"is_anomaly":true}
Debra      | Hall      | {"anomaly_score":0.5714649698133808,"is_anomaly":true}
Gerald     | Fuller    | {"anomaly_score":0.5980549926114661,"is_anomaly":true}
(4 rows)
```

```
=> SELECT * FROM (SELECT first_name, last_name, APPLY_IFOREST(team, hr, hits, avg, salary USING PARAMETERS
model_name='baseball_anomalies',
  contamination = 0.01) AS predictions FROM baseball) AS outliers WHERE predictions.is_anomaly IS true;
first_name | last_name |                predictions
-----+-----+-----
Jacqueline | Richards  | {"anomaly_score":0.777757463074347,"is_anomaly":true}
Debra      | Hall      | {"anomaly_score":0.5714649698133808,"is_anomaly":true}
Gerald     | Fuller    | {"anomaly_score":0.5980549926114661,"is_anomaly":true}
(3 rows)
```

APPLY_INVERSE_PCA

Inverts the [APPLY_PCA](#)-generated transform back to the original coordinate system.

Syntax

```
APPLY_INVERSE_PCA ( input-columns
  USING PARAMETERS model_name = 'model-name'
  [, exclude_columns = 'excluded-columns']
  [, key_columns = 'key-columns'] )
```

Arguments

input-columns

Comma-separated list of columns to use from the input relation, or asterisk (*) to select all columns. The following requirements apply:

- All columns must be a [numeric](#) data type.
- Enclose the column name in double quotes if it contains special characters.

Parameters

model_name

Name of the model (case-insensitive).

exclude_columns

Comma-separated list of column names from *input-columns* to exclude from processing.

key_columns

Comma-separated list of column names from *input-columns* that identify its data rows. These columns are included in the output table.

Examples

The following example shows how to use the APPLY_INVERSE_PCA function. It shows the output for the first record.

```
=> SELECT PCA ('pcamodel', 'world', 'country', HDI, em1970, em1971, em1972, em1973, em1974, em1975, em1976, em1977,

APPLY_INVERSE_SVD

Transforms the data back to the original domain. This essentially computes the approximated version of the original data by multiplying three matrices: matrix U (input to this function), matrices S and V (stored in the model).

Syntax

```

APPLY_INVERSE_SVD ( 'input-columns'
    USING PARAMETERS model_name = 'model-name'
    [, exclude_columns = 'excluded-columns']
    [, key_columns = 'key-columns'] )

```

Arguments

input-columns

Comma-separated list of columns to use from the input relation, or asterisk (*) to select all columns. The following requirements apply:

- All columns must be a [numeric](#) data type.
- Enclose the column name in double quotes if it contains special characters.

Parameters

model_name

Name of the model (case-insensitive).

exclude_columns

Comma-separated list of column names from *input-columns* to exclude from processing.

key_columns

Comma-separated list of column names from *input-columns* that identify its data rows. These columns are included in the output table.

Examples

```
=> SELECT SVD ('svdmodel', 'small_svd', 'x1,x2,x3,x4');
```

SVD

Finished in 1 iterations.

Accepted Rows: 8 Rejected Rows: 0

(1 row)

```
=> CREATE TABLE transform_svd AS SELECT
```

```
  APPLY_SVD (id, x1, x2, x3, x4 USING PARAMETERS model_name='svdmodel', exclude_columns='id', key_columns='id')
  OVER () FROM small_svd;
```

```
CREATE TABLE
```

```
=> SELECT * FROM transform_svd;
```

```
id | col1 | col2 | col3 | col4

APPLY_KMEANS

Assigns each row of an input relation to a cluster center from an existing k-means model.

Syntax

```
APPLY_KMEANS ( input-columns
```

```
  USING PARAMETERS model_name = 'model-name' [, match_by_pos = match-by-position] )
```

Arguments

input-columns

Comma-separated list of columns to use from the input relation, or asterisk (*) to select all columns.

Parameters

model_name

Name of the model (case-insensitive).

match_by_pos

Boolean value that specifies how input columns are matched to model features:

- **true** : Match by the position of columns in the input columns list.
- **false** (default): Match by name.

Privileges

Non-superusers: model owner, or USAGE privileges on the model

Examples

The following example creates k-means model **myKmeansModel** and applies it to input table **iris1** . The call to **APPLY_KMEANS** mixes column names and constants. When a constant is passed in place of a column name, the constant is substituted for the value of the column in all rows:

```
=> SELECT KMEANS('myKmeansModel', 'iris1', '*', 5
USING PARAMETERS max_iterations=20, output_view='myKmeansView', key_columns='id', exclude_columns='Species, id');
      KMEANS
-----
Finished in 12 iterations

(1 row)
=> SELECT id, APPLY_KMEANS(Sepal_Length, 2.2, 1.3, Petal_Width
USING PARAMETERS model_name='myKmeansModel', match_by_pos='true') FROM iris2;
id | APPLY_KMEANS
---+-----
 5 |          1
10 |          1
14 |          1

APPLY_KPROTOTYPES

Assigns each row of an input relation to a cluster center from an existing k-prototypes model.

Syntax

```
APPLY_KPROTOTYPES ( input-columns
USING PARAMETERS model_name = 'model-name' [, match_by_pos = match-by-position ] )
```

Arguments

input-columns

Comma-separated list of columns to use from the input relation, or asterisk (*) to select all columns.

Parameters

model_name

Name of the model (case-insensitive).

match_by_pos

Boolean value that specifies how input columns are matched to model features:

- **true** : Match by the position of columns in the input columns list.
- **false** (default): Match by name.

Privileges

Non-superusers: model owner, or USAGE privileges on the model

Examples

The following example creates k-prototypes model `small_model` and applies it to input table `small_test_mixed` :

```
=> SELECT KPROTOTYPES('small_model_initcenters', 'small_test_mixed', 'x0, country', 3 USING PARAMETERS
initial_centers_table='small_test_mixed_centers', key_columns='pid');
  KPROTOTYPES
-----
Finished in 2 iterations

(1 row)

=> SELECT country, x0, APPLY_KPROTOTYPES(country, x0
USING PARAMETERS model_name='small_model')
FROM small_test_mixed;
  country | x0 | apply_kprototypes
-----+-----+-----
'China'  | 20 |          0
'US'     | 85 |          2
'Russia' | 80 |          1
'Brazil' | 78 |          1
'US'     | 23 |          0
'US'     | 50 |          0
'Canada' | 24 |          0
'Canada' | 18 |          0
'Russia' | 90 |          2
'Russia' | 98 |          2
'Brazil' | 89 |          2
...
(45 rows)
```

APPLY_NORMALIZE

A UDTF function that applies the normalization parameters saved in a model to a set of specified input columns. If any column specified in the function is not in the model, its data passes through unchanged to `APPLY_NORMALIZE` .

Note

Note : If a column contains only one distinct value, `APPLY_NORMALIZE` returns NaN for values in that column.

Syntax

```
APPLY_NORMALIZE ( input-columns USING PARAMETERS model_name = 'model-name');
```

Arguments

input-columns

Comma-separated list of columns to use from the input relation, or asterisk (*) to select all columns. If you supply an asterisk, `APPLY_NORMALIZE` normalizes all columns in the model.

Parameters

model_name

Name of the model (case-insensitive).

Examples

The following example creates a model with `NORMALIZE_FIT` using the `wt` and `hp` columns in table `mtcars`, and then uses this model in successive calls to `APPLY_NORMALIZE` and `REVERSE_NORMALIZE`.

```
=> SELECT NORMALIZE_FIT('mtcars_normfit', 'mtcars', 'wt,hp', 'minmax');
NORMALIZE_FIT
-----
Success
(1 row)
```

The following call to `APPLY_NORMALIZE` specifies the `hp` and `cyl` columns in table `mtcars`, where `hp` is in the normalization model and `cyl` is not in the normalization model:

```
=> CREATE TABLE mtcars_normalized AS SELECT APPLY_NORMALIZE (hp, cyl USING PARAMETERS model_name = 'mtcars_normfit') FROM mtcars;
CREATE TABLE
=> SELECT * FROM mtcars_normalized;
   hp      | cyl

APPLY_ONE_HOT_ENCODER

A user-defined transform function (UDTF) that loads the one hot encoder model and writes out a table that contains the encoded columns.

Syntax

```
APPLY_ONE_HOT_ENCODER( input-columns  
  USING PARAMETERS model_name = 'model-name'  
  [, drop_first = 'is-first']  
  [, ignore_null = 'ignore']  
  [, separator = 'separator-character']  
  [, column_naming = 'name-output']  
  [, null_column_name = 'null-column-name'] )
```

Arguments

input-columns

Comma-separated list of columns to use from the input relation, or asterisk (*) to select all columns.

Parameters

model_name

Name of the model (case-insensitive).
, stores the categories and their corresponding levels.

drop_first

Boolean value, one of the following:

- **true** (default): Treat the first level of the categorical variable as the reference level.
- **false** : Every level of the categorical variable has a corresponding column in the output view

ignore_null

Boolean value, one of the following:

- **true** (default): Null values set all corresponding one-hot binary columns to null.
- **false** : Null values in *input-columns* are treated as a categorical level

separator

The character that separates the input variable name and the indicator variable level in the output table. To avoid using any separator, set this parameter to null value.

Default: Underscore (`_`)

column_naming

Appends categorical levels to column names according to the specified method:

- **indices** (default): Uses integer indices to represent categorical levels.
- **values** / **values_relaxed** : Both methods use categorical level names. If duplicate column names occur, the function attempts to disambiguate them by appending `_n`, where `n` is a zero-based integer index (`_0` , `_1` , ...).

If the function cannot produce unique column names , it handles this according to the chosen method:

- **values** returns an error.
- **values_relaxed** reverts to using indices.

Important

The following column naming rules apply if `column_naming` is set to **values** or **values_relaxed** :

- Input column names with more than 128 characters are truncated.
- Column names can contain special characters.
- If parameter `ignore_null` is set to true, **APPLY_ONE_HOT_ENCODER** constructs the column name from the value set in parameter `null_column_name` . If this parameter is omitted, the string `null` is used.

null_column_name

The string used in naming the indicator column for null values, used only if `ignore_null` is set to **false** and `column_naming` is set to **values** or **values_relaxed** .

Default: `null`

Note

Note : If an input row contains a level not stored in the model, the output row columns corresponding to that categorical level are returned as null values.

Examples

```

=> SELECT APPLY_ONE_HOT_ENCODER(cyl USING PARAMETERS model_name='one_hot_encoder_model',
drop_first='true', ignore_null='false') FROM mtcars;
cyl | cyl_1 | cyl_2

APPLY_PCA

Transforms the data using a PCA model. This returns new coordinates of each data point.

Syntax

```

APPLY_PCA ( input-columns
  USING PARAMETERS model_name = 'model-name'
  [, num_components = num-components]
  [, cutoff = cutoff-value]
  [, match_by_pos = match-by-position]
  [, exclude_columns = 'excluded-columns']
  [, key_columns = 'key-columns' ] )

```

Arguments

input-columns

Comma-separated list of columns that contain the data matrix, or asterisk (*) to select all columns. The following requirements apply:

- All columns must be a [numeric](#) data type.
- Enclose the column name in double quotes if it contains special characters.

Parameters

model_name

Name of the model (case-insensitive).

num_components

The number of components to keep in the model. This is the number of output columns that will be generated. If you omit this parameter and the `cutoff` parameter, all model components are kept.

cutoff

Set to 1, specifies the minimum accumulated explained variance. Components are taken until the accumulated explained variance reaches this value.

match_by_pos

Boolean value that specifies how input columns are matched to model features:

- `true` : Match by the position of columns in the input columns list.
- `false` (default): Match by name.

exclude_columns

Comma-separated list of column names from `input-columns` to exclude from processing.

key_columns

Comma-separated list of column names from `input-columns` that identify its data rows. These columns are included in the output table.

Examples

```
=> SELECT PCA ('pcamodel', 'world', 'country', HDI, em1970, em1971, em1972, em1973, em1974, em1975, em1976, em1977, em1978, em1979, em1980, em1981, em1982, em1983, em1984, em1985, em1986, em1987, em1988, em1989, em1990, em1991, em1992, em1993, em1994, em1995, em1996, em1997, em1998, em1999, em2000, em2001, em2002, em2003, em2004, em2005, em2006, em2007, em2008, em2009, em2010, gdp1970, gdp1971, gdp1972, gdp1973, gdp1974, gdp1975, gdp1976, gdp1977, gdp1978, gdp1979, gdp1980, gdp1981, gdp1982, gdp1983, gdp1984, gdp1985, gdp1986, gdp1987, gdp1988, gdp1989, gdp1990, gdp1991, gdp1992, gdp1993, gdp1994, gdp1995, gdp1996, gdp1997, gdp1998, gdp1999, gdp2000, gdp2001, gdp2002, gdp2003, gdp2004, gdp2005, gdp2006, gdp2007, gdp2008, gdp2009, gdp2010' USING PARAMETERS exclude_columns='HDI, country');

APPLY_SVD ( input-columns
  USING PARAMETERS model_name = 'model-name'
  [, num_components = num-components]
  [, cutoff = cutoff-value]
  [, match_by_pos = match-by-position]
  [, exclude_columns = 'excluded-columns']
  [, key_columns = 'key-columns' ] )
```

Arguments

input-columns

Comma-separated list of columns that contain the data matrix, or asterisk (*) to select all columns. The following requirements apply:

- All columns must be a [numeric](#) data type.
- Enclose the column name in double quotes if it contains special characters.

Parameters

model_name

Name of the model (case-insensitive).

num_components

The number of components to keep in the model. This is the number of output columns that will be generated. If neither this parameter nor the [cutoff](#) parameter is provided, all components from the model are kept.

cutoff

Set to 1, specifies the minimum accumulated explained variance. Components are taken until the accumulated explained variance reaches this value. If you omit this parameter and the [num_components](#) parameter, all model components are kept.

match_by_pos

Boolean value that specifies how input columns are matched to model columns:

- [false](#) (default): Match by name.
- [true](#) : Match by the position of columns in the input columns list.

exclude_columns

Comma-separated list of column names from [input-columns](#) to exclude from processing.

key_columns

Comma-separated list of column names from [input-columns](#) that identify its data rows. These columns are included in the output table.

Examples

```
=> SELECT SVD ('svdmodel', 'small_svd', 'x1,x2,x3,x4');
```

SVD

Finished in 1 iterations.

PREDICT_ARIMA

Applies an autoregressive integrated moving average ([ARIMA](#)) model to an input relation or makes predictions using the in-sample data. ARIMA models make predictions based on preceding time series values and errors of previous predictions. The function, by default, returns the predicted values plus the mean of the model.

Behavior type

[Immutable](#)

Syntax

Apply to an input relation:

```
PREDICT_ARIMA ( timeseries-column
  USING PARAMETERS param=value[,...] )
  OVER (ORDER BY timestamp-column)
  FROM input-relation
```

Make predictions using the in-sample data:

```
PREDICT_ARIMA ( USING PARAMETERS model_name = 'ARIMA-model'  
[, start = prediction-start ]  
[, npredictions = num-predictions ]  
[, output_standard_errors = boolean ] )  
OVER ()
```

Arguments

timeseries-column

Name of a NUMERIC column in *input-relation* used to make predictions.

timestamp-column

Name of an INTEGER, FLOAT, or TIMESTAMP column in *input-relation* that represents the timestamp variable. The timestep between consecutive entries should be consistent throughout the *timestamp-column*.

input-relation

Input relation containing *timeseries-column* and *timestamp-column*.

Parameters

model_name

Name of a trained ARIMA model.

start

The behavior of the **start** parameter and its range of accepted values depends on whether you provide a *timeseries-column*:

- No provided *timeseries-column*: **start** must be an integer ≥ 0 , where zero indicates to start prediction at the end of the in-sample data. If **start** is a positive value, the function predicts the values between the end of the in-sample data and the **start** index, and then uses the predicted values as time series inputs for the subsequent *npredictions*.
- *timeseries-column* provided: **start** must be an integer ≥ 1 and identifies the index (row) of the *timeseries-column* at which to begin prediction. If the **start** index is greater than the number of rows, **N**, in the input data, the function predicts the values between **N** and **start** and uses the predicted values as time series inputs for the subsequent *npredictions*.

Default :

- No provided *timeseries-column*: prediction begins from the end of the in-sample data.
- *timeseries-column* provided: prediction begins from the end of the provided input data.

npredictions

Integer ≥ 1 , the number of predicted timesteps.

Default : 10

missing

Methods for handling missing values, one of the following strings:

- 'drop': Missing values are ignored.
- 'error': Missing values raise an error.
- 'zero': Missing values are replaced with 0.
- 'linear_interpolation': Missing values are replaced by linearly-interpolated values based on the nearest valid entries before and after the missing value. If all values before or after a missing value in the prediction range are missing or invalid, interpolation is impossible and the function errors.

Default: Method used when training the model

add_mean

Boolean, whether to add the model mean to the predicted value.

Default: True

output_standard_errors

Boolean, whether to return estimates of the standard error of each prediction.

Default: False

Examples

The following example makes predictions using the in-sample data that the *arima_temp* model was trained on:

```
-> SELECT PREDICT_ARIMA(USING PARAMETERS model_name='arima_temp', npredictions=10) OVER();
index | prediction
-----+-----
 1 | 12.9794640462952
 2 | 13.3759980774506
 3 | 13.4596213753292
 4 | 13.4670492239575
 5 | 13.4559956810351
 6 | 13.4405315951159
 7 | 13.424086943584
 8 | 13.4074973032696
 9 | 13.3909657020137
10 | 13.374540947803
(10 rows)
```

You can also apply the model to an input relation:

```
-> SELECT PREDICT_ARIMA(temperature USING PARAMETERS model_name='arima_temp', start=100, npredictions=10) OVER(ORDER BY time) FROM
index | prediction
-----+-----
 1 | 15.0373821404594
 2 | 13.4707358943239
 3 | 10.5714574755414
 4 | 13.1957213344543
 5 | 13.5606204019976
 6 | 13.1604413418938
 7 | 13.3998222399722
 8 | 12.6110939669533
 9 | 12.9015211253485
10 | 13.2382768006631
(10 rows)
```

For an in-depth example that trains and makes predictions with an ARIMA model, see [ARIMA model example](#).

PREDICT_AUTOREGRESSOR

Applies an autoregressor (AR) or vector autoregression (VAR) model to an input relation. The function returns predictions for each value column specified during model creation.

AR and VAR models use previous values to make predictions. During model training, the user specifies the number of lagged timesteps taken into account during computation. The model predicts future values as a linear combination of the timeseries values at each lag.

Syntax

```
PREDICT_AUTOREGRESSOR ( timeseries-columns
  USING PARAMETERS model_name = 'model-name' [, param=value[...]] )
  OVER (ORDER BY timestamp-column)
  FROM input-relation
```

Note

The following argument, as written, is required and cannot be omitted nor substituted with another type of clause.

```
OVER (ORDER BY timestamp-column)
```

Arguments

timeseries-columns

The timeseries columns used to make predictions. The number of *timeseries-columns* must be the same as the number of value columns provided during model training.

For each prediction, the model only considers the previous **P** values of each column, where **P** is the lag set during model creation.

timestamp-column

The timestamp column, with consistent timesteps, used to make the prediction.

input-relation

The input relation containing the *timeseries-columns* and *timestamp-column*.

The *input-relation* cannot have missing values in any of the **P** rows preceding **start**, where **P** is the lag set during model creation. To handle missing values, see [IMPUTE](#) or [Linear interpolation](#).

Parameters

model_name

Name of the model (case-insensitive).

start

INTEGER >p or ≤0, the index (row) of the *input-relation* at which to start the prediction. If omitted, the prediction starts at the end of the *input-relation*.

If the **start** index is greater than the number of rows **N** in *timeseries-columns*, then the values between **N** and **start** are predicted and used for the prediction.

If negative, the **start** index is identified by counting backwards from the end of the *input-relation*.

For an *input-relation* of **N** rows, negative values have a lower limit of either -1000 or -(N-p), whichever is greater.

Default: the end of *input-relation*

npredictions

INTEGER ≥1, the number of predicted timesteps.

Default: 10

missing

One of the following methods for handling missing values:

- **drop** : Missing values are ignored.
- **error** : Missing values raise an error.
- **zero** : Missing values are replaced with 0.
- **linear_interpolation** : Missing values are replaced by linearly-interpolated values based on the nearest valid entries before and after the missing value. If all values before or after a missing value in the prediction range are missing or invalid, interpolation is impossible and the function errors. VAR models do not support linear interpolation.

Default: Method used when training the model

Examples

The following example makes predictions using an AR model for 10 timesteps after the end of the input relation:

```
-> SELECT PREDICT_AUTOREGRESSOR(Temperature USING PARAMETERS model_name='AR_temperature', npredictions=10)
       OVER(ORDER BY time) FROM temp_data;
index | prediction
-----+-----
 1 | 12.6235419917807
 2 | 12.9387860506032
 3 | 12.6683380680058
 4 | 12.3886937385419
 5 | 12.2689506237424
 6 | 12.1503023330142
 7 | 12.0211734746741
 8 | 11.9150531529328
 9 | 11.825870404008
10 | 11.7451846722395
(10 rows)
```

The following example makes predictions using a VAR model for 10 timesteps after the end of the input relation:

```
=> SELECT PREDICT_AUTOREGRESSOR(temp_location1, temp_location2 USING PARAMETERS
  model_name='VAR_temperature', npredictions=10) OVER(ORDER BY time) FROM temp_data_VAR;
index | temp_location1 | temp_location2
-----+-----+-----
 1 | 11.7583950082813 | 12.7193948948294
 2 | 11.8492948294829 | 12.2400294852222
 3 | 11.9917382847772 | 13.8385038582000
 4 | 11.2302988673747 | 13.1174827497563
 5 | 11.8920481717273 | 13.1948776593788
 6 | 12.1737583757385 | 12.7362846366622
 7 | 12.0397364321183 | 12.9274628462844
 8 | 12.0395726450372 | 12.1749275028444
 9 | 11.8249947849488 | 12.3274926927433
10 | 11.1129497288422 | 12.1749274927493
(10 rows)
```

See [Autoregressive model example](#) and [VAR model example](#) for extended examples.

PREDICT_LINEAR_REG

Applies a linear regression model on an input relation and returns the predicted value as a FLOAT.

Syntax

```
PREDICT_LINEAR_REG ( input-columns
  USING PARAMETERS model_name = 'model-name' [, match_by_pos = match-by-position] )
```

Arguments

input-columns

Comma-separated list of columns to use from the input relation, or asterisk (*) to select all columns.

Parameters

model_name

Name of the model (case-insensitive).

match_by_pos

Boolean value that specifies how input columns are matched to model features:

- **true** : Match by the position of columns in the input columns list.
- **false** (default): Match by name.

Examples

```
=> SELECT PREDICT_LINEAR_REG(waiting USING PARAMETERS model_name='myLinearRegModel')FROM
faithful ORDER BY id;
```

PREDICT_LINEAR_REG

```
-----
4.15403481386324

2.28552115094171
2.28552115094171
```

...
(272 rows)

PREDICT_LOGISTIC_REG

Applies a logistic regression model on an input relation.

PREDICT_LOGISTIC_REG returns as a FLOAT the predicted class or the probability of the predicted class, depending on how the `type` parameter is set. You can cast the return value to INTEGER or another [numeric](#) type when the return is in the probability of the predicted class.

Syntax

```
PREDICT_LOGISTIC_REG ( input-columns
USING PARAMETERS model_name = 'model-name'
[, type = 'prediction-type']
[, cutoff = probability-cutoff]
[, match_by_pos = match-by-position] )
```

Arguments

input-columns

Comma-separated list of columns to use from the input relation, or asterisk (*) to select all columns.

Parameters

model_name

Name of the model (case-insensitive).

type

Type of prediction for logistic regression, one of the following:

- **response** (default): Predicted values are 0 or 1.

- **probability** : Output is the probability of the predicted category to be 1.

cutoff

Used in conjunction with the **type** parameter, a FLOAT between 0 and 1, exclusive. When **type** is set to **response** , the returned value of prediction is 1 if its corresponding probability is greater than or equal to the value of **cutoff** ; otherwise, it is 0.

Default: 0.5

match_by_pos

Boolean value that specifies how input columns are matched to model features:

- **true** : Match by the position of columns in the input columns list.
- **false** (default): Match by name.

Examples

```
=> SELECT car_model,
        PREDICT_LOGISTIC_REG(mpg, cyl, disp, drat, wt, qsec, vs, gear, carb
                             USING PARAMETERS model_name='myLogisticRegModel')
FROM mtcars;
car_model | PREDICT_LOGISTIC_REG
```

```

PREDICT_MOVING_AVERAGE

Applies a moving-average (MA) model, created by [MOVING_AVERAGE](#), to an input relation.

Moving average models use the errors of previous predictions to make future predictions. More specifically, the user-specified "lag" determines how many previous predictions and errors it takes into account during computation.

Syntax

```
PREDICT_MOVING_AVERAGE ( timeseries-column
  USING PARAMETERS
    model_name = 'model-name'
    [, start = starting-index]
    [, npredictions = npredictions]
    [, missing = "imputation-method" ] )
OVER (ORDER BY timestamp-column)
FROM input-relation
```

Note

The following argument, as written, is required and cannot be omitted nor substituted with another type of clause.

OVER (ORDER BY *timestamp-column*)

Arguments

timeseries-column

The timeseries column used to make the prediction (only the last *q* values, specified during model creation, are used).

timestamp-column

The timestamp column, with consistent timesteps, used to make the prediction.

input-relation

The input relation containing the *timeseries-column* and *timestamp-column*.

Note that *input-relation* cannot have missing values in any of the *q* (set during training) rows preceding *start*. To handle missing values, see [IMPUTE](#) or [Linear interpolation](#).

Parameters

model_name

Name of the model (case-insensitive).

start

INTEGER $>q$ or ≤ 0 , the index (row) of the *input-relation* at which to start the prediction. If omitted, the prediction starts at the end of the *input-relation*.

If the *start* index is greater than the number of rows *N* in *timeseries-column*, then the values between *N* and *start* are predicted and used for the prediction.

If negative, the *start* index is identified by counting backwards from the end of the *input-relation*.

For an *input-relation* of *N* rows, negative values have a lower limit of either -1000 or $-(N-q)$, whichever is greater.

Default: the end of *input-relation*

npredictions

INTEGER ≥ 1 , the number of predicted timesteps.

Default: 10

missing

One of the following methods for handling missing values:

- **drop** : Missing values are ignored.
- **error** : Missing values raise an error.
- **zero** : Missing values are replaced with 0.
- **linear_interpolation** : Missing values are replaced by linearly-interpolated values based on the nearest valid entries before and after the missing value. If all values before or after a missing value in the prediction range are missing or invalid, interpolation is impossible and the function errors.

Default: Method used when training the model

Examples

See [Moving-average model example](#).

See also

- [MOVING_AVERAGE](#)
- [GET_MODEL_SUMMARY](#)

PREDICT_NAIVE_BAYES

Applies a Naive Bayes model on an input relation.

Depending on how the *type* parameter is set, PREDICT_NAIVE_BAYES returns a VARCHAR that specifies either the predicted class or probability of the predicted class. If the function returns probability, you can cast the return value to an INTEGER or another [numeric](#) data type.

Syntax

```
PREDICT_NAIVE_BAYES ( input-columns
  USING PARAMETERS model_name = 'model-name'
  [, type = 'return-type' ]
  [, class = 'user-input-class' ]
  [, match_by_pos = match-by-position] )
```

Arguments

input-columns

Comma-separated list of columns to use from the input relation, or asterisk (*) to select all columns.

Parameters

model_name

Name of the model (case-insensitive).

type

One of the following:

- **response** (default): Returns the class with the highest probability.
- **probability** : Valid only if **class** parameter is set, returns the probability of belonging to the specified class argument.

class

Required if **type** parameter is set to **probability** . If you omit this parameter, **PREDICT_NAIVE_BAYES** returns the class that it predicts as having the highest probability.

match_by_pos

Boolean value that specifies how input columns are matched to model features:

- **true** : Match by the position of columns in the input columns list.
- **false** (default): Match by name.

Examples

```
=> SELECT party, PREDICT_NAIVE_BAYES (vote1, vote2, vote3
  USING PARAMETERS model_name='naive_house84_model',
  type='response')
  AS Predicted_Party
  FROM house84_test;

PREDICT_NAIVE_BAYES_CLASSES

Applies a Naive Bayes model on an input relation and returns the probabilities of classes:

- VARCHAR **predicted** column contains the class label with the highest probability.
- Multiple FLOAT columns, where the first **probability** column contains the probability for the class specified in the predicted column. Other columns contain the probability of belonging to each class specified in the **classes** parameter.

Syntax

```
PREDICT_NAIVE_BAYES_CLASSES ( predictor-columns
  USING PARAMETERS model_name = 'model-name'
  [, key_columns = 'key-columns']
  [, exclude_columns = 'excluded-columns']
  [, classes = 'classes']
  [, match_by_pos = match-by-position] )
OVER( [window-partition-clause] )
```

Arguments

predictor-columns

Comma-separated list of columns to use from the input relation, or asterisk (*) to select all columns.

Parameters

model_name

Name of the model (case-insensitive).

key_columns

Comma-separated list of predictor column names that identify the output rows. To exclude these and other predictor columns from being used for prediction, include them in the argument list for parameter **exclude_columns** .

exclude_columns

Comma-separated list of columns from **predictor-columns** to exclude from processing.

classes

Comma-separated list of class labels in the model. The probability of belonging to this given class as predicted by the classifier. The values are case sensitive.

match_by_pos

Boolean value that specifies how predictor columns are matched to model features:

- **false** (default): Match by name.
- **true** : Match by the position of columns in the predictor columns list.

Examples

```
=> SELECT PREDICT_NAIVE_BAYES_CLASSES (id, vote1, vote2 USING PARAMETERS
model_name='naive_house84_model',key_columns='id',exclude_columns='id',
classes='democrat, republican', match_by_pos='false')
  OVER() FROM house84_test;
id | Predicted | Probability | democrat | republican

PREDICT_PLS_REG

Applies a [PLS_REG](#) model to an input relation and returns a predicted FLOAT value for each row in the input relation.

Syntax

```
PREDICT_PLS_REG ( input-columns
  USING PARAMETERS param=value[,...] )
```

Arguments

input-columns

Comma-separated list of predictor columns to use from the input relation or asterisk (*) to select all columns.

Parameters

model_name

Name of the model (case-insensitive).

match_by_pos

Boolean value that specifies how input columns are matched to model features:

- **true** : Match by the position of columns in the input columns list.
- **false** (default): Match by name.

Examples

The following example uses the [monarch_pls](#) model to make predictions on the [monarch_test](#) input relation:

```
=> SELECT PREDICT_PLS_REG (* USING PARAMETERS model_name='monarch_pls') FROM monarch_test;
PREDICT_PLS_REG
-----
2.88462577469318
2.86535009598611
2.84138719904564
2.7222022770597
3.96163808455087
3.30690898656628
2.99904802221049
(7 rows)
```

For an in-depth example, see [PLS regression](#).

See also

- [PLS_REG](#)
- [GET_MODEL_SUMMARY](#)
- [GET_MODEL_ATTRIBUTE](#)

PREDICT_PMML

Applies an imported PMML model on an input relation. The function returns the result that would be expected for the model type encoded in the PMML model.

PREDICT_PMML returns NULL in the following cases:

- The predictor is an invalid or NULL value.
- The categorical predictor is of an unknown class.

Note

PREDICT_PMML returns values of complex type [ROW](#) for models that use the [Output tag](#). Currently, Vertica does not support directly inserting this data into a table.

You can work around this limitation by changing the output to JSON with [TO_JSON](#) before inserting it into a table:

```
=> CREATE TABLE predicted_output AS SELECT TO_JSON(PREDICT_PMML(X1,X2,X3
USING PARAMETERS model_name='pmml_imported_model'))
AS predicted_value
FROM input_table;
```

Syntax

```
PREDICT_PMML ( input-columns
USING PARAMETERS model_name = 'model-name' [, match_by_pos = match-by-position] )
```

Arguments

input-columns

Comma-separated list of columns to use from the input relation, or asterisk (*) to select all columns.

Parameters

model_name

Name of the model (case-insensitive). For a list of supported PMML model types and tags, see [PMML features and attributes](#).

match_by_pos

Boolean value that specifies how input columns are matched to model features:

- **true** : Match by the position of columns in the input columns list.
- **false** (default): Match by name.

Examples

In this example, the function call uses all the columns from the table as predictors and predicts the value using the ' **my_kmeans** ' model in PMML format:

```
SELECT PREDICT_PMML(* USING PARAMETERS model_name='my_kmeans') AS predicted_label FROM table;
```

In this example, the function call takes only columns **col1**, **col2** as predictors, and predicts the value for each row using the ' **my_kmeans** ' model from schema ' **my_schema** ':

```
SELECT PREDICT_PMML(col1, col2 USING PARAMETERS model_name='my_schema.my_kmeans') AS predicted_label FROM table;
```

In this example, the function call returns an error as neither **schema** nor **model-name** can accept * as a value:

```
SELECT PREDICT_PMML(* USING PARAMETERS model_name='*.*') AS predicted_label FROM table;
SELECT PREDICT_PMML(* USING PARAMETERS model_name=*) AS predicted_label FROM table;
SELECT PREDICT_PMML(* USING PARAMETERS model_name='models.*') AS predicted_label FROM table;
```

- [IMPORT_MODELS](#)
- [EXPORT_MODELS](#)

PREDICT_POISSON_REG

Applies a Poisson regression model on an input relation and returns the predicted value as a FLOAT.

Syntax

```
PREDICT_POISSON_REG ( input-columns
USING PARAMETERS model_name = 'model-name' [, match_by_pos = match-by-position] )
```

Arguments

input-columns

Comma-separated list of columns to use from the input relation, or asterisk (*) to select all columns.

Parameters

model_name

Name of the model (case-insensitive).

match_by_pos

Boolean value that specifies how input columns are matched to model features:

- **true** : Match by the position of columns in the input columns list.
- **false** (default): Match by name.

Examples

```
=> SELECT PREDICT_POISSON_REG(waiting USING PARAMETERS model_name='MYModel')::numeric(20,10) FROM lin.fairful ORDER BY id;
predict_poisson_reg
-----
4.0230080811

3.5747254723
2.6921731651
4.6357580051
2.2817680621
4.9762900161
4.6357580051
2.0759884314
(9 rows)
```

PREDICT_RF_CLASSIFIER

Applies a random forest model on an input relation. PREDICT_RF_CLASSIFIER returns a VARCHAR data type that specifies one of the following, as determined by how the **type** parameter is set:

- The predicted class (based on popular votes)
- Probability of a class for each input instance.

Note

The predicted class is selected only based on the popular vote of the decision trees in the forest. Therefore, in special cases the calculated probability of the predicted class may not be the highest.

Syntax

```
PREDICT_RF_CLASSIFIER ( input-columns
    USING PARAMETERS model_name = 'model-name'
    [, type = 'prediction-type']
    [, class = 'user-input-class']
    [, match_by_pos = match-by-position] )
```

Arguments

input-columns

Comma-separated list of columns to use from the input relation, or asterisk (*) to select all columns.

Parameters

model_name

Name of the model (case-insensitive).

type

Type of prediction to return, one of the following:

- **response** (default): The class with the highest probability among all possible classes.
- **probability** : Valid only if the **class** parameter is set, returns the probability of the specified class.

class

Class to use when the **type** parameter is set to **probability** . If you omit this parameter, the function uses the predicted class—the one with the popular vote. Thus, the predict function returns the probability that the input instance belongs to its predicted class.

match_by_pos

Boolean value that specifies how input columns are matched to model features:

- **true** : Match by the position of columns in the input columns list.
- **false** (default): Match by name.

Examples

```
=> SELECT PREDICT_RF_CLASSIFIER (Sepal_Length, Sepal_Width, Petal_Length, Petal_Width
      USING PARAMETERS model_name='myRFModel') FROM iris;
PREDICT_RF_CLASSIFIER
-----
setosa
setosa
setosa
...
versicolor
versicolor
versicolor
...
virginica
virginica
virginica
...
(150 rows)
```

This example shows how you can use the PREDICT_RF_CLASSIFIER function, using the `match_by_pos` parameter:

```
=> SELECT PREDICT_RF_CLASSIFIER (Sepal_Length, Sepal_Width, Petal_Length, Petal_Width
      USING PARAMETERS model_name='myRFModel', match_by_pos='true') FROM iris;
PREDICT_RF_CLASSIFIER
-----
setosa
setosa
setosa
...
versicolor
versicolor
versicolor
...
virginica
virginica
virginica
...
(150 rows)
```

- [RF_CLASSIFIER](#)
- [PREDICT_RF_CLASSIFIER_CLASSES](#)
- [GET_MODEL_SUMMARY](#)

PREDICT_RF_CLASSIFIER_CLASSES

Applies a random forest model on an input relation and returns the probabilities of classes:

- VARCHAR **predicted** column contains the class label with the highest vote (popular vote).
- Multiple FLOAT columns, where the first **probability** column contains the probability for the class reported in the predicted column. Other columns contain the probability of each class specified in the **classes** parameter.
- Key columns with the same value and data type as matching input columns specified in parameter **key_columns** .

Note

Selection of the predicted class is based on the popular vote of decision trees in the forest. Thus, in special cases the calculated probability of the predicted class might not be the highest.

```
PREDICT_RF_CLASSIFIER_CLASSES ( predictor-columns
  USING PARAMETERS model_name = 'model-name'
  [, key_columns = 'key-columns']
  [, exclude_columns = 'excluded-columns']
  [, classes = 'classes']
  [, match_by_pos = match-by-position] )
OVER( [window-partition-clause] )
```

Arguments

predictor-columns

Comma-separated list of columns to use from the input relation, or asterisk (*) to select all columns.

Parameters

model_name

Name of the model (case-insensitive).

key_columns

Comma-separated list of predictor column names that identify the output rows. To exclude these and other predictor columns from being used for prediction, include them in the argument list for parameter **exclude_columns** .

exclude_columns

Comma-separated list of columns from **predictor-columns** to exclude from processing.

classes

Comma-separated list of class labels in the model. The probability of belonging to this given class is predicted by the classifier. Values are case sensitive.

match_by_pos

Boolean value that specifies how predictor columns are matched to model features:

- **false** (default): Match by name.
- **true** : Match by the position of columns in the predictor columns list.

Examples

```
=> SELECT PREDICT_RF_CLASSIFIER_CLASSES(Sepal_Length, Sepal_Width, Petal_Length, Petal_Width
      USING PARAMETERS model_name='myRFModel') OVER () FROM iris;
predicted | probability
-----+-----

PREDICT_RF_REGRESSOR

Applies a random forest model on an input relation, and returns with a FLOAT data type that specifies the predicted value of the random forest model—the average of the prediction of the trees in the forest.

Syntax

```
PREDICT_RF_REGRESSOR ( input-columns
      USING PARAMETERS model_name = 'model-name' [, match_by_pos = match-by-position] )
```

Arguments

input-columns

Comma-separated list of columns to use from the input relation, or asterisk (*) to select all columns.

Parameters

model_name

Name of the model (case-insensitive).

match_by_pos

Boolean value that specifies how input columns are matched to model features:

- **true** : Match by the position of columns in the input columns list.
- **false** (default): Match by name.

Examples

```
=> SELECT PREDICT_RF_REGRESSOR (mpg,cyl,hp,drat,wt
USING PARAMETERS model_name='myRFRegressorModel')FROM mtcars;
PREDICT_RF_REGRESSOR

PREDICT_SVM_CLASSIFIER

Uses an SVM model to predict class labels for samples in an input relation, and returns the predicted value as a FLOAT data type.

Syntax

```
PREDICT_SVM_CLASSIFIER (input-columns
USING PARAMETERS model_name = 'model-name'
    [, match_by_pos = match-by-position]
    [, type = 'return-type']
    [, cutoff = 'cutoff-value'] ] )
```

Arguments

input-columns

Comma-separated list of columns to use from the input relation, or asterisk (*) to select all columns.

Parameters

model_name

Name of the model (case-insensitive).

match_by_pos

Boolean value that specifies how input columns are matched to model features:

- **true** : Match by the position of columns in the input columns list.
- **false** (default): Match by name.

type

A string that specifies the output to return for each input row, one of the following:

- **response** : Outputs the predicted class of 0 or 1.
- **probability** : Outputs a value in the range (0,1), the prediction score transformed using the logistic function.

cutoff

Valid only if the **type** parameter is set to **probability** , a FLOAT value that is compared to the transformed prediction score to determine the predicted class.

Default: 0

Examples

```
=> SELECT PREDICT_SVM_CLASSIFIER (mpg,cyl,disp,wt,qsec,vs,gear,carb
USING PARAMETERS model_name='mySvmClassModel') FROM mtcars;
PREDICT_SVM_CLASSIFIER

PREDICT_SVM_REGRESSOR

Uses an SVM model to perform regression on samples in an input relation, and returns the predicted value as a FLOAT data type.

Syntax

```
PREDICT_SVM_REGRESSOR(input-columns
    USING PARAMETERS model_name = 'model-name' [, match_by_pos = match-by-position] )
```

Arguments

input-columns

Comma-separated list of columns to use from the input relation, or asterisk (*) to select all columns.

Parameters

model_name

Name of the model (case-insensitive).

match_by_pos

Boolean value that specifies how input columns are matched to model features:

- **true** : Match by the position of columns in the input columns list.
- **false** (default): Match by name.

Examples

```
=> SELECT PREDICT_SVM_REGRESSOR(waiting USING PARAMETERS model_name='mySvmRegModel')
      FROM faithful ORDER BY id;
PREDICT_SVM_REGRESSOR
-----
4.06488248694445

PREDICT_TENSORFLOW

Applies a TensorFlow model on an input relation, and returns with the result expected for the encoded model type.

Syntax

```
PREDICT_TENSORFLOW ( input-columns
                    USING PARAMETERS model_name = 'model-name' [, num_passthru_cols = 'n-first-columns-to-ignore' ]
                    OVER( [window-partition-clause] )
```

Arguments

input-columns

Comma-separated list of columns to use from the input relation, or asterisk (*) to select all columns.

Parameters

model_name

Name of the model (case-insensitive).

num_passthru_cols

Integer that specifies the number of input columns to skip.

Examples

Use PREDICT_TENSORFLOW with the `num_passthru_cols` parameter to skip the first two input columns:

```
=> SELECT PREDICT_TENSORFLOW ( pid,label,x1,x2
    USING PARAMETERS model_name='spiral_demo', num_passthru_cols=2 )
OVER(PARTITION BEST) as predicted_class FROM points;

--example output, the skipped columns are displayed as the first columns of the output
pid | label | col0 | col1
-----+-----+-----+-----
0 | 0 | 0.990638732910156 | 0.00936129689216614
1 | 0 | 0.999036073684692 | 0.000963933940511197
2 | 1 | 0.0103802494704723 | 0.989619791507721
```

- [PREDICT_TENSORFLOW_SCALAR](#)
- [Classifying data using naive bayes](#)
- [NAIVE_BAYES](#)
- [PREDICT_NAIVE_BAYES_CLASSES](#)

PREDICT_TENSORFLOW_SCALAR

Applies an imported TensorFlow model on an input relation. This function, unlike [PREDICT_TENSORFLOW](#), accepts one input column of type [ROW](#), where each field corresponds to an input tensor, and returns one output column of type [ROW](#), where each field corresponds to an output tensor.

For details about importing TensorFlow models into Vertica, see [TensorFlow integration and directory structure](#).

Syntax

```
PREDICT_TENSORFLOW_SCALAR ( inputs
    USING PARAMETERS model_name = 'model-name' )
```

Arguments

inputs

Input column of type [ROW](#) with fields of 1D [ARRAY](#)s that represent input tensors. These tensors can represent outputs for various input operations.

Parameters

model_name

Name of the model (case-insensitive).

Examples

This function can simplify the process for making predictions on data with many input features.

For instance, the [MNIST handwritten digit classification dataset](#) contains 784 input features for each input row, one feature for each pixel in the images of handwritten digits. The PREDICT_TENSORFLOW function requires that each of these input features are contained in a separate input column. By encapsulating these features into a single ARRAY, the PREDICT_TENSORFLOW_SCALAR function only needs a single input column of type [ROW](#), where the pixel values are the array elements for an input field:

--Each array for the "image" field has 784 elements.

```
=> SELECT * FROM mnist_train;
id |          inputs
---+-----
 1 | {"image":[0, 0, 0,..., 244, 222, 210,...]}
 2 | {"image":[0, 0, 0,..., 185, 84, 223,...]}
 3 | {"image":[0, 0, 0,..., 133, 254, 78,...]}
...
```

In this case, the function output consists of a single operation with one tensor. The value of this field is an array of ten elements, which are all zero except for the element whose index is the predicted digit:

```
=> SELECT id, PREDICT_TENSORFLOW_SCALAR(inputs USING PARAMETERS model_name='tf_mnist_ct') FROM mnist_test;
id |          PREDICT_TENSORFLOW_SCALAR
---+-----
 1 | {"prediction:0":["0", "0", "0", "0", "1", "0", "0", "0", "0", "0"]}
 2 | {"prediction:0":["0", "1", "0", "0", "0", "0", "0", "0", "0", "0"]}
 3 | {"prediction:0":["0", "0", "0", "0", "0", "0", "0", "1", "0", "0"]}
...
```

To view the expected input and output tensors for an imported TensorFlow model, call [GET_MODEL_SUMMARY](#):

```
=> SELECT GET_MODEL_SUMMARY(USING PARAMETERS model_name='tf_mnist_ct');
          GET_MODEL_SUMMARY
-----
=====
input_tensors
=====
name |type |dimensions
-----+-----
image |int32| [-1,784]

=====
output_tensors
=====
name  | type |dimensions
-----+-----
prediction:0 |int32| [-1,10]

(1 row)
```

PREDICT_XGB_CLASSIFIER

Applies an XGBoost classifier model on an input relation. [PREDICT_XGB_CLASSIFIER](#) returns a VARCHAR data type that specifies one of the following, as determined by how the `type` parameter is set:

- The predicted class (based on probability scores)
- Probability of a class for each input instance.

Syntax

```
PREDICT_XGB_CLASSIFIER ( input-columns
    USING PARAMETERS model_name = 'model-name'
    [, type = 'prediction-type' ]
    [, class = 'user-input-class' ]
    [, match_by_pos = 'match-by-position' ]
    [, probability_normalization = 'prob-normalization' ] )
```

Arguments

input-columns

Comma-separated list of columns to use from the input relation, or asterisk (*) to select all columns.

Parameters

model_name

Name of the model (case-insensitive).

type

Type of prediction to return, one of the following:

- **response** (default): The class with the highest probability among all possible classes.
- **probability** : Valid only if the **class** parameter is set, returns for each input instance the probability of the specified class or predicted class.

class

Class to use when the **type** parameter is set to **probability** . If you omit this parameter, the function uses the predicted class—the one with the highest probability score. Thus, the predict function returns the probability that the input instance belongs to the specified or predicted class.

match_by_pos

Boolean value that specifies how input columns are matched to model features:

- **true** : Match by the position of columns in the input columns list.
- **false** (default): Match by name.

probability_normalization

The classifier's normalization method, either **softmax** (multi-class classifier) or **logit** (binary classifier). If unspecified, the default **logit** function is used for normalization.

Examples

Use [PREDICT_XGB_CLASSIFIER](#) to apply the classifier to the test data:

```
=> SELECT PREDICT_XGB_CLASSIFIER (Sepal_Length, Sepal_Width, Petal_Length, Petal_Width
  USING PARAMETERS model_name='xgb_iris', probability_normalization='logit') FROM iris1;
PREDICT_XGB_CLASSIFIER

(90 rows)
```

See [XGBoost for classification](#) for more examples.

PREDICT_XGB_CLASSIFIER_CLASSES

Applies an XGBoost classifier model on an input relation and returns the probabilities of classes:

- VARCHAR **predicted** column contains the class label with the highest probability.

- Multiple FLOAT columns, where the first **probability** column contains the probability for the class reported in the predicted column. Other columns contain the probability of each class specified in the **classes** parameter.
- Key columns with the same value and data type as matching input columns specified in parameter **key_columns** .

All trees contribute to a predicted probability for each response class, and the highest probability class is chosen.

Syntax

```
PREDICT_XGB_CLASSIFIER_CLASSES ( predictor-columns)
  USING PARAMETERS model_name = 'model-name'
    [, key_columns = 'key-columns']
    [, exclude_columns = 'excluded-columns']
    [, classes = 'classes']
    [, match_by_pos = match-by-position]
    [, probability_normalization = 'prob-normalization' ] )
OVER( [window-partition-clause] )
```

Arguments

input_columns

Comma-separated list of columns to use from the input relation, or asterisk (*) to select all columns.

Parameters

model_name

Name of the model (case-insensitive).

key_columns

Comma-separated list of predictor column names that identify the output rows. To exclude these and other predictor columns from being used for prediction, include them in the argument list for parameter **exclude_columns** .

exclude_columns

Comma-separated list of columns from **predictor_columns** to exclude from processing.

classes

Comma-separated list of class labels in the model. The probability of belonging to each given class is predicted by the classifier. Values are case sensitive.

match_by_pos

Boolean value that specifies how predictor columns are matched to model features:

- **false** (default): Match by name.
- **true** : Match by the position of columns in the predictor columns list.

probability_normalization

The classifier's normalization method, either **softmax** (multi-class classifier) or **logit** (binary classifier). If unspecified, the default **logit** function is used for normalization.

Examples

After creating an XGBoost classifier model with **XGB_CLASSIFIER**, you can use **PREDICT_XGB_CLASSIFIER_CLASSES** to view the probability of each classification. In this example, the XGBoost classifier model "xgb_iris" is used to predict the probability that a given flower belongs to a species of iris:

```
=> SELECT PREDICT_XGB_CLASSIFIER_CLASSES(Sepal_Length, Sepal_Width, Petal_Length, Petal_Width
      USING PARAMETERS model_name='xgb_iris') OVER (PARTITION BEST) FROM iris1;
predicted | probability
-----+-----
setosa    | 0.9999650465368
setosa    | 0.9999650465368
setosa    | 0.9999650465368
setosa    | 0.9999650465368
setosa    | 0.999911552783011
setosa    | 0.9999650465368
setosa    | 0.9999650465368
setosa    | 0.9999650465368
setosa    | 0.9999650465368
setosa    | 0.9999650465368
setosa    | 0.9999650465368
setosa    | 0.9999650465368
setosa    | 0.9999650465368
setosa    | 0.9999650465368
versicolor | 0.99991871763563
.
.
.
(90 rows)
```

You can also specify additional classes. In this example, `PREDICT_XGB_CLASSIFIER_CLASSES` makes the same prediction as the previous example, but also returns the probability that a flower belongs to the specified `classes` "virginica" and "versicolor":

```
=> SELECT PREDICT_XGB_CLASSIFIER_CLASSES(Sepal_Length, Sepal_Width, Petal_Length, Petal_Width
      USING PARAMETERS model_name='xgb_iris', classes='virginica,versicolor', probability_normalization='logit') OVER (PARTITION BEST) FROM iris1;

(90 rows)
```

PREDICT_XGB_REGRESSOR

Applies an XGBoost regressor model on an input relation. `PREDICT_XGB_REGRESSOR` returns a FLOAT data type that specifies the predicted value by the XGBoost model: a weighted sum of contributions by each tree in the model.

Syntax

```
PREDICT_XGB_REGRESSOR ( input-columns
      USING PARAMETERS model_name = 'model-name' [, match_by_pos = match-by-position] )
```

Arguments

input-columns

Comma-separated list of columns to use from the input relation, or asterisk (*) to select all columns.

Parameters

model_name

Name of the model (case-insensitive).

match_by_pos

Boolean value that specifies how input columns are matched to model features:

- **true** : Match by the position of columns in the input columns list.
- **false** (default): Match by name.

Examples

See [XGBoost for regression](#).

REVERSE_NORMALIZE

Reverses the normalization transformation on normalized data, thereby de-normalizing the normalized data. If you specify a column that is not in the specified model, **REVERSE_NORMALIZE** returns that column unchanged.

Syntax

```
REVERSE_NORMALIZE ( input-columns USING PARAMETERS model_name = 'model-name' );
```

Arguments

input-columns

The columns to use from the input relation, or asterisk (*) to select all columns.

Parameters

model_name

Name of the model (case-insensitive).

Examples

Use **REVERSE_NORMALIZE** on the **hp** and **cyl** columns in table **mtcars** , where **hp** is in normalization model **mtcars_normfit** , and **cyl** is not in the normalization model.

```
=> SELECT REVERSE_NORMALIZE (hp, cyl USING PARAMETERS model_name='mtcars_normfit') FROM mtcars;
```

```

Management functions

Vertica has functions to manage various aspects of database operation, such as sessions, privileges, projections, and the catalog.

In this section

- [Catalog functions](#)
- [Cloud functions](#)
- [Cluster functions](#)
- [Data Collector functions](#)
- [Database functions](#)
- [Eon Mode functions](#)
- [Epoch functions](#)
- [LDAP link functions](#)
- [License functions](#)
- [Notifier functions](#)
- [Partition functions](#)
- [Privileges and access functions](#)
- [Projection functions](#)

- [Session functions](#)
- [Storage functions](#)
- [Table functions](#)

Catalog functions

This section contains catalog management functions specific to Vertica.

In this section

- [DROP_LICENSE](#)
- [DUMP_CATALOG](#)
- [EXPORT_CATALOG](#)
- [EXPORT_OBJECTS](#)
- [EXPORT_TABLES](#)
- [INSTALL_LICENSE](#)
- [MARK_DESIGN_KSAFE](#)
- [RELOAD_ADMINTOOLS_CONF](#)

DROP_LICENSE

Drops a license key from the global catalog. Dropping expired keys is optional. Vertica automatically ignores expired license keys if a valid, alternative license key is installed.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
DROP_LICENSE( 'license-name' )
```

Parameters

license-name

The name of the license to drop. Use the name (or long license key) in the **NAME** column of system table [LICENSES](#).

Privileges

Superuser

Examples

```
=> SELECT DROP_LICENSE('9b2d81e2-aab1-4cfb-bc07-fa9a696e8f5e');
```

See also

[Managing licenses](#)

DUMP_CATALOG

Returns an internal representation of the Vertica catalog. This function is used for diagnostic purposes.

DUMP_CATALOG returns only the objects that are visible to the user.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
DUMP_CATALOG()
```

Privileges

None

Examples

The following query obtains an internal representation of the Vertica catalog:

```
=> SELECT DUMP_CATALOG();
```

The output is written to the specified file:

```
\o /tmp/catalog.txt
SELECT DUMP_CATALOG();
\o
```

EXPORT_CATALOG

Note

This function and [EXPORT_OBJECTS](#) return equivalent output.

Generates a SQL script you can use to recreate a physical schema design on another cluster.

If you omit all arguments, this function exports to standard output all objects to which you have access.

The SQL script:

- Only includes objects to which the user has access.
- Orders CREATE statements based on object dependencies so they can be recreated in the correct sequence. For example, if a table is in a non-public schema, the required CREATE SCHEMA statement precedes the CREATE TABLE statement. Similarly, a table's CREATE ACCESS POLICY statement follows the table's CREATE TABLE statement.
- If possible, creates projections with a KSAFE clause, if any, otherwise with an OFFSET clause.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
EXPORT_CATALOG ( [ '[destination]' [, 'scope'] ] )
```

Arguments

destination

Where to send output. To write the script to standard output, use an empty string (" "). A [superusers](#) can specify a file path. If you specify only a file name, Vertica creates it in the catalog directory. If the file already exists, the function silently overwrites its contents.

scope

What to export. Within the specified scope, EXPORT_CATALOG exports all the objects to which you have access:

- DESIGN: Exports all catalog objects, including schemas, tables, constraints, views, access policies, projections, SQL macros, and stored procedures.
- DESIGN_ALL: Deprecated.
- TABLES: Exports all tables and their access policies. See also [EXPORT_TABLES](#).
- DIRECTED_QUERIES: Exports all directed queries that are stored in the database. For details, see [Managing directed queries](#).

Default : DESIGN

Privileges

None

Examples

Export all design elements in order of their dependencies:

```
=> SELECT EXPORT_CATALOG(
  '/home/dbadmin/xtest/sql_cat_design.sql',
  'DESIGN' );
EXPORT_CATALOG
-----
Catalog data exported successfully
(1 row)
```

Export only tables and their dependencies:

```
=> SELECT EXPORT_CATALOG (
  'home/dbadmin/xtest/sql_cat_tables.sql',
  'TABLES');
EXPORT_CATALOG
```

Catalog data exported successfully

(1 row)

See also

- [EXPORT_OBJECTS](#)
- [EXPORT_TABLES](#)
- [Exporting the catalog](#)

EXPORT_OBJECTS

Note

This function and [EXPORT_CATALOG](#) return equivalent output.

Generates a SQL script you can use to recreate non-virtual catalog objects on another cluster.

If you omit all arguments, this function exports to standard output all objects to which you have access.

The SQL script:

- Only includes objects to which the user has access.
- Orders CREATE statements based on object dependencies so they can be recreated in the correct sequence. For example, if a table is in a non-public schema, the required CREATE SCHEMA statement precedes the CREATE TABLE statement. Similarly, a table's CREATE ACCESS POLICY statement follows the table's CREATE TABLE statement.
- If possible, creates projections with a KSAFE clause, if any, otherwise with an OFFSET clause.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
EXPORT_OBJECTS( ['destination'] [, ['scope']] [, 'mark-ksafe'] )
```

Arguments

destination

Where to send output. To write the script to standard output, use an empty string (" "). A [superusers](#) can specify a file path. If you specify only a file name, Vertica creates it in the catalog directory. If the file already exists, the function silently overwrites its contents.

scope

The objects to export, a comma-delimited list, or an empty string to export all objects to which the user has access. If you specify a schema, the function exports all accessible objects in that schema.

For [stored procedures](#) with the same name but different formal parameters, you can export all implementations by exporting the parent schema, or specify the types or types and names of the formal parameters to identify the implementation to export.

mark-ksafe

Boolean, whether the generated script calls the [MARK_DESIGN_KSAFE](#) function. If true (default), MARK_DESIGN_KSAFE uses the correct K-safe argument for the current database.

Privileges

None

Examples

The following query exports all accessible objects to a named file:

```
-> SELECT EXPORT_OBJECTS(
  '/home/dbadmin/xtest/sql_objects_all.sql',
  '',
  'true');
EXPORT_OBJECTS
```

Catalog data exported successfully

(1 row)

To export a particular implementation of a stored procedure, specify either the types or both the names and types of the procedure's formal parameters. The following example specifies the types:

```
-> SELECT EXPORT_OBJECTS('',raiseXY(int, int));
EXPORT_OBJECTS
```

```
-----
CREATE PROCEDURE public.raiseXY(x int, y int)
LANGUAGE 'PLvSQL'
SECURITY INVOKER
AS '
BEGIN
RAISE NOTICE "x = %", x;
RAISE NOTICE "y = %", y;
-- some processing statements
END
';
```

```
SELECT MARK_DESIGN_KSAFE(0);
```

(1 row)

To export all implementations of an overloaded stored procedure, export its parent schema:

```
=> SELECT EXPORT_OBJECTS('public');
EXPORT_OBJECTS
```

```
-----
--
--
CREATE PROCEDURE public.raiseXY(x int, y varchar)
LANGUAGE 'PLvSQL'
SECURITY INVOKER
AS '
BEGIN
RAISE NOTICE "x = %", x;
RAISE NOTICE "y = %", y;
-- some processing statements
END
;
```

```
CREATE PROCEDURE public.raiseXY(x int, y int)
LANGUAGE 'PLvSQL'
SECURITY INVOKER
AS '
BEGIN
RAISE NOTICE "x = %", x;
RAISE NOTICE "y = %", y;
-- some processing statements
END
;
```

```
SELECT MARK_DESIGN_KSAFE(0);
```

```
(1 row)
```

See also

- [EXPORT_CATALOG](#)
- [EXPORT_TABLES](#)
- [Exporting objects](#)

EXPORT_TABLES

Generates a SQL script that can be used to recreate a logical schema—schemas, tables, constraints, and views—on another cluster. EXPORT_TABLES only exports objects to which the user has access.

The SQL script conforms to the following requirements:

- Only includes objects to which the user has access.
- Orders CREATE statements according to object dependencies so they can be recreated in the correct sequence. For example, if a table references a named sequence, a CREATE SEQUENCE statement precedes the CREATE TABLE statement. Similarly, a table's CREATE ACCESS POLICY statement follows the table's CREATE TABLE statement.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
EXPORT_TABLES( ['[destination]' [, '[scope]']] )
```

Note

If you omit all parameters, EXPORT_CATALOG exports to standard output all tables to which you have access.

Parameters

destination

Specifies where to send output, one of the following:

- An empty string (") writes the script to standard output.
- The path and name of a SQL output file. This option is valid only for [superusers](#). If you specify a file that does not exist, the function creates one. If you specify only a file name, Vertica creates it in the catalog directory. If the file already exists, the function silently overwrites its contents.

scope

Specifies one or more tables to export, as follows:

```
[database.]schema[table][,...]
```

- If set to an empty string, Vertica exports all non-virtual table objects to which you have access, including table schemas, sequences, and constraints.
- If you specify a schema, Vertica exports all non-virtual table objects in that schema.
- If you specify a database, it must be the current database.

Privileges

None

Examples

See [Exporting tables](#).

See also

- [Exporting tables](#)
- [EXPORT_CATALOG](#)
- [EXPORT_OBJECTS](#)

INSTALL_LICENSE

Installs the license key in the global catalog.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
INSTALL_LICENSE( 'filename' )
```

Parameters

filename

The absolute path name of a valid license file.

Privileges

Superuser

Examples

```
=> SELECT INSTALL_LICENSE('/tmp/vlicense.dat');
```

See also

[Managing licenses](#)

MARK_DESIGN_KSAFE

Enables or disables high availability in your environment, in case of a failure. Before enabling recovery, [MARK_DESIGN_KSAFE](#) queries the catalog to determine whether a cluster's physical schema design meets the following requirements:

- Small, unsegmented tables are replicated on all nodes.
- Large table [superprojections](#) are segmented with each segment on a different node.
- Each large table projection has at least one [buddy projection](#) for K-safety=1 (or two buddy projections for K-safety=2). Buddy projections are also segmented across database nodes, but the distribution is modified so segments that contain the same data are distributed to different nodes. See [High availability with projections](#).

[MARK_DESIGN_KSAFE](#) does not change the physical schema.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
MARK_DESIGN_KSAFE ( k )
```

Parameters

k

Specifies the level of K-safety, one of the following:

- 2: Enables high availability if the schema design meets requirements for K-safety=2
- 1: Enables high availability if the schema design meets requirements for K-safety=1
- 0: Disables high availability

Privileges

Superuser

Return messages

If you specify a *k* value of 1 or 2, Vertica returns one of the following messages.

Success:

```
Marked design n-safe
```

Failure:

```
The schema does not meet requirements for K=n.  
Fact table projection projection-name  
has insufficient "buddy" projections.
```

where *n* is a K-safety setting.

Notes

- The database's internal recovery state persists across database restarts but it is not checked at startup time.
- When one node fails on a system marked K-safe=1, the remaining nodes are available for DML operations.

Examples

```
=> SELECT MARK_DESIGN_KSAFE(1);  
mark_design_ksafe  
-----  
Marked design 1-safe  
(1 row)
```

If the physical schema design is not K-safe, messages indicate which projections do not have a buddy:

```
=> SELECT MARK_DESIGN_KSAFE(1);  
The given K value is not correct;  
the schema is 0-safe  
Projection pp1 has 0 buddies,  
which is smaller that the given K of 1  
Projection pp2 has 0 buddies,  
which is smaller that the given K of 1  
.  
.  
.  
(1 row)
```

See also

- [Identical segmentation](#)
- [Failure recovery](#)

RELOAD_ADMINTOOLS_CONF

Updates the admintools.conf on each UP node in the cluster. Updates include:

- IP addresses and catalog paths

- Node names for all nodes in the current database

This function provides a manual method to instruct the server to update `admintools.conf` on all UP nodes. For example, if you restart a node, call this function to confirm its `admintools.conf` file is accurate.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
RELOAD_ADMINTOOLS_CONF()
```

Privileges

[Superuser](#)

Examples

Update `admintools.conf` on each UP node in the cluster:

```
=> SELECT RELOAD_ADMINTOOLS_CONF();
   RELOAD_ADMINTOOLS_CONF
-----
admintools.conf reloaded
(1 row)
```

Cloud functions

This section contains functions for managing cloud integrations. See also [Hadoop functions](#) for HDFS.

In this section

- [AZURE_TOKEN_CACHE_CLEAR](#)

[AZURE_TOKEN_CACHE_CLEAR](#)

Clears the cached access token for Azure. Call this function after changing the configuration of Azure managed identities.

An Azure object store can support and manage multiple identities. If multiple identities are in use, Vertica looks for an Azure tag with a key of `VerticaManagedIdentityClientId`, the value of which must be the `client_id` attribute of the managed identity to be used. If the Azure configuration changes, use this function to clear the cache.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
AZURE_TOKEN_CACHE_CLEAR ( )
```

Privileges

Superuser

Cluster functions

This section contains functions that manage [spread](#) deployment on large, distributed database clusters and functions that control how the cluster organizes data for rebalancing.

In this section

- [CANCEL_REBALANCE_CLUSTER](#)

- [RELOAD_SPREAD](#)
- [SET_CONTROL_SET_SIZE](#)
- [SET_SCALING_FACTOR](#)
- [START_REBALANCE_CLUSTER](#)

CANCEL_REBALANCE_CLUSTER

Stops any rebalance task that is currently in progress or is waiting to execute.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
CANCEL_REBALANCE_CLUSTER()
```

Privileges

Superuser

Examples

```
=> SELECT CANCEL_REBALANCE_CLUSTER();
CANCEL_REBALANCE_CLUSTER
-----
CANCELED
(1 row)
```

See also

- [START_REBALANCE_CLUSTER](#)
- [REBALANCE_CLUSTER](#)

DISABLE_LOCAL_SEGMENTS

Disables local data segmentation, which breaks projections segments on nodes into containers that can be easily moved to other nodes. See [Local data segmentation](#) for details.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
DISABLE_LOCAL_SEGMENTS()
```

Privileges

Superuser

Examples

```
=> SELECT DISABLE_LOCAL_SEGMENTS();
DISABLE_LOCAL_SEGMENTS
-----
DISABLED
(1 row)
```

ENABLE_ELASTIC_CLUSTER

Enables elastic cluster scaling, which makes enlarging or reducing the size of your database cluster more efficient by segmenting a node's data into chunks that can be easily moved to other hosts.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
ENABLE_ELASTIC_CLUSTER()
```

Privileges

Superuser

Examples

```
=> SELECT ENABLE_ELASTIC_CLUSTER();
ENABLE_ELASTIC_CLUSTER
```

```
-----
ENABLED
(1 row)
```

ENABLE_LOCAL_SEGMENTS

Enables local storage segmentation, which breaks projections segments on nodes into containers that can be easily moved to other nodes. See [Local data segmentation](#) for more information.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
ENABLE_LOCAL_SEGMENTS()
```

Privileges

Superuser

Examples

```
=> SELECT ENABLE_LOCAL_SEGMENTS();
ENABLE_LOCAL_SEGMENTS
```

```
-----
ENABLED
(1 row)
```

REALIGN_CONTROL_NODES

Causes Vertica to re-evaluate which nodes in the cluster or subcluster are [control nodes](#) and which nodes are assigned to them as dependents when large cluster is enabled. Call this function after altering fault groups in an Enterprise Mode database, or changing the number of control nodes in either database mode. After calling this function, query the [V_CATALOG.CLUSTER_LAYOUT](#) system table to see the proposed new layout for nodes in the cluster. You must also take additional steps before the new control node assignments take effect. See [Changing the number of control nodes and realigning](#) for details.

Note

In Vertica versions prior to 10.0.1, control node assignments weren't restricted to be within the same Eon Mode subcluster. If you attempt to realign control nodes in a subcluster whose control nodes have dependents in other subclusters, this function returns an error. In this case, you must realign the control nodes in those other subclusters first. Realigning the other subclusters fixes the cross-subcluster dependencies, allowing you to realign the control nodes in the original subcluster you attempted to realign.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

In Enterprise Mode:

```
REALIGN_CONTROL_NODES()
```

In Eon Mode:

```
REALIGN_CONTROL_NODES('subcluster_name')
```

Parameters

subcluster_name

The name of the subcluster where you want to realign control nodes. Only the nodes in this subcluster are affected. Other subclusters are unaffected. Only allowed when the database is running in Eon Mode.

Privileges

Superuser

Examples

In an Enterprise Mode database, choose control nodes from all nodes and assign the remaining nodes to a control node:

```
=> SELECT REALIGN_CONTROL_NODES();
```

In an Eon Mode database, re-evaluate the control node assignments in the subcluster named analytics:

```
=> SELECT REALIGN_CONTROL_NODES('analytics');
```

See also

- [Changing the number of control nodes and realigning](#)
- [Fault groups](#)

REBALANCE_CLUSTER

Rebalances the database cluster synchronously as a session foreground task. REBALANCE_CLUSTER returns only after the rebalance operation is complete. If the current session ends, the operation immediately aborts. To rebalance the cluster as a background task, call

[START_REBALANCE_CLUSTER](#).

On large cluster arrangements, you typically call REBALANCE_CLUSTER in a flow (see [Changing the number of control nodes and realigning](#)). After you change the number and distribution of control nodes (spread hosts), run REBALANCE_CLUSTER to achieve fault tolerance.

For detailed information about rebalancing tasks, see [Rebalancing data across nodes](#).

Tip

By default, before performing a rebalance, Vertica queries system tables to compute the size of all projections involved in the rebalance task. This query can add significant overhead to the rebalance operation. To disable this query, set projection configuration parameter [RebalanceQueryStorageContainers](#) to 0.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
REBALANCE_CLUSTER()
```

Privileges

Superuser

Examples

```
=> SELECT REBALANCE_CLUSTER();
```

```
REBALANCE_CLUSTER
```

```
-----  
REBALANCED
```

```
(1 row)
```

RELOAD_SPREAD

Updates cluster changes to the catalog's Spread configuration file. These changes include:

- New or realigned control nodes
- New Spread hosts or fault group
- New or dropped cluster nodes

This function is often used in a multi-step process for large and elastic cluster arrangements. Calling it might require you to restart the database. You must then rebalance the cluster to realize fault tolerance. For details, see [Defining and Realigning Control Nodes](#).

Caution

In an Eon Mode database, using this function could result in the database becoming read-only. Nodes may become disconnected after you call this function. If the database no longer has [primary shard coverage](#) without these nodes, it goes into read-only mode to maintain data integrity. Once the nodes rejoin the cluster, the database will resume normal operation. See [Maintaining Shard Coverage](#).

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
RELOAD_SPREAD( true )
```

Parameters

true

Updates cluster changes related to control message responsibilities to the Spread configuration file.

Privileges

[Superuser](#)

Examples

Update the cluster with changes to control messaging:

```
=> SELECT reload_spread(true);
reload_spread
-----
reloaded
(1 row)
```

See also

[REBALANCE_CLUSTER](#)

[SET_CONTROL_SET_SIZE](#)

Sets the number of [control nodes](#) that participate in the spread service when large cluster is enabled. If the database is running in Enterprise Mode, this function sets the number of control nodes for the entire database cluster. If the database is running in Eon Mode, this function sets the number of control nodes in the subcluster you specify. See [Large cluster](#) for more information.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

In Enterprise Mode :

```
SET_CONTROL_SET_SIZE( control_nodes )
```

In Eon Mode:

```
SET_CONTROL_SET_SIZE('subcluster_name', control_nodes )
```

Parameters

subcluster_name

The name of the subcluster where you want to set the number of control nodes. Only allowed when the database is running in Eon Mode.

control_nodes

The number of control nodes to assign to the cluster (when in Enterprise Mode) or subcluster (when in Eon Mode). Value can be one of the following:

- Positive integer value: Vertica assigns the number of control nodes you specify to the cluster or subcluster. This value can be larger than the current node count. This value cannot be larger than 120 (the maximum number of control nodes for a database). In Eon Mode, the total of this value plus the number of control nodes set for all other subclusters cannot be more than 120.
- -1 : Makes every node in the cluster or subcluster into control nodes. This value effectively disables large cluster for the cluster or subcluster.

Privileges

[Superuser](#)

Examples

In an Enterprise Mode database, set the number of control nodes for the entire cluster to 5:

```
=> SELECT set_control_set_size(5);
SET_CONTROL_SET_SIZE
```

```
-----
Control size set
(1 row)
```

See also

- [Changing the number of control nodes and realigning](#)

SET_SCALING_FACTOR

Sets the scaling factor that determines the number of storage containers used when rebalancing the database and when using local data segmentation is enabled. See [Cluster Scaling](#) for details.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
SET_SCALING_FACTOR( factor )
```

Parameters

factor

An integer value between 1 and 32. Vertica uses this value to calculate the number of storage containers each projection is broken into when rebalancing or when local data segmentation is enabled.

Privileges

Superuser

Best practices

The scaling factor determines the number of storage containers that Vertica uses to store each projection across the database during rebalancing when local segmentation is enabled. When setting the scaling factor, follow these guidelines:

- The number of storage containers should be greater than or equal to the number of partitions multiplied by the number of local segments:
 $num-storage-containers \geq (num-partitions * num-local-segments)$
- Set the scaling factor high enough so rebalance can transfer local segments to satisfy the skew threshold, but small enough so the number of storage containers does not result in too many ROS containers, and cause [ROS pushback](#). The maximum number of ROS containers (by default 1024) is set by configuration parameter [ContainersPerProjectionLimit](#).

Examples

```
=> SELECT SET_SCALING_FACTOR(12);
SET_SCALING_FACTOR
```

```
-----
SET
(1 row)
```

START_REBALANCE_CLUSTER

Asynchronously rebalances the database cluster as a background task. This function returns immediately after the rebalancing operation is complete. Rebalancing persists until the operation is complete, even if you close the current session or the database shuts down. In the case of shutdown, rebalancing resumes after the cluster restarts. To stop the rebalance operation, call [CANCEL_REBALANCE_CLUSTER](#).

For detailed information about rebalancing tasks, see [Rebalancing data across nodes](#).

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
START_REBALANCE_CLUSTER()
```

Privileges

Superuser

Examples

```
=> SELECT START_REBALANCE_CLUSTER();
START_REBALANCE_CLUSTER
-----
REBALANCING
(1 row)
```

See also

[REBALANCE_CLUSTER](#)

Data Collector functions

The Vertica Data Collector is a utility that extends [system table](#) functionality by providing a framework for recording events. It gathers and retains monitoring information about your database cluster and makes that information available in system tables with negligible performance impact.

Collected data is stored on disk in the [DataCollector](#) directory under the Vertica [/catalog](#) path. You can use the information the Data Collector retains in the following ways:

- Query the past state of system tables and extract aggregate information
- See what actions users have taken
- Locate performance bottlenecks
- Identify potential improvements to Vertica configuration

Data Collector works in conjunction with an advisor tool called [Workload Analyzer](#), which intelligently monitors the performance of SQL queries and workloads and recommends tuning actions based on observations of the actual workload history.

By default, Data Collector is enabled and [retains information for all sessions](#). If performance issues arise, a superuser can disable Data Collector by setting the `EnableDataCollector` configuration parameter to 0.

In this section

- [CLEAR_DATA_COLLECTOR](#)
- [DATA_COLLECTOR_HELP](#)
- [FLUSH_DATA_COLLECTOR](#)
- [GET_DATA_COLLECTOR_POLICY](#)
- [SET_DATA_COLLECTOR_POLICY](#)
- [SET_DATA_COLLECTOR_POLICY \(using parameters\)](#)
- [SET_DATA_COLLECTOR_TIME_POLICY](#)

CLEAR_DATA_COLLECTOR

Clears all memory and disk records from Data Collector tables and logs, and resets collection statistics in the [DATA_COLLECTOR](#) system table.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
CLEAR_DATA_COLLECTOR( [ 'component' ] )
```

Arguments

component

Component to clear. If not specified, the function clears memory and disk records for all components.

Query [DATA_COLLECTOR](#) to get a list of components:

```
=> SELECT DISTINCT component, description FROM DATA_COLLECTOR
WHERE component ILIKE '%Depot%' ORDER BY component;
component | description
-----
DepotEvictions | Files evicted from the Depot
DepotFetches | Files fetched to the Depot
DepotUploads | Files Uploaded from the Depot
(3 rows)
```

Privileges

Superuser

Examples

By default, the function clears data collection for all components:

```
-> SELECT CLEAR_DATA_COLLECTOR();
CLEAR_DATA_COLLECTOR
-----
CLEAR
(1 row)
```

To clear memory and disk records for only one component, specify the component:

```
-> SELECT CLEAR_DATA_COLLECTOR('ResourceAcquisitions');
CLEAR_DATA_COLLECTOR
-----
CLEAR
(1 row)
```

See also

[Data Collector utility](#)

[DATA_COLLECTOR_HELP](#)

Returns online usage instructions about the Data Collector, the [DATA_COLLECTOR](#) system table, and the Data Collector control functions.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
DATA_COLLECTOR_HELP()
```

Privileges

None

Returns

The function returns information like the following (exact contents might differ from this example):

```
=> SELECT DATA_COLLECTOR_HELP();
```

Usage Data Collector

The data collector retains history of important system activities.

This data can be used as a reference of what actions have been taken by users, but it can also be used to locate performance bottlenecks, or identify potential improvements to the Vertica configuration.

This data is queryable via Vertica system tables.

Access a list of data collector components, and some statistics, by running:

```
SELECT * FROM v_monitor.data_collector;
```

The amount of data retained by size and time can be controlled with several functions.

To just set the size amount:

```
set_data_collector_policy(<component>,  
                           <memory retention (KB)>,  
                           <disk retention (KB)>);
```

To set both the size and time amounts (the smaller one will dominate):

```
set_data_collector_policy(<component>,  
                           <memory retention (KB)>,  
                           <disk retention (KB)>,  
                           <interval>);
```

To set just the time amount:

```
set_data_collector_time_policy(<component>,  
                               <interval>);
```

To set the time amount for all tables:

```
set_data_collector_time_policy(<interval>);
```

The current retention policy for a component can be queried with:

```
get_data_collector_policy(<component>);
```

Data on disk is kept in the "DataCollector" directory under the Vertica \catalog path. This directory also contains instructions on how to load the monitoring data into another Vertica database.

To move the data collector logs and instructions to other storage locations, create labeled storage locations using `add_location` and then use:

```
set_data_collector_storage_location(<storage_label>);
```

Additional commands can be used to configure the data collection logs.

The log can be cleared with:

```
clear_data_collector([<optional component>]);
```

The log can be synchronized with the disk storage using:

```
flush_data_collector([<optional component>]);
```

See also

- [DATA_COLLECTOR](#)
- [TUNING_RECOMMENDATIONS](#)
- [Analyzing workloads](#)
- [Data Collector utility](#)

FLUSH_DATA_COLLECTOR

Waits until memory logs are moved to disk and then flushes the Data Collector, synchronizing the log with disk storage.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
FLUSH_DATA_COLLECTOR( [ 'component' ] )
```

Arguments

component

Component to flush. If not specified, the function flushes data for all components.

Query [DATA_COLLECTOR](#) to get a list of components:

```
=> SELECT DISTINCT component, description FROM DATA_COLLECTOR
WHERE component ILIKE '%Depot%' ORDER BY component;
component | description
-----
DepotEvictions | Files evicted from the Depot
DepotFetches | Files fetched to the Depot
DepotUploads | Files Uploaded from the Depot
(3 rows)
```

Privileges

Superuser

Examples

By default, the function flushes the Data Collector for all components:

```
=> SELECT FLUSH_DATA_COLLECTOR();
FLUSH_DATA_COLLECTOR
-----
FLUSH
(1 row)
```

To flush only one component, specify it:

```
=> SELECT FLUSH_DATA_COLLECTOR('ResourceAcquisitions');
FLUSH_DATA_COLLECTOR
-----
FLUSH
(1 row)
```

See also

[Data Collector utility](#)

GET_DATA_COLLECTOR_POLICY

Returns a brief statement about the retention policy for the specified component.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
GET_DATA_COLLECTOR_POLICY( 'component' )
```

Arguments

component

Component to query.

Query [DATA_COLLECTOR](#) to get a list of components:

```

=> SELECT DISTINCT component, description FROM DATA_COLLECTOR
WHERE component ILIKE '%Depot%' ORDER BY component;
component | description
-----
DepotEvictions | Files evicted from the Depot
DepotFetches | Files fetched to the Depot
DepotUploads | Files Uploaded from the Depot
(3 rows)

```

Privileges

None

Examples

```

=> SELECT GET_DATA_COLLECTOR_POLICY('ResourceAcquisitions'),
       GET_DATA_COLLECTOR_POLICY
-----
1000KB kept in memory, 10000KB kept on disk. Synchronous logging disabled. Time based retention disabled.
(1 row)

```

See also

- [DATA_COLLECTOR](#)
- [Data Collector utility](#)

SET_DATA_COLLECTOR_POLICY

Updates selected retention policy properties for a specified component. [SET_DATA_COLLECTOR_POLICY \(using parameters\)](#) is another version of this function that uses named parameters instead of positional arguments.

Before you change a retention policy, you can view its current settings by querying the [DATA_COLLECTOR](#) table or by calling the [GET_DATA_COLLECTOR_POLICY](#) function.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
SET_DATA_COLLECTOR_POLICY('component', 'memory-buffer-size', 'disk-size' [, 'interval-time'] )
```

Arguments

component

The retention policy to update.

Query [DATA_COLLECTOR](#) to get a list of components:

```

=> SELECT DISTINCT component, description FROM DATA_COLLECTOR
WHERE component ILIKE '%Depot%' ORDER BY component;
component | description
-----
DepotEvictions | Files evicted from the Depot
DepotFetches | Files fetched to the Depot
DepotUploads | Files Uploaded from the Depot
(3 rows)

```

memory-buffer-size

Maximum amount of data, in kilobytes, that is buffered in memory before moving it to disk. The retention policy property MEMORY_BUFFER_SIZE_KB is set from this value. This value must be positive and greater than 0.

Consider setting this parameter to a high value in the following cases:

- Unusually high levels of data collection. If the value is too low, the Data Collector might be unable to flush buffered data to disk quickly enough to keep up with the activity level, which can lead to loss of in-memory data.
- Very large data collector records—for example, records with very long query strings. The Data Collector uses double-buffering, so it cannot retain in-memory records that are more than half the size of the memory buffer.

disk-size

Maximum disk space, in kilobytes, allocated for this component's Data Collector table. The retention policy property `DISK_SIZE_KB` is set from this value. If set to 0, the Data Collector retains only as much component data as it can buffer in memory, as specified by [memory-buffer-size](#).

interval-time

How long to retain data in the component's Data Collector table, an [INTERVAL](#). The `INTERVAL_TIME` retention policy property is set from this value. If the value is positive, it also sets the `INTERVAL_SET` policy property to true.

For example, if you specify the `TupleMoverEvents` component and set this value to two days (`'2 days'::interval`), the `DC_TUPLE_MOVER_EVENTS` Data Collector table retains records over the last 48 hours. Older Tuple Mover data is automatically dropped from this table.

Setting a component's policy's `INTERVAL_TIME` property has no effect on how much data storage the Data Collector retains on disk for that component. Maximum disk storage capacity is determined by the `DISK_SIZE_KB` property. Setting the `INTERVAL_TIME` property only affects how long data is retained by the component's Data Collector table. For details, see [Configuring data retention policies](#).

To disable the `INTERVAL_TIME` policy property, set this value to a negative integer. Doing so reverts two retention policy properties to their default settings:

- `INTERVAL_SET`: false
- `INTERVAL_TIME`: 0

With these two properties thus set, the component's Data Collector table retains data on all component events until it reaches its maximum limit, as set by the `DISK_SIZE_KB` retention policy property.

Privileges

Superuser

Examples

```
=> SELECT SET_DATA_COLLECTOR_POLICY('ResourceAcquisitions', '1500', '25000');
SET_DATA_COLLECTOR_POLICY
-----
SET
(1 row)
```

See also

- [SET_DATA_COLLECTOR_POLICY \(using parameters\)](#)
- [Configuring data retention policies](#)

SET_DATA_COLLECTOR_POLICY (using parameters)

Updates selected retention policy properties for a specified component. [SET_DATA_COLLECTOR_POLICY](#) is another version of this function that uses positional arguments instead of named parameters.

Before you change a retention policy, you can view its current settings by querying the [DATA_COLLECTOR](#) table or by calling the [GET_DATA_COLLECTOR_POLICY](#) function.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
SET_DATA_COLLECTOR_POLICY('component' USING PARAMETERS param=value[...])
```

Arguments

component

The retention policy to update.

Query [DATA_COLLECTOR](#) to get a list of components:

```
=> SELECT DISTINCT component, description FROM DATA_COLLECTOR
WHERE component ILIKE '%Depot%' ORDER BY component;
component | description
-----
DepotEvictions | Files evicted from the Depot
DepotFetches | Files fetched to the Depot
DepotUploads | Files Uploaded from the Depot
(3 rows)
```

Parameters

memKB (INTEGER)

Maximum amount of data, in kilobytes, that is buffered in memory before moving it to disk. The retention policy property MEMORY_BUFFER_SIZE_KB is set from this value. This value must be positive and greater than 0.

Consider setting this parameter to a high value in the following cases:

- Unusually high levels of data collection. If the value is too low, the Data Collector might be unable to flush buffered data to disk quickly enough to keep up with the activity level, which can lead to loss of in-memory data.
- Very large data collector records—for example, records with very long query strings. The Data Collector uses double-buffering, so it cannot retain in-memory records that are more than half the size of the memory buffer.

diskKB (INTEGER)

Maximum disk space, in kilobytes, allocated for this component's Data Collector table. The retention policy property DISK_SIZE_KB is set from this value. If set to 0, the Data Collector retains only as much component data as it can buffer in memory, as specified by [memory-buffer-size](#).

synchronous (BOOLEAN)

Whether to ensure that no data is lost by performing synchronous writes. By default, if the Data Collector cannot keep up with the activity level, it can drop data buffered in memory before writing it to disk. If it is important to retain all activity records, set this parameter to true.

retention (INTERVAL)

How long to retain data in the component's Data Collector table, an [INTERVAL](#). The INTERVAL_TIME retention policy property is set from this value. If the value is positive, it also sets the INTERVAL_SET policy property to true.

For example, if you specify the TupleMoverEvents component and set this value to two days (`'2 days'::interval`), the DC_TUPLE_MOVER_EVENTS Data Collector table retains records over the last 48 hours. Older Tuple Mover data is automatically dropped from this table.

Setting a component's policy's INTERVAL_TIME property has no effect on how much data storage the Data Collector retains on disk for that component. Maximum disk storage capacity is determined by the DISK_SIZE_KB property. Setting the INTERVAL_TIME property only affects how long data is retained by the component's Data Collector table. For details, see [Configuring data retention policies](#).

To disable the INTERVAL_TIME policy property, set this value to a negative integer. Doing so reverts two retention policy properties to their default settings:

- INTERVAL_SET: false
- INTERVAL_TIME: 0

With these two properties thus set, the component's Data Collector table retains data on all component events until it reaches its maximum limit, as set by the DISK_SIZE_KB retention policy property.

Privileges

Superuser

Examples

```
-> SELECT SET_DATA_COLLECTOR_POLICY('ResourceAcquisitions'
  USING PARAMETERS synchronous=TRUE, memKB=100, diskKB=50000);
set_data_collector_policy
-----
SET
(1 row)
```

SET_DATA_COLLECTOR_TIME_POLICY

Updates the INTERVAL_TIME retention policy property for a specified component or globally. Calling this function has no effect on other properties of the same component.

You can also set the retention policy using [SET_DATA_COLLECTOR_POLICY \(using parameters\)](#).

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

Volatile

Syntax

```
SET_DATA_COLLECTOR_TIME_POLICY( ['component',] 'interval-time' )
```

Arguments

component

Component to update. If not specified, the function updates the retention policy of all Data Collector components.

Query [DATA_COLLECTOR](#) to get a list of components:

```
=> SELECT DISTINCT component, description FROM DATA_COLLECTOR
WHERE component ILIKE '%Depot%' ORDER BY component;
component | description
-----
DepotEvictions | Files evicted from the Depot
DepotFetches | Files fetched to the Depot
DepotUploads | Files Uploaded from the Depot
(3 rows)
```

interval-time

How long to retain data in the component's Data Collector table, an [INTERVAL](#). The INTERVAL_TIME retention policy property is set from this value. If the value is positive, it also sets the INTERVAL_SET policy property to true.

For example, if you specify the TupleMoverEvents component and set this value to two days (`'2 days':interval`), the DC_TUPLE_MOVER_EVENTS Data Collector table retains records over the last 48 hours. Older Tuple Mover data is automatically dropped from this table.

Setting a component's policy's INTERVAL_TIME property has no effect on how much data storage the Data Collector retains on disk for that component. Maximum disk storage capacity is determined by the DISK_SIZE_KB property. Setting the INTERVAL_TIME property only affects how long data is retained by the component's Data Collector table. For details, see [Configuring data retention policies](#).

To disable the INTERVAL_TIME policy property, set this value to a negative integer. Doing so reverts two retention policy properties to their default settings:

- INTERVAL_SET: false
- INTERVAL_TIME: 0

With these two properties thus set, the component's Data Collector table retains data on all component events until it reaches its maximum limit, as set by the DISK_SIZE_KB retention policy property.

Privileges

Superuser

Examples

The following example sets a retention time for a single component. Other components are unaffected:

```
=> SELECT SET_DATA_COLLECTOR_TIME_POLICY('TupleMoverEvents ', '30 minutes':INTERVAL);
SET_DATA_COLLECTOR_TIME_POLICY
-----
SET
(1 row)
```

To set a retention time for all components, omit the first argument:

```
=> SELECT SET_DATA_COLLECTOR_TIME_POLICY('1 day':INTERVAL);
SET_DATA_COLLECTOR_TIME_POLICY
-----
SET
(1 row)
```

Database functions

This section contains the database management functions specific to Vertica.

In this section

- [CLEAR_RESOURCE_REJECTIONS](#)
- [COMPACT_STORAGE](#)
- [DO_LOGROTATE_LOCAL](#)
- [DUMP_LOCKTABLE](#)
- [DUMP_PARTITION_KEYS](#)
- [GET_CONFIG_PARAMETER](#)

- [KERBEROS_CONFIG_CHECK](#)
- [MEMORY_TRIM](#)
- [PURGE](#)
- [RUN_INDEX_TOOL](#)
- [SECURITY_CONFIG_CHECK](#)
- [SET_CONFIG_PARAMETER](#)
- [SET_SPREAD_OPTION](#)
- [SHUTDOWN](#)

CLEAR_RESOURCE_REJECTIONS

Clears the content of the [RESOURCE_REJECTIONS](#) and [DISK_RESOURCE_REJECTIONS](#) system tables. Normally, these tables are only cleared during a node restart. This function lets you clear the tables whenever you need. For example, you might want to clear the system tables after you resolved a disk space issue that was causing disk resource rejections.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Immutable](#)

Syntax

```
CLEAR_RESOURCE_REJECTIONS();
```

Privileges

Superuser

Examples

The following command clears the content of the `RESOURCE_REJECTIONS` and `DISK_RESOURCE_REJECTIONS` system tables:

```
=> SELECT clear_resource_rejections();
clear_resource_rejections
-----
OK
(1 row)
```

See also

- [DISK_RESOURCE_REJECTIONS](#)
- [RESOURCE_REJECTIONS](#)

COMPACT_STORAGE

Bundles existing data (`.fdb`) and index (`.pidx`) files into the `.gt` file format. The `.gt` format is enabled by default for data files created version 7.2 or later. If you upgrade a database from an earlier version, use `COMPACT_STORAGE` to bundle storage files into the `.gt` format. Your database can continue to operate with a mix of file storage formats.

If the settings you specify for `COMPACT_STORAGE` vary from the limit specified in configuration parameter `MaxBundleableROSSizeKB` , Vertica does not change the size of the automatically created bundles.

Note

Run this function during periods of low demand.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
SELECT COMPACT_STORAGE ('[[[database.]schema.]object-name]', min-ros-filesize-kb, 'small-or-all-files', 'simulate');
```

Parameters

[**database** .] **schema**

Database and [schema](#) . The default schema is `public` . If you specify a database, it must be the current database.

object-name

Specifies the table or projection to bundle. If set to an empty string, COMPACT_STORAGE evaluates the data of all projections in the database for bundling.

min-ros-filesize-kb

Integer ≥ 1 , specifies in kilobytes the minimum size of an independent ROS file. COMPACT_STORAGE bundles storage container ROS files below this size into a single file.

small-or-all-files

One of the following:

- **small** : Bundles only files smaller than the limit specified in *min-ros-filesize-kb*
- **all** : Bundles files smaller than the limit specified in *min-ros-filesize-kb* and bundles the *.fdb* and *.pidx* files for larger storage containers.

simulate

Specifies whether to simulate the storage settings and produce a report describing the impact of those settings.

- **true** : Produces a report on the impact of the specified bundle settings without actually bundling storage files.
- **false** : Performs the bundling as specified.

Privileges

[Superuser](#)

Storage and performance impact

Bundling reduces the number of files in your file system by at least fifty percent and improves the performance of file-intensive operations. Improved operations include backups, restores, and mergeout.

Vertica creates small files for the following reasons:

- Tables contain hundreds of columns.
- Partition ranges are small (partition by minute).
- Local segmentation is enabled and your factor is set to a high value.

Examples

The following example describes the impact of bundling the table **EMPLOYEES** :

```
=> SELECT COMPACT_STORAGE('employees', 1024,'small','true');
```

Task: compact_storage

On node v_vmart_node0001:

Projection Name :public.employees_b0 | selected_storage_containers :0 |
selected_files_to_compact :0 | files_after_compact : 0 | modified_storage_KB :0

On node v_vmart_node0002:

Projection Name :public.employees_b0 | selected_storage_containers :1 |
selected_files_to_compact :6 | files_after_compact : 1 | modified_storage_KB :0

On node v_vmart_node0003:

Projection Name :public.employees_b0 | selected_storage_containers :2 |
selected_files_to_compact :12 | files_after_compact : 2 | modified_storage_KB :0

On node v_vmart_node0001:

Projection Name :public.employees_b1 | selected_storage_containers :2 |
selected_files_to_compact :12 | files_after_compact : 2 | modified_storage_KB :0

On node v_vmart_node0002:

Projection Name :public.employees_b1 | selected_storage_containers :0 |
selected_files_to_compact :0 | files_after_compact : 0 | modified_storage_KB :0

On node v_vmart_node0003:

Projection Name :public.employees_b1 | selected_storage_containers :1 |
selected_files_to_compact :6 | files_after_compact : 1 | modified_storage_KB :0

Success

(1 row)

DO_LOGROTATE_LOCAL

Rotates logs and removes rotated logs on the current node.

If the following files exceed the specified maximum size, they are rotated:

- [vertica.log](#)
- [UDxFencedProcesses.log](#)
- [MemoryReport.log](#)
- [editor.log](#)
- [dbLog](#)

Rotated files are compressed and marked with a timestamp in the same location as the original log file: `path/to/logfile.log timestamp.gz`. For example, `/scratch_b/qa/VMart/v_vmart_node0001_catalog/vertica.log` is rotated to `/scratch_b/qa/VMart/v_vmart_node0001_catalog/vertica.log.2023-11-08-14-09-02-381909-05.gz`.

If a log file was rotated, the previously rotated logs (`.gz`) in that directory are checked against the specified maximum age. Rotated logs older than the maximum age are deleted.

To view previous rotation events, see [LOG_ROTATE_EVENTS](#)

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
DO_LOGROTATE_LOCAL([' max_size=log_size{K|M|G|T};max_age=log_age;force=force_value '])
```

Parameters

max_size = *log_size* {K|M|G|T}

String, the maximum size of logs (`.log`) to keep, where **K** is kibibytes, **M** is mebibytes, **G** is gibibytes, and **T** is tebibytes. This overrides the `LogRotateMaxSize` parameter.

Default : The default (not current) value of [LogRotateMaxSize](#)

max_age = *log_age*

[Interval literal](#) of rotated logs (`.gz`) to keep. This overrides the `LogRotateMaxAge` configuration parameter. If the unit is not specified, the unit is assumed to be days.

Default : The default (not current) value of [LogRotateMaxAge](#)

force= *force_value*

Boolean, whether to force rotation, ignoring the maximum size. You can also specify `true` by specifying `force` without the boolean value.

Default : `false`

Privileges

Superuser

Examples

To rotate logs that are larger than 1 kilobyte, and then remove rotated logs that are older than 1 day:

```
-> SELECT do_logrotate_local('max_size=1K;max_age=1 day');

do_logrotate_local
-----
Doing Logrotate
Considering file /scratch_b/qa/VMart/v_vmart_node0001_catalog/vertica.log
File size: 35753 Bytes
Force rotate? no
Renaming to /scratch_b/qa/VMart/v_vmart_node0001_catalog/vertica.log.2023-11-08-13-55-51-651129-05
Opening new log file /scratch_b/qa/VMart/v_vmart_node0001_catalog/vertica.log

Done with /scratch_b/qa/VMart/v_vmart_node0001_catalog/UDxLogs/UDxFencedProcesses.log

(1 row)
```

DUMP_LOCKTABLE

Returns information about deadlocked clients and the resources they are waiting for.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
DUMP_LOCKTABLE()
```

Privileges

None

Notes

Use DUMP_LOCKTABLE if Vertica becomes unresponsive:

1. Open an additional vsql connection.
2. Execute the query:

```
=> SELECT DUMP_LOCKTABLE();
```

The output is written to vsql. See [Monitoring the Log Files](#).

You can also see who is connected using the following command:

```
=> SELECT * FROM SESSIONS;
```

Close all sessions using the following command:

```
=> SELECT CLOSE_ALL_SESSIONS();
```

Close a single session using the following command:

```
=> SELECT CLOSE_SESSION('session_id');
```

You get the session_id value from the [V_MONITOR.SESSIONS](#) system table.

See also

- [CLOSE_ALL_SESSIONS](#)
- [CLOSE_SESSION](#)
- [LOCKS](#)
- [SESSIONS](#)

DUMP_PARTITION_KEYS

Dumps the partition keys of all projections in the system.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
DUMP_PARTITION_KEYS()
```

Note

The [ROS](#) objects of partitioned tables without partition keys are ignored by the tuple mover and are not merged during automatic tuple mover operations.

Privileges

User must have select privileges on the table or usage privileges on the schema.

Examples

```
=> SELECT DUMP_PARTITION_KEYS( );
Partition keys on node v_vmart_node0001
Projection 'states_b0'
Storage [ROS container]
No of partition keys: 1
Partition keys: NH
Storage [ROS container]
No of partition keys: 1
Partition keys: MA
Projection 'states_b1'
Storage [ROS container]
No of partition keys: 1
Partition keys: VT
Storage [ROS container]
No of partition keys: 1
Partition keys: ME
Storage [ROS container]
No of partition keys: 1
Partition keys: CT
```

See also

- [DUMP_PROJECTION_PARTITION_KEYS](#)
- [DUMP_TABLE_PARTITION_KEYS](#)
- [PARTITION_PROJECTION](#)
- [PARTITION_TABLE](#)
- [PARTITIONS](#)
- [Partitioning tables](#) in the Administrator's Guide

GET_CONFIG_PARAMETER

Gets the value of a [configuration parameter](#) at the specified level. If no value is set at that level, the function returns an empty row.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
GET_CONFIG_PARAMETER( 'parameter-name' [, 'level' | NULL] )
```

Parameters

parameter-name

Name of the configuration parameter value to get.

level

Level at which to get *parameter-name*'s setting, one of the following string values:

- **user** : Current user
- **session** : Current session
- **node-name** : Name of database node

If *level* is omitted or set to NULL, GET_CONFIG_PARAMETER returns the database setting.

Privileges

None

Examples

Get the AnalyzeRowCountInterval parameter at the database level:

```
=> SELECT GET_CONFIG_PARAMETER ('AnalyzeRowCountInterval');
GET_CONFIG_PARAMETER
-----
3600
```

Get the MaxSessionUDParameterSize parameter at the session level:

```
=> SELECT GET_CONFIG_PARAMETER ('MaxSessionUDParameterSize', 'session');
GET_CONFIG_PARAMETER
```

```
-----
2000
(1 row)
```

Get the UseDepotForReads parameter at the user level:

```
=> SELECT GET_CONFIG_PARAMETER ('UseDepotForReads', 'user');
GET_CONFIG_PARAMETER
```

```
-----
1
(1 row)
```

See also

- [SET_CONFIG_PARAMETER](#)
- [CONFIGURATION_PARAMETERS](#)

KERBEROS_CONFIG_CHECK

Tests the Kerberos configuration of a Vertica cluster. The function succeeds if it can kinit with both the keytab file and the current user's credential, and reports errors otherwise.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
KERBEROS_CONFIG_CHECK( )
```

Parameters

This function has no parameters.

Privileges

This function does not require privileges.

Examples

The following example shows the results when the Kerberos configuration is valid.

```
=> SELECT KERBEROS_CONFIG_CHECK();
kerberos_config_check
-----
ok: krb5 exists at [/etc/krb5.conf]
ok: Vertica Keytab file is set to [/etc/vertica.keytab]
ok: Vertica Keytab file exists at [/etc/vertica.keytab]
[INFO] KerberosCredentialCache [/tmp/vertica_D4/vertica450676899262134963.cc]
Kerberos configuration parameters set in the database
  KerberosServiceName : [vertica]
  KerberosHostname : [data.hadoop.com]
  KerberosRealm : [EXAMPLE.COM]
  KerberosKeytabFile : [/etc/vertica.keytab]
Vertica Principal: [vertica/data.hadoop.com@EXAMPLE.COM]
[OK] Vertica can kinit using keytab file
[OK] User [bob] has valid client authentication for kerberos principal [bob@EXAMPLE.COM]]
```

```
(1 row)
```

MEMORY_TRIM

Calls glibc function [malloc_trim\(\)](#) to reclaim free memory from malloc and return it to the operating system. Details on the trim operation are written to system table [MEMORY_EVENTS](#).

Unless you turn off memory polling, Vertica automatically detects when glibc accumulates an excessive amount of free memory in its allocation arena. When this occurs, Vertica consolidates much of this memory and returns it to the operating system. Call this function if you disable memory polling and wish to reduce glibc-allocated memory manually.

For more information, see [Memory trimming](#).

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
MEMORY_TRIM()
```

Privileges

Superuser

Examples

```
=> SELECT memory_trim();
       memory_trim
-----
Pre-RSS: [378822656] Post-RSS: [372129792] Benefit: [0.0176675]
(1 row)
```

PURGE

Permanently removes delete vectors from ROS storage containers so disk space can be reused. **PURGE** removes all historical data up to and including the [Ancient History Mark](#) epoch.

PURGE does not delete temporary tables.

Caution

PURGE can temporarily use significant disk space.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
SELECT PURGE()
```

Privileges

- Table owner
- USAGE privilege on schema

Examples

After you delete data from a Vertica table, that data is marked for deletion. To see the data that is marked for deletion, query system table [DELETE_VECTORS](#).

Run **PURGE** to remove the delete vectors from ROS containers.

```

=> SELECT * FROM test1;
number
-----
 3
12
33
87
43
99
(6 rows)
=> DELETE FROM test1 WHERE number > 50;
OUTPUT
-----
 2
(1 row)
=> SELECT * FROM test1;
number
-----
43
 3
12
33
(4 rows)
=> SELECT node_name, projection_name, deleted_row_count FROM DELETE_VECTORS;
 node_name | projection_name | deleted_row_count
-----+-----+-----
v_vmart_node0002 | test1_b1 | 1
v_vmart_node0001 | test1_b1 | 1
v_vmart_node0001 | test1_b0 | 1
v_vmart_node0003 | test1_b0 | 1
(4 rows)
=> SELECT PURGE();
...
(Table: public.test1) (Projection: public.test1_b0)
(Table: public.test1) (Projection: public.test1_b1)
...
(4 rows)

```

After the ancient history mark (AHM) advances:

```

=> SELECT * FROM DELETE_VECTORS;
(No rows)

```

See also

- [Purging deleted data](#)
- [PURGE_PARTITION](#)
- [PURGE_PROJECTION](#)
- [PURGE_TABLE](#)

RUN_INDEX_TOOL

Runs the Index tool on a Vertica database to perform one of these tasks:

- Run a per-block cyclic redundancy check (CRC) on data storage to verify data integrity.
- Check that the sort order in ROS containers is correct.

The function writes summary information about its operation to standard output; detailed information on results is logged in [vertica.log](#) on the current node. For more about evaluating tool output, see:

- [Evaluating CRC errors](#)
- [Evaluating sort order errors](#)

You can also run the Index tool on a database that is down, from the Linux command line. For details, see [CRC and sort order check](#).

Caution

Use this function only under guidance from Vertica Support.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
RUN_INDEX_TOOL ( 'taskType', global, '[projFilter]' [, numThreads ] );
```

Parameters

taskType

Specifies the operation to run, one of the following:

- **checkcrc** : Run a cyclic redundancy check (CRC) on each block of existing data storage to check the data integrity of ROS data blocks.
- **checksort** : Evaluate each ROS row to determine whether it is sorted correctly. If ROS data is not sorted correctly in the projection's order, query results that rely on sorted data will be incorrect.

global

Boolean, specifies whether to run the specified task on all nodes (true), or the current one (false).

projFilter

Specifies the scope of the operation:

- Empty string (") : Run the check on all projections.
- A string that specifies one or more projections as follows:
 - **projection-name** : Run the check on this projection
 - **projection-prefix** * : Run the check on all projections that begin with the string **projection-prefix** .

numThreads

An unsigned (positive) or signed (negative) integer that specifies the number of threads used to run this operation:

- **n** : Number of threads, ≥ 1
- **-n** : Negative integer, denotes a fraction of all CPU cores as follows:

```
num-cores / n
```

Thus, **-1** specifies all cores, **-2** , half the cores, **-3** , a third of all cores, and so on.

Default: 1

Privileges

Superuser

Optimizing performance

You can optimize meta-function performance by setting two parameters:

- **projFilter** : Narrows the scope of the operation to one or more projections.
- **numThreads** : Specifies the number of threads used to execute the function.

SECURITY_CONFIG_CHECK

Returns the status of various security-related parameters. Use this function to verify completeness of your TLS configuration.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
SECURITY_CONFIG_CHECK( 'db-component' )
```

Parameters

db-component

The component to check. Currently, **NETWORK** is the only supported component.

NETWORK : Returns the status and parameters for spread encryption, internode TLS, and client-server TLS.

Examples

In this example, SECURITY_CONFIG_CHECK shows that spread encryption and data channel TLS are disabled because EncryptSpreadComm is disabled and the data_channel TLS Configuration is not configured.

Similarly, client-server TLS is disabled because the TLS Configuration "server" has a server certificate, but its TLSMODE is disabled. Setting TLSMODE to 'Enable' enables server mode client-server TLS. See [TLS protocol](#) for details.

```
=> SELECT SECURITY_CONFIG_CHECK('NETWORK');
          SECURITY_CONFIG_CHECK
-----
Spread security details:
* EncryptSpreadComm = []
Spread encryption is disabled
It is NOT safe to set/change other security config parameters while spread is not encrypted!
Please set EncryptSpreadComm to enable spread encryption first

Data Channel security details:
  TLS Configuration 'data_channel' TLSMODE is DISABLE
  TLS on the data channel is disabled
  Please set EncryptSpreadComm and configure TLS Configuration 'data_channel' to enable TLS on the data channel

Client-Server network security details:
* TLS Configuration 'server' TLSMODE is DISABLE
* TLS Configuration 'server' has a certificate set
Client-Server TLS is disabled
To enable Client-Server TLS set a certificate on TLS Configuration 'server' and/or set the tlsmode to 'ENABLE' or higher

(1 row)
```

See also

- [Internode TLS](#)
- [TLS protocol](#)

SET_CONFIG_PARAMETER

Sets or clears a [configuration parameter](#) at the specified level.

Important

You can only use this function to set configuration parameters with string or integer values. To set configuration parameters that accept other data types, use the [appropriate ALTER statement](#).

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
SET_CONFIG_PARAMETER( 'param-name', { param-value | NULL}, [level] | NULL)
```

Arguments

param-name

Name of the [configuration parameter](#) to set.

param-value

Value to set for *param-name*, either a string or integer. If a string, enclose in single quotes; if an integer, single quotes are optional.

To clear *param-name* at the specified level, set to NULL.

level

Level at which to set *param-name*, one of the following string values:

- **user** : Current user.
- **session** : Current session, overrides the database setting.
- **node-name** : Name of database node, overrides session and database settings.

If *level* is omitted or set to NULL, *param-name* is set at the database level.

Note

Some parameters require restart for the value to take effect.

Privileges

[Superuser](#)

Examples

Set the [AnalyzeRowCountInterval](#) parameter to 3600 at the database level:

```
=> SELECT SET_CONFIG_PARAMETER('AnalyzeRowCountInterval',3600);
       SET_CONFIG_PARAMETER
```

```
-----
Parameter set successfully
(1 row)
```

Note

You can achieve the same result with ALTER DATABASE:

```
ALTER DATABASE DEFAULT SET PARAMETER AnalyzeRowCountInterval = 3600;
```

Set the [MaxSessionUDParameterSize](#) parameter to 2000 at the session level.

```
=> SELECT SET_CONFIG_PARAMETER('MaxSessionUDParameterSize',2000,'SESSION');
       SET_CONFIG_PARAMETER
```

```
-----
Parameter set successfully
(1 row)
```

See also

- [GET_CONFIG_PARAMETER](#)
- [CONFIGURATION_PARAMETERS](#)

SET_SPREAD_OPTION

Changes [spread](#) daemon settings. This function is mainly used to set the timeout before spread assumes a node has gone down.

Note

Changing Spread settings with SET_SPREAD_OPTION has minor impact on your cluster as it pauses while the new settings are propagated across the cluster. Because of this delay, changes to the Spread timeout are not immediately visible in system table [SPREAD_STATE](#) .

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
SET_SPREAD_OPTION( option-name, option-value )
```

Parameters

option-name

String containing the spread daemon setting to change.

Currently, this function supports only one option: [TokenTimeout](#) . This setting controls how long spread waits for a node to respond to a message before assuming it is lost. See [Adjusting Spread Daemon timeouts for virtual environments](#) for more information.

option-value

The new setting for *option-name* .

Examples

```
=> SELECT SET_SPREAD_OPTION( 'TokenTimeout', '35000');
```

```
NOTICE 9003: Spread has been notified about the change
```

```
SET_SPREAD_OPTION
```

```
-----  
Spread option 'TokenTimeout' has been set to '35000'.
```

```
(1 row)
```

```
=> SELECT * FROM V_MONITOR.SPREAD_STATE;
```

```
node_name | token_timeout
```

```
-----+-----  
v_vmart_node0001 | 35000
```

```
v_vmart_node0002 | 35000
```

```
v_vmart_node0003 | 35000
```

```
(3 rows);
```

See also

- [Adjusting Spread Daemon timeouts for virtual environments](#)
- [SPREAD_STATE](#)

SHUTDOWN

Shuts down a Vertica database. By default, the shutdown fails if any users are connected. You can check the status of the shutdown operation in the [vertica.log](#) file.

In Eon Mode, you can call [SHUTDOWN_WITH_DRAIN](#) to perform a graceful shutdown that drains client connections and then shuts down the database.

Tip

Before calling SHUTDOWN, you can close all current user connections and prevent further connection attempts as follows:

1. Temporarily set configuration parameter MaxClientSessions to 0.
2. Call [CLOSE_ALL_SESSIONS](#) to close all non-dbadmin connections.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
SHUTDOWN ( [ 'false' | 'true' ] )
```

Parameters

false

Default, returns a message if users are connected and aborts the shutdown.

true

Forces the database to shut down, disallowing further connections.

Privileges

Superuser

Examples

The following command attempts to shut down the database. Because users are connected, the command fails:

```
=> SELECT SHUTDOWN('false');
```

```
NOTICE: Cannot shut down while users are connected
```

```
SHUTDOWN
```

```
Shutdown: aborting shutdown
```

```
(1 row)
```

ALTER_LOCATION_SIZE

Eon Mode only

Resizes [the depot](#) on one node, all nodes in a subcluster, or all nodes in the database.

Important

Reducing the size of the depot is liable to increase contention over depot usage and require frequent [evictions](#). This behavior can increase the number of queries and load operations that are routed to communal storage for processing, which can incur slower performance and increased access charges.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Immutable](#)

Syntax

```
ALTER_LOCATION_SIZE( 'location', '[target]', 'size')
```

Parameters

location

Specifies the location to resize, one of the following:

- **depot** : Resizes the node's current depot.
- The depot's absolute path in the Linux filesystem. If you change the depot size on multiple nodes and specify a path, the path must be identical on all affected nodes . By default, this is not the case, as the node's name is typically this path. For example, the default depot path for node 1 in the **verticadb** database is **/vertica/data/verticadb/v_verticadb_node0001_depot** .

target

The node or nodes on which to change the depot, one of the following:

- Node name: Resize the specified node.
- Subcluster name: Resize depots of all nodes in the specified subcluster.
- Empty string: Resize all depots in the database.

size

Valid only if the storage location usage type is set to **DEPOT** , specifies the maximum amount of disk space that the depot can allocate from the storage location's file system.

You can specify **size** in two ways:

- **integer%** : Percentage of storage location disk size.
- **integer {K|M|G|T}** : Amount of storage location disk size in kilobytes, megabytes, gigabytes, or terabytes.

Important

The depot size cannot exceed 80 percent of the file system disk space where the depot is stored. If you specify a value that is too large, Vertica issues a warning and automatically changes the value to 80 percent of the file system size.

Privileges

[Superuser](#)

Examples

Increase depot size on all nodes to 80 percent of file system:

```
=> SELECT node_name, location_label, location_path, max_size, disk_percent FROM storage_locations WHERE location_usage = 'DEPOT' ORDER BY
node_name;
 node_name | location_label | location_path | max_size | disk_percent
-----+-----+-----+-----+-----
v_vmart_node0001 | auto-data-depot | /home/dbadmin/verticadb | 36060108800 | 70%
v_vmart_node0002 | auto-data-depot | /home/dbadmin/verticadb | 36059377664 | 70%
v_vmart_node0003 | auto-data-depot | /home/dbadmin/verticadb | 36060108800 | 70%
(3 rows)

=> SELECT alter_location_size('depot', '', '80%');
alter_location_size
-----
depotSize changed.
(1 row)

=> SELECT node_name, location_label, location_path, max_size, disk_percent FROM storage_locations WHERE location_usage = 'DEPOT' ORDER BY
node_name;
 node_name | location_label | location_path | max_size | disk_percent
-----+-----+-----+-----+-----
v_vmart_node0001 | auto-data-depot | /home/dbadmin/verticadb | 41211552768 | 80%
v_vmart_node0002 | auto-data-depot | /home/dbadmin/verticadb | 41210717184 | 80%
v_vmart_node0003 | auto-data-depot | /home/dbadmin/verticadb | 41211552768 | 80%
(3 rows)
```

Change the depot size to 75% of the filesystem size for all nodes in the analytics subcluster:

```
=> SELECT subcluster_name, subclusters.node_name, storage_locations.max_size, storage_locations.disk_percent FROM subclusters INNER JOIN
storage_locations ON subclusters.node_name = storage_locations.node_name WHERE storage_locations.location_usage='DEPOT';
 subcluster_name | node_name | max_size | disk_percent
-----+-----+-----+-----
default_subcluster | v_verticadb_node0001 | 25264737485 | 60%
default_subcluster | v_verticadb_node0002 | 25264737485 | 60%
default_subcluster | v_verticadb_node0003 | 25264737485 | 60%
analytics | v_verticadb_node0004 | 25264737485 | 60%
analytics | v_verticadb_node0005 | 25264737485 | 60%
analytics | v_verticadb_node0006 | 25264737485 | 60%
analytics | v_verticadb_node0007 | 25264737485 | 60%
analytics | v_verticadb_node0008 | 25264737485 | 60%
analytics | v_verticadb_node0009 | 25264737485 | 60%
(9 rows)
```

```
=> SELECT ALTER_LOCATION_SIZE('depot','analytics','75%');
ALTER_LOCATION_SIZE
-----
depotSize changed.
(1 row)
```

```
=> SELECT subcluster_name, subclusters.node_name, storage_locations.max_size, storage_locations.disk_percent FROM subclusters INNER JOIN
storage_locations ON subclusters.node_name = storage_locations.node_name WHERE storage_locations.location_usage='DEPOT';
 subcluster_name | node_name | max_size | disk_percent
-----+-----+-----+-----
default_subcluster | v_verticadb_node0001 | 31580921856 | 75%
default_subcluster | v_verticadb_node0002 | 31580921856 | 75%
default_subcluster | v_verticadb_node0003 | 31580921856 | 75%
analytics | v_verticadb_node0004 | 31580921856 | 75%
analytics | v_verticadb_node0005 | 31580921856 | 75%
analytics | v_verticadb_node0006 | 31580921856 | 75%
analytics | v_verticadb_node0007 | 31580921856 | 75%
analytics | v_verticadb_node0008 | 31580921856 | 75%
analytics | v_verticadb_node0009 | 31580921856 | 75%
(9 rows)
```

[Eon Mode architecture](#)

BACKGROUND_DEPOT_WARMING

Eon Mode only

Deprecated

Vertica version 10.0.0 removes support for foreground depot warming. When enabled, depot warming always happens in the background. Because foreground depot warming no longer exists, this function serves no purpose and has been deprecated. Calling it has no effect.

Forces a node that is warming its depot to start processing queries while continuing to warm its depot in the background. Depot warming only occurs when a node is joining the database and is activating its subscriptions. This function only has an effect if:

- The database is running in Eon Mode.
- The node is currently warming its depot.
- The node is warming its depot from communal storage. This is the case when the UseCommunalStorageForBatchDepotWarming configuration parameter is set to the default value of 1. See [Eon Mode parameters](#) for more information about this parameter.

After calling this function, the node warms its depot in the background while taking part in queries.

This function has no effect on a node that is not warming its depot.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
BACKGROUND_DEPOT_WARMING('node-name' [, 'subscription-name'])
```

Arguments

node-name

The name of the node that you want to warm its depot in the background.

subscription-name

The name of a shard that the node subscribes to that you want the node to warm in the background. You can find the names of the shards a node subscribes to in the SHARD_NAME column of the [NODE_SUBSCRIPTIONS](#) system table.

Note

When you supply the name of a specific shard subscription to warm in the background, the node may not immediately begin processing queries. It continues to warm any other shard subscriptions in the foreground if they are not yet warm. The node does not begin taking part in queries until it finishes warming the other subscriptions.

Return value

A message indicating that the node's warming will continue in the background.

Privileges

The user must be a superuser .

Examples

The following example demonstrates having node 6 of the verticadb database warm its depot in the background:

```
=> SELECT BACKGROUND_DEPOT_WARMING('v_verticadb_node0006');
      BACKGROUND_DEPOT_WARMING
```

Depot warming running in background. Check monitoring tables for progress.

- [CANCEL_DEPOT_WARMING](#)
- [ALTER_LOCATION_SIZE](#)
- [CANCEL_DRAIN_SUBCLUSTER](#)
- [CLEAN_COMMUNAL_STORAGE](#)
- [CLEAR_DATA_DEPOT](#)

CANCEL_DEPOT_WARMING

Eon Mode only

Cancels depot warming on a node. Depot warming only occurs when a node is joining the database and is activating its subscriptions. You can choose to cancel all warming on the node, or cancel the warming of a specific shard's subscription. The node finishes whatever data transfers it is currently carrying out to warm its depot and removes pending warming-related transfers from its queue. It keeps any data it has already loaded into its depot. If you cancel warming for a specific subscription, it stops warming its depot if all of its other subscriptions are warmed. If they aren't warmed, the node continues to warm those other subscriptions.

This function only has an effect if:

- The database is running in Eon Mode.
- The node is currently warming its depot.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
CANCEL_DEPOT_WARMING('node-name' [, 'subscription-name'])
```

Arguments

'**node-name**'

The name of the node whose depot warming you want canceled.

'**subscription-name**'

The name of a shard that the node subscribes to that you want the node to stop warming. You can find the names of the shards a node subscribes to in the SHARD_NAME column of the [NODE_SUBSCRIPTIONS](#) system table.

Return value

Returns a message indicating warming has been canceled.

Privileges

The user must be a superuser.

Usage considerations

Canceling depot warming can negatively impact the performance of your queries. A node with a cold depot may have to retrieve much of its data from communal storage, which is slower than accessing the depot.

Examples

The following demonstrates canceling the depot warming taking place on node 7:

```
=> SELECT CANCEL_DEPOT_WARMING('v_verticadb_node0007');
   CANCEL_DEPOT_WARMING
-----
Depot warming cancelled.
(1 row)
```

- [BACKGROUND_DEPOT_WARMING](#)
- [ALTER_LOCATION_SIZE](#)
- [CANCEL_DRAIN_SUBCLUSTER](#)
- [CLEAN_COMMUNAL_STORAGE](#)
- [CLEAR_DATA_DEPOT](#)

CANCEL_DRAIN_SUBCLUSTER

Eon Mode only

Cancels the draining of a subcluster or subclusters. This function can cancel draining operations that were started by either [START_DRAIN_SUBCLUSTER](#) or the draining portion of the [SHUTDOWN_WITH_DRAIN](#) function. CANCEL_DRAIN_SUBCLUSTER marks all nodes in the designated subclusters as not draining. The previously draining nodes again accept new client connections and connections redirected from load-balancing.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
CANCEL_DRAIN_SUBCLUSTER( 'subcluster-name' )
```

Arguments

subcluster-name

Name of the subcluster whose draining operation to cancel. Enter an empty string to cancel the draining operation on all subclusters.

Privileges

Superuser

Examples

The following example demonstrates how to cancel a draining operation on a subcluster.

First, you can query the [DRAINING_STATUS](#) system table to view which subclusters are currently draining:

```
=> SELECT node_name, subcluster_name, is_draining FROM draining_status ORDER BY 1;
node_name      | subcluster_name | is_draining
-----+-----+-----
verticadb_node0001 | default_subcluster | f
verticadb_node0002 | default_subcluster | f
verticadb_node0003 | default_subcluster | f
verticadb_node0004 | analytics       | t
verticadb_node0005 | analytics       | t
verticadb_node0006 | analytics       | t
```

The following function call cancels the draining of the **analytics** subcluster:

```
=> SELECT CANCEL_DRAIN_SUBCLUSTER('analytics');
CANCEL_DRAIN_SUBCLUSTER
```

```
-----
Targeted subcluster: 'analytics'
Action: CANCEL DRAIN
```

```
(1 row)
```

To confirm that the subcluster is no longer draining, you can again query the [DRAINING_STATUS](#) system table:

```
=> SELECT node_name, subcluster_name, is_draining FROM draining_status ORDER BY 1;
node_name      | subcluster_name | is_draining
-----+-----+-----
verticadb_node0001 | default_subcluster | f
verticadb_node0002 | default_subcluster | f
verticadb_node0003 | default_subcluster | f
verticadb_node0004 | analytics       | f
verticadb_node0005 | analytics       | f
verticadb_node0006 | analytics       | f
(6 rows)
```

See also

- [Drain client connections](#)
- [START_DRAIN_SUBCLUSTER](#)
- [DRAINING_STATUS](#)

CLEAN_COMMUNAL_STORAGE

Eon Mode only

Marks for deletion invalid data in communal storage, often data that leaked due to an event where Vertica cleanup mechanisms failed. Events that require calling this function include:

- Node failure
- Interrupted [migration](#) of an Enterprise database to Eon
- Restoring objects from backup

Tip

It is generally good practice to call `CLEAN_COMMUNAL_STORAGE` soon after completing an [Enterprise-to-Eon migration](#), and reviving the migrated Eon database.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
CLEAN_COMMUNAL_STORAGE ( [actually-delete] )
```

Parameters

actually-delete

BOOLEAN, specifies whether to queue data files for deletion:

- **true** (default): Add files to the reaper queue and return immediately. The queued files are removed automatically by the reaper service, or can be removed manually by calling [FLUSH_REAPER_QUEUE](#).
- **false**: Report information about extra files but do not queue them for deletion.

Privileges

Superuser

Examples

```
=> SELECT CLEAN_COMMUNAL_STORAGE('true')
CLEAN_COMMUNAL_STORAGE
-----
CLEAN COMMUNAL STORAGE
Task was canceled.
Total leaked files: 9265
Total size: 4236501526
Files have been queued for deletion.
Check communal_cleanup_records for more information.
(1 row)
```

CLEAR_DATA_DEPOT

Eon Mode only

Deletes the specified depot data. You can clear depot data of a single table or all tables, from one subcluster, a single node, or the entire database cluster. Clearing depot data can incur extra processing time for any subsequent queries that require that data and must now fetch it from communal storage. Clearing depot data has no effect on communal storage.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
CLEAR_DATA_DEPOT( [ 'table-name' [, 'target-depots' ] ] )
```

Arguments

To clear all depot data from the database cluster, call this function with no arguments.

table-name

Name of the table to delete from the target depots. If you omit a table name or supply an empty string, data of all tables is deleted from the target depots.

target-depots

The depots to clear, one of the following:

- *subcluster-name*: Name of the depot subcluster, [default_subcluster](#) to specify the [default database subcluster](#).
- *node-name*: Clears depot data from the specified node. Depot data on other nodes in the same subcluster are unaffected.

This argument optionally qualifies the argument for *table-name*. If you omit this argument or supply an empty string, Vertica clears all depot data from the database cluster.

Privileges

Superuser

Examples

Clear the cached data of one table from the specified subcluster depot:

```
=> SELECT CLEAR_DATA_DEPOT('t1', 'subcluster_1');
clear_data_depot
-----
Depot cleared
(1 row)
```

Clear all depot data that is cached on the specified subcluster.:

```
=> SELECT CLEAR_DATA_DEPOT("", 'subcluster_1');
clear_data_depot
-----
Depot cleared
(1 row)
```

Clear all depot data that is cached on the specified node:

```
=> select clear_data_depot("", 'v_vmart_node0001');
clear_data_depot
-----
Depot cleared
(1 row)
```

Clear all data of the specified table from the depots of all cluster nodes:

```
=> SELECT CLEAR_DATA_DEPOT('t1');
clear_data_depot
-----
Depot cleared
(1 row)
```

Clear all depot data from the database cluster:

```
=> SELECT CLEAR_DATA_DEPOT();
clear_data_depot
-----
Depot cleared
(1 row)
```

See also

[Managing depot caching](#)

CLEAR_DEPOT_ANTI_PIN_POLICY_PARTITION

Eon Mode only

Removes an [anti-pinning policy](#) from the specified partition.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
CLEAR_DEPOT_ANTI_PIN_POLICY_PARTITION( '[[database.]schema.]object-name', 'min-range-value', 'max-range-value' [, 'subcluster'] )
```

Arguments

[**database** .] **schema**

Database and [schema](#). The default schema is [public](#). If you specify a database, it must be the current database.

object-name

Table or projection with a partition anti-pinning policy to clear.

min-range-value , **max-range-value**

Range of partition keys in *table* from which to clear an anti-pinning policy, where *min-range-value* must be \leq *max-range-value*. To specify a single partition key, *min-range-value* and *max-range-value* must be equal.

subcluster

Name of a depot subcluster, `default_subcluster` to specify the [default database subcluster](#). If this argument is omitted, all database depots are targeted.

Privileges

Superuser

See also

- [Depot Eviction Policies](#)
- `SET_DEPOT_ANTI_PIN_POLICY_PARTITION`

`CLEAR_DEPOT_ANTI_PIN_POLICY_PROJECTION`

Eon Mode only

Removes an [anti-pinning policy](#) from the specified projection.

This is a meta-function. You must call meta-functions in a top-level `SELECT` statement.

Behavior type

[Volatile](#)

Syntax

```
CLEAR_DEPOT_ANTI_PIN_POLICY_PROJECTION( '[[database.]schema.]projection' [, 'subcluster' ] )
```

Arguments

[***database*** .] ***schema***

Database and [schema](#). The default schema is `public`. If you specify a database, it must be the current database.

projection

Projection with the anti-pinning policy to clear.

subcluster

Name of a depot subcluster, `default_subcluster` to specify the [default database subcluster](#). If this argument is omitted, all database depots are targeted.

Privileges

Superuser

See also

- [Depot Eviction Policies](#)
- `SET_DEPOT_ANTI_PIN_POLICY_PROJECTION`

`CLEAR_DEPOT_ANTI_PIN_POLICY_TABLE`

Eon Mode only

Removes an [anti-pinning policy](#) from the specified table.

This is a meta-function. You must call meta-functions in a top-level `SELECT` statement.

Behavior type

[Volatile](#)

Syntax

```
CLEAR_DEPOT_ANTI_PIN_POLICY_TABLE( '[[database.]schema.]table' [, 'subcluster' ] )
```

Arguments

[***database*** .] ***schema***

Database and [schema](#). The default schema is `public`. If you specify a database, it must be the current database.

table

Table with the anti-pinning policy to clear.

subcluster

Name of a depot subcluster, `default_subcluster` to specify the [default database subcluster](#). If this argument is omitted, all database depots are targeted.

Privileges

Superuser

See also

- [Depot Eviction Policies](#)
- `SET_DEPOT_ANTI_PIN_POLICY_TABLE`

`CLEAR_DEPOT_PIN_POLICY_PARTITION`

Eon Mode only

Clears a depot pinning policy from the specified table or projection partitions. After the object is unpinned, it can be [evicted from the depot](#) by any unpinned or pinned object.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
CLEAR_DEPOT_PIN_POLICY_PARTITION( '[[database.]schema.]object-name', 'min-range-value', 'max-range-value' [, subcluster ] )
```

Arguments

[**database** .] **schema**

Database and [schema](#). The default schema is `public`. If you specify a database, it must be the current database.

object-name

Table or projection with a partition pinning policy to clear.

min-range-value , **max-range-value**

Range of partition keys in *table* from which to clear a pinning policy, where *min-range-value* must be \leq *max-range-value*. To specify a single partition key, *min-range-value* and *max-range-value* must be equal.

subcluster

Name of a depot subcluster, `default_subcluster` to specify the [default database subcluster](#). If this argument is omitted, all database depots are targeted.

Privileges

Superuser

See also

- [Depot Eviction Policies](#)
- `SET_DEPOT_PIN_POLICY_PARTITION`

`CLEAR_DEPOT_PIN_POLICY_PROJECTION`

Eon Mode only

Clears a depot pinning policy from the specified projection. After the object is unpinned, it can be [evicted from the depot](#) by any unpinned or pinned object.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
CLEAR_DEPOT_PIN_POLICY_PROJECTION( '[[database.]schema.]projection', 'subcluster' ] )
```

Parameters

[**database** .] **schema**

Database and [schema](#). The default schema is `public`. If you specify a database, it must be the current database.

projection

Projection with a pinning policy to clear.

subcluster

Name of a depot subcluster, `default_subcluster` to specify the [default database subcluster](#). If this argument is omitted, all database depots are targeted.

Privileges

Superuser

See also

- [Depot Eviction Policies](#)
- [CLEAR_DEPOT_PIN_POLICY_PARTITION](#)
- [SET_DEPOT_PIN_POLICY_TABLE](#)

CLEAR_DEPOT_PIN_POLICY_TABLE

Eon Mode only

Clears a depot pinning policy from the specified table. After the object is unpinned, it can be [evicted from the depot](#) by any unpinned or pinned object.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
CLEAR_DEPOT_PIN_POLICY_TABLE( '[[database.]schema.]table' [, 'subcluster' ] )
```

Parameters

[**database** .] **schema**

Database and [schema](#). The default schema is `public`. If you specify a database, it must be the current database.

table

Table with a pinning policy to clear.

subcluster

Name of a depot subcluster, `default_subcluster` to specify the [default database subcluster](#). If this argument is omitted, all database depots are targeted.

Privileges

Superuser

See also

- [Depot Eviction Policies](#)
- [SET_DEPOT_PIN_POLICY_TABLE](#)

CLEAR_FETCH_QUEUE

Eon Mode only

Removes all entries or entries for a specific transaction from the queue of fetch requests of data from the communal storage. You can view the fetch queue by querying the [DEPOT_FETCH_QUEUE](#) system table. This function removes all of the queued requests synchronously. It returns after all the fetches have been removed from the queue.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
CLEAR_FETCH_QUEUE([transaction_id])
```

Parameters

* **transaction_id** *

The id of the transaction whose fetches will be cleared from the queue. If this value is not specified, all fetches are removed from the fetch queue.

Examples

This example clears all of the queued fetches for all transactions.

```
=> SELECT CLEAR_FETCH_QUEUE();
```

```
CLEAR_FETCH_QUEUE
```

```
-----  
Cleared the fetch queue.
```

```
(1 row)
```

This example clears the fetch queue for a specific transaction.

```
=> SELECT node_name,transaction_id FROM depot_fetch_queue;
```

```
node_name | transaction_id
```

```
-----+-----  
v_verticadb_node0001 | 45035996273719510  
v_verticadb_node0003 | 45035996273719510  
v_verticadb_node0002 | 45035996273719510  
v_verticadb_node0001 | 45035996273719777  
v_verticadb_node0003 | 45035996273719777  
v_verticadb_node0002 | 45035996273719777
```

```
(6 rows)
```

```
=> SELECT clear_fetch_queue(45035996273719510);
```

```
clear_fetch_queue
```

```
-----  
Cleared the fetch queue.
```

```
(1 row)
```

```
=> SELECT node_name,transaction_id from depot_fetch_queue;
```

```
node_name | transaction_id
```

```
-----+-----  
v_verticadb_node0001 | 45035996273719777  
v_verticadb_node0003 | 45035996273719777  
v_verticadb_node0002 | 45035996273719777
```

```
(3 rows)
```

DEMOTED_SUBCLUSTER_TO_SECONDARY

Eon Mode only

Converts a [primary subcluster](#) to a [secondary subcluster](#).

Vertica will not allow you to demote a primary subcluster if any of the following are true:

- The subcluster contains a [critical node](#).
- The subcluster is the only primary subcluster in the database. You must have at least one primary subcluster.
- The [initiator node](#) is a member of the subcluster you are trying to demote. You must call DEMOTED_SUBCLUSTER_TO_SECONDARY from another subcluster.

Important

This function call can take a long time to complete because all the nodes in the subcluster you are promoting or demoting take a global catalog lock, write a checkpoint, and then commit. This global catalog lock can cause other database tasks to fail with errors.

Schedule calls to this function when other database activity is low.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
DEMOTED_SUBCLUSTER_TO_SECONDARY('subcluster-name')
```

Parameters

subcluster-name

The name of the primary subcluster to demote to a secondary subcluster.

Privileges

Superuser

Examples

The following example demotes the subcluster `analytics_cluster` to a secondary subcluster:

```
=> SELECT DISTINCT subcluster_name, is_primary from subclusters;
subcluster_name | is_primary
-----+-----
analytics_cluster | t
load_subcluster | t
(2 rows)

=> SELECT DEMOTED_SUBCLUSTER_TO_SECONDARY('analytics_cluster');
DEMOTED_SUBCLUSTER_TO_SECONDARY
-----
DEMOTED SUBCLUSTER TO SECONDARY
(1 row)

=> SELECT DISTINCT subcluster_name, is_primary from subclusters;
subcluster_name | is_primary
-----+-----
analytics_cluster | f
load_subcluster | t
(2 rows)
```

Attempting to demote the subcluster that contains the initiator node results in an error:

```
=> SELECT node_name FROM sessions WHERE user_name = 'dbadmin'
AND client_type = 'vsq!';
node_name
-----
v_verticadb_node0004
(1 row)

=> SELECT node_name, is_primary FROM subclusters WHERE subcluster_name = 'analytics';
node_name | is_primary
-----+-----
v_verticadb_node0004 | t
v_verticadb_node0005 | t
v_verticadb_node0006 | t
(3 rows)

=> SELECT DEMOTED_SUBCLUSTER_TO_SECONDARY('analytics');
ERROR 9204: Cannot promote or demote subcluster including the initiator node
HINT: Run this command on another subcluster
```

FINISH_FETCHING_FILES

Eon Mode only

Fetches to the depot all files that are queued for download from communal storage.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
FINISH_FETCHING_FILES()
```

Privileges

Superuser

Examples

Get all files queued for download:

```
=> SELECT FINISH_FETCHING_FILES();
      FINISH_FETCHING_FILES
```

```
-----
Finished fetching all the files
(1 row)
```

See also

[Eon Mode concepts](#)

[FLUSH_REAPER_QUEUE](#)

Eon Mode only

Deletes all data marked for deletion in the database. Use this function to remove all data marked for deletion before the reaper service deletes disk files.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
FLUSH_REAPER_QUEUE( [sync-catalog] )
```

Parameters

*** *sync-catalog* ***

Specifies to [sync metadata](#) in the database catalog on all nodes before the function executes:

- **true** (default): Sync the database catalog
- **false** : Run without syncing.

Privileges

Superuser

Examples

Remove all files that are marked for deletion:

```
=> SELECT FLUSH_REAPER_QUEUE();
      FLUSH_REAPER_QUEUE
```

```
-----
Sync'd catalog and deleted all files in the reaper queue.
(1 row)
```

See also

[CLEAN_COMMUNAL_STORAGE](#)

MIGRATE_ENTERPRISE_TO_EON

Enterprise Mode only

Migrates an Enterprise database to an Eon Mode database. `MIGRATE_ENTERPRISE_TO_EON` runs in the foreground; until it returns—either with success or an error—it blocks all operations in the same session on the source Enterprise database. If successful, `MIGRATE_ENTERPRISE_TO_EON` returns with a list of nodes in the migrated database.

If migration is interrupted before the meta-function returns—for example, the client disconnects, or a network outage occurs—the migration returns an error. In this case, call `MIGRATE_ENTERPRISE_TO_EON` again to restart migration. For details, see [Handling Interrupted Migration](#).

You can repeat migration multiple times to the same communal storage location—for example, to capture changes that occurred in the source database during the previous migration. For details, see [Repeating Migration](#).

This is a meta-function. You must call meta-functions in a top-level `SELECT` statement.

Behavior type

[Volatile](#)

Syntax

```
MIGRATE_ENTERPRISE_TO_EON ( 'communal-storage-location', 'depot-location' [, is-dry-run] )
```

communal-storage-location

URI of communal storage location. For URI syntax examples for each supported schema, see [File systems and object stores](#).

depot-location

Path of Eon depot location, typically:

```
/vertica/depot
```

Important

Management Console requires this convention to enable access to depot data and activity.

is-dry-run

Boolean. If set to true, `MIGRATE_ENTERPRISE_TO_EON` only checks whether the Enterprise source database complies with all [migration prerequisites](#). If the meta-function discovers any compliance issues, it writes these to the migration error log `migrate_enterprise_to_eon_error.log` in the database directory.

Default: false

Privileges

Superuser

Examples

Migrate an Enterprise database to Eon Mode on AWS:

```
=> SELECT MIGRATE_ENTERPRISE_TO_EON ('s3://verticadbbucket', '/vertica/depot');
      migrate_enterprise_to_eon
-----
v_vmart_node0001,v_vmart_node0002,v_vmart_node0003,v_vmart_node0004
(1 row)
```

See also

[Migrating an enterprise database to Eon Mode](#)

`PROMOTE_SUBCLUSTER_TO_PRIMARY`

Eon Mode only

Converts a secondary subcluster to a [primary subcluster](#). You cannot use this function to promote the subcluster that contains the [initiator node](#). You must call it while connected to a node in another subcluster.

Important

This function call can take a long time to complete because all the nodes in the subcluster you are promoting or demoting take a global catalog lock, write a checkpoint, and then commit. This global catalog lock can cause other database tasks to fail with errors.

Schedule calls to this function when other database activity is low.

This is a meta-function. You must call meta-functions in a top-level `SELECT` statement.

Behavior type

[Volatile](#)

Syntax

```
PROMOTE_SUBCLUSTER_TO_PRIMARY('subcluster-name')
```

Parameters

subcluster-name

The name of the secondary cluster to promote to a primary subcluster.

Privileges

Superuser

Examples

The following example promotes the subcluster named analytics_cluster to a primary cluster:

```
=> SELECT DISTINCT subcluster_name, is_primary from subclusters;
subcluster_name | is_primary
-----+-----
analytics_cluster | f
load_subcluster | t
(2 rows)

=> SELECT PROMOTE_SUBCLUSTER_TO_PRIMARY('analytics_cluster');
PROMOTE_SUBCLUSTER_TO_PRIMARY
-----
PROMOTE SUBCLUSTER TO PRIMARY
(1 row)

=> SELECT DISTINCT subcluster_name, is_primary from subclusters;
subcluster_name | is_primary
-----+-----
analytics_cluster | t
load_subcluster | t
(2 rows)
```

- [CRITICAL_SUBCLUSTERS](#)

REBALANCE_SHARDS

Eon Mode only

Rebalances shard assignments in a subcluster or across the entire cluster in Eon Mode. If the current session ends, the operation immediately aborts. The amount of time required to rebalance shards scales in a roughly linear fashion based on the number of objects in your database.

Important

If your database has multiple [namespaces](#), REBALANCE_SHARDS rebalances the shards across all namespaces.

Run REBALANCE_SHARDS after you modify your cluster using [ALTER NODE](#) or when you add nodes to a subcluster.

Note

Vertica rebalances shards in a subcluster automatically when you:

- Remove a node from a subcluster.
- Add a new subcluster with the admintools command `db_add_subcluster` with the `-s` option followed by a list of hosts.

After you rebalance shards, you will no longer be able to restore objects from a backup taken before the rebalancing. (Full backups are always possible.) After you rebalance, make another full backup so you will be able to restore objects from it in the future.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
REBALANCE_SHARDS(['subcluster-name'])
```

Parameters

subcluster-name

The name of the subcluster where shards will be rebalanced. If you do not supply this parameter, all subclusters in the database rebalance their shards.

Privileges

Superuser

Examples

The following shows that the nodes in the in the newly-added [analytics_subcluster](#) do not yet have shard subscriptions:

```
=> SELECT subcluster_name, n.node_name, shard_name, subscription_state FROM
v_catalog.nodes n LEFT JOIN v_catalog.node_subscriptions ns ON (n.node_name
= ns.node_name) ORDER BY 1,2,3;
```

subcluster_name	node_name	shard_name	subscription_state
analytics_subcluster	v_verticadb_node0004		
analytics_subcluster	v_verticadb_node0005		
analytics_subcluster	v_verticadb_node0006		
default_subcluster	v_verticadb_node0001	replica	ACTIVE
default_subcluster	v_verticadb_node0001	segment0001	ACTIVE
default_subcluster	v_verticadb_node0001	segment0003	ACTIVE
default_subcluster	v_verticadb_node0002	replica	ACTIVE
default_subcluster	v_verticadb_node0002	segment0001	ACTIVE
default_subcluster	v_verticadb_node0002	segment0002	ACTIVE
default_subcluster	v_verticadb_node0003	replica	ACTIVE
default_subcluster	v_verticadb_node0003	segment0002	ACTIVE
default_subcluster	v_verticadb_node0003	segment0003	ACTIVE

(12 rows)

Rebalance the shards to [analytics_subcluster](#) , then confirm the rebalance was successful by querying the NODES system table:

```

=> SELECT REBALANCE_SHARDS('analytics_subcluster');
REBALANCE_SHARDS
-----
REBALANCED SHARDS
(1 row)

=> SELECT subcluster_name, n.node_name, shard_name, subscription_state FROM
v_catalog.nodes n LEFT JOIN v_catalog.node_subscriptions ns ON (n.node_name
= ns.node_name) ORDER BY 1,2,3;

subcluster_name | node_name | shard_name | subscription_state
-----+-----+-----+-----
analytics_subcluster | v_verticadb_node0004 | replica | ACTIVE
analytics_subcluster | v_verticadb_node0004 | segment0001 | ACTIVE
analytics_subcluster | v_verticadb_node0004 | segment0003 | ACTIVE
analytics_subcluster | v_verticadb_node0005 | replica | ACTIVE
analytics_subcluster | v_verticadb_node0005 | segment0001 | ACTIVE
analytics_subcluster | v_verticadb_node0005 | segment0002 | ACTIVE
analytics_subcluster | v_verticadb_node0006 | replica | ACTIVE
analytics_subcluster | v_verticadb_node0006 | segment0002 | ACTIVE
analytics_subcluster | v_verticadb_node0006 | segment0003 | ACTIVE
default_subcluster | v_verticadb_node0001 | replica | ACTIVE
default_subcluster | v_verticadb_node0001 | segment0001 | ACTIVE
default_subcluster | v_verticadb_node0001 | segment0003 | ACTIVE
default_subcluster | v_verticadb_node0002 | replica | ACTIVE
default_subcluster | v_verticadb_node0002 | segment0001 | ACTIVE
default_subcluster | v_verticadb_node0002 | segment0002 | ACTIVE
default_subcluster | v_verticadb_node0003 | replica | ACTIVE
default_subcluster | v_verticadb_node0003 | segment0002 | ACTIVE
default_subcluster | v_verticadb_node0003 | segment0003 | ACTIVE
(18 rows)

```

If your database has multiple namespaces, you can run the following query to confirm the rebalance was successful across all namespaces:

```

=> SELECT nodes.subcluster_name AS subcluster_name, vs_namespaces.name AS namespace_name, vs_shards.shardname, vs_nodes.name AS nodename
FROM vs_node_subscriptions
INNER JOIN vs_shards
ON vs_node_subscriptions.shardoid=vs_shards.oid
INNER JOIN vs_shard_groups ON vs_shard_groups.oid=vs_shards.shardgroupoid
INNER JOIN vs_nodes ON vs_nodes.oid=vs_node_subscriptions.nodeoid
INNER JOIN nodes ON nodes.node_id=vs_nodes.oid
INNER JOIN vs_namespaces ON vs_namespaces.oid=vs_shard_groups.namespaceoid;
subcluster_name | namespace_name | shardname | nodename | type | state
-----
default_subcluster | default_namespace | replica | v_verticadb_node0002 | SECONDARY | ACTIVE
default_subcluster | default_namespace | replica | v_verticadb_node0003 | SECONDARY | ACTIVE
default_subcluster | default_namespace | replica | v_verticadb_node0001 | PRIMARY | ACTIVE
default_subcluster | default_namespace | segment0001 | v_verticadb_node0002 | SECONDARY | ACTIVE
default_subcluster | default_namespace | segment0001 | v_verticadb_node0001 | PRIMARY | ACTIVE
default_subcluster | default_namespace | segment0002 | v_verticadb_node0002 | PRIMARY | ACTIVE
default_subcluster | default_namespace | segment0002 | v_verticadb_node0003 | SECONDARY | ACTIVE
default_subcluster | default_namespace | segment0003 | v_verticadb_node0003 | SECONDARY | ACTIVE
default_subcluster | default_namespace | segment0003 | v_verticadb_node0001 | PRIMARY | ACTIVE
default_subcluster | ns1 | replica | v_verticadb_node0002 | SECONDARY | ACTIVE
default_subcluster | ns1 | replica | v_verticadb_node0003 | SECONDARY | ACTIVE
default_subcluster | ns1 | replica | v_verticadb_node0001 | PRIMARY | ACTIVE
default_subcluster | ns1 | segment0001 | v_verticadb_node0002 | SECONDARY | ACTIVE
default_subcluster | ns1 | segment0001 | v_verticadb_node0001 | PRIMARY | ACTIVE
default_subcluster | ns1 | segment0002 | v_verticadb_node0002 | PRIMARY | ACTIVE
default_subcluster | ns1 | segment0002 | v_verticadb_node0003 | SECONDARY | ACTIVE
default_subcluster | ns1 | segment0003 | v_verticadb_node0003 | PRIMARY | ACTIVE
default_subcluster | ns1 | segment0003 | v_verticadb_node0001 | SECONDARY | ACTIVE
default_subcluster | ns1 | segment0004 | v_verticadb_node0002 | SECONDARY | ACTIVE
default_subcluster | ns1 | segment0004 | v_verticadb_node0001 | PRIMARY | ACTIVE
analytics_subcluster | default_namespace | replica | v_verticadb_node0005 | SECONDARY | ACTIVE
analytics_subcluster | default_namespace | replica | v_verticadb_node0006 | SECONDARY | ACTIVE
analytics_subcluster | default_namespace | replica | v_verticadb_node0004 | PRIMARY | ACTIVE
analytics_subcluster | default_namespace | segment0001 | v_verticadb_node0005 | SECONDARY | ACTIVE
analytics_subcluster | default_namespace | segment0001 | v_verticadb_node0004 | PRIMARY | ACTIVE
analytics_subcluster | default_namespace | segment0002 | v_verticadb_node0005 | PRIMARY | ACTIVE
analytics_subcluster | default_namespace | segment0002 | v_verticadb_node0006 | SECONDARY | ACTIVE
analytics_subcluster | default_namespace | segment0003 | v_verticadb_node0006 | SECONDARY | ACTIVE
analytics_subcluster | default_namespace | segment0003 | v_verticadb_node0004 | PRIMARY | ACTIVE
analytics_subcluster | ns1 | replica | v_verticadb_node0005 | SECONDARY | ACTIVE
analytics_subcluster | ns1 | replica | v_verticadb_node0006 | SECONDARY | ACTIVE
analytics_subcluster | ns1 | replica | v_verticadb_node0004 | PRIMARY | ACTIVE

analytics_subcluster | ns1 | segment0001 | v_verticadb_node0004 | PRIMARY | ACTIVE
analytics_subcluster | ns1 | segment0002 | v_verticadb_node0006 | PRIMARY | ACTIVE
analytics_subcluster | ns1 | segment0002 | v_verticadb_node0006 | SECONDARY | ACTIVE
analytics_subcluster | ns1 | segment0003 | v_verticadb_node0006 | PRIMARY | ACTIVE
analytics_subcluster | ns1 | segment0003 | v_verticadb_node0004 | SECONDARY | ACTIVE
analytics_subcluster | ns1 | segment0004 | v_verticadb_node0005 | SECONDARY | ACTIVE
analytics_subcluster | ns1 | segment0004 | v_verticadb_node0004 | PRIMARY | ACTIVE
(40 rows)

```

- See also
- [Namespaces and shards](#)
 - [Eon Mode concepts](#)

Changes the number of shards in the `default_namespace` . You can only change the number of shards in the `default_namespace` if it is the only `namespace` in your database. If your database contains any non-default namespaces, running `RESHARD_DATABASE` results in an error.

`RESHARD_DATABASE` does not immediately affect the storage containers in communal storage. After re-sharding, the new shards still point to the existing containers. If you increase the number of shards in the namespace, multiple shards will point to the same storage containers. Eventually, the Tuple Mover (TM) mergeout tasks will realign the storage containers with the new shard segmentation bounds. If you want the TM to immediately realign storage containers, call `DO_TM_TASK` to run a 'RESHARDMERGEOUT' task.

This function requires a global `catalog lock` (GCLX) during runtime. The runtime depends on the size of your catalog. The function does not disrupt most queries. However, the global catalog lock might affect data loads and DDL statements.

Important
`RESHARD_DATABASE` might be rolled back if you call `REBALANCE_SHARDS` during runtime. In some cases, rollback is caused by down nodes or nodes that fail during the re-shard process.

Syntax

```
RESHARD_DATABASE(shard-count)
```

Arguments

shard-count

A positive integer, the number of shards in the re-sharded `default_namespace` . For information about choosing a suitable `shard-count` , see [Choosing the initial node and shard counts](#) .

Privileges

Superuser

Examples

See [Reshard the default namespace](#) .

See also

- [RESHARDING_EVENTS](#)

SANDBOX_SUBCLUSTER

Creates a sandbox for a secondary subcluster.

Note

Vertica recommends using the admintools `sandbox_subcluster` command to create sandboxes. This command includes additional sanity checks and validates that the sandboxed nodes are UP after sandbox creation. However, you must use the `SANDBOX_SUBCLUSTER` function to add additional subclusters to an existing sandbox.

If sandboxing the first subcluster in a sandbox, the nodes in the specified subcluster create a checkpoint of the catalog at function runtime. When these nodes auto-restart in the sandbox cluster, they form a primary subcluster that uses the data and catalog checkpoint from the main cluster. After the nodes successfully restart, the sandbox cluster and the main cluster are mutually isolated and can diverge.

While the nodes in the main cluster sync their metadata to `/path-to-communal-storage/metadata/db_name` , the nodes in the sandbox sync to `/path-to-communal-storage/metadata/sandbox_name` .

You can perform standard database operations and queries, such as loading data or creating new tables, in either cluster without affecting the other cluster. For example, dropping a table in the sandbox cluster does not drop the table in the main cluster, and vice versa.

Because both clusters reference the same data files, neither cluster can delete files that existed at the time of sandbox creation. However, files that are created in the sandbox can be removed. Files in the main cluster can be queued for removal, but they are not processed until all active sandboxes are removed.

You cannot nest sandboxes, but you can have more than one subcluster in a sandbox and multiple sandboxes active at the same time. To add an additional secondary subcluster to an existing sandbox, you must first call `SANDBOX_SUBCLUSTER` in the sandbox cluster and then in the main cluster. For details, see [Adding subclusters to existing sandboxes](#) .

This is a meta-function. You must call meta-functions in a top-level `SELECT` statement. The function also requires a global catalog lock (GCLX) during runtime.

Behavior type

[Volatile](#)

Syntax

```
SANDBOX_SUBCLUSTER( 'sandbox-name', 'subcluster-name', 'options' )
```

Arguments

sandbox-name

Name of the sandbox. The name must conform to the following rules:

- Consist of at most 30 characters, all of which must have an ASCII code between 36 and 126
- Begin with a letter
- Unique among all existing databases and sandboxes

subcluster-name

Name of the secondary subcluster to sandbox. Attempting to sandbox a primary subcluster or a subcluster that is already sandboxed results in an error. The nodes in the subcluster must all have a status of UP and provide full subscription coverage for all shards.

options

Currently, there are no options for this function.

Privileges

[Superuser](#)

Examples

The following example sandboxes the **sc02** secondary subcluster into a sandbox named **sand** :

```
=> SELECT SANDBOX_SUBCLUSTER('sand', 'sc_02', '');
      SANDBOX_SUBCLUSTER
```

Subcluster 'sc_02' has been sandboxed to 'sand'. It is going to auto-restart and re-form.

(1 row)

If you query the [NODES](#) system table from the main cluster, you can see that the nodes of **sc_02** have a status of UNKNOWN and are listed as member of the **sand** sandbox:

```
=> SELECT node_name, subcluster_name, node_state, sandbox FROM NODES;
      node_name      | subcluster_name | node_state | sandbox
```

```
-----+-----+-----+-----
v_verticadb_node0001 | default_subcluster | UP      |
v_verticadb_node0002 | default_subcluster | UP      |
v_verticadb_node0003 | default_subcluster | UP      |
v_verticadb_node0004 | sc_02             | UNKNOWN  | sand
v_verticadb_node0005 | sc_02             | UNKNOWN  | sand
v_verticadb_node0006 | sc_02             | UNKNOWN  | sand
```

(6 rows)

When you issue the same query on one of the sandboxed nodes, the table shows that the sandboxed nodes are UP and the nodes from the main cluster are UNKNOWN, confirming that the cluster is successfully sandboxed:

```
=> SELECT node_name, subcluster_name, node_state, sandbox FROM NODES;
      node_name      | subcluster_name | node_state | sandbox
```

```
-----+-----+-----+-----
v_verticadb_node0001 | default_subcluster | UNKNOWN  |
v_verticadb_node0002 | default_subcluster | UNKNOWN  |
v_verticadb_node0003 | default_subcluster | UNKNOWN  |
v_verticadb_node0004 | sc_02             | UP      | sand
v_verticadb_node0005 | sc_02             | UP      | sand
v_verticadb_node0006 | sc_02             | UP      | sand
```

(6 rows)

You can now perform standard database operations in either cluster without impacting the other cluster. For instance, if you create a machine learning dataset named **train_data** in the sandboxed subcluster, the new table does not propagate to the main cluster:

```

--In the sandboxed subcluster
=> CREATE TABLE train_data(time timestamp, Temperature float);
CREATE TABLE

=> COPY train_data FROM LOCAL 'daily-min-temperatures.csv' DELIMITER ',';
Rows Loaded
-----
 3650
(1 row)

=> SELECT * FROM train_data LIMIT 5;
   time      | Temperature
-----+-----
1981-01-27 00:00:00 |    19.4
1981-02-20 00:00:00 |    15.7
1981-02-27 00:00:00 |    17.5
1981-03-04 00:00:00 |     16
1981-04-24 00:00:00 |    11.5
(5 rows)

--In the main cluster
=> SELECT * FROM train_data LIMIT 5;
ERROR 4566: Relation "train_data" does not exist

```

SET_DEPOT_ANTI_PIN_POLICY_PARTITION

Eon Mode only

Assigns the highest depot eviction priority to a partition. Among other depot-cached objects, objects with an anti-pinning policy are the most susceptible to eviction from the depot. After eviction, the object must be read directly from communal storage the next time it is needed.

If the table has another partition-level eviction policy already set on it, then Vertica [combines the policies](#) based on policy type.

If you alter or remove table partitioning, Vertica automatically clears all [eviction policies](#) previously set on partitions of that table. The table's eviction policy, if any, is unaffected.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```

SET_DEPOT_ANTI_PIN_POLICY_PARTITION (
  '[[database.]schema.]object-name', 'min-range-value', 'max-range-value' [, 'subcluster' ] )

```

Arguments

[*database* .] *schema*

Database and [schema](#). The default schema is [public](#). If you specify a database, it must be the current database.

object-name

Target of this policy.

min-range-value* , *max-range-value

Minimum and maximum value of partition keys in *object-name* to anti-pin, where *min-range-value* must be \leq *max-range-value*. To specify a single partition key, *min-range-value* and *max-range-value* must be equal.

If the new policy's partition key range overlaps the range of an existing partition-level eviction policy, Vertica gives precedence to the new policy, as described in [Overlapping Policies](#).

subcluster

Name of a depot subcluster, `default_subcluster` to specify the [default database subcluster](#). If this argument is omitted, all database depots are targeted.

Privileges

Superuser

See also

- [Anti-pinning policies](#)
- [CLEAR_DEPOT_ANTI_PIN_POLICY_PARTITION](#)

SET_DEPOT_ANTI_PIN_POLICY_PROJECTION

Eon Mode only

Assigns the highest depot eviction priority to a projection. Among other depot-cached objects, objects with an anti-pinning policy are the most susceptible to eviction from the depot. After eviction, the object must be read directly from communal storage the next time it is needed.

If the projection has another eviction policy already set on it, the new policy supersedes it.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
SET_DEPOT_ANTI_PIN_POLICY_PROJECTION ( '[[database.]schema.]projection' [, 'subcluster' ] )
```

Arguments

[**database** .] **schema**

Database and [schema](#). The default schema is `public`. If you specify a database, it must be the current database.

projection

Target of this policy.

subcluster

Name of a depot subcluster, `default_subcluster` to specify the [default database subcluster](#). If this argument is omitted, all database depots are targeted.

Privileges

Superuser

See also

- [Anti-pinning policies](#)
- [CLEAR_DEPOT_ANTI_PIN_POLICY_PROJECTION](#)

SET_DEPOT_ANTI_PIN_POLICY_TABLE

Eon Mode only

Assigns the highest depot eviction priority to a table. Among other depot-cached objects, objects with an anti-pinning policy are the most susceptible to eviction from the depot. After eviction, the object must be read directly from communal storage the next time it is needed.

If the table has another eviction policy already set on it, the new policy supersedes it.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
SET_DEPOT_ANTI_PIN_POLICY_TABLE ( '[[database.]schema.]table' [, 'subcluster' ] )
```

Arguments

[**database** .] **schema**

Database and [schema](#). The default schema is `public`. If you specify a database, it must be the current database.

table

Target of this policy.

subcluster

Name of a depot subcluster, `default_subcluster` to specify the [default database subcluster](#). If this argument is omitted, all database depots are targeted.

Privileges

Superuser

See also

- [Anti-pinning policies](#)
- [CLEAR_DEPOT_ANTI_PIN_POLICY_TABLE](#)

SET_DEPOT_PIN_POLICY_PARTITION

Eon Mode only

Pins the specified partitions of a table or projection to a subcluster depot, or all database depots, to reduce exposure to depot eviction.

If the table has another partition-level eviction policy already set on it, then Vertica [combines the policies](#) based on policy type.

If you alter or remove table partitioning, Vertica automatically clears all [eviction policies](#) previously set on partitions of that table. The table's eviction policy, if any, is unaffected.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
SET_DEPOT_PIN_POLICY_PARTITION (  
  '[[database.]schema.]object-name', 'min-range-value', 'max-range-value' [, 'subcluster' ] [, 'download' ] )
```

Arguments

[**database** .] **schema**

Database and [schema](#). The default schema is `public`. If you specify a database, it must be the current database.

object-name

Table or projection to pin. If you specify a projection, it must store the partition keys.

min-range-value , max-range-value

Minimum and maximum value of partition keys in `object-name` to pin, where `min-range-value` must be \leq `max-range-value`. To specify a single partition key, `min-range-value` and `max-range-value` must be equal.

If the new policy's partition key range overlaps the range of an existing partition-level eviction policy, Vertica gives precedence to the new policy, as described in [Overlapping Policies](#) below.

subcluster

Name of a depot subcluster, `default_subcluster` to specify the [default database subcluster](#). If this argument is omitted, all database depots are targeted.

download

Boolean, if true, SET_DEPOT_PIN_POLICY_PARTITION immediately queues the specified partitions for download from communal storage.

Default: false

Privileges

Superuser

Overlapping policies

If a new partition pinning policy overlaps the partition key range of an existing eviction policy, Vertica determines how to apply the policy based on the type of the new and existing policies.

Both policies are pinning policies

If both the new and existing policies are pinning policies, then Vertica collates the two ranges. For example, if you create two partition pinning policies with key ranges of 1-3 and 2-10, Vertica creates a single policy with a key range of 1-10.

Partition pinning policy overlaps anti-pinning policy

If the new partition pinning policy overlaps an anti-pinning policy, then Vertica issues a warning and informational message that it reassigned the range of overlapping keys from the anti-pinning policy to the new pinning policy.

For example, if you create an anti-partition pinning policy and then a pinning policy with key ranges of 1-10 and 5-20, respectively, Vertica truncates the earlier anti-pinning policy's key range:

policy_type	min_value	max_value
PIN	5	20
ANTI_PIN	1	4

If the new pinning policy's partition range falls inside the range of an older anti-pinning policy, Vertica splits the anti-pinning policy. So, given an existing partition anti-pinning policy with a key range of 1-20, a new partition pinning policy with a key range of 5-10 splits the anti-pinning policy:

policy_type	min_value	max_value
ANTI_PIN	1	4
PIN	5	10
ANTI_PIN	11	20

Precedence of pinning policies

In general, partition management functions that involve two partitioned tables give precedence to the target table's pinning policy, as follows:

- [COPY_PARTITIONS_TO_TABLE](#): Partition-level pinning is reliable if the source and target tables have pinning policies on the same partition keys. If the two tables have different pinning policies, then the partition pinning policies of the target table apply.
- [MOVE_PARTITIONS_TO_TABLE](#): Partition-level pinning policies of the target table apply.
- [SWAP_PARTITIONS_BETWEEN_TABLES](#): Partition-level pinning policies of the target table apply.

For example, the following statement copies partitions from table **t1** to table **t2** :

```
=> SELECT COPY_PARTITIONS_TO_TABLE('t1', '1', '5', 't2');
```

In this case, the following logic applies:

- If the two tables have different partition pinning policies, then the pinning policy of target table **t2** for partition keys 1-5 applies.
- If table **t2** does not exist, then Vertica creates it from table **t1** , and copies **t1** 's policy on partition keys 1-5. Subsequently, if you clear the partition pinning policy from either table, it is also cleared from the other.

- [Pinning Policies](#)
- [CLEAR_DEPOT_PIN_POLICY_PARTITION](#)

SET_DEPOT_PIN_POLICY_PROJECTION

Eon Mode only

Pins a projection to a subcluster depot, or all database depots, to reduce its exposure to depot eviction. For details on pinning policies and usage guidelines, see [Pinning Policies](#) .

If the projection has another eviction policy already set on it, the new policy supersedes it.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
SET_DEPOT_PIN_POLICY_PROJECTION ( ( [database.]schema.]projection'[, 'subcluster' ] [, download ] )
```

Arguments

[*database* .] *schema*

Database and [schema](#). The default schema is `public`. If you specify a database, it must be the current database.

projection

Projection to pin.

subcluster

Name of a depot subcluster, `default_subcluster` to specify the [default database subcluster](#). If this argument is omitted, all database depots are targeted.

download

Boolean, if true `SET_DEPOT_PIN_POLICY_PROJECTION` immediately queues the specified projection for download from communal storage.

Default: false

Privileges

Superuser

See also

- [Pinning Policies](#)
- [CLEAR_DEPOT_PIN_POLICY_PROJECTION](#)

`SET_DEPOT_PIN_POLICY_TABLE`

Eon Mode only

Pins a table to a subcluster depot, or all database depots, to reduce its exposure to depot eviction.

If the table has another eviction policy already set on it, the new policy supersedes it. After you pin a table to a subcluster depot, you cannot subsequently pin any of its partitions and projections in that depot.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
SET_DEPOT_PIN_POLICY_TABLE ( '[[database.]schema.]table' [, 'subcluster' ] [, download ] )
```

Arguments

[**database** .] **schema**

Database and [schema](#). The default schema is `public`. If you specify a database, it must be the current database.

table

Table to pin.

subcluster

Name of a depot subcluster, `default_subcluster` to specify the [default database subcluster](#). If this argument is omitted, all database depots are targeted.

download

Boolean, if true, `SET_DEPOT_PIN_POLICY_TABLE` immediately queues the specified table for download from communal storage.

Default: false

Privileges

Superuser

See also

- [Pinning Policies](#)
- [CLEAR_DEPOT_PIN_POLICY_TABLE](#)

`SHUTDOWN_SUBCLUSTER`

Eon Mode only

Shuts down a subcluster. This function shuts down the subcluster synchronously, returning when shutdown is complete with the message *Subcluster*

shutdown . If the subcluster is already down, the function returns with no error.

Stopping a subcluster does not warn you if there are active user sessions connected to the subcluster. This behavior is the same as stopping an individual node. Before stopping a subcluster, verify that no users are connected to it.

If you want to drain client connections before shutting down a subcluster, you can gracefully shutdown the subcluster using [SHUTDOWN_WITH_DRAIN](#)

Caution

This function does not test whether the target subcluster is critical (a subcluster whose loss would cause the database to shut down). Using this function to shut down a critical subcluster results in the database shutting down. Always verify that the subcluster you want to shut down is not critical by querying the [CRITICAL_SUBCLUSTERS](#) system table before calling this function.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
SHUTDOWN_SUBCLUSTER('subcluster-name')
```

Arguments

subcluster-name

Name of the subcluster to shut down.

Privileges

Superuser

Examples

The following example demonstrates shutting down the subcluster **analytics** :

```
=> SELECT subcluster_name, node_name, node_state FROM nodes order by 1,2;
subcluster_name | node_name | node_state
-----+-----+-----
analytics      | v_verticadb_node0004 | UP
analytics      | v_verticadb_node0005 | UP
analytics      | v_verticadb_node0006 | UP
default_subcluster | v_verticadb_node0001 | UP
default_subcluster | v_verticadb_node0002 | UP
default_subcluster | v_verticadb_node0003 | UP
(6 rows)

=> SELECT SHUTDOWN_SUBCLUSTER('analytics');
WARNING 4539: Received no response from v_verticadb_node0004 in stop subcluster
WARNING 4539: Received no response from v_verticadb_node0005 in stop subcluster
WARNING 4539: Received no response from v_verticadb_node0006 in stop subcluster
SHUTDOWN_SUBCLUSTER
-----
Subcluster shutdown
(1 row)

=> SELECT subcluster_name, node_name, node_state FROM nodes order by 1,2;
subcluster_name | node_name | node_state
-----+-----+-----
analytics      | v_verticadb_node0004 | DOWN
analytics      | v_verticadb_node0005 | DOWN
analytics      | v_verticadb_node0006 | DOWN
default_subcluster | v_verticadb_node0001 | UP
default_subcluster | v_verticadb_node0002 | UP
default_subcluster | v_verticadb_node0003 | UP
(6 rows)
```

Note

The "WARNING 4539" messages after calling SHUTDOWN_SUBCLUSTER occur because the nodes are in the process of shutting down. They are expected.

See also

- [Subclusters](#)
- [ALTER SUBCLUSTER](#)
- [CRITICAL_SUBCLUSTERS](#)

SHUTDOWN_WITH_DRAIN

Eon Mode only

Gracefully shuts down a subcluster or subclusters. The function drains client connections on the subcluster's nodes and then shuts down the subcluster. This is synchronous function that returns when the shutdown message has been sent to the subcluster.

Work from existing user sessions continues on draining nodes, but the nodes refuse new client connections and are excluded from load-balancing operations. dbadmin can still connect to draining nodes.

The nodes drain until either the existing connections complete their work and close or the user-specified timeout is reached. When one of these conditions is met, the function proceeds to shut down the subcluster.

For more information about the graceful shutdown process, see [Graceful Shutdown](#).

Caution

This function does not test whether the target subcluster is critical (a subcluster whose loss would cause the database to shut down). Using this function to shut down a critical subcluster results in the database shutting down. Always verify that the subcluster you want to shut down is not critical by querying the [CRITICAL_SUBCLUSTERS](#) system table before calling this function.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
SHUTDOWN_WITH_DRAIN( 'subcluster-name', timeout-seconds )
```

Arguments

subcluster-name

Name of the subcluster to shutdown. Enter an empty string to shutdown all subclusters in a database.

timeout-seconds

Number of seconds to wait before forcefully closing *subcluster-name*'s client connections and shutting down. The behavior depends on the sign of *timeout-seconds*:

- Positive integer: The function waits until either the runtime reaches *timeout-seconds* or the client connections finish their work and close. As soon as one of these conditions is met, the function immediately proceeds to shut down the subcluster.
- Zero: The function immediately closes any open client connections and shuts down the subcluster.
- Negative integer: The function marks the subcluster as draining and waits indefinitely to shut down the subcluster until all active user sessions disconnect.

Privileges

Superuser

Examples

In the following example, the function marks the subcluster named analytics as draining and then shuts it down as soon as either the existing client connections close or 300 seconds pass:

```
=> SELECT SHUTDOWN_WITH_DRAIN('analytics', 120);
NOTICE 0: Draining has started on subcluster (analytics)
NOTICE 0: Begin shutdown of subcluster (analytics)
          SHUTDOWN_WITH_DRAIN
```

```
-----
Set subcluster (analytics) to draining state
Waited for 3 nodes to drain
Shutdown message sent to subcluster (analytics)
```

(1 row)

You can query the DC_DRAINING_EVENTS table to see more information about draining and shutdown events, such as whether any user sessions were forcibly closed. This subcluster had one active user session when the shutdown began, but it closed before the timeout was reached:

```
=> SELECT event_type, event_type_name, event_description, event_result, event_result_name FROM dc_draining_events;
event_type | event_type_name | event_description | event_result | event_result_name
-----+-----+-----+-----+-----
0 | START_DRAIN_SUBCLUSTER | START_DRAIN for SHUTDOWN of subcluster (analytics) | 0 | SUCCESS
2 | START_WAIT_FOR_NODE_DRAIN | Wait timeout is 120 seconds | 4 | INFORMATIONAL
4 | INTERVAL_WAIT_FOR_NODE_DRAIN | 1 sessions remain after 0 seconds | 4 | INFORMATIONAL
4 | INTERVAL_WAIT_FOR_NODE_DRAIN | 1 sessions remain after 30 seconds | 4 | INFORMATIONAL
3 | END_WAIT_FOR_NODE_DRAIN | Wait for drain ended with 0 sessions remaining | 0 | SUCCESS
5 | BEGIN_SHUTDOWN_AFTER_DRAIN | Starting shutdown of subcluster (analytics) following drain | 4 | INFORMATIONAL
(6 rows)
```

See also

- [Graceful Shutdown](#)
- [DRAINING_STATUS](#)
- [START_DRAIN_SUBCLUSTER](#)
- [CANCEL_DRAIN_SUBCLUSTER](#)

START_DRAIN_SUBCLUSTER

Eon Mode only

Drains a subcluster or subclusters. The function marks all nodes in the designated subcluster as draining. Work from existing user sessions continues on draining nodes, but the nodes refuse new client connections and are excluded from load balancing operations. dbadmin can still connect to draining nodes.

To drain connections on a subcluster as part of a graceful shutdown process, you can call [SHUTDOWN_WITH_DRAIN](#). For details, see [Graceful Shutdown](#).

To cancel a draining operation on a subcluster, call [CANCEL_DRAIN_SUBCLUSTER](#). If all draining nodes in a subcluster are stopped, they are marked as not draining upon restart.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
START_DRAIN_SUBCLUSTER( 'subcluster-name' )
```

Arguments

subcluster-name

Name of the subcluster to drain. Enter an empty string to drain all subclusters in the database.

Privileges

Superuser

Examples

The following example demonstrates how to drain a subcluster named analytics:

```
=> SELECT subcluster_name, node_name, node_state FROM nodes;
```

```
subcluster_name | node_name | node_state
```

```
-----+-----+-----
default_subcluster | verticadb_node0001 | UP
default_subcluster | verticadb_node0002 | UP
default_subcluster | verticadb_node0003 | UP
analytics          | verticadb_node0004 | UP
analytics          | verticadb_node0005 | UP
analytics          | verticadb_node0006 | UP
(6 rows)
```

```
=> SELECT START_DRAIN_SUBCLUSTER('analytics');
       START_DRAIN_SUBCLUSTER
```

```
-----
Targeted subcluster: 'analytics'
```

```
Action: START DRAIN
```

```
(1 row)
```

You can confirm that the subcluster is draining by querying the [DRAINING_STATUS](#) system table:

```
=> SELECT node_name, subcluster_name, is_draining FROM draining_status ORDER BY 1;
```

```
node_name      | subcluster_name | is_draining
```

```
-----+-----+-----
verticadb_node0001 | default_subcluster | f
verticadb_node0002 | default_subcluster | f
verticadb_node0003 | default_subcluster | f
verticadb_node0004 | analytics          | t
verticadb_node0005 | analytics          | t
verticadb_node0006 | analytics          | t
```

- [Drain client connections](#)
- [CANCEL_DRAIN_SUBCLUSTER](#)
- [DRAINING_STATUS](#)

START_REAPING_FILES

Eon Mode only

Starts the disk file deletion in the background as an asynchronous function. By default, this meta-function syncs the catalog before beginning deletion. Disk file deletion is handled in the foreground by [FLUSH_REAPER_QUEUE](#).

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
START_REAPING_FILES( [sync-catalog] )
```

Parameters

*** sync-catalog ***

Specifies to [sync metadata](#) in the database catalog on all nodes before the function executes:

- **true** (default): Sync the database catalog
- **false** : Run without syncing.

Privileges

Superuser

Examples

Start the reaper service:

```
=> SELECT START_REAPING_FILES();
```

Start the reaper service and skip the initial catalog sync:

```
=> SELECT START_REAPING_FILES(false);
```

SYNC_CATALOG

Eon Mode only

Synchronizes the catalog to communal storage to enable reviving the current catalog version in the case of an imminent crash. Vertica synchronizes all pending checkpoint and transaction logs to communal storage.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
SYNC_CATALOG( [ 'node-name' ] )
```

Parameters

node-name

The node to synchronize. If you omit this argument, Vertica synchronizes the catalog on all nodes.

Privileges

Superuser

Examples

Synchronize the catalog on all nodes:

```
=> SELECT SYNC_CATALOG();
```

Synchronize the catalog on one node:

```
=> SELECT SYNC_CATALOG( 'node001' );
```

UNSANDBOX_SUBCLUSTER

Removes a subcluster from a sandbox.

Note

Vertica recommends using the admintools [unsandbox_subcluster](#) command to remove the sandbox's primary subcluster. This command automatically stops the sandboxed nodes, wipes the node's catalog subdirectories, and restarts the nodes. If you use the UNSANDBOX_SUBCLUSTER function, these steps must be completed manually.

After stopping the nodes in the sandboxed subcluster, you must run this function in the main cluster from which the sandboxed subcluster was spun-off. The function changes the metadata in the main cluster that designates the specified subcluster as sandboxed, but does not restart the subcluster and rejoin it to the main cluster.

If you are unsandboxing a secondary subcluster from the sandbox, Vertica recommends that you also call the UNSANDBOX_SUBCLUSTER function in the sandbox cluster. This makes sure that both clusters are aware of the state of the subcluster and that relevant system tables accurately reflect the subcluster's status.

To rejoin the subcluster to the main cluster and return the nodes to their normal state, you must complete the following tasks:

1. Wipe the catalog subdirectory from the sandboxed nodes. The main cluster provides the current catalog information on node restart.
2. Restart the nodes. On successful restart, the nodes should rejoin the main cluster.
3. If unsandboxing the last subcluster in a sandbox, remove the sandbox metadata prefix from the shared communal storage location. This helps avoid problems that might arise from reusing the same sandbox name.

Note

If you upgraded the Vertica version of the sandboxed subcluster, you must downgrade the version of the subcluster before rejoining it to the main cluster.

If there are no more active sandboxes, you can run [CLEAN_COMMUNAL_STORAGE](#) to remove any data created in the sandbox. The main cluster can also resume processing data queued for deletion.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
UNSANDBOX_SUBCLUSTER( 'subcluster-name', 'options' )
```

Arguments

subcluster-name

Identifies the subcluster to unsandbox. This must be a currently sandboxed subcluster.

options

Currently, there are no options for this function.

Privileges

[Superuser](#)

Examples

In the following example, the function unsandboxes the `sc_02` secondary subcluster from the `sand` sandbox. After stopping the nodes in the subcluster, you can unsandbox the subcluster by calling the `UNSANDBOX_SUBCLUSTER` function from the main cluster:

```
=> SELECT UNSANDBOX_SUBCLUSTER('sc_02', '');
      UNSANDBOX_SUBCLUSTER
```

Subcluster 'sc_02' has been unsandboxed. If wiped out and restarted, it should be able to rejoin the cluster.

(1 row)

To rejoin the nodes to the main cluster, you must wipe the local catalog from each of the previously sandboxed nodes—whose catalog location can be found by querying [NODES](#)—and then restart the nodes:

```
$ rm -rf paths-to-node-catalogs
```

```
$ admintools -t restart_node -s list-of-nodes -p password
```

After the nodes restart, you can query the `NODES` system table to confirm that the previously sandboxed nodes are UP and are no longer a member of `sand`:

```
=> SELECT node_name, subcluster_name, node_state, sandbox FROM NODES;
```

node_name	subcluster_name	node_state	sandbox
v_verticadb_node0001	default_subcluster	UP	
v_verticadb_node0002	default_subcluster	UP	
v_verticadb_node0003	default_subcluster	UP	
v_verticadb_node0004	sc_01	UNKNOWN	sand
v_verticadb_node0005	sc_01	UNKNOWN	sand
v_verticadb_node0006	sc_01	UNKNOWN	sand
v_verticadb_node0007	sc_02	UP	
v_verticadb_node0008	sc_02	UP	
v_verticadb_node0009	sc_02	UP	

(9 rows)

Because `sc_02` was a secondary subcluster in the sandbox, you should also call the `UNSANDBOX_SUBCLUSTER` function in the sandbox cluster. This makes sure that both clusters are aware of the state of the subcluster and that relevant system tables accurately reflect the subcluster's status:

```
=> SELECT UNSANDBOX_SUBCLUSTER('sc_02', '');
      UNSANDBOX_SUBCLUSTER
```

Subcluster 'sc_02' has been unsandboxed from 'sand'. This command should be executed in the main cluster as well.

(1 row)

If there are no more active sandboxes, you can run the [CLEAN_COMMUNAL_STORAGE](#) function to remove any data created in the sandbox. You should also remove the sandbox's metadata from the shared communal storage location, which can be found at `/path-to-communal-storage/metadata/sandbox_name`.

The following example removes the sandbox's metadata from an S3 bucket and then calls `CLEAN_COMMUNAL_STORAGE` to cleanup any data from the sandbox:

```
$ aws s3 rm /path-to-communal/metadata/sandbox_name

=> SELECT CLEAN_COMMUNAL_STORAGE('true');
      CLEAN_COMMUNAL_STORAGE
-----
CLEAN COMMUNAL STORAGE
Total leaked files: 143
Files have been queued for deletion.
Check communal_cleanup_records for more information.

(1 row)
```

Epoch functions

This section contains the epoch management functions specific to Vertica.

In this section

- [ADVANCE_EPOCH](#)
- [GET_AHM_EPOCH](#)
- [GET_AHM_TIME](#)
- [GET_CURRENT_EPOCH](#)
- [GET_LAST_GOOD_EPOCH](#)
- [MAKE_AHM_NOW](#)
- [SET_AHM_EPOCH](#)
- [SET_AHM_TIME](#)

ADVANCE_EPOCH

Manually closes the current epoch and begins a new epoch.

This is a meta-function. You must call meta-functions in a top-level `SELECT` statement.

Behavior type

[Volatile](#)

Syntax

```
ADVANCE_EPOCH ( [ integer ] )
```

Parameters

integer

Specifies the number of epochs to advance.

Privileges

Superuser

Notes

This function is primarily maintained for backward compatibility with earlier versions of Vertica.

Examples

The following command increments the epoch number by 1:

```
=> SELECT ADVANCE_EPOCH(1);
```

GET_AHM_EPOCH

Returns the number of the [epoch](#) in which the [Ancient History Mark](#) is located. Data deleted up to and including the AHM epoch can be purged from physical storage.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
GET_AHM_EPOCH()
```

Note

The AHM epoch is 0 (zero) by default (purge is disabled).

Privileges

None

Examples

```
=> SELECT GET_AHM_EPOCH();
      GET_AHM_EPOCH
```

```
-----
Current AHM epoch: 0
(1 row)
```

GET_AHM_TIME

Returns a [TIMESTAMP](#) value representing the [Ancient History Mark](#). Data deleted up to and including the AHM epoch can be purged from physical storage.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
GET_AHM_TIME()
```

Privileges

None

Examples

```
=> SELECT GET_AHM_TIME();
      GET_AHM_TIME
```

```
-----
Current AHM Time: 2010-05-13 12:48:10.532332-04
(1 row)
```

GET_CURRENT_EPOCH

The epoch into which data (COPY, INSERT, UPDATE, and DELETE operations) is currently being written.

Returns the number of the current epoch.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
GET_CURRENT_EPOCH()
```

Privileges

None

Examples

```
=> SELECT GET_CURRENT_EPOCH();
GET_CURRENT_EPOCH
-----
          683
(1 row)
```

GET_LAST_GOOD_EPOCH

Returns the [last good epoch](#) number. If the database has no projections, the function returns an error.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
GET_LAST_GOOD_EPOCH()
```

Privileges

None

Examples

```
=> SELECT GET_LAST_GOOD_EPOCH();
GET_LAST_GOOD_EPOCH
-----
          682
(1 row)
```

MAKE_AHM_NOW

Sets the [Ancient History Mark](#) (AHM) to the greatest allowable value. This lets you purge all deleted data.

Caution

After running this function, you cannot query historical data that precedes the current epoch. Only database administrators should use this function.

MAKE_AHM_NOW performs the following operations:

- Advances the epoch.
- Sets the AHM to the [last good epoch](#) (LGE) — at least to the epoch that is current when you execute **MAKE_AHM_NOW** .

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
MAKE_AHM_NOW ( [ true ] )
```

Parameters

true

Allows AHM to advance when one of the following conditions is true:

- One or more nodes are down.
- One projection is being refreshed from another (retentive refresh).

In both cases , you must supply this argument to **MAKE_AHM_NOW** , otherwise Vertica returns an error. If you execute **MAKE_AHM_NOW(true)** during retentive refresh, Vertica rolls back the refresh operation and advances the AHM.

Caution

If the function advances AHM beyond the last good epoch of the down nodes, those nodes must recover all data from scratch.

Privileges
Superuser

Setting AHM when nodes are down

If any node in the cluster is down, you must call `MAKE_AHM_NOW` with an argument of true; otherwise, the function returns an error.

Note

This requirement applies only to Enterprise mode; in Eon mode, it is ignored.

In the following example, `MAKE_AHM_NOW` advances the AHM even though a node is down:

```
=> SELECT MAKE_AHM_NOW(true);
WARNING: Received no response from v_vmartdb_node0002 in get cluster LGE
WARNING: Received no response from v_vmartdb_node0002 in get cluster LGE
WARNING: Received no response from v_vmartdb_node0002 in set AHM
      MAKE_AHM_NOW
-----
AHM set (New AHM Epoch: 684)
(1 row)
```

See also

- [SET_AHM_EPOCH](#)
- [SET_AHM_TIME](#)

SET_AHM_EPOCH

Sets the [Ancient History Mark](#) (AHM) to the specified epoch. This function allows deleted data up to and including the AHM epoch to be purged from physical storage.

`SET_AHM_EPOCH` is normally used for testing purposes. Instead, consider using [SET_AHM_TIME](#) which is easier to use.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
SET_AHM_EPOCH ( epoch, [ true ] )
```

Parameters

epoch

Specifies one of the following:

- The number of the epoch in which to set the AHM
- Zero (0) (the default) disables [PURGE](#)

Important

The number of the specified epoch must be:

- Greater than the current AHM epoch
- Less than the current epoch

Query the [SYSTEM](#) table to view current epoch values relative to the AHM.

true

Allows the AHM to advance when nodes are down.

Caution

If you advance AHM beyond the [last good epoch](#) of the down nodes, those nodes must recover all data from scratch.

Privileges

Superuser

Setting AHM when nodes are down

If any node in the cluster is down, you must call `SET_AHM_EPOCH` with an argument of true; otherwise, the function returns an error.

Note

This requirement applies only to Enterprise mode; in Eon mode, it is ignored.

Examples

The following command sets the AHM to a specified epoch of 12:

```
=> SELECT SET_AHM_EPOCH(12);
```

The following command sets the AHM to a specified epoch of 2 and allows the AHM to advance despite a failed node:

```
=> SELECT SET_AHM_EPOCH(2, true);
```

See also

- [MAKE_AHM_NOW](#)
- [SET_AHM_TIME](#)

SET_AHM_TIME

Sets the [Ancient History Mark](#) (AHM) to the epoch corresponding to the specified time on the initiator node. This function allows historical data up to and including the AHM epoch to be purged from physical storage. `SET_AHM_TIME` returns a `TIMESTAMPTZ` that represents the end point of the AHM epoch.

This is a meta-function. You must call meta-functions in a top-level `SELECT` statement.

Behavior type

[Volatile](#)

Syntax

```
SET_AHM_TIME ( time, [ true ] )
```

Parameters

time

A [TIMESTAMP/TIMESTAMPTZ](#) value that is automatically converted to the appropriate epoch number.

true

Allows the AHM to advance when nodes are down.

Caution

If you advance AHM beyond the [last good epoch](#) of the down nodes, those nodes must recover all data from scratch.

Privileges

Superuser

Setting AHM when nodes are down

If any node in the cluster is down, you must call `SET_AHM_TIME` with an argument of true; otherwise, the function returns an error.

Note

This requirement applies only to Enterprise mode; in Eon mode, it is ignored.

Examples

Epochs depend on a configured epoch advancement interval. If an epoch includes a three-minute range of time, the purge operation is accurate only to within minus three minutes of the specified timestamp:

```
=> SELECT SET_AHM_TIME('2008-02-27 18:13');
      set_ahm_time
```

```
-----
AHM set to '2008-02-27 18:11:50-05'
(1 row)
```

Note

The `-05` part of the output string is a time zone value, an offset in hours from UTC (Universal Coordinated Time, traditionally known as Greenwich Mean Time, or GMT).

In the previous example, the actual AHM epoch ends at 18:11:50, roughly one minute before the specified timestamp. This is because `SET_AHM_TIME` selects the epoch that ends at or before the specified timestamp. It does not select the epoch that ends after the specified timestamp because that would purge data deleted as much as three minutes after the AHM.

For example, using only hours and minutes, suppose that epoch 9000 runs from 08:50 to 11:50 and epoch 9001 runs from 11:50 to 15:50. `SET_AHM_TIME('11:51')` chooses epoch 9000 because it ends roughly one minute before the specified timestamp.

In the next example, suppose that a node went down at 11:00:00 AM on January 1st 2017. At noon, you want to advance the AHM to 11:15:00, but the node is still down.

Suppose you try to set the AHM using this command:

```
=> SELECT SET_AHM_TIME('2017-01-01 11:15:00');
```

Then you will receive an error message. Vertica prevents you from moving the AHM past the point where a node went down. Vertica returns this error to prevent the AHM from advancing past the down node's last good epoch. You can force the AHM to advance by supplying the optional second parameter:

```
=> SELECT SET_AHM_TIME('2017-01-01 11:15:00', true);
```

However, if you force the AHM past the last good epoch, the failed node will have to recover from scratch.

LDAP link functions

This section contains the functions associated with the Vertica [LDAP Link](#) service.

In this section

- [LDAP_LINK_DRYRUN_CONNECT](#)
- [LDAP_LINK_DRYRUN_SEARCH](#)
- [LDAP_LINK_DRYRUN_SYNC](#)
- [LDAP_LINK_SYNC_CANCEL](#)
- [LDAP_LINK_SYNC_START](#)

LDAP_LINK_DRYRUN_CONNECT

Takes a set of [LDAP Link connection parameters](#) as arguments and begins a dry run connection between the LDAP server and Vertica.

By providing an empty string for the `LDAPLinkBindPswd` argument, you can also perform an [anonymous bind](#) if your LDAP server allows unauthenticated binds.

The dryrun and `LDAP_LINK_SYNC_START` functions must be run from the clerk node. To determine the clerk node, query [NODE_RESOURCES](#):

```
=> SELECT node_name, dbclerk FROM node_resources WHERE dbclerk='t';
node_name | dbclerk
-----+-----
v_vmart_node0001 | t
(1 row)
```

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
LDAP_LINK_DRYRUN_CONNECT (
  'LDAPLinkURL',
  'LDAPLinkBindDN',
  'LDAPLinkBindPswd'
)
```

Privileges

Superuser

Examples

This tests the connection to an LDAP server at <ldap://example.dc.com> with the DN [CN=amir,OU=QA,DC=dc,DC=com](#) .

```
=> SELECT LDAP_LINK_DRYRUN_CONNECT('ldap://example.dc.com','CN=amir,OU=QA,DC=dc,DC=com','password');

ldap_link_dryrun_connect
-----
Dry Run Connect Completed. Query v_monitor.ldap_link_dryrun_events for results.
```

To check the results of the bind, query the system table LDAP_LINK_DRYRUN_EVENTS.

```
=> SELECT event_timestamp, event_type, entry_name, role_name, link_scope, search_base from LDAP_LINK_DRYRUN_EVENTS;
event_timestamp | event_type | entry_name | link_scope | search_base
-----+-----+-----+-----+-----
2019-12-09 15:41:43.589398-05 | BIND_STARTED | ----- | ----- | -----
2019-12-09 15:41:43.590504-05 | BIND_FINISHED | ----- | ----- | -----
```

See also

- [LDAP_LINK_DRYRUN_SEARCH](#)
- [LDAP_LINK_DRYRUN_SYNC](#)
- [Configuring LDAP link with dry runs](#)
- [LDAP link parameters](#)

LDAP_LINK_DRYRUN_SEARCH

Takes a set of [LDAP Link connection and search parameters](#) as arguments and begins a dry run search for users and groups that would get imported from the LDAP server.

By providing an empty string for the [LDAPLinkBindPswd](#) argument, you can also perform an [anonymous search](#) if your LDAP server's Access Control List (ACL) is configured to allow unauthenticated searches. The settings for allowing anonymous binds are different from the ACL settings for allowing anonymous searches.

The dryrun and LDAP_LINK_SYNC_START functions must be run from the clerk node. To determine the clerk node, query [NODE_RESOURCES](#) :

```
=> SELECT node_name, dbclerk FROM node_resources WHERE dbclerk='t';
node_name | dbclerk
-----+-----
v_vmart_node0001 | t
(1 row)
```

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
LDAP_LINK_DRYRUN_SEARCH (  
  'LDAPLinkURL',  
  'LDAPLinkBindDN',  
  'LDAPLinkBindPswd',  
  'LDAPLinkSearchBase',  
  'LDAPLinkScope',  
  'LDAPLinkFilterUser',  
  'LDAPLinkFilterGroup',  
  'LDAPLinkUserName',  
  'LDAPLinkGroupName',  
  'LDAPLinkGroupMembers',  
  [LDAPLinkSearchTimeout],  
  ['LDAPLinkJoinAttr']  
)
```

Privileges

Superuser

Examples

This searches for users and groups in the LDAP server. In this case, the `LDAPLinkSearchBase` parameter specifies the `dc.com` domain and a sub scope, which replicates the entire subtree under the DN.

To further filter results, the function checks for users and groups with the `person` and `group` objectClass attributes. It then searches the group attribute `cn`, identifying members of that group with the `member` attribute, and then identifying those individual users with the attribute `uid`.

```
=> SELECT LDAP_LINK_DRYRUN_SEARCH('ldap://example.dc.com','CN=amir,OU=QA,DC=dc,DC=com','$vertica$','dc=DC,dc=com','sub',  
'(objectClass=person)','(objectClass=group)','uid','cn','member',10,'dn');
```

```
ldap_link_dryrun_search
```

Dry Run Search Completed. Query v_monitor.ldap_link_dryrun_events for results.

To check the results of the search, query the system table `LDAP_LINK_DRYRUN_EVENTS`.

```
=> SELECT event_timestamp, event_type, entry_name, ldapurihash, link_scope, search_base from LDAP_LINK_DRYRUN_EVENTS;
```

event_timestamp	event_type	entry_name	ldapurihash	link_scope	search_base

See also

- [LDAP_LINK_DRYRUN_CONNECT](#)
- [LDAP_LINK_DRYRUN_SYNC](#)
- [Configuring LDAP link with dry runs](#)
- [LDAP link parameters](#)

LDAP_LINK_DRYRUN_SYNC

Takes a set of [LDAP Link connection and search parameters](#) as arguments and begins a dry run synchronization between the database and the LDAP server, which maps and synchronizes the LDAP server's users and groups with their equivalents in Vertica. This meta-function also dry runs the creation and orphaning of users and roles in Vertica.

The `dryrun` and `LDAP_LINK_SYNC_START` functions must be run from the clerk node. To determine the clerk node, query [NODE_RESOURCES](#):

```
=> SELECT node_name, dbclerk FROM node_resources WHERE dbclerk='1';
node_name | dbclerk
-----+-----
v_vmart_node0001 | 1
(1 row)
```

You can view the results of the dry run in the system table [LDAP_LINK_DRYRUN_EVENTS](#).

To cancel an in-progress synchronization, use [LDAP_LINK_SYNC_CANCEL](#).

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
LDAP_LINK_DRYRUN_SYNC (
  'LDAPLinkURL',
  'LDAPLinkBindDN',
  'LDAPLinkBindPswd',
  'LDAPLinkSearchBase',
  'LDAPLinkScope',
  'LDAPLinkFilterUser',
  'LDAPLinkFilterGroup',
  'LDAPLinkUserName',
  'LDAPLinkGroupName',
  'LDAPLinkGroupMembers',
  [LDAPLinkSearchTimeout],
  ['LDAPLinkJoinAttr']
)
```

Privileges

Superuser

Examples

To perform a dry run to map the users and groups returned from `LDAP_LINK_DRYRUN_SEARCH`, pass the same parameters as arguments to `LDAP_LINK_DRYRUN_SYNC`.

```
=> SELECT LDAP_LINK_DRYRUN_SYNC('ldap://example.dc.com','CN=amir,OU=QA,DC=dc,DC=com','$vertica$', 'dc=DC,dc=com','sub',
'(objectClass=person)','(objectClass=group)','uid','cn','member',10,'dn');
```

```
LDAP_LINK_DRYRUN_SYNC
```

```
-----
Dry Run Connect and Sync Completed. Query v_monitor.ldap_link_dryrun_events for results.
```

To check the results of the sync, query the system table `LDAP_LINK_DRYRUN_EVENTS`.

```
=> SELECT event_timestamp, event_type, entry_name, ldapurihash, link_scope, search_base from LDAP_LINK_DRYRUN_EVENTS;
 event_timestamp | event_type | entry_name | ldapurihash | link_scope | search_base

LDAP_LINK_SYNC_CANCEL

Cancels in-progress LDAP Link synchronizations (including those started by [LDAP_LINK_DRYRUN_SYNC](#)) between the LDAP server and Vertica.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
ldap_link_sync_cancel()
```

Privileges

Superuser

Examples

```
=> SELECT ldap_link_sync_cancel();
```

See also

- [LDAP_LINK_SYNC_START](#)
- [Configuring LDAP link with dry runs](#)

LDAP_LINK_SYNC_START

Begins the synchronization between the LDAP server and Vertica immediately rather than waiting for the next scheduled run set by the parameters [LDAPLinkInterval](#) and [LDAPLinkCron](#).

The dryrun and LDAP_LINK_SYNC_START functions must be run from the clerk node. To determine the clerk node, query [NODE_RESOURCES](#):

```
=> SELECT node_name, dbclerk FROM node_resources WHERE dbclerk='Y';
 node_name | dbclerk
-----+-----
v_vmart_node0001 | Y
(1 row)
```

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
ldap_link_sync_start()
```

Privileges

Superuser

Examples

```
=> SELECT ldap_link_sync_start();
```

[LDAP link parameters](#)

License functions

This section contains functions that monitor Vertica license status and compliance.

In this section

- [AUDIT](#)
- [AUDIT_FLEX](#)
- [AUDIT_LICENSE_SIZE](#)
- [AUDIT_LICENSE_TERM](#)
- [DISPLAY_LICENSE](#)
- [GET_AUDIT_TIME](#)
- [GET_COMPLIANCE_STATUS](#)
- [SET_AUDIT_TIME](#)

AUDIT

Returns the raw data size (in bytes) of a database, schema, or table as it is counted in an audit of the database size. Unless you specify zero error tolerance and 100 percent confidence level, **AUDIT** returns only approximate results that can vary over multiple iterations.

Important

The data size returned by **AUDIT** should not be compared with the compressed data size of objects reported in the **USED_BYTES** column of system tables like [STORAGE_CONTAINERS](#) and [PROJECTION_STORAGE](#).

AUDIT estimates the size for data in Vertica tables using the same data sampling method that Vertica uses to determine if a database complies with the licensed database size allowance. Vertica does not use these results to determine whether the size of the database complies with the Vertica license's data allowance. For details, see [Auditing database size](#).

For data stored in external tables based on ORC or Parquet format, **AUDIT** uses the total size of the data files. This value is never estimated—it is read from the file system storing the ORC or Parquet files (either the Vertica node's local file system, S3, or HDFS).

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
AUDIT('[[[database.]schema.]scope '], 'granularity' [, error-tolerance[, confidence-level]] )
```

Parameters

[**database** .] **schema**

Database and [schema](#). The default schema is **public**. If you specify a database, it must be the current database.

scope

Specifies the extent of the audit:

- Empty string (") audits the entire database.
- The name of the schema or table to audit.

The schema or table to audit. To audit the database, set this parameter to an empty string.

granularity

The level at which the audit reports its results, one of the following strings:

- **database**
- **schema**

- `table`

The level of granularity must be equal to or less than the granularity of `scope`. If you omit this parameter, granularity is set to the same level as `scope`. Thus, if `online_sales` is a schema, the following statements are identical:

```
AUDIT('online_sales', 'schema');  
AUDIT('online_sales');
```

If `AUDIT` sets granularity to a level lower than the target object, it returns with a message that refers you to system table `USER_AUDITS`. For details, see [Querying V_CATALOG.USER_AUDITS](#), below.

error-tolerance

Specifies the percentage margin of error allowed in the audit estimate. Enter the tolerance value as a decimal number, between 0 and 100. The default value is 5, for a 5% margin of error.

This argument has no effect on audits of external tables based on ORC or Parquet files. Audits of these tables always returns the actual size of the underlying data files.

Setting this value to 0 results in a full database audit, which is very resource intensive, as `AUDIT` analyzes the entire database. A full database audit significantly impacts performance, so Vertica does not recommend it for a production database.

Caution

Due to the iterative sampling that the auditing process uses, setting the error tolerance to a small fraction of a percent (for example, 0.00001) can cause `AUDIT` to run for a longer period than a full database audit. The lower you specify this value, the more resources the audit uses, as it performs more data sampling.

confidence-level

Specifies the statistical confidence level percentage of the estimate. Enter the confidence value as a decimal number, between 0 and 100. The default value is 99, indicating a confidence level of 99%.

This argument has no effect on audits of external tables based on ORC or Parquet files. Audits of these tables always returns the actual size of the underlying data files.

The higher the confidence value, the more resources the function uses, as it performs more data sampling. Setting this value to 100 results in a full audit of the database, which is very resource intensive, as the function analyzes all of the database. A full database audit significantly impacts performance, so Vertica does not recommend it for a production database.

Privileges

Superuser, or the following privileges:

- `SELECT` privilege on the target tables
- `USAGE` privilege on the target schemas

Note

If you audit a schema or the database, Vertica only returns the size of all objects that you have privileges to access within the audited object, as described above.

Querying V_CATALOG.USER_AUDITS

If `AUDIT` sets granularity to a level lower than the target object, it returns with a message that refers you to system table `USER_AUDITS`. To obtain audit data on objects of the specified granularity, query this table. For example, the following query seeks to audit all tables in the `store` schema:

```
-> SELECT AUDIT('store', 'table');  
      AUDIT  
-----  
See table sizes in v_catalog.user_audits for schema store  
(1 row)
```

The next query queries `USER_AUDITS` and obtains the latest audits on those tables:

```

=> SELECT object_name, AVG(size_bytes)::int size_bytes, MAX(audit_start_timestamp::date) audit_start
   FROM user_audits WHERE object_schema='store'
   GROUP BY rollup(object_name) HAVING GROUPING_ID(object_name) < 1 ORDER BY GROUPING_ID();
object_name | size_bytes | audit_start
-----+-----+-----
store_dimension | 22067 | 2017-10-26
store_orders_fact | 27201312 | 2017-10-26
store_sales_fact | 301260170 | 2017-10-26
(3 rows)

```

Examples

See [Auditing database size](#).

AUDIT_FLEX

Returns the estimated ROS size of `__raw__` columns, equivalent to the export size of the flex data in the audited objects. You can audit all flex data in the database, or narrow the audit scope to a specific flex table, projection, or schema. Vertica stores the audit results in system table [USER_AUDITS](#).

The audit excludes the following:

- Flex keys
- Other columns in the audited tables.
- Temporary flex tables

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
AUDIT_FLEX ('[scope]')
```

Parameters

scope

Specifies the extent of the audit:

- Empty string (") audits all flexible tables in the database.
- The name of a schema, projection, or flex table.

Privileges

Superuser, or the following privileges:

- SELECT privilege on the target tables
- USAGE privilege on the target schemas

Note

If you audit a schema or the database, Vertica only returns the size of all objects that you have privileges to access within the audited object, as described above.

Examples

Audit all flex tables in the current database:

```

dbs=> select audit_flex("");
audit_flex
-----
8567679
(1 row)

```

Audit the flex tables in schema `public` :

```
db> select audit_flex('public');
audit_flex
-----
8567679
(1 row)
```

Audit the flex data in projection `bakery_b0` :

```
db> select audit_flex('bakery_b0');
audit_flex
-----
8566723
(1 row)
```

Audit flex table `bakery` :

```
db> select audit_flex('bakery');
audit_flex
-----
8566723
(1 row)
```

To report the results of all audits saved in the `USER_AUDITS` , the following shows part of an extended display from the system table showing an audit run on a schema called `test` , and the entire database, `db` :

```

dbs=> \x
Expanded display is on.

dbs=> select * from user_audits;

AUDIT_LICENSE_SIZE

Triggers an immediate audit of the database size to determine if it is in compliance with the raw data storage allowance included in your Vertica licenses.

If you use ORC or Parquet data stored in HDFS, results are only accurate if you run this function as a user who has access to all HDFS data. Either run the query with a principal that has read access to all such data, or use a Hadoop delegation token that grants this access. For more information about using delegation tokens, see [Accessing kerberized HDFS data](#).

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
AUDIT_LICENSE_SIZE()
```

Privileges

Superuser

Examples

```
=> SELECT audit_license_size();
audit_license_size
-----
Raw Data Size: 0.00TB +/- 0.00TB
License Size : 10.00TB
Utilization : 0%
Audit Time   : 2015-09-24 12:19:15.425486-04
Compliance Status : The database is in compliance with respect to raw data size.

License End Date: 2015-11-23 00:00:00 Days Remaining: 60.53
(1 row)
```

AUDIT_LICENSE_TERM

Triggers an immediate audit to determine if the Vertica license has expired.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
AUDIT_LICENSE_TERM()
```

Privileges

Superuser

Examples

```
=> SELECT audit_license_term();
audit_license_term
-----
Raw Data Size: 0.00TB +/- 0.00TB
License Size : 10.00TB
Utilization : 0%
Audit Time   : 2015-09-24 12:19:15.425486-04
Compliance Status : The database is in compliance with respect to raw data size.

License End Date: 2015-11-23 00:00:00 Days Remaining: 60.53
(1 row)
```

DISPLAY_LICENSE

Returns the terms of your Vertica license. The information this function displays is:

- The start and end dates for which the license is valid (or "Perpetual" if the license has no expiration).
- The number of days you are allowed to use Vertica after your license term expires (the grace period)
- The amount of data your database can store, if your license includes a data allowance.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
DISPLAY_LICENSE()
```

Privileges

None

Examples

```
=> SELECT DISPLAY_LICENSE();
      DISPLAY_LICENSE
```

```
-----
Vertica Systems, Inc.
2007-08-03
Perpetual
500GB
```

```
(1 row)
```

GET_AUDIT_TIME

Reports the time when the automatic audit of database size occurs. Vertica performs this audit if your Vertica license includes a data size allowance. For details of this audit, see [Managing licenses](#) in the Administrator's Guide. To change the time the audit runs, use the [SET_AUDIT_TIME](#) function.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
GET_AUDIT_TIME()
```

Privileges

None

Examples

```
=> SELECT get_audit_time();
get_audit_time
```

```
-----
The audit is scheduled to run at 11:59 PM each day.
```

```
(1 row)
```

GET_COMPLIANCE_STATUS

Displays whether your database is in compliance with your Vertica license agreement. This information includes the results of Vertica's most recent audit of the database size (if your license has a data allowance as part of its terms), the license term (if your license has an end date), and the number of nodes (if your license has a node limit).

[GET_COMPLIANCE_STATUS](#) measures data allowance by TBs (where a TB equals 1024^4 bytes).

The information displayed by [GET_COMPLIANCE_STATUS](#) includes:

- The estimated size of the database (see [Auditing database size](#) for an explanation of the size estimate).
- The raw data size allowed by your Vertica license.
- The percentage of your allowance that your database is currently using.
- The number of nodes and license limit.
- The date and time of the last audit.
- Whether your database complies with the data allowance terms of your license agreement.
- The end date of your license.
- How many days remain until your license expires.

Note

If your license does not have a data allowance, end date, or node limit, some of the values might not appear in the output for [GET_COMPLIANCE_STATUS](#).

If the audit shows your license is not in compliance with your data allowance, you should either delete data to bring the size of the database under the licensed amount, or upgrade your license. If your license term has expired, you should contact Vertica immediately to renew your license. See [Managing licenses](#) for further details.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
GET_COMPLIANCE_STATUS()
```

Privileges

None

Examples

```
=> SELECT GET_COMPLIANCE_STATUS();
get_compliance_status
-----
Raw Data Size: 0.00TB +/- 0.00TB
License Size : 10.00TB
Utilization  : 0%
Audit Time   : 2015-09-24 12:19:15.425486-04
Compliance Status : The database is in compliance with respect to raw data size.

License End Date: 2015-11-23 00:00:00 Days Remaining: 60.53
(1 row)
```

The following example shows output for a Vertica for SQL on Apache Hadoop cluster.

```
=> SELECT GET_COMPLIANCE_STATUS();
get_compliance_status
-----
Node count : 4
License Node limit : 5
No size-compliance concerns for an Unlimited license

No expiration date for a Perpetual license
(1 row)
```

SET_AUDIT_TIME

Sets the time that Vertica performs automatic database size audit to determine if the size of the database is compliant with the raw data allowance in your Vertica license. Use this function if the audits are currently scheduled to occur during your database's peak activity time. This is normally not a concern, since the automatic audit has little impact on database performance.

Audits are scheduled by the preceding audit, so changing the audit time does not affect the next scheduled audit. For example, if your next audit is scheduled to take place at 11:59PM and you use SET_AUDIT_TIME to change the audit schedule 3AM, the previously scheduled 11:59PM audit still runs. As that audit finishes, it schedules the next audit to occur at 3AM.

Vertica always performs the next scheduled audit even where you have changed the audit time using SET_AUDIT_TIME and then triggered an automatic audit by issuing the statement, SELECT [AUDIT_LICENSE_SIZE](#). Only after the next scheduled audit does Vertica begin auditing at the new time you set using SET_AUDIT_TIME. Thereafter, Vertica audits at the new time.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
SET_AUDIT_TIME(time)
```

time

A string containing the time in 'HH:MM AM/PM' format (for example, '1:00 AM') when the audit should run daily.

Privileges

Superuser

Examples

```
=> SELECT SET_AUDIT_TIME('3:00 AM');
       SET_AUDIT_TIME
```

The scheduled audit time will be set to 3:00 AM after the next audit.

(1 row)

Notifier functions

This section contains functions for using and managing the notifier.

In this section

- [GET_DATA_COLLECTOR_NOTIFY_POLICY](#)
- [NOTIFY](#)
- [SET_DATA_COLLECTOR_NOTIFY_POLICY](#)

GET_DATA_COLLECTOR_NOTIFY_POLICY

Lists any notification policies set on a [Data collector](#) component.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
GET_DATA_COLLECTOR_NOTIFY_POLICY('component')
```

component

Name of the Data Collector component to check for notification policies.

Query [DATA_COLLECTOR](#) to get a list of components:

```
=> SELECT DISTINCT component, description FROM DATA_COLLECTOR
     WHERE component ILIKE '%Depot%' ORDER BY component;
component | description
-----
DepotEvictions | Files evicted from the Depot
DepotFetches | Files fetched to the Depot
DepotUploads | Files Uploaded from the Depot
(3 rows)
```

Examples

```
=> SELECT GET_DATA_COLLECTOR_NOTIFY_POLICY('LoginFailures');
       GET_DATA_COLLECTOR_NOTIFY_POLICY
```

Notifiable; Notifier: vertica_stats; Channel: vertica_notifications

(1 row)

The following example shows the output from the function when there is no notification policy for the component:

```
=> SELECT GET_DATA_COLLECTOR_NOTIFY_POLICY('LoginFailures');
       GET_DATA_COLLECTOR_NOTIFY_POLICY
```

Not notifiable;

(1 row)

See also

- [SET_DATA_COLLECTOR_NOTIFY_POLICY](#)
- [Producing Kafka messages using notifiers](#)

NOTIFY

Sends a specified message to a [NOTIFIER](#).

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
NOTIFY ( 'message', 'notifier', 'target-topic' )
```

Parameters

message

The message to send to the endpoint.

notifier

The name of the [NOTIFIER](#).

target-topic

String that specifies one of the following based on the *notifier* type:

- Kafka: The name of an existing destination Kafka topic for the message.

Note

If the topic doesn't already exist, you can configure your Kafka broker to automatically create the specified topic. For more information, see the [Kafka documentataion](#).

- Syslog: The [ProblemDescription](#) subject and [channel](#) value.
- SNS: [The topic ARN](#).

Privileges

Superuser

Examples

Send a message to confirm that an ETL job is complete:

```
=> SELECT NOTIFY('ETL Done!', 'my_notifier', 'DB_activity_topic');
```

SET_DATA_COLLECTOR_NOTIFY_POLICY

Creates/enables notification policies for a [Data collector](#) component. Notification policies automatically send messages to the specified [NOTIFIER](#) when certain events occur.

To view existing notification policies on a Data Collector component, see [GET_DATA_COLLECTOR_NOTIFY_POLICY](#).

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
SET_DATA_COLLECTOR_NOTIFY_POLICY('component','notifier', 'topic', enabled)
```

component

Name of the component whose change will be reported via the notifier.

Query [DATA_COLLECTOR](#) to get a list of components:

```
=> SELECT DISTINCT component, description FROM DATA_COLLECTOR
WHERE component ILIKE '%Depot%' ORDER BY component;
component | description
-----|-----
DepotEvictions | Files evicted from the Depot
DepotFetches | Files fetched to the Depot
DepotUploads | Files Uploaded from the Depot
(3 rows)
```

notifier

Name of the notifier that will send the message.

topic

One of the following:

- Kafka: The name of the Kafka topic that will receive the notification message.

Note

If the topic doesn't already exist, you can configure your Kafka broker to automatically create the specified topic. For more information, see the [Kafka documentataion](#).

- Syslog: The subject of the field `ProblemDescription`.
- SNS: [The topic ARN](#).

enabled

Boolean value that specifies whether this policy is enabled. Set to TRUE to enable reporting component changes. Set to FALSE to disable the notifier.

Examples

SNS notifier

The following example creates an SNS topic, subscribes to it with an SQS queue, and then configures an SNS notifier for the DC component `LoginFailures`:

1. [Create an SNS topic](#).
2. [Create an SQS queue](#).
3. [Subscribe the SQS queue to the SNS topic](#).
4. Set SNSAuth with your AWS credentials:

```
=> ALTER DATABASE DEFAULT SET SNSAuth='VNDDNVOPIUQF917O5PDB:+mcnVONVlBjOnf1ekNis7nm3mE83u9fjdwmlq36Z';
```

5. Set SNSRegion:

```
=> ALTER DATABASE DEFAULT SET SNSRegion='us-east-1'
```

6. Enable HTTPS:

```
=> ALTER DATABASE DEFAULT SET SNSEnableHttps=1;
```

7. [Create](#) an SNS notifier:

```
=> CREATE NOTIFIER v_sns_notifier ACTION 'sns' MAXPAYLOAD '256K' MAXMEMORYSIZE '10M' CHECK COMMITTED;
```

8. Verify that the SNS notifier, SNS topic, and SQS queue are properly configured:

1. Manually send a message from the notifier to the SNS topic with [NOTIFY](#):

```
=> SELECT NOTIFY('test message', 'v_sns_notifier', 'arn:aws:sns:us-east-1:123456789012:MyTopic')
```

2. [Poll the SQS queue](#) for your message.

9. Attach the SNS notifier to the `LoginFailures` component with [SET_DATA_COLLECTOR_NOTIFY_POLICY](#):

```
=> SELECT SET_DATA_COLLECTOR_NOTIFY_POLICY('LoginFailures', 'v_sns_notifier', 'Login failed!', true)
```

Kafka notifier

To be notified of failed login attempts, you can create a notifier that sends a notification when the DC component `LoginFailures` updates. The `TLSMODE 'verify-ca'` verifies that the server's certificate is signed by a trusted CA.

```
=> CREATE NOTIFIER vertica_stats ACTION 'kafka://kafka01.example.com:9092' MAXMEMORYSIZE '10M' TLSMODE 'verify-ca';
CREATE NOTIFIER
=> SELECT SET_DATA_COLLECTOR_NOTIFY_POLICY('LoginFailures','vertica_stats', 'vertica_notifications', true);
SET_DATA_COLLECTOR_NOTIFY_POLICY
-----
SET
(1 row)
```

The following example shows how to disable the policy created in the previous example:

```
=> SELECT SET_DATA_COLLECTOR_NOTIFY_POLICY('LoginFailures','vertica_stats', 'vertica_notifications', false);
SET_DATA_COLLECTOR_NOTIFY_POLICY
-----
SET
(1 row)
```

```
=> SELECT GET_DATA_COLLECTOR_NOTIFY_POLICY('LoginFailures');
GET_DATA_COLLECTOR_NOTIFY_POLICY
```

```
-----
Not notifiable;
(1 row)
```

Syslog notifier

The following example creates a notifier that writes a message to syslog when the [Data collector](#) (DC) component [LoginFailures](#) updates:

1. Enable syslog notifiers for the current database:

```
=> ALTER DATABASE DEFAULT SET SyslogEnabled = 1;
```

2. Create and enable a syslog notifier [v_syslog_notifier](#) :

```
=> CREATE NOTIFIER v_syslog_notifier ACTION 'syslog'
ENABLE
MAXMEMORYSIZE '10M'
IDENTIFIED BY 'f8b0278a-3282-4e1a-9c86-e0f3f042a971'
PARAMETERS 'eventSeverity = 5';
```

3. Configure the syslog notifier [v_syslog_notifier](#) for updates to the [LoginFailures](#) DC component with [SET_DATA_COLLECTOR_NOTIFY_POLICY](#) :

```
=> SELECT SET_DATA_COLLECTOR_NOTIFY_POLICY('LoginFailures',v_syslog_notifier, 'Login failed!', true);
```

This notifier writes the following message to syslog (default location: [/var/log/messages](#)) when a user fails to authenticate as the user [Bob](#) :

```
Apr 25 16:04:58
vertica_host_01
vertica:
Event Posted:
  Event Code:21
  Event Id:0
  Event Severity: Notice [5]

Partition functions

This section contains partition management functions specific to Vertica.

In this section

- [CALENDAR_HIERARCHY_DAY](#)
- [COPY_PARTITIONS_TO_TABLE](#)
- [DROP_PARTITIONS](#)
- [DUMP_PROJECTION_PARTITION_KEYS](#)
- [DUMP_TABLE_PARTITION_KEYS](#)
- [MOVE_PARTITIONS_TO_TABLE](#)
- [PARTITION_PROJECTION](#)
- [PARTITION_TABLE](#)
- [PURGE_PARTITION](#)
- [SWAP_PARTITIONS_BETWEEN_TABLES](#)

CALENDAR_HIERARCHY_DAY

Groups **DATE** partition keys into a hierarchy of years, months, and days. The [Tuple Mover](#) regularly evaluates partition keys against the current date, and merges partitions as needed into the appropriate year and month partition groups.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
CALENDAR_HIERARCHY_DAY( partition-expression[, active-months[, active-years] ] )
```

Arguments

partition-expression

The [DATE](#) expression on which to group partition keys, which must be identical to the table's **PARTITION BY** expression.

active-months

How many months preceding the current month to store unique partition keys in separate partitions, a positive integer.

A value of 1 means only partition keys of the current month are stored in separate partitions.

A value of 0 means all partition keys of the current month are merged into a partition group for that month.

For details, see [Hierarchical partitioning](#).

Default: 2

active-years

How many years preceding the current year to partition group keys by month in separate partitions, a positive integer.

A value of 1 means only partition keys of the current year are stored in month partition groups.

A value of 0 means all partition keys of the current and previous years are merged into year partition groups.

For details, see [Hierarchical partitioning](#).

Default: 2

Important

The `CALENDAR_HIERARCHY_DAY` [algorithm](#) assumes that most table activity is focused on recent dates. Setting ***active-years*** and ***active-months*** to a low number ≥ 2 serves to isolate most merge activity to date-specific containers, and incurs minimal overhead. Vertica recommends that you use the default setting of 2 for ***active-years*** and ***active-months***. For most users, these settings achieve an optimal balance between ROS storage and performance.

As a best practice, never set ***active-years*** and ***active-months*** to 0.

Usage

Use this function in the **GROUP BY** expression of a table [partition clause](#):

```
PARTITION BY partition-expression
GROUP BY CALENDAR_HIERARCHY_DAY(
  group-expression [, active-months [, active-years] ] )
```

For example:

```
=> CREATE TABLE public.store_orders
(
  order_no int,
  order_date timestamp NOT NULL,
  shipper varchar(20),
  ship_date date
);
=> ALTER TABLE public.store_orders
  PARTITION BY order_date::DATE
  GROUP BY CALENDAR_HIERARCHY_DAY(order_date::DATE, 3, 2) REORGANIZE;
```

Examples

See [Hierarchical partitioning](#).

COPY_PARTITIONS_TO_TABLE

Copies partitions from one table to another. This lightweight partition copy increases performance by initially sharing the same storage between two tables. After the copy operation is complete, the tables are independent of each other. Users can perform operations on one table without impacting the other. These operations can increase the overall storage required for both tables.

Note

Although they share storage space, Vertica considers the partitions as discrete objects for license capacity purposes. For example, copying a one TB partition would only consume one TB of space. Your Vertica license, however, considers them as separate objects consuming two TB of space.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
COPY_PARTITIONS_TO_TABLE (
  '[[{namespace. | database. }]schema.]source-table',
  'min-range-value',
  'max-range-value',
  '[[{namespace. | database. }]schema.]target-table'
  [, 'force-split']
)
```

Arguments

{ **namespace.** | **database.** }

Name of the database or [namespace](#) that contains *table*, depending on the mode of the database:

- Eon Mode: name of the [namespace](#) to which the table belongs. If no namespace is specified, the table is assumed to be in the [default_namespace](#). The namespaces of *staging-table* and *target-table* must have the same shard count.
- Enterprise Mode: name of the database. If you specify a database, it must be the current database.

schema

Name of the schema, by default [public](#). If you specify the namespace or database name, you must provide the schema name, even if the schema is [public](#).

source-table

The source table of the partitions to copy.

min-range-value, **max-range-value**

The minimum and maximum value of partition keys to copy, where *min-range-value* must be \leq *max-range-value*. To specify a single partition key, *min-range-value* and *max-range-value* must be equal.

target-table

The target table of the partitions to copy. If the table does not exist, Vertica creates a table from the source table's definition, by calling [CREATE TABLE](#) with [LIKE](#) and [INCLUDING PROJECTIONS](#) clause. The new table inherits ownership from the source table. For details, see [Replicating a table](#).

force-split

Optional Boolean argument, specifies whether to split ROS containers if the range of partition keys spans multiple containers or part of a single container:

- **true** : Split ROS containers as needed.
- **false** (default): Return with an error if ROS containers must be split to implement this operation.

Privileges

Non-superuser, one of the following:

- Owner of source and target tables
- TRUNCATE (if force-split is true) and SELECT on the source table, INSERT on the target table

If the target table does not exist, you must also have CREATE privileges on the target schema to enable table creation.

Table attribute requirements

The following attributes of both tables must be identical:

- Column definitions, including NULL/NOT NULL constraints
- Segmentation
- [Partition clause](#)
- Number of projections
- Shard count (Eon Mode only)
- Projection sort order
- Primary and unique key constraints. However, the key constraints do not have to be identically enabled. For more information on constraints, see [Constraints](#).

Note

If the target table has primary or unique key constraints enabled and copying or moving the partitions will insert duplicate key values into the target table, Vertica rolls back the operation.

- Check constraints. For [MOVE_PARTITIONS_TO_TABLE](#) and [COPY_PARTITIONS_TO_TABLE](#), Vertica enforces enabled check constraints on the target table only. For [SWAP_PARTITIONS_BETWEEN_TABLES](#), Vertica enforces enabled check constraints on both tables. If there is a violation of an enabled check constraint, Vertica rolls back the operation.
- Number and definitions of text indices.

Additionally, If access policies exist on the source table, the following must be true:

- Access policies on both tables must be identical.
- One of the following must be true:
 - The executing user owns the source table.
 - `AccessPolicyManagementSuperuserOnly` is set to true. See [Managing access policies](#) for details.

Table restrictions

The following restrictions apply to the source and target tables:

- If the source and target partitions are in different storage tiers, Vertica returns a warning but the operation proceeds. The partitions remain in their existing storage tier.
- The target table cannot be [immutable](#).
- The following tables cannot be used as sources or targets:
 - Temporary tables
 - Virtual tables
 - System tables
 - External tables

Examples

If you call `COPY_PARTITIONS_TO_TABLE` and the target table does not exist, the function creates the table automatically. In the following example, the target table `partn_backup.trades_200801` does not exist. `COPY_PARTITIONS_TO_TABLE` creates the table and replicates the partition. Vertica also copies all the constraints associated with the source table except foreign key constraints.

```
=> SELECT COPY_PARTITIONS_TO_TABLE (  
    'prod_trades',  
    '200801',  
    '200801',  
    'partn_backup.trades_200801');  
COPY_PARTITIONS_TO_TABLE  
-----  
1 distinct partition values copied at epoch 15.  
(1 row)
```

See also

[Archiving partitions](#)

[DROP_PARTITIONS](#)

Note

This function supersedes meta-function `DROP_PARTITION`, which was deprecated in Vertica 9.0.

Drops the specified table partition keys.

This is a meta-function. You must call meta-functions in a top-level `SELECT` statement.

Behavior type

[Volatile](#)

Syntax

```
DROP_PARTITIONS (  
    '[[database.]schema.]table-name',  
    'min-range-value',  
    'max-range-value'  
    [, 'force-split']  
)
```

Arguments

[*database* .] *schema*

Database and [schema](#). The default schema is `public`. If you specify a database, it must be the current database.

table-name

The target table. The table cannot be used as a dimension table in a pre-join projection and cannot have out-of-date (unrefreshed) projections.

min-range-value* , *max-range-value

The minimum and maximum value of partition keys to drop, where *min-range-value* must be \leq *max-range-value*. To specify a single partition key, *min-range-value* and *max-range-value* must be equal.

force-split

Optional Boolean argument, specifies whether to split ROS containers if the range of partition keys spans multiple containers or part of a single container:

- `true` : Split ROS containers as needed.
- `false` (default): Return with an error if ROS containers must be split to implement this operation.

Note

In rare cases, `DROP_PARTITIONS` executes at the same time as a [mergeout](#) operation on the same ROS container. As a result, the function cannot split the container as specified and returns with an error. When this happens, call `DROP_PARTITIONS` again.

Privileges

One of the following:

- DBADMIN
- Table owner
- USAGE privileges on the table schema and TRUNCATE privileges on the table

Examples

See [Dropping partitions](#).

See also

[PARTITION TABLE](#)

DUMP_PROJECTION_PARTITION_KEYS

Dumps the partition keys of the specified projection.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
DUMP_PROJECTION_PARTITION_KEYS( '[[database.]schema.]projection-name')
```

Parameters

[**database** .] **schema**

Database and [schema](#). The default schema is [public](#). If you specify a database, it must be the current database.

projection-name

Projection name

Privileges

Non-superuser: TRUNCATE on anchor table

Examples

The following statements create the table and projection [online_sales.online_sales_fact](#) and [online_sales.online_sales_fact_rep](#), respectively, and partitions table data by the column [call_center_key](#):

```
=> CREATE TABLE online_sales.online_sales_fact
(
  sale_date_key int NOT NULL,
  ship_date_key int NOT NULL,
  product_key int NOT NULL,
  product_version int NOT NULL,
  customer_key int NOT NULL,
  call_center_key int NOT NULL,
  online_page_key int NOT NULL,
  shipping_key int NOT NULL,
  warehouse_key int NOT NULL,
  promotion_key int NOT NULL,
  pos_transaction_number int NOT NULL,
  sales_quantity int,
  sales_dollar_amount float,
  ship_dollar_amount float,
  net_dollar_amount float,
  cost_dollar_amount float,
  gross_profit_dollar_amount float,
  transaction_type varchar(16)
)
PARTITION BY (online_sales_fact.call_center_key);

=> CREATE PROJECTION online_sales.online_sales_fact_rep AS SELECT * from online_sales.online_sales_fact unsegmented all nodes;
```

The following DUMP_PROJECTION_PARTITION_KEYS statement dumps the partition key from the projection [online_sales.online_sales_fact_rep](#):

```
=> SELECT DUMP_PROJECTION_PARTITION_KEYS('online_sales.online_sales_fact_rep');
```

Partition keys on node v_vmart_node0001

Projection 'online_sales_fact_rep'

Storage [ROS container]

No of partition keys: 1

Partition keys: 200

Storage [ROS container]

No of partition keys: 1

Partition keys: 199

...

Storage [ROS container]

No of partition keys: 1

Partition keys: 2

See also

- [Partitioning tables](#)
- [DUMP_PARTITION_KEYS](#)
- [DUMP_TABLE_PARTITION_KEYS](#)
- [PARTITION_PROJECTION](#)
- [PARTITION_TABLE](#)

DUMP_TABLE_PARTITION_KEYS

Dumps the partition keys of all projections for the specified table.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
DUMP_TABLE_PARTITION_KEYS ( '[[database.]schema.]table-name' )
```

Parameters

[*database* .] *schema*

Database and [schema](#). The default schema is [public](#). If you specify a database, it must be the current database.

table-name

Name of the table

Privileges

Non-superuser: TRUNCATE on table

Examples

The following example creates a simple table called [states](#) and partitions the data by state:

```
=> CREATE TABLE states (year INTEGER NOT NULL,
    state VARCHAR NOT NULL)
    PARTITION BY state;
=> CREATE PROJECTION states_p (state, year) AS
    SELECT * FROM states
    ORDER BY state, year UNSEGMENTED ALL NODES;
```

Now dump the partition keys of all projections anchored on table `states` :

```
=> SELECT DUMP_TABLE_PARTITION_KEYS( 'states' );
    DUMP_TABLE_PARTITION_KEYS
-----
Partition keys on node v_vmart_node0001
Projection 'states_p'
Storage [ROS container]
  No of partition keys: 1
  Partition keys: VT
Storage [ROS container]
  No of partition keys: 1
  Partition keys: PA
Storage [ROS container]
  No of partition keys: 1
  Partition keys: NY
Storage [ROS container]
  No of partition keys: 1
  Partition keys: MA

Partition keys on node v_vmart_node0002
...
(1 row)
```

MOVE_PARTITIONS_TO_TABLE

Moves partitions from one table to another.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
MOVE_PARTITIONS_TO_TABLE (
  '[[{namespace. | database. }]schema.]source-table',
  'min-range-value',
  'max-range-value',
  '[[{namespace. | database. }]schema.]target-table'
  [, force-split]
)
```

Arguments

{ **namespace.** | **database.** }

Name of the database or [namespace](#) that contains *table* , depending on the mode of the database:

- Eon Mode: name of the [namespace](#) to which the table belongs. If no namespace is specified, the table is assumed to be in the [default_namespace](#) . The namespaces of *staging-table* and *target-table* must have the same shard count.
- Enterprise Mode: name of the database. If you specify a database, it must be the current database.

schema

Name of the schema, by default `public` . If you specify the namespace or database name, you must provide the schema name, even if the schema is `public` .

source-table

The source table of the partitions to move.

min-range-value , max-range-value

The minimum and maximum value of partition keys to move, where `min-range-value` must be \leq `max-range-value` . To specify a single partition key, `min-range-value` and `max-range-value` must be equal.

target-table

The target table of the partitions to move. If the table does not exist, Vertica creates a table from the source table's definition, by calling [CREATE TABLE](#) with `LIKE` and `INCLUDING PROJECTIONS` clause. The new table inherits ownership from the source table. For details, see [Replicating a table](#) .

force-split

Optional Boolean argument, specifies whether to split ROS containers if the range of partition keys spans multiple containers or part of a single container:

- `true` : Split ROS containers as needed.
- `false` (default): Return with an error if ROS containers must be split to implement this operation.

Privileges

Non-superuser, one of the following:

- Owner of source and target tables
- `SELECT`, `TRUNCATE` on the source table, `INSERT` on the target table

If the target table does not exist, you must also have `CREATE` privileges on the target schema to enable table creation.

Table attribute requirements

The following attributes of both tables must be identical:

- Column definitions, including `NULL/NOT NULL` constraints
- Segmentation
- [Partition clause](#)
- Number of projections
- Shard count (Eon Mode only)
- Projection sort order
- Primary and unique key constraints. However, the key constraints do not have to be identically enabled. For more information on constraints, see [Constraints](#) .

Note

If the target table has primary or unique key constraints enabled and copying or moving the partitions will insert duplicate key values into the target table, Vertica rolls back the operation.

- Check constraints. For [MOVE_PARTITIONS_TO_TABLE](#) and [COPY_PARTITIONS_TO_TABLE](#) , Vertica enforces enabled check constraints on the target table only. For [SWAP_PARTITIONS_BETWEEN_TABLES](#) , Vertica enforces enabled check constraints on both tables. If there is a violation of an enabled check constraint, Vertica rolls back the operation.
- Number and definitions of text indices.

Additionally, if access policies exist on the source table, the following must be true:

- Access policies on both tables must be identical.
- One of the following must be true:
 - The executing user owns the source table.
 - `AccessPolicyManagementSuperuserOnly` is set to true. See [Managing access policies](#) for details.

Table restrictions

The following restrictions apply to the source and target tables:

- If the source and target partitions are in different storage tiers, Vertica returns a warning but the operation proceeds. The partitions remain in their existing storage tier.

- The target table cannot be [immutable](#).
- The following tables cannot be used as sources or targets:
 - Temporary tables
 - Virtual tables
 - System tables
 - External tables

Examples

See [Archiving partitions](#).

See also

- [COPY_PARTITIONS_TO_TABLE](#)
- [SWAP_PARTITIONS_BETWEEN_TABLES](#)

PARTITION_PROJECTION

Splits [ROS](#) containers for a specified projection. [PARTITION_PROJECTION](#) also purges data while partitioning ROS containers if deletes were applied before the [AHM](#) epoch.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
PARTITION_PROJECTION ( '['[database.]schema.']*projection'
```

Parameters

[[database](#) .] [schema](#)

Database and [schema](#). The default schema is [public](#). If you specify a database, it must be the current database.

projection ``

The projection to partition.

Privileges

- Table owner
- USAGE privilege on schema

Examples

In this example, [PARTITION_PROJECTION](#) forces a split of ROS containers on the [states_p](#) projection:

```
=> SELECT PARTITION_PROJECTION ('states_p');
PARTITION_PROJECTION
-----
Projection partitioned
(1 row)
```

See also

- [PARTITION_TABLE](#)
- [Partitioning tables](#)

PARTITION_TABLE

Invokes the [Tuple Mover](#) to reorganize ROS storage containers as needed to conform with the current partitioning policy.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
PARTITION_TABLE ( '['[schema.]table-name'
```

Parameters

[[database](#) .] [schema](#)

Database and [schema](#). The default schema is `public`. If you specify a database, it must be the current database.

table-name

The table to partition.

Privileges

- Table owner
- USAGE privilege on schema

Restrictions

- You cannot run `PARTITION_TABLE` on a table that is an anchor table for a live aggregate projection or a Top-K projection.
- To reorganize storage to conform to a new policy, run `PARTITION_TABLE` after changing the partition GROUP BY expression.

See also

- [PARTITION_PROJECTION](#)
- [Partitioning existing table data](#)

PURGE_PARTITION

Purges a table partition of deleted rows. Similar to `PURGE` and `PURGE_PROJECTION`, this function removes deleted data from physical storage so you can reuse the disk space. `PURGE_PARTITION` removes data only from the [AHM](#) epoch and earlier.

This is a meta-function. You must call meta-functions in a top-level `SELECT` statement.

Behavior type

[Volatile](#)

Syntax

```
PURGE_PARTITION ( '[[database.]schema.]table', partition-key )
```

Parameters

[***database*** .] ***schema***

Database and [schema](#). The default schema is `public`. If you specify a database, it must be the current database.

table

The partitioned table to purge.

partition-key

The key of the partition to purge.

Privileges

- Table owner
- USAGE privilege on schema

Examples

The following example lists the count of deleted rows for each partition in a table, then calls `PURGE_PARTITION()` to purge the deleted rows from the data.

```
=> SELECT partition_key,table_schema,projection_name,sum(deleted_row_count)
AS deleted_row_count FROM partitions
GROUP BY partition_key,table_schema,projection_name
ORDER BY partition_key;
```

```
partition_key | table_schema | projection_name | deleted_row_count
```

```
-----+-----+-----+-----
0      | public   | t_super   |         2
1      | public   | t_super   |         2
2      | public   | t_super   |         2
3      | public   | t_super   |         2
4      | public   | t_super   |         2
5      | public   | t_super   |         2
6      | public   | t_super   |         2
7      | public   | t_super   |         2
8      | public   | t_super   |         2
9      | public   | t_super   |         1
```

(10 rows)

```
=> SELECT PURGE_PARTITION('t',5); -- Purge partition with key 5.
      purge_partition
```

```
-----+-----+-----+-----
Task: merge partitions
```

```
(Table: public.t) (Projection: public.t_super)
```

(1 row)

```
=> SELECT partition_key,table_schema,projection_name,sum(deleted_row_count)
AS deleted_row_count FROM partitions
GROUP BY partition_key,table_schema,projection_name
ORDER BY partition_key;
```

```
partition_key | table_schema | projection_name | deleted_row_count
```

```
-----+-----+-----+-----
0      | public   | t_super   |         2
1      | public   | t_super   |         2
2      | public   | t_super   |         2
3      | public   | t_super   |         2
4      | public   | t_super   |         2
5      | public   | t_super   |         0
6      | public   | t_super   |         2
7      | public   | t_super   |         2
8      | public   | t_super   |         2
9      | public   | t_super   |         1
```

(10 rows)

See also

SWAP_PARTITIONS_BETWEEN_TABLES

Swaps partitions between two tables.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```

SWAP_PARTITIONS_BETWEEN_TABLES (
  '[[[namespace. | database. ]]schema.]staging-table',
  'min-range-value',
  'max-range-value',
  '[[[namespace. | database. ]]schema.]target-table'
  [, force-split]
)

```

Arguments

{ **namespace.** | **database.** }

Name of the database or [namespace](#) that contains *table*, depending on the mode of the database:

- Eon Mode: name of the [namespace](#) to which the table belongs. If no namespace is specified, the table is assumed to be in the [default_namespace](#). The namespaces of *staging-table* and *target-table* must have the same shard count.
- Enterprise Mode: name of the database. If you specify a database, it must be the current database.

schema

Name of the schema, by default [public](#). If you specify the namespace or database name, you must provide the schema name, even if the schema is [public](#).

staging-table

The staging table from which to swap partitions.

min-range-value , **max-range-value**

The minimum and maximum value of partition keys to swap, where *min-range-value* must be \leq *max-range-value*. To specify a single partition key, *min-range-value* and *max-range-value* must be equal.

target-table

The table to which the partitions are to be swapped. The target table cannot be the same as the staging table.

force-split

Optional Boolean argument, specifies whether to split ROS containers if the range of partition keys spans multiple containers or part of a single container:

- **true** : Split ROS containers as needed.
- **false** (default): Return with an error if ROS containers must be split to implement this operation.

Privileges

Non-superuser, one of the following:

- Owner of source and target tables
- Target and source tables: TRUNCATE, INSERT, SELECT

Requirements

The following attributes of both tables must be identical:

- Column definitions, including NULL/NOT NULL constraints
- Segmentation
- [Partition clause](#)
- Number of projections
- Shard count (Eon Mode only)
- Projection sort order
- Primary and unique key constraints. However, the key constraints do not have to be identically enabled. For more information on constraints, see [Constraints](#).

Note

If the target table has primary or unique key constraints enabled and copying or moving the partitions will insert duplicate key values into the target table, Vertica rolls back the operation.

- Check constraints. For [MOVE_PARTITIONS_TO_TABLE](#) and [COPY_PARTITIONS_TO_TABLE](#), Vertica enforces enabled check constraints on the target table only. For [SWAP_PARTITIONS_BETWEEN_TABLES](#), Vertica enforces enabled check constraints on both tables. If there is a violation of an enabled check constraint, Vertica rolls back the operation.
- Number and definitions of text indices.

Additionally, if access policies exist on the source table, the following must be true:

- Access policies on both tables must be identical.
- One of the following must be true:
 - The executing user owns the target table.
 - `AccessPolicyManagementSuperuserOnly` is set to true.

Restrictions

The following restrictions apply to the source and target tables:

- If the source and target partitions are in different storage tiers, Vertica returns a warning but the operation proceeds. The partitions remain in their existing storage tier.
- The target table cannot be [immutable](#).
- The following tables cannot be used as sources or targets:
 - Temporary tables
 - Virtual tables
 - System tables
 - External tables

Examples

See [Swapping partitions](#).

Privileges and access functions

This section contains functions for managing user and role privileges, and access policies.

In this section

- [ENABLED_ROLE](#)
- [GET_PRIVILEGES_DESCRIPTION](#)
- [HAS_ROLE](#)
- [RELEASE_SYSTEM_TABLES_ACCESS](#)
- [RESTRICT_SYSTEM_TABLES_ACCESS](#)

ENABLED_ROLE

Checks whether a Vertica [user role](#) is enabled, and returns true or false. This function is typically used when you create access policies on database roles.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
ENABLED_ROLE ( 'role' )
```

Parameters

role

The role to evaluate.

Privileges

None

Examples

See:

- [Creating column access policies](#)
- [Creating row access policies](#)

See also

[CREATE ACCESS POLICY](#)

[GET_PRIVILEGES_DESCRIPTION](#)

Returns the effective privileges the current user has on an object, including explicit, [implicit](#), [inherited](#), and [role-based](#) privileges.

Because this meta-function only returns [effective privileges](#), GET_PRIVILEGES_DESCRIPTION only returns privileges with fully-satisfied prerequisites. For a list of prerequisites for common operations, see [Privileges required for common database operations](#).

For example, a user must have the following privileges to query a table:

- Schema: USAGE
- Table: SELECT

If user Brooke has SELECT privileges on table `s1.t1` but lacks USAGE privileges on schema `s1`, Brooke cannot query the table, and GET_PRIVILEGES_DESCRIPTION does not return SELECT as a privilege for the table.

Note
Inherited privileges are not displayed if privilege inheritance is disabled at the database level with [DisableInheritedPrivileges](#).

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
GET_PRIVILEGES_DESCRIPTION('type', '[[database.]schema.]name');
```

Parameters

type

Specifies an object type, one of the following:

- `database`
- `table`
- `schema`
- `view`
- `sequence`
- `model`
- `library`
- `resource pool`

[database.] schema

Specifies a database and schema, by default the current database and `public`, respectively.

name

Name of the target object

Privileges

None

Examples

In the following example, user Glenn has set the REPORTER role and wants to check his effective privileges on schema `s1` and table `s1.articles`.

- Table `s1.articles` inherits privileges from its schema (`s1`).
- The REPORTER role has the following privileges:
 - SELECT on schema `s1`
 - INSERT WITH GRANT OPTION on table `s1.articles`
- User Glenn has the following privileges:
 - UPDATE and USAGE on schema `s1`.
 - DELETE on table `s1.articles`.

GET_PRIVILEGES_DESCRIPTION returns the following effective privileges for Glenn on schema `s1`:

```
=> SELECT GET_PRIVILEGES_DESCRIPTION('schema', 's1');
   GET_PRIVILEGES_DESCRIPTION
-----
SELECT, UPDATE, USAGE
(1 row)
```

GET_PRIVILEGES_DESCRIPTION returns the following effective privileges for Glenn on table `s1.articles` :

```
=> SELECT GET_PRIVILEGES_DESCRIPTION('table', 's1.articles');
   GET_PRIVILEGES_DESCRIPTION
-----
INSERT*, SELECT, UPDATE, DELETE
(1 row)
```

See also

- [Database users and privileges](#)
- [Database roles](#)
- [Granting and revoking privileges](#)

HAS_ROLE

Checks whether a Vertica [user role](#) is granted to the specified user or role, and returns true or false.

You can also query system tables [ROLES](#), [GRANTS](#), and [USERS](#) to obtain information on users and their role assignments. For details, see [Viewing user roles](#).

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Stable](#)

Syntax

```
HAS_ROLE( [ 'grantee' ,] 'verify-role' );
```

Parameters

grantee

Valid only for superusers, specifies the name of a user or role to look up. If this argument is omitted, the function uses the current user name ([CURRENT_USER](#)). If you specify a role, Vertica checks whether this role is granted to the role specified in *verify-role*.

Important

If a non-superuser supplies this argument, Vertica returns an error.

verify-role

Name of the role to verify for *grantee*.

Privileges

None

Examples

In the following example, a `dbadmin` user checks whether user `MikeL` is assigned the `administrator` role:

```
=> \c
You are now connected as user "dbadmin".
=> SELECT HAS_ROLE('MikeL', 'administrator');
   HAS_ROLE
-----
t
(1 row)
```

User `MikeL` checks whether he has the `regional_manager` role:

```
=> \c - MikeL
You are now connected as user "MikeL".
=> SELECT HAS_ROLE('regional_manager');
   HAS_ROLE
-----
f
(1 row)
```

The `dbadmin` grants the `regional_manager` role to the `administrator` role. On checking again, `MikeL` verifies that he now has the `regional_manager` role:

```

dbadmin=> \c
You are now connected as user "dbadmin".
dbadmin=> GRANT regional_manager to administrator;
GRANT ROLE
dbadmin=> \c - MikeL
You are now connected as user "MikeL".
dbadmin=> SELECT HAS_ROLE('regional_manager');
HAS_ROLE
-----
t
(1 row)

```

See also

- [GRANTS](#)
- [ROLES](#)
- [USERS](#)
- [Database users and privileges](#)

RELEASE_SYSTEM_TABLES_ACCESS

Allows [non-superusers](#) to access all non- [SUPERUSER_ONLY](#) system tables. After you call this function, Vertica ignores the `IS_ACCESSIBLE_DURING_LOCKDOWN` setting in table [SYSTEM_TABLES](#) . To restrict non-superusers access to system tables, call [RESTRICT_SYSTEM_TABLES_ACCESS](#) .

By default, the database behaves as though `RELEASE_SYSTEM_TABLES_ACCESS()` was called. That is, non-superusers have access to all non-`SUPERUSER_ONLY` system tables.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
RELEASE_SYSTEM_TABLES_ACCESS()
```

Privileges

Superuser

Examples

By default, non-superuser Alice has access to `client_auth` and `disk_storage` . She also has access to `replication_status` because she was [granted](#) the privilege by the dbadmin:

```

=> SELECT table_name, is_superuser_only, is_accessible_during_lockdown FROM system_tables WHERE table_name='disk_storage' OR table_name='dat
  table_name | is_superuser_only | is_accessible_during_lockdown
-----
client_auth | f | t
disk_storage | f | f
database_backups | t | f
replication_status | t | t
(4 rows)

```

The dbadmin calls [RESTRICT_SYSTEM_TABLES_ACCESS](#) :

```

=> SELECT RESTRICT_SYSTEM_TABLES_ACCESS();
  RESTRICT_SYSTEM_TABLES_ACCESS
-----
Dropped grants to public on non-accessible during lockdown system tables.
(1 row)

```

Alice loses access to `disk_storage` , but she retains access to `client_auth` and `replication_status` because their `IS_ACCESSIBLE_DURING_LOCKDOWN` fields are true:

```
-> SELECT storage_status FROM disk_storage;
ERROR 4367: Permission denied for relation disk_storage
```

The dbadmin calls `RELEASE_SYSTEM_TABLES_ACCESS()`, restoring Alice's access to `disk_storage` :

```
-> SELECT RELEASE_SYSTEM_TABLES_ACCESS();
      RELEASE_SYSTEM_TABLES_ACCESS
-----
Granted SELECT privileges on system tables to public.

(1 row)
```

RESTRICT_SYSTEM_TABLES_ACCESS

Prevents [non-superusers](#) from accessing tables that have the `IS_ACCESSIBLE_DURING_LOCKDOWN` flag set to false.

To enable non-superuser access to system tables restricted by this function, call [RELEASE_SYSTEM_TABLES_ACCESS](#).

This is a meta-function. You must call meta-functions in a top-level `SELECT` statement.

Behavior type

[Volatile](#)

Syntax

```
RESTRICT_SYSTEM_TABLES_ACCESS()
```

Privileges

Superuser

Examples

By default, `client_auth` and `disk_storage` tables are accessible to all users, but only the former is accessible after `RESTRICT_SYSTEM_TABLES_ACCESS()` is called. Non-superusers never have access to `database_backups` and `replication_status` unless explicitly [granted](#) the privilege by the dbadmin:

```
-> SELECT table_name, is_superuser_only, is_accessible_during_lockdown FROM system_tables WHERE table_name='disk_storage' OR table_name='dat
      table_name | is_superuser_only | is_accessible_during_lockdown
-----
client_auth    | f                  | t
disk_storage   | f                  | f
database_backups | t                  | t
replication_status | t                  | t
(4 rows)
```

The dbadmin then calls `RESTRICT_SYSTEM_TABLES_ACCESS()`:

```
-> SELECT RESTRICT_SYSTEM_TABLES_ACCESS();
      RESTRICT_SYSTEM_TABLES_ACCESS
-----
Dropped grants to public on non-accessible during lockdown system tables.

(1 row)
```

Bob loses access to `disk_storage` , but retains access to `client_auth` because its `IS_ACCESSIBLE_DURING_LOCKDOWN` field is true:

```
-> SELECT storage_status FROM disk_storage;
ERROR 4367: Permission denied for relation disk_storage

-> SELECT auth_oid FROM client_auth;
      auth_oid
-----
45035996273705106
45035996273705110
45035996273705114
(3 rows)
```

Projection functions

This section contains projection management functions specific to Vertica.

See also

- [V_CATALOG.PROJECTIONS](#)
- [V_CATALOG.PROJECTION_COLUMNS](#)
- [V_MONITOR.PROJECTION_REFRESHES](#)
- [V_MONITOR.PROJECTION_STORAGE](#)

In this section

- [CLEAR_PROJECTION_REFRESHES](#)
- [EVALUATE_DELETE_PERFORMANCE](#)
- [GET_PROJECTION_SORT_ORDER](#)
- [GET_PROJECTION_STATUS](#)
- [GET_PROJECTIONS](#)
- [PURGE_PROJECTION](#)
- [REFRESH](#)
- [REFRESH_COLUMNS](#)
- [START_REFRESH](#)

CLEAR_PROJECTION_REFRESHES

Clears projection refresh history from the [PROJECTION_REFRESHES](#) system table. PROJECTION_REFRESHES records information about successful and unsuccessful [refresh operations](#).

CLEAR_PROJECTION_REFRESHES removes information only for refresh operations that are complete, as indicated by the IS_EXECUTING column in PROJECTION_REFRESHES.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
CLEAR_PROJECTION_REFRESHES()
```

Privileges

Superuser

Examples

```
-> SELECT CLEAR_PROJECTION_REFRESHES();
CLEAR_PROJECTION_REFRESHES
-----
CLEAR
(1 row)
```

See also

- [REFRESH](#)
- [START_REFRESH](#)
- [Clearing projection refresh history](#)

EVALUATE_DELETE_PERFORMANCE

Evaluates projections for potential [DELETE](#) and [UPDATE](#) performance issues. If Vertica finds any issues, it issues a warning message. When evaluating multiple projections, EVALUATE_DELETE_PERFORMANCE returns up to ten projections with issues, and the name of a table that lists all issues that it found.

Note

EVALUATE_DELETE_PERFORMANCE returns messages that specifically reference delete performance. Keep in mind, however, that delete and update operations benefit equally from the same optimizations.

For information on resolving delete and update performance issues, see [Optimizing DELETE and UPDATE](#).

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
EVALUATE_DELETE_PERFORMANCE ( [ '[[database.]schema.]scope' ] )
```

Parameters

[*database* .] *schema*

Database and [schema](#). The default schema is [public](#). If you specify a database, it must be the current database.

scope

Specifies the projections to evaluate, one of the following:

- [*table* .] *projection*

Evaluate *projection*. For example:

```
SELECT EVALUATE_DELETE_PERFORMANCE('store.store_orders_fact.store_orders_fact_b1');
```

- *table*

Specifies to evaluate all projections of *table*. For example:

```
SELECT EVALUATE_DELETE_PERFORMANCE('store.store_orders_fact');
```

If you supply no arguments, `EVALUATE_DELETE_PERFORMANCE` evaluates all projections that you can access. Depending on the size of your database, this can incur considerable overhead.

Privileges

Non-superuser: SELECT privilege on the anchor table

Examples

`EVALUATE_DELETE_PERFORMANCE` evaluates all projections of table [example](#) for potential DELETE and UPDATE performance issues.

```
=> create table example (A int, B int,C int);
CREATE TABLE
=> create projection one_sort (A,B,C) as (select A,B,C from example) order by A;
CREATE PROJECTION
=> create projection two_sort (A,B,C) as (select A,B,C from example) order by A,B;
CREATE PROJECTION
=> select evaluate_delete_performance('example');
       evaluate_delete_performance
-----
No projection delete performance concerns found.
(1 row)
```

The previous example show that the two projections `one_sort` and `two_sort` have no inherent structural issues that might cause poor DELETE performance. However, the data contained within the projection can create potential delete issues if the sorted columns do not uniquely identify a row or small number of rows.

In the following example, Perl is used to populate the table with data using a nested series of loops:

- The inner loop populates column [C](#).
- The middle loop populates column [B](#).
- The outer loop populates column [A](#).

The result is column [A](#) contains only three distinct values (0, 1, and 2), while column [B](#) slowly varies between 20 and 0 and column [C](#) changes in each row:

```
=> \! perl -e 'for ($i=0; $i<3; $i++) { for ($j=0; $j<21; $j++) { for ($k=0; $k<19; $k++) { printf "%d,%d,%d\n", $i,$j,$k;}}}' | /opt/vertica/bin/vsqli -c "copy example from stdin delimiter ',' direct;"
```

Password:

```
=> select * from example;
```

```
A | B | C
```

EVALUATE_DELETE_PERFORMANCE is run against the projections again to determine whether the data within the projections causes any potential DELETE performance issues. Projection **one_sort** has potential delete issues as it only sorts on column A which has few distinct values. Each value in the sort column corresponds to many rows in the projection, which can adversely impact DELETE performance. In contrast, projection **two_sort** is

sorted on columns **A** and **B**, where each combination of values in the two sort columns identifies just a few rows, so deletes can be performed faster:

```
=> select evaluate_delete_performance('example');
       evaluate_delete_performance
```

The following projections exhibit delete performance concerns:

"public"."one_sort_b1"

"public"."one_sort_b0"

See `v_catalog.projection_delete_concerns` for more details.

```
=> \x
```

Expanded display is on.

```
dbadmin=> select * from projection_delete_concerns;
```

```
-[ RECORD 1 ]-----+-----
projection_id | 45035996273878562
projection_schema | public
projection_name | one_sort_b1
creation_time | 2019-06-17 13:59:03.777085-04
last_modified_time | 2019-06-17 14:00:27.702223-04
comment | The squared number of rows matching each sort key is about 159201 on average.
-[ RECORD 2 ]-----+-----
projection_id | 45035996273878548
projection_schema | public
projection_name | one_sort_b0
creation_time | 2019-06-17 13:59:03.777279-04
last_modified_time | 2019-06-17 13:59:03.777279-04
comment | The squared number of rows matching each sort key is about 159201 on average.
```

If you omit supplying an argument to `EVALUATE_DELETE_PERFORMANCE`, it evaluates all projections that you can access:

```
=> select evaluate_delete_performance();
       evaluate_delete_performance
```

The following projections exhibit delete performance concerns:

"public"."one_sort_b0"

"public"."one_sort_b1"

See `v_catalog.projection_delete_concerns` for more details.

(1 row)

GET_PROJECTION_SORT_ORDER

Returns the order of columns in a projection's `ORDER BY` clause.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
GET_PROJECTION_SORT_ORDER( '[[database.]schema.]projection' );
```

Parameters

[*database* .] *schema*

Database and [schema](#). The default schema is `public`. If you specify a database, it must be the current database.

projection

The target projection.

Privileges

Non-superuser: `SELECT` privilege on the anchor table

Examples

```
=> SELECT get_projection_sort_order ('store_orders_super');
           get_projection_sort_order
-----
public.store_orders_super [Sort Cols: "order_no", "order_date", "shipper", "ship_date"]

(1 row)
```

GET_PROJECTION_STATUS

Returns information relevant to the status of a [projection](#) :

- The current [K-safety](#) status of the database
- The number of nodes in the database
- Whether the projection is segmented
- The number and names of buddy projections
- Whether the projection is [safe](#)
- Whether the projection is [up to date](#)
- Whether statistics have been computed for the projection

Use [GET_PROJECTION_STATUS](#) to [monitor the progress](#) of a projection data refresh.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
GET_PROJECTION_STATUS ( '[[database.]schema.]projection' );
```

Parameters

[[database](#) .] [schema](#)

Database and [schema](#) . The default schema is [public](#) . If you specify a database, it must be the current database.

[projection](#)

The projection for which to display status.

Examples

```
=> SELECT GET_PROJECTION_STATUS('public.customer_dimension_site01');
           GET_PROJECTION_STATUS
-----
Current system K is 1.
# of Nodes: 4.
public.customer_dimension_site01 [Segmented: No] [Seg Cols: ] [K: 3] [public.customer_dimension_site04, public.customer_dimension_site03,
public.customer_dimension_site02]
[Safe: Yes] [UptoDate: Yes][Stats: Yes]
```

GET_PROJECTIONS

Returns contextual and projection information about projections of the specified anchor table.

Contextual information

- Database K-safety
- Number of database nodes
- Number of projections for this table

Projection data

For each projection, specifies:

- All buddy projections
- Whether it is segmented
- Whether it is safe
- Whether it is up-to-date.

You can also use [GET_PROJECTIONS](#) to [monitor the progress of a projection data refresh](#) .

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
GET_PROJECTIONS ( '[[database.]schema.]table' )
```

Parameters

[*database .*] *schema*

Database and [schema](#). The default schema is [public](#) . If you specify a database, it must be the current database.

table

Anchor table of the projections to list.

Privileges

None

Examples

The following example gets information about projections for VMart table [store.store_dimension](#) :

```
=> SELECT GET_PROJECTIONS('store.store_dimension');
-[ RECORD 1 ]---+
GET_PROJECTIONS | Current system K is 1.
# of Nodes: 3.
Table store.store_dimension has 2 projections.

Projection Name: [Segmented] [Seg Cols] [# of Buddies] [Buddy Projections] [Safe] [UptoDate] [Stats]
-----
store.store_dimension_b1 [Segmented: Yes] [Seg Cols: "store.store_dimension.store_key"] [K: 1] [store.store_dimension_b0] [Safe: Yes] [UptoDate: Yes]
[Stats: RowCounts]
store.store_dimension_b0 [Segmented: Yes] [Seg Cols: "store.store_dimension.store_key"] [K: 1] [store.store_dimension_b1] [Safe: Yes] [UptoDate: Yes]
[Stats: RowCounts]
```

PURGE_PROJECTION

Permanently removes deleted data from physical storage so disk space can be reused. You can purge historical data up to and including the Ancient History Mark epoch.

Caution

PURGE_PROJECTION can use significant disk space while purging the data.

See [PURGE](#) for details about purge operations.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
PURGE_PROJECTION ( '[[database.]schema.]projection' )
```

Parameters

[*database .*] *schema*

Database and [schema](#). The default schema is [public](#) . If you specify a database, it must be the current database.

projection

The projection to purge.

Privileges

- Table owner
- USAGE privilege on schema

Examples

The following example purges all historical data in projection `tbl_p` that precedes the Ancient History Mark epoch.

```
=> CREATE TABLE tbl (x int, y int);
CREATE TABLE
=> INSERT INTO tbl VALUES(1,2);
OUTPUT
-----
 1
(1 row)

=> INSERT INTO tbl VALUES(3,4);
OUTPUT
-----
 1
(1 row)

dbadmin=> COMMIT;
COMMIT
=> CREATE PROJECTION tbl_p AS SELECT x FROM tbl UNSEGMENTED ALL NODES;
WARNING 4468: Projection <public.tbl_p> is not available for query processing.
Execute the select start_refresh() function to copy data into this projection.
The projection must have a sufficient number of buddy projections and all nodes must be up before starting a refresh
CREATE PROJECTION
=> SELECT START_REFRESH();
      START_REFRESH
-----
Starting refresh background process.
=> DELETE FROM tbl WHERE x=1;
OUTPUT
-----
 1
(1 row)

=> COMMIT;
COMMIT
=> SELECT MAKE_AHM_NOW();
      MAKE_AHM_NOW
-----
AHM set (New AHM Epoch: 9066)
(1 row)

=> SELECT PURGE_PROJECTION ('tbl_p');
PURGE_PROJECTION
-----
Projection purged
(1 row)
```

See also

- [PURGE_TABLE](#)
- [STORAGE_CONTAINERS](#)
- [Purging deleted data](#).

REFRESH

Synchronously refreshes one or more table projections in the foreground, and updates the [PROJECTION_REFRESHES](#) system table. If you run REFRESH with no arguments, it refreshes all projections that contain stale data.

To understand projection refreshing in detail, see [Refreshing projections](#).

If a refresh would violate a table or schema disk quota, the operation fails. For more information, see [Disk quotas](#).

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
REFRESH ( [ '[[database.]schema.]table[,...]' ] )
```

Parameters

[***database*** .] ***schema***

Database and [schema](#). The default schema is **public**. If you specify a database, it must be the current database.

table

The anchor table of the projections to refresh. If you specify multiple tables, REFRESH attempts to refresh them in parallel. Such calls are part of the Database Designer deployment (and deployment script).

Returns

Note

If REFRESH does not refresh any projections, it returns a header string with no results.

Column	Returns
Projection Name	The projection targeted for refresh.
Anchor Table	The projection's associated anchor table.
Status	Projections' refresh status: <ul style="list-style-type: none">• queued : Queued for refresh.• refreshing : Refresh is in process.• refreshed : Refresh successfully completed.• failed : Refresh did not successfully complete.
Refresh Method	Method used to refresh the projection.
Error Count	Number of times a refresh failed for the projection.
Duration (sec)	How long (in seconds) the projection refresh ran.

Privileges

- [Superuser](#)
- Owner of the specified tables

Refresh methods

Vertica can refresh a projection from one of its buddies, if one is available. In this case, the target projection gets the source buddy's historical data. Otherwise, the projection is refreshed from scratch with data of the latest epoch at the time of the refresh operation. In this case, the projection cannot participate in historical queries on any epoch that precedes the refresh operation.

Vertica can perform incremental refreshes when the following conditions are met:

- The table being refreshed is partitioned.
- The table does not contain any unpartitioned data.
- The operation is a full projection refresh (not a partition range projection refresh).

In an incremental refresh, the refresh operation first loads data from the partition with the highest range of keys. After refreshing this partition, Vertica begins to refresh the partition with next highest partition range. This process continues until all projection partitions are refreshed. While the refresh operation is in progress, projection partitions that have completed the refresh process become available to process query requests.

The method used to refresh a given projection is recorded in the REFRESH_METHOD column of the [PROJECTION_REFRESHES](#) system table.

Examples

The following example refreshes the projections in two tables:

```
=> SELECT REFRESH('t1, t2');
      REFRESH
-----
Refresh completed with the following outcomes:

Projection Name: [Anchor Table] [Status] [Refresh Method] [Error Count] [Duration (sec)]
-----
"public"."t1_p": [t1] [refreshed] [scratch] [0] [0]"public"."t2_p": [t2] [refreshed] [scratch] [0] [0]
```

In the following example, only the projection on one table was refreshed:

```
=> SELECT REFRESH('allow, public.deny, t');
      REFRESH
-----
Refresh completed with the following outcomes:

Projection Name: [Anchor Table] [Status] [Refresh Method] [Error Count] [Duration (sec)]
-----
"n/a"."n/a": [n/a] [failed: insufficient permissions on table "allow"] [] [1] [0]
"n/a"."n/a": [n/a] [failed: insufficient permissions on table "public.deny"] [] [1] [0]
"public"."t_p1": [t] [refreshed] [scratch] [0] [0]
```

See also

- [CLEAR_PROJECTION_REFRESHES](#)
- [START_REFRESH](#)

REFRESH_COLUMNS

Refreshes table columns that are defined with the constraint [SET USING](#) or [DEFAULT USING](#). All refresh operations associated with a call to REFRESH_COLUMNS belong to the same transaction. Thus, all tables and columns specified by REFRESH_COLUMNS must be refreshed; otherwise, the entire operation is rolled back.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
REFRESH_COLUMNS ( 'table-list', '[column-list]'
  [, '[refresh-mode]' [, min-partition-key, max-partition-key [, force-split] ]
)
```

Arguments

table-list

A comma-delimited list of the tables to refresh: `[[database .] schema .] table [...]`

If you specify multiple tables, *refresh-mode* must be set to REBUILD.

column-list

A comma-delimited list of columns to refresh: `[[[database .] schema .] table .] column [...]` or `[[database .] schema .] table . *`, where asterisk (`*`) means to refresh all SET USING/DEFAULT USING columns in the table. For example:

```
SELECT REFRESH_COLUMNS ('t1, t2', 't1.*, t2.b', 'REBUILD');
```

If *column-list* is set to an empty string (`"`), REFRESH_COLUMNS refreshes all SET USING/DEFAULT USING columns in the specified tables.

The following requirements apply:

- All specified columns must have a SET USING or DEFAULT USING constraint.
- If REFRESH_COLUMNS specifies multiple tables, all column names must be qualified by their table names. If the target tables span multiple schemas, all column names must be fully qualified by their schema and table names. For example:

```
SELECT REFRESH_COLUMNS ('t1, t2', 't1.a, t2.b', 'REBUILD');
```

If you specify a database, it must be the current database.

refresh-mode

Specifies how to refresh SET USING columns:

- **UPDATE** (default): Marks original rows as deleted and replaces them with new rows. In order to save these updates, you must issue a COMMIT statement.
- **REBUILD** : Replaces all data in the specified columns. The rebuild operation is auto-committed.

If you specify multiple tables, you must explicitly specify REBUILD mode.

In both cases, REFRESH_COLUMNS returns an error if any SET USING column is defined as a primary or unique key in a table that [enforces those constraints](#) .

See [REBUILD Mode Restrictions](#) for limitations on using the REBUILD option.

min-partition-key , max-partition-key

Qualifies REBUILD mode, limiting the rebuild operation to one or more partitions. To specify a range of partitions, *max-partition-key* must be greater than *min-partition-key* . To update one partition, the two arguments must be equal.

The following requirements apply:

- The function can specify only one table to refresh.
- The table must be partitioned on the specified keys.

You can use these arguments to refresh columns with recently loaded data—that is, data in the latest partitions. Using this option regularly can significantly minimize the overhead otherwise incurred by rebuilding entire columns in a large table.

See [Partition-based REBUILD](#) below for details.

force-split

Boolean, whether to split ROS containers if the range of partition keys spans multiple containers or part of a single container:

- **true** (default): Split ROS containers as needed.
- **false** : Return with an error if ROS containers must be split to implement this operation.

Privileges

- Schemas of queried and flattened tables: USAGE
- Queried table: SELECT
- Flattened table: SELECT, UPDATE

UPDATE versus REBUILD modes

In general, UPDATE mode is a better choice when changes to SET USING column data are confined to a relatively small number of rows. Use REBUILD mode when a significant amount of SET USING column data is stale and must be updated. It is generally good practice to call REFRESH_COLUMNS with REBUILD on any new SET USING column—for example, to populate a SET USING column after adding it with ALTER TABLE...ADD COLUMN.

REBUILD mode restrictions

If you call REFRESH_COLUMNS on a SET USING column and specify the refresh mode as REBUILD, Vertica returns an error if the column is specified in any of the following:

- Table's partition key
- Unsegmented projection
- [Projection with expressions](#) , or any [live aggregate projection that invokes a user-defined transform function](#) (UDTF)
- Sort order or segmentation of any projection
- Any projection that omits an anchor table column that is referenced in the column's SET USING expression
- [GROUPED clause](#) of any projection

Partition-based REBUILD operations

If a flattened table is partitioned, you can reduce the overhead of calling REFRESH_COLUMNS in REBUILD mode, by specifying one or more partition keys. Doing so limits the rebuild operation to the specified partitions. For example, table `public.orderFact` is [defined](#) with SET USING column `cust_name` . This table is partitioned on column `order_date` , where the partition clause invokes Vertica function [CALENDAR_HIERARCHY_DAY](#) . Thus, you can call REFRESH_COLUMNS on specific time-delimited partitions of this table—in this case, on orders over the last two months:

```
=> SELECT REFRESH_COLUMNS ('public.orderFact',
    'cust_name',
    'REBUILD',
    TO_CHAR(ADD_MONTHS(current_date, -2), 'YYYY-MM')||'-01',
    TO_CHAR(LAST_DAY(ADD_MONTHS(current_date, -1))));
REFRESH_COLUMNS
-----
refresh_columns completed
(1 row)
```

Rewriting SET USING queries

When you call [REFRESH_COLUMNS](#) on a [flattened table](#)'s [SET USING](#) (or DEFAULT USING) column, it executes the SET USING query by joining the target and source tables. By default, the source table is always the inner table of the join. In most cases, cardinality of the source table is less than the target table, so REFRESH_COLUMNS executes the join efficiently.

Occasionally—notably, when you call REFRESH_COLUMNS on a partitioned table—the source table can be larger than the target table. In this case, performance of the join operation can be suboptimal.

You can address this issue by enabling configuration parameter [RewriteQueryForLargeDim](#). When enabled (1), Vertica rewrites the query, by reversing the inner and outer join between the target and source tables.

Important

Enable this parameter only if the SET USING source data is in a table that is larger than the target table. If the source data is in a table smaller than the target table, then enabling RewriteQueryForLargeDim can adversely affect refresh performance.

Examples

See [Flattened table example](#) and [DEFAULT versus SET USING](#).

START_REFRESH

Refreshes projections in the [current schema](#) with the latest data of their respective [anchor tables](#). START_REFRESH runs asynchronously in the background, and updates the [PROJECTION_REFRESHES](#) system table. This function has no effect if a refresh is already running.

To refresh only projections of a specific table, use [REFRESH](#). When you [deploy a design](#) through Database Designer, it automatically refreshes its projections.

If a refresh would violate a table or schema disk quota, the operation fails. For more information, see [Disk quotas](#).

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
START_REFRESH()
```

Privileges

None

Requirements

All nodes must be up.

Refresh methods

Vertica can refresh a projection from one of its buddies, if one is available. In this case, the target projection gets the source buddy's historical data. Otherwise, the projection is refreshed from scratch with data of the latest epoch at the time of the refresh operation. In this case, the projection cannot participate in historical queries on any epoch that precedes the refresh operation.

Vertica can perform incremental refreshes when the following conditions are met:

- The table being refreshed is partitioned.
- The table does not contain any unpartitioned data.
- The operation is a full projection refresh (not a partition range projection refresh).

In an incremental refresh, the refresh operation first loads data from the partition with the highest range of keys. After refreshing this partition, Vertica begins to refresh the partition with next highest partition range. This process continues until all projection partitions are refreshed. While the refresh operation is in progress, projection partitions that have completed the refresh process become available to process query requests.

The method used to refresh a given projection is recorded in the REFRESH_METHOD column of the [PROJECTION_REFRESHES](#) system table.

Examples

```
=> SELECT START_REFRESH();
       START_REFRESH
-----
Starting refresh background process.
(1 row)
```

See also

- [Refreshing projections](#)
- [CLEAR_PROJECTION_REFRESHES](#)

Session functions

This section contains session management functions specific to Vertica.

See also the SQL system table [V_MONITOR.SESSIONS](#).

In this section

- [CANCEL_REFRESH](#)
- [CLOSE_ALL_SESSIONS](#)
- [CLOSE_SESSION](#)
- [CLOSE_USER_SESSIONS](#)
- [GET_NUM_ACCEPTED_ROWS](#)
- [GET_NUM_REJECTED_ROWS](#)
- [INTERRUPT_STATEMENT](#)
- [RELEASE_ALL_JVM_MEMORY](#)
- [RELEASE_JVM_MEMORY](#)
- [RESERVE_SESSION_RESOURCE](#)
- [RESET_SESSION](#)

CANCEL_REFRESH

Cancels refresh-related internal operations initiated by [START_REFRESH](#) and [REFRESH](#).

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
CANCEL_REFRESH()
```

Privileges

None

Notes

- Refresh tasks run in a background thread in an internal session, so you cannot use [INTERRUPT_STATEMENT](#) to cancel those statements. Instead, use CANCEL_REFRESH to cancel statements that are run by refresh-related internal sessions.
- Run CANCEL_REFRESH() on the same node on which START_REFRESH() was initiated.
- CANCEL_REFRESH() cancels the refresh operation running on a node, waits for the cancelation to complete, and returns SUCCESS.
- Only one set of refresh operations runs on a node at any time.

Examples

Cancel a refresh operation executing in the background.

```
=> SELECT START_REFRESH();
      START_REFRESH
```

Starting refresh background process.

(1 row)

```
=> SELECT CANCEL_REFRESH();
      CANCEL_REFRESH
```

Stopping background refresh process.

(1 row)

See also

- [INTERRUPT_STATEMENT](#)
- [SESSIONS](#)
- [START_REFRESH](#)
- [PROJECTION_REFRESHES](#)

CLOSE_ALL_SESSIONS

Closes all external sessions except the one that issues this function. Call this function before [shutting down](#) the Vertica database.

Vertica closes sessions asynchronously, so another session can open before this function returns. In this case, reissue this function. To view the status of all open sessions, query system table [SESSIONS](#).

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
CLOSE_ALL_SESSIONS()
```

Privileges

Non-superuser: None to close your own session

Examples

Two user sessions are open on separate nodes:

```

=> SELECT * FROM sessions;
-[ RECORD 1 ]-----+-----
node_name      | v_vmartdb_node0001

CLOSE_SESSION

Interrupts the specified external session, rolls back the current transaction if any, and closes the socket. You can only close your own session.

It might take some time before a session is closed. To view the status of all open sessions, query the system table [SESSIONS](#).

For detailed information about session management options, see [Managing sessions](#).

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
CLOSE_SESSION ('sessionid')
```

Parameters

sessionid

A string that specifies the session to close. This identifier is unique within the cluster at any point in time but can be reused when the session closes.

Privileges

None

Examples

User session opened. Record 2 shows the user session running a **COPY DIRECT** statement.

```

=> SELECT * FROM sessions;
-[ RECORD 1 ]-----+-----
node_name      | v_vmartdb_node0001
user_name      | dbadmin
client_hostname | 127.0.0.1:52110
client_pid     | 4554
login_timestamp | 2011-01-03 14:05:40.252625-05
session_id     | stress04-4325:0x14
client_label   |
transaction_start | 2011-01-03 14:05:44.325781
transaction_id  | 45035996273728326
transaction_description | user dbadmin (SELECT * FROM sessions;)
statement_start | 2011-01-03 15:36:13.896288
statement_id    | 10
last_statement_duration_us | 14978
current_statement | select * from sessions;
ssl_state      | None
authentication_method | Trust
-[ RECORD 2 ]-----+-----
node_name      | v_vmartdb_node0002
user_name      | dbadmin
client_hostname | 127.0.0.1:57174
client_pid     | 30117
login_timestamp | 2011-01-03 15:33:00.842021-05
session_id     | stress05-27944:0xc1a
client_label   |
transaction_start | 2011-01-03 15:34:46.538102
transaction_id  | -1
transaction_description | user dbadmin (COPY ClickStream_Fact FROM
                        '/data/clickstream/1g/ClickStream_Fact.tbl'
                        DELIMITER '|' NULL '\n' DIRECT;)
statement_start | 2011-01-03 15:34:46.538862
statement_id    |
last_statement_duration_us | 26250
current_statement | COPY ClickStream_Fact FROM '/data/clickstream
                        /1g/ClickStream_Fact.tbl' DELIMITER '|' NULL
                        '\n' DIRECT;
ssl_state      | None
authentication_method | Trust

```

Close user session [stress05-27944:0xc1a](#)

```

=> \x
Expanded display is off.
=> SELECT CLOSE_SESSION('stress05-27944:0xc1a');
        CLOSE_SESSION
-----
Session close command sent. Check v_monitor.sessions for progress.
(1 row)

```

Query the sessions table again for current status, and you can see that the second session has been closed:

```

=> SELECT * FROM SESSIONS;
-[ RECORD 1 ]-----+-----
node_name      | v_vmartdb_node0001
user_name      | dbadmin
client_hostname | 127.0.0.1:52110
client_pid     | 4554
login_timestamp | 2011-01-03 14:05:40.252625-05
session_id     | stress04-4325:0x14
client_label   |
transaction_start | 2011-01-03 14:05:44.325781
transaction_id  | 45035996273728326
transaction_description | user dbadmin (select * from SESSIONS;)
statement_start | 2011-01-03 16:12:07.841298
statement_id    | 20
last_statement_duration_us | 2099
current_statement | SELECT * FROM SESSIONS;
ssl_state      | None
authentication_method | Trust

```

See also

- [CLOSE_ALL_SESSIONS](#)
- [SHUTDOWN](#)

CLOSE_USER_SESSIONS

Stops the session for a user, rolls back any transaction currently running, and closes the connection. To determine the status of the sessions to close, query the [SESSIONS](#) table.

Note

Running this function on your own sessions leaves one session running.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
CLOSE_USER_SESSIONS ( 'user-name' )
```

Parameters

user-name

Specifies the user whose sessions are to be closed. If you specify your own user name, Vertica closes all sessions except the one in which you issue this function.

Privileges

[DBADMIN](#)

Examples

This example closes all active session for user **u1** :

```

=> SELECT close_user_sessions('u1');

```

See also

- [CLOSE_ALL_SESSIONS](#)
- [CLOSE_SESSION](#)
- [SHUTDOWN](#)

GET_NUM_ACCEPTED_ROWS

Returns the number of rows loaded into the database for the last completed load for the current session. GET_NUM_ACCEPTED_ROWS is a [meta-function](#). Do not use it as a value in an INSERT query.

The number of accepted rows is not available for a load that is currently in process. Check the [LOAD_STREAMS](#) system table for its status.

This meta-function supports loads from STDIN, COPY LOCAL from a Vertica client, or a single file on the initiator. You cannot use GET_NUM_ACCEPTED_ROWS for multi-node loads.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
GET_NUM_ACCEPTED_ROWS();
```

Privileges

None

Note

The data regarding accepted rows from the last load during the current session does not persist, and is lost when you initiate a new load.

Examples

This examples shows the number of accepted rows from the vmart_load_data.sql meta-command.

```
=> \i vmart_load_data.sql;
=> SELECT GET_NUM_ACCEPTED_ROWS ();
GET_NUM_ACCEPTED_ROWS
-----
300000
(1 row)
```

See also

- [GET_NUM_REJECTED_ROWS](#)

GET_NUM_REJECTED_ROWS

Returns the number of rows that were rejected during the last completed load for the current session. GET_NUM_REJECTED_ROWS is a [meta-function](#). Do not use it as a value in an INSERT query.

Rejected row information is unavailable for a load that is currently running. The number of rejected rows is not available for a load that is currently in process. Check the [LOAD_STREAMS](#) system table for its status.

This meta-function supports loads from STDIN, COPY LOCAL from a Vertica client, or a single file on the initiator. You cannot use GET_NUM_REJECTED_ROWS for multi-node loads.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
GET_NUM_REJECTED_ROWS();
```

Privileges

None

Note

The data regarding rejected rows from the last load during the current session does not persist, and is dropped when you initiate a new load.

Examples

This example shows the number of rejected rows from the vmart_load_data.sql meta-command.

```

=> \i vmart_load_data.sql
=> SELECT GET_NUM_REJECTED_ROWS ();
GET_NUM_REJECTED_ROWS
-----
0
(1 row)

```

See also

- [GET_NUM_ACCEPTED_ROWS](#)

INTERRUPT_STATEMENT

Interrupts the specified statement in a user session, rolls back the current transaction, and writes a success or failure message to the log file.

Sessions can be interrupted during statement execution. Only statements run by user sessions can be interrupted.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
INTERRUPT_STATEMENT( 'session-id', statement-id)
```

Parameters

session-id

Identifies the session to interrupt. This identifier is unique within the cluster at any point in time.

statement-id

Identifies the statement to interrupt. If the **statement-id** is valid, the statement can be interrupted and **INTERRUPT_STATEMENT** returns a success message. Otherwise the system returns an error.

Privileges

Superuser

Messages

The following list describes messages you might encounter:

Message	Meaning
Statement interrupt sent. Check SESSIONS for progress.	This message indicates success.
Session <id> could not be successfully interrupted: session not found.	The session ID argument to the interrupt command does not match a running session.
Session <id> could not be successfully interrupted: statement not found.	The statement ID does not match (or no longer matches) the ID of a running statement (if any).
No interruptible statement running	The statement is DDL or otherwise non-interruptible.
Internal (system) sessions cannot be interrupted.	The session is internal, and only statements run by external sessions can be interrupted.

Examples

Two user sessions are open. RECORD 1 shows user session running **SELECT FROM SESSION** , and RECORD 2 shows user session running **COPY DIRECT** :

```

=> SELECT * FROM SESSIONS;
-[ RECORD 1 ]-----+-----
node_name          | v_vmartdb_node0001
user_name          | dbadmin
client_hostname    | 127.0.0.1:52110
client_pid         | 4554
login_timestamp    | 2011-01-03 14:05:40.252625-05
session_id         | stress04-4325:0x14
client_label       |
transaction_start  | 2011-01-03 14:05:44.325781
transaction_id     | 45035996273728326
transaction_description | user dbadmin (select * from sessions;)
statement_start    | 2011-01-03 15:36:13.896288
statement_id       | 10
last_statement_duration_us | 14978
current_statement  | select * from sessions;
ssl_state          | None
authentication_method | Trust
-[ RECORD 2 ]-----+-----
node_name          | v_vmartdb_node0003
user_name          | dbadmin
client_hostname    | 127.0.0.1:56367
client_pid         | 1191
login_timestamp    | 2011-01-03 15:31:44.939302-05
session_id         | stress06-25663:0xbec
client_label       |
transaction_start  | 2011-01-03 15:34:51.05939
transaction_id     | 54043195528458775
transaction_description | user dbadmin (COPY Mart_Fact FROM '/data/Mart_Fact.tbl'
                    DELIMITER '|' NULL '\n' DIRECT;)
statement_start    | 2011-01-03 15:35:46.436748
statement_id       | 5
last_statement_duration_us | 1591403
current_statement  | COPY Mart_Fact FROM '/data/Mart_Fact.tbl' DELIMITER '|'
                    NULL '\n' DIRECT;
ssl_state          | None
authentication_method | Trust

```

Interrupt the **COPY DIRECT** statement running in session **stress06-25663:0xbec** :

```

=> \x
Expanded display is off.
=> SELECT INTERRUPT_STATEMENT('stress06-25663:0x1537', 5);
        interrupt_statement
-----
Statement interrupt sent. Check v_monitor.sessions for progress.
(1 row)

```

Verify that the interrupted statement is no longer active by looking at the **current_statement** column in the **SESSIONS** system table. This column becomes blank when the statement is interrupted:

```

=> SELECT * FROM SESSIONS;
-[ RECORD 1 ]-----+-----
node_name      | v_vmartdb_node0001
user_name      | dbadmin
client_hostname | 127.0.0.1:52110
client_pid     | 4554
login_timestamp | 2011-01-03 14:05:40.252625-05
session_id     | stress04-4325:0x14
client_label   |
transaction_start | 2011-01-03 14:05:44.325781
transaction_id  | 45035996273728326
transaction_description | user dbadmin (select * from sessions;)
statement_start | 2011-01-03 15:36:13.896288
statement_id    | 10
last_statement_duration_us | 14978
current_statement | select * from sessions;
ssl_state      | None
authentication_method | Trust
-[ RECORD 2 ]-----+-----
node_name      | v_vmartdb_node0003
user_name      | dbadmin
client_hostname | 127.0.0.1:56367
client_pid     | 1191
login_timestamp | 2011-01-03 15:31:44.939302-05
session_id     | stress06-25663:0xbec
client_label   |
transaction_start | 2011-01-03 15:34:51.05939
transaction_id  | 54043195528458775
transaction_description | user dbadmin (COPY Mart_Fact FROM '/data/Mart_Fact.tbl'
                    DELIMITER '|' NULL '\n' DIRECT;)
statement_start | 2011-01-03 15:35:46.436748
statement_id    | 5

current_statement |
ssl_state      | None
authentication_method | Trust

```

See also

- [SESSIONS](#)
- [Managing sessions](#)

RELEASE_ALL_JVM_MEMORY

Forces all sessions to release the memory consumed by their Java Virtual Machines (JVM).

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
RELEASE_ALL_JVM_MEMORY();
```

Privileges

Must be a [superuser](#).

Examples

The following example demonstrates viewing the JVM memory use in all open sessions, then calling `RELEASE_ALL_JVM_MEMORY()` to release the memory:

```

=> select user_name,external_memory_kb FROM V_MONITOR.SESIONS;
user_name | external_memory_kb
-----+-----
dbadmin   |      79705
(1 row)

=> SELECT RELEASE_ALL_JVM_MEMORY();
           RELEASE_ALL_JVM_MEMORY
-----
Close all JVM sessions command sent. Check v_monitor.sessions for progress.
(1 row)

=> SELECT user_name,external_memory_kb FROM V_MONITOR.SESIONS;
user_name | external_memory_kb
-----+-----
dbadmin   |          0
(1 row)

```

See also

- [RELEASE_JVM_MEMORY](#)

RELEASE_JVM_MEMORY

Terminates a Java Virtual Machine (JVM), making available the memory the JVM was using.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
RELEASE_JVM_MEMORY();
```

Privileges

None.

Examples

User session opened. RECORD 2 shows the user session running COPY DIRECT statement.

```

=> SELECT RELEASE_JVM_MEMORY();
           release_jvm_memory
-----
Java process killed and memory released
(1 row)

```

See also

- [RELEASE_ALL_JVM_MEMORY](#)

RESERVE_SESSION_RESOURCE

Reserves memory resources from the general resource pool for the exclusive use of the Vertica backup and restore process. No other Vertica process can access reserved resources. If insufficient resources are available, Vertica queues the reservation request.

This meta-function is a session level reservation. When a session ends Vertica automatically releases any resources reserved in that session. Because the meta-function operates at the session level, the resource name does not need to be unique across multiple sessions.

You can view reserved resources by querying the [SESSIONS](#) table.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
RESERVE_SESSION_RESOURCE ( 'name', memory)
```

Parameters

name

The name of the resource to reserve.

memory

The amount of memory in kilobytes to allocate to the resource.

Privileges

None

Examples

Reserve 1024 kilobytes of memory for the backup and restore process:

```
=> SELECT reserve_session_resource('VBR_RESERVE',1024);
-[ RECORD 1 ]-----+-----
reserve_session_resource | Grant succeed
```

RESET_SESSION

Applies your default connection string configuration settings to your current session.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
RESET_SESSION()
```

Examples

The following example shows how you use RESET_SESSION.

Resets the current client connection string to the default connection string settings:

```
=> SELECT RESET_SESSION();
RESET_SESSION
-----
Reset session: done.
(1 row)
```

Storage functions

This section contains storage management functions specific to Vertica.

In this section

- [ALTER_LOCATION_LABEL](#)
- [ALTER_LOCATION_USE](#)
- [CLEAR_CACHES](#)
- [CLEAR_OBJECT_STORAGE_POLICY](#)
- [DO_TM_TASK](#)
- [DROP_LOCATION](#)
- [ENFORCE_OBJECT_STORAGE_POLICY](#)
- [MEASURE_LOCATION_PERFORMANCE](#)
- [MOVE_RETIRED_LOCATION_DATA](#)
- [RESTORE_LOCATION](#)
- [RETIRE_LOCATION](#)
- [SET_LOCATION_PERFORMANCE](#)
- [SET_OBJECT_STORAGE_POLICY](#)

ALTER_LOCATION_LABEL

Adds a label to a storage location, or changes or removes an existing label. You can change a location label if it is not specified by any storage policy.

Caution

If you label a storage location that contains data, Vertica moves the data to an unlabeled location, if one exists. To prevent data movement between storage locations, labels should be applied either to all storage locations or none.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
ALTER_LOCATION_LABEL ( 'path' , '[node]' , '[location-label]' )
```

Parameters

path

The storage location path.

node

The node where the label change is applied. If you supply an empty string, Vertica applies the change across all cluster nodes.

location-label

The label to assign to the specified storage location.

If you supply an empty string, Vertica removes that storage location's label.

You can remove a location label only if the following conditions are both true:

- No database object has a storage policy that specifies this label.
- The labeled location is not the last available storage for the objects associated with it.

Privileges

Superuser

Examples

The following ALTER_LOCATION_LABEL statement applies across all cluster nodes the label **SSD** to the storage location `/home/dbadmin/SSD/tables` :

```
=> SELECT ALTER_LOCATION_LABEL('/home/dbadmin/SSD/tables', '', 'SSD');
ALTER_LOCATION_LABEL
-----
/home/dbadmin/SSD/tables label changed.
(1 row)
```

See also

- [Altering location labels](#)
- [CLEAR_OBJECT_STORAGE_POLICY](#)
- [SET_OBJECT_STORAGE_POLICY](#)

ALTER_LOCATION_USE

Alters the type of data that a storage location holds.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
ALTER_LOCATION_USE ( 'path' , '[node]' , 'usage' )
```

Arguments

path

Where the storage location is mounted.

node

The Vertica node on which to alter the storage location. To alter the location on all cluster nodes in a single transaction, use an empty string (`''`). If the usage is SHARED TEMP or SHARED USER, you must alter it on all nodes.

usage

One of the following:

- **DATA** : The storage location stores only data files.
- **TEMP** : The location stores only temporary files that are created during loads or queries.
- **DATA,TEMP** : The location can store both types of files.

Privileges

Superuser

Restrictions

You cannot change a storage location from a USER usage type if you created the location that way, or to a USER type if you did not. You can change a USER storage location to specify DATA (storing TEMP files is not supported). However, doing so does not affect the primary objective of a USER storage location, to be accessible by non-dbadmin users with assigned privileges.

You cannot change a storage location from SHARED TEMP or SHARED USER to SHARED DATA or the reverse.

Monitoring storage locations

For information about the disk storage used on each node, query the [DISK_STORAGE](#) system table.

Examples

The following example alters a storage location across all cluster nodes to store only data:

```
=> SELECT ALTER_LOCATION_USE ('/thirdSL' , " , 'DATA');
```

See also

- [Altering location use](#)
- [RETIRE_LOCATION](#)
- [GRANT \(storage location\)](#)
- [REVOKE \(storage location\)](#)

CLEAR_CACHES

Clears the Vertica internal cache files.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
CLEAR_CACHES ( )
```

Privileges

Superuser

Notes

If you want to run benchmark tests for your queries, in addition to clearing the internal Vertica cache files, clear the Linux file system cache. The kernel uses unallocated memory as a cache to hold clean disk blocks. If you are running version 2.6.16 or later of Linux and you have root access, you can clear the kernel file system cache as follows:

1. Make sure that all data in the cache is written to disk:

```
# sync
```

2. Writing to the [drop_caches](#) file causes the kernel to drop clean caches, entries, and inodes from memory, causing that memory to become free, as follows:

- To clear the page cache:

```
# echo 1 > /proc/sys/vm/drop_caches
```

- To clear the entries and inodes:

```
# echo 2 > /proc/sys/vm/drop_caches
```

- To clear the page cache, entries, and inodes:

```
# echo 3 > /proc/sys/vm/drop_caches
```

Examples

The following example clears the Vertica internal cache files:

```
=> SELECT CLEAR_CACHES();
CLEAR_CACHES
```

Cleared
(1 row)

CLEAR_OBJECT_STORAGE_POLICY

Removes a user-defined storage policy from the specified database, schema or table. Storage containers at the previous policy's labeled location are moved to the default location. By default, this move occurs after all pending mergeout tasks return.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
CLEAR_OBJECT_STORAGE_POLICY ( 'object-name' [, 'key-min', 'key-max'] [, 'enforce-storage-move' ] )
```

Parameters

object-name

The object to clear, one of the following:

- *database* : Clears *database* of its storage policy.
- [*database* .] *schema* : Clears *schema* of its storage policy.
- [[*database* .] *schema* .] *table* : Clears *table* of its storage policy. If *table* is in any schema other than **public** , you must supply the schema name.

In all cases, *database* must be the name of the current database.

key-min

key-max

Valid only if *object-name* is a table, specifies the range of table partition key values stored at the labeled location.

enforce-storage-move

Specifies when the Tuple Mover moves all existing storage containers for the specified object to its default storage location:

- **false** (default): Move storage containers only after all pending mergeout tasks return.
- **true** : Immediately move all storage containers to the new location.

Tip

You can also enforce all storage policies immediately by calling Vertica meta-function [ENFORCE_OBJECT_STORAGE_POLICY](#).

Privileges

Superuser

Examples

This following statement clears the storage policy for table `store.store_orders_fact` . The **true** argument specifies to implement the move immediately:

```
=> SELECT CLEAR_OBJECT_STORAGE_POLICY ('store.store_orders_fact', 'true');
CLEAR_OBJECT_STORAGE_POLICY
```

Object storage policy cleared.

Task: moving storages

(Table: store.store_orders_fact) (Projection: store.store_orders_fact_b0)

(Table: store.store_orders_fact) (Projection: store.store_orders_fact_b1)

(1 row)

See also

- [Clearing storage policies](#)
- [ALTER_LOCATION_LABEL](#)
- [SET_OBJECT_STORAGE_POLICY](#)
- [ENFORCE_OBJECT_STORAGE_POLICY](#)

DO_TM_TASK

Runs a [Tuple Mover](#) (TM) operation and commits current transactions. You can limit this operation to a specific table or projection. When started using this function, the TM uses the GENERAL resource pool instead of the TM resource pool.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
DO_TM_TASK('task', '[[database.]schema.]{ table | projection}')
```

Parameters

task

Specifies one of the following tuple mover operations:

- **mergeout** : Consolidates ROS containers and [purge](#)s deleted records. For details, see [Mergeout](#).
- **reshardmergeout** : Realigns storage containers to the shard definitions created by a [RESHARD_DATABASE](#) call. Specify a table or projection and a range of partition values to limit the scope of the **reshardmergeout** operations.
- **analyze_row_count** : Collects a minimal set of statistics and aggregate row counts for the specified projections, and saves it in the database catalog. Collects the number of rows in the specified projection. If you specify a table name, DO_TM_TASK returns the row counts for all projections of that table. For details, see [Analyzing row counts](#).
- **update_storage_catalog** (recommended only for Eon Mode): Updates the catalog with metadata on bundled table data. For details, see [Writing bundle metadata to the catalog](#).

[database .] schema

Database and [schema](#). The default schema is **public**. If you specify a database, it must be the current database.

table | projection

Applies **task** to the specified table or projection. If you specify a projection and it is not found, DO_TM_TASK looks for a table with that name and, if found, applies the task to it and all projections associated with it.

If you specify no table or projection, the task is applied to all database tables and their projections.

Privileges

- Schema: USAGE
- Table: One of INSERT, UPDATE, or DELETE

Examples

The following example performs a mergeout on all projections in a table:

```
=> SELECT DO_TM_TASK('mergeout', 't1');
```

You can perform a re-shard mergeout task on a range of partitions of a table:

```
=> SELECT DO_TM_TASK('reshardmergeout', 'store_orders', '2001', '2005');
```

DROP_LOCATION

Permanently removes a retired storage location. This operation cannot be undone. You must first retire a storage location with [RETIRE_LOCATION](#) before dropping it; you cannot drop a storage location that is in use.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
DROP_LOCATION ( 'path', 'node' )
```

Arguments

path

Where the storage location to drop is mounted.

node

The Vertica node on which to drop the location. To perform this operation on all nodes, use an empty string (""). If the storage location is SHARED, you must perform this operation on all nodes.

Privileges

Superuser

Storage locations with temp and data files

If you use a storage location to store data and then alter it to store only temp files, the location can still contain data files. Vertica does not let you drop a storage location containing data files. You can use the [MOVE_RETIRED_LOCATION_DATA](#) function to manually merge out the data files from the storage location, or you can drop partitions. Deleting data files does not work.

Examples

The following example shows how to drop a previously retired storage location on `v_vmart_node0003` :

```
=> SELECT DROP_LOCATION('/data', 'v_vmart_node0003');
```

See also

- [Dropping storage locations](#)
- [ALTER_LOCATION_USE](#)
- [RESTORE_LOCATION](#)
- [RETIRE_LOCATION](#)

ENFORCE_OBJECT_STORAGE_POLICY

Enterprise Mode only

Applies storage policies of the specified object immediately. By default, the Tuple Mover enforces object storage policies after all pending mergeout operations are complete. Calling this function is equivalent to setting the *enforce* argument when using [RETIRE_LOCATION](#). You typically use this function as the last step before dropping a storage location.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
ENFORCE_OBJECT_STORAGE_POLICY ( 'object-name' [, 'key-min', 'key-max'] )
```

Arguments

object-name

The database object whose storage policies are to be applied, one of the following:

- *database* : Applies *database* storage policies.
- [*database* .] *schema* : Applies *schema* storage policies.
- [[*database* .] *schema* .] *table* : Applies *table* storage policies. If *table* is in any schema other than *public* , you must supply the schema name.

In all cases, *database* must be the name of the current database.

key-min , key-max

Valid only if *object-name* is a table, specifies the range of table partition key values on which to perform the move.

Privileges

One of the following:

- Superuser
- Object owner and access to its storage location.

Examples

Apply storage policy updates to the `test` table:

```
=> SELECT ENFORCE_OBJECT_STORAGE_POLICY ('test');
```

See also

- [CLEAR_OBJECT_STORAGE_POLICY](#)
- [RETIRE_LOCATION](#)
- [DROP_LOCATION](#)

- [Managing storage locations](#)

MEASURE_LOCATION_PERFORMANCE

Measures a storage location's disk performance.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
MEASURE_LOCATION_PERFORMANCE ( 'path', 'node' )
```

Parameters

path

Specifies where the storage location to measure is mounted.

node

The Vertica node where the location to be measured is available. To obtain a list of all node names on the cluster, query system table [DISK_STORAGE](#).

Privileges

Superuser

Notes

- If you intend to create a tiered disk architecture in which projections, columns, and partitions are stored on different disks based on predicted or measured access patterns, you need to measure storage location performance for each location in which data is stored. You do not need to measure storage location performance for temp data storage locations because temporary files are stored based on available space.
- The method of measuring storage location performance applies only to configured clusters. If you want to measure a disk before configuring a cluster see [Measuring storage performance](#).
- Storage location performance equates to the amount of time it takes to read and write 1MB of data from the disk. This time equates to:

$$IO\text{-time} = (time\text{-to-read-write-1MB} + time\text{-to-seek}) = (1/throughput + 1/latency)$$

Throughput is the average throughput of sequential reads/writes (units in MB per second).

Latency is for random reads only in seeks (units in seeks per second)

Note

The IO time of a faster storage location is less than a slower storage location.

Examples

The following example measures the performance of a storage location on v_vmartdb_node0004:

```
=> SELECT MEASURE_LOCATION_PERFORMANCE('/secondVerticaStorageLocation/', 'v_vmartdb_node0004');
```

WARNING: measure_location_performance can take a long time. Please check logs for progress

```
measure_location_performance
```

```
-----  
Throughput : 122 MB/sec. Latency : 140 seeks/sec
```

See also

- [CREATE LOCATION](#)
- [ALTER_LOCATION_USE](#)
- [RESTORE_LOCATION](#)
- [RETIRE_LOCATION](#)
- [Measuring storage performance](#)

MOVE_RETIRED_LOCATION_DATA

Moves all data from the specified retired storage location or from all retired storage locations in the database. [MOVE_RETIRED_LOCATION_DATA](#) migrates the data to non-retired storage locations according to the storage policies of the objects whose data is stored in the location. This function returns only after it completes migration of all affected storage location data.

Note

The Tuple Mover migrates data of retired storage locations when it consolidates data into larger [ROS](#) containers.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
MOVE_RETIRED_LOCATION_DATA(['location-path'] [, 'node'] )
```

Arguments

location-path

The path of the storage location as specified in the [LOCATION_PATH](#) column of system table [STORAGE_LOCATIONS](#). This storage location must be marked as retired.

If you omit this argument, [MOVE_RETIRED_LOCATION_DATA](#) moves data from all retired storage locations.

node

The node on which to move data of the retired storage location. If [location-path](#) is undefined on [node](#), this function returns an error.

If you omit this argument, [MOVE_RETIRED_LOCATION_DATA](#) moves data from * [location-path](#) * on all nodes.

Privileges

Superuser

Examples

1. Query system table [STORAGE_LOCATIONS](#) to show which storage locations are retired:

```
=> SELECT node_name, location_path, location_label, is_retired FROM STORAGE_LOCATIONS
WHERE is_retired = 't';
 node_name | location_path | location_label | is_retired
-----+-----+-----+-----
v_vmart_node0001 | /home/dbadmin/SSDLoc | ssd | t
v_vmart_node0002 | /home/dbadmin/SSDLoc | ssd | t
v_vmart_node0003 | /home/dbadmin/SSDLoc | ssd | t
(3 rows)
```

2. Query system table [STORAGE_LOCATIONS](#) for the location of the messages table, which is currently stored in retired storage location [ssd](#):

```
=> SELECT node_name, total_row_count, location_label FROM STORAGE_CONTAINERS
WHERE projection_name ILIKE 'messages%';
 node_name | total_row_count | location_label
-----+-----+-----
v_vmart_node0001 | 333514 | ssd
v_vmart_node0001 | 333255 | ssd
v_vmart_node0002 | 333255 | ssd
v_vmart_node0002 | 333231 | ssd
v_vmart_node0003 | 333231 | ssd
v_vmart_node0003 | 333514 | ssd
(6 rows)
```

3. Call [MOVE_RETIRED_LOCATION_DATA](#) to move the data off the [ssd](#) storage location.

```
=> SELECT MOVE_RETIRED_LOCATION_DATA('/home/dbadmin/SSDLoc');
MOVE_RETIRED_LOCATION_DATA
-----
Move data off retired storage locations done
(1 row)
```

4. Repeat the previous query to verify the storage location of the messages table:

```
=> SELECT node_name, total_row_count, storage_type, location_label FROM storage_containers
WHERE projection_name ILIKE 'messages%';
 node_name | total_row_count | location_label
-----+-----+-----
v_vmart_node0001 | 333255 | base
v_vmart_node0001 | 333514 | base
v_vmart_node0003 | 333514 | base
v_vmart_node0003 | 333231 | base
v_vmart_node0002 | 333231 | base
v_vmart_node0002 | 333255 | base
(6 rows)
```

See also

- [RETIRE_LOCATION](#)
- [RESTORE_LOCATION](#)
- [Managing storage locations](#)

RESTORE_LOCATION

Restores a storage location that was previously retired with [RETIRE_LOCATION](#).

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
RESTORE_LOCATION ('path', 'node')
```

Arguments

path

Where to mount the retired storage location.

node

The Vertica node on which to restore the location. To perform this operation on all nodes, use an empty string (""). If the storage location is SHARED, you must perform this operation on all nodes.

The operation fails if you dropped any locations.

Privileges

Superuser

Effects of restoring a previously retired location

After restoring a storage location, Vertica re-ranks all of the cluster storage locations. It uses the newly restored location to process queries as determined by its rank.

Monitoring storage locations

For information about the disk storage used on each node, query the [DISK_STORAGE](#) system table.

Examples

Restore a retired storage location on **node4** :

```
=> SELECT RESTORE_LOCATION ('/thirdSL', 'v_vmartdb_node0004');
```

See also

- [ALTER_LOCATION_USE](#)
- [DROP_LOCATION](#)

RETIRE_LOCATION

Deactivates the specified storage location. To obtain a list of all existing storage locations, query the [STORAGE_LOCATIONS](#) system table.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
RETIRE_LOCATION ( 'path', 'node' [, enforce ] )
```

Arguments

path

Where the storage location to retire is mounted.

node

The Vertica node on which to retire the location. To perform this operation on all nodes, use an empty string (""). If the storage location is SHARED, you must perform this operation on all nodes.

enforce

If **true** , the location label is set to an empty string and the data is moved elsewhere. The location can then be dropped without errors or warnings. Use this argument to expedite dropping a location.

Privileges

Superuser

Effects of retiring a storage location

RETIRE_LOCATION checks that the location is not the only storage for data and temp files. At least one location must exist on each node to store data and temp files. However, you can store both sorts of files in either the same location or separate locations.

If a location is the last available storage for its associated objects, you can retire it only if you set **enforce** to **true** .

When you retire a storage location:

- No new data is stored at the retired location, unless you first restore it using [RESTORE_LOCATION](#) .
- By default, if the storage location being retired contains stored data, the data is not moved. Thus, you cannot drop the storage location. Instead, Vertica removes the stored data through one or more mergeouts. To drop the location immediately after retiring it, set **enforce** to true.
- If the storage location being retired is used only for temp files or you use **enforce** , you can drop the location. See [Dropping storage locations](#) and [DROP_LOCATION](#) .

Monitoring storage locations

For information about the disk storage used on each node, query the [DISK_STORAGE](#) system table.

Examples

The following examples show two approaches to retiring a storage location.

You can retire a storage location and its data will be moved out automatically at a future time:

```
=> SELECT RETIRE_LOCATION ('/data' , 'v_vmartdb_node0004');
```

You can specify that data in the storage location be moved immediately, so that you can then drop the location without waiting:

```
=> SELECT RETIRE_LOCATION ('/data' , 'v_vmartdb_node0004', true);
```

See also

- [Retiring storage locations](#)
- [CREATE_LOCATION](#)
- [DROP_LOCATION](#)
- [RESTORE_LOCATION](#)

SET_LOCATION_PERFORMANCE

Sets disk performance for a storage location.

Note

Before calling this function, call [MEASURE_LOCATION_PERFORMANCE](#) to obtain the location's throughput and average latency .

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
SET_LOCATION_PERFORMANCE ( 'path', 'node' , 'throughput', 'average-latency')
```

Parameters

path

Specifies where the storage location to set is mounted.

node

Specifies the Vertica node where the location to set is available.

throughput

Specifies the throughput for the location, set to a value ≥ 1 .

average-latency

Specifies the average latency for the location, set to a value ≥ 1 .

Privileges

Superuser

Examples

The following example sets the performance of a storage location on node2 to a throughput of 122 megabytes per second and a latency of 140 seeks per second.

```
=> SELECT SET_LOCATION_PERFORMANCE('/secondVerticaStorageLocation/', 'node2', '122', '140');
```

See also

- [CREATE LOCATION](#)
- [Measuring storage performance](#)
- [Setting storage performance](#)

SET_OBJECT_STORAGE_POLICY

Creates or changes the storage policy of a database object by assigning it a labeled storage location. The Tuple Mover uses this location to store new and existing data for this object. If the object already has an active storage policy, calling **SET_OBJECT_STORAGE_POLICY** sets this object's default storage to the new labeled location. Existing data for the object is moved to the new location.

Note

You cannot create a storage policy on a USER type storage location.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
SET_OBJECT_STORAGE_POLICY (  
  '[[database.]schema.]object-name', 'location-label'  
  [, 'key-min', 'key-max'] [, 'enforce-storage-move' ] )
```

Parameters

[database .] schema

Database and [schema](#). The default schema is [public](#). If you specify a database, it must be the current database.

object-name

Identifies the database object assigned to a labeled storage location. The *object-name* can resolve to a database, schema, or table.

location-label

The label of *object-name*'s storage location.

key-min

key-max

Valid only if *object-name* is a table, specifies the range of table partition key values to store at the labeled location.

enforce-storage-move

Specifies when the Tuple Mover moves all existing storage containers for *object-name* to the labeled storage location:

- **false** (default): Move storage containers only after all pending mergeout tasks return.
- **true** : Immediately move all storage containers to the new location.

Tip

You can also enforce all storage policies immediately by calling Vertica meta-function [ENFORCE_OBJECT_STORAGE_POLICY](#)

Privileges

One of the following:

- Superuser
- Object owner and access to its storage location.

Examples

See [Clearing storage policies](#)

See also

- [Creating storage policies](#)
- [Moving data storage locations](#)
- [ALTER_LOCATION_LABEL](#)
- [CLEAR_OBJECT_STORAGE_POLICY](#)

Table functions

This section contains functions for managing tables and constraints.

See also the [V_CATALOG.TABLE_CONSTRAINTS](#) system table.

In this section

- [ANALYZE_CONSTRAINTS](#)
- [ANALYZE_CORRELATIONS](#)
- [COPY_TABLE](#)
- [DISABLE_DUPLICATE_KEY_ERROR](#)
- [INFER_EXTERNAL_TABLE_DDL](#)
- [INFER_TABLE_DDL](#)
- [LAST_INSERT_ID](#)
- [PURGE_TABLE](#)
- [REBALANCE_TABLE](#)
- [REENABLE_DUPLICATE_KEY_ERROR](#)

ANALYZE_CONSTRAINTS

Analyzes and reports on constraint violations within the specified scope

You can enable automatic enforcement of primary key, unique key, and check constraints when **INSERT** , **UPDATE** , **MERGE** , or **COPY** statements execute. Alternatively, you can use **ANALYZE_CONSTRAINTS** to validate constraints after issuing these statements. Refer to [Constraint enforcement](#) for more information.

ANALYZE_CONSTRAINTS performs a lock in the same way that **SELECT * FROM t1** holds a lock on table **t1** . See [LOCKS](#) for additional information.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
ANALYZE_CONSTRAINTS ('[[[database.]schema.]table ]' [, 'column[,...]'] )
```

Parameters

[**database .**] **schema**

Database and [schema](#). The default schema is `public`. If you specify a database, it must be the current database.

table

Identifies the table to analyze. If you omit specifying a schema, Vertica uses the current schema search path. If set to an empty string, Vertica analyzes all tables in the current schema.

column

The column in [table](#) to analyze. You can specify multiple comma-delimited columns. Vertica narrows the scope of the analysis to the specified columns. If you omit specifying a column, Vertica analyzes all columns in [table](#).

Privileges

- Schema: USAGE
- Table: SELECT

Detecting constraint violations during a load process

Vertica checks for constraint violations when queries are run, not when data is loaded. To detect constraint violations as part of the load process, use a [COPY](#) statement with the NO COMMIT option. By loading data without committing it, you can run a post-load check of your data using the [ANALYZE_CONSTRAINTS](#) function. If the function finds constraint violations, you can roll back the load because you have not committed it.

If [ANALYZE_CONSTRAINTS](#) finds violations, such as when you insert a duplicate value into a primary key, you can correct errors using the following functions. Effects last until the end of the session only:

- [DISABLE_DUPLICATE_KEY_ERROR](#)
- [REENABLE_DUPLICATE_KEY_ERROR](#)

Important

If a check constraint SQL expression evaluates to an unknown for a given row because a column within the expression contains a null, the row passes the constraint condition.

Return values

[ANALYZE_CONSTRAINTS](#) returns results in a structured set (see table below) that lists the schema name, table name, column name, constraint name, constraint type, and the column values that caused the violation.

If the result set is empty, then no constraint violations exist; for example:

```
> SELECT ANALYZE_CONSTRAINTS ('public.product_dimension', 'product_key');
Schema Name | Table Name | Column Names | Constraint Name | Constraint Type | Column Values
-----+-----+-----+-----+-----+-----
(0 rows)
```

The following result set shows a primary key violation, along with the value that caused the violation ('10'):

```
=> SELECT ANALYZE_CONSTRAINTS ("");
Schema Name | Table Name | Column Names | Constraint Name | Constraint Type | Column Values
-----+-----+-----+-----+-----+-----
store      t1      c1      pk_t1      PRIMARY      ('10')
(1 row)
```

The result set columns are described in further detail in the following table:

Column Name	Data Type	Description
Schema Name	VARCHAR	The name of the schema.
Table Name	VARCHAR	The name of the table, if specified.
Column Names	VARCHAR	A list of comma-delimited columns that contain constraints.
Constraint Name	VARCHAR	The given name of the primary key, foreign key, unique, check, or not null constraint, if specified.

Constraint Type	VARCHAR	Identified by one of the following strings: <ul style="list-style-type: none"> • PRIMARY KEY • FOREIGN KEY • UNIQUE • CHECK • NOT NULL
Column Values	VARCHAR	Value of the constraint column, in the same order in which Column Names contains the value of that column in the violating row. When interpreted as SQL, the value of this column forms a list of values of the same type as the columns in Column Names ; for example: ('1'), ('1', 'z')

Examples

See [Detecting constraint violations](#).

ANALYZE_CORRELATIONS

Deprecated

This function is deprecated and will be removed in a future release.

Analyzes the specified tables for pairs of columns that are strongly correlated. ANALYZE_CORRELATIONS stores the 20 pairs with the strongest correlation. ANALYZE_CORRELATIONS also analyzes statistics.

ANALYZE_CORRELATIONS analyzes only pairwise single-column correlations.

For example, state name and country name columns are strongly correlated because the city name usually, but perhaps not always, identifies the state name. The city of Conshohocken is uniquely associated with Pennsylvania, while the city of Boston exists in Georgia, Indiana, Kentucky, New York, Virginia, and Massachusetts. In this case, city name is strongly correlated with state name.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Stable](#)

Syntax

```
ANALYZE_CORRELATIONS ('[[[database.]schema.]table]' [, 'recalculate'] )
```

Parameters

[**database** .] **schema**

Database and [schema](#). The default schema is **public**. If you specify a database, it must be the current database.

table-name

Identifies the table to analyze. If you omit specifying a schema, Vertica uses the current schema search path. If set to an empty string, Vertica analyzes all tables in the current schema.

recalculate

Boolean that specifies whether to analyze correlated columns that were previously analyzed.

Note

Column correlation analysis typically needs to be done only once.

Default: **false**

Privileges

One of the following:

- [Superuser](#)
- User with USAGE privilege on the design schema

Examples

In the following example, ANALYZE_CORRELATIONS analyzes column correlations for all tables in the `public` schema, even if they currently exist:

```
=> SELECT ANALYZE_CORRELATIONS ('public.*', 'true');
ANALYZE_CORRELATIONS
-----
          0
(1 row)
```

COPY_TABLE

Copies one table to another. This lightweight, in-memory function copies the DDL and all user-created projections from the source table. Projection statistics for the source table are also copied. Thus, the source and target tables initially have identical definitions and share the same storage.

Note

Although they share storage space, Vertica regards the tables as discrete objects for license capacity purposes. For example, a single-terabyte table and its copy initially consume only one TB of space. However, your Vertica license regards them as separate objects that consume two TB of space.

After the copy operation is complete, the source and copy tables are independent of each other, so you can perform DML operations on one table without impacting the other. These operations can increase the overall storage required for both tables.

Caution

If you create multiple copies of the same table concurrently, one or more of the copy operations is liable to fail. Instead, copy tables sequentially.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
COPY_TABLE (
  '[[[namespace. | database. ]]schema.]source-table',
  '[[[namespace. | database. ]]schema.]target-table'
)
```

Parameters

{ **namespace.** | **database.** }

Name of the database or [namespace](#) that contains *table* , depending on the mode of the database:

- Eon Mode: name of the [namespace](#) to which the table belongs. If no namespace is specified, the table is assumed to be in the `default_namespace` . The namespaces of *staging-table* and *target-table* must have the same shard count.
- Enterprise Mode: name of the database. If you specify a database, it must be the current database.

schema

Name of the schema, by default `public` . If you specify the namespace or database name, you must provide the schema name, even if the schema is `public` .

source-table

The source table to copy. Vertica copies all data from this table to the target table.

target-table

The target table of the source table. If the target table already exists, Vertica appends the source to the existing table.

If the table does not exist, Vertica creates a table from the source table's definition, by calling [CREATE TABLE](#) with `LIKE` and `INCLUDING PROJECTIONS` clause. The new table inherits ownership from the source table. For details, see [Replicating a table](#) .

Privileges

Non-superuser:

- Source table: SELECT
- Target schema/table (new): CREATE
- Target table (existing): INSERT

Table attribute requirements

The following attributes of both tables must be identical:

- Column definitions, including NULL/NOT NULL constraints
- Segmentation
- Partitioning expression
- Number of projections
- Projection sort order
- Primary and unique key constraints. However, the key constraints do not have to be identically enabled.

Note

If the target table has primary or unique key constraints enabled and moving the partitions will insert duplicate key values into the target table, Vertica rolls back the operation. Enforcing constraints requires disk reads and can slow the copy process.

- Number and definitions of text indices.
- If the destination table already exists, the source and destination tables must have identical [access policies](#).

Additionally, if access policies exist on the source table, the following must be true:

- Access policies on both tables must be identical.
- One of the following must be true:
 - The executing user owns the source table.
 - `AccessPolicyManagementSuperuserOnly` is set to true. See [Managing access policies](#) for details.

Table restrictions

The following restrictions apply to the source and target tables:

- If the source and target partitions are in different storage tiers, Vertica returns a warning but the operation proceeds. The partitions remain in their existing storage tier.
- If the source table contains a sequence, Vertica converts the sequence to an integer before copying it to the target table. If the target table contains `IDENTITY` or named sequence columns, Vertica cancels the copy and displays an error message.
- The following tables cannot be used as sources or targets:
 - Temporary tables
 - Virtual tables
 - System tables
 - External tables

Examples

If you call `COPY_TABLE` and the target table does not exist, the function creates the table automatically. In the following example, `COPY_TABLE` creates the target table `public.newtable`. Vertica also copies all the constraints associated with the source table `public.product_dimension` except foreign key constraints:

```
=> SELECT COPY_TABLE ( 'public.product_dimension', 'public.newtable');
-[ RECORD 1 ]-----
copy_table | Created table public.newtable.
Copied table public.product_dimension to public.newtable
```

See also

[Creating a table from other tables](#)

`DISABLE_DUPLICATE_KEY_ERROR`

Disables error messaging when Vertica finds duplicate primary or unique key values at run time (for use with key constraints that are not automatically enabled). Queries execute as though no constraints are defined on the schema. Effects are session scoped.

This is a meta-function. You must call meta-functions in a top-level `SELECT` statement.

Behavior type

[Volatile](#)

Syntax

```
DISABLE_DUPLICATE_KEY_ERROR();
```

Privileges

Superuser

Examples

When you call `DISABLE_DUPLICATE_KEY_ERROR`, Vertica issues warnings letting you know that duplicate values will be ignored, and incorrect results are possible. `DISABLE_DUPLICATE_KEY_ERROR` is for use only for key constraints that are not automatically enabled.

```
=> select DISABLE_DUPLICATE_KEY_ERROR();
WARNING 3152: Duplicate values in columns marked as UNIQUE will now be ignored for the remainder of your session or until
reenable_duplicate_key_error() is called
WARNING 3539: Incorrect results are possible. Please contact Vertica Support if unsure
disable_duplicate_key_error
-----
Duplicate key error disabled
(1 row)
```

[ANALYZE_CONSTRAINTS](#)

[INFER_EXTERNAL_TABLE_DDL](#)

Deprecated

This function is deprecated and will be removed in a future release. Instead, use [INFER_TABLE_DDL](#).

Inspects a file in Parquet, ORC, or Avro format and returns a [CREATE EXTERNAL TABLE AS COPY](#) statement that can be used to read the file. This statement might be incomplete. It could also contain more columns or columns with longer names than what Vertica supports; this function does not enforce Vertica [system limits](#). Always inspect the output and address any issues before using it to create a table.

This function supports partition columns for the Parquet, ORC, and Avro formats, inferred from the input path. Because partitioning is done through the directory structure, there might not be enough information to infer the type of partition columns. In this case, this function shows these columns with a data type of UNKNOWN and emits a warning.

The function handles most data types, including complex types. If an input type is not supported in Vertica, the function emits a warning.

By default, the function uses strong typing for complex types. You can instead treat the column as a flexible complex type by setting the `vertica_type_for_complex_type` parameter to LONG VARBINARY.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
INFER_EXTERNAL_TABLE_DDL( path USING PARAMETERS param=value[,...] )
```

Arguments

path

Path to a file or directory. Any path that is valid for COPY and uses a file format supported by this function is valid.

Parameters

format

Input format (string), one of 'Parquet', 'ORC', or 'Avro'. This parameter is required.

table_name

The name of the external table to create. This parameter is required.

Do not include a schema name as part of the table name; use the `table_schema` parameter.

table_schema

The schema in which to create the external table. If omitted, the function does not include a schema in the output.

vertica_type_for_complex_type

Type used to represent all columns of complex types, if you do not want to expand them fully. The only supported value is [LONG VARBINARY](#). For more information, see [Flexible complex types](#).

Privileges

Non-superuser: READ privileges on the [USER-accessible storage location](#).

Examples

In the following example, the input file contains data for a table with two integer columns. The table definition can be fully inferred, and you can use the returned SQL statement as-is.

```
=> SELECT INFER_EXTERNAL_TABLE_DDL('/data/orders/*.orc'
  USING PARAMETERS format = 'orc', table_name = 'orders');
```

```
      INFER_EXTERNAL_TABLE_DDL
```

```
-----
create external table "orders" (
  "id" int,
  "quantity" int
) as copy from '/data/orders/*.orc' orc;
(1 row)
```

To create a table in a schema, use the [table_schema](#) parameter. Do not add it to the table name; the function treats it as a name with a period in it, not a schema.

The following example shows output with complex types. You can use the definition as-is or modify the VARCHAR sizes:

```
=> SELECT INFER_EXTERNAL_TABLE_DDL('/data/people/*.parquet'
  USING PARAMETERS format = 'parquet', table_name = 'employees');
```

```
WARNING 9311: This generated statement contains one or more varchar/varbinary columns which default to length 80
```

```
      INFER_EXTERNAL_TABLE_DDL
```

```
-----
create external table "employees"(
  "employeeID" int,
  "personal" Row(
    "name" varchar,
    "address" Row(
      "street" varchar,
      "city" varchar,
      "zipcode" int
    ),
    "taxID" int
  ),
  "department" varchar
) as copy from '/data/people/*.parquet' parquet;
(1 row)
```

In the following example, the input file contains a map in the "prods" column. You can read a map as an array of rows:

```
=> SELECT INFER_EXTERNAL_TABLE_DDL('/data/orders.parquet'
  USING PARAMETERS format='parquet', table_name='orders');
WARNING 9311: This generated statement contains one or more varchar/varbinary columns which default to length 80
  INFER_EXTERNAL_TABLE_DDL
```

```
-----
create external table "orders"(
  "orderkey" int,
  "custkey" int,
  "prods" Array[Row(
    "key" varchar,
    "value" numeric(12,2)
  )],
  "orderdate" date
) as copy from '/data/orders.parquet' parquet;
(1 row)
```

In the following example, the data is partitioned by region. The function was not able to infer the data type and reports UNKNOWN:

```
=> SELECT INFER_EXTERNAL_TABLE_DDL('/data/sales/*/*'
  USING PARAMETERS format = 'parquet', table_name = 'sales');
WARNING 9262: This generated statement is incomplete because of one or more unknown column types.
Fix these data types before creating the table
  INFER_EXTERNAL_TABLE_DDL
```

```
-----
create external table "sales"(
  "tx_id" int,
  "date" date,
  "region" UNKNOWN
) as copy from '/data/sales/*/*' PARTITION COLUMNS region parquet;
(1 row)
```

For VARCHAR and VARBINARY columns, this function does not specify a length. The Vertica default length for these types is 80 bytes. If the data values are longer, using this table definition unmodified could cause data to be truncated. Always review VARCHAR and VARBINARY columns to determine if you need to specify a length. This function emits a warning if the input file contains columns of these types:

```
WARNING 9311: This generated statement contains one or more varchar/varbinary columns which default to length 80
```

INFER_TABLE_DDL

Inspects a file in Parquet, ORC, JSON, or Avro format and returns a CREATE TABLE or CREATE EXTERNAL TABLE statement based on its contents.

The returned statement might be incomplete if the input data contains ambiguous or unknown data types. It could also contain more columns or columns with longer names than what Vertica supports; this function does not enforce Vertica [system limits](#). Always inspect the output and address any issues before using it to create a table.

This function supports partition columns, inferred from the input path. Because partitioning is done through the directory structure, there might not be enough information to infer the type of partition columns. In this case, this function shows these columns with a data type of UNKNOWN and emits a warning.

The function handles most data types, including complex types. If an input type is not supported in Vertica, the function emits a warning.

For VARCHAR and VARBINARY columns, this function does not specify a length. The Vertica default length for these types is 80 bytes. If the data values are longer, using the returned table definition unmodified could cause data to be truncated. Always review VARCHAR and VARBINARY columns to determine if you need to specify a length. This function emits a warning if the input file contains columns of these types:

```
WARNING 9311: This generated statement contains one or more varchar/varbinary columns which default to length 80
```

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
INFER_TABLE_DDL( path USING PARAMETERS param=value[...] )
```

Arguments

path

Path to a file or glob. Any path that is valid for COPY and uses a file format supported by this function is valid. For all formats except JSON, if a glob specifies more than one file, this function reads a single, arbitrarily-chosen file. For JSON, the function might read more than one file. See [JSON](#).

Parameters

format

Input format (string), one of 'Parquet', 'ORC', 'Avro', or 'JSON'. This parameter is required.

table_name

The name of the table to create. This parameter is required.

Do not include a schema name as part of the table name; use the [table_schema](#) parameter.

table_schema

The schema in which to create the table. If omitted, the function does not include a schema in the output.

table_type

The type of table to create, either 'native' or 'external'.

Default: 'native'

with_copy_statement

For native tables, whether to include a COPY statement in addition to the CREATE TABLE statement.

Default: false

one_line_result

Whether to return the DDL as a single line instead of pretty-printing. The single-line format might be easier to copy into SQL scripts.

Default: false (pretty-print)

max_files

(JSON only.) Maximum number of files in [path](#) to inspect, if [path](#) is a glob. Use this parameter to increase the amount of data the function considers, for example if you suspect variation among files. Files are chosen arbitrarily from the glob. For details, see [JSON](#).

Default: 1

max_candidates

(JSON only.) Number of candidate table definitions to show. The function generates only one candidate per file, so if you increase [max_candidates](#), also increase [max_files](#). For details, see [JSON](#).

Default: 1

Privileges

Non-superuser: READ privileges on the [USER-accessible storage location](#).

JSON

JSON, unlike the other supported formats, does not embed a schema in data files. This function infers JSON table DDL by instead inspecting the raw data. Because raw data can be ambiguous or inconsistent, the function takes a different approach for this format.

For each input file, the function iterates through records to develop a candidate table definition. A top-level field that appears in any record is included as a column, even if not all records use it. If the same field appears in the file with different types, the function chooses a type that is consistent with all observed occurrences.

Consider a file with data about restaurants:

```

{
  "name" : "Pizza House",
  "cuisine" : "Italian",
  "location_city" : [],
  "chain" : true,
  "hours" : [],
  "menu" : [{"item" : "cheese pizza", "price" : 7.99},
            {"item" : "spinach pizza", "price" : 8.99},
            {"item" : "garlic bread", "price" : 4.99}]
}
{
  "name" : "Sushi World",
  "cuisine" : "Asian",
  "location_city" : ["Pittsburgh"],
  "chain" : false,
  "menu" : [{"item" : "maki platter", "price" : "21.95"},
            {"item" : "tuna roll", "price" : "4.95"}]
}

```

The first record contains two empty arrays, so there is not enough information to determine the element types. The second record has a string value for one of them, so the function can infer a type of VARCHAR for it. The other array element type remains unknown.

In the first record menu prices are numbers, but in the second they are strings. Both FLOAT and the string can be coerced to NUMERIC, so the function returns NUMERIC:

```

=> SELECT INFER_TABLE_DDL ('/data/restaurants.json'
  USING PARAMETERS table_name='restaurants', format='json');
WARNING 0: This generated statement contains one or more varchar/varbinary types which default to length 80

      INFER_TABLE_DDL
-----
Candidate matched 1 out of 1 total files:
create table "restaurants"(
  "chain" bool,
  "cuisine" varchar,
  "hours" Array[UNKNWON],
  "location_city" Array[varchar],
  "menu" Array[Row(
    "item" varchar,
    "price" numeric
  )],
  "name" varchar
);

(1 row)

```

All scalar types can be coerced to VARCHAR, so if a conflict cannot be resolved more specifically (as in the NUMERIC example), the function can still return a type. Complex types, however, cannot always be resolved in this way. In the following example, records in a file have conflicting definitions of the `hours` field:

```
{
  "name" : "Sushi World",
  "cuisine" : "Asian",
  "location_city" : ["Pittsburgh"],
  "chain" : false,
  "hours" : {"open" : "11:00", "close" : "22:00" }
}
{
  "name" : "Greasy Spoon",
  "cuisine" : "American",
  "location_city" : [],
  "chain" : "false",
  "hours" : {"open" : ["11:00","12:00"], "close" : ["21:00","22:00"] },
}
```

In the first record the value is a ROW with two TIME fields. In the second record the value is a ROW with two ARRAY[TIME] fields (representing weekday and weekend hours). These types are incompatible, so the function suggests a [flexible complex type](#) by using LONG VARBINARY:

```
=> SELECT INFER_TABLE_DDL ('/data/restaurants.json'
  USING PARAMETERS table_name='restaurants', format='json');
WARNING 0: This generated statement contains one or more varchar/varbinary types which default to length 80

      INFER_TABLE_DDL
-----
Candidate matched 1 out of 1 total files:
create table "restaurants"(
  "chain" bool,
  "cuisine" varchar,
  "hours" long varbinary,
  "location_city" Array[varchar],
  "name" varchar
);

(1 row)
```

If you call the function with a glob, by default it reads one file. Set `max_files` to a higher number to inspect more data. The function calculates one candidate table definition per file and returns the definition that covers the largest number of files.

Increasing the number of files does not, by itself, increase the number of candidates the function returns. With more files the function can consider more candidates, but by default it returns the single candidate that represents the largest number of files. To see more than one possible table definition, also set `max_candidates`. There is no benefit to setting `max_candidates` to a larger number than `max_files`.

In the following example, the glob contains two files that differ in the structure of the menu column. In the first file, the menu field has two fields:

```
{
  "name" : "Bob's pizzeria",
  "cuisine" : "Italian",
  "location_city" : ["Cambridge", "Pittsburgh"],
  "menu" : [{"item" : "cheese pizza", "price" : 8.25},
            {"item" : "spinach pizza", "price" : 10.50}]
}
```

In the second file, the menu has different offerings at different times of day:

```
{
  "name" : "Greasy Spoon",
  "cuisine" : "American",
  "location_city" : [],
  "menu" : [{"time" : "breakfast",
    "items" :
      [{"item" : "scrambled eggs", "price" : "3.99"}]
    },
    {"time" : "lunch",
      "items" :
        [{"item" : "grilled cheese", "price" : "3.95"},
        {"item" : "tuna melt", "price" : "5.95"},
        {"item" : "french fries", "price" : "1.99"}]}]}
}
```

To see both candidates, raise both `max_files` and `max_candidates` :

```
=> SELECT INFER_TABLE_DDL ('/data/*.json'
  USING PARAMETERS table_name='restaurants', format='json',
max_files=3, max_candidates=3);
WARNING 0: This generated statement contains one or more float types which might lose precision
WARNING 0: This generated statement contains one or more varchar/varbinary types which default to length 80

      INFER_TABLE_DDL
-----
Candidate matched 1 out of 2 total files:
create table "restaurants"(
  "cuisine" varchar,
  "location_city" Array[varchar],
  "menu" Array[Row(
    "item" varchar,
    "price" float
  )],
  "name" varchar
);
Candidate matched 1 out of 2 total files:
create table "restaurants"(
  "cuisine" varchar,
  "location_city" Array[varchar],
  "menu" Array[Row(
    "items" Array[Row(
      "item" varchar,
      "price" numeric
    )],
    "time" varchar
  )],
  "name" varchar
);
(1 row)
```

Examples

In the following example, the input path contains data for a table with two integer columns. The external table definition can be fully inferred, and you can use the returned SQL statement as-is. The function reads one file from the input path:

```
=> SELECT INFER_TABLE_DDL('/data/orders/*.orc'
  USING PARAMETERS format = 'orc', table_name = 'orders', table_type = 'external');
```

INFER_TABLE_DDL

```
create external table "orders" (
  "id" int,
  "quantity" int
) as copy from '/data/orders/*.orc' orc;
(1 row)
```

To create a table in a schema, use the [table_schema](#) parameter. Do not add it to the table name; the function treats it as a name with a period in it, not a schema.

The following example shows output with complex types. You can use the definition as-is or modify the VARCHAR sizes:

```
=> SELECT INFER_TABLE_DDL('/data/people/*.parquet'
  USING PARAMETERS format = 'parquet', table_name = 'employees');
```

WARNING 9311: This generated statement contains one or more varchar/varbinary columns which default to length 80

INFER_TABLE_DDL

```
create table "employees"(
  "employeeID" int,
  "personal" Row(
    "name" varchar,
    "address" Row(
      "street" varchar,
      "city" varchar,
      "zipcode" int
    ),
    "taxID" int
  ),
  "department" varchar
);
(1 row)
```

In the following example, the input file contains a map in the "prods" column. You can read a map as an array of rows:

```
=> SELECT INFER_TABLE_DDL('/data/orders.parquet'
  USING PARAMETERS format='parquet', table_name='orders');
```

WARNING 9311: This generated statement contains one or more varchar/varbinary columns which default to length 80

INFER_TABLE_DDL

```
create table "orders"(
  "orderkey" int,
  "custkey" int,
  "prods" Array[Row(
    "key" varchar,
    "value" numeric(12,2)
  )],
  "orderdate" date
);
(1 row)
```

The following example returns the definition of a native table and the COPY statement, putting the table definition on a single line to simplify cutting and pasting into a script:

```
=> SELECT INFER_TABLE_DDL('/data/orders/*.orc'
  USING PARAMETERS format = 'orc', table_name = 'orders',
    table_type = 'native', with_copy_statement = true, one_line_result=true);
```

INFER_TABLE_DDL

```
create table "orders" ("id" int, "quantity" int);
copy "orders" from '/data/orders/*.orc' orc;
(1 row)
```

In the following example, the data is partitioned by region. The function was not able to infer the data type and reports UNKNOWN:

```
=> SELECT INFER_TABLE_DDL('/data/sales/*/*'
  USING PARAMETERS format = 'orc', table_name = 'sales', table_type = 'external');
WARNING 9262: This generated statement is incomplete because of one or more unknown column types. Fix these data types before creating the table
WARNING 9311: This generated statement contains one or more varchar/varbinary columns which default to length 80
```

INFER_TABLE_DDL

```
create external table "sales"(
  "orderkey" int,
  "custkey" int,
  "prodkey" Array[varchar],
  "orderprices" Array[numeric(12,2)],
  "orderdate" date,
  "region" UNKNOWN
) as copy from '/data/sales/*/*' PARTITION COLUMNS region orc;
(1 row)
```

In the following example, the function reads multiple JSON files and they differ in how they represent the **menu** column:

```
=> SELECT INFER_TABLE_DDL ('/data/*.json'
  USING PARAMETERS table_name='restaurants', format='json',
max_files=3, max_candidates=3);
WARNING 0: This generated statement contains one or more float types which might lose precision
WARNING 0: This generated statement contains one or more varchar/varbinary types which default to length 80
```

INFER_TABLE_DDL

Candidate matched 1 out of 2 total files:

```
create table "restaurants"(
  "cuisine" varchar,
  "location_city" Array[varchar],
  "menu" Array[Row(
    "item" varchar,
    "price" float
  )],
  "name" varchar
);
```

Candidate matched 1 out of 2 total files:

```
create table "restaurants"(
  "cuisine" varchar,
  "location_city" Array[varchar],
  "menu" Array[Row(
    "items" Array[Row(
      "item" varchar,
      "price" numeric
    )],
    "time" varchar
  )],
  "name" varchar
);
```

(1 row)

LAST_INSERT_ID

Returns the last value of an [IDENTITY](#) column. If multiple sessions concurrently load the same table with an IDENTITY column, the function returns the last value generated for that column.

Note

This function works only with IDENTITY columns. It does not work with [named sequences](#).

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
LAST_INSERT_ID()
```

Privileges

- Table owner
- USAGE privileges on the table schema

Examples

See [IDENTITY sequences](#).

PURGE_TABLE

Note

This function was formerly named `PURGE_TABLE_PROJECTIONS()`. Vertica still supports the former function name.

Permanently removes deleted data from physical storage so disk space can be reused. You can purge historical data up to and including the Ancient History Mark epoch.

Purges all projections of the specified table. You cannot use this function to purge temporary tables.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
PURGE_TABLE ( '[[database.]schema.]table' )
```

Parameters

[**database** .] **schema**

Database and [schema](#). The default schema is `public`. If you specify a database, it must be the current database.

table

The table to purge.

Privileges

- Table owner
- USAGE privilege on schema

Caution

`PURGE_TABLE` could temporarily take up significant disk space while the data is being purged.

Examples

The following example purges all projections for the store sales fact table located in the Vmart schema:

```
=> SELECT PURGE_TABLE('store.store_sales_fact');
```

See also

- [PURGE](#)
- [PURGE_TABLE](#)
- [STORAGE_CONTAINERS](#)
- [Purging deleted data](#)

REBALANCE_TABLE

Synchronously rebalances data in the specified table.

A rebalance operation performs the following tasks:

- Distributes data based on:
 - User-defined [fault groups](#), if specified
 - [Large cluster](#) automatic fault groups
- Redistributes database projection data across all nodes.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
REBALANCE_TABLE('[[database.]schema.]table-name')
```

Parameters

schema

Database and [schema](#). The default schema is `public`. If you specify a database, it must be the current database.

table-name

The table to rebalance.

Privileges

Superuser

When to rebalance

Rebalancing is useful or even necessary after you perform the following tasks:

- Mark one or more nodes as ephemeral in preparation of removing them from the cluster.
- Add one or more nodes to the cluster so that Vertica can populate the empty nodes with data.
- Change the [scaling_factor](#) of an elastic cluster, which determines the number of storage containers used to store a projection across the database.
- Set the control node size or realign control nodes on a [large cluster](#) layout
- Add nodes to or remove nodes from a [fault group](#).

Tip

By default, before performing a rebalance, Vertica queries system tables to compute the size of all projections involved in the rebalance task. This query can add significant overhead to the rebalance operation. To disable this query, set projection configuration parameter [RebalanceQueryStorageContainers](#) to 0.

Examples

The following command shows how to rebalance data on the specified table.

```
=> SELECT REBALANCE_TABLE('online_sales.online_sales_fact');
REBALANCE_TABLE
-----
REBALANCED
(1 row)
```

See also

- [REBALANCE_CLUSTER](#)
- [Rebalancing Data Across Nodes](#)
- [NODES](#)

REENABLE_DUPLICATE_KEY_ERROR

Restores the default behavior of error reporting by reversing the effects of [DISABLE_DUPLICATE_KEY_ERROR](#). Effects are session-scoped.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
REENABLE_DUPLICATE_KEY_ERROR();
```

Privileges

Superuser

Examples

```
=> SELECT REENABLE_DUPLICATE_KEY_ERROR();
REENABLE_DUPLICATE_KEY_ERROR
-----
Duplicate key error enabled
(1 row)
```

[ANALYZE_CONSTRAINTS](#)

Match and search functions

This section contains functions for text search and regular expressions, and functions used in the MATCH clause.

In this section

- [MATCH clause functions](#)
- [Regular expression functions](#)
- [Text search functions](#)

MATCH clause functions

Used with the [MATCH clause](#), the functions in this section return additional data about the patterns found or returned. For example, you can use these functions to return values representing the name of the event or pattern that matched the input row, the sequential number of the match, or a partition-wide unique identifier for the instance of the pattern that matched.

Pattern matching is particularly useful for clickstream analysis where you might want to identify users' actions based on their Web browsing behavior (page clicks). A typical online clickstream funnel is:

Company home page -> product home page -> search -> results -> purchase online

Using the above clickstream funnel, you can search for a match on the user's sequence of web clicks and identify that the user:

- Landed on the company home page.
- Navigated to the product page.
- Ran a search.
- Clicked a link from the search results.
- Made a purchase.

For examples that use this clickstream model, see [Event series pattern matching](#).

Note

GROUP BY and PARTITION BY expressions do not support window functions.

In this section

- [EVENT_NAME](#)
- [MATCH_ID](#)
- [PATTERN_ID](#)

EVENT_NAME

Returns a VARCHAR value representing the name of the event that matched the row.

Syntax

```
EVENT_NAME()
```

Notes

Pattern matching functions must be used in [MATCH clause](#) syntax; for example, if you call EVENT_NAME() on its own, Vertica returns the following error message:

```
=> SELECT event_name();
ERROR: query with pattern matching function event_name must include a MATCH clause
```

Examples

Note

This example uses the schema defined in [Event series pattern matching](#).

The following statement analyzes users' browsing history on [website2.com](#) and identifies patterns where the user landed on [website2.com](#) from another Web site (Entry) and browsed to any number of other pages (Onsite) before making a purchase (Purchase). The query also outputs the values for EVENT_NAME(), which is the name of the event that matched the row.

```

SELECT uid,
       sid,
       ts,
       refurl,
       pageurl,
       action,
       event_name()
FROM clickstream_log
MATCH
(PARTITION BY uid, sid ORDER BY ts
 DEFINE
  Entry AS RefURL NOT ILIKE '%website2.com%' AND PageURL ILIKE '%website2.com%',
  Onsite AS PageURL ILIKE '%website2.com%' AND Action='V',
  Purchase AS PageURL ILIKE '%website2.com%' AND Action = 'P'
 PATTERN
  P AS (Entry Onsite* Purchase)
 ROWS MATCH FIRST EVENT);
uid | sid | ts | refurl | pageurl | action | event_name
-----+-----+-----+-----+-----+-----+-----
1 | 100 | 12:00:00 | website1.com | website2.com/home | V | Entry
1 | 100 | 12:01:00 | website2.com/home | website2.com/floby | V | Onsite
1 | 100 | 12:02:00 | website2.com/floby | website2.com/shamwow | V | Onsite
1 | 100 | 12:03:00 | website2.com/shamwow | website2.com/buy | P | Purchase
2 | 100 | 12:10:00 | website1.com | website2.com/home | V | Entry
2 | 100 | 12:11:00 | website2.com/home | website2.com/forks | V | Onsite
2 | 100 | 12:13:00 | website2.com/forks | website2.com/buy | P | Purchase
(7 rows)

```

See also

- [MATCH clause](#)
- [MATCH_ID](#)
- [PATTERN_ID](#)
- [Event series pattern matching](#)

MATCH_ID

Returns a successful pattern match as an INTEGER value. The returned value is the ordinal position of a match within a partition.

Syntax

```
MATCH_ID()
```

Notes

Pattern matching functions must be used in [MATCH clause](#) syntax; for example, if you call MATCH_ID() on its own, Vertica returns the following error message:

```

=> SELECT match_id();
ERROR: query with pattern matching function match_id must include a MATCH clause

```

Examples

Note

This example uses the schema defined in [Event series pattern matching](#).

The following statement analyzes users' browsing history on a site called [website2.com](#) and identifies patterns where the user reached [website2.com](#) from another Web site ([Entry](#) in the [MATCH](#) clause) and browsed to any number of other pages ([Onsite](#)) before making a purchase (Purchase). The query also outputs values for the MATCH_ID(), which represents a sequential number of the match.

```

SELECT uid,
       sid,
       ts,
       refurl,
       pageurl,
       action,
       match_id()
FROM clickstream_log
MATCH
(PARTITION BY uid, sid ORDER BY ts
 DEFINE
  Entry AS RefURL NOT ILIKE '%website2.com%' AND PageURL ILIKE '%website2.com%',
  Onsite AS PageURL ILIKE '%website2.com%' AND Action='V',
  Purchase AS PageURL ILIKE '%website2.com%' AND Action = 'P'
 PATTERN
  P AS (Entry Onsite* Purchase)
 ROWS MATCH FIRST EVENT);

```

uid	sid	ts	refurl	pageurl	action	match_id
1	100	12:00:00	website1.com	website2.com/home	V	1
1	100	12:01:00	website2.com/home	website2.com/floby	V	2
1	100	12:02:00	website2.com/floby	website2.com/shamwow	V	3
1	100	12:03:00	website2.com/shamwow	website2.com/buy	P	4
2	100	12:10:00	website1.com	website2.com/home	V	1
2	100	12:11:00	website2.com/home	website2.com/forks	V	2
2	100	12:13:00	website2.com/forks	website2.com/buy	P	3

PATTERN_ID

Returns an integer value that is a partition-wide unique identifier for the instance of the pattern that matched.

Syntax

```
PATTERN_ID()
```

Notes

Pattern matching functions must be used in [MATCH clause](#) syntax; for example, if call PATTERN_ID() on its own, Vertica returns the following error message:

```

=> SELECT pattern_id();
ERROR: query with pattern matching function pattern_id must include a MATCH clause

```

Examples

Note

This example uses the schema defined in [Event series pattern matching](#).

The following statement analyzes users' browsing history on website2.com and identifies patterns where the user landed on website2.com from another Web site (Entry) and browsed to any number of other pages (Onsite) before making a purchase (Purchase). The query also outputs values for PATTERN_ID(), which represents the partition-wide identifier for the instance of the pattern that matched.

```

SELECT uid,
       sid,
       ts,
       refurl,
       pageurl,
       action,
       pattern_id()
FROM clickstream_log
MATCH
(PARTITION BY uid, sid ORDER BY ts
 DEFINE
  Entry AS RefURL NOT ILIKE '%website2.com%' AND PageURL ILIKE '%website2.com%',
  Onsite AS PageURL ILIKE '%website2.com%' AND Action='V',
  Purchase AS PageURL ILIKE '%website2.com%' AND Action = 'P'
 PATTERN
  P AS (Entry Onsite* Purchase)
 ROWS MATCH FIRST EVENT);

```

uid	sid	ts	refurl	pageurl	action	pattern_id
1	100	12:00:00	website1.com	website2.com/home	V	1
1	100	12:01:00	website2.com/home	website2.com/floby	V	1
1	100	12:02:00	website2.com/floby	website2.com/shamwow	V	1
1	100	12:03:00	website2.com/shamwow	website2.com/buy	P	1

Regular expression functions

A regular expression lets you perform pattern matching on strings of characters. The regular expression syntax allows you to precisely define the pattern used to match strings, giving you much greater control than wildcard matching used in the [LIKE](#) predicate. The Vertica regular expression functions let you perform tasks such as determining if a string value matches a pattern, extracting a portion of a string that matches a pattern, or counting the number of times a pattern occurs within a string.

Vertica uses the [Perl Compatible Regular Expression \(PCRE\)](#) library to evaluate regular expressions. As its name implies, PCRE's regular expression syntax is compatible with the syntax used by the Perl 5 programming language. You can read [PCRE's documentation](#) about its library. However, if you are unfamiliar with using regular expressions, the [Perl Regular Expressions Documentation](#) is a good introduction.

Note

The regular expression functions only operate on valid UTF-8 strings. If you try using a regular expression function on a string that is not valid UTF-8, the query fails with an error. To prevent an error from occurring, use the [ISUTF8](#) function as an initial clause to ensure the strings you pass to the regular expression functions are valid UTF-8 strings. Alternatively, or you can use the 'b' argument to treat the strings as binary octets, rather than UTF-8 encoded strings.

MATCH_COLUMNS

Specified as an element in a SELECT list, returns all columns in queried tables that match the specified pattern. For example:

```
=> SELECT MATCH_COLUMNS ('%order%') FROM store.store_orders_fact LIMIT 3;
order_number | date_ordered | quantity_ordered | total_order_cost | reorder_level
-----+-----+-----+-----+-----
191119 | 2003-03-09 | 15 | 4021 | 23
89985 | 2003-05-04 | 19 | 2692 | 23
246962 | 2007-06-01 | 77 | 4419 | 42
(3 rows)
```

Syntax

```
MATCH_COLUMNS ('pattern')
```

Arguments

pattern

The pattern to match against all column names in the queried tables, where *pattern* typically contains one or both of the following wildcard characters:

- `_` (underscore): Match any single character.
- `%` (percent sign): Match any string of zero or more characters.

The pattern can also include backslash (`\`) characters to escape reserved characters that are embedded in column names: `_` (underscore), `%` (percent sign), and backslash (`\`) itself.

Privileges

None

DDL usage

You can use `MATCH_COLUMNS` to define database objects—for example, specify it in [CREATE PROJECTION](#) to identify projection columns, or in [CREATE TABLE...AS](#) to identify columns in the new table. In all cases, Vertica expands the `MATCH_COLUMNS` output before it stores the object DDL. Subsequent changes to the original source table have no effect on the derived object definitions.

Restrictions

In general, `MATCH_COLUMNS` is specified as an element in a `SELECT` list. For example, `CREATE PROJECTION` can call `MATCH_COLUMNS` to specify the columns to include in a projection. However, attempts to specify columns in the projection's segmentation clause return with an error:

```
=> CREATE PROJECTION p_store_orders AS SELECT
MATCH_COLUMNS('%product%'),
MATCH_COLUMNS('%store%'),
order_number FROM store.store_orders_fact SEGMENTED BY MATCH_COLUMNS('products%') ALL NODES;
ERROR 0: MATCH_COLUMNS() function can only be specified as an element in a SELECT list
=> CREATE PROJECTION p_store_orders AS SELECT
MATCH_COLUMNS('%product%'),
MATCH_COLUMNS('%store%'),
order_number FROM store.store_orders_fact;
WARNING 4468: Projection <store.p_store_orders_b0> is not available for query processing. Execute the select start_refresh() function to copy data into this projection.
The projection must have a sufficient number of buddy projections and all nodes must be up before starting a refresh
WARNING 4468: Projection <store.p_store_orders_b1> is not available for query processing. Execute the select start_refresh() function to copy data into this projection.
The projection must have a sufficient number of buddy projections and all nodes must be up before starting a refresh
CREATE PROJECTION
```

If you call `MATCH_COLUMNS` from a function that supports a fixed number of arguments, Vertica returns an error. For example, the [UPPER](#) function supports only one argument; so calling `MATCH_COLUMNS` from `UPPER` as follows returns an error:

```
=> SELECT MATCH_COLUMNS('emp%') FROM employee_dimension LIMIT 1;
```

```
-[ RECORD 1 ]-----+-----
```

```
employee_key      | 1
employee_gender   | Male
employee_first_name | Craig
employee_middle_initial | F
employee_last_name  | Robinson
employee_age       | 22
employee_street_address | 5 Bakers St
employee_city      | Thousand Oaks
employee_state     | CA
employee_region    | West
```

```
=> SELECT UPPER (MATCH_COLUMNS('emp%')) FROM employee_dimension;
```

```
ERROR 10465: MATCH_COLUMNS() function can only be specified as an element in a SELECT list
```

In contrast, the HASH function accepts an unlimited number of arguments, so calling MATCH_COLUMNS as an argument succeeds:

```
=> select HASH(MATCH_COLUMNS('emp%')) FROM employee_dimension LIMIT 10;
```

```
HASH
```

```
-----
2047284364908178817
1421997332260827278
7981613309330877388

7056305566297085916
3328422577712931057
```

```
(10 rows)
```

Other constraints

The following usages of MATCH_COLUMNS are invalid and return with an error:

- Including MATCH_COLUMNS in the non-recursive (base) term query of a [RECURSIVE WITH](#) clause
- Concatenating the results of MATCH_COLUMNS calls:

```
=> SELECT MATCH_COLUMNS ('%store%')||MATCH_COLUMNS('%store%') FROM store.store_orders_fact;
```

```
ERROR 0: MATCH_COLUMNS() function can only be specified as an element in a SELECT list
```

- Setting an alias on MATCH_COLUMNS

Examples

The following CREATE PROJECTION statement uses MATCH_COLUMNS to specify table columns in the new projection:

```

=> CREATE PROJECTION p_store_orders AS SELECT
  MATCH_COLUMNS('%product%'),
  MATCH_COLUMNS('%store%'),
  order_number FROM store.store_orders_fact;
WARNING 4468: Projection <store.p_store_orders_b0> is not available for query processing. Execute the select start_refresh() function to copy data into this projection.
